Translational Neuroendocrinology at the Crossroads of Reproduction and Metabolism

Manuel Tena-Sempere[1,2]
[1]Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Cordoba, Spain; [2]Department of Cell Biology, Physiology, Immunology, University of Cordoba, Cordoba, Spain

Neuroendocrinology has astonishingly progressed since its inception, grounded on seminal findings of Prof. Geoffrey Harris in mid-20th century. A fascinating aspect of Neuroendocrinology for a young medical student as myself was the sophistication of the interactive neurohormonal mechanisms connecting key body functions, as metabolism, growth and reproduction. After 30-years in the field, I remain thrilled by these sophisticated systems. My research group is interested in dissecting the key pathways whereby our brain controls reproduction and energy balance, and how it decodes nutritional/ metabolic information to precisely integrate these fundamental bodily functions. Our focus is primarily basic research. In this domain, my team has actively analyzed the roles of kisspeptins and related neuropeptide systems in the control of puberty and fertility, and their interplay with metabolic signals and energy sensors, explaining the impact of conditions, such as obesity or subnutrition, on reproductive health. Despite our strong drive for basic research, my team has recently embraced more translational projects, aiming to exploit the potential applicability of our basic findings. This is illustrated by multiple research lines at my group, including the identification of novel molecular markers of metabolic health in pubertal children, and the search of new mechanisms and targets of intervention in common reproductive-metabolic disorders, as polycystic ovary syndrome and obesity-induced hypogonadism. These lines will be briefly overviewed in my presentation, also as a means to vindicate the value of translational neuroendocrinology, at the intersection between reproduction and metabolism, to tackle prevalent conditions, from obesity to pubertal disorders and infertility.

Chronotherapy in Congenital Adrenal Hyperplasia

Richard Ross
University of Sheffield, Sheffield, United Kingdom

A central tenet in medicine is that disruption of homeostatic mechanisms leads to disease and effective therapy must re-establish normal physiology. The sun imposes a 24-hour periodicity to life and circadian rhythms have evolved to maintain homeostasis through the 24-hour day/night cycle. In humans, there is a central clock that controls the sleep/wake cycle which metabolically is a fast/feed cycle. The clock maintains homeostasis by synchronising metabolism to the time of feeding; for example, regulating the hormones that maintain glucose homeostasis such as insulin and the glucocorticoid, cortisol. Loss of synchrony between the clock and hormonal rhythms results in loss of homeostasis as evidenced by obesity, depression, and diabetes in people undertaking shift work. Loss of the cortisol rhythm in congenital adrenal hyperplasia (CAH) results in poor disease control and increased mortality. To develop chronotherapy, you need to define the drug target rhythm, create a formulation to replicate that rhythm and then prove benefit in clinical trials. The physiology of hormones is more complex than that of non-native drugs. Hormones are secreted with varied rhythms, bound to multiple cognate binding proteins, and actively transported and cleared through enzymatic pathways in multiple organs. We have examined the diurnal rhythm of cortisol in healthy volunteers, created physiologically-based pharmacokinetic models, and tested various oral delayed and sustained formulations (development name Chronocort) of hydrocortisone in phase 1, 2 & 3 clinical trials. The output from this work is modified-release hydrocortisone (MRHC) capsules (tradename Efmody, Diurnal Ltd, Cardiff, UK) that replicate the cortisol diurnal rhythm and improve the disease control of CAH, the commonest hereditary form of adrenal insufficiency.ReferenceWhitaker MJ, Huatan H, Ross RJ. Chronotherapy based on modified-release hydrocortisone to restore the physiological cortisol diurnal rhythm. Drug Deliv Transl Res 2023;13:1-8.

The Parathyroid Hormone Saga: A Never Ending Story

Maria Luisa Brandi
FIRMO Foundation, Florence, Italy

Just before the turning of the 20th century a detailed series of connected events led to the understanding of the physiology, pathophysiology, chemical synthesis, cellular and molecular biology, and pharmacological use of parathyroid hormone (PTH) in the next 120 years. Thanks to scientists like Fuller Albright, Gerald D. Aurbach, John T. Potts, Karen K. Winer, Thomas J. Gardella, and many others, huge progress has been made over the decades through biotechnological advances to increase the medical knowledge regarding PTH. From 2002 the revolutionary pharmacological application of periodic administration of the PTH analog, teriparatide, in the treatment of osteoporosis opened to the development of PTH peptides as drugs to be used in bone and mineral disorders. After this success story a synthetic peptide of human PTH-related protein, abaloparatide, was approved for the treatment of osteoporosis. In 1994, before the development of teriparatide for osteoporosis, the first systematic investigation into synthetic human PTH 1-34 (later indicated as teriparatide) replacement therapy in hypoparathyroidism was launched. Only in 2015 human intact PTH was approved as the first hormone replacement therapy for treating hypoparathyroidism. The challenges ahead for medicinal chemists are to design compounds that affect the PTH receptor in a tissue selective manner. Such developments seem predictable, based on new advances in parathyroid research. ***"The saga of PTH will continue in the biotechnology of its analogs and the interest of pharmaceutical firms in this field's potential."***

Altered splicing process in metabolic (dysregulation)-associated fatty liver disease (MAFLD) progression

Manuel Gahete
University of Córdoba – Department of Cell Biology, Physiology and Immunology, Hospital Universitario Reina Sofía, Córdoba, Spain

Metabolic (dysregulation)-associated fatty liver disease (MAFLD) is the main cause of liver dysfunction, showing a prevalence of 20-30% in the general population and 57-74% among patients with obesity. MAFLD comprises a spectrum of chronic liver diseases, ranging from simple hepatic steatosis to non-alcoholic steatohepatitis or NASH, which can lead to advanced fibrosis and cirrhosis, increasing the risk of hepatocellular carcinoma (HCC). HCC is the most frequent, heterogeneous, aggressive and worst-prognosis primary liver subtype, representing 80-90% of all cases and exhibiting a 5-year survival rate of 17%. The development of HCC is a complex process that normally occurs in the context of chronic liver disease and cirrhosis, which has been recently shown to be closely associated with the presence of obesity and MAFLD. This represents a serious threat for global health in that the prevalence of obesity and MAFLD has increased dramatically and can lead to an increment of cases of advanced liver disease, cirrhosis and HCC. Therefore, we are trying to understand the cellular and molecular events associated to the development and progression of chronic liver disease. One of the most drastically altered biological processes during the progression of MAFLD is the processing of RNA and its alternative splicing. For

this reason, we are characterizing the landscape of spliceosomal (spliceosome components and splicing factors) changes occurring during the development and progression of chronic liver disease from MAFLD and NASH to HCC, as well as their molecular and clinical implications to identify novel molecular markers for the diagnostic and/or prognostic of the different stages of MAFLD, as well as therapeutic targets in the management of this prevalent pathology.

Care of childhood cancer survivors

Stephen Shalet
The Christie Hospital, Manchester, United Kingdom

By 2010 one in 250 of the adult population was a long-term survivor of childhood cancer (CC). In 2014 there were an estimated 420,000 CC survivors in the USA alone(Robison et al.2014). In a follow-up study of 14,000 aging survivors of CC (Mostoufi-Moab et al 2016), in whom the median age at cancer diagnosis was 6 years and at the last Follow-up 32 years, 44% had a least one endocrinopathy,16.7% had at least 2 endocrinopathies and 6.6% had 3 or more endocrinopathies. The key documented modalities of treatment that induced these endocrinopathies are radiotherapy and certain forms of chemotherapy. Over the last 40+ years the following endocrine sequelae have been noted: Hypopituitarism, Thyroid dysfunction, Thyroid tumours, Hyperparathyroidism, Hypogonadism and Infertility, Osteoporosis, Insulin Resistance and Diabetes Mellitus. Newer treatments for certain malignancies such as Proton Beam Therapy for medulloblastoma (Yock et al. 2016), whilst achieving comparable survival figures to those seen after conventional radiotherapy, are still associated with significant endocrine deficits (63% at 7 years). In general, the Paediatric Endocrinologist is reasonably aware of the endocrine requirements, the efficacy of therapy, and the safety issues for CC survivors during childhood. However this is a relatively new field for the Adult Endocrinologist expected to look after these patients during adult life.

Diagnosis and management of paraganglioma

William F. Young
Division of Endocrinology, Diabetes, Metabolism, and Nutrition, Mayo Clinic, Rochester, Minnesota, United States

The first patient with a catecholamine-secreting paraganglioma that was sucessfully resected was in 1926. Over the past 97 years, there has been a dramatic evolution in the clinical presentation, methods used to diagnose and localize, and germline genetic testing of paragangliomas (PGLs). When contrasted to adrenal pheochromocytoma, PGLs present the clinician with unique challenges, which include: 1) diverse location—they may be located anywhere from the tympanic membrane in the ear to the scrotum; 2) markedly variable size at detection—from 0.5 to 25 cm; 3) secretory status—sympathetic PGLs typically hypersecrete catecholamines (some uniquely secrete dopamine) and are located primarily between the mid-thorax to the pelvis; whereas, parasympathetic PGLs usually do not hypersecrete catecholamines and are located primarily between the skull base and upper mediastinum; 4) multiplicity—PGLs are frequently multiple and associated with pathogenic variants in the succinate dehydrogenase subunit genes; and, 5) increased risk of metastatic disease when compared to adrenal pheochromocytoma. These challenges will be discussed and practical clinical perspectives provided.

Novel form of hypophysitis: New kids on the block

Yutaka Takahashi
Division of Diabetes and Endocrinology, Nara Medical University, Japan

Hypophysitis is classified according to the anatomic location of pituitary involvement and the cause (primary or secondary forms). The primary forms are characterized by an idiopathic inflammatory process confined to the pituitary gland, while the secondary forms are triggered by a definite etiology. Recently, as a secondary form of hypophysitis, an immune-mediated paraneoplastic syndrome defined as paraneoplastic autoimmune hypophysitis has been reported. This novel clinical entity, paraneoplastic autoimmune hypophysitis consists of several conditions such as anti-PIT-1 hypophysitis and a part of isolated ACTH deficiency and immune checkpoint inhibitor-related hypophysitis with common underlying mechanisms, in which an ectopic pituitary antigen expression in the complicated tumor evoked autoimmunity against pituitary-specific antigens, resulting in hypophysitis and exhibiting the injury of specific anterior pituitary cells by cytotoxic T cells. These conditions can explain at least in part, the underlying mechanisms of acquired specific pituitary hormone deficiencies. In addition, it is important to apply a comprehensive discipline of onco-immuno-endocrinology to understand the pathophysiology and this approach, the expansion and application of immune-mediated paraneoplastic syndrome to endocrine diseases may give a new clue to understand pathophysiology of the autoimmunity against endocrine organs. In this lecture, the process and lessons from the journey to encounter this novel concept will be discussed.

The curious case of pituitary tumours

Márta Korbonits
Department of Endocrinology, William Harvey Research Institute, Barts and the London School of Medicine, Queen Mary University of London, London, United Kingdom

While just a few years ago we rarely thought about genetics when looking after patients with pituitary tumours, now this aspect of endocrinology, similar to many others, is keeping the genetic labs increasingly busy. Understanding the molecular mechanisms involved in pituitary tumorigenesis and discovering the importance of the microenvironment of these tumours led to deeper understanding of pituitary tumorigenesis. Applying these new discoveries to predict tumour behaviour and to design novel therapies are the challenge what pituitary researchers are facing now. Our lab concentrated on the role of one of the genes that is associated with the development of adenomas/pituitary neuroendocrine tumours. Loss-of-function heterozygote germline mutations in the aryl hydrocarbon receptor interacting protein (AIP) gene predispose to young-onset growth hormone- or prolactin-secreting tumours, which are often large and grow invasively. This is puzzling: why only young-onset; why only growth hormone- or prolactin-secreting tumours and why more aggressive than sporadic tumours? Using various in vitro and in vivo models, while enjoying working with skilful and talented collaborators, we attempted to answer these interesting questions. Acting as a co-chaperone, AIP interacts with the intracellular fragment of the RET receptor, activating a pathway involving PIT1 and leading to p53 accumulation and apoptosis. In one of our mouse models the pituitary-specific loss of AIP leads to abnormal pituitary development. We hypothesise that altered pituitary development may explain the strictly young-onset nature of the disease. As AIP mutation positive tumours are often large and invasive, we studied the tumour microenvironment in human and rodent samples and identified pathways leading to upregulation of pathways leading to cytokine activation and macrophage infiltration. These are just examples, how clinical observations lead to studies explaining the observed phenotype and potentially lead to better diagnostic, prognostic and therapeutic options.

PCOS – the many faces of a disease in women and men

Bulent O. Yildiz
Hacettepe University School of Medicine, Ankara, Turkey

Polycystic ovary syndrome (PCOS) is a common hormonal, metabolic and reproductive disorder characterized by androgen excess, ovulatory dysfunction and polycystic ovaries. The phenotypic presentation might differ between referral and unselected populations and varies within an individual over time and between individuals of different ethnic and geographic regions. Women with PCOS have increased prevalence of prediabetes and diabetes and have multiple risk factors for cardiometabolic disease and other comorbidities such as obstructive sleep apnea, endometrial cancer and mood disorders, which contribute to the health burden of the syndrome.The pathophysiology and intrinsic mechanisms underlying PCOS are complex with a strong genetic component. Earlier studies

have proposed several clinical and biochemical features for the male equivalent of PCOS, including premature baldness, increased adrenal androgen levels, insulin resistance and glucose intolerance. Even though the phenotype for male PCOS is still uncertain, available data from family studies suggest an increased risk for metabolic syndrome and type 2 diabetes in fathers and brothers of women with PCOS along with mothers and sisters. Recent studies provide evidence that PCOS-associated genetic risk for cardiometabolic disease could affect both women and men. Overall, the current name of "PCOS" might be misleading, not reflecting the complexity of the syndrome.

Are patients with diabetes insipidus oxytocin deficient?

Cihan Atila
University Hospital Basel, Department of Endocrinology, Diabetes & Metabolism, Basel, Switzerland

Arginine vasopressin (AVP) and oxytocin (OXT) are neuropeptides produced in hypothalamic nuclei and released into circulation from axon terminals projecting to the posterior pituitary. A disrupted hypothalamic-pituitary axis caused by inflammation, tumours, or head trauma can cause AVP deficiency, also known as central diabetes insipidus (cDI), a condition characterised by polyuria and consecutive polydipsia. Once diagnosed, desmopressin, a selective AVP receptor 2 agonist, is prescribed to overcome cDI symptoms. Despite treatment with desmopressin, patients often report residual psychological symptoms such as heightened anxiety levels, difficulties describing or expressing emotions, and depressed mood, leading to a reduced quality of life. Due to the anatomical proximity, a disrupted AVP system leading to cDI could also disturb the OXT system leading to OXT deficiency. The central oxytocinergic system is key in regulating socio-emotional functioning, including attachment and pair bonding, fear extinction, and emotion recognition. Therefore, increased psychopathological findings in patients with cDI may be caused — at least partially — by an additional OXT deficiency. However, OXT deficiency has never been proven and established as a disease entity. Few studies attempted to measure OXT in these patients and mainly focused on basal measurements delivering inconclusive results. Notably, similar to other pituitary hormones, single basal levels are unreliable in identifying a deficiency in this context and no standard provocation test for OXT has been established. Using an innovative provocation test with MDMA ('ecstasy'), our new data clearly indicate an OXT deficiency in patients with cDI, laying the groundwork for a new hypothalamic-pituitary entity. An important question, however, is whether this deficiency is related to alterations or dysfunctions in socio-emotional behaviour, which needs to be investigated in further interventional studies.

Tolvaptan for hyponatremia in cancer

Alessandro Peri
Pituitary Diseases and Sodium Alterations Unit, Careggi University Hospital, Department of Experimental and Clinical Biomedical Sciences "Mario Serio", University of Florence, Florence, Italy

Hyponatremia is the most common electrolyte disorder in hospitalized patients, including cancer patients. Multiple causes can lead to hyponatremia, but frequently this electrolyte disorder is due to the syndrome of inappropriate antidiuresis (SIAD). In cancer patients this syndrome is mostly secondary to ectopic secretion of arginine vasopressin by tumoral cells. In addition, several chemotherapeutic drugs induce the release of arginine vasopressin by the hypothalamus. There is evidence that hyponatremia is associated to a more negative outcome in a number of pathologies, including cancer. Many studies have demonstrated that in different cancer types both the progressionfree survival and the overall survival are negatively affected by hyponatremia, whereas the correction of serum [Na+] has a positive effect on patients' outcome. Tolvaptan, a vasopressin receptor type 2 antagonist, has been approved more than a decade ago in Europe for the treatment of hyponatremia secondary to SIAD. Tolvaptan effectively corrects hyponatremia and the risk of overcorrection can be minimized by frequent monitoring of serum [Na+] in the 24 hours after initiation of therapy and by avoiding concurrent use of other hyponatremia treatments. Interestingly, tolvaptan has been also approved for the treatment of autosominal dominant polycystic kidney disease. In this disease tolvaptan, at higher doses than dose used for the treatment of SIAD, counteracts cystogenesis by inhibiting the cAMP/PKA pathway. This unpredicted antiproliferative effect of tolvaptan led us to hypothesize that this molecule might counteract tumor cells growth. In vitro evidence confirmed this hypothesis and in different cancer cell lines (i.e. neuroblastoma, hepatocarcinoma, small cell lung cancer, colon cancer) tolvaptan effectively reduced cell proliferation and invasiveness. These results might thus open a new scenario, in which vasopressin type 2 receptor antagonists might have a role among pharmacological strategies against cancer, in addition to their effect in correcting hyponatremia. - Hyponatremia is the most frequent electrolyte alteration in hospitalized patients; - The most frequent cause of hyponatremia in cancer patients is the Syndrome of Inappropriate Antidiuresis (SIAD); - Hyponatremia is associated with a worse outcome in cancer patients; - The vasopressin receptor type 2 antagonist tolvaptan effectively corrects hyponatremia in SIAD; - In vitro evidence indicated that tolvaptan has an unpredicted antiproliferative effects in cancer cell lines, thus possibly opening a new scenario in treatment strategies against cancer.

Signalling in ACC pathogenesis

Kaitlin Basham
Huntsman Cancer Institute, University of Utah, United States

Adrenocortical carcinoma (ACC) is a routinely fatal cancer with no effective treatments. Understanding the genetic landscape of ACC is essential to develop novel therapeutic strategies. Recent large-scale cancer genomics projects have revealed core signalling pathways frequently altered in human ACC tumours, including the Wnt/b-catenin pathway. Aberrant Wnt activation is a hallmark of ACC observed in ~40% of tumours, and can be driven by diverse mutational events. These include well-characterised activating mutations in CTNNB1 (b-catenin) as well as newly identified loss-of-function alterations in ZNRF3, an E3 ubiquitin ligase that promotes Wnt receptor degradation. To study the functional role of ZNRF3 loss in ACC tumourigenesis, we developed a new mouse model to specifically ablate Znrf3 in the adrenal cortex. Our studies reveal that Znrf3 loss is permissive for ACC tumour progression, but not completely sufficient. We identify ageing and sex as key extrinsic factors that cooperate with Znrf3 loss by reshaping the immune microenvironment in order to permit malignant transformation. Further, we demonstrate that sex steroid hormones are a potent regulator of the anti-tumour immune response in the adrenal. Collectively, our studies highlight the intersection between paracrine Wnt signalling and endocrine hormone signalling in the pathogenesis of ACC. These pathways have important clinical implications and may be exploited for therapeutic benefit.

Immune contribution to ACC pathogenesis

Pierre Val
Institute of Genetics Reproduction and Development (iGReD), CNRS UMR 6293, Inserm U1103, Clermont Auvergne University, Clermont-Ferrand, France

The immune microenvironment plays a central but ambivalent role in tumourigenesis. During initial phases of neoplasia, both innate and adaptive immune cells recognize and destroy tumour cells. However, during the process of immunoediting, tumour cells progressively reshape the microenvironment and use immune cells to favour neoangiogenesis, tumour growth and metastasis. Until recently, the role of immune response in the pathogenesis of ACC had remained elusive. Analysis of the TCGA gene expression data had suggested that ACC were among the coldest tumours, consistent with the potent immunosuppressive action of glucocorticoids (GCs), produced locally. This was confirmed by immunohistochemical analyses showing that both CD4+ and CD8+ T cells were scarce in ACC. It further showed that tumours with highest levels of GCs were the coldest and the most aggressive. Consistent with low levels of T cells infiltration, clinical trials targeting the PD1/PD-L1 axis failed to significantly increase ACC patients' overall survival. Interestingly, analysis of a mouse model harbouring deletion of Znrf3 (the most frequent genetic alteration in ACC patients) showed that highly phagocytic MERTK+/TREM2+ macrophages, were efficiently recruited in preneoplastic lesions in male adrenals, preventing formation of aggressive tumours. In contrast, infiltration of MERTK+/TREM2+ macrophages was lower in female adrenals, allowing for tumour

progression and formation of metastatic ACC at 18 months. Analysis of TCGA data further showed that male ACC patients had generally higher levels of phagocytic macrophages signatures, correlated with better prognosis than female patients. Investigation of the mechanisms underlying this sexual dimorphism, showed that testosterone was responsible for the recruitment of phagocytic macrophages, through senescence induction. We are now investigating the downstream targets of androgens to identify factors that could be used to trigger phagocytic macrophage differentiation in ACC patients. This could constitute an exciting alternative therapeutic approach for this cancer, associated with dismal prognosis.

S2.3

Sexual dimorphism in ACC pathogenesis

Andreas Schedl
Université Côte d'Azur, CNRS, Inserm, iBV, Nice, France

Sex is an important parameter that influences biology and physiology of almost every organ. Sex bias is not restricted to homeostatic conditions, but is also evident in the predisposition and progression of diseases. The adrenal cortex, in particular, displays dramatic sex differences and the majority of adrenocortical diseases occur more frequently in women than in men. Understanding how sex hormones affect biology on the molecular level has therefore become an important focus, as it may help us to develop therapeutic approaches that take sex into account. In this presentation, I will provide an overview of the impact of sex on adrenal diseases. I will summarize experimental data from model systems that have revealed strikingly dimorphic expression profiles between the two sexes and demonstrated the important role of androgens in suppressing proliferation of steroidogenic cells and the recruitment of their precursors. Finally, I will highlight recent results in mouse models for adrenocortical tumors that explore the sex specific responses of the adrenal cortex to hyperactivation of the b-catenin pathway and further reveal the growth suppressing function of androgens in this disease context.

Non-classical actions of vitamin D: What have we learned?

S4.1

Role of vitamin D in the prevention of T1 and T2 diabetes

Dimitrios Papadimitriou
Pediatric Endocrinologist, Aretaieion University Hospital, Athens, Greece

Since the statistical error in the RDA calculation for vitamin D has been revealed, and verified, concerns have been raised, turning the perpetual vitamin D debate groundless. Daily vitamin D up to 1000 IU <6 m, 1500 6 m-1 yr, 2500 1-3 yrs, 3000 4-8 yrs, 4000 >8 yrs are the IOM's upper tolerable limits not requiring medical supervision according to the Endocrine Society Practice Guideline Committee. The hazard ratio for all-cause mortality plateaus with 25(OH)D >50 ng/ml. 600/4000/10000 IU/day up/downregulate 162/320/1289 white blood cell genes. 4000 IU/day inhibits inflammatory hyperactivity regulating/differentiating humoral and cell-mediated immunity. T1D is the final consequence of β-cell autoimmunity but β-cell stress in T2D provokes an immune attack as well. 25(OH)D >40 ng/mL improves insulin secretion, rescues β-cells suppressing macrophage adhesion/migration and >50 ng/ml reduces T2D risk by 76%, favoring regression by 30% with no adverse events. Non-maternal T1Abs appear at 3-6 months of age with 100% lifetime T1D risk, suggesting a window for intervention during seroconversion. Primary prevention from birth with 2000 IU/day cholecalciferol reduced T1D incidence by 80% at 1 yr. T1D hits 1:300 with rising incidence increasingly affecting younger children. However, T1D has plateaued and decreased in Finland after 25(OH)D population concentrations reaching 40 ng/ml following fortification of dairy products. Screening with T1Abs at ages 2-6 yrs is sensitive but lacks a feasible preventive strategy. In a pilot clinical trial seroconversion to even multiple T1Abs was reverted within 7 m with oral calcitriol, leading to the ongoing PRECAL study (PREvention of Type 1 Diabetes with oral CALcitriol and analogues, ISRCTN17354692) with confirming results in preventing and reverting even relapses of seroconversion to T1Abs, but also to thyroid/celiac disease Abs in young children presenting early autoimmunity. Primary prevention of T1D with cholecalciferol and secondary with calcitriol/analogues seem promising, plausible, possibly cost-effective, and safe, if started well before pre-T1D, close to seroconversion.

Randomized clinical trials with vitamin D

Stefan Pilz
Department of Endocrinology and Diabetology, Medical University of Graz, Graz, Austria

Vitamin D deficiency is associated with several adverse skeletal and extra-skeletal outcomes including cancer, cardiovascular diseases, and mortality. Large randomized controlled trials (RCTs) have been conducted over the last few years with the aim to evaluate the cause-and-effect relationship of vitamin D and health outcomes. These RCTs failed to document significant effects of vitamin D on their primary outcome measures, whereas explorative analyses and meta-analyses suggest potential benefits of vitamin D regarding cancer mortality, acute respiratory infections, and asthma as well as chronic pulmonary disease exacerbations. Findings from vitamin D RCTs did not indicate significant safety concerns, except for RCTs in severely ill patients or with intermittent high-dose vitamin D treatment. Drawing final conclusions on vitamin D is, however, limited as the majority of vitamin D RCTs was not conducted in participants suffering from vitamin D deficiency and because many of these RCTs allowed for vitamin D supplementation in the placebo groups. Thus, the design of vitamin D RCTs adhered to drug RCTs and did not sufficiently account for vitamin D as a nutrient with a unique metabolism including its role as a precursor for the hormone calcitriol. Moreover, recently published RCTs did not specifically address the role of vitamin D in the prevention and treatment of rickets and osteomalacia, that remain the scientific basis for vitamin D guidelines. The learnings from the

scientific history of vitamin D with its probably overwhelming hype based on observational studies and the severe limitations of large vitamin D RCTs, that still leave us with many knowledge gaps, will hopefully inform the design of future research activities on vitamin D and other research fields.

Dopamine receptor dynamics: How to shake prolactinomas

Erika Peverelli
University of Milan, Milan, Italy

Prolactinomas are the most frequent pituitary tumors, and dopamine agonists (DA) are their first-choice treatment, since they normalize PRL levels and reduce tumor size in the majority of patients, by binding to dopamine receptor type 2 (DRD2) on tumoral cells. However, drug resistance occurs in a subset of patients, involving different steps following receptor activation or during the final biological responses. Although resistance to DA has been correlated with a reduced DRD2 expression, or with an altered ratio between the two isoforms of DRD2, the success of the therapy also requires the proper functioning of the machinery of signal transduction and receptor intracellular trafficking. A variety of molecules, including β-arrestins, filamin A (FLNA) and splicing factors might affect the efficacy of therapy. FLNA is a cytoskeleton actin-binding protein crucial for DRD2 expression, membrane localization and signaling. Since FLNA phosphorylation switches FLNA function from a scaffold that allows DRD2 signal transduction to a signal termination protein that hampers all DRD2 antitumoural effects in prolactinoma cells, new possible pharmacological approaches can target FLNA post-translational modification. The scaffold protein β-arrestin 2 is essential for DRD2 inhibitory effects on AKT phosphorylation with a consequent reduction of cell proliferation in prolactinoma cells. This observation not only suggest a potential role of β-arrestin 2 as a biomarker predicting prolactinoma responsiveness to treatment with DA, but also a novel pharmacological strategy based on functionally selective or biased DRD2 agonists that preferentially activate the 2-arrestin 2-mediated pathway at the expense of the canonical G-protein-mediated ones. Alternative splicing is a crucial mechanism for gene regulation, generating different functional proteins, and this process can be dysregulated in cancer. In particular, a severe dysregulation of splicing-machinery components in all the pituitary tumor subtypes compared to normal pituitaries has been observed. Somatic mutations in splicing factor3 subunitB1 (SF3B1) were found in about 20% of PRL-secreting pituitary tumors in a single paper, associated with PRL hypersecretion, increased cell proliferation and invasion. These data provide the rationale for investigating new therapeutic strategies based on SF3B1 inhibition, as well as for testing the effects of splicing alterations on DRD2 expression and responsiveness to treatment with DA. Further studies of the complex mechanisms involved in the resistance of prolactinomas to DRD2-targeted therapy could provide the basis for the development of both new prognostic biomarkers that can be used for patient selection and management and novel targets for the pharmacological treatment of these tumors.

S5.3

Alternative medical treatments for prolactinomas

Renata Simona Auriemma
Università Federico II di Napoli, Naples, Italy

Dopamine agonists (DA), mainly cabergoline, are nowadays recommended as the treatment of choice for patients with prolactinomas of any size to lower PRL levels, decrease tumour size, and restore gonadal function. However, some patients do not adequately respond to DA, and resistance to DA may occur in 20-30% of patients treated with bromocriptine and nearly 10-20% of those receiving cabergoline. In these patients, multimodal therapy, including surgery and/or radiotherapy, may be required. Recent evidence also supports the use of surgery as first-line therapy for patients with enclosed and not invasive prolactinomas. Aggressive and malignant prolactinomas refractory to all treatment strategies may benefit from the administration of the oral alkylating chemotherapeutic agent temozolomide, whose efficacy in terms of tumour growth control accounts for up to 50% of patients with prolactinomas. Temozolomide is nowadays recommended as first-line chemotherapy for aggressive pituitary tumours and pituitary carcinomas, following documented tumour growth. Responsiveness to temozolomide may be predicted by the evaluation of O(6)-methylguanine methyl transferase (MGMT) status by immunohistochemistry, as high MGMT expression is generally suggestive of a lack of response. The effectiveness of temozolomide has been shown to increase when combined with radiotherapy given its radio-sensitizing properties, thus offering a further therapeutic option for those individuals with aggressive or malignant prolactinomas. Aside from surgery, radiotherapy, and chemotherapy with temozolomide, alternative treatment schedules have been investigated or are nowadays tested in clinical and preclinical models, but the experience is still too scant to draw definitive conclusions. Among them, alternative hormonal treatments, cytotoxic drugs, peptide receptor radionuclide therapy, mTOR/Akt inhibitors, anti-VEGF bevacizumab, tyrosine kinase inhibitors and immunotherapy with immune checkpoint inhibitors, appeared to offer promising results. Future research will clarify the potential applications of such treatments, driving endocrinologists in the choice of the best-tailored therapy for patients with aggressive and malignant prolactinomas.

The effect of ambient temperature on adipose tissue

Barbara Cannon
The Wenner-Gren Institute, Stockholm University, SE-106 91 Stockholm, Sweden

There are many effects on adipose tissue metabolism of housing mice at different temperatures. Considering the situation from a thermoregulatory perspective, it may – in retrospect – be evident that one cannot expect to observe any effect of e.g. UCP1 ablation under "normal housing" conditions. This is because at normal animal house conditions (≈20 °C), the mice experience significant cold, and they must increase their metabolism by 50-100 % (as compared to mice living at thermoneutrality) to compensate for the heat loss. This clearly means that any heat production deriving from diet-induced thermogenesis will be used in the struggle to keep up the body temperature: the mice have to produce extra heat or they will become hypothermic and die. Thus, any heat from any diet-induced thermogenesis will merely be experienced as extra heat - but if this is absent, it has to be substituted for with some other "heat". Thus, UCP1 KO mice have to

produce the same amount of heat as have wildtype mice, to survive under normal housing conditions. How this is accomplished is presently not really clarified. Under normal housing conditions, UCP1 KO do not show overt shivering (as they do when exposed to the much greater "standard" cold (=4°C). As these mice are devoid of adrenergically induced nonshivering thermogenesis, the heat must be produced in other ways, perhaps through increased muscular tone. In any case, these mice cannot allow themselves to reduce their metabolism due to the absence of UCP1: thermogenesis must be maintained, and thus there will be no "unused energy" to be stored, resulting in no obesity development under these conditions. The situation is principally very different with mice living at thermoneutrality that resembles the human situation. Here, any differences in thermogenesis (energy expenditure) should be directly observable since they are not used for thermoregulation. Mice at thermoneutrality therefore yield a fully different result. When given a high-fat diet, UCP1 KO mice become clearly more obese than the wildtype mice – although they do not develop the massive obesity seen in *ob/ob* mice.

Aberrant/illicit expression of receptors in adrenal lesions

S7.1

GnRH in primary aldosteronism

André Lacroix
Department of Medicine, Centre de Recherche du Centre hospitalier de l'Université de Montréal (CHUM), Montréal, Québec, Canada

The mechanisms regulating aldosterone secretion in primary aldosteronism (PA) independently from the renin-angiotensin axis include diverse genetic and molecular mechanisms. One mechanism results from the activation of aberrantly expressed GPCR which are diverse and highly prevalent in adrenal tissues of patients with PA, either from aldosteronoma or bilateral adrenal hyperplasia. The levels of expression of GPCR vary greatly between different PA tissues particularly for ACTH (MC2R) and serotonin (HTR4R) receptors with local increased presence of mast cells and serotonin production in adrenocortical tissues. Transcriptome studies or *in vivo* stimulation studies have identified greatly variable expression of GnRHR or LHCGR or aldosterone response to stimuli in approximately 30% of PA patients. In some, PA became evident during pregnancy or after menopause, following activation by placental hCG or increased levels of LH after menopause. In one case, repeated episodes of severe hypertension and hypokalemia with transient PA during pregnancy was secondary to LHCGR in an aldosteronoma revealed outside of pregnancy by stimulation with HCG during 5 days and again during adrenal vein sampling. The molecular mechanisms leading to aberrant GnRHR or LHCGR are not completely elucidated. Somatic β-catenin (*CTNNB1*) mutations was suggested to induce ectopic LHCGR and GnRHR during pregnancy or menopause, but not confirmed in several patients with aldosterone response to GnRH or LH tests in vivo. More recently, overexpression of those aberrant receptors required combined mutations of *GNA11*or *GNAQ*in *CTNNB1*-mutant aldosterone-producing adenomas presenting in puberty, pregnancy or menopause. Thus, aldosterone secretion in patients with PA is not autonomous or constitutive despite the activation of aldosterone synthase by ion-channel or other genes mutations, but is dysregulated by the activation of diverse and variable aberrant expression of several GPCR by their ligands.

LHCG Receptor in pheochromocytoma

Antoine-Guy Lopez[1], Céline Duparc[2], Sylvie Renouf[2] , Jean-Christophe Sabourin[3], Alexandre Buffet[4] , Anne-Paule Gimenez-Roqueplo[4], Christophe Dubessy[2], Estelle Louiset[2] & Hervé Lefebvre[1]

[1]Univ Rouen Normandie, INSERM, NORDIC UMR 1239, CHU Rouen, Department of Endocrinology, F-76000 Rouen, France; 2Univ Rouen Normandie, INSERM, NORDIC UMR 1239, F-76000 Rouen, France; 3Univ Rouen Normandie, INSERM, UMR 1245, CHU Rouen, Department of Pathology, Tumor BioBank-Centre for Biological Resources, F-76000 Rouen, France; 4Univ Paris, PARCC, INSERM, Department of Genetics, AP-HP, European Hospital Georges Pompidou, Paris, France

Pheochromocytomas/paragangliomas (PPGL) are catecholamine-producing neuroendocrine tumors that account for less than 1% of all hypertension cases. Despite their rarity, these tumors must be early detected and treated to prevent potentially life-threatening adrenergic crises. Unfortunately, PPGL are frequently unrecognized during pregnancy, leading to a high risk of either maternal or fetal complications. In return, pregnancy can trigger catecholamine secretory discharges in patients with PPGL through diverse mechanisms which are not totally understood. The observation that symptoms of catecholamine excess may occur during the first trimester of gestation suggests that pregnancy may activate the secretory activity of PPGL through the involvement of gestational hormones. We have recently reported a case of silent pheochromocytoma revealed in a pregnant woman by adrenergic myocarditis. *In vitro* studies revealed that hCG stimulated epinephrine secretion by cultured cells derived from the patient's pheochromocytoma. The tumor expressed the LHCG receptor (LHCGR), which was colocalized with catecholamine-producing enzymes. Expression of the LHCGR was also detected in an independent series of pheochromocytomas. *In silico* studies have been conducted in The Cancer Genome Atlas (TCGA) cohort and French COMETE databases which contain genomic and transcriptomic analyses of solid tumor types including PPGL. They revealed that PPGL display the highest expression levels of LHCGR mRNA among the 32 tumor types of TCGA. Interestingly, LHCGR expression level was higher in epinephrine-secreting PPGL, *i.e.* related to RET, NF1, TMEM127, MAX mutations, vs other subgroups of PPGL, and in pheochromocytomas vs paragangliomas. These data show that pregnancy can favor adrenergic crises in patients with PPGL through hCG-induced stimulation of epinephrine production by the tumors. They indicate that preconceptional diagnosis is particularly important in patients with gene mutations that predispose to epinephrine-secreting pheochromocytomas, who may experience signs of catecholamine excess as soon as the first trimester of gestation.

Lessons from Laron syndrome

Haim Werner
Department of Human Molecular Genetics and Biochemistry, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel

Laron syndrome (LS) is a rare genetic endocrinopathy that results from mutation or deletion of the growth hormone receptor (*GH-R*) gene. LS is the best characterized entity under the spectrum of the congenital insulin-like growth factor-1 (IGF1) deficiencies and is typically associated with dwarfism and obesity. Epidemiological studies have shown that LS patients do not develop cancer whereas heterozygous family members have a tumor prevalence similar to the general population. To identify genes and signaling pathways that are differentially expressed in LS and that may help delineate a biochemical and molecular basis for cancer protection, we conducted a genome-wide profiling of LS patients. Analyses were based on our collection of Epstein-Bar virus (EBV)-immortalized lymphoblastoid cell lines derived from LS patients, relatives and healthy controls. Bioinformatic analyses identified differences in gene

representation in a number of pathways, including apoptosis, metabolic control, cytokine biology, Jak-STAT and PI3K-AKT signaling, etc. Genes involved in positive control of cell cycle, motility, growth and oncogenic transformation are, in general, down-regulated in LS patients. These genetic events seem to have a major impact on the biological properties of LS cells, including proliferation, apoptosis, response to oxidative stress, etc. Furthermore, genomic analyses allowed us to identify novel IGF1 downstream target genes that have not been previously linked to the IGF1 signaling pathway. In summary, by '*mining*' genomic data from LS patients we were able to generate clinically-relevant information in oncology and, potentially, in other areas in which the IGF1 system is involved.

S8.3

Lessons from experimental animal models

John Kopchick
Edison Biotechnology Institute & Heritage College of Medicine, Ohio University

Reports dating back to the 1950s have implicated human Growth Hormone (GH) in the initiation and invasive progression of several types of human cancers. A major hurdle in treating cancer is resistance to therapy. Recently, through a series of mechanistic studies using *in vitro* models and in silico analyses of human cancer patient databases, we have identified a covert role of GH in promoting cancer drug resistance via direct upregulation of: (i) the expression of ATP-binding cassette containing multi-drug transporters (ABC transporters) leading to increased drug efflux, (ii) the epithelial-to-mesenchymal transition (EMT) associated gene expression program, and (iii) the mediators of fibrosis and extracellular matrix remodeling. Additionally, based on the known effects of GH and robust expression of GHR in multiple cell types that constitute the tumor microenvironment, autocrine/paracrine GH putatively exerts potent tumor supportive actions. Therefore, we hypothesized that combining a GHR antagonist to chemotherapy can markedly improve therapeutic outcome in human cancers. Melanoma and liver cancer jointly and annually constitute $>150{,}000$ patients and $>60{,}000$ deaths respectively in the US, much due to therapy resistance. We used a syngeneic murine model of both cancers using C57BL6 mice transgenic for a GHR antagonist (GHA mice) compared to wild-type (WT) littermates, both implanted with either B16F10 melanoma or Hepa-1-6 hepatoma cells. GHA expression drastically sensitized melanoma tumors to cisplatin treatment and hepatoma tumors to sorafenib treatment. Additionally, the five-year survival rates of human pancreatic cancer and cholangiocarcinoma are a dismal 10% in 2022, indicating an urgent need for new therapeutic approaches for both these devastating diseases. For this, we used immunocompromised Nude mice for human pancreatic cancer xenografts treated $\pm$ GHA (Pegvisomant and another GHA in development in our laboratory) combined with gemcitabine. GHA markedly sensitized pancreatic cancer xenografts to gemcitabine, leading to ~40% of mice being tumor-free at the end of study. GHA similarly sensitized human cholangiocarcinoma xenografts in Nude mice to gemcitabine-cisplatin therapy. Mechanistically and in all cases, GHA led to a marked reduction in gene expression of multidrug efflux transporters, EMT markers, and fibrosis mediators. Collectively, our data provides strong pre-clinical evidence for treatment regimens combining GHR antagonism and chemotherapy leading to highly efficacious tumor clearance.

DOI: 10.1530/endoabs.90.S8.3

Pitfalls in osteoporosis treatment transition

S9.1

Denosumab discontinuation

Bente Langdahl
Aarhus University Hospital, Aarhus, Denmark

Denosumab is an effective treatment of osteoporosis that leads to substantial increases in bone mass and clinically important reductions in fracture risk with few side effects. Most patients should continue treatment; however, some patients may need to discontinue treatment due to co-morbidities or side effects. Furthermore, some patients want to discontinue treatment because of normal or near-normal BMD and absence of fractures after years on treatment. Unlike bisphosphonates but like most other pharmacological treatments, there is no continuing effect of denosumab after discontinuing the administration. Due to the accumulation of RANKL and possibly osteoclasts during treatment with denosumab a rebound activation of bone resorption is seen in patients discontinuing denosumab after more than 1-2 years of treatment. This can partly be prevented by the administration of bisphosphonates, primarily zoledronate. The patients need frequent monitoring with p-CTX and in some cases multiple administrations of zoledronate during the first year after discontinuation in order to prevent bone loss.

S9.2

Changing treatment within and between pharmacological classes

Marija Pfeifer
Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Osteoporosis is characterized by decreased bone mineral density (BMD) and deterioration of bone microarchitecture increasing fracture risk. The main goal of osteoporosis treatment is preventing osteoporotic fractures. The most important predictor of treatment mediated fracture risk reduction is the increase in BMD. Treatment of osteoporosis falls into three pharmacological classes: antiresorptive agents (SERMs, oestrogen, bisphosphonates (BP), denosumab), osteo-anabolic drugs (teriparatide, abaloparatide), and dual-action drug romosozumab (mAb inhibiting sclerostin). The most commonly used are antiresorptive therapies. We switch from less potent raloxifene or ibandronate to more potent oral BPs alendronate or risedronate, or to the most potent antiresorptive drugs zoledronic acid i.v. or denosumab s.c., when more potent treatment and hip fracture prevention is needed. Namely, with raloxifene and ibandronate no significant reductions of non-vertebral or hip fractures were seen. When there are indications to discontinue denosumab a BP should be introduced. If denosumab treatment was short (1 year) an oral agent will do; after long-term treatment zoledronic acid should be applied 6 and 12 months after the last denosumab injection. In the case of treatment failure with a potent antiresorptive (significant decrease in BMD or new fractures after 12 months of adequate osteoporosis treatment) an anabolic agent is usually introduced for 24 months or dual-acting romosozumab for 12 months. It is obligatory to switch from anabolic or dual-action agent to antiresorptive agent when anabolic treatment is accomplished. In patients with very high fracture risk or those with very low BMD (T score $<$ -3 SD) at presentation the initial osteo-anabolic treatment should be introduced. Anabolic agents induce the fastest increase of BMD and reduce fracture risk more rapidly and to a greater extent than antiresorptive medications. After atypical femoral fracture or osteonecrosis of the jaw caused by long-term BPs or denosumab therapy, an osteo-anabolic agent can be introduced if no contraindications exist.

The impact of paediatric obesity and its complications in adulthood

S10.1

Fatty liver in children

Joel Lavine
Columbia University, New York, United States

Nonalcoholic fatty liver disease (NAFLD) has become the leading cause of chronic liver disease in children and adolescents in the United States, disproportionately affecting certain ethnic and racial groups. A 2 to 3-fold rise in the prevalence of obesity and overweight in children over the last 3 decades highly relates to the NAFLD epidemic. There are concerns that children with nonalcoholic steatohepatitis (NASH) are more prone to progress to cirrhosis, which may increase liver-related mortality in adulthood. Also worrisome is the recognition that cardiovascular risk and type 2 diabetes in children and adolescents are associated with fatty liver. Pediatric fatty liver disease often

displays a histologic pattern distinct from that recognized in adults. Liver biopsy remains the gold standard for diagnosis of NASH. Further pediatric-specific noninvasive biomarker development is needed to diagnose and monitor those with NASH. Targeted therapies to improve liver histology and metabolic abnormalities associated with fatty liver are needed, as unique regulatory considerations impede pediatric therapeutic trials with agents demonstrating current promise in adults. Randomized-controlled trials in children and adolescents to date show improvement in particular histologic aspects of NASH, for which vitamin E appears effective. Public health awareness and lifestyle interventions are needed to promote healthy diets, exercise, and lifestyle modifications to prevent and reduce the burden of disease.

BULLET POINTS:-

- Fatty liver disease (NAFLD) has become the most common cause of chronic liver disease in pediatric populations in developed nations.
- Certain ethnic groups such as indigenous Mexican-Americans, South Pacific Islanders, and Middle Easterners are more prone, and male gender, obesity and insulin resistance are most frequent concomitants
- The unique histologic pattern of earlier-onset NAFLD in children demonstrates a pattern of periportal steatosis and fibrosis, with relative lack of hepatocellular ballooning, in contrast to the later onset and adult pattern with panacinar steatosis, ballooning cell injury, and perivenular fibrosis.
- Limited randomized clinical controlled trials in pediatrics utilizing liver histology demonstrate utility and safety of vitamin E to improve NASH histology, while no agents have yet been proven in pediatrics to improve fibrosis.
- In order to mitigate this problem, better noninvasive tests validated in pediatric cohorts need attention, and extrapolated efficacy of drugs shown effective in adult trials need to be shown to be safe before widespread use. Until then, prevention and treatment needs to be aimed at identifying those at risk and promoting healthy lifestyle interventions.

S10.2

Transition of obese children to adulthood

Beatrice Dubern
Service de Nutrition et Gastroentérologie Pédiatriques, Hôpital Trousseau, AP-HP, Inserm UMR-S 1269 Nutriomics, Paris, France

Obesity is defined as excess body fat mass with adverse health consequences and is a chronic disease often associated with co-morbidities when it persists into adulthood. It is therefore important to support adolescents with obesity during the period of transition to adulthood in order to avoid the possible worsening of their medical condition. This risk is particularly important in the specific case of monogenic or syndromic obesities, especially as it is also a period of fragility with important psychosocial aspects. Since recently, dedicated organizations to transition have emerged such as specific platforms, to facilitate coordination between health professionals and help young people to integrate their dedicated care pathway as adult.

Endocrine disrupting chemicals on the HPG axis at different life stages

S11.1

EDCs in precocious puberty

Samim Özen
Ege University Faculty of Medicine, Department of Pediatrics, Division of Pediatric Endocrinology, İzmir, Turkey

Puberty is the process of physical change that occurs between childhood and adulthood, during which adolescents reach sexual maturity and become capable of reproduction. The onset and course of puberty are under the control of the neuroendocrine system. Factors affecting the timing and regulation of the functions of this system may alter the onset and course of puberty. Recent studies have demonstrated a progressive decrease in the age of onset of puberty in children around the world. Although the exact reason for this shift is not completely understood, it is generally accepted to be the outcome of a complex interaction between genetic, epigenetic, endocrine, and environmental factors. It is also known that owing to the acceleration of industrialization throughout the world, a gradual but significant increase has occurred in the number and amount of environmental pollutants. Some of these environmental pollutants are natural or synthetic chemicals with considerable effects on the endocrine system. The chemicals that have negative effects on the endocrine system are called endocrine disrupting chemicals (EDCs). EDCs exert their effects through different mechanisms: by binding to the relevant hormone receptors; by direct action on cell signaling pathways or on the central nervous system and the neuroendocrine system. Several EDCs such as phytoestrogens, topical and natural estrogens, pesticides, industrial chemicals, and phthalates have been identified as possible agents affecting pubertal development in humans. These chemicals may exert their estrogenic effects either directly by binding to estrogen receptors, increasing aromatase activity, and increasing estrogen sensitivity, or indirectly by their effect on GnRH, leading to an increase in endogenous estrogen production. In this part of the panel, the roles of EDCs in precocious puberty will be discussed with examples from animal and human studies.

S11.2

EDCs in PCOS

Eleni A. Kandaraki
Department of Endocrinology, Diabetes and Metabolism, HYGEIA Hospital, Athens, Greece

Polycystic ovary syndrome (PCOS) is now globally recognised as the most common endocrinopathy in women of reproductive age and has a prevalence of 5-21% depending on the criteria used (NIH, Rotterdam or Androgen Excess Society). What is special about the syndrome is its dual entity involving both the reproductive and metabolic profile of the women affected. As a result, any intrinsic or extrinsic factors affecting both these components, could lead to pathophysiological alterations which characterize PCOS. In fact, the heterogenicity of the syndrome suggests that apart from the genetic background, the role of the environment and lifestyle are equally important. In particular, during the last twenty years, interest has been drawn to the impact of certain environmental toxins, referred by the term 'Endocrine Disruptors' or 'Endocrine Distruptive Chemicals (EDCs)', which may modify both reproductive and metabolic pathways. Western Civilization advancement in industrial products and food processing have led to increased daily exposure to Plasticizers, such as Bisphenol A and phthalates, as well as dietary glycotoxins, such as Advanced glycation end products (AGEs), which may exert adverse effects on reproduction and metabolism throughout the female life span.

Role of EDCs during conception and embryo development

Pauliina Damdimopoulou[1,2]
[1]Division of Obstetrics and Gynecology, Department of Clinical Science, Intervention and Technology, Karolinska Institutet, Stockholm, Sweden; [2]Department of Gynecology and Reproductive Medicine, Karolinska University Hospital, Stockholm, Sweden

Human-made chemicals have become an inevitable part of life. There are approximately 100 000 chemicals on the European market and 70% of them have not been assessed for human health risks. As a consequence, every citizen faces exposure to mixtures of poorly characterized chemicals that include, for instance, flame retardants, plasticizers, additives in personal care products, and persistent organic pollutants. The exposures correlate with multiple adverse health outcomes including infertility. My research has centred on women living in Sweden. Complex mixtures of persistent organic pollutants were found in every woman of reproductive age participating in our studies, and the levels correlated with lower ovarian reserve, longer time-to-pregnancy, and smaller chances to succeed in infertility treatments. The chemicals were present in follicular fluid at similar levels to serum, indicating direct exposure of the maturing oocytes.

Several associations were found between exposure and markers of ovarian function and fertility. For example, the concentration of the perfluoroalkyl substance PFOS in follicular fluid associated with higher basal antral follicle count but lower embryo quality in women undergoing IVF tretments. In controlled exposure experiments, PFOS disrupted gene expression and DNA methylation in bovine blastocysts at human relevant levels. Further, our *in vitro* studies with human endometrial cells showed that PFOS might also disrupt decidualization. Finally, persistent organic pollutants including PFOS were found to cross the placenta and deposit to vital organs in human foetuses. In summary, exposure to human-made chemicals is life-long and starts before birth. Epidemiological research together with experimental studies suggest multiple associations between chemicals and adverse fertility outcomes including altered oocyte maturation and embryo development. It is essential that chemical hazards towards fertility in women are better studied. Immediate actions should include development of assays that can be applied to study the safety of chemicals already in commerce, and new ones to come before they enter the market.

Doping effects on non-reproductive organs: How the love of muscle can break a heart

Elena Vorona
University Hospital Münster, Münster, Germany

High doses of anabolic-androgenic steroids (AAS), especially when taken concomitantly with multiple other preparations, can lead to a decrease in high-density lipoprotein (HDL) cholesterol and an increase in low-density lipoprotein (LDL) cholesterol. After long-term, high-dose AAS abuse, atherosclerosis may develop, leading to coronary artery disease, cerebral vascular disease or peripheral artery disease. The degree of atherosclerosis appears to be dependent on the duration of AAS exposure. Long-term AAS users show altered electrophysiological activity of the myocardium with a significantly higher incidence of abnormal electrocardiograms after exercise. In some cases, AAS abuse resulted in a long-term elevation of blood pressure. Activation of the sympathetic autonomic nervous system, decreased parasympathetic modulation and structural cardiac changes appear to be possible causes of arterial hypertension. Some AAS in high doses cause water retention, which may be associated with arterial hypertension. AAS can cause concentric left ventricular myocardial hypertrophy, may also impair left ventricular diastolic function, which seems to be irreversible and detectable even after several years of AAS withdrawal. AAS abuse can cause a sudden cardiac death in apparently healthy young athletes. The most common causes of sudden death in young competitive athletes are hypertrophic cardiomyopathy and previously undiagnosed congenital heart failure. Other causes include coronary artery spasms, premature coronary atherosclerosis, thrombotic coronary artery occlusions due to an increased platelet aggregation and an increase in haematocrit, and direct cardiotoxic effects on cardiomyocytes.

In silico, in vitro, in vivo testing methods for EDC

S14.1

Development of High Throughput Screening methods for the Thyroid Hormone System

Caroline Frädrich
Charité-Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Institut für Experimentelle Endokrinologie, 10115 Berlin, Germany

Current strategies for identifying substances that adversely affect the thyroid hormone (TH) system (e.g. endocrine disrupting compounds [EDC]) are exclusively focussed on changes in serum TH concentrations and thyroid histopathology. This is based on the assumption that altered TH concentrations in serum directly result in impaired TH action in tissues. However, TH action is also regulated by hormone transport into cells and tissues (e.g. MCT8), activation of T4 to T3 by deiodination (DIO1-3), iodine recycling (DEHAL1), and interaction of T3 with TRs isoforms. Therefore, an analysis of EDC effects based on serum analysis and thyroid histopathology is insufficient and needs to be extended. Evaluation of the large number of chemicals for their thyroid hormone system disrupting (THSD) potential requires high-throughput screening (HTS) tests for rapid characterization of human and ecosystem hazards. In addition, a panel of reference chemicals and data describing their bioavailability and bioactivity for specific molecular targets, cellular pathways, and biological processes is needed. Such reference panels need to be validated by in vitro assays and integrated into regulatory test guidelines in order to increase confidence in the predictive value of hazard identification by in vitro methods. We developed a robust HTS platform for MCT8, DIO2, DIO3 and DEHAL1, based on the versatile Sandell-Kolthoff-Reaction to identify causal relationships for chemicals that have thyroid hormone system-mediated (adverse)effects. In total, we screened more than 40,000 compounds for each of the targets and were able to detect drugs, pesticides, and novel chemicals as potential THSD compounds. The versatile HTS platform is an ideal tool to define the causal relationships of a chemical that has thyroid hormone-dependent effects, to identify further research needs of these effects, to prioritize the multitude of substances/chemicals that should be further investigated, and to support regulatory decision making without having to resort to animal-based methods.

Screening of metabolism-disrupting chemicals on pancreatic β-Cells

Reinaldo Sousa dos Santos[1,2]
[1]Instituto de Investigación, Desarrollo e Innovación en Biotecnología Sanitaria de Elche (IDiBE), Universidad Miguel Hernández de Elche, Alicante, Spain; [2]CIBER de Diabetes y Enfermedades Metabólicas Asociadas, Instituto de Salud Carlos III, Spain

Diabetes prevalence has been worryingly growing in recent decades, reaching pandemic proportions. Genetic and environmental factors play a role in diabetes aetiology. While the genetic background may predispose individuals to the disease, environmental factors, including exposure to chemical pollutants that can disrupt metabolic functions (also known as metabolism disrupting chemicals or MDCs), may act as triggers to diabetes development. Despite growing evidence suggesting a relationship between exposure to MDCs and diabetes susceptibility, there is a lack of test protocols that allow the identification of MDCs with diabetogenic activity. According to the European regulation of chemicals, information on a chemical's endocrine mode of action and related adverse effects relevant for human health are required as criteria to identify MDCs. Nevertheless, there are no suitable in vitro tests for regulatory purposes that identify the potential metabolism disrupting effects of compounds. In GOLIATH, a project within the Horizon 2020 programme of the European Commission seeking to address the urgent need to develop test protocols that allow the identification of MDCs, one of our aims is to design test methods that identify MDCs that could affect β-cells. For this purpose, we used human and rat β-cell lines as well as dispersed mouse islet cells as in vitro models. We tested six chemicals at concentrations within human exposure (from 0.1 pM to 1 μM): Bisphenol-A, tributyltin, perfluorooctanoic acid, triphenylphosphate, triclosan, and dichlorodiphenyldichloroethylene. To test these chemicals, we followed an adverse outcome pathway framework, where we studied the molecular initiated event and key events, including gene expression and reactive oxygen species production. Finally, we evaluated viability and glucose-stimulated insulin secretion as adverse effects. We propose that the optimization of the test methods detailed in our study could be incorporated into a set of protocols for the identification of MDCS.

Effects of kisspeptin in patients with low sexual desire?

Waljit S Dhillo
Imperial College London, London, United Kingdom

Successful reproduction in humans at a population level, is reliant on the careful co-ordination of reproductive hormones with associated behaviours. Kisspeptin is a neuropeptide that is critical for normal hypothalamic function of the reproductive hormonal axis. However beyond its hormonal effects, non-human data suggests an emerging role for kisspeptin in a range of animal behaviours through extra-hypothalamic downstream neuroendocrine pathways. Until recently, the roles of kisspeptin in human behaviour were unknown. Investigating this through a multi-method approach employing behavioural, neuroimaging and hormonal analyses has revealed several novel neuroendocrine actions of kisspeptin in human behaviour, ultimately with clinical potential. We have shown that kisspeptin administration to healthy men enhances limbic brain activity (the main behavioural system), specifically in response to sexual stimuli. Furthermore, these changes in brain activity correlate with associated behavioural parameters such as reward, mood, and sexual aversion, providing key functional significance. In addition, attraction is a key initiator of sexual behaviour in humans and so was examined in a further study. Here, kisspeptin increases brain activity specifically in 'attraction and beauty centres' in direct response to olfactory and visual attraction cues. The next step in this series of studies was to translate these findings into patients for the first time. Hypoactive Sexual Desire Disorder (HSDD) is characterised by a deficiency of sexual desire with marked distress and affects up to 10% of men and women. Current treatment options are limited in safety and effectiveness. Kisspeptin administration to men with HSDD ($n=32$) potently increases penile tumescence (by 56%,$P=0.002$) and sexual desire ($P=0.02$), through modulations of sexual brain processing. In women with HSDD ($n=32$), kisspeptin administration increases self-reported ratings of feeling 'sexy' ($P=0.03$), with associated sexual brain processing changes. Collectively, these studies lay the foundation for future clinical applications of kisspeptin in patients with psychosexual disorders.

Intriguing aspects in the management of hypothalamic amenorrhea

Sarah Berga
Dept OBGYN, Jacobs SMBS | UB SUNY, OBGYN & Women's Health Program Development, Buffalo, New York, US

The proximate cause of functional hypothalamic amenorrhea (FHA) is reversible suppression of GnRH drive that results in chronic anovulation and low estradiol levels that preclude endometrial growth and shedding. Clinical management of FHA requires not only understanding the neuromodulation of GnRH drive, but also how cognitive and behavioral concomitants suppress GnRH drive. FHA results in a constellation of neuroendocrine concomitants that include activation of the hypothalamic-pituitary adrenal (HPA) axis and suppression of the HP-thyroidal (HPT) axis in addition to insufficient GnRH drive to support folliculogenesis. Hypercortisolism is the hallmark of stress and may elicit undernutrition and overnutrition depending on fuel availability, genotype, and individual factors. In monkeys and women, energy deficiency elicited by undernutrition combined with increased energy expenditure synergized with social stress to compromise ovulatory function. In monkeys, when high-fat, high-sugar food was plentiful, stressed (subordinated) female monkeys ate more than unstressed (dominant) ones and overeating was reversed by CRH antagonism. Our monkey model of stress-induced overeating may explain why obesity tracks with social stress in humans. While thin women with FHA reported attitudes such as perfectionism and high drive for thinness, attitudes associated with stress-induced overeating remain to be better characterized. The clinical management of FHA requires identifying and remediating behaviors that elicit the above constellation of neuroendocrine adaptations. Our monkey model focused on understanding the role of CRH as a modulator of GABAergic function and disordered eating. In women, we identified some of the mechanisms by which cognitive variables associated with FHA and utilized these insights to pioneer the use of cognitive behavior therapy to reverse FHA and its neuroendocrine concomitants. The neuroendocrine constellation of FHA results in antagonism of estrogen and insulin action and results in health consequences beyond reproduction compromise due to anovulation. Treatment guidelines should recognize the potential impact of FHA on pregnancy and offspring and acute and chronic compromise of cardiovascular, brain, bone, and metabolic health.

Molecular basis of thyroid development and function

S16.1

Single cell transcriptomic analysis of zebrafish thyroid gland or thyroid organoids

Sabine Costagliola
IRIBHM-ULB-Brussels, Brussels, Belgium

The thyroid gland regulates growth and metabolism by producing thyroid hormones in follicles composed of thyrocytes. So far, thyroid cells were thought to be a homogeneous population. To uncover genetic heterogeneity in the thyrocyte

population and to molecularly characterize the non-thyrocyte cells surrounding mature follicles or follicles in development, we have developed single-cell transcriptome atlas of mouse and human thyroid organoids derived from pluripotent stem cells and zebrafish thyroid gland. Our results identify and validate transcriptional differences within the nominally homogeneous mature thyrocyte population. Furthermore, these single-cell transcriptome analyzes identified cells that form the "niche" involved in thyrocyte development and maturation *in vivo* and in vitro, such as immune cells, fibroblasts, and cardiac cells. In addition, we identified TGF-beta as a negative regulator of thyroid maturation *in vitro*. Our study highlights the potential of molecular characterization of single cells for understanding and improving thyroid development and maturation *in vivo* and *in vitro*.

Presenting the future of prostate cancer

S18.1

The non-coding prostate cancer genome

Nathan Lack[1,2,3]
[1]Vancouver Prostate Centre, University of British Columbia, Vancouver, BC, Canada; [2]Department of Medical Pharamcology, School of Medicine, Koc University, Istanbul, Turkey; [3]Koç University Research Centre for Translational Medicine (KUTTAM), Koç University, Istanbul, Turkey

Understanding the mechanisms that underly prostate cancer initiation and progression requires a comprehensive annotation of the cancer genome. While most research has focused on protein coding genes, there is increasing basic and clinical evidence that the much larger non-coding genome plays a critical role in prostate cancer tumourigenesis. The non-coding genome harbours numerous functional elements that regulate the expression of all protein-coding genes, including oncogenes and tumour suppressor. Genetic alterations to these regulatory elements can drive tumour development, progression, and response to therapy. The development and adaptation of functional genomic methodologies has allowed us to begin to annotate the non-coding genome and characterize the impact on gene expression in prostate cancer. By looking beyond only protein coding genes to the DNA that controls expression, we can gain a better understanding of how prostate cancer arises and how to effectively treat this lethal disease.

S18.2

Cellular plasticity and neuroendocrine phenotypes in prostate cancer

Amina Zoubeidi
Canada Research Chair (Tier 1), Professor at the Dept. of Urologic Sciences, Michael Smith Scholar, Faculty of Medicine, University of British Columbia, Senior Scientist, Vancouver Prostate Centre, Vancouver, British Columbia, Canada

Lineage plasticity has been postulated to contribute to the failure of targeted- and immuno-therapies. In prostate cancer (PCa), the discovery that advanced metastatic castration-resistant PCa (CRPC) classified as adenocarcinoma remains fueled by the androgen receptor (AR) has ushered the development of potent AR pathway inhibitors (ARPIs), notably abiraterone and enzalutamide undoubtedly benefiting the survival of patients with advanced disease. However, a subset of patients (~20%) relapse with tumors that are no longer dependent on AR activity and, instead, activate lineage programs including stem cell and neuronal pathways. These tumors, termed treatment emergent neuroendocrine prostate cancer (tNEPC), are particularly aggressive in that no targeted therapeutic strategies exist, leading to a poor prognosis with an overall survival of only 1 year. Managing NEPC patients and developing novel therapeutic strategies have so far proven challenging due to knowledge gaps in the underlying molecular mechanisms governing tumor cell plasticity and neuroendocrine differentiation. Despite similar genetic profiles, CRPC and NEPC are distinguished by extensive transcriptional landscape rewiring. To begin addressing this, we integrated genomic, transcriptomic, epigenomic, and proteomic data that has informed us that ARPI therapy can activate a lineage switch owing to dynamic and reversible epigenetic regulations. The changes in the epigenetic landscape create an favorable environment for transcription factors to be “reprogrammed”. In particular, we uncovered new androgen receptor (AR) binding sites that allow AR to flow between alternative binding profiles and identified the neuronal determinant factor ASCL1 to facilitate phenotypic switching guided by the epigenetic modifier EZH2. This cross talk between lineage determinant transcription factors creates an opportunity to targeting EZH2 in lineage plasticity. Hence, these pre-clinical data have guided the initiation of a new arm in the Genomic Umbrella Neoadjuvant Study and other Biomarker Trials (NCT04812366) using EZH2 inhibitor.

S18.3

Targeting androgen receptor-persistent signalling in advance prostate cancer

Adam Sharp
Institute of Cancer Research, London, United Kingdom, Royal Marsden NHS Foundation Trust, London, United Kingdom

Prostate cancer is the most commonly diagnosed non-cutaneous malignancy in men and a leading cause of male mortality. The androgen receptor (AR) remains the major therapeutic target with therapies that inhibit the AR signaling axis improving the outcome for patients with advanced castration-sensitive and castration-resistance prostate cancer. Despite these advances, primary and secondary resistance to AR targeting therapies is common, with evidence of ongoing AR signaling in the majority of cases. This is, in part, driven by the emergence of AR aberrations that include AR amplification, AR activating mutations, and constitutively active AR splice variants, that drive resistance to therapies targeting the AR. Nearly all currently available AR signaling axis inhibitors function through the AR ligand binding domain and have limited/no activity against AR aberrant oncogenic signaling. Therefore, the discovery and delivery of new therapeutic strategies that can block AR aberrant signaling, remains an area of unmet clinical need. Attractive strategies to overcome persistent oncogenic AR signaling include targeting AR transcription, AR RNA splicing, AR co-regulator activity, the AR N-terminus, and AR degradation, to directly impact aberrant AR activity. These approaches are currently in clinical development and undergoing evaluation in early phase clinical trials.

Oxidative stress in thyroid disease?

S19.1

Iodine deficiency disorders

Murat Faik Erdoğan
Ankara University School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Iodine deficiency (ID) is a public health problem and has considerable consequences other than endemic goiter, known as iodine deficiency disorders (IDD). Neonatal hypothyroidism, growth retardation, and cretenism are the results of severe ID. Neuronal migration and myelination of fetal brain requires iodine. Thus, insufficient iodine intake during pregnancy may cause permanent fetal brain damage. ID in prenatal period and early childhood has unfavorable effects on cerebral development. The duration and severity of maternal ID were suggested to be associated with worse clinical outcomes. Iodine requirement which is 150 µg/d increases toover 250 µg/d during pregnancy. On the other hand, the effect of mild-moderate ID on the long term neuromotor development of fetus is not well established. Severe ID in pregnancy is also thought to be a risk factor for pregnancy outcome, such as stillbirth , miscarriage, preterm delivery, and birth of small-for-gestational weight babies. Although ID can be easily prevented by quite inexpensive iodization strategies, it continues to be the most important cause of irreversible but also preventable mental retardation worldwide. However this strategy alone is inefficient during the pregnancy and lactation period. World Health Organization (WHO) recommends 250 µg/d iodine intake for pregnant and lactating women whereas routine supplementation programs with iodized salt provides about 100 -150 µg/d. Thus, routine iodine containing supplements are much recommended in the United States and Europe but current data indicates that it has not become much widespread.

Update on consequences of long-term exposure/treatment with glucocorticoids

S20.1

Impairment of the HPA axis after treatment with glucocorticoids

Paul M Stewart
Division of Endocrinology and Metabolism, Faculty of Medicine, Prince of Songkla University, Thailand and Endocrinology/ Rheumatology, University of Leeds and Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom

1% of western populations take chronic oral corticosteroids and this rises to 3% in subjects aged over 70 years old. When inhaled, topical and parenteral steroids are added to this burden, iatrogenic Cushing's becomes a major health issue. High doses of medroxyprogesterone acetate can cause glucocorticoid effects and drug interactions may impair the metabolism of some glucocorticoids (eg fluticasone), thereby increasing their potency. Patients may develop the classical features of Cushing's including growth failure, osteoporosis, myopathy and CVS risk factors all of which contribute to increased mortality. In our unpublished meta-analysis of 128 studies comprising 51,380 patients with inflammatory disease taking corticosteroid therapy, SMR was 1.84 (CI 1.27-2.41) with dose of glucocorticoid associated with higher SMR. Through the HPA feedback mechanism, iatrogenic Cushing's leads to adrenal suppression and low endogenous cortisol levels. Adrenal suppression depends upon the potency of preparation used, its dose, route and duration of administration. There are no "hard and fast rules", but adrenal suppression should be anticipated in any patient taking the equivalent of 7.5 mg prednisolone/day for over 3 weeks. The diagnosis relies on a low circulating cortisol concentration that fails to respond adequately following a short synacthen test (250 mg ACTH). Circulating ACTH concentrations may be reduced as are ACTH dependent steroids such as DHEAS. In the absence of an evidence base for management, a "treat whilst we wait" policy seems the safest way forward. Patients taking the daily equivalent of 7.5 mg prednisolone are unlikely to experience clinical features of adrenal withdrawal; however supplemental doses of steroid may be required in the event of intercurrent illness in patients taking <20 mg prednisolone/day or equivalent. Patients withdrawing from corticosteroids frequently experience fatigue, poor sleep, impaired QoL, arthralgia and have a risk of adrenal crisis. Patients should be issued with a Steroid Alert card and counselled regarding increasing steroid doses with stress/ intercurrent illness. Switching patients to tailored and more physiological doses of hydrocortisone is advocated by some. Clinical trials of selective inhibitors of 11b-HSD1 are underway in an attempt to mitigate against iatrogenic Cushings. Finally, ongoing education around surveillance, diagnosis and risk of adrenal crisis across patients and other clinical specialists is urgently required.

S20.2

The impacts of glucocorticoids on brain outcomes and behaviour

Joanna Spencer-Segal
Department of Internal Medicine, Division of Metabolism, Endocrinology, and Diabetes, Michigan Neuroscience Institute, Ann Arbor, Michigan, United States

Critically ill patients are exposed to high levels of corticosteroids during their illness. While corticosteroid treatment has a modest effect on illness severity and survival dependent on the underlying diagnosis, observational and randomized data suggests that it also influences long-term neuropsychiatric outcomes. The mechanisms by which corticosteroid exposure during acute illness alters long-term brain function and neuropsychiatric risk are unknown. Because of the importance of the hippocampus for memory and mood and its known glucocorticoid sensitivity, we hypothesized that corticosteroid treatment during illness has long-term effects on hippocampal function in survivors. We tested this hypothesis in male and female mice using a widely used sepsis model, cecal ligation and puncture. Long-term CLP survivors exhibited anxiety-like behavior, increased central hypothalamic-pituitary-adrenal (HPA) axis activity, and persistent systemic and neuro-inflammation. Corticosterone treatment during illness primarily modified cognitive outcomes, improving non-fear memories from the time of the illness but impairing the formation of new memories. Corticosteroid-treated mice showed persistent downregulation of activity-dependent hippocampal genes suggesting a sustained decrease in hippocampal neural activity. The results suggest that corticosteroid treatment during sepsis influences hippocampal function in survivors via long-lasting changes to hippocampal activity. The relationships between gene expression, behavior, and neuroendocrine activity pointed to the importance of neural activity as well as inflammation and oxidative metabolism in functional outcomes.

The socioeconomic consequences of Cushing's syndrome: a nationwide cohort study

Andreas Ebbehoj
Department of Clinical Medicine - The Department of Endocrinology and Diabetes, Aarhus University, Aarhus, Denmark

Endogenous Cushing's syndrome (CS) causes a host of recognized physical and psychological complications, but the socioeconomic consequences of CS have not been as well-described. We recently conducted a comprehensive analysis of how patients' socioeconomic factors change before diagnosis and after treatment compared to healthy controls. In a Danish nationwide cohort, patients with CS had lower rates of employment, lower income, delayed educations, and negatively affected family lives. The negative socioeconomic trends began up to six years before the CS diagnosis was made. Both our data and previous studies indicate that socioeconomic factors show some improvement after treatment, but never fully normalize and the prognosis varies considerably by patient factors. The management of non-somatic issues in patients during their recovery phase lacks evidence-based guidance. Multiple studies have identified recurring themes of unmet patient needs. Incorporating initiatives on patient education, support groups, and specialized rehabilitation into clinical practice could address some of these issues.

The role of muscle in metabolic diseases

S21.1

Myokines in health, resilience and disease

Cedric Moro
Paul Sabatier University, Toulouse, France

The health benefits of exercise are well-recognized and are observed across multiple organ systems. These beneficial effects reduce disease risk and mortality. The molecular mechanisms that underlie the beneficial effects of exercise, however, remain poorly understood. With emergence of –omics technologies, the number of exercise-associated signalling molecules that have been identified has rapidly expanded. Signalling moieties released by skeletal muscle are defined as myokines. They can be released during acute and/or chronic exercise and exert their effects through endocrine, paracrine and/or autocrine pathways. Myokines have beneficial effects on the immune, cardiovascular, metabolic and neurological systems. However, very few of them have been shown to target adipose tissue, in particular in humans. We recently identified Growth and Differentiation factor 15 (GDF15) as a novel myokine. GDF15 is rapidly released in response to muscle contraction to promote lipolysis in human white adipose tissue. Since GDF15 has emerged as an interesting anti-obesity therapy through its central effects on appetite suppression, potential peripheral effects should not be neglected.

The role of exosomes in clinical aspects of metabolic disease

Juan M Falcon-Perez
Exosomes Laboratory and Metabolomics Platform. Center for Cooperative Research in Biosciences (CIC bioGUNE), Basque Research and Technology Alliance (BRTA), Exosomes Laboratory, 48160, Derio, Spain, Centro de Investigación Biomédica en Red de Enfermedades Hepáticas Y Digestivas (CIBERehd), 28029, Madrid, Spain, IKERBASQUE, Basque Foundation for Science, 48013, Bilbao, Spain

Extracellular vesicles (EVs) constitute a novel biological entity to identify biomarkers, and as active players in the development of liver diseases. Omics technologies have been widely applied to characterize the content and function of EVs secreted by liver cells in different pathological scenarios including drug-induced liver injury (DILI), NAFLD and metabolic syndrome. Thus, transcriptomics and proteomics of these EVs have provided several low invasive candidate biomarkers for cirrhosis in serum and urine. The transcriptomic analysis of EVs and the cells that secrete those EVs made possible the identification of a sorting RNA signal that can incorporate the RNAs into the EVs to be exported out of the cells. Another important contribution of the omics technologies to the hepatic EVs, in this case done by metabolomics has been the demonstration that hepatic EVs carry several active enzymes that are able to modify the serum metabolic composition what could have important implications for endothelial functioning. The integration of several omics technologies combined by using different experimental settings including the analysis of the cells, the EVs secreted by those cells, and the cells exposed to those EVs allow to dissect the EVs-mediated mechanisms underlying the development and progression of liver diseases and it provides novel therapeutics targets.

Diagnosis of GHD in adults

Andrew R Hoffman
Department of Medicine, Moro University School of Medicine, Stanford, CA, United States

Adult GH deficiency (AGHD) is a common sequela in patients with pituitary or brain tumors or in patients with a history of traumatic brain injury or cranial irradiation. In addition, approximately one third of children who were diagnosed with GH deficiency will remain GH deficient as adults. Since AGHD is characterized by diminished cardiovascular health, abnormal body composition, decreased muscle strength and aerobic capacity, poor quality of life, and increased mortality, it is important to make this diagnosis and to offer appropriate GH replacement therapy to these patients. In order to do so, it is necessary to select the appropriate patients to test and to understand how to perform and interpret the panoply of tests that have been devised to make the correct diagnosis. In patients with panhypopituitarism or in adults with a history of childhood-onset GHD due to a genetic or an identified organic cause, a low serum IGF-I is sufficient to make the diagnosis of AGHD. In all other patients, a growth hormone stimulation test is required, since a single random measurement of GH, which is secreted in a pulsatile fashion, lacks precision and because a significant number of patients with AGHD will have normal levels of IGF-I. The various GH stimulation tests and the controversies regarding their interpretation will be discussed in the context of identifying those patients who are at high risk of having AGHD.

The X chromosome and male fitness

Csilla Krausz
Department of Biomedical, Experimental and Clinical Sciences Mario Serio, University of Florence, Florence 50139, Italy

Male infertility affects 7% of the general population and in about 50% of cases the aetiology remains unknown. The routine genetic testing is based on karyotype analysis and the screening of Y chromosome deletions. For long time the role of the other sex chromosome, the X chromosome, in spermatogenesis remained largely unexplored. While both sex chromosomes are derived from a pair of autosomes around 300 million years ago, their current size and gene content differs dramatically. The X chromosome has remained relatively stable in magnitude with around 155 Mb, the Y chromosome decreased to around 55 Mb. The importance of the Y chromosome in male fitness is undeniable since it contains the SRY gene and other testis specific genes relevant to normal spermatogenesis. Although some earlier study predicted that the evolutionary history of the X chromosome indicates its potential specialization in male fitness, up to recently, only three genes (among them the androgen receptor gene) were considered candidate genes for male infertility. In order to provide a comprehensive picture on the role of the nearly 800 protein-coding genes on the X chromosome, we performed a large-scale screening in 2,354 azoospermic/-cryptozoospermic men from four independent cohorts. We identified a total of 55 novel genes not previously linked to male infertility. Among them 21 genes recurrently mutated and strongly associated with and 34 genes moderately associated with azoospermia/cryptozoospermia,. The most frequently affected prioritized gene, RBBP7, was found mutated in 10 men across all cohorts, and our functional studies in Drosophila support its role in germ stem cell maintenance. Collectively, this multicentre study represents a significant step towards the definition of the missing genetic etiology in idiopathic severe spermatogenic failure and significantly reduces the knowledge gap of X-linked genetic causes of azoospermia/cryptozoospermia, contributing to the development of future diagnostic gene panels.

The Leydig cell biomarker INSL3 as a predictor of age-related morbidity

Ravinder Anand-Ivell
School of Biosciences, University of Nottingham, Nottingham, United Kingdom

Insulin-like peptide 3 (INSL3) is produced by the mature Leydig cells of the adult testes and secreted into the bloodstream in a constitutive manner, where it represents an important biomarker of Leydig cell functional capacity. It specifically activates the G-protein-coupled receptor, RXFP2, which is expressed on Leydig cells themselves, on male germ cells, and on bone cells, where INSL3 promotes healthy bone physiology. Unlike testosterone, INSL3 exhibits negligible within-individual variance, although in a population circulating INSL3 may vary by up to 10-fold between individuals. By making use of the European Male Aging Study (EMAS) cohort we investigated the relationship between circulating INSL3 and the incidence of age-dependent morbidity, in comparison with total testosterone and other HPG axis parameters. Like testosterone, INSL3 is an index of hypogonadism and consequently, after correcting for age, correlates with conditions such as diabetes, cardiovascular disease, sexual function, hypertension, bone density, and frailty. Such associations may be due to the mutual relationships not only between INSL3 and testosterone, but also with BMI, or smoking. However, when multiple regression analysis was used to assess such relationships between morbidity in the second phase of the EMAS study and either INSL3 or testosterone in the same individuals in the first phase of the study, with blood samples collected 4 to 5 years previously, then INSL3 was significantly and independently predictive for 6 of the conditions later assessed, whereas testosterone was predictive for only 3 of these. Because of its low within-individual (though high between-individual) variance, even over long periods of time (several years at least), circulating INSL3 is an excellent biomarker for possible hypogonadism and dependent future conditions. Our current research is investigating the mechanisms behind these relationships and addressing the question why some individual men may have high or low INSL3 throughout their adult lives.

Obesity and metabolic syndrome in Type 1 Diabetes

Raquel N Faradji
SMNE President, RENACED-DT1 Director, Clínica EnDi Director, Centro Médico ABC, Mexico City, Mexico

In recent years there has been an increase in the incidence and prevalence of overweight and obesity around the world. Overweight and obesity are more common among people living with type 1 diabetes (T1D) than originally anticipated[1] . The SEARCH study found 21% of T1D patients are overweight[2] and 12.6%[3] are obese. The T1D Exchange Study found an obesity rate of 13.1% in adolescents[4] . The DCCT-EDIC Study found that the obesity prevalence, in the intensive treatment arm, increased from 1% at baseline in the DCCT to 31% at 12 years follow-up of EDIC[5] . RENACED-DT1 found 42.4% of overweight and 8.1% of obesity in Mexican patients with T1D[6] . Updated results (2022) will be presented during the meeting on the prevalence of obesity for the overall population and for T1D patients for Belgium, Kuwait and Mexico. Risk factors for overweight and obesity include non-physiological insulin administration route (subcutaneous), decrease in exercise due to hypoglycemia fear, excessive carbohydrate intake secondary to hypoglycemia, and hormonal changes[1] . Obesity increases the risk of cardiovascular disease. In people living with T1D it is difficult to quantify the degree of insulin resistance (IR). Those using >1 IU of insulin/kg/day are considered IR. IR and metabolic syndrome can also be calculated by the estimated glucose disposal rate eGDR (7), that takes into account the waist to hip ratio, presence or absence of hypertension and HbA1c. Patients with eGDR $<$ 7.5 mg/kg/min are considered IR[7] . Drugs used for type 2 diabetes treatment have been studied in T1D and have demonstrated decrease in weight and slight improvement in metabolic control in T1D subjects but are not approved for their use. It is imperative to address, prevent and find treatments for obesity in T1D.

Testosterone replacement in metabolic disorders. To give or not to give

Pablo Knoblovits
Endocrinology and Metabolic Division Hospital Italiano de Buenos Aires, Buenos Aires, Argentina

Several studies have shown that men with obesity, insulin resistance, prediabetes, and type 2 diabetes mellitus (DM2) have significantly lower testosterone (T) levels and a higher prevalence of hypogonadism than men with normal metabolic status. It is estimated that between 30 and 40% of men with T2DM have low levels of T, assessed as total T, free T, or bioavailable T. But, as part of the integrative metabolic system, testosterone has insulin-sensitizing hormone properties through several mechanisms. So, the metabolic state and the reproductive axis are normally in a balance of mutual convenience. In that sense, while low T is a risk factor for a future metabolic condition, any metabolic condition is a risk factor for developing low T. I will discuss the evidence for the utility of testosterone replacement therapy in hypogonadal men to improve metabolic status. In men undergoing treatment with changes to healthier habits, does the addition of exogenous T improve the results of these treatments?

Obesity fuels prostate cancer: A source of diagnostic biomarkers and therapeutic targets

Andre Sarmento-Cabral[1,2,3,4]

[1]Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Cordoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Cordoba, Spain; [3]Reina Sofia University Hospital (HURS), Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain

In the last years, obesity, and its associated metabolic comorbidities, have been proposed as risk factors for prostate cancer (PCa) development and linked to a more aggressive disease (e.g., PCa with poor prognosis, shorter time to develop biochemical recurrence and metastasis, and associated with increased mortality). In this sense, PCa represents the most common cancer-type in developed countries among men and it is one of the leading causes of cancer-related deaths in this collective, representing a major health problem worldwide. Unfortunately, early detection and clinical management of PCa face severe limitations. Currently, PCa initial diagnosis is mainly based on plasma prostate specific antigen (PSA) levels, a biomarker that exhibits profound drawbacks (i.e., poor specificity and predictive value). Particularly, when plasma PSA levels range between 3-10 ng/ml, also known as “grey zone”, the sensitivity, specificity, and predictive capacity of PSA is significantly worsened. Consequently, a high number of biopsies are required to detect the tumors, reducing patient quality of life. Likewise, clinical management of advanced PCa also faces major limitations, including the development of resistance to hormonal (i.e., AR pathway inhibitors) and chemical therapies (e.g., taxanes). Hence, new non-invasive and personalized diagnostic/prognostic biomarkers, as well as more effective therapeutic tools for PCa are urgently needed. In line with this idea, the endocrine/metabolic alterations that occur under an obesity state, impact normal prostate gland function; however, the precise mechanisms involved in the pathological association between obesity and cancer are still not fully elucidated. In this context, recent studies from our and other groups have demonstrated that factors belonging to different endocrine/metabolic systems (e.g., ghrelin axis, adipokines) as well as molecular components involved in the regulation of the transcriptome (e.g., miRNome, splicing machinery) are significantly altered in PCa samples, which might be useful as diagnostic/prognostic biomarkers and therapeutic targets (particularly under obesity conditions).

Circulating DNA to identify targetable mutation in metastatic endocrine cancers

Rodrigo Toledo[1,2]
[1]Gastrointestinal and Endocrine Tumors Group, Vall d'Hebron Institute of Oncology (VHIO), Vall d'Hebron Barcelona Hospital Campus, Barcelona, Spain; [2]Centro de Investigación Biomédica en Red de Cáncer (CIBERONC), Institute of Health Carlos III (ISCIII), Madrid, Spain

Pheochromocytomas or Paragangliomas (PPGLs) are catecholamine-producing tumors with a 15% to 20% risk of developing metastasis, which is related to poor prognosis and shorter survival. Despite PPGL metastasis can present an indolent course for years, it eventually progresses leading to the death of the patient. As is usually the case for rare tumors, drug development for PPGL has been very slow and there are currently no effective therapies for progressive PPGL metastasis. We here applied a circulating tumor DNA (ctDNA)-based approach to a) assess the prognostic value of the levels of ctDNA analyses, b) to characterize the genomic landscape of metastatic PPGLs, and c) to identify potential therapeutic targets that can guide personalized treatments to the patients. We will present the results of our ctDNA-based analysis in a large cohort of metastatic PPGLs from an international consortium composed of groups from the ENSAT and A5 Networks, and other groups.

Debate Sessions

Should diabetes insipidus be re-named?

D1.1

Pro: Should diabetes insipidus be re-named?

John Newell-Price
Department of Oncology and Metabolism, The Medical School, University of Sheffield, Sheffield, United Kingdom

All those involved in delivery of health care are obliged to deliver safe and effective management for patients. Effectiveness is often achieved where specialists for the condition are involved. In contrast, patient-safety depends of recognition of the condition in question and then use of appropriate treatment and management, regardless of who is seeing the patient. This is particularly the case where there may be a rare disease confused for a common one, and where the treatments needed are completely different. It is in this scenario that there is**an absolute need to rename the condition formally known as 'diabetes insipidus'**. Patients with this condition may present to the generalist and be confused with patients who have **'diabetes mellitus'**, with reports for some of desmopressin not being made available or not being given resulting in life-threatening dehydration, and for others having frequent glucose finger prick testing when it was not needed. Whilst the word 'diabetes' is time-honoured being first used around 250-300 BC and is derived from Greek meaning 'syphon – to pass through', it has no place in the 21st century as a descriptor for the pathophysiological condition of **'AVP deficiency or resistance'**; the continued use of 'diabetes insipidus' perseverates patient risk. and for this reason its use must be abandoned. There are precedents for name change in medicine, and although this takes time and effort to achieve, the end goal of enhancing patient safety justifies the endeavour!

DOI: 10.1530/endoabs.90.D1.1

D1.2

Con: Should diabetes insipidus be re-named?

Stylianos Tsagarakis
Department of Endocrinology and Diabetes, Evangelismos Hospital, Athens, Greece

Recently, a position statement of a working group for renaming diabetes insipidus (DI) appeared in several renowned endocrine journals aiming to promote a change in the established name of DI. According to this position statement, the major arguments for renaming DI are: (a) it does not optimally reflect the underlying pathophysiology (b) it is often confused with diabetes mellitus (DM) leading to treatment errors and consequent adverse outcomes for patients. Although the above arguments sound reasonable there are still good reasons against changing the name of DI. Diabetes insipidus is a well-established medical term that has been in use for many years. The term "diabetes" runs deep in history and elegantly and accurately describes polyuria which is the hallmark symptom in all patients with DI. On the other hand, nowadays only a proportion of DM patients suffer from polyuria, while even more inappropriate is the use of terms like "pre-diabetes". So, renaming DI and maintaining DM does not sound a choice which optimally reflects the underlying pathophysiology and clinical presentation of these disorders. What is true, for both health care providers and patients, is that the real need to change the name of a rare disease like DI, is its potential confusion with a very common disease like DM. However, is it certain that renaming DI will solve the existing problems? Owing to its rarity, DI is often neglected by health-care professionals, and increased awareness of this disease is urgently needed. In line with this, non-availability of desmopressin has been noticed in many emergency situations and obviously this is not going to be corrected by renaming DI. Also, a substantial proportion of patients with central DI suffer from additional anterior pituitary hormone deficits which if neglected are equally detrimental for the patients. So, renaming DI can only partly improve a situation for which the major challenge is to increase awareness and improve education and upskilling of healthcare workforce, to avoid serious untoward events during the emergency care of these rare patients. It should also be noticed that changing the name of DI would likely create problems with statistical reporting and library database searching, while the suggested use of both names for some years from now-on will add more complexity for both patients and non-aware healthcare providers. In conclusion, like for most rare diseases it may be more productive to focus on improving patient care and finding better ways of management, rather than changing its name.

Should patients with adrenal incidentaloma and autonomous cortisol secretion be treated with surgery?

D3.1

Pro: Should patients with adrenal incidentaloma and autonomous cortisol secretion be treated with surgery?

Olivier Chabre
Univ.Grenoble Alpes, Service d'Endocrinologie CHU Grenoble Alpes, Unité Mixte de Recherche INSERM-CEA-UGA UMR1036 38000 Grenoble Alpes France

Adrenal incidentalomas (AI) are recognized more and more frequently, due to the widespread use of CT. Although unexpected, these tumors raise the question of a putative morbidity related either to their proliferation potential or to their endocrine secretion. Regarding proliferation it is now established that a low (<10 UH) and homogeneous density on unenhanced CT scan is specific for a benign adrenocortical adenoma, which do not need to be operated for fear that they may become malignant. Regarding secretion some patients may have previously unrecognized overt Cushing's syndrome (CS) and should be operated. By contrast there is a debate regarding patients with no overt CS, but an autonomous secretion of cortisol (ASC), defined by plasma cortisol level >50 nmol/l after 1 mg dexamethasone-suppression.

We will argue here that many of these patients should also benefit from surgery, based on the following points:

- There is good evidence for an association of ASC with diabetes, hypertension, and an increased mortality, both cardiovascular and global.
- Several retrospective studies reported that patients with ASC who were operated showed improvement of hypertension and metabolic control.
- One recent prospective randomized controlled study demonstrated improvement of hypertension and metabolic control and the promising results of another larger randomized control are expected soon.
- A meta-analysis of laparoscopic unilateral adrenalectomy has reported no mortality and very little morbidity: for AI with ASC there may be transient adrenal insufficiency, related to the previous hypothalamic/pituitary suppression by ASC, but this must be understood as another proof that ASC does have significant clinical effect.
- The cost of surgery is considerably lower than the alternative of a life-long medical anticortisolic treatment.

We believe that these points should lead us to perform adrenalectomy in most patients with AI and confirmed ASC who do not have specific risks for surgery and who accept it.

Background
Adrenocortical carcinoma (ACC) is a rare cancer associated with hereditary syndromes in 10% of cases. However, data on germline variants (GVs) in adult patients with sporadic ACC are limited.
Methods
We analyzed germline DNA from 150 adult patients with sporadic ACC sequentially referred to our centers between 1998-2019. We designed a custom panel of 17 genes potentially involved in the pathogenesis of ACC: AIP, APC, ARMC5, ARNT, BRCA1, BRCA2, CTNNB1, IGF2, MEN1, MSH2, MSH6, PDE8B, PDE11A, PRKACA, PRKACB, PRKAR1A, and TP53. NGS data were analyzed by a semi-automated bioinformatic pipeline. All GVs were studied using effect predictor tools (PolyPhen and SIFT). Specific databases (ClinVar, Varsome, gnomAD, IARC TP53, HGMD) were used for variant classification according to ACMG criteria. Variants interpreted as pathogenic (P) or likely pathogenic (LP) were considered as positive. Clinical, pathological and genomic data were analyzed in different Cox models to study prognostic impact of covariates for disease-free survival (DFS), progression-free survival (PFS) and overall survival (OS).
Results
We identified 21 unique GVs in in 9 genes including APC ($n=3$), ARMC5 ($n=3$), MSH2 ($n=3$), PDE11A ($n=3$), TP53 ($n=3$), MSH6 ($n=2$), PDE8B ($n=2$), AIP ($n=1$) and CTNNB1 ($n=1$). Eleven positive GVs were found in 14/150 patients (9.3%). We found a new GV in TP53 (G105D) in a patient who was later found to have a sister with ACC and, for the first time, 3 GVs in ARMC5 (P731R). Patients with ARMC5 GVs had large cortisol-secreting tumors and one case displayed combined pathologic features of ACC and macronodular cortical disease. Positive GVs were associated with a shorter OS (50 vs 142 months, HR 1.81; 95%CI, 0.86-3.82,$P=0.118$) and PFS (8 vs 30 months, HR 3.11; 95%CI, 1.57-6.16,$P=0.001$) but not DFS (27 vs 32 months, HR 1.07; 95%CI, 0.52-2.22,$P=0.845$). At multivariate analysis, known clinical factors (age, surgery of primary ACC, ENSAT stage, hypercortisolism) were found to have prognostic impact on OS. However, GVs remained independent predictors of PFS and OS in metastatic patients.
Conclusions
In a series of 150 patients with ACC, we found that 9.3% of them had positive GVs. We describe for the first time the presence of ARMC5 GVs in patients with ACC and we found a novel pathogenic variant of TP53. Pathologic features of one ARMC5 case suggest a possible progression from macronodular adrenal hyperplasia to ACC. Finally, the present findings suggest that GVs can affect ACC progression and survival of affected patients.

How can we use human organoids in EDCs research?

Nicole Caporale[1,2]
[1]Human Technopole, Milan, Italy; [2]Department of Oncology and Hemato-oncology, University of Milan, Milan, Italy

The pathophysiology of human neurodevelopment entails complex interactions between individual genetic backgrounds and environmental exposures. Endocrine Disruptive Chemicals (EDCs), a heterogeneous class of compounds widely present in our environment, can interfere with human endocrine system and the effects of this exposure on the developing brain can cause adverse neurodevelopmental effects. As opposed to previous works focusing on single compounds, we studied an EDC mixture associated to language delay in a longitudinal pregnancy cohort study. We integrated the epidemiological results with in vitro molecular testing on human fetal neural progenitors, and cortical brain organoids (CBO). Transcriptomic analysis revealed that chronic exposure to the mixture altered genes related to epigenetic regulation, cell proliferation, and neuronal maturation. Moreover it down-regulated bona fide ASD-causing genes (annotated with the highest scores in the Simons Foundation Autism Research Initiative (SFARI) gene database), thus indicating that EDC exposure interferes with the same molecular targets implicated in the pathogenesis of ASD cases caused by genetic mutations. Experimental results were then used to determine that up to 54% of the investigated women exceeded exposure levels of concern, emphasizing the need to take mixtures into account for chemical testing, and providing an integrative framework to guide risk assessment (1). Building on that, we are deepening our investigation of causal links between endocrine pathways alteration and developmental neurotoxicity in the ENDpoiNTs project (https://endpoints.eu/), where we systematically exposed CBO to single compounds and mixtures of several hormones and EDCs, thus establishing a molecular and cellular atlas of endocrine impact on the developing human brain cortex. We also established a novel experimental platform to carry out high throughput developmental disease modelling and EDC exposure on CBO. We implemented and benchmarked a new strategy to multiplex CBO from multiple induced pluripotent stem cell lines (generating mosaic CBO), and leveraged single cell transcriptomics to deconvolve individual cell identity-using variant calling. We thus integrated our longitudinal (up to day 300 CBO) single cell datasets, where all the relevant clusters of neurodevelopmental cell populations were annotated and analysed, and we deeply characterised specific neuronal (excitatory and inhibitory lineages) and glial developmental trajectories. This work represents a unique resource for using brain organoids to perform disease modelling at scale, towards an in vitro epidemiology paradigm, for neurotoxicological studies on multiple genetic backgrounds.

Lipodystrophies: Are they really rare?

Barış Akıncı
Dokuz Eylul University, Izmir, Turkey

Lipodystrophy is a rare disease characterized by generalized or partial lack of adipose tissue. Lipodystrophy is associated with leptin deficiency and leads to severe insulin resistance and metabolic abnormalities. A previous literature review reported an estimated prevalence of less than one in a million based on the assumption that only one-fourth of the patients with lipodystrophy may have been reported. Later, the prevalence of lipodystrophy was estimated through a search of electronic medical records that revealed a prevalence of 1.3–4.7 cases/million. The prevalence of lipodystrophy in Europe was reported as 2.63 cases/million (0.96 and 1.67 cases/million for generalized and partial lipodystrophy, respectively). In contrast to previous estimates, a recent study in the United States (US), using large clinical cohorts, reported an estimated clinical prevalence of lipodystrophy disorders of 1 in 20,000 individuals, with an estimated genetic prevalence of disease of ~1 in 7,000 in the general population. In this session, we will shortly review the natural history of lipodystrophy and try to understand why lipodystrophy is an underdiagnosed condition and many patients with lipodystrophy experience a long journey to diagnosis. We will look at specific subtypes of lipodystrophy which create a real diagnostic challenge. We will also have a deeper look at the recent US prevalence study and discuss the possibility of overestimation of the prevalence of lipodystrophy based on the methodology used. Finally, we will explore innovative ways of diagnosing lipodystrophy and overview basic tips that can help overcome this diagnostic challenge.

Identifying new receptors in the regulation of fertility

Daniel J Bernard
Department of Pharmacology and Therapeutics, McGill University, Montreal, Quebec, Canada

Inhibins and activins were discovered based on their abilities to inhibit and stimulate follicle-stimulating hormone (FSH) secretion from pituitary gonadotrope cells. These ligands are members of the TGFbeta superfamily of secreted ligands. Current dogma suggests that activin B produced by gonadotropes stimulates FSH production in an autocrine/paracrine manner. Inhibins A and B from the gonads suppress FSH by competing for binding to activin receptors. This binding is aided by the co-receptor betaglycan. Recent research from our lab challenges elements of this model. First, inhibins A and B use distinct co-receptors in gonadotropes to suppress FSH. The newly discovered inhibin B co-receptor, TGFBR3L, may be a new drug target to regulate FSH levels. Second, activin B is dispensable for FSH production. Rather, another TGFbeta ligand, myostatin, which is produced in skeletal muscle, is the main driver of FSH synthesis. Myostatin shares properties with activins, including some receptors and soluble binding proteins. This explains, in part, the misattribution of activin action in FSH regulation. We will discuss the clinical significance of these findings.

New medical treatments for Graves' orbitopathy new guideline on immunological treatments

Petros Perros[1,2]
[1]Department of Endocrinology, Royal Victoria Infirmary, Newcastle upon Tyne, United Kingdom; [2]Translational and Clinical Research Institute, Newcastle University, Newcastle upon Tyne, United Kingdom

Graves' orbitopathy (GO) affects 20-40% of patients with Graves' disease. Some patients require several treatment modalities with outcomes that are often far from ideal. The quest for disrupting the autoimmune process with targeted therapies began with the emergence of biologics developed for rheumatoid arthritis. In the meantime basic research revealed an important potential role for cross-talk between the TSH and IGF-1 receptors on orbital fibroblasts. This attracted commercial interest, which steamrolled a monoclonal antibody into the GO therapeutic arena. Teprotumumab, an IGF-1 receptor blocker and a failed anti-cancer drug, was revived and repurposed. Thus a new era was born, unveiling unprecedented efficacy in GO including reduction in proptosis and resolution of diplopia. But this came with significant baggage. Unexpected side-effects, a significant relapse rate and an extraordinary high cost. Clinicians in the USA (the only country where the drug is licensed presently) have embraced it and seem to use it widely including for patients with characteristics that were exclusionary in the clinical trials that led to FDA approval. The commercial success of teprotumumab has stimulated interest in the drug development industry and currently several trials are underway in a race to bring competitors to the market. This is good news for patients with GO, but the soaring costs are a concern. The teprotumumab paradigm brings to the forefront two important questions: do endocrinologists have the power to prevent the emergence of GO among their patients with Graves' disease and bypass the need for astronomically expensive treatments? Do professional organisations have a role in curtailing the greed of the pharmaceutical industry? There is ground to argue that the answer to both questions is yes. Recent guidance from the European and American Thyroid Associations joint Consensus Statement and from the European Group on Graves' Orbitopathy have provided their valuable perspectives.

Pituitary dysfunction in trauma

Fahrettin Kelestimur
Department of Endocrinology, School of Medicine, Yeditepe University, Istanbul, Turkey

The leading causes of TBI which may result in pituitary dysfunction are car accidents, falls, sports-related head injuries, violence and war accidents. The prevalence of pituitary dysfunction is approximately 15% following TBI. GH is the most common hormone lost after TBI, followed by gonadotropins (FSH and LH), ACTH and TSH. The proposed pathophysiological mechanisms responsible for the development of pituitary dysfunction after TBI include sella turcica fractures, genetic predisposition, autoimmunity, ischemic changes, hypoxia, increased intracranial pressure, diffuse axonal injury, and persistent neuroinflammation. Recent studies revealed that pituitary dysfunction may also occur in athletes dealing with combative sports including boxing, kickboxing and football. These types of sports are characterized by chronic repetitive head trauma and they are accepted as mild TBI (mTBI) or concussion. The pituitary volume on MRI in retired boxers with hypopituitarism is significantly lower when compared to the boxers with normal pituitary function and healthy subjects. Pituitary dysfunction in TBI victims including athletes may occur during acute phase just after head trauma, it may improve with time or new deficiencies may develop during follow-up. Severity of TBI, patients demographics, radiologic abnormalities and hypopituitarism, ACTH deficiency in particular during acute phase are the risk factors for TBI-induced pituitary dysfunction. Cortisol, thyroid hormone and AVP deficiencies should be investigated during early phase after TBI and screening of gonadotropins and GH is recommended to be delayed 6 to 12 months following TBI. Hypopituitarism may be very easily overlooked because of non-specific or mild symptoms at least in some patients. For this reason, the great majority of the patients suffered from TBI remain undiagnosed and untreated. We recommend an approach to the diagnosis of pituitary dysfunction in the patients with head injury history in routine clinical practice. Treatment of hypopituitarism due to TBI is the appropriate replacement of deficient hormones.

Advantages and disadvantages of surgery, radioactive iodine, and long-term anti-thyroid drug therapy for Graves' hyperthyroidism

Marek Ruchala
Department of Endocrinology, Metabolism and Internal Medicine, Poznań University of Medical Science, Poznań, Poland

Graves' disease (GD) is an autoimmune thyroid disorder being the most frequent cause of hyperthyroidism in iodine-sufficient countries. There are three main ways to treat GD: pharmacotherapy, radioiodine treatment (RAI) and thyroidectomy. During the lecture certain advantages and disadvantages of those three methods will be discussed. Advantages of anti-thyroid drugs (ATDs) include their immunosuppressive action and outpatient therapy. Disadvantages are higher relapse rate (about 50%, especially in younger patients, with large goiter, and higher free thyroid hormones), long duration of therapy, side effects (about 13%) and lack of histopathological verification if concomitant focal lesions occur. Benefits of RAI is lower risk of relapse (about 15%), outpatient therapy, no need for hospitalization or anesthesia. It is a good option for older patients, with contraindications for surgery. Weaknesses include the need for following radiation safety procedures, the risk of increase in TRAb level following therapy and thus exacerbation of orbitopathy, lack of histopathological verification if concomitant focal lesions occur, and often is associated with the need for lifelong L-thyroxine substitution. Pros of surgery are histopathological verification of concomitant lesions, lower risk of relapse (about 10%), decrease of TRAb level, lower risk of orbitopathy exacerbation. It is a good option for patients with large or nodular goiter as well as for patients who want to achieve stable euthyroidism quickly. Cons of surgery are the need for hospitalization and anesthesia and longer reconvalescence. Treatment of GD may be associated with side effects or cause permanent damage to the thyroid gland and the need for hormonal treatment for the rest of patients' life. Thus, at each stage of the therapeutic process, an objective judgment made by the physician, taking into account the needs and preferences of the patient, as well as the available diagnostic and therapeutic methods, is necessary.

Menopause and adrenal incidentalomas - a distinct endocrine association

Sanja Ognjanovic
Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, Department for Endocrine Tumors and Hereditary Cancer Syndromes, Belgrade, Serbia

Adrenal incidentalomas (AIs) are tumours accidentally detected by various imaging methods applied without suspecting adrenal pathology, indicating that most of them are nonfunctional. The most frequent hormonal alteration in AIs is autonomous cortisol secretion (ACS), a condition of altered hypothalamic-pituitary-adrenal axis activity, established on the biochemical parameters of hypercortisolism, without phenotype expression of Cushing's syndrome. Since mild hypercortisolism is associated with metabolic complications such as abdominal obesity, insulin resistance, hyperglycemia, atherogenic dyslipidemia, and hypertension, which are a cluster of the metabolic syndrome, thenew term 'metabolic autonomous cortisol syndrome' (MACS) has been suggestedfor this condition.The prevalence of AIs ranges from 3% in 50-year-old patients up to 10% in the elderly. Depending on the applied diagnostic criteria, the prevalence of ACS in patients with AIs is estimated at 5-30%. Given that the overall prevalence of ACS is up to 2%, a significant part of the population may have MACS comorbidities. Postmenopausal aging is accompanied by an unfavorable change in body composition towards an increase in abdominal adiposity. Consequently, this is associated with greater lipolytic activity and inflammation, resulting in the onset or deterioration of cardiometabolic complications. Studies on the influence of regional fat distribution suggest that preservation of gluteo-femoral subcutaneous adipose tissue, independently of the presence of abdominal obesity, could have beneficial effects on insulin sensitivity, and the glucose and lipid metabolism. Regardless of the degree of cortisolemia in postmenopausal women with AIs, tissue specific glucocorticoid sensitivity may influence body composition as well as metabolic parameters determining the individual predisposition for the development of MACS. Chronic mild hypercortisolism is associated with an increased risk of osteoporosis and fragility fractures, but glucocorticoid receptor gene polymorphism may modulate skeletal sensitivity to the glucocorticoid excess.

Case Study: Complex case of acromegaly

Anna Hawkins
Barking, Havering & Redbridge University Hospitals NHS Trust, United Kingdom

Presenting the complex journey of a 36 year old lady who following over 2 years of symptoms was found to have raised IGF1 and prolactin. She had microscopic transsphenoidal resection of pituitary adenoma. This was followed by different medical therapies and Gamma knife radiotherapy. She was also referred to many other specialists for Acromegaly related conditions and surveillance. The pathway to diagnosis can be full of barriers and may take many years for a patient to travel along. It is not only medical and surgical interventions a patient needs but psychosocial care and support as well. The Endocrine Specialist Nurse is often the only consistent link for a patient with Acromegaly on what is often a challenging journey.

Giulia Rastrelli
Department of Experimental and Clinical Biomedical Sciences, Andrology, Women's Endocrinology and Gender Incongruence Unit, Careggi Hospital, University of Florence, Florence, Italy

Testosterone (T) declines with ageing and chronic diseases, including obesity and metabolic conditions. This results in T levels in the hypogonadal range in up to 15% of middle-aged elderly men from European general population. These are at risk to develop the clinical consequences of decreased T. Low T is associated with reduced sexual desire, erectile dysfunction and orgasmic impairment. Restoring T levels using T replacement therapy is able to improve the symptoms. However, it is pivotal to understand that not only low T but also ageing and comorbidities have a role in inducing sexual dysfunction. Therefore, a careful assessment is necessary to discern the underlying risk factors and to decide the appropriate treatment. In fact, particularly for erectile dysfunction, the benefits of T therapy are eroded by the detrimental effect of metabolic disorders. Men with low T are at higher risk for cardiovascular events. The underlying mechanisms are deemed to be multiple and only partially known. Whether the treatment is beneficial is still unclear and some data suggest that it may be even detrimental. In the last decade, several studies have been published showing an association between T treatment and adverse cardiovascular outcomes. However, these studies have been criticized for several flaws. Current evidence form meta-analyses suggest a neutral effect of T treatment on cardiovascular events. A known consequence of low T reduced bone mass and osteoporosis. T therapy is able to restore bone mass. However, data showing that T treatment is able to reduce risk of bone fractures are currently lacking.

Testosterone Replacement Therapy: Overview

Saundra Hendricks
Houston Methodist Hospital Houston, Texas, United States

The interest in replacing testosterone, the most important male hormone, dates to back to antiquity. Ancient Roman and later in the Middle Ages European, Arabic and Chinese physicians prescribed the ingestion of animal testes to restore male virility. Fast forward through an interesting and questionable history of organotherapy that includes various concoctions of questionable sources for xenotransplantation of testes to modern attempts to replace testosterone. Modern testosterone therapy includes formulations administered by various means. Injectable testosterone therapy has been available for decades and has historically been given IM. A 2022 trial suggests that similar pharmacokinetics and mean serum testosterone levels can be achieved using subcutaneous injections, making self-administration easier. Buccal patches placed on the gums also delivers controlled release testosterone directly into the systemic circulation, bypassing first-pass hepatic metabolism and increasing bioavailability. Nasal testosterone has been available in the US since 2014 and EU since 2020 for treatment of low testosterone. Transdermal administration includes gels, liquids and patches. The first patch became available in the 1980s and was placed on shaved scrotum. A 2020 Dutch study followed 12 men for 4 years and found 7 of 12 men found this an acceptable therapy. A more acceptable patch is placed in any of several locations, but not the scrotum. Gels are applied to specified areas defined by the manufacturer. Subdermal pellets were first developed in the 1940s and surgically placed in the hip area or other fatty tissue. Oral replacement has met with difficulties of poor absorption and liver toxicity. Testosterone undecanoate became available in oral formulation in the EU in the 1970s and the US in 2014. The future of testosterone deficiency treatment may include novel therapies such

as androgen receptor modulators and other methods to increase endogenous testosterone production.

Education programmes for patients with adrenal insufficiency: Evaluations based on patients experiences

Lotte Brinkman[1*], Kirsten Davidse[1*] & Wanda Geilvoet[1]
Department of Internal Medicine, Division of Endocrinology, Erasmus University Medical Center, Rotterdam, Netherlands

Introduction
Adequate hormone replacement therapy in adrenal insufficiency (AI) is essential. Patients should have basic knowledge about their condition and how to minimise the change on an adrenal crisis. Education on how and when hydrocortisone replacement therapy should be adjusted together with instruction and practice an emergency injection are considered important measures to prevent a crisis. A nurse-led group-based education programme (GEP) was developed, and given from September 2018 until March 2020. In an aim to provide patients with education during COVID-19 pandemic, a video was developed based on the GEP. Both ways of education are evaluated.
Methods
Patients who followed the GEP ($n=67$) or watched the video ($n=139$) were recruited to fill in a questionnaire in retrospect. The questionnaire assessed experiences on content, contact with clinical nurse specialist and applicability in daily life. Furthermore, it contained self-reported marks before and after education, multiple choice and open questions. Also, electronic medical records for demographic data were studied.
Results
The composition of both groups seems similar when looking at gender and age. In the GEP-group 48,8% was men versus 54,7% in the video-group. The average age of the GEP-participants was 57.6 years compared with 58.0 years in the video-group. Remarkable is a doubling of the percentage participants with AI as a result of immunotherapy in the video-group. The self-reported marks were significantly improved after the GEP (P0.003). In the video-group, first analysis also showed an increase in the mean of self-reported marks from 4.81 (SD 2.6) to 7.3 (SD 1.4). In both groups the desire for repetition was regularly mentioned. Especially the video-group participants indicated they would like to receive the education sooner after diagnosis and guided practising the emergency injection was missed.
Conclusion
Overall, repeated education was explicitly indicated by a large proportion of participants in both groups. Further analysis in the video-group is being conducted.

Careers for Nurses Beyond Bedside: 1. Careers in Academia; 2. Careers in Pharmaceutical Industries

Annie Topping
Professor of Nursing and Head of School, School of Nursing and Midwifery, University of Birmingham and University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Unlike many other academic disciplines nursing is a relative newcomer to higher education in many countries. Although baccalaureate level preparation has been available in various forms since 1920 the real momentum for graduate nursing at point of qualification accelerated in the 1980s and 1990s. The development of nurse graduate education has nevertheless brought the realisation of many long fought professional ambitions but also created an academic nursing workforce. This can feel to newly appointed academic staff more akin to a second career undertaken in a parallel universe; and a journey sometimes embarked upon ill-prepared. This presentation will seek to describe the modern University and differences between research intensive and teaching orientated institutions. This will serve as a backcloth to explain the challenges for new nursing academics delivering education to meet regulatory, professional and workforce requirements whilst carving their own research and scholarly aspirations. This will be contrasted with the development of clinical academic roles namely PhD prepared clinical leaders combine clinical leadership with active engagement in research and may hold joint or honorary positions in higher education institutions. Lastly strategies that can be employed to navigate a successful career in academia to better contribute to the future of nursing and future generations of nurses will be discussed.

Fish oil supplementation during pregnancy attenuates sex-specific changes induced by perinatal maternal high-fat diet in mitochondria of rat skeletal muscle at weaning

Juliana Woyames[1], Isabela Martins[1], Manuella Souza[1], Jessika Oliveira Neto[1], Cherley Andrade[1], Georgia Atella[2], Isis Trevenzoli[1] & Carmen Pazos Moura[1]
[1]Universidade Federal do Rio de Janeiro, Carlos Chagas Filho Biophysics Institute, Rio de Janeiro, Brazil; [2]Universidade Federal do Rio de Janeiro, Leopoldo de Meiss Biochemistry Institute, Rio de Janeiro, Brazil

Perinatal maternal high-fat (HF) and isocaloric diet induced obesity and metabolic disorders in the offspring since weaning. At adulthood, oxidative soleus skeletal muscle of HF male offspring exhibited lipid accumulation and mitochondrial damage. At birth, HF offspring have higher n-6:n-3 polyunsaturated fatty acids (PUFA) plasma ratio. We hypothesized that HF offsprings mitochondria of skeletal muscle exhibit damages at weaning that could be mitigated by fish oil (FO, rich in n-3PUFA) supplementation during pregnancy. Female Wistar rats consumed an isocaloric, control (C: 11% lipids) or high-fat diet (HF: 29% lipids) from 8 weeks preconception until lactation. Part of the HF mothers received HF diet supplemented with FO (3%, HFFO: 35% lipids) only during pregnancy. FO did not attenuate the increase in weight gain, glycemia, and adiposity induced by maternal HF diet in male (M) and female (F) offspring at weaning. In the soleus muscle, HF-M offspring tended to higher content of triglycerides ($P=0.08$). HF-F offspring tended to a higher content of monounsaturated fatty acids ($P=0.06$) and a higher rate of de novo lipogenesis ($P=0.01$). FO increased the docosahexaenoic acid content in soleus of both sexes ($P<0.05$). HF-M and -F offspring showed reduced mitochondria density. They exhibited misalignment of sarcomeres, increased damaged mitochondria ($P<0.0001$), with reduced mitochondrial area ($P<0.0001$) and perimeter ($P<0.0001$), attenuated by FO ($P<0.05$). HF-M exhibited lower protein expression of mitochondrial biogenesis marker PGC1α ($P=0.04$), mitochondrial transcriptional factor *Tfam* mRNA ($P=0.06$), thermogenic/mitochondriogenesis marker *Sln* ($P=0.002$), uncoupling protein 3 (UCP3: $P=0.059$), and antioxidant protein mitochondrial superoxide dismutase ($P=0.03$) suggesting impaired mitochondriogenesis and increased oxidative stress, mechanisms contributing to reduced mitochondria density and to higher damaged mitochondria. Decreased mitochondrial fission marker (p-DRP1, $P=0.02$), concomitant with smaller and less circular mitochondria, suggests reduced fission. FO attenuated these changes and, additionally, increased the fusion marker mitofusin-2. Electron transport chain proteins were unaltered in HF offspring of both sexes, however, HFFO-M exhibited increased mitochondrial complexes I ($P=0.005$) and III ($P=0.04$). Differently, HF-F exhibited lower protein expression of mitochondrial fusion marker OPA1 ($P=0.02$ vs C), reversed by FO ($P=0.03$) accompanied by larger mitochondria, suggesting increased fusion that may contribute to reduced mitochondrial density in HFFO-F ($P=0,0002$ vs HF). Additionally, FO increased PGC1α ($P=0.03$) and UCP3 ($P=0.06$), partially attenuating mitochondria damage. Therefore, maternal FO supplementation during pregnancy partially mitigates sex-specific alterations in skeletal muscle mitochondria induced by maternal HF diet in offspring at weaning, which may have repercussions on offspring phenotype throughout life.

Semaglutide alters tongue transcriptome along with the improvement of taste perception and increased brain activation in response to sweet tasting solution in obese women with PCOS

Mojca Jensterle[1], Andrej Vovk[2], Jernej Kovac[2], Saba Battelino[3], Simona Ferjan[1], Barbara Hrast[2], Tadej Battelino[4] & Andrej Janez[1]
[1]Department of Endocrinology, Diabetes and Metabolic Diseases, University Medical Centre Ljubljana, Ljubljana, Slovenia; [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; [3]Department of Otorhinolaryngology and Cervicofacial Surgery, University Medical Centre Ljubljana, Ljubljana, Slovenia; [4]Department of Endocrinology, Diabetes and Metabolism, University Children's Hospital, University Medical Centre Ljubljana, Ljubljana, Slovenia

Background
Obese individuals may perceive the taste of caloric dense food as less intense, resulting in decreased activation of the reward system. Preclinical research provides some insights into the role of GLP-1 in the gustatory coding. The impact of GLP-1 receptor agonists on the tongue and taste perception remains largely unaddressed in clinical settings.
Aim
to investigate the impact of semaglutide on the tongue transcriptome, taste perception and brain response to visual food cues and sweet tasting solution.
Methods
Thirty obese women with polycystic ovary syndrome (age 33.7 $\pm$ 6.1 years, BMI 36.4 $\pm$ 4.4 kg/m^2, mean $\pm$ SD) were randomized to once weekly semaglutide (SEMA) 1.0 mg s.c. or placebo in a 16-week, single-blind, placebo-controlled study. Participants underwent the biopsies of the tongue. Transcriptomic profile of tongue tissue was assessed as changes in expression level measured by RNA sequencing (NovaSEQ 6000 sequencer, Illumina). Taste sensitivity was evaluated by chemical gustometry using a validated examination method consisting of 16 taste strips including 4 different concentrations of sweet, sour, salty and bitter. The change in neural response to visual food cues and to sweet-tasting solution was assessed by functional MRI. In the first task, subjects were shown a series of calorie-dense, calorie-low food and non-food cues. In the second task, the neural responses to the tasting of sweet solution dripped on the tongue was assessed. Both tasks were performed in fasting state and repeated after the meal ingestion. Change in eating behaviour was evaluated by the Three-Factor Eating Questionnaire (TFEQ-R18).
Results
A total of 1326 genes were differentially expressed in the tongue tissue between the SEMA and placebo with log FC >0.7 or $<.7$ and FDR <0.05. Gene ontology analysis identified altered pathways in WNT signalling, fat cell differentiation, reproductive regulation and carbohydrate and fatty acid metabolism. Semaglutide improved taste sensitivity for all four basic tastes. The ability to resist emotional eating improved in SEMA group. Furthermore, semaglutide decreased activation in response to food pictures in the right putamen after the meal ($P<0.001$) and increased activation in response to sweet solution in the region of angular gyrus ($P<0.001$).
Conclusion
Semaglutide modified transcriptomic profile in the tongue along with improved taste perception. Furthermore, it decreased activation in putamen in response to high caloric food cues and increased activation of angular gyrus in response to sweet tasting solution. This implies an impact of semaglutide on gustatory coding up to brain integrative centres.

Neuronostatin receptor GPR107 as a potential biomarker and therapeutic target in chronic liver disease

Antonio Garcia-Estrada[1,2,3,4], Natalia Hermán-Sánchez[1,2,3,4], Juan Luis López-Cánovas[1,2,3,4], Prudencio Sáez-Martínez[1,2,3,4], Javier M Zamora-Olaya[1,5,6], Manuel Rodriguez-Peralvarez[1,5,6], Raul M Luque[1,2,3,4] & Manuel D. Gahete[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Cordoba, Spain; [3]Reina Sofia University Hospital (HURS), Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain; [5]Department of Hepatology and Liver Transplantation, Reina Sofia University Hospital (HURS), Cordoba, Spain; [6]CIBER Hepatic and Digestive Diseases (CIBERehd), Cordoba, Spain

Metabolic associated fatty liver disease (MAFLD) is rapidly becoming a major aetiology for the development of hepatocellular carcinoma (HCC, the most common liver cancer) in the context of chronic liver disease. Current therapeutical options for MAFLD (dietetic/lifestyle intervention and/or pharmacological approaches) are still insufficient and the cellular and molecular mechanisms underlying this disease are yet to be fully understood. Our group previously reported that the neuronostatin (NST)/GPR107 system could be used as a potential biomarker in prostate cancer progression and aggressiveness. Therefore, we aimed to explore the role of NST and its putative receptor GPR107 in the MAFLD-HCC spectrum. For this purpose, GPR107 expression was analysed in 2 internal retrospective cohorts with chronic liver disease samples [cohort 1: HCC vs adjacent tissue ($n=93$)/cohort 2: HCC vs adjacent ($n=58$), cirrhotic ($n=39$) and healthy tissue ($n=5$)], 13 external validation cohorts (6 with HCC and 7 with MAFLD) and 3 liver cancer cell lines (HepG2, Hep3B and SNU-387). Functional assays (proliferation, wound healing, colony and hepatosphere formation) were also implemented in liver cancer cells to evaluate the impact of NST application and/or GPR107 expression modulation (overexpression/silencing). Overexpression of GPR107 in tumour samples was observed in cohort 1 and validated in 5 out of 6 external HCC cohorts. Moreover, GPR107 expression levels positively correlated with key cancer aggressiveness

biomarkers (e.g. MKI67, CDK1, RB, C-MYC), and were associated with microvascular invasion. In 4 out of 7 external MAFLD cohorts, we detected a gradual increase in GPR107 expression through the MAFLD-HCC progression, suggesting a role in hepatocarcinogenesis. Regarding GPR107 expression in cell lines, it was primarily detected in Hep3B, followed by SNU-387, and was not detected in HepG2. Functional assays revealed a decrease in cell proliferation in response to NST in all studied cell lines. On the other hand, GPR107 overexpression in Hep3B and SNU-387 increased, while its silencing decreased, cell proliferation. Lastly, combined NST administration and GPR107 overexpression reduced Hep3B and SNU-387 proliferation vs GPR107 overexpression alone, whereas the combination of NST application and GPR107 silencing showed no significant difference from GPR107 silencing. Altogether, our data demonstrate that GPR107 is overexpressed in the MAFLD progression towards HCC, suggesting that the NST/GPR107 system might be a novel vulnerability in chronic liver disease, and that could be exploited as a diagnostic and prognostic biomarker and a therapeutic target in MAFLD-HCC.

Associations between handgrip strength and skeletal muscle mass with all-cause mortality and cardiovascular mortality: a prospective cohort study of UK Biobank

Jingjing Zeng[1], Linqi Wei[2], Bo Chen[1], Menglin Fan[1] & Shaoyong Xu[1,3]
[1]Xiangyang Central Hospital, Affiliated Hospital of Hubei University of Arts and Science, Center for Clinical Evidence-Based and Translational Medicine, Xiangyang, China; [2]Wuhan University of Science & Technology, College of Medicine, Wuhan, China; [3]Xiangyang Central Hospital, Affiliated Hospital of Hubei University of Arts and Science, Department of Endocrinology, Xiangyang, China

Background
Handgrip strength (HGS) and skeletal muscle mass (SMM) are associated with all-cause and cardiovascular disease (CVD)-specific mortality risk in type 2 diabetes (T2DM) patients. However, the pattern of this association was unclear. We aimed to explore the pattern of associations between HGS and SMM with all-cause and CVD mortality risk in a diabetic population.
Method
Data were obtained from the UK Biobank (application number 92014), a large prospective cohort study. HGS was measured using a Jamar J00105 hydraulic hand dynamometer, and the mean values of left and right HGS were expressed in absolute units (kg). SMM was measured using bioelectrical impedance method. Considering the influence of individual body size, SMM/height^2 was used for subsequent analysis. Death data are available via links to the National Health Service Information Centre.
Results
The mean age of the 13392 T2DM patients was 60.39 $\pm$ 6.76 years and 8350 (52.35) were male. With a mean follow-up of 12.52 years, there were 3006 (22.45%) deaths, including 746 (5.57%) CVD deaths. Cox proportional risk model showed that compared with the highest quartile of HGS (Q4), the all-cause and CVD mortality risk increased progressively with decreasing muscle strength (P-trend <0.05). As a continuous variable, a 1 SD decrease in HGS was found to increase the risk of all-cause mortality by 30.9% in men (HR: 1.309, 95% CI: 1.241-1.381) and 25.6% in women (HR: 1.256, 95% CI: 1.112-1.420); the risk of CVD mortality increased by 35.0% in men (HR: 1.350, 95% CI: 1.219-1.496) and 43.4% in women (HR: 1.434, 95% CI: 1.087-1.894). Decreased SMM/height^2 was not associated with increased mortality risk when SMM/height^2 was quartile divided and when used as a continuous variable. However, when the third quartile (Q3) of SMM/height^2 was used as a reference, an increased mortality risk was found in men for Q1 and in women for both Q1 and Q4 . The multivariable restricted cubic regression splines with 4 knots showed that there was no non-linear evidence between HGS with all-cause mortality and CVD mortality risk (Pnon-linear >0.05), while SMM/height^2 showed a U-shaped non-linear relationship with all-cause mortality and CVD mortality risk (Pnon-linear <0.05).
Conclusion
HGS showed a linear downward trend with mortality risk, whereas SMM/height^2 showed a U-shaped relationship, and either too low or too high muscle mass was associated with increased risk of CVD and all-cause mortality. Because HGS is a simple, non-invasive, and inexpensive measure, it could be used to predict mortality risk.

Randomized double-blind placebo-controlled trial on levothyroxine and liothyronine combination therapy: The levolio study

Giulia Brigante[1,2], Daniele Santi[1,2], Gisella Boselli[1], Gianluca Margiotta[1], Rossella Corleto[1], Maria Laura Monzani[1,2], Andrea Craparo[1], Michela Locaso[1], Samantha Sperduti[1,3], Neena Roy[1], Livio Casarini[1,3], Tommaso Trenti[4], Manuela Varani[4], Maria Cristina De Santis[4], Laura Roli[4], Vincenzo Rochira[1,2] & Manuela Simoni[1,2,3]
[1]University of Modena and Reggio Emilia, Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]Azienda Ospedaliero-Universitaria of Modena, Unit of Endocrinology, Department of Medical Specialties, Modena, Italy; [3]University of Modena and Reggio Emilia, Center for Genomic Research, Modena, Italy; [4]Azienda USL Modena, Department of Laboratory Medicine and Anatomy Pathology, Modena, Italy

Introduction
Despite normal thyroid-stimulating hormone serum levels, up to 60% of hypothyroid patients are dissatisfied with the treatment. Animal studies suggest that the persistence of symptoms may derive from peripheral hypothyroidism. Combination treatment with levothyroxine and liothyronine is a theoretically plausible solution but its efficacy is still questionable.
Aim
To evaluate the effects of personalized twice-daily combination therapy on peripheral tissues and quality of life in thyroidectomized patients, considering also the influence of genetic variants of *DIO2* and *MCT10*.
Methods
Double-blind, randomized, placebo-controlled study in which 141 thyroidectomized subjects, with serum thyroglobulin <0.2 ng/ml and negative anti-thyroglobulin antibodies, with TSH within the normal range, were randomized to study (levothyroxine + liothyronine in the morning and liothyronine in the evening; $n=70$) or placebo group (levothyroxine + placebo in the morning and placebo in the evening; $n=71$). Pituitary-thyroid axis compensation was assessed after 6, 12 and 24 weeks. Clinical parameters, quality of life (evaluated with ThyPro-39 questionnaire), tissue markers (sex hormone binding globulin, serum lipids, bone metabolism markers) were evaluated at 12 and 24 weeks. *DIO2* and *MCT10* single nucleotide polymorphisms were genotyped.
Results
At baseline, both groups had free triiodothyronine/thyroxine (fT3/fT4) ratio below the physiologic range, which normalized after 6 months only in the study group (0.32 $\pm$ 0.08 vs 0.26 $\pm$ 0.05, $P<0.001$). Combination treatment required greater dose adjustments (25% vs 54%, $P<0.001$), due to TSH reduction below the reference range, with no signs or symptoms of hyperthyroidism. After 6 months, the study group had improved emotionality, anxiety, depression, and overall impact of the disease on quality of life ($P<0.05$). However, no preference for combination therapy was recorded. Tissue markers of peripheral thyroid function and BMI did not change in either group. Genetic variants did not influence any of the analyzed outcomes.conclusions: Six months of combination treatment normalizes fT3/fT4 ratio, improves quality of life but does not lead to changes in known tissue markers. However, therapeutic schemes and liothyronine formulation still need to be improved.

Faecal microbiota signature in hypothyroid patients with refractoriness to levothyroxine treatment

Camilla Virili[1], Silvia Capriello[1], Ilaria Stramazzo[1], Simone Filardo[2], Marisa Di Pietro[2], Rosa Sessa[2] & Marco Centanni[1]
[1]Sapienza University of Rome, Medico-Surgical Sciences and Biotechnologies, Latina, Italy; [2]Sapienza University of Rome, Public Health and Infectious Diseases, Rome, Italy

Despite an accurate management, in about 20% of hypothyroid patients showing an increased need for oral levothyroxine (LT4), the leading cause of treatment refractoriness remains unknown. Some studies hypothesized the relationship between gut microbiota composition and thyroid homeostasis, but the possible involvement of microflora in the efficacy of LT4 treatment has not been evaluated yet, and this represents the aim of our study. We examined the faecal microflora composition of 48 euthyroid (TSH <0.8-$2.5>$ mU/l) patients with Hashimoto's thyroiditis, subdivided in three groups: A) 13 patients not treated with LT4 (median age = 52 years); B) 22 patients reaching target TSH with a dose of LT4 of 1.24 mg/ kg/day (median age = 49 years); C) 13 patients reaching target TSH with a high dose of LT4 of 1.75 mg/kg weight/day (+35%; $P=0.0001$) (median age =

56 years). All treated patients took LT4 in fasting state, avoiding food and drugs interfering with LT4 absorption and action. Moreover, none of the included patients followed unbalanced diets, had disorders or used drugs interfering with faecal microbial composition. From each patient fecal samples were provided. Microbiota composition was determined via 16s rDNA sequencing of the hypervariable region V3-4 on Illumina MiSeq. Alpha and beta-diversity indices and all statistical analysis were computed in Qiime2. The gut microbiota of groups A and B showed a similar composition, while patients with refractoriness to L-T4 treatment (group C) showed a lower relative abundance of Firmicutes (66.58%) as compared to those in group A (76.8%, $P = 0.039$) or in group B (80.8%,$P = 0.012$). By contrast, patients of group C showed significantly increased Bacteroidetes (21.5%) as compared to both groups A and B ($P = 0.04$), as well as significantly higher relative abundance of Proteobacteria (9.28 vs 2.89% $P = 0.04$) as compared to patients with normal L-T4 absorption. By merging group A and B together, it appears that the ratio between Firmicutes and Bacteroidetes is more than doubled in patients with T4 refractoriness (3.05 to 6.28). Alpha-Diversity Analysis revealed that patients of group A who showed higher Shannon's Diversity as well as Pielou's evenness indexes as compared to patients of group C. Beta-Diversity Analysis measured as weighted UniFrac showed a statistically significant clustering (A vs C;$P = 0.006$ and B vs C;$P = 0.018$). This is the first analysis of fecal microbiota composition in patients with refractoriness to levothyroxine treatment, showing that a peculiar microbial signature characterizes patients with high levothyroxine requirement.

The variable clinical spectrum of Thyroid Hormone Resistance Syndrome type β: two different presentations of the same disease

Mafalda Martins Ferreira[1], Sofia Lopes[2], Cátia Araújo[2], Patrícia Oliveira[2], Carolina Moreno[2] & Isabel Paiva[2]
[1]Centro Hospitalar e Universitário de Coimbra, Endocrinology, Diabetes and Metabolism, Coimbra, Portugal

Thyroid hormone resistance syndrome(THRS) occurs in 1:40000 live births and can be diagnosed after a period of enigmatic changes in thyroid hormones(TH). Patients may be clinically euthyroid, have clinical hypo or hyperthyroidism. Mostly,it is an autosomal dominant disease due to germline mutations in THRβ-gene(exons 7-10). Resistance to peripheral action of TH leads to absence of TSH suppression (which can be normal/elevated) despite elevated fT4 and fT3.

Case 1:

A 38-year-old-man was referred because of persistent elevations of TH (TSH 43 µUI/ml (0.4-4.0), fT4 2.7 ng/dl (0.7-1.5), fT3 3.4 pg/ml (1.8-4.2)) – together with depression, a palpabre goitre and hyperlipidemia; his sister had "hypothyroidism". The pituitary-MRI excluded a thyrotropinoma; the remaining pituitary function was normal. Autoimmune thyroid disease was excluded. Genetic analysis confirmed a heterozygous G344R mutation(exon 9) in THRβ-gene: his sister had the same mutation; his 11-year-old daughter had normal TH. He begun treatment with levotyroxine(L-T4) up to 200 µg/daily: TSH reduced to 27 µUI/ml, fT4 1,8 ng/dl, fT3 4,1 pg/ml. The patient improved substantially, but lost follow-up until 15 years later, when he presented with TSH 112 µUI/ml, fT4 1,9 ng/dl, fT3 4,1 pg/ml under L-T4 125 µg/daily. He had gained weight, attempted suicide,and had elevation of CK and liver enzymes. He resumed the 200 µg/daily L-T4 dose: TSH decreased to 73 µUI/ml and he clinical and biochemical improved.

Case 2:

A 20-year-old-woman with short stature(148 cm), sensorineural deafness and attention deficit disorder, with TSH 5,4 µUI/ml, fT4 4,1 ng/dl, fT3 4,3 pg/ml was diagnosed with THRS after a confirmed heterozygous G344R mutation in THRβ-gene. Her brother had the same mutation. She underwent hemithyroidectomy due to a follicular adenoma and TSH slightly increased to 6,9 µUI/ml. She was under liothyronine, with maximum doses of 25 µg/bid: TSH 5,0 µUI/ml, fT4 1,8 ng/d, fT3 4,2 pg/ml. At 47-years-old, she is not under any thyroid replacement hormone but begun atenolol due to palpitations and insomnia: TSH 4,2 µUI/ml, fT4 2,29 ng/dl and fT3 7,0 pg/ml (1,8-4,2).

Discussion

Frequently, THRS treatment is not necessary unless signs of decompensation appear (great elevation of TSH together with elevated fT3 and fT4 levels), common if concomitant thyroiditis or previous ablative therapy. The woman from case 2 underwent thyroid surgery, however TSH remained minimally elevated, and years later she developed hyperthyroidism. In case 1, despite the absence of apparent causes for the decompensation, high doses of L-T4 were needed to resolve clinical hypothyroidism. More case reports are needed to better understand the course of this widely variable clinical presentation disease.

TSH suppression increases the risk of sarcopenia and frailty in the long-term follow-up of elderly patients with differentiated thyroid carcinoma

Meric Coskun[1], Esra Cataltepe[2], Hacer Dogan Varan[2], Eda Ceker[2], Yasemin Bektas[3], Yasemin Kuscu[3], Mehmet Muhittin Yalcin[1], Mujde Akturk[1], Fusun Balos Toruner[1], Mehmet Ayhan Karakoc[1] & Alev Eroglu Altinova[1]
[1]Gazi University , Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey; [2]Gazi University, Faculty of Medicine, Geriatric Medicine, Ankara, Turkey; [3]Gazi University, Faculty of Medicine, Ankara, Turkey

Objective

In differentiated thyroid carcinoma (DTC), TSH suppression with levothyroxine (L-T4) is a standard treatment for reducing tumor recurrence after total thyroidectomy. This study aims to evaluate the effect of long-term TSH suppression on the development of sarcopenia and frailty in elderly patients with DTC.

Method

Seventy patients aged 60 years and older with stable TSH levels during the last year and under L-T4 due to DTC were included in the study. The anterior thigh muscle thickness was measured by ultrasound and the Sonographic Thigh Adjustment Ratio (STAR) Index was calculated. Reduced muscle strength was diagnosed with a hand grip test. Walking speed, Fried Frailty Index and the Physical Activity Scale for the Elderly (PASE) scores were calculated.

Results

Median age of the patients was 65 years (min-max: 60-80) and 64.3% were women. The patients were followed up for 11 (2-30) years. Median TSH was 1.10 µIU/ml (IQR = 1.13). While active suppression (TSH < 0.1) was applied to 4.3% of the cases, 22.9% had low (0.1-0.49), 60.0% had low-normal (0.5-2), and 12.9% had normal (2.1-4) TSH levels. The anterior thigh muscle thickness was 37.5 (9.5) mm, and the STAR Index was 1.21 (0.39). Muscle mass was reduced in 35.7% of the cases. TSH was found to be significantly low in the group with reduced muscle mass compared to the group having no muscle mass reduction (0.71 (1.07) vs 1.20 (1.08); $P = 0.014$). Reduced muscle strength was present in 17.2% of the patients in the hand grip test. TSH levels of the reduced muscle strength group was lower than normal muscle strength group (0.66 (0.97) vs 1.18 (1.17); $P = 0.037$). According to the Fried Frailty Index, 58.5% of the cases was prefrail and/or frail while the remaining cases were robust. TSH was lower in the group at high risk of frailty than in the robust group (0.77 (0.88) vs 1.39 (1.07); $P = 0.002$). TSH showed a positive correlation with walking speed ($r = 0.258$, $P = 0.031$) and STAR Index ($r = 0.254$, $P = 0.034$), and a negative correlation with Fried Frailty Index ($r = -0.399$, $P = 0.001$). TSH below 1.325 µIU/ml was found to increase the risk of frailty with a sensitivity of 80.49% and a specificity of 58.62% (AUC = 0.719, $P = 0.001$). Logistic regression analysis indicated that TSH was an independent predictor of frailty development ($P = 0.006$).

Conclusion

In elderly patients with TSH suppression due to DTC, muscle strength and muscle mass decrease, and the risk of frailty increases in the long term. Close follow-up of these patients for sarcopenia and frailty is recommended.

DOI: 10.1530/endoabs.90.OC2.4

OC2.5

Circulating Long Non-Coding RNAs as a non-invasive markers to help differentiate benign from malignancy in indeterminate thyroid nodules

Susmita Dutta[1], Soham Tarafdar[1], Nitai P. Bhattacharyya[1], Pradip Mukhopadhyay[1] & Sujoy Ghosh[1]
[1]Institute of Post Graduate Medical Education and Research, Dept. of Endocrinology & Metabolism, Kolkata, India

Introduction

Molecular testing is being increasingly used to detect malignancy in indeterminate thyroid nodules (Bethesda 3 & 4) which pose diagnostic dilemma. Long non-coding RNAs are crucial for metastasis, angiogenesis, and tumour growth of various cancers. Clinical utility of plasma lncRNAs as non-invasive diagnostic markers for thyroid cancer especially in indeterminate nodule remains unexplored.Methodology: We selected lncRNAs relevant to thyroid neoplasm from LncRNA Disease 2.0 database. The lncRNAs thus selected were PVT1, HOTAIR, NEAT1, MALAT1, BANCR, HOTTIP, GAS5, H19, and GAS8-AS1. We compared the expression (using quantitative real-time PCR (qRT-PCR)) of these lncRNAs in biopsy proven differentiated thyroid cancer patients versus benign thyroid nodule subjects and healthy controls as part of first phase of study (discovery cohort). We then proceeded to determine cut-off of change of level of expression (ΔCT) for these lncRNAs (by performing a Receiver operating-characteristic (ROC) curve. These cut-offs was then applied in a validation cohort

to test the ability of the same to help differentiate benign from differentiated thyroid malignancy (indeterminate nodules). We also determined the expression of these lncRNAs in FNAC materials and tissue samples for cross validation. Finally we rechecked the expression in plasma 2 weeks after surgery.
Results
We compared the plasma expression of the nine circulating lncRNAs in patients with thyroid cancer ($n=25$), benign thyroid nodules ($n=40$), and healthy controls ($n=39$) in the discovery cohort and the expression of PVT1, MALAT1, and BANCR were found to be significantly different between benign and malignant nodules ($P<0.001$). Cut off for ΔCT (obtained by ROC) for PVT1, MALAT1 and BANCR were 4.64, 6.28 and 5.94 respectively. We applied these cut-offs in a validation cohort (N=158, indeterminate nodules) and PVT1, MALAT1 and BANCR was able to differentiate malignant from benign nodule with 96.20%, 87.34% and 84.81% accuracy. PVT1 and BANCR were up-regulated in all differentiated thyroid cancer but MALAT1 was only up-regulated in PTC, but not in FV-PTC and FTC. Cross-validation of our data in FNAC material and histopathology sample reconfirmed our findings (PVT1, MALAT1 and BANCR were up-regulated similar to that in plasma (similar quantum of increased expression)). Post-operatively plasma samples were tested and it was found that the over expression of PVT1, MALAT1 and BANCR normalized to levels similar to benign nodules.
Conclusion
Plasma PVT1, MALAT1, and BANCR may be useful molecular non-invasive diagnostic markers to help differentiate benign from malignant thyroid nodules, including in those presenting with indeterminate thyroid nodules.

CD3+CD8+CD20+T lymphocytes behave differently in autoimmune thyroiditis and related polyautoimmune disorders: A pilot study

Ilaria Stramazzo[1], Giorgio Mangino[1], Poupak Fallahi[2], Maria Giulia Santaguida[3], Lucilla Gargano[3], Silvia Capriello[1], Camilla Virili[1] & Marco Centanni[1]
[1]Sapienza University of Rome, Medico-Surgical Sciences and Biotechnologies, Latina, Italy; [2]University of Pisa, Department of Translational Research and New Technologies in Medicine and Surgery, Pisa, Italy; [3]AUSL Latina, Endocrinology Unit, Latina, Italy

The presence and the role of $CD20^+$ T cells in humans has been described in autoimmune disorders such as multiple sclerosis and rheumatoid arthritis. In healthy subjects, $CD3^+CD20^+$ T cells are detected in all lymphatic organs and in the cerebrospinal fluid and represent about 5% of circulating T cells. Some reports described their production of high levels of IL-17A and/or IFN-γ. This study was aimed at investigating the behavior of $CD3^+CD20^+$ T lymphocytes in patients with Hashimoto's thyroiditis, isolated or in a frame of polyautoimmunity. Sixty five patients with HT, aged from 23 to 69 years (M=14; F=51), 23 of whom in isolated form and 42 with a further autoimmune disorder [16 with gastric atrophy (HT+GA), 15 with vitiligo (HT+V) and 11 with celiac disease (HT+CD)] were investigated. Twenty sex- and age-matched healthy subjects represented the control group (HD). The chronic use of interfering drugs, the presence of severe or chronic disorders, pregnancy and lactation were considered as exclusion criteria. Whole blood samples were obtained and quickly stained with the specific fluorescent-labelled antibodies. Red blood cells were then lysed by adding 1 ml of hypotonic buffer and samples were analyzed on a FACs ARIA II Flow Cytometer (BD). The percentages of $CD3^+CD20^+$ T and the one of $CD4^+CD20^+$ T lymphocytes were similar in all groups. The subpopulation $CD8^+CD20^+$ T in the whole group of autoimmune patients was higher than in HD ($P=0.0089$). Those with isolated HT also showed higher percentages of $CD8^+CD20^+$ T than in HD patients, without reaching statistical significance. $CD8^+CD20^+$ T cells subset was clearly different (ANOVA:$P=0.0058$) in the presence of associated autoimmune disorders, as compared with HD. In particular, an increased percentage of these cells was observed in HT+GA as compared to HD ($P=0.0257$), unlike in patients with HT+CD, all in gluten-free diet, in whom the $CD8^+CD20^+$ T cells subset was similar to the one in HD. Interestingly, when subdivided by thyroid function, HT hypothyroid patients showed a doubled percentages of $CD8^+CD20^+$ T cells than in euthyroid patients and in HD ($P=0.0115$). These preliminary findings indicate that the presence of $CD8^+CD20^+$ T lymphocytes is associated with a worst thyroid function and it is differently modulated in HT patients with or without poly-autoimmunity.

Diagnosing Vasopressin Deficiency (Central Diabetes Insipidus) using Copeptin following Hypertonic Saline and Arginine Stimulation

Julie Refardt[1], Cihan Atila[1], Irina Chifu[2], Emanuele Ferrante[3], Zoran Erlic[4], Juliana Drummond[5], Beatrice Mantovani[6], Roos Drexhage[7], Sailer Clara Odilia[1], Andrea Widmer[1], Susan Felder[1], Andrew Powlson[8], Nina Hutter[1], Deborah Vogt[1], Mark Gurnell[8], Beatriz Santana Soares[5], Hans Hofland[7], Felix Beuschlein[4], Martin Fassnacht[2], Bettina Winzeler[1] & Mirjam Christ-Crain[1]
[1]University Hospital Basel, Endocrinology, Basel, Switzerland; [2]University Hospital and University of Wuerzburg, Germany; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milano, Italy; [4]University Hospital Zurich, Zurich, Switzerland; [5]Medical School of the Federal University of Minas Gerais, Belo Horizonte, Brazil; [6]University of Milan, Milano, Italy; [7]Erasmus MC , Rotterdam, Netherlands; [8]University of Cambridge & Addenbrooke's Hospital, Cambridge, United Kingdom

Background
The main challenge in the diagnosis of arginine vasopressin deficiency (AVP-deficiency, formerly known as central diabetes insipidus), is its distinction against primary polydipsia. Hypertonic saline stimulated copeptin showed a high diagnostic accuracy of 97% in distinguishing between AVP-deficiency and primary polydipsia (Fenske W, Refardt J, NEJM 2018), but comprises discomfort for patients and requires close sodium monitoring. Arginine stimulated copeptin showed a similar diagnostic accuracy of 93% (Winzeler B, Lancet 2019) with the test being generally well tolerated. A head-to-head comparison is needed to find the best diagnostic test. We hypothesize that the arginine stimulation test is non-inferior to the hypertonic saline stimulation test (non-inferiority margin 10%) for the diagnosis of AVP-deficiency with an easier test protocol and better tolerability.
Methods
Between 2018 and 2022, 164 patients with hypotonic polyuria from seven tertiary medical centers underwent hypertonic saline and arginine stimulation in randomized order for diagnostic evaluation. Serum copeptin levels were measured at sodium-level of >149 mmol/l after hypertonic saline and 60 minutes after arginine infusion, respectively. The final diagnosis was made after treatment response at three-month follow-up blinded to copeptin levels. The main outcome measure was the overall diagnostic accuracy using the pre-defined copeptin cut-off of 4.9 pmol/l for the hypertonic saline and 3.8 pmol/l for the arginine stimulation.
Results
Of the 157 evaluable patients, 69 (44%) were diagnosed with AVP-deficiency and 88 (56%) with primary polydipsia. Of the 69 AVP-deficiency patients, 41 (59%) were judged to have a complete and 28 (41%) to have a partial defect. Copeptin samples are currently being measured in batch analysis and the diagnostic accuracy and tolerability results of both tests will be presented at the Endocrine Society meeting.
Conclusion
This prospective multicentre study will determine which test should be used for the differentiation between AVP-deficiency and primary polydipsia.

Protein supplementation increases plasma sodium levels and urinary urea excretion in patients with chronic SIAD – A monocentric open-label proof-of-concept study -The treasure study

Sophie Monnerat[1], Cihan Atila[1], Fabienne Baur[1], Michael Dickenmann[2] & Mirjam Christ-Crain[1]
[1]University Hospital Basel, Department of Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University Hospital Basel, Clinic for Transplantation Immunology and Nephrology, Basel, Switzerland

Introduction
The syndrome of inappropriate antidiuresis (SIAD) is the most common cause of euvolemic hyponatremia. Besides fluid restriction, increasing free water clearance is an effective treatment approach that can be achieved through osmotic diuresis by administering oral urea. Dietary proteins are metabolized into soluble excretable urea by the liver. We hypothesized that dietary protein could increase free water clearance through urea-induced osmotic diuresis and therefore aimed to investigate the effect of high-protein supplementation on plasma sodium levels in outpatients with chronic SIAD.

Methods
This is an interim analysis of a monocentric open-label proof-of-concept trial conducted at the University Hospital of Basel in Switzerland since October 2021. Adult outpatients with chronic SIAD of any etiology were eligible. Patients received 90 g protein daily for 7 days in the form of protein powder dissolved in a maximum of 1L of liquid of choice. After a wash-out period of at least a week, patients received 30 g of oral urea daily for 7 days. Patients were asked to keep their baseline fluid intake unchanged throughout the study. The primary endpoint was the increase in sodium levels from baseline to the end of the 7-day protein supplementation.
Results
Fourteen patients, 11 females and 3 males, with chronic SIAD were included. Median [IQR] age was 68 [61, 80] and median duration of hyponatremia was 21 months [3, 59]. At baseline, median plasma sodium concentration was 130 mmol/l [128, 133]. Eight patients had mild hyponatremia (130-134 mmol/l), 4 had moderate hyponatremia (125-129 mmol/l), and 2 patients had profound hyponatremia ($<$125 mmol/l). After 7 days of 90 g daily protein supplementation ($n=14$), sodium levels increased by a median of 3.5 mmol/l [0.5, 5.8], blood urea nitrogen increased by a median of 4.3 mmol/l [1.7, 5.1] and urinary urea corrected for urine creatinine increased by a median of 25.3 mmol/mmol [15.6, 31.2]. After 7 days of oral urea ($n=8$), sodium levels increased by a median of 2 mmol/l [1, 3], blood urea nitrogen increased by a median of 8.5 mmol/l [3.8, 10.2] and urinary urea corrected for urine creatinine increased by a median of 31 mmol/mmol [21.1, 39.8].
Conclusion
This analysis suggests that high-protein supplementation with protein powder increases plasma sodium levels in patients with chronic SIAD. The increase in urea concentration in both plasma and urine upon protein supplementation is comparable to the increase upon oral urea administration, which supports protein-induced ureagenesis to be the underlying mechanism of action.

[18F]FET PET-MRI; a novel and improved technique for detection of small functional pituitaryadenomas

Ilanah Pruis[1], Rutger Balvers[2], Anita Harteveld[1], Richard Feelders[3], Meike Vernooij[1], Marion Smits[1], Erik Verburg[1], Sophie Veldhuijzen van Zanten[1] & Sebastian Neggers[1]
[1]Erasmus MC, Department of Radiology and Nuclear Medicine, Rotterdam, Netherlands; [2]Erasmus MC, Department of Neurosurgery, Rotterdam, Netherlands; [3]Erasmus MC, Internal Medicine Section Endocrinology, Rotterdam, Netherlands

Background
Small functional pituitary adenomas can cause severely disabling symptoms and early death, however, surgical planning is often complicated due to inconclusive diagnostic MRI in up to 40% of patients and therefore hamper cure rates. We here introduce a novel method for the detection of small functional pituitary adenoma by O-(2-[18F]-fluoroethyl)-L-tyrosine ([18F]FET) PET-MRI.
Methods
Patients with Cushing's disease (CD) or acromegaly with a suspected primary or recurrent small functional pituitary adenoma underwent [18F]FET PET-MRI. Focal uptake of [18F]FET was evaluated by a single nuclear radiologist and MRI was separately evaluated by a single neuroradiologist. Outcomes were compared with clinical follow-up and sensitivity and positive predictive values (PPV) were calculated.
Findings
Consecutive 28 patients, 68% female, mean age 50 years (range: 24 – 71), with CD ($n=22$; 79% or acromegaly ($n=6$; 21%) were scanned. 17 CD patients with a primary diagnosis had also undergone IPSS and 3 (50%) had a primary acromegaly diagnosis. 14/22 CD patients (64%) and 1/6 acromegaly underwent transsphenoidal surgery after [18F]FET PET, others are waiting or refused. Twenty-two CD patients (100%) had a positive [18F]FET PET, allowing to identify pituitary adenomas as small as 3 mm in size on accompanying MRI. 11/14 CD patients who underwent subsequent transsphenoidal surgery are biochemically in remission; rendering an estimated sensitivity of 100% and a PPV between 78 – 100% to detect CD. Four acromegaly patients (67%) had a positive [18F]FET PET. One acromegaly patient was biochemically in remission after transsphenoidal surgery.
Conculsion
[18F]FET PET-MRI shows high accuracy for localizing small functional pituitary adenoma in patients with CD and acromegaly. The diagnostic yield of this hybrid imaging technique exceeds that of MRI alone and IPSS and provides a welcome improvement for diagnosis, planning of surgery and follow-up.

[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrine Unit, Milan, Italy; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Clinical Chemistry Unit, Milan, Italy; [3]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [4]University of Milan, International Medical School, Milan, Italy; [5]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neonatology and Neonatal Intensive Care Unit, Milan, Italy

Background and Aim
Congenital growth hormone deficiency (cGHD) is a rare but life-threatening condition whose diagnosis is challenging in the absence of reliable reference values, both in healthy neonates and in preterm ones. We recently estimated GH reference interval in 1036 healthy, at-term newborns (HN) form dried blood spot samples using a previously validated analytical method. Aim of this study is to provide values for random GH in preterm newborns (PN).
Methods
GH was evaluated in 78 PN (M:F 51:49%) attending the Neonatal Intensive Care Unit of Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan. GH measurement was performed as above described at 48 hours after birth (GH1). In 41 out of 78 PN a second GH determination (GH2, at 15 days after birth) was also available.
Results
Median (IQR) GH1 values were 14.9 µg/l (9.8-21.1). No gender differences were found ($P=0.089$). The percentile 5th (3.4 µg/l) calculated in PN was lower than the lower limit of reference interval estimated in HN (reference limit at percentile 5.0th: 7.0 µg/l, 90%CI 6.7-7.3). In PN, decreasing GH levels were associated with increasing invasiveness of ventilation (no ventilation: 20.1, CPAP/biphasic: 15.1, high flows ventilation: 12.4, invasive ventilation: 5.4; overall KW $P=0.026$). Indeed, GH was significantly lower in PN needing invasive ventilation than not ventilated ones (Bonferoni's correction $P=0.048$). A low-to-moderate, although significant, correlation (rho$=0.295$, $P=0.009$), was found between GH levels and gestational age (GA). No association was, instead, found with maternal age ($P=0.072$), smoke ($P=0.138$), parity ($P=0.520$) or other neonatal variables, including jaundice ($P=0.276$) and auxological parameters (all $p>0.05$). Considering PN with both GH determinations ($n=41$), GH1 levels were significantly higher than GH2 (14.4 vs 9.8 µg/l, respectively, $P=0.018$). GH decreased in most neonates (26/41$=$63%), as expected after the first week of life. Interestingly, in PN with GH increase (GH2$>$GH1), GA was significantly lower than in those with GH decrease (GH1$>$GH2), with a median 30 vs 33 weeks ($P=0.024$).
Conclusions
Our data show for the first time that PN have lower median GH levels than HN. GH in PN is associated with ventilation and GA. The latter finding, along with the association between lower GA and increase in GH2 levels could be explained by an incomplete maturity at birth of the somatotropic axis in very PN, with the subsequent GH increase reflecting an extra-uterine maturation of the axis itself.

Interest of serum and salivary cortisol diurnal cycle in the positive diagnostic of Cushing syndrome and in the differential diagnosis of pseudo-Cushing syndrome

Bonnet Fideline[1,2,3], Jonathan Poirier[4], Ralph El Khoury[4], Christelle Laguillier-Morizot[2,3], Marie-Clémence Leguy[2], Louis Thomeret[1,3], Lucas Bouys[1,3,4], Laurence Guignat[4], Guillaume Assié[1,3,4], Lionel Groussin[1,3,4], Jean Guibourdenche[2,3] & Jerome Bertherat[1,3,4]
[1]Cochin Institute, Inserm U1016-CNRS UMR8104, Paris, France; [2]Cochin Hospital, Hormonology, Paris, France; [3]Paris Cité University, Paris, France; [4]Cochin Hospital, Endocrinology, Paris, France

Introduction
Biological diagnosis of Cushing syndrome relies on three parameters: 24 hours-free urinary cortisol; serum cortisol after 1 mg dexamethasone suppression test; late-night serum or salivary cortisol. These tests allow the diagnosis of cortisol

excess but do not help in etiological diagnosis, particularly in the distinction between pseudo-Cushing and ACTH-dependent Cushing syndrome, which is often challenging. The aim of this study was to evaluate the performances of cortisol diurnal cycle in serum and saliva for both the positive diagnosis of Cushing syndrome and the differential diagnosis of pseudo-Cushing syndrome.
Materials and Methods
Patients having performed a complete cortisol diurnal cycle in both serum and saliva during their hospitalization in Cochin Hospital Endocrinology department from 2012 to 2018 were included. Their clinical and biological characteristics were collected from Cochin electronic medical record. Pseudo-Cushing syndrome was diagnosed in patients with repeated biological anomalies but whose follow-up allowed the elimination of hypercortisolism. Serum and saliva cortisol during diurnal cycle were determined in competition immunoassays.
Results
466 patients were included in this study: 311 control subjects and 55 patients with pseudo-Cushing syndrome, grouped in "No-Cushing" ($n=366$); 73 patients with ACTH-dependent Cushing syndrome and 27 patients with cortisol-producing unilateral adrenal adenoma, grouped in "Cushing" ($n=100$). Salivary cortisol showed a good correlation with serum cortisol at all the times of the diurnal cycle (Spearman R ranging from 0.76 at 8 h to 0.88 at 20 h, $P<0.0011$). Considering the distinction between "Cushing" and "No-Cushing" groups; ^{24}H-cortisol level was expectedly the most discriminant parameter. ROC analysis of 24H-cortisol showed equivalent diagnostic performances in both saliva and serum (AUC = 0.95) giving a sensitivity of 89% and a specificity of 90% with a cut-off of **6.2** nmol/l and **175** nmol/l, respectively. Using these cut-offs, the proportion of false positive was > 20% in the pseudo-Cushing group, highlighting the difficulty of this differential diagnosis. Interestingly, the ratio maximal/minimal cortisol level during the day in serum allowed a good discrimination between pseudo-Cushing and ACTH-dependent Cushing syndrome groups, a cut-off of **3** giving a sensitivity of 86% and a specificity of 91% (AUC = 0.93). This ratio in saliva was less performant (AUC = 0.82).
Discussion
Saliva cortisol correlates well with serum cortisol at all the times of diurnal cycle; ^{24}H-saliva cortisol performing as well as 24H-serum cortisol for the positive diagnostic of Cushing syndrome. A ratio of maximal/minimal cortisol level in serum > 3 is highly predictive of pseudo-Cushing versus ACTH-dependent Cushing syndrome diagnosis.

For all ERCUSYN investigators
Background
Patients with Cushing's syndrome (CS) have an increased risk of developing venous thromboembolic complications. There is currently no standard practise for thromboprophylaxis in CS patients.
Aim
To study the details of VTE in patients included in The European Registry on Cushing's syndrome (ERCUSYN) and study various thromboprophylaxis protocols used among the centres where VTE's were reported.
Methods
A retrospective observational cohort study; data extraction from the registry was taken on the 07.02.2022. Additional data were requested for all VTE-positive cases and obtained in 93% of cases.
Results
There were 95 VTE among 2173 CS patients (prevalence of 4.4 %). Among the 57 centres included in the database, events were reported in 28. Details on VTE were available for 86 (88.4%) patients. One VTE was diagnosed in 69 patients, two VTE's in 9, and 3 VTE's in 6. All together there were 105 VTE. Deep venous thrombosis (DVT) was diagnosed in 50(47,6%) cases, pulmonary embolism (PE) in 29(27,6%) cases, other VTE in 21(20%) cases, and PE/DVT with VTE in uncommon locations or together were diagnosed in 5(4,8%) cases. At the time of the VTE only 30.4% were anticoagulated, on low-molecular-weight heparin (LMWH) (68%), vitamin-K antagonist (VKA) (24%), or on Xa-inhibitor 8%. Following the VTE 93.4% were anticoagulated, the agent used varying widely: 41% received VKA, 34.6% LMWH, 21.8% Xa inhibitor and 2.6% aspirin. The duration of anticoagulation varied from 2 weeks until lifelong (40%). Compression stockings were used in 50.9% of the VTE cases. Looking at the centre's routine thromboprophylaxis protocols, 43% anticoagulated on a routine basis. 8,3% anticoagulated only pituitary CS, 25% both pituitary and ectopic source CS and 66.7% anticoagulated all CS patients regardless of the aetiology. Anticoagulation schemes varied as far as anticoagulation initiation, the duration of thromboprophylaxis given and agent used; 25.6% anticoagulated preoperatively, 22.2% after confirmation of the diagnosis of CS, 33.3% only in particular situations: high-risk patients, following VTE or if medical therapy for hypercortisolism was started. In 75% of the centres LMWH was used, and less frequently VKA and Xa inhibitors.
Conclusion
We report a high VTE rate in CS patients within ERCUSYN. Most patients were not anticoagulated at the time of the event. There is no uniformly used thromboprophylaxis scheme in centres that reported VTE events. To our knowledge this is the largest registry-based study to date looking at VTE in CS patients.

Gender-affirming hormone treatment: friend or foe? Long term follow-up of 755 transgender and gender diverse people

Giorgia Spaggiari[1,2], Lorenzo Marinelli[3], Marta Cacciani[4], Sofia Scipio[4], Andreina Bichiri[3], Alessandra Profeta[3], Antonio Raffaele Michele Granata[1,2], Ezio Ghigo[3], Manuela Simoni[1,4], Giovanna Motta[3] & Daniele Santi[1,2,4]
[1]Azienda Ospedaliero-Universitaria of Modena, Unit of Endocrinology, Department of Medical Specialties, Modena, Italy; [2]Azienda Ospedaliero-Universitaria of Modena, Unit of Andrology and Sexual Medicine of the Unit of Endocrinology, Department of Medical Specialties, Modena, Italy; [3]University of Turin, Division of Endocrinology, Diabetes and Metabolism, Department of Medical Sciences, Turin, Italy; [4]University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy

Background
Gender-affirming hormone treatment (GAHT) is the cornerstone in the therapeutic management of transgender and gender diverse (TGD) people, which are currently classified as transgender assigned-female-at birth (t-AFAB) and assigned-male-at birth (t-AMAB) subjects. Due to its hormonal nature, GAHT is commonly handled by the endocrinologist and available guidelines on this topic mimic the recommendations for cis-gender hypogonadal populations. However, the GAHT long term management remains challenging, since the clinician must juggle a balance between achieving the phenotypic characteristics of the perceived gender and minimizing adverse effects. Although several longitudinal studies evaluated GAHT approaches, a focus on the challenges that the clinician should face off is still lacking.
Aim
Of the study: To investigate the long term therapeutic management of TGD people, considering hormonal targets, treatment adjustments and GAHT safety.
Methods
A retrospective, longitudinal, observational, multicentre clinical study was carried out, enrolling TGD subjects consecutively attending two Italian Endocrinology Units (Turin and Modena) from 2005 until 2022. Both t-AFAB and t-AMAB subjects were included, recording all data derived from routine outpatient evaluations. Each subject was managed with specific and personalized follow-up depending on the clinical practice of the Centre, as well as on the presence of adverse events, in accordance to the guidelines in force.
Results
Comprehensively, 302 t-AFAB and 453 t-AMAB were enrolled, showing similar follow-up average duration ($P=0.974$) and visits number ($P=0.384$). However, hormonal targets were reached more frequently in t-AFAB (63.6%) rather than in t-AMAB (23.3%) subjects. In addition, less time ($P=0.002$), fewer follow-up visits ($P=0.006$) and less changes in therapeutic schemes ($P=0.024$) were required in t-AFAB to achieve the therapeutic goal. Accordingly, t-AFAB showed

a higher adherence to medical prescriptions compared to t-AMAB subjects ($P<0.001$). During follow-up, the rate of both hypertension ($P=0.015$) and dyslipidaemia ($P<0.001$) increased in t-AFAB subjects, whereas t-AMAB ones showed a significant increase only in dyslipidaemia rate ($P<0.001$). No significantly increased rate of cardiovascular events was detected in both groups.
Discussion
Here, we described for the first time a long term follow-up during GAHT in a large cohort of Italian TGD people. This real-world clinical snapshot shows that hormonal balance is reached more frequently and more easily in transgender AFAB compared to AMAB subjects. Probably, these latter would require a thicker clinical management to overcome the higher intrinsic complexity of feminizing treatments, at least contributing to the poor therapeutic adherence observed in such subjects.

Inhibition of RANKL in the testis increased the number of motile sperm in a sub-group of infertile men with preserved Sertoli cell function

Christine Hjorth Andreassen[1,2,3], Li Juel Mortensen[1,2,3], Rune Holt[1,2,3], Nadia Krarup Knudsen[1,2,3], John Erik Nielsen[2,3], Anders Juul[2,3,4], Anne Jørgensen[2,3] & Martin Blomberg Jensen[1,2,3,5]
[1]Copenhagen University Hospital – Rigshospitalet, Group of Skeletal, Mineral, and Gonadal Endocrinology, Department of Growth and Reproduction, Copenhagen OE, Denmark; [2]Copenhagen University Hospital – Rigshospitalet, Department of Growth and Reproduction, Copenhagen OE, Denmark; [3]Copenhagen University Hospital – Rigshospitalet, International Centre for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen OE, Denmark; [4]University of Copenhagen, Department of Clinical Medicine, Copenhagen N, Denmark; [5]HSDM/HMS Harvard University, Division of Bone and Mineral Research, Boston, Massachusetts, United States

Currently, no treatment options exist to improve semen quality for the majority of infertile men. Proper interaction between germ and Sertoli cells in the testis is critical for sperm production, and a recent study suggested that Denosumab, an inhibitor of RANKL signaling, may stimulate sperm production in some infertile men. Here, we show in animal and human studies how expression of the RANKL signaling system is critical for both Sertoli cell function and the testicular response to Denosumab. RANKL was removed globally in mice using the Cre-LoxP system. qPCR and immunohistochemistry were used to investigate OPG expression in human testis with full spermatogenesis or Sertoli cell-only (SCO) syndrome, fetal testis, as well as cultures of human testis tissue treated with Denosumab. Reproductive hormones, semen quality, and anti-Müllerian hormone (AMH) levels were measured in 100 infertile men, who subsequently were randomized to a single subcutaneous injection with Denosumab (60 mg) or placebo (1 mL NaCl). After 80 and 160 days, semen samples were analyzed, and blood samples collected. Mice with global RANKL deletion had increased testicular and epididymal weight. OPG expression was high in Sertoli cells from human testis with SCO in contrast to testis with full spermatogenesis or fetal testis. In human testicular cultures with low or moderate OPG expression Denosumab increased germ cell proliferation and decreased apoptosis, while Denosumab had no effect in testis with spermatogenic arrest or high expression of OPG in Sertoli cells. In infertile men, low serum AMH was associated with poor Sertoli cell function and decreased semen quality. In the randomized placebo-controlled clinical trial one dose of Denosumab did not increase semen quality compared to placebo. However, in a sub-group of men with baseline serum AMH > 35 pmol/l Denosumab increased the inhibin B/FSH ratio and number of motile sperm cells, which is the best predictor of male fertility potential. This translational study suggests that the effect of Denosumab depends on the function of Sertoli cells with high OPG expression being a marker of dysfunction. AMH may be used to select the sub-group of infertile men who may benefit from Denosumab treatment; however, further investigation is critical for understanding the interplay between Sertoli cell function, spermatogenesis, and RANKL inhibition.

The association between selected serum microRNAs, adipokine concentrations, and body composition assessed with dual-energy X-ray absorptiometry in young women with polycystic ovary syndrome

Anna Krentowska[1], Donata Ponikwicka-Tyszko[2], Agnieszka Lebkowska[1], Agnieszka Adamska[3], Justyna Hryniewicka[3], Maria Sztachelska[2], Gabriela Milewska[4], Slawomir Wolczynski[4] & Irina Kowalska[1]
[1]Medical University of Białystok, Department of Internal Medicine and Metabolic Diseases, Białystok, Poland; [2]Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Department of Biology and Pathology of Human Reproduction, Białystok, Poland; [3]Medical University of Białystok, Department of Endocrinology, Diabetology and Internal Medicine, Białystok, Poland; [4]Medical University of Białystok, Department of Reproduction and Gynaecological Endocrinology, Białystok, Poland

Introduction
Polycystic ovary syndrome (PCOS) is associated with an increased risk of abdominal obesity, what is regulated by numerous genetic, epigenetic, and environmental factors. MicroRNAs (miRNAs) are known regulators of gene expression, involved in the development of metabolic disturbances. Dual-energy X-ray absorptiometry (DXA) is an accurate method of body composition analysis. The aim of the present study was to investigate the association between circulating miRNAs, adipokine concentrations, and body composition in PCOS patients.
Materials and methods
The studied group comprised 102 patients with PCOS (age: 24.3 ± 3.6 years; BMI: 24.7 ± 5.0) and 64 healthy women (age: 25.0 ± 3.4 years; BMI: 23.4 ± 3.7) as a control group. All women underwent anthropometric measurements, body composition analysis with DXA, and transvaginal ultrasound. Concentrations of sex hormones, sex hormone-binding globulin, adiponectin, leptin, lipids, as well as glucose and insulin during oral glucose tolerance test were measured. Serum levels of miR-27a, miR-106b, miR-181a, miR-193b, and miR-320 were assessed with real-time polymerase chain reaction.
Results
The studied groups did not differ in terms of age or BMI. No differences regarding body composition or the concentrations of leptin and adiponectin were observed. Expression levels of miR-27a and miR-193b were higher in PCOS patients, while miR-181a and miR-320 were higher in the control group (all $P<0.05$). In the PCOS group, significant correlations were observed between adiponectin concentration and the levels of miR-181a ($R=0.30$; $P=0.008$) and miR-320 ($R=0.24$, $P=0.031$), as well as between miR-106b and leptin concentration ($r=-0.25$; $P=0.045$). Additionally, the levels of miR-27a and miR-320 correlated with visceral adipose tissue (VAT) mass ($R=0.23$, $P=0.021$; $r=-0.25$, $P=0.013$, respectively) and android/gynoid (A/G) ratio ($R=0.25$, $P=0.011$; $r=-0.21$, $P=0.040$, respectively). The levels of miR-193b were associated with A/G ratio ($R=0.29$, $P=0.003$), fat mass index ($R=0.22$, $P=0.024$), and lean mass index ($R=0.32$, $P<0.001$). No such correlations were observed in healthy women, although in this group, miR-27a correlated with adiponectin concentration ($r=-0.37$, $P=0.010$), while miR-106b with leptin concentration ($R=0.34$, $P=0.046$) and fat free mass ($R=0.37$, $P=0.002$). In linear regression analysis, both miR-181a and miR-320 were associated with VAT mass independent of age, BMI, and waist circumference only in PCOS patients.
Conclusions
The expression levels of circulating miRNAs are altered in PCOS. Body composition, especially visceral adiposity, and adipokine secretion, seem to be associated with the expression of miR-27a, miR-181a, miR-193b, and miR-320 in this group, although functional studies are necessary to verify this hypothesis.

A complex crosstalk between estrogen receptor β isoform signaling regulates human granulosa cell growth

Clémentine Marie[1], Raphaël Corre[1], Alice Pierre[1], Celine Guigon[1], Joëlle Cohen-Tannoudji[1] & Stéphanie Chauvin[1]
[1]Unité BFA UMR 8251, CNRS-Université Paris Cité, ERL Inserm U1133, Physiologie de l'Axe Gonadotrope, Paris, France

Estradiol (E2), produced by granulosa cells (GCs) of ovarian follicles, plays an essential role in folliculogenesis by controlling follicular development and selection. E2 actions are principally mediated by the two nuclear receptors, ERα and ERβ. These two receptors are differently expressed in GCs, with ERβ being predominant. After ligand binding and receptor dimerization, ERα and ERβ mainly regulate gene transcription through direct interaction with specific DNA motifs (estrogen-response elements, ERE), or by tethering onto other transcription factors such as c-Fos/c-Jun (activator protein-1, AP-1). In Human, four alternative splicing isoforms of ERβ (ERβ1, ERβ2, ERβ4 and ERβ5) are described and highly expressed in GCs. Little is known about their biological activities, except that only the longest form ERβ1 can bind E2. Therefore, the aim of our study was to identify the role of each ERβ isoform on GCs growth, as well as deciphering the nature of their respective transcriptional activities. For this purpose, we overexpressed each ERβ isoform in a human

immortalized GC line (HGrC1) to assess their respective role on cell proliferation and apoptosis. By scoring BrdU incorporation and measuring Annexin-V binding to membrane apoptotic proteins, we showed that ERβ2 and ERβ5 induced cell proliferation whereas ERβ1 and ERβ4 increased GCs apoptosis. Interestingly, transfection of ERβ isoforms in HGrC1 cells exhibited various effects on GCs fate, whether they were expressed alone or together. For example, pro-apoptotic activities of ERβ1 and ERβ4 were lost when both isoforms were co-expressed. To understand the underlying mechanisms of these effects, we examined ERβ transcriptional activities, with or without ligand, on luciferase reporter constructs driven by ERE or AP-1 dependent promoters. We found that only ERβ1 elicited ligand-dependent and ligand-independent transactivation at ERE sites. ERβ2, ERβ4 and ERβ5 (alone or together) did not influence ERβ1 transactivity. In addition, ERβ2, ERβ4 or ERβ5 showed a ligand-independent transactivation at AP-1 sites that impaired ERβ1 transactivity but led to gene transcription activation when all isoforms were co-transfected. In conclusion, our study demonstrates an important role of each ERβ isoform on GCs proliferation and apoptosis. Importantly, it reveals that although being E2-insensitive and unable to transactivate gene expression through ERE sites, ERβ2, ERβ4 and ERβ5 display biological effects. Their direct activities on AP1 sites as well as their potential non-genomic signaling are under current investigation. Hence, changes in the complex crosstalk between ERβ isoform signaling could contribute to uncontrolled cell growth such as that encountered in tumor cells.

In the ovary, the G protein-coupled estrogen receptor (GPER) forms heteromeric complexes with the follicle-stimulating hormone receptor (FSHR), reprogramming FSH-induced signals and determining the follicular fate. Based on the structural similarity, we evaluated whether GPER interacts with the luteinizing hormone (LH)/choriogonadotropin (hCG) receptor (LHCGR) modulating gonadotropin-dependent signals. LHCGR-GPER heteromers were evaluated in transiently transfected HEK293 cells co-expressing specifically tagged receptors and biosensors, and signals were collected by bioluminescence resonance energy transfer (BRET) and photo-activated localization microscopy using photoactivatable dyes (PD-PALM). Cells were treated by LH/hCG and signalling analyses were performed by evaluating G proteins coupling and displacement, intracellular Ca2+, cAMP and inositol monophosphate (IP1) increase by BRET and homogeneous time-resolved fluorescence (HTRF). Activation of gene transcription regulated by nuclear factor of activated T-cells (*NFAT*) and cAMP response element (*CRE*) promoters was performed using a reporter system. Data were analysed by non-linear regression or Kruskal-Wallis test and Dunn's post-hoc test ($P<0.05$; $n=4$ to 6), as appropriate. Super-resolution microscopy revealed that about 20% of FLAG-GPER and HA-LHCGR form heteromers on the cell surface, and results were confirmed by BRET detecting yFP-GPER and rluc-LHCGR interaction ($r^2=0.91$; $n=6$). The presence of GPER induces concentration-dependent displacement of Gαq to LHCGR, resulting in depletion of hCG-induced Ca^{2+} response under GPER/lHCGR co-expression (AUC LHCGR= 5169±506 vs AUC LHCGR+GPER= 3621±277; $P<0.05$; $n=6$). Consistently, all other Gαq-dependent events, i.e. IP1 production (LH= 2.72±0.49 nM; hCG= 10.89±2.55 nM; $p\geq0.05$; $n=4$) and *NFAT* promoter activation (LHCGR LH= 2.4±0.3 vs LHCGR+GPER LH= 0.6±0.1; LHCGR hCG= 2.5±0.3 vs LHCGR+GPER hCG= 0.7±0.1; $n=5$; $P<0.05$), were inhibited in GPER/lHCGR co-expressing cells treated with LH/hCG. This is not in cells expressing LHCGR alone, where gonadotropins induced Gαq-dependent signalling ($P<0.05$; $n=6$). Interestingly, GPER-LHCGR complexes have no impact on LH/hCG-induced cAMP/protein kinase A (PKA) pathway activation ($p>0.05$; $n=6$), suggesting that GPER specifically inhibits Gαq-, but not Gαs-mediated signals. Control experiments were performed using a biosensor-tagged mutant GPER (GPERmut) unable to form heteromers with LHCGR. PD-PALM and BRET methods revealed the absence of GPERmut/lHCGR complexes and the lack of receptor-receptor interaction ($r^2=0.05$; $n=6$). Under these conditions, cell treatment with LH/hCG induced IP1 accumulation and gene transcription (LHCGR vs LHCGR+GPER; $P>0.05$; $n=5$). In conclusion, GPER interacts with LHCGR in the cell surface, biasing LH/hCG-induced signals via specific inhibition of Gαq-dependent cascades. These data suggest that reproductive functions may be modulated by GPER/lHCGR heteromers in the ovary.

The severity of hot flashes is associated with the risk for incident metabolic syndrome and new-onset hypertension after the menopause

Elena Armeni[1,2], Areti Augoulea[1], Andreas Efstathiou[1], Panagiota Chatzivasileiou[1], George Kaparos[3], Nikolaos Vlahos[1], Makarios Eleftheriades[1] & Irene Lambrinoudaki[1]

[1]National and Kapodistrian University of Athens, 2nd Department of Obstetrics and Gynecology, Aretaieio Hospital, Athens, Greece; [2]Royal Free Hospital, NHS Foundation Trust, Department of Diabetes and Endocrinology, London, United Kingdom; [3]National and Kapodistrian University of Athens, Biochemical Laboratory, Athens, Greece

Introduction

A growing body of evidence supports the possible association between the severity of climacteric symptoms and long-term cardiometabolic risk. We aimed to assess the possible link between the severity of hot flashes and the risk for cardiometabolic manifestations after the menopausal transition.

Methods

This cohort study was conducted in the Menopause Clinic, National and Kapodistrian University of Athens, Aretaieio Hospital, Athens, Greece. We reviewed outpatient records corresponding to 6,250 women, with no evidence of metabolic syndrome (MetSyn) at baseline and who were not on treatment with menopause hormone therapy (MHT) or selective estrogen modulators. Women should have had at least two full consultations 12 months apart. The eligible cases were matched one-two-one for age and the severity of hot flashes at baseline. We selected 825 women, stratified into three groups (no hot flashes vs mild vs moderate-to-severe). All participants were monitored for 15 years after their first visit (FU) for the development of MetSyn, new onset hypertension, and dyslipidemia.

Results

At the time of the first assessment, there was no association between the severity of hot flashes and the prevalence of hypertension and dyslipidemia (no vs mild vs moderate/severe: hypertension, 14.9% vs 20.9% vs 20.7%; dyslipidemia 8.4% vs 10.5% vs 6.9%). Women who experience severe symptoms at baseline had a higher prevalence of MetSyn and hypertension at 15-year follow-up (no vs mild vs moderate/severe, MetSyn 22.6% vs 17.1% vs 28.2%, $P=0.049$; hypertension, 26.9% vs 32.9% vs 38.9%, $P=0.025$). The time-to-diagnosis of MetSyn or hypertension was lower in women with more severe symptoms at baseline (KM curve, moderate/severe vs mild vs no, MetSyn 11.4±0.4 yrs vs 12.9±0.3 yrs vs 13.1±0.2 yrs; hypertension, 10.5±0.4 yrs vs 11.5±0.3 yrs vs 12.7±0.2 yrs; log-rank $P<0.001$ both cases). Cox-regression analysis showed that diagnosis of MetSyn was associated with moderate/severe hot flashes (HR=1.797, $P=0.021$), moderate alcohol consumption (HR=0.5, $P=0.003$), LDL-cholesterol (HR=1.007, $P=0.016$), intense exercise (HR=2.105, $P=0.048$), BMI (HR=1.095, $P=0.025$), age (HR=0.889, $P<0.001$). The diagnosis of hypertension was associated with moderate/severe hot flashes (HR=1.902, $P=0.004$), intense exercise (HR=2.276, $P=0.008$), current smoking (HR=1.664, $P=0.008$), moderate alcohol intake (HR=0.439, $P<0.001$), SBP (HR=1.029, $P<0.001$), BMI (HR=1.1, $P=0.007$), age (HR=0.888, $P<0.001$). The models were also adjusted for waist circumference, HOMA-IR, lipids, DBP.

Conclusions

Moderate-to-severe hot flashes were associated with incident risk for MetSyn and new-onset hypertension in young postmenopausal women. These observations bear implications for the use of MHT in women shortly after the menopausal transition.

Congenital Adrenal hyperplasia (CAH) refers to a group of autosomal-recessive inherited disorders of impaired adrenal steroidogenesis. The most common form is 21-hydroxylase deficiency (21-OHD) caused by mutations in the *CYP21A2* gene. Patients lack glucocorticoids and in some cases mineralocorticoids, and present with androgen excess causing hypoglycemia, live-threatening salt wasting, virilisation, and precocious puberty. Treatment includes the replacement of deficient steroid hormones and restoring negative feedback towards CRH and pituitary ACTH secretion to suppress hyperandrogenemia. This often requires the administration of supra-physiological doses of glucocorticoids which may cause significant treatment-related side effects. As recent advances have shed light on the steroidogenic mechanisms and the genetics of CAH, multiple novel treatment approaches are being developed to holistically manage CAH patients, to minimize glucocorticoid exposure and to achieve better patient outcomes. However, novel drugs lack effective *in-vivo* models for pre-clinical testing. In this work, we present the first viable and humanized mouse model in which the mouse gene *Cyp21a1* is replaced by the human orthologue *CYP21A2* with the integrated human point mutation p.R484Q. Twenty-weeks-old homozygous mice showed hyperplastic adrenals and an expression of the human *CYP21A2* gene. Tandem mass spectrometry measurements of plasma at 20 weeks showed decreased corticosterone and 11-deoxycorticosterone levels in both male and female homozygous animals. Additionally, progesterone levels in homozygous mice were significantly higher ($P<0.01$) than in wildtype mice. We also observed increased aldosterone levels in female mutants, whereas blood pressure did not differ between wildtype and mutant mice strains. ACTH levels were elevated in both male and female homozygous animals. Tetrahydrocorticosterone (THB), a major glucocorticoid metabolite could be detected in 24-hours-urine in wildtype mice but not in homozygous mutant animals. While mutant male mice were fertile with normal appearing testes, females were infertile, remaining in the diestrus phase with a reduced number of ovarian follicles. In conclusion, we show that the humanized mutant *CYP21A2* mice may represent an excellent animal CAH model to test novel treatment strategies. It will potentially contribute to achieving overarching treatment goals to prevent comorbidities resulting from hormone – related derangements and treatment-related side effects among CAH patients. The animal model will play a pivotal role in supporting the transition from basic research to clinical application.

Background
Testicular Adrenal Rest Tumors (TART) in patients with congenital adrenal hyperplasia due to 21-hydroxylase deficiency (21OHD) or 11-hydroxylase deficiency (11OHD) are benign lesions causing testicular damage and infertility. We hypothesize that high ACTH exposure due to poor hormonal control during early life is promoting development of TART later in life.
Objective
This study aims to examine the relation between early CAH diagnosis and consequent start of adequate glucocorticoid treatment (<1 month vs>1 month but<1 year vs>1 year) ánd the development of TART as well as the relationship between biochemical disease control during infancy and early childhood and the development of TART.
Methods
In this retrospective open cohort study, data was collected from the I-CAH registry; an international database of pseudonymized information on CAH patients. The study included 189 male patients from 22 centers with 21OHD ($n=182$) or 11OHD ($n=7$) in which at least one testicular ultrasound (US) was performed.
Results
TART was detected by US in 38% of the patients. Prevalence varied enormously between centers. Salt-wasting phenotype was associated with a 3.2 (confidence interval: 1.1-9.0) times higher risk of TART diagnosis compared to simple virilizing phenotype. When adjusted for CAH phenotype, a delayed CAH diagnosis of more than 1 year, compared to a diagnosis within 1 month of life, was associated with a 2.4 (1.3-4.7) times higher risk of TART diagnosis later in life. Biochemical disease control (undertreatment versus adequate treatment or overtreatment) or bone age advancement (as a consequence of poor disease control) in the four yearly visits did not predict TART diagnosis later in life. Increased height SDS at the end of the four-year follow-up period, but not at earlier visits, was associated with a 1.3 (1.1-1.5) times higher risk of TART diagnosis later in life.
Conclusion
A delayed CAH diagnosis of more than 1 year versus CAH diagnosis within 1 month of life is associated with a higher risk of TART development, what might be attributed to high ACTH exposure of the neonatal testes. However, the relation between a delayed CAH diagnosis and TART diagnosis may be confounded by a potential link between delayed CAH diagnosis and experience in and quality of CAH care. The number of patients per center did not allow for normalization of potential center-specific effects. Nonetheless, neonatal screening may help improving CAH treatment and lower the risk of TART development later in life.

Background
Modified-release hydrocortisone (MRHC) capsules (Efmody, Diurnal Ltd, Cardiff, UK), have been developed to replicate the cortisol diurnal rhythm and shown to improve CAH disease control1. We have examined relative bioavailability of MRHC and disease control of congenital adrenal hyperplasia (CAH) patients switched from standard therapy to MRHC.
Methods
An open label, randomised, 2 period, crossover study comparing the relative bioavailability of MRHC capsules with immediate-release hydrocortisone tablets (Cortef, Pfizer) in dexamethasone-suppressed healthy volunteers was performed (NCT03343327). The Primary Endpoint was area under the cortisol concentration time curve extrapolated to infinity ($AUC_{0\text{-inf}}$), with bioequivalence considered met if the ratio $AUC_{0\text{-inf}}$ was between 80-125%. For disease control in classic CAH patients switched to MRHC, we reviewed data from the phase 3 randomised study of standard treatment versus MRHC (NCT02716818). Patients were randomised either to continue standard treatment or switched to MRHC at the same hydrocortisone dose equivalent (HDE = prednisolone dose × 5; dexamethasone × 80)[1]. Patients were assessed at baseline and after 4 weeks by 24 hr 2-hourly sampling of 17-hydroxyprogesterone (17OHP) with change from baseline in the natural log 24 hr 17OHP standard deviation score (SDS) profile calculated (17OHP SDS 24-hour profile).
Results
24 subjects completed the relative bioavailability study. 20 mg MRHC capsules showed AUC bioequivalence to 20 mg reference hydrocortisone: Mean $AUC_{0\text{-inf}}$ was 2650 vs 2450 h × nmol/l, ratio of 108% (90% confidence interval (CI) 103 – 113%). In the phase 3 study, 122 patients were recruited of which 105 were included in the 4-week analysis; standard treatment ($n = 52$) MRHC at the same dose as standard treatment ($n = 53$). The mean 9am 17OHP at baseline vs 4 weeks was: 41 vs 6 (nmol/l) for the MRHC group and 21 vs 18 (nmol/l) in the standard treatment group. At 4 weeks, a greater reduction in the 17OHP SDS 24-hour profile was observed in the MR-HC group than the standard therapy group; treatment effect (90% CI) −0.26 (-0.46 to −0.07), $P = 0.007$. There were no adrenal crises in the MRHC group and 3 in the standard treatment group for the whole phase 3 cohort over 6 months.
Conclusions
MRHC capsules are bioequivalent to immediate release hydrocortisone for AUC, however the more physiological exposure means that switching patients from standard treatment to MRHC at the same hydrocortisone dose equivalent results in improved CAH control. The incidence of adrenal crisis on MRHC is at the lower end of that reported in cohort studies.

Adrenal Insufficiency Associated with Biallelic Mutations in Porphyria Genes

Chris Smith[1], Adam Jackson[2], Ahmed Al-Salihi[1], Andreas Janecke[3], Elisabeth Steichen[3], Denise Darby[2], Liezel Griffin[4], Siddharth Banka[4], Solaf Elsayed[5], Li Chan[1] & Louise Metherell[1]
[1]WHRI, QMUL, Centre for Endocrinology, London, United Kingdom; [2]University of Manchester, Manchester, United Kingdom; [3]University Hospital of Innsbruck, Innsbruck, Austria; [4]Salford Royal Hospital, Dermatology Centre, Manchester, United Kingdom; [5]Ain Shams University, Medical Genetics Department, Cairo, Egypt

Adrenal insufficiency (AI) is life-threatening and can present alone or in combination with other co-morbidities. Here we describe families with a novel association of AI with porphyria caused by biallelic mutations in protoporphyrinogen oxidase (*PPOX*) or coproporphyrinogen oxidase (*CPOX*). The porphyrias are a group of disorders caused by defects in one of eight enzymes within the haem biosynthetic pathway, divided into acute porphyrias, resulting in mainly neurovisceral symptoms, or cutaneous porphyrias, mainly affecting the skin. Acute porphyria attacks can be life-threatening, resulting in permanent disability or death. Variegate porphyria and hereditary coproporphyria are associated with autosomal dominant mutations in *PPOX* and *CPOX* respectively, with biallelic inheritance rarely reported and knockout mice that are embryonic lethal. We performed whole exome sequencing (WES), array Comparative Genomic Hybridization (aCGH) and whole genome sequencing (WGS) in 3 families with AI and variegate or hereditary porphyria. In kindred 1, with 4 affected individuals, WES revealed a homozygous mutation, p.Glu339Lys, in *PPOX*. aCGH and WGS revealed no Copy Number Variants (CNVs) and no other variants, in genes causing AI, common to all affected individuals. In families 2 and 3, homozygous mutations in *CPOX* p.(Pro367Ala) in one patient and p.(Ser28Ter) in two siblings were identified by WGS and WES respectively, with a clinical picture of AI and hereditary coproporphyria. Unlike other acute porphyria kindreds, the heterozygous parents were asymptomatic, manifesting neither porphyria nor AI, suggesting that the level of enzyme function is key for both phenotypes. Reduced PPOX/CPOX activity could cause AI through either; (i) a dearth of haem for steroidogenic CYP450 enzyme action, (ii) toxicity of intermediate porphyrins or (iii) increased oxidative stress. To investigate the mechanism, we first created H295R, human adrenocortical cells, with differing degrees of *PPOX*-knockdown (KD) by shRNA. Proliferation, measured by MTT assay or GFP accumulation, was lower in *PPOX*-KD cells at 72 hours and mitochondrial respiration was diminished, possibly due to toxicity of porphyrin precursors. *CYP11A1* expression was unaltered whereas *STAR* and *CYP17A1* were significantly lower in *PPOX*-KD cells. Finally, and definitively, knockdown of at least 60% PPOX protein in H295R cells reduced cortisol output by 2.2-fold ($P < 0.01$) at baseline and 1.9-fold ($P < 0.0001$) in forskolin stimulated cells. Similar *CPOX* studies are underway. These studies show that cortisol is reduced in individuals with biallelic *PPOX/CPOX* mutations and, in conjunction with previous cases of AI in association with other genes in the pathway, suggests adrenal function should be monitored in individuals with porphyria.

Moving to liquid chromatography-tandem mass spectrometry to assess hypercortisolism states through dexamethasone suppression test: comparison with two routinely used immunoassays

Laura Rotolo[1,2], Lorenzo Tucci[1,2], Valentina Vicennati[1,2], Uberto Pagotto[1,2], Guido Di Dalmazi[1,2] & Flaminia Fanelli[2]
[1]S. Orsola-Malpighi Polyclinic, Endocrinology and Diabetes Care and Prevention Unit, Bologna, Italy; [2]Alma Mater Studiorum – Bologna University, Center for Applied Biomedical Research, Dept. of Medical and Surgical Sciences, Bologna, Italy

Background
The dexamethasone suppression test (DST) is among essential tests for hypercortisolism diagnosis. Due to high sensitivity and specificity, liquid chromatography-tandem mass spectrometry (LC-MS/MS) is replacing obsolete immunoassays (IA) for steroid measurement. However, exhaustive data about IA and LC-MS/MS concordance in the frame of DST are still not available.
Aim
To compare cortisol measurements by two routine IAs and LC-MS/MS in basal (F0) and post-DST (Fdst) sera. To assess between-method concordance in diagnosing hypercortisolism.
Methods
We enrolled 330 patients with hypercortisolism suspicion or adrenal mass. Of these, 287 patients had their paired F0 and Fdst measured by ElecsysE170 (Roche), and 43 by DxI800 (Beckman). All samples were also measured by a validated LC-MS/MS method. Methods were compared by Wilcoxon test and Passing and Bablok regression. We evaluated between-methods concordance in classifying patients in "non-secreting" (NS) (Fdst < 18 ng/ml), "possible autonomous cortisol secretion" (PACS) (Fdst:18-50 ng/ml) and "autonomous cortisol secretion" (ACS) (Fdst ≥ 50 ng/ml).
Results
F0 levels assayed by ElecsysE170 (median (min-max): 151.0 (47.0-380.0) ng/ml) were significantly higher than by LC-MS/MS (116.8 (38.1-249.5) ng/ml)) ($P < 0.001$), with significant proportional overestimation (slope(95CI): 1.366(1.309-1.423)) and constant underestimation (intercept(95CI): −7.9(-14.1–1.8)) of the former and $R = 0.916$. Comparing DxI800 vs LC-MS/MS resulted in higher values (134.0 (52.0-269.0) ng/ml vs 115.1 (55.3-207.8) ng/ml, respectively) ($P < 0.001$), significant slope (1.337(1.226-1.451)) and intercept (-18.6(-33,3–7.3)) and $R = 0.955$. Regarding Fdst levels, no significant differences were found between ElecsysE170 (14.0 (3.00-290.0) ng/ml) and LC-MS/MS (13.70 (2.72-168.7) ng/ml) ($P = 0.060$), with no significant proportional or

constant errors and $R=0.907$. No difference was obtained for DxI800 (14.0 (6.0-258.0) ng/ml) vs LC-MS/MS (13.3 (6.9-199.0) ng/ml) ($P=0.160$), with no proportional error, $R=0.910$, and a small significant constant underestimation (intercept: −2.8; 95CI: −4.9–0.7). According to ElecsysE170, we classified 186 patients (64.8%) as NS, 88 (30.7%) as PACS and 13 (4.5%) as ACS. When using LC-MS/MS, 13 (7%, false negatives) of NS, 19 (21.6%, false positives) of PACS and 3 (23.1%, false positives) of ACS were not confirmed, with total 35 (12.2%) misdiagnoses. When using DxI800 Fdst, 26 (60.5%) were NS, 14 (32.5%) were PACS and 3 (7.0%) were ACS. Of these, LC-MS/MS did not confirm 1 (3.8%, false negative) within NS and 1 case (33.3%, false positive) within ACS classes, with total 2 (4.7%) misdiagnoses.
Conclusions
Unexpectedly, concordance between LC-MS/MS and IAs is poorer at basal than DST-suppressed cortisol levels. Nonetheless, a non-negligible amount of patients may receive a different diagnosis when using the more specific and accurate LC-MS/MS measurement.

Background
Venous thromboembolism(VTE) is a well-known perioperative complication in patients with Cushing's syndrome(CS) and may be preventable. A recent report highlighted that thromboprophylaxis management in patients with CS still varies considerably across Endo-ERN reference centers but the actual incidence of VTE and its management in individual patients is unclear.
Aim
To collect epidemiological and clinical data of new cases of CS reported on the European Registries for Rare Endocrine Conditions(EuRRECa) electronic reporting tool(e-REC) and Endo-ERN.
Methods
A survey was conducted for new patients with CS reported by e-REC by reference centers within Endo-ERN in the last 2 years. A total of 180 patients were reported with CS and the survey was completed by 26 clinicians in 11 centres in 6 countries. Risk factors, VTE occurrence, and thromboprophylaxis regimens were analysed.
Results
One hundred and thirteen patients had Cushing disease (62.8%), 59 CS (32.3%) and 8 patients ectopic CS (4.4%). 136 (75.6%) were female with a mean age of 45 ± 16.2 years (range 3-80). Overweight (BMI 25-30 kg/m^2) and obesity (BMI ≥30 kg/m^2) were common findings with 78 (43.3%) and 61 (33.9%) patients respectively. 121 had hypertension (67.2%), 38 had diabetes mellitus (21.1%). 11 patients reported VTE(6.1%) prior to CS diagnosis. Medical treatment of CS consisted of metyrapone ($n=50$, 27.8%), ketoconazole ($n=16$, 8.9%), osilodrostat ($n=3$;1.7%), and mitotane ($n=1$, 0.56%). One hundred and twelve patients (64.4%) did not receive cortisol lowering treatment before surgery. CS was completely controlled in 35 patients (19.4%) and partially in 31 (17.2%) before surgery. Most patients were operated ($n=167$, 92.8%), first surgery in 76.6% of patients. 136 patients received thromboprophylaxis before surgery, mostly using Low-molecular weight-heparins (94.2%). In 42 cases, thromboprophylaxis was started the day of surgery (30.4%), in 51 stopped within one week after surgery (36.9%). VTE was reported in only 4 cases (2.2%), all of them in uncontrolled CS. Of these, 3 VTE's occurred months before surgery, in patients with history of VTE and high VTE risk, 2 of them developing VTE while on anticoagulant treatment for previous VTE. Only 1 VTE occurred after surgery(6 weeks) in a patient who received thromboprophylaxis the first week after surgery. No severe bleeds were observed during thromboprophylaxis.
Conclusion
The results of this survey suggest a heterogenous policy on pre-surgery cortisol lowering treatment and thromboprophylaxis. In this survey VTE's were only observed in subjects without cortisol lowering therapy and with additional VTE risks. In addition, we observed no major bleeds in patients on thromboprophylaxis. Therefore this survey paves the way for the standardization of thromboprophylaxis regimens in subjects with CS.

RNA splicing landscape of pancreatic neuroendocrine neoplasms reveal novel clinico-molecular associations

Ricardo Blázquez-Encinas[1,2,3], Sergio Pedraza-Arevalo[1,2,3], Víctor García Vioque[1,2,3], María Trinidad Moreno Montilla[1,2,3], Rita T Lawlor[4,5], Vita Rovite[6], Aldo Scarpa[4,5], Alejandro Ibañez Costa[1,2,3] & Justo P. Castaño[1,2,3]
[1]University of Cordoba, Córdoba, Spain; [2]Maimonides Biomedical Research Institute of Cordoba (IMIBIC), Córdoba, Spain; [3]Reina Sofia University Hospital (HURS), Córdoba, Spain; [4]ARC-NET: Centre for Applied Research on Cancer, Verona, Italy; [5]University of Verona, Verona, Italy; [6]Latvian Biomedical Research and Study Centre, Riga, Latvia

Neuroendocrine neoplasms (NENs) are a highly heterogeneous group of tumors that arise from the diffuse neuroendocrine system and whose incidence has increased over the last years. Among them, pancreatic NENs (PanNENs) are relatively common and one of the most studied NENs. PanNENs are characterized by a low number of mutations, with some genes frequently mutated, such as *MEN1*, *ATRX*/*DAXX*, and mTOR signaling pathway genes. Despite genomics, transcriptomics and epigenomics studies that have helped improved understanding of the molecular features of PanNENs, there is still vast unexplored ground for better comprehension of this disease. In this context, the process of RNA splicing, which is the removal of introns from pre-RNA molecules, is known to be dysregulated in many diseases and it has even been shown to contribute to every hallmark of cancer. Our group has previously demonstrated that RNA splicing is also dysregulated in PanNENs, where it opens up new therapeutic avenues. However, clinical and molecular implications of this dysregulation are still very poorly understood. In this work, we aimed to describe the spliceosomic landscape, that sums alternative splice variants, events and splicing machinery components expression, as well as their potential relationship, how it is related to the pathology of PanNENs and its contribution to their high heterogeneity, tumorigenesis and behavior. With this aim, we explored two different cohorts of 175 and 66 PanNENs samples, including RNA-seq, mutational and clinicopathological data, integrated to better understand the disease. The expression levels of splicing variants/events and splicing machinery components in each sample were quantified using SUPPA-2 and DESeq-2, respectively. We used dimensionality reduction techniques to classify samples according to their spliceosomic landscape and later explored their relationship with pathological and mutational data. Results revealed important associations between clinical data, such as hormone secretion (tumor functionality), tumor grade or metastasis, and specific splicing profiles, implying a relevant role of alternative splicing in PanNENs pathophysiology. Additionally, the most common mutations in PanNENs showed specific splicing landscapes. Further analysis and experiments will be required to ascertain whether splicing alterations are merely a subsidiary effector of hierarchically higher molecular changes or, contrarily, function as tumor drivers. In conclusion, our study represents the first spliceosomic study in PanNENs and provides original information to better understand the heterogeneity and pathophysiology of these tumors.

Aminoacyl-tRNA synthetases as diagnostic, prognostic, and therapeutic tools in MAFLD-derived hepatocellular carcinoma

Natalia Hermán-Sánchez[1,2,3,4], Juan L. López-Cánovas[1,2,3,4], Víctor Amado[1,5,6], Javier M Zamora-Olaya[1,5,6], Manuel Rodríguez-Perálvarez[1,5,6], Raul M Luque[1,2,3,4] & Manuel D. Gahete[1,2,3,4]
[1]Maimónides Institute of Biomedical Research of Córdoba (IMIBIC), Córdoba, Spain; [2]University of Córdoba, Department of Cell Biology, Physiology and Immunology, Córdoba, Spain; [3]CIBER Pathophysiology of Obesity and Nutrition (CIBERobn), Córdoba, Spain; [4]Reina Sofía University Hospital (HURS), Córdoba, Spain; [5]Reina Sofía University Hospital, Department of Hepatology and Liver Transplantation, Córdoba, Spain; [6]CIBER Hepatic and Digestive Diseases (CIBERehd), Córdoba, Spain

Metabolic dysfunction-associated fatty liver disease (MAFLD) is a growing cause of hepatocellular carcinoma (HCCs); however, the molecular characteristics of MAFLD-derived HCCs are still to be elucidated. To provide novel insights in this field, we performed the first quantitative proteomic analysis of HCC samples from different aetiologies. Particularly, cytosolic and nuclear proteome of liver tissues from HCC patients ($n=42$; HCC vs adjacent tissue) and healthy controls ($n=5$) were determined by SWATH-MS-based proteomics. This proteomic profile allowed for the discrimination of two tumoral subgroups. One of them, which included all the MAFLD-derived HCC patients, was associated to aggressive parameters and to a profound dysregulation of the aminoacyl-tRNA synthetases (ARSs), which are essential components of the tRNA aminoacylation machinery. The alteration of the 9 ARSs dysregulated in the proteomic cohort was confirmed in different *in silico* MAFLD and HCC cohorts, wherein they were associated to aggressive features (i.e., survival and recurrence), and to the metabolic status of the patients (i.e., obesity). Indeed, the general upregulation of the ARSs machinery was identified as a prognostic marker in different mRNA and protein cohorts in that HCC patients with high expression of ARSs had worse survival and a higher recurrence. The valine tRNA-aminoacyl synthetase, VARS1, was selected for studying the functional and molecular consequences of ARSs dysregulation in HCC as its expression was altered in most HCC cohorts and associated to the presence of obesity. For that, *in vitro* assays (proliferation, migration, colonies/tumorspheres) were performed in liver cancer cell lines (HepG2, Hep3B, SNU-387) after the modulation of the expression (silencing and overexpressing) of *VARS1*. VARS1 modulation had a reduced effect on proliferation/migration although it significantly altered the dedifferentiation capacity of the cells (colony establishment and spheres formation). The molecular mechanism underlying this effect was assessed through quantitative proteomics in Hep3B and SNU-387 cell lines after overexpressing *VARS1*. This analysis (and further confirmation by western blot) demonstrated a decreased expression of the scaffold protein *MAGI-1*, a known tumour suppressor in HCC, associated with the overexpression of *VARS1*. Thus, VARS1 might be exerting its role through the modulation of MAGI-1-mediated cell junctions. Our study demonstrates the dysregulation of the tRNA-aminoacylation machinery as a diagnostic and prognostic marker in MAFLD and HCC and the potential of these proteins, especially VARS1, as therapeutic targets in tumoral stages.

Tumor microenvironment of adrenocortical carcinoma dissected by single-cell RNA-sequencing

Anne Jouinot[1,2], Yoann Martin[1], Thomas Foulonneau[1], Yanis Bendjelal[1], Philip Calvet[1], Florian Violon[1,3], Mathilde Sibony[1,3], De Murat Daniel[1], Roberta Armignacco[1], Karine Perlemoine[1], Franck Letourneur[1], Brigitte Izac[1], Muriel Andrieu[1], Annabel Berthon[1], Bruno Ragazzon[1], Lionel Groussin[1,2], Rossella Libe[1,2], Jerome Bertherat[1,2] & Guillaume Assié[1,2]

[1]Institut Cochin, INSERM U1016, CNRS UMR8104, Paris Cité University, Paris, France; [2]Endocrinology, AP-HP Hôpital Cochin, Paris, France; [3]Pathology, AP-HP Hôpital Cochin, Paris, France

Background

Molecular classification is important for diagnosis and prognosis of adrenocortical tumors (ACT). Transcriptome profiles separate benign ACT ("C2" cluster) from carcinomas (ACC) and identify two groups of ACC, "C1A" ("steroid" and "proliferation" signatures) and "C1B" ("immune" signature), of poor and better prognosis respectively. However, these signatures were characterized at the tissue level ("bulk") and our knowledge of the cellular composition of ACC is limited. The aim of this study was to dissect the tumor microenvironment composition in "C1A" and "C1B" ACC.

Methods

We performed single-nuclei RNA-sequencing (10×) of ~170,000 cells from human normal adrenal ($n=4$), benign ACT ($n=14$) and ACC ($n=20$). Bioinformatic analyses were conducted using CellRanger and Seurat pipelines to construct a single-cell atlas of normal and tumoral adrenal cortex. This atlas was then used to estimate the cell proportions (Cibersortx) in "bulk" transcriptome data of 216 ACC patients: a microarray dataset (ENSAT 2014, $n=46$), a full-length RNA-sequencing dataset (TCGA, $n=78$) and a 3' RNA-sequencing dataset (ENSAT 2021, $n=92$). Finally, we tested the association of tumor microenvironment composition with hormone secretion and outcome.

Results

Microenvironment of steroid cells was composed of fibroblasts (4.6% of total cells), endothelial cells (5.1%), myeloid cells (9.9%) and lymphoid cells (1.3%). Comparing "C1A" and "C1B", only minor differences were observed for proportions of fibroblasts (2.4% and 2.8% respectively, $P<0.001$), endothelial cells (4.0% and 3.3%, $P<0.001$) and myeloid cells (10.4% and 13.3%, $P<0.001$). In ACC microenvironment, fibroblasts, endothelial cells and myeloid cells corresponded mainly to cancer-associated fibroblasts (expressing *PDGFRB* and *FN1*), tumor-associated endothelial cells (expressing *ANGPT2* and *VWF*) and tumor-associated macrophages (expressing *CD163* and *F13A1*) respectively. Comparing "C1A" and "C1B", a subpopulation of immune cells was enriched in "C1B" ACC. Deconvolution in bulk transcriptomes showed that this population is associated with non-cortisol secreting tumors (t-test $P=0.002$, $P<0.001$ and $P=0.03$), longer disease-free survival (Logrank $P=0.006$, $P<0.001$ and $P<0.001$) and longer overall survival (Logrank $P=0.004$, $P=0.006$ and $P<0.001$ in ENSAT 2014, TCGA and ENSAT 2021 datasets respectively).

Conclusion

A specific population of immune cells may be repressed by glucocorticoid secretion, leading to immune system escape in poor prognosis "C1A" ACC. This may impact immunotherapy strategies in this cancer.

CAR-T cell therapy exerts effective antitumor efficacy under immunosuppressive conditions in adrenocortical carcinoma

Marc Philipp Schauer[1,2], Laura-Sophie Landwehr[1], Weber Justus[2], Barbara Altieri[1], Redundo-Frutos Rodrigo[2], Maier Tanja[3], Oppelt Daniel[1], Matthias Kroiss[1,3,4], Silviu Sbiera[1], Hudecek Michael[2] & Martin Fassnacht[1,4]

[1]University Hospital Würzburg, Department of Internal Medicine I, Division of Endocrinology & Diabetes, Würzburg, Germany; [2]University Hospital Würzburg, Center for Cellular Immunotherapy, Würzburg, Germany; [3]LMU Hospital Munich, Department of Internal Medicine IV, Munich, Germany; [4]Comprehensive Cancer Center Mainfranken, Würzburg, Germany

Background

Adrenocortical carcinoma (ACC) is a very rare and aggressive, endocrine malignancy with still limited treatment options. Approximately 60% of patients with ACC show endogenous glucocorticoid excess which could be one potential cause, why first clinical trials with immunotherapies, like immune checkpoint inhibitors, showed only modest results. Due to the lack of an ACC-specific antigen structure, other immunotherapeutic approaches, like specialized cancer treatments using chimeric antigen receptor (CAR) therapy in ACC, have not been tested so far. In this study, we evaluated the expression of a new enticing tumor antigen (TA*) structure and investigated the effect of TA-specific CAR-T cells *in vitro*.

Methods

TA expression has been initially evaluated at mRNA level by qRT-PCR and at the protein level by qFACS analysis in five human ACC cell lines. TA mRNA expression has been investigated in 54 adrenocortical tissues (13 normal adrenal glands (nAG) and 41 ACC samples). Chromogenic immunohistochemistry (IHC) was assessed in 135 paraffin-embedded ACC tissues. In addition, RNAscope single cell analyses in an IHC subcohort of 30 ACC tumor samples was performed. At last, functional testing was conducted for four different TA-specific CAR-T cell modifications, including proliferation, tumor killing and cytokine release.

Results

All five ACC cell lines express the investigated TA. TA expression at mRNA level was present in 60.92% and at protein level at 75.56% of all ACC samples. TA expression was significantly higher in ACC compared to nAG (0.00 vs 0.0015, $P=0.0146$) and in metastasis more than primary tumors (0,0021 vs 0,0060, $P=0.0020$). High TA mRNA levels were also strongly associated with glucocorticoid excess, (0.0066 vs 0.0010, $P=0.0341$) ENSAT tumor stage (0.0032 vs 0.0005, $P=0.0091$) and sex (0.0012 vs 0.0039, $P=0.0237$). Furthermore, RNAscope single cell analysis revealed fairly homogenous TA expression in ACC. *In vitro* treatment showed effective cytotoxic effects of TA-specific CAR-T cells in cell lines (74.9% specific lysis of NCI-H295R cells, E-T 1:1) and primary tumor cells as well as CAR-T cell proliferation upon antigen contact and cytokine release in all five TA positive cell lines.

Conclusions

Our preliminary results showed that the investigated TA is sufficiently and fairly homogenous expressed in human ACC specimens and that TA-specific CAR-T cells exert effective antitumor efficacy under immunosuppressive conditions on ACC cells *in vitro*.

Key words: CAR-T cell therapy, adrenocortical carcinoma, glucocorticoids, immunotherapy

*The evaluated ACC-specific tumor antigen is kept confidential for the time being for patent law reasons

WEE1 kinase inhibitor, adavosertib (AZD1775), as a novel potential therapeutic strategy in advanced adrenocortical carcinoma

Mariangela Tamburello[1], Silviu Sbiera[1], Weber Justus[2], Juliane Lippert[1], Mario Detomas[1], Marc Philipp Schauer[1,2], Hanna Urlaub[1], Sonja Steinhauer[1], Otilia Kimpel[1], Laura-Sophie Landwehr[1], Hantel Constanze[3,4], Sandra Sigala[5], Cristina Ronchi[1,6], Michael Hudecek[2], Kiseljak-Vassiliades Katja[7], Martin Fassnacht[1] & Barbara Altieri[1]
[1]University Hospital Würzburg, Division of Endocrinology and Diabetes, Department of Internal Medicine I, Würzburg, Germany; [2]Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II,, Würzburg, Germany; [3]University Hospital of Zürich; [3]Department of Endocrinology, Diabetology and Clinical Nutrition, Zürich, Switzerland; [4]University Hospital Carl Gustav Carus Dresden, Medizinische Klinik und Poliklinik III, Dresden, Germany; [5]University of Brescia, Department of Molecular and Translational Medicine, Brescia, Italy; [6]University of Birmingham, Institute of Metabolism and System Research, United Kingdom; [7]University of Colorado Anschutz Medical Campus, Aurora, United States

Background
Adrenocortical cancer (ACC) is a rare malignant neoplasm with a dismal prognosis, particularly in advanced disease. For these patients only limited therapeutic options are available. Adavosertib (AZD1775) is a potent inhibitor of tyrosine kinase WEE1 that regulates cell cycle checkpoints, slowing cell cycle progression and leading to mitotic entry in the presence of DNA damage. Therefore, its use could potentiate existing DNA damage-based therapies. Here, we evaluate the expression of WEE1 in ACC tissues and ACC cell lines and investigate the effect of adavosertib alone or in combination with cisplatin or gemcitabine *in vitro*.
Methods
WEE1 mRNA expression has been evaluated in 91 adrenocortical tissues (19 normal adrenal glands/NAG; 20 adenomas/ACA; 52 ACC) and 5 available ACC cell lines. Immunohistochemistry was assessed in 114 paraffin-embedded ACC tissues (with known *TP53* mutation status) and evaluated by automated image analysis. WEE1 expression was correlated with clinical outcome. In vitro cell viability was evaluated by CellTiter-Glo assay following exposure of cells for 96h to increasing concentrations of adavosertib alone or in combination with cisplatin or gemcitabine according to the Chou and Talalay method. Cell apoptosis and cell cycle were analyzed by flow cytometry.
Results
WEE1 levels were significantly higher in ACC compared to NAG (0.032 vs 0.012, respectively, $P=0.04$) but not to ACA. Low WEE1 mRNA levels were associated with better overall survival (HR 0.32, 95% CI 0.12-0.86, $P=0.02$), independently of established prognostic factors, whereas only a trend was observed at protein level (HR 0.31, 95% CI 0.07-1.26, $P=0.10$). WEE1 staining was significantly higher in *TP53* mutated ACC ($n=34$) compared to wild type ($n=80$; median score 97 vs 72, $P<0.001$). Exposure of NCI-H295R, JIL-2266 and CU-ACC2 cells to adavosertib induced cytotoxicity with IC50 of 1.17, 1.35 and 0.4 μM, respectively. CU-ACC1 and MUC-1 showed less sensitivity to adavosertib alone, but its effect was enhanced by cisplatin and gemcitabine and this additive-synergic effect was observed in all cell lines. Upon 48h of treatment with adavosertib alone (1.25 μM), all cell lines showed an increased frequency of dead cells and apoptotic cells with enrichment of cells in the S phase, compared to the DMSO control.
Conclusion
Our results showed high WEE1 expression in ACC tissue and cell lines. WEE1-inhibitor adavosertib exerts a cytotoxic effect on ACC cells inducing apoptosis and cell cycle perturbation. Cisplatin and gemcitabine, commonly used in ACC treatment, enhanced the adavosertib effect, giving a new pharmacological option in ACC over standard therapies.

OC6.6

Cellular landscape of adrenocortical carcinomas determined by molecular profiling of primary, recurrent and metastatic tumour samples at single-nuclei resolution.

Barbara Altieri[1], David S. Tourigny[2,3], Ali Kerim Secener[4], Silviu Sbiera[1], Panagiota Arampatzi[5], Sascha Sauer[4], Martin Fassnacht[1] & Cristina Ronchi[1,6,7]
[1]Division of Endocrinology and Diabetes, University Hospital of Würzburg, Würzburg, Germany; [2]School of Mathematics, University of Birmingham, Birmingham, United Kingdom; [3]Irving Institute for Cancer Dynamics, Columbia University, New York, United States; [4]Max Delbrück Center for Molecular Medicine, Berlin, Germany; [5]Core Unit SysMed, University of Würzburg, Würzburg, Germany; [6]Institute of Metabolism and System Research, University of Birmingham, Birmingham, United Kingdom; [7]Centre for Endocrinology, Diabetes and Metabolism (CEDAM), Birmingham Health Partners, Birmingham, United Kingdom

Background
Molecular mechanisms of malignant adrenocortical tumorigenesis remain elusive despite previous comprehensive genomic studies. Nonetheless, cellular heterogeneity of primary, recurrent and metastatic adrenocortical carcinoma (ACC) haven't been fully investigated.
Aim
To characterize the molecular profile of different cell subtypes in primary, recurrent and metastatic ACC by single-nuclei RNA sequencing (snRNA-Seq), using adult human normal adrenal glands (NAG, $n=6$) and adrenocortical adenomas (ACA, $n=12$) as reference.
Methods
Single nuclei were isolated from 14 ACC samples, including 6 primary tumours, 3 local recurrence and 5 ACC metastasis from 9 different patients. Genomic alterations were evaluated by targeted next-generation sequencing in 6 cases, whereas *CTNNB1* mutation were excluded by Sanger sequencing in the remaining 3 cases. snRNA-Seq was performed using 1CellBio. Seurat R package was used for data analysis, integration and exploration. Integration of datasets was performed by anchor pairs between ACC and NAG. Identification of cell subpopulations was performed using unsupervised clustering followed by differential gene expression analysis, with cluster annotation based on marker genes and scores for hallmark gene sets or the gene signatures of previously identified ACA cell populations.
Results
The ACC tumour microenvironment was relatively devoid of immune cells compared to NAG, emphasising that ACC is an immunological cold tumour. The integrated analysis revealed the presence of 7 subpopulations of cortical-derived cells in ACC. Among these, ACC recurrence and metastasis were highly represented by a cell population overexpressing *IGF2*, *DLK1*, and the translationally controlled tumour protein *TPT1*, and significant enrichment of ribosomal biogenesis and proliferation-associated signalling pathways. A second major subpopulation, enriched within primary ACC samples, displayed a transcriptional signature of increased cholesterol homeostasis and steroid synthesis similar to that observed in our cortisol-producing ACA. The intra-tumour differential gene expression analysis revealed that a decrease in expression of steroid hormone production genes, an upregulated cellular proliferation, an increased expression of *IGF2, DLK1, TPT1* as well as the silencing of *MEG3* and *MEG8* are distinguishing ACC from NAG/ACA cells. Cortical cells statistically indistinguishable from NAG made up the remaining bulk of the ACC cell population, while smaller subpopulations were highly enriched with cell cycle genes or characterized by *ACSM3*, *KRTCAP2* or *ZNF331*.
Conclusion
Our analyses represent the first molecular characterization of ACC at single-nuclei level, allowing the investigation of the molecular heterogeneity of ACC. The transcriptomic signatures showed the presence of 7 different subpopulations, including a specific cell population overexpressing *IGF2, DLK1* and *TPT1* associated to recurrent and metastatic ACC.

Investigating intranasal kisspeptin as a novel, effective and preferable route of delivery using human, rodent and pharmaceutical models

Edouard G Mills[1], Magda Swedrowska[2], Virginia Delli[3], Konstantina Chachlaki[3], Mauro Sérgio[3], Laurine Decoster[3], Gaetan Ternier[3], Layla Thurston[1], Maria Phylactou[1], Bijal Patel[1], Lisa Yang[1], Sophie Clarke[1], Beatrice Muzi[1], Emma Alexander[1], Muhammad Choudhury[1], Paul Bech[1], Ali Abbara[1], Ben Forbes[2], Paolo Giacobini[3], Vincent Prevot[3], Alexander Comninos[1] & Waljit Dhillo[1]
[1]Imperial College London, Section of Endocrinology and Investigative Medicine, London, United Kingdom; [2]King's College London, Institute of Pharmaceutical Science, London, United Kingdom; [3]Inserm, Laboratory of Development and Plasticity of the Neuroendocrine Brain, Lille Neuroscience and Cognition, Lille, France

Background
Kisspeptin is a critical activator of hypothalamic GnRH neurons and is essential for reproductive health. Emerging data reveals that kisspeptin-based therapeutics have substantial potential to treat reproductive, psychosexual and bone disorders. However, current delivery is limited to the subcutaneous or intravenous routes, presenting barriers to development. Alternative routes of administration would

overcome this and capitalise on the benefits of kisspeptin-based therapies. To address this, we comprehensively investigated the therapeutic potential of intranasal kisspeptin administration for the first time using a series of human, rodent and pharmaceutical studies.

Methods

Human studies: Healthy men ($n=12$) and a patient group of women with hypogonadism (due to Hypothalamic Amenorrhoea [HA], $n=5$) completed a randomised, double-blind, crossover, placebo-controlled study investigating the acute effects of intranasal kisspeptin-54 administration vs 0.9% saline placebo. After monitored self-administration of intranasal kisspeptin (doses: 3.2-25.6 nmol/kg [healthy men] and 12.8 nmol/kg [women with HA]) or placebo, plasma kisspeptin and serum reproductive hormones were measured every 15mins for 4hrs. Next, we undertook *rodent studies* in adult C57BL/6J male mice to elucidate the putative mechanism by which intranasally administered kisspeptin can stimulate reproductive hormone release, using intranasal delivery of fluorescently-tagged kisspeptin-54 and a series of c-Fos experiments. Thereafter, we conducted *pharmaceutical studies* to characterise the chemical stability of kisspeptin-54 in solution for nasal delivery in real-time.

Results

Human studies: in healthy men, intranasal kisspeptin rapidly and dose-dependently increased plasma kisspeptin at doses 6.4-25.6 nmol/kg ($P<0.01$ for all doses vs placebo), with peak rises within 15-30 minutes. In parallel, intranasal kisspeptin acutely and robustly increased serum LH at doses 6.4-25.6 nmol/kg ($P<0.01$ for all doses vs placebo) with peak rises at 30 minutes. Similarly, in patients with HA, intranasal kisspeptin acutely increased plasma kisspeptin ($P=0.004$ vs placebo) and serum LH ($P=0.004$ vs placebo). *Animal studies*: To provide mechanistic insight, we demonstrate in male mice that GnRH neurons located in the olfactory bulb express kisspeptin receptors and that intranasal delivery of fluorescently-tagged kisspeptin-54 binds to the olfactory epithelium. *Pharmaceutical studies*: Kisspeptin-54 in 0.9% saline remained within pharmaceutically accepted limits for stability for up to 60 days at 4°C revealing realistic pharmaceutical potential.

Conclusion

We demonstrate robust clinical effects in both healthy volunteers and patients with hypogonadism and provide mechanistic and pharmaceutical evidence for intranasal delivery as a novel, non-invasive and effective kisspeptin administration route for the management of reproductive disorders that would be preferable to patients and clinicians alike and so transform the ongoing development of kisspeptin-based therapeutics.

BRF1-Mediated Paracrine Signalling by a Subset of SOX2-Expressing Stem Cells is required for Normal Development of the Stem Cell Compartment and Terminal Differentiation of Pituitary Committed Progenitors

Juan Pedro Martínez-Barbera[1], Saba Manshaei[2], Thea Willis[3], Virinder Reen[4], Hussayn Pallikonda[4], Dominic Withers[4], Jesus Gil[4] & Cynthia Andoniadou[3]

[1]UCL Great Ormond Street Institute of Child Health, Developmental Biology and Cancer, London, United Kingdom; [2]UCL Great Ormond Street Institute of Child Health, United Kingdom; [3]King's College London, Centre for Craniofacial and Regenerative Biology, United Kingdom; [4]MRC London Institute of Medical Sciences, United Kingdom

Introduction

Hormone-producing pituitary cell lineages derive from SOX2+ embryonic precursors. These cells maintain multipotency into early postnatal life, acting as the resident population of pituitary stem cells (PSCs) and contributing extensively to all the endocrine cell lineages. Additionally, paracrine signalling from PSCs is important for cell proliferation of neighbouring progenitors (PMC7803373). It is not known if SOX2+ PSCs are involved in the regulation of additional cell attributes during normal physiology, and if there is functional heterogeneity among the SOX2+ PSC population.

Experimental Methods

We have carried out single cell RNA-Sequencing of SOX2+ PSCs from $Sox2^{Egfp/+}$ mouse pituitaries at three postnatal stages from P3 to P56 and used computational approaches to analyse their molecular signatures. A novel conditional mouse model expressing a constitutively active mutant form of the RNA binding factor BRF1 ($R26^{stop\text{-}mBRF1}$) has been used to attenuate the expression of several cytokines and chemokines in SOX2+ cells (PMC4589897).

Results

We show that the SOX2+ PSC population consists of three subgroups (SC1, SC2 and SC3). While SC1-SC2 express abundant cytokines and secreted factors, suggesting paracrine function, SC3 expressing *Lef1*, is identified as a committing PSC cluster. Key markers of PSC clusters SC1-SC2 include the RNA binding factor BRF1. We show that BRF1 is highly expressed in PSCs in both mouse and human pituitaries by IHC. Secondly, we show that the dysregulation of BRF1 in embryonic SOX2+ cells using the *Hesx1-Cre* driver (PMC3461924) results in pituitary hypoplasia and severe hypopituitarism due to a failure of the PIT1 and SF1 cell-lineage committed progenitors to terminally differentiate into hormone-producing cells. Additionally, there is a significant reduction of the stem cell compartment, manifested by lower numbers of SOX2/SOX9+ stem cells. This phenotype is recapitulated when using a *Sox2-CreERT2* driver (PMID24094324). The differentiation failure can be rescued *in vitro* through co-culture of mutant cells with wild-type stem cells, as well as in vivo, in mutant pituitaries where activation of constitutively active BRF1 is restricted to few SOX2+ PSCs in a mosaic manner. Finally, we identify key ligands underlying this differentiation phenotype, and demonstrate a partial restoration of terminal differentiation in the mutant, when cultured in the presence of these ligands.

Conclusion

We provide evidence indicating the presence of functionally distinct groups of SOX2+ pituitary stem cells and reveal a critical role for a PSC subset in the development of the stem cell compartment and in driving terminal differentiation of committed progenitors.

The mesenchymal stem cells induce immunosuppressive microenvironment in pituitary tumors

Daniel Marrero-Rodríguez[1], Keiko Taniguchi[2], Victor A Cortes-Morales[3], Alejandra Valenzuela-Perez[2], Sandra Vela-Patiño[2], Amayrani Cano-Zaragoza[2], Florencia Martinez[2], Jacobo Kerbel[2], Sergio Andonegui-Elguera[2], Erick Gomez-Apo[4], Laura Chavez-Macias[4], Juan Jose Montesinos[3] & Moises Mercado[2]

The tumor microenvironment (TME) includes diverse cellular components such as mesenchymal stem cells (MSC) and immune cells. MSC are a subset of heterogeneous cell populations characterized by the expression of CD105, CD73, and CD90 that can differentiate into chondrocytes, osteoblasts, and adipocytes *in vitro*. They are known to have immunomodulatory capabilities. Our aim was to isolate and characterize the immunomodulatory capabilities of MSC from pituitary tumors (PT) and non-tumoral gland as well as to describe the immune TME. We isolated and cultivated MSC from LH/FSH-PT and ACTH-PT, as well as non-tumoral pituitary glands. The MSC obtained from PT and non-tumoral gland were co-cultured in the presence of monocytes from healthy donors and their ability to transform into M0, M1 or M2 macrophages was assessed by flow cytometry. The results showed that pituitary tumors derived MSC induce an immunosuppressive M2 macrophage state, by increasing the expression of CD14 and CD206 markers, and decreasing HLA-DR. Upon co-culturing them with naïve T cells, PT MSC were capable inducing a Treg phenotype. To identify PT TME, we performed tumor whole transcriptome characterization and cellular deconvolution using CIBERSORT. Our analysis was indicative of a strong presence of M2 macrophages, TCD4+ and TCD8+ cells, which was confirmed by immunofluorescence, suggesting an immunosuppressive TME. Thus, the MSC immunosuppressive induction correlates directly with immune TME. ACTH-PT derived MSC showed a stronger anti-inflammatory activity than LH/FSH-PT. We also characterized the transcriptomic differences between non-tumoral and PT derived MSC by means of RNAseq. We found differences between the non-tumoral MSC and pituitary tumor derived MSC, but mainly between ACTH- and LH/FSH-PT derived MSC. In conclusion our data suggest that the presence of MSC influence an immunosuppressive tumor microenvironment alongside with tumor cells.

Introduction

Paradoxical increase of GH following oral glucose load has been described in ~30% of patients with acromegaly and has been related to the ectopic expression of the glucose-dependent insulinotropic polypeptide (GIP) receptor (GIPR) in somatotropinomas. Recently, we identified germline pathogenic variants of lysine demethylase 1A (*KDM1A*) in patients with GIP-dependent primary bilateral macronodular adrenal hyperplasia with Cushing's syndrome. Patients also displayed a deletion of chromosome 1p, including the *KDM1A* locus in their adrenal tissues, resulting in complete loss of KDM1A expression. The ectopic expression of GIPR in both adrenal and pituitary lesions suggests a common molecular mechanism. The aim of our study was to search for genetic abnormalities of *KDM1A* in somatotroph pituitary adenomas.

Methods

We collected somatotropinoma specimens from acromegalic patients followed in two tertiary endocrine centers in France and one in Italy. Somatic DNA was studied by targeted exome NGS and array-CGH. *GIPR* and *KDM1A* expression was quantified in the tumors using digital droplet PCR.

Results

We included 186 patients: 108 patients (70.6 %) had a classic pathological GH response after oral glucose load, whereas 45 patients (29.4%) displayed a paradoxical rise of GH concentrations. Patients with a paradoxical response displayed higher IGF-1 levels (360 $\pm$ 111.8% above ULN vs 309.8 $\pm$ 107.3 %, $P=0.0130$) and less invasive and smaller tumors (14.5 $\pm$ 5.58 mm vs 18.5 $\pm$ 8.73 m, $P=0.0066$). We did not identify any *KDM1A* pathogenic variants amongst the 146 somatotropinomas analyzed by targeted-NGS. However, we identified a recurrent 1p deletion encompassing the *KDM1A* locus in 26 tumors. This 1p deletion was more frequently, but not exclusively, found in patients with paradoxical GH response compared to those with classic GH response. This somatic deletion of one *KMD1A* allele was associated with a lower KDM1A expression ($P=4.5e-5$) and a higher GIPR expression ($P=0.0005$).

Discussion

Unlike in GIP-dependent PBMAH, we did not identify *KDM1A* genetic variants in a large cohort of acromegalic patients, independently of their GH response pattern to oral glucose loading. We identified recurrent 1p deletion in some tumors and pituitary adenomas with a loss of one *KDM1A* copy due to chromosome 1p deletion harbored higher levels of *GIPR* transcripts than adenomas diploid for the *KDM1A* locus. If *KDM1A* haploinsufficiency leads to partial transcriptional derepression at the GIPR locus and a paradoxical rise of GH after glucose load warrants further investigations.

The main target of pharmacological therapy for growth hormone (GH)-secreting pituitary tumors (GH-PitNET) is the somatostatin receptor type 2 (SST2). However, approximately half of patients treated with octreotide, an SST2 agonist, show a low response rate or are octreotide-resistant. Here we present mechanistic data that shows co-treatment with simufilam, a novel oral therapeutic candidate, enhances sensitivity to octreotide. We previously showed that the cytoskeleton protein filamin A (FLNA) is recruited to bind SST2 upon agonist stimulation, and this interaction is required for SST2 signaling in GH-PitNET cells. However, when phosphorylated at Ser2152, FLNA no longer enables SST2 signaling and all SST2 anti-tumor effects are abolished. Simufilam is a FLNA-binding small molecule shown to modulate FLNA's conformation and its interactions with partner proteins in disease states. We postulated that simufilam may restore FLNA's linkage to SST2 and therefore FLNA's ability to enable SST2 signal transduction. To test this hypothesis, we assessed simufilam's effects on FLNA phosphorylation, FLNA-SST2 complex formation, SST2 signal transduction, GH secretion and cell proliferation/apoptosis, in human primary cultured GH-PitNET cells and in the rat pituitary tumor cell line GH4C1. Simufilam treatment reduced FLNA phosphorylation on Ser2152 in GH4C1 cells (-28$\pm$13% after 10 min, $P<0.01$ vs basal) and in primary human GH-PitNET cells (-59%). Additionally, FLNA-SST2 complexes in GH4C1 cells fell below basal levels after 1h octreotide treatment (-29$\pm$6.8%, $P<0.05$ vs bas) but were still elevated after 1h co-incubation with octreotide + simufilam (135$\pm$19.7%, $P<0.05$ vs bas). Simufilam did not affect the ability of octreotide to inhibit GH secretion in GH4C1 or primary GH-PitNET cells that are *in vitro* responsive to octreotide; however, a combination of simufilam + octreotide reduced GH secretion in primary GH-PitNET cells that are *in vitro* resistant to octreotide ($n=2$) (-42$\pm$3.5%, $P<0.001$ vs bas). Simufilam slightly reduced cell proliferation (-15$\pm$10.1%, $P<0.05$ vs bas) and ERK phosphorylation (-21$\pm$18.8%, $P<0.05$ vs bas), while increasing cell apoptosis (+17.8$\pm$7.3%, $P<0.05$ vs bas) in the GH4C1 cell line. Interestingly, co-treatment with simufilam + octreotide in GH4C1 potentiated the pro-apoptotic effect of the single drugs (+13$\pm$5% octreotide, $P<0.001$ vs bas; +36.8$\pm$9.2% octreotide + simufilam, $P<0.01$ vs bas, $P<0.05$ vs octreotide or simufilam alone). In conclusion, simufilam reduced FLNA phosphorylation, enhanced and prolonged the octreotide-induced FLNA-SST2 interaction and promoted SST2 signal transduction in human primary cultured GH-PitNET cells. These data suggest that co-treatment with simufilam may enhance the efficacy of octreotide or other somatostatin analog drugs in the management of pituitary tumors.

Craniopharyngiomas (CPs) are a relatively benign subtype of epithelial tumors that typically originate from the sellar and suprasellar regions of the brain. These endocrine tumors are classified as adamantinomatous (ACP) or papillary (PCP)

based on their histological characteristics. Unfortunately, the diagnosis of CPs is frequently made at an advanced stage of tumor development, and therefore relevant associated comorbidities are often present. The first-line treatment is typically surgical intervention; however, complete resection is often not achieved leading to high rates of recurrence. Therefore, there is an urgent need to identify alternative diagnostic, prognostic, and therapeutic tools to improve the management of CPs. Recently, growing evidence indicates that RNA splicing-process is altered in different endocrine-related tumors which leads to the generation of altered spliceosome components (SCs), splicing factors (SFs), and/or aberrant splicing-variants (SVs) associated with cancer progression, aggressiveness and development. Therefore, our aim was to explore the putative oncogenic role of key splicing-related factors in CPs through: 1) interrogating the expression profile of key splicing machinery components in ACP ($n=36$) and PCP ($n=4$) vs control samples [$n=11$; normal-pituitaries (NP)]; and 2) implementing different bioinformatic and functional approaches (RNAseq and CP primary cell-cultures). Our results revealed a substantial number of SCs and SFs are drastically altered in ACP vs NP, and also when primary vs recurrent ACP were compared. Specifically, 4 SFs were identified as the most discriminating diagnostic/prognostic factors, being corroborated in additional human cohorts. These SFs were also associated with key clinical parameters suggesting a potential oncogenic role in CPs. Moreover, dysregulation of 2 of these SFs was also corroborated in RNAseq of an additional cohort of 18 ACP vs 3 NP. *In vitro* overexpression of these SFs in primary ACP-derived cells revealed a critical functional role of these SFs in ACP. In fact, the *in vitro* overexpression induced the phosphorylation of MAPK and AKT pathways and reduced the phosphorylation JAK/STAT, NF-kB and TGFB which might be associated with CP tumorigenesis. Finally, relevant SVs that are associated to CP development and progression (e.g., *GNAS*) were identified as potential oncogenic linkers with the observed splicing-machinery dysregulation. In conclusion, spliceosome is drastically altered in CPs, wherein some SFs could represent attractive novel diagnostic/prognostic and therapeutic targets for this endocrine pathology.

Clinical picture of early infancy PTH-resistance syndromes: is it time to improve diagnostic criteria?

Giulia Del Sindaco[1,2,3], Angela Pagnano[2,4], Jugurtha Berkenou[3], Emanuele Ferrante[4], Anya Rothenbuhler[3,5], Maura Arosio[2,4], Giovanna Mantovani[1,2] & Agnès Linglart[3,5,6]
[1]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, ERN BOND, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [3]AP-HP, Service d'endocrinologie et diabète de l'enfant, ERN BOND, ERN for rare endocrine disorders, et Platforme d'expertise des maladies rares, Hôpital Bicêtre Paris Saclay, Le Kremlin-Bicêtre, France; [4]Endocrinology Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [5]AP-HP, Centre de Référence des maladies rares du métabolisme du Calcium et du Phosphate, Filière OSCAR, Paris, France; [6]Université de Paris Saclay, INSERM, U1185, Le Kremlin-Bicêtre, France

Since the first description of inactivating PTH/PTHrP signaling disorders (iPPSDs, historically named pseudohypoparathyroidism (PHP)) a remarkable clinical variability was observed, especially in clinical presentation, which seems to be age-dependent. The main clinical features, including PTH resistance, brachydactyly and short stature, develop during mid and late childhood, whilst minor clinical features such as a round face, rapid weight gain and subclinical hypothyroidism are the most prevalent signs in toddlers, e.g., age <2 years. The latter are included among minor criteria for diagnosis and present a large overlap with other conditions, therefore a significant delay in diagnosis has been reported. The aim of our study was to analyse a large cohort of iPPSD patients and to describe early natural history of the disease, to improve the diagnosis and reduce the diagnostic delay, through the development of new diagnostic criteria for early infancy. We collected data from 117 patients diagnosed with iPPSDs regularly followed-up at the Endocrinology Unit of two European tertiary centres. We retrospectively collected data on the age of onset of main clinical and hormonal features. In our cohort the mean age at diagnosis was 7.2 ± 6.7 years old. The onset of PTH resistance and brachydactyly, major criteria for diagnosis, was significantly different from that of both TSH resistance and obesity (median age 6.1, 5.8, 1.85 and 2 years old, respectively). In contrast, no statistically significant difference was detected between the age onset of PTH resistance and brachydactyly and the age onset of TSH resistance and obesity. We can therefore speculate that these two pairs of symptoms are tightly age-related. As for diagnostic criteria, we studied the distribution of both major and minor criteria in patients before 2 years. Minor criteria were more represented than major criteria in this population ($P=0.002$). Indeed, in 64% of patients before 2 years none of the major criteria was described, conversely 71% of these population had already developed at least 1 minor criteria. In details, 20% of patients had developed TSH resistance and obesity before 2 years, while only 2% of patients had developed PTH resistance, brachydactyly and ectopic ossifications before 2 years. In conclusion, the clinical picture of iPPSDs in early infancy differs from that of adults, thus current diagnostic criteria may not be appropriate for children. In detail, the combination of early onset obesity and elevated TSH levels, currently included among minor criteria, should trigger the genetic screening in infants before 2 years old.

Eneboparatide, a Novel PTH-1 Receptor Agonist, Has No Impact on Bone Parameters Following Chronic Treatment of Non-Human Primates

Guillaume Ravel[1], Thomas Delale[1], Stéphane Milano[1], Sophie Chirat[2], Michael Verset[2], Emilie Latronico[3], Soraya Allas[1] & Michael D. Culler[4]
[1]Amolyt Pharma, Ecully, France; [2]Charles River Laboratories France, Saint Germain Nuelles, France; [3]Voxcan, Dommartin, France; [4]Amolyt Pharma, Cambridge, Massachusetts, United States

Eneboparatide (AZP-3601) is a novel, synthetic, 36-amino-acid peptide agonist of the parathyroid hormone type 1 receptor (PTHR1), with potent selectivity for the R0 conformation. This results in prolonged calcemic responses, while having a short circulating half-life. Eneboparatide is being developed for the treatment of chronic hypoparathyroidism (cHP). Studies in hypoparathyroid animal models and, most recently, in hypoparathyroid patients, have demonstrated that eneboparatide is effective in maintaining normal serum calcium in the absence of calcium/vitamin D supplementation and in normalizing urinary calcium excretion without deleterious impact on bone parameters. To further examine the effect of chronic eneboparatide treatment on bone, both 13-week and 39-week studies were conducted in non-human primates (NHP), which are considered a relevant species with regard to eneboparatide effects on serum calcium. Groups of 3 or 4 Cynomolgus monkeys of each sex were given daily subcutaneous injections of either vehicle or eneboparatide at doses of 1, 2.5 or 10 µg/kg for either 13 or 39 weeks. At the end of the 13-week study, right femur, right tibia and the L4 lumbar vertebra were collected from 3 animals/group/sex and bone mineral density (BMD) was measured by dual-energy X-ray absorptiometry. The left femur was submitted to histopathological examination. There was no evidence of any treatment-related effect on either BMD or histopathology. In the 39-week study, blood samples were collected from 4 animals/group/sex prior to and during weeks 4, 8, 13, 26 and 39 of treatment for measurement of bone biomarkers. In-life BMD of left femur, left tibia and L4 lumbar vertebra was measured by quantitative computed tomography prior to and during weeks 26 and 39 of treatment. At the end of the treatment period, femurs were processed for histopathological examination. Analysis of blood samples for the anabolic bone biomarker, N-terminal propeptide of type 1 procollagen (P1NP), and the catabolic bone biomarker, C-terminal telopeptide (CTX), revealed no treatment-related changes at any time in either sex. Prior to treatment, BMD was homogeneous among all groups for all the three bone sites examined. Over the course of the study, there were no statistically significant changes in BMD as compared to pre-treatment values, regardless of sex or eneboparatide treatment. Subsequent histological examination of the femur revealed no noteworthy findings. These results, demonstrating an absence of deleterious effect of chronic eneboparatide treatment on bone in NHP, further substantiate the potential of eneboparatide as an ideal treatment for hypoparathyroidism.

OC8.3

The thiazide challenge test to differentiate between primary hyperparathyroidism and secondary hyperparathyroidism due to idiopathic hypercalciuria.

Ewout Verly[1], Charlotte Verroken[1] & Bruno Lapauw[1]
[1]UZ Gent (Ghent University Hospital), Endocrinology, Ghent, Belgium

Background
Treatment of primary hyperparathyroidism (PHPT) and secondary hyperparathyroidism due to idiopathic hypercalciuria (SHPT-IH) is markedly different. Nevertheless, differentiating one from another remains a challenge and robust diagnostic tools are lacking. The thiazide challenge test (TCT) has been proposed

as a means to aid clinicians in their decision making. However, evidence supporting its use is scarce.
Materials and Methods
We performed a retrospective analysis of 25 patients who underwent a TCT at the Ghent University Hospital (Belgium). We assessed serum and urinary samples before and after testing, clinical and imaging outcomes as well as therapy and long-term follow-up to evaluate the efficacy of the TCT. Based on literature and the calcium load test, other potentially useful parameters were calculated.
Results
Baseline serum albumin-adjusted calcium (AACa) and serum total calcium (TCa) were not significantly different between patients with PHPT and SHPT-IH (2.54 (±0.072) vs 2.55 mmol/l (±0.13) and 2.63 (±0.069) vs 2.64 mmol/l (±0.15) respectively). During the TCT, AACa rose 0.11 mmol/l (±0.10) in patients with PHPT and 0.0071 mmol/l (±0.10) in patients with SHPT-IH. The change in AACa is significantly different between both groups (one-sided $P=0.025$). A similar result was found for TCa, which rose 0.14 mmol/l (±0.12) in patients with PHPT compared to 0.012 mmol/l (±0.15) in patients with SHPT-IH (one-sided $P=0.024$). The TCT can detect PHPT based on an increment in AACa of at least 0.10 mmol/l or in TCa of at least 0.13 mmol/l with a calculated sensitivity of 81.8% and a specificity of 77.8%. Serum parathormone (PTH) levels and urinary calcium excretion (UCE) did not differ between patients with PHPT and SHPT-IH (101.7 ng/l (±26.9) vs 105.7 ng/l (±53.8) and 10.9 mmol/24 hours (±3.0) vs 9.4 mmol/24 hours (±3.2) respectively). PTH levels, UCE, the calcium-phosphorous ratio (Ca/P), the PTH-inhibition rate (PTH-IR) and the parathyroid function index (PF-index) did not differ significantly between patients with PHPT and SHPT-IH during the TCT.
Conclusion
The TCT can aid in discriminating patients with PHPT from those with SHPT-IH based on the rise in serum calcium. It can be easily used in all patients with nephrolithiasis or hypercalciuria, an elevated PTH, and a normal to slightly elevated serum calcium. Even though mild hypokalemia occurs frequently, and caution is warranted, no severe side effects were observed. Other variables such as serum PTH, UCE, Ca/P, PTH-IR and PF-index did not differentiate between both groups. Larger prospective trials are necessary to reassess the relevance of different biochemical parameters and the diagnostic potential of the TCT.

Aim
Thyroid Stimulating Hormone (TSH) suppression treatment may have a detrimental effect on bone tissue in differentiated thyroid cancer (DTC) patients. The current study aimed to investigate vertebral fracture, bone mineral density measurements, and TSH levels in DTC patients under levothyroxine (LT4) suppression treatment after total thyroidectomy and/or radioiodine ablation therapy in a multicentric setting.
Material and Method
This multicentric cross-sectional study was conducted at 21 medical centers from 12 cities in Turkey. Clinical data, serum TSH, free thyroxine (FT4), Thyroglobulin (Tg), and antithyroglobulin (Anti-Tg) levels were all recorded during the most recent visit. TSH serum concentrations were classified as TSH < 0.1 mU/l, TSH 0.1-0.5 mU/l and TSH > 0.5 mU/l according to TSH suppression recommendation of American Thyroid Association guidelines. Systolic and diastolic blood pressure and pulse rate were measured. Mineral densities were measured with a GE Lunar DXA scanner. Lateral vertebral X-rays were reviewed blindly. The vertebral fractures were defined according to Genant's semi-quantitative method as grade 1-4.
Results
A group of 990 DTC patients (F/M:829/161,51.4±11.5 years) were enrolled. The mean disease duration was 5.2±4.4 years. LT4 daily dosage was 131.1±37.5 mg/day. The patient's femur neck BMD ($P=0.65$) and L1-L4 BMD ($P=0.86$) levels were similar according to TSH suppression levels. Serum calcium, phosphor, parathormone, and 25-OHD3 levels were similar between groups. Four hundred sixty-eight lateral vertebral x-ray evaluations revealed that 200 patients had fractures. Mean vertebral fracture number was 5.43. The patients with vertebral fractures were older ($P<0.001$), The daily dosage ($P<0.001$) and dose per kg ($P=0.015$) were lower in the fracture group compared to the nonfracture group. The fracture group's femur neck BMD ($P=0.001$) and L1-L4 BMD ($P=0.003$) were lower. The TSH levels of the patients with fractures were higher ($P=0.0082$).
Conclusion
The femur and L1-L4 BMD levels of patients in this study group were similar according to TSH suppression levels. Studies to date have also yielded conflicting results. Frequent monitoring and avoiding unnecessary TSH suppression especially in older patients is essential to prevent detrimental effects.

Idiopathic Infantile Hypercalcemia (IIH) is a rare inborn form of severe vitamin D hypersensitivity, with an estimated incidence of 1:33.000 live birth and a high degree of misdiagnosis. Since the identification of CYP24A1 loss-of-function variants inducing IIH in 2011, over 41 pathogenic variants have been described, and represent the major genetic drivers of IIH[1]. CYP24A1 encodes the main catalytic hydroxylase of the bioactive form of vitamin D (1,25D3). Upon binding to its nuclear receptor VDR, 1,25D3 regulates intestinal calcium absorption, renal calcium reabsorption and bone resorption, thus playing a key role in calcium homeostasis. IIH phenotype embraces a wide range of clinical features and the current therapeutic protocols, aimed to control long-lasting and recurrent hypercalcemic episodes, do not selectively target vitamin D signalling. In addition, long-term and high-dose regimens negatively impact patient's quality of life, and a protracted administration is not always advisable. Thus, there is a significant unmet medical need for selective treatments for this metabolic disorder. We have shown that the VDR antagonist ZK168281 (ZK) normalizes VDR signaling and prevents 1.25D3-induced hypercalcemia in wild type mice, without any obvious side effect[2]. To determine the therapeutic potency of ZK for IIH, we generated CYP24A1-null mice and showed that they recapitulate the human disease, including biochemical changes in mineral metabolism (e.g. hypercalcemia, hypercalciuria), renal abnormalities (e.g. nephrolithiasis, tubular fibrosis and glomerular injury), suppressed levels of parathyroid hormone and bone mineralization defects. Moreover, we demonstrated that serum calcium

levels and renal calcium excretion fall back within physiological ranges in Cyp24a1-null mice treated for 2 weeks with ZK. In addition, we showed that this treatment improves nephrocalcinosis and renal fibrosis of Cyp24a1-null mice, highlighting the therapeutic potency of ZK. As little is known about the tissue-specific molecular events secondary to hypercalcemia induced by CYP24A1-deficiency, we performed a comparative genome-wide transcriptomic analysis in the key vitamin D target tissues, namely intestine, kidney and bone. In depth bio-informatic analysis revealed the key pathways involved in the disease, and importantly, we demonstrated that ZK normalizes these transcriptomic alterations of Cyp24a1-null mice. Thus, this compound, that selectively targets VDR, represents a potent and safe therapeutic option and opens new avenue for the treatment of refractory rare diseases secondary to hypervitaminosis-D.

Skeletal phenotypes in postmenopausal women with primary hyperparathyroidism (PHPT)

Sabrina Corbetta[1], Laura Gianotti[2], Elena Castellano[2], Francesca Raineri[2], Elisabetta Munari[3], Gregorio Guabello[4], Laura Pierotti[5], Elisa Dinoi[5], Simone Della Valentina[5] & Filomena Cetani[5]
[1]Endocrinology and Diabetology Service, IRCCS Ospedale Galeazzi Sant'Ambrogio, Department of Biomedical, Surgical and Dental Sciences, University of Milan, Milano, Italy; [2]AO S.Croce e Carle Cuneo, SC Endocrinologia Diabetologia e Metabolismo, Cuneo, Italy; [3]Endocrinology and Diabetology Service, IRCCS Istituto Ortopedico Galeazzi, Department of of Medical Biotechnology and Translational Medicine, University of Milan, Milano, Italy; [4]Endocrinology and Diabetology Service, IRCCS Ospedale Galeazzi Sant'Ambrogio, Milano, Italy; [5]Endocrine Unit 2, University Hospital of Pisa, Pisa, Italy

Current clinical presentation of PHPT is mild disease with an increased risk of fragility fractures. PHPT predominantly occurs in postmenopausal women, who have an increased risk of osteoporosis and fractures due to ageing and loss of estrogen.

Aims

To explore skeletal phenotypes in postmenopausal women affected by PHPT with a wide clinical and biochemical spectrum of disease.

Patients

Postmenopausal (at least 5 years from last menses) women with PHPT were retrospectively evaluated at three third level Italian centers for management of osteoporosis and mineral metabolism disorders ($n=120$ from Milan, $n=134$ from Cuneo, $n=132$ from Pisa).

Methods

Data were collected from clinical records and analyzed by nonparametric Spearman correlation and multiple linear regression. Hierarchical clusterization by Wards' method and Euclidean similarity index identified skeletal phenotype clusters; differences among clusters were detected by Kruskall-Wallis ANOVA.

Results

Considering the whole 386 PHPT women [aged 68.0 (61.0-74.0) years], fractures (clinical and morphometric vertebral, femur, humerus, pelvic, wrist fractures) positively correlated with phosphatemia and negatively with lumbar and neck T-scores. Cluster analysis based on fractures number, phosphatemia, lumbar and neck T-scores, identified 4 clusters: the most frequent phenotype ($n=307$) included women with lumbar osteoporosis and neck osteopenia with a prevalence of fractures of 29.5% (0-3 fractures, minimum-maximum) and higher 24-hours urinary calcium corrected for body weight (UCa). The second phenotype included women ($n=16$) with more important lumbar and neck osteoporosis who all experienced multiple (3-6) fractures. The third phenotype included women ($n=37$) with neck osteopenia/osteoporosis and mild lumbar osteopenia with a prevalence of fractures of 23.3% associated with lower UCa and estimated glomerular filtration rate (eGFR). The forth phenotype included women ($n=19$) with lumbar and neck osteopenia with a very low prevalence of fractures (2.1%, no more than 1 fracture). In this cluster, women were younger and heavier, with lower PTH levels. Unexpectedly, ionized and total calcium, phosphate, bone and total alkaline phosphatase, 25hydroxyvitamin D (25OHD) levels, and kidney stones prevalence (ranging 21.1-30.2%) were similar among the 4 clusters. Fractures were predicted by lumbar T-score. Besides, lumbar T-score was predicted by body mass index, 25OHD, eGFR and neck T-score.

Conclusions

Skeletal involvement in this large retrospective series of postmenopausal women with PHPT presented with heterogeneous phenotypes associated with different prevalence of fractures. Fractures were related with bone mineral density, but not with PHPT severity, suggesting that other factors besides PHPT should be considered in the evaluation of the bone involvement in postmenopausal women with PHPT.

Identification of adrenocortical masses malignancy and aggressivity through radiomics: a pilot study

Lorenzo Tucci[1,2], Giulio Vara[2,3], Ilaria Improta[1,2], Antonio De Leo[2,4], Saverio Selva[5], Caterina Balacchi[3], Donatella Santini[4], Cristina Mosconi[2,3], Valentina Vicennati[1,2], Uberto Pagotto[1,2] & Guido Di Dalmazi[1,2]
[1]S. Orsola-Malpighi Polyclinic, Endocrinology and Diabetes care and Prevention Unit, Bologna, Italy; [2]Alma Mater Studiorum – Bologna University, Medical and Surgical Sciences, Bologna, Italy; [3]S. Orsola-Malpighi Polyclinic, Radiology Unit, Bologna, Italy; [4]S. Orsola-Malpighi Polyclinic, Anatomic Pathology Unit, Bologna, Italy; [5]S. Orsola-Malpighi Polyclinic, General Surgery Unit, Bologna, Italy

Background

Adrenal lipid poor adenoma (LPA) and adrenocortical cancer (ACC) may overlap in computerized tomography (CT). Radiomics recently emerged as new tool for malignant behavior identification.

Aim

To assess radiomics utility for identification of ACC and LPA in adrenocortical masses with unenhanced (UE) CT scan attenuation ≥ 10 Hounsfield Unit (HU).

Methods

We retrospectively enrolled 50 patients, 38 radiologically defined LPA with 6-12 months of radiologic stability or benign histological exam ($n=11$), and 12 ACC with histological exam (2 patients with Weiss score $=3$; 4 patient with ki67 $\geq 10\%$). All patients underwent CT with UE scan, arterial (ACE), venous (VCE) and 15' delayed (DCE) contrast enhanced phases, on which radiomics was performed with LIFEx software (©LITO 2022-2023). We performed a two-steps multivariate analysis for each CT phase to evaluate predictors of malignancy (Weiss score ≥ 3). Multivariate analysis first step was completed within single radiomics feature classes, then first step predictors were altogether employed for multivariate analysis second step. Second step predictors were utilized for receiver operating characteristic curve analysis and estimation of positive (PPV) and negative predictive value (NPV). We conducted multivariate analysis for each CT phase, within single radiomics feature classes, to evaluate predictors of ki67 values, as aggressivity marker.

Results

In UE, surface to volume ratio (SVR) and Run Length Non-Uniformity (RLNU) predicted malignancy (Odds Ratio (OR) $=2.718$; 95% Confidence Interval (CI) $=$ 1.56-4.75; $P<0.001$), with 83.3% sensibility, 94.3% specificity, 83.3% PPV, 94.7% NPV. Model including HU total lesion glycolysis (TLG), standard deviation, variation coefficient and maximum gray level predicted ki67 ($R^2=$ 0.984; $P<0.001$). In ACE, SVR and Feret diameter predicted malignancy [OR $=$ 2.718; 95% CI $=1.57$-4.745; $P<0.001$], with 83.3% sensibility, 92.1% specificity, 76.9% PPV, 94.6% NPV. Model including HU TLG, energy, variation coefficient and total calcium score predicted ki67 ($R^2=0.998$; $P<0.001$). In VCE, SVR and compacity predicted malignancy [OR $=2.719$; 95% CI $=1.54$-4.79; $P<0.001$], with 83.3% sensibility, 92.1% specificity, 76.9% PPV, 94.5% NPV. Model including HU maximum histogram gradient, root mean square and intensity histogram minimum grey level predicted ki67 ($R^2=0.979$; $P<0.001$). In DCE, SVR and RLNU predicted malignancy [OR $=2.718$; 95% CI $=1.54$-4.79; $P<0.001$], with 83.3% sensibility, 91.9% specificity, 76.9% PPV, 94.5% NPV. Model including HU TLG and median absolute deviation predicted ki67 ($R^2=0.98$; $P<0.001$).

Conclusion

Radiomics seems useful to identify adrenal masses nature, even without CT contrast enhanced phases. Among other radiomics parameters, SVR and HU intensity-based features seem to be powerful predictors of adrenocortical masses malignancy and aggressivity.

FLNA-binding partner Wee1 as a new potential pharmacological target in adrenocortical carcinomas

Emanuela Esposito[1,2], Rosa Catalano[1], Emma Nozza[1,2], Anna Maria Barbieri[4], Sara Maioli[1], Jens Albrecht Ernst Geginat[1], Giusy Marra[1], Donatella Treppiedi[3], Genesio Di Muro[1,4], Federica Mangili[3], Costanze Hantel[5,6], Serena Palmieri[3], Sofia Frigerio[3], Emanuele Ferrante[3], Maura Arosio[1,3], Giovanna Mantovani[1,3] & Erika Peverelli[1,3]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]University of Milan, PhD Program in Experimental Medicine, Milan, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [4]University Sapienza of Rome, PhD Program in Endocrinological Sciences, Rome, Italy; [5]University Hospital Zurich (USZ) and University of Zurich (UZH), Department of Endocrinology, Diabetology and Clinical Nutrition, Zurich, Switzerland; [6]University Hospital Carl Gustav Carus Dresden, Medizinische Klinik und Poliklinik III, Dresden, Germany

The cytoskeletal actin-binding protein filamin A (FLNA) is poorly expressed in adrenocortical carcinomas (ACC) compared to adenomas (ACA), and this might contribute to sustain the increased cell proliferation by downregulating IGF1R expression and its downstream signaling. In mouse neural progenitor cells, increased protein expression levels of the CDK1 kinase Wee1 have been found after loss of FLNA. This protein has a leading role in regulating the G2-M checkpoint and functions as a mitotic inhibitor. Wee1 is overexpressed in several cancer types and its pharmacological inhibitor Adavosertib (AZD1775) is currently undergoing clinical trials. Aims of the present project are to investigate the role of FLNA in regulating Wee1, the effects of Wee1 inhibition on cell proliferation and apoptosis, as well as the effects of FLNA levels on AZD efficacy in human H295R and MUC-1 cell lines. The analysis of protein expression levels of FLNA and Wee1 in 6 ACC and 8 normal adrenal tissues revealed that ACC express lower levels of FLNA (0.4 ± 0.7 and 2.9 ± 0.9, respectively, $P<0.05$), while significantly increased Wee1 (0.26 ± 0.1 and 0.01 ± 0.06, respectively, $P<0.001$). In MUC-1 cells a correlation between Wee1 and FLNA expression was shown. Indeed, FLNA silencing induced an increased expression of Wee1, phosphorylated CDK1 and cyclin B1 ($+1.6\pm0.2$, $+1.7\pm0.4$ and $+1.4\pm0.2$ fold, $P<0.001$ vs negative control, respectively). On the contrary, FLNA overexpression resulted into a reduced expression of Wee1, phosphorylated CDK1 and cyclin B1 (-$51\pm5\%$, $P<0.001$, $-60\pm5\%$, $P<0.001$, $-67\pm20\%$, $P<0.01$ vs mock). Treatment with AZD1775 induced a dose-dependent reduction of cell proliferation (-$32\pm4.6\%$, $P<0.001$; $-78\pm4.8\%$, $P<0.001$ vs bas at 250 nM) and an increase of apoptosis ($+6\pm1.5$-fold, $P<0.001$; $+4\pm0.5$-fold, $P<0.001$ vs bas at 1 μM) in H295R and MUC-1 cell lines, respectively. Flow cytometric analysis of apoptotic subpopulations showed that, in MUC-1, Wee1 inhibition specifically stimulated an increase of the early apoptotic cells ($+5$-fold, $P<0.001$ vs bas at 1 μM). Moreover, AZD1775 induced a time-dependent reduction of CDK1 phosphorylation, with a maximum after 2 hours (-$67\pm9.5\%$, $P<0.01$; $-90.5\pm1.7\%$, $P<0.001$ vs bas at 250 nM in H295R and MUC-1, respectively). Interestingly, FLNA knockdown potentiated AZD1775 effects on cell proliferation (-$51\pm6.4\%$, $P<0.01$ vs negative control at 250 nM) in MUC-1 cells. In conclusion, this work demonstrates that low FLNA levels in ACC correlate to a high Wee1 expression, contributing to an increased cell growth. Moreover, it proposes Wee1 inhibition as a new potential therapeutic approach for ACC, particularly for those lacking FLNA.

Background
The management of adjuvant mitotane therapy in patients with adrenocortical carcinoma (ACC) is challenging. Plasma mitotane concentrations > 14 mg/l have been associated with efficacy in the treatment of advanced ACC; however, data in the adjuvant setting are mixed. Moreover, there is no consensus on how to assess the optimal exposure to mitotane and all the proposed methods have inherent limitations. We have recently proposed a new method analogous to what is established for the anticoagulant warfarin, the time in target range (TTR). We aimed to evaluate whether the TTR is a factor influencing recurrence-free survival (RFS) in patients with ACC on adjuvant mitotane.
Methods
This is an international, retrospective, cohort study undertaken in 18 centers in 8 countries, under the auspices of the European Network for the Study of Adrenal Tumors (ENSAT), including adult patients with ACC who were treated with adjuvant mitotane for at least 1 year following tumor resection, with the availability of at least 3 mitotane measurements per year. TTR was calculated with the Rosendaal method and expressed as the number of months with plasma mitotane concentration > 14 mg/l. The following potential predictive factors for RFS have been investigated: patient sex and age, ENSAT stage, hormone secretion, resection status, Weiss score, Ki67 index, and TTR. Data are expressed as median and interquartile range.
Results
From a total of 254 patients, 157 fulfilled inclusion criteria and were analyzed (F/M 94/63; age 49, 41-58 years), with a follow-up of 49 (33-92) months. The key baseline features were: 7.0% stage I, 69.4% II, 22.3% III, 1.3% IV; 51.6% secreting tumors; 87.2% R0, 2.6% R1, 10.2% RX; Weiss score 5 (4-7); Ki67 index 11 (5-20). All patients initiated mitotane within 3 months from surgery and were treated for 25 (22-36) months, with a TTR of 14 (6-21) months. At multivariate analysis, Ki67 index (HR 1.07, 95% CI, 1.02-1.12; $P<0.01$) and Weiss score (HR 1.7, 95% CI, 1.16-2.47; $P<0.01$) were associated with an increased risk of recurrence, while female sex (HR 0.14, 95% CI, 0.04-0.58; $P<0.01$) and TTR (HR 0.80, 95% CI, 0.70-0.90; $P<0.001$) were associated with a reduced risk.
Conclusions
The present findings show that the patients who are exposed to plasma mitotane > 14 mg/l for longer periods have better RFS. These findings provide indirect evidence of the value of adjuvant therapy with mitotane and support the importance of drug monitoring and dose adjustment in clinical practice to improve treatment response.

Recovery of adrenal function after stopping mitotane in patients with adrenocortical carcinoma

Barbara Altieri[1], Otilia Kimpel[1], Felix Megerle[1], Mario Detomas[1], Irina Chifu[1], Marcus Quinkler[2], Kroiss Matthias[1,3] & Martin Fassnacht[1,4]

[1]Division of Endocrinology and Diabetes, University Hospital of Würzburg, Würzburg, Germany; [2]Department of Endocrinology & Metabolism, Charité Universitätsmedizin Berlin, Berlin, Germany; [3]Department of Medicine IV, University Hospital, LMU Munich, Munich, Germany; [4]Comprehensive Cancer Center Mainfranken, University of Würzburg, Würzburg, Germany

Background
Mitotane is regularly used in patients with adrenocortical carcinoma (ACC) adjuvantly, in patients with high risk of recurrence, and in advanced disease. Multiple effects of mitotane result in adrenal insufficiency in virtually all patients. However, it is unclear how frequently the hypothalamic-pituitary-adrenal (HPA) axis is recovering after treatment discontinuation. Here, we aim to investigate the HPA axis after treatment with mitotane.
Methods
We screened patients with ACC treated with mitotane for ≥12 months since 2000 and discontinued treatment without evidence for disease. Minimum follow-up after mitotane discontinuation was 1 year. Data on patients and tumor characteristics, mitotane treatment, and information on HPA axis were analyzed. Primary endpoint was time to adrenal recovery. Explorative analysis of predictive factors (e.g. sex, age, follow-up in reference center, cumulative mitotane dose and plasma levels, duration of treatment, and dose of hydrocortisone-equivalent replacement) was performed using univariate and multivariate Cox regression.
Results
56 patients (36 women) treated with mitotane alone ($n=47$) or in combination with radiotherapy ($n=3$) or chemotherapy ($n=6$) were included. Median duration of mitotane treatment was 25 (14-122) months, with a median average daily dose of 2.8 g (0.70-10.10). The average daily dose of hydrocortisone-equivalent replacement during mitotane treatment was in median 49.4 mg (25.7-66.9). Complete adrenal recovery was documented after a median of 26 (95% CI 19.6-32.4) months in 32 (57.1%) patients. Among these, 22 (68.7%) achieved HPA recovery within 24 months. However, when patients were followed in reference centers ($n=38$), a significantly larger proportion of cases (71.1%) achieved HPA recovery (HR=4.65, 95%CI=1.76-12.25, $P=0.002$). Partial and insufficient recovery were observed in 9 (16.1%) and 15 (26.8%) patients, respectively. In 4 patients (7.1%) with a follow-up>60 months, a long-term adrenal insufficiency has to be assumed. A maximum mitotane peak ≥27 mg/l as well as plasma levels ≥12 mg/l at discontinuation correlated with significant longer time to adrenal recovery (HR=0.24, 95% CI=0.07-0.85, $P=0.03$, and HR=0.45, 95% CI=0.21-0.95, $P=0.03$, respectively). A higher mitotane exposure, as assessed by the area under the curve of mitotane plasma levels, was slightly associated with longer adrenal recovery (HR=0.5, 95% CI=0.2-1.0, $P=0.06$). At multivariate analysis, only plasma levels ≥12 mg/l at discontinuation slightly correlated with longer time to HPA recovery (HR=0.47, 95% CI=0.21-1.06, $P=0.07$).
Conclusions
Our study demonstrates that adrenal recovery occurs in most patients treated with mitotane. Testing for adrenal insufficiency is performed more often in reference centers. Therefore, a sufficient patient follow-up including education on glucocorticoid reduction is needed after mitotane discontinuation.

Generation of novel tools for the study and development of targeted therapeutic approaches for pheochromocytoma and paraganglioma

Yasmine Kemkem[1], Alice Santambrogio[1], Bertille Montibus[1], Thea Willis[1], James Kaufman-Cook[1], Emily Lodge[1], Val Yianni[1], Rebecca J. Oakey[1] & Cynthia L. Andoniadou[1,2]
[1]King's College London, London, United Kingdom; [2]Dresden University of Technology, Dresden, Germany

Pheochromocytomas and paragangliomas (PPGLs) are rare neuroendocrine tumours, which arise from neural crest (NC)-derived structures: the adrenal medulla and the paraganglia. Around one third of PPGLs are associated with inherited cancer susceptibility genes, the highest rate among all tumour types. Currently, the only diagnostic criterion for malignant disease is the presence of metastasis and no molecular or histological features have been identified that help predict risk. Additionally, understanding the pathogenesis of PPGLs and development of new therapies is hindered by the lack of validated disease models. In many tumours, cancer cells with stem-like properties are at the root of tumour initiation/maintenance due to their ability to self-renew and proliferate, but a stem cell population of the adrenal medulla has not been identified. We show that SOX2, a well-characterised marker of multiple stem cell populations, is expressed in a subset of uncommitted Schwann-cell precursors, which generate chromaffin cells and sympathetic neurons and that SOX2 expression persists postnatally and in adulthood in adrenomedullary sustentacular cells. Using the inducible Sox2-CreERT2 driver, *in vivo* lineage tracing in neonates and adults demonstrates that murine neural crest-derived SOX2+ cells expand to self-renew and give rise to new chromaffin, supporting their function as a novel progenitor/stem cell population. This population is therefore ideal to target for expression of tumour-inducing mutations, to generate transgenic models of PPGLs. We establish a system to isolate and culture pure murine and human populations of adrenomedullary SOX2+ stem cells *in vitro* and demonstrate that these cells can be expanded and gene-edited, to express mutant forms of Succinate Dehydrogenase subunits (SDHx), responsible for most hereditary PPGL cases. Finally, normal and mutated SOX2+ adrenomedullary stem cells can be implanted *in vivo* onto the chick chorioallantoic membrane (CAM), where they can be assayed for expansion, contribution of chromaffin cells and tumourigenic properties including invasion and metastasis.

Previous use of anabolic androgenic steroids is associated with persistent impaired myocardial microcirulation

Yeliz Bulut[1], Jon J. Rasmussen[1], Niels Brandt-Jacobsen[1], Martin Lyngby Lassen[2], Philip Hasbak[2] & Caroline Kistorp[1]
[1]Rigshospitalet, Copenhagen University Hospital, Department Of Endocrinology, Copenhagen, Denmark; [2]Rigshospitalet, Copenhagen University Hospital, Department of Clinical Physiology, Nuclear Medicine & PET, and Cluster for Molecular Imaging, Copenhagen, Denmark

Background and Aim
Ongoing anabolic androgenic steroids (AAS) use has been linked with left ventricle dysfunction, while information on the effects years after discontinuation is limited. Furthermore, the underlying mechanism behind the impaired cardiac function is unknown. Early signs of cardiomyopathy, such as microvascular dysfunction with global or regional reduced myocardial perfusion can be measured noninvasively by cardiac positron emission tomography (PET) with Rubidium-82 (Rb-82). The aim of this study was to assess myocardial flow reserve (MFR) by PET/CT Rb-82 in current and previous AAS users compared with healthy never user control participants.
Methods
Community-based cross-sectional study including men involved in recreational training. A standard cardiac PET/CT Rb-82 was performed at rest and after adenosine stress-induced. History of AAS use was obtained using a standardized questionnaire. A MFR<2.5 was used as a validated definition of impaired in men without obstructive coronary artery disease.
Results
We included 28 current and 22 former AAS users and 14 recreational athletes with no prior AAS use. The mean (SD) age was 33 (9) years. Accumulated duration of AAS use, geometric mean (95 CI%) was 184 (108; 312) weeks among current users and 99 (52; 187) weeks among former users ($P=0.126$). Duration since AAS cessation, geometric mean (95 CI%) was 17 months (10; 28,) and 13 (59%) former users discontinuated AAS more than one year prior to inclusion. Analyzed as continuous variable, both former and current users exhibited lower mean (SD) MFR, 3.1 (0.9) ($P=0.028$) and 3.3 (1.2) vs 4.1 (0.9) ($P=0.046$) as compared with controls of never users. The prevalence of impaired MFR (<2.5) was increased in former and current AAS users compared with controls, 36% and 25% vs 7%, trend test ($P=0.026$). Among previous users, every doubling of accumulated AAS duration was associated with an increased risk of impaired MFR age-adjusted OR of 2.9 [1.05; 810] ($P=0.039$).
Conclusions
Previous and current users of AAS exhibited impaired MFR, suggesting persistent impaired cardiac microcirculatory function.

CRTC2 activates the epithelial-mesenchymal transition of diabetic kidney disease through the CREB-Smad2/3 pathway

Li Yujie[1] & Wenbo Wang[2]

[1]The Second Affiliated Hospital of Shandong University of Traditional Chinese Medicine, Geriatrics Department, Jinan, China; [2]The Second Affiliated Hospital of Shandong University of Traditional Chinese Medicine, Orthopaedics Department, Jinan, China

Background

Epithelial-mesenchymal transition (EMT) plays a key role in tubulointerstitial fibrosis, which is a hallmark of diabetic kidney disease (DKD). Our previous studies have shown that CRTC2 can regulate glucose metabolism and lipid metabolism at the same time. However, it is still unclear whether CRTC2 participates in the EMT process of DKD.

Methods

We used protein-protein network (PPI) analysis to determine differentially expressed genes in DKD and EMT. Then we constructed STZ plus high-fat diabetic mice model and used HK-2 cells that have been verified to confirm the bioinformatics research results. The efects of CRTC2 on epithelial-mesenchymal transition of diabetic kidney disease through the CREB-Smad2/3 signaling pathway were investigated *in vivo* and *in vitro* using Q-PCR, WB, IHC and double luciferase reporter gene experiments.

Results

Firstly, bioinformatics research showed that CRTC2 may promote the EMT process of diabetic renal tubules through the CREB-Smad2/3 signaling pathway. Furthermore, Western blot results showed that overexpressed CRTC2 could reduce the expression of E-cadherin. CRTC2 and α-SMA were increased in STZ mice. Luciferase activity of α-SMA, the key protein of EMT, was sharply increased in response to overexpressed CRTC2 and decreased by silencing in CREB and Smad2/3. In the Q-PCR experiment, the mRNA of α-SMA increased significantly when CRTC2 was overexpressed and decreased partly when CREB and Smad2/3 were silenced. However, E-cadherin had the opposite result.

Conclusion

This study demonstrated that CRTC2 activates the EMT process via the CREB-Smad2/3 signaling pathway in diabetic renal tubules.

Characterization of the insulinotropic and glucose lowering actions of hybridized amphibian host defence peptide, tigerinin-1R

Ayodele Abiodun Falobi[1], Joy Nneka Edeani[1], Wendy Amy Ofosu[2], Lesley Smyth[2], Olivia Corcoran[1], Simon Dunmore[1] & Opeolu Ojo[1,3]
[1]University of Wolverhampton, Diabetes Research Group, Wolverhampton, United Kingdom; [2]University of East London Stratford Campus, London, United Kingdom; [3]IRiD Bioscience, Stoke-on-Trent, United Kingdom

Aim

Our previous studies indicated the potential antidiabetic actions of the amphibian host-defence peptide, tigerinin-1. Tigerinin-1R was conjugated with gastric inhibitory polypeptide (GIP) as part of strategies for further development of its therapeutic effects. This study characterises the insulin-releasing and cytotoxic properties of the resulting hybrid peptide.Method: Pure G-TGN was commercially synthesized G-TGN. Insulin releasing effects were assessed using BRIN-BD11 cells incubated with graded concentrations (0 – 3 μM) of the peptide. Cytotoxicity and effect of G-TGN on cell viability were assessed by LDH and MTT assays respectively. Actions of G-TGN on erythrocyte haemolysis, in the presence of increasing glucose concentration, on intracellular calcium level and membrane depolarisation, and on glucose tolerance in diet-induced diabetic mice were investigated.

Results

G-TGN stimulated non-toxic insulin secretion at concentrations ≥ 10 nM ($P<0.05$ to $P<0.001$). At 3 μM, G-TGN was more potent than native tigerinin-1R (1.5-fold, $P<0.01$) and GIP (1.3-fold, $P<0.05$). G-TGN did not affect cell viability nor cause erythrocyte lysis. Insulin-releasing effect of G-TGN was glucose dependent (1.1 mM to 5.6 mM, 1.3-fold, $P<0.05$ and 5.6 mM to 16.7 mM, 1.7-fold, $P<0.01$) and increase in incubations containing KCl (30 mM, 3.6-fold, $P<0.001$) and tolbutamide (200 μM, 2.4-fold, $P<0.01$). Verapamil (50 nM, 23%, $P<0.05$), diazoxide (300 μM, 27%, $P<0.05$) and absence of calcium (19%, $P<0.05$) reduced the effects of G-TGN. G-TGN enhanced intracellular calcium (23%, $P<0.01$) and increased membrane depolarisation (19%, $P<0.05$), and improved glucose tolerance *in vivo* (versus tigerinin-1R, 19%, $P<0.05$; versus GIP, 13%, $P<0.05$).

Conclusion

Hybridization of tigerinin-1R with GIP enhanced its potential and encourages further development of its therapeutic potentials.

The role of logic learning machine in predicting lipid goal attainment among type 2 diabetes outpatients: Results from the AMD annals study group

Davide Masi[1], Rita Zilich[2], Riccardo Candido[3], Giacomo Guaita[4], Marco Muselli[5], Paola Ponzani[6], Pierluigi Santin[7], Damiano Verda[5] & Nicoletta Musacchio[8]
[1]Sapienza University of Rome, Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Italy; [2]Mix-x SRL, IVREA (TO), Italy; [3]Azienda Sanitaria Universitaria Giuliano Isontina, Trieste; [4]Diabetes and Endocrinology UNIT ASL SULCIS, Carbonia-Iglesias, Italy; [5]Rulex Innovation Labs, Rulex Inc, Genoa, Italy; [6]Diabetes and Metabolic Disease Unit ASL 4 Liguria; [7]Deimos; [8]Diabetes Medical Association (AMD), Milan, Italy

Introduction

Lowering low-density lipoprotein cholesterol (LDL-C) via lifestyle change or pharmacologic therapy can reduce the cardiovascular risk (CV) in patients with type 2 diabetes (T2D). However, the response to lipid-lowering interventions is not uniform and a significant proportion of T2D patients do not reach the recommended LDL-C target. Elucidating the factors associated with lipid goal attainment represents an unmet clinical need.

Material and method

This is a retrospective, cross-sectional study based on data from the Annals of the Diabetes Medical Association (AMD) database, which includes the electronic medical records of 1.186.247 patients treated in various Italian diabetes clinics between 2005 and 2019. In this study, we used Rulex®, a type of Logic Learning Machine (LLM) approach to extract and classify the most relevant variables that could predict the achievement of an LDL-C value below 2.60 mmol/l within two years (defined as T2Y) from the time of lipid therapy prescription (T0).

Results

Overall, 11.252 patients (45.46% female) with T2D and dyslipidemia were evaluated. Stratification according to CV risk showed that, at T0, 97.7% of patients were at very high risk and 2.3% at high risk. At T0, 95.79% of patients were prescribed statins, and only 9.16% ezetimibe. The treatment goal at T2Y was achieved in 61.4% of cases. The LLM model was endowed with a precision of 69% and an accuracy of 67% (AUC-ROC: 0.775, $P<0.001$) to predict the attainment of LDL-C target. LDL-C values at T0 and six months later (T6M) exhibited the highest significance in this predictive model. Other predictors identified by LLM were: uninterrupted treatment between T0 and T2Y, higher HDL-C levels, younger age, anti-hypertensive drug administration, lower glycosylated hemoglobin levels, a higher Q-score, a lower BMI, lower micro-albuminuria levels and male gender. For each of the initial LDL-C ranges analyzed, the LLM also indicated the minimum reduction that should be achieved by T6M to increase the probability of reaching the therapeutic goal within T2Y, thus offering a new helpful tool to guide the physician's therapeutic attitude.

Conclusion

This is the first study describing the application of a LLM approach on real-world data to identify variables involved in lipid goal attainment. Our results suggest that a follow-up visit should be recommended within six months after the start of lipid therapy in all T2D patients. The present study also underscores the importance of initiatives to establish a more aggressive lipid management strategy for specific patient subgroups.

Establishing a regional registry for hyperosmolar hyperglycaemic state to share best practice: initial results and future implications

Emily Warmington[1], Wai Nga Alice Yip[1], Sophie Mounouchos[2], Lucy Bomphrey[3], Joseph Dalzell[4], Hari Panneerselvam[5], Jonathan Webber[6], Khetan Dhatariya[7], Punith Kempegowda[6] & DEKODE Working Group[8]
[1]University of Birmingham, College of Medical and Dental Sciences, Birmingham, United Kingdom; [2]The Dudley Group NHS Foundation Trust, Dudley, United Kingdom; [3]Walsall Manor Hospital, Walsall, United Kingdom; [4]Sandwell and West Birmingham Hospitals NHS Trust, Birmingham, United Kingdom; [5]The Wye Valley NHS Trust, Hereford, United Kingdom; [6]Queen Elizabeth Hospital, Birmingham, Birmingham, United Kingdom; [7]Norfolk and Norwich University Hospitals NHS Foundation Trust, Norwich, United Kingdom; [8]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom

Introduction

Hyperosmolar hyperglycaemic state (HHS) is an acute complication of diabetes which requires prompt recognition to prevent morbidity and death. Owing to its

low prevalence, clinicians report a lack of confidence in management, which may result in delayed diagnosis and worsened outcomes. The limited literature on HHS management means most guidelines are based solely on expert opinion, resulting in significant discrepancies between care in centres.
Aim
s: This study aimed to establish a registry of HHS cases in order to identify baseline HHS management, share best practices across hospitals and highlight areas for improvement.
Methods
The study retrospectively analysed patients with HHS from March 2021 to January 2023 across eight hospitals within the West Midlands. Cases were identified from patient notes using criteria from the Joint British Diabetes Societies (JBDS) HHS guidelines[1]: serum osmolality > 320 mOsmol/kg and glucose > 25 mmol/l. Osmolality was calculated using the formula [(2× sodium) + (2× potassium) + glucose + urea]. HHS resolution was documented as the earliest event of either serum osmolality falling below 300 mOsmol/kg, when fixed rate intravenous insulin infusion (FRIII) was stopped or when the team documented HHS resolution in the clinical notes. Patient demographics, precipitating cause of HHS and management regime were also collected. Data was analysed using SPSS and results presented as frequencies, median and interquartile range (IQR).
Results
68 cases of HHS were identified. 73.5% had the correct diagosis documented and just 42.6% had serum osmolality measured during stay. The most common causes of HHS were intercurrent illness (48.5%), sepsis (16.2%) and new diagnosis of diabetes (13.2%). Median serum osmolality at diagnosis was 352 mOsmol/kg (IQR: 334.63-375.07) and patients recieved a median of 6750 ml fluid (IQR: 4000-10500) until HHS resolution. 27.9% had FRIII commenced within the first hour of diagnosis and 51.8% were also given basal insulin. While the length of stay was similar for HHS across included hospitals, there was a significant difference in HHS duration between sites ($P < 0.001$).
Conclusion
These results suggest there is a need to improve awareness of HHS and the guidelines for its management amongst clinicians. By establishing a registry of HHS cases over several hospital trusts, best practices can be shared between healthcare professionals. Expanding the scope of this project to include other regions will allow uniform clinical care to be provided to HHS patients nationally.

A study of 512 diabetes-related ketoacidosis episodes shows no added risk or impact on outcomes during Ramadan: Results from DEKODE study

Punith Kempegowda[1,2], Lakshmi Rengarajan[1,2], Haaziq Sheikh[3], Vina Soran[4], Catherine Cooper[5], Parth Narendran[6], Wasim Hanif[2], Muhammad Ali Karamat[7], Ateeq Syed[7] & Team Dekode[1]
[1]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [2]Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; [3]Haberdashers' Adams Grammar School, Newport, England, United Kingdom; [4]University of Birmingham Medical School, Birmingham, United Kingdom; [5]Queen Charlotte's and Chelsea Hospital, London, United Kingdom; [6]University of Birmingham, Institute of Immunology and Immunotherapy, Birrmingham, United Kingdom; [7]Birmingham Heartlands Hospital, Department of Diabetes and Endocrinology, Birmingham, United Kingdom

Background
With increasing ethnic diversity in the Western World, it is important to establish the safety of religious practices such as fasting during Ramadan. There is limited information about severity and outcome of diabetes-related ketoacidosis (DKA) during Ramadan outside Middle East.
Objective
We studied differences in severity, DKA-related complications and outcomes of DKA before (Shaban), during (Ramadan) and after Ramadan (Shawwal).
Methods
All DKA events in Shaban, Ramadan and Shawwal from 2014 to 2022 at various tertiary and regional hospitals in the United Kingdom participating in the DEKODE (Digital Evaluation of Ketosis and Other Diabetes-related Emergencies) were included in this study. The diagnosis of DKA was defined as per the national guidelines. DKA parameters at presentation and during management, were investigated according to timing of DKA episode, diabetes type, and ethnicity. Data were analysed using Stata/SE V.16.1 for Mac. Data was found to be non-normally distributed using Shapiro-Wilk tests. Skewed data were presented as median and IQR. Discrete data were summarised as number (%) and statistical comparisons were made using chi-squared tests. These parameters were further investigated in subgroup analyses according to timing of DKA episode (before, during, and after the month of Ramadan), diabetes classification (type 1 and type 2), and ethnicity (Black, White, Asian, Mixed, Other).
Results
512 DKA episodes were identified for this study. Excluding urea and serum osmolality, there were no differences at presentation of DKA during Ramadan compared to Shaban and Shawwal. There was no significant difference in the outcome of DKA as measured by DKA duration (Shaban vs Ramadan vs Shawwal: 14.3 (8.9-24.4) vs 15.1 (9.5-22.8) vs 15.3 (9.6-23.2) hours, $P = 0.800$) and length of stay (Shaban vs Ramadan vs Shawwal: 3.6 (1.9-8.8) vs 4.1 (2.1-8) vs 4.1 (2.1-9.7), $P = 0.670$). Also, there was no significant difference in the number of hypoglycaemias, hypokalemia and hyperkalemia associated with DKA management during Shaban, Ramadan and Shawwal. Overall, there were no year-based differences between the years of 2014 to 2022. People with T1DM had higher acidosis and more hyperglycaemic events during Shawwal compared to T2DM. Across ethnicity, South Asians had more severe DKA in Ramadan compared to Shaban and Shawwal.
Conclusion
In the largest of its kind study in the Western world, we demonstrate no difference in DKA frequency during Ramadan. The increased severity of DKA during Shawwal, particularly in people with T1DM, suggests future guidelines should focus on the period following Ramadan to mitigate risk.

Copper-based therapeutics increase sodium/iodide symporter (NIS) transcription and enhance radioiodide uptake in thyroid cancer cells

Katie Brookes[1], Ling Zha[1], Jana Kim[2], Benjamin Small[3,4], Merve Kocbiyik[1], Selvambigai Manivannan[1], Vinodh Kannappan[3,4], Weiguang Wang[3,4], Kavitha Sunassee[2], Philip Blower[2], Hannah Nieto[1], Vicki Smith[1], Martin Read[1] & Christopher Mccabe[1]
[1]Institute of Metabolism and Systems Research, University of Birmingham, Birmingham, United Kingdom; [2]School of Biomedical Engineering & Imaging Sciences, King's College London, London, United Kingdom; [3]Research Institute in Healthcare Science, Faculty of Science and Engineering, University of Wolverhampton, Wolverhampton, United Kingdom; [4]Disulfican Ltd, University of Wolverhampton Science Park, Wolverhampton, United Kingdom

Introduction
New drug approaches are urgently required to improve radioiodide (RAI) uptake for efficient ablation of thyroid cancer cells in RAI-refractory disease. Employing high-throughput screening of FDA-approved compounds we recently identified drugs capable of robust induction of sodium iodide symporter (NIS) activity to promote RAI uptake[1]. In particular, a leading drug candidate – the well-established anti-alcoholism drug disulfiram (DSF) – had not been previously implicated in regulating NIS. A better understanding of how DSF can be used to modulate NIS function *in vivo* is now needed prior to clinical evaluation.
Materials and Methods
NIS function was monitored *in vitro* by RAI (^{125}I) uptake assays, and NIS expression via Western blotting and TaqMan-RTPCR. Technetium-99m pertechnetate (^{99m}Tc) uptake was used to evaluate NIS function in Balb/c mice following intravenous administration.
Results
We demonstrate that the ability of DSF to increase RAI-uptake in thyroid TPC-1 (3.1-fold; $P < 0.01$) and 8505C (4.9-fold; $P < 0.001$) cells can be significantly potentiated by combination with Cu^{2+} to 5.1-fold and 18.9-fold increases respectively. Despite promising data, DSF has poor bioavailability *in vivo* due to its rapid metabolism to diethyldithiocarbamate (DDC) within the stomach and circulation with subsequent methylation in the liver. Whilst methylated DDC did not have any effect on NIS function, DDC chelated to divalent copper ions [$Cu(DDC)_2$] was highly effective at increasing RAI uptake (up to 8-fold; $P < 0.001$) in multiple thyroid cell types and induced significant NIS protein expression (up to 36.2-fold; 250 nM; $P < 0.001$). Interestingly, a transcriptional effect of $Cu(DDC)_2$ was revealed via significant induction of NIS mRNA levels in TPC-1 (8.5-fold; $P < 0.001$) and 8505C (104.8-fold; $P < 0.001$) cells. In wild-type Balb/c mice the intraperitoneal administration of albumin nano-encapsulated

$Cu(DDC)_2$ significantly induced thyroidal uptake of technetium-99m (^{99m}Tc) after 30 min (~40% increase; $n=11$ per group; 3 mg/kg dose; $P<0.001$), as well as increasing thyroidal mRNA levels of NIS (1.9-fold; $P<0.01$), thyroid peroxidase (1.8-fold; $P<0.001$) and thyroglobulin (1.3-fold; $P<0.05$). Importantly, a significant positive correlation between thyroidal ^{99m}Tc uptake and higher NIS mRNA levels ($r_s=0.4477$, $P=0.0169$) was apparent in $Cu(DDC)_2$-treated mice. Additionally, thyroidal ^{99m}Tc-uptake ($P<0.05$) and NIS expression ($P<0.05$) were induced following intravenous administration of albumin nano-encapsulated $Cu(DDC)_2$ (~30%; $n=5$; 5 mg/kg dose).

Discussion

Our study demonstrates a promising drug strategy utilising a disulfiram metabolite to enhance NIS function *in vivo*, with clinical potential to improve treatment effectiveness in RAI-refractory thyroid cancer patients.

Introduction

Polycystic ovary syndrome affects 10% of women and comes with a 2-3fold increased risk of type 2 diabetes, hypertension, and fatty liver disease. Androgen excess, a cardinal feature of PCOS, has been implicated as a major contributor to metabolic risk. Adrenal-derived 11-oxygenated androgens represent an important component of PCOS-related androgen excess and are preferentially activated in adipose tissue. We aimed to identify PCOS sub-types with distinct androgen profiles and compare their cardiometabolic risk parameters.

Methods

We cross-sectionally studied 488 treatment-naïve women with PCOS diagnosed according to Rotterdam criteria [median age 28 (IQR 24-32) years; BMI 27.5 (22.4-34.6) kg/m^2] prospectively recruited at eight centres in the UK & Ireland ($n=208$), Austria ($n=242$) and Brazil ($n=38$). All participants underwent a standardised assessment including clinical history, anthropometric measurements, fasting bloods and a 2-hour oral glucose tolerance test. We quantified 11 androgenic serum steroids, including classic and 11-oxygenated androgens, using a validated multi-steroid profiling tandem mass spectrometry assay. We measured serum insulin to calculate HOMA-IR and the Matsuda insulin sensitivity index (ISI). Steroid data were analysed by unsupervised k-means clustering, followed by statistical analysis of differences in clinical phenotype and metabolic parameters.

Results

Machine learning analysis identified three stable subgroups of women with PCOS with minimal overlap and distinct steroid metabolomes: a cluster characterised by mainly gonadal-derived androgen excess (testosterone, dihydrotestosterone; GAE cluster; 21.5% of women), a cluster with predominantly adrenal-derived androgen excess (11-oxygenated androgens; AAE cluster; 21.7%), and a cluster with comparably mild androgen excess (MAE cluster; 56.8%). Age and BMI were similar between groups. As compared to GAE and MAE, the AAE cluster had the highest rates of hirsutism (76.4% vs 67.6% vs 59.9%) and female pattern hair loss (32.1% vs 14.3% vs 21.7%). The AAE cluster had significantly increased insulin resistance as indicated by higher values for fasting insulin,120 min insulin and HOMA-IR, and lower ISI than GAE and MAE clusters (all $P<0.01$). The AAE cluster also had a 2-3fold higher prevalence of impaired glucose tolerance and newly diagnosed type 2 diabetes.

Conclusion

Unsupervised cluster analysis revealed three PCOS subtypes with distinct androgen excess profiles. Women within the adrenal androgen excess cluster had a significantly higher prevalence of insulin resistance, impaired glucose tolerance and type 2 diabetes. These results implicate 11-oxygenated androgens as major drivers of metabolic risk in PCOS and provide proof-of-principle for an androgen-based stratification tool that could guide future preventative and therapeutic strategies in women with PCOS.

Effects of semaglutide, PYY3-36, antagonists of the GLP-1/NPY-Y2 receptors, and empagliflozin on non-alcoholic fatty liver disease

Niklas Haerting[1], Gloria Herzog[2], Alexander Nickel[3], Michael Kohlhaas[3], Martin Fassnacht[1,3], Christian Ziegler[1,4] & Ulrich Dischinger[1,3]

[1]University Hospital Würzburg, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]University of Würzburg, Institute of Pathology, Würzburg, Germany; [3]University Hospital Würzburg, Comprehensive Heart Failure Center, Würzburg, Germany; [4]University Hospital Carl Gustav Carus, Department of Internal Medicine III, Dresden, Germany

Background

Non-alcoholic fatty liver disease (NAFLD) is a common comorbidity in obese individuals. GLP-1 agonists, such as semaglutide, and SGLT-2 inhibitors, such as empagliflozin, are well known to be beneficial in NAFLD, while other incretins, like peptide tyrosine tyrosine 3-36 (PYY3-36), might be also useful for the treatment of NAFLD. We directly compared the effects of semaglutide alone and in combination with peptide tyrosine tyrosine 3-36 (PYY3-36), empagliflozin and semaglutide + empagliflozin as well as antagonists of GLP-1 and PYY on liver health.

Methods

High-fat diet (HFD)-induced obese male Wistar rats ($n=55$; mean weight 262 g) were randomized into the following treatment groups: semaglutide, semaglutide + PYY3-36, empagliflozin, semaglutide + empagliflozin, JNJ-31020028 (NPY-Y2 receptor antagonist), JNJ-31020028 + exendin 9-39 (GLP-1 antagonist), and saline. Animals had free access to high- and low-fat diet. Body weight and food preference were measured on a daily basis. After an observation period of 8 weeks, liver samples were histologically evaluated (modified Kleiner steatosis score for rodents, higher scores indicating higher grades of steatosis).

Results

Semaglutide and more pronounced semaglutide + PYY3-36 treatment led to weight loss, reduced overall food intake and (less pronounced) reduced high-fat preference compared to saline controls. Although less effective regarding food intake/body weight, semaglutide monotherapy revealed similar beneficial effects on the liver as semaglutide + PYY3-36, which had both antisteatotic effects (mean score 0.7 ± 1.2 for semaglutide alone and 0.2 ± 0.5 for the combination). Empaglifolzin had no effects on body weight and food preference, but was effective in reducing steatosis alone (mean score 0.8 ± 0.8) and more pronounced in combination with semaglutide (mean score 0.0 ± 0.0). JNJ-31020028, an antagonist of the NPY-Y2 receptor, and the combination of JNJ-31020028 and exendin 9-39 led to an increased high-fat diet preference and to the worsening of steatosis compared to saline treatment (mean score 2.3 ± 0.6 in both groups).

Conclusions
Semaglutide, semaglutide + PYY3-36 combination therapy, empagliflozin, and semaglutide + empagliflozin are highly effective in improving liver health. Interestingly, treatment with GLP-1 and PYY (NPY-Y2-R) antagonists led to the aggravation of hepatic steatosis. This underlines the potential of GLP-1 and PYY-36 agonists in the treatment of obesity and related NAFLD. The positive effects of empagliflozin on liver health, however, seem to be independent of body weight and food preference. Further approaches will go for underlying mechanistical aspects.

Background
Medical treatment with cortisol-lowering drugs is commonly used following pituitary surgical failure or recurrence of hypercortisolism in patients with Cushing's disease (CD). Studies using late-night salivary cortisol (LNSF) measurement have shown persistent disruption of the circadian secretion of cortisol despite normalization of UFC in a subset of medically treated CD patients.Study aim Our objective was to assess the long-term cortisol exposure in CD patients medically treated using hair-cortisol (HF) and hair-cortisone (HE) measurement.
Study design
The Haircush multicenter prospective study included three groups (G) of females with a history of CD: G1 = 16 patients with normal UFCs following medical treatment with a stable drug dosage of osilodrostat, metyrapone, ketoconazole, pasireotide or cabergoline; G2 = 13 control patients in remission following pituitary surgery and with a normal pituitary-adrenal function; G3 = 15 control patients receiving stable recommended doses of hydrocortisone (15-25 mg/d) following bilateral adrenalectomy (BLA). Patients were evaluated during 3 months with their usual treatments. Two late-night saliva and 24 h urine samples were collected in G1 patients every month and only at the end of the study end in G2 and G3 patients. A clinical examination and 3-cm hair sample was collected at the end of the study in all patients. The outcome measures were a clinical Cushing's score and centralized measurements of HE, HF, LNSF and late-night salivary cortisone (LNSE), and UFC using LC – MS/MS.
Results
Despite having almost all UFCs within the normal range, G1 patients had increased HE concentrations as compared to G2 controls ($P = 0.003$). G1 patients also had increased clinical score ($P = 0.001$), UFC ($P = 0.03$), LNSF and LNSE ($P = 0.0001$) and increased variability in the latter parameters ($P = 0.004$). G3 patients with BLA had increased HF ($P = 0.002$) and HE (p = 0.003) compared to G2 controls contrasting with similar LNSE. Six of the 15 G1 patients exhibited increased HE concentrations above the range of G2 controls and had increased requirement of antihypertensive drugs compared to G1 patients with normal HE ($P = 0.05$).
Conclusion
A single HE measurement identifies chronic mild persistent hypercortisolism in a subset of medically-treated CD patients despite normalized UFCs. Persistent hypercortisolism was at least partly due to an altered circadian rhythm of free serum cortisol. HE could replace multiple saliva and urine analysis to assess the control of hypercortisolism in medically treated CD patients once UFC is normalized. Our results also suggest that patients treated with BLA should receive lower hydrocortisone dosage than that usually prescribed.

Calcium and vitamin D supplementation in rats with sulpiride-induced hyperprolactinemia

Danijela Radojkovic[1], Milica Pesic[1], Vojislav Ćirić[1], Saša Radenković[1] & Milan Radojkovic[1]
[1]Medical Faculty, University Nis, Serbia, Nis, Serbia

Background
Hyperprolactinemia, caused by chronic use of antipsychotics, is associated with impaired bone density and increased risk of fractures. We examined if calcium and vitamin D supplementation have influence on Prlr gene expression in the duodenum, vertebrae and kidneys in female rats with sulpiride-induced hyperprolactinemia.
Methods
Wistar female rats 21 weeks old were divided into: Group S: 10 rats that were intramuscular administrated Sulpiride (10 mg/kg) twice daily for 6 weeks; Group D: 10 rats that were administrated Sulpiride (10 mg/kg) twice daily for 6 weeks, calcium 50 mg daily and vitamin D 500 IU per day for last 3 weeks; and age matched nulliparous rats as a control group: 7 rats, 21 weeks old (C). Laboratory analysis included measurements of serum ionized calcium, phosphorus, urinary calcium and phosphorous excretion, osteocalcin (OC), vitamin D, and prolactin. Relative quantification of prolactin receptor (*Prlr*) gene expression in duodenum, vertebrae and kidneys was determined using real-time PCR.
Results
PRL concentrations were significantly higher in group S and D, compared to C ($P < 0.001$). Ionized calcium was significantly increased in the group S compared to C ($P < 0.001$) and without significance between group D and C. Serum phosphorus was not significantly changed in S and D compared to C. Urinary calcium was decreased in group S compared to C but without significance and significantly increased in D compared to C ($P < 0.001$); urinary phosphorous was not significantly changed neither in S nor in D. OC was significantly decreased in group D compared to C ($P < 0.001$) and without significance between groups S and C. Expression of the Prlr gene was significantly lower in the duodenum ($P < 0.01$) and higher in vertebrae and kidneys in the sulpiride-induced hyperprolactinemia (S) than in the control group. Significantly higher Prlr expression in the duodenum was verified ($P < 0.01$), along with increased Prlr gene expression in vertebrae and kidneys, in rats with sulpiride-induced hyperprolactinemia and calcium and vitamin D supplementation, than in the C group.
Conclusions
In sulpiride-induced hyperprolactinemia, down-regulation of Prlr gene expression in duodenum could be underlying reason for diminished intestinal calcium absorption. In order to maintain calcium homeostasis, since intestinal absorption is compromised, prolactin will rapidly take calcium from skeletal system, thanks to increased Prlr gene expression in the vertebra. Calcium and vitamin D supplementation in the sulpiride-induced hyperprolactinemia significantly increased Prlr gene expression in duodenum which could improve intestinal calcium absorption and reduce the harmful effect on the bone system.

Assessment of clinical and histopathological predictors for remission after transsphenoidal surgery for acromegaly

Mark Postma[1], Henriëtte Westerlaan[2], Annet Willems[1], Anke van den Beukel[1], Jos Kuijlen[3], Rob Vergeer[3], Melanie van der Klauw[1], Wilfred den Dunnen[4] & André van Beek[1]
[1]University Medical Center Groningen, Endocrinology, Groningen, Netherlands; [2]University Medical Center Groningen, Radiology, Medical Imaging Center, Groningen, Netherlands; [3]University Medical Center Groningen, Neurosurgery, Groningen, Netherlands; [4]University Medical Center Groningen, Pathology and Medical Biology, Groningen, Netherlands

Background
Transsphenoidal surgery (TSS) is the primary treatment of choice in acromegaly. Previous research succeeded to some extent in predicting remission after TSS. However, it was based mainly on clinical and radiological data, lacking histopathological evaluation.
Objective
To produce a clinicopathological prediction model for remission after TSS for acromegaly, enabling clinicians to better inform patients on expected treatment outcome.
Design
Single-center study with retrospective data collection on patients with acromegaly in a large tertiary referral center in The Netherlands. Overall, 100 patients with acromegaly in whom TSS was performed as primary therapy between January 2000 and July 2019 were included.
Methods
Data were collected on sex, age, biochemistry (IGF1, GH nadir during OGTT, random GH) at diagnosis, 3 months to 1 year postoperatively and at last visit, use of preoperative medication, applied postoperative treatment (repeated surgery, radiotherapy and medical therapy), tumour subtype according to the WHO 2017 classification and proliferation markers (Ki-67, p53 and mitotic index). All available diagnostic and first postoperative MRI's were reassessed by an

experienced neuroradiologist and classified according to the Knosp classification. In addition, tumour volume (cm3), maximum tumour diameter (mm) and T2-weighted MRI signal were determined. Uni- and multivariate regression models were used to identify predictors of early biochemical remission (12 weeks to 1 year postoperatively) according to the consensus criteria and long-term remission (age- and sex-normalized IGF1, absence of postoperative treatment until last follow-up and absence of a tumour remnant on postoperative MRI).
Results
Median duration of follow-up was 11.8 years from diagnosis and 11.1 years from surgery. Forty-six (46.5%) patients were found to be in early biochemical remission, forty-one (42.7%) were in long-term remission. In univariate logistic regression larger tumour volume (odds ratio [OR] 0.86, $P=0.023$), larger maximum tumour diameter (OR 0.85, $P<0.001$), higher modified Knosp classification grade (OR 0.44, $P<0.001$), presence of cavernous sinus invasion (OR 0.054, $P=0.006$) and higher random GH at diagnosis (OR 0.98, $P=0.008$) were significantly associated with lower remission rates. In multivariate logistic regression, a simple model with only maximum tumour diameter as independent variable predicted best for both early biochemical remission (OR 0.85, 95% CI 0.78-0.93, $P<0.001$, sensitivity 78.9%, specificity 71.8%) and long-term remission (OR 0.75, 95% CI 0.66-0.86, $P<0.001$, sensitivity 79.4%, specificity 78.0%).
Conclusion
maximum tumour diameter is the best predictor for remission after TSS for acromegaly in this single center cohort.

Androgen Receptor Binding by DDE at the BF3 Site Favors Release of Bound Dihydrotestosterone

Angel Tamez[1], Naila Bravo[2], Emily Garcia[2], Frank Dean[2], Jeffrey Evanseck[1] & Evangelia Kotsikorou[2]
[1]Duquesne University, Chemistry and Biochemistry, Pittsburgh, United States; [2]The University of Texas Rio Grande Valley, Chemistry, Edinburg, United States

The androgen receptor (AR) function is inhibited by endocrine disrupting chemicals (EDCs) such as DDT and DDE leading to problems in embryonic development and negative health outcomes for adults. EDCs may bind in the steroid binding pocket and disrupt AR function by leading to altered receptor conformations. However, this may not be the only way EDCs interfere with the receptor. Estébanez-Perpiñá et al identified binding function 3 (BF3) as a surface binding site for small hydrophobic compounds that disrupted AR activity. We found that DDT, DDE, and related compounds induced the release of bound dihydrotestosterone (DHT) from the AR ligand binding domain with IC50 values ranging from 54 to 82 μM. In addition, mutant AR genes with single amino acid changes in the BF3 site showed a reduced sensitivity for the ability of DDE to disrupt AR activity *in vivo* using a reporter assay. These results suggested that DDE interacts with the BF3 site and allosterically regulates AR activity. We used molecular dynamics (MD) simulations methods to test whether DDE bound to BF3 induces allosteric changes in the AR structure, altering the dynamic behavior of AR with bound steroid. Accelerated MD simulations identified possible exit pathways for DHT and steered MD simulations showed that the free energy of steroid unbinding was decreased for the exit pathways studied when DDE was bound in the BF3 site. These results suggested that AR dynamics are impacted by DDE interacting with the BF3 site, destabilizing the steroid in its binding pocket and reducing the energy required for steroid release, thus disrupting AR function.

Effect of circadian disruption on the hypothalamic control of reproduction in female mice

Simonneaux Marine[1], Kretz Mathilda[2], Bahougne Thibault[3], Simonneaux Valérie[4] & Nathalie Jeandidier[3]
[1]INCI-CNRS UPR 3212, Equipe Rythmes Neuroendocriniens de la Reproduction, Strasbourg, France; [2]CHRU Strasbourg, Endocrinology, Diabetes, Nutrition, Strasbourg, France; [3]CHRU Strasbourg/UdS, Endocrinology, Diabetes, Nutrition, Strasbourg, France; [4]INCI- CNRS UPR3212, Equipe Rythmes Neuroendocriniens de la Reproduction, Strasbourg, France

In female mammals, the timing of the preovulatory LH surge depends on the combination of the positive estrogen feedback and a circadian signal which synchronizes the LH surge with the transition between the resting and active period at the end of the follicular phase, when arousal is maximal. Previous results have demonstrated that a functional biological clock, located in the suprachiasmatic nucleus (SCN), is required for optimal female fertility. In this context, we have investigated the consequences a chronodisruptive environment could have on the female mammals' gonadotropic axis using a female mouse model of shiftwork. This is a relevant issue since an increasing number of women are working in non-standard work schedules in our modern 24 h/7 d society, and shift work is associated with reproductive deficits. Adult female mice were either kept in regular light/dark schedules or exposed to a model of shift work conditions (3 weeks rotation a 10-hour phase advance for three days and a 10-hour phase delay for four days). Daily rhythms in SCN vasopressin-containing neurons, kisspeptin neurons, LH secretion on the day of proestrus, as well as fertility parameters, were compared between both groups of mice. The chronodisruptive protocol reduces the number of the vasopressin neurons known to transmit the daily information to the kisspeptin neurons, abolished activation of kisspeptin neurons typically observed at the light/dark transition, and reduced the amplitude and altered the timing of the preovulatory LH surge. Furthermore, when female mice exposed to chronic shift are mated with a male, the number of gestation is reduced as compared to those observed in control female mice. Our results indicate that chronic shift desynchronizes the hypothalamic-pituitary-ovarian axis. Notably, chronic exposure to disrupted light/dark cycles impairs the vasopressin-induced daily activation of kisspeptin neurons which can explain the altered LH secretion and the reduced fertility in female mice. In future experiments, we will investigate whether peripheral clocks within the gonadotropic axis are also altered by chronic shift. Altogether, these experiments will provide a better understanding of circadian disruption's potential on the daily reproductive rhythms of female mammals.

Effects of perinatal tributyltin exposure in Wistar rats on body parameters, insulin, leptin, milk composition and ultrastructure of the pancreatic islets in dams and offspring

Rosiane Aparecida Miranda[1], Cherley Borba Vieira de Andrade[2], Egberto Gaspar de Moura[3] & Patricia Cristina Lisboa[3]
[1]State University of Rio de Janeiro, Physiology, Rio de Janeiro, Brazil; [2]State University of Rio de Janeiro, Histology and Embriology, Rio de Janeiro, Brazil; [1]State University of Rio de Janeiro, Physiology, Rio de Janeiro, Brazil

Tributyltin (TBT) is a biocide organotin compound widely used as an antifouling in boat paints. This substance is a factor of contamination to water and food, especially marine fish. As an endocrine disruptor, TBT can interact with hormonal pathways and can induce gonadal dysfunction and glycemic dyshomeostasis; however, the effects caused by maternal exposure to TBT are scarce. Here, we investigate maternal exposure to low dose of TBT, considered safe, during pregnancy and lactation on the metabolism of dams as well as male and female offspring. For this, pregnant Wistar rats were exposed on the 7th day of gestation until weaning (21st day of lactation) by gavage to vehicle (0.1% ethanol, Control group) or TBT (100 ng/kg of body weight, bw, TBT group). Morphometric parameters, milk composition and plasma hormone profile from dams and offspring at birth and weaning were evaluated. Analyses of the fragments of pancreas were performed by Transmission Electron Microscopy (TEM) at weaning. Ethical protocol: CEUA/010/2019. Student t test was used to statistical analyses ($n=8$/group). In dams, TBT exposure increased the body fat at the end of pregnancy ($+38\%$, $P=0.007$). In the milk, total protein and cholesterol contents were increased ($+18\%$, $P=0.03$ and $+73\%$, $P=0.01$, respectively), lactose was reduced (-30%, $P=0.03$), but insulin and leptin was unaltered at weaning. Regarding the offspring, females had reduced bw and nasoanal length at birth (-8%; $P=0.003$; -10%; $P<0.0001$, respectively), while the males did not show changes of these parameters. Offspring from both sexes have delayed eye opening during development. Only female offspring showed decreased plasma insulin and leptin levels at weaning (-43%; $P=0.03$; -45%; $P=0.04$, respectively). The pancreatic islets of dams and offspring from both sexes showed few preserved mitochondria, many granules with crystallized insulin scattered throughout the cytoplasm and endoplasmic reticulum with dilated cistern regions, indicating a reticulum stress process. The amount of our data evidence that tributyltin exposure during gestation and lactation alters insulin and leptin levels of female offspring and causes pancreas impairment in dams and offspring from both sexes at weaning. Thus maternal TBT exposure at a low dose affects mothers and offspring suggesting the development of future chronic diseases, as diabetes mellitus.

Micronutrient deficiency screening in obese patients

Berriche Olfa[1], Rahma Khalaf[1], Nadia Ben Amor[1], Rym Ben Othman[1], Amel Gamoudi[1], Awatef Kacem[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition , Department A , Tunis, Tunisia

Background and Aim
A direct link between obesity and micronutrient deficiencies has been established. These nutritional dificencies are mainly caused by poor-quality diets but also due to increased demands and have been associated with a wide range of physiological and functional impairments. The aim of this study was to assess the nutritional status of obese patients and to investigate the possible association between funnctional disorders and micronutrient intake.
Methods
This is a cross-sectional descriptive study including 50 obese patients.Dietary intake was assessed by trained nutritionists using a 24-hour recall method. Functional disorders were detected by the Screening of Micronutrient Deficiency (DDM) questionnaire validated by the European Institute of Dietetics and Micronutrition (IEDM) that evaluates mood, gastro-intestinal, osteoarticular, infectious, skin and circulatory disorders. Statistical associations between the questionnaire's results and dietary intake were assessed using the SPSS 25.0 version.
Results
Mean age was 41, 54 ± 12, 48 years with female predominance (88%). Mean BMI was 40.33 ± 6.39 kg/m^2. Vitamin A, D, C, and B6 deficiency was noted in 74%, 100%, 96% and 68% of cases, respectively. Magnesium, iron, zinc, copper, and selenium deficiency was noted in 82%, 6%, 24%, 22% and 8% of cases, respectively. There were a significant and negative association between fatigue, mood disorders and vitamin B6 and magnesium intake ($r = -0.485$; $P < 0.01$ and $r = -0.292$; $P = 0.039$, respectively), osteoarticular and degenerative disorders and vitamin A intake ($r = -0.297$; $P = 0.036$), infectious disorders and vitamin C, selenium and iron intake ($r = -0.368$; $P = 0.09$, $r = -0.336$; $P = 0.017$ and $r = -0.292$; $P = 0.04$, respectively), skin diseases and beta-carotene intake ($r = -0.344$; $P = 0.014$) and circulatory system diseases and vitamin B9 intake ($r = -0.394$; $P = 0.005$). Gastrointestinal disorders were not significantly associated with dietary intake.
Conclusion
Evaluating micronutriment deficiencies is an important step in identifying the underlying cause of many chronic symptoms and conditions in obese patients in order to improve their treatment and quality of life.

Pregnant women in the Faroe Islands are iodine depleted

Herborg Líggjasardóttir Johannesen[1,2], Stig Andersen[3,4] & Anna Sofía Veyhe[2,5]
[1]National Hospital of the Faroe Islands, Tórshavn, Faroe Islands; [2]Center of Health Science, University of the Faroe Islands, Torshavn, Faroe Islands; [3]Department of Clinical Medicine, Aalborg University, Aalborg, Denmark; [4]Arctic Health Research Centre, Aalborg University Hospital, Aalborg, Denmark; [5]Department of Occupational Medicine and Public Health, The Faroese Hospital System, Tórshavn, Faroe Islands

Introduction
Iodine deficiency is a significant global health issue of various severity depending on the age of the deficiency. The foetal period is the most critical stage in life, negatively impacting the brain and neurodevelopment. Hence, the developing foetus is a crucial issue, and the present study focussed on iodine nutrition among pregnant women from the Faroe Islands. The need for iodine increases in pregnancy, and the recommended target for median urinary iodine concentration is 150-250 µg/l.Method: We recruited 630 participants in a nationwide, cross-sectional study of pregnant women. They were primarily Caucasian women referred to routine obstetric ultrasound from 2020 through 2022 in gestational week 18. Participants donated a spot urine sample and completed an iodine-specific questionnaire. Iodine was determined using the Sandell-Kolthoff reaction modified according to Wilson and van Zyl.
Results
The participation rate was 70%. The overall median urinary concentration was 110 µg/l for the two years of collecting data. Interestingly, the median UIC decreased from 121 µg/l during the first year of inclusion to 96 µg/l during the second year ($P < 0.01$). Conversely, the number of samples in the excessive range decreased from 9.1% to 3.6% ($P < 0.001$). Dietary data are underway.
Conclusion
The marked change over time raises concerns about the validity of cross-sectional studies of iodine nutrition with short-term data collection. The time trend may have several explanations, including a change in the intake of local foods rich in iodine, which needs follow-up. Finally, according to the WHO recommendations, our nationwide study demonstrated that Faroese pregnant women were iodine depleted.

OC12.6

Effects of perinatal exposure to endocrine-disrupting chemical Tetrabromobisphenol A on neurodevelopment in mice

YongIn Kim[1], KangMin Kim[1] & Eui-Bae Jeung[1]
[1]Chungbuk National University, Laboratory of Veterinary Biochemistry and Molecular Biology, College of Veterinary Medicine, Cheongju-si, Chungcheongbuk-do, South Korea

Tetrabromobisphenol A (TBBPA) is a brominated flame retardant and is widely used in electronic goods, plastics and furniture. TBBPA is frequently detected in water, soil, organisms and even in human breast milk. It is accessible to both the developing fetus and the nursing pups following maternal exposure. Though some regulatory agencies have asserted that consumer exposures to TBBPA are unlikely to have adverse implications for human health, the safety of TBBPA has been questioned. Reported evidence of endocrine-disruption of TBBPA in brain has raised concerns regarding its effects on neurodevelopment and behavioral functions. The present study examined the effects of exposure to TBBPA on neurodevelopment. The Developmental Neurotoxicity Test(DNT) was performed to determine whether TBBPA is a developmental neurotoxicant. Additionally, maternal mice were administered 0, 0.24 and 2.4 mg/kg TBBPA. Mice offspring underwent behavior tests for assessment of locomotor, depressive, compulsive, cognitive, and social behaviors. Gene expression pattern change at transcriptional level in the brain was investigated with real-time PCR. As a result, we classified TBBPA as a developmental neurotoxicant from the DNT. In addition, the TBBPA-treated mice offspring showed abnormalities in motor activity, compulsive-like behavior, social interaction patterns and spatial learning. Aberrant gene expression, such as acetylcholinesterase (AChE) and tyrosine hydroxylase (TH), were found in the perinatal TBBPA-treated mice offspring brain. To summarize, these findings suggest that perinatal exposure to TBBPA interferes with brain development and behavioral functions in mice. Therefore, it is necessary to pay more attention to the potential effects of TBBPA in the early development of brain.

Polychlorinated biphenyls (PCBs) modulate AHR pathways leading to the altered expression of genes involved in extra-cellular matrix (ECM) remodeling and epigenetic regulation in thyrocytes

Aurelio Minuti[1,2], Federica Aliquò[1], Fiorenza Giani[3], Martina Laganà[4], Marta Ragonese[4], Angela Avenoso[1], Salvatore Cannavò[4], Michele Scuruchi[5], Angela D'Ascola[5] & Rosaria Ruggeri[4]
[1]University of Messina, Dept Biomedical and Dental Sciences, and Morpho-Functional Images, Messina, Italy; [2]University of Messina, Deot Biomedical and Dental Sciences, and Morphofunctional Images, Messina, Italy; [3]University of Catania, Dept Clinical and Experimental Medicine, Catania, Italy; [4]University of Messina, Department of Human Pathology of Adulthood and Childhood DETEV, Messina, Italy; [5]University of Messina, Dept Clinical and Experimental Medicine, Messina, Italy

Background
PCBs are chemical pollutants able to promote inflammation and carcinogenesis. They can accumulate in human tissues through the food chain causing a variety of adverse health effects. The NF-E2 p45-related factor 2 (NRF2) and the aryl hydrocarbon receptor (AHR) are ligand activated transcription factors controlling pathways modulating xenobiotic metabolism. Increasing evidence indicate the involvement of AhR in regulating extracellular matrix (ECM) homeostasis. ECM is a complex network of multidomain macromolecules. Endothelial cell-specific molecule 1 (ESM-1), a soluble dermatan sulfate proteoglycan, also known as endocan, is up-regulated in different pathological conditions, including cancer, driving tumor progression, tumor vascularization and metastasis. In the landscape of non-coding RNAs, the long-non coding RNAs (>200 nucleotides) are a new class of epigenetic regulators that play a key role in homeostatic and pathological mechanisms, especially in cancer.Purpose. The present study was aimed at investigating the effects of dioxin-like pentachlorobiphenyls (PCBs) on aryl hydrocarbon receptor (AHR)/nuclear factor erythroid 2 – related factor 2 (NRF-2) pathway and related long noncoding RNAs (lncRNAs) and endothelial cell-specific molecule 1 (ESM-1) in thyrocytes.

Methods
Primary human thyrocytes were exposed to increasing doses (5 and 10 μM) of 2,3′,4,4′,5-pentachlorobiphenyl (PCB-118) and 3,3′,4′,4′,5 pentachlorobiphenyl (PCB-126) for 24 h. Cell culture and medium were collected to assess: mRNA levels of AHR, NRF-2, CYP1A1, lncRNAs (HOTAIR, MALAT-1, MEG-3), ESM-1, metalloproteinases (MMP) -3, MMP-9 and IL-1β by qPCR; protein levels of AHR and ESM-1 by western blot and ELISA, and ROS production by a commercial kit.
Results
Treatment with PCB-126 and PCB-118 at both doses after 24 h significantly increased mRNA levels of AHR, NRF-2, CYP1A1, MMP-3, MMP-9, IL-1β and intracellular ROS accumulation. Furthermore, PCBs, especially PCB-118, enhanced ESM-1, HOTAIR and MALAT-1 expression and reduced MEG-3 mRNA levels. Furthermore, AHR and ESM-1 protein levels increased after PCB-126 and PCB-118 exposure at both concentrations in a dose dependent manner.
Discussion
Our data demonstrated that PCB-118 and PCB-126 may induce AHR/NRF-2 pathway activation with a consequent ROS production and inflammatory responses in thyrocytes. This condition led to an increase in ESM-1, a circulating proteoglycan involved in angiogenesis and overexpressed in several tumors, and MMP-3 and MMP-9 that cause ECM remodeling. Furthermore, PCBs can induce epigenetic modifications by increasing lncRNAs MALAT-1 and HOTAIR expression and reduce anti-oncogenic lncRNA MEG3.
Conclusion
These results suggest new mechanisms underlying toxic effects of PCBs exposure on thyrocytes, indicating ESM-1 and lncRNAs as putative key factors of thyroid tumorigenesis.

Bisphenols in adrenocortical cell culture: Further evidence for the relevance of endocrine disruptive chemicals for adrenal gland functionality

Benedikt Pötzl[1], Lydia Kuerzinger[1], Sabine Kendl[1,2], Martin Fassnacht[1], Max Kurlbaum[1] & Ulrich Dischinger[1]

[1]University Hospital Würzburg, Division of Endocrinology and Diabetes, Department of Internal Medicine I, Würzburg, Germany; [2]University Hospital Würzburg, Central Laboratory, Core Unit Clinical Mass Spectrometry, Würzburg, Germany

Background
Bisphenol A (BPA) is known to act as an endocrine disruptor in different organs. However, its impact on adrenal gland functionality is largely unknown. This also applies to its substitute substances bisphenol F (BPF) and S (BPS). Therefore, experiments addressing this subject are urgently needed.
Methods
The human adrenocortical cell lines NCI-H295R and MUC-1 were treated with increasing concentrations (1 nM – 1 mM) of bisphenol A, F, and S. Concentrations of fifteen adrenal steroids in cell supernatants were measured via liquid-chromatography-tandem-mass spectrometry (LC-MS/MS) after different periods of exposure (24 h, 72 h). Cell viability was monitored to assess cytotoxicity.
Results
All tested bisphenols inhibit steroid production significantly compared to untreated cells in a dose- and time-dependent manner in both cell lines: in the NCI-H295R hormone levels of 11-deoxycortisol, testosterone, androstenedione, dihydrotestosterone and cortison were significantly decreased after 72 hours of exposure (at $>$ 100 μM BPA and BPF respectively, $P<0.05$). For instance, 100 μM BPA treatment resulted in a 0.29-fold decrease of testosterone, and a 0.43-fold decrease of cortison. Interestingly, BPA and BPF showed ambiguous effects on some parameters, e.g. a 0.39-fold decrease of progesterone was detected in 100 μM BPA, while BPF led to a 26-fold increase. Furthermore, we found an increased level of estradiol, 21-deoxycortisol and 17-hydroxyprogesterone in BPF-treated cells ($P<0.05$). The same experiments are currently performed for BPS. At large, reported effects were confirmed in MUC-1 cells, which seem to be more resilient against tested bisphenols. In this sense, calculated median lethal doses (LD50) were: BPA 110.1 μM, BPS 229.4 μM, BPF 344.5 μM for NCI-H295R and BPA 279.4 μM BPF 356.8 μM and BPS 1.31 mM for MUC-1.
Conclusions
Our results provide further evidence that bisphenol A, F, and S act as disruptors of steroidogenesis and steroid secretion. Underlying mechanisms and pathways are still widely unknown. This reinforces the need for further research efforts focusing on EDCs' effects on the adrenal gland.

Increased risk of erythrocytosis in men with type 2 diabetes treated with combined sodium-glucose cotransporter-2 inhibitor and testosterone replacement therapy

Aidar Gosmanov[1,2] & Darren Gemoets[3]
[1]Albany Stratton VA Medical Center, Medicine/Endocrinology, Albany, United States; [2]Albany Medical College, Medicine/Endocrinology, Albany, United States; [3]Albany Stratton VA Medical Center, Research and Development, Albany, United States

Purpose of Study
Sodium-glucose cotransporter-2 inhibitors (SGLT-2i) and testosterone replacement therapy (TRT) can increase red blood cell production through different mechanisms. Little is known if combination therapy poses risk of erythrocytosis (ERY) in real world clinical practice.
Methods
This was a retrospective nationwide cohort study of US Veterans with type 2 diabetes (T2D) without prior history of ERY who were prescribed SGLT-2i and/or TRT between 3/2013 – 10/2022, had no missing medical records data, and had adequate adherence based on the proportion of days covered >80%. Patients were divided into 3 groups: SGLT-2i only, TRT only, or combination. Odds Ratio (OR) of new ERY defined as hematocrit (Hct) level>54% within 365 days of therapy initiation was calculated by logistic regression model adjusted for case-mix. This study was approved by the IRB of Stratton VAMC, Albany, NY.
Results
Baseline clinical and biochemical characteristics were well balanced among the groups except higher rate of uncontrolled T2D in the SGLT-2i group and lower obstructive sleep apnea (OSA) prevalence in the TRT group (Table). Of the entire cohort, total of 732 (1.4%) patients developed ERY. In models adjusted for baseline Hct, age, BMI, OSA, diuretic use, and smoking status, patients on combination therapy had significantly higher odds of ERY compared to those on SGLT-2i (OR 3.86, 95% CI (2.35 – 6.12)) or TRT alone (OR 2.05, 95% CI (1.29 – 3.09)). The unadjusted ORs were comparable as well. The odds of developing ERY in each group were independent of baseline Hct.
Conclusions
For the first time, we demonstrated that in large cohort of patients combined therapy with SGLT-2i and TRT is associated with increased ERY risk compared with either treatment alone. Given rising prevalence of SGLT-2i use, providers should consider periodic Hct assessment in persons receiving both SGLT-2i and TRT.

Utility of urinary metabolomic signatures to differentiate biopsy confirmed diabetic and non-diabetic kidney disease

Madhurima Basu[1,2], Sk Ramiz Islam[3], Pradip Mukhopadhyay[1], Sanghamitra Sengupta[4], Nitai Pada Bhattacharyya[1], Arpita Raychoudhury[5], Soumen Kanti Manna[3] & Sujoy Ghosh[1]
[1]Institute of Post Graduate Medical Education and Research, Department of Endocrinology and Metabolism, Kolkata, India; [2]IPGME&R, Endocrinology, Kolkata, India; [3]Saha Institute of Nuclear Physics (HBNI), Biophysics& Structural Genomics Division, Kolkata, India; [4]University of Calcutta, Department of Biochemistry, Kolkata, India; [5]Institute of Post Graduate Medical Education and Research, Department of Nephrology, Kolkata, India

Background
Renal involvement in T2DM can be due to diabetes per se (Diabetic Kidney Disease) or causes other than diabetes (non-diabetic kidney disease). Currently available clinical, biochemical, and radiological markers fail to differentiate DKD from NDKD. Renal biopsy remains gold standard for diagnosis. Urinary signatures may provide a non-invasive alternative to that end. In cell culture and in animal models with diabetes and kidney disease, dysregulation of several metabolites has been reported. This has not been explored in humans with biopsy-proven kidney disease DKD and NDKD subjects.
Aims
To identify the expression of urinary metabolic signatures as putative marker for differentiation of biopsy-confirmed DKD and NDKD subjects.
Methods
Consecutive patient with renal involvement (eGFR >30 ml/min/m^2 to <60 ml/min/m^2 and/or ACR>300 mg/ mg) were subjected to biopsy and classified as per ISN/RPS Classification. We also recruited subjects with T2DM without nephropathy (eGFR >60 ml/min/m^2 and ACR<30 mg/ mg) for comparison. Morning urine sample were collected for analysis by Gas Chromatography and mass spectrometry. Features were extracted and analysed using appropriate statistical method.
Results
We recruited first 110 subjects who agreed to undergo renal biopsy. Among those 110 subjects, 73 (66.4%) had DKD; 20 (18.2 %) had NDKD; and 17 (15.4 %) had mixed kidney disease. We included only those with pure DKD or NDKD and T2DM subjects without nephropathy for analysis of urinary metabolomics. Urinary metabolites (M1, M2, M3, M4) were found to be depleted in patients with kidney disease (both in DKD and NDKD as compared to T2DM ($P<0.004$, $P<0.006$, and $P<0.01$, <0.03 respectively). M5 was exclusively depleted in NDKD. Level of M6($P<0.01$), M7($P<0.03$) was increased and M8($P<0.05$), M9($P<0.03$), M10($P<0.02$) was decreased in DKD subjects. Analysis of fragmentation pattern indicated that theSemetabolites putatively belong to central carbon metabolism, fatty acid metabolism, purine metabolism in addition to metabolites exclusively of non-endogenous (microbial) origin.
Conclusion
Urinary metabolomics analysis may help to distinguish DKD and NDKD subjects. Our results warrant validation in another cohort.

RC1.3

Sex specific associations of serum selenium and selenoprotein P with type 2 diabetes mellitus and hypertension in the Berlin Aging Study II

Kamil Demircan[1], Sandra Hybsier[1], Thilo Samson Chillon[1], Valentin Max Vetter[2], Eddy Rijntjes[1], Elisabeth Steinhagen-Thiessen[2], Ilja Demuth[2] & Lutz Schomburg[1]
[1]Charité – Universitätsmedizin Berlin, Institute of Experimental Endocrinology, Berlin, Germany; [2]Charité – Universitätsmedizin Berlin, Department of Endocrinology and Metabolic Diseases (including Division of Lipid Metabolism), Biology of Aging working group, Berlin, Germany

Objective
The aim of this study was to investigate sex-specific associations of two established serum selenium biomarkers, i.e. total selenium and selenoprotein P with type 2 diabetes mellitus (T2D) and hypertension in a large cohort of older people.
Methods
1500 participants with available selenium measurements from the Berlin Aging Study II (BASE-II) were included in this study. In the serum samples, spectroscopy was used to quantify total selenium, and ELISA was used to measure selenoprotein P. T2D was diagnosed based on antidiabetic medication, self-reported T2D, or laboratory parameters. Hypertension was diagnosed based on self-report, blood pressure measurements, or anti-hypertensive medication. Dose-dependent associations were quantified applying multiple adjusted regression models.
Results
The median (interquartile range) age of the cohort was 68 (65,71) years, and 767 (51%) of the participants were women. 191 (13%) participants were diagnosed

Table.

Variable	All Patients(n=53075)	SGLT2i Only (n=11712)	TRT Only (n=40769)	Both (n=594)	Effect Size
Age, yrs (Mean±SD)	62.54 (9.26)	65.51 (8.67)	61.69 (9.25)	61.77 (8.80)	0.01
BMI, kg/m^2 (Mean±SD)	34.15 (6.59)	34.03 (6.19)	34.16 (6.70)	35.86 (6.16)	0.00
White Race,% (n)	74.2 (39379)	78.5 (9195)	72.9 (29728)	76.8 (456)	0.05
Black Race,% (n)	15.2 (8068)	12.1 (1413)	16.1 (6569)	14.5 (88)	0.05
Hematocrit,% (Mean±SD)	41.37 (4.02)	41.81 (3.78)	41.22 (4.08)	42.64 (3.61)	0.08
Hemoglobin A1c,% (Mean±SD)	7.49 (1.51)	8.54 (1.22)	7.18 (1.45)	8.31 (1.20)	0.04
OSA,% (n)	25.6 (13564)	37.3 (4371)	21.8 (8869)	54.5 (324)	0.16
Diuretic use,% (n)	39.5 (20945)	38.1 (4468)	39.8 (16243)	39.8 (234)	0.01

with T2D and 1126 (75%) were diagnosed with high blood pressure. Total selenium and selenoprotein P displayed a statistically significant, positive correlation (r= 0.59, $P< 0.001$), and both selenium and selenoprotein P were elevated in those with self-reported Se supplementation. In the whole cohort, selenium and selenoprotein P were not associated with T2D. In men, selenoprotein P displayed a positive association with T2D, and the odds ratio (OR) (95% confidence interval (CI)) for one unit (mg/dl) increase in selenoprotein P was 1.22 (1.00, 1.48). In the whole cohort, selenium was non-linearly associated with hypertension, and comparing to the lowest quartile (Q1), participants with higher selenium levels (Q3) had a lower OR (95% CI) of 0.66 (0.45, 0.96). In sex-specific analyses, this finding proved to be specific for men. Selenoprotein P was positively associated with hypertension, OR (95% CI) per one unit increase (mg/dl) was 1.15(1.01,1.32).

Conclusions

The noted independent and dose-dependent associations suggest a potential role of Se status in the risk of T2D and hypertension in older subjects, with differences in associations based on sex and the selenium biomarker assessed.

Angiotensin-converting enzyme in type II diabetes: effects of combined training on cardiovascular components and blood components

Andreia Matos[1,2,3], Ângela Gil[1,2], Isanete Alonso[1,4], João P. Magalhães[5], Ana Carolina Santos[1,2], Rogério Ribeiro[6], João F. Raposo[6], Luís B. Sardinha[5] & Manuel Bicho[1,2]

[1]Genetics Laboratory, Ecogenetics and Human Health, Instituto de Saúde Ambiental-ISAMB, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal; [2]Instituto de Investigação Científica Bento da Rocha Cabral, Lisbon, Portugal, 3i3S-Instituto de Investigação e Inovação em Saúde, Tumour and Microenvironment Interactions Group, University of Porto, Porto, Portugal; [4]Hospital St. Louis, Lisbon, Portugal; [5]Exercise and Health Laboratory, Interdisciplinary Centre for the Study of Human Performance, Faculty of Human Kinetics, University of Lisbon, Lisbon, Portugal; [6]Education and Research Center, APDP, Lisbon, Portugal

Objectives

The angiotensin-converting enzyme (*ACE1*) gene is one of the most studied genes in the pathogenesis of type II diabetes (T2DM) and cardiovascular disease. However, in the context of exerciSemodels in T2DM, they are not yet fully understood. We intended to characterize the genetic profile of individuals with T2DM from an inter-individual point of view using prognostic markers and cardiovascular risk. On the other hand, relate it with the profile obtained with the type of training: high-intensity intervals (HIIT) with resistance (RT); and moderate continuous (MCT) with RT.

Methods

Subjects with T2DM ($n=80$, 59 years old) underwent a 1-year randomized clinical trial (clinicaltrials.gov ID:NCT03144505) and were randomized into three groups (control, $n=27$; HIIT with RT, $n=25$; MCT with RT, $n=29$). Biochemical parameters were determined by ELISA or standard methods at baseline and after 1 year of follow-up. *ACE1* I/D genetic polymorphism was determined by PCR-RFLP.

Results

After 1 year, training had implications for c-peptide, insulin levels and basophil percentage in T2DM. Interestingly, although no differences were observed in the distribution of *ACE1* genotypes, we observed that *ACE1* DD (versus ID+II) individuals showed changes in VO2 max percentages, both in the initial phase of the study and after 12 months of training and follow-up. This finding may be related to a state of pseudo-hypoxia, due to aldosterone dysregulation and concomitant increase in sodium reabsorption in T2DM. When we used the Mendelian randomization model, that is, selecting the DD genotype of *ACE1*, we verified that individuals submitted to HIIT (versus control) presented alterations both in the percentage of monocytes, as in the mean of mean globular hemoglobin and mean corpuscular volume ($P<0.05$). On the other hand, in the same model, but for the MCT, we only verified that the DD individuals from *ACE1* presented alterations in the number of platelets at the end of the training period.

Conclusions

Some blood count components have been associated with cardiovascular risk in patients with T2DM. With this study, we observed a differential profile between patients with *DMII* in the cardiovascular component possible related with *ACE1* polymorphism.

Continuous subcutaneous insulin infusion (CSII) and growth in children with type 1 diabetes

Cátia Araújo[1], Inês Manique[2], Carla Baptista[1], Isabel Paiva[1], Alice Mirante[3], Joana Caetano[3], Rita Cardoso[3] & Isabel Dinis[3]

[1]Centro Hospitalar Universitário de Coimbra, Serviço de Endocrinologia, Diabetes e Metabolismo, Coimbra, Portugal; [2]Centro Hospitalar Universitário de Lisboa Central, Serviço de Endocrinologia, Lisboa, Portugal; [3]Centro Hospitalar Universitário de Coimbra, Unidade de Endocrinologia Pediátrica, Diabetes e Crescimento, Hospital Pediátrico de Coimbra, Coimbra, Portugal

Introduction

Type 1 diabetes (T1D) is the most frequent children's endocrinopathy in Portugal. The duration of the disease and metabolic control may affect the final height of pediatric patients. Despite the metabolic advantages of technological advances, such as continuous subcutaneous insulin perfusion (CSII), the effect on growth is unclear.

Aim

To assess the impact of T1D treatment, with multiple daily injections (MDI) or CSII, on growth.

Materials and methods

Retrospective study with T1D patients born between 1996 and 2004. Considering 2 therapeutic groups (MDI vs CSII), patients were evaluated regarding age and pubertal Tanner stage at diagnosis, duration of T1D, metabolic control, presence of other autoimmune diseases, height and standard deviation (SD) at diagnosis and at age 18 and Mid Parental Target Height (MPTH). To compare growth between groups, the difference between the height SD at 18 years and MPTH SD was used (DifSD).

Results

From 131 patients, 52.7% were males ($n=69$). The mean age at T1D diagnosis was 9.4 ± 4.3 years, mean disease duration was 8.6 ± 4.3 years and total HbA1c was $7.5\pm1\%$. MDI group included 73 patients and the CSII group 58 patients (> 6 months, mean time of 3.8 ± 2.6 years). At diagnosis, most were at Tanner Stage I on both groups (38 vs 46). Height SD at diagnosis was similar (0.18 ± 1.16 vs 0.17 ± 1, $P=0.91$). HbA1c was lower in the CSII group ($7.7\%\pm1.2$ vs $7.3\%\pm0.68$ $P=0.02$) as well as MPTH SD (-0.67 ± 0.8 vs -0.3 ± 0.9, $P=0.005$). Mean height SD at age 18 was not different between groups (-0.21 ± 0.98 vs -0.13 ± 0.96, $P=0.98$). One patient had short stature without pathological cause. DifSD was lower in the CSII group (0.5 ± 0.9 vs 0.17 ± 0.9, $P=0.02$) and was associated with age at diagnosis and duration of DM1. There was no association between DifSD and pubertal Tanner stage at diagnosis, HbA1c and the presence of other autoimmune diseases.

Conclusions

The height SD at 18 years was comparable with the population without DM1. Despite the limitations of HbA1c in assessing glycemic control, it was lower in the CSII group. Even though MPTH has been reached regardless of the treatment, the difSDS in the group with CSII was lower, suggesting further fulfillment of growth potential.

Emdocrinology and Metabolism, Istanbul, Turkey; [2]Istanbul University-Cerrahpasa; [3]Marmara University, Istanbul, Turkey; [4]Mef University, Istanbul, Turkey; [5]Istanbul University, Istanbul, Turkey; [6]Yildiz Technical University, Istanbul, Turkey

Background and objectives

Diabetes is estimated to affect more than half a billion people worldwide, of which approximately 9.5 million live in Turkey. Currently, glucoSemeasurements are made with invasive techniques (eg finger puncture or interstitial glucose sensors) that can negatively affect monitoring. In addition, since glucose results cannot be seen by physicians/nurses in real time, treatment decisions are delayed and diabetes control becomes difficult. As a group of researchers from the fields of medicine, engineering and informatics, we aimed to develop a non-invasive saliva glucose sensor and an integrated diabetes management system

Materials and methods
We developed disposable nanoelectromechanical (NEMS) biosensors, electronic equipments (potentiostat) and a software for integrated monitoring of diabetes.
Results
First, the triple electrode structure was coated with ZnO nanorods and glucose oxidase. After the biosensor properties were characterized, the produced sensor structure was packaged and made ready for clinical use. Sensor calibration and performance tests were performed in saliva with multiple tests. Using artificial saliva, It was shown that substances such as vitamin C, paracetamol, etc. in the environment did not cause interference in glucoSemeasurement. A lag time of approximately 10 minutes was found between the salivary glucose and capillary blood glucoSemeasurements (ie, the zero-minute salivary glucose level was found to be highly correlated with the capillary blood glucose level 10 minutes ago; r = 0.986, $P < 0.001$).
Conclusion
Within the scope of this project, we have developed a prototype system includes low-cost, disposable biosensors and a software to facilitate integrated diabetes management. Easy-to-implement and low cost such systems will increase patient comfort in diabetes management, improve quality of life and facilitate follow-up.

Increased risk of Graves' orbitopathy following Covid-19 vaccination
Ilaria Muller[1,2], Dario Consonni[1,2], Erica Crivicich[1], Francesco Di Marco[1], Nicola Currò[2] & Mario Salvi[2]
[1]University of Milan, Milano, Italy; [2]Policlinico of Milan, Milano, Italy

Background
Vaccination is a widely adopted measure against the severe-acute-respiratory-syndrome-coronavirus-2 (SARS-CoV-2) causing Covid-19 pandemic. Both SARS-CoV-2 infection and Covid-19 vaccines have been associated with several thyroid disorders. We studied the risk of Graves' orbitopathy (GO) following Covid-19 vaccination.
Methods
The study included 98 consecutive patients (71 females and 27 males, mean-age 50 years) attending our tertiary referral centre for new-onset ($n = 90$) or reactivation ($n = 8$) of GO occurred in the period Jan 2021 – Aug 2022, immediately following the extensive Covid-19 vaccination campaign launched in late 2020. GO was associated to Graves' disease in 91 (93%), euthyroidism in 5 (5%) and Hashimoto's thyroiditis in 2 (2%) patients. Family history for thyroid/autoimmune disorders was positive in 54 (55%) patients. We used a self-controlled-case-series study design, validated in assessing vaccine safety. For each vaccinated patient, we calculated person-days in time-windows after each dose, defined as "exposed" if GO onset/reactivation occurred 1-30 days after vaccination and "unexposed" if occurring outside such time-window. Poisson regression models were fitted to calculate incidence rate ratio (IRR) and 95% confidence-intervals (CI) of exposed vs unexposed. Sensitivity analyses were conducted considering only new-onset GO, gender, age, smoking, Covid-19 vaccine type and number of doses.
Results
Covid-19 vaccines were administered in 81 (83%) and never in 13 (13%) patients; data were missing in 4 patients. Of the 81 vaccinated subjects, 25 (31%) developed GO 1-30 days after vaccination (exposed) and 56 (69%) outside such time-window (unexposed). The overall IRR for GO was 3.12 (CI 1.94-5.02) and as high as 5.10 (CI 2.61-9.93) in patients below 50 years of age. Gender, smoking, Covid-19 vaccine type and number of doses did not significantly impact on the overall IRR, also when restricting the analysis to cases of new disease onset only. The GO severity was similar across the study subgroups. SARS-CoV-2 infection occurred in 23/98 (23%) patients during the study period and seemed not associated with GO.
Conclusions
This study shows a 3-fold increased risk of either developing or reactivating GO shortly after Covid-19 vaccination, rising-up to 5-fold in subjects of less than 50 years of age. Possible mechanisms involve the interaction of the spike protein with the widely expressed ACE-II receptor, cross-reactivity of the spike with thyroid self-proteins or immune reactions induced by adjuvants. Until more safety data about Covid-19 vaccines will be available, caution and strict monitoring of individuals undergoing vaccination is suggested, especially if young and prone to develop thyroid autoimmunity.

Overtreatment of differentiated thyroid cancer: impact on real world clinical practice of conservative guidelines, as recorded by the Italian Thyroid Cancer Observatory Study
Giorgio Grani & Silvia D'Elia
On behalf of Italian Thyroid Cancer Observatory, Italy

Background
The incidence of differentiated thyroid cancers is increasing, mainly due to the overdiagnosis of small papillary thyroid cancers (less than 1 cm, previously known as microcarcinomas). There is a broad consensus in reducing the surgery extent and the use of radioiodine treatment in low-risk cases by most recent clinical practice guidelines focusing on thyroid cancer treatment. The adoption in real clinical practice is usually slow. The aim of this study is to estimate the changes in real clinical practice, using prospective, observational data of the Italian Thyroid Cancer Observatory (ITCO) study.
Methods
The web-based ITCO database was started in 2013 and now includes prospectively collected data on more than 12 000 patients with confirmed diagnosis of thyroid cancer, from 51 different clinical centers. Data about initial treatment and follow-up clinical assessment are prospectively collected by the treating physicians, according to their usual clinical practice. The study is registered at ClinicalTrials.gov (NCT04031339). For the purposes of this evaluation, we grouped the cases according to the year of the initial treatment: group 1 (2013-2015) and group 2 (2016-2020). We then calculated the rate of patients treated with lobectomy and the rates of patients not submitted to radioiodine ablation, according to their risk of persistent/recurrent disease, as estimated by the system proposed by the 2015 ATA Guidelines for differentiated thyroid cancer.
Results
The final cohorts included 6873 patients. The rates of lobectomies (without completion thyroidectomy) increased from 1.7% to 6.9% ($P < 0.001$) in patients with low risk of persistent or recurrent disease according to the ATA Guidelines, and from 0.6% to 2.3% for intermediate-risk patients ($P = 0{,}004$). About the radioiodine treatment, its use is decreased from 41.7 to 30.6% in low-risk patients ($P < 0.001$); and from 87.8% to 74.5% in intermediate-risk patients ($P < 0.001$). In all risk classes, the avoidance of radioiodine treatment did not impact the short-term outcomes (as estimated by the 1-year response to treatment, evaluated according to the suggestions of the ATA Guidelines).
Conclusions
For patients with low- or intermediate-risk thyroid cancer, real-world clinical application of practice guidelines is progressively recorded, even if the overall adherence is still low and there is ample room for improvement.

[1]Basurto University Hospital – OSI Bilbao-Basurto, Radiology, Bilbao , Spain; [2]Basque Country University, Medicine, Leioa, Spain; [3]Basurto University Hospital, Radiology, Bilbo, Spain; [4]Donostia University Hospital – OSI Donostialdea, Radiology, Donostia, Spain; [5]Basurto University Hospital, Endocrinology, Bilbo, Spain; [6]Basurto University Hospital, Endocrine Surgery, Bilbo, Spain; [7]Basurto University Hospital, Pathology, Bilbao, Spain

CNB is increasingly being used as a diagnostic test for thyroid nodules with an inadequate (Bethesda 1) or indeterminate (Bethesda 3 and 4) FNAC results, which can account for up to 30% of the samples in some studies. CNB, using larger specimens and histological sections rather than cytological samples, allows better definition. We propose a simplified four-tiered classification of CNB specimens instead of the Bethesda system and evaluate its efficiency compared to definitive surgical diagnosis. CNB samples were classified as inadequate, benign, follicular tumor (FT) or malignant. The last two were considered neoplastic surgical indications. Follicular tumors included samples with numerous follicles, usually

microfollicles, with scant colloid and insufficient nuclear changes to be considered a follicular variant of papillary thyroid cancer (FV-PTC). Thyroidectomy was recommended for benign biopsies based on clinical sings, patient preference, or goiter growth. Inadequate samples were usually biopsied again. The final results of the last CNB were compared with the histological results of surgery. CNBs were collected since 2005, when we adopted it as main diagnostic test because our poor FNAC results. A total of 1,687 thyroid nodules were operated on in 1,506 patients out of more than 6,000 CNBs from 2005 to 2022: 23 with inadequate CNB, 865 with benign CNB, 294 diagnosed as follicular tumors in CNB (94 oxyphilic) and 505 as malignant (478 PTC). Inadequate CNBs revealed 18 benign lesions and five malignancies. three with other biopsied nodules with surgical indication in the same gland. Of the 865 benign CNBs, 820 were benign nodules and 45 were neoplastic, 26 were follicular adenomas and 19 were malignant (16 PTC and three follicular carcinomas). Follicular tumors were 39 benign nodules (13.3%) and 253 neoplastic: 215 follicular adenomas (73.1%) and 40 malignant (13.6%): 19 PTCs, ten FTCs, nine HCCs, one MTC and one invasive parathyroid carcinoma. Malignant CNBs were confirmed in 493/505 nodules. Eleven were hyperplastic and one was an oxyphilic adenoma. The overall sensitivity of malignant CNB was 96.3%. The specificity of benign CNB was 98.7%. The positive predictive value of malignant CNB was 97.6% and the negative predictive value of benign CNB was 94.8%. Only 17.4% of the operations were due to an indeterminate biopsy (FT) and only 13.6% of these were malignant, although 79.9% corresponded to neoplastic lesions, more of which were adenomas. CNB confirmed as a very reliable diagnostic technique, with high diagnostic efficiency of the proposed four-tiered classification.

RC2.4

Cell free DNA Integrity index to differentiate benign from malignant thyroid nodules

Soham Tarafdar, Susmita Dutta, Nitai P. Bhattacharyya, Pradip Mukhopadhyay & Sujoy Ghosh
IPGMER , SSKM Hospital, Endocrinology, Kolkata, India

Introduction
Cell-free DNA (cfDNA) integrity in plasma has been investigated as a non-invasive marker in cancer. Thyroid cancer the most common endocrine malignancy sometimes presents as indeterminate nodules and difficult to diagnose without histopathology.
Aim of the study
The present study aims to test the hypothesis that the presence of longer DNA strands circulating in plasma can be considered a marker for thyroid cancer.
Methods
Patients presenting with thyroid nodules underwent ultrasonography with Thyroid Image Reporting and Data Systems (TIRADS) scoring and FNAC (Bethesda classification). All patients in Bethesda 3,4,5,6 underwent surgery and histopathological confirmation. Patients in Bethesda 2 (cosmetic concerns, compressive symptoms) underwent surgery, rest were presumed benign on the basis of USG, FNAC features and clinical follow-up. Cell-free DNA was extracted from plasma and quantified. We adopted a quantitative real-time PCR (qPCR) approach based on the quantification of two amplicons of different length (67 and 180 bp respectively) to evaluate the integrity index 180/67 for APP gene. The genomic DNA isolated from the MDA-T32 papillary thyroid cancer cell line was used as reference to determine the relative DNA strand integrity because culture cells contained highly intact genomic DNA. The Ct value of the 180 bp for a sample was subtracted from that for the MDA-T32 control to obtain a (ΔCt) value for 180 bp. Likewise, the Ct value of a 67 bp for the sample was subtracted from that for the MDA-T32 control to obtain a (ΔCt) value for 67 bp. CfDNA Integrity index was calculated by ratio of ΔCt180/ΔCt 67 bp.
Results
A total of 131 subjects were recruited, of these 72 were benign and 59 had differentiated thyroid cancer proven by histopathology. CfDNA integrity index was higher in differentiated thyroid carcinoma patients (median 0.45, 95% CI: 0.36-0.52) than in subjects with benign nodules (median 0.32, 95% CI: 0.27-0.39). The cell free DNA integrity index 180/67 was significantly higher in malignant nodules compared and benign nodules ($P=0.001$).
Conclusions
CfDNA integrity index 180/67 could be a parameter for monitoring cfDNA fragmentation in thyroid cancer patients and a promising marker in the diagnosis of thyroid nodules that warrants further validation in future prospective trials.

[1]Unit of Endocrinology-University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena , Italy; [2]University of Modena and Reggio Emilia, International Ph.D. School in Clinical and Experimental Medicine (CEM), Modena, Italy; [3]University of Modena and Reggio Emilia, Center for Genomic Research, Modena, Italy; [4]Azienda Ospedaliero-Universitaria dImodena, Department of Medical Specialties, Baggiovara Hospital, Modena, Italy

Thyroid cancer is the most common type of endocrine tumor and reaches the peak of incidence between the age of twenty and fifty years. It has 4-fold higher prevalence in females than males, suggesting that estrogens and their receptors could be involved in thyroid cancer pathogenesis. Previous studies demonstrated allosteric interference operated by G protein-coupled estrogen receptor (GPER) to molecules structurally similar to the thyroid-stimulating hormone (TSH) receptor (TSHR). We hypothesize that G protein-coupled estrogen receptor (GPER) may interact with TSHR, differently modulating proliferative signals in healthy *versus* cancer thyroid cells. Mechanistic experiments evaluating TSHR/GPER heteromers and signaling were performed on papillary thyroid carcinoma (K1), follicular thyroid epithelial (Nthy-ori 3-1) and COS7 (control) cell lines, and confirmed in papillary, follicular, and anaplastic tumors *versus* healthy primary thyroid tissues by immunofluorescence (IF) and proximity ligation assay (PLA). Cell lines were co-transfected with specific plasmids to evaluate effects on the TSH-induced activation of Gαs and Gq protein-associated transduction pathways, under TSHR/GPER co-expression. Cell lines were treated with 300 nM TSH and 730 pM estradiol. Intracellular levels of cAMP and calcium ion (Ca^{2+}) increase were measured by bioluminescence resonance energy transfer (BRET), while IP1 by homogeneous time resolved fluorescence (HTRF). Results were compared by Kruskall-Wallis test ($n=6$; $P<0.05$) and corrected by Dunn's post-hoc test. We found TSHR/GPER co-expression and physical interaction in healthy thyroid follicles using two different methods (IF and PLA), and confirmed these results in cell lines by BRET. Surprisingly, no GPER expression was found in histological sections of papillary, follicular and anaplastic thyroid cancer, as confirmed by the absence of IF signal and heteromers. In TSHR expressing cell lines, TSH activated Gαq-mediated signals, i.e. IP1 ($n=6$; $P<0.05$) and Ca^{2+} ($n=3$; $P<0.05$), and cell proliferation, while it was not under TSHR/GPER co-expression. Control experiments with Gq and PLC inhibitors, i.e. YM-254890 and U73122, confirmed GPER-like inhibition of TSH-induced IP1 production. Instead, the presence of GPER unaffected TSH/GαS-mediated cAMP production ($n=6$; $p\geq0.05$). Cell treatment with estradiol and GPER antagonist (5 μM; G15) had no effects ($n=6$; $p\geq0.05$), revealing that GPER inhibits TSHR/Gq regardless of ligands. GPER/TSHR heteromers drive potentially protective effects in thyroid cells, while the lack of GPER unlock TSH/Gq-dependent proliferative intracellular pathways in tumor cells. This data suggests that lack of GPER may be related to thyroid tumor pathogenesis.

Background
Acromegaly is associated with an increased left ventricular mass, as reported in echo-based and more recently in few cardiac MRI studies. One possible explanation of this increased ventricular mass could be water retention and consequently edema of the ventricular wall.
Methods
In this prospective, cross-sectional study 26 patients with active acromegaly and 31 control subjects of comparable age and sex were investigated by cardiac MRI. Patients were explored before and after GH/IGF-I lowering treatment. Cardiac morphology, function and myocardial tissue characteristics were assessed. T2 times were used as a reflect of intramyocardial water content.
Results
Ventricular mass (58.1 (54.7; 68.6) vs 46.0 (41.3; 49.8) g/m^2; $P<0.001$) and volume (97.3 (88; 101.2) vs 81.6 (78.0; 96.2) ml/m^2; $P=0.0069$) were higher in patients compared to controls, without affecting cardiac function. T2 times were not increased in active acromegaly. Both, intracellular (87.9 (71.2; 103.6) vs 67.2 (51.6; 76.9) g/m^2; $P<0.001$) and extracellular (31.9 (26.1; 36.6) vs 21.8 (19.2;24.7) g/m^2; $P<0.001$) myocardial mass were higher in patients compared to controls. GH, but not IGF-I strongly correlated with myocardial mass ($r=0.756$; $P<0.001$). In multiple regression analysis, in addition to male sex and HDL cholesterol, the presence of acromegaly was an independent predictor of total myocardial mass and extracellular mass, whereas systolic arterial blood pressure predicted intracellular mass. GH/IGF-I lowering treatment reduced intracellular mass and ventricular volume, without affecting other myocardial tissue characteristics.
Discussion
Acromegaly results in a disease specific form of myocardial hypertrophy, characterized by an increase in intra- and extracellular mass, which is reversed after GH/IGF-I lowering treatment. This increase in ventricular mass is different to previous observations in essential hypertension. No differences in T2 times suggest against myocardial water retention in active acromegaly as explication of increased extracellular mass.

The spectrum of cardiac disease in patients with acromegaly: results from the SUM trial

Dario De Alcubierre[1,2] , Tiziana Feola[1,3], Alessia Cozzolino[1], Riccardo Pofi[1,4], Rosa Pirchio[5], Nicola Galea[1], Maria Cristina De Martino[5], Rosario Pivonello[5], Andrea Isidori[1] & Elisa Giannetta[1]

[1]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [2]Claude Bernard University, Cancer Research Centre of Lyon (CRCL), INSERM U1052, CNRS UMR5286, Lyon, France; [3]Neuromed Institute, IRCCS, Neuroendocrinology, Pozzilli, Italy; [4]Oxford University, Oxford Center for Diabetes Endocrinology and Metabolism, Oxford, United Kingdom; [5]Università degli Studi di Napoli "Federico II", Naples, Italy, Dipartimento dImedicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy

Introduction
Cardiac abnormalities are common in patients with acromegaly and contribute to the increased morbidity and mortality of the disease. Cardiac magnetic resonance (CMR) is the established, non-invasive gold standard for measuring morpho-functional changes of the heart. We aimed to detect cardiac alterations in patients with acromegaly through CMR and to identify potential risk factors associated with cardiac impairment.
Materials and methods
This is a prospective case-control study. Consecutive patients with acromegaly, screened in the SUM study (EudraCT number: 2015-004498-34), either cured or with active disease, entered the study and were compared with a sex, age, and BMI-matched control group. Metabolic, clinical, and CMR parameters were assessed and compared between groups. Parametric and non-parametric tests were performed, as appropriate.
Results
Twenty patients with acromegaly (7 females, mean age 48 years; 13 males, mean age 50 years) and 17 controls were included. No significant differences were observed in the prevalence of cardiometabolic comorbidities, including dyslipidemia, glucoSe-metabolism impairment, hypertension, and obesity, between patients and controls. CMR parameters were indexed to body surface area. Left ventricular-end-diastolic volume (LV-EDVi) and LV-end-systolic volume (LV-ESVi) were higher in patients with acromegaly than in controls ($P<0.001$), as were left ventricular mass (LVMi) ($P=0.001$) and LV-stroke volume (LV-SVi) ($P=0.028$). Right-ventricle (RV) EDVi and ESVi were higher, whereas RV-ejection fraction (RV-EF) was lower ($P=0.002$) in patients with acromegaly than in controls ($P<0.001$). None of the patients had LV hypertrophy according to conventional CMR thresholds. IGF-1 levels directly correlated with cardiac CMR parameters: LV-EDVi ($r=0.47$; $P=0.037$), LVMi ($r=0.45$; $P=0.044$), and LV-SVi ($r=0.500$, $P=0.025$). Indeed, a subgroup analysis in patients with biochemically uncontrolled disease ($n=3$) showed higher LV-EDVi ($P=0.034$), LV-SVi ($P=0.033$), LVMi ($P=0.002$) and RV-SVi ($P=0.044$) compared to cured ($n=6$) and controlled patients ($n=11$). No differences were found when data were stratified according to the presence or absence of the main cardiometabolic comorbidities. Lastly, after adjusting cardiac parameters for the normal population age and sex reference ranges, as well as physiological sex-related differences, male acromegalics showed higher LVMi ($P=0.025$) and interventricular septum thickness ($P=0.003$) than females.
Conclusions
Our results confirm CMR as a useful tool for the diagnosis of acromegalic cardiomyopathy: a cluster of biventricular structural and functional impairment, resembling the dilated cardiac phenotype, which likely results from specific pathways triggered by GH-IGF-1 excess. Interestingly, sex-related differences advocate a possible interaction of sexual hormones in cardiac disease progression, but further studies are needed to confirm these findings.

SGLT2 Inhibitors in a case series of diabetic acromegaly patients: Effects beyond diabetes

Meliha Melin Uygur[1] & Anna Abbasgholizadeh[2]

[1]Recep Tayyip Erdoğan University Faculty of Medicine, Department of Endocrinology and Metabolism Disease, Rize, Turkey; [2]Marmara University Faculty of Medicine, Department of Endocrinology and Metabolism Disease, Istanbul, Turkey

Objective
There has been no consensus on the medical management of diabetes in acromegaly patients. The primary approach is like the general population, and metformin is considered first-line therapy. Sodium-glucose cotransporter inhibitors (SGLT2is) are a novel antidiabetic class which has an improving effect on insulin resistance. There is no recommendation regarding their use for diabetic acromegaly patients despite their potential beneficial effects by inducing glucosuria, osmatic diuresis, and cardiovascular safety. Euglycemic diabetic ketoacidosis might constitute a barrier related to insulin deficiency since GH per se increases lipid oxidation and ketone bodies. A recent pilot study showed the ability of an adjuvant Eucaloric very-low-carbohydrate ketogenic diet controlled IGF-I levels in patients with acromegaly whose disease was uncontrolled with first-generation somatostatin receptor ligand therapy[1]. Thus, we aimed to evaluate the outcomes of SGLT2is on diabetes control, also control of IGF-1 levels in a subset of acromegaly patients.

Table 1 Anthropometric and biochemical parameters of patients at basal and 3. month

	Weight (kg)		Glucose (mg/dl)		GH (μg/l)		IGF-1(μg/l)		HbA1c (%)		Creatinine (mg/dl)	
month	0	3	0	3	0	3	0	3	0	3	0	3
Mean	92.63	90.42	106.83	105.50	1.41	1.32	224.03	200.30	6.65	6.18	0.90	0.98

Methods
We conducted a proof-of-concept study involving 6 patients (3 women, 3 men) to investigate whether a 3-month, SGLT2 is as adjuvant treatment to metformin (if not contraindicated) would affect IGF-I concentrations besides glucose parameters in patients with uncontrolled acromegaly. The treatment of acromegaly remained stable during the intervention.
Results
We showed a decrease in mean glucose, Hemoglobin A1C (HbA1c), and insulin-like growth factor 1 (IGF-1) levels. Body weight also showed a pattern of decline. Although blood ketone levels did not increase, serum creatinine levels showed an increasing trend. We had to withdraw a patient do the increased creatinine level (Table 1).
Conclusion
İt is noteworthy that a patient-tailored approach should be initiated not only for managing acromegaly and diabetes separately but also for combining therapies to enhance the effects. Although SGLT-2 inhibitors seem to have favorable effects on acromegaly patients, a caution on renal functions should be considered. Far-reaching studies are needed to evaluate the utility and adverse effects of this unique antidiabetic class in acromegaly patients.

Objective
SAGIT, a new instrument designed for therapeutic decision, is not routinely used yet. While the medical treatment was mostly planned according to disease activity by hormonal evaluation, the therapeutic decision has tried to be standardized with the SAGIT instrument. The aim of this study is to reassess the therapeutic decisions by clinicians in the management of acromegaly according to the SAGIT instrument.
Material and Method
This multicenter, retrospective study was conducted at twelve experienced centers from our country and included patients with acromegaly who needed medical treatment, primary or post-surgery. Characteristics of patients and the components of SAGIT:(S) signs/symptoms, (A) associated comorbidities, (G) growth hormone (GH) levels, (I) insulin-like growth factor-1 (IGF1) level, and (T) tumor features were recorded at baseline, before and 3,6, and 12 months after medical treatment. The relationship between SAGIT scores and therapeutic decisions was evaluated.
Results
Of 322 (175 females/147 males) patients enrolled, 38 patients received primary medical treatment, whereas 284 patients received post-surgical medical treatment. A SAGIT score of 6 was significantly detected as the optimal cutoff for an evaluation of acromegaly disease activity based on hormonal control only with GH and IGF1 levels at each visit. The clinician's therapeutic decisions at every visit were assessed according to the cutoff level of SAGIT score for disease activity (Table 1). In patients with the uncontrolled disease according to the SAGIT score at the 3rd and 6th months visits and whoSemedical treatment was unchanged, a significant decrease in SAGIT score both between the 3rd and 6th, and 6th and 12th months were found ($P=0.002$, $P<0.001$, respectively). However, it was revealed that adequate disease control could not be achieved as the SAGIT scores remained at 6 and above for both the 6th and 12th months visits.
Conclusion
If clinicians had changed therapeutic decisions according to the SAGIT criteria, more than 50% of patients would have required treatment intensification for the patients found to be uncontrolled according to the optimal cutoff SAGIT score of 6, also shown in the validation studies. As a result, the SAGIT scores of these patients remained equal to or above the cutoff point during the 12-month follow-up. This result showed that the SAGIT instrument should be emphasized more strongly to achieve individualized treatment.

Discontinuation of long-term growth hormone treatment in adults with severe growth hormone deficiency: A United Kingdom web-based survey of endocrine practice

Sherwin Criseno[1,2,3], Helena Gleeson[1,3], Andrew Toogood[1,3], Neil Gittoes[1,2,3], Annie Topping[4,5] & Niki Karavitaki[1,2,3]
[1]University Hospitals Birmingham NHS Foundation Trust, Endocrinology, Diabetes and Metabolism, Birmingham, United Kingdom; [2]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [3]Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, United Kingdom; [4]University Hospitals Birmingham NHS Foundation Trust, Nursing, Birmingham, United Kingdom; [5]University of Birmingham, School of Nursing, Institute of Clinical Sciences, College of Medical and Dental Sciences, Birmingham, United Kingdom

Introduction
In adults, treatment of growth hormone deficiency (GHD) with daily recombinant human growth hormone (GH) injections has shown to improve many clinical features associated with GHD. Currently, many adults with GHD receive GH indefinitely, even when they fail to report any obvious benefits from this treatment. Additionally, evidence on the impact of discontinuing long-term GH therapy is limited. We conducted a survey of UK endocrine clinicians (doctors and specialist nurses) between 01/06/2022 and 31/08/2022 to understand the current practice of offering GH treatment discontinuation in adults with GHD.
Methods
A web-based multiple-choice questionnaire was developed and administrated by an online platform Survey Monkey®. The survey was distributed to the UK Society for Endocrinology membership. It consisted of 15 questions with sections on demographics, number of adult patients treated with GH, number of adult patients on GH replacement therapy for more than 5 years and the current practice/criteria used by the clinicians when offering a period of GH treatment discontinuation.

Results
102 endocrine clinicians completed the survey, majority of which were from England ($n=91$, 89%). Of the 102 participants, 65 (33 endocrinologists and 32 specialist nurses) indicated active involvement in managing adult patients with GHD. Amongst the 65 respondents, 27.7% ($n=18$) were routinely offering a period of GH discontinuation to patients who have been on treatment for a long time. However, only 6% ($n=4$) confirmed that that a clinical guideline/protocol was in use to guide the practice of GH treatment discontinuation in adults. 29.2% of clinicians ($n=19$) supported that GH treatment discontinuation should be routinely offered to adult patients with GHD on long-term treatment and a further 60% ($n=39$) would consider treatment discontinuation for long-term users of GH treatment whilst 9.2% ($n=6$) indicated discontinuation should not be offered. At post-discontinuation review, majority of clinicians would complete IGF-1 level measurement (84.6%, $n=55$), quality of life assessment by AGHD questionnaire (89.2%, $n=58$) and signs and symptoms assessment (75.4%, $n=49$).
Conclusions
This first survey of GH treatment discontinuation practice in the UK highlights areas of uncertainty amongst endocrine clinicians regarding the appropriateness of offering GH treatment discontinuation in adults with GHD who have been on long-term therapy. Although a significant number of clinicians consider GH treatment discontinuation could be routinely offered to adult patients, this survey highlights the need for research to assess the effects of GH treatment discontinuation in adults, to guide the development of evidence-based recommendations to inform clinical practice.

Sars-CoV-2 infection leads to significant and long-lasting changes in women's reproductive health

Kristina Saravinovska[1], Ljiljana Marina[1,2], Dunja-Simona Petkovic[1,3], Neda Delic[2], Antoan Stefan Sojat[1], Tijana Petkovic[1], Natalija Antic[1], Sladjana Mihajlovic[2,4], Milan Lackovic[4], Nevena Radonjic[5], Miomira Ivovic[1,2], Zorana Arizanovic[1] & Svetlana Vujovic[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, National Centre for Infertility and Endocrinology of Gender, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [3]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, National Centre for Infertility and Endocrinology of Gender , Belgrade, Serbia; [4]Clinical Hospital Centre "Dragisa Misovic", Department of Obstetrics and Gynecology, Belgrade, Serbia; [5]Upstate Medical University, Department of Psychiatry and Behavioral Sciences, Syracuse, NY, United States

Background
Reproductive health is a state of complete physical, mental, and social well-being. So far, there is limited evidence about the consequences of Sars-CoV-2 infection on women's reproductive health.
Aim
To determine the effects of Sars-CoV-2 infection on women's reproductive health.
Methods
We created an anonymous survey about reproductive health and shared it with women of reproductive age between May 2022 and December 2022. All women used their menstrual cycle (MC) diary while filling out the survey. Surveys were stratified into two groups based on RT-PCR/Antigen test results: positive (CP) or negative (CN). All reported changes in CP referred to time after the Sars-CoV-2 infection and in CN to a pandemic period in general.
Results
704 women completed the survey. Based on inclusion, exclusion, and complete data availability 461 surveys were taken into the final analysis: 129/28% CN-mean age 28.8 ± 9.7, mean BMI 22.5 ± 4.1 kg/m^2 and 332/72% CP, mean age 28.3 ± 8.7, mean BMI 22.3 ± 3.7 kg/m^2. There was no difference in age or BMI between the groups ($p>0.05$). 303/65.7% reported being vaccinated. When compared to CN, 253/54.8% CP reported changes in MC ($P<0.001$); 94/20.3% CP reported shortening of MC length ($P=0.001$) with a mean shortening of 3.3 days, as well as more pronounced premenstrual syndrome symptoms (PMS) ($P<0.001$); 83/18% CP reported heavier menstrual bleeding (HMB) ($P<0.001$); 64/13.8% CP reported more painful menstrual bleeding (MB) ($P=0.017$); 45/9.76% reported prolonged MB duration ($P=0.026$); 32/6.9% CP reported a dyad consisting of shortening of MC length, and HMB ($P=0.003$); 258/55.9% CP reported that the changes in their MC are still present ($P=0.005$) with an average duration of 290 days. Age, BMI nor vaccination did not affect changes in MC ($p>0.05$). In fact, vaccination had a protective effect against MC changes, which was close to statistical significance ($P=0.087$, $B=-0.542$, OR 0.582; 95% CI=0.312-1.083). Regarding mental health when compared to CN surveys, 116/25.1% CP reported having low mood ($P=0.036$); 89/19.3% CP reported poor sleep ($P=0.017$); 24/5.2% CP surveys reported excessive alcohol use ($P=0.006$). Mental health changes did not affect changes in MC ($p>0.05$). In CP group, the duration of Sars-CoV-2 infection was the most significant predictor of changes in MC ($P=0.009$, $B=0.070$, OR 1.072; 95% CI=1.02-1.13).
Conclusions
Sars-CoV-2 infection leads to long-lasting changes in women's reproductive health. Possible consequences are yet to be elucidated as the most remarkable change was the shortening of MC length which is an important clinical predictor of reproductive axis aging and lower fertility rate.

Evolution of cardiovascular risk markers in polycystic ovary syndrome: Results from a long-term monocentric cohort study

Carolina Cecchetti[1], Srdjan Pandurevic[1], Paola Dionese[1], Elisabetta Belardinelli[1], Laura Rotolo[1], Flaminia Fanelli[2], Luca Bergamaschi[3], Carmine Pizzi[3], Uberto Pagotto[1] & Alessandra Gambineri[1]
[1]Via Giuseppe Massarenti, 9, Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Italy;Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum, University of Bologna, Italy, Bologna, Italy; [2]Via Giuseppe Massarenti, 9, Center for Applied Biomedical Research, Dept. Of Medical and Surgical Sciences, Alma Mater Studiorum – Bologna University, Bologna, Italy, Bologna, Italy; [3]Via Giuseppe Massarenti, 9, Unit of Cardiology, Department of Specialist, Diagnostic and Experimental Medicine, Alma Mater Studiorum, University of Bologna, Italy; Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum, University of Bologna, Italy, Bologna, Italy

Background
Many questions concerning polycystic ovary syndrome (PCOS) remain unsolved, such as the long term evolution of cardiovascular (CV) risk markers and the risk for CV events.
Methods
A total of 119 PCOS patients diagnosed in 2009 by NIH criteria at our Unit were evaluated at baseline for cardiovascular risk markers (hypertension, diabetes mellitus-DM, dyslipidaemia, obesity, carotid intima media thickness-cIMT, and epicardial fat thickness-EFT) and cardiovascular events. All subjects were subsequently reevaluated between 2020 and 2021.
Results
Participants mean age was 39.9 ± 7.6 years at baseline and 51.9 ± 7.6 years at the end of the study, with a prevalence of menopausal state of 6.1% and 39.3%, respectively. At baseline, no major or minor CV events were detected, but 2 cases of angina pectoris (1.7%), 1 case of transient ischaemic attack (0.8%), 3 cases of arterial revascularization (2.5%), and 1 case of cardiac insufficiency (0.8%) were documented at the end of the study. Prevalence of hypertension, type 2 DM, dyslipidaemia, and obesity were initially 27.2%, 12.2%, 59.0% and 32.1%, and 44.4%, 18.6%, 87.2% and 47.2% at final reevaluation ($P<0.001$, $P=0.065$, $P<0.001$, $P<0.05$ vs baseline, respectively). cIMT was significantly increased at final examination (0.58 ± 0.16 mm vs 0.81 ± 0.27 mm, $P<0.001$), and the% of patients with cIMT$\geq$ 1 mm or with carotid plaques passed from 1% to 26.4% ($P<0.001$). In contrast, a significant decrease in EFT was detected from baseline to the end of the study (0.86 ± 0.35cm and 0.41 ± 0.23cm, $P<0.001$).
Conclusions
This cohort study shows that PCOS is indeed characterized by a high prevalence of cardiovascular risk markers, with a tendency to increase over time; nonetheless, not all cardiovascular risk markers worsen steadily, with some interesting beneficial variations occuring in the late reproductive or early post-menopausal years.

DOI: 10.1530/endoabs.90.RC4.2

Introduction
Polycystic ovary syndrome (PCOS) is the most prevalent endocrinopathy among women during reproductive age. Using ESHRE/ASRM diagnosis of PCOS is considered when 2 of 3 criteria are present: polycystic ovary morphology (PCOM), oligo/anovulation (ANOV) and hyperandrogenism (HA). These criteria form four different phenotypes: A (ANOV, HA, PCOM), B (ANOV, HA), C (HA, PCOM) and D (ANOV, PCOM). Several studies have found differences in anthropometric, hormonal and metabolic characteristics between PCOS phenotypes. Among the non-insulin-derived indices, the single-point insulin sensitivity estimator (SPISE) index showed better accuracy than other indicators in the prediction of metabolic syndrome. The aim of this study was to analyze anthropometric and metabolic characteristics in different PCOS phenotypes and compared to control group.
Subjects and methods
We analyzed 307 women with PCOS divided into four phenotypes groups PCOS-A ($n=126$, age 25.63 ± 4.6 years, BMI 24.97 ± 6.2 kg/m^2), PCOS-B ($n=40$, age 26.13 ± 6.4 years, BMI 28.33 ± 7.3 kg/m^2), PCOS-C ($n=83$, age 26.06 ± 5.6 years, BMI 24.91 ± 5.4 kg/m^2) and PCOS-D ($n=58$, age 25.26 ± 4.6 years, BMI 21.09 ± 3.1 kg/m^2) and 87 women in control group (age 29.25 ± 5.8, BMI 23.33 ± 6.1 kg/m^2). Body composition was analyzed using bioimpedance. Lipid indices, basal glucose and insulin were measured, while HOMA-IR and SPISE index were calculated.
Results
Compared to control group only women with PCOS-B had higher BMI, waist circumference (WC), body fat mass, body and trunk fat percentage ($P<0.001$, $P<0.001$, $P=0.001$, $P=0.002$, $P=0.008$, respectively), while same characteristics were higher in phenotypes PCOS-A, B and C in comparison to PCOS-D phenotype. Women with PCOS-B had more body fat mass and higher WC compared to PCOS-A group. Both control group and all patient with PCOS showed similar HOMA-IR and basal insulin levels, but SPISE index was statistically lower in PCOS-B group compared to controls and in PCOS A, B and C group compared to PCOS-D group, as well in PCOS-A than in PCOS-B group. SPISE index showed strong negative correlation in all phenotype groups with body and trunk fat mass, body and trunk fat percentage, total body water, BMI and WC and negative correlation with HOMA-IR in PCOS-A, B and C group ($r=-0.368$, $P<0.001$, $r=-0.433$, $P=0.013$, $r=-0.405$, $P<0.001$, respectively).
Conclusion
Not all patient with PCOS have same cardiometabolic risk factors. PCOS-B phenotype showed most prominent metabolic risk factor profile. SPISE index seems to represent accurate risk marker in more metabolic weighted PCOS-A and PCOS-B. The assessment of different risk factors in PCOS phenotypes could be used for prediction of long-term metabolic outcomes.

Is AMH a regulator of autophagy in the ovary?

Lecot-Connan Tatiana[1], Boumerdassi Yasmine[2], Magnin Francoise[3], Binart Nadine[3], Sonigo Charlotte[4] & Isabelle Beau[3]
[1]APHP, Endocrinology, Le Kre mlin-Bicetre, France; [2]APHP, Biologie de la Reproduction, Bondy, France; [3]Inserm, 1185, Le Kre mlin-Bicetre, France; [4]Universite Paris-Saclay, Le Kre mlin-Bicetre, France

Background
The reserve pool of primordial follicles (PMF) is finely regulated by molecules implicated in follicular growth or PMF survival. Anti-Müllerian Hormone (AMH), produced by granulosa cells of growing follicles, is known for its inhibitory role in the initiation of PMF growth. We observed in a recent *in vivo* study that injection of AMH into mice seemed to induce an activation of autophagy, a cytoplasmic lysosomal-dependent degradation system, which is important for starvation adaptation and cellular quality control. Furthermore, we observed an activation of the transcription factor FOXO3a by AMH, which is also known to regulate autophagy. Many studies highlighted the key role of autophagy in the ovary at different stages of folliculogenesis and particularly in PMF survival. The objective of our study was to understand how AMH stimulates autophagy and in particular what is the role of the transcription factor FOXO3a which is involved in the maintenance of PMF in quiescence but also in the regulation of autophagy.
Methods
We used an *in vitro* approach on organotypic cultures of prepubertal mouse ovaries, treated or not with AMH. Autophagy was monitored by immunofluorescence and western-blot analysis of LC3, a specific marker of autophagosomes. The phosphorylation status of FOXO3a was analyzed by Western blot. The expression of genes involved in autophagy was quantified by RT-qPCR.
Results
We showed that autophagosome biosynthesis and autophagic flux are increased in AMH-treated ovaries. AMH also induces a FOXO3a dephosphorylation which is translocated to the nucleus where it exerts its transcriptional activity. We observed that the transcription of FOXO3a target genes involved in autophagy (*Atg16l1*, *Gabarapl2*, *Wipi2*, *Atg2a*, *Ulk1*, *Zfyve1*, *Atg5*) is significantly increased in AMH treated ovaries.
Discussion
This *in vitro* approach shows that AMH is able to stimulate autophagy in mouse ovaries by increasing the expression of a number of FOXO3a target genes involved in this process. This is a completely new role for this hormone which protects the pool of primordial follicles by inhibiting their growth but also by inducing autophagy to allow them to survive.

Women carrying CYP21A2 mutations display clinical findings and metabolic/hormonal profile analogous to women with non classical congenital adrenal hyperplasia and polycystic ovary syndrome

Sarantis Livadas[1], Dimitrios Goulis[2], Elisabetta eBelardinelli[3], Elena Armeni[4], Beatrice Solmi[3], Stavroula Veneti[2], Irene Lambrinoudaki[5], Carolina Cecchetti[3], Djuro P. Macut[6] & Alessandra Gambineri[3]
[1]Athens Medical Centre, Athens, Greece, 2, Unit of Reproductive Endocrinology, 1st Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Greece; [3]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [4]Royal Free Hospital NHS Foundation Trust, London, UK; [5]Second Department of Obstetrics and Gynecology, Aretaieio Hospital, Medical School, National and Kapodistrian University of Athens, Greece; [6]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

Heterozygotes carrying CYP21A2 gene mutations are found in 5-10% of the general population in Mediterranean countries. Accumulating data suggest a survival advantage of this population, despite the fact that carriers of two mutations suffer from either classical or non-classical congenital adrenal hyperplasia (NC-CAH), an entity with increased mortality. In an attempt to elaborate on this issue we evaluated females of reproductive age with CYP21A2 heterozygocity (HET). We have analyzed data from 56 HET were compared with 105 controls, 64 untreated females suffering from NC-CAH and 63 women with Polycystic ovary syndrome (PCOS), of similar age and BMI. We have found that the prevalence of hirsutism (54 vs 8%) and acne (44 vs 4%) was higher in HET than controls and the degree of menstrual irregularities was similar between HET and NC-CAH and worse than controls. The lipidemic profile was significantly better in HET compared to PCOS (Cholesterol 170.20 ± 37.06 vs 187.67 ± 39.34 mg/dl, HDL 61.42 ± 26.11 vs 46.81 ± 8.58 mg/dl). However, Testosterone 0.78 ± 0.45 vs 0.50 ± 0.25 ng/dl), SHBG (38.20 ± 20.11 vs 56.20 ± 31.37 nmol/l), FAI (9.56 ± 3.45 vs 5.37 ± 1.24) and DHEAS concentrations (2.62 ± 1.31 vs 1.27 ± 0.94 nmol/l) were comparable among HET, NC-CAH, PCOS and significantly higher than controls, as well as insulin (13.88 ± 7.96 vs 7.51 ± 2.82 IU/l) and HOMA-IR (2.95 ± 1.60 vs 1.65 ± 0.67). Androstenedione (5.97 ± 2.88 vs 8.80 ± 3.45 ng/ ml) and 17hydroxy-progesterone (4.32 ± 2.02 vs 13.75 ± 8.34 ng/ ml) values were lower than the corresponding ones in NC-CAH, but significantly higher in HET than PCOS and controls. Finally, ovarian Pcomorphology prevalence was found similar in HET to NC-CAH and PCOS. Therefore, we conclude that women pf reproductive age carrying CYP21A2 mutations display a favorable lipidemic profile, but a similar degree of hyperandrogenic signs, menstrual disturbances, insulin resistance, hyperandrogenemia and ovarian morphology with women suffering from either PCOS or NC-CAH. Therefore, it is obvious that these women, when identified they should be carefully followed up.

Bone and sexual health in adult women with complete androgen insensivity syndrome: A single centre experience

Eriselda Profka[1], Giulia Rodari[1], Federico Giacchetti[1], Claudia Giavoli[1,2], Maura Arosio[1,2] & Giovanna Mantovani[1,2]

[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]University of Milan, Department of Clinical Sciences and community Health, Milan, Italy

Background
Low bone mineral density (BMD) and reduced sexual satisfaction have been reported in complete androgen insensitivity syndrome (CAIS). Nevertheless, conclusive data on the prevalence and on the optimal management of these conditions are still lacking.
Aims
To assess bone and sexual health in adult women with CAIS with and without gonadectomy.
Methods
Single-centre, prospective study of 27 adult CAIS (age 35.2±8.7 years), 22 patients with gonadectomy (age 13.4±7.1 years) and 5 with intact gonads. All patients with gonadectomy were on hormonal replacement therapy (HRT) (median age of start 16 years, range 12.5-19.5 years). Two patients were on testosterone therapy while all the others on estradiol (8 transdermal and 12 on oral formulation). Adherence to HRT was assessed through self-reporting and it was intermittent in two patients. The primary outcome was the evaluation of bone health, as measured with dual-energy x-ray absorptiometry and morphometric vertebral fractures. Secondary outcomes were sexual function, as measured with the Female Sexual Function Index (FSFI) and Female Sexual Distress Scale-Revised (FSDS-R) and body uneasiness, as measured with the Body Uneasiness Test (BUT).
Results
in all patients, BMD Z-score was reduced at lumbar spine (LBMD-Z -1.66±0.88) and at the hip (THBMD-Z -0.4±0.8). In particular, LBMD-Z and THBMD-Z was −1.4±0.64 and 0.04±0.62 in patients with intact gonads and −1.7±0.9 and -0.5±0.8 in patients with gonadectomy, respectively. LBMD-Z was <-2 in 2 patients with intact gonads and in 8 patients with gonadectomy. No fractures were recorded in any patient. FSFI, FSDS-R and BUT tests were collected in 20 patients. Eleven patients (4 with intact gonads) showed a sexual dysfunction at FSFI (score <26,55). Interestingly, in the group with intact gonads, 3 of 4 patients with sexual dysfunction had testosterone levels below normal range. When considering FSDS-R, 12 patients (2 with intact gonads) showed a hypoactive sexual desire disorder (HSDD) (score >11). Similarly, 9 patients (2 with intact gonads) reported body uneasiness at BUT (Global Severity Index >1.2).
Conclusions
Our results confirm the reduction of BMD in CAIS with and without gonadectomy. Moreover, sexual dysfunction, HSDD and body uneasiness is common. Preservation of gonads not always guarantees optimal hormone levels and gonadectomy must be considered after spontaneous pubertal development. The lack of defined guidelines on the most appropriate management of CAIS, reinforces the need to perform further investigations, in order to establish an adequate treatment, thus guaranteeing an improvement quality of life and reducing the risk of complications.

Background
Adrenocortical carcinoma (ACC) is a rare cancer associated with hereditary syndromes in 10% of cases. However, data on germline variants (GVs) in adult patients with sporadic ACC are limited.
Methods
We analyzed germline DNA from 150 adult patients with sporadic ACC sequentially referred to our centers between 1998-2019. We designed a custom panel of 17 genes potentially involved in the pathogenesis of ACC: AIP, APC, ARMC5, ARNT, BRCA1, BRCA2, CTNNB1, IGF2, MEN1, MSH2, MSH6, PDE8B, PDE11A, PRKACA, PRKACB, PRKAR1A, and TP53. NGS data were analyzed by a semi-automated bioinformatic pipeline. All GVs were studied using effect predictor tools (PolyPhen and SIFT). Specific databases (ClinVar, Varsome, gnomAD, IARC TP53, HGMD) were used for variant classification according to ACMG criteria. Variants interpreted as pathogenic (P) or likely pathogenic (LP) were considered as positive. Clinical, pathological and genomic data were analyzed in different Cox models to study prognostic impact of covariates for disease-free survival (DFS), progression-free survival (PFS) and overall survival (OS).
Results
We identified 21 unique GVs in in 9 genes including APC ($n=3$), ARMC5 ($n=3$), MSH2 ($n=3$), PDE11A ($n=3$), TP53 ($n=3$), MSH6 ($n=2$), PDE8B ($n=2$), AIP ($n=1$) and CTNNB1 ($n=1$). Eleven positive GVs were found in 14/150 patients (9.3%). We found a new GV in TP53 (G105D) in a patient who was later found to have a sister with ACC and, for the first time, 3 GVs in ARMC5 (P731R). Patients with ARMC5 GVs had large cortisol-secreting tumors and one case displayed combined pathologic features of ACC and macronodular cortical disease. Positive GVs were associated with a shorter OS (50 vs 142 months, HR 1.81; 95% CI, 0.86-3.82, $P=0.118$) and PFS (8 vs 30 months, HR 3.11; 95% CI, 1.57-6.16, $P=0.001$) but not DFS (27 vs 32 months, HR 1.07; 95%CI, 0.52-2.22, $P=0.845$). At multivariate analysis, known clinical factors (age, surgery of primary ACC, ENSAT stage, hypercortisolism) were found to have prognostic impact on OS. However, GVs remained independent predictors of PFS and OS in metastatic patients.
Conclusions
In a series of 150 patients with ACC, we found that 9.3% of them had positive GVs. We describe for the first time the presence of ARMC5 GVs in patients with ACC and we found a novel pathogenic variant of TP53. Pathologic features of one ARMC5 case suggest a possible progression from macronodular adrenal hyperplasia to ACC. Finally, the present findings suggest that GVs can affect ACC progression and survival of affected patients.

Study of somatic molecular heterogeneity in bilateral macronodular adrenocortical disease (BMAD) by NGS panel in a cohort of 26 patients

Florian Violon[1,2], Lucas Bouys[1,3], Giannone Gaetan[1], Patricia Vaduva[1], Karine Perlemoine[1], Annabel Berthon[1], Bruno Ragazzon[1], Mathilde Sibony[1,2] & Jerome Bertherat[1,3]
[1]Cochin Institute, Endocrine Tumor Signaling Pathway and Genomic, Paris, France; [2]Cochin Hospital, Pathology, Paris, France; [3]Cochin Hospital, Endocrinology, Paris, France

Introduction
Bilateral macronodular adrenal disease (BMAD) is a genetically heterogeneous disease that can be caused by *ARMC5* or *KDM1A* alterations. Indeed, a germline and somatic event leading to a bi-allelic inactivation of *ARMC5* or *KDM1A* are responsible for 20 and 1% of BMAD cases, respectively. Genetic analysis identified three molecular groups: *ARMC5*, *KDM1A* and no genetic cause known to date. Although there is a high heterogeneity in the somatic events identified in the different nodules from *ARMC5* mutated patients, the somatic events were never studied on several nodules from *KDM1A* mutated patients. The aim of this work was to study the mutational profile of different nodules from the same patient in a cohort of BMAD to describe the somatic alterations of patients with pathologic germline *ARMC5* or *KDM1A* variants and to look for potential pure somatic genetic alterations in patients with no known genetic cause.
Patients and methods
26 patients underwent surgery for BMAD at the Cochin Hospital between 2006 and 2021. 148 DNA samples were extracted from formalin-fixed and paraffin-

embedded material after macrodissection. Qualified DNA were sequenced by Illumina NGS sequencing for a panel of 7 genes: *ARMC5*, *GNAS*, *KDM1A*, *PDE8B*, *PDE11A*, *PRKACA* and *PRKAR1A*.
Results
For 3 patients all DNA samples ($n=23$) were too degraded to be analyzed. Out of the 7 patients with a germline pathological *ARMC5* variant, 6 had 2 to 8 pathological somatic *ARMC5* variants for 3 to 10 nodules sampled. The last patient had one unique somatic event detected on 5 nodules. Out of the 3 patients with a germline pathological *KDM1A* variant, each nodule had a loss of heterozygosity. Out of the 13 patients without a pathological *ARMC5* or *KDM1A* variant, no genetic alterations were found. In patients for whom a germline pathological variant was known, we detected a somatic event in 56 of the 61 nodules sampled (92%).
Discussion
Our study is the first to explore the mutational profile of different nodules from the same patient isolated by macrodissection on a series of BMAD and the first to study this profile in patients with bi-allelic *KDM1A* inactivation. We confirm the heterogeneity of *ARMC5* secondary events and show a high homogeneity of *KDM1A* alterations. In patients without germline alteration no somatic alterations were found suggesting that the molecular mechanisms in these patients remain to be discovered.

RC5.4

Primary bilateral macronodular adrenal hyperplasia (PBMAH) is likely a genome instability disease due to ARMC5's role in resolving transcription-replication conflict

Linjiang Lao[1], Isabelle Bourdeau[1], Lucia Gagliardi[2], Xiao He[1], David Torpy[2], Hamish Scott[3], Andre Lacroix[1], Hongyu Luo[1] & Jiangping Wu[1]
[1]Centre Hospitalier de l'Universite de Montreal (CHUM), CHUM Research Center, Montréal, Canada; [2]Royal Adelaide Hospital, Royal Adelaide Hospital, Adelaide, Australia; [3]Adelaide Medical School, Adelaide, Australia

ARMC5 mutations are associated with PBMAH risks, but the ARMC5 action mechanism remains unknown. We discovered that ARMC5 was part of a novel ubiquitin ligase (E3) specific for RPB1, the largest Pol II subunit. ARMC5 deletion significantly reduced RPB1 ubiquitination and increased RPB1 accumulation. Surprisingly, the degradation of not only RPB1 but all the 12 subunits of Pol II was compromised in the absence of ARMC5, suggesting that this E3 acts on RPB1 and molecules in its vicinity, and ARMC5 mutation causes an enlarged Pol II pool. The stalled Pol II due to DNA damage needs to be removed by degradation via the ubiquitin/proteasome system, or else the transcription machinery will suffer from a genome-wide jam and transcription decrease. However, a combined analysis of RPB1 ChIP-seq and RNA-seq of the ARMC5 KO adrenals revealed that a lack of this major Pol II-specific E3 did not lead to a generalized transcription decrease. This suggests that either under physiological conditions, Pol II stalling is not common, or there is a so-far unknown mechanism to recycle the stalled Pol II. Although ARMC5 mutations are associated with adrenal hyperplasia, the proliferation of most types of KO cells was reduced. This raises an intriguing possibility that the physiological function of the E3 is to remove Pol II from the DNA track to resolve the transcription-replication conflict. Failure to do so in the S phase will slow down replication accompanied by genome instability, which is a pro-oncogenic condition. The enlarged Pol II pool in the KO adrenals led to differential expression of 1486 genes. The majority of these genes were upregulated, and some of the upregulated ones were oncogenes. The expression of StAR, the rate-limiting enzyme in cortisol biogenesis, was reduced, probably as a secondary effect of the enlarged Pol II pool; this decrease explains the reduced cortisol secretion per cell in PBMAH. ARMC5 was previously incorrectly called a tumor suppressor gene. We now know that it affects more upstream processes controlling the general replication and transcription. Based on our findings, we propose the following model. The defective ARMC5-containing E3 leads to an enlarged Pol II pool and compromises transcription-replication conflict resolution. The former upregulates some oncogenes. The latter causes oncogenic genome instability and, at the same time, reduced replication. The sum effect of all these conflicting forces is the pathogenesis of slow-growing tumors or hyperplasia such as PBMAH.

Clinical relevance of targeted sequencing in paraffin-embedded samples for prognostic classification of adrenocortical carcinoma

Juliane Lippert[1], Ulrich Dischinger[1], Silke Appenzeller[2], Alessandro Prete[3], Stefan Kircher[4], Kassiani Skordilis[5], Yasir Elhassan[3], Barbara Altieri[1], Martin Fassnacht[1] & Cristina Ronchi[3]
[1]University Hospital of Wuerzburg, Division of Endocrinology and Diabetes, Wuerzburg, Germany; [2]University of Wuerzburg, Core Unit Bioinformatics, Wuerzburg, Germany; [3]University of Birmingham, Institute of Metabolism and System Research, Birmingham, United Kingdom; [4]University of Wuerzburg, Institute of Pathology, Wuerzburg, Germany; [5]University Hospitals Birmingham NHS Foundation Trust, Department of Histopathology, Birmingham, United Kingdom

Adrenocortical carcinoma (ACC) is a rare malignant tumour with heterogeneous outcome. Prognostic classification relies on individual clinical/histopathological parameters that have limited performance. Recent studies proposed the use of selected DNA-based biomarkers to improve prognostication of ACC. Aim of the study was to perform a comparative analysis of DNA-based biomarkers (BM) for prognostic assessment of ACC by evaluating their added value to the established prognostic S-GRAS score, a combination of five clinical/histopathological parameters. A total of 194 formalin-fixed, paraffin-embedded (FFPE) samples from patients with histologically confirmed ACC were analysed. Targeted DNA sequencing and pyrosequencing were used to detect single nucleotide variations (SNV) in ACC-specific genes (two different panels with 100 and 33 genes, respectively) and methylation in the promoter region of *PAX5*. ENSAT tumour stage, age, symptoms, resection status, and Ki-67 index were collected for calculation of the S-GRAS score. Endpoints were overall survival (OS), progression-free survival (PFS), and disease-free survival (DFS). Prognostic role of each parameter was evaluated by uni- and multivariable Cox regression analysis and compared by Harrell's C-index. The prognostic role of following DNA-based BMs was confirmed at univariable analysis: more than one SNV-affected gene (BM1), alterations in Wnt/β-catenin and Rb/p53 pathways (BM2) and hypermethylated *PAX5* (BM3) ($P<0.01$ for both OS and PFS). However, only BM2 and BM3 showed an independent prognostic impact at multivariable analysis including S-GRAS score ($P<0.05$ for all three endpoints, HR between 1.4 and 1.9). Importantly, looking at the C-index, the best discriminant prognostic model was represented by the combination of DNA-based BM2 and BM3 with S-GRAS (combined score) as compared to S-GRAS alone, which was the second best prognostic factor (C-index for OS 0.734 vs 0.704, for PFS 0.697 vs 0.676, for DFS 0.674 vs 0.633, respectively). In conclusion, targeted DNA-based biomarkers evaluated on routinely available FFPE samples improve prognostication of ACC beyond combined clinical/histopathological parameters. This approach is easily applicable in clinical practice and may help to optimise patient's management.

[1]University of Milan, Department of Clinical Sciences and community Health, Milano, Italy; [2]University of Milan, PhD Program in Experimental Medicine, Milan, Italy; [3]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy; [4]University Sapienza of Rome, PhD Program in Endocrinological Sciences, Rome, Italy; [5]University Hospital Zurich (USZ) and University of Zurich (UZH), Department of Endocrinology, Diabetology and Clinical Nutrition, Zurich, Switzerland; [6]University Hospital Carl Gustav Carus Dresden, Medizinische Klinik und Poliklinik III, Dresden, Germany; [7]University of Brescia, Section of Pharmacology, Department of Molecular and Translational Medicine, Brescia, Italy

Adrenocortical carcinomas (ACC) are rare endocrine tumors that originate in the cortex of the adrenal gland. They are characterized by the overexpression of insulin-like growth factor 2 (IGF2), whose bond with two tyrosine-kinase receptors, IGF1R and IR, activates a cancer-promoting signalling cascade. Another component of the IGF system is mannose 6-phosphate/insulin-like growth factor 2 receptor (IGF2R), a scavenger receptor able to bind specifically IGF2. Its main role is to internalise IGF2 and direct it to lysosomal degradation,

suggesting an anti-oncogenic role. However, the study of its involvement in different tumors has highlighted a diverse role, even making it a marker of poor prognosis. Aim of the present study was to deepen the knowledge on IGF2R role in ACC investigating its expression levels, involvement in the proliferative mechanism and interaction with the other receptors of the IGF2 pathway. IGF2R expression was evaluated in two human ACC cell lines (MUC-1 and H295R), 7 ACC tissue samples, and 7 normal adrenal tissues (NA). Our results showed that ACC tissues and cell lines had increased IGF2R protein levels compared to NA ($P<0.01$). To investigate IGF2R role in cell proliferation we altered its expression in MUC-1 and H295R cell lines. We demonstrated that IGF2R genetic silencing reduced cell proliferation (-11.65±8.73% $P<0.01$ in MUC-1; -14.02±12.35% $P<0.01$ in H295R). Similarly, IGF2R-neutralizing antibody incubation exerted anti-mitotic effects (-16.85±2.57% $P<0.05$ in MUC-1). On the opposite, IGF2R transient transfection promoted cell growth (+14.84± 12.54% $P<0.01$ in MUC-1; +24.49±15.62% $P<0.001$ in H295R). To investigate the molecular mechanism involved, we tested the effect of IGF2R manipulations on the expression of the other receptors of the IGF2 pathway. MUC-1 silenced for IGF2R showed a significant decrease in IGF1R protein expression (-35 ±37% $P<0.05$); accordingly, after IGF2R transfection, IGF1R protein level was increased (+20±6% $P<0.001$). In conclusion, IGF2R is involved in the mechanisms driving cell proliferation in ACC, possibly relating also to the alteration of IGF1R expression. Since its upregulation in ACC and its pro-mitotic action, IGF2R may represent a promising therapeutic target for the treatment of ACC.

Adrenocortical carcinoma (ACC) is a rare malignancy with dismal prognosis. Deregulated microRNA (miRNA) expression has been implicated in ACC aggressiveness. Nevertheless, the mechanisms underlying such deregulations remain unknown. Aberrant Wnt/β-Catenin signaling has been reported in about 40% of ACC and is associated with poor outcome. In the present work, we aimed to investigate the link between constitutive activation of Wnt/β-Catenin pathway and miRNA expression alterations in ACC. To this end, we used inducible shRNA-mediated gene silencing of β-Catenin (β-Cat) in ACC cells. The miRnome of ACC cells was analyzed using RNA-Sequencing. Selected miRNAs and mRNAs were validated using quantitative PCR and functional experiments. Prognostic values of Wnt/β-Catenin pathway components or mutational status and their correlations with miRNA/mRNA expressions were determined in COMETE-ENSAT and TCGA cohorts. We carried out the first miRnome analysis in β-Catenin-deficient (β-Cat-) ACC cells. Twelve upregulated miRNAs and 42 downregulated miRNAs among which miR-139-5p and miRNAs of the 14q32 locus were identified in β-Cat- cells. Downregulation of selected poor prognosis-associated miRNAs was confirmed using RT-qPCR. Remarkably, the expression of the intronic miR-139-5p was decreased by 90% in β-Cat- cells with a concomitant repression of its host gene phosphodiesterase 2A and upregulation of its target gene N-Myc Downstream-Regulated Gene 4 (NDRG4). In ACC patients, miR-139-5p levels were highly correlated with the levels of PDE2A and anti-correlated with those of NDRG4. MiR-139-5p and PDE2A expressions were higher in patients with mutations in components of Wnt/β-Catenin signaling pathway or high expression of LEF1, with LEF1 proving a better predictor of prognosis than Wnt/β-Catenin signaling pathway mutational status. These findings suggest that in addition to inducing protein-coding target genes in ACC, constitutively active Wnt/β-Catenin signaling upregulates the expression of a subset of miRNAs involved in tumour aggressiveness and poor clinical outcome.

Pheochromocytomas and paragangliomas (PPGLs) are rare neuroendocrine neoplasms (NENs) that arise in the adrenal medulla and paraganglia, respectively. As occurs in the rest of NENs, PPGLs commonly present a high density of somatostatin receptors (SSTs) on their membrane. However, unlike in most NENs, somatostatin analogues (SSAs) do not represent a suitable therapeutic target in PPGLs, and the mechanisms underlying this mismatch are still unclear. In this study, we aim to identify the molecular elements and processes involved in the lack of response of PPGL to SSAs, with the ultimate goal of sensitizing PPGL to these drugs. To this end, we first explored by RNA-seq analysis two cohorts of 204 and 95 samples, and the TCGA dataset, focusing on determining the profile of SSTs in PPGL samples and the differences in their expression depending on driver genes mutations. Then, in vitro assays were performed using two cell lines representative of the pathology: rat PC-12 cells and human SK-N-AS cells (wildtype and *SDHB*-KD). We determined their response to somatostatin, cortistatin, SSAs (octreotide and pasireotide) and specific SSTs agonists on different functional assays, including cell proliferation, colony formation and wound healing, as well as key intracellular signaling pathways. Transcriptomic analyses revealed a marked difference in the expression pattern of SSTs between the different PPGL molecular clusters, with a clear divergence in the type of SSTs expressed across the mutated driver genes. In striking contrast, we did not observe any antitumor effect in response to somatostatin, cortistatin or SSAs in vitro. Interestingly, however, the use of selective agonists for each SST revealed antiproliferative effects in human cells, specifically in those lacking *SDHB*, whereas, no significant effects were observed on colony formation and migration assays. Current analyses are focused on the elements downstream SST signaling. Taken together, our results suggest previously unrecognized molecular associations between the SST system and PPGL subtypes and invite to further explore the underlying mechanisms behind their lack of response to SSA therapy.

Introduction
Current guidelines propose temozolomide (TMZ) as the first-line chemotherapy for aggressive pituitary neuroendocrine tumors (PitNETs), but no clinical trials have been conducted and clinical experience in this context is limited.
Patients and methods
A retrospective study of patients with aggressive pitNETs treated with TMZ was conducted by the members of the Neuroendocrinology Working Area of the Spanish Society of Endocrinology and Nutrition.
Results
Twenty-eight patients (9 women and 19 men), aged 46.6 + 16.9, from 10 Spanish Neuroendocrinology Units were included. Visual disturbances were present in 82.1%, headache in 71.4% and hypopituitarism in 67.9%. Four patients had Cushing's disease (one of them Nelson's syndrome), 9 prolactinomas and 15 clinically non-functioning pituitary adenomas (NFPAs). Among the 15 NFPA, immunohistochemistry was positive for ACTH in 7 cases, for GH in 3 cases, for prolactin in one case, for gonadotrophins in one case, and 3 tumors were negative for all pituitary hormones. Median size at diagnosis was 10.5 cm^3 (IQR 4.7-22.5), with cavernous invasion in 88% and no metastases. Pre-TMZ treatment, these data were 5.2 cm^3 (IQR 1.9-12.3), 89.3% and 14.3% (2 intracranial and 2 spinal metastases). Before TMZ treatment all patients had undergone surgery (1-5 surgeries, median 2), 25 (89.3%) had received radiotherapy (7 of them reirradiated) and 13 (46.4%) had received cabergoline. One patient interrupted TMZ prematurely due to intercurrent complications. The other 27 patients received a median of 13 cycles (range 3-66) of TMZ with a median final daily dose of 300 mg (IQR 200-334). Eight patients (29.6%) had a significant reduction (>30%) in tumor volume and 14 (51.9%) attained tumor stabilization. After a median follow-up of 29 months (IR 10-55), 8 out of those 22 progressed (median time from treatment to progression 16.5 months, RI 7-27). Four patients received a new course of TMZ treatment. Seven patients (25%) died (all of them because of tumor progression or complications of treatments) at 77 months (IQR 42-136) from diagnosis and 29 months (IQR 16-55) from TMZ first treatment. Adverse effects occurred in 18 patients (14 mild and 4 moderate or severe).
Conclusions
TMZ is an effective medical treatment for aggressive pitNET (81.5% tumor shrinkage or stabilization) but is sometimes followed by tumor progression. Its safety profile is acceptable. After a median follow-up of 29 months, we observed a 25% mortality.

Much more than hormonal resistance: estrogen receptor activating mutations mediate chemotherapy resistance in breast cancer

Marwa Taya[1,2], Keren Merenbakh-Lamin[1], Zohar Honig[1], Ido Wolf[1,2] & Tami Rubinek[1,2]
[1]Tel Aviv Sourasky Medical Center – Ichilov, Oncology, Tel Aviv-Yafo, Israel; [2]Tel Aviv University, School of Medicine, Tel Aviv-Yafo, Israel

Resistance to endocrine treatment develops with time in virtually all patients with metastatic breast cancer (BC), and eventually most of them are treated with chemotheray. Our group and others discovered a group of mutations in the ligand binding domain (LBD) of the estrogen receptor (ER), that are the direct cause of resistance in ~40% of the patients. The most common mutations are Y537S and D538G ER. Clinical data indicate an association between those ER mutations worse prognosis. The aim of this study was to study the role of ER mutations in promoting (i) resistance to chemotherapy; (ii) identify mechanisms mediating chemo-resistance. We studied chemo-resistance, using viability, colony formation and apoptosis assays, in MCF7 BC cells stabely expressing the WT-ER or Y537S and D538G ER mutations (mut-ER). The results showed that mut-ER cells exhibit elevated resistance to paclitaxel and doxorubicin. Nest, we studied the expression of the MDR1 gene, that encodes an ATP pump that is associated with chemoresistance. We observed increased expression of MDR1 mRNA and protein in mut-ER cells. Furthermore, we observed activation of the JNK pathway in mut-ER cells as evidanced by increased JNK and cjun phosphorylation, as well as cjun transcriptional activity. Our next goal was to find out whether cjun regulates MDR1 expression in mut-ER cells. Indeed, chromatin immunoprecipitation assay showed that cjun bound MDR1 promoter. Inhibition of JNK using SP600125 decreased MDR1 expression and also restored sensitivity to chemotherapy. Moreover, immunohistochemical studies of mut-ER tumors in mice, showed higher expression of MDR1 and cjun compared to WT-ER tumors. Finally, we analyzed duration of response to chemotherapy among 51 breast cancer patients with endocrine resistance, of which mut-ER was detected in 20 patients, whereas 31 had WT-ER. The analysis showed a significant shorter duration of chemotherapy treatment among patients with mut-ER, indicative of refractory response. In conclusion, ER activating mutations are associated with resistance to chemotherapy, mediated by the cjun-MDR1 axis. Our studies suggest novel, non-endocrine, therapeutic approaches aimed at targeting chemoresistance.

The frequency of differentiated thyroid carcinoma recurrence in retrospective analysis of 3087 consecutive patients

Iwona Palyga[1,2], Maciej Rumian[1], Alicja Kosel[1], Maciej Albrzykowski[1], Paulina Krawczyk[1], Agata Kalwat[1], Danuta Gąsior-Perczak[1,2], Agnieszka Walczyk[1,2], Artur Kuchareczko[1,2], Janusz Kopczyński[2], Magdalena Chrapek[1], Stanislaw Gozdz[1,2] & Aldona Kowalska[1,2]
[1]Jan Kochanowski University, Collegium Medicum, Kielce, Poland; [2]Holycross Cancer Centre, Endocrinology, Kielce, Poland,

Introduction
An increase in the incidence of differentiated thyroid cancer (DTC) has been observed in recent decades. Despite the excellent prognosis, DTC patients remain on lifelong oncologic follow-up after treatment, due to fear of recurrence.
Aim
Was to evaluate the frequency of real recurrence, defined as appearance of structural or biochemical disease after >12 month period of no evidence of disease (NED) in DTC patients.
Material and methods
A retrospective analysis of medical records of 3087 consecutive DTC patients (after the operation alone or operation and 131-I therapy) being under observation from 1998 to 2021. Clinicopathological features including histology, tumor size, extrathyroidal extension, angioinvasion, multifocality, resection margin involvement, lymph node (LN) and distant metastases, were obtained from all the patients. Moreover, the stage of the disease was assessed or reassessed according to TNM 8th edition of UICC and response to therapy according to the ATA recommendation, in all the patients. Only patients with an excellent response were submitted to further analysis. The percentage of recurrence and cumulative recurrence rate (CRR) were analyzed.
Results
Females accounted for 85.4% of the patients. Papillary TC was the most common in 2827 patients (91.6%). Median age was 52 years (range: 13-86 years). Median tumour size- 9 mm (range 0-144 mm). 15% of the patients had LN and 2.7% distant metastases. Excellent response to therapy was observed in 2302 patients (74.6%)- among them true recurrence developed in 34 patients (1.5%). The recurrence was significantly more common in patients with: other than PTC type of TC ($P=0.009$), larger tumour size ($P<0.0001$), angioinvasion ($P=0.0015$) and lymph node metastases ($P=0.0063$), TNM stage ($P=0.0013$) and treated with 131-I ($P=0.0045$). In the univariate analysis, histological type-PDTC (HR: 9.581 CI:2.278-40.293 P=0.002), tumour size 11-40 mm (HR:2.703 CI:1.291-5.662 $P=0.008$) and >40 mm (HR: 6.879 CI:2.423-19.533 $P<0.001$), LN metastases (HR: 3,861 CI:1.752-8.511 $P<0,001$), angioinvasion (HR: 4.836 CI: 1.186 – 10.698 $P<0.001$), stage II TNM (HR: 5.4945 CI:2.389 – 12.636 $P<0.001$) were associated with a risk of recurrence. Higher CRR was observed in poorly differentiated and oncocytic TC, than in FTC and PTC.
Conclusion
1. Real recurrence is rare in patients with DTC- it accounts for 1,5%.
2. Despite of excellent response to the therapy, patients with advanced stage of disease have higher risk of recurrence.

C-peptide level concomitant with hypoglycemia gives better performances than insulin for the diagnosis of endogenous hyperinsulinism: a monocentric study of 159 fasting trials

Bonnet Fideline[1,2,3], Clara Devin[4], Louis Thomeret[1,3], Christelle Laguillier-Morizot[2,3], Marie-Clémence Leguy[2], Anna Vaczlavik[1,4], Lucas Bouys[1,3,4], Corinne Zientek[2], Léopoldine Bricaire[4], Laura Bessiene[4], Laurence Guignat[4], Rossella Libe[4], Helen Mosnier-Pudar[4], Guillaume Assié[1,3,4], Lionel Groussin[1,3,4], Jean Guibourdenche[2,3] & Jerome Bertherat[1,3,4]
[1]Cochin Institute, Inserm U1016-CNRS UMR8104, France; [2]Cochin Hospital, Hormonology, Paris, France; [3]Paris Cité University, Paris, France; [4]Cochin Hospital, Endocrinology, Paris, France

Introduction
The gold standard for insulinoma diagnosis is still 72-hours fasting trial with the aim to trigger Whipple's triad. In this context, biological diagnosis of endogenous

hyperinsulinism relies on the occurrence of a hypoglycemia, concomitant with inadequate high insulin and C-peptide levels. However, diagnostic cut-offs are not consensual among the different learned societies (*Endocrine Society 2009, NANETS 2010, ENETS 2012*). The objective of this work was thus to propose optimized cut-offs for these three parameters for the diagnosis of endogenous hyperinsulinism.

Methods

All the patients having performed a fasting trial in Cochin Hospital Endocrinology Department between February 2012 and August 2022 were included. The results of glycemia, insulin and C-peptide levels during fasting trial were collected and analyzed.

Results

One hundred and fifty-nine patients were included: 26 with endogenous hyperinsulinism and 133 without endogenous hyperinsulinism. ROC analysis of glycemia nadir during fasting trial identified the value of 2.3 mmol/l as the optimal cut-off, ensuring a sensitivity of 100% associated with a specificity of 81%. The median time to glycemia nadir was 22.5 (min 8 – max 66.5) hours in the group of patients with endogenous hyperinsulinism in comparison to a median of 62.5 (min 24 – max 84) hours in the group of hypoglycemic controls. ROC analysis of insulin and C-peptide levels concomitant with hypoglycemia $<$ 2.3 mmol/l showed very good diagnostic performances of both parameters with respective cut-offs of 3.1 mUI/l (sensitivity = 96%; specificity = 92%) and 0.30 nmol/l (sensitivity = 96%; specificity = 100%). Insulin to glycemia ratio as well as C-peptide to glycemia ratio (in pmol/mmol) at the time of glycemia nadir did not show better diagnostic performances than C-peptide alone.

Conclusion

A C-peptide level 0.3 nmol/l concomitant with a hypoglycemia $<$ 2.3 mmol/l appears as the best criterion to make the diagnosis of endogenous hyperinsulinism. Insulin level can be underestimated on hemolyzed blood samples, frequently observed in fasting trial, and thus shows lower diagnostic performances.

Dopamine receptor type 2 (DRD2) represents the main target for pharmacological therapy with dopamine agonists (DAs) in PRL-secreting neuroendocrine pituitary tumors (PRL-PitNET), even if about 10% of patients is resistant. A single paper recently described a somatic mutation in the gene encoding splicing factor 3B subunit 1 (SF3B1) in about 20% of patients with PRL-PitNET, that was associated with PRL hypersecretion, increased cell proliferation and invasion and reduced progression free survival. SF3B1 is a key component of pre-mRNA processing, crucial for splicing machinery assembly. Aims of the study were: 1) to characterize the genetic profile of PRL-PitNET, searching for somatic mutations in SF3B1^{R625H} hotspot region; 2) to test in tumoral lactotroph cells the effects of SF3B1 inhibitor pladienolide-B and the role of SF3B1 in affecting DRD2 agonist cabergoline antitumoral effects. SF3B1^{R625H} hot-spot region has been sequenced in PRL-PitNET tissues and rat PRL-secreting pituitary tumoral cells mmQ. SF3B1 was inhibited with pladienolide-B or silenced by siRNA technique, and cells have been analysed to measure cell proliferation, apoptosis, secretion and cell cycle markers activation. No mutation in SF3B1 gene was found in our cohort of PRL-PitNET ($n = 40$), nor in rat lactotroph mmQ cells. Pladienolide-B 50 nM treatment strongly reduced cell proliferation (-92 $\pm$ 5%, $P < 0.001$) and increased apoptosis (+10-fold, $P < 0.001$) in mmQ, and similar results were found in primary PRL-PitNET cultured cells, wild-type for SF3B1. Moreover, pladienolide-B reduced PRL secretion in primary cells (-45 $\pm$ 6.5%, $P < 0.001$). SF3B1 silencing in mmQ cells abolished cabergoline inhibitory effects on cell proliferation (-22 $\pm$ 4.8%, $P < 0.001$), AKT phosphorylation (-31 $\pm$ 24.6%, $P < 0.01$), cyclin D3 (-23 $\pm$ 7.6%, $P < 0.05$) and increase of p27 levels (+20 $\pm$ 8.6%, $P < 0.05$). In addition, SF3B1 knock down was associated with DRD2 reduction (-66.4 $\pm$ 8% of DRD2 transcript, $P < 0.05$, and -51 $\pm$ 13.2% of DRD2 protein, $P < 0.001$), and the same effects were observed after pladienolide-B incubation. On the other hand, cabergoline reduced SF3B1 protein expression levels in mmQ (-60 $\pm$ 40%, $P < 0.05$) and in 2 PRL-PitNET (-43 $\pm$ 6.1%, $P < 0.01$). Our data did not confirm the presence of SF3B1^{R625H} mutations in a multicentre cohort of PRL-PitNET. In contrast, we observed that SF3B1 seems to play a relevant role in tumoral lactotroph cells. Indeed, SF3B1 inhibitor pladienolide-B exerted antiproliferative, proapoptotic and antisecretory effects in PRL-PitNET cells wild-type for SF3B1. Moreover, SF3B1 is required for expression and signalling of DRD2.

Transcription factor analysis for pituitary tumours: Are results always consistent and reliable?

Prishila Fookeerah[1,2], Winny Varikatt[3,4] & Mark McLean[1,2,4]

[1]Westmead Hospital, Department of Diabetes and Endocrinology, Sydney, Australia; [2]Western Sydney University, School of Medicine, Sydney, Australia; [3]Institute of Clinical Pathology and Medical Research, Tissue Pathology and Diagnostic Oncology, Sydney, Australia; [4]University of Sydney, Faculty of Medicine and Health, Sydney, Australia

Background

Improved diagnostic precision is achieved with the addition of transcription factor (TF) analysis to characterise pituitary tumours. Clinicopathological studies have demonstrated a reduction in the prevalence of true null cell tumours (NC) and a rise in plurihormonal (PH) tumours, in comparison to methods based on hormone staining. There remains a high degree of heterogeneity in epidemiological and clinical patterns seen in studies. We hypothesise that variations in methodological and diagnostic criteria contribute to inconsistencies observed. We therefore reviewed methodological approaches to pituitary tumour diagnosis in recent studies.

Methods

A PubMed search was conducted with keywords "pituitary tumour" (and variations in nomenclature), "classification", "transcription factor" and "clinicopathological". Abstracts of studies involving pituitary tumours, published in English between 2015 to February 2023 were screened for relevance. Studies were excluded if they did not assess for presence or absence of all 3 TF or if analyses were limited to tumour subsets only. Case reports and review articles were excluded. Remaining studies were evaluated for their methodology, type of antibody and scoring strategy. Outcomes were number of NC and PH tumours.

Results

Of the 13 studies included in this review, 9 were conducted retrospectively using stored tissue blocks. Threshold definitions for positive identification of tumour types varied from 5% tumour cells positive to 80%. Mean storage time of oldest specimens used in retrospective studies was 17.1 $\pm$ 6.8 years at time of publication. There was a positive linear correlation between number of tumours classified as NC and the age of tissue used for analysis ($R^2 = 0.71$, $P = 0.03$). Five studies with clinical data reported that 33-100% of NC tumours showed radiological invasion. In the non-functioning tumour category, the percentage of individual tumour subtypes varied substantially across all studies: 6.9 $\pm$ 4.7% silent PIT1, 17.4 $\pm$ 7.9% silent corticotroph tumours, 67.1 $\pm$ 10.1% gonadotroph tumours, 5.5 $\pm$ 4.5% NC tumours and 3.2 $\pm$ 3.0% silent PH tumours. Studies that used a cut-off of 5% or 10% tumour cells to define TF positivity were able to diagnose PH tumours. When a high cut-off of 80% was applied, PH tumours were not identified.

Conclusion

Higher proportion of NC tumour classification is seen with older tumour specimens, possibly representing false negative staining. Positivity cut-off influences the ability to detect PH tumours. We highlight the need for large prospective studies and a standardised approach to assessment of transcription factor expression before developing guidelines for clinical management based on TF analysis.

AZP-3813, a bicyclic, 16-amino acid peptide antagonist of the human growth hormone receptor, effectively suppresses IGF1 in beagle dogs

Guillaume Ravel[1], Clémentine Chalmey[1], Corentin Berardet[1], David Duracher[1], Haruaki Kurasaki[2], Tatsuya Tomiyama[2], Patrick Reid[2] & Michael D. Culler[3]

[1]Amolyt Pharma, Ecully, France; [2]PeptiDream Inc, Kawasaki City, Kanagawa, Japan; [3]Amolyt Pharma, Cambridge, United States

Medical treatment of acromegaly is based on either suppressing pituitary growth hormone (GH) secretion or by inhibiting GH action by preventing interaction with its receptor in order to suppress the elevated levels of insulin-like growth factor 1 (IGF1). AZP-3813 is a 16-amino acid, bicyclic peptide antagonist of the GH receptor (GHR) with K_D of 1.9 nM for the human GHR. Previously, AZP-3813 was demonstrated to suppress IGF1 secretion in juvenile rats in a dose-related manner, and to maintain IGF1 suppression when given daily for extended periods. To examine the ability of AZP-3813 treatment to suppress IGF1 levels in normal dogs, we injected adult, non-fasted, male Beagle dogs subcutaneously with AZP-3813 at doses of 0.1, 1 or 10 mg/kg. Three dogs received a single 0.1 mg/kg dose of AZP-3813 and, after 7 days, the same dogs received a single 10 mg/kg dose of AZP-3813. A second group of three dogs received 1 mg/kg AZP-3813 daily for 5 days. Blood was collected 3 days and immediately before treatment, and at 15 min, 30 min, and 1, 2, 4, 8, 24, 48, 72 and 96 hours after the single injections of 0.1 and 10 mg/kg AZP-3813, and after the first and fifth injections for dogs receiving 1 mg/kg AZP-3813 daily for five days. Pre- and 24 hour post-injection samples were assayed for total IGF1 content by radioimmunoassay, and all samples were analyzed for AZP-3813 content by LC-MS/MS. Maximal blood concentrations (C_{max}) of AZP-3813 were observed 4 hours following injection, and were 0.72 ± 0.028, 7.2 ± 0.36 and 58.9 ± 2.8 mg/ml for the 0.1, 1 and 10 mg/kg doses, respectively. After the fifth injection of 1 mg/kg, blood levels of AZP-3813 were 8.7 ± 0.34 mg/ml, indicating compound accumulation. Elimination curves for all doses were parallel with a half-life of 14.2 ± 0.47 hours. While the 0.1 mg/kg dose of AZP-3813 was ineffective (-2.2 ± 7.1% decrease from baseline), 24 hours after injection of 1 and 10 mg/kg AZP-3813, IGF1 levels were suppressed by 21.4 ± 2.7% and 27.8 ± 1.5%, respectively. The repeated injection of 1 mg/kg AZP-3813 maintained a similar magnitude of IGF1 suppression through 72 hours following the fifth injection, while suppression of IGF1 was maintained at a similar level through 72 hours after the single injection of 10 mg/kg. These results demonstrate that the potent GHR antagonist activity of AZP-3813 translates to a sustained suppression of IGF1 in normal dogs and further support the development of AZP-3813 as a potential therapy for acromegaly.

Effects of prolactin excess and treatment with cabergoline on bone mineral density and fracture risk in men

Guendalina Del Vecchio[1], Federica Sorice[1], Roberta Scairati[1], Rosa Pirchio[1], Sara Di Meglio[1], Rosario Pivonello[1,2], Annamaria Colao[1,2] & Renata Simona Aurie mma[1]

[1]Dipartimento dImedicina Clinica e Chirurgia, Sezione di Endocrinologia, Università Federico II di Napoli, Naples, Italy; [2]UNESCO Chair for Health Education and Sustainable Development, Federico II University, Naples, Italy

Purpose

The present study aims to investigate the effects of hyperprolactinemia (HPRL) and its pharmacological control with Cabergoline (CAB) on the risk of fractures in male patients affected by prolactinoma.

Methods

Observational single-center study was conducted on 39 male patients (median age $49 \pm 12,4$ y) with prolactinoma, including 37 with macroprolactinoma and 2 with empty sellae. In patients PRL levels at diagnosis (PRL 0'), PRL at evaluation (PRL 1'), treatment duration (TD), CAB cumulative (CD) and mean dose (CM) were calculated. In the whole study population ($n=39$), anthropometric parameters (weight, height, BMI), testosterone dose, metabolic (vitamin D, serum calcium, fasting glucose, HbA1c), hormonal (FSH, LH, parathormone, total testosterone) parameters were evaluated. BMD was assessed by means of lumbar (LTS) and femoral neck t-scores (FTS), derived from bone mineralometry. Comparison of numerical data between patient groups stratified by quartiles of age, BMI, testosterone levels, PRL 0', PRL 1' and CM was detected.

Results

Based on the age quartiles, a statistically significant difference was found in the BMI between the four groups ($P=0.03$), particularly between the I and II groups ($P=0.022$). While no statistically significant differences in other parameters were found between the four groups. Based on testosterone quartiles, a statistically significant difference was found in PRL 1' ($P=0.018$), particularly between group I and group II ($P=0.017$). Furthermore, no statistically significant differences were found in the groups of patients divided into quartiles of BMI, PRL 0', PRL 1', CM between parameters considered. At correlation study, no correlation was found between Femoral and Lumbar T-Score and PRL levels, testosterone, Cab dose, and BMI; while age was indirectly and significantly correlated with serum calcium levels ($r=-0.39$; $P=0.019$) and PRL values were directly and significantly correlated with Cab mean dose ($r=0.55$; $P=0.003$) and with disease duration ($r=0.404$; $P=0.036$). No other significance was found in the regression analysis.

Conclusions

In accordance with previous studies, hyperprolactinemia seems to be an independent risk factor on the alteration of bone mineral density and consequent fracture risk. As expected, a reduced level of calcium was found with increasing age. Finally, a data of particular interest was the detection of an influence of cabergoline on PTH levels.

Background
Hypophysitis is a rare group of disease characterized with infla mmation of the pituitary gland. Rarity of the disease obviates development of a treatment strategy. We aimed to present the nationwide data of the demographics, clinical and radiological characteristics, treatment modalities and responses of the patients diagnosed with hypophysitis in a retrospective manner.
Methods
The endocrinology clinics all over the country were invited to the study. The patients' charts and computer-based records were retrospectively reviewed by an endocrinologist from each center. Protocol templates were used for data collection which were analyzed by the principal investigators.
Results
The data of 154 patients (109 female, 45 male) with a median (range) age of 37 (16-82) years from 30 clinics was analyzed. The most common symptoms were headache (57.1%), polyuria-polydipsia (47.4%), and fatigue (30.5%). The most common pituitary MRI findings were stalk thickening (67.6%), increased contrast enhancement (34.5%), and absence of neurohypophyseal bright spot (31.1%). The diagnosis of 110 patients was based on clinical and radiological evaluation, while 8 were performed biopsy, and 36 surgery. 115 patients (90 female, 25 male) had primary hypophysitis, 31 secondary hypophysitis (13 histiocytosis, 8 sarcoidosis, other:10), and 8 were undetermined. The median (range) follow-up was 23.5 (1-300) months. 52 (45.2%) patients presumably had lymphocytic hypophysitis, 21 of whom had histologic verification. 71 patients (62.8%) with primary hypophysitis had at least one anterior pituitary hormone deficiency, and 46 (40.7%) had diabetes insipidus. In primary hypophysitis group 54 patients were followed without interventions, and 50% (23/46) had radiologic improvement. 26 patients were started on steroid therapy with a median (range) metilprednisolone starting dose of 100 mg (40-1000), and a median treatment duration of 6 weeks (2-12). 64.7% (11/17) of the patients had radiologic improvement. The patients treated with glucocorticoids had more severe MRI findings at presentation compared to those that were followed without interventions. 36 patients with primary hypophysitis were performed surgery. The main indication was presence of compression symptoms and/or indeterminate diagnosis in 24 (66.6%) patients, while unresponsiveness to steroid therapy and assumption of a functional adenoma were other reasons. 2 patients had radiologic progression despite surgery followed by steroid therapy.
Conclusion
The study provides follow-up data of a nationwide large cohort diagnosed with hypophysitis. Clinically and radiologically mild cases might be followed without interventions. Glucocorticoids proved efficacious in some cases though the optimal dose and duration are not known. Surgery may be preferred for treatment-resistant and indeterminate cases.

Acquired Hypothalamic dysfunction in childhood: "What do patients need? "

Ichelle van Roessel[1], Johan de Graaf[2,3,4], Nienke Biermasz[3,4], Evangelia Charmandari[5] & Hanneke van Santen[1]
[1]Wilhelmina Children's Hospital, Department of Pediatric Endocrinology, Utrecht, Netherlands; [2]Dutch Pituitary Foundation, Nijkerk, Netherlands; [3]Leiden University Medical Center, Department of Endocrinology, Leiden, Netherlands; [4]Endo-ERN European Reference Network on Rare endocrine conditions; [5]Aghia Sophia Children's Hospital, Department of Pediatric Endocrinology, Athens, Greece

Introduction
Hypothalamic dysfunction (HD) during childhood can occur due to (treatment of) a suprasellar brain tumor. HD may not only result in pituitary dysfunction, but also in severe hyperphagia, decreased energy expenditure, diabetes insipidus with adipsia, disturbance of circadian rhythm, temperature dysregulation and behavioral problems. Currently there is no effective treatment for HD while HD has major impact on quality of life. To provide optimal care and to design the most relevant studies, aiming to improve quality of life, it is essential to understand the patients' needs . For this reason, an online questionnaire was conducted, to address the most relevant problems and the unmet needs of patients with HD as well as their perspective on future research and clinical approaches.
Methods
Through the different patient advocacy groups, SIOPe craniopharyngioma working group and the ENDO-ERN platform, a world-wide online survey was disseminated to patients with childhood onset HD following treatment for a brain tumor (April 2022 – October 2022).
Results
In total, 361 patients responded to the survey. Most were above 18 years old when filling out the questionnaire (63.7%), and 71.7% were diagnosed more than six years ago. The majority had been diagnosed with a craniopharyngioma (78%). In total 63% had panhypopituitarism. Obesity and fatigue were considered the most important health problems for patients (in respectively 48.8% and 46.5%). Patients indicated to want more support with food choices and diet, exercise and psychosocial assistance. In total 18% of patients indicated that there is a lack of information by their doctors on the disease and 14% reported a need for more psychological support. According to the patients, there is a need for more centralized care. Patient ideas for future research included (1) alternative ways for hormone administration (without injection, hydrocortisone by pump), (2) new treatments for hypothalamic obesity, (3) ways to improve early diagnosis of the suprasellar tumor.
Conclusion
According to the patient perspective, the care of patients with acquired HD should be more centralized and from an early stage onwards there should be more focus on quality of life and late consequences. Research should focus on fatigue, hypothalamic obesity and early diagnostics. Ideally, care should be delivered by doctors who have a holistic view of the patient in a multidisciplinary expert team where information is shared with patients but also between subspecialists.

Targeting adipocyte ESRRA rebalances bone and marrow adipocyte homeostasis through opposite regulation of LEPTIN and SPP1

Tongling Huang[1], Zihui Wang[1,2], Zhaocheng Lu[1], Lu Gao[1], Jun Gao[1], Lixin Cheng[3] & Min Guan[1]
[1]Shenzhen Institute of Advanced Technology, Chinese Academy of Sciences, Institute of Biomedicine and Biotechnology, Shenzhen, China; [2]University of Chinese Academy of Sciences, Beijing, China; [3]Shenzhen People's Hospital, First Affiliated Hospital of Southern University of Science and Technology, Second Clinical Medicine College of Jinan University, Shenzhen, China

Osteoporosis is a progressive disease characterized by excessive bone loss which is often accompanied by augments in marrow adiposity as a result of estrogen deficiency, metabolic abnormalities or medications. Nuclear receptor estrogen-related receptor alpha (ESRRA) has a demonstrated role in energy homeostasis and fat metabolism. To determine if ESRRA is a potential therapeutic target for regulating fat-bone balance, we generated an adipocyte-specific ESRRA knockout mice (ESRRAAKO) by using an Adiponectin recombinase which labels mature adipocytes within peripheral adipose depots and most bone marrow adipocytes (BMAds) derived from mesenchymal stem cells (BMSCs). We found that ESRRAAKO mice were protected from bone loss after ovariectomy or diet-induced obesity (DIO). Interestingly, marrow adipocytes were more resistant to estrogen deprivation and overfeeding than visceral white adipose tissue (WAT) in ESRRAAKO mice. Furthermore, $CD31^{hi}$ $Emcn^{hi}$ vessel (termed as type H vessels) formation was improved in ESRRAAKO mice following ovariectomy or DIO. By using microCT analysis, bone histology, immunofluorescence staining, calcein double labeling and ELISA assays, we demonstrated that loss of ESRRA in adipocytes alleviated fat-bone imbalance with reduction of marrow adipocytes expansion, stimulation of type H vessel formation and enhancement of trabecular bone formation. By using methods such as RNA-seq, Duo-luciferase reporter, chromatin immunoprecipitation assay, qRT-PCR and immunofluorescence staining of adipose sections, we revealed that ESRRA oppositely regulates transcriptional expression of *Spp1* and *Leptin* within both WAT adipocytes and BMAds. SPP1 has been characterized as an negatively charged matrix glycoprotein preferring to anchor in bone environment. We performed transwell assay and matrigel tube formation assay of endothelial cells (ECs) cultured in conditioned medium from either gWAT or BMAds supplemented with anti-SPP1 neutralizing antibody or recombinant SPP1, and confirmed that increased secretion of SPP1 from ESRRAAKO mice enhancing the ability of ECs to migrate and form capillary-like network structures compared to control mice. On the other hand, LEPTIN is known to promote bone adipogenesis by LEPTIN/lepR signaling in BMSCs. In contrast, we further revealed that ESRRA ablation resulted in the suppression of LEPTIN secretion from adipocytes conferring osteogenic differentiation while constraining adipogenic differentiation of BMSCs. Finally, pharmacological treatment in DIO mice with an ESRRA specific inverse agonist compound 29 enhanced bone formation coupled with a reduction of MAT expansion. Collectively, our results proved that adipocyte

ESRRA inhibition favored bone formation and may have important therapeutic implication in bone diseases associated with fat-bone imbalance.

Sarcopenia, low bone mineral density and hidden obesity in young adult Men Living with HIV (MLWH): prevalence and relationship with sex steroids

Sara De Vincentis[1,2], Maria Chiara Decaroli[1,2], Carla Greco[1,2], Chiara Diazzi[2], Flaminia Fanelli[3], Marco Mezzullo[3], Uberto Pagotto[3], Giovanni Guaraldi[4] & Vincenzo Rochira[1,2]

[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena , Italy; [2]Unit of Endocrinology, Department of Medical Specialties, Azienda Ospedaliero-Universitaria Policlinico of Modena, Italy; [3]Department of Medical and Surgical Sciences, Center for Applied Biomedical Research, Alma Mater Studiorum University of Bologna, Italy; [4]Multidisciplinary Metabolic Clinic, Unit of Infectious Diseases, University of Modena and Reggio Emilia, Italy

Background

HIV is associated with decreased bone mineral density (BMD) and decreased muscle mass. Osteoporosis and sarcopenia often co-exist and their onset is multifactorial. Sex steroids play a key role in the homeostasis of bone health and body composition in HIV-uninfected men, but data in MLWH are scanty.

Aim

To investigate the frequency of low BMD and sarcopenia and their relationship with gonadal function in MLWH younger than 50.

Methodology

Prospective, cross-sectional, observational study on MLWH with ongoing antiretroviral therapy. Body composition and BMD were obtained by dual-energy X-ray absorptiometry (DXA). Sarcopenia was defined as appendicular lean mass/height^2 (ALMI) <7.26 kg/m^2; low BMD was defined for Z-score <2.0 at lumbar or femoral site. Patients were classified according to body mass index (BMI) and body fat percentage: hidden obesity was defined wherein BMI was 18.5-25.0 kg/m^2 and the body fat percentage was $>20\%$. Serum total testosterone (TT) and estradiol (E2) were measured by liquid chromatography-tandem mass spectrometry; free testosterone (cFT) was calculated by Vermeulen equation.

Results

A total of 316 MLWH aged 45.3 ± 5.3 years were enrolled. BMD was normal in 265 MLWH (86.0%) and reduced in 43 (14.0%); sarcopenia was detected in 107 MLWH (33.8%). Sarcopenic MLWH had lower cFT ($P=0.002$), E2 ($P=0.002$), E2/T ratio ($P=0.017$), and reduced BMD at both lumbar and femoral site compared to non-sarcopenic patients. Furthermore, sarcopenic patients had lower BMI ($P<0.001$) along with increased total fat percentage ($P=0.038$); accordingly, the prevalence of hidden obesity was greater in sarcopenic than non-sarcopenic subgroup (71.0% vs 37.7%; $P<0.001$). The E2/TT ratio was lower in patients with low BMD compared to those with normal BMD ($P=0.023$), although TT, E2, and cFT did not differ. Patients with lower E2/TT values had an increased likelihood risk of sarcopenia ($P=0.044$) and low BMD ($P=0.025$). No difference was found for age and HIV duration comparing patients for low BMD or sarcopenia. Finally, ALMI was directly associated with BMD Z-scores at any site.

Conclusions

Sarcopenia and low BMD are common findings among young adult MLWH and these conditions are strictly related each other. Within the multidimensional network of factors leading to reduced BMD and lean mass, an imbalanced E2/TT ratio seems to be more relevant rather than TT or E2 alone. The prevalence of hidden obesity is high, especially in sarcopenic MLWH, and it may be overlooked by weight measurement alone with a consequent undermanagement of the increased cardiometabolic risk.

CYP24A1 mutation as a rare cause of hypercalcemia during pregnancy

Liisa Kullamaa, Sanni SÖderlund, Marianna Viukari, Niina Matikainen & Camilla Schalin-Jäntti

Helsinki University Hospital, Department of Endocrinology, Helsinki, Finland

Clinical case

A 27-year-old pregnant woman (24 weeks of gestation) was investigated as her Hb level (87 g/l) was low. Laboratory work-up revealed severe, non-PTH dependent hypercalcemia (see Table). This was her first pregnancy, and serum calcium measured once previously 12 years earlier had been normal. The patient had symptoms of increased thirst, constipation and hyperemesis.

Lab	Result	Reference range
S-Ca-ion	1.76 mmol/l/pH7.4	1.16-1.3
eGFR	66 ml/min/1.73 m^2	>89
24-h U-Ca	11.72 mmol	1.3-6.5
fP-PTH	<4.6 ng/l	18-80
P-PTHrP	<0.50 pmol/l	<1.3
S-D-25	84 nmol/l	>50
S-D-1,25	238 pmol/l	48 – 190
S-LZM	15 mg/l	<12

Diagnostic work up and Treatment

Rehydration and close monitoring of calcium concentration was initiated. Hematological investigations, including bone marrow biopsy, were normal. Whole body MRI did not reveal any malignancy. In addition to PTH, PTHrp concentration was also suppressed. The patient was put on oral **prednisolone**, but the effect was not sustained. Next, genetic causes of hypercalcemia during pregnancy were considered. Both FHH and MEN-1 syndrome are characterized by PTH-dependent hypercalcemia. A CYP24A1 mutation was suspected, and **low-calcium diet** was initiated on the 30th gestational week, before the results of genetic analysis were obtained. Mutation screening of the *CYP24A1* gene revealed a homozygous inactivating mutation c.1186C>T; p.(Arg396Trp). The patient was started on a **diet strictly avoiding both calcium and vitamin D**, which lowered her serum calcium to a nadir of 1.28 mmol/l/pH7.4. The fetus was regularly monitored during pregnancy and no signs of growth retardation were noted. The patient delivered a healthy child at 38 weeks of gestation. After delivery, the patient's calcium levels remained normal on a regular diet. The patient's sister was found to be heterozygous for the same gene mutation. Her calcium levels remained normal during pregnancy.

Discussion

During pregnancy, intestinal calcium absorption in the mother almost doubles to ensure the requirements of the fetus, which is mediated by increased S-D-1,25 and estrogen concentrations. Inactivating mutation in *CYP24A1*, encoding vitamin D-24-hydroxylase, can further accumulate active vitamin-D metabolites and present as hypercalcemia during pregnancy. In addition, the amount of vitamin D and calcium supplements used may influence calcium concentrations during pregnancy.

Encaleret (CLTX-305) normalized mineral homeostasis parameters in patients with autosomal dominant hypocalcemia type 1: Results over 12 months in a phase 2 study (NCT04581629)

Michael Collins[1], Iris Hartley[1], Kelly Roszko[1], Edward Nemeth[2], Karen Pozo[1], Winsome Boykin[1], Arun Mathew[3], Mary Scott Roberts[3] & Scott Adler[3]

[1]National Institutes of Health, Skeletal Diseases and Mineral Homeostasis Section, Bethesda, United States; [2]MetisMedica; [3]Calcilytix Therapeutics, Inc, San Francisco, United States

Autosomal dominant hypocalcemia type 1 (ADH1), caused by gain-of-function calcium-sensing receptor gene (*CASR*) variants, is characterized by low parathyroid hormone (PTH) levels, hypocalcemia, hypercalciuria, hyperphosphatemia and hypomagnesemia. Conventional therapy (calcium and active vitamin D) worsens hypercalciuria, which may result in renal complications. Calcilytics, such as encaleret, are negative allosteric modulators of the calcium-sensing receptor (CaSR). They decrease the hypersensitivity of ADH1 variants to extracellular calcium and normalize biochemical abnormalities in rodent models of ADH1. This Phase 2b open-label study examined the effect of the oral investigational calcilytic encaleret on mineral homeostasis in participants with ADH1. It was comprised of 3 periods followed by a long-term extension (LTE). Conventional therapy was discontinued prior to encaleret initiation. Periods 1&2 examined dose-finding and safety/tolerability. Dosing was optimized and safety and efficacy were assessed over 24 outpatient weeks in Period 3 (P3); all participants continued in the LTE. Thirteen adults with ADH1 were enrolled. Encaleret was individually titrated to normalize albumin-corrected calcium (cCa) and minimize hypercalciuria. Encaleret was well-tolerated with no serious adverse events reported. There were no treatment discontinuations or withdrawals prior to the LTE; one participant withdrew during the LTE for family planning. The mean $\pm$ SD encaleret sulfate dose at week 24 of P3 (P3W24, $n=13$) was 86 ± 70 mg BID and remained stable through month 6 of the LTE (LTEM6, $n=12$; 75 ± 66 mg BID). Twenty-four hour mean $\pm$ SD values from P3W24 and LTEM6 compared to baseline are shown. This study represents a molecularly-

Background
Conventional therapy for chronic hypoparathyroidism (cHP) is often unable to maintain stable normal serum calcium (Ca) levels for a full 24 h, to control symptoms, to prevent the detrimental long-term effects on the kidney and to preserve normal bone architecture. Eneboparatide (AZP-3601) is a novel 36-amino-acid peptide specifically designed to activate the R^0 conformation of the PTH receptor 1, that results in a prolonged calcemic response and a sustained reabsorption of urinary calcium (uCa). We report the results of two consecutive cohorts (C1 and C2) of cHP patients enrolled in a phase 2 multi-center open-label study.
Methods
Patients conventional therapy was adjusted to have albumin-adjusted serum Ca (sCa) within the target range of 7.8 to 9.0 mg/dl before treatment with eneboparatide. From Day 1 onwards, patients received a daily sc. administration at a starting dose of 20 µg (C1; $n=12$) or 10µg eneboparatide/-day (C2; $n=16$), while reducing oral Ca and active vitamin D (vitD) intake. Up-titration to a maximum of 60 µg (C1) or 80 µg/day (C2) was allowed. 24 hr-uCa, serum bone biomarkers (s-CTX and P1NP) were assessed. DXA scan was performed in C2.
Results
24 patients (18 women), with a mean (SD) age of 56 (11) years and mostly post-surgery etiology were taking on average 0.61 (0.26) µg/day active vitD and 1733 (1442) mg oral Ca at baseline. Eneboparatide was well tolerated with no serious adverse events. In C2 the 10µg starting dose required an earlier up-titration to 20µg in most patients. After 3-month treatment with eneboparatide, 88% of patients were off active vitD and oral Ca supplements ($\leq$500 mg/day) while mean sCa was maintained within the target range. Mean reduction in 24 hr-uCa from baseline after 3 months was 63% and 58%, in C1 and C2, respectively, including normalization in all 6 patients with hypercalciuria at baseline in C1 and 6 of 7 patients in C2. Bone biomarkers increased and remained within the normal range for the duration of the study, averaging 352 (166) and 477(252) ng/l for CTX (ULN=900 ng/l)) and 54(17) and 65(31) ng/l for P1NP (ULN=74 ng/l), in C1 and C2 at D84 respectively. In C2, BMD, T and Z scores did not significantly change at 3 months.
Conclusion
Eneboparatide allowed independence from conventional therapy and maintenance of sCa within a target range primarily via enhanced reabsorption of uCa while producing a balanced resumption of bone turnover. Data support advancement to Phase 3 and selection of 20µg as starting dose.

Background
Conventional therapy with oral calcium (Ca) and active vitamin D (vitD) supplementation for chronic hypoparathyroidism (cHP) can induce or aggravate hypercalciuria and may lead to detrimental long-term renal complications. Eneboparatide (AZP-3601) is a novel 36-amino-acid peptide with a short half-life designed to activate the R^0 conformation of the PTH 1 receptor which produces a prolonged calcemic response. This phase 2a study examined the effects of eneboparatide on urinary Ca (uCa) excretion in two consecutive cohorts (C1 and C2) of cHP patients.
Methods
Following an optimization period, during which Ca and active vitD doses were adjusted to achieve baseline albumin-adjusted serum calcium within the target range of 7.8 to 9.0 mg/dl, patients received a daily sc. injection of eneboparatide at initial doses of 20 µg/day (C1) or 10 µg/day (C2), while simultaneously reducing their Ca and active vitD intake. Subsequent up-titration to a maximum daily dose of 60 µg (C1) or 80 µg (C2) was allowed. Twenty-four-hour urinary Ca excretion (24 h-uCa), fractional excretion of Ca (FECa), 24 h-urinary phosphate (24 h-uP) and serum phosphate (sP) were assessed at baseline and at D84. Pooled data from 24 patients who completed the study are presented here.
Results
Twenty-four patients (18 women) aged (SD) 56 (11) years were taking 0.61 (0.26) µg/day active vitD and 1733(1442) mg oral Ca at baseline. At D84, active vitD and oral Ca were discontinued in 88% of patients, while mean albumin-adjusted serum calcium remained within the target range. Mean 24 h-uCa decreased from 325 (172) mg/24 h at baseline to 207 (107) mg/24 h and 130 (91) mg/24 h at D14 and D84, respectively. In 13 patients with hypercalciuria at baseline, we observed

a 67% reduction of 24 h-uCa at D84 and a normalization of 24 h-uCa in 12 (92%). From baseline to D84, mean FECa decreased in the entire population and in patients with hypercalciuria. Between baseline and D84, 24 h-uP excretion increased from 721 (331) mg/24 h to 794 (238) mg/24 h while mean sP decreased from 4.3 (0.8) mg/dl to 3.7 (0.6) mg/dl.
Conclusion
These data demonstrate that eneboparatide treatment maintained sCa within the target range after withdrawal of conventional therapy, likely acting via a potent effect on the tubular reabsorption of calcium. The observed significant improvement in both uCa and sP is expected to translate to a clinically meaningful benefit for cHP patients in the long-term.

Symptoms of glucocorticoid-induced adrenal insufficiency – A systematic evaluation of clinician- and patient-reported symptoms and their rated relevance

Marie Louise Lund[1], Jakob Bue Bjørner[2,3,4], Hajir Al-Jorani[5], Victor Brun Boesen[1], Anja Fenger Dreyer[5], Simon Bøggild Hansen[6], Nanna Thurmann Jørgensen[1], Marianne Klose[1], Randi Tei[6], Torquil Watt[1], Ulla Feldt-Rasmussen[1,7] & Stina Willemoes Borresen[1]
[1]Copenhagen University Hospital, Rigshospitalet, Department of Endocrinology and Metabolism, Copenhagen, Denmark; [2]QualityMetric incorporated, LLC, , Johnston, RI, United States; [3]University of Copenhagen, Department of Public Health, Copenhagen, Denmark; [4]National Research Centre for the Working Environment, Copenhagen , Denmark; [5]Odense University Hospital, Department of Endocrinology, Odense, Denmark; [6]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus, Denmark; [7]Institute of Clinical Medicine, Faculty of Health and Clinical Sciences, University of Copenhagen, Copenhagen, Denmark

Context
Glucocorticoid-induced adrenal insufficiency is the most frequent type of adrenal insufficiency, but its symptomatology has not been thoroughly studied.
Objective
To describe the predominant symptoms experienced by patients with glucocorticoid-induced adrenal insufficiency and rate these symptoms' significance for patients' perceived need for supplemental hydrocortisone stress dose.
Methods
The 80 symptoms in the Patient-Reported Outcomes version of the common Terminology Criteria for Adverse Events (PRO-CTCAE) questionnaire, were presented to 11 endocrinologists from four Danish tertiary endocrine referral centres. The endocrinologists rated the symptoms' relevance and could add additional symptoms. Symptoms with a mean score ≥ 1 ("minor relevance") were evaluated by a Delphi panel including 3 senior investigators who excluded symptoms found irrelevant for a need for hydrocortisone stress doses. The remaining items were presented to adult patients with longstanding glucocorticoid-induced adrenal insufficiency receiving hydrocortisone replacement treatment. During interviews, participants first described their symptoms of glucocorticoid-induced adrenal insufficiency and subsequently rated the PRO-CTCAE symptoms from 1 (completely irrelevant) to 5 (very important) according to the *significance* in realising the need of hydrocortisone stress doses. New symptoms were added for the next participants to rate. Importance scores were calculated as the percentage of the participants experiencing the symptom times the mean significance rating.
Results
The PRO-CTCAE symptom review by 11 endocrinologists identified 17 relevant symptoms of glucocorticoid-induced adrenal insufficiency. The Delphi round removed three symptoms. Thirty patients (20 women) were included with mean (SD) age 58.4 (14.2) years and with median (range) duration of glucocorticoid-induced adrenal insufficiency of 5 (0.5-31) years, after glucocorticoid treatment of mainly asthma and rheumatological disorders. They reviewed the 14 symptoms and added 14 symptoms. The symptoms most frequently experienced were fatigue (87%), feeling generally unwell (80%), weariness (80%), difficulty concentrating (63%), and nausea (60%). The symptoms with the highest mean significance scores were dizziness (4.33), nausea (4.29), vomiting (4.20), fatigue (4.15), and feeling generally unwell (4.09). The symptoms with the highest importance scores were fatigue (360), feeling generally unwell(325), weariness (293), nausea (253), and difficulty concentrating (250).
Conclusions
The presented new knowledge of the patients' self-perceived symptoms of glucocorticoid-induced adrenal insufficiency can improve the clinical understanding of the condition. Additionally, this systematically investigation of symptoms has led to the development of a symptom measurement tool used in two ongoing clinical trials on glucocorticoid-induced adrenal insufficiency.
Funding
Achieved from the Novo Nordisk Foundation as part of a collaborative grant entitled "DOUBLE EDGE – Characterization and mitigation of adverse effects of glucocorticoid treatment"(NNF20OC0063280).

RC9.2

Frequency of stress dose adjustment and adrenal crisis in children and adults with congenital adrenal hyperplasia

Lea Tschaidse[1], Sophie Wimmer[1], Matthias Auer[1], Christian Lottspeich[1], Hanna F. Nowotny[1], Ilja Dubinski[2], Heinrich Schmidt[2], Marcus Quinkler[3] & Nicole Reisch[1]
[1]Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, Munich, Germany; [2]Klinikum der Universität München, Department of Pediatric Endocrinology, Munich, Germany; [3]Endocrinology in Charlottenburg, Berlin, Germany

Background
Patients with congenital adrenal hyperplasia due to 21-hydroxylase deficiency (CAH) require lifelong glucocorticoid replacement therapy, including stress dose adjustment to prevent life-threatening adrenal crises (AC). Previous studies indicate a high incidence of inadequate stress dose adjustment and AC in patients with CAH. The aim of this study was to prospectively assess AC incidence, frequency and details of stress dose adjustment as well as knowledge of the disease in adult and paediatric patients with CAH as well as their caregivers.
Methods
A total of 38 children and their caregivers and 162 adults with CAH were included in this prospective, multi-centre study. To collect data on frequency, cause, duration and dosage of dose adjustments and the occurrence of AC, a patient diary was used. In case of AC, additional medical records were reviewed and patient interviews were conducted. Additionally, it was assessed if current sick day rules of the German Society of Endocrinology (DGE) were followed adequately. Knowledge of the disease was assessed using the CAH Knowledge Assessment Questionnaire (CAHKAQ) in the German version.
Results
We found an AC incidence of 8.4 per 100 patient years (py) in 145 adults and 5.1 in 100 py in 29 children. In the adult cohort, a total of 195.4 dose adjustments per 100 py were recorded, in the children cohort a total of 169.7 per 100 py. According to the DGE recommendations, in 24.1% of cases in adult patients dose adjustment was unnecessary and in 33.9% of cases dosage of adjustment was incorrect. A total of 34.8% of dose adjustments in adults were performed correctly. There was a significant positive correlation of the frequency of dose adjustments and the incidence of AC ($r = .24$, $p = .011$) and CAHKAQ Score ($r = .23$, $p = .014$) in adults. In the children cohort, 4.3% of dose adjustments were unnecessary and in 19.1% of cases dosage of adjustment was incorrect. A total of 72.3% cases of dose adjustments in children were conducted correctly.
Conclusion
Children and adults with CAH show a high incidence of AC and stress dose adjustments. The majority of stress dose adjustments in adults were not in accordance to the recommendations of the DGE, whilst in children the majority of dose adjustments was conducted correctly. These findings underline the need for structured and repeated education of patients to avoid inadequate dose adjustments while preventing AC, with particular focus on the timing of transition.

Fingerprints of increased susceptibility to adrenal crises in patients with chronic adrenal insufficiency

Irina Chifu[1], Freytag Janik[1], Marcus Quinkler[2], Sabine Herterich[3], Burger-Stritt Stephanie[4] & Stefanie Hahner[1]
[1]University Hospital Würzburg, Endocrinology and Diabetes, Würzburg, Germany; [2]Endocrinology in Charlottenburg, Berlin, Germany; [3]University Hospital Würzburg, Clinical Chemistry and Laboratory Medicine, Würzburg, Germany; [4]Uppsala University Hospital, Endocrinology, Uppsala, Sweden

Background
Potentially fatal adrenal crises (AC) still occur in educated patients with adrenal insufficiency (AI). Identifying predisposing factors is necessary for prevention in this patient population.

Objectives
Investigating clinical and biochemical fingerprints of increased susceptibility to AC.
Material and methods
Our study population included 260 patients with chronic AI, classified as high and low risk according to the frequency of experienced AC per patient-years. Besides classical clinical and biochemical data, following parameters were assessed: 24 h urinary cortisol, salivary cortisol day profile, steroid profile in serum, plasma and urinary catecholamines, polymorphisms (SNPs) of the glucocorticoid receptor (NR3C1), mineralocorticoid receptor (NR3C2), HSD11B1, HSD11B2 and FKBP5, information on therapy adjustments and patient education.
Results
27% ($n=71$) of the patients were classified as having a high risk for AC. This group was treated with higher glucocorticoid replacement doses (12 ±4 vs 11 ±4 mg hydrocortisone-equivalent /m^2/day, $P=0.03$) and displayed significantly higher salivary cortisol levels in the morning (pre-dose) and at noon compared to the low risk group (morning 0.034 (0.034-0.23) vs 0.038 (0.034-1.6) µg/dl, $P=0.02$, noon: 0.36 (0.03-5.5) vs 0.7 (0.03-3.4), $P=0.04$). Plasma metanephrine levels were significantly lower in the high risk group (17 ±12 vs 22 ±12 ng/, $P<0.01$). Overall, prevalence of risk genotypes of the analysed SNPs was low. Several NR3C1, NR3C2 und HSD11B1 SNPs related to impaired steroid sensitivity were significantly associated with AC frequency. Analysis of dose adjustments performed by patients themselves in case of AC revealed a significantly higher frequency of self-injected hydrocortisone in high risk patients (56% vs 19%, $P=0.021$), whereas low risk patients increased their oral doSemore often (81% vs 52%, $P=0.06$). Frequency of prophylactic stress dose adjustments (eg for intense physical activity) over a period of 6 months was also significantly higher in high risk compared to low risk patients (100% vs 73%, $P<0.01$).
Conclusion
The higher glucocorticoid replacement dose and higher frequency of prophylactic dose adjustments seen in high risk patients fit to previous observations and might simply reflect increased caution but could also be regarded as an indicator of increased vulnerability, as also suggested by lower plasma metanephrine levels. The association between the risk for AC and SNPs of both glucocorticoid and mineralocorticoid receptor as well as HSD11B1 also implies a genetic susceptibility to AC. These observations require validation in prospective studies.

Dysregulations in CLOCK genes in immune cells in congenital adrenal hyperplasia depending on the type of glucocorticoid replacement regimens

Jing Ju, Hanna F. Nowotny, Lea Tschaidse, Matthias Auer & Nicole Reisch
LMU Klinikum, Divison of Endocrinology, Medizinische Klinik and Poliklinik IV, Munich, Germany

Background
Glucocorticoid (GC) substitution therapy in patients with congenital adrenal hyperplasia due to 21-hydroxylase deficiency (CAH) is not able to perfectly mimic physiological circadian profiles. Unphysiologically high doses, as well as unphysiological variations in GC concentrations might cause adverSemetabolic, cardiovascular and immunological effects. Previous publications have demonstrated dysregulations in immune cell profiles of patients with primary adrenal insufficiency (PAI) under standard hydrocortisone (HC) therapy most likely via dysregulations of clock gene expression. GCs have been shown to modulate expression of certain clock genes and are involved in creating a stable 24-hour rhythm of various cell types and physiological pathways. Thus, changes in GC profiles might differentially affect cell functions.
Methods
Cross-sectional single-center study including 75 patients with CAH and 50 sex- and BMI- matched healthy controls. Patients were divided into three groups depending on type of glucocorticoid medication: HC ($n=28$), prednisone/prednisolone ($n=33$) and modified-release hydrocortisone treatment (MR-HC $n=14$). Peripheral blood mononuclear cells (PBMCs) were isolated from all subjects using a Ficoll density gradient centrifugation within 4 hours after sample collection. Real-time qPCR was carried out for expression of the following nine clock genes (*CLOCK*, *ARNTL*, *CRY1*, *CRY2*, *NR1D1*, *WEE1*, *TIMELESS*, *CREB1*, *PER3*).
Results
CLOCK gene mRNA expression was reduced in *CLOCK* ($P<0.0001$), *CRY1* ($P<0.0001$), and *TIMELESS* ($P<0.0001$) in patients versus controls regardless of type of GC medication used. *WEE1* and *CRY2* mRNA expression were only reduced in patients using conventional GCs as HC (*WEE1* $P=0.0018$, *CRY2* $P=0.0002$) and prednisone/prednisolone (*WEE1* $P<0.0001$, *CRY2* $P=0.0001$). Compared to controls, *ARNTL* mRNA expression was only reduced in patients treated with prednisone/prednisolone ($P=0.0436$). There was no change in *NR1D1*, *CREB1* or *PER3* expression between the different treatment groups and controls. Least changes in mRNA expression compared to healthy controls were observed in patients treated with MR-HC (*CLOCK* $P=0.0001$, *TIMELESS* $P=0.0003$, *WEE1* $P=0.7960$, *CRY2* $P=0.1119$).
Conclusion
CAH patients receiving conventional therapy exhibit dysregulations of CLOCK gene expression in PBMCs. Least disturbance of CLOCK gene mRNA expression compared to healthy controls was observed in those patients treated with MR-HC preparations. Further studies are needed to explicitly analyze these effects in CLOCK gene expression on the clinical phenotype including adverSemetabolic, cardiovascular and immunological events.

Higher maternal cortisol associated with lower blood pressure in offspring from 3 months to 5 years of age in the odense child cohort

Hajir Al-Jorani[1], Richard Christian Jensen[1,2], Mikaela Jonasson[1], Anna Birukov[3,4], Anne Vibeke Schmedes[5], Henrik Thybo Christesen[6], Anja Fenger Dreyer[1], Tina Kold Jensen[2], Dorte Glintborg[1], Boye Lagerbon Jensen[7] & Marianne Andersen[1]
[1]Odense University Hospital, Department of Endocrinology, Odense C, Denmark; [2]University of Southern Denmark, Department of Clinical Pharmacology, Pharmacy and Environmental Medicine, Odense C, Denmark; [3]Harvard T.H. Chan School of Public Health, Department of Nutrition, Boston MA, United States; [4]German Institute of Human Nutrition Potsdam-Rehbrücke, Department of Molecular Epidemiology, Nuthetal, Germany; [5]Lillebaelt Hospital, Department of Biochemistry and Immunology, Vejle, Denmark; [6]Odense University Hospital, Hans Christian Andersen Children's Hospital, Odense C, Denmark; [7]University of Southern Denmark, Department of Molecular Medicine, Odense C, Denmark

Background
Synthetic glucocorticoid exposure in late pregnancy may be associated with higher blood pressure in offspring. We hypothesized that endogenous cortisol in pregnancy relates to offspring blood pressure (OBP).
Objective
To investigate associations between maternal cortisol status in 3rd trimester pregnancy and OBP.
Methods
We included 1,317 mother-child pairs from Odense Child Cohort (OCC), an observational prospective cohort. Serum (s-) cortisol and 24 h urine (u-) cortisol and cortisone were assessed in gestational week 28. Offspring systolic (SBP) and diastolic (DBP) blood pressure were measured at age 3, 18 months and 3 and 5 years. Associations between maternal cortisol and OBP were examined by mixed effects linear models.
Results
All significant associations between maternal cortisol and OBP were negative. In boys in pooled analyses (3 and 18 months, 3 and 5 years of age), 1 nmol/l increase in maternal s-cortisol was associated with average decrease in SBP of -0.003 mmHg (95% CI: -0.005; -0.0003)) and DBP of -0.002 mmHg (95% CI: -0.004; -0.0004)) after adjusting for confounders. At 3 months of age, higher maternal s-cortisol was significantly associated with lower SBP (β=-0.01 mmHg (95% CI: -0.01; -0.004)) and DBP (β=-0.010 mmHg (95% CI: -0.012; -0.011)) in boys after adjusting for confounders and remained significant after adjusting for potential intermediate factors.
Conclusion
We found temporal sex dimorphic negative associations between maternal s-cortisol levels and OBP, with significant findings in boys. We conclude that physiological maternal cortisol is not a risk factor for higher blood pressure in offspring up to 5 years of age.

Immunohistochemical analysis of somatostatin receptor 2 and the tumor microenvironment in a large set of pheochromocytomas and paragangliomas

Masaki Uchihara[1], Akiyo Tanabe[1], Kotaro Umamoto[1], Akiko Miyagi Maeshima[2], Yuki Kojima[3], Kazuki Sudo[3], Tatsunori Shimoi[3], Yuto Yamazaki[4], Hironobu Sasano[4], Akihiko Shimomura[5], Chikako Shimizu[5], Kan Yonemori[3] & Hiroshi Kajio[1]

[1]National Center for Global Health and Medicine, Department of Diabetes, Endocrinology and Metabolism, Shinjuku-ku, Tokyo, Japan; [2]National Cancer Center Hospital, Department of Diagnostic Pathology, Japan; [3]National Cancer Center Hospital, Department of Medical Oncology, Japan; [4]Tohoku University Graduate School of Medicine, Department of Pathology, Japan; [5]National Center for Global Health and Medicine, Department of Breast and Medical Oncology, Japan

Introduction
Pheochromocytoma and paraganglioma (PPGL) are rare endocrine tumors with few effective treatment options for malignant cases. Novel therapeutic indications, such as 177Lu-DOTA-TATE and immune checkpoint inhibitors (ICIs) for patients with PPGL, have been investigated in several clinical trials. Emerging evidence shows that somatostatin receptor 2 (SSTR2) in other cancer types correlates with the tumor microenvironment (TME) activation and could be a predictive biomarker of ICIs as well as 177Lu-DOTA-TATE. Among gastroenteropancreatic neuroendocrine tumors, SSTR2 expression is associated with a low-grade tumor. However, the association between the expression of SSTR2 and TME and clinical features in PPGL has not yet been reported.
Methods
We studied the immunohistochemical expression of SSTR2A and the immune cells, including tumor infiltrating lymphocytes (CD4 and CD8), tumor associated macrophages (CD68 and CD163), and angiogenic markers (CD31 and intratumoral hemorrhage areas) using specific antibodies on archived formalin-fixed, paraffin-embedded tissue of tumor samples in 53 patients with PPGL diagnosed between 1988 and 2020 in two national center hospitals in Japan. We compared those data with clinical and histopathological factors.
Results
The cohort consisted of 23 (43.4%) patients with pheochromocytoma and 30 (56.6%) patients with paraganglioma, including 27 aggressive tumors (metastasis or local invasion) and 29 functional PPGLs with a mean follow-up duration of 81.1 ± 82.6 months. The median age was 46 (range, 17-80), and 62.3% of the patients were female. The expression of SSTR2A was strongly increased in 19 samples (35.8%). The positive staining score for SSTR2A was significantly more frequently associated with aggressive tumors (78.9% vs 35.3%, $P=0.004$), high Ki-67 index (5.15 [1.6 – 29.6] vs 2.35 [0.2 – 46.9], $P=0.001$), high GAPP score (6.40 ± 1.80 vs 4.84 ± 1.97, $P=0.013$), and high PASS score (9.33 ± 3.52 vs 6.94 ± 3.35, $P=0.029$) compared to the negative staining score for SSTR2A. No correlation was found between the staining score for SSTR2A expression and other factors: functional status, primary tumor sites, tumor size, intratumoral hemorrhage areas, and the positive cells of CD4, CD8, CD31, CD68, and CD163.
Conclusion
SSTR2A could be a predictive marker of more aggressive PPGL and would play an essential role in further clinical investigations in patients with PPGL. Whereas, since SSTR2A was expressed independently of clinical features and TME status, immunohistochemical analysis of SSTR2A for each tumor should be performed for treatment selection.

Gold and cerium oxide nanoparticles reduce liver steatosis and inflammation in rats with steatohepatitis

Gregori Casals[1,2,3,4], Elena Lecue[1,2], Shayan Shahbazi[1,2], Dongdong Guo[5], Meritxell Perramon[1,2], Muling Zeng[5], Wladimiro Jiménez[1,2,3,4], Manuel Morales-Ruiz[1,2,3,4], Eudald Casals[5] & Guillermo Fernández-Varo[1,2,3]
[1]Hospital Clínic de Barcelona, Bioquímica y Genética Molecular, Barcelona, Spain; [2]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain; [3]CIBEREHD – Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas, Spain; [4]Universitat de Barcelona, Barcelona, Spain; [5]Wuyi University, School of Biotechnology and Health Sciences, Jiangmen, China

Introduction
Metabolic dysfunction-associated fatty liver disease (MAFLD) is characterized by the presence of hepatic steatosis, which can progress to non-alcoholic steatohepatitis (NASH), fibrosis, and hepatocellular carcinoma. There are no licensed therapies to halt MAFLD progression, despite it is becoming the most important etiology for advanced liver disease.
Aim
The aim of the study was to evaluate the therapeutic potential of inorganic nanoparticles (NPs) (cerium oxide [CeO_2NPs], gold [AuNPs] and their combination in the same nanostructure [AuCeO2NPs]) in an experimental model of fatty liver disease.
Methods
Steatohepatitis was induced in Wistar rats by a methionine-choline-deficient (MCD) diet. A first pilot protocol included 10 rats on MCD diet for 3 weeks, which were randomly administered intravenously (iv) with CeO_2NPs (0.25 mg/kg; $n=5$) or vehicle ($n=5$) at weeks 1 and 2. CeO_2NPs significantly reduced hepatic steatosis and IL1β expression, although without changes in transaminases. Therefore, in a second protocol, mesoporous silica ($mSiO_2$) coating of the inorganic NPs was designed to improve their stability and biological effects. The NPs were administered iv (weeks 1 and 2) in 5 groups of 8 animals on MCD diet for 3 weeks (group1: CeO_2NPs@$mSiO_2$, group 2: AuNPs@$mSiO_2$, group 3: $AuCeO_2$NPs@$mSiO_2$, group 4: $AuCeO_2$NPs, and group 5 [vehicle]: $mSiO_2$). Biodistribution of NPs was analyzed by inductively coupled plasma mass spectrometry (ICP-MS). Standard parameters of liver and renal function and lipid profile were measured in a chemistry analyzer (Mindray). The effects on liver steatosis, infla mmation and metabolism were assessed by histological examination, gas chromatography mass spectrometry and the analysis of the expression of 88 genes related to liver steatosis and infla mmation (customized Rat Fatty Liver RT^2 Profiler^{TM} PCR Array, Qiagen).
Results
Biodistribution analysis revealed that cerium and gold accumulated mainly in the liver and spleen. Treatments with AuNPs@$mSiO_2$ and $AuCeO_2$NPs@$mSiO_2$ were the most effective in reducing hepatic steatosis ($49 \pm 2\%$, $50 \pm 1\%$ vs $55.0 \pm 1\%$; $P<0.05$) and ALT levels (114 ± 10, 110 ± 9 vs 190 ± 29 U/l; $P<0.05$). These effects were associated with a significant improvement (fold regulation >1.50; $P<0.05$) on the hepatic expression of 21 (Au@$mSiO_2$) and 50 ($AuCeO_2$NPs@$mSiO_2$) of the 88 analyzed genes, which were mainly related with reduced infla mmatory response and adipokine signalling, and improvements in metabolic pathways involved in oxidative phosphorylation and lipid metabolism and transport.
Conclusion
Treatment with gold and cerium oxide NPs coated with $mSiO_2$ improve hepatic steatosis and infla mmation in an experimental model of steatohepatitis.

Increased risk of cirrhosis in post-menopausal women with NAFLD

Chioma Izzi-Engbeaya[1,2], Pei Eng[1], Aleksandra Dunin-Borkowska[1], Roberta Forlano[1,2], Benjamin H Mullish[1,2], Giordano Sigon[1], Vicky Lin[1], Tricia Tan[1,2], Michael Yee[2], Pinelopi Manousou[1,2] & Waljit Dhillo[1,2]
[1]Imperial College London, United Kingdom; [2]Imperial College Healthcare NHS Trust, United Kingdom

Background
Non-alcoholic liver disease (NAFLD) affects up to 30% of adults worldwide. With the prevalence of NAFLD increasing after menopause, women aged >55 years are more likely to progress to advanced fibrosis than men. Moreover, liver decompensation secondary to NAFLD is more frequent in women compared to men. However, the causes of these differential outcomes are not fully understood.
Methodology
We performed a retrospective cohort study utilising a database of consecutive patients followed up in the specialist multi-disciplinary NAFLD Clinic at Imperial College Healthcare NHS Trust (London, UK) with their first clinic review between 2009 and 2020. NAFLD was diagnosed either clinically or histologically. Clinical, biochemical, radiological and histological data were collected up to December 2022. Postmenopausal women were defined as women aged ≥55 years at their first clinic visit. Cirrhosis was diagnosed based on a combination of clinical, biochemical and/or radiological features or based on histology, when available. Multivariate logistic regression was performed to identify variables independently associated with cirrhosis. Statistical significance was set at $P<0.05$.
Results
750 patients with NAFLD were included in this study, with a median (IQR) follow-up of 6 (3-8) years; 293 (39%) were female, 323 (43%) Caucasian, 161 (22%) South Asian, 75 (10%) Middle Eastern, median (IQR) age: 52 (42-60) years. At initial clinic review, fewer postmenopausal women (compared to age-matched men) had a Fibrosis-4 (FIB-4) score >1.3 (73% v 84%, $P<0.05$). However, similar proportions of postmenopausal women and age-matched men had an initial liver stiffness measurement ≥8 kPa (64% v 68%, $P=0.27$). Initial prevalence of type 2 diabetes, cardiovascular disease and obesity, as well as use of GLP-1 receptor agonists and SGLT2 inhibitors were similar between the two groups. Overall, postmenopausal women ($n=156$) had increased risks of being diagnosed with cirrhosis (OR 2.18 (95%CI 1.11-4.26), $P<0.05$) when compared to all other patients, as well as compared to age-matched men ($n=149$) alone (OR

2.58 (95%CI 1.14-6.02), $P<0.05$). There were insufficient data on reproductive hormone use for this variable to be included in the analyses.
Conclusions
In this diverse cohort from a tertiary care centre, being a postmenopausal woman is associated with worse outcomes than being a man of any age or a younger woman. These disparities occur despite postmenopausal women presenting to specialised secondary care clinics with similar co-morbidities and receiving similar medication to age-matched men. Therefore, tailored management strategies may be required to improve outcomes in postmenopausal women with NAFLD.

The maintenance of long-term weight loss after semaglutide withdrawal in obese women with PCOS treated with metformin: A 2-year observational study

Mojca Jensterle[1], Simona Ferjan[1], Katja Goricar[2] & Andrej Janez[1]
[1]University Medical Centre Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]Institute of Biochemistry and Molecular Genetics, Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Background
Withdrawal of anti-obesity medication is frequently followed by weight regain due to compensatory biological changes that prevent the maintenance of long-term weight loss. In STEP 1 trial extension participants regained two-thirds of their prior weight loss during the 1-year off-treatment follow-up period after withdrawal of semaglutide 2.4 mg and discontinuation of active lifestyle intervention support. There are some studies implying that metformin might attenuate weight regain after weight loss in women with polycystic ovary syndrome (PCOS). To date, the amount of weight regain after semaglutide withdrawal in obese women with PCOS who continue treatment with metformin has not yet been evaluated.
Aims
We explored changes in body weight, cardiometabolic and endocrine parameters in obese women with PCOS 2 years after semaglutide cessation.
Methods
25 obese women with PCOS (33.7 ± 5.3 years, body mass index (BMI) 36.1 ± 3.9 kg/m^2, mean ± SD) were treated with once-weekly subcutaneous semaglutide 1.0 mg as an adjunct to metformin 2000 mg/day and lifestyle intervention for 16 weeks. At week 16, semaglutide was discontinued. Treatment with metformin 2000 mg/day and promotion of lifestyle intervention were continued during the 2-year follow up period. weight, cardiometabolic and endocrine parameters were assessed to 2 years after semaglutide discontinuation.
Results
During semaglutide treatment phase, weight decreased from 101 (90-106.8) kg to 92 (83.3-100.8) kg. 2 years after semaglutide withdrawal, weight was 95 (77-104) kg. The net weight loss 2 years after discontinuation of semaglutide remained significant when compared to baseline (-7 (-14.3 to -1.5) kg, $P=0.001$). Improvements in cardiometabolic parameters including decrease in total and LDL cholesterol, triglycerides and fasting glucose and glucose after OGTT that had seen during semaglutide-treatment phase, reverted towards baseline two years after semaglutide cessation. The reduction in free testosterone from 6.16 (4.07-9.71) to 4.12 (2.98-6.93) pmol/l ($P=0.004$) and in androstenedione from 6.62 (4.36-8.77) to 5.49 (3.78-6.84) nmol/l, ($P=0.002$), observed during semaglutide treatment phase remained significant for 2 years ($P=0.045$ and $P=0.023$, respectively).
Conclusion
Two years after semaglutide withdrawal, women with PCOS regained one-third of their prior weight loss. Improvements of cardiometabolic variables reverted to baseline, whereas improvement of endocrine parameters achieved during semaglutide treatment phase persisted 2 years after semaglutide cessation. The role of metformin in attenuation of weight regain after semaglutide discontinuation needs to be explored in randomized controlled studies in different insulin resistant populations.

Kisspeptin does not have detrimental metabolic effects in women

Chioma Izzi-Engbeaya[1], Muhammad Choudhury[1], Bijal Patel[1], Beatrice Muzi[1], Ambreen Qayum[1], Edouard G Mills[1], Maheen Ahsan[1], Maria Phylactou[1], Sophie Clarke[2], Laura Aslett[1], Alexander Comninos[1], Ali Abbara[1], Tricia Tan[1] & Waljit Dhillo[1]
[1]Imperial College London, Department of Metabolism, Digestion and Reproduction, London, United Kingdom; [2]University College Hospitals NHS Trust, London, United Kingdom

Background
There is emerging evidence that kisspeptin, a hormone with well-established reproductive effects, may also have important metabolic effects. Acute kisspeptin administration enhances insulin secretion under hyperglycaemic conditions in male rodents and men, and kisspeptin receptor agonism improves steatohepatits in male mice in a rodent model of non-alcoholic fatty liver disease. However, the metabolic effects of kisspeptin may exhibit sexual dimorphism as female (but not male) kisspeptin receptor knockout mice have reduced food intake. Kisspeptin administration has been shown to have no effect on food intake in men, but the effect of kisspeptin on food intake in women has not been investigated.
Methods
We performed a single-blinded randomized controlled crossover study in women with overweight or obesity (BMI >25 kg/m^2) who had not received exogenous estrogens or progestins in the preceding 3 months. Each woman attended two study visits (in random order) following a 14-hour fast. During each study visit either an intravenous infusion of kisspeptin-54 at a rate of 1.0 nmol/kg/hr, or a rate-matched vehicle infusion, were administered for 120 minutes. At regular intervals during the study visits, blood samples were taken. Participants completed visual analogue scales (VAS) to assess hunger prior to the start of the infusions, 30 minutes after the start of the infusions (pre-meal) and 75 minutes after the start of the infusion (post-meal). Forty-five minutes after the start of each infusion, the women were given an *ad libitum* meal. All data are presented as mean ± SD.
Results
Seventeen women (BMI 34 ± 7 kg/m^2, $n=12$ with BMI >30 kg/m^2) completed both study visits. Kisspeptin administration increased LH levels ($P<0.01$), consistent with its known reproductive effects. However, pre-meal estradiol levels were unaffected by kisspeptin administration ($P=0.34$). Kisspeptin administration did not affect appetite pre-meal (hunger VAS scores at 30 mins: kisspeptin 5.2 ± 2.7 vs vehicle 5.9 ± 2.3, $P=0.33$) nor post-meal (hunger VAS scores at 75 mins: kisspeptin 0.5 ± 1.0 vs vehicle 0.4 ± 0.6, $P=0.87$). Food intake was similar during kisspeptin and vehicle infusions (kisspeptin 604 ± 267 kcal vs vehicle 560 ± 217 kcal, $P=0.41$). Glucose ($P=0.97$) and insulin ($P=0.68$) levels were similar during the infusions.
Conclusions
This is the first study to investigate the metabolic effects of kisspeptin in women. Similar to findings in men with BMI <25 kg/m^2, acute administration of a pharmacologically active dose of kisspeptin to women with BMI >25 kg/m^2 did not affect appetite or food intake. These data provide reassurance that kisspeptin receptor agonism is unlikely to have undesirable orexigenic effects in humans.

Metformin counteracts adverse metabolic effects of glucocorticoids in healthy subjects

Susanne Thierry[1], Caspar Joyce Peterson[1], Tarik Delko[1], Vasco Iten[1], Michael Epstein[2], Michael Kühne[1], Christine Meyer-Zürn[1] & Eleonora Seelig[1]
[1]Universitätsspital Basel, Basel, Switzerland; [2]Statistical Consulting, Letchworth, United Kingdom

Background
Glucocorticoids are powerful anti-infla mmatory drugs. However, metabolic side effects are common and limit their long-term use. Furthermore, the underlying mechanisms of adverSemetabolic effects are not well known, and this lack of knowledge results in poor treatment. We have previously shown that the antidiabetic drug metformin prevents glucocorticoid-induced metabolic effects in older, sick patients. Here, we investigate metformin in a young and healthy population on high-dose glucocorticoids to establish the role of metformin and identify potential mechanisms counteracting glucocorticoid-induced side effects.
Methods
In a randomized, placebo-controlled, cross-over trial, we compared metformin to placebo during high-dose glucocorticoid treatment in 18 lean, healthy males. All participants received prednisone 30 mg/d for two 8-day periods separated by a 28-day washout period. During one period, participants additionally had metformin; during the other, they received a placebo. Metabolic assessments were performed before and after each study period, including a mixed meal tolerance test (MMTT) and blood metabolomics.

Results
18 male subjects (mean age 27 standard deviation [SD] ±5.2 years, BMI 22.9 ± 1.8 kg/m^2) completed the study. Glucose levels during the MMTT increased with placebo (glucose change in incremental area under the concentration-time curve [AUC] 1.18 ±1.12 mmol/l) but remained stable with metformin (0.02 ±1.25 mmol/l, $P=0.01$). Insulin AUC increased with placebo (94 ±183 pmol/l) but not with metformin (-182 ±168 pmol/l, $P<0.001$). Accordingly, whole-body insulin sensitivity improved with metformin (6.4 ±11.8) compared to placebo (-8.2 ± 10.65, $P<0.001$). Pathway enrichment analysis of metabolites revealed that metformin impacts free fatty acid and bile acid synthesis in the postprandial state.
Conclusion
Metformin prevents the detrimental effects of glucocorticoids on glucose homeostasis by improving insulin sensitivity. Our findings confirm metformin's role in preventing and treating glucocorticoid-induced side effects. Furthermore, the impact of metformin on free fatty acid flux and bile acid synthesis supports that adipose tissue and the gut are sites of metformin action.

Childhood and adolescent obesity associated with classic congenital adrenal hyperplasia and 21-hydroxylase deficiency

Naween Kumar & Sudhir Chandra Jha
Darbhanga Medical College & Hospital, Darbhanga, India

Introduction
The most prevalent hereditary disease of adrenal steroid production is congenital adrenal hyperplasia (CAH), which is caused by a 21-hydroxylase deficiency. With or without salt wasting, patients with the typical form of CAH exhibit androgen excess. Leptin participates in endocrine and metabolic processes in addition to controlling energy balance. This study examined BMI values for children and teens with CAH in comparison to population-based benchmarks. Current BMI SD scores were associated with potential contributing variables such glucocorticoid therapy, skeletal development, birth weight and length, and parental BMI (SDS). The effects of blood leptin levels that had been adjusted for BMI, gender, and Tanner stage were examined.
Method
80 patients with CAH were a part of this study. All patients underwent replacement therapy and had molecular genetic studies reveal they all had classic CAH. In accordance with current recommendations, the effectiveness of therapy was assessed during follow-up visits based on the clinical presentation and laboratory measurement results. The patients were divided into groups based on their existing metabolic control, simple virilizing, and salt wasting. A commercial radio-immunoassay was used to quantify leptin levels and convert them to SDS. Standard parametric and nonparametric approaches were applied for statistical analyses.
Results
Patients with CAH ranged in chronologic age from 0.20 to 17.9 years. In the entire group, the BMI SDS ranged from 2.6 to 4.2 and was significantly higher than 0.14 subjects had a BMI SDS of 3.0, which showed high prevalence of obesity among patients with CAH than the general population. BMI SDS and chronological age showed a positive correlation. Between children using other medications, the BMI SDS did not substantially differ. Doses of hydrocortisone showed a favorable correlation with BMI SDS. Children receiving medicine did not have high relative probability of having a BMI SDS of 3.0 than those receiving hydrocortisone therapy. Children with obese parents had high relative risk of childhood obesity than children without obese parents (relative risk: 4.85). Serum leptin levels were in the range of 0.11 to 31 g/l, and were strongly linked with Tanner stage, chronologic age, and BMI SDS.
Conclusion
Children and teenagers with CAH are more likely to become obese. Elevated BMI SDS was caused by age, advanced bone age maturation, despite obesity not linked to birth weight and length, serum leptin levels, or glucocorticoid dosage.

Immune checkpoint inhibitors and severe insulinopenic diabetes mellitus: A single center experience

Ruti Karov[1], Roy Eldor[1], Tamara Kolitz[1], Michal Ehrenwald[1], Eugene Feigin[1] & Yona Greenman[1]
[1]Tel Aviv-Souraski Medical Center, Institute of Endocrinology, Metabolism and Hypertension, Tel Aviv-Yafo, Israel

Introduction
Severe insulinopenic diabetes (SID) is a rare complication of treatment with immune checkpoint inhibitors (ICPI). We describe herein the clinical characteristics, natural history and potential predictors of SID in cancer patients treated with ICPI.
Methods
We identified and retrospectively retrieved pertinent clinical data of all patients who presented with new onset SID following treatment with ICPI between 2015 and 2022 at the Tel Aviv-Sourasky Medical Center.
Results
The study cohort comprised 1621 ICPI-trated patients, of whom 12 patients (0.8%) developed SID. Seven were males (53.8%). Median age was 67 (IQR 60.5-77) years. Eight patients (61.5%) were treated with PD-L1 inhibitors, 3 (23.1%) with PD-1 inhibitors and 2 (15.4%) with a combination of PD1 and CTLA4 inhibitors . Two patients had a prior diagnosis of type 2 diabetes treated with oral medications while 2 other patients had a prior diagnosis of impaired fasting glucose. Three patients (23.1%) developed a concomitant thyroid dysfunction under ICPI. Median time from the initiation of ICPI to presentation of SID was 4 months (IQR 1-9). Five of the patients presented with SID within a month from exposure (38.5%). DKA was the presenting symptom in eleven patients (84.6%), 3 of which were treated with a SGLT2i . One patient (7.7%) died within one week of DKA presentation.
Conclusions
This is one of the largest single center series describing the onset and characteristics of SID following ICPI treatment.

COVID-19 vaccination and Graves' disease: A population based, matched case-control study

Alexander Gorshtein[1], Adi Turjeman[2], Hadar Duskin-Bitan[3], Leonard Leibovici[2] & Eyal Robenshtok[3]
[1]Rabin Medical Center, Endocrinology, Petah Tikva, Israel; [2]Rabin Medical Center, Research authority, Petach Tikva, Israel; [3]Rabin Medical Center, Endocrinology, Petach Tikva, Israel

Objective
Vaccination against coronavirus disease 2019 (COVID-19) an important component of coping with the pandemic. Anecdotal cases and case series reported an association

(Abstract RC11.2)

Age (Years)	Gender	Medication	Prior DM	DKA	Time between exposure and presentation (months)	Underlying malignancy	Concomitant Thyroid dysfunction
82	M	Nivolumab	DM2	+	13	HL	None
74	M	Avelumab	-	-	8	RCC	Hyperthyroidism
58	M	Pembrolizumab	-	+	4	MELANOMA	None
70	F	Pembrolizumab	DM2	+	4	Gastric Adeno CA	None
62	F	Nivolumab	IFG	+	29	Adeno CA Lung	None
66	F	Pembrolizumab	-	+	1	Ovarian Adeno CA	None
82	F	Pembrolizumab	-	+	1	Gastric Adeno CA	None
61	F	Pembrolizumab	-	+	9	Skin SCC	Hypothyroidism
67	M	Durvalumab	-	+	1	NSCLC	Hyperthyroidism
57	F	Ipilimumab + Opdivo	-	+	1	MELANOMA	Unknown
78	M	ipilimumab + Nivolumab	-	+	1	MELANOMA	None
76	M	Nivolumab	IFG	-	9	RCC	None
60	M	Pembrolizumab	-	+	4	Head and Neck SCC	None

This cohort emphasizes the importance of patient education and awareness for this potentially life-threatening complication. Better characterization of ICPI-induced diabetes will improve patient care and enhance our understanding of immune-mediated diabetes.

between COVID-19 vaccination and the development of Graves' disease. We used data from Israel's largest health care organization to determine whether COVID-19 vaccination was associated with the incidence of Graves' disease.
Methods
We analyzed data from Clalit Health Services (CHS), which insures 4.7 million patients. A population-based, matched, case-control study was performed. Cases were defined as adult patients diagnosed with Graves' disease between December 2020 and November 2022. Each case was matched in a ratio of 1:2 with control based on age, gender, and autoimmune disease. Each control was assigned an index date which was identical to that of his/her matched case, which was defined as the date of Graves' disease diagnosis. Time between vaccination date and the diagnosis of Graves' disease/index date was assessed.
Results
A total of 726 patients with Graves' disease were matched with 1452 controls. The median age of the cohort was 40 (interquartile range, 30-53) years, and 25.5% (555/2178) were men. Similar proportions of study patients and controls have received the first, the second and the third dosage of COVID-19 vaccine. Positive test for COVID-19 was detected in 21.2% (154/726) of Graves' disease patients and 19.4% (282/1452) of controls ($P=0.33$). In a univariate analysis, first COVID-19 vaccine was not associated with the incidence of Graves' disease [odds ratio 95% confidence interval: 1.15 (0.92-1.43)]. The mean time between first COVID-19 vaccination and the diagnosis of Graves' disease for cases or index date for controls was not significantly different [275.69 days (standard deviation 144.37) for cases compared to 275.45 days (standard deviation 145.76) for controls].
Conclusions
We have found no association between COVID-19 vaccination and the incidence of Graves' disease. Our study adds data to the thyroid safety of COVID-19 vaccine.

Mapping endometrial cell-type-specific disease signatures and endometrial organoids in polycystic ovary syndrome

Gustaw Eriksson[1], Congru Li[1], Sanjiv Risal[1], Han-Pin Pui[1], Sara Torstensson[1], Angelica Hirschberg Linden[2], Sophie Petropoulos[3], Qiaolin Deng[1] & Elisabet Stener-Victorin[1]
[1]Karolinska Institutet, Department of Physiology and Pharmacology, Karolinska Institutet, Stockholm, Sweden; [2]Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden; [3]Karolinska Institutet, Department of Clinical Science, Stockholm, Sweden

Women with polycystic ovary syndrome (PCOS) suffer from reduced fertility linked to implantation failure and miscarriage, as well as endometrial cancer, all associated with endometrial dysfunction. We hypothesize that cell-type-specific endometrial dysfunction in insulin-resistant and hyperandrogenic women with PCOS contributes to their endometrial dysfunction and that treatment aimed at improving insulin sensitivity and decreasing androgen excess has the potential to reverse identified alterations. To uncover cell-type-specific disease signatures and molecular pathways for PCOS-specific endometrial dysfunction, we first extracted single-nuclei (sn) from frozen endometrial biopsies taken in the proliferative phase (day 7-10) from controls ($n=5$) and women with PCOS ($n=10$) at baseline and in PCOS after 16 weeks of metformin ($n=7$) or lifestyle management ($n=3$) for snRNA-sequencing. The 10× Genomics protocol allowed us to sequence ≈10,000 nuclei/sample and ≈20,000 reads/nuclei. A total of 248,694 nuclei were captured and 6 major cell types were identified. The three largest cell clusters were i) stromal cells (124,055 nuclei), ii) epithelial cells (105,095 nuclei) and iii) immune cells (13,596), whilst iv) uterine smooth muscle cells, v) endothelial and vi) lymphatic cell clusters consisted of < 3000 nuclei. Subsetting epithelial cells revealed functional lumenal, glandular, and ciliated cell types as well as proliferative cells. In the immune cell cluster, both myeloid and lymphoid lineage cells were identified, of which uterine NK-cells (uNK) and macrophages (uM) were the largest populations. Several differentially expressed genes (DEGs) of the epithelial subtypes, uNKs, uMs and stromal cells were identified in women with PCOS compared with controls. DEGs between PCOS cases and controls were enriched in pathways related to cilium organization in the ciliated epithelium, extracellular matrix structure in stromal cells, and cysteine-type endopeptidase activity in uM. Of note, both 16 weeks of treatment with metformin and lifestyle management restored multiple DEGs in each subtype. This rigorous mapping of the human PCOS endometrium improves our understanding of cellular complexity and specific cell types. It provides new mechanistic insights into disease-specific endometrial dysfunction(s), and several of the identified dysfunctions can be reversed by current first-line interventions.

RC11.4

Treatment with osilodrostat in ACTH-independent Cushing's syndrome

Magdalena Stasiak[1], Emilia Adamska[1] & Andrzej Lewinski[1,2]
[1]Polish Mother's Memorial Hospital – Research Intitute, Department of Endocrinology and Metabolic Diseases, Lodz, Poland; [2]Medical University of Lodz, Department of Endocrinology and Metabolic Diseases, Lodz, Poland

Introduction
Cushing's disease (CD) is the most common cause of hypercortisolism. Therefore, the majority of studies focused on the efficacy and safety of novel steroidogenesis inhibitors included CD patients only. This is exactly the case with osilodrostat – new potent inhibitor of 11β-hydroxylase. However, approximately 10% of hypercortisolism result from cortisol-secreting adrenal adenoma. Data on potential differences in the treatment with osilodrostat between CD and Cushing's syndrome of adrenal origin (ACS) are lacking.
Aim
Hereby, we presents two patients with ACS, in whom, the response and doses of osilodrostat were different from CS patients regardless whether the CS patients were treated in our centre or described in the literature.
Cases:
Case 1
A 55-year-old women with cortisol secreting left adrenal adenoma, with UFC 2× upper normal limit (UNL). Decompensated diabetes mellitus and hypertension were contraindications for surgery. Osilodrostat was started with a dose of 2 mg/day and gradually increased to 8 mg/day with – surprisingly – simultaneous increase in UFC to 10 × UNL, severe deterioration of hypertension and life-threatening hypokalaemia of 2.1 mmol/l, despite active potassium supplementation. Due to the extremely high hypercortisolism, the dose was increased by 5 mg every two days up to 45 mg, with gradual decrease of cortisol level and UFC normalisation with the dose of 45 mg/day.
Case 2
A 45-year-old women with ACS and UFC 5 × UNL, was treated with osilodrostat, starting from 2 mg/day and increasing by 2 mg/day every day, and then, from the dose of 10 mg/day, increasing by 5 mg every other day, with no cortisol reduction up to the dose of 20 mg/day. The dose was escalated up to 45 mg/day, and after a week of treatment UFC normalisation was reached. No side effects was observed, no potassium supplementation was required.
Conclusions
1. Doses of osilodrostat required for ACS are usually much higher than those in CD.
2. Dose acceleration can be faster and the risk of overdosing and later necessity of dose reduction is low
3. Low initial doses can be ineffective or can even cause exacerbation of hypercortisolism
4. Typical dose which allowed to safe adrenalectomy with UFC slightly below upper normal limit was 45 mg/day
5. Side effects of osilodrostat can be rapid with severe hypokalaemia even despite active potassium supplementation or can be totally absent with potassium level above 4.0 mmol/l without any supplementation. Therefore, cloSemonitoring of potential side effects is mandatory.

Pregnancy after bariatric surgery – Experience from a tertiary hospital

Helena Urbano Ferreira[1], Madalena von Hafe[2], Helena Dias[3], Juliana Gonçalves[1], Teresa Rodrigues[3], Sandra Belo[1] & Paula Freitas[1]
[1]São João Universitary Hospital Center, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]São João Universitary Hospital Center, Department of Pediatrics, Porto, Portugal; [3]São João Universitary Hospital Center, Department of Obstetrics, Porto, Portugal

Introduction
Maternal obesity is associated with an increased risk of gestational diabetes, large for gestational age (LGA) newborns, preterm delivery, congenital malformations, and fetal death. On the other hand, bariatric surgery before pregnancy is associated with a reduction of obesity-associated complications, but also with an increased risk of small for gestational age (SGA) newborns, fetal growth restriction and micronutrient deficiencies during pregnancy.
Aim
To evaluate the effect of bariatric surgery on maternal and fetal outcomes.
Methods
This was a retrospective observational study that included pregnant women followed by a multidisciplinary obesity team in a tertiary hospital, from September 2019 to March 2022. Participants were included in one of two groups:

(1) women with a history of gastric bypass or sleeve gastrectomy before pregnancy ($n=83$); (2) women with BMI$\geq$35 kg/m^2, without a history of bariatric surgery ($n=166$). Participants with loss of follow-up were excluded. Medical files were review for demographic and clinical data. Statistical analysis was performed using IBM SPSS Statistics 27. Multivariate analysis was performed to adjust for the following confounders: BMI prior to surgery in group (1) and BMI prior to pregnancy in group (2), maternal age, smoking during pregnancy, and history of thyroid dysfunction or essential hypertension.

Results

After adjusting for confounders, pregnancy after bariatric surgery was associated with higher gestational weight gain (10.97$\pm$7.08 vs 7.21$\pm$5.95, $\beta=0.294$, $P<0.001$), newborns with lower weigh percentile (36.85$\pm$20.93 vs 48.47$\pm$27.90, $\beta=-13.327$, $P<0.001$), an increased risk of iron deficiency (81.8% vs 67.2%, OR 2.480, $P=0.013$) and vitamin B12 deficiency (44.0% vs 24.4%, OR 2.357, $P=0.016$), and lower rates of gestational diabetes (16.9% vs 32.5%, OR 0.359, $P=0.003$), and cesarian section (22.9% vs 34.7%, OR 0,518, $P=0.044$). No statistically significant differences were observed between groups regarding preterm delivery (12.0% vs 6.0%, OR 2.422, $P=0.083$), gestational hypertension (4.8% vs 9.6%, OR 1.573, $P=0.608$), preeclampsia (2.4% vs 7.2%, OR 0.545, $P=0.548$) or fetal growth restriction (4.8% vs 0.6%, OR 11.247, $P=0.062$).

Conclusion

Pregnancy after bariatric surgery was associated with a lower risk of gestational diabetes and cesarian section, and a higher risk of micronutrient deficiencies. Risks and benefits of bariatric surgery before pregnancy must be considered in the decision making of obesity treatment in women of fertile age.

Prognostic parameters of adrenocortical carcinoma. Single-centre confirmatory study of GRAS and S-GRAS scoring systems

Judit Tőke[1,2,3], Lilla Welsch[1,4], Erik Bényei[1,4], Zoltán Sápi[5], Katalin Borka[6], Gergely Huszty[7], János Horányi[7], Eszter Balázs[8], András Laki[1], Ildikó Kalina[8], Andrea Uhlyarik[1], Peter Igaz[1,2,3,9] & Miklós Tóth[1,2,3]

[1]Semmelweis University, Department of Internal Medicine and Oncology, Budapest, Hungary; [2]European Reference Network on Rare Endocrine Conditions; [3]ENS@T Research Center of Excellence; [4]Semmelweis University, Students' Scientific Association; [5]Semmelweis University, Department of Pathology and Experimental Cancer Research, Budapest, Hungary; [6]Semmelweis University, Department of Pathology, Forensic and Insurance Medicine, Budapest, Hungary; [7]Semmelweis University, Department of Surgery, Transplantation and Gastroenterology, Budapest, Hungary; [8]Semmelweis University, Medical Imaging Centre, Budapest, Hungary; [9]Semmelweis University, Department of Endocrinology, Budapest, Hungary

Introduction

Adrenocortical carcinoma (ACC) is a rare disease with a poor prognosis. In recent years, two prognostic scoring systems incorporating relevant clinicopathological features of ACC (ENSAT stage, grade, resection status, age at diagnosis, tumour symptoms) have been proposed: the GRAS and S-GRAS scoring systems. The prognostic value of these systems has been demonstrated in large, multicentre studies.

Aim

To su mmarize the clinicopathological features of ACC patients treated in our centre, to determine the individual prognostic value of each feature, and to compare these values with the prognostic value of the calculated GRAS and S-GRAS scores, and thus to validate them on a single-centre patient population.

Methods

For our retrospective study, we used data from 86 patients with ACC treated at Semmelweis University, Hungary between 01/01/2000 and 31/08/2022. Descriptive statistical methods were used to su mmarize clinicopathological characteristics. To determine the correlation of data with survival, we performed Kaplan-Meier survival analysis using a log-rank test and univariate Cox regression. For statistical calculations, $P<0.05$ was considered significant.

Results

The mean age of the patients at diagnosis was 50.9$\pm$15.21 years. At baseline, the most frequent clinicopathological features were ENSAT stage IV ($n=33$), R0 resection status ($n=34$) and cortisol excess ($n=48$). Of the parameters studied, a significantly increased risk of mortality was associated with cortisol excess (RR=2.87 $P<0.001$), higher (III-IV) ENSAT stage (RR=2.2, $P=0.002$), R1/2 resection status (RR=2.42, $P=0.001$) and Ki67 index above 10% (RR=3.82, $P=0.012$). Among the prognostic scores, a high GRAS score (3-4 points) (RR=2.6, $P<0.001$) and a high S-GRAS score (5-9 points, 7-9 points) (RR=2.47, $P<0.005$, RR=9.45, $P<0.001$) were associated with a higher risk of death.

Conclusions

Among the studied parameters, tumour grade, resection status, cortisol production and tumour stage could be considered independent prognostic factors. High GRAS and high S-GRAS scores were associated with poorer overall survival and increased mortality risk. The clinical applicability of these scoring systems is enhanced by the fact that their prognostic value was also confirmed in a single-centre study with a relatively low number of patients.

Introduction
Classic congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency (21OHD) is a rare autosomal recessive disorder characterized by deficiency of cortisol and oftentimes aldosterone, with elevated adrenocorticotropic hormone (ACTH) and steroid precursors that are shunted toward excess androgen production. A phase 2 study of adults with classic 21OHD demonstrated that crinecerfont–an oral, non-steroidal, selective corticotropin-releasing factor type 1 (CRF_1) receptor antagonist–substantially reduced elevated hormone markers after 14 days of treatment. The current study evaluated the effect of crinecerfont in adolescents with classic 21OHD, a population that may be especially challenging to manage due to the hormonal changes associated with puberty.
Methods
Eligible adolescents (14–17 years of age) with classic 21OHD received open-label crinecerfont (50 mg BID) for 14 days. Plasma ACTH and serum 17-hydroxyprogesterone (17OHP), androstenedione, and testosterone were assessed over 24 hours before (baseline) and after 14 days of crinecerfont treatment. For each participant, morning window values were calculated by averaging the samples collected at 0700h and 1000h (before morning glucocorticoid dose). Participants' glucocorticoid and fludrocortisone regimens were maintained during crinecerfont treatment.
Results
Eight participants (3 males, 5 females, ages 14-16 years) were included for analyses. At baseline, median morning window hormone concentrations were as follows: ACTH (226.2 pg/mL); 17OHP (7703.7 ng/dL); androstenedione (367.9 ng/dL); and in females, testosterone (63.5 ng/dL). At Day 14, median percent reductions in these parameters were as follows: ACTH (-57.1%); 17OHP (-69.5%); androstenedione (58.3%); and in females, testosterone (-76.2%). A $\geq$50% reduction from baseline to Day 14 in ACTH, 17OHP, and androstenedione was observed in 62.5%, 75.0%, and 50.0% of participants, respectively. Furthermore, 67% (2/3) of males with elevated androstenedione/-testosterone ratios ($\geq$0.5) at baseline achieved normal ratios ($<$0.5) at Day 14. Twelve treatment-emergent adverse events (TEAEs) were reported, with the most common being headache ($n=2$). Per investigator judgement, all TEAEs were mild and the majority were unrelated to study treatment. There were no serious AEs, discontinuations due to AEs, or safety concerns related to routine laboratory tests, vital signs, or electrocardiograms.
Conclusions
In adolescents with classic 21OHD, substantial median reductions (57-76%) in adrenal androgens and androgen precursors were observed after 14 days of crinecerfont treatment, consistent with results from a similar study of adults with classic 21OHD. Further studies are warranted to evaluate whether longer-term treatment with crinecerfont can allow for lower, more physiologic glucocorticoid dosing, consequently improving clinical outcomes such as weight, metabolic risk, growth/development, and fertility.

Pivotal Role of miRNAs during Establishment of the Mineralocorticoid Signaling Pathway and Kidney Development

Hani Imene[1], VU Thi An[1], Brillet Riwan[2], Perrot Julie[1], Jerome Bouligand[1], Guegan Justine[2], Nadia Cherradi[3], Peter Kamenicky[1], Lombès Marc[1], Martinerie Laetitia[1] & Say Viengchareun[1]
[1]Institut National De La Sante Et De La Recherche Medicale, Inserm U1185, le kremlin-bicetre, France; [2]ICM Institute for Brain and Spinal Cord, Paris, France; [3]Institute National De La Santé Et De La Recherche Médicale, U1292, Grenoble, France

The Mineralocorticoid Receptor (MR, *NR3C2*) mediates sodium-retaining action of aldosterone. Recently, we have shown that the physiological sodium loss observed in newborns in their first days of life is due to a low renal MR expression. However, the underlying molecular mechanisms remain unknown to date. In the adult renal KC3AC1 cell line, we demonstrated that variations in extracellular tonicity, which exist in the nephron, modulate MR expression by posttranscriptional mechanisms involving recruitment of microRNAs (miRNAs) such as miR-30c-2-3p and miR-324-5p. These posttranscriptional regulators can bind to the 3'-untranslated (3'-UTR) region of target mRNA to modulate their stability and/or translation. Thus, we hypothesize that these same mechanisms may be responsible for the modulation of renal MR expression in the perinatal period, where variations in tonicity are observed due to the transition from intra-amniotic to extra-uterine life. Using primary culture of renal epithelial cells from neonatal mouse kidneys, harvested at day of birth (D0) and at Day 8 postnatal (D8), we showed that only miR-30c-2-3p regulates MR expression at D8. Therefore, we performed a complete transcriptomic analysis (RNA-Seq and miRNA-Seq) of kidneys collected at D0 and D8 to identify all miRNAs specifically involved in the regulation of MR expression in the perinatal period. To identify all the deregulated miRNAs and transcripts and to specify their involvement in biological processes and signaling pathways, we performed a comprehensive bioinformatics analysis. Then, we mainly focused on deregulated miRNAs that could modulate MR expression and affect mineralocorticoid signaling pathway. miR-Sequecing enabled us to identify 221 differentially expressed miRNAs. We first selected 3 underexpressed (miR-30a-5p, miR-30e-5p, and miR-802-5p) and 3 overexpressed (miR-431-5p, miR-409-3p, and miR-92a-1-5p) candidate miRNAs (FDR $<$ 0.05 and log2FC$>$1) having putative binding sites in MR 3'-UTR. Paradoxically, our results showed that over-expression of miR-30a-5p, miR-30e-5p, or miR-802-5p increased MR expression (from 50 to 100%, $P<0.05$) at D0, suggesting that these miRNAs could either positively modulate MR expression during renal development or involve an intermediate factor. Conversely, overexpression of miR-92a-1-5p, miR-431-5p, and miR-409-3p at D8 induced a decrease (from 30-40%, $P<0.05$) in MR expression, suggesting that these miRNAs could also modulate MR expression in the postnatal period. Currently, we are evaluating whether these miRNAs could be used as severity or prognostic biomarkers of sodium loss in neonates by quantifying their expression in urinary exosomes of preterm and term infants with the goal to better understand molecular mechanisms regulating MR expression in the perinatal period.

Late onset congenital adrenal hyperplasia after the fifth decade of life: case series

Laura Zaifu[1], Roxana Dusceac[2], Laura Naglabeala[2], Dan Niculescu[1,2] & Catalina Poiana[1,2]
[1]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [2]Department of Pituitary and Neuroendocrine Disorders, C. I. Parhon National Institute of Endocrinology, Bucharest, Romania

Introduction
Congenital adrenal hyperplasia (CAH) is an autosomal recessive disorder that is caused by mutations of genes involved with adrenal steroidogenesis. The mutations mostly occur in the 21-hydroxylase gene and rarely in the 3β-hydroxysteroid dehydrogenase gene or 11β-hydroxylase genes. Our aim is to present a series of 3 cases of patients with late onset CAH, probably due to 21-hydroxylase deficiency, after 50 years of age.
Case series
Patient 1 - The first patient was initially diagnosed with a 6.4/4.5 cm right adrenal adenoma and left micronodular adrenal hyperplasia. He underwent right adrenalectomy due to the large size of right adrenal adenoma. After surgery the lab tests showed: low serum cortisol; ACTH = 2000 pg/ml (3-66); very high LH, FSH and progesterone; normal DHEAs; testosterone = 3.06 ng/ml (1.75-7.81); basal 17-hydroxyprogesterone = 254 ng/ml; 17-hydroxyprogesterone 1h after administration of ACTH = 1154 ng/ml. After the diagnosis was established, the patient was treated with Prednisone and Fludrocortisone. Patient 2 - The patient was diagnosed with hypospadias at the age of 3 for which he underwent multiple surgeries, which has only recently been corrected. He presented to our department after having a pelvis MRI which detected the presence of a hypoplastic uterus, vagina (opening to the urethra), ovaries and a hypoplastic prostate. The abdominal CT showed right macronodular adrenal hyperplasia and left micronodular adrenal hyperplasia. He had very high LH, FSH and progesterone; normal DHEAs; testosterone = 1.71 ng/ml (1.75-7.81); basal 17-hydroxyprogesterone = 720

ng/ml; 17-hydroxyprogesterone 1h after administration of ACTH = 1320 ng/ml. Unlike the first patient the lab tests showed minimal adrenal insufficiency, therefore this patient did not require glucocorticoid and mineralocorticoid replacement. Patient 3 - This patient presented hypospadias in the first years of life similar the second patient. He had bilateral macronodular adrenal hyperplasia with minimal adrenal insufficiency; high progesterone; basal basal 17-hydroxyprogesterone = 36 ng/ml; 17-hydroxyprogesterone 1h after administration of ACTH = 1002 ng/ml; testosterone = 1.52 ng/ml (1.75-7.81). The mean age at diagnosis for these patients was 53.3 years. The karyotype of these patients was 46XX. On clinical examination all three patients had missing testicles in the scrotum and hypoplastic penis.
Conclusion
Although CAH is a very rare condition, the clinical signs and lab tests leading to the diagnosis of these three patients were different and polymorphic. The diagnosis after the fifth decade of life of these 46 XX patients with congenital adrenal hyperplasia has numerous psychosocial implications, as they have a male gender identity.

Hypogonadism in men with congenital adrenal hyperplasia. A retrospective longitudinal analysis with a special focus on testicular adrenal rest tumors and 11-oxygenated androgens

Matthias Auer[1], Christian Lottspeich[2], Martin Bidlingmaier[2], Hanna F. Nowotny[2], Lea Tschaidse[2], Richard Auchus[3] & Nicole Reisch[2]
[1]Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, Munich, Germany; [2]Klinikum der Universität München, Munich, Germany; [3]University of Michigan, Division of Metabolism, Endocrinology and Diabetes, Ann Arbor, United States

Background
Hypogonadism is frequent in men with congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency (21OHD). It has recently been demonstrated that testicular adrenal rest tumors (TART) are a source of 11-oxygenated androgens that might impair testicular function, in addition to their local compressive effects. Data on long-term course of testicular function in men with 21OHD and the role of potential influential factors such as presence of TART and 11-oxygenated androgen formation is sparse.
Methods
Retrospective single-center study in 30 men with classic 21OHD ($n = 11$ with TART, $n = 16$ without TART, $n = 3$ unknown). Median age at baseline was 31.0 years (IQR 26-38). The median observation period was 12 years (IQR 8-13). Levels of testosterone (T), 17-hydroxyprogesterone (17-OHP), androstenedione (A4) and 11-oxygenated androgens were measured simultaneously by LC-MS/MS.
Results
On average, 43.2% (No TART) and 54.6% (TART) of all T measurements in each individual patient were below the reference range (n.s.) with gonadotropin levels being inappropriately normal or suppressed in most patients. In multivariate mixed model analysis, including age, BMI, type of glucocorticoid (GC), GC-equivalence dosage and phenotype, T levels were comparable between men with and without TART. T levels remained stable during the observation period in men without TART (Baseline 11.37 $\pm$ 1.52 nmol/l, last visit 12.1 $\pm$ 2.1 nmol/l) and increased in those with TART (Baseline 9.48 $\pm$ 1.68 vs. last visit 14.9 $\pm$ 2.3 nmol/l ($P = 0.006$). At baseline, the A4/T-ratio was significantly higher in men with TART (1.39 $\pm$ 1.63) than in those without (0.27 $\pm$ 1.63), and there was a Time*Group interaction, indicating a decrease in the A4/T-ratio in men with TART ($P = 0.04$). This resulted in a trend for the A/T-ratio being higher in men with TART (0.5 $\pm$ 1.6 vs 0.3 $\pm$ 1.5; $P = 0.057$) across the whole observation period. 11-ketotestosterone levels were higher in men with TART (1.8 $\pm$ 0.006 nmol/l) than in men without TART (0.68 $\pm$ 0.006 nmol/l) but remained unchanged over time in both groups.
Conclusion
A normal serum T does not exclude hypogonadotropic hypogonadism in men with 21OHD, which is a common problem that appears to remain stable in the long run. The presence of TART does not have a negative effect on T-levels. In contrast, the detection of TART should prompt further assessment, including A4, gonadotropins, and 11-ketotestosterone, followed by treatment optimization to improve gonadal T production.

Catestatin is associated with the impairment of carbohydrate metabolism

Olena Pankova & Oleksii Korzh
Kharkiv National Medical University, Department of General Practice - Family Medicine, Kharkiv, Ukraine

Background
Arterial hypertension (AH) and 2 type diabetes mellitus (2TDM) are the critical risk factors for the development of cardiovascular diseases. Catestatin (CTS) is known as a marker of AH via its antiadrenergic and vasodilating actions, but also can improve insulin sensitivity.
Objective
To investigate the relations between CTS levels and parameters of carbohydrate metabolism in patients with AH, including AH with 2TDM, and establish the prognostic potential of CTS among this population of patients.
Materials and Methods
The present study was designed as a single-center cross-sectional study and performed in accordance with all ethical principles of the Helsinki Declaration. The study protocol was approved by the local ethics committee. Each study participant signed a written informed consent prior to any protocol procedures. We enrolled in the study 136 subjects, moreover, 106 of them had primary AH and 30 are healthy volunteers. Furthermore, 51 hypertensive patients have comorbid 2TDM. The diagnosis of AH was established according to the 2018 ESC/ESH guidelines for the management of AH. The diagnosis of 2TDM was determined according to the 2022 ADA Standards of Medical Care in Diabetes. The clinical examination and medical history data, as well as blood samples, were collected at the screening visit. The routine biochemistry parameters were analyzed on the same day. The plasma samples for CTS determinations were stored at -80°C for later analysis. Plasma CTS levels were measured by an enzyme-linked immunosorbent assay (ELISA), using a commercial kit (E4996Hu, BT Lab, Shanghai, China) according to the manufacturer's instructions. The data were presented as a mean $\pm$ SD. Statistical significance was defined as $P < 0,05$. Statistical data were analyzed using SPSS statistical software (SPSS 25.0 for Windows, IBM, Armonk, NY, USA).
Results
The mean CTS concentration was 5,38 $\pm$ 1,22 ng/ml. CTS plasma levels were significantly lower in patients with AH in comparison with control subjects (5,02 $\pm$ 1,09 vs. 6,64 $\pm$ 0,72 ng/ml; $P < 0,001$). Moreover, the patient with AH and 2TDM had significantly decreased CTS levels compared with the hypertensive patient without 2TDM (4,47 $\pm$ 1,16 vs. 5,61 $\pm$ 0,61ng/ml; $P < 0,001$). CTS significantly negatively correlated with such characteristics of carbohydrate metabolism as insulin ($r = -0,382$; $P < 0,001$), glucose ($r = -0,45$; $P < 0,001$), index HOMA-IR ($r = -0,481$; $P < 0,001$), and HbA1c ($r = -0,525$; $P < 0,001$).
Conclusions
In this study, we established the negative associations between CTS levels and parameters of carbohydrate metabolism, which allows us to consider CTS as a predictor of the development of 2TDM and determines its future diagnostic potential for both AH and 2TDM.

Patients with NF1 need routine hormonal screening towards pheochromocytoma

Ewelina Rzepka, Anna Bogusławska, Anna Kurzyńska, Marta Opalinska, Elwira Przybylik-Mazurek, Alicja Hubalewska-Dydejczyk & Aleksandra Gilis-Januszewska
Jagiellonian University Medical College, Chair and Department of Endocrinology, Cracow, Poland

Up to 40% of pheochromocytoma cases have a genetic background. The prevalence of pheochromocytoma in neurofibromatosis type 1 (NF1) was reported to be from 0.1 to 5.7%. However, the actual incidence of pheochromocytoma in NF1 seems to be underestimated. Current recommendations on NF1 do not include systematic biochemical screening for the presence of pheochromocytoma. Our aim was to analyse clinicopathological characteristics of pheochromocytoma in the course of NF1 syndrome with additional comparison to non-NF1 cases. We performed a database search for pheochromocytoma patients, diagnosed and treated in Endocrinology Department, University Hospital in Cracow from 2005 to 2022. In the group of 183 patients with histologically confirmed pheochromocytoma, 8 cases with NF1 were identified (4.4%). The group of NF1 patients comprise 4 men and 4 women. Median patient's age was 44 years (range: 29-70 years). Most cases were diagnosed incidentally (6/7). The most common manifestation of the disease was

hypertension (5/8). In majority of patients (6/8), NF1 diagnosis was stated based on clinical picture, in two cases genetic testing was performed. The median size of the tumour was 4.2 cm (range: 2.4-10.8 cm). In all cases with preoperative 68Ga DOTATATE PET/CT imaging (3/8), pathological tracer uptake was seen. 24-hour urinary fractionated metanephrines were significantly elevated in 6 cases. One patient had aggressive, metastatic tumour, which subsequently led to patient's death, the rest of patients remained disease-free during follow-up (median time: 44.5 months). One patient had synchronous bilateral disease. In three cases, accompanying neoplasms from different origin were observed (adrenocortical carcinoma, prostate cancer, GIST of the jejunum). PASS score was defined in 6 patients - in majority of cases it exceeded 3 (range 4-10). In 4 subjects, histopathological examination revealed composite pheochromocytoma with ganglioneuroma component. There were no significant differences between NF1 and non NF1 pheochromocytomas regarding sex, age, tumour size, PASS score, levels of metanephrines. In patients with NF1, composite pheochromocytoma was diagnosed much more often than in non-NF1 cases (with p value = 0.003). Pheochromocytoma in the course of NF1 is very often diagnosed incidentally. Most commonly it is manifested by hypertension, which could be easily overlooked. Sometimes it could metastasize, leading to patient's death. A routine hormonal assessment towards pheochromocytoma in patients with NF1 may improve patient's safety and treatment outcomes. NF1 should be excluded in all cases with composite pheochromocytoma, since this type of tumour is more commonly diagnosed in NF1 patients.

Treatment compliance affects the reliability of clinically and biochemically important variables used for the titration of mineralocorticoid treatment in primary adrenal insufficiency

Riccardo Pofi[1], Ilaria Bonaventura[2], Joanne Duffy[3], Zoe Maunsell[4], Brian Shine[4], Andrea Isidori[2] & Jeremy Tomlinson[1]
[1]Oxford Centre for Diabetes, Endocrinology and Metabolism and NIHR Oxford Biomedical Research Centre, Department of Endocrinology, Oxford, United Kingdom; [2]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [3]Heartlands Hospital, Department of Clinical Chemistry and Immunology, Birmingham, Oxford, United Kingdom; [4]Oxford University Hospitals NHS Foundation Trust, Department of Clinical Biochemistry, Oxford, United Kingdom

Background
There is currently no agreed consensus for the optimization and titration of mineralocorticoid (MC) therapy in patients with primary adrenal insufficiency (PAI).
Objective
To measure serum (sFC) and urine (uFC) fludrocortisone levels and explore their relationship with biochemically and clinically important variables (including treatment compliance) in order to evaluate their usefulness as markers to guide the MC replacement titration.
Methods
Multi-centre, observational, cross-sectional study on 41 patients (median age 39 years, IQR 27-56) with PAI on MC replacement therapy (median dose 100 mg/d, range 50-400). sFC and uFC levels (measured by LC-MS/MS), plasma renin concentration (PRC), electrolytes (Na^+, K^+), mean arterial blood pressure (MAP), total daily Glucocorticoid (dGC, hydrocortisone equivalents) and MC (dMC) dose, anthropometrics and assessment of GC and MC treatment compliance were incorporated into statistical models.
Results
We observed a close relationship between sFC and uFC ($r=0.434$, $P=0.005$) as well as between sFC and the time from the last FC dose ($r=-0.355$, $P=0.023$). Total daily MC dose was related to dGC dose ($r=0.556$, $P<0.001$), K^+ ($r=-0.388$, $P=0.013$) as well as sFC ($r=0.356$, $P=0.022$) and uFC ($r=0.531$, $P<0.001$) levels. PRC was related to Na^+ levels ($r=0.517$, $P<0.001$) and MAP ($r=-0.427$, $P=0.006$), but not to MC dose, sFC or uFC . Multiple linear regression analyses did not support a role for sFC, uFC or PRC measurements and confirmed K^+ ($B=-44.593$, $p=0.005$) as the most important variable to guide dMC titration. However, when compliance was inserted into the model, it was the only factor affecting dMC.
Conclusions
sFC and uFC levels are not helpful in dMC titration in PAI. Clinicians should continue to rely on clinical and biochemical important variables (electrolytes, blood pressures and symptoms) to guide their decisions on MC dose adjustment, being aware that patient's compliance to treatment is a major contributor for the reliability of such clinical markers.

SARS-CoV-2 provoked acute adrenal crisis with severe hypovolaemic hyponatraemia

Naychi Kyaw Kyaw[1], Kieran Mullins[1], Aneliya Sirkova[2] & Gideon Mlawa[3]
[1]Queen's Hospital (Barking, Havering and Redbridge Universities NHS Foundation Trust), Respiratory Department, Romford, London, United Kingdom; [2]Queen's Hospital (Barking, Havering and Redbridge Universities NHS Foundation Trust), Specialty Doctor, Diabetes and Endocrinology, Romford, London, United Kingdom; [3]Queen's Hospital (Barking, Havering and Redbridge Universities NHS Foundation Trust), Diabetes and Endocrinology Department, Romford, London, United Kingdom

Hyponatraemia is the commonest electrolyte disturbance among inpatients. Prompt diagnosis and management of the underlying cause is important. A 49-year-old Caucasian male presented to the emergency department with a two-day history of fever, altered mental status, vomiting, diarrhoea and postural dizziness. A rapid point of care RT-PCR test resulted positive for the SARS-CoV-2. A provisional diagnosis was presented of COVID-19 encephalopathy. The patient was usually fit and well, worked as a heating engineer and had no known immunodeficiency. Medical history was notable for atypical polymyalgia rheumatica treated with oral glucocorticoids more than two years prior. Admission laboratory studies were significant for a serum sodium level of 130mmol/l. Despite supportive treatment and with normal saline his clinical condition deteriorated over the first seventy-two hours of admission culminating in orthostatic syncope during clinical examination on day three. Repeat laboratory testing revealed serum sodium had fallen to 118 mmol/l. Urine sodium and osmolality were high. Random cortisol was reported as 6 nmol/l. Following intravenous resuscitation with high dose glucocorticoids and hypertonic saline his condition improved with slow normalisation of serum sodium, restoration of extracellular fluid volume and abatement of orthostatic symptoms. A tetracosactide stimulation test was performed with t = 0 min cortisol level of 9nmol/l and t = 30 min 39 nmol with a pre-test serum ACTH level of 4ng/L. A t = 60 min cortisol was not performed. The remainder of the pituitary profile including serum thyroid stimulating hormone was unremarkable. Magnetic resonance (MR) imaging of the Sella revealed no evidence of pituitary adenoma and subsequent MR adrenals showed bilateral adrenal atrophy. Lumbar puncture revealed quiet cerebrospinal fluid. Adrenal antibodies were not available at the time of writing. The patient was discharged on oral hydrocortisone and remains well at three months follow up. The presumptive diagnosis in this case is acute SARS-CoV-2 infection precipitating acute adrenal crisis in a predisposed individual. The unexpectedly low plasma ACTH was surmised to be due to acute illness. The patient awaits formal endocrinological evaluation. This case highlights the importance of prompt diagnosis and expedient management of hyponatraemia and particularly in high stakes cases where the underlying mechanism is adrenal failure. Although an uncommon cause of hyponatraemia it is critical to exclude adrenal insufficiency when approaching such patients. Timely recognition of adrenal crisis is associated with reduced complications and mortality associated with this disease.

Determination of dexamethasone level by liquid chromatography with tandem mass spectrometry after low-dose dexamethasone suppression test

Tomas Brutvan[1], Marcela Kotasova[2], Jan Sevcik[2], Drahomira Springer[2] & Jana Ježková[1]
[1]General University Hospital of 1st Faculty of Medicine of Charles University, 3rd Department of Internal Medicine, Praha 2, Czech Republic; [2]General University Hospital of 1st Faculty of Medicine of Charles University, Institute of Clinical Biochemistry and Laboratory Medicine, Praha 2, Czech Republic

Introduction
Low-dose dexamethasone suppression test is used to screen for excess cortisol production (Cushing's syndrome). It is recommended to use cut-off for suppression of serum cortisol (SC) < 50 nmol/l after 1 mg dexamehason suppression test (DST). Plasma dexamethasone levels are affected by many factors resulting in lower test specificity. Simultaneous analysis of dexamethasone and cortisol levels can improve diagnostic accuracy of DST. We used cut-off level of plasma dexamethasone > 3 nmol/l, which was validated in our previous study. The aim of the study was to detect the rate of false positive results by measuring plasma dexamethasone level after DST.

Methods
The prospective study of DST was carried out in 116 patients (71 female, 45 male) and 100 healthy controls (60 female and 40 male). The patients' cohort consisted of individuals with unilateral adrenal lesion ($n=28$), bilateral adrenal lesion ($n=30$), pituitary tumor ($n=21$) and clinically suspected Cushing's syndrome ($n=37$). Serum cortisol was determined by chemiluminescence immunoassay (Atellica Siemens). Plasma cortisol and dexamethason were determined by liquid chromatography with tandem mass spectrometry (2D-LC-MS/MS).
Results
Sixty-nine patients (59%) achieved SC <50 nmol/l. All of them had sufficient plasma dexamethasone level (>3 nmol/l). Forty-seven patients (41%) had SC >50 nmol/l, out of whom 44 achieved sufficient plasma dexamethasone levels while three did not. In this group of 47 patients further endocrinological examination ruled out hypercortisolism in 20 patients including 3 patients with insufficient dexamethasone levels and confirmed overt Cushing's syndrome in 16 patients. Eleven patients were found to have possible autonomous cortisol secretion. In the group of 100 healthy controls, SC <50 nmol/l was reached in 91 cases (91%). Nine individuals had SC >50 nmol/l, out of whom two patients had a level of plasma dexamethasone <3 nmol/l. In all nine individuals further endocrinological examination excluded hypercortisolism.
Conclusion
2D-LC/MS/MS is considered to be the golden standard in the analysis of both steroid hormones and dexamethasone. Insufficient plasma dexamethasone levels were found in 2% of subjects and were therefore the cause of false positivity of 1 mg dexamethasone suppression test. Simultaneous measurement of plasma dexamethasone and cortisol improved the specificity of DST. The results confirm that DST can be falsely positive even in healthy individuals with sufficient levels of dexamethasone.

Prevalence and incidence of type 2 diabetes mellitus in patients with adrenal incidentalomas: A study of 709 cases

Noemi Brox Torrecilla, Ana García Cano, Héctor F. Escobar-Morreale, Pablo Valderrábano, Alejandra Tobar & Marta Araujo-Castro
Ramón y Cajal Hospital, Madrid, Spain

Aim
To evaluate the prevalence and incidence of type 2 diabetes in patients with nonfunctioning adrenal incidentalomas (NFAI) and autonomous cortisol secretion (ACS) coming from a cohort of adrenal incidentalomas consecutively evaluated in a tertiary hospital in a predefined period (2013-2020).
Methods
In this retrospective study, adrenal incidentalomas $\geq$1cm with ACS and NFAI were included. ACS was defined by a post-dexamethasone suppression test (DST) serum cortisol $\geq$1.8 µg/dl, in the absence of signs of hypercortisolism, and NFAI as a DST $<$1.8 µg/dl and no biochemical evidence of other hormonal hypersecretion.
Results
Inclusion criteria were met by 709 patients, 231 with ACS and 478 with NFAI. At the diagnosis of the adrenal incidentaloma, type 2 diabetes was present in in 172 (24.3%) patients, 13 were under treatment only with life-style changes (diet and exercise), 98 with oral antidiabetics, 16 with insulin in monotherapy and 45 with insulin and oral antidiabetic drugs in combination. No difference in its prevalence was found between patients with ACS and NFAI (27.7% vs. 22.6%, $P=0.137$). Neither in the proportion of type 2 diabetic patients under insulin therapy (33.9% vs. 23.1%, $P=0.130$). However, fasting plasma glucose and HbA1c levels were significantly higher in patients with ACS than with NFAI (112.3 ± 35.56 vs 105.0 ± 29.05 mg/dl, $P=0.004$ and 6.5 ± 1.36 vs. 6.1 ± 0.89%, $P=0.005$, respectively). Furthermore, patients with type 2 diabetes had higher urinary free cortisol (54.8 $\pm$101.52 vs. 38.3 ± 29.08 µg/dl; $P=0.039$) and late-night salivary cortisol levels (5.0 ± 5.73 vs. 3.5 ± 3.57 µg/dL, $P=0.010$) than those without type 2 diabetes. After a media follow-up of 28 months [IQR 2.0-125.3], a total of 24 patients developed type 2 diabetes. No differences in incidence were found between patients with ACS and NFAI (HR 1.17, 95% 0.52-2.64).
Conclusion
Type 2 diabetes affects a quarter of patients with adrenal incidentalomas, with no differences in its prevalence and incidence in patients with ACS and NFAI. However, the glycemic control seems to be worse in those who have associated ACS. Also, higher levels of urinary and salivary cortisol are found in patients with type 2 diabetes compared to those without type 2 diabetes.

Diagnostic accuracy of 18F-FDG PET/TC for the characterization of adrenal lesions in a heterogeneous population

Martina Romanisio[1], Tommaso Daffara[1], Rosa Pitino[1], Alice Ferrero[1], Marco Zavattaro[1], Federica Biello[2], Alessandra Gennari[2], Gian Mauro Sacchetti[3], Gianluca Aimaretti[1], Flavia Prodam[1,4] & Marina Caputo[1,4]
[1]Endocrinology, Department of Translational Medicine, Novara, Italy; [2]Oncology, Department of Translational Medicine, Novara, Italy; [3]Department of Nuclear Medicine, Novara, Italy; [4]Department of Health Sciences, Novara, Italy

Purpose
Diagnosis of adrenal lesions requires hormonal investigation and morphological characterization; when CT and MRI imaging are equivocal, 18F-FDG-PET/CT could be a useful tool, although sensitivity and specificity varied among cohorts. The use of tumour-to-liver maximum standardized uptake values (SUVratio) was found to be accurate, but the best threshold value has not been identified yet. A SUVratio $>$ 1.5 was associated with malignancy with a good performance. The aim of the study was to evaluate the performance of the SUVratio $>$ 1.5 in our heterogenous population.
Patients and methods
Retrospective analysis of Endocrinology, Surgery and Oncological Units on patients who received care for adrenal lesions (2013-2022). The cohort was narrowed down to patients who underwent 18F-FDG-PET/CT to assess the risk of malignancy for adrenal nodules. Benignity was defined by histology or when the lesion remained stable or had a minimal increase in diameter ($<$20% and $<$5 mm) on the 12-month follow-up imaging. The performance of SUVratio $>$ 1.5 proposed and the optimal SUVratio in our population was calculated by ROC curves.
Results
177 patients with adrenal lesions were selected; of them, 36 underwent 18FDG-PET/CT and were included (17 M/19 F, age at diagnosis 61.2 $\pm$11.7 years); 6 patients had bilateral lesions, leading to a total of 42 adrenal lesions (diameter 36.1 $\pm$20.3 mm). Twenty-nine lesions were classified as benign, 11 as malignant and 2 as pheochromocytomas. Considering malignancies, 8 patients had adrenal metastases (2 of them bilateral) and 1 adrenocortical carcinoma (ACC). The diagnosis of adrenal masses with a SUVratio $>$ 1.5 was: 10 adrenal metastases, 1 ACC, 2 non-functioning adrenal adenomas, 1 adrenal hyperplasia and 1 pheochromocytoma. In the whole population, the SUVratio agreed with the diagnosis in 38 cases (90.5%); in the 4 discordant cases with a SUVratio $>$ 1.5 and non-malignant lesion, the diagnosis was: 2 non-functioning adenomas, 1 hyperplasia, and 1 pheochromocytoma. The SUVratio cut-off of 1.5 showed 100% Sn, 87% Sp, 73% PPV, and 100% NPV. The SUVratio cut-off calculated in our population was 1.55 (Sn 100%, Sp 73.7%, AUC 0.868), with similar values excluding both pheochromocytomas and metastases from the analysis (SUVratio cut-off 1.49, Sn 100%, Sp 96.3%, AUC 0.988).
Conclusion
18F-FDG PET/CT could help in decision making process avoiding unnecessary surgery. The SUVratio cut-off of 1.5 has a good performance in a heterogenous population with adrenal lesions.

HPA axis suppression in patients treated with glucocorticoids: relationship to dose, duration and likelihood of recovery

Maria Gregori[1], Paul Carroll[1], Sonu Thakali[1], Louise Breen[1], Anand Velusamy[1], Barbara McGowan[1], Dulmini Kariyawasam[1], Kathryn Tremble[2] & Aaisha Saqib[1]
[1]Guy's and St Thomas' NHS Foundation Trust, Diabetes and Endocrinology, London, United Kingdom; [2]Darent Valley Hospital, Dartford, United Kingdom

Background
Tertiary adrenal insufficiency (TAI) is a complication of long-term exogenous steroid use which results in suppression of the hypothalamic-pituitary-adrenal (HPA) axis. The short synacthen test (SST) is used to assess HPA axis function and recovery during glucocorticoid weaning. This study examined the effect of steroid preparation, dosage and therapy duration on HPA axis suppression.
Method
A retrospective analysis of 950 SSTs performed between 2016 and 2021. Of these 950, 772 (81%) were first SSTs and 178 (19%) were repeat SSTs. Patients under investigation for TAI were identified ($n=$ 512) and included in the analysis, those with suspected primary or secondary adrenal insufficiency were excluded. Data

collected included patient demographics, details of steroid use and where available 9am cortisol, baseline ACTH and SST results.
Results
Of the 512 patients 35% failed the SST (peak cortisol <420 nmol/l, ROCHE GEN 2). 33% of those receiving oral steroids had evidence of TAI, compared to 22% and 6% of those receiving inhaled or topical monotherapy, respectively. Most at risk of HPA axis suppression were patients taking combination therapy of oral with either inhaled or topical steroids, with evidence of TAI in 44% and 41% respectively. No patients receiving both topical and inhaled steroids had evidence of TAI. Prednisolone equivalent dose did not differ significantly between those who passed or failed their SST (mean 5.39mg vs 6.01mg, $P = .54$). Total steroid duration was not a predictor of HPA axis recovery [recovery 63.7 months vs non recovery 70.5 months, $P = .64$]. 178 repeat SSTs were conducted in 125 patients who failed initial SST. The mean number of repeat SSTs in this cohort was 1.5 (SD 1.1, range 1-8). Overall, 34% of patients undergoing repeat SST demonstrated recovery of the HPA axis with a mean time to recovery of 13.2 months (SD 9.8, range 2.5-49).
Conclusion
Those most at risk of HPA axis suppression are groups on combination therapy of oral with either inhaled or topical preparations, this is of particular relevance to patients with conditions such as asthma or eczema where severe disease can often necessitate dual therapy. 67% of patients on oral steroids had no evidence of TAI. Mean prednisolone equivalent dose or steroid duration did not predict HPA axis recovery. 34% patients undergoing repeat SST testing demonstrated recovery of the HPA axis, indicating that with careful medication adjustment many patients can reverse a suppressed HPA axis.

Prolonged Adrenocortical Blockade Following Interruption of Osilodrostat in ACTH-dependent Cushing's syndrome

Jonathan Poirier[1], Fidéline Bonnet-Serrano[2,3], Louis Thomeret[3], Lucas Bouys[1,3] & Jérôme Bertherat[1,3]
[1]Assistance Publique - Hôpitaux de Paris, Hôpitaux Universitaires Paris-Centre, Service d'Endocrinologie et Maladies Métaboliques, Paris, France; [2]Assistance Publique - Hôpitaux de Paris, Hôpitaux Universitaires Paris-Centre, UF d'Hormonologie, Paris, France; [3]Institut Cochin, Inserm U1016-CNRS UMR8104-Université Paris Cité, Paris, France

Introduction
Osilodrostat is the newest approved steroidogenic inhibitor drug for the treatment of Cushing's syndrome (CS). In this presentation, we describe 3 patients who experienced an unexpectedly prolonged adrenal insufficiency following interruption of this treatment.
Methods
A monocentric retrospective analysis (October 2019 to January 2023) of ACTH-dependent CS patients controlled with Osilodrostat was performed to identify patients with proven adrenal blockade persisting at least 4 weeks after cessation of Osilodrostat. Hormonal evaluation included basal serum cortisol, and DHEA-S as well plasma ACTH, aldosterone and renin levels determination. Stimulation test results with ACTH 250mcg and CRH 100mcg injection were also analyzed, when available.
Results
We identified 25 CS patients controlled by Osilodrostat and 5 among them experienced an unplanned treatment interruption due to adverse events or drug intolerance. Persistence of adrenocortical blockade was observed in 3 of those patients and lasted from 6 weeks to 9 months depending on cases. The reasons for Osilodrostat interruption were either a skin eruption (case 1) or a severe adrenal insufficiency secondary to infectious episodes (cases 2 and 3), requiring mineralocorticoid supplementation in the most acutely ill patient (case 3). Osilodrostat daily doses were 2, 4 and 10 mg/day at the time of interruption, respectively. Total Osilodrostat treatment duration before cessation did not seem to predict the severity of this outcome. On their latest hormonal evaluation, every patient showed an insufficient serum cortisol peak response to ACTH stimulation test, although 2/3 patients had a normal basal cortisol serum value > 250 mmol/l. Basal ACTH was high (>13 pmol/l) in the 3 patients. DHEA-S values were suppressed in all cases under Osilodrostat treatment and remained low during all the follow-up duration after cessation. At the latest available follow-up, Fludrocortisone supplementation was still necessary in the patient with mineralocorticoid deficit (case 3). CRH test was performed in 2 patients showing a significant response of ACTH but not of cortisol.
Conclusion
The duration of adrenal blockade in these 3 patients is hardly explained by the drug's half-life (~4h) and remains to be elucidated. Additional research is also needed to identify predictors of this long-term effect on adrenal function. This highlights the importance of monitoring adrenal function and preventing adrenal crisis in patients at risk even after Osilodrostat interruption.

Opioid Use and Adrenal Insufficiency in Olmsted County, MN, USA: A Population-Based Study

Mitra Moazzami, Sara J. Achenbach, Elizabeth J. (Beth) Atkinson & Irina Bancos
Mayo Clinic, Rochester, United States

Background
Chronic opioid use may lead to adrenal insufficiency (AI) due to suppression of the hypothalamic-pituitary-adrenal axis. We aimed to determine incidence of AI and mortality in patients treated with chronic opioid therapy in a standardized geographically well-defined population.
Methods
In this population-based cohort study we assessed the standardized incidence rate of first time met chronic opioid use and adrenal insufficiency in adult residents of Olmsted County, MN, USA, from January 1, 2005, to December 31, 2021. The Rochester Epidemiology Project was used as a database since it links medical records for all patients in Olmsted County since 1966. Incidence rates were standardized for age and sex according to the 2020 US white population. Chronic opioid use was defined as opioid therapy for at least 3 months of consecutive use of either transdermal fentanyl or oral opioids based on prescription database. AI was defined based on presence of chronic ($\geq$ 6 months) glucocorticoid therapy. Elixhauser morbidity index was used.
Findings
Between 2005 and 2021, 8359 patients (mean age 60.8 years, 60% women) were identified to have chronic opioid use. Standardized incidence rates for chronic opioid use decreased from 533 (95% Confidence Interval, CI 484-583) per 100 000 person-years in 2005 to 138 (95% CI 116-159) in 2021. After 15 years of follow-up and adjusting for the competing risk of death, an estimated 11.3% (95% CI 10.4-12.3%) of patients treated with chronic opioids met criteria for AI at a mean age of 64.8 years (61% women). When compared to referent subjects, and after adjusting for age, sex, prior hospitalizations, morbidity index, and year of index date, patients on chronic opioids were at higher risk to be diagnosed with AI (Hazard ratio, HR of 2.2, 95% CI 1.9-2.6). When compared to referent subjects, and after adjusting for morbidity index, history of hospitalizations, age, and sex, and AI, patients treated with opioids had a higher mortality (HR 1.74, 95% CI 1.61-1.87). Diagnosis of AI was independent predictor of mortality in patients treated with chronic opioids (HR 2.27, 95% CI 2-2.58).
Interpretation
We show a decrease in chronic opioid use between 2005 and 2021. Patients treated with chronic opioids demonstrated a 11.3% of cumulative incidence of AI. Patients treated with chronic opioids and concomitant AI had higher mortality even after adjusting for morbidity and prior hospitalizations.

Neonatal endotoxin exposure alters glucocorticoid levels in lymphoid organs of adult mice

Melody Salehzadeh[1,2], Anna Mazurenko[2,3], Sarah Lim[3] & Kiran Soma[1,2,3,4]
[1]The University of British Columbia, Zoology, Vancouver, Canada; [2]Djavad Mowafaghian Centre for Brain Health, Vancouver, Canada; [3]The University of British Columbia, Psychology, Vancouver, Canada; [4]The University of British Columbia, Graduate Program in Neuroscience, Vancouver, Canada

The neonatal immune system is not fully developed, making neonates more susceptible to early-life infection. Early-life activation of the immune system has lasting implications for health and disease. Glucocorticoids (GCs) are steroid hormones that modulate the immune response and increase in response to immune activation. GCs are produced by the adrenal glands and also by lymphoid organs (e.g., bone marrow, thymus, spleen). In neonatal mice, GC levels increase acutely in blood and lymphoid organs in response to the endotoxin, lipopolysaccharide (LPS, derived from *E. coli*). Yet, it is not known how early-life LPS exposure affects lymphoid organ GC levels in adulthood. We assessed whether LPS administration during the neonatal period ('first hit') in mice affects GC regulation in blood and lymphoid organs in adulthood when challenged again with LPS ('second hit'). We administered LPS (50 μg/kg i.p.) or saline (vehicle control) to male and female

C57BL/6J neonatal mice at post-natal day (PND) 4 and 6. We further split the mice into two groups and administered LPS (50 μg/kg i.p.) or saline in adulthood (PND90) (2x2 design). 4 hr after LPS administration at PND90, we collected whole blood, bone marrow, thymus, and spleen. We bisected the tissues and measured a panel of 10 steroids via liquid chromatography tandem mass spectrometry (LC-MS/MS) and transcripts of key steroidogenic enzymes (*Cyp11b1*, *Hsd11b1*, *Hsd11b2*), GC receptor (GR), and mineralocorticoid receptor (MR) via RT-qPCR. Neonatal LPS treatment altered LPS-stimulated, but not baseline, GC levels in adult mice. Specifically, neonatal LPS treatment increased lymphoid, but not blood, levels of corticosterone (main active GC in mice) and 11-dehydrocorticosterone (corticosterone metabolite) in LPS-treated males, but not females. Transcripts of key steroidogenic enzymes were present in all lymphoid organs, and there were effects of neonatal treatment in LPS-treated adults for some transcripts. Transcripts of GR and MR were present in all lymphoid organs, and neonatal LPS treatment decreased GR and MR transcript levels in the spleen of LPS-treated males and females. These results suggest that LPS exposure during early life has long-term effects on GC signaling in lymphoid organs. Importantly, these data demonstrate that lymphoid organs modulate local GC levels independently of circulating GC levels. Local GC production is a potential mechanism by which early-life bacterial infections can exert long-lasting programming effects on the immune system.

Immunophenotypic differences in patients with primary adrenal insufficiency of different etiology

Hanna F. Nowotny[1], Thomas Marchant Seiter[1], Jing Ju[1], Adrian Gottschlich[2], Holger Schneider[1], Stephanie Zopp[1], Frederick Vogel[1], Lea Tschaidse[1], Matthias Auer[1], Christian Lottspeich[1], Sebastian Kobold[2,3,4], Simon Rothenfußer[2], Felix Beuschlein[1,5], Martin Reincke[1], Leah Braun[1] & Nicole Reisch[1]
[1]LMU Klinikum, Medizinische Klinik and Poliklinik IV, Division of Endocrinology, Munich, Germany; [2]LMU Klinikum, Medizinische Klinik and Poliklinik IV, Division of Clinical Pharmacology, Munich, Germany; [3]German Cancer Consortium (DKTK), Partner Site Munich, Munich, Germany; [4]Helmholtz Munich, Research Center for Environmental Health (HMGU), Einheit für Klinische Pharmakologie (EKLiP), Neuherberg, Germany; [5]Universitätsspital Zürich (USZ) und Universität Zürich (UZH), Klinik für Endokrinologie, Diabetologie und Klinische Ernährung, Zurich, Switzerland

Background
Primary adrenal insufficiency (PAI) has been associated with increased risk of infection, adrenal crises and a higher mortality rate. This is caused by altered circadian cortisol profiles, which ultimately lead to immune cell dysregulation. In this study, we aim to characterize differences in immunophenotype of PAI patients of three different etiologies.
Methods
Cross-sectional single center study including 28 patients with congenital adrenal hyperplasia (CAH), 27 patients after bilateral adrenalectomy due to Cushing's syndrome (BADx), 21 patients with Addison's disease (AD) – all substituted with a stable daily median dose of 25 mg hydrocortisone (IQR 5 mg for BADx and AD and IQR 10 mg for CAH) – and 52 healthy controls. Peripheral blood mononuclear cells were isolated and used for analysis of immune cell subsets using multicolor flow cytometry after four-hour stimulation with phorbol myristate acetate (PMA)/Ionomycin, as well as a K562 based natural killer (NK-) cell cytotoxicity assay and qPCR analysis of clock gene expression.
Results
The percentage of IFNγ-secreting T helper (Th1) in AD ($P=0.0024$) and cytotoxic (Tc1) cells in CAH ($P=0.0055$) and AD patients ($P=0.0075$) was significantly reduced compared to controls. We additionally observed a downregulation of the percentage of IL-4$^+$ Th2 cells in AD patients ($P=0.0157$) and Tc2 cells in AD ($P=0.0154$) and CAH patients ($P=0.0012$) compared controls. IL-17 producing T-cells were also downregulated in patients with AD compared to the other patient groups and controls ($P<0.0001$). NK-cell cytotoxicity (NKCC) was reduced in all subsets of PAI patients compared to controls with the smallest change in patients with CAH (mean specific lysis 57.5% in controls, 21.7% in CAH, -0.5% in AD and -28.7 in BADx). Activated NK-cell percentages were upregulated in BADx ($P=0.0008$) and AD patients ($P=0.0348$) compared to controls, also expressed as an increase in degranulation marker CD107a expression (BADx $P<0.0001$; AD $P=0.0002$). In contrast to NK-cell activating receptors, expression percentage of NK-cell inhibiting receptor CD94 was upregulated in both BADx and AD patients ($P<0.0001$).
Conclusion
This study presents novel data on immunophenotypic differences in subsets of PAI of differential etiology. Further analysis of potential influencing factors of immune regulation is necessary to determine the impact of imprinting effects of long-term GC excess and effects of elevated glucocorticoid and androgen precursors or 11oxC19 concentrations.

What are the lived experiences of family and carers for adults during an acute episode of adrenal crisis: A qualitative analysis using focus group interview

Deepa Patel[1] & Sofia Llahana[2]
[1]Royal Free London NHS Foundation Trust, Diabetes and Endocrinology, London, United Kingdom; [2]City, University of London, School of Health Sciences, London, United Kingdom

Purpose
To gain an understanding of lived experiences of the role of family and carers during an acute episode of adrenal crisis through qualitative interviews with family carers. To gain an understanding of the role of family members and cares during an acute episode and to make recommendations for future standards of care in supporting family and carers to support self-management for loved ones, and health care professionals.
Methods
This study used the Braun and Clarke's 2006 approach to thematic analysis to explore qualitative data derived from five focus-group interviews to investigate the impact of Adrenal Insufficiency (AI) on family members and carers. Stratified by Adrenal Insufficiency type and country of residence in depth interviews were conducted to gain insight and understanding of the barriers and enablers to adherence, self-management to treatment, preventative strategies to minimise the risk of AC, and the provision of patient education and care services during the COVID – 19 Pandemic. Purposive sampling methodology was used to select a sample of participants which were recruited via Patient Advocacy Groups or patient charities providing support for adrenal insufficiency in the UK (emailing lists and social media). Participants were allocated to their respective groups on a first come-first- serve basis based on their AI type, and country of residence.
Results
Five themes were identified with a total of 18 sub themes. The five main themes were inadequate awareness of AI of the holistic considerations of AI, individuals with AI are experts in their management, lack of access to endocrine specialists to help live well with AI, lack of AI treatment knowledge in health care professionals and limited practical and emotional support. The family carers reported issues with gaining access, lack of appointments over the last 2 years and a lack of knowledge of AI by HCPs, which in some cases resulted in initial misdiagnosis of other conditions such as COVID-19 instead of an AC. A large portion of the feedback received from the focus group interview suggested that the education and training given for the emergency kit was severely lacking. Family carers reported accessing patient advocacy groups (PAGs), extremely helpful in accessing resources for clinical information and as a support mechanism.
Conclusion
The finding will support and guide international standards of care services for families and healthcare professionals, and will inform future research studies in supporting family carers and healthcare services to promote self-care strategies.

Autonomous cortisol secretion and bone mineral density: Is screening worthwhile?

Miguel Saraiva & Isabel Palma
Centro Hospitalar Universitário do Porto, Endocrinology, Diabetes and Metabolism, Universidade do Porto, Porto, Portugal

Introduction
Some studies have already described an association between mild autonomous cortisol secretion and poorer bone quality and increased risk of fracture. However, no consensus exists on this topic and currently there are no guidelines recommending bone status evaluation in patients suffering from this condition.
Aims
To evaluate bone mineral density in patients diagnosed with autonomous cortisol secretion (ACS) and possible autonomous cortisol secretion (PACS).
Methods
Cross-sectional study with adult patients with ACS or PACS currently under follow-up at our center. The 1mg overnight dexamethasone test was used to define

both entities: PACS if the post-dexamethasone serum cortisol level was 1.9–5.0μg/dL and ACS if it was >5.0μg/dL. Bone mineral density was evaluated by dual-energy x-ray absorptiometry directed at the lumbar spine and femoral neck.
Results
A total of 39 patients were included, 21 (53.8%) of them were women (all post-menopausal). Their median age was 67.0(59.0-73.0) years and their median BMI was 26.6(23.3-29.8) Kg/m^2. 26 (66.7%) were diagnosed with PACS and 13 (33.3%) with ACS. Fourteen (35.9%) patients had type 2 Diabetes mellitus, 16 (41.0%) had dyslipidemia and 8 (20.5%) had obesity. The overall prevalence of osteopenia was 46.2% ($n=18$) and of osteoporosis was 20.5% ($n=8$). When analyzing the prevalence of osteopenia and osteoporosis by subgroups, no significant differences were found between both sexes, in elderly patients, smokers, patients with diabetes or patients with obesity (p>0.05). Patients with bilateral adenomas were not more frequently diagnosed with osteoporosis ($P=0.664$) or osteopenia ($P=0.708$). Similarly, no differences were found in patients that had elevated urinary cortisol ($P=0.515$ and $P=0.124$) or elevated late-night salivary cortisol ($P=0.137$ and $P=0.813$). Patients who had more than one adrenal adenoma were also not more frequently diagnosed with osteoporosis ($P=0.351$) or osteopenia ($P=0.757$), as well as patients with big adenomas –>4cm in diameter – ($P=0.652$ and $P=0.520$). Patients diagnosed with ACS were not more frequently diagnosed with osteopenia than patients diagnosed with PACS (30,8% vs 53,8%, $P=0.173$) but were more frequently diagnosed with osteoporosis (45,5% vs 12,0%, $P=0,026$).
Conclusions
Both osteopenia and osteoporosis were prevalent in patients with PACS or ACS. Comparing to the overall prevalence of osteoporosis in the Portuguese population (10.2%), this numbers were alarmingly high. Therefore, it seems legit to screen for bone disease in this population, in order to provide directed treatment and eventually consider adrenalectomy. It would also be interesting to screen for asymptomatic vertebral fractures and to analyze bone turnover markers in this population.

RESCUE: Effect of supplemental hydrocortisone during stress in glucocorticoid-induced adrenal insufficiency; A study protocol for a multicentre, randomised, double blinded, placebo-controlled clinical trial

Stina Willemoes Borresen[1], Simon Bøggild Hansen[2,3], Hajir Al-Jorani[4,5], Lise Sofie Bislev[2], Jakob Bue Bjørner[6,7,8], Victor Brun Boesen[1], Louise Lehmann Christensen[4,5], Anja Fenger Dreyer[4,5], Dorte Glintborg[4], Richard Christian Jensen[4], Nanna Thurmann Jørgensen[1,9], Marianne Klose[1], Marie Louise Lund[1,9], Jelena Stankovic[2,3], Randi Tei[2], Torquil Watt[1,9], Jens Otto Lunde Jørgensen[2,3], Marianne Skovsager Andersen[4,5] & Ulla Feldt-Rasmussen[1,9]
[1]Copenhagen University Hospital, Rigshospitalet, Department of Medical Endocrinology and Metabolism, Copenhagen, Denmark; [2]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus, Denmark; [3]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark; [4]Odense University Hospital, Department of Endocrinology and Metabolism, Odense, Denmark; [5]University of Southern Denmark, Department of Clinical Research, Odense, Denmark; [6]University of Copenhagen, Department of Public Health, Copenhagen, Denmark; [7]QualityMetric incorporated, LLC, Johnston, RI, United States; [8]National Research Centre for the Working Environment, Copenhagen, Denmark; [9]University of Copenhagen, Department of Clinical Medicine, Faculty of Health and Clinical Sciences, Copenhagen, Denmark

Background
Long-term, low-dose prednisolone treatment ($\leq$5mg/day) is associated with adrenal insufficiency in >33% of patients. Nevertheless, the clinical consequences of glucocorticoid-induced adrenal insufficiency in patients receiving ongoing low-dose glucocorticoid treatment are unknown. Current clinical guidelines do not recommend routine evaluation of adrenal function during low-dose glucocorticoid treatment, and patients are not routinely instructed to increase glucocorticoid intake during stress.
Aim
To determine the effect of supplemental hydrocortisone during mild to moderate stress on health-related quality of life (HRQoL) in patients with polymyalgia rheumatica/giant cell arteritis (PMR/GCA) receiving ongoing low-dose ($\leq$5mg/day) prednisolone treatment.
Methods
A multicentre, randomised, double blinded, placebo-controlled, clinical trial (EudraCT number 2021-002528-18). The study includes patients with PMR/GCA receiving ongoing prednisolone treatment $\leq$5mg/day. Eligible patients undergo an ACTH test, and 250 patients with a stimulated cortisol $<$420nmol/l (biochemical adrenal insufficiency) are randomised 1:1 to either supplemental doses of placebo or hydrocortisone during stress. Patients continue prednisolone treatment and tapering hereof according to current clinical guidelines and add on supplemental study drug in situations of stress according to the study protocol. In situations of severe stress (risk of developing adrenal crisis), patients receive open label hydrocortisone treatment according to routine clinical care. Seventy-five patients with stimulated cortisol $\geq$420 nmol/l constitute a control group. The participants undergo screening (ACTH test) and baseline examinations, 6 month's HRQoL reporting and follow-up ACTH tests and examinations at 3 and 6 months.
Outcomes
HRQoL is evaluated using a specially developed study smartphone application (app) and with generic and disease-specific questionnaires (SF-36v2, Addiqol-30, CushingQol and Single item Sleep Quality Scale). The app prompts daily 'end-of-day' assessments and obtains information about intercurrent illness, injury, or stress, and symptoms attributable to adrenal insufficiency. The primary outcome is ecological momentary assessments of the Multidimensional Fatigue Inventory, *General Fatigue* scale, in situations of stress. This scale is prompted to the patient five times daily at semi-randomised time points, for three days, if triggered by stress, or at fixed timepoints monthly (unstressed conditions). Secondary outcomes include the other HRQoL measures (key secondary outcomes), incidence and grade of adrenal crises, PMR/GCA treatment characteristics, measures of exogenous Cushing's syndrome (body composition, muscle strength, bone quality, metabolic and cardiovascular risk) and biomarkers for adrenal insufficiency, glucocorticoid sensitivity and action.
Funding
Achieved from the Novo Nordisk Foundation as part of a collaborative grant entitled 'DOUBLE EDGE – Characterization and mitigation of adverse effects of glucocorticoid treatment' (NNF20OC0063280).

Reduction of albuminuria after surgical and medical treatment of primary aldosteronism

Gerald Sng, Meifen Zhang & Troy Puar
Changi General Hospital, Department of Endocrinology, Singapore, Singapore

Introduction
Primary aldosteronism (PA) is a common cause of secondary hypertension that can lead to renal sequelae. Treatment of hyperaldosteronism leads to reductions in albuminuria and glomerular hyperfiltration. We aimed to evaluate the effect of treatment on albuminuria and temporal changes in renal function after treatment with both surgery and medications.
Methods
We prospectively recruited patients with PA over three years. Spot urine samples for albumin were collected at baseline and one-year post-treatment. Degree of albuminuria was categorized based on the KDIGO classification. Serum creatinine values were collected at baseline and annually up to three years post-treatment, while estimated glomerular filtration rates (eGFR) were calculated using the MDRD equation. All patients keen for surgical cure were offered adrenal vein sampling (AVS). Patients with unilateral PA were treated with surgery, while those with bilateral disease were given medical therapy.
Results
Fifty-seven patients were recruited in the study, with no drop-outs. Forty-eight patients underwent AVS, and all had successful bilateral cannulation. Eventually, 25 patients underwent adrenalectomy whilst 32 patients received medications. Patients treated with surgery were younger, had more severe hypokalemia, and were less likely to have ischemic heart disease and hyperlipidemia. Overall, in 18 patients, there was improvement in albuminuria category, it remained the same in 19 patients, and worsened in 5 patients. In the surgical group, albuminuria improved significantly, from median 46.0mg/g to 6.0mg/g, $P=0.001$. In the medical group, albuminuria changed from median 41.5mg/g to 18.5mg/g, $P=0.356$. Significant declines in eGFR after treatment was observed in both groups. In the surgical group, eGFR continued to decline year-on-year until the second year when it stabilized, whereas in the medical group, there was greater eGFR decline in the first year and then it stabilized. Overall, over three years, there was no difference in the magnitude of decline between the surgical and medical groups (8.1ml/min/1.73m^2 vs 7.4ml/min/1.73m^2, $P=0.992$).
Discussion
Treatment of PA leads to reversal of glomerular hyperfiltration and resultant decline in eGFR. However, renal function is subsequently stable after the initial decline. The improvement of renal function is best observed in the improvement

of albuminuria amongst patients with PA, with surgical treatment associated with a greater degree of improvement.

Transfer Of Congenital Adrenal Hyperplasia Patients From The Pediatric ClinicTo The Adult Clinic: A Single Center Experience

Gamze Bilik Oyman[1], Tuğçe Kandemir[2], hulya hacisahinogullari[1], gulsah yenidunya yalin[1], Melek Yıldız[2], Nurdan Gul[1], Ayse Kubat Uzum[1], Sukran Poyrazooglu[2], Ozlem Soyluk Selcukbiricik[1], Firdevs Bas[2] & Feyza Darendeliler[2]

[1]Istanbul University Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology, Istanbul, Turkey; [2]Istanbul University Faculty of Medicine, Department of Paediatrics, Division of Paediatrics Endocrinology, Istanbul, Turkey

Introduction

Effective management of the transition from childhood to adulthood in congenital adrenal hyperplasia (CAH) can reduce the problems that may arise in the follow-up during adulthood.

Aim

Evaluation of the clinical characteristics and sociodemographic data of CAH patients transferred from the Pediatric Endocrinology Clinic to the Adult department of our hospital and the comparison of the 2 transition models carried out during this period was the primary aim of this study.

Methods

Thirty-six patients who have been transferred from the pediatric endocrinology clinic to the adult endocrinology clinic between 2001 and 2022 were included in the study. Clinical data were obtained from the hospital medical records. Transition was carried out by two models.While Model 1 included one visit, Model 2 included two visits with an interval of 4-6 months and with participation of pediatric and adult endocrinologists at 'Transition Outpatient Clinic'. Sociodemographic characteristics, frequency and duration of follow-up, clinical features, comorbidities (glucose metabolism disorder, dyslipidemia, TARTs, adrenal crisis,..), treatment modalities, doses and treatment compliance were evaluated and compared according to the transfer model.

Results

Eighteen patients were raised as female and the remaining of them raised as male. Karyotype analysis revealed 46,XX in 47.2% of the patients and 46,XY in 22.2% of them. The mean age $\pm$ SD of cases at transition time was 20.1 $\pm$ 1.8 years (range;17.5-24.2). Consanguineous marriage rate among the parents of the patients was 55.6%. The CAH subtypes were 21 hydroxylase deficiency (61.1%),11 beta hydroxylase deficiency (25%), 17 hydroxylase deficiency (11.1%),and non-classical CAH (2.8%).Of the 36 patients, 19 (52%) were transferred using Model 1 and 17 (47%) using Model 2. There was no difference in terms of comorbidity such as hypertension,glucose metabolism disorder,TARTs,adrenal crisis frequency between the transfer models and also between pediatric and adult follow-up period. Obesity frequency was 22.2% before transition and it was 35.5% after transition.However low bone mineral density was detected in 16.7%($n=4$) patients before and 56.3%($n=9$) patients after transition (p:0.0088). Before transition the percentage of patients receiving hydrocortisone(33.3%) as glucocorticoid option was higher than that in post-transition period (9.7%) (p:0.0018).The hydrocortisone equivalent dose of steroid therapy was also higher before the transition (18.5 $\pm$15.9 mg/m^2/day vs 9.9 $\pm$ 4.7 mg/m^2/day, p:0.002).Pregnancy rate of the cohort was 16.7%.

Conclusion

The two transition models evaluated in our study seem to have no difference in terms of comorbidities and follow-up parameters. It may be more appropriate to compare models in large size cohorts.

A Case of Orbital and Adrenal Masses

Amina Al-Qaysi, Ioannis Spiliotis[1] & Asif Ali

Milton Keynes University Hospital, Endocrinology & Diabetes Department, Milton Keynes, United Kingdom

Introduction

Adrenal incidentalomas (AIs) are increasingly being identified due to more frequent use of cross-sectional imaging modalities. Recent studies reported AIs being identified in 7.3% of abdominal CT imaging. Most adrenal incidentalomas are adenomas that may have secretory activity.

Case Report

An 80-year-old lady presented to our Emergency department with one week's history of worsening right eye bulging and discomfort. She was found to have right proptosis on examination with no clinical evidence of hormonal excess or deficiency, and her initial blood tests were unremarkable. Her general practitioner arranged for an outpatient CT scan of the chest, abdomen and pelvis that took place earlier that day prompted by the history of anorexia and weight loss of 6kg over two months duration. This CT scan showed a heterogenous solid right adrenal mass measuring 6.9 x 8.1 x 7.8 cm, with numerous enlarged retroperitoneal lymph nodes and nodular thickening of the left adrenal gland. Our Ophthalmology colleagues recommended arranging a MRI orbit, which showed a poorly enhancing right orbit mass measuring 2.4 x 1.7 x 2.0 cm partially encases the optic nerve. Urgent plasma metanephrines and urine steroid profile were sent prior to biopsies, and the treating team was advised to avoid beta blockade pending the results. The patient was found to have a palpable firm right neck lump during her admission and a CT-neck scan confirmed right upper cervical lymphadenopathy. The Ophthalmology team advised that biopsying the orbital mass would be challenging, therefore a right submandibular lymph node biopsy was performed after the plasma metanephrines and urine steroid profile showed normal results. Histology showed a diffuse large B-cell lymphoma of non-germinal centre phenotype. The Haematology team commenced the patient on R-CHOP chemotherapy. The patient was discharged home with follow up with our Haematology and Ophthalmology colleagues. We plan to arrange for abdominal cross-sectional imaging to monitor the response of the adrenal mass to chemotherapy.

Discussion

The adrenal gland involvement in lymphoma is reported in up to 24% of the cases. While benign cortical adenomas are the most common cause for AIs, other differential diagnoses include pheochromocytoma and adrenocortical carcinoma. This case highlights the importance of the prompt multidisciplinary workup and management approach. Careful assessment is required to evaluate for the presence of hormonal deficiency or excess in every case.

The majority of adrenocortical carcinomas (ACC) overexpress insulin-like growth factor 2 (IGF2). Although IGF2 drives a proliferative autocrine loop by binding to IGF1R and the isoform A of the insulin receptor (IRA), most studies focused on IGF1R. Recently, a high expression of IRA was observed in ACC vs normal adrenal tissues (NA), suggesting its potential involvement in modulating IGF2 effects in adrenocortical tumorigenesis. Aim of this study was to investigate the specific roles of IGF1R and IR in mediating IGF2 tumorigenic effects in ACC. Western blot analyses showed a higher IGF1R protein expression in both ACC ($n=8$) and adrenocortical adenomas (ACA, $n=8$) vs NA ($n=8$) (mean 1.04 $\pm$ 0.88 and 1.29 $\pm$ 1.11 vs 0.36 $\pm$ 0.12, respectively). Interestingly, although real-time qPCR showed a high variability and no significant differences in IGF1R, IR, IRA and IRB expression among the 3 groups, IRA/IRB ratio was higher than 2 in 5/8 (62.5%) ACC, 1/8 (12.5%) ACA and 0/8 (0%) NA, further supporting an implication of IRA in IGF2 pathway in ACC. Genetic silencing of IGF1R, IR and IGF1R + IR was performed in human ACC cell lines derived from both primary tumor (H295R) and metastasis (MUC-1, TVBF-7) and in 2 primary ACC cultures derived from primary tumor. All cell models used

presented an active IGF2 autocrine loop, as demonstrated by the ELISA assay measuring the presence of IGF2 in culture media. We observed different effects of IGF1R and/or IR knockdown on cell proliferation depending on the cell model. In H295R, neither single nor double IGF1R and IR silencing had an effect on cell proliferation, with no variation on cyclin E1 and B1 expression. Likewise, no changes were detected in ACC primary cultured cells after IGF1R or IR silencing. Instead, in MUC-1 IGF1R knockdown decreased cell proliferation (-19.32 ± 15.48%, $P < 0.01$) and cyclin E1 expression (-30 ± 25%, $P < 0.05$), and a further reduction was observed in IGF1R + IR silenced cells (-47.21 ± 7.18%, $P < 0.001$ vs bas and $P < 0.01$ vs cells silenced for IGF1R) with a diminished expression of both cyclin E1 (-36 ± 26%, $P < 0.05$) and cyclin B1 (-55 ± 37%, $P < 0.01$). Similarly, in TVBF-7, even if no variations were found after IGF1R or IR silencing, a significant reduction was observed in IGF1R + IR silenced cells (-44.08 ± 10.52%, $P < 0.001$). In conclusion, our preliminary data showed a high heterogeneity among different cell models with a tumor-specific role of IGF1R and IR, and seem to suggest that these receptors play a key role in promoting cell growth in ACC metastases but not in primary tumor.

Whole Exome Sequencing Identified Mutations in Genes Involved in the Synthesis of Atrial Natriuretic Peptide from the Heart in Hypertensive Cardiovascular Disease Patients

Sania Rauf[1,2], Abida Arshad[1], Roger Foo[3], Maleeha Akram[1], Shumaila Naz[2] & Syed Shakeel Raza Rizvi[1]
[1]Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Department of Zoology, Wildlife and Fisheries, Rawalpindi, Pakistan; [2]University of Wah, Quaid Avenue, Wah Cantt, Pakistan, Department of Biosciences, Wah Cantt, Pakistan; [3]Genome Institute of Singapore (GIS), Singapore, Singapore, Singapore

The heart not only has a mechanical function of pumping blood through vessels but also acts as an endocrine gland. In its endocrine function, the heart releases atrial natriuretic peptide (ANP), a hormone of a large family of natriuretic peptides. ANP is secreted from cardiac atria as an inactive preprohormone. In post-translational modification, 25-amino acid signal sequence is cleaved from preprohormone to produce proANP of 126-amino acid, which is the major form of ANP stored in intracellular granules of atria. Following stimulation of atrial cells by increased blood pressure, proANP is released and rapidly converted to 28-amino acid C-terminal mature ANP on cell surface by cardiac transmembrane serine protease corin. ANP regulates salt-water balance and blood pressure by promoting renal sodium and water excretion and stimulating vasodilation. Among other factors, calcium dependent secretion activator (CADPS) is one of the proteins that controls ANP secretion from the heart in stressed situations. Defects in the ANP pathway contribute to major diseases such as hypertension, cardiac hypertrophy and heart failure. The present study was designed to screen hypertensive cardiovascular patients to determine possible pathogenic mutations in genes involved in the synthesis of ANP from the heart using whole exome sequencing (WES). Thirteen hypertensive cardiovascular patients from three families (3 patients in 1st, 21-48 years; 5 in 2nd, 43-72 years and 5 patients in 3rd, 19-47 years of age) were selected for WES. DNA Isolation Kit (QIAamp DNA mini-Kit) was used to extract genomic DNA at City Lab, Rawalpindi, Pakistan, which was then taken to Genome Institute of Singapore (GIS), Singapore, where final dilutions of 25µl DNA were outsourced to Proteomics Lab, Macrogen Asia Pacific, Singapore for WES. Subsequent bioinformatics analysis was performed at GIS, Singapore. We identified 3 mutations in 2 genes, *CADPS* and *CORIN*, involved in the synthesis of ANP from the heart. Two variants in *CADPS* gene were observed; one splicing likely pathogenic variant (c. 969 + 3A>G) in all patients of family 1 and other missense (c. 308A>C, p. Glu103Ala) variant of uncertain significance (VUS) was witnessed in two patients of family 2. Both variants were already reported but are extremely rare in GnomAD database. In addition, a novel splicing (c. 618-2_618-1insT) VUS was identified in *CORIN* gene in only one patient of family 1. In conclusion, our results identified mutations in two genes involved in the synthesis of ANP from the heart, which may cause hypertension related cardiovascular diseases.

Background
There have been conflicting reports on fertility, reproduction rates and pregnancy outcomes in women with congenital adrenal hyperplasia (CAH). Identification of potential modifiable influential factors of pregnancy outcomes in these women has been hampered in the past by either small sample sizes or data derived from epidemiological samples.
Methods
Retrospective multi-center study including a total number of 72 women with CAH ($n = 34$ Non-classic (NC), $n = 21$ simply virilizing (SV), $n = 17$ with salt wasting (SW).) Data on pregnancies were collected using self-designed questionnaires, patients' and maternity records. In total, 133 pregnancies, 112 live births and 25 abortions were documented.
Results
Median age of the first pregnancy was 30.0 years and did not significantly differ between phenotypes. Across the entire cohort, it took almost two years on average to become pregnant for the first time (median 18.0 months, n.s.). Of all women 83.9% became pregnant spontaneously while the remaining had to use assisted reproductive techniques. The average number of life births of 1.4-1.6 children per woman was similar between all three groups ($P = 0.813$) and comparable to the general population. There was also no significant group difference in terms of spontaneous abortions (0.2-0.6 per women, $P = 0.360$). Most of the children in our cohort were delivered in a timely manner, however, rates of primary cesarean section in all groups were higher than those reported for the general population (NC 45.2%, SV 76.2%, SW 70,6%; $P = 0.056$). Of all children 11.3% in our cohort were small for gestational age (SGA), without a difference between phenotype groups. Gemini pregnancies were documented in 7 cases, 4 of whom had undergone assisted reproduction. Pregnancy complications such as gestational diabetes ($n = 3$) and pre-eclampsia ($n = 2$) were rare. Of the 42 women who had a cesarean section at the birth of their first child, ten were unplanned, including four cases required emergency cesarean section.
Conclusion
Our findings indicate that latency to first pregnancy is still prolonged in patients with CAH independent of phenotype, while fertility rates are comparable to the general population. Rate of primary cesarean sections were not only high in women with classic but also with non-classic CAH.

Response to Crinecerfont Treatment in Adults with Classic Congenital Adrenal Hyperplasia Is Correlated with Elevated Baseline Hormone Levels But Not Glucocorticoid Dose

Richard Auchus[1], Kyriakie Sarafoglou[2], Patricia Y. Fechner[3], Maria Vogiatzi[4], Nagdeep Giri[5], Eiry Roberts[5], Julia Sturgeon[5], Jean L. Chan[5] & Robert Farber[5]
[1]University of Michigan Medical School, Ann Arbor, United States; [2]University of Minnesota Medical School, Minneapolis, United States; [3]University of Washington School of Medicine, Seattle Children's Hospital, Seattle, United States; [4]The Children's Hospital of Philadelphia, Philadelphia, United States; [5]Neurocrine Biosciences, Inc., San Diego, United States

Introduction
Corticotropin-releasing factor type 1 (CRF_1) receptor antagonists, such as crinecerfont, have recently been investigated for the treatment of classic congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency (21OHD), a rare autosomal disease characterized by cortisol deficiency, elevated adrenocorticotropic hormone (ACTH), and excess androgen production. In a study of adults with 21OHD, treatment with crinecerfont for 14 days led to median percent reductions of >60% for 17 hydroxyprogesterone (17OHP, -64%), ACTH (-66%), and androstenedione (-64%) . Post hoc analyses were conducted to assess whether baseline hormone levels and glucocorticoid (GC) dose correlated with treatment response.
Methods
Males and females (18-50 years) with 21OHD and elevated 17OHP concentrations (≥1000 ng/dL) were studied in a sequential cohort design with the following open-

label crinecerfont regimens: 50 or 100 mg once daily at bedtime (cohorts 1 and 2, respectively); 100 mg once daily with the evening meal (cohort 3); 100 mg twice daily with meals (cohort 4) for 14 days. Participants could enroll in more than 1 cohort. Correlations between baseline ACTH, 17OHP, androstenedione, GC dose, and magnitude of change from baseline (CFB) to Day 14 hormone levels were assessed using the average concentration of samples collected before the morning GC dose (0600h, 0800h, and 1000h) as well as the average concentration over a full 24-hour sampling period.
Results
Eighteen participants (11 women, 7 men) were enrolled: cohort 1 ($n=8$), cohort 2 ($n=7$), cohort 3 ($n=8$), cohort 4 ($n=8$). Baseline GC regimens included hydrocortisone ($n=10$), prednisone or equivalent ($n=7$), and hydrocortisone + prednisone or equivalent ($n=1$), with mean total daily dose (hydrocortisone equivalent) of 14 mg/m^2/day (range, 6-25). Significant correlation was found between baseline concentration and CFB to Day 14 for 17OHP (morning window, $r=0.735$; 24 hour average, $r=-0.646$), with the greatest reductions from baseline observed in participants with the highest baseline concentrations. Similar correlations were observed for ACTH (morning window, $r=0.906$; 24-hour average, $r=-0.828$) and androstenedione (morning window, $r=0.887$; 24-hour average, $r=-0.898$). No correlation was found between baseline GC dose and CFB to Day 14 for 17OHP (morning window, $r=0.115$; 24-hour average, $r=0.215$).
Conclusions
In adults with 21OHD treated with crinecerfont, there was a high correlation between androgen and precursor treatment response and baseline hormone levels, but not with baseline GC dose, indicating that those with more elevated baseline hormone levels could have greater response, whereas androgen reduction could occur across a broad range of GC doses.

Can Inflammation-Based Scores Help Predict Treatment Response in Advanced Adrenocortical Carcinoma?

Alessandra Mangone[1,2], Barbara Altieri[3], Mario Detomas[3], Alessandro Prete[2,4], Haider Abbas[5], Miriam Felicitas Asia[6], Yasir Elhassan[2,4], Giovanna Mantovani[1,7] & Cristina Ronchi[2,3,4]
[1]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [2]University of Birmingham, Institute of Metabolism and System Research, United Kingdom; [3]University Hospital, University of Würzburg, Division of Endocrinology and Diabetes, Department of Internal Medicine I, Germany; [4]Birmingham Health Partners, Centre for Endocrinology, Diabetes and Metabolism (CEDAM), Birmingham, United Kingdom; [5]Queen Elizabeth Hospital, University Hospitals of Birmingham NHS Trust, Oncology Department, United Kingdom; [6]Queen Elizabeth Hospital, University Hospitals of Birmingham NHS Trust, Department of Endocrinology, Birmingham, United Kingdom; [7]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milan, Italy

Background
Treatment for advanced adrenocortical carcinoma (ACC) consists of mitotane alone or combined with etoposide, doxorubicin and cisplatin (EDP), yet their efficacy is limited and burdened with significant toxicity. Moreover, markers of response are lacking. Inflammation-based scores have been proposed as prognostic factors in several malignancies including ACC, and recently also as predictors of gemcitabine + capecitabine efficacy, second-line treatment in progressive disease. We therefore investigated the role of inflammation-based scores in predicting response to first-line therapy in advanced ACC.
Methods
We performed a retrospective analysis of patients with advanced ACC treated with mitotane alone or EDP ± mitotane in two European centres. We investigated clinical parameters (tumour stage at diagnosis, resection status, Ki67 index, time from diagnosis to treatment start, performance status, plasma mitotane levels, time in mitotane target ≥80%, cortisol hypersecretion at treatment initiation) and pre-treatment inflammation-based scores [neutrophil-to-lymphocyte-ratio (NLR), platelet-to-lymphocyte-ratio (PLR), monocyte-to-lymphocyte-ratio (MLR), derived neutrophil-to-lymphocyte ratio (dNLR), serum albumin]. Primary and secondary endpoints were overall-survival (OS) and time-to-progression (TTP) from treatment initiation, respectively. We additionally evaluated the best objective response to treatment, defined according to RECIST 1.1 criteria.
Results
We included 90 eligible patients (59% women, median age: 51 years) treated with mitotane monotherapy ($n=40$) or EDP ± mitotane ($n=50$). In the mitotane cohort, NLR ≥ 5 and PLR ≥ 190 predicted shorter OS (HR: 145.83, 95%CI: 1.87-11323.83, $P=0.025$; HR: 165.50, 95%CI: 1.76-15538.04, $P=0.0027$, respectively), remaining significant at Cox regression multivariable analysis including resection status, time from diagnosis to start treatment, ECOG performance status, cortisol hypersecretion and time in mitotane target. NLR was also associated with shorter TTP (HR: 2.58, 95%CI: 1.28-5.20, $P=0.008$), but only at univariable analysis. Patients with NLR ≥ 5 showed a worse response to mitotane than those with NLR < 5 ($P=0.040$). In the EDP cohort, NLR ≥ 5 predicted shorter OS (HR: 2.52, 95%CI: 1.30-4.88, $P=0.006$) and TTP (HR: 1.95, 95%CI: 1.04-3.66, $P=0.037$), which was not confirmed at multivariable analysis.
Conclusion
Inflammation-based scores, calculated from routinely measured parameters, may help predict response to first-line pharmacotherapy in advanced ACC. These findings will be validated in larger cohorts.

The impact of Bariatric Surgery on the 1mg Dexamethasone Suppression Test in patients with Severe Obesity

Anna Casteràs[1], Enzamaria Fidilio[1], Marta Comas[1], Angel Michael Ortiz[1], Betina Biagetti[1], Alba Zabalegui[1], Francesca Filippi[2,3], Marina Giralt[2], Roser Ferrer[2], Ramon Vilallonga[4] & Andreea Ciudin[1]
[1]Hospital Universitari Vall d'Hebron, Diabetes and Metabolism Research Unit, Vall d'Hebron Institut de Recerca (VHIR), Universitat Autònoma de Barcelona., Endocrinology and Nutrition Department, Barcelona, Spain; [2]Hospital Universitari Vall d'Hebron, Department of Biochemistry, Barcelona, Spain; [3]Hospital Universitari Vall d'Hebron, Clinical Pharmacology Department, Barcelona, Spain; [4]Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Endocrine, Metabolic and Bariatric Unit, General Surgery Department, Barcelona, Spain

Background
The cortisol suppression test with 1 mg dexamethasone (DST) is a screening test for hypercortisolism with high sensitivity (95%) for serum cortisol cut-off < 1.8 µg/dl. However, cortisol tests may give false positive in patients with severe obesity (SO). On the other hand, bariatric surgery (BS) is the most effective treatment for SO, and the operated population is growing. At present there is no reliable data regarding the impact of BS on DST results in patients with SO, as well as on the role of the DST as predictor of response to BS. On these bases we performed the present study.
Objectives
a) To explore the impact of BS on the results of the DST. b) To evaluate the impact of cortisol suppression on the response to BS (in terms of weight loss).
Methods
Prospective study including patients with SO scheduled for BS at our site between January-2019 and March-2020. Patients with overt clinical endogenous hypercortisolism or corticosteroid treatment were excluded. All the patients underwent at baseline and 12 months after BS complete medical history, anthropometric data, biochemical analysis and DST.
Results
23 patients were included, 69.6% females, mean age 44.4 ± 9.3years, BMI 45.97 ± 8.23kg/m^2, excess weight (EW) 59.76 ± 25.07 kg (according to BMI 25kg/m^2). All the patients presented DST < 1.8ug/dl before BS, while 1 case had a higher cortisol value after BS. Cortisol after DST was significantly higher 12m post-BS than baseline (0.82 ± 0.29ug/dl vs 0.94 ± 0,31 ug/dl, $P=0.05$). There was direct correlation between BMI and DST suppression level at baseline ($P<0.01$), without any relationship with age, gender, menopausal state or associated comorbidities. Regarding weight response to BS, 11 (47.8%) patients achieved a weight loss of >75% of the EW at 12m. Patients with a suppression of cortisol < 0.8 ug/dl were less likely to achieve this threshold ($P<0.02$, AUC 0.79, S 0.73 and E 0,75) ($P=0.03$)
Conclusions
All the patients with SO suppressed cortisol below 1.8 ug/dl in the pre-BS DST. Cortisol after DST increases following BS, and may not suppress properly in some patients. A DST cortisol threshold < 0,8 ug/dl before BS predicted a lower weight loss, reaching less than 75% of the EW at 1 year.

Role of macrophages in zona glomerulosa differentiation

Diana Garcia, James Wilmouth, Julie Olabe, Antoine Martinez & Pierre Val
iGReD, Clermont-Ferrand, France

Maturation of the definitive adrenal cortex occurs between 3 and 6 weeks post-partum and involves onset of CYP11B2 expression and establishment of the laminin-encased 3D structure of glomeruli that contain rosettes of 10 to 15 zona

glomerulosa (zG) cells that work in coordination to produce optimal amounts of aldosterone. Although this process is dependent on canonical WNT/b-catenin signaling, cellular sources of WNT ligands remain elusive and the mechanisms involved in the extensive extra-cellular matrix remodeling associated with rosette/glomeruli morphogenesis are unknown. Beyond their role in innate immunity, macrophages are involved in extra-cellular matrix remodeling under a wide variety of pathophysiological conditions and have the capacity to produce WNT ligands. This, together with the presence of macrophages within the zG cells, strongly suggest that macrophages may play a role in zG morphogenesis and differentiation. Supporting this idea, a recent publication has shown that intra-tissular aldosterone concentration was reduced in the absence of macrophages under stress conditions. However, whether macrophages play a direct role in controlling aldosterone secretion or an indirect role by remodelling the postnatal zG is unknown. The presence of tissue resident macrophages in a specific zone is dependent on the production of trophic factors such as IL34, CSF1, CSF2 or CX3CL1 by nearby, tissue resident 'niche' cells. In return, macrophages are thought to provide positive 'feedback' signals to their niche, generating mutually beneficial circuits between the niche and its macrophages. To gain insight into the role of macrophages in zG morphogenesis and homeostasis, we used single cell sequencing and RNAscope analyses to show expression of CX3CL1 in the zG and of CX3CR1 in macrophages. Interestingly, CX3CL1 expression in the zG was downstream of WNT signalling, suggesting existence of a bi-directional interaction between macrophages and zG. To further study the role of macrophages during the maturation of the zG, we pharmacologically depleted macrophages by the small molecule inhibitor Pexidartinib at different time points between 3- and 12-weeks post-partum, when maturation of the zG occurs. Short-term depletion of macrophages resulted in a more disorganized and elongated zG, suggesting a delay in maturation. However, long-term depletion of macrophages resulted in exacerbated maturation of the rosettes, suggesting that the short-term zG defect was followed by establishment of a compensatory mechanism to allow formation of rosettes even in the absence of macrophages. Whether these perturbations of the zG are correlated with an altered production of aldosterone is still under study.

Bone metabolism and dual-release Hydrocortisone: results from a real-life study

Davide Ferrari[1], Valentina Sada[1], Valeria Hasenmajer[1], Dario De Alcubierre[1], Giulia Puliani[2], Marianna Minnetti[1], Alessia Cozzolino[1], Ilaria Bonaventura[1], Alessandra Tomaselli[1], Riccardo Pofi[3], Andrea Lenzi[1] & Andrea M. Isidori[1]
[1]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [2]Scientific Institute for Research, Hospitalization and Healthcare (IRCCS) Regina Elena National Cancer Institute, Oncological Endocrinology Unit, Rome, Italy; [3]University of Oxford, Oxford Center for Diabetes, Endocrinology and Metabolism, Oxford, United Kingdom

Background
Patients with adrenal insufficiency (AI) require long-term glucocorticoid (GC) replacement therapy and generally show an increased prevalence of bone metabolism alterations. Only few data are available on bone safety of dual-release Hydrocortisone (DR-HC) therapy.
Objective
To evaluate bone metabolism in both primary AI (PAI) and secondary AI (SAI) during long-term therapy with DR-HC.
Methods
We studied patients with AI on short-acting, immediate-release GC therapy (hydrocortisone or cortisone acetate) before and up to 60 months after the switch to an equivalent dose of DR-HC, collecting data on bone turnover markers, femoral and lumbar spine areal bone mineral density (aBMD) and trabecular bone score (TBS). Any concomitant condition (hypo- or hyperparathyroidism, early menopause, malignancies) or medication (PTH, anti-resorptive therapy) that could influence bone parameters was considered as exclusionary.
Results
31 patients (18 PAI and 13 SAI, 18 females, 9 post-menopausal) with a median age of 51 (range 20-77) years, were included. Patients on established immediate-release glucocorticoid therapy were switched to an equivalent dose of DR-HC at baseline. Median duration of AI at baseline was 36 months (range 12-432). Median daily hydrocortisone- equivalent doses before switching to DR-HC were 14.7 [12.0-17.3] mg/kg/m2 in PAI and 11.0 [10.1 – 13.2] mg/kg/m2 in SAI. Any other hormonal disorders (i.e. diabetes, hypothyroidism, hypogonadism, Growth Hormone deficiency) were adequately controlled throughout the study. All patients had normal calcium and phosphorus levels and most were under cholecalciferol therapy, with mean Vit D 30.0 $\pm$13.2 ng/mL at baseline. At baseline, 48% of patients had aBMD values compatible with osteopenia and 16% had a diagnosis of osteoporosis in at least one site. Compared to baseline, no significant difference was observed in aBMD at femur neck, total hip and total lumbar spine at 24 (P= .825; P=.453; P=.637), 36 (P=.637; P=.460; P=.607), 48 (P=.202; P=.996; P=.379) and 60 months (P=.175; P=.528; P=.983) of DR-HC therapy. Interestingly, TBS values significantly decreased after 48 (P=.021) and 60 months (P=.032), although a physiological decline of bone microarchitecture with aging is expected. Alkaline phosphatase, C-terminal telopeptide and osteocalcin levels showed no differences in all timepoints. Moreover, no differences were found between PAI and SAI patients in all the evaluated parameters.
Conclusions
DR-HC is a safe treatment option in terms of bone health in patients with AI, maintaining stable bone mass, bone quality and bone turnover while aging.

Inflammation-based scores in benign adrenocortical tumours are related to the degree of cortisol excess

Vittoria Favero[1,2], Alessandra Mangone[3], Yasir Elhassan[2,4], Miriam Felicitas Asia[5], Rowan Hardy[2], Iacopo Chiodini[1,6], Alessandro Prete[2,4] & Cristina Ronchi[2,4]
[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy; [2]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [3]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [4]Birmingham Health Partners, Centre for Endocrinology, Diabetes and Metabolism, Birmingham, United Kingdom; [5]Queen Elizabeth University Hospital, Birmingham, United Kingdom; [6]Ospedale Niguarda Cà Granda, Unit of Endocrinology, Milan, Italy

Glucocorticoids play a significant role in immune modulation and regulation of inflammation. In patients with endogenous glucocorticoid excess (Cushing's syndrome [CS]) multiple haematological alterations are recognized, such as neutrophil leukocytosis, lymphopenia, and eosinopenia, often leading to severe clinical complications. However, little is known in patients with mild autonomous cortisol secretion (MACS). Serum inflammation-based scores may reliably reflect systemic inflammation and predict outcomes in several diseases. The aim of this study was to evaluate inflammation-based scores in patients with ACTH-independent cortisol excess and investigate their relationship with cortisol hypersecretion levels. A cohort of 391 patients (median age 61 years, 59.6% women) was evaluated: 231 patients with nonfunctioning adrenocortical tumors (NFAT), 138 with MACS (serum cortisol after 1-mg overnight dexamethasone suppression test >50 nmol/l and absence of typical CS features), and 22 with CS. Patients with other types of benign adrenal tumours (e.g. myelolipoma), phaeochromocytoma, active malignancies, infections, and autoimmune or haematological diseases were excluded. We evaluated the cortisol profile and the following inflammation-based scores at initial diagnosis: Neutrophil-to-Lymphocyte Ratio (NLR), Lymphocyte-to-Monocyte Ratio (LMR), Platelet-to-Lymphocyte Ratio (PLR), Systemic Immune-Inflammation Index (SII, obtained by multiplying absolute platelet count and NLR), and Prognostic Nutrition Index (PNI, calculated by serum albumin and lymphocyte count reflecting immune-related nutritional status). Data are expressed as median (interquartile range). Serum cortisol after 1-mg overnight dexamethasone positively correlated with NLR (r=0.283) and SII (r=0.225) and negatively with LMR (r=-0.23) (each $P<0.001$). NLR, SII and LMR significantly differed among the three groups of patients, while PLR and PNI were similar among CS, MACS and NFAT. In particular, NLR and SII were significantly higher in both CS [3.80(1.92-4.37) and 859.6(459.7-1355.2)] and MACS [2.71(2.05-3.60) and 730(485.9-961.5)] compared to NFAT [2.21(1.68-2.94) and 562.9(412.1-837.6)] (P=0.001 and $P<0.001$ for NLR and P=0.002 and P=0.01 for SII, respectively). On the contrary, LMR was lower in patients with CS [2.23(1.82-3.47)] and MACS [3.12(2.42-4.5)] than in those with NFAT [3.62(2.85-4.55)], but also significantly lower in CS compared to MACS, all $P<0.05$. In conclusion, the neutrophil-based scores (NLR and SII) and monocyte-based score (LMR) correlated with the degree of endogenous cortisol excess being altered in both patients with ACTH-independent CS and MACS. Moreover, LMR was the only score that showed a significant difference between CS and MACS. These findings suggest that, similar to overt CS, mild autonomous cortisol excess also influences the immune system function which can contribute to the MACS-associated comorbidities.

Primary hyperparathyroidism and bilateral pheochromocytoma with MAX mutation: Case report

Chaima Benabid, Safia Achir, Numydia Nebti & Zakia Arbouche
Universitary Hospital Center Benimessous, Endocrinology, Algiers, Algeria

Introduction
Pheochromocytomas(PC)are rare catecholamine-producing neuroendocrine tumors. Germline variants of the MYC-associated factor (MAX) gene have been associated with familial PC and paragangliomas (PGL) with an autosomal dominant pattern of inheritance and an overall frequency estimated at 1.9%. Other endocrine and non endocrine tumors can be associated to germline MAX mutations.
Case presentation
We report a case of a 37 years old male patient, with no particular personal or family history, who presented with a bilateral PC diagnosed following severe hypertension with paroxysmal Menard's triad, high urinary normetanephrine = 32.26 µmol/24h (> 10x normal value, confirmed the diagnosis of PC). Abdominal CT scan showed 3 bilateral adrenal nodules. MIBG scintigraphy showed no suprarenal or extra suprarenal fixation. Patient underwent a bilateral adrenalectomy and histologic study confirmed the diagnosis of PC(PASS <3). A truncating heterozygous germline MAX variant located on exon 4(c.223 C>T(p.Arg75*)was identified. Reassessment at 3 years after surgery showed no signs of recurrence (no hypertension and negative urinary metanephrins) .Moreover, our patient's lab findings were compatible with an asymptomatic hypercalcemic primary hyperparathyroidism(PHPT), a superior parathyroid nodule was found on cervical ultrasound with a significant in-situ PTH level (5059pg/ml). Patient was referred to surgery for parathyroidectomy.
Discussion
The MAX gene is the tenth PCC/PGL susceptibility gene described, it encodes a transcription factor involved in cell proliferation, differentiation and apoptosis. this mutation is responsible for multiple and/or bilateral PCs and PGL. The biological pattern of catecholamine secretion with a predominance of normetanephrines described in this mutation and explained by a low expression of the PNMT enzyme was found in our patient. Hypercalcemia has been reported in 4 other individuals with germline MAX mutations and PC, one of them reported as PHPT with germline MAX pathologic variant(PV):c.223C >T(p.Arg75*)which is similar to the variant of our patient suggesting that this variant may be associated with PHPT with parathyroid adenoma. Other endocrine and non-endocrine tumors that have been occasionally reported in this syndrome are absent in our patient.
Conclusion
Germline MAX mutations are associated with PCs, PGLs, parathyroid adenomas, other endocrine and non endocrine tumors suggesting that MAX is a novel multiple endocrine neoplasia gene. Screening of PHPT should be considered in the individuals carrying the PV c.223C>T (p.Arg75*).First-degree relatives of an individual with a known *MAX* pathogen variant should be offered molecular genetic testing.

The cardiometabolic risk in patients with non-functioning adrenal incidentaloma: an observational, retrospective and propensity score matched study

Mirko Parasiliti Caprino[1], Fabio Bioletto[1], Gabriella Tomaiuolo[1], Anna Roux[2], Chiara Lopez[1], Martina Bollati[1], Matteo Procopio[1], Stefano Arata[1], Ezio Ghigo[1], Emanuela Arvat[2], Roberta GIORDANO[3] & Mauro Maccario[1]
[1]University of Turin, Endocrinology, Diabetes and Metabolism, Turin, Italy; [2]University Of Turin, Oncologic Endocrinology, Italy; [3]University of Turin, Department of Clinical and Biological Sciences, Orbassano, Italy

Introduction
Recent studies found an increased cardiometabolic risk in patients with Non-Functioning Adrenal Incidentaloma (NFAI), but all these data have low quality of evidence.
Objective
To establish whether cardiometabolic risk and complications in NFAI patients can be associated to the presence of a non-secreting adrenal tumor, independently from potential confounding factors.
Subjects and Methods
In this cross-sectional and retrospective study, all the NFAI patients referred to the University Hospital of Turin, between 2000 and 2022, were consecutively enrolled and compared with subjects not affected by adrenal disease. For each patient, clinical and biochemical data were evaluated, in addition to their cardiovascular (CV) risk scores and cardiometabolic outcomes.
Results
A total of 2381 subjects were enrolled in the study (1137 patients with NFAI, including 831 with arterial hypertension and 306 with normal blood pressure values; 1244 non-NFAI, of which 1177 hypertensive patients and 67 normotensives). In the NFAI group, a significant increase of the CV risk was observed exclusively among subjects suffering from hypertension and it was calculated using risk scores (SCORE: $4.93 \pm 5.79\%$ vs $3.94 \pm 6.77\%$, $P=0.006$; Framingham Risk Score: $11.03 \pm 9.32\%$ vs $9.45 \pm 8.97\%$, $P=0.002$; Cuore project: $15.63 \pm 15.66\%$ vs $11.46 \pm 13.42\%$, $P=0.000$). Moreover, the NFAI group presented globally higher AASI (Ambulatory Arterial Stiffness Index) values compared to the subjects with no adrenal mass, both among patients with arterial hypertension (0.47 ± 0.16 vs 0.43 ± 0.14; $P=0.022$) and among those with normal blood pressure values (0.45 ± 0.14 vs 0.31 ± 0.08; $P=0.012$). Regarding cardiometabolic complications, at multivariate logistic regression, NFAI proved to be independently associated with aortic ectasia (OR 2.779, 95% CI 1.287-6.001, $P=0.009$), correcting for age, sex, metabolic syndrome (MS) and previous CV events. To minimize the impact of differences between the NFAI and non-NFAI groups, propensity score matching (1:1) was used. Even in this analysis, NFAI retained a statistically significant association with aortic ectasia ($\beta=0.074$, 95% CI 0.016-0.131, $P=0.012$). The matching variables were the same covariates applied in the logistic regression. Conversely, no significant associations with MS, type II diabetes, eGFR <60 mL/min/1.73m^2, microalbuminuria, atrial fibrillation or hypertensive cardiomyopathy were found.
Conclusions
The results of this study suggest the presence of an augmented cardiometabolic risk in patients affected by NFAI. Considering cardiometabolic complications, we described for the first time an association between NFAI and aortic ectasia. If these data will be confirmed in longitudinal studies, NFAI could be considered a condition of high cardiovascular risk and, therefore, patients with this disease could benefit from appropriate cardiometabolic follow-up and treatment.

Characterisation of a Three-Dimensional (3D) Cell Culture Model of Adrenocortical Carcinoma

Sarah Feely[1], Padraig Donlon[1], Nathan Mullen[1], Anna Sorushanova[1], David P Finn[2], Brendan Hernan[2], Oliver Carroll[3], Peter Owens[4], Abhay Pandit[3], Constanze Hantel[5] & Michael C Dennedy[1]
[1]Lambe Institute, Discipline of Pharmacology & Therapeutics, School of Medicine, Galway, Ireland; [2]Galway Neuroscience Centre and Centre for Pain Research, NCBES, Discipline of Pharmacology & Therapeutics, Galway, Ireland; [3]Science Foundation Ireland (SFI) Centre for Research in Medical Devices (CURAM), Biomedical Science Building, Galway, Ireland; [4]University of Galway, Centre for Microscopy and Imaging, Galway, Ireland; [5]Department of Medicine IV,, University Hospital, Munich, Germany

Adrenocortical carcinoma (ACC) is a rare malignancy associated with a poor prognosis (1). Current treatments are limited with surgical resection the only option for a complete cure (2). The development of translational therapies is limited by pre-clinical disease models. Three-dimensional (3D) cell culture models can accurately reflect the tumour micro-environment but are lacking in ACC (3). In the current study, we developed and characterised novel 3D models of MUC-1, HAC15 and H295R within a type-1 Collagen matrix. Viability of each model was assessed by Sytox Blue staining. Live/dead imaging using confocal microscopy was carried out to determine the distribution of live and dead cells within the 3D models. Metabolic activity was assessed via AlamarBlue staining with Ki67 detecting proliferation. Steroidogenic capacity was determined using Liquid chromatography tandem mass spectrometry and real time- polymerase chain reaction (RT-qPCR). The morphology of the cells was imaged using confocal microscopy. All cells were successfully cultured in a type 1 collagen matrix. H295R and MUC-1 models show optimum viability up until day 7 but a decrease compared to when the corresponding cell line was cultured in monolayer. HAC15 model maintains a constant level of viability over 21 days in culture. All three models increase their metabolic and proliferative activity over time. All were steroidogenic, with HAC15 and H295R cells showing an increased expression of aldosterone when stimulated with angiotensin II when cultured in 3D compared to monolayer. Decreased levels of cortisol production were reported in all 3D models compared to when cultured in monolayer. In the current study, we successfully developed 3D cell culture models for ACC. Each cell line in a 3D model showed behaviour reflective of the 3D tumour micro-environment. Each cell line in a 3D model showed: (i) lower overall viability compared to monolayer- reflective of cell turnover and necrosis in the 3D tumour microenvironment, and (ii) an increase in metabolic

activity and proliferation reflective of cell turnover in the 3D microenvironment. Similar findings have been shown in the literature for other 3D cancer cell culture models. All were steroidogenic in nature. This model will be used in the future studies to test novel and traditional therapeutics to test the translational relevance of this model to ACC, as a reliable, animal sparing model.

Comparison of Plasma Levels of Metanephrines Obtained by Direct Venipuncture vs Indwelling Intravenous Cannula in Hypertensive Patients

Wannida Pisutsawat[1], Thiti Snabboon[1,2], Prangareeya Santisitthanon[3], Natnicha Houngngam[2] & Parichat Yimnoi[3]
[1]Faculty of Medicine, Chulalongkorn University, Division of Endocrinology and Metabolism, Department of Medicine, Bangkok, Thailand; [2]King Chulalongkorn Memorial Hospital The Thai Red Cross Society, Excellence Center in Diabetes, Hormones and Metabolism, Bangkok, Thailand; [3]King Chulalongkorn Memorial Hospital The Thai Red Cross Society, Division of Endocrinology and Metabolism, Department of Medicine, Bangkok, Thailand

Background
The diagnosis of pheochromocytoma and paraganglioma (PPGL) requires the measurement of plasma metanephrines; however, several pre-analytical parameters can lead to false positive test results. During venipuncture, pain perception may activate the sympathetic nervous system, increasing catecholamine metabolite levels. Furthermore, hypertension patients exhibit sympathetic hyperactivity compared to normotensive subjects. The purpose of this study was to compare the plasma levels of metanephrines obtained by direct venipuncture to those obtained by an indwelling intravenous cannula in hypertensive patients, as well as the effect of pain intensity on plasma levels of metanephrines.
Methods
Sixty-eight hypertensive patients, 17 men and 51 women, with a mean age of 55 years (range 31-77 years) were enrolled in the study. After at least 30 minutes of supine rest, we collected blood samples through an indwelling intravenous cannula and then promptly via direct venipuncture on the contralateral arm. A visual analogue scale was used to gauge the level of pain experienced during blood collection. Plasma concentrations of free metanephrines, which included plasma free metanephrine, normetanephrine, and 3-methoxytyramine, were determined by the liquid chromatography-tandem mass spectrometry method.
Results
Plasma normetanephrine levels obtained by direct venipuncture were significantly higher than those obtained by an indwelling intravenous cannula (mean difference 4.14 pg/mL; 95% CI 0.22 to 8.06; p-value 0.039 and mean percentage difference 8.06%; 95% CI 2.44 to 13.69%; p-value 0.006). However, the sample results were within the reference range. On the contrary, plasma levels of 3-methoxytyramine and metanephrine did not differ substantially between the two sampling techniques (mean difference 1.26 ng/L, 95%CI -0.44 to 2.95 and -0.98 pg/mL; 95%CI -2.52 to 0.56, respectively). Furthermore, there was no correlation between pain score and variation in plasma metanephrine levels.
Conclusions
This study proposes an optimal sample collection route using an indwelling intravenous cannula for the diagnosis of PPGL among hypertensive patients. Despite the minimal differences, clinicians should be aware that this pre-analytical component could cause incorrect diagnoses and unnecessary investigations.

Purpose
To evaluate the prevalence of autonomous cortisol secretion (ACS) in patients with primary aldosteronism (PA) and its implications on cardiometabolic and surgical outcomes.
Methods
A retrospective multicenter study of PA patients who underwent 1mg-dexamethasone suppression test (DST) in follow-up in 21 Spanish tertiary hospitals. ACS was defined as a cortisol post-DST >1.8μg/dL (confirmed ACS if >5μg/dL and possible ACS if between 1.8-5μg/dL) in absence of specific clinical features of hypercortisolism. A control group with ACS without PA (ACS group) matched by age and DST levels was included for comparing the cardiometabolic profile with the ACS-PA group.
Results
The prevalence of ACS-PA in the global cohort of patients with PA ($n=176$) was 29.0% ($n=51$). Ten patients had confirmed ACS and 41 possible ACS. The cardiometabolic profile of patients with ACS-PA and PA was similar, except for an older age (59.3 ± 11.22 vs. 55.5 ± 11.87 years, $P=0.049$) and a larger tumor size of the adrenal lesion (24.4 ± 14.01 vs. 17.3 ± 6.84mm, $P<0.001$) in the ACS-PA group. Additionally, as it would be expected, cortisol post-DST were higher (4.1 ± 4.20 vs. 1.1 ± 0.40μg/dL, $P<0.001$) and ACTH levels lower (15.0 ± 10.97 vs. 20.2 ± 10.55 pg/mL, $P=0.030$) in ACS-PA patients than in the PA group. When comparing the ACS-PA group ($n=51$) and the ACS group ($n=78$), the prevalence of hypertension (OR 7.7 [2.64-22.32]) and of cardiovascular events (OR 5.0 [2.29-11.07]) was higher in ACS-PA patients than in ACS patients. However, patients with isolated ACS presented greater levels of HbA1c than ACS-PA patients (5.8 ± 0.82 vs. 6.5 ± 1.47%, $P=0.024$). Of the 176 patients of the PA cohort, 59 underwent adrenalectomy: 20 of the ACS-PA group and 39 of the PA group. Biochemical cure was reached in 94.9%, hypertension cure in 37.3% and hypertension improvement in 54.3%. The coexistence of ACS in patients with PA (ACS-PA) did not affect the surgical outcomes, being the proportion of biochemical and clinical cure similar between ACS-PA and PA groups (100% vs. 92.3%, $P=0.203$ and 45.0% vs. 33.3%, $P=0.380$, respectively). When compared patients with ACS-PA who underwent adrenalectomy ($n=20$) and those medically treated ($n=31$), no differences in the evolution of the cardiometabolic profile was detected between both groups, but surgery led to a greater increase in serum potassium levels.
Conclusion
Co-secretion of cortisol and aldosterone affects a third part of patients with PA. Its presence is more common in patients with larger tumors and an older age. However, the cardiometabolic and surgical outcomes of patients with ACS-PA and PA are similar.

Predictive performance of aldosterone-to-renin ratio in the diagnosis of primary aldosteronism in patients with resistant hypertension

Fabio Bioletto[1], Chiara Lopez[1], Martina Bollati[1], Stefano Arata[1], Matteo Procopio[1], Federico Ponzetto[2], Guglielmo Beccuti[1],

Giulio Mengozzi[2], Ezio Ghigo[1], Mauro Maccario[1] & Mirko Parasiliti Caprino[1]
[1]University of Turin, Department of Medical Sciences, Turin, Italy; [2]University of Turin, Clinical Biochemistry Laboratory, Turin, Italy

Background
The systematic use of confirmatory tests in the diagnosis of primary aldosteronism (PA) increases costs, risks and complexity to the diagnostic work-up. In light of this, some authors proposed aldosterone-to-renin (ARR) cut-offs and/or integrated flow-charts to avoid this step. Patients with resistant hypertension (RH), however, are characterized by a dysregulated renin-angiotensin-aldosterone system, even in the absence of PA. Thus, it is unclear whether those strategies might be applied with the same diagnostic reliability in the setting of RH. Aim of this study was to evaluate the predictive performance of the ARR in the diagnosis of PA in a prospective cohort of patients with true RH. More specifically, we set out to determine whether specific ARR cut-offs could allow the unambiguous identification of patients with PA, without the need of a confirmatory test.
Methods
We prospectively enrolled 129 consecutive patients diagnosed with true resistant hypertension and no other causes of secondary hypertension. All patients underwent full biochemical assessment for PA, including both basal measurements and saline infusion test (SIT). PA was diagnosed when the following conditions were met at the same time: baseline plasma aldosterone concentration (PAC) $\geq$ 15 ng/dL, ARR $\geq$ 40 (ng/dL)/(ng/mL/h), and PAC after SIT $\geq$ 10 ng/dL.
Results
34/129 patients (26.4%) were diagnosed with PA. Among basal measurements, the parameter that provided the best diagnostic performance was ARR, which displayed a moderate accuracy in distinguishing patients with PA from those with essential RH (AUC = 0.883). At multivariable logistic regression, serum potassium levels were identified as the second-best predictor of PA. After stratifying the patients according to the presence/absence of hypokalemia, an ARR > 238.4 (ng/dL)/(ng/mL/h) provided a 100% specificity for the diagnosis of PA in normokalemic patients, with a sensitivity of 25% (AUC = 0.852). An ARR > 115.6 (ng/dL)/(ng/mL/h) provided a 100% specificity for the diagnosis of PA in hypokalemic patients, with a sensitivity of 64% (AUC = 0.941).
Conclusions
Among normokalemic patients, there is a wide overlap in ARR values between those with PA and those with essential RH; the possibility to skip a confirmatory test should thus be considered with caution in this setting. A better discriminating ability can be seen in the presence of hypokalemia; in this case, ARR alone may be sufficient to skip confirmatory tests in a suitable percentage of patients.

Regulation of stem/progenitor cells of the HPA axis during stress adaptation

Panagiota Siatra[1,2], Diana Cozma[1,2], Ilona Berger[1,2], Ioannis Oikonomakos[1], Marily Theodoropoulou[3], Stefan Bornstein[1,2,4], Cynthia Andoniadou[2,4] & Charlotte Steenblock[1,2]
[1]University Hospital Carl Gustav Carus, Department of Internal Medicine III, Dresden, Germany; [2]Technical University of Dresden, Medical School, Dresden,; [3]Ludwig-Maximilians-University of Munich, Department of Internal Medicine IV, Münich, Germany; [4]King's College London, Guy's Hospital, London, United Kingdom

Chronic stress is a pervasive concern in the modern society. A long-term hyper activation of the hypothalamic-pituitary-adrenal (HPA) axis leads to elevated amounts of stress hormones [e.g. ACTH and glucocorticoids (GCs)]. This can incur maladaptation that eventually contributes to mental illness, cardiovascular dysfunctions, diabetes, cancer and autoimmune diseases. Emerging key players for stress adaptation of the HPA axis are stem/progenitor cell populations. In this study, we aim to unravel the mechanisms involved in the regulation of stem/progenitor cells of the HPA axis during stress adaptation. To that aim, we incorporated an *in vitro* system of non-adherent spheroids from primary adrenocortical mouse cells that were stimulated with ACTH. The treatment resulted in the increased growth of the spheroids compared to unstimulated controls indicating a potential role of the hormone in cell proliferation and stem cell behaviour. This result is in line with the enlarged adrenals observed in patients with Cushing's syndrome. To assess the contribution of stem cells during stress adaptation in the adrenal cortex *in vivo*, we performed immobilization stress and lineage tracing studies using the tamoxifen inducible *Gli1:CreERT2/R26R:eYFP* mouse line. By combining these results along with single-cell RNA-seq technology, we aim to shed light into molecular factors involved in the adult adrenal cortex regeneration and remodelling. To follow the effect of GC excesses on the negative feedback loop observed during a normal stress response on the pituitary gland, we stimulated adherent primary anterior pituitary colonies with dexamethasone and corticosterone. GC treatment led to downregulation of *Pomc* expression, a precursor polypeptide for ACTH and other hormones, in the treated colonies compared to the control. This downregulation caused by GCs could be mediated through different gene targets of the glucocorticoid receptor as well as via paracrine signalling from pituitary stem cells. Altogether, our results will provide us with more profound knowledge of mechanisms underlying interactions between stressors and stem/progenitor cells of the HPA axis along with novel therapeutic targets for stress-associated disorders.

Perception of female patients with congenital adrenal hyperplasia and their parents on genital surgery: a retrospective survey

Lea Tschaidse, Andrea Sappl, Matthias Auer, Christian Lottspeich, Hanna F. Nowotny & Nicole Reisch
Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, Munich, Germany

Background
Congenital adrenal hyperplasia due to 21-hydroxylase deficiency (CAH) is associated with ACTH-driven adrenal androgen excess. In women with classic CAH, this regularly causes prenatal virilisation of the external genitalia, commonly corrected by genital surgery during the first years of life. This practice, however, has been questioned and is discussed highly controversial. The aim of this study was to retrospectively assess the perspective of affected patients and their parents on genital surgery in CAH.
Methods
Adult female patients with classic CAH and their parents were enrolled in this single-center, cross-sectional, survey study. The patient's questionnaire included the female Sexual Function Index (fSFI; score 0-36) and female Sexual Quality of Life (SQOL-F; score 8-108) questionnaire, whilst the parent's questionnaire contained the Decision Regret Scale (DRS; score 0-100), with higher scores indicating better sexual function, better sexual quality of life or higher levels of regret.
Results
A total of 46 females with a mean age of 34.9 years (18-66) and 22 parents with a mean age of 60.5 years (47-80) were included in this study. All patients had classic CAH, 29 (63.0%) salt-wasting (SW), 17 (37.0%) simple-virilizing (SV) CAH. About half of the patients (45.7%) had undergone one genital surgery in their life, 52.2 % more than one. Most surgeries (60.9%) were performed up to the age of 5 years, 9.4% at 6-11 years, 21.9% at 12-17 years and 7.9% at 18 years and older. According to the patients, in 67.2% of cases, the decision to undergo surgery had been made by parents, in 3.8% of cases by the patients and in 19.2% of cases together. The fSFI was completed by 25 patients with a total median (IQR) score of 20.2 (5.7) the SQOL-F with a median (IQR) score of 93.0 (31.0) by 31 patients. There were no significant statistical differences between SW and SV patients in fSFI (18.4 (6.8) vs. 20.3 (4.5); $P = .177$) or SQOL-F (93.0 (52.6) vs. 94.0 (29.4); $P = .435$). Concerning the parents, 72.2 % showed no to mild regret concerning the decision of surgery (DRS 0-25) and 27.8% showed moderate to strong regret (DRS >26).
Conclusion
Female patients with classic CAH often undergo genital surgery at a young age, with their parents mostly responsible for treatment decisions. As adults, they present with sexual dysfunction whilst showing good sexual quality of life. Most parents have few or no regrets about the decision to have genital surgery performed on their children.

Symptoms and Steroid Dose Adjustments Associated with the SARS-CoV-2 Vaccine in Patients with Adrenal Insufficiency

David McLaren[1], Grace Crowe[1], Christine Cassidy[2], Irum Rasool[1], mohamed elsabbagh[1], Ahmad Eyadeh[1], Nang Poe Poe Han Htwe[1], Melinda Gerrard[1], Emma Ward[1], Saifuddin Kassim[1], Afroze Abbas[1], Ahmed Al-Qaissi[1], Steve M Orme[1], Khyatisha Seejore[1], Nikolaos Kyriakakis[1], Deirdre Maguire[2], Julie Lynch[1] & Robert D Murray[1]
[1]Leeds Centre for Diabetes and Endocrinology, Department of Endocrinology, St James's University Hospital, Diabetes and Endocrinology, Leeds,

United Kingdom; [2]Harrogate District Hospital, Diabetes and Endocrinology, Harrogate, United Kingdom

Background
Following vaccination for SARS-CoV-2 a significant proportion of individuals experience moderate to severe symptoms. In patients with adrenal insufficiency (AI) this has been reported to translate in to need for increased glucocorticoids and incipient or frank adrenal crises. We assessed occurrence of symptoms, need for glucocorticoid dose adjustment and crises in a large cohort of patients with AI following vaccination for SARS-CoV-2.
Methods
Consecutive patients with AI completed a questionnaire relating to symptoms and steroid dose adjustments following both their 1st and 2nd SARS-CoV-2 vaccination. 14 common symptoms associated with the SARS-CoV-2 infection/vaccination were scored 0-10, with 10 being the most severe, providing a total symptom score of 0-140.
Results
290 consecutive patients completed the questionnaire (154 F; mean 57.9 [range 17 to 90] years; 38 PAI, 252 SAI). 145 (50%) documented a previous adrenal crisis within the previous five years. Fully completed questionnaires and data on 1st and 2nd vaccine received were available in 279. For the initial vaccine, 176, 100, & 3 received the Astra-Zeneca (AZ), Pfizer-BioNTech (PB) and Moderna (MD) vaccines respectively. For the second vaccine, 170, 99 &10 received the AZ, PB and MD vaccines respectively. The AZ vaccine had greater symptom burden compared with PB (17.7 +/-23.9 Vs. 11.3 +/-20.0; $P=0.001$). Younger age, female gender and previous adrenal crises correlated with higher symptom score after both 1st and 2nd vaccines ($P<0.05$). Total symptom burden was lower after the 2nd compared with the 1st for all vaccine subtypes. Symptom burden was not different in patients with PAI and SAI. Symptoms commenced a mean of 11.4 and 15.7 hours post-vaccine, lasting a mean of 58.9 and 49.2 hours for the 1st and 2nd vaccine dosage regardless of whether or not the steroid dose was increased. 34.8% and 31.4% increased their steroid dosage for a mean of 3.0 and 2.6 days following the first and second vaccines respectively. No difference in the proportion requiring dose increase was observed between PAI and SAI, or between genders. Patients with previous adrenal crises in the last five years were more likely to increase their steroid dosage. 3.1% (7AZ, 2PB) and 1.1% (2PB, 1MD) required an emergency hydrocortisone injection.
Conclusions
Around a third of patients with AI increased their steroid dosage to manage symptoms associated with the SARS-CoV-2 vaccination, however this was not different between vaccine subtypes despite differences in symptom burden. Few patients required an emergency hydrocortisone injection.

Atorvastatin use is associated with decreased testosterone levels in type 2 diabetes men

Ameni Terzi[1], Elyes Kamoun[1], Ibtissem Oueslati[1], Hammami Bassem[2], Nadia Khessairi[1], Meriem Yazidi[1], Fatma Chaker[1], Feki Moncef[2] & Melika Chihaoui[1]
[1]Rabta, Endocrinologie, Tunisia; [2]Rabta, Biochemistry, Tunisia

Introduction
Statins are used in the management of hypercholesterolemia and the prevention of cardiovascular diseases. However, by reducing cholesterol biosynthesis, steroidogenesis and particularly testosterone synthesis may be affected. The aim of our study was to assess the effect of high doses of statin therapy on testosterone levels in type 2 diabetes male patients.
Methods
This was a single-center, prospective study, during the period march 2021 - July 2022, including 60 men with type 2 diabetes mellitus, aged between 40 and 65 years, statin-free, and in whom the indication of a treatment with high dose of statin was indicated. The patients had two visits, before and six months after the daily intake of 40mg of atorvastatin. During each visit, they underwent a clinical examination including the Androgen Deficiency in the Aging Male (ADAM) questionnaire and a fasting blood sample was collected for biological and hormonal measurements including total testosterone, sex hormone binding globulin, and gonadotrophins.
Results
The median age was 58 years (IQR:52-62). The median duration of diabetes was 81 months (IQR: 26-132). The prevalence of a positive ADAM questionnaire increased from 73% to 85% after statin use ($P<10^{-3}$). Its median score raised from 4 (IQR: 2-6.75) to 6 (IQR: 3-8), $P<10^{-3}$. We noted a significant increase in the prevalence of a decreased libido from 22% to 47% and erectile dysfunction from 70% to 75% and a significant decrease in nocturnal erections and the frequency of sexual intercourses. Twenty-two patients developed gynecomastia. The median of total and calculated bioavailable and free testosterone significantly decreased from 15.1, 6.3, and 0.3 to 12.7, 5.7, and 0.2 respectively, with no change in FSH and LH levels. Three patients (5%) developed hypogonadism.
Conclusion
Long-term high dose statin therapy induced clinical symptoms of hypogonadism and a reduction in testosterone levels.

Differences in the extracellular matrix protein signature of the outermost zone of the rat adrenal gland

Jean Lucas Kremer[1,2], Verônica Feijoli Santiago[1], Fernanda Bongiovani Rodrigues[1], Giuseppe Palmisano[1] & Claudimara Ferini Pacicco Lotfi[1]
[1]University of São Paulo, Institute of Biomedical Science, São Paulo, Brazil; [2]University of São Paulo, Anatomy, Sao Paulo, Brazil

Changes in the composition of the extracellular matrix (ECM) induce different cell signaling in normal tissues and in pathological conditions. ECM alteration in the adrenal microenvironment may contribute to both the development and function of adrenal gland. The adrenal gland consists of a cortex, with three concentric zones, glomerulosa (ZG), fasciculata (ZF) and reticularis (ZR), and the medulla (M), surrounded by a capsule. Here, we describe the differences among the ECM signatures of fractions obtained from rat adrenal glands, the outer fraction (OF), the inner fraction (IF) and the medulla (M). Sprague-Dawley rats (250 $\pm$30g, $n=6$) were euthanized by decapitation and adrenal glands were removed and decapsulated to separate the capsule/zona glomerulosa (OF) from the zona fasciculata/reticularis (IF) followed by removal of medulla (M). The samples were frozen in liquid nitrogen and stored at -80°C. ECM enrichment through decellularization was achieved through incubation in 1% Triton-X for 2h30 min at room temperature following incubation in 4.0% deoxycholate until complete decellularization. The absence of remaining intact cells was certified by DNA quantification and microscopy analysis of decellularized tissues stained with DAPI. Pellets containing ECM proteins were treated as described in Trombetta-Lima et al. (J. Proteome Res. 2021, 20, 4693-4707). We compared the proteomic profiles of OF, IF and M fractions samples ($n=6$). Raw files of LC-MS/MS were processed into MaxQuant software version 2.1.4 using Andromeda search engine against SwissProt *Ratus norvegicus* and *Mus musculus* combined databases (54,778 and 17,121 entries, respectively, downloaded from Uniprot.org November 2022). The total identified and regulated proteins were compared with MatrisomeDB 2.0. Our analysis revealed that 69, 144 and 121 total proteins were detected in OF, IF and M decellularized fractions, respectively. Ninety-two proteins were identified as common to the OF, IF and M fractions, 23 of which are ECM proteins. Among the total proteins from adrenal fractions analyzed, 89 were regulated proteins, 22 of which are ECM proteins. Four proteins were differentially expressed in the OF, 22 in the IF and 8 in the M. Only the OF showed 3 differentially expressed ECM proteins, which are Fibrillin 2 (Fbn2), Collagen XIV alfa1 (Col14a1) and Collagen IV alfa3 (Col4a3) which will be validated by immunoblotting and immunohistochemistry. Therefore, we report differences in ECM composition of the outermost zone of rat adrenal that may influence adrenal pathophysiology.

ARMC5 regulates SIRT1 expression in adrenocortical cells

Annabel Berthon[1,2], Faucz Fabio[2], Feldman Benjamin[2], Drougat Ludivine[2], Espiard Stephanie[3], Jerome Bertherat[4] & Constantine Stratakis[2,5]
[1]Institut Cochin, Paris, France; [2]National Institutes of Health, Bethesda, United States; [3]Institut National de la Santé et de la Recherche Médicale (INSERM), U1190, European Genomic Institute for Diabetes (EGID), Lille, France; [4]Institut Cochin, Centre de Référence Maladies Rares de la Surrénale, Service d'Endocrinologie, ENDO-ERN HCP, Hôpital Cochin, AP-HP, Paris, France; [5]Research Institute, ELPEN, Pikermi, Athens GR19009 & Human Genetics & Precision Medicine, IMBB, FORTH, Heraklion, Greece

Pathogenic *ARMC5* variants are the main genetic cause of Primary Bilateral Macronodular Adrenal Hyperplasia (PBMAH) explaining roughly 20% of index cases. These variants found both at germline and somatic level are mostly

frameshift and nonsense leading to a loss of its function. *ARMC5* acts then, as a tumor suppressor gene but little was initially known on its function. Using an RNAseq analysis on transient zebrafish models of *Armc5* up- and down-regulation, we identified transcriptional alterations of several members of SIRT1 signaling in our models suggesting that ARMC5 may regulate the desacetylase SIRT1 and its signaling in adrenocortical cells. Consistently, there is a significant increase of SIRT1 protein in PBMAH tissues mutated for *ARMC5* compared to PBMAH without known genetic alterations. Interestingly, we show that ARMC5 interacts with SIRT1 in the H295R human adrenocortical cells and that *ARMC5* knockdown leads to a decrease of SIRT1 ubiquitination. These results are consistent with 2022 reports demonstrating that ARMC5 acts as a protein adaptor for Cullin 3 complex, recruiting protein substrate to be ubiquitinated by this complex in order to lead to their proteosomal degradation. We speculate that SIRT1 could be a new protein substrate for the Cullin3-ARMC5 complex. While we analyze the global protein acethylation profile in PBMAH tissues, we observe an elevation of acetylated protein in absence of *ARMC5* suggesting either a global reduction of protein desacethylation or increase of acethylation. To access more specifically the potential consequence of *ARMC5* loss on SIRT1 activity, we measure SIRT activity and demonstrate a decrease of its activity in PBMAH mutated for *ARMC5* as well as in adrenal cells of 18-month-old *Armc5*$^{+/-}$ mice presenting an elevation of plasma corticosterone level. The decrease of SIRT1 activity leading to an abnormal protein acetylation could then, play a role in the development of PBMAH and in the cortisol hypersecretion. Altogether, these data support that ARMC5 could regulate SIRT1 protein accumulation (possibly through the Cullin3 complex) but could also regulate its activity by a mechanism that remains to be determined.

Significance of exogenous estradiol on plasma cortisol during ACTH stimulation in women with pituitary insufficiency

Laura Aagaard, Jesper Krogh, Marianne Klose & Mikkel Andreassen
Rigshospitalet, København, Denmark

Objective
Exogenous estradiol increases cortisol binding globulin (CBG) and total cortisol (TC), and therefore it is debated if estradiol supplementation should be paused before evaluation of the adrenal axis. The aim was to evaluate how oral and transdermal estradiol influence TC in hypogonadal women with, or at risk of developing, adrenal insufficiency (AI)
Methods
This was a crossover study in 17 women with secondary hypogonadism who were tested without estradiol (baseline) and after 12 weeks on oral estradiol (2 mg) and transdermal estradiol (100 µg/day). At the end of the interventions, the following samples were measured: salivary cortisol, p-cortisol, s-CBG, and other pituitary hormones and binding proteins. Afterwards, a short 30 minute ACTH stimulation test was performed with a TC cut-off threshold for AI of 420 nmol/l.
Results
Estradiol levels were significantly higher on oral (0.45 (0.28-0.65) and transdermal estadiol (0.27 (0.09-0.44) compared to baseline (0.09 (0.09-0.09) nmol/l), $P<0.005$. Plasma SHBG was higher on oral vs. transdermal estradiol (92 ± 36 vs 48 ± 17 nmol/l, $P<0.001$). TC before ACTH stimulation was 124 (27-311) at baseline, 105 (15-262) on transdermal and 201 (26-315) nmol/l on oral estradiol, $P=0.015$. TC after ACTH stimulation parallels that of baseline cortisol, but without any significant changes; baseline 309 (54-492), transdermal estradiol 304 (48-492) and oral estradiol 440 (74-600) nmol/l. Three participants crossed the TC cut-off threshold for AI between interventions: Patient 1: 401 at baseline vs. 442 on transdermal vs. 487 nmol/l on oral estradiol. Patient 2: 423 at baseline vs. 390 on transdermal vs. 490 nmol/l on oral estradiol. Patient 3: 395 on transdermal vs. 559 nmol/l on oral estadiol (the patient did not complete the no intervention period). Data on CBG and salivary cortisol are under preparation.
Conclusion
In opposite to oral estradiol transdermal estradiol did not influence the adrenal axis. In patients with overt AI TC was not influenced by oral estradiol. Thus, a diagnosis of severe AI can probably not be missed if ACTH test is performed in patients on oral estradiol. Three of 17 patients with borderline AI changed status from insufficient to sufficient when put on oral estradiol. Adrenal testes independent of CBG levels are warranted to secure reliable results during conditions with altered plasma CBG and to avoid inconvenient pause of gonadal substitution. Measurement of salivary cortisol or CBG might be away to move forward, and these data will soon be available in the present study.

Modulation of calcium signaling 'on demand' in adrenocortical cells to decipher the molecular mechanisms responsible for primary aldosteronism

Fedlaoui Bakhta[1], Cosentino Teresa[1], Al Sayed Zeina[1], Giscos-Douriez Isabelle[1], Hulot Jean-Sebastien[1,2], Fabio Fernandes-Rosa[1], Travers Simon[1,3], Baron Stephanie[3], Zennaro Maria-Christina[1,4] & Sheerazed Boulkroun[1]
[1]Paris Cardiovascular Research Center (PARCC), INSERM, University Paris Cité, Paris, France; [2]CIC1418 and DMU CARTE, Assistance Publique Hôpitaux de Paris (AP-HP), Hôpital Européen Georges Pompidou, Paris, France; [3]Assistance Publique Hôpitaux de Paris (AP-HP), Hôpital Européen Georges Pompidou, Service de Physiologie, Paris, France; [4]Assistance Publique Hôpitaux de Paris (AP-HP), Hôpital Européen Georges Pompidou, Service de Génétique, Paris, France

Introduction
Primary aldosteronism (PA) is the most frequent form of secondary hypertension. Over the past 10 years, important discoveries have been made regarding the genetic basis of aldosterone producing adenoma and familial forms of primary aldosteronism. In most cases, genetic abnormalities are found in genes coding for ion channels (*KCNJ5, CACNA1D, CACNA1H, CLCN2*) and pumps (*ATP1A1, ATP2B3*). These mutations affect intracellular ion homeostasis and/or cell membrane potential, leading to increased intracellular calcium concentrations and activation of calcium signalling, which is the main regulator of aldosterone biosynthesis.
Objective
The objective of our work was to elucidate, using chemogenetic tools, the molecular mechanisms underlying the development of PA by modulating sodium entry into the cells, thus mimicking some of the known mutations identified in PA.
Methods
We have developed an adrenocortical H295R-S2 cell line stably expressing a chimeric ion channel receptor formed by the extracellular ligand-binding domain of the α7 nicotinic acetylcholine receptor fused to the ion pore domain of the serotonin receptor 5HT3α named α7-5HT3. Its activation by a selective agonist named PSEM-817 leads to sodium entry into the cells. This cell line was characterized in terms of intracellular calcium concentrations, cell proliferation, steroid production, electrophysiological properties and gene expression.
Results
Treatment of α7-5HT3 expressing cells with increasing concentrations of PSEM-817 (from 10^{-9} to 10^{-5} M) induced significant cell membrane depolarization, leading to the opening of voltage gated calcium channel and increased intracellular calcium concentrations. Activation of calcium signaling resulted in increased *CYP11B2* (coding for aldosterone synthase) mRNA expression and aldosterone biosynthesis but did not affect cell proliferation measured at different time points (8h, 24h, 48h, 72h). Interestingly, calcium kinetics analyses revealed significant differences in response to treatment with PSEM-817, which leads to sodium entry into cells, or with potassium. Gene expression analyses, by RNA sequencing, revealed the activation of different specific signaling pathways in response to treatment with Angiotensin II, potassium and PSEM-817.
Conclusions
Our results suggest that modulation of intracellular sodium concentrations may activate specific signaling pathways, different from those induced by angiotensin II and potassium. This cell line, in which we can modulate the intracellular calcium concentration 'on demand' through modulation of sodium entry into the cells, is a useful tool for a better understanding of the alterations of intracellular ion balance and calcium signaling in the pathophysiology of PA.

Relative adrenal insufficiency in liver cirrhosis: a common but often forgotten critical condition

Tijana Petkovic[1], Ljiljana Marina[1,2], Dunja-Simona Petkovic[1], Jelena Martinov Nestorov[2,3], Djordje Culafic[2,3], Jelena Jovanovic[3], Miomira Ivovic[1,2], Antoan Stefan Sojat[1], Natalija Antic[1], Kristina Saravinovska[1], Zorana Arizanovic[1] & Svetlana Vujovic[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Centre of Serbia, National Centre for Infertility and Endocrinology of Gender, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [3]Clinic for Gastroenterology and Hepatology, University Clinical Centre of Serbia, Hepatology Department, Belgrade, Serbia

Introduction
Relative adrenal insufficiency (RAI) is common in critically ill patients and is characterized by the normal adrenal reserve for homeostatic demands and inadequate cortisol response in acute stress situations. RAI can also occur in

patients with liver cirrhosis, both compensated and decompensated. However, it is often forgotten and difficult to diagnose due to the overlap between clinical symptoms of adrenal insufficiency and decompensated liver disease. Also, hypothalamic pituitary adrenal axis analysis in patients with cirrhosis is not performed routinely so many of these cases remain undiagnosed or misdiagnosed.
Case report
A male patient, 54 years of age, was admitted to Hepatology Department, Clinic for Gastroenterology and Hepatology due to a alcoholic liver cirrhosis (Child B) with esophageal varices grade 2/3 and refractory ascites. He was initially diagnosed in 2017 and had daily ascites drainage through permanent peritoneal catheter placed in his regional medical centre in 2021. At admission, he complained of abdominal pain, fatigue, nausea and diarrhea. Biochemical and hormonal evaluation showed hyponatremia 124 mmol/l, hyperkalemia 5.9 mmol/l, normal renal function, very low cholesterol 2.08 mmol/l, high TSH 13 mIU/L, with low fT4 8.1 pmol/l, low ACTH 0.6 pmol/l with low-normal cortisol 233 nmol/l, which is why he was sent for an endocrinological evaluation. In the physical examination, the patient was awake, communicative, afebrile, and hypotensive with no signs of haemorrhagic syndrome and besides hypotension of 80/50 mmHg, no other typical clinical sign of hypocortisolism. Based on electrolyte status, low ACTH, low normal cortisol and hypotension the Synacthen test was performed which showed an inadequate cortisol response: 237 nmol/l (0 min), 323 nmol/l (30 min) and 385 nmol/l (60 min). Hydrocortisone treatment was initiated and after two days all reported complaints resolved along with electrolyte and blood pressure normalization. Also, levothyroxine supplementation was initiated.
Conclusion
Diagnosis and treatment of RAI in cirrhotic patients remains controversial. Empiric glucocorticoid treatment is not recommended in asymptomatic patients. However, patients who are symptomatic benefit from glucocorticoid replacement as it was the case in our patient. These patients should have a close and careful follow up for sings of cortisol overtreatment and/or infection.

Metastatic composite pheochromocytoma manifesting as severe bone pain

Mair Minasyan, Ewelina Rzepka, Aleksandra Gilis-Januszewska & Alicja Hubalewska-Dydejczyk
Jagiellonian University Medical College, Chair and Department of Endocrinology, Cracow, Poland

Composite pheochromocytomas (CP) are rare and constitute 3% of pheochromocytomas. So far, less than 100 cases were described in the literature. We present a case of 60 years old man. He was admitted to ER department due to severe bone pain around chest, ribs and vertebra. CT scan showed expansive, 100x87 mm, non-homogenic left adrenal gland tumour as well as metastatic bone lesions. The 24-hour urinary fractionated metanephrines were significantly elevated - 86195 ug/24h (normal range:88,0-440,0), 10214,1ug/24h (normal range:0,0-220,0) and 3302,4 ug/24h (52,0-341,0) for urinary fractionated normetanephrine, 3-methoxytyramine, and metanephrine, respectively. Patient presented no typical symptoms suggestive of pheochromocytoma like hypertension or tachycardia. Tc-99m somatostatin analogues scintigraphy revealed pathological tracer uptake in the left adrenal gland and bones. Patient underwent left adrenalectomy preceding by pharmacological pre-treatment with alpha-receptor blockers. Histopathology showed composite pheochromocytoma with ganglioneuroma component (Ki67 15%, PASS 9). Due to results of MIBG scan, which showed massive bone metastases, patient was qualified for stem cells preservation followed by radioisotope therapy (I-131 MIBG). Initial genetic testing (MAX, RET, SDHB/SDHD, VHL, MEN1) didn't confirm genetic background, further genetic testing results (TMEM, EPAS FH, SDHA, SDHAF2) are expected. In conclusion, metastatic potential of pheochromocytoma in this case should be suspected based on large tumour dimension (> 6 cm), secretion of norepinephrine and dopamine, as well as distinct histological features (Ki67>3%, PASS>6). Due to its rarity, it is not well known if non-pheochromocytoma component in CP poses any prognostic factor, which needs further investigations.

Introduction
Testosterone-based gender-affirming hormone therapy (GAHT) may have negative consequences on cardiovascular risk, with reported increased blood pressure, decreased HDL-cholesterol, and weight gain. Still, data on cardiometabolic changes in transgender men on GAHT remain controversial. Testosterone-based GAHT also modifies body composition and lean muscle mass, but the degree to which affects serum creatinine and other measures of kidney function is still not clear.
Objectives
To characterize the change in cardiometabolic risk factors (blood pressure, weight, lipid profile) and serum creatinine in transgender people initiating masculinizing GAHT.
Methods
Single-centre retrospective study, including a cohort of 60 transgender males, with follow-up between 2015-2022. Data collection was performed before and after one year of initiating GAHT and included levels of total-cholesterol, HDL-cholesterol, LDL-cholesterol, triglycerides, and serum creatinine; blood pressure and weight. Estimated glomerular filtration rate (eGFR) was calculated based on CKD-EPI equation for cisgender. We excluded people: with previous renal failure or dyslipidemia; under therapies with influence on lipid profile/renal function; submitted to ovariectomy.
Results
Transgender males average age was 22.5 $\pm$6.7 years. Prescribed GAHT consisted of testosterone enanthate/cypionate, monthly average dose 290 $\pm$60mg. After 12 months of GAHT, there were no significant changes on weight or blood pressure. Regarding lipid profile, there was a decrease in HDL-cholesterol (-7.6mg/dL, IC 95% [-13.5;-1.7]), increase in triglycerides (+ 12.5mg/dL, IC 95% [0.2;24.9]), and increase in LDL-cholesterol (+ 14.1mg/dL, IC 95% [4.8;23.5]). We also found an increase in serum creatinine (+ 0.110 mg/dL, IC 95% [0.078;0.142]) and a reduction in eGFR (-16.0 ml/min/1.73m^2, IC 95% [-20.0;-12.0]). In a univariate regression model adjusted for testosterone dose and weight, we found significant changes in HDL-cholesterol (-7.8 mg/dL, $P = 0.027$, $r = 0.153$) and serum creatinine (+ 0.101 mg/dL, $P < 0.001$, $r = 0.307$).
Conclusion
We observed an unfavorable trend in lipid profile in transgender males after one year of GAHT. Healthcare professionals should monitor and discuss lifestyle interventions and pharmacological therapy with patients who are at risk of developing cardiovascular disease. Serum creatinine also changed, resulting in a decreased eGFR. However, this presumably may reflect the corresponding increase in muscle mass, rather than a true change in GFR. Our results raise the question of how to estimate GFR based on equations in transgender people, as one of the variables is gender, and serum creatinine is affected by GAHT.

Safe observation of early recurrence of asymptomatic pheochromocytomas in MEN2 patients

Marie Puerto[1], Alexandre Buffet[2], Magalie Haissaguerre[1], Marie-Laure Nunes[1], Duval Mathilde[1], Najah Haythem[3], Laurence Amar[4] & Antoine Tabarin[3]
[1]Hôpital Haut-Lévêque - CHU de Bordeaux, Endocrinology, Pessac, France; [2]Hôpital Européen Georges Pompidou, Genetics, Paris, France; [3]Hôpital Haut-Lévêque - CHU de Bordeaux, Endocrine Surgery, Pessac, France; [4]Hôpital Européen Georges Pompidou, Hypertension Unit, Paris, France

Controlateral recurrence of pheochromocytoma is frequent in MEN2 patients. Cortical sparing adrenalectomy is currently recommended in this situation, but conveys a risk of adrenal insufficiency in up to 45 % of patients. The natural history of recurrent pheochromocytome is poorly known. Thus, appropriate timing of surgery and the possibility to postpone safely surgery remain debatable. We report our experience of long-term follow up of non-operated 16 pheochromocytomas in 13 MEN2 carriers. At diagnosis of MEN2 pheochromocytoma, 11/13 patients were normotensive and 2 were treated with calcic inhibitors. 7/13 had normal metanephrines values, contrasting with abnormal imaging studies. 6/13 had a median metanephrine level of 1.8 x ULN (range : 1.1 – 4.0 x ULN). Median tumor size at diagnosis was 12 mm (range : 8 – 24 mm). During follow-up (median duration of follow-up 5 years ; range : 2 – 26 years), median tumor growth was 0.5 mm/year (range : 0 – 2.1 mm/year). Among the 7 initially 'non-secreting' patients, metanephrine levels increased from 1.2 to 4.6 x ULN in 5 patients and remained normal in 2 patients. Among the initially 'secreting' patients, metanephrines increased from 1.8 to 4.6 x ULN. Tumor growth and metanephrine increments were correlated ($r = 0.8$, $P < 0.01$). No hypertension was reported in initially normotensive patients. No morbid cardiovascular event occurred in any patient. Surgery of 7/16 pheochromocytomas was performed after 2 to 26 years of follow-up. The reasons were : occurrence of mild symptoms (heart palpitations) in 4

patients, absence of previous contralateral surgery in 3 patients. Despite delaying surgery, parameters of per-operative hemodynamic instability were significantly milder than those of a control group of hypertensive sporadic pheochromocytomas ($P<0.05$).

Conclusion

tumoral and secretory progression is slow in MEN2 pheochromocytomas. In early-stage, asymptomatic recurrence, a careful follow-up allows to postpone safely complementary surgery and its attendant risk of adrenal insufficiency.

Pheochromocytomas in patients with Parkinson's disease: a diagnostic and therapeutic challenge

Julia Calvo Latorre[1], Bharat Patel[2], Anum Sheikh[1], Florika Radia[2] & Rahat Ali Tauni[1]

[1]West Hertfordshire Teaching Hospitals NHS Trust, Diabetes & Endocrinology, Watford, United Kingdom; [2]West Hertfordshire Teaching Hospitals NHS Trust, Watford, United Kingdom

Dopamine agonists can falsely elevate plasma and urinary metanephrines, thus making the diagnosis of pheochromocytomas in patients taking these medications challenging. We present the case of an 80-year-old female care home resident with a background of hypertension, Parkinson's disease (PD), dementia and pernicious anaemia. She presented with weight loss, unilateral leg swelling and abdominal distension. A computed tomography (CT) showed a 5.6 cm heterogeneously enhancing left adrenal mass. The patient reported no symptoms consistent with a phaeochromocytoma and the physical examination revealed no stigmata of an endocrinopathy. Biochemistry showed significantly raised plasma metanephrine, normetanephrine and 3-methoxytyramine, favouring the diagnosis of a pheochromocytoma over a false positive result due to carbidopa/levodopa. Urinary metanephrines were also high and an iodine-123 metaiodobenzylguanidine (MIBG) scan revealed increased radiotracer uptake in the left adrenal, confirming the diagnosis. Surgical treatment was discussed with the patient and her daughter and in view of significant frailty, comorbidities, high surgical risk and absence of symptoms, it was pragmatically agreed to manage her conservatively. Medical treatment with alpha blockers followed by beta blockers was not thought to be in her best interest due to risk of postural hypotension and falls in presence of PD and because blood pressure was well controlled on ramipril. An interval CT scan did not show any change in the size or characteristics of the lesion, further supporting conservative management. She is currently being followed up in the endocrine clinic. This case emphasises the need to interpret measurements of catecholamines and their metabolites in the context of confounding medications like carbidopa/levodopa, which can falsely elevate plasma and urine metanephrines, especially 3-methoxythyramine and urinary dopamine. Clinicians need to be mindful of such a pitfall, not rely on biochemical or radiological diagnosis only and consider early functional imaging with MIBG scintigraphy, gallium-68 DOTATATE positron emission tomography (PET) or fludeoxyglucose-PET, amongst others. We suspect that our patient's lesion grew to such a large size due to her lack of hormone-related symptoms as symptomatic phaeochromocytomas are often diagnosed when relatively smaller. Apart from a diagnostic challenge, patients with PD and other comorbidities can also be challenging to manage, as they are often high-risk surgical candidates, and adrenalectomy, which would otherwise be a gold standard curative treatment, is not an option. Shared decision making, multidisciplinary team approach with a view to provide individualised, holistic care and good communication with patients and their families are key elements in management.

Differentiation of Pluripotent Stem Cells into Steroidogenic Cells with the Application of Artificial Intelligence

Ioannis Oikonomakos[1,2,3], Melissa Sanabria[1,4], Yasmine Neirijnck[3], Stefan Bornstein[1,2], Andreas Schedl[3] & Charlotte Steenblock[1,2]

[1]University of Technology, Dresden, Germany, [2]University Hospital Carl Gustav Carus, Dresden, Germany, [3]Université Côte d'Azur – Campus Valrose, IBV, Nice, France, [4]Center for Molecular and Cellular Bioengineering, Biotechnology Center, Dresden, Germany

Adrenal insufficiency is a life-threatening condition in which the adrenal glands fail to produce adequate amounts of steroid hormones thus leading to severe disturbances of body homeostasis. Today's treatment options are limited to hormone replacement therapies that are, however, hampered by serious side effects. Cell replacement therapies with adrenocortical stem cells could present a potential cure, but the culture of such stem cells has proven difficult. We have developed an *in vitro* protocol for the differentiation of mESCs into adrenocortical steroidogenic cells. Our protocol recapitulates key steps in embryonic development by fating the cells towards the adrenal primordium. Molecular analysis demonstrated upregulation of fetal adrenal markers and the expression of genes coding for adrenal cortex specific steroidogenic enzymes (e.g. *Cyp21A1*). Indeed, steroidomics profiling revealed the secretion of adrenal cortex specific steroid hormones into the culture medium. The proportion of steroidogenic cells produced in our differentiation protocol remained, however, relatively low for therapeutic purposes. Machine Learning (ML) has been shown to be a powerful tool for improving the interpretation of biological data (1,2). To improve culture conditions and increase the yield of properly differentiated cells, we aim to apply ML methods to our *in vitro* differentiation protocol. In pilot studies, a VGG-16 convolutional neural network followed by random forest classification was employed to distinguish phase contrast images from different stages of differentiating cells based on their morphology. Indeed, we were able to distinguish cells based on the treatment they had received and to predict their differentiation. We are currently planning to optimize our *in vitro* differentiation protocol by taking into consideration the input from the ML model. In the future, we will incorporate more molecular data to increase our prediction accuracy (3). Once high yields of differentiated adrenocortical cells have been obtained, they will be tested for long term engraftment and hormone production *in vivo* (transplantation experiments). Taken together, we have generated glucocorticoid producing adrenocortical cells from pluripotent stem cells *in vitro*. In the long run, our protocols may pave the way for the development of cell replacement therapies for patients suffering from adrenal insufficiencies.

Is there any link between non-classic adrenal hyperplasia (NCAH) and glucose metabolism?

Bartosz Domagała[1], Aleksandra Gamrat[1], Anna Skalniak[2], Elwira Przybylik-Mazurek[2], Malgorzata Trofimiuk-Muldner[2] & Alicja Hubalewska-Dydejczyk[2]

[1]University Hospital in Krakow, Department of Endocrinology, Endocrine Oncology and Nuclear Medicine, Krakow, Poland, [2]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland

Introduction

There are data reporting an increased risk of cardiovascular and metabolic complications in patients with NCAH. This is frequently attributed to glucocorticoid (over)use. It seems that long-term exposure to increased androgens concentration may also itself lead to diminished insulin sensitivity and increased risk of prediabetes and diabetes.

Aim

The aim of the study was to assess the link between NCAH diagnosis and glucose metabolism disturbances.

Material and methods

The study included 327 subjects (315 females and 12 males, median age 25 years) referred for a cosyntropin stimulation test due to the suspected NCAH. Serum 17-OH-progesterone (17-OHP) was measured with ELISA assay. The diagnosis of NCAH was confirmed if the initial or stimulated 17-OHP concentration exceeded 10.0 ng/ml. None of the tested subjects was treated with glucocorticoids. The Mann-Whitney U and Yates' $\chi 2$ tests were used in statistical analyses, with $P<0.05$ as cut-off value of statistical significance.

Results

62 patients (60 females, 2 males; median age 26 years) were diagnosed with NCAH, the rest of tested subjects were considered the control group. Type 2 diabetes was diagnosed earlier in 10 subjects in the entire study group (6 of them were diagnosed with NCAH). There was no significant difference in the fasting glucose levels ($P=0.08$) and BMI ($P=0.32$) between subjects with and without NCAH diagnosis (median fasting glucose: 4.96 mmol/l and 4.86 mmol/l, respectively; median BMI: 23.82 kg/m^2 and 23.26 kg/m^2, respectively). Diabetes was significantly more frequent in patients with NCAH diagnosis ($P=0.004$; power: 0.74). The median 17-OHP was higher in patients with diabetes compared to those without it at both 30 (12.25 ng/ml vs 3.25 ng/ml; $P=0.003$) and 60 minutes (14.93 ng/ml vs 3.95 ng/ml; $P=0.046$) after stimulation.

Conclusions

NCAH seems to be linked to increased diabetes risk, even before glucocorticoid treatment is initiated. It seems advisable to screen NCAH patients for glucose metabolism disorders.

Does this patient really have a pheochromocytoma? A retrospective analysis of patients undergoing adrenalectomy overdiagnosed with pheochromocytoma

Karolina Zawadzka[1,2], Piotr Małczak[1], Michał Wysocki[3], Piotr Major[1], Michał Pędziwiatr[1] & Magdalena Pisarska-Adamczyk[4]
[1]Jagiellonian University Medical College, 2nd Department of General Surgery, Kraków, Poland; [2]Jagiellonian University Medical College, Doctoral School of Medical and Health Sciences, Kraków, Poland; [3]Ludwik Rydygier Memorial Specialized Hospital, Department of General Surgery and Surgical Oncology, Kraków, Poland; [4]Jagiellonian University Medical College, Department of Medical Education, Kraków, Poland

Background
Pheochromocytoma and paraganglioma (PPGL) are rare endocrine tumours that secrete catecholamines. Methoxycatecholamines in free plasma or fractionated methoxycatecholamines in 24-hour urine collections are the recommended tests for the diagnosis of pheochromocytoma, based on which patients are referred for surgical removal of the adrenal gland. However, false-positive results from these tests remain a problem and some patients are referred for adrenalectomy due to suspected pheochromocytoma, but the verifying histopathological examination does not confirm the diagnosis.
Aim
The aim of the study was to assess the characteristics of patients overdiagnosed as pheochromocytoma and undergoing treatment with adrenalectomy.
Methods
Data from 107 adult patients, who underwent laparoscopic adrenalectomy for suspected pheochromocytoma between January 2012 and December 2022, were retrospectively analysed. The patients were divided into two groups: the first, in which the postoperative histopathological examination confirmed the diagnosis of pheochromocytoma ($n=74$), and the second, in which the suspicion of pheochromocytoma was not confirmed ($n=33$).
Results
Following histopathological examination of the postoperative material, the diagnosis for 30.8% of the tumours clinically suspected as pheochromocytoma was reclassified. The tumours that were most frequently over-diagnosed as pheochromocytomas were adrenocortical adenomas ($n=16$) and adrenocortical hyperplasia ($n=10$). In addition, 3 adrenocortical carcinomas, 1 oncocytic tumour, 1 myelolipoma, 1 metastatic neuroendocrine carcinoma and 1 completely normal adrenal gland were misclassified as pheochromocytoma. Patients with histopathologically confirmed pheochromocytoma were younger (median 56, IQR 23 years vs median 63, IQR 8 years, $P=0.027$) and had a lower BMI (median 26, IQR 6.4 kg/m^2 vs median 29.6, IQR 7.6 kg/m^2, $P<0.001$). In addition, patients with pheochromocytomas had significantly higher concentrations of metanephrine (median 1119.5, IQR 2868 vs median 175.2, IQR 136 µL/24 h, $P<0.0001$) and normetanephrine (median 4399.4, IQR 4703 vs median 659.73, IQR 501.9 µL/24 h, $P<0.0001$) determined in the daily urine collection. There were no statistically significant differences between tumours histopathologically confirmed as pheochromocytoma and false-positive pheochromocytoma with regard to sex, methoxytyramine levels, morning and evening cortisol levels, aldosterone, plasma renin activity, adrenocorticotropic hormone. The size of the adrenal gland on preoperative CT scan and the size of the tumour on histopathology were also not significantly different between groups.
Conclusions
There is still a considerable number of patients undergoing adrenalectomy for suspected pheochromocytoma in whom histopathological verification does not confirm the initial diagnosis. A significant proportion of these are benign tumours that do not need surgical treatment.

Non-specific uptake of magnetic iron oxide nanoparticles by Adrenocortical carcinoma and Endothelial cells

Anna Sorushanova[1], Padraig Donlon[1], Nathan Mullen[1], Obdulia Covarrubias-Zambrano[2], Jose Covarrubias[2], Sunitha Varghese[2], Constanza Hantel[3], Peter Owens[4], Martin O'Halloran[5], Punit Prakash[6], Stefan Bossman[2] & Michael Conall Dennedy[1]
[1]University of Galway, Discipline of Pharmacology & Therapeutics, School of Medicine, Galway, Ireland; [2]The University of Kansas Medical Center, Department of Cancer Biology, Kansas, United States; [3]University Hospital Zurich, Department of Endocrinology, Zurich, Switzerland; [4]University of Galway, Centre for Microscopy & Imaging, Galway, Ireland; [5]University of Galway, Translational Medical Device, Galway, Ireland; [6]Kansas State University, Department of Electrical and Computer Engineering, Kansas, United States

Adrenocortical carcinoma is a rare malignant tumour that starts in the adrenal gland, accounting for 4% of all adrenal tumours. Functioning ACC can cause symptoms related to the overproduction of hormones and large tumours can press on nearby organs. Primary treatment for ACC tumour is surgery to remove the tumour, and may also include Chemotherapy or Radiation to stop the cancer cells from spreading. Therefore, more affective therapies for delivering therapeutics to the tumour are highly desirable. Magnetic iron oxide nanoparticles (MIONPs) have been gaining traction over the years for treatment of various cancers as they can be produced in various shapes and sizes, with the ability to modify the surface by coating the nanoparticles. Hence, MIONP delivered chemotherapy with associated hyperthermia has become an area of great interest. In this study, MIONPs have been used at different concentrations to evaluate non-specific nanoparticle uptake and rate of uptake by adrenal cortical and endothelial cells, as well as gain understanding of the location of nanoparticles within the cell. MIONPs were provided by The University of Kansas. Adrenal Cortical cell-lines (MUC1, H295R and HAC15) and Endothelial cell-line (HUVEC) were used in this study. Cells were incubated with MIONPs were for 24 h at concentrations ranging from 0.5 to 50 µg/ml. MIONP uptake, rate of uptake and vaibility was assessed by Flow Cytometry. Confocal Microscopy was used to image cellular morphology, and live imaging was carried out to view live uptake. Cellular proliferation was assessed by Ki-67. "Seahorse" technology was used to assess the effect of MIONPs on mitochondrial acttivity. Intracellular location of MIONPs was visualused TEM. The effect on steroidogenesis in the presence of MIONPs was assessed by Mass Spectrometry. Steroidogenic enzyme expression was assessed by RT-PCR. Viability, the location of MIONPs and proliferation post 7 days were assessed by Flow Cytometry, TEM and Ki-67. Following 24 hour incubation, Flow Cytometry showed significant uptake by Adrenocortical and Endothelial cells at 10 µg/ml MIONP concentration. Confocal and TEM images revealed MIONPs reside in the cytoplasm and in the vesicles of the cells. Live Confocal imaging showed movement of HAC15 cells towards MIONPs for phagocytosis. We demonstrated that ACC cells uptake MIONPs in a time and dose dependent manner. MIONP concentration from 0.5 to 10 µg/ml showed no cytotoxic affect, while cytotoxic affect was observed at 50 µg/ml. 10 µg/ml MIONP concentration was deemed optimal for ACC and Endothelial cells.

Cushingoid features in a patient with adrenal insufficiency secondary to combined inhaled steroid and Itraconazole therapy

Kalyani Nagarajah[1], Lindsay George[1] & Andrew Lansdown[2]
[1]Department of Medicine, University Hospital Llandough, Endocrinology and Diabetes, Cardiff, United Kingdom; [2]University Hospital of Wales, Department of Endocrinology, Cardiff, United Kingdom

Background
Iatrogenic adrenal insufficiency (AI) refers to primary, secondary, or tertiary hypoadrenalism associated with drug administration, surgery, or irradiation. The most common cause of secondary adrenal insufficiency is exogenous glucocorticoids. Hepatic metabolism of inhaled corticosteroids (ICS) takes place via cytochrome P450 3A4. Nevertheless, it can be decreased by enzyme inhibitors such as itraconazole or ritonavir, thus leading to an increase in the bioavailability of ICS. This can result in an accumulation of the steroid drug and a Cushing's syndrome whilst also leading to suppression of adrenocorticotropic hormone (ACTH) and hypoadrenalism. We report here a case of coexisting secondary adrenal insufficiency and iatrogenic Cushings syndrome from combined inhaled steroid therapy and Itraconazole.
Case
A 45-year-old female with known bronchiectasis, childhood asthma, atopic eczema and Allergic bronchopulmonary aspergillosis (ABPA) was taking Itraconazole 200mg twice daily for her ABPA for over three years. In addition, she was also on combined therapy with Symbicort (budesonide /formoterol) 200/6 inhaler, Mometasone 50 mg nasal spray and topical Hydrocortisone 1% cream. She presented to her general practitioner initially with a few months' history of fragile, paper-thin skin and developing easy bruising. She had also had central weight gain and had developed puffy, rounded facial features. Her symptoms had progressively worsened over the previous one year. Her initial investigations were two 9am serum cortisol levels of <28 nmol/l. An ACTH stimulation (Short Synacthen) Test demonstrated both basal and 30 minute cortisol values of <28nmol/l. Her combined therapy was complicated by profound adrenal shutdown and impairment of inhaled steroid clearance which resulted in paradoxical Cushingoid features.

Discussion
This case emphasises the importance of considering assessing the hypothalamic-pituitary-adrenal-axis, when considering combined therapy with Itraconazole and inhaled steroid treatment. Clinicians should be aware of the potential occurrence of iatrogenic Cushing syndrome and secondary adrenal insufficiency due to the association of inhaled corticosteroids with itraconazole.

Unexpected cause of hypertension associated with hypokalemia

Raluca Trifanescu[1,2], Iustin-Daniel Toma[1,2], Maria-Alexandra Mohora[2], Ileana Popescu[3], Ileana Nitu[4] & Catalina Poiana[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [2]C. I. Parhon National Institute of Endocrinology, Pituitary and Neuroendocrine Disorders, Bucharest, Romania; [3]Bucharest Emergency University Hospital, Cardiology, Bucharest, Romania; [4]C. I. Parhon National Institute of Endocrinology, Cardiology, Bucharest, Romania

Background
Prolonged ingestion of licorice has been known to cause hypokalemia and resistant hypertension amongst other disturbances. This is due to glycyrrhizin that inhibits the 11-β-hydroxysteroid dehydrogenase enzyme type 2 which results into increased plasma cortisol levels that stimulate the mineralocorticoid receptors resulting into apparent mineralocorticoid excess.
Case report
A 45-year-old woman resident in an iodine sufficient area, heavy smoker, was referred by her cardiologist to a tertiary endocrine center due to uncontrolled hypertension, for the past 4-5 years, with maximum systolic blood pressure of 200 mmHg, a transient paresthesia episode and hypokalemia. She denied any headaches, sweating, tremors or pallor, but was affirming rapid heartbeats. Physical examination revealed normal body mass index, regular heart rhythm with H $r=80$/min, blood pressure of 145/80 mmHg in clinostatism with 140/80 mmHg in orthostatism and no reddish-purple striae. Biochemical assessment revealed moderate anemia, moderate hypokalemia (K= 2.9 mmol/l), eunatremia (Na= 142 mmol/l). The ECG showed flattened T-waves. After 30 mEq KCl iv and oral potassium supplementation her K levels increased to 3.2 mmol/l). Hormonal assessment revealed a low-renin hypertension: mineralocorticoid axis after 2 h of standing and 5-15 minutes of sitting showed plasma aldosterone at the lower limit of normal (29.3 pg/ml) and suppressed direct plasma renin (= 1.92 pg/ml - 4 days after stopping beta blocker treatment), with aldosterone/renin ratio= 1.52 ng/dl/ng/l (non-diagnostic for primary aldosteronism). Glucocorticoid axis, plasma catecholamines (plasma metanephrines= 33.7 pg/ml, plasma normetanephrines= 82 pg/ml), thyroid function, PTH and IGF1 levels were normal. Abdominal ultrasound was unremarkable, however the native computed tomography revealed right adrenal hyperplasia. Upon a thorough dietary history, the patient stated that she was ingesting, for the past 20 years, licorice based candies in excessive amounts (around 160 grams/day). She was discharged with oral potassium supplementation, 10 mg of Amlodipine daily and the indication to withdraw all licorice candies ingestion.
Follow-up
One month after licorice withdrawal, serum potassium level was normal (4.5 mmol/l) without any supplements and blood pressure normalized.
Conclusion
This case highlights the importance of dietary history in patients with hypertension, hypokalemia and hormonal picture of pseudohyperaldosteronism. Apparent mineralocorticoid excess due to increased licorice ingestion should be considered for differential diagnosis of secondary hypertension.

Coagulation parameters in patients with adrenal incidentalomas and mild cortisol secretion: sex difference matters

Ilaria Bonaventura[1], Marianna Minnetti[1], Dario De Alcubierre[1], Alessandra Tomaselli[1], Davide Ferrari[1], Valentina Sada[1], Francesco Angelini[1], Valeria Hasenmajer[1], Alessia Cozzolino[1], Emilia Sbardella[1], Riccardo Pofi[2], Andrea Lenzi[1] & Andrea M. Isidori[1]
[1]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [2]Oxford Centre for Diabetes, Endocrinology and Metabolism and NIHR Oxford Biomedical Research Centre, Department of Endocrinology, Oxford, United Kingdom

Background
Patients with Cushing's syndrome (CS) typically show an alteration in the intrinsic coagulation pathway, leading to an increased risk of venous thromboembolism. Cortisol autonomy has been variably associated with higher risk of cardiovascular events and mortality compared to patients with non-functioning adrenal adenomas (NFA), particularly in women younger than 65 years. However, dedicated studies describing coagulation status in patients with adrenal incidentaloma are lacking.
Aim
To describe the effects of cortisol autonomy (defined as non-suppressible serum cortisol on dexamethasone-suppression testing, DST) on coagulation parameters in patients with adrenal incidentaloma enrolled in the ITACA study (NCT04127552) and to investigate sex differences.
Methods
A prospective study on 90 asymptomatic patients with adrenal incidentaloma was performed (62% female, mean age 62 ± 10). Patients with clinically apparent hormonal excess, active malignancy, history of thrombosis or taking hormone replacement therapy and anticoagulants were excluded. According to DST, three groups were defined: 41 NFA (<50 nmol/l), 39 possible autonomous cortisol secretion (PACS, 50 to 138 nmol/l) and 10 ACS (>138 nmol/l). Coagulation markers (fVIII, fVII, fV, fibrinogen, PT, aPTT, platelets) and coagulation inhibitors (Antithrombin III, Protein C, Protein S) were evaluated.
Results
A weak positive correlation was found between DST and platelets ($r=0.217$; $P=0.042$). Nevertheless, no differences in coagulation markers and inhibitors were observed among the three groups. A sub-group analysis by sex was performed in PACS and NFA groups. In PACS group, females compared with males had significantly decreased levels of aPTT ($aPTT_{Female}$ 28.7 sec ± 2.7 *vs* $aPTT_{Male}$ 32.1 sec ± 4.7, $P<0.01$) and increased levels of fVIII ($fVIII_{Female}$ 155% [125-163] *vs* $fVIII_{Male}$ 117% [95-121], $P=0.037$), fibrinogen ($fibrinogen_{Female}$ 3.67 g/l [2.62-4.60] *vs* $fibrinogen_{Male}$ 2.98 g/l [2.42-3.39] $P=0.018$), ATIII ($ATIII_{Female}$ 106.5% ± 12.5 *vs* $ATIII_{Male}$ 91.8% ± 5.5, $P<0.01$) and Protein C ($Protein\ C_{Female}$ 138% [117-149] *vs* $Protein\ C_{Male}$ 109% [87-129], $P=0.039$). Moreover, the frequency to have altered fVIII levels was greater in females than in males (81.2% *vs* 18.8%; OR 4.33, 95%CI 0.94 to 20.03, $P=0.05$). No sex differences were found in NFA group.
Conclusion
Overall, asymptomatic patients with adrenal incidentaloma, seem not to show alterations in coagulation parameters, in contrast to patients with overt CS. However, considering the presence of sex differences in coagulation markers and inhibitors, females with adrenal adenoma show alterations in coagulation pathways, especially those with a DST >50 nmol/l who therefore might benefit, in selected cases, from anticoagulation prophylaxis before and after adrenal surgery.

Cardiometabolic and bone health in postmenopausal women with glucocorticoid replacement therapy due to adrenal insufficiency; where do we stand

Efstratios Kardalas[1], Anna Angelousi[2], Dimitra Argyro Vassiliadi[1] & Stylianos Tsagarakis[1]
[1]Evangelismos General Hospital, Endocrinology Diabetes and Metabolism, Athens, Greece; [2]National University of Athens, Laiko Hospital, Internal Medicine, Athens, Greece

Background
Individuals with adrenal insufficiency (AI) receive life-long glucocorticoid (GC) replacement therapy (CGRT), which often exceeds normal daily physiological GC production, leading to detrimental effects on cardiometabolic parameters and bone health.
Objective
Assessment of glucose, lipid and bone metabolism in AI postmenopausal patients in relation to the cause of AI and the CGRT dose.
Methods
114 AI postmenopausal women were retrospectively studied (37 primary AI [PAI] and 37 secondary AI [SAI] patients and 40 AI patients following Cushing's syndrome (CS) treatment [post-CS AI]). Biochemical glucose and lipid parameters and bone mineral density (BMD) in lumbar spine (LS) and femoral neck (FN) were evaluated at baseline and at the follow-up (2 years). Additionally, patients were divided in 3 groups based on their total daily hydrocortisone (H/C) doses (TDH/CD); low dose (LD) (TDH/CD ≤ 15 mg) (21 patients), medium dose (MD) (15 mg < TDH/CD ≤ 25 mg) (50 patients) and high dose (HD) (TDH/CD > 25 mg) (43 patients)

Results
At baseline all patients had comparable age, body mass index. duration of AI, age of menopause and. Significantly more PAI patients were on LD and more post-CS AI ones on HD. Although mean daily GC dose was equal among groups, PAI patients received significantly less GC per body surface area (BSA) ($P=0.045$). Additionally, they had P1NP levels ($P=0.013$) and lower HbA1c, TChol and LDL values compared with the other ones ($P=0.043$, 0.018 and 0.001, respectively). After 2 years' time, TDH/CD decreased among all patients. Furthermore, P1NP values remained higher and TChol and LDL values lower among the PAI patients. Regarding TDH/CD, at baseline HD patients had worse lipid profile, increased bone turnover and lower BMD and T-Score in FN and LS. At 2 years follow-up, HD patients continued to exhibit deteriorated lipid values, elevated b-cross laps and lower BMD and T-Score in LS but not in FN in comparison to the other patients.
Conclusions
PAI patients had increased bone formation and better glucose and lipid profile compared to SAI and post-CS AI patients, and this difference persisted during the two years follow-up. This possibly related to the use of lower GC doses per BSA in PAI patients. Additionally, HD therapy in AI patients exerts a longitudinal and persistent negative effect on the glucose and lipid profile and the bone metabolism. Our data enforce the need for the lowest possible GC replacement dose and the routine follow up for all AI patients.

Retrospective study of steroid weaning in tertiary adrenal insufficiency comparing prednisolone and hydrocortisone

Muhammad Fahad Arshad[1,2], Charlotte Elder[1,3], John Newell-Price[1,2], Richard Ross[1] & Miguel Debono[1,2]
[1]The University of Sheffield, Sheffield, United Kingdom; [2]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom; [3]Sheffield Children's Hospital, Sheffield, United Kingdom

Background
The hypothalamic-pituitary-adrenal (HPA) axis can be suppressed by long-term exogenous glucocorticoids, resulting in tertiary adrenal insufficiency (AI). International expert consensus suggests that during weaning, prednisolone be converted to hydrocortisone to allow HPA axis reactivation(1). There is, however, little evidence to support this practice.
Aim
To compare HPA axis recovery during treatment with prednisolone and immediate-release hydrocortisone.
Methods
This is a retrospective study of patients diagnosed with tertiary AI (failed short synacthen test [SST]) attending a dedicated adult endocrine steroid clinic between 2015-2022. Patients were either weaned down to a physiological replacement dose of prednisolone or had been converted to immediate-release hydrocortisone. Patients were followed up with repeat SST to confirm HPA axis recovery demonstrated by a subsequent normal SST.
Results
276 patients had SST of which 161 had an abnormal result. After excluding patients with no subsequent SST or taking different or multiple steroids, a total of 119 patients were included in final analysis: 41 on prednisolone and 78 on hydrocortisone (48 previously on hydrocortisone; 30 converted during study period). The rate of HPA axis recovery in prednisolone group was 61% ($n=25$), compared to 24% ($n=19$) in hydrocortisone group ($P<0.001$). There was no mean difference in age (60 v 55 years; −4.3 years, 95%CI −10.5, 1.9), sex (females 63% v 59%; $P=0.64$), baseline cortisol at 1st SST (144 v 124 nmol/l; -19.7 nmol/l 95%CI -56.5, 17.0), baseline ACTH (22 v 30 ng/ml; 7.4 ng/ml 95%CI-3.0, 18.3), or duration of underlying diagnosis (4353 v 5360 days; 1133 days 95%CI -747, 3014) between the two groups. Mean follow up duration in prednisolone group was significantly lower (354 v 579 days; 225 days 95%CI 98.6, 350.8). Recovery rate in patients ($n=30$) in prednisolone to hydrocortisone switch subgroup also had similar recovery rate (27%) to overall hydrocortisone group.
Conclusion
This is the first study to compare HPA axis recovery during treatment with prednisolone and hydrocortisone. HPA axis recovery was more common in the prednisolone-treated patients and recovery time shorter compared to those on hydrocortisone. Prospective randomised studies with standardised treatment regimens are required to confirm our findings as selection bias may have influenced the conversion to immediate-release hydrocortisone in patients predicted to have slower recovery of the HPA axis.

Introduction
Bilateral Macronodular Adrenocortical Disease (BMAD) is a rare cause of Cushing syndrome due to bilateral adrenocortical macronodules. Germline inactivating variants of the tumor suppressor gene *ARMC5* have been described by our group 10 years ago and are responsible for 20-25% of apparently sporadic BMAD cases and 80% of familial presentations. *ARMC5* patients present with a more pronounced phenotype than wild-type patients, in terms of cortisol excess, number of nodules, and prevalence of Cushing's complications. *ARMC5* screening is now routinely performed for BMAD patients and families.
Methods
Based on literature review and on our own observations, this study aims to give an overview of both published and unpublished *ARMC5* genetic alterations and to compile the available evidence to discriminate pathogenic from benign variants.
Results
135 different germline variants (97 previously reported and 38 novels from our center) are identified in 212 unrelated patients, including 62 (46%) missense substitutions, 39 (29%) frameshift deletions or insertions, 24 (18%) nonsense variants, 4 (3%) affecting splice sites, 4 (3%) in-frame variants and 2 (1%) large deletions. The variants are spread on the entire coding sequence of the gene and most of them are private, with few recurrent hotspots (only 6 variants have been found in 5 or more different index patients). The pathogenic nature of *ARMC5* variants is established according to the recommendations of the American College of Medical Genetics, on the basis of their frequency in the general population, *in silico* predictions, familial segregation and tumor DNA sequencing. Indeed, in addition to the germline events, somatic 16p loss-of-heterozygosity and 70 different somatic events are described, leading to a bi-allelic inactivation of the gene, in accordance with a tumor suppressor gene model. Besides BMAD, the presence of a germline *ARMC5* variant has also been associated with the occurrence of meningiomas in 9 patients, with the demonstration of a second somatic event in 2 of them.
Conclusion
This work is the first extensive analysis of all the *ARMC5* genetic alterations reported so far in the literature with the addition of 38 unpublished variants identified in our center. A total of 196 different *ARMC5* alterations are reported here: 135 germline and 70 somatic variants (9 reported both as germline and somatic alterations). The present study is an important source of information and provides a list of variants, classified upon their pathogenic nature, which could help clinicians and geneticists to discriminate pathogenic from benign variants.

Anxiety, depression, quality of life and sleep: new insights in adrenal insufficiency care through salivary cortisol and cortisone diurnal rhythm measurement

Lorenzo Tucci[1,2], Valentina Vicennati[1,2], Valentina Bissi[2], Greta Galante[2], Giacomo Colombin[1,2], Kimberly Coscia[1,2], Ilaria Improta[1,2], Laura Rotolo[1,2], Flaminia Fanelli[2], Uberto Pagotto[1,2] & Guido Di Dalmazi[1,2]
[1]S. Orsola-Malpighi Polyclinic, Endocrinology and Diabetes Care and Prevention Unit, Bologna, Italy; [2]Alma Mater Studiorum - Bologna University, Center for Applied Biomedical Research, Deptartment Of Medical and Surgical Sciences, Bologna, Italy

Background
Adrenal insufficiency patient (AIP) care is mostly based on symptoms or clinical signs of inadequate glucocorticoid replacement treatment (GRT). Salivary

cortisol (F) and cortisone (E) recently emerged as new tools for AIP management, although poorly employed in clinical practice.
Aim
To assess associations between salivary glucocorticoid measures and life quality, anxiety depressive symptoms, sleep quality in AIP.
Method
We enrolled 29 healthy subjects (HS) and 52 AIPs under cortisone acetate (CA, $n=27$) or hydrocortisone or dual release hydrocortisone (HC, $n=25$). At observation day, subjects gathered 9 saliva samples at pre-established times from 07:00 (for AIP, immediately before the first GRT dose) to 23:00. Contextually, AIPs completed Addison disease specific quality-of-life questionnaire (AddiQoL-30; subdomains: Fatigue, Symptoms and Emotions), Hospital Anxiety and Depression Scale (HADS; subdomains: Anxiety and Depression) and Pittsburgh Sleep Quality Index (PSQI). E and F were quantified by liquid chromatography-tandem mass spectrometry. Due to GRT oral contamination, we considered F for CA and E for HC. Glucocorticoid exposure was estimated as area under the curve (AUC). F and E rhythms were determined with cosinor analysis. Z-scores (ZS) of F and E values at each time point, AUCs and cosinor parameters were calculated in the overall population including HS and AIPs. Linear and logistic multivariate regression analysis were performed including questionnaire scores as dependent variable and age, disease duration, ongoing GRT scheme duration, GRT equivalent-hydrocortisone dose, GRT type, body mass index, waist circumference and, one at a time, ZS parameters as covariates.
Results
Concerning AddiQoL, ZS-$AUC_{07:00\rightarrow07:30}$ negatively predicted Emotions ($R^2=0.125$, $P=0.040$). ZS-$AUC_{14:00\rightarrow16:00}$ negatively predicted overall score ($R^2=0.208$, $P=0.007$), Fatigue ($R^2=0.280$, $P=0.001$) and Emotions ($R^2=0.12$, $P=0.045$). ZS-$AUC_{21:00\rightarrow23:00}$ positively predicted Symptoms ($R^2=0.124$, $P=0.041$). Regarding HADS, ZS-$AUC_{14:00\rightarrow16:00}$ positively predicted the overall score ($R^2=0.338$, $P=0.004$) in model with ongoing GRT scheme duration, whereas ZS-$AUC_{19:30\rightarrow21:00}$ negatively predicted Depression ($R^2=0.136$, $P=0.045$). About PSQI, ZS-14:00 ($R^2=0.422$, $P=0.020$) and ZS-amplitude ($R^2=0.147$, $P=0.037$) positively predicted the overall score, whereas increasing ZS-$AUC_{12:30\rightarrow16:00}$ predicted abnormal PSQI (OR: 2.382; CI 95%: 1.099-5.164; overall percentage: 69%; $P=0.028$).
Conclusions
Elevated morning and, to a higher extent, afternoon glucocorticoid exposure predicted poorer life quality, stronger anxiety depressive symptoms, lower sleep quality. Interestingly, reduced evening glucocorticoid exposure predicts worse life quality and anxiety depressive symptoms, possibly indicating the need for greater glucocorticoid coverage at the end of the day. Hence, measurement of salivary cortisol and cortisone maybe useful predictors of physical and psychological wellbeing in AIP and could be employed for GRT management.

Genetic Aetiology of Primary Adrenal Insufficiency in Sudan

Chris Smith[1], Mohamed Abdullah[2,3], Samar Hassan[2], Younus Qamar[1], Charlotte Hall[1], Saptarshi Maitra[1], Avinaash Maharaj[1], Lucia Mariela Marroquin Ramirez[1], Jordan Read[1], Li Chan[1], Louise Metherell[1] & Salwa Musa[2,4]
[1]WHRI, QMUL, Centre for Endocrinology, London, United Kingdom; [2]Gaafar Ibn Auf Pediatric Tertiary Hospital, Department of Paediatric Endocrinology and Diabetes, Khartoum, Sudan; [3]University of Khartoum, Department of Paediatrics, Khartoum, Sudan; [4]Al-Neelain University, Department of Paediatrics and Child Health Faculty of Medicine, Khartoum, Sudan

Primary adrenal insufficiency (PAI) in children is usually congenital with more than 25 causal genes leading to overlapping phenotypes. A genetic diagnosis is helpful to guide management and genetic counselling but can be challenging in resource limited settings where facilities for antibodies and genetic testing may be unavailable. Studies from Africa are rare but, in Sudan, the most common genetic aetiologies for PAI are congenital adrenal hyperplasia (CAH; mostly *CYP21A2*) and Triple A syndrome (*AAAS*). Here we describe other genetic etiologies of PAI in a cohort of 29 Sudanese families. 36 patients from 29 Sudanese families (22M) were included in this series. Inclusion criteria were clinical presentation of PAI paired with biochemical finding of low cortisol and high ACTH, and/or a negative response to synacthen stimulation. Exclusion criteria were clinical and/or genetic diagnosis of CAH or Triple A syndrome. Candidate gene sequencing (CGS) of commonly causative genes; *MC2R*, *MRAP*, *CYP11A1* and *STAR*, was followed by whole exome sequencing (WES) in mutation negative individuals and family members (where available). Qiagen Clinical Interpretation tool was used to filter variants from VCF files, and the Integrative Genomics Viewer (IGV) employed to look for small/large deletions in known causal genes. The genetic aetiology was determined in 16/29 families ($n=19$ patients). Only 1 individual was diagnosed by CGS, having *MC2R* mutation p.R146H. Other mutations were discovered in; *NNT* ($n=5$) including a novel, synonymous variant (c.2193G>A; p.T731=) causing aberrant splicing p.(Glu867_Thr731del) in three families, *ABCD1* ($n=4$), *NROB1* ($n=1$), *CYP11A1* ($n=1$), and *CYP11B1-CYP11B2* fusion ($n=3$). IGV analysis detected a deletion of the last five exons of *AIRE* in two families ($n=4$), meaning *ABCD1, AIRE* and *NNT* are the most frequently mutated genes in this population. PAI in Sudan has heterogeneous aetiology and gaining a genetic diagnosis is priceless to the patient and family, helping to guide healthcare management and provide vital information on the prognosis. Unconventional mutations in known genes or novel genes may be responsible for the remaining undiagnosed cases. CGS as a pre-screening tool may be helpful where founder effects are known, e.g. p.(T731=) mutation in *NNT* in Sudan, but WES and whole genome sequencing (WGS) are likely to become the standard to achieve this, with their ability to find single nucleotide variations and deletions respectively, especially where causative genes are already established. The challenge will then shift to proving the consequence of variants found, as seen here with the "silent" *NNT* variant.

UK Lung cancer screening guidelines; are functional adrenal lesions being missed?

Rebecca Sagar[1], Andrew Scarsbrook[2], Matthew Callister[3] & Afroze Abbas[1]
[1]Leeds Teaching Hospitals, Leeds Centre for Diabetes and Endocrinology, Leeds, United Kingdom; [2]Leeds Teaching Hospitals Trust, Department of Radiology, Leeds, United Kingdom; [3]Leeds Teaching Hospitals Trust, Department of Respiratory Medicine, Leeds, United Kingdom

Background
Adrenal incidentalomas are common and require investigation to exclude malignancy and evidence of hormone overproduction. Prospective screening programmes are essential for early detection of cancer but often lead to incidental findings which have potential health economic implications and may increase patient anxiety. With regards to investigation of incidental adrenal nodules, current national lung cancer screening recommendations are not in keeping with current endocrinogy guidelines regarding which nodules need further investigation. This study aimed to assess the characteristics of the patients identfied with adrenal nodules from the UK Regional Lung Cancer Screening trial.
Methods
Data were collected retrospectively on patients over a three year period. Inclusion criiteria were adult patients who had undergone a computerised-tomography scan as part of the lung cancer screening trial with an adrenal nodule >1cm incidentally identified. Demographics, imaging characterisitics (maximum axial diameter, Hounsfield Units - HU), biochemistry and outcome data were recorded.
Results
A total of 187 patients were included (55% male), mean age 69.8 years $\pm$ 7 (SD). 145 (77%) had a unilateral lesion, mean size of 2.3 ± 0.9cm. 17(9%) lesions were >4cm and 26(14%) had HU above 10. Overall 183 (98%) of the cohort underwent associated functional hormone tests, 94 (51%) had cortisol >50nmol/l on overnight dexamethasone suppression test. Of those who had plasma metanephrines, two (1%) were signifiantly elevated and 5(5%) had aldosterone:renin suggesting possible primary hyperaldosteronism (PA). Following review in the Adrenal MDT one patient was diagnosed with phaeochromocytoma and 2 with Conn's syndrome. 59 patients were diagnosed with mild autonomous cortisol secretion (MACS). Of the patients with MACS, 49 had further investigations; 13(27%) had pre-diabetes, 7(14%) had hypertension and 2(4%) had osteoporosis identified. Three patients underwent surgery. If the lung screening guidelines had been followed only 17(9%) patients would have been referred to the adrenal team and 52 of the patients with MACS would not have undergone further investigation.
Conclusions
Amongst this cohort of patients, a majority had postive functional testing requiring further review. Although this has an impact on resources, important diagnoses were made as a result, including phaeochromocytoma, PA and MACS. Additionally, further co-morbidities assoicated with MACS including pre-diabetes and hypertension were identified allowing earlier intervention. Based on these data, 91% of investigated lesions would not have warranted further evaluation if the national lung cancer referral recommendations had been followed. This analysis highlights the additional diagnoses that would have resulted from investigating all adrenal nodules greater than 1cm in diameter.

The Relationship Between Autonomic Cortisol Secretion and Metabolic Diseases in Cases with Adrenal Incidentaloma

Beril Turan Erdogan[1], Berna Evranos Ogmen[2], Muhammed Sacikara[1], Cevdet Aydin[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Backgorund
Adrenal incidentalomas (AI) are lesions discovered incidentally on imaging without clinical symptoms or examination findings. AI can produce hormones in 5-30% of cases. Autonomic cortisol secretion (ACS) is the most common of these. Although ACS is asymptomatic, it increases the risk of metabolic disorders.
Methods
Patients aged ≥18 years with adrenal adenoma and upper abdominal MRI who presented and were examined in the endocrinology outpatient clinic, had their data retrospectively documented. Comorbidities, examinations and hormonal tests and results of these patients were evaluated. Those who failed dexamethasone suppression tests (cortisol >1.8 g/dl) and did not have Cushing's syndrome were classified as ACS.
Results
Among the 465 patients, 311 (66.9%) were women with a mean age of 54.8±10.2 (18-82). Of the patients, 31.4% had diabetes mellitus (DM), 53.8% had hypertension (HT), 30.8% had hyperlipidemia (HL), 11.8% had coronary artery disease (CAD), 1.3% had heart failure (HF) and. Hormone testing revealed that 31 (6.6%) of the patients had primary aldosteronism, 7 (1.5%) had pheochromocytoma, and 75 (16.1%) had ACS. Patients with and without ACS were compared for the presence of other additional diseases and adenoma size (Table-1). DM, HT and HL were higher in the ACS group ($P<0.05$, for each). Adenoma size was larger in the ACS group ($P<0.05$). Although the gender distribution was similar in both groups ($P>0.05$), the OCS patient was older ($P=0.006$).
Conclusion
Individuals with large adenomas are more likely to have ACS. Large adrenal adenomas should be monitored for ACS and associated cardiometabolic risks, as well as necessary treatments.

Table 1 Comparison of patient characteristics with and without autonomic cortisol secretion

Autonomic cortisol secretion	Yes $n=75$	No $n=390$	P

Influence of liver steatosis and fibrosis on cardiovascular function and prognosis of HFpEF patients

Ana Rita Leite[1,2], Marta Borges-Canha[1,2], António Angélico-Gonçalves[1], Francisco Vasques-Nóvoa[1], Francisca Saraiva[1], Ana Cristina Oliveira[1], Madalena von Hafe[1], Catarina Vale[1], Davide Carvalho[2], Joao Sergio Neves[1,2] & Adelino F. Leite-Moreira[1]
[1]Cardiovascular Research and Development Center, Department of Surgery and Physiology, Faculty of Medicine, University of Porto, Porto, Portugal; [2]Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar Universitário de São João, Porto, Portugal

Introduction
Non-alcoholic fatty liver disease (NAFLD) and Heart Failure with Preserved Ejection Fraction (HFpEF) are two syndromes with increasing clinical relevance, mainly due to the rising prevalence of metabolic syndrome. Despite sharing a common metabolic background, the association between NAFLD severity and HFpEF has not yet been well explored.
Aim
To evaluate the association of NAFLD steatosis and fibrosis scores with cardiovascular function and the risk of cardiovascular events in a cohort of individuals with stable HFpEF.
Methods
We included individuals with stable HFpEF followed in the Heart Failure (HF) Outpatient clinic at Centro Hospitalar Universitário de São João in Porto, Portugal. Patients with significant alcohol consumption were excluded. At enrolment, a comprehensive collection of clinical/imaging data and biological samples was performed. Cardiac structure and function were evaluated by echocardiography. Endothelial function and vascular properties were assessed by Reactive Hyperemia Index (RHI), measured using EndoPAT™2000 device, and pulse-wave velocity. We calculated the hepatic steatosis risk using Fatty Liver Index (FLI) and Hepatic Steatosis Index (HSI), and the liver fibrosis risk using NAFLD Fibrosis Score (NFS) and BARD score. We used linear regression models to analyze the associations between NAFLD scores and parameters of cardiac and vascular function. We performed a survival analysis to evaluate the association between NAFLD scores and the risk for a composite endpoint of urgent visits due to acute HF, HF hospitalization or cardiovascular death. Models were adjusted for age, sex, and type-B natriuretic peptides.
Results
Sixty-one patients were included. The mean age was 73.8±9.2 and 54% were female. Higher FLI and HSI levels were associated with higher posterior wall thickness [β=0.15 (0.03; 0.26); $P=0.016$; β=0.06 (0.01; 0.11); $P=0.032$, respectively]. Higher NFS index was associated with higher E/e' ratio [β=0.77 (0.00; 1.55); $P=0.049$] and E/A ratio [β=0.44 (0.01; 0.88); $P=0.044$]. Increasing BARD categories were associated with higher interventricular septum thickness [β=0.56 (0.07; 1.04); $P=0.025$] and E/e' ratio [β= 1.24 (0.36; 2.12); $P=0.007$]. A negative association was found between HSI and RHI (β=-0.04 (-0.07; -0.00); $P=0.038$). In the survival analysis, we found that higher HSI levels and higher BARD categories were associated with an increased risk for the combined outcome [HR=1.10 (1.04; 1.18); $P=0.002$; HR=2.40 (1.37; 4.20), $P=0.002$, respectively].
Conclusions
These results suggest that the presence of liver steatosis or fibrosis are associated with increased ventricular mass, impaired endothelial and diastolic functions, and with a higher risk for cardiovascular events, in individuals with stable HFpEF.

Glucocorticoid-induced adrenal insufficiency: Identification of diagnostic and prognostic biomarkers based on two randomized controlled trials - REFINE

Simon Bøggild Hansen[1,2], Anja Fenger Dreyer[3,4], Stina Willemoes Borresen[5], Hajir Al-Jorani[3,4], Lise Sofie Bislev[1], Victor Brun Boesen[5], Louise Lehmann Christensen[3], Dorte Glintborg[3], Richard Christian Jensen[3], Nanna Thurmann Jørgensen[5,6], Marianne Klose[5], Marie Louise Lund[5], Jelena Stankovic[1,2], Randi Tei[1], Torquil Watt[5,6], Paul M Stewart[7], Marianne Andersen[3,4], Ulla Feldt-Rasmussen[5,6] & Jens Otto Jørgensen[1,2]
[1]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus N, Denmark; [2]Aarhus University, Department of Clinical Medicine, Aarhus N, Denmark; [3]Odense University Hospital, Department of Endocrinology, Odense C, Denmark; [4]University of Southern Denmark, Department of Clinical Research, Odense C, Denmark; [5]Copenhagen University Hospital, Rigshospitalet, Department of Endocrinology and Metabolism, Copenhagen, Denmark; [6]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [7]University of Leeds, Faculty of Medicine & Health, Leeds, United Kingdom

Background
The risk and course of glucocorticoid-induced adrenal insufficiency (GIA) are unclear and current evidence is retrospective and based on small and selected study populations. However, the prevalence of glucocorticoid use is at least 3 %, which underscores the need for unbiased and prospective assessment of the prevalence and clinical consequences of GIA.
Objectives
To identify biomarkers of GIA as regards diagnosis, prognosis and responsiveness to hydrocortisone replacement.
Patients and Methods
The study (REFINE) is nested in two ongoing randomized controlled trials, RESCUE and REPLACE (Table 1). Both studies screen potential participants by an ACTH test with GIA defined as a stimulated 30 minute plasma cortisol concentration <420 nmol/l. We aim to prospectively screen 2.800 and enroll 555 patients in the two studies. Patients contribute blood samples at the baseline visits and after completion of the RCTs. Demographics, lifestyle factors, disease characteristics, co-morbidities, medication and patient reported outcomes (PROs) are recorded at baseline and at study end. We aim to generate diagnostic, prognostic and predictive GIA biomarkers with a stepwise analysis. First step involves univariate analyses to identify single biomarkers and generating an outline of variables for the proceeding analyses. Further analyses will proceed in two directions, prediction and explanatory associations.

Table 1 (Abstract P564)

Study	Population	Other inclusion criteria	Grouping based on ACTH-test: ACTH-stimulated cortisol at inclusion	Intervention (RCT groups)	Study length
RESCUE $n=325$	- Patients with giant cell arteritis and/or polymyalgia rheumatica	Ongoing prednisolone treatment $\geq$0 mg/day and $\leq$ 5 mg/day	RCT: <420 nmol/l ($n=250$) Control: $\geq$420 nmol/l ($n=75$)	Hydrocortisone vs placebo during stress	6 months
REPLACE $n=230$	- Age $\geq$50 years - Prednisolone treatment $\geq$12 weeks	Planned cessation of prednisolone treatment $\geq$2 weeks and $\leq$ 12 weeks ago	RCT: 100-419 nmol/l ($n=150$) Control 1: <100 nmol/l ($n=20$) Control 2: $\geq$420 nmol/l ($n=60$)	Hydrocortisone vs placebo	12 months

Selection of candidate variables for our prediction models will be based on findings in our univariate analyses and published literature and include among others a broad spectrum of clinical, biochemical, genetic as well as patient-, disease- and treatment-related variables. Our approach to establish multivariate predictions models will adhere to current guidelines.

Perspectives

This study, together with the results of RESCUE and REPLACE, will support clinical decision-making as regards predicting, diagnosing and managing GIA.

Funding

Achieved from the Novo Nordisk Foundation as part of a collaborative grant entitled "DOUBLE EDGE – Characterization and mitigation of adverse effects of glucocorticoid treatment" (NNF20OC0063280).

The degree of cortisol secretion is associated with cardiometabolic complications in patients with nonfunctioning adrenal tumors

Vittoria Favero[1], Carmen Aresta[2], Chiara Parazzoli[1], Elisa Cairoli[2], Cristina Eller Vainicher[3], Serena Palmieri[3], Antonio Salcuni[4], Maura Arosio[3,5], Luca Persani[1,6], Alfredo Scillitani[7], Valentina Morelli[2] & Iacopo Chiodini[1,8]

Maria della Misericordia, Unit of Endocrinology and Metabolism, Milan, Italy; [5]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy; [6]IRCCS Istituto Auxologico Italiano, Department of Endocrine and Metabolic Diseases & Lab of Endocrine and Metabolic Research, Milan, Italy; [7]Ospedale "Casa Sollievo della Sofferenza" IRCCS, San Giovanni Rotondo (FG), Italy; [8]Ospedale Niguarda Cà Granda, Unit of Endocrinology, Milan, Italy

Most adrenal incidentalomas are benign and can be divided into nonfunctioning adrenal tumors (NFAT) and tumors with mild autonomous cortisol secretion (MACS). Several studies suggest that MACS may result in an increased risk for mortality and cardiometabolic disease. The cardiometabolic risk in MACS is possibly related to the increased frequency of cardiovascular risk factors such as diabetes mellitus (DM) and hypertension (HT) induced by cortisol excess. This is confirmed by the evidence that DM and HT ameliorate after adrenalectomy in patients with MACS. Recent data suggested that not only MACS but also NFAT patients may have an increased risk of cardiovascular events (CVE). The mortality risk in NFAT seems to be comparable to that in MACS and adrenalectomy seems to be beneficial for hypertension and diabetes mellitus even in patients with NFAT. Therefore, the aim of our study was to assess: i) the association between HT, DM, obesity, dyslipidemia, and CVEs with cortisol secretion; ii) the cut-off of the cortisol secretion parameters for identifying NFAT patients with a worse cardiometabolic profile.

Patients and Methods:

In 615 NFAT patients (i.e. with 1mg overnight dexamethasone suppression test, F-1mgDST <1.8 μg/dl) F-1mgDST and adrenocorticotroph hormone (ACTH) levels and data on associated manifestations and CVE prevalence were collected.

Results

HT, DM and HT plus DM were associated with F-1mgDST levels (area-under-curve: 0.588 ± 0.023, 0.610 ± 0.028, 0.611 ± 0.033, respectively, $P<0.001$ for all comparisons) but not with ACTH. The cut-off for identifying patients with either HT or DM or HTplusDM was set at $\geq$1.2 μg/dl (33 nmol/l). As compared with patients with F-1mgDST <1.2 μg/dl ($n=289$), patients with F-1mgDST $\geq$1.2 μg/dl ($n=326$) had lower ACTH levels (17.7 ± 11.9 vs 15.3 ± 10.1 pg/ml, respectively, $P=0.008$), and higher age (62.5 ± 10.9 vs 57.5 ± 12.3 years, respectively, $P<0.001$), prevalence of HT (38.1% vs 52.5% respectively $P<0.001$), DM (13.1% vs 23.3%, respectively, $P=0.001$), HTplusDM (8.3% vs 16.9%, respectively, $P<0.002$) and CVE (7.3% vs 3.2%, respectively, $P=0.028$). F-1mgDST$\geq$1.2 μg/dl was associated with either HT (odd ratio, OR, 1.55, 95% confidence interval, 95%CI 1.08-2.23, $P=0.018$) or DM (OR 1.60, 95%CI 1.01-2.57, $P=0.045$) after adjusting for age, gender, obesity, dyslipidemia, and DM (for HT) or HT (for DM), and with the presence of HTplusDM (OR 1.96, 95%CI 1.12-3.41, $P=0.018$) after adjusting for age, gender, obesity, and dyslipidemia.

Conclusions

In NFAT patients cortisol secretion is associated with the prevalence of HT and DM; patients with F-1mgDST $\geq$1.2 μg/dl could have a worse cardiometabolic profile.

Evaluation of CYP11B2 immunostaining findings and cure rates of primary aldosteronism subtyped by anatomical imaging and functional methods

Marianna Viukari[1], Helena Leijon[2], Tiina Vesterinen[2], Ilkka Pörsti[3,4], Pasi I. Nevalainen[4] & Niina Matikainen[1]

[1]Helsinki University Hospital and University of Helsinki, Endocrinology, Helsinki, Finland; [2]Helsinki University Hospital and University of Helsinki, HUSLAB, Department of Pathology, Helsinki, Finland; [3]Tampere University, Faculty of Medicine and Health Technology, Tampere, Finland; [4]Tampere University Hospital, Endocrine Unit, Department of Internal Medicine, Tampere, Finland

Background

The best lateralization method to ascertain cure after surgery in unilateral primary aldosteronism (PA) is debated. Risk of persistent of PA in those with non-classical adrenal histopathology remains poorly characterized.

Objective

We examined the value of anatomical compared with functional subtyping and the significance of immunohistochemical analysis of CYP11B1 and CYP11B2 for the outcome and histopathological diagnosis of primary aldosteronism.

Design

A retrospective multicenter study of patients operated for PA.

Methods

We identified 277 subjects with a diagnosis of primary hyperaldosteronism (E26.0) who had an adrenalectomy sample available in the Finnish biobanks during 1.1.2000-31.12.2019. Adrenal slides from biobanks were analyzed centrally after CYP11B2 staining and clinical data were obtained from patient registries.

Results

Altogether 179 (64.6%) patients underwent adrenalectomy based on anatomical lateralization on CT or MRI, whereas 43 (15.5%), 14 (5.4%) and 35 (12.6%) were operated based on functional lateralization in adrenal venous sampling (AVS); ^{11}C-metomidate (^{11}C-MTO) -PET or [^{131}I] norcholesterol scintigraphy, respectively. Adrenalectomy based on functional subtyping more likely resulted in complete or partial clinical cure than anatomical subtyping -based adrenalectomy (88.5 % vs. 72.5 %, $P=0.002$). Re-evaluation of adrenal samples with CYP11B2 staining revealed aldosterone-producing adenoma (APA) in 146 (67.3 %) subjects and changed the original histopathological diagnosis in 91 (33.2 %) of the subjects. Aldosterone-producing nodules (APN) were more frequently present in those who did not reach clinical cure (22.4 % vs 9.4 %, $P=0.012$) whereas aldosterone-producing micronodules (APM) were common overall (83.4 %) and did not impact the outcome of adrenalectomy. Frequency of APAs and non-classical features did not differ according to the subtyping method used.

Conclusions

Lateralization detected in functional subtyping can identify unilateral aldosterone production more accurately than anatomical imaging. CYP11B2 staining is elemental for the histopathological diagnosis and complements the postoperative

clinical data. Our results suggest the need for prompt long-term follow-up in patients with APNs even after removal of an APA.

A case of bilateral adrenal haemorrhages

Umer Qazi
Sherwood Forest, Endocrinology, United Kingdom

Background
Adrenal haemorrhage is a rare clinical presentation with an incidence of only 5 in 1,000,000 [1]. 10% of these are bilateral adrenal haemorrhages, which has very high mortality rate of 15 % [2]
Case summary
22 years old female had C-section for persistent to breech presentation at term. She has a history of preterm delivery due to chorioamnionitis during previous pregnancy. Patient had about 1.2L post-partum haemorrhage. She deteriorated after 24 h of C-section, with hypotension pyrexia, and decreased urinary output. The blood result showed acute kidney injury (AKI), raised INR, raised procalcitonin>100ng/ml, severely deranged liver function tests, hyperkalaemia (K^+ 6.9mmol/l) and hyponatremia (Na^+ 129mmol/l). CT-abdomen showed bilateral acute adrenal haemorrhages. She was started on IV hydrocortisone along with treatment for post-partum haemorrhage, sepsis, and AKI in critical care. Following clinical improvement, hydrocortisone dose was reduced, and she had a short Synacthen test which showed subnormal response to Cosyntropin (cortisol of 207 nmol/l and 192 nmol/l) with raised ACTH of 102 ng/l. She was discharged on hydrocortisone 10/5/5 dose with outpatient endocrine follow up.
Discussion
Bilateral adrenal haemorrhages have been reported in patients with infection, trauma and anticoagulants [3]. Due to very high mortality rate, it is important to have a very high index of suspicion for treatment. IV steroids are the key if there is a suspicion of adrenal insufficiency in patients. In this case the aetiology of bilateral adrenal haemorrhage is likely multifactorial, including postpartum haemorrhage and sepsis. It is also important to distinguish in such cases whether the adrenal insufficiency is not due to central cause as postpartum haemorrhages was also noted. In this case the anterior Pituitary hormones were normal, and ACTH was raised.

Assessment of Practice around Corticosteroid Sick Day Rules in Transplant and Oncology Services of a Tertiary Hospital in UK

Ammara Naeem[1], Ahmed Yousseif[1], Bernard Khoo[1], Efthimia Karra[1] & Eleni Armeni[1,2]
[1]Royal Free Hospital NHS Trust, Endocrine and Diabetes, London, United Kingdom; [2]National and Kapodistrian University of Athens, 2nd Department of Obstetrics and Gynaecology, Athens, Greece

Introduction
Long term treatment with corticosteroids has been widely used, due to the well documented immunosuppressive and anti-inflammatory activity. Corticosteroids are among the most widely prescribed drugs in oncology and post-transplant patients. However, long-term treatment with a dose of corticosteroids, which equals prednisolone 5mg/day for at least 4 weeks, is very likely to result in suppressed function of the hypothalamic pituitary adrenal (HPA) axis, a condition known as tertiary adrenal insufficiency. Patients on long-term corticosteroids should be well educated on steroid sick day rules, including the risk of adrenal crisis. We aimed to assess the practice of healthcare professionals (HCP) involved in the care of transplant and oncology patients requiring treatment with corticosteroids long-term.
Method
This prospective qualitative study aimed to evaluate the educational practice of corticosteroid sick day rules among the HCP (clinician and nurses). For this purpose, we selected HCPs primarily looking after Transplant (Liver and Kidney) and Oncology patients at Royal Free Hospital NHS Trust, requiring prolonged course of corticosteroids. A survey including a set of questions was circulated among the relevant staff.
Results
Of the 30 respondents (27 physicians and 3 specialist nurses), 66% mentioned being aware of adrenal suppressive doses of corticosteroids and 70% mentioned being aware of the corticosteroid sick day rules. However, regarding corticosteroid sick day rules counselling, only 40% confirmed counselling the patients at the time of initiation of long-term corticosteroids and 27% counselled on subsequent contact after initiating treatment. Variability was observed in the content of education where 50% of HCP counselled on illness with fever, 7% counselled on treatment around major/minor surgery and Covid-19, while 27% mentioned that they do not offer specific advice on sick day rules. Regarding testing of HPA-function, majority (60%) of respondents considered testing for suspected adrenal insufficiency and would refer the patients to Endocrine Services. However, variability was observed in the timing of testing.
Discussion and Conclusion
This is the first evaluation of the education practice on corticosteroid sick day rules in oncology and transplant services of a tertiary hospital. Our results highlight the need for standardised education on sick day rule counselling along with issuing the steroid emergency card to these patients. Specific guidance and clinician training to standardise sick day rule counselling across non-endocrine specialties should be undertaken to improve the level of care of patients on long-term corticosteroids and to reduce hospital admissions with adrenal crises.

An Analysis of Genes Involved in Vasoconstriction Causing Hypertension and Related Cardiovascular Diseases Using Whole Exome Sequencing

Sania Rauf[1,2], Abida Arshad[1], Roger Foo[3], Maleeha Akram[1], Shumaila Naz[2] & Syed Shakeel Raza Rizvi[1]
[1]Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Department of Zoology, Wildlife and Fisheries, Rawalpindi, Pakistan; [2]University of Wah, Quaid Avenue, Wah Cantt, Pakistan, Department of Biosciences, Wah Cantt, Pakistan; [3]Genome Institute of Singapore (GIS), Singapore, Singapore, Singapore

Hypertension is associated with vascular changes characterized by endothelial dysfunction, increased vascular contraction, and arterial remodelling. Vascular smooth muscle (VSM) cells, which constitute bulk of vascular wall, are critically involved in these processes through their highly plastic and dynamic features and ability to undergo phenotypic differentiation. Stimulation of VSM cells by pro-hypertensive neurohumoral stimuli such as acetylcholine and norepinephrine, and vasoactive peptides like angiotensin-II and endothelin-1 induce activation of receptors coupled to phospholipase C (PLC), leading to generation of second messengers, inositol trisphosphate (IP3) and diacylglycerol (DAG). IP3 increases intracellular Ca2+ and causes vasoconstriction. VSM contraction plays an important role in regulation of peripheral vascular resistance and blood pressure. Vascular dysfunction, excessive vasoconstriction and vasospasm could lead to major cardiovascular disorders such as hypertension and coronary artery disease. In this study, hypertensive cardiovascular patients were screened using whole exome sequencing (WES) to find possible pathogenic mutations in different genes involved in vasoconstriction. Thirteen hypertensive cardiovascular patients from three families (3 patients in 1st, 21-48 years; 5 in 2nd, 43-72 years and 5 patients in 3rd, 19-47 years of age) were selected for WES. Genomic DNA was extracted (DNA Isolation Kit, QIAamp DNA mini-Kit) at City Lab, Rawalpindi, Pakistan. DNA obtained was taken to Genome Institute of Singapore (GIS), Singapore, where final dilutions of 25µl DNA were outsourced to Proteomics Lab, Macrogen Asia Pacific, Singapore for WES. Subsequent bioinformatics analysis was performed at GIS, Singapore. We identified a novel splicing variant in SARAF gene (in two patients of family 1) involved in norepinephrine signalling pathway and a novel frameshift variant in NOX4 gene (in all patients of family 1 and 3, and two patients of family 2) involved in angiotensin-II signalling pathway. This study also found a missense variant in ADCY10 gene (in three patients each of family 2 and 3) involved in norepinephrine signalling pathway, a missense variant in TLR4 gene (in one patient of family 1 and three patients of family 2), which is upregulated by angiotensin-II and a splicing variant in GNAQ gene (in all patients of family 1 and two patients each of family 2 and 3) that encodes a protein associated with α-adrenergic receptor and angiotensin-II receptor. Variants identified in ADCY10, TLR4 and GNAQ genes were reported earlier but are extremely rare in GnomAD database. In conclusion, we report novel mutations in two genes and variants in three genes involved in vasoconstriction in hypertensive cardiovascular patients.

An Unexpected Enzyme in Vascular Smooth Muscle Cells: Angiotensin II Upregulates Cholesterol-25-Hydroxylase Gene Expression

Kinga Bernadett Kovács[1], Janka Borbála Gém[1], András Balla[1,2] & László Hunyady[1,3]
[1]Semmelweis University, Department of Physiology, Budapest, Hungary; [2]MTA-SE Laboratory of Molecular Physiology, Budapest, Hungary; [3]Institute of Enzymology, Research Centre for Natural Sciences, Budapest, Hungary

Angiotensin II (AngII) is a vasoactive peptide hormone and the effector of the renin-angiotensin-aldosterone system. It exerts its main physiological effects through type 1 angiotensin II receptor (AT1R), but it can also contribute to the development of cardiovascular diseases. Likewise, oxysterols such as 25-hydroxycholesterol (25-HC), the product of cholesterol-25-hydroxylase (CH25H), can have harmful effects on the vasculature since they affect vascular smooth muscle cells (VSMCs) negatively. However, there is no established connection between AngII and 25-HC production in VSMCs. Our study aimed to explore how AngII affects Ch25h gene expression in rat primary VSMCs. RNA-sequencing was used to determine which genes are differentially expressed in VSMCs stimulated with AngII compared to vehicle-stimulated cells. We performed qRT-PCR measurements to asses Ch25h mRNA levels in our VSMC samples. VSMCs were stimulated with AngII for various time spans to determine Ch25h expression changes over time. We used multiple inhibitors to specify which signaling pathways are involved in the AngII-induced Ch25h expression changes. LC-MS/MS was used to measure 25-HC levels in the supernatant of AngII-stimulated VSMCs. Our data show that Ch25h expression was robustly upregulated in response to AngII stimulus, Ch25h mRNA levels were at a peak one hour after stimulation. The AT1R, Gq/11, and p38 MAP kinase inhibitors prevented the AngII-induced Ch25h upregulation. LC-MS/MS results demonstrated that 25-HC is present in the supernatant of AngII-stimulated VSMCs. 25-HC concentration was highest (on average 8.2 ng/ml) four h after AngII stimulation. Based on our results we conclude that AngII-induced Ch25h upregulation is AT1R, Gq/11 and p38 MAP kinase signaling dependent in primary rat VSMCs. The elevation of 25-HC levels in AngII-stimulated VSMC supernatants means that CH25H enzyme is active and functional in primary rat VSMCs. Our study demonstrated that AngII stimulus induces Ch25h upregulation and subsequently 25-HC production in VSMCs. Our findings can lead to the better understanding of mechanisms in the pathogenesis of cardiovascular diseases. This work was supported by the National Research, Development and Innovation Fund (NKFI K139231 and NVKP_16-1-2016-0039).

Expression of genes involved in parathyroid tumorigenesis identified different gene signatures in parathyroid adenomas

Chiara Verdelli[1], Riccardo Maggiore[2], Giulia Stefania Tavanti[1] & Sabrina Corbetta[3]
[1]Laboratory of Experimental Endocrinology, IRCCS Ospedale Galeazzi Sant'Ambrogio, Milano, Italy; [2]Endocrine Surgery, IRCCS Ospedale San Raffaele, Milano, Italy; [3]Endocrinology and Diabetology Service, IRCCS Ospedale Galeazzi Sant'Ambrogio, Department of Biomedical, Surgical and Dental Sciences, University of Milan, Milano, Italy

The expression of key molecules involved in fundamental cell processes and epigenetic gene expression modulation is altered in human parathyroid tumours, due to gene mutations, loss of heterozygosity, aberrant gene promoter methylation, DNA copy number variations. We performed a gene profiling of 26 parathyroid tumorigenesis-related genes in a series of 32 sporadic parathyroid adenomas (PAds) surgically removed from patients with primary hyperparathyroidism, with the aim to detect specific gene signatures. Gene expression data were analyzed by unsupervised hierarchical clustering analysis using Euclidean wardd2. Clusterization was performed considering the expression of oncosuppressors (*MEN1*, *CDC73*, *RASSF1A*, *YAP1*, *CTNNB1*), embryonic transcription factors (*GCM2*, *TBX1*, *PAX1*, *GATA3*), cell cycle genes (*CCND1*, *CDKN1B*/p27, *CDKN1A*/p21, *TP73*), and long noncoding RNAs (*NEAT1*, *HAR1B*, *HOXA3AS*, *HOXA6AS*, *VLDLR-AS1*, *SNHG6*). Additionally, all PAd samples were profiled for parathyroid-related genes (*CASR*, *VDR*, *PTH*) and microRNAs (miR-372, miR-517c, miR-126-5p, miR-93-5p). Three distinct transcriptional signatures were identified: cluster 1 (C1) included 9 PAds, while clusters 2A (C2A) and 2B (C2B) included 18 and 5 PAds, respectively. Principal components analysis showed that the main driver was represented by the expression of the LncRNA *HAR1B* (PC1, 88.4% of variance), followed by *TP73* (PC2, 3.8%) and *CDKN1B*/p27 (PC3, 3.5%). PAds included in C2A had lower expression levels of the oncosuppressors *CDC73*, *RASSF1A*, *CTNNB1*, and of the transcription factors *GCM2*, *GATA3*, *TBX1*, *PAX1* than C1 PAds. Interestingly, PAds in C2A had lower levels of *CCND1* than C1 and C2B, and concomitantly lower levels of the proapoptotic *RASSF1A*-induced gene *TP73*. Moreover, *HAR1B*, *HOXA3AS*, *VLDRAS1*, *SNHG6* expression levels were lower in C2A PAds. Besides, C2A and C2B included 4 PAds overexpressing the C19MC genes miR-372 and miR-517c. However, the gene expression signature of PAds included in C2A differed from that of C2B PAds, which had higher expression of *MEN1* and *YAP1*, and of *HOXA6AS*. Interestingly, the gene signatures of PAds in C2A and C2B were associated with deeply reduced expression of *CASR* and *VDR* when compared with PAds in C1. Biochemical parameters, namely circulating ionized calcium ($[Ca^{2+}]$), total calcium and PTH were similar in patients harbouring PAds included in C2A and C1, while the gene signature of PAds in C2B was associated with higher Ca^{2+} and total calcium. No difference in age at diagnosis as well as tumour size could be detected. In conclusion, in PAds transcriptional signature of critical genes involved in parathyroid tumorigenesis was heterogeneous, suggesting the role of several pathways, which claimed to be investigated.

Long-term trajectories of bone metabolism parameters and bone mineral density (BMD) in obese patients treated with metabolic surgery: a real-world, retrospective study

Carla Greco[1,2], Francesca Passerini[3], Silvia Coluccia[2], Marta Teglio[2], Mario Bondi[1], Fouzia Mecheri[4], Vincenzo Trapani[4], Alessandro Volpe[4], Patrizia Toschi[5], Bruno Madeo[1], Manuela Simoni[1,2], Vincenzo Rochira[1,2] & Daniele Santi[1,2]
[1]Azienda Ospedaliero-Universitaria of Modena, Italy, Department of Medical Specialties, Unit of Endocrinology, Italy; [2]University of Modena and Reggio Emilia, Modena, Italy, Department Biomedical, Metabolic and Neuronal Sciences, Unit of Endocrinology, Italy; [3]University of Modena and Reggio Emilia, Modena, Italy, Department of Biomedical, Metabolic and Neural Sciences, Unit of Internal and Metabolic Medicine, Italy; [4]Division of General, Emergency Surgery and New Technologies, Ospedale Civile di Baggiovara, Modena, Italy, Italy; [5]Department of Metabolic Diseases and Clinical Nutrition, Azienda Ospedaliero-Universitaria of Modena, Modena, Italy, Italy

Background and Aim
Potential adverse effects of metabolic surgery on skeletal integrity remains an important concern. Bone loss is common after surgery due to multiple factors including vitamin D deficiency, altered calcium metabolism, mechanical load reduction and hormonal pattern changes. It is still not clear if the effects on bone health and calcium homeostasis vary according to each surgical technique. Further, long-term data of different surgical approaches are poor. Thus, this study aimed to describe changes in bone metabolism in subjects with severe obesity undergoing both Roux-en-Y gastric by-pass (RYGB) and sleeve gastrectomy (SG).
Methodology
A single center, retrospective, observational clinical study on real-world data was performed enrolling subjects undergoing metabolic surgery.
Results
One hundred twenty-three subjects were overall enrolled, including 31 men (25.2%) and 92 women (74.8%). RYGB procedure was performed in 67 (62.6%) and SG in 46 (37.4%) patients. The mean age at baseline was $48.2 + 7.9$ years, ranging from 28.9 to 63.4 years. The entire cohort was evaluated until 16.9 ± 8.1 months after surgery, while a small group was evaluated up to 4.5 years. All individuals were treated after surgery with calcium and vitamin D integration. Both calcium and phosphorous serum levels significantly increased after metabolic surgery and remained stable during follow up. These trends did not differ between RYGB and SG ($P = 0.245$). Ca/P ratio decreased after surgery compared to baseline ($P < 0.001$) and this decrease remained among follow up visits. While 24-h urinary calcium remained stable across all visits, 24-h urinary phosphorous showed lower levels after surgery ($P = 0.014$), also according to surgery technique. Parathyroid hormone decreased ($P < 0.001$) and both vitamin D ($P < 0.001$) and C-terminal telopeptide of type I collagen ($P = 0.001$) increased after surgery. Moreover, no significant change in osteoporosis/osteopenia rate by DXA evaluation was detected one and two years after surgery ($P = 0.109$). Despite this, significant bone mineral density (BMD) reduction was detected at femoral site after surgery ($P = 0.032$ and $P < 0.001$, respectively), also after adjustment for gender.
Conclusion
We demonstrated that calcium and phosphorous metabolism remains slightly rearranged even after several years since metabolic surgery, irrespective of calcium and vitamin D supplementation. This rearrangement is characterized by a phosphorous serum levels increase, together with a persistent bone loss, suggesting that supplementation alone may not ensure the maintenance of bone health in these patients and further therapeutic strategies are needed for longtime including lifestyle, physical exercise and bone active therapy in patients at high risk of fractures.

Evaluation of PTH deprivation effects on anxiety and stress response in a rat model of Chronic Post-Surgical Hypoparathyroidism

Federica Saponaro[1], Grazia Chiellini[1], Cristina Dettori[1], Marco Scalese[2] & Francesca Ronca[1]
[1]University of Pisa, Department of Pathology, Pisa, Italy; [2]Institute of Clinical Physiology, National Council of Research, Pisa, Italy

Introduction
Hypoparathyroidism (HypoPT) is a rare endocrine disease which is characterized by hypocalcaemia and undetectable or inappropriately low serum parathyroid hormone (PTH). Post-surgical HypoPT (PS-HypoPT) is the most common cause, caused by accidental parathyroid removal/injury during neck surgery. From a neuropsychological standpoint, patients with PS-HypoPT present cognitive and neuropsychological symptoms: the more plausible pathophysiological mechanism resides in a direct effect of PTH in the central nervous system (CNS), since PTH Receptor 1 (PTHR1) and more abundantly PTH Receptor 2 (PTHR2) have been shown to be present in many areas of brain. However, these mechanisms are still not completely elucidated. The aim of this study was to evaluate the effects of PTH deprivation on CNS in an animal model (rat) of post-surgical hypoparathyroidism, by a cognitive/behavioural assessment approach.
Methods
A rat model (Sprague Dawley) of PS-HypoPT was obtained by the surgical removal of parathyroids at 5 weeks of age and treated with gluconate calcium 1% in drinking water to maintain normocalcemia. An experimental group of 20 PS-HypoPT rats and 20 healthy Sprague Dawley controls (WT) shamed operated, underwent biochemical testing (serum calcium) and behavioural testing namely Open Field and Elevated Plus Maze. Open Field (OF) provides information about locomotion and anxiety-related behaviours: when rats are placed into an open field, the higher is the "anxiety" level, the higher the proportion of time spent close to the wall. Elevated Plus Maze (EPM) assesses anxiety-related behaviours in rodents to explore open, unprotected spaces, compared to dark, enclosed spaces. The higher the "anxiety" levels, the lower the proportion of explorations in the open spaces in favour of the dark spaces.
Results
In OF test, the time and distance spent in the zone of interest (centre of arena) were significantly lower in the PTx group, compared with WT ($P<0.01$ and $P<0.01$). These data suggest a higher level of anxiety in PTx animals. In the EPM experiment the time spent in the close arm was significantly higher in the PTx group, compared with WT ($P<0.01$, Figure 6). This suggests a higher level of anxiety and stress in PTx group.
Conclusions
Animal model of PS-Hypo shows a higher level of anxiety and stress compared to controls. The model resembles the condition of patients with PS-Hypo. This condition could be related to the direct effect of PTH deprivation in brain in PSHypo. Further study are ongoing to highlight the molecular mechanisms.

Clinical application of vitamin D metabolites measurement using LC-MS/MS – a case of a patient with persistent hypercalcemia and two pathogenic mutations in CYP24A1 gene and parathyroid adenoma

Dorota Leszczynska[1], Alicja Szatko[1], Julia Latocha[2], Magdalena Kochman[1], Maria Duchnowska[1], Anna Wójcicka[3], Waldemar Misiorowski[1], Wojciech Zgliczyński[1] & Piotr Glinicki[1]
[1]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [2]Centre of Postgraduate Medical Education, Students' Scientific Group affiliated to the Department of Endocrinology, Warsaw, Poland; [3]Warsaw Genomics, Warsaw, Poland

Introduction
24-hydroxylase, encoded by a CYP24A1 gene, is a crucial enzyme entailed in catabolism of vitamin D. Loss-of-function mutations of CYP24A1 result in hypercalcemia, not adequately concomitant high levels of 1,25(OH)2D and low PTH levels. The variety of clinical manifestations depends on age – mutations can lead to fatal infantile hypercalcemia among neonates (typically precipitated by supplementation of vitamin D), whereas adults' symptoms are usually mild. The differential diagnosis of PTH-independent hypercalcemia includes i.a. malignancy and granulomatous diseases.
Case Presentation
We report a case of a 58-year-old woman with a history of parathyroid adenoma leading to hypercalcemia, hypercalciuria and unsuppressed PTH concentration. Preoperatively, in ultrasonography, technetium-99m (99mTc) sestamibi scintigraphy, followed by biopsy, the suspected mass adjoining the upper pole of left lobe of thyroid gland was found. The patient underwent parathyroidectomy (histopathology report confirmed parathyroid adenoma), significant decrease in serum calcium was observed. Three years after the parathyroidectomy, the patient was admitted to the Department of Endocrinology because of hypercalcemia, and recurrent primary hyperparathyroidism was suspected. However, the results of biochemical tests (calcium 2.88 mmol/l (reference range 2.15-2.50 mmol/l)), PTH (intact) 7.75 pg/ml (reference range 15–65 pg/ml) and slightly elevated 1,25(OH) 2D serum concentration (90.6 pg/ml (reference range 25-86.5 pg/ml)) demonstrated PTH-independent hypercalcemia. Further investigation required the exclusion of the most common causes of PTH-independent hypercalcemia (granulomatous diseases, hypercalcemia of malignancy, vitamin D intoxication) - the results of diagnostic tests did not reveal the cause of elevated calcium concentration. Subsequently, vitamin D metabolites were measured using liquid chromatography with tandem mass spectrometry (LC/MS-MS), revealing high 25(OH)D3 (72.62 ng/ml), low 24,25(OH)2D3 (0.09 ng/ml) and elevated 25(OH) D3 / 24,25(OH)2D3 ratio (806.9 (reference range 7.0-23.6)) – suggesting the defect in vitamin D catabolism. The molecular analysis of CYP24A1 gene was conducted using Next-Generation Sequencing (NGS), two pathogenic variants were identified p.(Arg396Trp) and p.(Glu143del) (rs114368325 and rs777676129).
Conclusions
Presented case shows the importance of accurate clinical evaluation of hypercalcemia. Rarely multiple causes of hypercalcemia may coexist, which complicates the diagnostic process. In patients with PTH-independent hypercalcemia, the measurement of vitamin D metabolites using LC-MS/MS analytical technique, followed by genetic testing (e.g. NGS technology), may help to identify carriers of CYP24A1 mutations.

Background
Individuals with hypoparathyroidism often experience a range of symptoms associated with reduced health-related quality of life (HRQoL) and work productivity. Conventional therapy aims to alleviate hypocalcemia and acute symptoms but fails to restore normal parathyroid hormone (PTH) physiology or improve HRQoL. In the PaTHway trial, 79% of participants treated with TransCon PTH vs. 5% placebo ($P<0.0001$) met the primary efficacy endpoint (normal serum calcium and independence from conventional therapy [no active vitamin D and $\leq$ 600 mg/day of calcium]) (Khan AA *et al*, JBMR, 2022). This analysis assessed the impact of TransCon PTH on hypoparathyroidism-related symptoms, functioning, and well-being; HRQoL; and work limitations in the PaTHway trial.
Methods
PaTHway is a randomized, double-blind, placebo-controlled, 26-week phase 3 trial designed to evaluate the efficacy, safety, and tolerability of TransCon PTH. Patient-Reported Outcomes were collected at baseline and Weeks 10, 20, and 26. Descriptive statistics are reported for the Hypoparathyroidism Patient Experience Scale (HPES), 36-Item Short-Form Health Survey (SF-36), and Work Limitations Questionnaire (WLQ). Higher scores are associated with improved HRQoL (SF-36) but greater symptom frequency/impact (HPES) and more self-reported difficulties at work (WLQ).

Results
Overall, 82 participants received at least one dose of study drug, and 79 completed blinded treatment (60 TransCon PTH, 19 placebo). The TransCon PTH group had greater improvements in all mean HPES scores than placebo. With 26 weeks of TransCon PTH treatment, mean HPES-Symptom cognitive and physical domain scores improved from 39.3 and 41.4 at baseline to 18.1 and 21.6, respectively. Mean HPES-Impact daily life, psychological well-being, physical functioning, and social life and relationship domain scores ranged from 25.2-35.9 at baseline and improved to 11.4-17.3. With TransCon PTH, but not placebo, all mean SF-36 subscale scores improved from baseline to Week 26; mean physical functioning, role emotional, role physical, vitality, social function, and bodily pain scores improved into the normative range for the United States general population from Week 10 through 26. Employed participants treated with TransCon PTH had lower mean WLQ scores at Weeks 10, 20, and 26 than placebo. With TransCon PTH, mean WLQ scores improved from 32.0 at baseline to 11.3 at Week 26 for time management, 27.8 to 8.9 for mental-interpersonal demands, 31.2 to 9.9 for output tasks, and 20.4 to 9.0 for physical tasks.
Conclusions
TransCon PTH reduced hypoparathyroidism-related symptoms and self-reported difficulties at work and increased functioning and well-being. Longitudinal improvements in HRQoL were also seen with TransCon PTH treatment.

In vitro study of rapid non-genomic effects of 25(OH)D3 in preosteoblastic cells

Simone Donati[1], Gaia Palmini[1], Cinzia Aurilia[1], Irene Falsetti[1], Francesca Marini[2], Gianna Galli[1], Roberto Zonefrati[2], Teresa Iantomasi[1] & Maria Luisa Brandi[2]
[1]University of Florence, Department of Experimental and Clinical Biomedical Sciences, Florence, Italy; [2]Fondazione Italiana Ricerca Sulle Malattie dell'Osso (F.I.R.M.O Onlus), Florence, Italy

Background
Calcifediol ($25(OH)D_3$), the major circulating form and the direct precursor of the biologically active form of vitamin D, has been identified as an agonist ligand for vitamin D receptor (VDR) with anti-proliferative effects and gene regulatory function despite having a lower receptor affinity respect than the biologically active form of vitamin D_3. In fact, recent studies have suggested that $25(OH)D_3$ can regulate gene expression by direct binding to VDR. So, considering this, our purpose has been to investigate whether $25(OH)D_3$ could be able to activate rapid non-genomic pathways, similarly to what was observed with the biologically active form of vitamin D. In this light, we analyzed *in vitro* the Ca^{2+} intracellular following exposure to 10^{-5} M $25(OH)D_3$ in mesenchymal stem cells (MSCs) derived from human adipose tissue (hADMSCs), which had been previously described as excellent cell model systems for studying the hormonal effects of $1\alpha,25(OH)_2D_3$.
Methods
hADMSC lines were established from small subcutaneous adipose tissue biopsies. Changes in intracellular Ca^{2+} concentration on hADMSCs exposed to 10^{-5} M of $25(OH)D_3$ were determined in Fluo-4-AM loaded cells and evaluated by Laser Scanning Confocal Microscopy (LSCM). As a positive control, cells were treated with 10^{-5} M calcium ionophore A23187. Statistical analysis was carried out by ANOVA followed by Bonferroni's test with predefined experimentwise (αT) = 0.05.
Results
We showed that 4 cells, one for each cell line tested, exposed to 10^{-5} M calcium ionophore A23187 as well as 17 cells treated with 10^{-5} M $25(OH)D_3$ responded positively with a significant increase of intracellular Ca^{2+} levels. In particular, three of them reached a maximum comparable to what was achieved in cells treated with 10^{-5} M calcium ionophore A23187, whereas the other cells showed a weaker response. The average ratio of the maximum fluorescence intensity changes of the cells treated with $25(OH)D_3$ and calcium ionophore compared to the baseline fluorescence was 356% and 473%, respectively.
Conclusions and future perspective
Our data demonstrated for the first time the ability of $25(OH)D_3$ to trigger rapid non-genomic effects like other steroid hormones, such as the increase in intracellular Ca^{2+} levels in hADMSCs. Nowadays, we are profiling experiments on the same cell model to study whether calcifediol could be able also to stimulate rapid cAMP signaling pathway. These findings could lead to a greater vitamin D endocrine system understanding, paving the way for the identification of novel therapeutical targets.

Bone mineral density in children and adolescents with Cystic Fibrosis

Gizem Tamer[1,2], Hubertus Gerardus Maria Arets[1], Cornelis Kors van der Ent[1], Hanneke Margo van Santen[2] & Hetty Jacoba van der Kamp[2]
[1]Wilhelmina Kinderziekenhuis (WKZ), Paediatric Pulmonology, Utrecht, Netherlands; [2]Wilhelmina Kinderziekenhuis (WKZ), Paediatric Endocrinology, Utrecht, Netherlands

Background
Bone health can be affected in (young) adults with Cystic Fibrosis (CF) due to different risk factors in childhood. We aimed to analyze the prevalence of low bone mineral density (BMD) during childhood in patients with CF, its risk factors and course in time.
Methods
A longitudinal prospective cohort study was performed in children with CF aged 8-18. Anthropometric, DEXA scans and endocrine data were collected. BMD z-scores were adjusted for height. Low BMD and too low BMD scores were defined as a z-score $<$-1 and $<$-2 respectively. We analyzed if BMD was associated to body mass index standard deviation score (BMI-SDS), vitamin D status, lung function (FEV1%) and cystic fibrosis related diabetes. Patients on corticosteroids in the last 6 months were excluded.
Results
One hundred-and-two children with CF (50 boys, 52 girls) were included, with a mean age of 13.0 $\pm$ 3.23 yrs. The mean BMI z-score was -0.04 $\pm$ 1.10 and mean FEV1%-value was 85.7 $\pm$ 18.5. Mean adjusted BMD z-scores for lumbar spine (LS) and total body less head (TBLH) were 0.05 $\pm$ 1.13 and 0.14 $\pm$ 1.08 respectively, with no differences between sexes. Eighteen children (17.6%) had (too) low LS BMD, and 17 (16.7%) had (too) low TBLH BMD z-scores. In multiple linear regression analysis, TBLH-BMD z-scores were positively associated to BMI-SDS and FEV1%-values ($P=0.004$) and LS-BMD z-scores were positively associated to BMI-SDS ($P=0.007$). Forty-nine children (22 boys, 27 girls) had a second DXA-scan on average 2.15 $\pm$ 0.37 years after the 1st scan at a mean age of 14.9 $\pm$ 3.09 yrs. A significant mean decrease was seen in TBLH BMD-z score of -0.70 $\pm$ 0.76 ($P<0.001$). After multiple testing, LS BMD z-scores were positively associated to BMI-SDS ($P=0.003$).
Conclusion
Most children with CF have normal BMD, however BMD seems to decrease in time. To ensure optimal bone health, nutritional status must be monitored especially in children with decreased lung function.

Plasma Sodium Increase Is Associated With an Increase in Bone Formation in Outpatients With Chronic SIAD - A Predefined Secondary Analysis of the SANDx Trial

Sophie Monnerat, Julie Refardt, Laura Potasso, Christian Meier & Mirjam Christ-Crain
University Hospital Basel, Department of Endocrinology, Diabetology and Metabolism, Basel, Switzerland

Introduction
Hyponatremia is the most common electrolyte disorder encountered in clinical practice and is associated with increased mortality and morbidity, including an increased risk for osteoporosis and fragility fractures. Preclinical studies suggest osteoclast upregulation whereas a clinical study showed improved osteoblast fuction after hyponatremia normalization in hospitalized patients with SIAD.
Methods
This is a secondary analysis of a double-blind, crossover, placebo-controlled trial investigating the effect of 4-week treatment with empagliflozin 25mg/day as compared to placebo in outpatients with chronic SIAD (SANDx Trial, NCT03202667). The primary objective was to investigate the relationship between the change in bone formation index (BFI), defined as PINP/CTX, and the change in plasma sodium levels. Secondary objectives included the relationship between the change in the osteoblasts markers procollagen type 1 N (P1NP) and osteocalcin and the osteoclasts markers C-telopeptide crosslink (CTX), and the change in plasma sodium levels over the treatment periods. Linear mixed models were built with the bone markers as dependent variables, patients as random-effect and the following fixed-effects: week of treatment, serum cortisol, 25-OH vitamin D and bone marker concentration at baseline, age, gender and smoking status. Spearman correlation coefficients between bone markers and sodium levels were calculated.
Results
Six out of the 11 outpatients with a chronic SIAD were female (median [IQR] age 73 years [66, 78]). A sodium increase of 1 mmol/l was associated with an increase

of 5.21 in BFI (95%-CI: 1.41, 9.00, $P=0.013$) and with an increase of 1.48 ug/l in P1NP (95%-CI: 0.26, 2.62, $P=0.03$). Plasma sodium concentration was not associated with a change in osteocalcin ($\beta = 0.32$; 95%-CI: -0.09, 0.72, $P=0.18$), nor with a change in CTX ($\beta = 0.003$; 95%-CI: -0.008, 0.014, $P=0.324$). The effect of sodium on bone markers was independent from empagliflozin. Changes in plasma sodium were positively correlated with changes in BFI and P1NP (BFI:$\rho = 0.55$, $P<0.001$; P1NP:$\rho = 0.45$, $P=0.004$) but not with CTX and osteocalcin (CTX:$\rho = -0.21$, $P=0.184$; Osteocalcin:$\rho = 0.34$, $P=0.149$).

Conclusion

An increase in plasma sodium levels in outpatients with chronic SIAD was associated with an increase in bone formation index (P1NP/CTX), which was triggered by an increase in the osteoblast marker P1NP. This supports the importance of treating hyponatremia, particularly in older adults in whom chronic hyponatremia is also associated with falls.

Heart rate and blood pressure, but not pulse wave velocity, are higher among adults with hereditary hypophosphatemia compared to healthy controls: a cross-sectional study

Rasmus Espersen[1,2], Signe Beck-Nielsen[3,4] & Lars Rejnmark[2,4]
[1]Regional Hospital Central Jutland, The Emergency Department, Viborg, Denmark; [2]Aarhus University Hospital, Department of Endocrinology and Internal Medicine, Aarhus, Denmark; [3]Aarhus University Hospital, Centre for Rare Diseases, Aarhus, Denmark; [4]Aarhus University, Department of Clinical Medicine, Aarhus, Denmark

Introduction

Hereditary hypophosphatemia (HH) are rare diseases, characterized by increased levels of fibroblast growth factor 23 (FGF23), excessive renal phosphate wasting and inappropriately low 1,25-dihydroxy-vitamin D causing hypophosphatemia. In children, the diseases manifest as rickets and osteomalacia, in adults only osteomalacia. Studies in cardiovascular risk among patients with HH are few and inconclusive. Some have found left ventricular hypertrophy in children and adolescents with X-linked hypophosphatemic rickets, but not in adults with HH. Isolated conditions with increased blood levels of FGF23 are not associated with increased risk of cardiovascular disease (CVD). However, complications to conventional medical treatment with phosphate and active vitamin D such as nephrocalcinosis and hyperparathyroidism are associated with increased cardiovascular risk. Pulse-wave velocity (PWV) is a measurement of arterial stiffness being an independent predictor cardiovascular risk.

Materials and methods

We performed a cross-sectional study of 50 adults with HH and 43 age- and gender-matched controls. Heart rate (HR), blood pressure (BP) and PWV were evaluated in the morning with the participants in a fasting state using the SphygmoCor® XCEL (AtCor Medical, Sydney, Australia). According to guidelines, PWV multiplied by 0.8 is reported.

Results

Mean systolic BP was significantly higher in HH (128, 95%CI: 124-133 mmHg) vs controls (118, 95% CI: 114-121 mmHg), $P<0.001$, as was diastolic BP: HH (75, 95%CI: 72-78 mmHg) vs controls (69, 95%CI: 67-72 mmHg), $P=0.003$. HR was significantly higher in HH (64, 95%CI: 61-66 s^{-1}) vs controls (59, 95%CI: 57-61 s^{-1}), $P= 0.008$. There was no statistically significant difference between groups for PWV: HH (6.7, 95%CI: 6.2-7.1 m/s) vs controls (6.2, 95%CI: 5.7-6.7 m/s), $P=0.13$.

Conclusion

In adults with HH, we found a significantly higher HR as well as a higher systolic and diastolic BP, which is associated with an increased risk for hypertension and CVD. Although PWV was not increased, our results suggest a higher risk for the development of hypertension and thereby CVD. We suggest measurements of BP and HR as routine workups by doctors taking care of adults with HH. Further studies are needed to explore eventual risks for hypertension and CVD in HH.

Two cases of parathyromatosis in patients with recurrent primary hyperparathyroidism

Magdalena Matejkova Behanova[1], Petr Libánský[2], Markéta Vaculová[2], Renata Chmelová[3], Kateřina Personová[1], Josef Vcelak[4] & Petr Vlcek[1]
[1]University Hospital Motol Prague, Clinic for Nuclear Medicine and Endocrinology, Prague, Czech Republic; [2]University Hospital Motol Prague, 3rd Department of Surgery, Prague, Czech Republic; [3]University Hospital Motol, Department of Pathology and Molecular Medicine, Prague, Czech Republic; [4]Institute of Endocrinology, Department of Molecular Endocrinology, Prague, Czech Republic

Introduction

Parathyromatosis is a rare cause of recurrent hyperparathyroidism defined as small nodules of hyperfunctioning parathyroid tissue in the soft tissues of the neck or mediastinum. The most common cause is probably the implantation of parathyroid cells into surrounding tissue during surgery and the risk of parathyromatosis increases with repeated parathyroid surgery. There is an overlap in the histologic features in parathyromatosis, atypical adenoma, and parathyroid carcinoma. Parathyromatosis still remains a difficult diagnostic a therapeutic task. We describe two cases of parathyromatosis in reccurent primary hyperparathyroidism. Both cases were negative in genetic testing for mutations in *MEN1*, *RET*, *CASR* and 14 other genes associated with hereditary parathyroid diseases.

Case Report 1

64 years old woman was referred to the third parathyroid surgery for recurrent hyperparathyroidism. Laboratory: calcium 2,8 mmol/l, PTH 12,92 pmol/l (normal range 1,3 - 7,6), normal renal function. Previous surgery: 1. parathyroidectomy of one left parathyroid gland in 2012, 2. bilateral neck exploration with removal of the left cervical thymic tissue (containing parathyroid adenoma) and the fragment tissue (supposed parathyroid adenoma) from the right side in 5/2021. The fragment tissue from the right side consisted of adipose tissue with two foci of parathyroid tissue. The third surgery represented unilateral right cervical exploration with block cervical subcutaneous tissue removal and removal of the lower right thyroid pole in 10/2022. Histopathology: nodular parathyroid tissue with smooth noninfiltrative borders, without capsules, no vascular invasion, without mitotic activity – corresponding to parathyromatosis.

Case Report 2

52 years old women was referred to the fourth parathyroid surgery for recurrent hyperparathyroidism. Laboratory: calcium 2,79 mmol/l, PTH 24,6 pmol/l (normal range 1,3 - 7,6), normal renal function. Previous surgery: 1. total thyroidectomy + left upper parathyroid removal in 2008, 2. focused left parathyroid removal in 2019, 3. parathyroidectomy of 2 adenomas (both right) and pretracheal thymic tissue removal with parathyroid adenoma and other fragment of parathyroid tissue in 1/2021. The fourth surgery represented unilateral right exploration with removal of one lower right adenoma and pretracheal adipose tissue resection in 2/2022. Histopathology: noduli of parathyroid tissue corresponding to hyperplasia or parathyromatosis.

Conclusion

Our two cases represent parathyromatosis after repeated surgery. Both of them were referred for reoperation with only mild hypercalcemia. Excesive repeated parathyroid surgery should be carefully considered. Supported by Ministry of Health Czech Republic - DRO (Institute of Endocrinology - EÚ, 00023761)

Impact of a single oral bolus of 120,000 IU of cholecalciferol on vitamin D metabolites in the elderly: the results of randomized open study

Dorota Leszczynska[1], Alicja Szatko[1], Konrad Kowalski[2], Dorota Raczkiewicz[3], Magdalena Ostrowska[1], Waldemar Misiorowski[1], Wojciech Zgliczyński[1] & Piotr Glinicki[1]
[1]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [2]Masdiag Laboratory, Warsaw, Poland; [3]Centre of Postgraduate Medical Education, Department of Medical Statistics, School of Public Health, Warsaw, Poland

Background

Vitamin D is a dietary micronutrient responsible for calcium and phosphorus metabolism and multiple extraskeletal actions. The assessment of vitamin D status is commonly based on measurement of 25(OH)D total concentration in serum. However, the usage of LC-MS/MS analytical technique allows to reliably assess a panel of vitamin D metabolites in serum or plasma, which may help to investigate the metabolic paths of vitamin D, especially in populations at risk of deficiency.

Methods

A randomized, two-arms, open study was conducted on 58 patients (28 female and 30 male; aged from 61 to 96 years old). The primary aim was to assess the effects of a single, high, oral dose of vitamin D_3 (120.000 IU) on serum 25(OH)D_3, 25(OH)D_2, 24,25(OH)$_2D_3$, 3-epi-25(OH)D_3 and 1,25(OH)$_2D_3$ concentrations (measured by LC-MS/MS), calculated 24,25(OH)$_2D_3$/25(OH)D_3 ratio and 25(OH)D_3/3-epi-25(OH)D_3 ratio at baseline, 3 days and 7 days after

administration, compared to control group. The secondary aim was assessment of influence of percentage of fat tissue on serum metabolites of vitamin D and their changes after bolus dose.
Results
56.6% study group attained a serum $25(OH)D_3$ concentration >30 ng/ml. All subjects, except for one patient achieved a serum $25(OH)D_3$ concentration >20 ng/ml after administration. No one exceed reference value of vitamin D (30–50 ng/ml). Among participants who received vitamin D_3 there were significant increase in $25(OH)D_3$, 3-epi-$25(OH)D_3$, $1,25(OH)_2D_3$, $24,25(OH)_2D_3$ on 3rd day after administration. $24,25(OH)_2D_3$ concentration gradually grew, achieving the highest concentration on 7th day. The percentage increase of $25(OH)D_3$ was negatively correlated with baseline $25(OH)D_3$ ($r=$-0.688, $P = 0.001$). Positive correlation between percentage increase in $25(OH)D_3$ and a percentage increase serum concentration of $24,25(OH)_2D_3$ ($r=0.954$, $P< 0.001$), 3-epi-$25(OH)D_3$ ($r=8.03$, $P<0.001$) and $1,25(OH)_2D_3$ ($r=0.789$, $P<0.001$) were found. None of the study participants developed hypercalcemia. The baseline concentration of analyzed metabolites of vitamin D in serum and their percentage increase were neither dependent on BMI nor percentage of fat tissue.
Conclusions
High dose of vitamin D rapidly increases $25(OH)D_3$ concentration in the elderly patients. The response to the bolus of vitamin D includes activation of 3-epimerase, followed by production of $24,25(OH)_2D_3$, which protects from excessive increase of active form of vitamin D.

No effects of high-dose vitamin D supplementation on white blood cell count, CRP and risk of upper respiratory tract infections in infertile men – Secondary analyses from a randomized clinical trial

Gustav Wall-Gremstrup[1], Rune Holt[2], Anders Juul[3,4,5], Niels Joergensen[6,7] & Martin Blomberg Jensen[2,8]
[1]Copenhagen University Hospital-Rigshospitalet,, Group of Skeletal, Mineral and Gonadal Endocrinology, Department of Growth and Reproduction, København, Denmark; [2]Copenhagen University Hospital-Rigshospitalet, Group of Skeletal, Mineral and Gonadal Endocrinology, Department of Growth and Reproduction, Denmark; [3]Copenhagen University Hospital – Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [4]Copenhagen University Hospital – Rigshospitalet, International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Denmark; [5]University of Copenhagen, Department of Clinical Medicine, Denmark; [6]Copenhagen University Hospital – Rigshospitalet, Department of Growth and Reproduction, Denmark; [7]Copenhagen University Hospital – Rigshospitalet, International Center for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Denmark; [8]Harvard University, Division of Bone and Mineral Research, Boston, United States

Background
vitamin D has been associated with different beneficial effects on the immune system. The vitamin D activating (CYP2R1 and CYP27B1) and inactivating (CYP24A1) enzymes, including the vitamin D receptor (VDR) are expressed in several types of white blood cells (WBC). A range of studies have explored whether vitamin D positively affects risk of and severity of respiratory tract infections such as tuberculosis, influenza, cold and COVID-19.
Objective
To determine the effect of high-dose vitamin D supplementation on WBC count, CRP and self-reported upper respiratory tract infections in infertile men.
Method
A single-center, double-blinded, randomized, placebo-controlled clinical trial (NCT01304927). Sample of 307 infertile men. The active group ($n=151$) initially received 300,000 IU cholecalciferol followed by 1400 IU + 500 mg calcium daily for 150 days, compared to the placebo group ($n=156$). The primary endpoint was to assess the effect on semen quality, which has previously been reported. The effects on WBCs (Leucocytes, neutrophile, basophile, eosinophile, lymphocytes and monocytes), CRP and self-reported symptoms of cold, influenza and fever were secondary endpoints.
Results
At baseline serum $25OHD_3$ were negatively correlated with leucocyte (* $r=$-.207; $P<0.001$), neutrophil (* $r=$-.151; $P=0.009$), eosinophil (* $r=$-.158; $P=0.007$), lymphocyte (* $r=$-.191; $P<0.001$) and monocyte (* $r=$-.160; $P=0.006$) counts. Moreover, at baseline men with vitamin D insufficiency (serum $25OHD \leq 50$ nmol/l) had significant higher eosinophile, lymphocytes and monocytes compared to men with vitamin D sufficiency (serum $25OHD > 50$ nmol/l) (0.22 x 10^9/l vs. 0.19 x 10^9/l; $P=0.038$, 2.1 x 10^9/l vs. 2.0 x 10^9/l; $P=0.046$ and 0.48 x 10^9/l vs. 0.44 x 10^9/l; $P=0.024$, respectively). After the vitamin D intervention there were no differences in WBC count, CRP or number self-reported upper respiratory tract infections (25% vs 20%, $P=0.062$) between men receiving vitamin D supplementation compared to men receiving placebo. Furthermore, a predefined subgroup analysis of men with vitamin D insufficiency (serum $25OHD \leq 50$ nmol/l), showed no difference in WBC count, CRP or self-reported respiratory infections between men receiving vitamin D supplementation compared to men receiving placebo.
*r: Pearson correlations coefficient.
Conclusions
High-dose vitamin D supplementation did not alter WBCs, CRP or risk of upper respiratory tract infections. However, serum $25OHD_3$ were negatively correlated with the majority of WBC, which indicates that 25hydroxylation of vitamin D may be linked with inflammation and WBC turnover.

Vertebral fractures in acromegaly

Madalina Sorohan[1,2], Ionela Baciu[1,2], Simona Galoiu[1,2], Andra Caragheorgheopol[2], Carmen Iordachescu[2] & Catalina Poiana[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Bucure?ti, Romania; [2]C.I. Parhon National Institute of Endocrinology, Bucure?ti, Romania

Introduction
Acromegalic bone disease is characterized by an increased prevalence of fragility vertebral fractures (VFs). However, an effective, non-invasive and cost-efficient imaging technique that can diagnose early bone alterations in this category of patients is yet to found. The use of bone mineral density (BMD) is not as useful as in other causes of osteoporosis as excess GH leads to specific microarchitectural alteration of trabecular bone, which don't translate to an important decrease in BMD. Trabecular bone score (TBS) is a more novel technique proposed for use in these patients.
Methods
We performed a cross-sectional study on 71 acromegalic patients, with either controlled, cured or uncontrolled disease. The turnover markers evaluated for both groups were alkaline phosphatase, osteocalcin, the C-terminal telopeptide of type I collagen and total procollagen type 1 amino-terminal propeptide (P1NP) and the imaging techniques performed were dual x-ray absorptiometry to evaluate BMD, T and Z scores of the lumbar spine (LS), femoral neck (FN) and total hip (TH), TBS and x-ray scans of the thoracic and lumbar spine.
Results
The patients had a prevalence of moderate of severe VFs of 29.6%, mild fractured not having been taken into consideration. Acromegaly subjects with and without hypogonadism had no significant differences in terms of BMD (LS: 1.07 ± 0.176 vs. 1.129 ± 0.23 g/cm2, $P=0.229$, FN: 0.999 ± 0.151 vs. 0.954 ± 0.124 g/cm2, $P=0.198$, TH: 1.03 ± 0.148 vs. 0.996 ± 0.148 g/cm2, $P=0.349$), TBS (1.182 ± 0.148 vs. 1.141 ± 0.183, $P=0.308$), or VFs prevalence (31.81% vs. 25.92%, $P=0.597$). Acromegaly patients with VFs had significantly lower osteocalcin and P1NP levels than those without VFs, as well as lower BMD at all skeletal sites (LS: 1.015 ± 0.18 vs. 1.124 ± 0.199 g/cm2, $P=0.034$; FN: 0.904 ± 0.117 vs. 1.015 ± 0.14 g/cm2, $P=0.002$; TH: 0.933 ± 0.13 vs. 1.052 ± 0.141 g/cm2, $P=0.001$). Nonetheless, TBS did not present significant differences in fractured compared to non-fractured patients (1.131 ± 0.171 vs. 1.181 ± 0.158, $P=0.238$). Furthermore, males and females with acromegaly did not have statistically significant differences in BMD, TBS of VFs frequency. Also, disease activity did not influence BMD, TBS or VFs prevalence.
Conclusions
According to our results, vertebral fractures are frequent in acromegaly, with a prevalence of around 30%, and are associated with lower BMD but not with TBS. Moreover, the presence of hypogonadism does not influence BMD, TBS or VFs prevalence in these patients and neither do gender or disease activity.

Association of Dietary Intakes of Calcium/Phosphorous with Biochemical Osteomalacia and its Components

Al-Daghri Nasser[1], Shaun Sabico[1], Kaiser Wani[1], Syed Danish Hussain[1], Sobhy Yakout[1], Naji Aljohani[2], Suma Uday[3] & Wolfgang Högler[4]
[1]King Saud University, Biochemistry, RIyadh, Saudi Arabia; [2]King Fahad Medical City, Medicine, Riyadh, Saudi Arabia; [3]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom; [4]Johanned Kepler University, Pediatrics and Adolescent Medicine, Linz, Austria

Background
Our previous study revealed a high prevalence of abnormal mineralization markers namely low 25 hydroxyvitamin D (47.9%); high serum alkaline phosphatase (3.7%) and low calcium-phosphate product (9.8%) suggestive of biochemical signs of osteomalacia (OM, defined as any two of these risk factors). OM was more prevalent in girls (11.2%) compared to boys (5.0%). In this follow-up study, we aimed to evaluate if biochemical OM was associated with low intakes of calcium and phosphorous.
Methods
Saudi adolescents ($n=2938$, 57.8% girls), aged 12-17 years from 60 different secondary and preparatory year schools in Riyadh, Saudi Arabia were included in this study. A dietary recall for daily intakes of nutrients/minerals using a validated computerized food database "ESHA—the Food Processor Nutrition Analysis program" was collected. Compliance to reference daily intake (RDI) was calculated. Fasting blood samples were collected and circulating levels of 25 hydroxyvitamin D, alkaline phosphatase, calcium, phosphate, and C-terminal telopeptide (CTX) were analyzed.
Results
A total of 1703 Saudi adolescents (991 girls, 712 boys) provided the dietary recall data. A major proportion (89.6%, 92.2%) of the participants failed to achieve the RDI of 1000 mg/day and 10 mg/day of dietary calcium and vitamin D respectively. The average daily dietary calcium intake was significantly lower in girls compared to boys (median levels of 294.3 and 345.5 mg/day respectively, $P<0.001$). In contrast, boys reported lower dietary intakes of phosphorous compared to girls ($P<0.01$). Interestingly, no significant correlation in status of biochemical OM or its individual risk factors with dietary calcium intake was found, irrespective of sex. However, circulating 25 hydroxyvitamin D and alkaline phosphatase levels correlated negatively with daily dietary intakes of phosphorous in girls ($r=-0.18$, $P<0.001$) and boys ($r=-0.14$, $P<0.05$) respectively.
Conclusions
This study suggests a need for vitamin D fortification and increased dietary calcium in the diet of Saudi adolescents. The results also show that all adolescents exceeded the RDI for dietary phosphorous but none met the RDI for dietary calcium and vitamin D, and none had sufficient 25 hydroxyvitamin D levels (>50nmol/l). We speculate that the high phosphate diet may somehow compensate for the insufficient supply with calcium and vitamin D. This insufficient supply would otherwise have caused a much higher prevalence of biochemical OM than the 6.2% we observed.

4D-CT parathyroid increases the likelihood of localising parathyroid adenoma (PA) in patients with primary hyperparathyroidism (PHPT) and non-diagnostic Tc99m-Sestamibi + I-123 subtraction scan

May Thin Khine[1], Manish Pandit[2] & Brian Lee[1]
[1]Sandwell and West Birmingham Hospitals NHS Trust, Department of Diabetes, Endocrinology and Lipid Metabolism, Birmingham, United Kingdom; [2]Sandwell and West Birmingham Hospitals NHS Trust, Department of Physics and Nuclear Medicine, Birmingham, United Kingdom

Introduction
Tc99m-Sestamibi + I-123 subtraction using planar and SPECT-CT (SPECT-CT ^{99m}Tc-MIBI parathyroid) is commonly used to investigate primary hyperparathyroidism (PHPT). We previously reported the sensitivity and positive predictive value of 4D CT parathyroid as the second line investigation in patients with non-diagnostic SPECT-CT ^{99m}Tc-MIBI parathyroid (https://www.endocrine-abstracts.org/ea/0041/ea0041ep164). A common cause of indeterminate SPECT-CT ^{99m}Tc-MIBI parathyroid is the confounding factor of multi-nodular goitre or nodules. We have continued to use this investigative modality regarding pre-operative parathyroid adenoma (PA) localisation and informed patients the chance of finding parathyroid lesion in question at surgery. Patients with positive SPECT-CT ^{99m}Tc-MIBI parathyroid were referred without 4D CT parathyroid for surgery as appropriate.
Description of methods/design
We have retrospectively reviewed and analysed our case series of patients with surgically proven PA who had also 4D-CT parathyroid following non-diagnostic ^{99m}Tc-MIBI parathyroid. Demographic data (age, sex, pre and postoperative calcium/PTH) were presented as descriptive statistics. Histopathology report of surgical specimens was also verified. Sensitivity and specificity of 4D-CT was calculated with surgically proven PA as the reference standard.
Results
A total of 13 patients had non-diagnostic ^{99m}Tc-MIBI parathyroid for PHPT; 10 had positive 4D-CT parathyroid (9 confirmed PA or hyperplasia, 1 normal parathyroid tissue following surgery). 3 had normal 4D-CT parathyroid (2 confirmed PA and 1 histology showed normal parathyroid tissue). In patients with surgically proven PA, 4D-CT parathyroid performed pre-operatively demonstrated a sensitivity of 82% and a positive predictive value of 90%.
Conclusion
In our case series of patients with non-diagnostic ^{99m}Tc-MIBI parathyroid for investigation of PHPT, 4D-CT parathyroid demonstrated a consistent diagnostic value for pre-operative evaluation. Although the number of cases is small, which may limit the power of this study, it remains the preferred second line investigation of choice with high sensitivity and predictive value that allows accurate PA localisation for parathyroid surgery. With this imaging modality, both patients and the operating surgeon can be better informed of the high likelihood of finding of PA prior to surgery.

Keywords
Hyperparathyroidism, 4D-CT parathyroid, calcium metabolism.

Polymorphisms in genes related to iron metabolism and DNA methylation and their interaction with estradiol in susceptibility to osteoporosis in postmenopausal women

Laura Aguiar[1,2,3], Joana Ferreira[1,2,3], Ana Paula Barbosa[3,4], Mário Rui Mascarenhas[3,4], Paula Faustino[3,5], Ângela Inácio[1,2,3] & Manuel Bicho[1,2,3]
[1]Instituto de Investigação Científica Bento da Rocha Cabral, Lisbon, Portugal; [2]Laboratório de Genética, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [3]Instituto de Saúde Ambiental, Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; [4]Clínica de Endocrinologia, Diabetes e Metabolismo de Lisboa, Lisbon, Portugal; [5]Departamento de Genética Humana, Instituto Nacional de Saúde Doutor Ricardo Jorge, Lisbon, Portugal

Introduction
Osteoporosis is a multifactorial disease characterized by reduced bone mass and increased risk of fragility fractures. Menopause predisposes women to osteoporosis due to declining estrogen levels. Iron is known to play a relevant role in the development of osteoporosis since iron suppresses osteoblast formation and may also stimulate osteoclast resorption of bone. Also, homocysteine is a known risk factor for osteoporotic fractures and is related to DNA methylation, suggesting that polymorphisms in genes affecting both can increase susceptibility to the development of osteoporosis.
Objectives
This study aimed to investigate the potential implication of genetic polymorphisms in genes related to iron metabolism and DNA methylation and their interaction with estradiol in the development of osteoporosis in a sample of postmenopausal women.
Material and methods
A case-control study was carried out for a sample of 305 Portuguese postmenopausal women, of which 156 had osteoporosis and 149 had normal bone mass. Polymorphic analyses on the *HFE* (H63D and C282Y) and *MTHFR* (C677T) genes were performed by PCR-RFLP. The *Hp* phenotype was determined by polyacrylamide gel electrophoresis. Plasma 17β-estradiol concentration was determined by ELISA. The results were adjusted for age and body mass index. All statistical analyzes were performed using SPSS software, version 24.0.
Results
An association was found between 17β-estradiol and osteoporosis, being a protective effect observed in the presence of higher levels of estradiol [OR (95% CI) = 0.456 (0.215-0.968); $P=0.041$]. Significant differences were found for the *MTHFR* gene, with the TT genotype being protective for osteoporosis [OR (95% CI) = 0.283 (0.097-0.823); $P=0.021$]. Also, women who had the *Hp* 1 allele and higher levels of estradiol had increased protection for osteoporosis [OR (95% CI) = 0.270 (0.081-0.859); $P=0.032$], as well as in the presence of the T allele of the C677T polymorphism and higher levels of estradiol [OR (95% CI) = 0.100 (0.026-0.375); $P=0.001$].
Conclusion
Since these genes are related to iron metabolism and DNA methylation, the results of this study suggest their participation in interaction with estradiol for the development of osteoporosis in postmenopausal women.

Vitamin D status and biomarkers of bone health in diabetic adolescents and children in a multi-ethnic cohort

Clement K. M. Ho[1], Nicole K. L. Lee[2] & Rashida F. Vasanwala[2]
[1]Sengkang General Hospital, Singapore, Singapore; [2]KK Women's and Children's Hospital, Singapore, Singapore

Objectives
This prospective study aimed at investigating (1) the prevalence of vitamin D deficiency and insufficiency in diabetic adolescents and children in a multi-ethnic cohort, and (2) any association between vitamin D status and ethnic background, glycaemic control (HbA1C), biomarkers of metabolic bone health and lipids.
Methodology
Venous blood was drawn from 199 patients with type 1 diabetes (mean age ± SD, 8.2 ± 3.7 years) and 48 patients with type 2 diabetes (mean age ± SD, 12.7 ± 2.7 years) during their outpatient appointments in a tertiary hospital. Vitamin D status was classified according to serum 25-hydroxyvitamin D (25OHD) concentrations as deficient (less than 12 ng/ml), insufficient (12-20 ng/ml) or sufficient (more than 20 ng/ml) (Munns *et al*, 2016). Concentrations of biomarkers were measured on Abbott Alinity (calcium, magnesium, phosphate, alkaline phosphatase, HbA1C, total cholesterol, LDL-cholesterol and HDL-cholesterol) and Beckman Access II [25OHD and parathyroid hormone (PTH)] automated analysers.
Results
Vitamin D insufficiency (25OHD from 12 to 20 ng/ml) was highly prevalent in both type 1 (42%) and type 2 (50%) diabetes patients, whereas vitamin D deficiency (25OHD <12 ng/ml) was detected in 11% of type 1 and 15% of type 2 diabetes patients respectively. Deficiency or insufficiency of vitamin D was particularly common in the Indian and Malay ethnic groups. Patients of Indian extraction had the lowest mean (± SD) serum 25OHD among all four ethnic groups: 16.1 (± 5.6) ng/ml and 14.1 (± 3.8) ng/ml in type 1 and type 2 diabetes patients respectively. Among type 1 patients, Malays had lower 25OHD than the Chinese ($P<0.01$) and Others ($P<0.05$) ethnic groups. Vitamin D deficiency was found to be associated with lower calcium ($P<0.001$) and higher PTH ($P<0.001$) concentrations compared with the sufficiency group (25OHD >20 ng/ml) in type 1 diabetes patients but not in type 2 patients. Concentrations of magnesium, phosphate, alkaline phosphatase, HbA1C, total cholesterol, HDL-cholesterol and LDL-cholesterol were not associated with 25OHD in either of the two types of diabetes patients.
Conclusions
Statistically significant differences in 25OHD concentrations were detected among the four ethnic groups. Ethnicity is a risk factor for vitamin D deficiency in both types of diabetes. Vitamin D deficiency was also associated with biomarkers of poorer metabolic bone health (lower calcium and higher PTH) in type 1 diabetes patients.

A single center experience with opportunistic diagnosis of osteoporosis by artificial intelligence-the time has come
Yehonatan Beeri[1], Gal Ben-Arie[1,2], Ilan Shelef[1,2] & Merav Fraenkel[1,3]
[1]Ben Gurion University of the Negev, Faculty of Health Science, Be'er Sheva, Israel; [2]Soroka Medical Center, Radiology, Be'er Sheva, Israel; [3]Soroka Medical Center, Endocrinolgy, Be'er Sheva, Israel

Background
Osteoporosis (OP) is underdiagnosed and frequently left untreated. CT derived bone mineral density (BMD) and identification of vertebral compression fracture (VCF) on CT done for another indication are 2 new artificial intelligence (AI) based techniques for opportunistic diagnosis of OP. Our aim was to assess the clinical impact of opportunistic diagnosis of OP
Methods
This retrospective study included men and women over age 50, insured by Clalit HMO, who underwent a CT scan for any reason at our institution and were identified by NanoxAI software as having a VCF in one or more vertebrae. Patients were excluded if a radiologist did not confirm the VCF, had a prior diagnosis of a motor vehicle accident (MVA), multiple myeloma, or spinal metastases. CT-derived BMD was calculated using Hounsfield units (HU) and when available results of DXA-BMD were retrieved. Demographic, clinical, and biochemical data including medication purchase were collected from the electronic medical records.
Results
In a 4 months period, one hundred and fifty-one patients with VCF met the inclusion and exclusion criteria, of which only 71 (47%) had a prior diagnosis of osteoporosis. Of the 71 patients with prior diagnosis of OP only 12.7% purchased any OP medication in the 2 years prior to the index CT. Patients without a prior diagnosis of osteoporosis were younger (mean age 73.02 vs. 77.27; $P=0.016$) and had higher rates of male gender (58.8 vs. 26.8%; $P<0.001$). Ethnicity and marital status were similar in both groups as were rates of prior diagnosis of diabetes mellitus and rheumatoid arthritis. Twenty-five-dihydroxy vitamin D levels were higher and alkaline. phosphate levels were lower in patients with a prior diagnosis of OP (69.25 vs. 53.29 nmol/l; $P=0.038$), and (101 vs. 78 U/l; $P=0.025$) respectively. Only 28% of the cohort underwent BMD-DXA scans in the 4 years prior to the index CT; T scores were significantly lower in the group with prior diagnosis of OP in spine (-0.29 vs. -2.22; $P<0.001$), femur neck (-1.66 vs. -2.42; $P=0.009$) and total hip (-1.18 vs. -2.3; $P=0.004$). while CT derived BMD equivalents were similarly low in both groups with VCF irrespective of prior diagnosis of OP (95.05 vs. 90.33 HU $P=0.540$).
Conclusion
Our results highlight the underdiagnosis and the treatment gap in osteoporosis which was significantly higher in men. Routine opportunistic diagnosis of OP by AI is feasible and will contribute to improved diagnosis and treatment of OP.

Primary hyperparathyroidism in an adolescent presenting with genu valgus progressing to extensive bone disease; a case report
Nipun Lakshitha de Silva[1], Mihiran Denagama Jayalath[2], Chaminda Sampath W. K.[3], Ranga Perera[1] & Chandana Karunathilake[1]
[1]Faculty of Medicine, General Sir John Kotelawala Defence University, Clinical Sciences, Colombo, Sri Lanka; [2]University Hospital, General Sir John Kotelawala Defence University, Colombo, Sri Lanka; [3]University Hospital, General Sir John Kotelawala Defence University, Radiology, Colombo, Sri Lanka

Background
Primary hyperparathyroidism which is rare in adolescents presents commonly with non-specific symptoms and systemic complaints. Though there are few reported cases of genu valgus, progression to extensive bone disease with fractures has not been commonly reported. Additionally, hypercalcaemia at the time of presentation was almost universal.
Case presentation
A 12-year-old male had been evaluated for bilateral (left > right) genu valgus and short stature. Serum calcium and phosphate levels had been normal. X-ray of the femora and pelvic bones had not shown additional abnormalities. Valgus deformity progressed despite left femoral plating, and a left distal femoral medial closed wedge osteotomy had been performed at 15 years. Plain imaging at that time had shown localised osteopaenia. At the age of 17 years, he developed multiple fragility fractures of his left hip rendering him wheelchair-bound. Further evaluation revealed a serum PTH level of 2571 (10-65) pg/ml with calcium of 2.82 (2.2-2.6) mmol/l and inorganic phosphate of 1.7 (2.2-4.7) mg/dl. The alkaline phosphatase level was 4785 IU/l and the vitamin D level was 24.96 ng/ml. The lumbar spine DXA scan showed a Z-score of -5.8. Diffusely scattered lytic bone lesions with associated bone expansion suggestive of brown tumours of hyperparathyroid bone disease were noted in the CT scan of humeri. There were no features of rickets. A left parathyroid adenoma measuring 51×30x16 mm was localised. He underwent left parathyroidectomy and left thyroid lobectomy after which his PTH level dropped to 4.03 pg/ml. Histology confirmed a benign parathyroid adenoma. He developed hypocalcaemia which was managed successfully with calcium and alfacalcidol replacement. Three months after the surgery, his alkaline phosphatase level dropped to 380 IU/l.
Conclusions
Cases of adolescents presenting with genu valgus due to primary hyperparathyroidism have been reported before. However, fractures and severe bone disease are exceedingly rare. Initial normocalcaemia, probably related to concomitant vitamin D deficiency could have masked the diagnosis leading to delayed diagnosis and extensive irreversible bone disease. High-index of suspicion and close surveillance is warranted in atypical presentations to avoid a delayed diagnosis of underlying metabolic disease.

CYP24A1 mutation - a rare cause of hypercalcemia and nephrocalcinosis in adulthood
Ludmila Brunerova[1], Ondrej Reeš[1], Veronika Zoubkova[2] & Pavel Votypka[2]
[1]Faculty Hospital Kralovske Vinohrady, Department of Internal Medicine, Prague, Czech Republic; [2]2nd Faculty of Medicine, Charles University and Motol University Hospital, Department of Biology and Medical Genetics, Prague, Czech Republic

Background
CYP24A1 gene encodes the enzyme vitamin D 24-hydroxylase, which converts active vitamin D to inactive metabolites. More than 20 currently described, usually biallelic pathogenic variants of this gene are responsible for idiopathic infantile hypercalcemia manifested typically in childhood (often in newborns)

with hypercalcemia, hypercalciuria and nephrocalcinosis. However, a few patients (mostly with monoallelic heterozygous pathogenic variant) can develop mild symptoms – typically intermittent hypercalcemia dependant on vitamin D exposure together with hypercalciuria and nephrocalcinosis - in adulthood.
Case description
We present the case of 43-year old male patient with hypertension and heterozygous Leiden mutation who was sent to endocrinological examination due to hypoparathyroidism, fluctuating hypercalcemia, hypercalciuria and CKDG2A1 caused probably by nephrocalcinosis. Complete laboratory and imaging methods (parameters of calcium-phosphate metabolism, bone scintigraphy and PET-CT) excluded PTH-related peptide-mediated hypercalcemia and granulomatosis. Genetic analysis of gene encoding calcium-sensing receptor did not show any pathogenic variants. Finally, the genetic analysis of CYP24A1 gene revealed the presence of a novel combination of two heterozygous pathogenic variants: CYP24A1: c. 443T>C p.(Leu148Pro) and c.1186C>T p.(Arg396Trp). Unfortunately, the segregation analysis of the proband's parents in order to confirm trans-heterozygosity (as considered) of the pathogenic variants was not performed due to unwillingness of his parents to undergo the testing.
Conclusion
Differential diagnosis of patients with hypercalciuria, nephrocalcinosis and hypercalcemia related to vitamin D exposure should include CYP24A1 gene mutation. To our knowledge, we were the first to describe this novel combination of two heterozygous pathogenic variants of CYP24A1.

Incidence and clinical correlates of persistent hyperparathyroidism among kidney transplant patients at a tertiary specialty center

Cassie Bustamante & Pepito Dela Pena
National Kidney And Transplant Institute, Internal Medicine, Quezon, Philippines

Background
Secondary hyperparathyroidism (HPT) is a common complication seen in 12-54% of end stage renal disease patients (ESRD), owing to the calcium and phosphorus perturbations in these patients[1]. Successful kidney transplantation (KT) is expected to correct these abnormalities, however, it is not uncommon for hyperparathyroidism to persists post-transplantation [2,4,5,22]. Persistent hyperparathyroidism is associated with significant mortality and morbidity but remains to be underdiagnosed [3,22,23,34]. Local data on the incidence and associated risk factors is still scarce.
Objectives
The aim of this study was to identify the incidence of persistent hyperparathyroidism among kidney transplant recipients. Also, the risk factors for persistent hyperparathyroidism among kidney transplant patients and the effects of kidney transplantation on parathyroid hormone, calcium and phosphorus were identified.
Methods
This is a single center observational cohort study with retrospective chart review. A total of 38 kidney transplant recipients with from July 2017 to September 2019 were included.
Results
The incidence of persistent hyperparathyroidism after kidney transplantation was 60.5%. Kidney transplant recipients had a decrease in intact parathyroid hormone (iPTH) levels by 77.74%. The absolute change was similar between those with vs without persistent hyperparathyroidism. Moreover, serum phosphorus significantly decreased post-transplantation. Patients with pre-kidney transplantation intact parathyroid hormone $>$ 400 pg/ml, pre-kidney transplantation alkaline phosphatase $>$ 290 IU/l, and chronic glomerulonephritis as an etiology of end stage renal disease were identified as risk factors.
Conclusion
Several risk factors for persistent hyperparathyroidism development were identified. High risk patients must be evaluated for parathyroid enlargement and evaluated closely pre- and post-kidney transplantation.

Cardiovascular aspects of primary hyperparathyroidism

Baltagi Myriam, Bchir Najla, Bel Hadj Sliman Chayma, annam benchhida, Zouaoui Chadia & Haroun Ouertani
Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Introduction
Primary hyperparathyroidism (PHPT) is typically characterized by elevated serum calcium associated with elevated or non-suppressed levels of parathyroid hormone (PTH). These biochemical features are both known to affect the cardiovascular (CV) system. There is a conflicting debate regarding the CV manifestations of PHPT. the aim of our study is to evaluate the cardiovascular profile in patients with PHPT.
Methods
We conducted a retrospective descriptive study at the military hospital of Tunis including 32 patients hospitalized for the management of PHPT. Clinical and paraclinical data were collected from medical records.
Results
Our population consisted of 13 men and 19 women with a mean age of 59,4 $\pm$ 13 years old. Hypertension, type 2 diabetes and dyslipidemia were found in respectively 31%, 21% and 6% of cases. Our patients were smokers in 12% of cases. Two patients had a medical history of a stroke and none of the patients had coronaropathy. Sixty-two percent of our patients were overweight and only one patient was obese with a mean body mass index equal to 25,6 $\pm$ 3,6 Kg/m^2. The mean blood pressure was 140/80 mmHg. The mean heart rate was 82 $\pm$ 19 bpm. The electrocardiogram was pathological in 25% of the cases, revealing shortening in the QT interval. All patients had echocardiography. It was pathological in six patients having shown hypertensive cardiopathy in four patients, left ventricular hypertrophy in five patients associated with mitral insufficiency in one patient, and an ischemic heart failure in one patient.
Conclusion
Based on the current evidence, cardiovascular disease is not included among the criteria needed for parathyroidectomy. Thus, long-term longitudinal randomized trials are needed to determine the impact of surgery on cardiovascular diseases and mortality in PHPT.

Case Studies of Pet Colina for Hyperparathyroidism Diagosis

Lidia Urbon Lopez de Linares, Susana Garcia Calvo, Alfonso Maldonado & Manuela Moreira
Hospital San Telmo, Palencia, Spain

Introduction
The diagnosis of hyperparathyroidism can be challenging especially when surgery is mandatory and imaging techniques can not find the adenoma. PEt colina is a non-invasive diagnostic test that creates images of the parathyroid glands and detects abnormal activity. It is increasingly used and especially useful when there are no pathological findings in parathyroid scintigraphy.
Methods
This is a retrospective observational study with data from 10 patients with diagnosis of hyperparathyroidism and no pathological findings in scintigraphy
Results
All the patients had been diagnosed with hyperparathyroidism and had normal parathyroid scintigraphy. The medium PTH level was 174 pg/ ml (48,7) and the medium calcium level was 11,08 mg/ dl (0,87). A parathyroid scintigraphy was performed to all of them without pathological findings. Afterwards they went under a PET colina. The results showed an hyperfunctioning adenoma in 8 of them. After a parathyroidectomy all of them were cured. In 2 patients there were no findings.
Conclusion
Although scintigraphy remains the gold standard for the diagnosis of parathyroid adenomas there are a significant number of patients which show no results. Under these circumstances PET colina has proved to be an useful test.

Primary hyperparathyroidism related to ectopic thymic parathyroid tissue: about two cases

Zeineb Rekaya, Najla Bchir, Zouaoui Chadia, Lina Ghram & Haroun Ouertani
Hopital Militiare Principal de Tunis, Endocrinology, Tunis, Tunisia

Introduction
Primary hyperparathyroidism (PHPT) is a common endocrine disorder most commonly caused by a single adenoma of the parathyroid gland and rarely related to ectopic thymic parathyroid adenoma.
Observation
1st case: we report a case of a 46-year-old woman, diagnosed with PHPT. Scintigraphy concluded to a left inferior parathyroid adenoma. She underwent a focal parathyroid surgery and the adenoma was located in the thymus. The histopathology had shown an hyperplasic parathyroid tissue within a thymic parenchyma. Soon after surgery, persistent hypercalcemia up to 3mmol/l with elevated PTH level were noted. A skeletal survey showed generalized decrease in bone density. The neck ultrasonography was unremarkable as well as CT neck scan. Parathyroid scintigraphy showed a probable right inferior parathyroid adenoma. The patient was discharged with plans of a secondary surgical revision.
2nd case: Our case is of a 66-year-old woman operated for multinodular goiter: total thyroidectomy with left parathyroidectomy of a 7 mm adenoma that was found during surgery. Two years later, hypercalcemia(3 mmol/l) hypophosphatemia(0.6mmol/l)and overtly elevated PTH level, all contributed to the diagnosis of PHPT. Scintigraphy showed a mediastinal ectopic parathyroid adenoma, cervicothoracic CT scan showed an ectopic parathyroid adenoma of 13.7 mm in the left thymic cavity. The diagnosis of a persistent PHPT related to a mediastinal ectopic parathyroid adenoma was adopted. The patient underwent, a left thymectomy surgery. Her PTH and serum calcium levels decreased significantly. No new lesions could be detected on any of the follow-up visits.
Discussion
Parathyroid glands and the thymus share a common embryological origin which could explain the presence of ectopic thymic parathyroid.

Pregnancy and Lactation Associated Osteoporosis -A Rare Case Report

Ketevan Chanturishvili[1,2], Nino Zavrashvili[1,2], Qetevan Gvazava[1,2], Natia Margvelashvili[1,2] & Natia Shonia[1,2]
[1]Tbilisi Institute of Medicine, Endocrinology, Tbilisi, Georgia; [2]David Tvildiani Medical University, Endocrinology, Tbilisi, Georgia

Context
Pregnancy and lactation -associated osteoporosis (PLO) is an uncommon condition affecting women during late pregnancy and the early postpartum period. PLO is manifested with fractures usually in spine or occasionally in the hip with severe and prolonged pain and height loss. Pathogenesis of this rare condition is still not completely understood.
Case Presentation
We report a 28 y/o female patient presenting with severe back pain during postpartum period. Vertebral and Lumbar MRI revealed Th11, Th12, L1, L2 and L4 compressive fractures while DEXA scan reported severe osteoporosis - L1-L4 Z-score = -5.1 with maximal reduction of BMD in L4 -Z score - 5.6. Secondary causes of osteoporosis such as: celiac disease, Cushing Syndrome, hyperparathyroidism and hyperthyroidism were excluded. Patient was prescribed Calcium, Vitamin D, denosumab 60 mg SC every 6 months and lifestyle modification. She was consulted about the risks of severe osteoporosis, as well as possible teratogenic effects of the antiosteoporotic medication and proper contraception was advised. On repeated DEXA scan after 1 year showed improvement in bone density. After 18 months of PLO diagnosis unplanned pregnancy was confirmed. Regarding the challenges of maternal and fetal health the group discussion with Endocrinologist and Gynecologist was conducted. Patient was informed about the risks of further fractures during pregnancy and postpartum, risks of discontinuation and subsequently withdrawal of denosumab, as well as possible teratogenic effects of osteoporosis treatment. After careful judgment patient decided to terminate pregnancy and continue osteoporosis treatment with Calcium, Vitamin D and bisphoshonates.
Conclusion
We should bear in mind the possibility of pregnancy and lactation -associated osteoporosis in women with persistent back pain during pregnancy or postpartum period. Early diagnosis, proper management and patient education is crucial for maternal as well as for fetal health. Lack of data regarding antiosteoporotic treatment during pregnancy is a challenge for patients and the care takers. Further research and more evidence is needed for further guidance.

Impact of the Covid19 pandemic on patients with primary hyperparathyroidism

Bel Hadj Sliman Chayma, Bchir Najla, Baltagi Myriam, Annam Benchhida, Zouaoui Chadia & Haroun Ouertani
Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Introduction
The development of the Covid-19 pandemic infection, which started in March 2020 in Tunisia, has impacted all medical specialties. Endocrine care professionals were part of this battle, as many patients with endocrine diseases including primary hyperparathyroidism (PHPT) were also affected by the pandemic. the aim of our study was to evaluate the Impact of the Covid19 pandemic on patients with PHPT.
Methods
This is a retrospective descriptive study of 28 patients diagnosed with PHPT and hospitalized between January 2018 and December 2021 at the endocrinology department of the military hospital of Tunisia. Clinical and paraclinical data were collected from medical records.
Results
Our population consisted of 10 men and 18 women with a mean age of 61.14 ± 12.16 years. The mean calcemia was 3 ± 0.4 mmol/l. The mean PTH was equal to 318 ± 337 pg/ml. COVID-19 infection was noted in 69.1% of our patients. Sixty-eight per cent of them required hospitalization. Irregular follow-up during the covid pandemic was noticed in 64% of our patients and 57% were lost to follow-up. only eight patients (29.6%) underwent surgery during this period and the surgery was delayed for the other patients. Among those who did not undergo surgery, four patients developed renal lithiasis during this period and five patients had a decrease in bone density.
Conclusion
The management of PHPT during the COVID-19 pandemic, when surgery is not possible and hospital visits are limited, presented a challenging clinical situation. Appropriate distant follow-up and monitoring of these patients was essential until the resolution of the pandemic.

Osteoporosis issues & Complementary Medicine: Three years Experiences in Asian population

S Pal[1], T Roy[1] & G Kumari[2]
[1]SFCCP, Med, Meerut, India; [2]Tnm Hosp, Mumbai, India

Issues
No specific centre in asia for Osteoporosis patients treatment/rehabilitation. We used locally available Complementary Indian Medicines [CAM] for providing home based care in rural/tribal areas.
Aims
To provide CAM to poor patients in collaboration with Traditional-faith-hearers. Evaluated cost-efficacy of CAM & response of pain of fractures to CAM alongside analgesics.
Methods
from April 2014 to November 2018, 122 patients [n = 122] of RA aged 34-67 years enrolled. 68% females, 32% males. 43% returned to villages after prolonged therapy in city hospitals on allopathic drugs. 12% physical deformities. self report questionnaire distributed to patients attending NGO clinics Our NGO nurses treated patients with TFH in providing CAM. Mud therapy 21%, Bach-flower remedy 40%, Accupressure/Accupuncture 57%, Hydrotherapy 24%, Hypnotherapy 75%, ayurvedic therapy 82%, 26% on Unani Medicines, 61% on Homeopathic medicines, 72% on Herbal-Oil-TFH massage therapy, 58% Aromatherapy.
Results
We treated patients in 16 sessions CAM. feedback Performa given to subjects & responses evaluated periodically to modify treatment methodology. Our NGO module in functioning stages shown graphically to IOF-2010 conference participants. Average pain recorded weekly on a scale of 1 to 10. mean score pain fell from 8.2 (SD 1.4) to 3.8 (SD 2.7) points, which is highly significant ($P < 0.001$). Symptom relief($n = 90$), Gr-1 wanting to find alternatives to drugs($n = 95$). Cost of CAM 52% cheaper compared to Allopathic medicines & islocally & has high acceptance
Conclusion
122 of patients used & preferred CAMs. Cost wise cheaper & patient compliance better. 12 % dropped out of sheer frustration/fatigue. Patients need Psychosocial-Rx, Palliative-care-centers. Realizing divergent versions of CAM, multicentre study on this burning issue must be carried out. At ECE-2023 We shall form group with researchers from USA/Europe to substantially improve CAM approach. We NGO-representatives from developing nations need exposure to research technicalities/-methodologies used by European/American experts in management of osteoporosis. This is indeed possible by my participation at 2023 ECE congress

Characteristics of hypoparathyroidism in a tertiary referral hospital

Yosra Abderrahim, Bilel Ben Amor, Marwa El Arem, Ines Bayar, Ekram Hajji, Sana Abid[1], Héla Marmouch, Hanene Sayadi & Inès Khochteli
University Hospital Fattouma Bourguiba, Endocrinology Department, Monastir, Tunisia

Introduction
Hypoparathyroidism (HypoPT) is a rare endocrine disease characterized by abnormally low concentrations of PTH resulting in hypocalcemia. Etiologies are various and are dominated by postoperative HypoPT. HypoPT needs a lifelong treatment and follow-up in order to maintain appropriate calcium levels and prevent chronic complications.
Patients and Methods
A retrospective descriptive study was conducted at the endocrinology department in Fattouma Bourguiba University hospital.
Results
Twenty patients were included. The sex ratio was 1:3 with a mean age of 42.7 ± 17.9 years. The age at diagnosis was between 3 and 66 years. The main found etiologies were postsurgical hypoparathyroidism in 57.9% of patients, auto-immune in 26.3% and isolated genetic hypoparathyroidism in 15.7 %. Thyroid surgery was indicated for thyroid carcinoma (36.4%), multinodular goiter (34.6%) and Grave disease (27.2%). Auto-immune HypoPT was associated to Type 1 diabetes (60%), auto-immune thyroiditis (20%), Biermer's disease (20%) and coeliac disease (20%). The average calcium and PTH levels at diagnosis were respectively 2.07 ± 0.19mmol/l and 8.75 ± 6.43pg/l. All patients were treated by calcium carbonate with a mean daily dose of 3400 mg [1000-8000] along with active vitamin D analogs (alfacalcidol) with a mean daily dose of 1µg [0.25-2]. Twenty five percent of patients needed oral magnesium supplements.
Conclusion
To achieve treatment targets, the majority of patients with HypoPT, as shown in our study, require high doses of calcium and vitamin D supplements leading to multiple daily intake of medications that impair their quality of life.

Chronic hypoparathyroidism is associated with skeletal muscle dysfunction and restrictive lung disease

Saroj Sahoo[1], Takasi Anush Babu[2], Zia Hashim[3], Zafar Neyaz[4], Vinita E. Mani[5], Neeraj Jain[6], Eesh Bhatia[7] & Anjali Mishra[8]
[1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Endocrinology, Lucknow, India; [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Endocrinology, India; [3]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Pulmonary medicine; [4]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Radiodiagnosis, India; [5]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Neurology, Lucknow, India; [6]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Radiodiagnosis, Lucknow, India; [1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Endocrinology, Lucknow, India; [8]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Endocrine Surgery, Lucknow, India

Introduction
Whether patients with non-surgical hypoparathyroidism have skeletal muscle dysfunction is not studied. It is also not known if skeletal muscle dysfunction involves respiratory muscles and results in a restrictive lung disease (RLD).
Aim
To assess skeletal muscle and pulmonary function in patients with non-surgical hypoparathyroidism, who were asymptomatic for overt muscle and lung diseases.
Methods
Thirty patients with non-surgical hypoparathyroidism (mean age 37.7 years, 60% males) and forty healthy-controls were assessed for skeletal muscle function by hand-grip strength, short physical performance battery (SPPB) test, dual-energy x-ray absorptiometry, and electromyography. Pulmonary function was assessed in all by spirometry and diaphragmatic ultrasound. Those with a restrictive pattern on spirometry further underwent body plethysmography and diffusion lung capacity for carbon monoxide to confirm presence of RLD.
Results
Patients with hypoparathyroidism had lower levels of serum calcium (2.25 ± 0.15 vs 2.4 ± 0.12 mmol/l, $P < 0.001$), magnesium [median (interquartile-range) 0.74 (0.69-0.82) vs 0.78 (0.69-0.90) mmol/l, $P = 0.04$], hand-grip strength (18.08 ± 8.36 vs 22.90 ± 7.77 kg, $P = 0.01$) and SPPB score (9.5 [7-10] vs 12 [12-12], $P < 0.001$) compared to healthy-controls. Electromyographic evidence of myopathy was seen in 23% (5 of 22) patients with hypoparathyroidism, but none of the controls ($P = 0.08$). The proportion of patients with a RLD was higher in the group with hypoparathyroidism compared with controls (21% vs 0%, $P = 0.01$). Diaphragmatic excursion (4.22 ± 1.38 vs 5.18 ± 1.53 cm, $P = 0.01$) and thickness (3.79 ± 1.18 vs 4.28 ± 0.94 mm, $P = 0.05$) on deep inspiration were reduced in patients with hypoparathyroidism. Lean body mass was comparable in both the groups. In the multivariable analysis, the average of measurements of serum calcium in the previous year predicted hand-grip strength and SPPB score in patients with hypoparathyroidism.
Conclusion
Detailed testing of patients with hypoparathyroidism who were asymptomatic for overt muscle and lung diseases revealed significant impairment in parameters of skeletal muscle function. A substantial proportion of patients with hypoparathyroidism had electromyographic evidence of myopathy and RLD.

Localization studies in 443 patients with primary hyperparathyroidism by using a stepwise approach

Gülşah Balcı[1], Adile Begum Bahcecioglu Mutlu[2], Fatma Avcı Merdin[2] & Murat Erdogan[2]
[1]Ankara University, School of Medicine, Department of Internal Medicine, Ankara, Turkey; [2]Ankara University, School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Objective
Primary hyperparathyroidism (PHP) is a common endocrine disorder diagnosed biochemically, common use of autoanalyzers increased the incidence of PHP throughout last decades. Minimally invasive parathyroidectomy has been preferred to the explorative surgical approach due to shorter operating time, lower complication rate, and smaller incision size. Thus localization studies have become very important. We aimed to investigate clinical and laboratory characteristics of patients, causes and success of localization studies in a large cohort of PHP in a retrospective manner.
Methods
Study included 443 patients with PHP diagnosed between January 2010 and January 2021. Clinic characterisrics, biochemical parameters, findings of imaging studies for localization and postoperative histopathological results were examined. Ultrasonography (US), US-guided PTH-washout analysis; ^{99m}Technetium -Sestamibi/^{123}Iodine Scintigraphy(MIBI -SPECT/CT) were used as initial localization techniques. Four Dimensional Computed Tomography(4D-CT), 18F-Fluorocholine Positron Emision Tomography (18F-FCH PET/CT) were used as advanced imaging methods for patients whose parathyroid lesions could not be localized with initial methods.
Results
79%($n = 350$) of patients were female, the mean age was 59.9 ± 13. Mean ± SD serum Calcium(Ca), Phosphate(PO_4) and Parathormone(PTH) levels were 10.9 ± 0.8 mg/dl, 2.7 ± 0.5 mg/dl and 192.7 ± 82.3 pg/ml, respectively. 12.9% of the patients had normocalcemic hyperparathyroidism. The incidence of osteoporosis was 42.6%($n = 150$). PTH levels were significantly higher in the patient group with osteoporosis($P = 0.017$). The most common surgical method was minimally invasive surgery at 81.2%. Histopathological evaluation resulted in single adenoma in 98.1% of patients and hyperplasia in 1.5%, cancer in %0.4. A significant positive correlation was found between adenoma volume with serum Ca and PTH levels ($P < 0.001$). The most common location of parathyroid lesions was right lower pole of thyroid gland with 49.6%. 4D-CT and 18F-FCH PET/CT were used in 60 and 43 patients, respectively. Positive predictive values(PPV) of imaging modalities: US, US-guided PTH-washout analysis, MIBI-SPECT/CT, 4D-CT and 18F-FCH PET/CT were 83.6%, 91.8%, 81.2%, 88.9% and 97.7%, respectively.
Conclusion
Calcium and PTH levels could give an idea for the size of the adenoma. Using initial localization studies (i.e US combined with PTH washout, MIBI-SPECT/CT) most of the adenomas could be localized. For those patients who required advanced imaging modalities, 4D-CT is highly effective, but 18-FCH PET/CT has the highest PPV for parathyroid adenoma localization.

Parathyroid hormone levels following denosumab therapy vs. zoledronic acid therapy for osteoporosis

Pnina Rotman Pikielny[1], Tzipi Hornik Lurie[2], Liat Barzilai-Yosef[3], Erez Ramaty[3], Sofia Braginski Shapira[3] & Michal Kasher Miron[3]
[1]Meir Medical Center, Kfar Sava, Israel; affiliated with Sackler Faculty of Medicine, Tel Aviv University, Institute of Endocrinology, Diabetes and Metabolism, Kfar-Saba, Israel; [2]Meir Medical Center, Research Institute, Kfar-Sava, Israel; [3]Meir Medical Center, Institute of Endocrinology, Diabetes and Metabolism, Affiliated with the Sackler Faculty of Medicine, Tel Aviv University, Kfar-Saba, Israel

Background
Denosumab (DMAb) and zoledronic acid (ZA) are potent, anti-resorptive agents used to treat patients with osteoporosis. It has been suggested that they increase parathyroid hormone (PTH) levels in response to their antiresorptive effect, and that PTH elevation might be responsible for DMAb modeling actions on bone. The timeline and magnitude of PTH elevation post-DMAb and ZA has not been characterized in a large patient population.
Objective
To characterize PTH levels post-DMAb injection vs. baseline and vs. ZA injection.
Material and Methods
Female osteoporotic patients, $\geq$50 years, treated with DMAb or ZA, 2008–2020 were included if PTH was $<$1.5ULN before injection and if they had at least one PTH measurement 6 months after DMAb or 12 months after ZA injection. Exclusion criteria were creatinine $>$2mg/dl or diagnosis of hyperparathyroidism. Post-injection PTH levels were linked time-wise to previous injections.
Results
A total of 35,375 women, $\geq$50 years received DMAb or ZA for the first time in 2008–2020; 26,341 met the exclusion criteria. Of the remaining women, 5,640 received a first DMAb injection and 3,394 ZA. The DMAb group was older (73.2 vs. 69.8 years), was treated more frequently with osteoporosis medications before the injection (56.5% vs. 50.3%) and more had sustained a fracture (15.8% vs. 13.9%) compared to the ZA group. Vitamin D level was 80.9$\pm$21.9 nmol/l. Repeat PTH was available for 2,206 DMAb patients and 1,444 ZA. Among 772 PTH measurements in the first month post-DMAb, it was $>$1.5ULN in 156 (20.1%) and $>$2.5ULN in 74 (5.1%), whereas among 807 PTH measurements 5-months post-injection, it was $>$1.5ULN in 112 (13.9%) and $>$2.5ULN in 9 (1.1%). One-month post-ZA, PTH was $>$1.5ULN in 35/169 (20.7%) and $>$2.5ULN in 11 (6.5%), and decreased to $>$1.5ULN in 23/213 (10.7%) and to $>$2.5ULN in 2/213 (0.9%), 5 months after injection.
Discussion
This is the first study to examine PTH levels in a large population receiving DMAb or ZA injections, with precisely-timed PTH measurements post-injection. PTH levels increased by $>$1.5ULN in 20% of osteoporotic patients who received DMAb or ZA, while it increased to $>$2.5ULN in ~5% post-injection. PTH levels $>$2.5ULN declined gradually after treatment in both groups. It seems that PTH elevation is related to the antiresorptive effects of the drugs and is not a disease phenomenon. It is suggested to avoid checking PTH in the first few months post-DMAb and ZA therapy.

Bioluminescence and autofluorescence of parathyroid glands to identify an intra-thyroidal parathyroid tumour

Zhimin Lin, James Wai Kit Lee & Kee Yuan Ngiam
National University Hospital (NUH) - Singapore, Singapore, Singapore

Bioluminescence is bringing new and exciting possibilities to the field of endocrine surgery, because we are able to better harness the property of autofluorescence of the parathyroid glands. Parathyroid glands have an inherent ability to produce infra-red autofluorescence at the wavelength of 820 nm to 830 nm, if the gland absorbs light at the wavelength of 750 nm. With highly sensitive technology and the ability to filter out other reflected light and noise, it is now possible to identify the infra-red light emitted by parathyroid glands and cells. We would like to share a case of primary hyperparathyroidism that could not be identified and localised pre-operatively, but a right thyroid nodule was identified. Intra-operatively, a neck exploration was strongly suggestive of an intrathyroidal parathyroid lesion in the known right thyroid nodule. With the aid of a specialised near infra-red (NIR) camera, autofluorescence was detected from the thyroid nodule, helping to confirm our preliminary diagnosis, and proceeded with a right hemithyroidectomy. Intra-operative measurement of the parathyroid hormone confirmed an adequate drop in the parathyroid hormone levels after the excision of the right hemithyroid. Post-operative pathological assessment also confirmed the presence of parathyroid tissue in the thyroid tumour. The accuracy of parathyroid gland detection can be greatly enhanced with the employment of highly sensitive NIR technology, and help shape the development better strategies to approach parathyroid surgery. Other applications of this technology in the setting of neck surgery will be discussed.

Healthcare resource utilization associated with post-surgical and non-surgical chronic hypoparathyroidism in England: A linked Clinical Practice Research Datalink, Hospital Episode Statistics, and Office for National Statistics retrospective analysis

Alden Smith[1], Caoimhe T. Rice[2], Sara J. Carvalho[2], Jennifer Davidson[2], Mico Hamlyn[2], Christopher Sibley[1] & Wahidullah Noori[1]
[1]Ascendis Pharma, Palo Alto, United States; [2]CorEvitas, Speciality EMR Data Division, Cheshire, United States

Background
Hypoparathyroidism, a rare endocrine disorder characterised by low serum calcium due to low or insufficient parathyroid hormone levels, most commonly occurs post-surgery although can also occur due to predisposing genetic conditions or idiopathically. Hypoparathyroidism requires long-term medical management to minimise complications and detrimental impacts on health-related quality of life. Few real-world studies, particularly in the UK, have quantified healthcare resource use (HCRU) associated with chronic hypoparathyroidism.
Aims
To describe demographic characteristics and HCRU associated with post-surgical and non-surgical chronic hypoparathyroidism, compared with matched controls without hypoparathyroidism, using a Clinical Practice Research Datalink (CPRD), Hospital Episode Statistics (HES), and Office of National Statistics deaths registrations linked dataset.
Methods
Primary care data from CPRD linked to HES and death registrations in England, were used to retrospectively identify two adult hypoparathyroidism cohorts. The first, incident chronic hypoparathyroidism induced by surgery or radiotherapy between 01/04/2008–22/03/2019, with a look-back to 01/04/2007 to identify prior surgery or radiotherapy. The second, prevalent chronic hypoparathyroidism that was not surgically induced between 01/04/2008–22/03/2020. Both cohorts were indexed upon diagnosis of chronic hypoparathyroidism, defined as having two diagnosis codes 6-36 months apart or ongoing calcium or vitamin D analogue prescription in lieu of a second diagnosis code. Both hypoparathyroidism cohorts were matched with controls on age and gender. We estimated all-cause inpatient admissions and bed days per person per year (PPPY) for individuals with chronic hypoparathyroidism and those without.
Results
183 individuals with surgical and 447 with non-surgical chronic hypoparathyroidism were identified. Individuals in the post-surgical cohort were younger than those in the non-surgical (mean age: 53.3 vs 57.1 years) and a higher proportion were female (73.8% vs 62.7%). Over a median follow-up time of 56.5 months, individuals with post-surgical chronic hypoparathyroidism incurred more admissions (mean 14.1 PPPY vs 0.4 PPPY, mean difference 13.7, [11.9–15.5], $P<0.001$) and annual bed days (mean 7.9 PPPY vs 0.9 PPPY, mean difference 7, [5.4–8.8], $P<0.001$) compared to controls. The same trend was observed amongst individuals with chronic non-surgical hypoparathyroidism, who, over a median follow-up time of 44.9 months, had more admissions (4.5 PPPY vs 0.4 PPPY, mean difference 4.0, [2.9–5.6], $P<0.001$) and bed days (14.9 days PPPY vs 1.7 days PPPY, mean difference 13.2, [11.8-14.6], $P<0.001$) than controls.
Conclusion
Our results suggest that HCRU is significantly greater for individuals with chronic hypoparathyroidism compared to non-hypoparathyroidism controls, highlighting the need for effective treatment options in patients with chronic hypoparathyroidism.

Evaluation of Breast Calcification, Calcification Characteristics and BI-RADS (Breast Imaging-Reporting and Data System) Categories in Patients with Primary Hyperparathyroidism

Fatma Dilek Dellal Kahramanca[1], Sevgul FAKI[1], Ekin Yiğit Köroğlu[1], Arzu Özsoy[2], Ahmet Dirikoc[3], Oya Topaloglu[3], Reyhan Ersoy[3] & Bekir Cakir[3]

[1]Ankara City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara City Hospital, Radiology, Ankara, Turkey; [3]Ankara Yildirim Beyazit University Faculty of Medicine, Endocrinology and Metabolism, Ankara, Turkey

Aim
It is hypotethically thought that increased frequency of breast cancer in patients with primary hyperparathyroidism(PHPT)may be due to the fact that calcium accumulation in the breast may be higher in patients with PHPT giving rise to more breast-related examinations. Although there are many studies or case reports showing calcification in many organs and tissues, in PHPT, there is not any study investigating breast calcification in these patients in the literature. We aimed to determine the frequency and features of breast calcification and distribution of BI-RADS scores in patients with PHPT.
Method
Female patients $\geq$40 years old with PHPT and and age-matched healthy women were included. Demographical, antropometric and laboratory findings were noted. Mammography was performed in all patients and controls. Calcification types and BIRADS scores were recorded. Clustered microcalcification, ductal calcification, linear thin or segmental calcification were considered suspicious calcification. Skin calcification, scattered, punctate, vascular calcification and macrocalcification were termed as benign calcification. Two groups were compared in terms of demographical, laboratory findings, presence of calcification, calcification types and BI-RADS in mammography. Patients were divided in two groups according to the duration of PHPT as less or more than 48 months.
Results
Sixty-one patients and 75 control were enrolled. While age distribution was similar(57.0$\pm$7.9 vs 55$\pm$7.5, $P=0.153$), body mass index was higher in patient group(32.4$\pm$6.7 vs 29.2$\pm$6.2 kg/m^2, $P=0.005$). Median duration of PHPT was 46(1-85) months. BI-RADS score was comparable and the most frequent score was BIRADS-0. Presence of breast calcification and calcification types were not different in two groups. Demographical, laboratory and mammographic findings are summarized in table. Presence of calcification was similar in PHPT patients with disease duration of less and more than 48 months. There was not any cut-off for disease duration that can predict presence of calcification. Of the 3 patients(all was with PHPT)who underwent excisional breast biopsy, one resulted in invasive breast ca, one as atypical ductal hyperplasia, and the other as benign.
Conclusion
Female patients with PHPT did not have an increased incidence of breast calcification compared to healthy women, suggesting that calcification is not responsible for the increased incidence of breast cancer in these patients. Distribution of BI-RADS scores was also not affected by the presence of PHPT.

	PHPT ($n=61$, 44.9%)	Control ($n=75$, 55.1%)	p

SPECT/CT parathyroid scintigraphy in primary hyperparathyroidism: minimizing the risk of negative results by biochemical parameters assessment

Anna Drynda[1], Karolina Kucharczyk[1], Grzegorz Sokolowski[2], Malgorzata Trofimiuk-Muldner[2] & Alicja Hubalewska-Dydejczyk[2]
[1]Jagiellonian University Medical College, Students' Scientific Group at the Department of Endocrinology, Kraków, Poland; [2]Jagiellonian University Medical College, Chair and Department of Endocrinology, Kraków, Poland

Primary hyperparathyroidism (PHP) diagnosis in clinical practice is based on biochemical blood tests. Since a single parathyroid adenoma causes about 85% of cases, the treatment of choice is parathyroidectomy, preceded by imaging studies. Ultrasound and [^{99m}Tc]sestamibi scanning can enable adenoma localization. However, the latter method is of higher sensitivity, especially if combined with anatomical imaging. In some cases, the radiotracer uptake in adenoma tissue is insufficient, leading to negative imaging results. This study aimed to compare parathormone (PTH), calcium, and serum phosphate levels among patients diagnosed with PHP with positive and negative parathyroid nuclear hybrid imaging (SPECT/CT) and to evaluate biochemical parameters' ability to predict imaging results.
Results
563 patients with suspected primary hyperthyroidism (84% females, median age 62 years, IQR 19 years; 16% males, median age 59 years, IQR 25 years) who underwent [^{99m}Tc]sestamibi SPECT/CT imaging between 2010 and 2022, were included in this study. The imaging result was positive in 257 cases (46%). Patients with positive imaging were characterized by higher PTH (median 124.5 pg/ml vs 96.6 pg/ml; $P<0.05$), higher calcium (median 2.76 mmol/l vs 2.67 mmol/l; $P<0.05$), and lower serum phosphate concentrations (median 0.82 mmol/l vs 0.89 mmol/l; $P<0.05$). Based on ROC analysis, the following threshold values for nuclear imaging were proposed for calcium, PTH, and serum phosphate concentrations, respectively: calcium $\geq$3.11 mmol/l (AUC 0.73; PPV 72%; sensitivity = 37%; specificity = 88%); phosphate $\leq$ 0.45 mmol/l (AUC 0.65; PPV 55%; sensitivity = 36%; specificity = 79%); PTH $\geq$ 260 pg/ml (AUC 0,70; PPV 78%; SENS = 33%; SPEC = 92%).
Conclusions
Before offering preoperative hybrid nuclear imaging to a patient with PAH, attention should be paid to the results of biochemical tests to limit unnecessary radiation exposure. Indeed, if calcium and parathormone concentrations are slightly above the upper reference values, the probability of a negative imaging result seems to be high.

Evaluation of Laboratory Findings of Primary Hyperparathyroidism in Geriatric Patients

Murat Calapkulu[1], Muhammed Erkam Sencar[2], Davut Sakiz[3], Merve Tekinyildiz[4], İlknur Ozturk Unsal[5] & Erman Cakal[5]
[1]Igdır State Hospital, Endocrinology and Metabolism, Igdır, Turkey; [2]Medicana International Hospital, Endocrinology and Metabolism, Ankara, Turkey; [3]Mardin Training and Research Hospital, Endocrinology and Metabolism, Mardin, Turkey; [4]University of Health Sciences Dıskapı Yıldırım Beyazıt Training and Research Hospital, Internal Medicine, Ankara, Turkey; [5]University of Health Sciences Dıskapı Yıldırım Beyazıt Training and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey

Evaluation of Laboratory Findings of Primary Hyperparathyroidism in Geriatric Patients
Background
Primary hyperparathyroidism (PHPT) is an endocrine disease characterized by excessive secretion of parathormone (PTH) from one or more parathyroid glands. In recent studies, it has been reported that the PHPT clinic has turned into a largely asymptomatic disease in recent years. There are few studies on the effect of aging on laboratory findings of PHPT. We aimed to evaluate the laboratory findings of PHPT in the geriatric patient population and to determine the differences by comparing them with general PHPT patients in the current study.
Methods
A total of 182 patients operated on with the diagnosis of PHPT in our center between 2017-2019 were included in the current study. The patients' demographic, laboratory, and pathological data were recorded by scanning the files. Patients were divided into two groups as $<$65 years old and $\geq$65 years old.
Results
The patients comprised 149 females and 33 males with a mean age of 55.1$\pm$12.3 years. The full demographic and clinical data of the PHPT patients are reported in Table 1. No differences were found in serum PTH, calcium, phosphorus, alkaline phosphatase, creatinine, or 25-OH-D levels between the two groups. Urinary calcium levels were found to be significantly lower in geriatric patients. There was a significant negative correlation between urinary calcium level and age. The frequency of kidney stones was found to be less frequent in the geriatric patient group (12.9%& 32.1%, p:0.01). When postoperative transient hypocalcemia was evaluated, no significant difference was found between the two groups.
Conclusion
Clinical and laboratory findings of PHPT are affected by aging. Recent studies have shown that the disease is more often asymptomatic in the geriatric population than in young people and is characterized by a predominance of bone

Table 1 Demographic and laboratory data of primary hyperparathyroidism patients

Parameter	≥65 years (n:46)	<65 years (n:136)	*P*-value
Age (years)	70.9±4.9	49.7±9.1	**<0.001**
Gender (F/M)	40/6	109/27	0.30
Serum parathormone (pg/ml)	134.1 (76-764)	136 (71-922)	0.89
Serum calcium (mg/dl)	11.2±0.9	11.2±0.8	0.87
Serum phosphorus (mg/dl)	2.6±0.6	2.7±0.5	0.18
Urine calcium excretion (mg/day)	262 (101-646)	350.5 (108-1033)	**0.002**
Serum ALP (U/l)	103 (47-260)	109.5 (53-773)	0.30
Serum creatinine (mg/dl)	0.83±0.19	0.83±0.2	0.99
25-OH-D (ng/ml)	20.5±11.1	17.3±10.5	0.08
Adenoma weight (gr)	0.7 (0.12-5)	0.91 (0.1-10)	0.26

involvement. Clinical and laboratory findings of PHPT in geriatric patients may be better elucidated in multicenter studies involving larger patient populations.

A Phase 1/2, Open-Label, Multiple Ascending Dose Clinical Study to Evaluate the Safety, Tolerability, Pharmacokinetics, and Pharmacodynamics of INZ-701 in Adults with ENPP1 Deficiency

Robert Wermers[1], Rainard Fuhr[2], Dirk Schnabel[3], Terra Arnason[4], Alix Bensacon[5], Borut Cizman[6], Deborah Wenkert[7], Yves Sabbagh[6] & Kurt Gunter[6]

[1]Mayo Clinic, Division of Medicine, Division of Endocrinology, Diabetes, Metabolism, and Nutrition and Department of Medicine, Rochester, United States; [2]Parexel International GmbH, Early Phase Clinical Unit Berlin, Berlin, Germany; [3]Charitè, Universitätsmedizin, Center for Chronic Sick Children, Pediatric Endocrinology, Berlin, Germany; [4]University of Saskatchewan, Division of Endocrinology, Department of Medicine, Saskatoon, Canada; [5]Hôpital Universitaire Necker Enfants Malades, Endocrino-diabetologie pediatrique, Paris, France; [6]Inozyme Pharma, Boston, United States; [7]Wenkert & Young, LLC (Former Employee, Inozyme Pharma), Thousand Oaks, United States

Background
ENPP1 Deficiency is a rare disorder due to inactivating mutations in the *ENPP1* gene. It is characterized by low levels of inorganic pyrophosphate (PPi), a critical regulator of mineralization; subsequent pathologic soft tissue calcification results in ~50% infant mortality and life-long musculoskeletal and cardiovascular morbidities. No targeted therapy exists for this disease. INZ-701 is a recombinant ENPP1-Fc investigational product.
Purpose
To determine the safety, tolerability, immunogenicity, pharmacokinetics and pharmacodynamics of INZ-701 following subcutaneous administration in adults with ENPP1 Deficiency.
Methods
Phase 1/2, multicenter, open-label, multiple ascending dose study including three cohorts of three adults each, with genetic confirmation and PPi <1300 nM (NCT04686175). Following ethical committee approval, participants were dosed at Day 1, then twice weekly from Day 8 through Day 32.
Results
In the first patient cohort receiving 0.2 mg/kg INZ-701, INZ-701 was well-tolerated with no serious adverse events or injection site reactions. A rapid (≤ 6 hrs) ~4-fold increase in PPi was noted in all three participants. Mean PPi increased from 262 $\pm$ 114 nM (screening) to a mean sustained level through Day 32 of 1374 $\pm$ 457nM (in the normal range), representing a ~5-fold increase in PPi. Steady state was reached approximately by Day 29 with a ~4-fold accumulation from Day 1, based on $AUC_{0\text{-}72hrs}$ and showed good correlation with INZ-701 activity. The half-life of INZ-701 (~126 hrs) suggests the potential for once-weekly dosing. Participants from the first cohort have enrolled in an open label extension study.
Conclusions
At the lowest dose studied, INZ-701 demonstrated a rapid and sustained increase in PPi levels in all participants, was well tolerated, and exhibited a favorable safety profile with a potential for once weekly dosing. Results from cohorts two (0.6 mg/kg dose) and three (1.8 mg/kg dose) are anticipated in early 2023.

Surgical fixation of ankle fractures with bioresorbable magnesium implants: A first-in-human HR-pQCT assessment of the implantation site

Ines Fößl[1], Victor Labmayr[2], Annelie Martina Weinberg[2], Patrick Holweg[2] & Barbara Obermayer-Pietsch[1]

[1]Medical University of Graz, Department of Internal Medicine, Division of Endocrinology and Diabetology, Graz, Austria; [2]Department of Orthopaedics and Trauma, Medical University of Graz, Graz, Austria

Background
Bioresorbable implants should provide stability for fracture healing and resorb thereafter to make implant removal obsolete. Here, we report follow-up data of 6 patients treated with bioresorbable magnesium screws following medial malleolus fractures.
Purpose
Assessment of the implantation site and implant resorption of 11 implants in 6 patients with HR-pQCT (high resolution peripheral quantitative computed tomography).
Methods
Isolated, bimalleolar or trimalleolar ankle fractures were surgically treated with bioresorbable screws (Magnesium 99.1%, Calcium 0.45%, Zinc 0.45%) in 20 patients. After at least 2.5 years patients were clinical assessed and HR-pQCT-scans were performed. Screw residuals were evaluated in a binary approach for every axial slice generated by the HR-pQCT (residual present vs. not present). Evaluations included total volume, bone volume, and volume of the trabeculae-free space.
Results
All patients showed clinical evidence of fracture healing without clinical complications twelve weeks after the surgery. With full weight bearing and absence of pain in the fractured ankle. After 2.5 years, all observed implants were resorbed for the most part. Of 11 implants, 3 were dissolved without visible residuals. Minor residuals were present in 10% of slices (0%-33%). However, in 2 female study participants >50 years secondary expansions of the drilling channel were observed, where trabeculae were absent. Screw volume before implantation was 243.3 mm^3, and the trabeculae-free cavities were 596.1 mm^3 in mean size (239,2–1109,1mm^3) with the largest cavities in the bone with the lowest bone volume per total volume (BV/TV).
Conclusion
Bioresorbable magnesium screws for fracture fixation are providing fracture healing and satisfactory clinical outcome after one year. Surgical removal is not necessary. Especially in patients with decreased bone mineral density the dynamic and impact of implant resorption needs to be studied further.
Key words
HRpQCT, bioresorbable implant, magnesium screw, ankle fracture

FGF-23 levels in patients with normocalcemic primary hyperparathyroidism

Elena Chertok Shacham[1], Nimra Maman[2], Tatyana Lazareva[3] & Avraham Ishay[1]

[1]Emek Medical Center, Endocrinology, Afula, Israel; [2]Emek Medical Center, Statistics, Afula, Israel; [3]Emek Medical Center, Internal Medicine Department, Afula, Israel

Introduction
Normocalcemic primary hyperparathyroidism (NPHPT) is a variant of primary hyperparathyroidism with consistently normal albumin-adjusted or free-ionized calcium levels. It may be an early stage of classic primary hyperparathyroidism or could represent a primary renal or bone disorder or result from another pathophysiologic mechanism leading to invariably elevated PTH levels.
Aim of the study
The study aims to check and compare the FGF-23 levels in three groups of patients: patients with PHPT, patients with NPHPT, and patients with normal calcium and PTH levels.
Methods
Our study included patients who were referred to the endocrinology clinic with a presumptive diagnosis of primary hyperparathyroidism, an isolated increased level of PTH, or reduced bone densitometry. For each patient, we performed blood analysis of FGF-23, calcium, phosphate, vitamin D [25(OH)D3], estimated

glomerular filtration rate (eGFR), bone turnover markers, and urine analysis for calcium/creatinine ratio.
Results
Our study included 105 patients. Thirty patients with hypercalcemic PHPT (HPHPT group), thirty patients with elevated PTH and normal calcium levels (NPHPT group), and 45 patients with normal calcium and PTH levels in the control group. FGF 23 level was 59.5 ± 23 pg/ml in the NPHPT group, 77 ± 33 pg/ml in the HPHPT group, and 49.7 ± 21.7 pg/ml in the control group ($P = 0.012$). The phosphate level was lowest in the HPHPT group: 2.9 ± 0.6 vs 3.5 ± 0.44 in the NPHPT and 3.8 ± 0.5 in the control groups ($P = 0.001$). No differences were found in eGFR, 25(OH)D3, C-terminal telopeptide type I collagen (CTX) and procollagen type 1 N-terminal propeptide (P1NP) levels, and bone densitometry scores between the three study groups. There was a significant positive relationship between PTH and FGF23 levels in two out of three groups of patients (HPHPT and NPHPT groups) when all three groups of patients were analyzed together ($P = 0.000$). A significant negative correlation was found between the FGF-23 level and GFR in all three study groups ($P = 0.023$).
Conclusion
Our findings suggest that NPHPT is an early stage of PHPT. Further studies are needed to determine the role of FGF-23 and its usefulness in NPHPT.

Therapeutic Options for Inoperable Local Relapse of Parathyroid Carcinoma with Symptomatic Hypercalcemia: a Case Report

Bárbara Filipa Araújo, Ana Carreira, Carolina Moreno, Dírcea Rodrigues, Sandra Paiva & Isabel Paiva
Centro Hospitalar e Universitário de Coimbra, Endocrinology Department, Coimbra, Portugal

Introduction
Parathyroid carcinoma (PC) is an extremely rare malignancy. A complete surgical excision is often difficult, and persistent/recurrent disease occurs in up to 65% of cases. Progression often leads to symptomatic hypercalcemia, the major contributor to poor quality of life and mortality. Treatment options beyond surgical resection are limited. Denosumab is an approved therapy for refractory hypercalcemia of malignancy, and its use in unresectable PC has been described, with favourable results. The use of radiotherapy (RT) in PC has few reported cases in the literature, but could also serve as a valid alternative for inoperable local relapse. We present a case in which both denosumab and RT were used as palliative treatment approaches.
Case description
A 72-year-old women with unresectable recurrence of PC was admitted with severe hypercalcemia (15.5mg/dl) and acute kidney injury. Additional investigation revealed PTH = 1951pg/dl (9-72), obstructive nephrolithiasis and cervical lymph node metastases. Two weeks later, she underwent urgent palliative surgery due to refractory hypercalcemia, with marked improvement (calcium = 10.8mg/dl, PTH = 480pg/dl). 5 months later, she presented with symptomatic hypercalcemia (13.8mg/dl), despite therapy with zoledronic acid 4mg/month and cinacalcet 150mg/day. Cervical ultrasound confirmed tumour recurrence. Intravenous saline and bisphosphonate were, again, ineffective, with calcium nadir on the second day (11.6mg/dl) and subsequent increase (12.5mg/dl). Then, denosumab was started and calcium levels reduced on the third day (11.5mg/dl), with nadir on the seventh (10.8mg/dl). She was discharged under cinacalcet 180mg/day and denosumab 60mg/month. In the following months there were stable calcium levels (10.0-11.3mg/dl), despite ascending PTH levels (11993pg/ml). 6 months later she presented again with symptomatic hypercalcemia (13.8mg/dl). The multidisciplinary tumor board decided to opt for RT. It was delivered a radiation dose of 30 Gy in 10 fractions of 3 Gy, using an arc technique with 6 MV photons, at the cervical lesions. She tolerated well RT, and only developed grade I dermatitis. 3 months after RT, there was a progressive decrease in PTH (6453pg/ml) and calcium levels (9.7mg/dl). Currently, at 9-month RT-follow-up, calcium levels are within range (8.8-9.2mg/dl), and PTH levels are stable (4149-4858pg/ml), without further hospitalizations.
Conclusion
The approach to a relapse of PC remains a challenge. In inoperable cases, with severe hypercalcemia refractory to calcimimetic agents and bisphosphonates, treatment with denosumab may result in rapid reduction of calcium levels. As highlighted by this case, RT has also a role as a palliative treatment, with achievement of metabolic and symptomatic control of the disease.

Hyperparathyroidism in pregnancy, should we favour surgical intervention?

Adnan Zaina & Shezifi Eli
Bar-Ilan University, Azrieli Faculty of Medicine, Division of Endocrinology and Metabolism, Israel

Primary hyperparathyroidism (PHPT) during pregnancy is an uncommon condition that may have consequences for either mother, offspring, or both. Treatment can be either surgical or conservative.
The study aims
To compare maternal and fetal adverse outcomes between surgically (operated group) vs conservatively (non-operated group) treated mothers with gestational PHPT and to investigate the correlation between serum calcium and PTH values with complication rates.
Methods
A systematic review of all cases of PHPT during pregnancy, published in peer-reviewed English literature on PubMed and ScienceDirect from 1990 to 2021, was conducted.
Results
98 manuscripts were included in the study describing 368 cases of gestational hyperparathyroidism. 134 (36.4%) underwent parathyroidectomy, and 234 (63.6%) were treated conservatively. The mean age was 30.8 ± 5.5 and 31.6 ± 5.7, respectively. Median calcium levels were higher in the operated group, 12.2 mg/dl Vs. non-operated group 11.1 mg/dl ($P < 0.001$). PTH values had a mean of 132.5 pg/ml and 122.7 pg/ml for the respective groups ($P = 0.126$). Maternal and fetal complications were reported in 28.5% and 31% of cases. The rate of mild and moderate maternal complications was significantly higher in the operated group, reaching 50 (37.3%) compared to 40 (17.1%) in the non-operated group, respectively ($P < 0.01$). Fetal complications were significantly lower in the operated group. With 8.2% vs.13.7% for mild, 4.5% vs. 9.4% for moderate, and 1.5 vs. 12.4% for severe complications, respectively ($P < 0.001$). Favorable outcomes were obtained when the surgery took place during the second trimester. We identified a positive correlation between adverse maternal outcomes, serum calcium, and serum PTH values.
Conclusions
Parathyroidectomy seems to be favorable over conservative management when postoperative maternal and fetal complications are considered.

DOI: 10.1530/endoabs.90.P309

Table 1: (Abstract P309) Comparison of the outcomes between the operated and non-operated groups.

Maternal complications	None	Mild	Moderate	Severe	NR	*P*-value
Total study population ($n = 368$)	263 (71.5%)	62 (16.8%)	28 (7.6%)	4 (1.1%)	11	<0.001
Non-operated group ($n = 234$)	180 (76.9%)	25 (10.7%)	15 (6.4%)	4 (1.7%)	10	
Operated group ($n = 134$)	83 (61.9%)	37 (27.6%)	13 (9.7%)	0	1	
Preoperative complications		24 (17.9%)	6 (4.4%)	0		0.23
Postoperative complications		13 (9.7%)	7 (5.2%)	0		
Fetal complications						
Non-operated group ($n = 234$)	140 (59.8%)	32 (13.7%)	22 (9.4%)	29 (12.4%)	11	<0.001
Operated group ($n = 134$)	114 (85.1%)	11 (8.2%)	6 (4.5%)	2 (1.5%)	1	
Combined groups ($n = 368$)	254 (69%)	43 (11.7%)	28 (7.6%)	31 (8.4%)	12

The impact of a post hip fracture FLS on mortality and recurrent fracture - a tertiary medical center retrospective study

Hadar Alkobi-Weiss[1], Adi Goldbart[2], Lior Hassan[2], Vera Polischuk[1,3], Yan Press[1,3], Ethel Siris[4], Uri Yoel[1,5] & Merav Fraenkel[1,5]
[1]Ben Gurion University of the Negev, Faculty of Health Science, Be'er Sheva, Israel; [2]Soroka Medical Center, Clinical Research Center, Be'er Sheva, Israel; [3]Soroka Medical Center, Geriatrics, Be'er Sheva, Israel; [4]Columbia University Medical Center, Division of Endocrinology, New York, United States; [5]Soroka Medical Center, Endocrinolgoy, Be'er Sheva, Israel

Background
Rates of osteoporosis treatment following hip fractures are low. Fracture liaison service (FLS) has been shown to increase medical treatment for osteoporosis and decrease mortality. The aim of our study was to assess the impact of in hospital FLS on mortality and second hip fracture.
Methods
This retrospective study included patients over 65 years of age, insured by "Clalit" health service who were admitted to Soroka University Medical Center (SUMC) for rehabilitation at the Geriatrics department following the surgical repair of hip fracture. We compared rates of the composite outcome of mortality and/or second hip fracture in two equal time periods: before and after the implementation of SUMC FLS. Data were captured from the electronic medical charts including mortality, demographics, medical history, drug purchase and lab before and after hip fracture.
Results
319 and 667 patients fulfilled study criteria in the pre and post FLS periods, respectively. Baseline characteristics of both cohorts were similar excluding eGFR that was lower and rates of PPI and steroid use that were higher in the FLS cohort. Rates of endocrine consultation (93.4% vs 3.4% $P<001$), performance of DXA-BMD scan (42.3% vs. 7.5% $P<0.001$), parenteral anti osteoporosis treatment (65.2% vs 3.1% $P<0.001$) were higher in the FLS cohort, while use of oral bisphosphonates was lower (26.1% vs 56/4% $P<0.001$). Multivariable cox regression adjusted for age, comorbidities (expressed as the Charlson comorbidity index) and FIM (functional independence measure) score, demonstrated that the implementation of the FLS decreased the composite outcome of recurrent hip fracture and mortality only in patients under age 80 OR 0.55 (95% CI 0.36-0.83; $P=0.004$).
Conclusions
Implementation of in hospital post hip fracture FLS increased rates of endocrine consultation, performance of DXA BMD and rates of parenteral treatment for osteoporosis. The FLS decreased the composite outcome of mortality and second fracture among patients under age 80.

Hypocalcemia and pulseless electric activity revealing chromosome 22q11.2 deletion syndrome in the midst of a conglomerate of potential etiologic factors

Eric Balti[1,2,3], Husein Dashty[1], Ballaux Dominique[1] & Coremans Peter[1]
[1]VITAZ Hospital, Department of Endocrinology and Diabetes, Sint-Niklaas, Belgium, [2], [3], Department of Endocrinology, Diabetology and Metabolism, Universitair Ziekenhuis Brussel, Brussels, Belgium

Background
Chromosome 22q11.2 deletion syndrome has been reported in about 1 per 347 to 992 living births. Hypocalcemia occurs in up to 80.4% of cases.
Case description
A 28-year-old man, known with autism spectrum disorder (ASD), presented at the emergency department (ED) for limbs muscle cramps. Medical history included chronic myeloid leukemia treated with tyrosine kinase inhibitor (TKI) the last 10 years, gastric bypass and recurrent fractures due to osteoporosis managed by alendronate. The preceding four months, alendronate was switched to zoledronate because of digestive adverse effects. After administration of zoledronate, the patient experienced exacerbation of the muscle stiffness. At the ED, upper limbs spasms (Trousseau's sign) hindered blood pressure measurement. Shortly after arrival, the patient suddenly developed pulseless electric activity, requiring advanced cardiopulmonary resuscitation, endotracheal intubation and admission to the intensive care unit. Investigations revealed a long QTc at 513 msec, severe hypocalcemia (ionized Ca 0.66 mmol/l [range 1.17-1.33]), normal magnesium, hypophosphatemia (0.49 mmol/l [0.78-1.42]), normal vitamin D and inappropriately low parathyroid hormone (PTH) level (38 ng/l [range 7-70]). Low calcium level was recorded immediately after initiation of TKI ruling out gastric bypass and biphosphonate as primary etiologic factors. Genetic testing was requested based on inappropriately low PTH, asymmetric crying facies, mild epicanthal fold and malar flatness. Deletions of chromosome 22q11.2 spanning catechol-O-methyltransferase *(COMT)* and T-box transcription factor 1 *(TBX1)* genes locations were identified. Upon discharge, calcium level improved under oral calcium, magnesium and calcitriol. TKI and biphosphonate were interrupted.
Discussion
In our patient, identification of chromosome 22q11.2 deletion confirmed a constitutional defect in calcium metabolism, which might have been sequentially exacerbated by initiation of TKI, gastric bypass and biphosphonate. Hypocalcemia in DiGeorge syndrome results from hypoparathyroidism and could occurs not only in the neonatal period, but also in adulthood. Other clinical characteristics of the disease encompass cardiac defects, abnormal facies, thymic hypoplasia, cleft palate (CATCH-22). While ascertainment of *TBX1* deletion relates to hypoparathyroidism that of *COMT* gene could be associated to psychiatric defects including ASD and psychosis.
Conclusion
This case highlights the diagnostic complexity of hypocalcemia in a setting of multiple potential etiologic factors. It raises the call to keep in mind that chromosome 22q11.2 deletion syndrome is not that uncommon and can be revealed in adulthood. Specific phenotype, specifically in the setting of hypocalcemia in a patient with inappropriately low PTH, should prompt clinicians to order genetic testing independently of the patient's age.

Teriparatide in the challenging management of hypoparathyroidism, our experience in one medical center in Argentina

Susana Mallea-Gil, Yamila Sanchez, Bibiana Coca, Cindy Lopez, Maria de los Angeles Sosa, Silvina Sankowicz, Maria Marta Aparicio & Carolina Ballarino
Hospital Militar Central, Endocrinology, Buenos Aires, Argentina

Hypoparathyroidism is an endocrine deficiency whose substitution treatment with PTH 1-84 is only available in compassionate use in Argentina. There is a subgroup of patients in which the conventional therapy with calcium, calcitriol, phosphorous chelators, magnesium and diuretics does not reach an adequate clinical and/or biochemical compensation. Although teriparatide (PTH 1-34) is not approved for patients with hypoparathyroidism, it is a plausible therapeutic resource.
Objective
To show our experience in the use of teriparatide in patients with primary and secondary hypoparathyroidism.
Material and Methods
Retrospective study, we assessed the medical records of 8 patients with hypoparathyroidism who were treated with teriparatide, 2 with primary-idiopathic

Lab tests	Pre-Teriparatide (mean)	Post-Teriparatide (mean)	p
Calcemia (mg/dl)	6.9	8.17	**0.023**
Phospathemia (mg/dl)	5	4	**0.009**
Calciuria (mg/24 hs)	141	313	0.131

Table 1 (Abstract P312)

TREATMENT	Daily doses (mean)		Quantity of pills (mean)		% of decrease
	Pre-Teriparatide	Post-Teriparatide	Pre-Teriparatide	Post-Teriparatide	
Calcium carbonate g/d	2.5	0.8	5.1 (4-12)	1.7 (1-5)	67%
Calcium citrate g/d	1.9	0.9	6.2 (2-10)	2.8 (1-6)	55%
Calcitriol ug/d	0.5	0.25	2 (1-3)	1 (1-3)	50%
Total *			15 (9-28)	7 (1-14)	53%

*Diuretics, magnesium and Vitamin D were included

and 6 post-thyroidectomy. Six women, mean age: 41.8 years (34-56), time of diagnosis: 10.9 years (2-40). The main cause to prescribe teriparatide was symptomatic hypocalcemia in 4 patients and hypocalcemia in their lab tests in the other 4; all of them with high doses of medication, negative impact in their quality of life and some needed multiple hospitalizations because of hypocalcemia. We assessed the doses of carbonate and citrate of calcium, calcitriol and diuretics before and after 6 months of teriparatide, clinical response, lab tests outcomes and follow-up.
Results
Of the six patients with post-surgical hypoparathyroidism, 4 had papillary thyroid carcinoma, 1 multinodular goiter and 1 Grave's disease. The dose of teriparatide was 20 mg in 7 and 40 mg in 1, mean time of treatment: 3.45 years (0.8-7). The decrease in medication could not be assessed in one patient because it was necessary to start the treatment with teriparatide immediately after thyroid surgery. Conclusions: The treatment with teriparatide achieved significant and steady improvement in the values of calcium and phosphorus in most patients. The daily intake of carbonate and citrate of calcium, and of calcitriol decreased about 50%. Teriparatide treatment avoided frequent hypocalcemia-related hospitalizations. Long-term safety studies are necessary when teriparatide is used as an alternative to PTH 1-84.

Permanent Hypoparathyroidism Consecutive to Thyroidectomy: Clinical Characterization in a Tertiary Center in Quito-Ecuador

Stefany Baquero, Gabriela Guevara, Xavier Villota Acosta, Rossana Ruiz Urbaez, Cristhian García, Antonio Palacios & Jorge Luis Salazar Vega
Hospital Eugenio Espejo, Endocrinology, Quito, Ecuador

Background
Acquired hypoparathyroidism due to thyroid surgery for thyroid cancer is the most common postsurgical etiology in a tertiary health center in Ecuador. Therefore, the data published from our country is limited. An observational cross-sectional study was carried out to determine the clinical, biochemical and therapeutic characteristics of patients with permanent hypoparathyroidism in the endocrinology department.
Results
102 patients were included in this trial, 96.1% were women. In the patients with suspected thyroid cancer (75.49%), the detection of nodules was incidental in a 13.73%. Total thyroidectomy without lymph node dissection was performed in 54.9%, thyroidectomy plus central dissection in 41.18%, and total thyroidectomy with right or left lateral dissection in 3.92%. The most prevalent definitive diagnosis was the one associated with malignancy in 61 patients (59.80%), and 98.3% of those due to papillary carcinoma. Tumor size in 57.38% was greater than 2 cm. Lymph node metastases occurred in 49.18%, with more than 5 nodes in 33.33%. According to the operating protocol, parathyroid resection was reported in only one patient (1.64%), however, in 19 (31.15%) there was no description of this data. During follow-up the clinical characteristics were variable. 21.57% were asymptomatic and 78.43% presented one or more of the following symptoms or signs: limb paraesthesias (44.36%), Chvostek's sign (25.56%), Trousseau's sign (11.28%), facial paresthesias (7.53%), spontaneous tetany (4.5%), arrhythmias (1.5%), fatigue (1.5%), laryngospasm (0.75%). Calcium carbonate supplementation in 67.4% of the patients was maintained at a dose between 1500 and 3000 mg/day, in 31.37% lower doses between 500 and 1000 mg/day were needed, only in 3.92% higher doses were necessary, equal or greater at 4000 mg/day. Regarding calcitriol, 33.33% were not supplemented with this drug, in the rest of the patients the most common dose was 0.5 to 1 mg/day. An association was found between suboptimal clinical control of hypoparathyroidism and patients who had more than 1 surgery ($P=0.046$). There was also an association between a tumor size greater than 2 cm and the requirement of calcium doses greater than 1500 mg/day ($P=0.001$).
Conclusion
The characterization in our study showed several similarities with those reported in the literature. Future research is needed to determine the impact of the disease on the quality of life of the people affected, establish costs and improve the use of resources and optimize interventions in our patients.
Key words
Hypoparathyroidism, postoperative, thyroidectomy, calcium, calcitriol.

PTH increasing with BMI associated with cortical bone density

Meliha Melin Uygur
Recep Tayyip Erdoğan University Faculty of Medicine, Department of Endocrinology and Metabolism Disease, Rize, Turkey

Objective
The goal in this study was to evaluate serum parathormone (PTH) and 25-hydroxy-vitamin D (25OHD), calcium levels and bone mineral density (BMD) in patients with obesity and determine the relationship between biochemical bone parameters, body mass index (BMI) and trabecular/cortical BMD over a wide range of body weights.
Methods
We examined 337 women (mean age 41.35 years old; BMI 45.47 kg/m^2) who were classified into three categories of BMI 30-40, 40-50, 50-60 including obese-class I-II (BMI 30-34.9 and BMI 35-39.9) and obese-class III (BMI>40). Bone mineral density (g/cm^2), trabecular, and cortical bone components were measured by dual energy *X*-Ray absorptiometry; and calcium, PTH, and 25OHD were analyzed.
Results
Mean age was similar among the BMI groups. PTH levels were significantly higher in BMI group 2 and 3 than group 1 ($P=0.003$), though 25OHD and calcium levels were not significantly different among the groups ($P=0.82$,0.052; respectively). Postmenopausal women with obesity had lower cortical BMD than premenopausal women ($P<0.001$). There was a negative correlation between PTH levels and cortical BMD ($P=0.001$). Menopause status, BMI and PTH but not age were the predictors for cortical BMD (R2= 0.346, $P<0.001$) (Table-1).
Conclusion
Increased PTH levels were seen in patients with higher BMI without a significant difference in calcium and 25OHD levels. PTH was negatively associated with cortical BMD. Whether or not PTH levels in obesity influences fracture risk needs to be further explored[1, 2].

Study on prevalence of hypercalcemia due to chronic liver disease and correlation with its severity

Laiju Vijayan[1], Vimal M V[2], Anish Kumar[3] & Sunil Prashanth[4]
[1]Malankara Mission Hospital, Internal Medicine, Thrissur, India; [2]Aster MIMS, Endocrinology, Kozhikode, India; [3]Aster MIMS, Gastroenterology, Kozhikode, India; [4]Aster MIMS, Internal Medicine, kozhikode, India

Introduction
Chronic liver disease (CLD) is usually not described as a common cause of hypercalcemia unless there is hepatoma. Of late, there are some reports suggesting CLD as a cause for hypercalcemia. The exact mechanism contributing to hypercalcemia in CLD is poorly understood. It usually correlates with the severity of disease.
Aim of the study
To assess the prevalence of hypercalcemia in patients with chronic liver disease
To study the relation of hypercalcemia to the severity and duration of chronic liver disease.
Materials and Methods
Patients getting hospitalised with chronic liver disease in a tertiary referral centre between 2016 and 2018 were included in the study. Patients with known hypercalcemic disorders, malignancies and those on active Vitamin D supplements were excluded. Besides Liver function tests, Prothrombin time and AFP, Corrected Calcium estimation was done in all patients. In patients who had corrected Calcium>10.5 mg/dl, Parathyroid hormone and Vitamin D assays were performed. Patients who were found to have hypercalcemia were followed up for next 1 year.

Results
251 patients participated in the study. 24 patients (9.6%) was found to have hypercalcemia. 3 /24 had hyperparathyroidism. In the rest, 21 patients, no definitive etiology was found. Hypercalcemia was attributed to chronic liver disease. Majority of the patients (76%) in the hypercalcemia group had Child C score, while only 25% in the non hypercalcemia group had Child C score. The mean bilirubin level was significantly high in hypercalcemic group when compared to non hypercalcemic group (6.67mg/dl vs 2.16 mg/dl). There was no significant renal dysfunction among patients with hypercalcemia compared to patients with normocalcemia.
Conclusion
Hypercalcemia is fairly common among patients with advanced CLD. It correlates well with the severity of liver disese and bilirubin levels.

[1]Endocrinology and Nutrition Unit, San Cecilio Clinical University Hospital, Granada, Spain; [2]Institute of Biosanitary Research of Granada (ibs.GRANADA), Granada, Spain; [3]Nuclear Medicine Unit, San Cecilio Clinical University Hospital, Granada, Spain; [4]Clinical Analysis Unit, San Cecilio Clinical University Hospital, Granada, Spain; [5]CIBER on Frailty and Healthy Aging (CIBERFES), Carlos III Health Institute, Granada, Spain; [6]Department of Computer Science and Artificial Intelligence, University of Granada, Granada, Spain; [7]Andalusian Institute for Research in Data Science and Computational Intelligence, (Instituto DaSCI), Granada, Spain; [8]Department of Medicine, University of Granada, Granada, Spain

Introduction
Hypophosphatasia (HPP) is an inherited disease, characterized by a non-tissue-specific alkaline phosphatase deficiency that leads to abnormal mineralization of bone tissue, which promotes fragility fractures. A defective muscle status could have important clinical repercussions on fracture risk. The aim of this work was to evaluate the relationship between bone and muscle compartment.
Material and Methods
Observational cross-sectional study in adults with PPH. Demographic (age, sex), analytical (alkaline phosphatase (ALP), normal range: 30-120 U/l), and clinical variables (fractures, kilograms (kg) of muscle strength with Jamar dynamometer -cut-off point: <p10 of Spanish population-, rectus femoris quadriceps muscle mass with ultrasound -Sonosite S-Nerve®- and bone mineral density with dual energy X-ray absorptiometry expressed according to T and Z-score. Statistical analysis was performed with IBM SPSS v.25.
Results
Twenty-one subjects were studied. 54% women, mean age: 49 ± 18 years. The mean FA was 28 ± 12U/l. 41% presented at least 1 bone fracture. Mean dynamometry was 28 ± 11kg, 100% with good muscle strength. In the nutritional morphological assessment, the mean Y-axis measurement was 1.5 ± 0.7 and muscle area, 4.8 ± 2.5. The mean T-score in lumbar spine (L1-L4) was -0.8 ± 1.5 and in femoral neck (FC) -1.3 ± 0.9. The mean Z-score in L1-L4 was 0.08 ± 1 and in CF 0.06 ± 1.1. Muscle strength was positively correlated with Y-axis ($r=0.52$, $P=0.02$), with muscle area ($r=0.51$, $P=0.02$), with T and Z-score in CF ($r=0.64$, $P=0.002$) and with T and Z-score in L1-L4 ($r=0.51$, $P=0.02$).
Conclusions
There is a high prevalence of fractures in patients with PPH. A positive correlation was observed between the muscle and bone compartments. Therefore, enhancing the muscle compartment in PPH patients could reduce the risk of fracture in these patients.

Calcinosis cutis as a rare manifestation of primary hyperparathyroidism: a case report

Illias Hamny[1] & Melanie Mendes[2]
[1]Hospices Civils de Lyon, Rhône, Lyon, France; [2]Assistance Publique – Hôpitaux de Paris, Paris, France

Background
Calcinosis cutis is a rare manifestation characterized by calcium deposits in the skin and subcutaneous tissues, mostly found in auto-immune diseases. A case of calcinosis cutis (on the vertex and the face) associated to hyperparathyroidism is presented. We discuss the etiology, diagnosis and management of this rare condition, along with a short review of the literature
Case presentation
We report a case of calcinosis cutis with primary hyperparathyroidism. A 77 year-old woman initially presented a rash associated with a severe pruritus responsible for significant impact on quality of life. The rash was only located on the vertex, the face and the ears and associated to externalization of small grains and filaments. She also presented a hypercalcemia due to primary hyperparathyroidism. It was a moderate hypercalcemia (average 2.85 mmol/l) with PTH 100 ng/l (N 15-65). The renal assessment was normal and the bone mineral density (BMD) was subnormal (femoral neck Tscore -1.7 and lumbar Tscore -2.1). The morphological assessment found an ectopic parathyroid adenoma of 15 mm near the thyroid cartilage. The patient had a cutaneaous biopsy of the calcinosis and the anatomopathological analysis did not found any specific element of calcinosis. The analysis of the small grains stated they were calcium grains.. No auto-immune or infectious cause was found (ANCA, ANA, anti Sm, anti-RNP, anti SSA SSB, HIV, HBV and HCV serologies, and parasitological stool examination). We assumed that it was a cutaneous manifestation of the primary hyperparathyroidism; although it is extremely rare. We reported less than 5 cases in the literature and most of them had calcinosis cutis due to secondary hyperparathyroidism; only one case had primary hyperparathyrodism. By performing a neck surgery to remove the parathyroid adenoma, the calcemia normalized immediately while it took around 3 months to see a favorable evolution of the calcinosis.
Conclusion
Although, calcinosis cutis is rarely associated to primary hyperparathyroidism, it should be evoked in patients with a negative auto-immune or infectious assessment, with a hypercalcemia due to hyperparathyroidism and a rash. If the diagnosis of calcinosis cutis is confirmed in these patients, the surgery of the parathyroid adenoma enables a favorable, although slow, evolution.

Rare association of primary hyperparathyroidism with type 3 multiple autoimmune syndrome

Ghachem Aycha[1,2], Hamza Elfekih[1,2], Sabbagh Ghada[1,2], Ghada Saad[1,2], Barkallah Fatma[1,2], Yosra Hasni[1,2] & Molka Chadli Chaieb[1,2]
[1]Faculty of Medicine Ibn El Jazzar, University of Sousse, Sousse, Tunisia; [2]Endocrinology-Diabetology Department, Endocrinology-Diabetology Department

Introduction
Primary hyperparathyroidism (PHPT) is most commonly sporadic and in rare circumstances, it can develop as part of multiple endocrine neoplasia (MEN). There are few cases described in the literature reporting an association of PHPT with myasthenia gravis and multiple autoimmune syndrome (MAS). These patients may present only with clinical signs of PHPT making it difficult to suspect the coexistence of MAS. Here, we report the case of type 3 MAS in a woman with PHPT due to a parathyroid adenoma.
Observation
A 53-year-old female patient consulted our department for asthenia. She had hypothyroidism due to Hashimoto's thyroiditis, treated with levothyroxine. She had also pernicious anemia treated with vitamin B12 replacement. Her TSH and hemoglobin levels were within the normal reference range. The diagnosis of PHPT was made after a phosphocalcic assessment showing the association of hypercalcemia at 2.89 mmol/l (2,25-2,65 mmol/l) with hypophosphatemia at 0.77 mmol/l (0,8-1,2 mmol/l) and elevated PTH level at 95 pg/ml (10-65 pg/ml). Morphological and functional exams confirmed a right inferior parathyroid adenoma. screening for MEN was negative. She underwent parathyroidectomy and kept a normal serum calcium level (2.28 mmol/l) during the follow-up. The patient was still asthenic with onset of skeletal muscle weakness leading to the diagnosis of myasthenia gravis. Her acetylcholine receptor antibodies levels were positive (1.2 mmol/l; reference range: <0.5 nmol/l).
Discussion
The coexistence of myasthenia gravis with autoimmune thyroid disease and pernicious anemia is well-recognized as type 3 MAS. PHPT is known to be associated with MEN and only few cases reports mentioned its presence with myasthenia gravis and thymoma. Screening for thymoma is necessary since it is present in 15% of myasthenia gravis cases and since thymus and parathyroid glands have common embryologic origin.

Unexpected first finding in primary hyperparathyroidism; peripheral giant cell granuloma in the mandibula

İpek Köroğlu[1], Zeynel Abidin Sayıner[1], Alper Aytekin[2] & Ersin Akarsu[1]
[1]Gaziantep University, Endocrinology and Metabolism, Gaziantep, Turkey; [2]Gaziantep University, General Surgery, Gaziantep, Turkey

Aim and Introduction
Peripheral giant cell granulomas (PHDG) are uncommon exophytic lesions of the oral cavity that originate from the periosteum or periodontal membrane as a polypoid mass. Mandibular involvement is more common than maxillary involvement. Patients with primary hyperparathyroidism can infrequently exhibit PHDG in the early stages of the disease. We wanted to present our case who was examined for giant cell granuloma developing in the mandibula and was found to have parathyroid adenoma.
Case
A 47-year-old female patient with no known history of systemic disease applied to an external center due to swelling in the gingiva. The patient applied to us after a biopsy was taken due to a bone cyst detected at the level of the left second premolar tooth, and a giant cell granuloma that was detected. The patient's creatinin was 0.5 mg/dl (0.51-0.95), PTH level was 163.9 ng/l (12-88), calcium was 10.1 mg/dl (8.8-10.6), phosphorus was 2.8 mg/dl (2.5-4.5), vitamin D was 10 ug/l (30-100), Alcaline Phosphatase was 182 U/l (30-120) and albumin was 41 g/l (35-52). On the ultrasonography of the thyroid, a 3x4x7 mm hypoechoic nodular formation compatible with a parathyroid adenoma was observed in the inferior right thyroid lobe. SESTAMIBI parathyroid scintigraphy revealed a nodular lesion compatible with adenoma. Excision of a parathyroid adenoma was planned for the patient. In the inferior right lobe, a 1x0.5 cm mass consistent with an adenoma was removed. PTH decreased to 53 ng/l 15 minutes after specimen extraction in the patient whose pre-operative PTH was 161 ng/l. The macroscopic appearance of the specimen was reported as a 0.5 g weight, uniformly encapsulated yellow-brown nodular excision material. A peripheral giant cell granuloma developing in the jaw in a patient with normocalcemic primary hyperparathyroidism was evaluated as an early complication of the disease.
Conclusion
Giant cell granulomas that develop in peripheral bones such as the jaw may also occur in the early stages of the disease, and it should not be forgotten that they may be the first sign of the disease. Patients with giant cell granuloma in the oral cavity should be examined for hyperparathyroidism even if the calcium level is normal. Although there is no definitive treatment protocol, parathyroid adenoma excision can be performed.

Evaluation of bone impact in a population of patients with Cushing's disease

Debbah Wissam[1], Mouna Mezoued[1], Bessaid Khadidja[2] & Malha Azzouz[1]
[1]Bologhine Hospital, Endocrinology, Alger, Algeria; [2]Bologhine Hospital, Alger, Algeria

Introduction
Osteoporosis is a well-recognized complication of Cushing's disease (CD). It results from a combination of systemic and local effects that glucocorticoids have on bone and mineral metabolism. The prevalence of osteoporosis due to excess endogenous cortisol has been reported at 50-59%, trabecular bone is more severely affected in CS than cortical bone.
Goal of the study:
To assess the prevalence of bone involvement in patients with Cushing's disease.
Patients and methods
This is a retrospective study of a sample of 69 patients with ACTH-dependent Cushing's disease, collected between (January 2000–December 2022), followed in the endocrinology department of Bologhine. We excluded patients with exogenous Cushing's syndrome and a history of metabolic bone disease and systemic disease such as rheumatoid arthritis, bronchial asthma, or a history of taking bone-affecting antiepileptic drugs. BMD was measured by dual-energy X-ray absorptiometry (DXA) at the level of the lumbar spine (L1–L4, AP) and femur, recorded in terms of absolute mineral content in g/cm ^{2} and Z -score, T-score at both sites.
Results
On a sample of 69 patients: The average age is 43 years, with a sex ratio of 4/1 (4 F, 1 M). Only 43 patients among them (69) benefited from a BMD. Osteoporosis is found in 48.8% of patients, osteopenia in 39.5% and only 11.6% of the cohort have normal BMD. Severe osteoporosis, ie osteoporosis associated with a bone fracture, was present in 3 cases with case of vertebral compression. The Z-score values were significantly lower at the vertebral level with an average of (-1.9) than at the femoral level with an average of (-1.1) ($P=$ 0.001). The difference in BMD was not significant between patients without cycle disorders and oligo-/amenorrhoeic patients with Cushing's disease. (P-value: 0.43) We found a negative correlation with morning plasma cortisol and BMD at the vertebral level ($r^2 = 0.22$, $P=$ 3.55X 10^{-15}) and at the hip ($r^2 = 0.13$, $P=$ 5.25X10^{-15}) although that is not statistically significant.
Conclusion
Our study clearly showed that vertebral BMD in patients with Cushing's disease is more affected than femoral BMD. Osteoporosis must therefore be systematically sought and treated in order to avoid these complications which can compromise the prognosis.

Severe persistent hypocalcemia and hungry bone syndrome after parathyroidectomy in a patient with giant parathyroid adenoma and concurrent osteoblastic bone metastasis from prostate cancer

Alida Nicoleta Dumitru[1], Alina Sucaliuc[2], Octavian Alexandrescu[2], Catalina Pena[1] & Daniel Grigorie[2]
[1]C.I. Parhon National Institute of Endocrinology, Thyroid 2, Bucureşti, Romania; [2]C.I. Parhon National Institute of Endocrinology, Bucureşti, Romania

Introduction
Hungry bone syndrome (HBS) is a rare condition that can appear after surgery for hyperparathyroidism, characterized by hypocalcemia, hypophosphatemia, low calciuria, especially in patients with severe primary hyperparathyroidism, bone lesions and elevated alkaline phosphatase. We present a case of severe persistent hypocalcemia after resection of a giant parathyroid adenoma in a patient with concurrent osteoblastic bone metastasis from prostate cancer.
Case report
A 60 year-old man, who recently underwent surgery for prostate adenocarcinoma, was admitted with newly diagnosed parathyroid adenoma identified during his oncological follow-up. He described generalized weakness, intense back-pain and constipation. Personal history includes gastric resection with gastroenteroanastomosis. Blood tests showed hypercalcemia of 13.6 – 14 mg/dl, normophosphatemia 2.6mg/dl and high alkaline phosphatase of 555U/l, high parathyroid hormone (PTH) 605 pg/ml and bone turnover markers: C-telopeptide 3.32ng/ml, P1NP 1168 ng/ml, osteocalcin 304 ng/ml. Medical treatment with intravenous Zoledronic acid, rehydration, pain relievers was initiated. Full-body CT scan revealed a large right-inferior parathyroid adenoma and multiple osteosclerotic lesions. Parathyroidectomy was performed and histopathological examination confirmed an 9 g and 37/18/19mm parathyroid adenoma. The postoperative period was characterized by severe hypocalcemia (range between 6.6-8.24 mg/dl), hypophosphatemia (range between 1.9-2.6 mg/dl), normal PTH, and also an inflammatory syndrome with acute pain due to chondrocalcinosis crisis of 1st left metatarsophalangeal joint and left knee joint. The patient was discharged with improved clinical and biochemical features on high doses of citrate-calcium and calcitriol.
Conclusion
This case reflects the rare occurence of many mechanisms concurring to hypocalcemia: hungry bone syndrome, osteoblastic metastasis and gastric resection.

Clinical profile of primary hyperparathyroidism patients in a tertiary endocrine center in Kathmadu, Nepal

Ansumali Joshi, Smriti Khadka, Srijana Karmacharya & Sushmita Shrestha
Kathmandu Diabetes and Thyroid Centre, Endocrine, Lalitpur, Nepal

There is limited data on primary hyperparathyroidism in Nepal. We did a retrospective study, where we analyzed data of sixteen patients who presented in our endocrine clinic from January 2016 to December 2022. Among them 10 patients (62.5%) were female and 6 (37.5%) were male. The mean age of the patients was 53.88 +/- 17.72 years ranging from 24 to 82 years. The mean BMI of the patients was 28.38 +/- 5.22 kg/m^2. The most common presenting features were bone and joint pain (38.89%) followed by fatigue and muscle weakness (33.33% each). Renal calculi were present in seven cases (38.89%). Two patients (12.5%) had acute pancreatitis. Hypertension was present in 50% of the cases and diabetes was present in 2 cases only (12.5%). DEXA san was done in 4 patients (25%); one

patient had osteoporosis and two had osteopenia. No patient had fragility fracture. Mean eGFR was 73 +/- 21.10 ml/min/1.73 m2. The mean corrected serum calcium concentration was 12.12 +/- 2.65 mg/dl. The mean serum 25(OH) Vitamin D concentration was 24.05 +/- 13.55 ng/ml. The mean parathyroid hormone was 342.56 +/- 231.35 pg/ml ranging from 81.80 pg/ml to 926.90 pg/ml. Serum phosphorus level was investigated in fourteen patients and the mean phosphorus level was 2.80 +/ 0.76 mg/dl. 24hr urinary calcium was evaluated among 10 patients and the mean was 295.07+/-133.67 mg. Ultrasonography of neck was done in thirteen patients; among them parathyroid adenoma was seen in 10 patients (76.92%). Sestamibi scan was done in all patients which showed parathyroid adenoma in thirteen patients (81.25%) and in three patients (18.75 %) there was no evidence of parathyroid adenoma. Seven of them (53.84%) had left inferior parathyroid adenoma whereas five (38.46%) had right inferior parathyroid adenoma and one (7.69%) patient had left superior parathyroid adenoma. Ten patients (62.5%) underwent surgery to remove parathyroid adenoma. Six patients (37.5%) refused surgery. Patients who refused surgery received Cinacalcet. Before surgery, two patients received IV Zolendronic acid. Postoperatively the mean PTH was 39.32 +/- 27.29 pg/ml ranging from 2 to 126 pg/ml. The mean corrected serum calcium was 9.13 +/- 0.82 mg/dl and the mean serum phosphorus of seven patients was 2.9 +/- 0.38 mg/dl.

Epidemiologic, clinical and biological aspects of primary hyperparathyroidism: About 107 cases

Sidi Mohamed Aghrabatt, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
Faculty Of Medicine And Pharmacy, Casablanca, Morocco

Introduction
Primary hyperparathyroidism is one of the most common endocrinopathies with an estimated prevalence in the general population of 1 to 6/1000.
Objective
To describe the epidemiological, clinical and biological characteristics of patients with primary hyperparathyroidism.
Patients and methods
Retrospective descriptive study, including patients hospitalized in the Endocrinology Department of the Ibn Rochd University Hospital of Casablanca from January 1988 to December 2022. The data collection was carried out with the help of the patients' files, the data collected are the following: age, sex, pathological history, history of the disease, clinical examination, paraclinical examination, management, histological study of the operative part as well as the postoperative evolution. The analysis of the files was done with SPSS software.
Results
The mean age was 52.7 years (10-78), the sex ratio M/F was 0.16. Symptomatology was dominated by bone pain (63%), pathological fractures (42%) and digestive disorders. The mean blood calcium level was 126.19 mg/l. The 24-hour calciuria was elevated in 27 patients. The mean phosphorus level was 21.16 mg/l. Mean PTH was 993.11 pg/ml. The data from our study showed vitamin D deficiency in 83 with a mean Vit D level of 14.09 ng/dl. The average duration of symptoms was around 24 months. Pathological fracture was found in 46 patients, digestive disorder in 17 patients, renal lithiasis in 17 patients and vesicular lithiasis in 4 patients. 96 patients underwent cervical ultrasound, which revealed a parathyroid nodule in 78 cases. Scintigraphy was performed in 31 cases showing pathological fixation in 24 cases. CT scans were performed in 65 patients and revealed a parathyroid adenoma in 51 cases. 89 patients underwent surgery, with associated thyroid surgery in 49 patients. Pathological examination showed parathyroid adenoma in 76 cases, parathyroid hyperplasia in 10 cases and parathyroid carcinoma in 2 cases.
Conclusion
Primary hyperparathyroidism is a frequent endocrinopathy with clinical polymorphism, the main etiology being parathyroid adenoma. The main complications were pathological fractures and renal lithiasis.

Introduction
Osteoporosis is a prevalent skeletal disease associated with increased fracture risk, morbidity, and mortality. Several meta-analyses have investigated the association between non-genetic, non-pharmacologic factors and osteoporosis risk.
Purpose
We aimed to perform an umbrella review of the literature to systematically evaluate the available evidence.
Methods
Meta-analyses of observational studies evaluating the association between non-genetic, non-pharmacologic factors and osteoporosis risk in mainly adult populations were identified by searching MEDLINE (via PubMed), Scopus and CENTRAL databases up to March 2022. The epidemiological validity and methodological quality of the evidence were graded based on commonly accepted criteria.
Results
Twenty-nine meta-analysis publications were identified (41 individual meta-analyses, 33 risk factors, 242 primary study comparisons). Assessed risk factors included nutritional exposures, disease entities (gastrointestinal, endocrinological, dermatological, other systems), infections, biomarkers, and lifestyle characteristics. Of the 41 meta-analyses, 2 (5%) were graded as of high validity evidence to support the association with higher osteoporosis risk (hyponatremia, peptic ulcer), and 4 (10%) as of moderate validity (lower total dairy or fruit intake, Parkinson's disease, higher urine cadmium). Of the 29 meta-analyses, 2 (7%) were judged as of high quality (fruit intake, atopic dermatitis). Most meta-analyses evaluated as of high/moderate validity or high quality included a few primary longitudinal studies.
Conclusion
Despite the breadth of the meta-analytical literature on osteoporosis risk factors, only hyponatremia, peptic ulcer, lower total dairy or fruit intake, Parkinson's disease, and higher urine cadmium were evaluated as of high/moderate validity. Identifying epidemiologically robust risk factors could help guide clinical practice and public health policy.

Usefulness of 18F-Fluorocholine Positron Emission Tomography–Computed Tomography in locating parathyroid adenomas in primary hyperparathyroidism

Sara Mera Carreiro[1], Blanca Bernaldo Madrid[1], Laura Avila Anton[1], Noelia Sánchez-Maroto García[1], Maglen Meneses Navas[2], Aida Ortega Candil[2], Mario Pazos Guerra[1], Patricia Espinosa De Los Monteros[1], Fernando Hernández Olmeda[1], santiago ochagavia camara[3] & Maria Paz de Miguel Novoa[1]
[1]Hospital Universitario Clinico San Carlos, Endocrinology and Nutrition, Madrid, Spain; [2]Hospital Universitario Clinico San Carlos, Nuclear Medicine, Madrid, Spain; [3]Hospital Universitario Clinico San Carlos, General Surgery, Madrid, Spain

Background
Parathyroidectomy is the only definitive treatment for primary hyperparathyroidism (PHPT). Identifying parathyroid adenomas (PA) before surgery is essential to perform minimally invasive surgery and to achieve higher cure rates.
Methods
Retrospective study of patients with PHTP who underwent 18F-Fluorocholine Positron Emission Tomography- Computed Tomography (18FCH-PET-CT) between 2019 and 2021 at our center due to non-localization of PA or discrepancy in previous imaging studies. Diagnostic accuracy of 18FCH-PET-CT and its concordance with other studies and the gold-standard (surgical location) were evaluated.

Results
86 patients with 18FCH-PET-CT, 99mcTc methoxyisobutylisonitrile scintigraphy (MIBI) and ultrasound (US) were included for analysis.18FCH-PET-CT was positive in 53 patients(61.6%) and negative or inconclusive in 33(38.4%). Group with positive 18FCH-PET-CT($n=53$): 77.3% female; 60 mean age. 86% hypercalcemia, 26.4% lithiasis; 37.1% osteoporosis. Mean serum calcium 11 mg/dl; median PTH 125 pg/ml and mean VitD 29.7 ng/ml. In this group, 28 patients underwent surgery and 25 are on the surgery waiting list (SWL). 18FC-PET-CT 100% match the surgical location allowing minimally invasive surgery in 18 out of 28 patients(64.2%). 5 PA were only located with 18FCH-PET-CT. These PA were smaller, with lower mean serum calcium and lower median PTH than those also located by US and/or MIBI. 9 PA were located with US but not with MIBI; and 5 with MIBI but not with US; in both subgroups localization matched with 18FCH-PET-CT and surgery. There were 6 discordant cases between US and MIBI, 1 US and 5 MIBI matched 18FCH-PET-CT and surgery. In 3 cases the PA was located with MIBI and US therefore 18FCH-PET-CT was not needed. Patients on SWL with positive 18FCH-PET-CT($n=25$). 11 PA were only located with 18FCH-PET. 6 PA were located with US but not with MIBI; and 2 with MIBI but not with US; in both subgroups localization matched with 18FCH-PET-CT. There were 6 cases discordant between US and MIBI, 3 US and 3 MIBI matched 18FCH-PET-CT. Group with negative 18FCH-PET-CT($n=33$): 69.6% female; 57 mean age. 48% hypercalcemia, 33% lithiasis; 48% osteoporosis. Mean serum calcium 10.3 mg/dl; median PTH 112 pg/ml and mean VitD 35 ng/ml. In this group in 22 patients US and MIBI were also negative.
Conclusions
18FCH-PET-CT was superior to US and MIBI locating PA, allowing us to perform minimally invasive surgery on our patients. PA identified only with 18FCH-PET-CT were smaller, with lower mean serum calcium and lower median PTH than those also located by US and/or MIBI.

Similarities and differences between thyroid and parathyroid nodules on ultrasound: the PARATH-US study

Dolly Yazgi[1], Carine Richa[1], Sylvie Salenave[1], Peter Kamenicky[1], Amel Bourouina[2], Lorraine Clavier[3], Jacques Young[1], Philippe Chanson[1] & Luigi Maione[1]
[1]Paris Saclay University, Endocrinology and Reproductive Diseases, Le Kremlin-Bicêtre, France; [2]Athis-Mons, Hopital Privé d'Athis-Mons, Sce Endocrinologie, Athis-Mons, France; [3]Melun, GHSIF- hôpital de Melun, Diabetology-Endocrinology, Melun, France

Context
Cervical ultrasound is a frequently used and an accessible operator-dependent tool, which contributes to the characterization of thyroid nodules and to the preoperative localization of pathological parathyroid glands. However, thyroid nodules may be confused with parathyroid lesions. There is no study directly comparing thyroid and parathyroid nodules on ultrasound.
Objectives
1) To describe the ultrasonographic characteristics of parathyroid lesions and to establish bio-radiological correlations; 2) to identify specific features differentiating them from thyroid nodules, by using the EU-Tirads ultrasound stratification scoring risk.
Patients/Methods
PARATH-US is a single-center study. We included 160 parathyroid lesions proved biologically (through intranodular PTH measurement) or histopathologically after surgical excision and compared them with 169 age, sex and maximal diameter-matched thyroid nodules in patients undergoing ultrasound examination in the Endocrinology Department of Bicêtre Hospital from 2016 to 2022.
Results
160 parathyroid lesions belonging to 141 patients (53.8 ± 18.5 years, 104 women, serum calcium levels 2.94 ± 0.33 mmol/l, PTH levels 377.9 ± 614.6 ng/l) were included. 66.4% of them were adenomas, 27.6% hyperplasias, 4.3% atypical adenomas. The maximal diameter of parathyroid lesions was 14.3 ± 7.5 mm, their volume 0.89 ± 2.18 ml. 62.7% of the lesions were solid, 85.4% were separated from the thyroid parenchyma by a hyperechoic septum and 56.7% had intranodular vascular spot. Parathyroid hyperplasias were smaller (0.57 ± 0.76 vs 1.31 ± 2.74 cm3, $P=0.037$) and had less vascular spots (26% vs 73.5% $P=0.004$) than adenomas. In patients harboring a unique parathyroid lesion, strong positive correlations were found between serum calcium, PTH levels and lesion diameter/volume (r>0.58 and $P<0.001$ for all comparisons). Parathyroid lesions more frequently presented an anterior hyperechoic septum than thyroid nodules (85.4 vs. 5.2%, $P<0.0001$, positive predictive value (PPV) set at 99% [95% CI 97-100]). Parathyroid lesions presented with various morphologies, and had more often a non-oval shape than thyroid nodules (55.8 vs. 17.4%, $P<0.0001$, PPV 82% [75-87]). Marked hypoechogenicity (EU-Tirads 5) was found more often within parathyroid lesions (41.2%) than thyroid nodules (18.9%, $P<0.01$, PPV 67% [59-74]). Conversely, the prevalence of kystic content was found more frequently in thyroid than in parathyroid nodules (12,4% vs. 3,6%, $P=0.0037$).
Conclusion
We describe the ultrasound characteristics of a large series of parathyroid adenomas/hyperplasias. We show that parathyroid lesions present high-risk ultrasound features, if confused with thyroid nodules. We demonstrate the presence of specific morphological ultrasound characteristics, which help differentiating parathyroid from thyroid lesions

Evaluation Of Progranulin Expression in Parathyroid Adenomas and Its Relationship with Clinical Parameters

Bilge Can Uyar[1], Nese Cinar[2], Yelda Dere[3], Onder Ozcan[4] & Gulhan Akbaba[2]
[1]Mugla Sitki Kocman University Faculty of Medicine, Department of Internal Medicine, Mugla, Turkey; [2]Mugla Sitki Kocman University Faculty of Medicine, Department of Endocrinology and Metabolic Diseases, Mugla, Turkey; [3]Mugla Sitki Kocman University Faculty of Medicine, Department of Medical Pathology, Mugla, Turkey; [4]Mugla Sitki Kocman University Faculty of Medicine, Department of General Surgery, Mugla, Turkey

Introduction
Primary hyperparathyroidism (PHPT) clinic occurs when the parathyroid glands secrete excess parathormone (PTH) due to hyperplasia, adenomatous or carcinomatous change. In the pathogenesis of the disease, dysregulation has been observed in extracellular signal-regulated 1/2 (ERK 1/2) pathways from the mitogen activated protein kinase (MAPK) family, c-Jun N-terminal kinase (JNK) pathways, and phosphatidylinositol-3 kinase (PI3K) pathways. Progranulin (PGRN) is a glycoprotein found in many tissues in the body, activation of MAPK, JNK and PI3K pathways by PGRN has been observed in studies. Based on these shared pathways, PGRN expression in parathyroid adenomas and its clinical effects were investigated.
Methods
182 cases were included in our study, consisting of 102 PHPT patients who were operated on with adenomas and 80 cases in the control group. The biochemical and clinical data was evaluated. Anti-GRN antibody was applied at 1/300 dilution to the parathyroid samples and statistical analysis was performed. Tissues without staining were considered negative, staining between 1% and 25% were considered weak positive and tissues with staining above 25% were considered strong positive.
Results
While the mean age of the patients was 59.63 ± 12.15 years, the mean age of the control group was 57.01 ± 12.47 years. 91 of 102 patients were female and 11 were male; in the control group 67 were female and 13 were male. No statistical significance was found in terms of age and gender distribution ($P=0.156$, $P=0.378$). Of 102 patients, staining with anti-GRN was negative in 59, mild in 26 and strong in 17. All samples in the control group showed strong staining. PGRN expression was significantly lower in the patient group ($P<0.001$). Staining scores were compared with biochemical and clinical parameters, no significant difference was found ($P>0.05$). The mean calcium levels in the patient and control group were 11.33 ± 0.9 and 9.31 ± 0.45 mg/dl respectively. The mean PTH in the patient group was 173.80 ± 95.35 pg/ml. Biochemical and clinical parameters were compared in the patient group, positive correlation was found with calcium and PTH levels ($P<0.001$); phosphorus and forearm bone density were negatively correlated with PTH levels ($r=-0.38$, $P<0.001$; $r=-0.32$ $P=0.015$). Calcium and phosphorus levels were also negatively correlated ($r=-0.40$ $P<0.001$).
Conclusion
We found that PGRN expression was significantly decreased in sporadic parathyroid adenomas compared to the control group. PGRN may be an important factor in pathogenesis of parathyroid adenomas, more comprehensive studies are needed to investigate the clinical associations and examine the underlying molecular pathways.

A long and challenging journey from the first non-typical gastrointestinal manifestations to the diagnosis of primary hyperparathyroidism and MEN 1

Małgorzata Kiluk, Agnieszka Łebkowska, Irina Kowalska & Monika Karczewska-Kupczewska
Medical University of Bialystok, Department of Internal Medicine and Metabolic Diseases, Białystok, Poland

Introduction
Primary hyperparathyroidism (PHPT), as a state of chronic hypercalcemia, can be manifested by non-typical symptoms which can delay the proper diagnosis for many years and lead to serious preventable complications affecting the patient's quality of life.
Case report
A 52-year-old woman with hypertension, thyroid nodular goiter treated with radioactive iodine and a 20-year history of gastric and duodenal ulcerative disease, complicated by gastric perforation in 2002 and bleeding from duodenal ulcers in 2019, was admitted to the hospital in January 2020 due to general and muscle weakness and ongoing diarrhea for many years resolving only after PPI treatment, which made her incapable of working. Laboratory tests revealed serum concentrations of calcium 3.04 mmol/l (2.10-2.55), phosphate 0.68 mmol/l (0.74–1.52), urinary calcium 14.76 mmol/24 h (2.50-7.50), serum concentrations of PTH 282.8 pg/ml (15.0-68.3), alkaline phosphatase 120 IU/l (37-123). Other relevant laboratory findings were: serum concentrations of gastrin 735 ng/l (13-115) and chromogranin A 1597.67 ng/ml (<100), and normal renal and thyroid function. Neck ultrasound showed a hypoechoic, marginal vascularized lesion 7x6x10mm behind the right thyroid lobe. In a further step, fine needle aspiration and 99 Tc-sestamibi scan were performed, confirming the presence of a single parathyroid adenoma in this location. Moreover, a compression fracture of the L2 vertebra (asymptomatic) and bilateral adrenal tumors, but no renal stones or pancreatic lesion, were detected in abdominal CT. Osteoporosis was confirmed in DEXA. Somatostatin receptor scintigraphy (SRS) did not detect any abnormalities. After excluding pheochromocytoma, the patient underwent parathyroidectomy. However, after surgical treatment, persistent hypercalcemia (2.71mmol/l) and elevated PTH level (378.9 pg/ml) were observed. Conventional imaging, such as neck CT and MRI, 99 Tc-sestamibi scan did not show the localization of the lesion. The diagnostics was extended by performing 18F-fluorocholine PET/CT and revealed hyperfunctioning parathyroid tissue of 8mm in size, between the C7 vertebra and the esophagus. The patient required reoperation, which was followed by the development of hypoparathyroidism, although the peptic ulcer disease and persistent diarrhea resolved spontaneously. Considering the presence of bilateral adrenal tumors, multiple parathyroid adenomas and PPI-dependent diarrhea, a genetic test was performed, confirming multiple endocrine neoplasia type 1 (MEN 1).
Conclusions
The presented case shows how difficult and long the process from first symptoms to proper diagnosis could be. Recurrent peptic ulcers should always prompt to look for secondary causes, especially PHPT.

Cardiac MRI revealed altered structural and functional myocardium in patients with primary hyperparathyroidism: preliminary results

Uğur Özberk[1], Tuncay Hazirolan[2], Selin Ardali Düzgün[2], Tomris Erbaş[3] & Suleyman Nahit Sendur[3]
[1]Hacettepe University School of Medicine, Department of Internal Medicine, Ankara, Turkey; [2]Hacettepe University School of Medicine, Department of Radiology, Ankara, Turkey; [3]Hacettepe University School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Aim
The primary objective of this study was to evaluate the structural and functional cardiac parameters with MRI in patients with primary hyperparathyroidism (pHPT) before and after successful surgery.
Method
In this prospective study 16 patients with pHPT were included. Detailed cardiac magnetic resonance imaging (MRI) examinations were performed preoperatively and at six months post-surgery. Following parameters were measured: Left ventricle ejection fraction (LVEF), left ventricle end-diastolic volume (LVED), left ventricle stroke volume and left ventricle stroke index; left ventricle cardiac output and cardiac index; left ventricle end-diastolic wall mass, left ventricle peak filling rate and peak filling time; E and A, mitral deceleration time, left atrium volume index (LAVI). In addition, pre-contrast T1-T2 relaxation times and ECV values were analyzed.
Results
The mean $\pm$SD age of the 16 patients was 54 $\pm$ 12 years. The majority of the patients were female (F/M: 11/5). Only two patients had symptomatic pHPT, rest were asymptomatic. Evaluation of the asymptomatic patients revealed nephrolithiasis in four (26%) and osteoporosis in six (46%). All of the patients had sporadic disease. The mean $\pm$SD levels of PTH and calcium were 170 $\pm$ 84 pg/ml and 11.2 $\pm$ 0.5 mg/dl, respectively before surgery. The culprit lesion was adenoma in 15 (93%) and hyperplasia and adenoma could not be differentiated in one. After successful surgery PTH and calcium were decreased: 64 $\pm$ 28 pg/ml and 9.7 $\pm$ 0.2 mg/dl, respectively. Comparative cardiac MR images demonstrated lower apical global ECV values postoperatively. Apical global ECV values decreased from 27.9 $\pm$ 3.6% to 26.4 $\pm$ 2.6%, (P =0.015). The both atrial (late ventricular filling velocities from 43.80 $\pm$ 12.97 cm/s to 37.10$\pm$ 11.89 cm/s, P=0.047) and ventricular (left ventricular ejection fraction from 62.81 $\pm$ 3.74% to 60.31 $\pm$ 4.65%, P=0.021; early ventricular filling velocities from 43.78 $\pm$ 9.25 cm/s to 36.10 $\pm$ 9.57 cm/s, P=0.017) systolic forces of the heart were reduced after the control of PTH secretion. There were no differences in other MRI parameters.
Conclusion
In this first study that evaluates structural and functional cardiac MRI parameters in a cohort of patients with pHPT (especially in asymptomatic patients) we showed that apical ECV values, which is an indicator of myocardial fibrosis, were improved after successful surgery. Moreover, we determined that myocardium contracts stronger in primary hyperparathyroidism.

Hypercalcitoninemia in a large cohort of adult and paediatric patients with PTH-resistance syndromes

Arianna Cremaschi[1,2], Giulia Del Sindaco[1,2], Angela Pagnano[1,2], Alessia Dolci[1], Andrea Contarino[1,2], Emanuele Ferrante[1], Maura Arosio[1,2], Agnès Linglart[3,4,5] & Giovanna Mantovani[1,2]
[1]IRCCS Cà Granda Foundation Ospedale Maggiore Policlinico, Endocrinology Unit, Milano, Italy; [2]University of Milan, Department of Clinical Sciences and Community Health, Milano, Italy; [3]AP-HP, Service d'endocrinologie et diabète de l'enfant, ERN BOND, ERN for rare endocrine disorders, Platforme d'expertise des maladies rares, Hôpital Bicêtre Paris Saclay, Le Kremlin-Bicêtre, France; [4]AP-HP, Centre de Référence des maladies rares du métabolisme du Calcium et du Phosphate, filière OSCAR, Paris, France; [5]Université de Paris Saclay, INSERM, U1185, Le Kremlin-Bicêtre, France

Inactivating PTH/PTHrP signaling disorders (iPPSDs, historically named pseudohypoparathyroidism (PHP)) are a group of rare disorders associated with resistance to parathormone (PTH) and other hormones due to impaired hormonal signaling via G protein coupled receptors. Hypercalcitoninemia has been reported in these patients, however very few reports are available. The aim of this study was to further investigate the prevalence and characteristics of hypercalcitoninemia in both paediatric and adult iPPSD patients. We retrospectively collected data from two cohorts of iPPSD patients, both in regular follow-up at two European Endocrinology tertiary centres. The first cohort included 88 paediatric patients with available calcitonin (CT) measurements, and the second consisted of 43 adult patients with at least one simultaneous measurement of CT and PTH. In the latter cohort, c-cell function was assessed by calcium stimulation test in 19 patients. In the paediatric cohort 65.9% had hypercalcitoninemia with mean basal CT levels of 24.9$\pm$26.8 ng/l, 12.1% developed hypercalcitoninemia before the age of 2 and 65.5% before the age of 10. In the adult cohort, 53.5% had hypercalcitoninemia with mean CT levels of 21.6$\pm$8.3 ng/l. Calcitonin measurements remained stable throughout a mean follow-up time of 59$\pm$47.3 months. No correlations were detected between CT levels and PTH levels (P=0.5). Other etiologies of hypercalcitoninemia were excluded, i.e. renal failure and drug interferences, and all patients underwent regular thyroid ultrasound to screen for medullary thyroid cancer (MTC). We also performed calcium stimulation test in 19 patients and we compared CT levels with a control group of 33 healthy patients and a group of 20 patients with pathological evidence of MTC or c-cell hyperplasia (MTC-CCH). We found that there was a statistically significant difference in both basal (P=0.034) and stimulated (P=0.002) CT levels in control and iPPSD groups, as well as control and MTC-CCH group (basal CT levels P=0.000; stimulated CT levels P=0.000), on the contrary there was no significant difference in both values in iPPSD and MTC-CCH group. Our study confirms that elevated calcitonin levels are commonly found in both adult and paediatric patients with PTH-resistance syndromes. Our findings suggest that it may be a condition that develops in early age and remains stable throughout time. Moreover, these patients show an hyperresponsiveness to calcitonin stimulation test. Differential diagnosis with MTC based on CT levels, both basal and stimulated, can be challenging.

Trabecular bone score increases the proportion of patients with asymptomatic primary hyperparathyroidism meeting surgical criteria

Matteo Malagrinò[1], Anna Piazza[1], Nicolò Bisceglia[1], Marcello Bernardi Boari[2], Giulia Vandi[1], Paola Altieri[1], Uberto Pagotto[1] & Guido Zavatta[1]

[1]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy; [2]Department of Radiology, IRCCS Azienda Ospedaliero-Universitaria di Bologna Policlinico S Orsola-Malpighi

Context
Several studies have shown that Trabecular Bone Score (TBS) predicts fractures independently of Bone Mineral Density (BMD) measured with Dual Energy X-ray Absorptiometry (DXA), even in patients with Primary Hyperparathyroidism (PHPT), known to have deteriorated bone microarchitecture. Low TBS values alone are still not considered as a single criterium to recommend parathyroid surgery. Measuring bone quality in patients with PHPT may be helpful to identify a proportion of patients at increased fracture risk regardless of the other known criteria used to recommend parathyroidectomy.
Objective
To describe the prevalence of low bone quality measured by TBS in a cohort of patients diagnosed with PHPT to evaluate its impact on the clinical management of PHPT.
Design
Cross-sectional, observational.
Setting
Academic.
Patients
From February 2021 to January 2023, 133 patients with asymptomatic classical PHPT (i.e. with elevated total, albumin adjusted, or ionized serum calcium) were consecutively evaluated. All patients underwent complete serum and urinary assessment in the same laboratory, bone density test with TBS by using the same DXA machine, and renal ultrasound to screen for nephrolithiasis or nephrocalcinosis. We selected 119 patients who had a DXA performed at all 3 sites along with TBS. We retrospectively applied to each patient the recently revised criteria for parathyroid surgery as per the V International Workshop.
Main outcome measures
TBS, BMD, and biochemistries. TBS <1.200 was used to discriminate low bone quality.
Results
Mean age of the patients was 67 ± 12 years and most were women (102/119, 85.7%). TBS was low in 34/119 patients (28.6%) with PHPT. Patients met the criteria for parathyroid surgery respectively due to hypercalcemia (>1 mg/dl above the upper normal limit) (16/119, 13.4%), hypercalciuria (>250mg/day for females or > 300mg/day for males) (53/119, 44.5%), any previous clinical fragility fracture or morphometric vertebral fracture (28/119, 23.5%), reduced GFR (<60ml/min) (19/119, 15.9%), age less than 50 years (8/119, 6.7%), nephrolithiasis (20/119, 16.8%). Among the 29 patients not meeting any surgical criteria, 3 (10.3%) had low TBS. Among those with BMD T-score above -2.5 at all three sites, TBS was reduced in 6/48 (12.5%) patients. Lower TBS was associated with increasing age and lower BMD T-scores, with a strong association with osteoporosis at 1/3 distal radius (Odds-Ratio: 3.98, $P=0.001$).
Conclusions
By implementing routine TBS measurement, an estimated additional 10% of patients, who would otherwise not meet the current listed surgical recommendations, could benefit from curative parathyroid surgery to reduce fracture risk.

Introduction
Bone mineral density (BMD) is considered a valid surrogate of bone strength in postmenopausal women, however it lacks sensitivity in individual fracture risk assessment in the setting of women with early breast cancer (EBC) patients treated with aromatase inhibitors (AIs). Indeed, mechanical resistance of bone only partially depends on bone quantity, and bone geometry and size play an important role in bone resistance to fractures. In this cross-sectional study, we assessed for the first time the association between vertebral fractures (VFs) and parameters of bone geometry in women with EBC patients treated with AIs. Moreover, we aimed also to provide a preliminary information on the possible effects of anti-resorptive drugs on bone geometry parameters.
Methods
HR-positive EBC postmenopausal women who were candidates to AIs therapy, with normal renal function, without any bone metabolic disorders, and no previous or current treatment with anti-osteoporotic drugs or glucocorticoids. Were consecutively evaluated for bone strain index (BSI), dual-X-ray absorptiometry (DXA) based parameters of bone geometry and morphometric VFs. Subjects were categorized in 3 groups in order to evaluate the impact of AIs and denosumab on bone geometry: AI-naive, AI-treated minus (AIDen-) or plus (AIDen+) denosumab.
Results
A total of 610 EBC patients entered the study: 305 were AI-naive, 187 AIDen-, and 118 AIDen+. In the AI-naive group, fractured patients compared to non-fractured ones presented a lower total hip BMD (mean 0.77 vs 0.84, $P=0.001$) and T-score (1.38 vs 0.86, $P=0.001$), but higher femoral BSI (femoral neck BSI 1.93 vs 1.70, $P=0.001$). Concerning bone geometry parameters, AI-naive fractured patients reported a significant increase in femoral narrow neck (NN) ($P=0.037$) endocortical width ($P=0.035$), femoral NN subperiosteal width ($P=0.045$), intertrochanteric buckling ratio (BR) ($P=0.007$), femoral shaft (FS) BR ($P=0.007$) and endocortical width ($P=0.035$), as compared to non-fractured patients. Some of these associations were maintained also in AI-treated women. Specifically, AIDen-fractured patients showed higher values of BR ($P=0.014$), lower cortical thickness ($P=0.033$) and higher FS endocortical width ($P=0.019$) as compared to non-fractured subjects. Conversely, CSA and CSMI in both IT area and FS area were significantly decreased according to the presence of VFs in the AIDen+ population.
Conclusion
This study suggests how DXA-derived bone geometry parameters can be variably associated with VFs in EBC patients, either AI-naive or AI treated in combination with denosumab. This finding reflects the need of a tailored choice of fracture risk parameters in the 3 subgroups of EBC patients.

Hyperglycemia-induced unique transcriptional changes in osteocytes

Joshua Stokar[1,2], Vladislav Temkin[1], Irina Gurt[1], Natan Lishinsky[1,2], Lynne Cox[3] & Rivka Dresner-Pollak[1,2]
[1]Hadassah Medical Center, Endocrinology, Jerusalem, Israel; [2]The Hebrew University of Jerusalem, Faculty of Medicine, Jerusalem, Israel; [3]University of Oxford, Biochemistry, Oxford, United Kingdom

Introduction
Diabetes leads to skeletal fragility and an increased fracture risk. As a master regulator of bone-remodeling, osteocyte dysfunction may play a role in the pathogenesis of diabetes-related skeletal fragility. To study the effects of hyperglycemia on the osteocyte in-isolation, we used the osteocyte-like cell line IDG-SW3 taking an unbiased multi-omics-based approach.
Methods
IDG-SW3 cells were plated in a differentiation osteogenic medium under 3-conditions: normal glucose (5mM; NG), high-glucose (25mM; HG) and mannitol 20mM with glucose 5mM to control for the hyperosmolarity induced by HG. Media was changed twice weekly for 28 days, with cells harvested at 1,3,7,14, 21 and 28-days post differentiation induction. 3-biological-replicates were used for each condition with the entire experiment repeated 3-times. RNA was extracted from cell lysates 14 days after induction to osteogenesis with bulk RNA-SEQ performed. Protein was extracted at day 16 after induction to osteogenesis with proteomics analysis by LCMS.
Results
HG conditions led to lower PH in the supernatant and a delay in markers of osteocyte differentiation. RNA-SEQ analysis revealed 1340 differently expressed genes (767 up 573 down; DEGs). Interestingly, mannitol led to a much smaller transcriptional change with only 103 DEGS vs NG (cut-off of FC>2 and p.adj <0.05) with just 38 DEGs in common between the comparisons. Ingenuity Pathway Anaylsis (IPA) of DEGs (HG vs NG) revealed significant deactivation of the autophagy related pathways CLEAR Signaling (Z-score -3.015, -log[B-H *P*-value] 8.31) and Phagosome Formation (Z-score -3.43, -log[B-H *P*-value] 1.458); a pattern not observed in mannitol vs NG. Proteomics analysis revealed HG led to activation of the senescence pathway (Z-score 1.213 -log[B-H *P*-value] 3.66) and deactivation of the CLEAR signaling pathway

score -0.755 -log[B-H *P*-value] 3.03). **Conclusion:** These results reveal the differential effects of hyperosmolarity and hyperglycemia on transcriptional changes and cell differentiation in the osteocyte, which may play a role in the pathophysiology of diabetes-related skeletal fragility. Specifically, the deactivation of autophagy and activation of senescence pathways induced by hyperglycemia in osteocytes warrant future research, as they may serve potential therapeutic targets for prevention and treatment of diabetes-related skeletal fragility.

Low trabecular bone score better predicts prevalent vertebral fractures in younger rather than older women starting endocrine therapy for breast cancer

Matteo Malagrinò, Anna Piazza, Nicolò Bisceglia, Giulia Vandi, Paola Altieri, Uberto Pagotto & Guido Zavatta
Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy

Context
Although Trabecular Bone Score (TBS) has been widely and independently associated with fragility fractures, its diagnostic power in certain populations remains to be established. Women initiating aromatase inhibitors for breast cancer should be screened for bone health to prevent cancer treatment-induced bone loss as much as possible. TBS is regarded as an adjunctive tool to evaluate these patients, but thresholds of pharmacologic interventions are still a gray zone, especially in younger women.
Objective
To test the diagnostic power of TBS to predict prevalent vertebral fractures at the start of endocrine therapy for breast cancer. Low TBS was defined as <1.2.
Design
Cross-sectional, real-life.
Setting
University hospital.
Patients
We retrospectively evaluated 223 consecutive ambulatory women with newly diagnosed early breast cancer from February 2021 to November 2022. They all underwent a prespecified protocol which included mineral biochemistries with bone turnover markers, bone mineral density with TBS, and endocrine consultation. Lateral X-rays images of the spine performed just before breast surgery were reviewed to screen for asymptomatic vertebral fractures.
Results
Mean age of the patients was 61 ± 12 years. Overall, 65 patients (29%) had normal bone density (BMD), 90 patients (40%) had osteopenia, and 68 patients had osteoporosis (31%), with 35/223 (15.7%) women having low TBS. The prevalence of low TBS progressively increased with decreasing BMD (6.2% in normal BMD, 10% with osteopenia, and 32.3% with osteoporosis; $P<0.001$). Vertebral fracture prevalence was 24/223 (10.8%). BMD category was highly associated with prevalent vertebral fractures ($P<0.001$), but this was not the case for low TBS alone ($P=0.597$). A low TBS highly correlated with advanced age ($P<0.001$), independent of other clinical or biochemical parameters (age, BMD T-score, renal function, 25-OH vitamin D, PTH). ROC analyses showed that TBS Area Under Curve (AUC) was 0.647 ($P=0.021$), comparable ($P=0.561$) to that of femur neck T-score (AUC $=0.688$, $P=0.003$) for detecting prevalent vertebral fractures. Notably, the diagnostic power of TBS was much higher in women younger than 65 years, with TBS AUC being 0.769 ($P=0.032$), with femur neck BMD being much less accurate (AUC 0.564, $P=0.339$). By contrast, TBS AUC dropped to 0.484 ($P=$NS) in older women, whereas femur neck T-score retained its expected diagnostic accuracy (AUC 0.690, $P=0.008$).
Conclusions
TBS rather than BMD could better predict prevalent vertebral fractures in women younger than 65 initiating aromatase inhibitors, as compared to older women. In the latter group, femur neck BMD T-score was confirmed to be more accurate.

Association Between Primary Hyperparathyroidism and Cardiovascular Outcomes: A Systematic Review and Meta-analysis

Siang-Ke Kong[1], Ming-Chieh Tsai[1,2,3], Chun-Lin Yeh[2], Yu-Cheng Tsai[2] & Wen-Hsuan Tsai[1]
[1]Mackay Memorial Hospital, Division of Endocrinology and Metabolism, Department of Internal Medicine, Taipei, Taiwan; [2]Mackay Medical Collage, Department of Medicine, New Taipei City, Taiwan; [3]College of Public Health, National Taiwan University, Institute of Epidemiology and Preventive Medicine, Taipei, Taiwan

Background
Parathyroid hormone excess is associated with increased risk of cardiovascular disease (CVD). The aim of the study is to evaluate the correlation between primary hyperparathyroidism (PHPT) and CVD or cardiovascular death (CV death).
Method
Database research was conducted via PubMed and Embase on November 21st, 2022, with key words as following: "cardiovascular disease" "cardiovascular death" and "primary hyperparathyroidism". A total of 10 cohort studies and 1 randomized controlled trial were included in our analysis. Our primary outcomes were CV death and CVD. Patients with PHPT were compared to general population. We also compare patients that had received parathyroidectomy (PTX) to those without PTX. The variables were pooled as hazard ratios or standard mortality ratios, and a meta-analysis using random-effects model was performed.
Result
A total of 11 studies were identified, including 259,218 PHPT patients with or without PTX, and of which 192,315 were women (74.1%). The average of mean ages reported in 9 studies available was 61.9 years. PHPT was associated with higher risk of CV death when compared to general population (RR 1.61 [95% confidence interval (CI) 1.47-1.78]); however, there was no significant difference of CVD risk between patients with PHPT and general population (RR 1.73 [95% CI 0.87-3.47]. When compared to patients without PTX, PTX had lower risk of CV death (RR 0.75 [95% CI 0.71-0.80]) and CVD (RR 0.92 [95% CI 0.90-0.94]).
Conclusions
Patients with PHPT had higher risk of CV death than general population, and PTX reduced the risk of CV death and CVD.

Effectiveness of Jugular Venous Sampling of Parathormone in Imaging Negative Patients with Primary Hyperparathyroidism

Kenan Sakar[1], Anil Ugurlu[2], Mehmet Kapan[2], Gulhan Akbaba[1], Nesat Cullu[3], Onder Ozcan[4], Ozcan Dere[4], Ozan Kandemir[5], Yelda Dere[6] & Nese Cinar[1]
[1]Mugla Sitki Kocman University Faculty of Medicine, Department of Endocrinology and Metabolism, Muğla, Turkey; [2]Mugla Sitki Kocman University Faculty of Medicine, Department of Internal Medicine, Muğla, Turkey; [3]Mugla Sitki Kocman University Faculty of Medicine, Department of Radiology, Muğla, Turkey; [4]Mugla Sitki Kocman University Faculty of Medicine, Department of General Surgery, Mugla,; [5]Mugla Sitki Kocman University Faculty of Medicine, Department of Nuclear Medicine, Mugla, Turkey; [6]Mugla Sitki Kocman University Faculty of Medicine, Department of Pathology, Mugla, Turkey

Introduction
The only curative treatment of primary hyperparathyroidism (pHPT) is surgery. Accurate pre-operative localization of abnormal parathyroid glands is an essential prerequisite to reduce the complication risk associated with surgery. We aimed to determine the diagnostic value of jugular venous sampling (JVS) in cases of pHPT in which the location of parathyroid adenomas could not be determined through various preoperative imaging studies.
Methods
A retrospective study was conducted with 22 patients with pHPT who underwent bilateral JVS. The samples were collected from the most inferior portion of each internal jugular vein and sent for standart PTH measurement. $>10\%$ gradient difference between the sides was accepted as positive. The patients' laboratory results, preoperative ultrasonography (US) and parathyroid scintigraphy findings, JVS results, and postoperative pathology results were recorded.
Results
JVS was performed in 22 patients (1 M/21 F) with pHPT. 15 of the patients had negative ultrasound and scintigraphy findings. Gradient differences were found in a total of 12 patients (54%), 9 on the right and 3 on the left. Gradient difference was found in JVS in 6 patients with negative scintigraphy and in 5 patients with negative US findings. Although 4 of them were positive in ultrasound and 3 of them were positive in scintigraphy, no gradient difference was found in JVS. Among 12 patients, the JVS gradient localization was found to be incompatible with surgical exploration in only one patient. All patients' pathology results were reported as parathyroid adenoma.

Discussion
In cases with small or multiple parathyroid lesions, the location of lesions cannot be determined using US and ^{99m}Tc-sestamibi SPECT. JVS is generally recommended to lateralize the lesion in scintigraphy-negative patients undergoing primary surgery. Alvarado *et al.* found a 56% positive lateralization in a study with both positive and negative pHPT patients, and a positive lateralization of 76% in the control group without parathyroid disease. The authors reported that JVS was not sufficient to determine the location of imaging negative parathyroid adenomas. On the otherhand, Denise *et al.* found that JVS was correct in in localization the side of the abnormal gland in 81% of the patients with pHPT.
Conclusions
JVS may be used as an adjunctive technique for preoperative localization of parathyroid lesions that cannot be located by non-invasive imaging studies if a gradient difference is reached and more extensive studies are needed to confirm the role of this tecnique before surgery.

Impact of Zoledronate or Denosumab on Bone-related Biochemical Parameters in Osteoporotic Postmenopausal Women with Primary Hyperparathyroidism

Katarina Mlekus Kozamernik[1,2], Luka Ležaić[2,3], Marko Hočevar[2,4] & Tomaž Kocjan[1,2]
[1]UMC Ljubljana, Endocrinology, Ljubljana, Slovenia; [2]Faculty of medicine University of Ljubljana, Ljubljana, Slovenia; [3]UMC Ljubljana, Department of Nuclear Medicine, Ljubljana, Slovenia; [4]Institute of Oncology, Surgery, Ljubljana, Slovenia

Introduction
Antiresorptive treatment can preserve bone mineral density (BMD) in patients with primary hyperparathyroidism (PHPT) when surgery is not feasible or desired. We aimed to compare the impact of zoledronate vs denosumab on bone-related biochemical parameters in this population.
Methods
We analyzed preliminary data from our ongoing randomized trial on osteoporotic postmenopausal women with PHPT who are being treated either with zoledronate 5 mg iv once a year (ZOL group) or with denosumab 60 mg sc every six months (DMAB group) (ClinicalTrials.gov Identifier NCT04085419). Here we compare their laboratory parameters and bone turnover markers at baseline and three months after starting the treatment.
Results
We studied 21 osteoporotic females (with mean BMD at LS 0.841 (SD 0.132), TH 0.749 (0.117), FN 0.645 (0.084), 1/3R 0.500 (0.066) g/cm^2) aged 76.2 (7.1) years and 26.9 (9.7) years from menopause with BMI 28.78 (4.4) kg/m^2. Eight patients received zoledronate (ZOL), and thirteen were treated with denosumab (DMAB). There were no statistically significant differences in baseline characteristics between the two groups. Three months (3M) after starting treatment, there was a statistically significant fall in serum calcium (S-Ca) levels in the ZOL group only (baseline S-Ca 2.7 mmol/l (0.1) vs. 3M S-Ca 2.6 mmol/l (0.1); $P=0.033$). Intact parathyroid hormone (iPTH) values increased in both groups; the increase did not differ between the two groups (ZOL Δ iPTH 44.28 (113.54) vs. DMAB Δ iPHT 42.84 (63.33); $P=0.9$). Baseline 25 OH vitamin D was similar in both groups, with the average value 56.8 (18.8) nmol/l, and remained unchanged after treatment. Bone turnover markers decreased statistically significantly in both groups (ZOL CTX baseline 0.495 (0.3) vs. 3M 0.098 (0.12) μg/l; $P<0.01$; ZOL P1NP baseline 74.5 (28.3) vs. 3M 19.9 (9.9) μg/l; $P<0.01$; DMAB CTX baseline 0.89 (0.77) vs. 3M 0.01 (0.01) μg/l; $P<0.01$; DMAB P1NP baseline 79.7 (34.4) vs. 3M 14.05 (4.9) μg/l; $P<0.01$). The differences between the groups were not statistically significant (ZOL Δ CTX 0.4 (0.3) vs. DMAB Δ CTX 0.88 (0.77) μg/l; $P=0.1$ and ZOL Δ P1NP 54.55 (24.86) vs. DMAB Δ P1NP 65.65 (32.08) μg/l; $P=0.4$).
Conclusion
Preliminary analysis showed a significant decline in calcium levels only in the ZOL group. Bone turnover markers significantly decreased in both groups—the apparent numerical difference in decrease after ZOL vs after DMAB was not statistically significant.

Three Times Unlucky-Severe Hypercalcaemia of Immobility Compounded by Undiagnosed Hyperthyroidism and Milk Alkali Syndrome

Rhiannon May & Jana Bujanova
University Hospital Southampton, Southampton, United Kingdom

Background
Immobility can be associated with severe hypercalcaemia, especially when compounded by other risk factors such as concurrent hyperthyroidism and high dietary calcium/milk intake and associated complications such as renal stones and fractures.
Clinical case
59y female presented acutely with confusion, vomiting, constipation and muscle weakness. She had history of obesity, stable Crohn's disease with no recent increase in colonostomy output. Her calcium was high at 4 mmol/l (n-2.2-2.6 mmol/l), PTH low, but not suppressed at 2 pmol/l (n- 1.8-6.8 pmol/l), ALP- 138 U/l (n- 30-130 U/l), bicarbonate- 27.3 mmol/l, pH- 7.375. Screen for myeloma, sarcoid and cancer was negative. FT4 raised at 19 pmol/l (n- 7.7-15.1 pmol/l) and TSH 0.01 mu/l (n- 0.34-5.6 mu/l). CT scan excluded cancer and identified stones in kidneys and bladder and healed pubic ramus fractures suggesting a more insidious onset. She had moderate goitre. No history of lithium, calcium supplements, antacids use. Three months prior to presentation had cCa- 2.78 mmol/l, but not investigated. Dietary enquiry revealed consumption of minimum of 2-3 pints (1.1-1.7l) of semi-skimmed milk per day alongside at least two yogurts and cheddar cheese. This intake was calculated to be at least 1910-1614 mg/daily of calcium [2-3 x 704 mgs of calcium (milk) + 2 x 140 mg (yoghurts) + 222 mg (30g of cheddar cheese)]. Social enquiry revealed she has been completely bedbound for eight months due to severe knee osteoarthritis and malunion ulna fracture and chronic elbow dislocation impacting her ability to use walking aids. Patient responded to IV hydration and pamidronate infusion. Treatment with carbimazole was commenced and reduced calcium intake was advised. She was referred for urgent ulna reunion surgery followed by knee surgery. Her calcium reduced to 2.86 mmol/l and subsequently to 2.68 mmol/l during follow up. Her thyroid function normalised.
Conclusion
Our patient had hypercalcaemia of immobility, hyperthyroidism and milk alkali syndrome. It is important to be aware of these rarer causes (even in patients not obviously suffering paralysis from a spinal cord injury or a stroke) when alternative diagnoses have been excluded and explore them in detail at presentation. Immobilisation affects balance between bone formation and resorption by increased sclerostin secretion by osteocytes, which diminishes the bone formation stimuli by blocking the Wnt-Runx2 pathway in the osteoblast. This was paired with increased bone turn over from hyperthyroidism, oral calcium load and diminished renal calcium excretion from milk alkali syndrome.

DOI: 10.1530/endoabs.90.P584

Evidence of a non-classical phenotype of hypoparathyroidism in a cohort of adult patients with iron overload diseases

Selene Evangelisti[1,2], Sara De Vincentis[1,2], Barbara Rossi[1,2], Maria Chiara Decaroli[1,2], Michela Locaso[1,2], Francesca Ferrara[3] & Vincenzo Rochira[1,2]
[1]University of Modena and Reggio Emilia, Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]Azienda Ospedaliero-Universitaria di Modena Policlinico di Modena, Ospedale Civile di Baggiovara, Unit of Endocrinology, Department of Medical Specialties, Modena, Italy; [3]Azienda Ospedaliero-Universitaria di Modena-Policlinico, Internal Medicine Unit and Centre for Hereditary Anemias, ERN-EuroBloodNet Center for Iron Disorders, Modena, Italy

Background
Iron overload disorders (IOD) are associated with a higher occurrence of unbalanced calcium (Ca)-phosphorous (P) metabolism, including hypoparathyroidism (HPT). However, data about prevalence and presentation of HPT in this setting are scanty. A Ca/P ratio <2.32 has been proposed to detect HPT in the general population.
Aim
To characterize Ca-P homeostasis, particularly the prevalence of HPT, in a cohort of adult patients with IOD compared to healthy subjects. Furthermore, the performance of Ca/P ratio in identifying concealed forms of HPT in IOD patients was tested.
Methods
A single-center, cross-sectional, case-control study was carried out including 58 IOD patients (39 patients with β-thalassemia (β-T) and 19 patients with hereditary hemochromatosis (HH)) and 76 controls. The main outcomes were: serum Ca, P, Ca/P ratio and intact parathyroid hormone (PTH). Primary hypoparathyroidism (pHPT) was defined as hypocalcemia with low/inappropriately normal PTH, whereas subclinical hypoparathyroidism (sHPT) as serum Ca at the lower limit of normal range with low PTH.
Results
IOD patients had lower serum Ca ($P=0.032$), higher serum P ($P=0.004$) and lower Ca/P ratio ($P<0.001$) compared to controls, whereas no difference was found for serum PTH. Patients with β-T had higher serum P ($P<0.001$), lower Ca/P ratio ($P<0.001$) and lower serum PTH ($P<0.001$) compared to patients with HH and

controls, whereas no difference was found for serum Ca among subgroups. On the other hand, Ca/P did not significantly differ comparing HH and controls. pHPT was found in 6 patients with β-T (15.4%) and in none patients with HH; sHPT was found in 19 patients with β-T (48.7%) and in 1 patient with HH (5.3%). IOD patients with HPT showed lower Ca/P ratio ($P<0.001$) compared to IOD patients without HPT. A Ca/P ratio <2.32 allowed the correct identification of 19 out of the 26 IOD patients with overt or sub-clinical HPT (sensitivity 73.1%; specificity 87.5%). IOD patients with Ca/P ratio <2.32 had an almost 20-fold increased likelihood to be affected by HPT (OR 19.0 [4.9-74.0]; $P<0.001$).

Conclusions

Despite a low prevalence of overt pHPT, the non-classical phenotype sHPT seems to be a common finding in IOD patients. The Ca/P is useful to detect HPT even in this context. A periodic evaluation of serum Ca and P should be included in the follow-up of these patients to early detect an unbalanced mineral metabolism.

How well are guidelines followed in the follow-up of hypoparathyroid patients?

Beril Turan Erdogan[1], Caglar Keskin[1], Şefika Burçak Polat[2], Narin Nasiroglu Imga[1], Didem Ozdemir[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]

[1]Ankara City Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Yildirim Beyazit University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Background

Hypoparathyroidism (HypoPT) is a rare condition that is characterized by hypocalcemia and hyperphosphatemia due to low or inappropriately normal serum levels of parathyroid hormone (PTH) for at least 6 months. The long-term complications of hypoparathyroidism indicate the necessity of screening them. In the follow-up of these patients according to hypoparathyroidism guidelines is recommended; calcium, phosphorus, albumin, magnesium, creatinine, and eGFR levels should be checked annually or more frequently than clinical status. A 24-hour urine calcium excretion is recommended once a year. Renal imaging is recommended in patients with elevated creatinine or high urinary calcium excretion, or patients suggesting renal stones. For basal ganglia calcification, brain MRI or CT is advised. A yearly eye examination is recommended for cataracts. In our study, in the long-term follow-up of hypoparathyroidism patients, it was examined whether the guidelines were followed.

Methods

Between February 2019 and September 2021, patients aged ≥ 18 years with hypoparathyroidism who were followed by the routine scheduled monitoring visit at the outpatient clinic of the endocrine and had their data retrospectively documented. Comorbidities, imaging, and hormonal tests and results of these patients were evaluated.

Results

Among the 264 patients, the mean age was 49.34 ± 12.98 (22-91). 211 (79.9%) of the participants were female. All patients' had blood biochemistry tests. Of the patients, 3% had eye examinations, 9.8% had brain imaging, 18.6% had renal imaging, 11 % had 24 h urinary Ca results. Cataract was observed in 2 (0.8%), basal ganglia calcification was observed in 4 patients (1.5%). Nephrocalcinosis or nephrolithiasis was observed in 2 patients (0.8%). Hypercalciuria was defined as a 24 h urine calcium excretion >300 mg/24 h and was observed in 8 of participants with hypoparathyroidism. (Table 1)

Table 1 Hypoparathyroidism complications screening

	Total ($n=264$)
Eye screening	8 (3)
Normal	5 (1.9)
Cataract	2 (0.8)
Glaucoma	1 (0.3)
Brain imaging	26 (9.8)
Normal	22 (8.3)
Calcification	4 (1.5)
Renal imaging	49 (18.6)
Normal	47 (17.8)
Renal stone	2 (0.8)
24 h Urinary Ca	29 (11)
24 h Urine Ca normal (<300 mg/24 h)	21
24 h Urine Ca elevated(>300 mg/24 h)	8

Conclusion

In the follow-up of patients with hypoparathyroidism, the guidelines cannot be followed much in intensive outpatient clinic conditions. These patients screening for complications is as important as blood tests.

Serum Vitamin D Levels in a Group of Migraine Patients Compared With Healthy Controls: A Case–Control Study

Zeliha Yarar[1], Hatice Çalışkan Burgucu[2], Mustafa Altaş[3] & Mustafa Kulaksizoglu[1]

[1]Meram Faculty of Medicine, Necmettin Erbakan University, Department of Endocrinology and Metabolism, Konya, Turkey; [2]Konya Cİty Hospital, Department of Endocrinology and Metabolism, Konya, Turkey; [3]Meram Faculty of Medicine, Necmettin Erbakan University, Department of Neurology, Konya, Turkey

Objective

Migraine is a common primary headache disorder that affects 12-15% of the general population. Also, vitamin D deficiency is a global health problem. A few studies have shown relationship between serum vitamin D levels and headache. The aim of this study was to investigate the difference in serum levels of 25-Hdroxy vitamin d [25(OH)D] between migraine patients and healthy controls and also to determine the relationship of vitamin D deficiency with frequency and severity of migraine.

Materials and Methods

204 newly diagnosed migraine patients and age- and sex- matched 204 control subjects were enrolled in this case -control study. Migraine diagnosis was settled according to the International Classification of Headache Disorders-III diagnostic criteria. The demographic and clinical data (migraine subtypes, frequency and severity of migraine) of the participants were recorded. Blood samples were obtained and 25(OH)D serum concentrations were determined using enzyme-linked immunosorbent assay (ELISA). Serum 25(OH)D $\leq$ 20, 21-29 and ≥ 30 ng/ml were considered deficient, insufficient, and sufficient, respectively.

Results

The mean concentration of 25(OH)D was 15.30 ± 9.93 ng/ml in migraine group and 14.62 ± 7.93 in controls. There was no significant difference in 25(OH)D concentration between migraine group and controls ($P=0.443$). There was no correlation between 25(OH)D level and headache characteristics including aura, attack severity and frequency ($P>0.05$). The number of subjects with vitamin d deficiency and insufficiency was similar between migraine group and controls ($P=0.365$).

Conclusions

We did not find significant difference in vitamin D levels among between case and controls. Also no significant correlation was noted between headache parameters (frequency and severity) and serum vitamin D levels. Further studies with larger sample sizes are required to confirm our results.

Vitamin D deficiency persists despite rising use of vitamin D supplements in Western Greece

Ioannis Zoupas[1], Dimitra Bantouna[2], Sarantis Livadas[3,4], Nicholas Angelopoulos[5], Juan C Jaume[6], Evaggelos Karvounis[7], Shanawaz Imam[6] & Rodis Paparodis[6,8]

[1]National and Kapodistrian University of Athens, Athens, Greece; [2]Private Practice, Patra, Greece; [3]Endocrinology, Diabetes and Metabolism Clinics, Private Practice, Athens, Greece; [4]Athens Medical Center, Athens, Greece; [5]Endocrinology, Diabetes and Metabolism Clinics, Private Practice, Kavala, Greece; [6]The University of Toledo Health Science Campus, Center for Diabetes and Endocrine Research, Toledo, United States; [7]Euroclinic Hospital, Endocrine Surgery Center of Excellence, Athens, Greece; [8]Endocrinology, Diabetes and Metabolism Clinics, Private Practice, Patras, Greece

Introduction

Use of supplements (VDS) and vitamin-D measurements have been rising in the recent past globally. Despite increasing intake, our observations reveal that a

large percentage of the population remains deficient (VDD). We designed the present real-world study, to address this controversy.
Methods
We collected data from patients attending our clinics between March 2014 and December 2022. We recorded our subjects' gender, age, history of VDS use, duration and dose, and vitamin-D measurements, when available. We estimated the ratio of patients with vitamin-D adequacy (>30ng/ml) (VDA) by year and month of measurement, stratified by the dose of VDS intake: low-dose ($\leq$ 1200IU/day)(LD), medium-dose (1201-3000IU/day)(MD), high-dose (>3000IU/day)(HD), duration of intake: short-term-use($<$12months), long-term-use ($\geq$12months)(LT), and use at present: current-users(CU), past-users(discontinued for $\geq$2months)(FU), non-users(NU).
Results
Out of 10,292patients, data on VDS intake were available in $n=8605$ patients(83.6%): NU, $n=7212$(71.4%), FU, $n=566$(5.6%) and CU, $n=827$ (8.2%). Vitamin-D measurements were available in $n=6912$ patients (67.2%); NU $n=5644$ (81.7%), FU $n=507$ (7.3%), CU $n=761$ (11.0%). Vitamin-D measurement was available in 42.1% of patients in 2014 rising gradually to 86.8% in 2022, $P<0.001$. The cohort's mean vitamin-D was 23.1 ± 9.1ng/ml. VDD was found in $n=5401$ (78.1%). VDD was identified in 55.2% of CU, 76.8% of FU and 84.5% of NU ($P<0.001$). The rate of VDD went down with the dose of VDS used both in FU(LD 83.9%, MD 78.8%, HD 73.0%, $P<0.05$) and CU (LD 60.1%, MD 53.2%, HD 51.9%, $P<0.05$). The rate of VDD reached its nadir in August(62.1%) and September(61.2%), but rose to >70% in October and >80% during the remaining months, $P<0.001$. Intake of VDS at any time went up from 2.9% in 2014 to 35.2% in 2022($P<0.001$), and the VDD rate went down from 85.2% in 2014, to 74.5% in 2022. The serum vitamin-D increased from 21.7 ± 9.0ng/ml in 2014 to 25.0 ± 10.3ng/ml in 2022, $P<0.001$. Longer duration of VDS intake lowered the risk of VDD (LT vs ST use OR 0.51, 95%CI 0.38-0.69, $P<0.0001$). LT use of VDS in HD yielded the lowest risk (30.2%), while ST and LT use of VDS in LD yielded the highest risk of VDD (81.6% and 83.3% respectively).
Conclusions
Despite a gradual increase in vitamin-D measurements, and VDS intake, most patients attending our clinics remain VDD. A modestly effective strategy in controlling that epidemic is the long-term intake of higher doses of VDS, but efficacy goes down shortly after stopping treatment. Studies are urgently in need to solve this major global health issue.

Denosumab for Osteoporosis in Patients With Primary Hyperparathyroidism in a Tertiary Hospital in Spain

Gabriela Alexandra Zapata Maldonado[1], Alberto Isla[2], María Piedra[1], Laura Ramos Ramos[1] & Luis Vázquez[1]
[1]Hospital Universitario Marqués de Valdecilla, Endocrinology and Nutrition Department, Santander, Spain; [2]University of Cantabria, Faculty of Medicine, Santander, Spain

Introduction
Osteoporosis is a frequent complication associated with primary hyperparathyroidism (PHPT), and surgery is the most effective treatment once established. However, many patients are not candidates for it, and different medical options have been investigated. We aimed to assess the efficacy of denosumab (DMAB) in increasing bone mineral density (BMD) and preventing PHPT-related complications.
Methods
Case-control study defining cases (Group 1 G1) as those patients who received DMAB and control (Group 2 G2) as those who had undergone surgery or had received bisphosphonate treatment.
Results
17 patients of G1 with a mean age of 75,71 years and 56 patients of G2 with a mean age of 62,90 years ($P<0,0001$) were recruited. The mean follow-up time for G1 was 2 years and for G2 was 3,2 years. At baseline total serum calcium and normalized ionic serum calcium mean were 9,77 mg/dl and 1,34 mmol/l in G1 vs 10,32 mg/dl and 1,44 mmol/l in G2 ($P=0,001$). PTH mean level was 80,88 pg/ml in G1 and 108,89 in G2 ($P=0,008$). 8 (47.06%) patients from G1 vs 11 (19.64%) patients from G2 had undergone parathyroidectomy before follow-up ($P=0,024$), and 2 (11.76%) patients from G1 vs 25 (44.64%) patients from G2 underwent surgery during follow-up ($P=0,01$). At the follow-up end levels of total calcium and ionized calcium decreased -1,52% and -1,81% in G1 vs -8,44% and -14,54% in G2. PTH levels increased 61,64% in G1 and decreased 28,04% in G2. Patients showed an increase in BMD at the lumbar spine by 6.51% in G1 and 4.63% in G2. In the distal third of the radius, BMD decreased by 0.29% in G1 and 0.25% in G2 ($P=0,986$). Only in G2 did BMD increase by 4.04% in the femoral neck and 2.42% for the total neck. No skeletal fractures or treatment-related adverse events were observed during the follow-up. Only 26.79% of patients in G2 had nephrolithiasis after follow-up.
Conclusions
Denosumab treatment is safe and effective in preserving BMD, especially in the lumbar spine in those patients with PHPT who have a contraindication to undergo parathyroidectomy.

Post-thyroidectomy development of posterior reversible encephalopathy syndrome (PRES) due to over-replacement of hypocalcemia

Olga Papalou, Nikolaos Katechakis, Chrysoula Koukoula, Aikaterini Beka, Dimitra Baikousi, Kyriaki Gkoufa, Angeliki Mandrapylia, Theodora Stratigou, Dimitra Vassiliadi & Stylianos Tsagarakis
Evangelismos Hospital, Department of Endocrinology Diabetes and Metabolism, National Expertise Center for Rare Endocrine Diseases, Athens, Greece

A 61-year-old woman was admitted to the Emergency Department with generalized seizures. She reported general malaise, anorexia, headache and multiple episodes of vomiting that started about 12 h before admission. She had a history of recent thyroidectomy, and she was on oral calcium carbonate (3 gr/day) and alpha calcidol (3 mg/day). Non-contrast head CT scan was negative for major findings. Laboratory work up revealed hypercalcemia (corrected calcium 14,4 mg/dl), renal impairment (creatinine 2.9 mg/dl) and compensated metabolic alkalosis. Further neurological workup with brain MRI revealed cortical swelling and FLAIR signal abnormalities of both occipital, parietal and right frontal lobes, consistent with posterior reversible encephalopathy syndrome (PRES). The patient's encephalopathy resolved after resolution of hypercalcemia and she had no neurological deficits on discharge. She was restarted on lower doses of calcium for hypoparathyroidism and is on close follow-up. This case illustrates the difficulties in managing postoperative hypoparathyroidism and highlights a rare but serious complication of iatrogenic hypercalcemia.

Clinical Features of Patients with Primary Hyperparathyroidism in Mugla: A Single-Center Experience

Kenan Sakar[1], Anil Ugurlu[2], Irmak Taskiran Uyar[2], Gulhan Akbaba[1], Ismail Kirli[2], Nesat Cullu[3], Onder Ozcan[4], Ozcan Dere[4], Ozan Kandemir[5], Yelda Dere[6] & Nese Cinar[1]
[1]Mugla Sitki Kocman University Faculty of Medicine, Department of Endocrinology and Metabolic Diseases, Mugla, Turkey; [2]Mugla Sitki Kocman University Faculty of Medicine, Department of Internal Medicine, Mugla, Turkey; [3]Mugla Sitki Kocman University Faculty of Medicine, Department of Radiology, Mugla, Turkey; [4]Mugla Sitki Kocman University Faculty of Medicine, Department of General Surgery, Mugla, Turkey; [5]Mugla Sitki Kocman University Faculty of Medicine, Department of Nuclear Medicine, Mugla, Turkey; [6]Mugla Sitki Kocman University Faculty of Medicine, Department of Pathology, Mugla, Turkey

Introduction
Primary hyperparathyroidism (pHPT) is the third most frequently seen endocrine disease with autonomous overproduction of parathyroid hormone (PTH) in one or

more parathyroid glands. It's associated with osteoporosis, bone fractures, nephrolithiasis, renal failure and increased cardiovascular risk. We aimed to investigate the distribution of the clinical manifestations and biochemical features in patients with pHPT.
Methods
A retrospective study was performed in 156 patients [19M (12.2%)/137F (87.8%)] with pHPT. The patients' comorbidities, complications, laboratory results, preoperative imaging findings and postoperative pathology results were recorded.
Results
The mean age of the patients was 59.49 ± 12.38 years. The mean calcium level was 11.12 ± 1.05 mg/dl, the mean phosphorus level was 2.63 ± 0.54 mg/dl, the mean parathormone level was 176.12 ± 237.34 pg/ml, the mean 25(OH)D level was 22.19 ± 11.49 ng/ml. Among patients, 70 (45%) had hypertension, 81 (51.9%) had osteoporosis, 46 (29.9%) had nephrolithiasis, 20 (12.9%) had a history of bone fracture. 19 of the patients (12.1%) had normocalcemic primary hyperparathyroidism with normal serum calcium and elevated PTH levels (NHPT). Of the patients with NHPT, 14 (73.7%) had hypertension, 11 (57.9%) patients had osteoporosis, 3 (15.8%) had nephrolithiasis and 4 (21.0%) had a history of bone fracture. The location of abnormal parathyroid gland was found in the ultrasound of 85 patients (62.5%) and in the parathyroid scintigraphy of 81 patients (63.3%). 73 patients (46.7%) were operated and among them, 68 patients had adenoma and 5 had hyperplasia in pathology reports. Among patients undergone surgery, 7 parathyroid adenomas were located in the right superior, 26 in the right inferior, 6 in left superior, 27 in left inferior part of the thyroid gland.
Discussion
The profile of pHPT is changing with older age at presentation. The most common complications of pHPT patients were osteoporosis and nephrolithiasis consistent with the literature. The emergence of nephrolithiasis and bone fracture is decreasing. The prevalence of NHPT was higher than other studies reporting prevalance between 0.5% and 0.7%. Complications such as osteoporosis and bone fracture were also commonly observed in patients with NHPT.
Conclusion
Most patients with PHPT in Mugla still exhibit classic clinical and biochemical features. Due to increased risk of complications in NPHPT patients, their complications should be well screened.

Densitometry misinterpretation leading to unnecessary denosumab prescription

Mirna Hrabar, Jelena Andrić, Ivona Šamle & Vlatka Pandžić Jakšić
University Hospital Dubrava, Department of Endocrinology, Diabetes and Metabolic Diseases, Zagreb, Croatia

Background
Bone mineral density (BMD) measurement is an important tool for fracture risk assessment, but should be used with awareness of its performance and analysis pitfalls.
Case Presentation
A 59-year-old patient underwent her first densitometry as part of a routine medical check-up. She had no previous fractures and no risk factors that could impair bone health. The results showed that her BMD was in the range of low bone mass. Four years later, densitometry was performed again with the same device, but without calibration for the least significant change. Based on the very low T-score of -3.7 at the lumbar spine, osteoporosis was diagnosed and denosumab therapy was initiated. There were no newly acquired comorbidities, and secondary causes of osteoporosis were not investigated. The third densitometry was performed a year later, at the age of 64, before she came to our clinic. This time, a lumbar spine T-score of -2.3 was obtained with a different device. This was again discordant to the second densitometry, as such a rapid improvement after the administered therapy would not be expected. We reviewed all three densitometry reports and found that her second densitometry, which showed osteoporosis, had incorrect vertebral labelling: Th12-L3 were measured instead of L1-L4. Even without taking into account that she had previously received three denosumab doses, the Fracture Risk Assessment Tool was low and estimated 5.1% risk of major osteoporotic and 0.5% risk of hip fractures. It was evident that she did not need osteoporosis treatment. Although the risk of rebound effects after short-term denosumab therapy and low C-telopeptide was low, we gave her a dose of zoledronate seven months after the last denosumab application.
Conclusions
Justified indications for BMD (re)testing, careful analysis of results and interpretation of reports are mandatory to avoid overdiagnosis and misdiagnosis of osteoporosis, which could lead to ineffective, costly, and even damaging consequences.

The clinical and etiological aspects of primary hyperparathyroidism

Baltagi Myriam, Bchir Najla, Bel Hadj Sliman Chayma, annam benchhida, Zouaoui Chadia & Haroun Ouertani
Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Introduction
Primary hyperparathyroidism (PHPT) is a common endocrine disorder characterized by inappropriate secretion of parathyroid hormone leading to hypercalcemia. The aim of our study is to evaluate the clinical and etiological aspects of PHPT in our series.
Methods
This is a retrospective descriptive study including 32 patients followed for PHPT at the endocrinology department of the military hospital of Tunisia between January 2018 and December 2022. Clinical and paraclinical data were collected from medical records.
Results
The mean age was 59,4 ± 13 years with a predominance of women: sex ratio (H/F) = 0,68. PHPT was discovered fortuitously by a routinely biological check-up in 40,6% of cases and by an incidentaloma in 15,6% of cases. The diagnosis of PHPT was revealed by complications in 28,1% of cases (bone pain in 25% of cases, renal lithiasis in 3,1% of cases) and by the presence of general signs related to hypercalcaemia in 15,6% of cases. The mean calcemia was 2.98 ± 0,36 mmol/l with severe hypercalcemia (up to 3.5 mmol/l) in 9.4 % cases. Patients had hypophosphoremia in 19,4 % of cases and hypercalciuria in 60,8% of cases. The mean parathormone level was 292,9 ± 322,2pg/ml. The mean 25-OH-vitamin D level was 16.23 ± 9,05ug/dl. Normocalcemic HPTP was present in one case. Renal ultrasound showed lithiasis in 53% of cases. None of the patients had nephrocalcinosis. Thirty-four percent of cases had renal insufficiency. Bone densitometry revealed osteoporosis in 9.4% of cases, osteopenia in 50% of cases and was normal in 40.6% of cases. A cervical ultrasonography associated with a Technicium-SestaMIBI parathyroid scintigraphy was performed in all our patients. The etiologies identified were a parathyroid adenoma in 75% of cases and parathyroid hyperplasia in 25% of cases among which one case of multiple endocrine neoplasia type 1.
Conclusion
Most often, the presentation of PHPT is asymptomatic with the advent of the routine measurement of serum calcium. A rigorous etiological assessment and screening for complications is needed to provide optimal management.

Therapeutic and evolutive aspects of primary hyperparathyroidism

Bel Hadj Sliman Chayma[1], Bchir Najla, Baltagi Myriam, Annam Benchhida, Zouaoui Chadia & Haroun Ouertani
Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Introduction
Surgery is the only curative treatment for primary hyperparathyroidism (PHPT). However, some patients may present a persistence or a recurrence after surgical treatment. The aim of our study was to evaluate the therapeutic and evolutive aspects of PHPT after the first surgery.
Methods
A retrospective study was conducted at the endocrinology department of military hospital of Tunis including 32 patients diagnosed with PHPT over a period of four years (between 2018 and 2022). Clinical and paraclinical data were collected from medical records.
Results
Our population was composed of 13 men and 19 women with a mean age of 59 ± 13 years old. The mean parathormone (PTH) level was 292 ± 322 pg/ml. The mean calcemia was 3 ± 0,4 mmol/l. All our patients received rehydration. Three percent were treated with bisphosphonates. Nineteen patients underwent surgery. Adenectomy was performed for 17 patients and removal of 3/4 of the parathyroids for two patients. The anatomopathological examination revealed parathyroid

adenoma in 75% of cases and parathyroid hyperplasia in 25% of patients. Regarding patients who have underwent surgery, the evolution was marked by a remission rate in 42% of cases. Persistence of PHPT was observed in 10 patients (53%). Among these patients, three had multiple adenomas, one had an ectopic adenoma of the superior mediastinum and six had hyperplasia of other parathyroids. Recurrence of PHPT was observed in one patient who had hyperplasia of parathyroids related to multiple endocrine neoplasia type 1.
Conclusion
Persistence and recurrence rates highlight the importance of preoperative topographic investigation and intraoperative PTH measurement to improve the prognosis of PHPT.

Surgery of primary hyperparathyroidism during pregnancy: case series

Petr Libánský[1], Martina Fialová[1], Jana Jezkova[2], Mikulas Kosak[2], Magdalena Matejkova Behanova[3], Jitka Moravcova[4], Josef Vcelak[4], Markéta Vaculová[1] & Robert Lischke[1]
[1]University Hospital Motol, 3rd Surgery Clinic, Prague, Czech Republic; [2]Charles University Prague, 3-rd Department of Internal Medicine, Prague, Czech Republic; [3]University Hospital Motol, Department of Molecular Endocrinology, Prague, Czech Republic; [4]Institute of Endocrinology, Department of Molecular Endocrinology, Prague, Czech Republic

Background
Primary hyperparathyroidism can occur at any age, the typical patient is a postmenopausal woman, primary hyperparathyroidsim is found rare by pregnant women. The maternal symptoms are similar to the symptoms by postmenopausal women.
Materials and methods
Among the years 2000-2022 we have performed 3459 operations (including 6,6% reoperations) with diagnosis of hyperparathyroidism, there were six women, who underwent parathyroidectomy during pregnancy. The median maternal age was 30 years. All women had before operation localization of adenoma by ultrasonography, one woman had localization by the MRI. All woman were operated during the second trimester. Postoperative care was without complication, two patients had parestezie. All patient had genetic testing before or after the operation.
Result
Incidence of primary hyperparathyroidism by pregnant women is rare. By the diagnosis of primary hyperparathyroidism is indicated surgical therapy. The base of localization examination by pregnant women is examination of ultrasonography. Operation in pregnancy would be due in the second trimester. By pregnant women always due the genetic tests.

Better late than never - a very rare cause of short stature

Carmen Dorogi[1], Ana-Silvia Corlan[2], Ioana Golu[1,2], Andreea Daniela Toma[2,3] & Mihaela Vlad[1,2]
[1]"Pius Brinzeu" Emergency County Hospital Timisoara, Romania, Timi?oara, Romania; [2]2nd Department of Internal Medicine – Discipline of Endocrinology, "Victor Babes" University of Medicine and Pharmacy Timisoara, Romania, Timi?oara, Romania; [3]Victor Babeş University of Medicine and Pharmacy, Endocrinology, Timi?oara, Romania

Introduction
X-linked hypophosphatemic rickets (XLH) is a very rare cause of growth deficiency that can be diagnosed even in adulthood. The mutation of the PHEX gene in these patients causes higher levels of FGF-23 and hypophosphatemia.
Case presentation
A 20-year-old male patient was admitted into our clinic due to short stature, walking difficulties, joint and muscle pain, predominantly in the lower limbs. He described the presence of symptoms since childhood. The family history revealed that his mother, aunt and maternal grandfather had short stature with similar appearance. In paediatrics service he was diagnosed with familial hypophosphatemic rickets at the age of two and was treated with 1-alpha(OH)D3 and a rich phosphorus diet until the age of seven. No genetic or FGF- 23 testing was performed at that time. On physical exam, the patient had a height of 156 cm, a disharmonic dwarfism, many dental abscesses, waddling gait, genu varum and lower limbs deformities. The laboratory tests showed a normal serum calcium and hypophosphatemia with FePO4 of 24%. Radiological findings revealed bilateral coxarthrosis and genu varum. Due to heredity, XLH was the most likely diagnosis in this case. FGF-23 was in the upper normal range confirming the diagnosis. Genetic testing and counselling were recommended, for the analysis of the PHEX gene mutation, due to the desire of this patient to have a child.
Conclusion
Being so rare, XHL as a cause of short stature can be easily overlooked. XLH should be considered in the differential diagnosis of short stature with low serum phosphate, regardless of age.

Polycyclic aromatic hydrocarbons (PAHs) are common environmental pollutants derived from the incomplete combustion of organic materials. In urban and industrial areas, level of pollution with these compounds is high, which leads to numerous negative health effects. Some literature data indicate the involvement of PAHs in the development of obesity, however, there is no data showing the distribution patterns of PAHs in human adipose tissue (AT) and their impact on the process of adipogenesis. The aim of our study was to investigate the concentration of 16 priority PAHs in the plasma and three types of AT: mesenteric, omental, and subcutaneous in French and Polish bariatric patients ($n = 10$ per group). Next, we analyzed correlation between concentration of the four most abundant PAHs and BMI of patients as well level of adipokines in plasma and AT. Using the mouse preadipocytes 3T3-L1 cell line we determined the dose-dependent effect of naphthalene (1-500 ng/ml) on adipocytes viability (CK-8 assay), proliferation (BrdU assay) and differentiation (Red oil staining, qRT-PCR) as well effect on its endocrine function (ELISA assay) ($n = 6$). Statistical analysis was carried out using the Student's t-test or one-way ANOVA to compare differences between group ($P \leq 0.05$) while correlations were analyzed with the Pearson correlation coefficient, two-tailed ($P \leq 0.05$). We observed that the concentrations of the 16 tested PAHs were higher in adipose tissue than in plasma, indicating bioaccumulation. In addition, in French patients, the concentration of naphthalene in both plasma and omental AT correlated with BMI as well as the concentration and expression of the gene for adiponectin, chemerin and resistin. We demonstrated for the first time that naphthalene stimulates viability and proliferation of 3T3-L1 cells. Moreover, it has a significant impact on the differentiation of preadipocytes by increasing lipid content in cells, upregulation of genes involved in adipogenesis, and stimulating chemerin secretion by differentiated 3T3-L1 cells. Taken together those findings, we conclude that PAHs and more particularly naphthalene could be an obesogen molecule and increase the risk of obesity. Funding: Study was supported by Région Centre Val de Loire (HAPOFERTI project number 32000496). Ewa Mlyczynska obtained funding as a part of PhD scholarship program—BGF doctorate from Campus France and Jagiellonian University programs: Excellence Initiative –Jagiellonian University.

Continuous Glucose Monitoring in Hospitalized Type 2 Diabetes Patients

David Veríssimo, Joana Vinhais, Vânia Machado, Sandra Silva, Catarina Ivo, Ana Cláudia Martins, Joao Silva, Dolores Passos, Luis Lopes, J Jácome Castro & Mafalda Marcelino
Hospital das Forças Armadas, Serviço de Endocrinologia, Lisboa, Portugal

Introduction
Continuous glucose monitoring systems (CGM) have revolutionized the monitoring of diabetes, allowing real-time measurement of interstitial glucose levels. Although these devices are suitable for patients on insulin therapy, they are not yet routinely used in an inpatient setting. The difficulty observed in the glycemic control of hospitalized patients under intensive insulin therapy led to the development of a protocol to study the application of CGM in these patients.
Aim
Primary endpoint was the increase in the time in range (glycemic readings between 100-180mg/dl) in hospitalized patients with CGM. Secondary endpoint was the reduction in the number of hypoglycemic events.
Methods
Prospective study of 60 hospitalized patients with type 2 diabetes on intensive insulin therapy. Patients were randomized into two groups of 30 individuals: an intervention group monitored through CGM (Freestyle Libre™ 2) and a control group whose glycemic profile was monitored using point-of-care capillary blood glucose (CBG), with at least three readings per day.
Results
Both groups were similar regarding age (74.4 years vs. 76.8 years, $P=0.277$), gender (higher prevalence of males, 83.3% vs. 63.3%, $P=0.143$), diabetes duration (12 years vs. 14 years, $P=0.824$), diabetes associated complications (assessed using the Diabetes Complications Severity Score; $P=0.151$) and outpatient treatment ($P=0.570$). No differences were observed on admission diagnosis (most frequently due to an infectious disease, 53.3% vs. 48.3%, $P=0.157$), nor regarding the analytical values on admission (namely hemoglobin: 12.6 mg/dl vs. 11, 7 mg/dl, $P=0.158$, HbA1c: 7.1% vs. 7.2%, $P=0.158$ and creatinine: 1.4 vs. 1.3, $P=0.158$). CGM had a positive impact on glycemic control, with more readings per day (6 vs. 4, $P<0.001$), improved time in range (100-180 mg/dl) (53.5% vs. 36.5%, $P=0.032$), and less time above range (26% vs. 53%, $P=0.008$), in particular values above 250 mg/dl (6% vs. 25%, $P=0.003$). A lower mean glucose (162 mg/dl vs. 207 mg/dl, $P<0.001$) and lower estimated HbA1c (7.3% vs. 8.8% $P=0.001$) were also observed in the CGM group, but there was no difference in glycemic variability (34.2% vs. 34.8% $P=0.181$). Regarding hypoglycemia, the small number of hypoglycemic events per patient in each group did not allow an adequate comparison (CGM 0 (0-5) vs. CBG 0 (0-2); $P=0.107$). CGM showed no difference in reducing mortality, length of hospital stays, nor infection rate, compared to CBG ($P=1.000$, $P=0.455$ and $P=0.606$, respectively).
Conclusion
The results obtained in this prospective study encourage the use of CGM in optimizing the control of type 2 diabetes during hospitalization.

Ceramides In Epicardial Adipose Tissue from Coronary Diabetic Patients: New Markers of Tissue Metabolism?

Gabriela Berg[1], Jeanniel Campos[1], Patricia Ancel[2], Ljubica Svilar[2], Juan Patricio Nogueira[3], Anne Dutour[2], Jean Charles Martin[2], Bénédicte Gaborit[2], Miguel Rubio[4], Laura Schreier[1] & Magalí Barchuk[1]
[1]INFIBIOC, Faculty of Pharmacy and Biochemistry, University of Buenos Aires, Buenos Aires, Argentina; [2]National Institute of Health and Medical Research (INSERM), Marseille, France; [3]Teaching and Research Service, Formosa Central Hospital, National University of Formosa, Formosa, Formosa, Argentina; [4]Division of Cardiovascular Surgery, Hospital de Clínicas "José de San Martín", University of Buenos Aires, Buenos Aires, Argentina

Ceramides (Cer), which are known to be altered in plasma before the onset of coronary artery disease (CAD), have been proposed as new markers for cardiovascular disease (CVD) risk. Serum Cer18:1/C16:0, Cer18:1/C18:0 and Cer18:1/C24:1 to Cer18:1/24:0 indexes are proposed to be indicative of CAD. Epicardial adipose tissue (EAT) is a visceral adipose tissue, surrounding and in direct contact with the myocardium and coronary arteries, which volume is considered a risk factor for CVD. Studies from our laboratory demonstrated an increase in EAT Cer total content from CAD patients. We also reported an increase in Lipoprotein Lipase (LPL) activity in EAT from CAD and Diabetes Mellitus 2 (DM2) patients, suggesting that LPL would be involved in EAT expansion. EAT Cer content was directly associated with LPL activity. Our aim was to evaluate the association between EAT Cer indexes and LPL activity, and markers of EAT lipid metabolism, in CAD patients with and without DM2.
Methods
Patients undergoing coronary by-pass graft (CAD, $n=24$), with and without DM2 (DM2, $n=7$; No-DM2, $n=17$), and patients without CAD (noCAD, $n=13$) were studied. In EAT, LPL activity, Angiopoietin-like protein 4, Glycosylphosphatidylinositol anchored high density lipoprotein binding protein-1 (GPIHBP1), Peroxisome Proliferator Activated Receptor γ (PPARγ), VLDL-Receptor(R) and Fatty Acid Binding Protein-4 expression were assessed. Tissue lipidome was evaluated by UHPLC-MS.
Results
CAD-DM2 patients presented a deleterious and atherogenic metabolic profile compared to the other groups. CAD-No DM2 and CAD-DM2 presented a higher Cer18:1/C24:1 to Cer18:1/24:0 index than noCAD ($P=0.017$ and $P=0.003$ respectively), with no differences between CAD diabetic and CAD no diabetic patients. This index was directly associated with LPL activity ($r=0.373$, $P=0.042$), PPARγ ($r=0.637$, $P=0.009$), GPIHBP1 ($r=0.497$, $P=0.18$) and VLDL-R ($r=0.441$, $P=0.031$). No differences were found among groups neither in Cer18:1/C16:0 nor Cer18:1/C18:0 to Cer18:1/24:0 indexes.
Conclusion
This is the first time that a relation between LPL, its regulators and Cer is reported in AT. EAT Cer indexes could be suggested as markers of the tissue metabolism in CAD and DM2.

Long-Term Diabetes Remission Rates In A Group of Type 2 Diabetic Patients After Sleeve Gastrectomy and Rou and Y Bypass Metabolic Surgery: A Single-Centered Experience

Simge Saydam[1], Murat Tuğberk Bakar[2], Tuğçe Erol[1] & Dilek Gogas Yavuz[1]
[1]Marmara University Pendik Research And Education Hospital, Internal Medicine, Istanbul, Turkey; [2]Marmara Üniversitesi Prof. Dr. Asaf Ataseven Hastanesi, Public Health, Istanbul, Turkey

Introduction
Various rates were reported regarding diabetes remission and improvement in hyperglycemia in many studies from different populations. Determinants of diabetes remission have not been definitively established so far. In this study, we aimed to evaluate the long-term glycemic status after bariatric surgery in diabetic obese patients followed by Marmara University Endocrinology Outpatient Clinic.
Method
The retrospective study included 233 type 2 diabetic obese patients who underwent either sleeve gastrectomy or gastric bypass between 2011-2021. Preoperative, postoperative sixth month, first year, and second year data were collected from the patient files. In the analysis of the dependent variables, patients who fulfilled whole visits were included. The glycemic status of diabetic patients at postoperative first and second year visits was classified as complete remission, partial remission, recovery, no change, and recurrence in accordance with the criteria of the American Society of Bariatric and Metabolic Surgery, 2022. Remission ratios were calculated for each visit, seperately. Logistic regression was used to analyse the factors affecting diabetes remission for the whole diabetic group.
Results
Postoperative BMI values were significantly lower than the preoperative level ($P<0,001$), additionally remained similar between the first and the second years. BMI change was found to be similar between gastric bypass and sleeve gastrectomy. Fasting blood glucose and HbA1c levels were significantly lower than the preoperative levels as well ($P<0,001$). 24.9% ($n=58$) of the patients were on insulin preoperatively. This ratio was found to be 3.5% ($n=6$) in the first year and 3.3% ($n=4$) in the second year. Complete remission rate was 68.0% ($n=132$) in the first year. In the second year, complete remission and recurrence rates were 59.5% ($n=72$) and 8.3% ($n=10$), respectively. Remission rates were similar among the two surgical procedures. To determine the factors affecting remission across the whole sample, a regression model was conducted. Duration of diabetes, preoperative insulin usage, preoperative BMI, and the type of the surgery were included in the model. Preoperative insulin use of patients was associated to diabetes remission outcomes. Patients who were not taking insulin before the surgery were more likely to experience postoperative diabetes remission (OR=7.523, $P<0.001$, 95%CI 3,075-18.404 for the 1st year; OR=5.096, $P=0.002$, 95%CI 1.781-14.577 for the 2nd year).

Conclusion
At the postoperative first and second year checkpoints, complete remisson rates were 68.0% and 59.5%, and recurrence rate was 8.3% in the second year. Not using insulin preoperatively made the probability of diabetes remission 5.1 times higher.

A Quality Improvement initiative to assess differences of diabetic ketoacidosis (DKA) management across hospitals in the United Kingdom

Joseph Dalzell[1], Maria Skaria[2], Saima Kauser-Malik[2], Rajeev Raghavan[3], Shamanth Soghal[4], Maria Tabasum[5], Nabeel Ahmed[5], Jael Nizza[5], Jayashekara Acharya[6], Sanjay Saraf[7] & Team Dekode[2]
[1]Sandwell and West Birmingham Hospitals NHS Trust, Birmingham, United Kingdom; [2]University of Birmingham, Birmingham, United Kingdom; [3]The Royal Wolverhampton NHS Trust, Wolverhampton, United Kingdom; [4]Queen Elizabeth Hospital, Birmingham, Birmingham, United Kingdom; [5]Wirral University Teaching Hospitals NHS Foundation Trust, Liverpool, United Kingdom; [6]The Wye Valley NHS Trust, Hereford, United Kingdom; [7]Good Hope Hopsital, Birmingham, United Kingdom

Background
Joint British Diabetes Societies (JBDS) have developed guidelines for the treatment and management of diabetic ketoacidosis (DKA) in adults in the United Kingdom (UK). Multiple single center audits are known to assess compliance to guidelines. However, unified data on DKA management across multiple centers is unknown.
Aims
To study the precipitating factors and assess for differences in DKA management across UK hospitals.
Methods
A retrospective analysis of 443 DKA admissions across six hospitals between October 2021 and September 2022 was undertaken. DKA was defined as all of: glucose >11 mmol/l or known diabetes, bicarbonate <15 mmol/l and/or venous pH <7.3, blood ketones >3 mmol/l and/or urinary ketones $++$ or more. Patients <16 years or who self-discharged before the DKA resolution were excluded. Data on precipitating factors, fixed rate intravenous insulin infusion (FRIII), fluids prescription, hourly glucose and ketone monitoring were collected. Differences in management across hospitals was analyzed using Kruskal-Wallis Test. Deviations from guidelines are expressed in percentage. 100% represents optimal adherence whilst values below and above 100% indicate that measures applied were less than or more than recommended respectively. A p value of <0.05 was considered significant.
Results
Since the objective is to identify best practice and not to compare, hospitals are coded A to F to ensure anonymity. Variations were found in fluid prescription (A – 92.1%, B – 101.3%, C - 89.7%, D – 76.0%, E – 98.3%, F – 115.5%; $P=<0.001$), glucose monitoring(A – 103.1%, B -86.1, C- 88.9%, D - 106.4%, E – 99.2%, F – 95.7%; $P=<0.001$) and ketones monitoring(A – 71.5%, B – 85.1%, C – 70.0%, D – 59.3%, E - 65.0%, F- 85.7%; $P=<0.001$). No significant difference was found between hospitals in FRIII prescription (A- 99.5%, B – 100.0%, C – 100.0%, D – 100.0%, E – 93.9%, F-99.8%; $P=$ 0.064). Intercurrent illness(36.6%), suboptimal compliance(32.1%), COVID(3.6%), drugs (0.2%), immunotherapy (0.2%), first presentation of diabetes (8.8%), sepsis (2.9%), SGLT2 (0.9%), surgery (0.9%), undetermined (12.0%) were the precipitating aetiologies recorded.
Conclusion
Suboptimal concordance with recommended treatment and intercurrent illness were the common precipitating factors for DKA across sites. Despite common guidelines and similar precipitating factors, significant inter-hospital variation in DKA management was observed across hospitals. Establishment of a centralized registry coupled with regular stakeholder feedback could help minimize interhospital variation and improve patient outcomes.

Vitamin B12 and diabetic peripheral neuropathy in type 2 diabetic patients

Meriem Adel[1], Manel Jemel[1], Marwa Chiboub[1], Anis Grassa[1], Amel Ellouz[2], Hajer Kandara[1], Ines Kammoun[1], Rahma Mahjoub[2] & Emna Talbi[2]
[1]Nutrition, Endocrinology, Tunis, Tunisia; [2]Nutrition, Biochemistry, Tunis, Tunisia

Introduction
Metformin is a cornerstone in the treatment of type 2 diabetes, but in recent years several studies have shown that metformin use is associated with a 4-24% decrease in vitamin B12 levels. It is estimated that this problem occurs in approximately 10-30% of patients using metformin and may contribute to distal symmetrical polyneuropathy (DSPN), a very common and clinically relevant diabetic complication.
Objective
To study vitamin B12 concentrations in type 2 diabetic patients receiving metformin and presenting with DSPN.
Patients and methods
A cross-sectional study was conducted over a period of 19 months, from 1 February 2021 to 30 September 2022, including 123 type 2 diabetic patients treated with metformin consulting at the National Institute Zouhaier Kallel Tunisia. The presence of DSPN was determined by the "douleur neuropathique" DN4 test and its severity was assessed by the Toronto Clinical Neuropathy Score(TCSS). Vitamin B12 and folate levels were determinated for all participants.
Results
The mean age of our population was 60.99 $\pm$ 6.85 years (81 females and 42 males). The mean average DN 4 score and TCSS score were 5.31 $\pm$ 1.21 and 9.5 $\pm$ 3.36, respectively. The mean duration of metformin use was 14.6 ± 7.27 years with a mean dose of 1923 ± 575.4 mg/day. Fifty seven percent of patients had mild neuropathy, 23.5% moderate neuropathy and 19.5% severe neuropathy. The mean serum Vitamin B12 level was 353.77 $\pm$ 178.22 pg/ml with extremes ranging from 64.47 to 918.4 pg/ml. Eighteen and a half percent of the population had a vitamin B12 deficiency (level <200 pg/ml) and 29.8% had a borderline level (level between 200 and 300 pg/ml). The Mean average of vitamin B12 level was 387,73 $\pm$ 190.97 in mild neuropathy, 319,04 $\pm$ 151,54 in moderate neuropathy and et 296,72 $\pm$178,22 in severe neuropathy. There was correlation between TCSS and vitamin B12 levels ($P=0.016$). Daily metformin dose and duration did not correlate with TCSS ($P=0.8$ and 0.45 respectively) or vitamin B12 levels.
Conclusion
Our study shows a positive association between vitamin B12 deficiency and the severity of neuropathy in type 2 diabetic patients on metformin. Therefore, We recommand a regular screening for vitamin B12 deficiency. Deficient patients were supplemented with parenteral vitamin B12. We consider a control of TCSS and DN 4 score 6 months later.

Diabetes and associated risk factors for cardiovascular mortality in Cuba: prospective study of 146,556 participants

Ileydis Iglesias[1], Nurys Bárbara Armas Rojas[2], Sarah Lewington[3], Ben Lacey[3], Richard Peto[4], Julie Burret[5] & Oscar Díaz Díaz[6,7]
[1]Instituto Nacional de Endocrinología, Diabetes, Habana, Cuba; [2]Instituto de Cardiología y Cirugía Cardiovascular, Epidemiología, La Habana, Cuba; [3]University of Oxford, Epidemiología, Oxford, United Kingdom; [4]University of Oxford, Oxford, United Kingdom; [3]University of Oxford, Epidemiología, Oxford, United Kingdom; [6]Instituto Nacional de Endocrinología, Diabetes, La Habana, Cuba; [7]Instituto de Endocrinología, Diabetes, La Habana, Cuba

Background
Cardiovascular disease accounts for about one-third of all premature deaths (ie, age <70) in Cuba. Yet, the relevance of major risk factors, including diabetes,

systolic blood pressure (SBP), and body-mass index (BMI), to cardiovascular mortality in this population remains unclear.
Methods
In 1996–2002, 146,556 adults were recruited from the general population in five areas of Cuba. Participants were interviewed, measured (height, weight and blood pressure) and followed up by electronic linkage to national death registries until Jan 1, 2017; in 2006–08, 24,345 participants were resurveyed. After excluding all with missing data, cardiovascular disease at recruitment, and those who died in the first 5 years, Cox regression (adjusted for age, sex, education, smoking, alcohol and, where appropriate, BMI) was used to relate cardiovascular mortality rate ratios (RRs) at ages 35–79 years to SBP, diabetes and BMI; RR were corrected for regression dilution to give associations with long-term average (ie, "usual') levels of SBP and BMI.
Results
After exclusions, there were 125,939 participants (mean age 53 [SD12]; 55% women). Mean SBP was 124 mmHg (SD15), 5% had diabetes, and mean BMI was 24.2 kg/m^2 (SD3.6); mean SBP and diabetes prevalence at recruitment were both strongly related to BMI. During follow-up, there were 4112 cardiovascular deaths (2032 ischemic heart disease, 832 stroke, and 1248 other). Cardiovascular mortality was positively associated with SBP (>=120mmHg), diabetes, and BMI (>=22.5 kg/m2): 20 mmHg higher usual SBP about doubled cardiovascular mortality (RR 2.02, 95%CI 1.88–2.18]), as did diabetes (2.15, 1.95–2.37), and 10 kg/m2 higher usual BMI (1.92, 1.64–2.25). RR were similar in men and in women. The association with BMI and cardiovascular mortality was almost completely attenuated following adjustment for the mediating effect of SBP. Elevated SBP (>=120 mmHg), diabetes and raised BMI (>=22.5 kg/m2) accounted for 27%, 14%, and 16% of cardiovascular deaths, respectively.
Conclusions
This large prospective study provides direct evidence for the effects of these major risk factors on cardiovascular mortality in Cuba. Despite comparatively low levels of these risk factors by international standards, the strength of their association with cardiovascular death means they nevertheless exert a substantial impact on premature mortality in Cuba.

The dual GIP/GLP-1 receptor co-agonist Tirzepatide vs GLP-1 receptor agonists as add-on to basal insulin in uncontrolled type 2 diabetes mellitus: A rapid review of randomized controlled trials and meta-analysis

Giuseppe Lisco[1], Anna De Tullio[1], Olga Disoteo[2], Vincenzo De Geronimo[3], Giuseppina Piazzolla[1], Giovanni De Pergola[4], Vito Angelo Giagulli[1], Emilio Jirillo[1], Edoardo Guastamacchia[1], Carlo Sabbà[1] & Vincenzo Triggiani[1]
[1]University of Bari "Aldo Moro", Interdisciplinary Department of Medicine - Section of Internal Medicine, Geriatrics, Endocrinology and Rare Diseases, School of Medicine, Bari, Italy; [2]Grande Ospedale Metropolitano Niguarda, Diabetology Unit, Milan, Italy; [3]Policlinico Morgagni CCD, 95125 Catania, Italy., Unit of Endocrinology, Catania, Italy; [4]National Institute of Gastroenterology "Saverio de Bellis", Research Hospital, Unit of Geriatrics and Internal Medicine, Castellana Grotte (BA), Italy

Tirzepatide, a once-weekly dual co-agonist of Glucose-Dependent Insulinotropic Polypeptide (GIP) and Glucagon-Like Peptide 1 (GLP-1) receptors, has been demonstrated to improve glucose control and reduced body weight in different therapeutic approaches. With this rapid review and meta-analysis, we systematically reviewed the efficacy and safety of injectable incretin-based therapy added to basal insulin compared to basal insulin plus background treatments titrated rigorously to target fasting glycemia. The results were reviewed considering data from the SURPASS-5 trial, which demonstrated that Tirzepatide, in add-on to basal insulin, significantly improves several glycemic and extra glycemic endpoints. Eleven randomized clinical trials were identified and included in the meta-analysis. GLP-1 receptor agonists (GLP-1RAs) or Tirzepatide added to basal insulin than rigorously titrated basal insulin significantly ameliorates glucose control (Δ HbA1c = -1%, 95% CI -1.25; -0.74, I2 94%; Δ FPG = -14.6 mg/dl, 95% CI -21.6-; -7.6, I2 90%). Moreover, the chance to achieve optimal glucose control (i.e., HbA1c <7%) is significantly higher in the former treatment (RR 2.62, 95% CI 2.10; 3.26, I2 89%). GLP-1RAs or Tirzepatide added to basal insulin than rigorously titrated basal insulin significantly reduces body weight significantly (Δ weight = -3.95 kg, 95% CI -5.1, -2.79, I2 96%) without affecting the risk of hypoglycemia (Rr=1.01, 95% CI 0.86; 1.18, I2 7.7%). More precisely, Tirzepatide provides an impressive weight loss in a dose-dependent manner (-7.6 kg with Tirzepatide 5 mg/week, and -12.6 kg with 15 mg/week), exceeding the weight loss observed with GLP-1RAs. Injectable incretin-based therapy plus basal insulin remains a potent and safe therapeutic approach in uncontrolled type 2 diabetes previously treated with basal insulin. Thanks to a potent antihyperglycemic effect and an impressive induction of weight loss, Tirzepatide is expected to ameliorate the management of "diabesity" in these usually difficult-to-treat patients.

Utility of using Continuous Glucose Monitoring based MetaSense in OneCare Diabetes care program in driving the metabolic outcomes in People with Diabetes Mellitus – A real world data from urban India

Basavaraj G S[1,2], Zareen Fatema[3], Mahesh DM[4], Srinivas Dasyam[5] & Narendra BS[6]
[1]Narayana Institute of Cardiac Sciences, Department of Endocrinology, Diabetes & Metabolism, Bangalore, India; [2]OneCare, Medical Affairs, Bangalore, India; [3]OneCare, Medical Research, Bangalore, India; [4]Aster Hospital, Bangalore, Bnagalore, India; [5]OneCare, IT and Product Development, Bangalore, India; [6]Sattva Speciality Clinics, Bangalore, India

Background
As adoption of continuous glucose monitoring (CGM) continues to expand, lot more studies are investigating the effects of CGM on HbA1C and hypoglycaemia risks in people with Diabetes Mellitus (PwD). In PwD, established benefits of usage of CGM along with digital diabetes self-management and education (DSME) program in Indian real-world context are scarce. OneCare compares patients engaged in its "IMPACT" DSME program alone vs program assisted by CGM.
Methods
A proof-of-concept, prospective study was conducted in PwD enrolled in the OneCare IMPACT program for 12 weeks. It is a virtual, personalized lifestyle program to support diabetes self-management through team of CDEs, yoga and physical trainer, emotional wellness coach and OneCare app to track patients' everyday physical activity, self-monitoring of blood glucose, and dietary patterns. Patients in the group 1 (n=30) received the regular IMPACT program, while those in group 2 (n=27) had CGM (Abbott Libre) inserted on enrolment in addition to the program. CGM data were used by the health coach to educate and engage patients, (MetaSense- a sophisticated software and service layer) in the program. Data on HbA1c, weight, CGM metrics, were used for analysis.
Results
Upon enrolment to IMPACT program, both the patient groups had a significant decline in HbA1c (%) [group1 from 8.3 to 7.3 (P= <.001); group2 from 9.4 to 6.9 (P= <.001)]. Among patients on CGM, only 25 % had TIR >70 %, 37% of patients had a Time below range <90mg/dl. MetaSense usage in group2, however led to significantly better mean reductions in HbA1c (%) vs group1 [2.51±2.17 Vs 0.91±1.05; (P= <.001) respectively]. A significant difference in mean weight reduction was observed in group assisted with and without MetaSense respectively [2.2±0.8 vs 0.81 ±1.86 (P<0.001)]. MetaSense usage significantly predicted reduction in HbA1c on a simple linear regression model [HbA1c reduction$n$=-.682+1.601*(MetaSense) where, MetaSense use: 0= No, 1 = Yes; (R^2 = .18, P= <.001)]. 18% of the variation in HbA1c is explained by MetaSense.
Conclusion
CGM can be a very useful tool to motivate, educate and teach PwD in clinical practice leading on to a better involvement of the patient in self-management issues. Addition of MetaSense to existing structed digital DSME "IMPACT' program leads to better outcomes with respect to HbA1c and weight. However many other factors may also be influencing the outcome of this study. Hence a well-planned study is encouraged to delineate the role of MetaSense.

Left hemiparesis and urinary incontinence as presentation of pancreatic Insulinoma in a young female. A Case report and review of literature

Adishah Çerma, Marjeta Kermaj & Agron Ylli
UHC "Mother Tereza", Endocrinology, Tirana, Albania

Introduction
Insulinoma is a rare tumor, with peak incidence at 30 -60 years of age and more frequent in women. It is associated with a myriad of clinical manifestations: from

clearly defined adrenergic and neuroglycopenic symptoms to asymptomatic hypoglycemia. We present the case of a 20-year-old patient with pancreatic insulinoma, which was surgically resected only after her second hospitalization due to repeated negative imaging.

Case presentation

A 20-year-old female patient presented in the Emergency Department in a stuporous state, following an episode of left hemiparesis, numbness and urinary incontinence. She had a three-month history of weakness and somnolence during the day but didn't suffer from any disease. Her blood glucose in admission was 24 mg/dl. After IV glucose administration, she recovered completely and was hospitalized for further evaluation of her hypoglycemia. During her hospital stay, she experienced episodes of tiredness and somnolence associated with fasting and postprandial hypoglycemia, in 2–3-hour intervals. In a blood sample after 8 h of fasting, her glucose was 24 mg/dl and insulin 17.4 µU/ml (≥ 3 µU/ml). Abdominal CT and MRI with contrast were negative. She was discharged from the hospital under diet tips for insulinoma to prevent hypoglycemia and Diazoxide treatment. Her low glycemic values continued despite the diet and up-titration of the Diazoxide dosage, which resulted in subsequent adverse reactions (palpebral edema, lip swelling, malaise and later, hirsutism). Having no improvement in her glycemic profile, Diazoxide was then stopped. In her second hospitalization 3 months later, her measured Insulin and C-peptide levels were very high with a blood glucose of merely 22 mg/dl. MRI with contrast identified a pancreatic lesion 11x9mm with no contrast enhancement. Surgical excision was performed and biopsy confirmed insulinoma. Glycemic values returned to the normal range but two weeks following surgery, our patient had acute pancreatitis and underwent a second surgical intervention. She discharged 2 weeks later in a good general condition.

Conclusion

Diagnosis of insulinoma in a young patient can be challenging, because the symptoms usually are atypical and nonspecific, and may precede the detection of a lesion. A careful imaging evaluation is necessary to identify the lesion early, with the aim of its surgical removal as soon as possible.

Covid-induced relapse of exogenous insulin autoimmune syndrome successfully treated with Rituximab and plasmapheresis

Hamdi Frikha, Mouna Mnif, Dhoha Ben Salah, Nesrine Dhieb, Mouna Elleuch, Fatma Mnif, NABILA REKIK Majdoub, Nadia Charfi, Faten Haj Kacem Akid & Mohamed Abid

Hedi Chaker University Hospital, Department of Endocrinology, Sfax, Tunisia

Introduction

Exogenous insulin autoimmune syndrome (EIAS) is a rare cause of hypoglycemia in patients with diabetes treated with exogenous insulin. Flares of auto-immune diseases following covid-19 infection have been widely reported.

Case report

A 15-year-old type 1 diabetes female patient treated with detemir and glulisine was diagnosed with EIAS based on major glycemic instability and an elevated anti exogenous insulin autoantibody titer of 40 IU (NV < 0.4), after excluding other differentials. The evolution under high dose oral corticosteroids was favorable. Following a covid-19 infection there was a reappearance of severe nocturnal hypoglycemia and diurnal hyperglycemic phases concomitantly with an elevation of auto-antibody titer. The patient was treated with a course of rituximab 500mg twice followed by three sessions of plasma exchange. A clinical and biological remission was obtained (anti-insulin auto antibodies 4 IU/l).

Discussion

In recent years, the incidence of autoimmune hypoglycemia has gradually increased due to increased administration of exogenous insulin. Beside genetic susceptibility, immunogenicity is influenced by insulin type. There is still no consensus on EIAS management although most of authors recommend corticosteroids and immunosuppressants. Many studies hypothesized that SARS-cov2 may induce auto-immune responses. To our knowledge, this is the first report of EIAS relapse following covid-19 infection.

Gender differences in smoking cessation? Results of a randomized controlled trial of dulaglutide-assisted smoking cessation

Fabienne Baur[1,2], Coynel David[3,4], Cihan Atila[1,2], Sophia Lengsfeld[1,2], Thilo Burkard[5], Andrea Meienberg[5], Cemile Bathelt[1,2], Mirjam Christ-Crain[1,2] & Bettina Winzeler[1,2]

[1]University Hospital Basel, Department of Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University of Basel, Department of Clinical Research, Basel, Switzerland; [3]University of Basel, Transfaculty Research Platform Cognitive and Molecular Neurosciences, Basel, Switzerland; [4]University of Basel, Division of Cognitive Neuroscience, Basel, Switzerland; [5]University Hospital Basel, Medical Outpatient and Hypertension Clinic, ESH Hypertension Centre of Excellence, Basel, Switzerland

Introduction

Smoking harms women more than men and women seem to be less successful in quitting. Greater concerns about post-cessational weight in women and gender differences in craving and reward processing have been postulated as possible explanations. Our group recently showed that the GLP-1 analogue dulaglutide reduces post-cessational weight gain. We hypothesize that women compared to men might profit more from the weight-lowering effects of dulaglutide in terms of abstinence rates.

Methods

This is a predefined secondary analysis of a placebo-controlled, double-blind, single-center randomized trial including 255 daily smokers (155 women, 100 men). Participants received weekly dulaglutide (1.5mg) or placebo (0.9% sodium chloride) subcutaneous injections for 12 weeks in addition to standardized smoking cessation care. Smoking status was self-reported and confirmed by end-expiratory carbon monoxide measurement. We analyzed gender differences after 12 weeks of dulaglutide / placebo treatment in weight change, abstinence rates and craving assessed by a visual analogue scale (VAS, minimum 1, maximum 10). Additionally, fMRI was performed in a subset of participants and craving and neuronal activity in response to smoking cue videos were examined for gender differences.

Results

Median [IQR] age at inclusion was 42 [32,53] years in females and 44 [34,53] years in males. Mean (SD) BMI was 26.0 (5.0) kg/m^2 and 28.9 (4.9) kg/m^2, respectively. After 12 weeks, 61% of females in the dulaglutide and 65% in the placebo group were abstinent, compared to 66% and 64% of male participants. Among quitters, there were no gender differences in absolute or percentual weight change neither on dulaglutide (difference: 0.2 kg, 95%-CI [-1.2, 1.6]; $P = 0.762$ / 0.7%, 95%-CI [-0.9, 2.3]; $P = 0.382$) nor on placebo treatment (difference: 0.0 kg, 95%-CI [-1.0, 1.0]; $P = 0.954$ / -0.6 %, 95%-CI [-1.8, 0.6]; $P = 0.340$). There is no evidence for either a direct association of gender with change in craving (mean difference females vs. males: 0.05 points, 95%-CI [-1.34, 1.43], $P = 0.947$) or that the effect of gender on change in craving might depend on dulaglutide treatment (interaction term: $P = 0.712$). Smoking cessation was directly associated with a decline in craving (mean difference quitters vs. persistent smokers: -3.07 points, 95%-CI [-4.67, -1.47], $P < 0.001$); however, this did not depend on gender (interaction term: $P = 0.380$). Data of the fMRI substudy are currently being analyzed and will be presented at the congress.

Conclusion

Our data showed similar abstinence rates, post-cessational weight changes and craving intensity in females and males.

Background

Rare variants in the melanocortin-4 receptor (MC4R) pathway are associated with early-onset, severe obesity and hyperphagia. Setmelanotide, an MC4R agonist,

reduced body mass index (BMI) and decreased hunger in patients with obesity due to biallelic variants in genes encoding proopiomelanocortin (POMC), proprotein convertase subtilisin/kexin type 1 (PCSK1), or leptin receptor (LEPR) in Phase 3 trials. The current analysis assesses the durability of setmelanotide efficacy over 3 years in the subgroup of patients who achieved clinically beneficial weight loss.
Methods
Patients aged ≥6 years with POMC, including PCSK1, or LEPR deficiency obesity who demonstrated clinical benefit and acceptable safety after treatment with setmelanotide in a prior (index) trial continued treatment in a long-term extension trial (NCT03651765). Age-appropriate weight measures and safety were assessed. Changes in weight-related measures from index trial baseline were evaluated in patients who achieved ≥10% weight reduction (age ≥18 years) or ≥0.3-point BMI Z score reduction (age <18 years) after 1 year of treatment.
Results
Across all patients ($n=24$), mean (SD) percent changes in BMI were −24.8% (8.2%; $n=24$), −21.0% (13.0%; $n=23$), and −24.0% (17.9%; $n=15$) at 12, 24, and 36 months, respectively. In patients ≥18 years old ($n=11$), mean (SD) percent changes in weight were −25.1% (7.7%; $n=11$), −22.9% (12.5%; $n=11$), and −24.4% (13.2%; $n=8$) at 12, 24, and 36 months, respectively. In patients <18 years old ($n=13$), mean (SD) reductions in BMI Z score were observed at Month 12 (−1.31 [0.66]; $n=13$), 24 (−1.10 [0.79]; $n=11$), and 36 (−1.01 [1.22]; $n=4$). No new safety issues were observed during long-term treatment.
Conclusions
Patients who achieved ≥10% body weight or ≥0.3-point BMI Z score reduction at 1 year demonstrated persistent and clinically significant benefit at 3 years, supporting long-term use of setmelanotide in adult and pediatric patients with obesity due to POMC and LEPR deficiency.

Study of the prevalence, clinical correlates, and cardiovascular outcomes of central and primary hypogonadism in type 2 diabetes mellitus

Biagio Cangiano[1,2], Maria Elena Lunati[3], Ruggiero Bollino[1], Antonio Conti[2], Elena Galazzi[2], Paolo Fiorina[4], Luca Persani[1] & Marco Bonomi[1]
[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan,; [2]IRCCS Istituto Auxologico Italiano; [3]ASST Fatebenefratelli Sacco, Milan, Italy; [4]University of Milan, "L. Sacco' Department of Biomedical and Clinical Sciences, Milan, Italy

Background
In patients affected with type 2 diabetes mellitus (T2DM) a high prevalence of hypogonadism has been reported, even if there is no consensus on its metabolic and cardiovascular implications, especially according to the type of hypogonadism. The aim of this observational study is to evaluate: (1) the prevalence of different types of hypogonadism in T2DM according to validated criteria from the EMAS study; (2) look for correlations of gonadal status with severity or duration of diabetes, its complications, dyslipidemia, therapies, BMI, age and smoking habit; (3) the incidence according to the gonadal function of major adverse cardiovascular events (MACE) intended as acute coronary syndrome, cerebrovascular events and/or newly diagnosed coronaropathy requiring revascularization;
Patients and Methods
We evaluated 106 male patients, consecutively enrolled in diabetology clinics, between 18 and 80 years old; patients with already known pituitary or gonadal diseases, acute diseases, malnutrition, or using interfering drugs were excluded. Each patient underwent a complete evaluation of the gonadal axis including SHBG to define his gonadal status (according to EMAS criteria), a treadmill test, and information on diabetes and its complications, therapies, glucose and lipidic metabolism was collected. Only 7 began testosterone replacement therapy (TRT) after diagnosing hypogonadism. A follow up of 36 months was carried out to look for MACEs.
Results
We found evidence of hypogonadism in 49% of T2DM patients: 31% of them having hypogonadotropic forms (HH), and 18% having primary hypogonadism (PH). PH was found to be associated with higher age, and creatinine levels, whereas HH was directly correlated with BMI. Finally, we found a significant increase in MACEs at 36 months in HH compared to other patients (Fisher test $P=0.047$), no one after the beginning of testosterone treatment.
Conclusions
We found a higher prevalence of HH e PH in T2DM outpatients than previously reported due to the finding of compensated PH and mild HH, which can be diagnosed only evaluating gonadotropins and SHBG respectively. We confirmed the known association of HH with BMI, and the correlation of PH with age and creatinine, suggesting different clinical implications for these two forms of hypogonadism and a possible effect of renal function on testicular ageing, or a common cause for organ dysfunction. Finally, the significantly higher prevalence of three years MACEs in HH could suggest this condition as a sign of cardiovascular disease and hints at a possible role of gonadal axis function as a predictive factor in T2DM.

A Challenging Case of Diabetic Ketoacidosis Due to Thyrotoxicosis

Athanasia Kalantzi, Danai Barlampa, Eirini Kaliakatsou, Ioanna Tsironi, Labrini Papanastasiou, Theodora Kounadi & Athina Markou
Athens General Hospital "G. Gennimatas", Endocrinology and Diabetes, Athens, Greece

Purpose
To present a rare case of diabetic ketoacidosis due to thyrotoxicosis and massive pulmonary embolism.
Case presentation
A 40-year-old man from Cameroun, with history of type 2 diabetes treated with gliclazide and metformin, presented with vomiting and abdominal pain. His vital signs were: blood pressure 140/80 mmHg, heart rate 184 beats per minute and temperature 38.2 °C. On admission, laboratory investigation revealed hyperglycemia, hyperosmolality and metabolic acidosis with ketonouria. On examination, the thyroid gland was tender at palpation. Thyroid function tests showed thyrotoxicosis whereas the thyroid ultrasound scan diminished vascularity. Thyroid autoantibodies were negative. The patient was treated with iv fluids, continuous iv infusion of insulin and enoxaparin in prophylactic dose. Alongside, ibuprofen 1800mg daily, propranolol 80mg daily and prednisolone 30mg daily were given as acute thyroiditis treatment. Other causes of ketoacidosis were excluded (negative antibodies for latent autoimmume diadetes of the adult, c peptide: 3.3ng/ml, absent biochemical or clinical signs of infection) which lead to the deduction that the main cause of diabetic ketoacidosis was indeed thyrotoxicosis. During his hospitalization, the patient presented a prefainting episode with hypoxemia and hypotension. The ABGs revealed respiratory alkalosis while the laboratory results showed high levels of d-dimmers and thrombocytopenia. CTPA identified multiple deficits in main and sub-main arterial branches, confirming the diagnosis of massive pulmonary embolism. Since the patient was on prophylactic enoxaparin treatment, heparin induced thrombocytopenia (HIT) was suspected, nevertheless antibody testing was negative. Due to low platelets, thrombolysis was considered unsafe and the patient underwent successful thromboaspiration, with subsequent clinical and hemodynamic improvement. Although the antibodies for HIT were negative the patient was treated with γ-globulin which resulted in gradual platelet increase. All other inherited and acquired coagulation disorders were excluded and no deep vein thrombosis was found. Insulin dose requirements were reduced along with tapering of prednisolone dose. On long term follow up he maintained normal thyroid function and good glycaemic control solely on metformin 1700mg daily and sitagliptin 100mg daily.
Conclusion
Diabetic ketoacidosis is a rare complication in type 2 diabetes patients during acute illness. Thyrotoxicosis due to acute thyroiditis is a rare precipitating factor that should be considered in tachycardic febrile patients with diabetic ketoacidosis. Thyrotoxicosis induced diabetic ketoacidosis can be a highly challenging condition to treat and intensive monitoring is required.

Effects of Glucagon-Like Peptide-1 Analogs on Sexual Desire: A randomized, double-blind, placebo-controlled crossover trial

Sophia Lengsfeld[1], Flavia Hasenböhler[1], Leila Probst[1], Fabienne Baur[1], Yara Emara[1], Cemile Bathelt[1], Laura Werlen[1,2], Deborah Vogt[1,2], Brida Caviezel[1], Tanja Vukajlovic[1], Mirjam Christ-Crain[1] & Bettina Winzeler[1]
[1]University Hospital Basel, Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University Hospital Basel, Departement of Clinical Research, Basel, Switzerland

Background
GLP-1 analogs are prescribed for diabetes and obesity due to their well-known insulinotropic, satiation-promoting and appetite-suppressant effects. Several

studies also investigated the effects of GLP-1 analogs on reward to addictive drugs such as alcohol, nicotine and cocaine. Pre-clinical studies suggest that sexual desire, as another type of natural reward, could also be affected by GLP-1 analogs. Since sexuality is a very important aspect of human wellbeing and the use of GLP-1-analogs is becoming more frequent in a broad spectrum of diabetic and obese patients in all age groups, the aim of this study was to investigate the influence of GLP-1-analogs on sexual desire and sex hormones.
Methods
This was a single-center, randomized, double-blind, placebo-controlled, crossover trial conducted at the University Hospital Basel in Switzerland. We enrolled healthy eugonad men of normal weight (BMI 18.5-25kg/m^2 or BMI 25.1-30kg/m^2 and waist circumference $<$102 cm), aged between 18 and 50 years who reported an active and satisfactory sex life. Participants were randomized to dulaglutide and placebo in random order. In the primary analysis, we tested the difference in change in sexual desire, assessed via the Massachusetts General Hospital - Sexual Functioning Questionnaire (MGH-SFQ), after four weeks of treatment with dulaglutide compared to placebo using a paired *t*-test. In secondary analyses, we examined the effect of four weeks of treatment with dulaglutide as compared to placebo on hormones of the reproductive axis (total testosterone, FSH, LH) using paired *t*-tests and adjusted for multiple comparisons using the Bonferroni-Holm procedure.
Results
Between May 2021 and February 2022, 24 out of 26 randomized participants completed the study. The average MGH-SFQ change from baseline after 4 weeks of dulaglutide was 1.0 (SD 2.2) and 0.4 (SD 2.7) under placebo (estimated difference in change of the MGH-SFQ sum score from baseline to end of treatment under dulaglutide and under placebo 0.6 (95% CI: [-0.8-2.0], *P*-value = 0.402). Analyzed hormones of the gonad axis did not show statistically significant differences.
Conclusion
In healthy men, dulaglutide had no clinically relevant effect on sexual desire nor on analyzed hormones of the gonad axis.

Association between advanced glycation end products (AGEs) and diabetic retinopathy in Latvia

Zane Svikle[1], Beate Peterfelde[1,2,3], Dace Petersone[4], Renate Nagobade[2,3], Julija Janceva[2,3], Janis Valeinis[4], Kristine Baumane[1,3] & Jelizaveta Sokolovska[1]
[1]University of Latvia, Faculty of Medicine, Riga, Latvia; [2]University of Latvia, Residency Development Programme, Riga, Latvia; [3]Riga East University Hospital, Ophthalmology Department, Riga, Latvia; [4]University of Latvia, Faculty of Physics, Mathematics and Optometry, Riga, Latvia

Background
Diabetic retinopathy is a common complication of diabetes mellitus and the leading cause of blindness in the working-age population in the developed world. Novel biomarkers are needed to improve the screening efficiency for the prevention and early treatment of this condition. Accumulation of advanced glycation end products (AGEs) is considered as one of pathogenetic pathways in development of diabetic complications. AGEs are formed in the process of non-enzymatic glycation of proteins. AGEs assessment could represent a long-term memory of prolonged hyperglycemia and could be an important biomarker in diabetic retinopathy.
Aim
The aim of the current study was to compare AGEs risk groups in patients with different stages of diabetic retinopathy in Latvia.
Methods
Altogether 115 patients with type 1 diabetes and type 2 diabetes were enrolled in the study. Patients were stratified into three groups according to the severity of diabetic retinopathy: "no retinopathy" group; "non-proliferative retinopathy" included patients with mild, moderate and severe non-proliferative retinopathy; group of "proliferative retinopathy" included patients with non-high and high risk proliferative retinopathy and status post laser-photocoagulation. AGEs risk groups (0- normal, 1- mild risk, 2- intermediate risk, 3- high risk) were determined using AGE reader (Diagnoptics). Statistical analysis was performed using programme R: Wilcoxon, Kruskal-Wallis, Fisher, Chi-square test, Kendall's T test and Spearman's correlation.
Results
Subjects in the group of "no retinopathy" (n=57) compared to "non-proliferative retinopathy" (n=29) and "proliferative retinopathy" (n=29) were statistically significantly older, had shorter duration of diabetes, higher prevalence of type 2 diabetes, lower HbA1c and low density lipoprotein levels, less diabetic maculopathy cases. In the group of proliferative retinopathy there was a higher albumin/creatinine ratio in urine. AGEs risk groups were statistically significantly related with the presence and severity of diabetic retinopathy (P=0.000) and also moderately positively correlated with the progression of diabetic retinopathy (Spearman correlation=0.438).
Conclusion
In this study, we demonstrated differences in AGEs risk groups between patients with different stages of diabetic retinopathy in Latvia. AGEs risk group could be used as one of non-invasive biomarkers of diabetic retinopathy.

Protective Role of Matrix Metalloproteinase-2 -1306 C/T and -1575 G/A Gene Polymorphisms Against Type 2 Diabetes Mellitus: A Case Control Study

Sameh Sarray[1,2], Meriem Dallel[3], Laila Ben lamine[3], Nejla Sellami[3], Amira Turki[4], Roland Brock[5] & mohamed Ghorbel[6]
[1]Arabian Gulf University, Medical Biochemistry, Manama, Bahrain; [2]Faculty of Sciences, University Tunis EL Manar, Biochemistry, Manar, Tunisia; [3]Laboratory of Human Genome and Multifactorial Diseases (LR12ES07), Faculty of Pharmacy of Monastir, Monastir, Tunisia; [4]Faculty of Applied Medical Sciences, Northern Borders University,, Arar, Saudi Arabia; [5]Radboud Institute for Molecular Life Sciences, University Medical Center,, Biochemistry, Nijmegen, Netherlands; [6]CHU Farhat Hached, Sousse, Sousse, Tunisia

Aims
Genetic variations mediating matrix metalloproteinase-2 (MMP-2) expression may result in individual differences in susceptibility to particular diseases. Our aim was to investigate the possible association of certain MMP-2 gene variants with type 2 diabetes mellitus (T2DM) in a Tunisian population.
Subjects and Methods
A case-control study involving 310 normoglycemic control subjects and 791 T2D patients was performed. A total of four MMP-2 SNPs (-1306 C/T; -1575 G/A; -735 C/T and rs9923304 C/T were selected for this study, based on their established minor allele frequency (MAF) $>$5% in Caucasians and association with T2DM comorbidities. Genotyping of MMP-2 variants was performed by real time PCR. Replicated blinded quality control samples were included to evaluate reproducibility of the genotyping procedure; concordance was $>$ 99%.
Results
The MAF of the -1306C/T and the -1575G/A MMP-2, were significantly different between T2DM cases and controls. Setting homozygous wild-type genotype carrier as reference, a reduced risk of T2DM was seen with the -1306C/T and the -1575G/A genotypes. The inheritance hypothesis for this polymorphism was tested according to three genetic models: codominant, dominant, and recessive. According to the dominant model, individuals with GT + TT genotypes of the -1575G/A MMP-2 SNP had a 0.68-fold reduced risk of developing the disease (P=0.012). Moreover, a significant association was shown under the dominant model of the -1306C/T polymorphism with P=0.007 and OR (95% CI) = 0.66 (0.49–0.89), which revealed a 0.66-fold reduced risk within individuals with CT + TT vs individuals with a double homozygote CC genotype. This association persists after controlling for the BMI, total cholesterol and triglyceride covariates as three adjustments models. Haploview analysis revealed limited linkage disequilibrium between the tested MMP-2 and variants, with most haplotypes (99.5%) captured by 7 MMP-2 haplotypes. Taking the GCCC haplotype as reference for MMP-2 (OR=1.00), a reduced frequency of TTCC haplotypes (P=0.04) and the GTCC haplotype (P=3.5x 10^{-5}) was noted in T2D which indicates a protective nature of these two haplotypes for T2D development. Conclusions: To the best of our knowledge, our study is the first to demonstrate the potential of -1306 C/T and -1575 G/A MMP-2 SNPs to reduce the risk of developing type 2 diabetes mellitus.

Clinical profiling of Acanthosis nigricans in Emirati patients and its association with sex-specific differences in insulin secretion and insulin resistance: a case-control study

Lara Al-Olabi, Budour Alkaf & Adam J. Buckley
Imperial College London Diabetes Centre, Research, Abu Dhabi, United Arab Emirates

Background
Acanthosis nigricans (AN) is a cutaneous condition characterised by pigmented hyperkeratosis of the skin flexures and neck and occurs most commonly in association with hyperinsulinaemia and insulin resistance (IR). A high prevalence of hyperinsulinaemia and abnormal glucose intolerance has been reported in the Emirati population. Current knowledge of AN suggests that it is a strong visible cutaneous marker associated with IR and can precede the onset of hyperglycaemia. We explored associations of IR, type 1 diabetes (T1DM) and type 2 diabetes (T2DM) with AN (independent of BMI), compared to a control group without AN.
Methods
Case-control study conducted at Imperial College London Diabetes Centre (ICLDC, UAE). Individuals aged <40 years with a clinical diagnosis of AN at <18 years and controls without AN aged <40 years; with or without a diagnosis of diabetes were included. A total of 416 patients, 141 with AN, 275 without AN were recruited. IR was assessed using the Homeostatic Model Assessment of insulin resistance (HOMA2-IR) score.
Results
Mean HOMA2-IR was 0.9, 3.0, 3.6 and 4.2 in individuals with T1DM, NGT, Prediabetes and T2DM, respectively. BMI (OR = 1.13, $P<0.0001$***) and HOMA2-IR (OR = 1.16, $P=0.008$**) were independently and significantly associated with AN. Among individuals with T2DM, HOMA2-IR was significantly higher in association with AN features in women ($P=0.03$*) but not in men ($P=0.23$). Sex-specific differences in associations between AN and HOMA2-B and HOMA2-S were noted. Men with AN demonstrated higher HOMA2-B (OR = 1.01, $P=0.0353$*) than men without AN, while HOMA2-S was significanlty lower in women with AN OR = 0.98, $P=0.0032$**) than without; HOMA2-S in men and HOMA2-B in women were not significantly associated with AN.
Conclusion
This is the first report we are aware of investigating AN and its association with IR, T1DM and T2DM in both males and females in a case-control study in an Emirati population. Awareness and early identification of AN as a clinical marker of IR enables timely recognition of underlying metabolic complications.

Paediatric Type 2 Diabetes in a single centre in East London in the period 2008-2018

Farah Abdelhameed[1,2], Anna Giuffrida[3], Ben Thorp[4], Myuri Moorthy[4] & Evelien Gevers[2,4]
[1]Warwick Medical School, University of Warwick, Coventry, United Kingdom; [2]Barts and The London Medical School, Queen Mary University of London, William Harvey Research Institute, London, United Kingdom; [3]University of Catania, Medical School, Catania, Italy; [4]Royal London Hospital, Barts Health NHS Trust, London, United Kingdom

Objective
Incidence of paediatric type 2 diabetes appears to be increasing. We describe our cohort of paediatric type 2 diabetes at Barts Health NHS Trust in East London (UK) over the period 2008-2018 to gain insight in incidence, complications and outcomes.
Methods
Retrospective cohort study. Data collection from Twinkle (electronic database for diabetes) and paper notes.
Results
Fourty patients (25 female) were diagnosed with T2D at an age of 13.9 ± 1.7 years. Sixty percent were Asian compared to 28% in our T1D cohort. New patients doubled from 2.6/year in 2009-2013 to 5.3/year in 2014-2018. Currently, T2D accounts for 12.5% of our paediatric diabetes cohort. Sixty eight percent had co-morbidities. Learning disabilities were common, more so in males than females (47% vs 16%). At diagnosis, mean BMI was 32.4 ± 6.71 kg/m^2, BMI SDS 2.87 ± 0.70. BMI was 31.7 kg/m^2 for females ($n=23$) and 33.8 kg/m^2 for males ($n=13$) ($P=0.35$). Patients diagnosed in 2014-2018 had higher mean BMI SDS, compared to 2008-2013 (3.06 ± 0.56 vs 2.52 ± 0.81, $P=0.02$) but a lower HbA1c at diagnosis (69.4 ± 19.2 mmol/mol vs 89.0 ± 19.2 mmol/mol, $P=0.02$). BMI and BMI SDS did not change during 2 years follow-up. Mean HbA1c at diagnosis was 75.2 ± 21.0 mmol/mol, decreasing to 55.0 ± 17.4 mmol/mol after 3 months ($P=0.001$) but increasing to 63.0 ± 25.5 mmol/mol at 1 year ($P=0.07$). HbA1c <48 mmol/mol was achieved in 22/37 patients, but only 9/37 patients maintained this for a year, and 2 patients relapsed after this year. Diabetes complications included hypertension ($n=9/21$), dyslipidaemia ($n=9/30$), raised ALT ($n=7/30$), fatty liver ($n=7/24$) and sleep apnoea ($n=6/26$) with similar frequency at diagnosis and during follow-up. Metformin was started in 38/40 patients, 7 patients reduced the dose and 6 stopped due to side effects. 14/37 patients started also on long-acting insulin (0.30 ± 0.16 U/kg), and in 6 combined with prandial insulin (0.42 ± 0.20U/kg). Thirty patients had left paediatrics by 2022, 15 succesfuly transitioned to adult services, 7 were lost to follow up and discharged to their GP, and 4 were discharged to their GP due to diabetes reversal. Mean HbA1c one year after transition ($n=9$) was 70.3 ± 28.2 mmol/mol compared to 74.7 ± 27.6 mmol/mol at transition and 74.7 ± 24.9 mmol/mol at diagnosis.
Conclusion
High burden of co-morbidities and complications is common amongst youth with T2D. Current management does not achieve permanent reduction in BMI or HbA1c, although temporary reduction in HbA1c is achieved in many patients. New treatment approaches are needed to improve outcomes, including strategies for follow-up after transition to adult services.

Assessment of insulin-releasing and glucose-lowering actions of aqueous extracts of Pterocarpus mildbraedii cellular and diet-induced mice models of type 2 diabetes

Opeolu Ojo[1,2], Ayokunle Benjamin Falana[1], Ayodele Abiodun Falobi[1], Simren Kaur Heer[1], Mojisola Adie[1], Joy Nneka Edeani[1], Gabriel Anyanwu[3] & Uju Ejike[3]
[1]University of Wolverhampton, Wolverhampton, United Kingdom; [2]IRiD Bioscience, Stokes-on-Trent, United Kingdom; [3]Bingham University, Department of Biochemistry, Karu, Nigeria

Aim
The use of commonly consumed vegetables, such as *Pterocarpus mildbraedii*, in the treatment of metabolic conditions is consistent with the food-as-medicine strategy. To characterise its pharmacological actions, this study assessed insulin-releasing and glucose lowering effects of effects of *P. mildbraedii* in models of type 2 diabetes.
Methods
Clonal pancreatic cells, BRIN-BD11, were treated *P. mildbraedii* extracts (0 - 0.1-1000μg/ml) in the presence or absence of insulin secretagogues, inhibitors and extracellular calcium. Cytotoxicity and actions of *P. mildbraedii* on cell viability, cell proliferation, intracellular calcium concentration, membrane depolarisation and glucose uptake were assessed together with its *in vivo* actions on diet-induced diabetes.
Results
P. mildbraedii stimulated non-toxic concentration-dependent insulin secretion at all concentrations tested (0.1-1000μg/ml, 1.1-3.4-fold, $P<0.01$-0.001). *P. mildbraedii* extract produced no significant effect on cell viability. Actions of the extract were inhibited by verapamil (50nM, 49%, $P<0.001$), diazoxide (300μM, 50%, $P<0.01$) and absence of calcium (47%, $P<0.01$). Insulinotropic effects increased in incubations containing KCl (30mM, 1.2-fold, $P<0.05$) and different glucose concentration (1.1 to 5.6mM, 1.8-fold, $P<0.01$; 5.6 to 16.7mM, 1.1-fold, $P<0.05$). Enhanced cell proliferation (21%, $P<0.01$), membrane depolarisation (27%, $P<0.05$), intracellular calcium concentration (31%, $P<0.001$), glucose uptake (31%, $P<0.01$) were observed in vitro. Glucose tolerance improved (42%, $P<0.01$) in high-fat fed mice.
Conclusions
These results indicate significant antidiabetic actions of *P. mildbraedii* and suggests the involvement of the ATP-dependent pathway of insulin secretion.

Acceptability of the switch from parenteral to oral semaglutide in patients with type 2 diabetes mellitus and obesity: Patient satisfaction, and changes in HbA1c, body weight, systolic blood pressure and tryglicerides

Francisco Javier Martinez Martin[1,2], Borja Santana Ojeda[1], Carlos Rios-Gomez[1], Ricardo Jose de Leon-Durango[1], Alba Hernandez-Lazaro[1], Claudia Arnas-Leon[1,2], Carmen Acosta-Calero[3], Agnieszka Kuzior[2], Marta Martin-Perez[4] & Debora Garcia-Alamo[1]

[1]Hospital Universitario de Gran Canaria Dr. Negrín, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [2]Hospitales Universitarios San Roque, Endocrinology & Nutrition, Las Palmas de Gran Canaria, Spain; [3]Hospital Universitario de Gran Canaria Dr. Negrín, Cardiology, Las Palmas de Gran Canaria, Spain; [4]Clínica Cajal, Family Medicine, Las Palmas de Gran Canaria, Spain

Introduction
During most of the autumn of 2022, the standard maintenance presentation of parenteral semaglutide (1.0 mg for weekly dosage) was temporarily unavailable. Many of the patients using this dose were switched to the standard maintenance dose of oral semaglutide (14 mg daily). The leaflet included with the product specifies that the 14 mg daily oral dose is equivalent to the 0.5 mg parenteral weekly dose, but this is most likely an interpolation, as there are no reported head-to-head comparisons of the comercially available doses of oral and parenteral semaglutide in the literature.
Methods
We obtained data retrospectively from patients with obesity and type 2 diabetes who had switched from 1.0 mg parenteral semaglutide to 14 mg oral, forced by the unavailability of the parenteral presentation. Body weight, BMI, SBP, HbA1c, triglycerides and reported side effects were obtained from the clinical records. The patients answered anonymally a simple web-based questionnaire with two questions: -Their satisfaction with the switch from parenteral to oral semaglutide was: [very high/high/fair/low/very low/no answer]. -Would they switch back to parenteral semaglutide when available [yes/no/no answer]. All patients included gave their informed consent.
Results
48 patients who had been at least 3 months with parenteral semaglutide 1.0 mg weekly and switched to oral semaglutide 14 mg daily were recruited, with available data in the last month before the switch and new data 2-4 months after the switch. 26 (54%) were female, mean $\pm$ sd age was 57 $\pm$ 13 years, and diabetes duration vas 8.4 $\pm$ 6.2 years. There was a non-significant reduction in BMI (-0.3 $\pm$ 0.2 kg/m^2), in HbA1c (-0.41 $\pm$ 0.25%), in SBP (-4 $\pm$ 2 mmHg) and a non-significant increase in triglycerides (+16 $\pm$ 12 mg/dl). 7 (15%) of the patients reported new or worsened minor gastrointestinal side effects but there were no withdrawals. Reported satisfaction with the switch was 16/18/15/4/0/1 [very high/high/fair/low/very low/no answer]. The intention to switch back was 18/29/1 [yes/no/no answer].
Conclusions
In this group of patients with obesity and type 2 diabetes we did not find inferior results with oral semaglutide 14 mg daily vs. parenteral semaglutide 1 mg weekly. A solid majority of the patients (70%) reported high or very high satisfaction with the switch, and 62% had no intention of switching back. The reported side effects of the switch were infrequent and minor. We conclude that the acceptability of switching parenteral to oral semaglutide was high in our patients, with no apparent inferiority in clinical results.

Introduction
It is known that very-low-calorie-ketogenic-diet (VLCKD) has beneficial effects on body weight in overweight diabetic patients. Adopting this diet with artificial meals or natural foods in type 2 diabetes (T2DM) has been largely studied, and conflicting results have been reported regarding its effects on glycemic profiles, dyslipidemia, and liver function. In fact, the high level of fat content in natural foods could have a negative impact on hepatic steatosis, and high protein content in artificial meals may affect renal function.
Case
We describe a 62-year-old female patient with T2DM complicated by diabetic nephropathy who underwent a VLCKD. When T2DM was diagnosed in 2010, her glycated hemoglobin (HbA1c) was 61 mmol/mol and body mass index (BMI) was 37.1 kg/m^2. She also had dyslipidemia and severe hepatic steatosis. She was initially managed with metformin and a Mediterranean diet with an improvement in glycemic control and discrete weight loss (HbA1c 49 mmol/mol, BMI 34.8 kg/m^2). Three years later, she presented poor glycemic control (HbA1c 65 mmol/mol), regain of body weight and diabetic nephropathy appeared (estimated glomerular filtration rate, eGFR, 49 ml/min/1.73m^2, albuminuria 266 mg/l). Therefore, metformin was discontinued, basal insulin therapy was started, and liraglutide (until 1.8 mg/day) was added to improve weight loss. Metabolic control improved quickly and remained stable over time, but she only had minimal weight loss (BMI from 35.5 to 35.1 kg/m2 in four years despite therapy). Therefore, in August 2019, she was advised to start a VLCKD. Just one month after, she had a remarkable improvement in glycemic control, so she discontinued all therapy. After six months of diet, not only the excellent glycemic control (HbA1c 37 mmol/mol) persisted, but there were also an important weight loss (BMI 29.9 kg/m2), together with amelioration of dyslipidemia, hepatic steatosis, and diabetic nephropathy (eGFR 61.5 ml/min/1.73m^2, albuminuria 1.6 mg/l). In February 2020, VLCKD was replaced by a low-calorie-diet followed for one year, in which she had partial weight gain and worsening renal function. Then, she switched a low-carbohydrate-diet and all parameters improved again.
Discussion
The best dietary approach in subjects with T2DM remains debated. However, in literature, it has been suggested that not only VLCKD seems to be safe and effective in obese diabetic patients with impaired renal function and liver disease, but that it may even help significantly improving both, as in this case.

En route to sarcopenia biomarkers: dp-ucMGP in relation to muscle mass and function

Veronika Tandl[1], Natascha Schweighofer[1], Olivia Trummer[1], Christoph W. Haudum[1], Alice F. Lind[1], Ewald Kolesnik[2], Ines Mursic[1], Daniel Scherr[2], Andreas Zirlik[2], Thomas R. Pieber[1], Nicolas D. Verheyen[2] & Barbara Obermayer-Pietsch[1]
[1]Medical University of Graz, Department of Internal Medicine, Division of Endrocrinology and Diabetology, Graz, Austria; [2]Medical University of Graz, Department of Internal Medicine, Division of Cardiology, Graz, Austria

Sarcopenia is characterized by progressive loss of both mass and function of skeletal muscle when ageing. It poses a serious issue for healthcare systems, as it is associated with increased risk of falls, osteoporosis, and mortality. To date, no ideal serum biomarkers for the diagnosis of this complex condition have been identified. Matrix-GLA-protein (MGP), primarily known as a vitamin K dependent calcification inhibitor, is present and active in bone, muscle, and adipose tissue. It acts as an adipokine and has been linked to reduced muscle strength. Therefore, its dephosphorylated and uncarboxylated isoform (dp-ucMGP) was investigated as a potential biomarker in sarcopenia. To find associations of dp-ucMGP and sarcopenia related parameters, data from the BioPersMed cohort ("Biomarkers for Personalized Medicine") were analyzed. The cohort included 1022 asymptomatic volunteers (58 $\pm$ 9 years) at moderate cardiovascular risk. In 760 persons, serum measurements of dp-ucMGP were analyzed with the InaKtif MGP Kit using the IDS-iSYS Multi-Discipline Automated System. Body composition was measured by Lunar iDXA and clinical and physical performance data were collected. Several sarcopenia definitions were used, based on either muscle mass (appendicular muscle mass [ASM] or appendicular muscle mass index [AMMI]) or muscle function (handgrip strength [HGS] or 400m walk test). Dp-ucMGP plasma levels correlated negatively with gait speed (Spearman's rho [ρ] = 0.192; $P < 0.001$). Using gait speed for defining groups, serum levels were higher in the sarcopenia compared to the non-sarcopenia group (716 $\pm$ 306.6 vs. 491 $\pm$ 164.4 pmol/l; $P = 0.006$). The highest dp-ucMGP quartile also showed the highest risk of reduced HGS, another marker of physical performance (Odds ratio [OR] = 3.688; 95% CI 1.007 - 13.502). Other than with muscle function, dp-ucMGP showed a positive correlation to the muscle mass parameters AMS ($\rho = 1.102$; $P = 0.005$) and AMMI ($\rho = 0.122$; $P = 0.001$). Serum levels were lower in persons with sarcopenia than without, using both ASM and AMMI for defining groups ($P < 0.001$ and $P = 0.012$, respectively). The lowest dp-ucMGP quartile had the highest risk for reduced muscle mass (i.e., AMMI), decreasing with each quartile. In sum, dp-ucMGP plasma levels are lower in sarcopenia defined by muscle mass (i.e., ASM and AMMI), but higher in sarcopenia defined by muscle function (i.e., HGS and gait speed). Serum dp-ucMGP can be considered as a potential biomarker candidate for characterizing sarcopenia and may be a promising link between bone, fat, and muscle.

Epicardial Fat, a cardiovascular risk factor with implications in kidney function

Carolina M. Perdomo[1], Nerea Martín-Calvo[2], Ana Ezponda Casajús[3], Francisco J. Mendoza[3], Gorka Bastarrika Alemañ[3], Guilherme V. de Assunção[4], Nuria García-Fernández[5], Gema Fruhbeck[1] & Javier Escalada[1]
[1]Clínica Universidad de Navarra, Endocrinology and Nutrition, Pamplona, Spain; [2]University of Navarra, Department of Preventive Medicine and Public Health, Pamplona, Spain; [3]Clínica Universidad de Navarra, Department of Radiology, Pamplona, Spain; [4]Centro Hospitalar Universitário do Porto, Department of Endocrinology and Nutrition, Porto, Portugal; [5]Clínica Universidad de Navarra, Department of Nephrology, Pamplona, Spain

Aim
Epicardial adipose tissue (EAT) has important physiologic functions, nonetheless, excessive EAT leads to a proinflammatory state with adverse effects on the myocardium. EAT has also been associated with adverse outcomes in chronic kidney disease (CKD) patients. We think that visceral adipose tissue (VAT) and organ-specific ectopic fat plays an important role in cardiorenal dysfunction. The aim of our study is to analyse the relationship between EAT and the risk of developing albuminuria.
Methods
We reviewed the records of subjects who underwent a routine health check-up, had a computed tomography whole body scan and blood test in the same visit at our Center from July 1, 2003 to December 31, 2006 and had at least one follow-up control (181 patients were included in the analysis). EAT was quantified semiautomatically including voxels with attenuation values between -45 to -190 HU. EAT was adjusted for body surface area (EATi; normal limit: 68.1 cm^3/m^2). The outcome was defined as the presence of albuminuria at follow-up. Micro-albuminuria and macro-albuminuria were defined as urinary albumin-creatinine ratio (UACR) >30 mg/gCr and >300 mg/gCr in spot urines, respectively.
Results
Mean age was 55.9 ± 8.5 years (76.8% were men). Seventy-seven (43%) subjects had normal EATi and 104 (57%) an abnormal EATi. Patients with abnormal EATi were predominantly men, older and had a higher glycemia, HOMA-IR, a more detrimental lipid profile, hyperuricemia, worse liver function ($P<0.05$), a higher prevalence of metabolic syndrome disorders, higher indices of adiposity and higher CAC Score. We observed a 36.5% (95% CI: 20.2-52.8), 54.3% (95% CI: 42.7-65.8) and 85.3% (95% CI: 73.0-97.6) of subjects with abnormal EATi in each tertile of VAT, respectively. The proportion of subjects with abnormal EATi was significantly higher at the third tertile of VAT compared with the first tertile (diff: 49% 95% CI: 25% - 72%) ($P<0.01$). After a median follow up of 11.22 years (25th percentile: 4.7; 75th percentile: 14.9), 32 events of albuminuria were registered. Mean (sd) albuminuria of those subjects was 242 mg/gCr (769.13). Patients with high levels of EATi had an increased risk of albuminuria after adjustment for age, sex, BMI, diabetes and antiplatelet therapy, medical treatment for diabetes, dyslipidemia, hypertension, or hyperuricemia at baseline using the IPW method: HR (95% CI) 4.05 (1.19-13.82) ($P=0.025$).
Conclusions
EAT is associated with renal dysfunction assessed through urinary albumin-creatinine ratio. Our results, endorse the term Obesity-related Adipose tissue Disease (OrAD) to collectively englobe the diverse pathologies related to adiposopathy.

Central Actions of Leptin Sensitizer Celastrol

Miriam Bernecker[1,2,3,4], Sonja Schriever[1,2], Ekta Pathak[1,2], Michael Sterr[5], Heiko Lickert[4,5], Jessica Yue[6,7] & Paul Pfluger[1,2,3,4]
[1]Helmholtz Munich, Institute for Diabetes and Obesity, Neuherberg, Germany; [2]Helmholtz Munich, Research Unit Neurobiology of Diabetes, Neuherberg, Germany; [3]Helmholtz Munich, International Helmholtz Research School for Diabetes, Neuherberg, Germany; [4]Technical University of Munich, Medical Faculty, Munich, Germany; [5]Helmholtz Munich, Institute of Diabetes and Regeneration Research, Neuherberg, Germany; [6]Alberta Diabetes Institute, Edmonton, Canada; [7]University of Alberta, Department of Physiology, Edmonton, Canada

Celastrol, a triterpene compound derived from the thunder god vine (Tripterygium wilfordii), has shown promising efficacy in preclinical models for the management of metabolic disorders such as obesity and diabetes. The compound exhibits anti-inflammatory properties and has been shown to enhance insulin sensitivity and modulate lipid metabolism. The observed weight loss effects are thought to be primarily mediated by its ability to augment leptin sensitivity. Despite extensive research, its exact mode of action remains poorly understood. We and others suggested that the therapeutic effects of celastrol may, to a large extent, be mediated by the hypothalamus and its neural circuits that control food intake and appetite. However, no studies to date had explored the direct metabolic effects of celastrol after central application. In this study, we aimed to specifically examine whether centrally administered celastrol can regulate energy and glucose metabolism in rodents. Using mice, we show that the subchronic treatment with intracerebroventricular (icv) 3 celastrol improves sensitivity to leptin in animals that were fed a high-fat diet. By hyperinsulinemic-euglycemic clamp measurements we further demonstrate that rats fed a high-fat diet exhibit improved glucose metabolism when acutely infused with icv 3 celastrol. In order to determine cellular targets mediating these effects, we employed single nucleus RNA sequencing of hypothalamic leptin receptor-expressing cells. We reveal dramatic transcriptional effects of celastrol in a leptin resistant state of diet-induced obese mice as well as the transcriptional signature of leptin together with a celastrol pre-treatment. Our results suggest a previously unappreciated weight loss-independent mechanism of action of celastrol in the regulation of glucose homeostasis and new insights for potential molecular targets in the treatment of obesity and leptin resistance.

Cardiac Autonomic Regulation and Metabolic Syndrome: Clinical Use of A Unitary Autonomic Nervous System Index

Luca Giovanelli[1], Mara Malacarne[1], Giuseppina Bernardelli[2,3], Alessandro Ardigò[1], Nadia Solaro[4] & Daniela Lucini[1,3]
[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Milan, Italy; [2]University of Milan, DISCCO Department, Milan, Italy; [3]Istituto Auxologico Italiano, IRCCS, Exercise Medicine Unit, Milan, Italy; [4]University of Milano-Bicocca, Department of Statistics and Quantitative Methods, Milan, Italy

Background
Metabolic syndrome (MetS) represents a huge public health problem worldwide, being associated with an increased risk of cardiovascular and oncological diseases, and all-cause mortality. There is compelling evidence supporting a key role of dysfunctional autonomic nervous system (ANS) in such an association as well as the mutual correlation between the components of MetS. Autonomic Nervous System Index (ANSI) is a percent ranked (0–100) unitary proxy of cardiac autonomic regulation (CAR), extracted from the autoregressive spectral analysis of heart rate variability (HRV) by combining the three most informative indexes. It is a simple and non-invasive method to evaluate and monitor ANS function, being by design free of age and gender bias [1].
Aims
To investigate CAR by means of ANSI in patients affected with MetS.
Methods
133 patients referred to the Exercise Medicine Clinic of Istituto Auxologico IRCCS underwent assessment of CAR - by means of ANSI - alongside lifestyle with ad hoc questionnaires focusing on weekly physical activity volume, nutrition quality, and perception of stress, fatigue and somatic symptoms. Participants were retrospectively subdivided into two groups according to the presence or not of MetS criteria (established by the Joint Interim Statement in 2009 [2]).
Results
58 subjects were affected with MetS, while 75 were not (non-MetS). Non-MetS patients were characterized by a significant prevalence of females and lower age as compared with MetS counterpart. ANSI (free of age and gender bias) was significantly impaired (32.9 vs 44.8, $P=0.007$) in MetS subset. No significant differences were found in terms of lifestyle between the groups.
Conclusions
This is the first study assessing CAR by means of ANSI in MetS patients. Such findings indicate neurovegetative dysregulation in MetS. Intriguingly, in view of the increased cardiovascular risk mediated via - among others – ANS impairment in MetS, early screening for ANS dysfunction with simple but reliable methods may be clinically advantageous, with a view to undertaking and monitoring therapeutic strategies that aim to restore autonomic balance (e.g., personalized lifestyle management programs).

Early impact of bariatric surgery on obesity-related kidney dysfunction

Miruna Maria Popa[1,2], Anca Sirbu[1,2], Elisabeta Malinici[1,2], Carmen Sorina Martin[1,2], iulia soare[1,2], Carmen Gabriela Barbu[1,2], Catalin Copaescu[3] & Simona Fica[1,2]

[1]"Carol Davila" University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania; [2]"Elias" Emergency University Hospital, Endocrinology and Diabetes, Bucharest, Romania; [3]"Ponderas" Academic Hospital, General Surgery, Bucharest, Romania

Background

Renal dysfunction is known to be more prevalent amongst patients with obesity. Metabolic and bariatric surgery is associated with positive renal effects through intricate pathways. We aimed to determine the short-term impact of laparoscopic sleeve gastrectomy (LSG) on renal function and to identify parameters associated with its variation.

Materials and methods

We performed a retrospective study on 268 patients (115 males and 153 females) evaluated before and six months after LSG. Clinical and anthropometrical data were collected, as well as an extensive biological panel and body composition assessment using whole-body dual-energy X-ray absorptiometry (DXA). CKD-Epi (2021) formula was used to estimate glomerular filtration rate (eGFR) both pre- and postoperatively.

Results

Mean baseline BMI was 44.25 kg/m^2 ($\pm$ 6.17 kg/m^2) and mean 6 months excess weight loss percentage (EWL) was 70.04% ($\pm$17,38%). Diabetes mellitus (DM) and hypertension had a prevalence of 18.3 and 50% respectively. Mean eGFR (ml/min/1.73 m^2) was 87,68 (15.92), with a cumulative prevalence of mild and moderate renal dysfunction of 55.2%. The prevalence of renal hyperfiltration was surprisingly low (0.7%). Six months postoperatively, mean eGFR increased to 93.23 ($P<0.001$) and the prevalence of renal dysfunction decreased to 40.7%. Interestingly, this improvement correlated with EWL (rho = -0.307, $P=0.001$), total lean mass (rho = -0.257, $P=0.012$) and appendicular skeletal muscle mass index (ASMI; rho = -0.264, $P=0.01$) variations in males, as opposed to total visceral adipose tissue (VAT) mass (rho = -0.235, $P=0.01$) and LDL cholesterol (rho = -0.187, $P=0.02$) variations in females. Of these, EWL, VAT mass and LDL cholesterol variations were independent predictors in a model adjusted for the remission of either hypertension or DM.

Discussion and conclusions

Our results are in line with previous findings on the positive impact of LSG on renal function. Hyperfiltration is thought to be associated with early stages of obesity-related glomerulopathy and its low prevalence suggests delayed presentation in our cohort. The identified differences might point to gender-specific drivers of kidney dysfunction associated with obesity and its resolution. Specifically, visceral adiposity seems to play a more prominent role in females. If confirmed by further studies, this could aid in the optimization of medical treatment.

Testosterone serum levels predict the severity of metabolic dysfunction associated fatty liver disease (MAFLD) in hypogonadal men

Daniele Santi[1,2,3], Giorgia Spaggiari[2,3], Fabio Nascimbeni[4], Simonetta Lugari[4], Cristina Felicani[4], Leonardo Dalla Valentina[1,3], Ali Ahmad[1,3], Antonio Raffaele Michele Granata[2,3], Pietro Andreone[4] & Manuela Simoni[1,2]

[1]University of Modena and Reggio Emilia, Department of Biomedical, Metabolic and Neural Sciences, Modena, Italy; [2]Azienda Ospedaliero-Universitaria of Modena, Unit of Endocrinology, Department of Medical Specialties, Modena,; [3]Azienda Ospedaliero-Universitaria of Modena, Unit of Andrology and Sexual Medicine of the Unit of Endocrinology, Department of Medical Specialties, Modena, Italy; [4]Azienda Ospedaliero-Universitaria of Modena, Operating Unit of Internal and Metabolic Medicine, Modena,

Background

Metabolic dysfunction associated fatty liver disease (MAFLD), the leading cause of chronic liver disease, is defined as the presence of hepatic steatosis and metabolic risk factors. Both testosterone and estradiol seem to have a pivotal role in hepatic lipid homeostasis, although underlying mechanisms are still unclear. Low testosterone serum levels result independently associated with MAFLD, but no studies so far evaluated MAFLD prevalence and severity in hypogonadal men.

Aim of the study

To evaluate MAFLD prevalence and severity in a cohort of hypogonadal men.

Methods

A prospective, observational, clinical trial was conducted enrolling hypogonadal men (testosterone serum levels <3 ng/ml) and collecting medical history, anthropometrical characteristics, hormonal (testosterone, estradiol, sex hormone binding globulin [SHBG] and prolactin) and biochemical (liver enzymes, lipid profile, glycemia and glycated haemoglobin) parameters. Each patient underwent hepatic ultrasound to evaluate the presence and grade of steatosis, and Fibroscan® and 2-dimensional shear weave elastography (2D-SWE) techniques for the assessment of liver stiffness. A liver stiffness $\pm$ 8 kPa was considered diagnostic for liver fibrosis.

Results

Twenty-six hypogonadal men (age 59.9 $\pm$ 13.8 years, body mass index 33.9 $\pm$ 7.4 kg/m^2) were enrolled, of which 20 (76.9%) presented secondary hypogonadism, and six (23.1%) a primary form. Eighteen patients (69.2%) were already under androgen replacement therapy (mean treatment duration 4.5 $\pm$ 3.7 years), presenting mean testosterone serum levels above the lower level of the reference range (3.9 $\pm$ 2.9 ng/ml). Hepatic steatosis was detected in 16 patients (61.5%), divided into mild (7.7%), moderate (26.9%) and severe (26.9%) grades. No difference in liver steatosis presence/grade was detected between androgen-replaced patients compared to untreated ones. Liver stiffness was 6.8 $\pm$ 5.4 KPa (IQR 16.2 $\pm$ 7.1%) at Fibroscan® and 7.7 $\pm$ 10.3 KPa (IQR/M 21.5 $\pm$ 8.1%) at 2D-SWE. Liver fibrosis was detected in five men (19.2%) at Fibroscan® and in 4 (15.4%) at 2D-SWE. The presence of liver fibrosis according to both elastography techniques was not associated to any biochemical parameter. However, multivariate analysis showed that liver stiffness was predicted by alanine transaminase (ALT) (B: 0.780, $P<0.005$) and testosterone (B: -1.819, $P=0.022$) serum levels.

Discussion

Here, we demonstrated a high prevalence of liver steatosis in hypogonadal men, especially of moderate/severe grades. Moreover, using different elastography techniques, we highlighted an unexpectedly high prevalence of liver fibrosis, occurring in more than 15% of cases. Although our results need further confirmation in larger cohorts, the inverse correlation between liver stiffness and testosterone serum levels at least suggests the need to assess the presence of MAFLD in hypogonadal patients.

Understanding the cultural fit of the REDE model for physician-based communication skills training: A focus group discussion with South Indian patients with T2DM

Chitra Selvan[1], Tejal Lathia[2], Shweta Chawak[3], Praneeta Katdare[4] & Mahati Chittem[4]

[1]Ramaiah Medical College, Ramaiah University of Applied Sciences, Bengaluru, India; [2]Apollo Hospitals, Navi Mumbai, India; [3]Jindal School of Psychology & Counselling, India; [4]Indian Institute of Technology Hyderabad, India

Background

In India, physicians recognise the need for communication skills training (CST) so as to improve patients' physical and mental wellbeing. Yet, there is a lack of culturally informed and evidence-based training programs in the current medical curriculum. In our pilot study, we explored the cultural suitability of the Relationship: Establishment, Development and Engagement (REDE) model for CST for Indian physicians. The REDE model proposes three ways (i.e., establishing, developing and engaging) for physicians to foster a meaningful interaction and, subsequently, relationship with patients. Our pilot study supported the appropriateness of the REDE model of communication for Indian physicians. Therefore, using a larger sample representing mainly South Indians, the current study aimed at understanding patients' experience and expectations using the framework of the REDE model.

Aim

(1) To document the experiences and expectations of communication from one's treating physician among South Indian patients with type 2 diabetes mellitus (T2DM) and (2) to understand the cultural fit of the REDE model to train Indian physicians in communication skills.

Methods

Using convenient sampling, 61 patients (mean age = 52.19 years) with T2DM were recruited for the study from 5 cities in South India (Hyderabad = 12,

Chennai = 11, Bengaluru = 09, Trivandrum = 18, Mumbai = 11). Eight recorded focus group discussions were carried out virtually, exploring patients' thoughts, feelings, needs and efforts towards establishing a communicative relationship with their physician. The data were analysed using conventional content analysis.
Results
Three themes were constructed: (1) *"A friendly nature in conversations helps in treatment*': Essential skills in establishing a relationship with a patient, (2) "*Respond well and listen more*': The bridge to developing a long-lasting meaningful relationship, and (3) a desire for a conversation balanced with technical details and a thoughtful, sensitive and empathic approach.
Discussion & Conclusion
This study underscores the need to introduce a CST program to engender physicians' ability to build strong, meaningful, and enduring relationships with their patients. In particular, the findings suggested a shift in Indian patients' preference for a collaborative and empathic relationship with their physician than the previously accepted authoritative/paternalistic model of care. Further, the study findings support the cultural fit of all the three components of the REDE model to develop a CST for Indian physicians treating patients with T2DM. These findings will aid in developing a REDE-model based CST program for Indian physicians' treating patients with T2DM.

Glycemic variability in type 1 diabetics treated with human insulin
Faten Mahjoub[1], Ines Bani[1], Nadia Ben Amor[1], Abir El Amri[2], Ramla Mizouri[1], Rym Ben Othman[1] & Jamoussi Henda[1]
[1]National Institute of Nutrition and Food Technology, A, Tunisia; [2]University of Medicine of Tunis, Tunisia
Introduction
Type 1 diabetes is an endocrinopathy due to insulin deficiency. Its treatment consists in administering an exogenous insulin simulating the physiological secretion. The objective of this study was to evaluate glycemic variability in a group of adolescents with type 1 diabetes treated with human insulin.
Method
This is a cross-sectional study, including type1 diabetic patients treated with human insulin, who underwent continuous glucose monitoring (CGM) for 6 days. We analyzed the CGM data for each patient and we calculated the coefficient of variability of glucose (CV), mean of glycemic excursions (MAGE) and the mean of daily differences (MODD). The Time Above Range (TAR) defined as >180 mg/dl, the Time Below Range (TBR) defined as <70 and <54 mg/dl and the Time In Range (TIR) were derived From CGM.
Results
We included 36 patients with type 1 diabetes with an average age of 17 ± 1.8 years old. Nineteen patients were female and seventeen were male. The average duration of diabetes was $6.6\pm$ 4.6 years. The average total insulin dose was 55.6 $\pm$ 18 UI (0.92 ± 0.31UI/Kg), the average total dose of rapid insulin was 20 $\pm$ 8 UI ($0.33\pm$ 0.12 UI/Kg) and that of basal insulin was 35 ± 12UI (0.6 ± 0.22UI/Kg) . The average CV was 38 ±11%, and more than half of the patients (58.3%) had a coefficient of variability greater than 36%. In addition, the mean MAGE was 141 ± 46 mg/dl and only 2 patients had a MAGE $\leq$ 65 mg /dl. Furthermore, the average MODD was 91 ± 42 mg/dl and 77.8% of patients had MODD ≥60 mg/dl. Time in range varied from 4 to 88% with an average of 37 ± 19%. Time below range varied from 0% to 36% with an average of 7 ± 9%. The mean of time above range was 55 ± 23%. TIR was negatively correlated with total insulin dose ($r=$-0.41, $P=0{,}013$). TAR was positively correlated with the dose of rapid insulin ($r=0{,}34$ $P=0{,}039$). The dose of rapid insulin was positively correlated with TAR ($r=0{,}34$ $P=0{,}039$) and negatively correlated with TIR ($r=$-0.47 $P=0{,}004$).
Conclusion
In our study we concluded that the majority of patients are overdosed in basal insulin and have high glycemic variability.

Depressive Symptoms in Patients With Type 1 and Type 2 Diabetes: prevalence and associated factors
Rahma Khalaf, Sana Khamassi, Fatma Boukhayatia, Mehrez Achwak, Nesrine Dhieb, Haifa Abdesselem, Kamilia Ounaissa & Chiraz Amrouche
National Institute of Nutrition, Outpatient departement and functional exploration, Tunis, Tunisia

Background and Aim
Patients with type1 and type2 diabetes both have a high prevalence of depressive symptoms. The aim of this study was to evaluate the prevalence of depressive symptoms and associated factors in patients with diabetes.
Methods
This is a cross-sectional study conducted in 140 patients with diabetes. Patients' demographic characteristics, current treatments, glycemic control, cardiovascular risk factors, diabetes-related complications were collected. Treatment adherence was evaluated by Medication Adherence Questionnaire (MAQR) of Morisky-Green. Tobacco dependence was evaluated by the Mini fagerstrom test. Patients were asked to complete the 9-item Patient Health Questionnaire(PHQ-9)to evaluate depressive symptoms. Total PHQ-9 score ranges from 0 to 27. In this study, we combined scores10–27 ("moderately severe or severe") to improve precision of estimates. We defined PHQ-9 total scores ≥10 as clinically relevant depression(CRD)[1].
Results
Of the study population, mean age was 54.88 ± 12.97 years with female predominance (55.6%),87.3% of patients had type 2 diabetes. Mean diabetes duration was 13.43 ± 7.3 years, mean glycated hemoglobin was 9.7% ±1.76 and mean BMI was $28.3\pm$ 7.5Kg/m^2. Among the subgroup of type 2 diabetes patients,20.4% of patients used oral glucose-lowering drugs(OGLDs) only, and 79.6% used OGLDs plus insulin, In the whole population study,70.5% reported depressive symptoms(PHQ-9 score$\geqslant5$) and 36% had CRD. CRD was significantly associated with female sex (70%vs46,1%; $P=0{,}007$), high tobacco dependance (100% vs 57%; $P=0{,}01$) and poor treatment adherence (54% vs 36 %; $P=0{,}03$). Patients with CRD had higher total cholesterol (4.67 ± 1.22 mmol/l vs $4.14\pm$ 0.98 mmol/l; $P=0.008$), higher HDLc($1.31\pm$ 0.59 mmol/l vs 1.12 $\pm$ 0.27mmol/l; $P=0{,}012$) and higher LDLc(1.06 ± 0.35 vs 0.91 ± 0.3mmol/l; $P=0.015$). Diabetes treatment, type of diabetes, microvascular and macrovascular complications did not statisticcaly differ between the two groups.
Conclusion
Depressive symptoms are common in patients with diabetes calling for routine screening to reduce the double burden of diabetes and depression and their negative interaction.

IADPSG Vs Carpenter and Coustan Criteria for the Diagnosis of Gestational Diabetes Mellitus in a Spanish Population: Is it Worth Switching?
Virginia Martin Borge[1], Sharona Azriel Mira[1], Taida García-Riaño García[2], Jose Rubio Valtueña[2], Gema García Romero de Tejada[1] & Jose Antonio Balsa Rubio[1]
[1]Infanta Sofia University Hospital, Endocrinology, San Sebastián de los Reyes (Madrid), Spain; [2]Infanta Sofia University Hospital, Obstetrics and Gynecology, San Sebastián de los Reyes, Spain

Objective
The aim of this study was to evaluate maternal and perinatal outcomes before and after implementation of the International Association of Diabetes and Pregnancy Study Groups (IADPSG) criteria for testing of gestational diabetes mellitus (GDM).
Methods
This is a retrospective cohort study of women with GDM followed at a single university hospital. We compared maternal and neonatal outcomes of singleton pregnancies in women with GMD before (from January to December 2014) and after (from January to December 2016) the introduction of IADPSG criteria for the diagnosis of GDM. The same therapeutic interventions were offered to women with GDM diagnosed by both criteria.
Results
Use of IADPSG compared to Carpenter and Coustan (C& C) criteria increased the rate of women diagnosed with GDM (6.4% vs 11.9%, $P=0.001$). The IADPSG group had a lower rate of small for gestational age (14.8 vs 4.8%, $P=0.001$), but there were no differences in cesarean delivery rate (22.9 vs 22.9 %, $P=0.988$), instrumental delivery rate (11.4 vs 9.5%, $P=0.542$), large for gestational age rate (17.0 vs 20.6 %; $P=0.404$), and neonatal intensive care unit admission rate (15.6 vs 11.4%, $P=0.244$). Insulin use was similar in both groups (45.8 vs 43.0%, $P=0.115$), but a basal-bolus regimen was used more frequently in the C& C group (13.6 vs 7.0%, $P=0.031$). There were no significant differences in any other pregnancy outcomes. To better characterize the differences in the rate of SGA, we analyzed maternal and neonatal outcomes stratifying the IADPSG group according to whether women were diagnosed by FPG in the first trimester (FPG-IADPSG group) or by 75 g OGGT in the second trimester (OGGT-IADPSG group). There were no significant differences in the rates of maternal and neonatal outcomes among the three groups except for SGA, which remained more frequent in the C& C group than in the FPG-IADPSG and OGTT-IADPSG groups (14.0% vs 4.8% vs 4.4%, respectively; $P=0.006$). Only the C& C screening (OR 3.76, 95% CI 1.65-8.57), and smoking habit (OR 3.31, 95% CI 1.44-7.59) were associated with SGA in the multivariate logistic regression model to evaluate predictors of this outcome.
Conclusion
Except for a decrease in the rate of small for gestational age, adopting the IADPSG criteria was associated with more GDM diagnoses without better maternal and neonatal outcomes.

Substantial Burden Associated With Hyperphagia and Obesity in Children With Bardet-Biedl Syndrome

Robert Haws[1], Jeremy Pomeroy[1], Usha G. Mallya[2], Brieana Buckley[2], Ariane Faucher[3] & Ryan Kyle[3]
[1]Marshfield Clinic Research Institute, Marshfield, WI, United States; [2]Rhythm Pharmaceuticals, Inc., Boston, MA, United States; [3]Statlog Inc., Montreal, QC, Canada

Background
Bardet-Biedl syndrome (BBS) is a rare melanocortin-4 receptor (MC4R) pathway disease characterized by early-onset, severe obesity and hyperphagia associated with primary cilia dysfunction. Patients with rare MC4R pathway diseases of obesity and hyperphagia, including BBS, experience high disease burden, but the relationship between hyperphagia and body weight in patients with BBS is not fully understood. We assessed the correlation between hyperphagia score and obesity in children with BBS.
Methods
Data (2014-2021) from CRIBBS, an international registry of patients with BBS, were analyzed. For children who had $\geq$4 weight assessments, the degree of hyperphagia was derived from the Hyperphagia Questionnaire completed by the caregiver 4 years after CRIBBS recruitment. Hyperphagia Questionnaire scores range from 11 to 55, with higher values indicating more severe hyperphagia. Body weight was measured yearly. Average Hyperphagia Questionnaire scores by weight category (ie, obese, body mass index [BMI] $>$95th percentile; overweight, BMI $\geq$85th and $<$95th percentiles) and the correlation between Hyperphagia Questionnaire score and BMI percentile are reported.
Results
Of 107 eligible children, 39 had the Hyperphagia Questionnaire completed by their caregiver at Year 4 and were included in the analyses. At the time of the hyperphagia assessment, the mean age was 10.4 (range, 4 to 17) years, and 56.4% were male. The mean Hyperphagia Questionnaire score was 24.1 (median, 26.0; range, 11.0 to 39.0). The mean Hyperphagia Questionnaire score increased by weight category, from 13.0 [median, 12.0] among the 5 children (12.8%) with weight within the reference range/underweight to 22.8 [median, 24.0] among the 5 children (12.8%) with overweight and to 26.2 [median, 26.0] among the 29 children (74.4%) with obesity. The Hyperphagia Questionnaire score and BMI percentile were positively and significantly correlated ($r=0.34$; $P=0.03$).
Conclusions
Children with BBS experienced burden due to hyperphagia, which was correlated with obesity, suggesting that treatments impacting hyperphagia may result in weight loss and quality of life improvements in these children.

Indications that the vitamin D-endocrine system is altered in obese people

Subhash Kumar[1], Shaibal Guha[2] & Amit Kumar Das[3]
[1]Diabetes and Obesity Care Center, Patna, India; [2]Positive Health Centre, Patna, India; [3]Shree Hospital & Maternity, Muzaffarpur, India

Background
In obese patients compared to non-obese subjects, serum immunoreactive parathyroid hormone (PTH) is higher and decreases with weight loss.
Objectives
To find out if obesity affects the vitamin D endocrine system and if the resulting secondary hyperparathyroidism is linked to a decrease in urine calcium.
Material and Methods
25 healthy individuals were examined. Between the ages of 21-30 years, there were 13 obese people and 12 non-obese subjects. They were only allowed to consume purified water and were fed a steady diet of 300 mg of calcium, 800 mg of phosphorus, 15 meq of magnesium, 100 meq of sodium, and 60 meq of potassium each day. For the analysis of serum calcium, ionized calcium, phosphorus, magnesium, creatinine, Gla protein, 25-hydroxyvitamin D, 1,25-dihydroxy vitamin D, and immune-reactive PTH, fasting blood samples were taken. Calcium, phosphorus, salt, potassium, magnesium, creatinine, and cyclic AMP were measured in 24-hour urine samples.
Results
Those who were obese weighed an average of 105 ± 5 kg, compared to non-obese (67 ± 1 kg; $P<0.02$).. While mean serum calcium, mean serum ionized calcium, and mean serum phosphorus were similar between the two groups, mean serum immunoreactive PTH (517 ± 47 vs. 242 ± 32 pg/ml, $P<0.002$), mean serum 1,25 dihydroxy vitamin D (36 ± 1 vs. 29 ± 1 ng/ml, $P<0.02$), and mean serum Gla protein (32 ± 1 vs. 22 ± 2 ng/ml, $P<0.02$) were significantly higher. Mean blood 25-hydroxyvitamin D levels were substantially lower in obese men and women than in nonobese individuals (7 ± 2 s. vs. 21 ± 1% ng/ml, $P<0.002$). Mean urine phosphorus was the same in both groups, however mean urinary calcium was considerably lower in the obese group (114 ± 11 mg/d vs. 165 ± 12 mg/d, $P<0.02$) and had higher mean urinary cyclic AMP (3.17 ± 0.42 mg/dl vs. 1.83 ± 0.24 mg/dl GF, $P<0.02$) and creatinine clearance (215 ± 12 mg/d vs. 172 ± 5 mg/d, $P<0.02$). Both urine cyclic AMP and serum immunoreactive PTH were significantly correlated with percentage of ideal body weight ($r=0.523$, $P<0.02$) and the percentage of ideal body weight ($r=0.715$, $P<0.02$), respectively.
Conclusion
Secondary hyperparathyroidism is linked to greater renal tubular reabsorption of calcium and elevated levels of circulating 1,25(OH)2D, is a feature of the vitamin D endocrine system change seen in obese people. They have lower levels of serum 25-OHD due to feedback regulation of the precursor's synthesis in the liver brought on by higher levels of serum 1,25(OH)2D.

Does intermittent fasting improves metabolic and inflammatory parameters in obeseadult ?

Faten Mahjoub, Bejaoui Arij, Nadia Ben Amor, Ines Bani, Nesrine Dhieb, Ramla Mizouri, Rym Ben Othman & Jamoussi Henda
National Institute of Nutrition and Technology, A, Tunis, Tunisia

Introduction
During these last years, Intermittent fasting was emerging as an approach that improves weight and metabolic outcomes in obese subjects.
Objective
To investigate the effects of 16:8 intermittent fasting on metabolic and inflammatory parameters in adult obese.

Methods
This is a comparative interventional study conducted in 60 obese women consulting the obesity unit of the Institute of Nutrition of Tunis during the period ranging from May to August 2022. The patients were divided into 2 groups matched for age and sex. G1: standard hypocaloric diet and G2: intermittent fasting 16:8. Anthropometric measurements and biological parameters were taken at T0 and T1 (3 months after the dietary intervention).
Results
The mean age was 35.81 ± 8.92 years. Decreases in weight ($P = 0.005$) and Waist circumference ($P < 10\text{-}3$) were significantly greater in patients on the 16:8 IF compared with those on the standard hypocaloric diet. Patients who adhered to intermittent fasting had a greater decrease in fasting blood glucose with a significant difference between the two groups ($P = 0.003$), HbA1c ($P = 0.006$), insulin levels ($P = 0.003$), insulin resistance ($P < 10\text{-}3$), uric acid ($P = 0.010$) compared to patients in the hypocaloric diet group. The variation in lipid parameters was not significant between the two groups. Except for a statistically significant increase in HDL-c in group 2 ($P = 0.001$). The variation in IL-6 concentration was +0.06 and -0.26 pg/ml respectively for the low-calorie diet group and the intermittent fasting group with $P = 0.007$. No significant variation in TNFα levels was observed afterthe two type of diets.
Conclusion
The results of this study suggest that intermittent fasting is a feasible and effective acceptable dietary model for the management of obese women.

Vitamin D supplementation reduces oxidative stress caused by hyperuricemia in type 2 diabetes mellitus patients

Mahmoud A. Alfaqih[1], Ebaa Ababneh[2] & Mai Sater[1]
[1]Arabian Gulf University, Medical Biochemistry, Manama, Bahrain; [2]Jordan University of Science and Technology, Physiology and Biochemistry, Irbid, Jordan

Introduction
It is suggested that hyperuricemia in type 2 diabetes (T2DM) patients causes reactive oxygen species (ROS) accumulation, which causes the destruction of beta cells of the pancreas and contributes to T2DM. This study aimed to analyze the relationship between vitamin D deficiency (which is reciprocally related to Serum Uric Acid (SUA) levels), hyperuricemia, and levels of ROS scavengers in T2DM patients, and to investigate the effect of vitamin D supplementation on these parameters.
Materiel & Methods
The study included 26 T2DM patients with vitamin D deficiency who received vitamin D supplements for three months. HbA1c, insulin, SUA, xanthine oxidase (XO) levels, lipid peroxidation, Glutathione Peroxidase (GPx) activity, GSH/GSSG ratio, and vitamin D levels were measured prior to and after supplementation.
Results
Adenosine deaminase (ADA) and XO levels and activity were elevated in T2DM patients, along with SUA levels. Vitamin D supplementation resulted in significant (P value $< .005$) decreases in HbA1c, HOMA-IR, SUA, XO levels, ADA levels, and activity, lipid peroxidation, and GPx activity. A significant increase in GSH/GSSG ratio was also observed.
Conclusion
Vitamin D supplementation reduces oxidative stress caused by high levels of uric acid observed in T2DM patients by reducing the activity of ADA and XO enzymes.

A study to evaluate clinical and metabolic profile in a type 1 diabetes cohort receiving dpp4 inhibitor plus SGLT2 inhibitor compared to either drug alone as an adjuvant therapy

Chethan Dev K & Bipin Kumar Sethi
Care Hospitals, Endocrinology, Hyderabad, India

Introduction
There is always been a need for safe and effective adjuvant therapy in type 1 Diabetes not just for glycemic control but also for cardio-renal benefits.
Objectives
To evaluate whether addition of DPP-4 inhibitors reduces the ketogenic potential of SGLT2i when used as an adjuvant therapy in type 1 Diabetes.
Materials & Methods
20 type 1 Diabetes subjects above 18 years of age with poorly controlled glycemia (HbA1c 7 to 10%) were included in the study. At baseline along with physical examination, biochemical parameters-FPG, PPG, HBA1C, beta-hydroxybutyrate and fasting Glucagon were collected. This cohort was then treated with sitagliptin for 3 months, dapagliflozin for 3 months and combination of sitagliptin and dapagliflozin for 3 month adjuvant to insulin. At the end of each 3 months period anthropometric and biochemical parameters were assessed.
Results & observation
The plasma Glucagon levels compared with the baseline (30.99pg/ml), did not change with sitagliptin (29.89 pg/ml), increased significantly with dapagliflozin (55.89pg/ml) [+24.9pg/ml ($P < 0.05$)] and the combination treatment failed to reduce the Glucagon level 49.37pg/ml. The median ketone (beta-hydroxybutyrate) levels compared to the baseline [0.11(0.04 -0.87)] were numerically lower with sitagliptin [0.06(0.02 - 0.33)] and higher with dapagliflozin [0.14(0.04 - 1.16)]. However, the combination treatment failed to reduce the ketone levels [0.17(0.02 - 0.92)]. There was a statistically significant improvement in glycemic parameter, HbA1c with each of the intervention. On comparing with the baseline the mean difference of HbA1c after sitagliptin was 1.39%, after dapagliflozin was 1.08% and after the combination treatment was 1.59%. This was achieved with no change in the insulin dose. There was a reduction in weight, BMI, SBP and DBP with individual as well as combination treatment. Change in waist circumference was minimal.
Conclusions
Sitagliptin and dapagliflozin either alone or in combination as adjuvant therapy in type 1 diabetes results in a significant improvement in glycaemia. Sitagliptin failed to reduce fasting plasma glucagon and blood ketone (beta-hydroxybutyrate) levels when added to dapagliflozin. It thus appears that the ketogenic potential of dapagliflozin cannot be brought down by addition of sitagliptin. Thus, DPP4 inhibitors and SGLT2 inhibitors can be a useful adjuvant in the therapy of type 1 DM, but SGLT2 inhibitors should be used only after understanding the potential risk for ketosis.

Development and Validation of Blood Glucose Measurement Knowledge Scale - BGM-Knowledge Scale

Selda Celik[1], Elif Bulbul[1], Esin Erdem[2] & Derya Gokmen[3]
[1]University of Health Sciences Turkey, Hamidiye Faculty of Nursing, İstanbul, Turkey; [2]Usak Training and Research Hospital, Department of Diabetes Training, Uşak, Turkey; [3]Ankara University, Faculty of Medicine, Department of Biostatistics, Ankara, Turkey

Aim
Self-monitoring of blood glucose has an important place in ensuring diabetes management. This study aims to develop a reliable instrument to assess blood glucose measurement knowledge in diabetic patients. The purpose of the scale is to assess blood glucose measurement knowledge in diabetic patients.
Method
The data were collected from 240 patients in the diabetes polyclinic of a training and research hospital between March and September 2022. The scale item pool was created using the data obtained from the literature review and expert opinions. A validity analysis was performed for construct, content, and convergent validity. Kuder-Richardson-20 and test-retest reliability were used to assess the reliability of the scale.
Results
Among the patients included in the study, 57.9% were female, and 91.3% were married. The duration of diabetes was 10.78 ± 8.04 years; 79.6% had type 2 diabetes, and 37.1% used OAD + insulin. The researchers developed the final 3-point Likert-type "Blood Glucose Measurement Knowledge Scale (BGM-Knowledge Scale)" with 24 items. The scale content validity index was 0.91, and the convergent validity analysis result was 0.591 ($P < 0.01$). The scale items were subjected to one-factor CFA to confirm the structure of the scale with factorial weights ranging between 0.532 and 0.991. Kuder-Richardson-20 of the total scale was 0.90. The Kuder-Richardson 20 of the total scale was 0.90, and the test-retest result showed that the scale did not change over time (ICC = 0.947; $P < 0.01$).
Conclusion
The BGM-Knowledge Scale is a reliable and valid measurement tool to measure the knowledge level of diabetic patients about blood glucose measurement.

Higher SHBG, Apo A1, HDL and adiponectin might be connected with lower cardiovascular risk in women with type 1 diabetes and LADA

Spomenka Ljubic[1,2], Anamarija Jazbec[3], Tomislav Bulum[1,2], Martina Tomic[1,4] & Dario Rahelic[1,2]
[1]University Clinic Vuk Vrhovac, Zagreb, Croatia; [2]Merkur Clinical Hospital, Zagreb, Croatia; [3]School of Medicine, University of Zagreb, Zagreb, Croatia; [2]Merkur Clinical Hospital, Zagreb, Croatia

Aim
Low sex hormone-binding globulin (SHBG) is accompanied with onset of diabetes (DM) and increased cardiovascular risk (CVR). Proinflammatory cytokines, including adiponectin (APN) influence SHBG production. Lipid accumulation product (LAP) advocates as an indicator of increased CVR. We investigated the influence of different types of DM and sex on CVR through changes in SHBG and related risk factors.
Methods
Due to the non-normal distribution of individual dependent variables, they were log transformed [HbA1c, homocysteine (HCY), SHBG, interleukin-6 (IL-6), triglycerides (TG)]. Differences for analysed variables were tested using two factors analysis of variance (ANOVA) by gender, type of diabetes (DM1, DM2 and latent autoimmune: LADA) and their interaction. ANOVA and Tukey's post hoc test was also used for testing differences according to LAP quartiles (1st group: LAP < Q1; 2nd group: Q1 ≤ LAP < Med; 3rd group: Med ≤ LAP < Q3, 4th group: LAP ≥ Q3), separately in women and men. For all statistical tests, a significance level of 5% was considered statistically significant.
Results
SHBG level was significantly higher in women (especially in DM1) in comparison to men, and in autoimmune diabetes (DM1 and LADA) in comparison to DM2. There was no difference in SHBG between DM1 and LADA. Statistically significant interaction indicates that SHBG does not behave approximately equally between men and women according to the type of diabetes. APN level was significantly higher in women, without differences according to type of DM. High density lipoprotein (HDL) and apolipoprotein A1 (ApoA1) were higher in women and those with autoimmune diabetes (DM1 and LADA) in comparison with DM2, with no statistical difference between DM1 and LADA. Significant differences were determined in women and men for Apo A1, HDL, TG and HCY according to LAP quartiles. In women significant differences were determined for SHBG, fasting C-peptide (FCP) and IL-6; the difference for APN was bordered (P = 0.068). When the differences were significant, higher quartiles of LAP are characterised with increased TG, HCY, FCP and IL-6, whereas SHBG, ApoA1, APN and HDL were decreased.
Conclusions
Lower values of SHBG, HDL i Apo A1 in men and in DM2 pointed at higher CVR. APN was significantly higher in women without the difference according to the type of DM, while SHBG, HDL, and ApoA1 levels were higher in women and those with DM1 and LADA in comparison with DM2 suggesting CV protection in women with autoimmune diabetes.

Machine learning-derived low density lipoprotein cholesterol (LDL-C) estimation agrees better with directly measured LDL-C than conventional equations in individuals with type 2 diabetes mellitus.

Gerald Sng[1], You Liang Khoo[2], Hong Chang Tan[1] & Yong Mong Bee[1]
[1]Singapore General Hospital, Department of Endocrinology, Singapore, Singapore; [2]Singapore General Hospital, Health Services Research Unit, Singapore, Singapore

Introduction
Elevated low-density lipoprotein cholesterol (LDL-C) is an important risk factor for atherosclerotic cardiovascular disease (ASCVD). Direct LDL-C measurement is not widely performed. LDL-C is typically estimated using the Friedewald (FLDL), Martin-Hopkins (MLDL) or Sampson (SLDL) equations, which may be inaccurate at high triglycerides (TG) or low LDL-C levels. We aimed to determine if machine learning (ML)-derived LDL-C levels agree better with direct LDL-C than conventional equations in patients with type 2 diabetes mellitus (T2DM).
Methods
We performed a retrospective cohort study on T2DM patients from a multi-institutional diabetes registry in Singapore from 2013 to 2020. Directly measured LDL-C values were compared against LDL-C values estimated by the FLDL, MLDL and SLDL equations, and ML models using linear regression (LR), random forest (RF) and k-nearest neighbours (KNN) using measures of agreement and correlation. Values were considered discordant if estimated LDL-C was <1.8 mmol/l but directly measured LDL-C was ≥1.8 mmol/l as this might lead to undertreatment in a real-world setting. A repeat train and test was performed on the subset of patients with TG values >4.5 mmol/l.
Results
11,475 patients with 39,417 sets of unique lipid panel results were included in the final analysis. 31,533 sets of results were used in the training set and 7,884 sets of results were used in the test set. All three ML models demonstrated better goodness-of-fit with lower root-mean-square-error values than any of the conventional equations, as well as stronger correlation with higher R^2 and r values. Of the three ML models, LR performed the least well (rmse 0.231, R^2 0.954 and r 0.977, P < 0.001) as compared to RF (rmse 0.209, R^2 0.962 and r 0.981, P < 0.001) or KNN (rmse 0.212, R^2 0.961 and r 0.98, P < 0.001). All three ML methods had much lower discordance rates (LR 2.17%, RF 2.18%, KNN 2.04%) than conventional equations (FLDL 23.14%, SLDL 17.90%, MLDL 14.22%). ML methods performed less well in the subset of patients with TG >4.5 mmol/l, although all three models still demonstrated better goodness-of-fit and correlation. Discordance rates were lower as well (LR 3.69%, RF 3.69%, KNN 2.30%), although the MLDL equation had the lowest discordance rate in this subgroup (1.84%).
Discussion
Conventional LDL-C estimation equations have disadvantages and are reported to perform poorly at high TG levels. ML methods may offer an alternative to allow more accurate estimation of LDL-C and to reduce misclassification and undertreatment in T2DM patients at high ASCVD risk.

Development and Validation of the Blood Glucose Measurement Competence Evaluation Form- BGM-CEF

Selda Celik[1], Elif Bulbul[1], Esin Erdem[2] & Derya Gokmen[3]
[1]University of Health Sciences Turkey, Hamidiye Faculty of Nursing, Istanbul, Turkey; [2]Usak Training and Research Hospital, Department of Diabetes Training, Uşak, Turkey; [3]Ankara University, Faculty of Medicine, Department of Biostatistics, Ankara, Turkey

Aim
Self-monitoring of blood glucose has an important place in ensuring diabetes management. For diabetic individuals to measure their blood glucose level correctly with recommended frequency and technique, their blood glucose measurement technique, knowledge, and skills should be checked regularly with reliable measurement tools. This study aimed to develop a reliable instrument for assessing blood glucose self-monitoring skills in diabetic patients. The purpose of the scale is to evaluate the level of blood glucose self-monitoring in diabetic patients.
Method
This is a methodological study. The scale item pool was developed in line with the data obtained from the literature review and expert opinions. Validity analyses were evaluated with construct validity and content validity. Cronbach's alpha coefficient, test-retest and parallel form reliability were used to assess reliability. In determining the study sample, it was planned to have a ratio of 10 times the number of scale items and data collected from 207 patients. The study data were collected through face-to-face interviews held with the participants by the researchers in June-December 2021 in a diabetes clinic of a research hospital.
Results
Among the patients included in the study, 60.4% were female, diabetes duration was 10.42 ± 8.14 years, 78.3% had Type 2 diabetes, 35.7% used OAD + insulin, and 78.74% performed the recommended number of blood glucose measurements. In the study, a 3-point Likert-type "Blood Glucose Measurement Skill Assessment Form" consisting of 17 items was developed. The Scope Validity Index of the scale is 0.86. Seventeen items explained 79% of the total variance. One-factor Confirmatory Factor Analysis was performed to confirm the structure of the scale with factor weights ranging between 0.606 and 0.990. Cronbach's alpha of the total scale was 0.82. Intraclass Correlation Coefficient was 0.975 (P < 0.01), and the correlation coefficient of parallel form reliability was 0.611 (P < 0.01).
Conclusions
The blood Glucose Measurement Competence Evaluation Form-BGM-CEF is a valid and reliable measurement tool which assesses the blood glucose self-measurement skills of diabetic patients.

Bruns-Garland syndrome (diabetic amyotrophy) associated with SGLT2 inhibitor and its rapid HbA1c improvement: a case-report

kalyani Nagarajah[1], Grigorios Panagiotou[2] & Julia Karen Platts[3]
[1]Department of Medicine, University Hospital Llandough,, Endocrinology and Diabetes, Llandough, United Kingdom; [2]Department of Medicine, University Hospital Llandough, Department of Endocrinology and diabetes, Llandough, United Kingdom; [2]Department of Medicine, University Hospital Llandough,, Department of Endocrinology and diabetes, Llandough, United Kingdom

Background
Bruns Garlands syndrome is a rare disorder in people living with diabetes, manifesting as unilateral or bilateral muscle pain, weakness and atrophy in the proximal region of the lower limbs. Herein, we present the case of a patient with Bruns-Garland syndrome caused by sodium/glucose co-transporter 2 inhibitors (SGLT2i).
Case description
A 55-year-old male with background of type 2 diabetes for 5 years, and currently on oral therapy, presented to the emergency admissions unit with ketosis, acidosis and borderline hyperglycaemia (ketones 6 mmol/l, pH 7.21 and blood glucose of 11 mmol/l, respectively). On further questioning, his diabetes control was suboptimal with some mild tingling sensation in his lower limbs first noticed a year ago; Empagliflozin was added to his therapy at that time, resulting in significant weight loss of about 8 kgs over 6 weeks and a substantial reduction in HbA1c from 103 to 48 mmol/mol in less than 6 months. On examination, he had widespread vitiligo, and proximal muscle wasting with bilateral lower limb weakness, reduced reflexes and paraesthesia, suggestive of peripheral neuropathy. Baseline myopathy screening was negative. Imaging studies were negative for sinister causes of weight loss. MRI spine was inconclusive, suggesting mild degenerative changes with multifocal disc prolapses and nerve root impingements, but no spinal canal stenosis. Nerve conduction studies of upper and lower limbs revealed a moderately severe, length dependent sensorimotor axonal neuropathy. This was confirmed with electromyography indicating an axonal peripheral neuropathy, with superimposed bilateral lumbar plexopathy/femoral neuropathy, suggestive of acute on ongoing neurogenic changes in bilateral lower limbs distally and proximally. Despite HbA1c improvement, his symptoms further progressed to debilitating proximal myopathy, with severe paraesthesia and burning sensation over his thighs in the next few months, despite Vitamin B12 levels replacement therapy.
Conclusion
Rapid improvement of HbA1c with SGLT2i or a direct effect of SGLT2i can significantly worsen background neuropathic changes leading to Bruns-Garland type diabetic amyotrophy. With the widespread use of SGLT2i, it is important that physicians treating patients with diabetes recognise these symptoms and consider this association in patients developing fatigue and weakness.

Investigation of Brain CD47 Expression and Its Relation with Cognitive Functions in Diabetic Mice Models

Nil Kirisciogluu[1], Amirhooman Asadi[1], Mucahit Guyen[1], Esra Ozkan[1], Ahmet Kocabay[1], Oguzhan Deyneli[2], Dilek Yazici[2] & Yildiz Tutuncu[1,3]
[1]Koc University, Koç University Research Center for Translational Medicine (KUTTAM), Istanbu, Turkey; [2]Koc University, School of Medicine, Endocrinology and Metabolism, Istanbu, Turkey; [3]Koc University, School of Medicine, Immunology, Istanbu, Turkey

Background
Diabetes Mellitus (DM) is an endocrine disorder resulting in hyperglycaemia that affects many vital organs of the body like the brain. The molecular mechanisms underlying dementia, memory loss and cognition dysfunction caused by DM are still not very clear. CD47 is a cell surface protein working in the homeostasis of the immune system. The causal relationship of CD47 has been shown in neurodegenerative diseases. CD47 also has a role in pancreatic islet cells and their maintenance in T1DM models.
Aim
Tha aims of the study are to determine cognitive funcitons in healthy and diabetic mice, to examine CD47 expression in brain tissue of healthy and diabetic mice and to determine its relationship with cognitive functions in T1DM and T2DM mice models.
Methods
This study was done using 39 CD1 male mice which were grouped as control ($n=12$), T1DM ($n=11$) and T2DM ($n=16$). T1DM and T2DM were induced by streptozocin and high-fat diet, respectively. Glucose levels of 200mg/dl or higher at the 2nd hour of oral glucose tolerance test established the diagnosis of DM in the T2DM group. Blood glucose of the mice was measured from the tail tip blood every week in all groups. Cognition tests {Control Open Field (COF) test, Y-Maze test, Novel Object Recognition (NOF) tests] were conducted to evaluate the animals' (control and type 1 DM group) cognitive functions. After sacrification, immunofluorescent staining and imaging were done to investigate the expression of CD47 in hippocampus region of brain tissue (in all 3 groups).
Results
The cognitive scores in the 2 out of 3 tests (COF, $P=0.03$; NOR, $P=0.01$,; Y-Maze, $P=$NS) in the T1DM group were significantly lower compared to the controls. CD47 expression was increased in both the T1DM and T2DM mice compared to controls ($P=0.014$). No correlation was observed between CD47 expression and cognitive functions in the T1DM mice.
Conclusion
Cognitive scores are decreased in T1DM mice compared to controls. CD47 expression is increased in the brains of diabetic mice compared to controls. There does not seem to be any correlation of CD47 expression and cognitive functions in diabetic mice. The explanation may be that CD47 levels in the brain may be elevated as a way of cells to protect themselves from excess blood glucose independent of cognitive functions.

Debilitating post-prandial hypoglycaemia as a sole presentation of coeliac disease responding to gluten free diet and plasma exchange for autoimmune neuromyotonia

Hina Aslam, Mark Green, Emily Clarke, Jana Bujanova & Muhammad Umer Malik
[1]Southampton General Hospital, Southampton, United Kingdom

Post-prandial hypoglycaemia (PPH) can be associated with debilitating symptoms. Causes include altered physiology post-bariatric and upper gastrointestinal (GI) surgery and rarely noninsulinoma pancreatogenous hypoglycemia syndrome and insulin antibodies. We present a case of 49y female with no prior GI surgery presenting with debilitating hypoglycaemia with blood glucose falling to 2.8 mmol/l responding to glucose. Freestyle Libre monitoring confirmed hypoglycaemia 2-3 h post meals in keeping with PPH. BMI- 30.3, HbA1c-47 mmol/mol, am cortisol-462 nmol/l. The usual dietary recommendations were difficult to implement due to xerostomia in Sjogren's syndrome (SS) requiring mashed diet with fluids increasing diet's glycaemic index and GI transit. Patient also had autoimmune neuromyotonia presenting with muscular twitching and cramping responding well to regular plasma exchange (PLEX) sessions. Interestingly, patient observed improvement in intensity and frequency of her hypoglycaemia after PLEX raising a possibility of autoimmune cause. We postulated that PLEX might have either somehow improved her GI mobility by alleviating neuromyotonia or removed other untested antibodies involved in autoimmune hypoglycaemia (TTG IgA, insulin antibodies or insulin receptor antibodies). Although she did not have typical GI symptoms apart from mild bloating, TTG IgA were positive at 46.2 u/ml (0-15), endomysial antibodies negative. Duodenal biopsies showed increased intraepithelial lymphocytes, but no definite villous blunting confirming coeliac disease (CD). Gluten free diet (GFD) was commenced with a complete and sustained resolution of hypoglycaemia. Patient described GFD effect on her hypoglycaemic symptoms and quality of life as life changing.
Discussion
CD should be considered in work up of PPH especially in patients with other concurrent autoimmune diagnoses. CD can lead to reduced GI glucose absorption, but the exact mechanism of PPH in our case was intriguing. Concurrent mechanisms such as gut dysmotility in neuromyotonia, diet in Sjogren's syndrome and possibly presence of untested insulin antibodies might have compounded presentation in our case. Neuromyotonia presents with muscle cramps due to peripheral nerve hyperexcitability mainly affecting limbs and trunk. However, it has been reported that autonomic nervous system can also rarely be affected, which may present with gut dysmotility or excessive sweating. Testing for antibodies to insulin or insulin receptor was considered after hypoglycaemia response to plasmapheresis but was deferred given her complete response to GFD. Antibodies to insulin bind insulin after its postprandial secretion and subsequently release it independently of glycemia, predisposing to hypoglycaemia. Autoantibodies to the insulin receptor typically cause severe insulin resistance, but rarely they can also cause hypoglycaemia.

Gastrointestinal symptoms in patients with Diabetes Mellitus: Prevalence and associated factors

Rahma Khalaf, Berriche Olfa, Sana Khamassi, Nesrine Dhieb, Ramla Mizouri, Nadia Ben Amor, Rym Ben Othman, Amel Gamoudi, Awatef Kacem & Jamoussi Henda
National Institute of Nutrition, Department A, Tunis, Tunisia

Backgroud and Aim
Gastrointestinal (GI) symptoms are reportedly common in diabetes mellitus (DM) with a conflicting data on its prevalence in this specific population. The aim of our study is to determine the prevalence of GI symptoms and its associated factors.
Methods
This is a cross-sectional study conducted on 60 patients with DM. Anthropometric parameters, glycemic control, duration of diabetes and diabetic treatment were collected. Lower and upper GI symptoms were recognized using a questionnaire containing 10 questions about the frequency of GI symptoms that had been troublesome in the preceding 3 months. The frequency of each symptom was rated on a 4-point Likert scale and coded as not at all, rarely, sometimes or often. For the purposes of this analysis, a positive answer was recorded when the troublesome symptom was reported to occur sometimes and often.
Results
Mean age was 48,1 ± 15,46 years with female predominance (68.4%). More than two thirds (77.1%) of patients had type2DM treated by insulin in 79.4% of cases and 41.3% had hypertension treated with Renin-angiotensin-aldosterone system inhibitors, Calcium channel blockers, Betablocker and Thiazide diuretics in 83.3%,35.1%,29.4.% and 23.5% of cases respectively. In the whole population study, lower GI symptoms were noted in 54.2% of patients including abdominal pain, diarrhea, constipation, and flatulence, reported in 35.4%,0%,47.9%,47.9% of cases, respectively. Upper GI symptoms were noted in 33.3% of patients including vomiting, heartburn and gastroesophageal reflux symptoms, reported in 14.6%, 22.9% and 31.3% of cases respectively. Upper GI symptoms were significantly associated with type2 diabetes (29.7% vs 2.7%; $P=0.02$). Diabetes duration and treatment, glycemic control and hypertension treatment were not significantly associated with upper GI symptoms. Lower GI symptoms were significantly associated with type2 DM(51.4% vs 8.1%; $P=0.04$) and treatment with Calcium channel blockers (35.5% vs 0 %; $P=0.04$). Glycemic control and diabetes treatment and duration were not significantly associated with lower GI symptoms.
Conclusion
Type2 DM was associated with higher prevalence of upper and lower GI symptoms. No significant association was established with diabetes control, duration and treatment. However, our study highlights the effect of calcium channel blockers on GI symptoms, supported by other studies[1].

Role of C-peptide, body mass index and age in classification of diabetes

Zouaoui Chadia, Bel Hadj Sliman Chayma, Bchir Najla, Baltagi Myriam, Annam Benchhida & Haroun Ouertani
Military Hospital of Tunis, Endocrinology, Tunis, Tunisia

Introduction
Classification of diabetes is challenging in some cases, especially in the presence of inaugural ketosis with a negative autoimmune laboratory test. The aim of our study is to determine the role of age, body mass index (BMI), and fasting plasma C-peptide (FCP) in the classification of diabetes.
Methods
This is a descriptive cross-sectional study that included 51 patients aged between 20 and 65 years hospitalized at the Endocrinology Department of the Military Hospital of Tunis for inaugural ketosis without a precipitating factor, with a duration of diabetes ranging from 6 months to 5 years. They underwent a metabolic biological assessment, an autoimmune laboratory test (anti-GAD65 + anti-IA2 antibodies), a fasting plasma C-peptide level. Our patients were divided into two groups: 31 patients with positive anti-GAD65 and/or anti-IA2 antibodies (AC+) and 20 patients with negative antibodies (AC-). Clinical and laboratory data were collected from medical records.
Results
Our population included 45 men and 6 women. Mean age was 34.3 ± 10.8 years. A family history of type 1 diabetes and type 2 diabetes were present in 11.8 % and 60.8 % of the cases respectively. Hypertension, dyslipidemia, obesity, and thyroid disease were reported at 9.8 %, 17.6 %, 21.6 %, and 9.8 % respectively. The mean age at onset of diabetes in AC+ patients was 27.5 ± 8.3 years and 36.3 ± 10.1 years in AC- patients ($P=0.002$). The mean BMI was 24.5 ± 3.4 Kg/m^2 in AC+ patients and 28.2 ± 6.7 Kg/m^2 in AC-patients ($P=0.024$). FCP level was 0.6 ± 0.7 ng/ml in AC+ patients and 1.7 ± 1 ng/ml in AC-patients ($P<10^{-3}$). An FCP level greater than 0.8 ng/ml was positively correlated with the absence of autoimmunity ($P<10^{-3}$). Its area under the ROC curve was 0.850. Its sensitivity was 84% and specificity 85%.
Conclusion
The classification of diabetes is based on several factors including the age of onset, body mass index (BMI) and FCP levels. These markers along with the autoimmune status can be used to differentiate between type 1 and type 2 diabetes, and to adjust the therapeutic regimen.

Background and aim
Early glycemic control and weight reduction in diabetes has been associated with prevention of progression of β-cell dysfunction and reduction in diabetes-related complications. Digital therapeutics (DTx) platforms can provide evidence-based therapeutic interventions to improve glycemic control using sustainable behavior change. This study aims at assessing the real-world effectiveness of the Fitterfly Diabetes program in improving glycemic control and weight management among people with newly diagnosed T2DM.
Methods
De-identified data of 102 participants with T2DM (diabetes duration <1 year, mean age: 42.96 ± 11.54 years, gender: 30.39% (31/102) female) was analyzed. All the participants completed 90-days on the program and were provided with the Fitterfly mobile application for digital logging of meals and physical activity, remote lifestyle coaching, and live video consultations by experts (psychologists, physiotherapist and nutritionist). The participants were divided into 3 categories based on baseline BMI: normal (≤ 22.9 kg/m^2), overweight (23.0-24.9 kg/m^2), and obese (≥25.00 kg/m^2). The outcomes were evaluated at beginning and end of the program. All the data has been shown as median (IQR).
Results
Among all the participants, the baseline median HbA1c, weight, and BMI was found to be 7.00 (6.30, 8.52) %, 76.20 (70.00, 87.25) kg, and 27.70 (24.64, 30.90) kg/m^2 respectively. Reduction in HbA1c, weight, and BMI was observed by -0.75 (-2.30, -0.20) %, -3.00 (-5.00, -1.00) kg, and -1.00 (-1.88, -0.39) kg/m^2 respectively ($P<0.0001$ for all). Among participants with baseline HbA1c of ≤ 6.4 %, 6.5-8.4%, 8.5-10.5%, and ≥10.6% the reduction in HbA1c was observed by -0.20 (-0.30, 0.00) %, -0.70 (-1.40, -0.30) %, -2.95 (-3.45, -2.15) %, and -5.50 (-6.40, -3.85) % respectively ($P<0.01$ for all). After completion of program, 70.59 % (72/102) participants had achieved recommended HbA1c value ≤ 6.5 %. Reduction in BMI among participants in normal, overweight, and obese category was observed by -0.77 (-1.06, -0.10) kg/m^2, -0.69 (-1.34, 0.15) kg/m^2 and -1.20 (-1.96, -0.46) kg/m^2 ($P<0.01$ for all) respectively.
Conclusion
The Fitterfly Diabetes DTx program led to improved glycemic control and effective weight management among people with newly diagnosed T2DM. The program can help in providing continuous support for implementing lifestyle changes and can help in holistic management of diabetes.

Transition from childhood to adult care in type 1 diabetes mellitus: Single-center experience

Betül Yiğit Yalçın[1], Ummahan Tercan[2], Melek Yıldız[2], Hulya Hacisahinogullari[1], Gulsah Yenidunya Yalin[1], Nurdan Gul[1], Ozlem Soyluk Selcukbiricik[1], Ayse Kubat Uzum[1], Sukran Poyrazooglu[2], Firdevs Bas[2], Kubilay Karşıdağ[1], Ilhan Satman[1] & Feyza Darendeliler[2]
[1]Istanbul University Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, istanbul, Turkey; [2]Istanbul University Faculty of Medicine, Department of Paediatrics, Division of Paediatrics Endocrinology, istanbul, Turkey

Introduction
Type 1 diabetes mellitus (T1DM) requires lifelong management, and a well-designed protocol may facilitate transition from child-centered healthcare systems to adult-oriented systems.
Aim
We aimed to evaluate sociodemographic data, clinical features and laboratory parameters that may affect the transition period and post-transition process in T1DM patients.
Materials and Methods
We retrospectively analyzed 64 patients with T1DM who were transitioned from pediatric to adult endocrinology outpatient clinic in Istanbul University, Istanbul Faculty of Medicine. Patients were followed up between 2001-2022 and completed their pediatric follow-up and participated in the pediatric-to-adult transition. The patients have been transferred to adult care with two different transition models. In model 1, transition was conducted in a single meeting, in model 2 it was conducted in a 4-6 month period. Demographic data, clinical and metabolic parameters, presence of diabetic complications and comorbidities, and treatment modalities were examined.
Results
Sixty-four patients were included in the analysis (43.7% female, age at diagnosis 9.4 ± 3.9). The mean age at last visit in pediatric care and at transition were 17.3 ± 0.5 and 20.2 ± 1.4 years, respectively. The median time in adult care follow up was 3.3 (min 0.3-20.9) years except for 5 subjects who lost-to-follow-up after one visit, and 4 subjects who were recently transferred. Mean body mass index at the time of transition was 24.1 ± 1.7 kg/m^2. While frequency of obesity was 1.6% in last pediatric visit, it increased up to 9.6% in last adult care visit. Use of insulin pump in adult care was higher (4.7% vs 12.5%; $P = 0.11$). Total insulin doses were significantly higher at transition than in last adult care visit (0.95 vs 0.75 IU/kg/day; $P < 0.01$). Basal insulin ratio was higher in adulthood (43.1% vs. 52.8%; $P < 0.01$). Routine control visit per year for diabetes care was higher in pediatrics follow-up ($P < 0.01$). Mean HbA1c was significantly lower in adulthood (8.9% vs. 8.3%; $P < 0.01$). Frequency of autoimmune thyroiditis and coeliac disease did not differ in pediatric and adult care. Although frequency of micro and macrovascular complications increased in adult care, no significant difference was found in acute and chronic complications. There was no difference between transition models 1 and 2 regarding diabetes care.
Conclusion
Obesity has increased in adulthood. Although total insulin doses decreased in adulthood, basal insulin ratio increased. Diabetes control get better in adulthood. Planned transition models have positive impact on diabetes care of adult patients.
Keywords
Type 1 diabetes mellitus, transition, diabetes care

Effects of Diospyros Kaki Derived Exosomes on Beta Cell Homeostasis

Bilge Kabataş[1], Merve Yildirim[1], Olcay Eren[1], Naz Unsal[1] & Simge Eren[2]
[1]Yeditepe University, Genetics and Bioengineering, İstanbul, Turkey; [2]Şişli Etfal Research and Traiing Hospital, Pediatric Endocrinology, İstanbul, Turkey

Introduction
Exosomes are nanoparticles containing bioactive molecules reflecting individual physiological status, regulating metabolism, and repairing damaged tissues. Exosomes are extracellular vesicles with nano-sized features (30-150 nm) involved in cell-to-cell communication and maintaining homeostasis. The function of exosomes is different according to their cargo and they can contain lipids, proteins and nucleic acids. Exosomes originating from mammalian cells as well as plant cell-derived play an important role in interspecies interaction. Exosomes, which are a very important discovery in studies aimed at elucidating the pathophysiology of diabetes, are still being investigated for their roles in treatment methods and cell interactions. In our study, we aimed to examine the effects of Diospyros Kaki-derived exosomes on beta cell homeostasis.
Methods
Three different doses of Diospyros Kaki-derived exosome were given to pancreatic beta cells isolated from spraque dowley rats in vitro. In order to evaluate the toxic effect of given date exosomes on beta cells, Mts analyzes were first measured at 24, 48 and 72 h. As it can be seen from MTS analysis, 50 mg/dl was found as optimum dose for treatment. After choosing the effective dose, total RNA isolation, cDNA and PCR analyzes were performed. As a result of PCR experiments, the amount of increase and decrease in gene expressions were analyzed.
Results
Effects of administration of Diospyros Kaki-derived exosomes on beta cells were analyzed via MTS and PCR techniques. After optimum dose were defined by MTS analysis, diabet specific genes such as preproinsülin, Transforming growth factor beta and Pdx-1 expressions were analyzedvia PCR. In addition, expression of preproinsülin, Transforming growth factor beta and Pdx-1 genes which are spesific for for the growth, secretion function, and survival of beta-cells, increased 3, 4 and 2 fold changes respectively. Furthermore, Diaspyros Kaki derived exosomes significantly increased beta-cell proliferation upon 50mg/ml concentration and no toxic effects were observed.
Conclusion
This study demonstrates the contribution of Diospyros Kaki-derived exosomes to beta cell proliferation in a pancreatic beta cells culture modelling diabetes mellitus. Our findings suggests that the use of Diospyros Kaki-derived exosomes should potentially be considered and studied in the future in the treatment of beta-cell associated diabetes mellitus.

New risk score for cardiovascular mortality in frail elderly people with type 2 diabetes

Olga Vasovic[1,2,3]
[1]Euromedic Health System, Endocrinology, Belgrade, Serbia; [2]College of Sports and Health, Geriatrics, Belgrade, Serbia; [3]Euromedic Health System, Endocrinology, Belgrade, Serbia

Background
Cardiovascular mortality is the leading cause of death in elderly people with diabetes. Traditional cardiovascular risk factors are not principal predictors for cardiovascular events in frail elderly.
Aim
This prospective study examined biomarkers associated with cardiovascular mortality in 253 community dwelling elderly aged 65 to 99 years. Patients were divided into four main groups: GROUP A-Patients with type 2 diabetes and history of MACE; GROUP B-Patients with type 2 diabetes, without MACE; GROUP C-Patients without diabetes, with MACE; GROUP D-Patients without diabetes and without MACE– the control group.
Methods
Patients were followed for a six months period. We checked medical records for presence of new MACE or cardiovascular death. MACE was defined as self-reported and medically documented myocardial infarction and/or stroke. Cardiovascular mortality was defined as mortality from myocardial infarction, heart failure, stroke, aneurism, or complications after vascular surgery. Baseline biochemical measurements were made from fasting blood samples performed at home on the morning of the baseline examination. We investigated traditional risk factors, inflammatory markers and albumin as marker of malnutrition. We also considered other standard biochemical measurements as potential risk factor. The associations between mortality risk and different biomarkers were assessed using Cox proportional hazards (PH) regression. We used cutoff points based on ROC analysis to form dichotomy variables from significant multivariable predictors. Differences in Kaplan-Meier survival curves were tested by Log rank test.
Results
Significant multivariate predictors for cardiovascular mortality were: albumin $<$ 40 g/l, BMI <25 kg/m^2, total bilirubin <10.5µmol/l, BUN ≥ 6.5 mmol/l and hsCR$P \geq 2.25$ mg/l. We built the score system with these five predictors. The score was positive if someone had three or more of these five predictors positive and we called it inflammatory-malnutrition-renal involved score (IMRIS). Presence of prior MACE raised risk for cardiovascular mortality approximately twice (RR 2.113; $P < 0.001$), and positive IMRIS nearly four times (RR 3.908; $P < 0.001$). In group with T2D relative risk for cardiovascular mortality with positive IMRIS was 3.884 ($P < 0.001$), vs.3.871 ($P < 0.001$) in group without T2D. In group with prior MACE relative risk for cardiovascular mortality with positive IMRIS was 4.326 ($P < 0.001$), vs.3.185 ($P = 0.001$) in patients without MACE. In the control group low HDL-cholesterol was the only predictor for cardiovascular mortality (HDL$\leq$ 1.51, RR 2.643; $P = 0.004$).

Conclusion
In our study new proposed IMRIS score was predictive for cardiovascular mortality in patients with T2D regardless of traditional cardiovascular risk factors and metabolic control.

Insulin resistance and hyperglycemia induce mitochondrial dysfunction and a metabolic towards use of gluconeogenic amino acids in epithelial kidney cells

Patricia Braga[1,2,3], Raquel Bernardino[3,4], Bárbara Guerra-Carvalho[2,3,5], David F. Carrageta[2,3], Anabela Rodrigues[1,3,6], Pedro F. Oliveira[5] & Marco Alves[2,3]
[1]Unit for Multidisciplinary Research in Biomedicine (UMIB), Institute of Biomedical Sciences Abel Salazar (ICBAS), University of Porto, Nephrology, Dialysis and Transplantation, Porto, Portugal; [2]Unit for Multidisciplinary Research in Biomedicine (UMIB), Institute of Biomedical Sciences Abel Salazar (ICBAS), University of Porto, Laboratory of Physiology, Department of Imuno-physiology and Pharmacology, Porto, Portugal; [3]ITR-Laboratory for Integrative and Translational Research in Population Health, Porto, Portugal; [4]Unit for Multidisciplinary Research in Biomedicine (UMIB), Institute of Biomedical Sciences Abel Salazar (ICBAS), University of Porto, Porto, Portugal; [5]University of Aveiro, LAQV-REQUIMTE and Department of Chemistry, Aveiro, Portugal; [6]Santo António General Hospital, Department of Nephrology and Department of Clinical Pathology, Porto, Portugal

Diabetic nephropathy (DN) and insulin resistance (IR) in kidney cells are considered the main cause of end-stage renal failure. Additionally, hyperglycemia and increased fatty (FA) acids are observed in patients with type 2 diabetes mellitus, where lipid accumulation has been correlated to IR. Nonetheless, the impact of IR in early disease stages is still unclear. Moreover, proximal renal tubular cells have high mitochondrial content where aerobic respiration is their primary mechanism of ATP production, being particularly susceptible to metabolic and mitochondrial injury from hyperglycemia. Herein, we will explore the impact of mild (11 mM) to severe hyperglycemia (22 mM) as well as IR under normoglycemia (5 mM) in *in vitro* conditions in renal epithelial cells' metabolic and mitochondrial bioenergetics profiles. To do so, we used a human epithelial kidney cell line (HK-2), which was cultured in increasing concentrations of glucose (5mM, 11 mM and 22 mM). Lipid cytotoxicity was used to induce insulin resistance (IR), through the administration of Palmitic Acid (PA), for 24 h. The effect of hyperglycemia and IR in the consumption/production of metabolites were analyzed by nuclear magnetic resonance. Additionally, *in vivo* mitochondria function was assessed by seahorse analytics, as well as mitochondrial complex I (CI) and II activities. We also evaluated free FA oxidation and lipid accumulation. Our results demonstrated that PA was able to induce IR and altered the metabolic fingerprint in HK-2 secretome since Glucose, Glutamine, Lactate, Pyruvate, Alanine, Isoleucine, and Glutamate concentrations increased in comparison to the same conditions without PA-induced IR, where gluconeogenic amino acids played a key role to supply energy. It was also observed that FA was not the preferential carbon source for HK-2 cells, resulting in its accumulation. Mitochondrial parameters (basal respiration, ATP production, proton leak, maximal and spare respiration capacity) of HK-2 cells are increased in mild hyperglycemia conditions but decreased when cultured in high hyperglycemia with IR. Furthermore, in this condition, there was a decrease in the CI activity of the electron transport chain. Our data demonstrated that progression from mild to severe hyperglycemia induces a metabolic shift, where gluconeogenic amino acids are crucial to supply energy requirements. Furthermore, this progression allied to IR induced mitochondrial dysfunction, suggesting that this time point between mild to severe hyperglycemia might disclose a "window" of opportunity to help to target and treat the early kidney disease associated with hyperglycemia and IR.

Effects of a combinatory treatment with semaglutide and a NPY Y2 receptor selective PYY 3-36 analogue in diet-induced obese rats: surpassing bariatric surgery?

Marie Oertel[1], Julia Theisen[2], Katharina Ecker[2], Michael Kohlhaas[2], Alexander Nickel[2], Martin Fassnacht[1], Christioph Maack[2], Vasco Sequeira[2] & Ulrich Dischinger[1]
[1]University Hospital Würzburg, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]University Hospital Würzburg, Comprehensive Heart Failure Center, Würzburg, Germany

Background
Combinatory treatments with analogues of incretins might mimic the beneficial effects of bariatric surgery. We could show in the past that a combinatory treatment with PYY 3-36 and liraglutide leads to a similar body weight loss as Roux-en-Y gastric bypass (RYGB). We hypothesize that a combination of semaglutide and a modified PYY 3-36 analogue with increased selectivity for the neuropeptide Y receptor type 2 (NNC0165-1273) exceeds the weight-reducing effects of bariatric surgery.
Methods
High-fat (45%) and high-fructose diet (HFD)-induced (8 weeks) obese male Wistar rats were randomized into the following treatment groups: (1) NNC0165-1273 + semaglutide, (2) semaglutide, (3) saline. NNC0165-1273 was given continuously via osmotic minipump (0.08 µmol/kg/d), semaglutide was given once daily s.c. at a dose of 120µg/kg. Animals were kept on a free choice high- and low-fat diet after start of the respective intervention. Body weight and food preference were measured daily for 8 weeks post intervention.
Results
NNC0165-1273 + semaglutide treatment led to an impressive and long-lasting body weight loss (max. -23.9%), which was superior to semaglutide monotherapy (max. -9.9%) and saline treatment (+8%). Compared to an earlier study with diet-induced obese rats, NNC0165-1273 + semaglutide was even more effective than RYGB. Additionally, NNC0165-1273 + semaglutide led to a strong decrease of HFD preference.
Conclusions
A combination of NNC0165-1273 and semaglutide is highly effective in terms of body weight loss in diet-induced obese rats and might be superior to the weight reducing effects of RYGB.

The impact of Diabetes Mellitus in patients with Pulmonary Fibrotic Disease; disease progression and bronchoalveolar lavage evaluation

Panagiotis-Nikolaos Tsakalomatis[1], Eirini Vasarmidi[2], Eliza Tsitoura[2], Eleni Bibaki[2], Katerina Antoniou[2] & Paraskevi Xekouki[1]
[1]University General Hospital of Heraklion, Endocrinology and Diabetes Clinic, Heraklion, Crete, Greece; [2]University General Hospital of Heraklion, Department of Respiratory Medicine, Heraklion, Crete, Greece

Rationale/Objective
Diabetes Mellitus (DM) and Interstitial lung Disease (ILD) share common pathogenetic pathways involving inflammatory cells and in particular monocytes and macrophages. Diabetic patients are at higher risk of developing pulmonary fibrosis, whereas DM is a major comorbidity in ILD patients. In our study, we analyzed retrospectively patients with ILD and aimed to examine differential characteristics between patients with and without DM, including disease parameters and alveolar macrophage evaluation.
Material and methods
256 patients with Pulmonary Fibrosis (Idiopathic or not) seen in the Department of Respiratory Medicine and in Endocrinology and Diabetes Clinic the University Hospital of Heraklion from January 2014 to July 2022, were enrolled; 76 with DM and 180 without DM. Clinical characteristics of all patients including age, smoking habits, BMI, pulmonary function at baseline and disease progression up to 2 years follow-up, were collected. In all of the included patients, bronchoscopy was performed and bronchoalveolar lavage (BAL) was obtained. The levels of mtROS were measured in fresh BAL alveolar macrophages by flow cytometry using MitoSOXRed (Invitrogen) superoxide indicator.
Results
Our results showed that ILD patients with DM had a statistically increased smoking history, and a tendency to rapid disease progression, although not significant. In accordance with previous reports, we did not find any other significant difference between disease baseline characteristics or disease progression and mortality between ILD patients with or without DM. Interestingly, we observed a significantly increased macrophage population in BAL of patients with DM. In the subgroup analysis of IPF patients, there was a trend of increased percentage of alveolar macrophages in BAL of patients with DM, while there were decreased levels of oxidized mitochondria in macrophages of these patients.
Conclusions
Our preliminary results showed increased macrophage population in BAL of ILD patients with DM, while there were reduced levels of oxidized mitochondria in the alveolar macrophages of IPF patients with DM. It is unknown if targeted anti-

diabetic treatment results in these observations, and further studies are required to assess whether antidiabetic medications could decrease mitochondrial ROS in alveolar macrophages of ILD patients.

Keywords
Pulmonary fibrosis, interstitial lung disease, alveolar macrophages, diabetes mellitus

How do diabetes-related ketoacidosis outcomes compare between hospitals? Results from a quality improvement project

Abigail Hallum[1], Arjun Narendran[2], Joseph Dalzell[1], Catherine Needs[3], Arun George[4], Parth Narendran[5], Parijat De[1], Alexandra Lubina Solomon[6], Senthil Krishnasamy[7], Rajeev Raghavan[4] & Dekode Working Group[8]
[1]Sandwell and West Birmingham NHS Trust, Diabetes and Endocrinology, West Bromwich, United Kingdom; [2]Imperial College London, School of Medicine, United Kingdom; [3]Wirral University Teaching Hospital NHS Foundation Trust, Diabetes and Endocrinology, Birkenhead, United Kingdom; [4]The Royal Wolverhampton NHS Trust, Diabetes and Endocrinology, Wolverhampton, United Kingdom; [5]University Hospitals Birmingham NHS Foundation Trust, Diabetes and Endocrinology, Birmingham, United Kingdom; [6]Dudley Group NHS Foundation Trust, Diabetes and Endocrinology, Dudley, United Kingdom; [7]Walsall Healthcare NHS Trust, Diabetes and Endocrinology, Walsall, United Kingdom; [8]University of Birmingham, Institute of Metabolism and Systems Research, Birmingham, United Kingdom

Background
The appropriate and timely management of diabetes-related ketoacidosis (DKA) has important implications for patient outcomes. Despite the availability of national management guidelines to promote standardised care, we do not know if there are differences in DKA outcomes and complications between hospitals.
Aim
To assess for differences in DKA outcomes and treatment complications between hospitals.
Methods
This retrospective study was done as part of an ongoing quality improvement project which utilises a centralised DKA registry. All episodes satisfying national diagnostic criteria admitted to six hospitals (anonymised as A to F) in the West Midlands region of the United Kingdom from October 2021 to September 2022 were included. People aged <16 years or who self-discharged before biochemical resolution of DKA were excluded. We collected pseudonymised data on dates and times of hospital admission, discharge, DKA diagnosis, and DKA resolution, alongside the number of hyperkalaemic, hypokalaemic and hypoglycaemic events during DKA treatment. We used the Independent-Samples Kruskal-Wallis test to look for differences in DKA duration and length of stay between hospitals. Chi-square analysis was performed to assess for differences in the proportion of DKA episodes complicated by hyperkalaemia, hypokalaemia and hypoglycaemia between sites.
Results
In total, 442 DKA episodes were analysed. We found significant differences between hospitals in length of patient stay (median in days; A-2.1, B-2.5, C-3.5, D-3.6, E-2.5, F-3.0; $P<0.001$), DKA duration (median in h; A-13.3, B-13.4, C-18.5, D-15.1, E-17.1, F-16.3; $P=0.002$), and the proportion of DKA episodes complicated by hypokalaemia (A-37.3%, B-19.6%, C-39.3%, D-25.4%, E-45.2%, F-43.6%; $P=0.01$). However, there were no significant inter-hospital differences in the proportion of DKA episodes complicated by hyperkalaemia (A-33.3%, B-26.1%, C-28.7%, D-30.3%, E-16.7%, F-33.3%; $P=0.534$) or hypoglycaemia (A-15.7%, B-15.2%, C-17.2%, D-9.2%, E-23.8%, F-17.9%; $P=0.197$).
Conclusions
Despite use of similar guidelines, there are significant variations in some DKA outcomes and treatment complications between hospital sites. Ongoing use of a centralised data collection system with periodic analysis may help to identify best practices to be shared between centres. Going forwards, this may facilitate more uniform patient care and hence minimise inter-hospital variations in DKA outcomes.

RNA-seq profiling from white adipocyte to brown adipocyte-like cells trans-differentiation of 3T3-L1 by β3-adrenergic stimulation

Soon Jib Yoo, Oak-Kee Hong[2], Eun-Sook Kim[1] & Hyuk-Sang Kwon[1]
[1]The Catholic University of Korea, Endocrinology, Seoul, South Korea; [2]The Catholic University of Korea, Endocrinology, Seoul, South Korea

Beige adipocytes can be induced from white adipocytes (WAT) and precursors upon stimulation by cold temperatures and act like brown adipocytes (BAT) to increase energy expenditure. Most *in vivo* studies examining the mechanisms for the induction of beige/brown adipocytes have focused on subcutaneous white adipose tissue (sWAT) in the mouse. To better understand the development of beige/brown adipocytes from mammalian sWAT, we induced WAT and BAT from 3T3-L1 preadipocytes by exposure to classical differentiation protocols. We transdifferentiated BAT from 3T3-L1 white adipocytes by stimulus β3-adrenergic agonist (CL316,243). Furthermore, we used RNA-Seq to investigate whether differentiation protocol can influence the transcriptome of adipocyte browning. The expression of white and brown fat-specific markers was increased in WAT and BAT after 10 days of differentiation. At 6 days differentiation treatment of white adipocyte with CL316,243 for 48 h produced more adipocytes with multilocular phenotype, typical of brown adipocytes. An increase in uncoupler protein-1(UCP1) and Peroxisome proliferator-activated receptor-γ co-activator-1α (PGC-1α) and decrease aP2, white adipocyte marker suggested that CL316,243 transdifferentiates browning. RNA-seq was used to determine genes regulated by the fat browning process and identify the key differences between the two functionally distinct adipocytes. Taken together, we provide detailed adipocyte-specific gene expression profiles affected by adipocyte trans-differentiation.

Cabergoline counteracts adipose and skeletal muscle lipid accumulation through promoting oxidative pathway: an *in vivo* and *in vitro* preclinical study

Mariarosaria Negri[1], Claudia Pivonello[2], Feliciana Amatrudo[1], Roberta Patalano[1], Tatiana Montò[1], Donatella Paola Provvisiero[1], Chiara Simeoli[1], Cristina de Angelis[1], Renata Simona Auriemma[1], Annamaria Colao[1,3], Raffaella Crescenzo[4] & Rosario Pivonello[1,3]
[1]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Naples, Italy; [2]Università Federico II di Napoli, Dipartimento di Sanità Pubblica, Naples, Italy; [3]Federico II University, UNESCO Chair for Health Education and Sustainable Development, Naples, Italy; [4]Federico II University, Department of Biology, Task Force on Microbiome Studies, Naples, Italy

Obesity, characterized by an abnormal body fat accumulation mainly caused by a chronic imbalance between energy intake and expenditure, is a massive public health problem. Targeting excessive fat deposition in adipose tissue and ectopic fat accumulation in skeletal muscle through promoting lipid oxidation pathway may represent a promising strategy to counteract obesity. This study aims at investigating the effects of cabergoline (CAB), a dopamine agonist, on adipose and skeletal muscle tissues' lipid accumulation by monitoring the protein levels of the main lipogenic markers in adipose tissue and by analyzing lipid oxidation pathway in both adipose and skeletal muscle tissues in *in vivo* and *in vitro* preclinical models. To this aim, 2 groups of 60-days aged male Wistar rats receiving a high-fat and fructose-rich diet for 28 days were analyzed: one receiving an oral dose of CAB 0.6 mg/kg of body weight every 3 days for a total duration of 2 weeks (HFFC), the other one receiving placebo (HFF). Moreover, in white adipocytes 3T3L1, lipid accumulation through Red Oil staining and oxidative pathway through WB analysis were performed after 3 days of CAB 10^{-10}-10^{-6} M. HFFC visceral adipose tissues showed a significant decrease of PPARγ ($P<0.05$) and adiponectin ($P<0.01$) proteins, with a concomitant strong inhibition of leptin (60%) and FAS (75%) proteins compared to HFF. Moreover, HFFC visceral adipose tissues showed a significant reduction of pACC ($P<0.05$) and a strong increase in pAMPK Thr172 (74%) with a concomitant moderate stimulation of PKA catalytic subunit (PKA-Cα) (18%). Similarly, HFFC subcutaneous adipose tissues showed a significant decrease of leptin ($P<0.01$) and adiponectin ($P<0.01$) and a strong inhibition of PPARγ (70%) compared to HFF. Moreover, HFFC subcutaneous adipose tissues displayed a strong increase in pACC Ser72 (30%) associated with a significant stimulation of PKA-Cα ($P<0.001$) compared to HFF. Likewise, HFFC soleus tissues showed a significant increase in pACC Ser72 ($P<0.05$) associated with a significant stimulation of PKA-Cα ($P<0.01$) compared to HFF. Concomitantly, in white 3T3L1, Red Oil demonstrated that CAB 10^{-8}M and 10^{-6}M significantly inhibited lipid accumulation ($P<0.001$), while WB revealed that CAB 10^{-6}M significantly stimulated pAMPK Thr172 ($P<0.05$) and slightly decreased PPARγ, leptin and FAS proteins compared to untreated 3T3L1. These preliminary preclinical data demonstrate a novel CAB lipolitic effect in murine adipose and muscle tissues mediated by oxidation pathway.

Background
In patients with Bardet-Biedl syndrome (BBS), signaling impairments in the melanocortin-4 receptor (MC4R) pathway lead to hyperphagia and severe obesity, which negatively impact quality of life (QOL). We evaluated the impact of setmelanotide, an MC4R agonist, on age-appropriate weight-related parameters, hunger, and QOL in a Phase 3 trial of patients with BBS to further characterize clinical benefit in this patient population.
Methods
Patients $\geq$6 years old with BBS and obesity were enrolled into a Phase 3 trial (NCT03746522) and received 52 weeks of setmelanotide treatment. Hunger was assessed with an 11-point Likert scale in patients $\geq$12 years old without cognitive impairment. QOL was assessed in adults using the Impact of Weight on Quality of Life-Lite (IWQOL-Lite) and in pediatric patients using the Pediatric Quality of Life Inventory (PedsQL). Clinically meaningful improvements in weight-related parameters were defined as $\geq$5% reduction in body weight for adults and $\geq$0.2-point decrease in BMI Z score and/or $\geq$5–percentage point decrease in percent of the 95th BMI percentile for pediatric patients. Clinically meaningful improvement in hunger was defined as a $\geq$1-point within-patient reduction in hunger score. In adult and pediatric patients, patient-relevant improvements in QOL were defined as an increase in IWQOL-Lite score of 7.7-12 and increase in PedsQL score of $>$4.4, respectively. Stabilization of weight-related parameters was also assessed.
Results
In total, 28 of 32 patients (88%) had clinically meaningful or patient-relevant improvements that met thresholds in $\geq$1 measure at the last study visit. Three of 4 patients without improvement showed weight stabilization; thus, 31 of 32 patients (97%) experienced clinically meaningful and/or patient-relevant improvement or weight stabilization. Setmelanotide was generally well tolerated; 1 patient discontinued study drug during placebo treatment because of an adverse event.
Conclusions
Most patients with BBS showed clinically meaningful or patient-relevant improvement following setmelanotide, as measured by decreases in age-appropriate weight-related parameters, decreases in hunger, and overall improvements in QOL. Clinical benefit from antiobesity medications should be assessed beyond weight loss, especially in patients with BBS.

Enhanced antibacterial activity of green ZnO NPs against multi-drug resistant bacterial pathogens from diabetic foot ulcer using Aristolochia indica

Subhash Kumar[1] & Surendra Prasad Singh[2]
[1]Diabetes & Obesity Care Center, Diabetes, Patna, India; [2]Patna Medical College Hospital, Community Medicine, Patna, India

Introduction
Diabetic foot ulcers (DFU) have developed into a more common complication among people with uncontrolled diabetes, who also have higher morbidity rates and are more prone to polymicrobial infections that spread quickly and cause irreparable tissue damage. The most difficult aspect of treating diabetic foot ulcers (DFU) is the rising prevalence of multi-drug resistant germs, which necessitates the use of a novel antimicrobial agent.
Objective
In this study, the bactericidal effects of ZnO nanoparticles (ZnO NPs) green produced from *Aristolochia indica* against Multi-drug Resistant Organisms (MDROs) were examined.
Method
Transmission electron microscopy (TEM), Atomic Force Microscopy (AFM), and zeta potential measurements were used to characterise ZnO nanoparticles. To ascertain if the effects were bactericidal or bacteriostatic, MIC/MBC assays were carried out. At 1x MIC and 2x MIC doses of ZnO NPs, time-kill tests, protein leakage, and flow cytometric analyses assessed bacterial cell death. The results of each experiment were run in triplicate, and they were presented as the mean SEM of three separate experiments. $P<0.04$ was regarded as statistically significant. The means were statistically compared using One-way ANOVA, followed by post hoc Dunnett's and Tukey's Multiple Comparison Tests using GraphPad Prism version 5.
Results
ZnO NPs with a zeta potential of -21.8 $\pm$ 2 mV and a size of 22.4 nm showed exceptional bactericidal activity, with MIC/MBC ranging from 24 to 300 g/ml and a considerable decline in viable count after 1 hour. Bacterial cell death caused by ZnO NPs was confirmed by protein leakage and flow cytometric analysis.
Conclusion
Due to its improved bactericidal effects even against clinical bacterial infections that are practically resistant to existing stronger antibiotics, the current work offers new insight into the development of green produced ZnO NPs as an alternative therapeutic agent. However, more research is required to fully understand the mechanism underlying antibacterial activity. It is also recommended that this synthesis method can be used to other biological applications, such as larvicidal and antifungal medicines. This study came to the conclusion that the green synthesis technique offers a trustworthy, environmentally friendly method for creating antimicrobial ZnO NPs to fight antibiotic medication resistance.

Diabetes Distress among Type 1 Diabetic adolescents in India

Bharat Saboo[1], Vipul Chavda[2], Aniket Inamdar[3], Ajoy Tewari[4] & Dhruvi Hasnani[5]
[1]Prayas Diabetes Center, Diabetology, Indore, India; [2]Rudraksha Institute of Medical Sciences, Diabetology, Ahmedabad, India; [3]Samarpan Clinic, Diabetology, Omerga, India; [4]Jai Clinic and Diabetes Care Centre, Lucknow,; [5]Rudraksha Institute of Medical Sciences, Ahmedabad, India

Introduction
Diabetes distress, a term used to describe negative emotions associated with diabetes, is the key factor responsible for the elevated risk of psychological burden and compromised self-management. The aim of this study is to determine the prevalence of diabetes-related distress among adolescent patients with type 1 diabetes (T1D) and to ascertain various factors associated with it.
Materials and methods
In this cross-sectional study, 102 T1D patients with age 12-20 years visiting a diabetic clinic in the Department of Diabetology from March 2022 to October 2022 were enrolled. The patient's demographic and clinical details were noted in a pre-designed proforma. T1D distress scale (T1DDS) was used to measure diabetes distress and distress was classified as severe, moderate, and no/little distress.
Results
Of the 102 T1D patients, 36 % ($n=36$) had diabetes-related distress, of which 31% had moderate and 3 % had severe distress. The average total distress score was 1.70 $\pm$ 0.62 and higher mean scores were of powerlessness, negative social perception, and eating distress. Distress was higher among females, in those with the onset of diabetes in teens rather than in childhood. There is a significant impact of glycated haemoglobin (HbA1c) on the severity of diabetes distress as demonstrated by Pearson's correlation ($r=.530$, $n=102$, $P=<.001$)
Conclusion
The present study highlights the association of diabetes distress in adolescents with various factors, most significantly poor glycemic control, and therefore emphasizes the need for developing psychological interventional strategies in

routine diabetes care to improve the mental well-being and self-management of diabetic patients.

Usefulness of Intermittent Intersticial Glucose Monitoring in Patients Admitted to The Intensive Care Unit of The Hospital Universitario San Cecilio in Granada

Raúl Rodríguez Juárez[1], María del Carmen Andreo-Lopez[1], Elena Martínez[1], Javier García[1], María Teresa Cruces Moreno[2] & Pablo José López Ibarra[1]
[1]UCG Endocrinología y Nutrición, Hospital Universitario San Cecilio de Granada, Granada, Spain; [2]UCG Cuidados Intensivos, Hospital Universitario San Cecilio de Granada, Granada, Spain

Objective
The carbohydrate metabolism dysfunctions are common in critical ill patients with diabetes or stress hyperglycaemia and the correct management of them has an important prognostic value. Despite its limitations, capillary glucose (CG) was collected more than arterial glucose (gold standard) because of its good correlation. However, the usefulness of intermittent intersticial glucose monitoring (IGM) in keeping blood glucose within target range in critical ill patients its controversial. Therefore, we will evaluate IGM and CG correlation in critical ill patients with diabetes or stress hyperglycaemia.
Materials and Methods
Prospective longitudinal observational study with 6 diabetic or stress hyperglycaemia patients admitted to the Intensive Care Unit (ICU). Demographic (sex, age), clinical (DM, hypertension, obesity), hemodynamic (need for vasoactives) and metabolic (A1c-type glycosylated hemoglobin (HbA1c) determined by laboratory analysis, presence of angiopathic complications, CG and IGM measurements (in mg/dl)) variables were collected. The statistical analysis was performed with the IBM SPSS v.25 programme (Statistical significance $P<0.05$).
Results
67% were males with a mean age of 65.5 ± 21.5 years. 100% were hypertensive and 50% obese. 67% were type 2 diabetic with a mean HbA1c 6.5 ± 1.6% and 75% had angiopathic complications. 67% required vasoactives. Statistical analysis shows a strong and positive correlation between CG and MIG values ($r=0.8$, $P=0.0$).
Conclusions
There is a strong and positive correlation between MIG and CG values, which highlights the probable usefulness of the first one in patients admitted to the ICU. Therefore, it could be feasible as a glycemic management tool in the critically ill patient by improving GC measurements limitations. More studies are needed for prove this.

Dapagliflozin Improves Glycemic control and Liver Function with Body Weight Loss as Add-on therapy to Metformin Plus Evogliptin: A 24-week, Randomized, Double-blind, Clinical Trial

In-Kyung Jeong[1], Kyung Mook Choi[2], Kyung Ah Han[3], Kyoung-Ah Kim[4], injoo kim[5], Seung jin Han[6], Byung Wan Lee[7], Won-Young Lee[8] & Soon Jib Yoo[9]
[1]Kyung Hee University Hospital at Gangdong, Endocrinology and Metaboliam, Seoul, South Korea; [2]Korea University Guro Hospital, Seoul, Korea, Endocrinology and Metaboliam, Seoul, South Korea; [3]Nowon Eulgi Medical Center, Endocrinology and Metaboliam, Seoul, South Korea; [4]Dongguk University Ilsan Hospital, Endocrinology and Metaboliam, Goyang-si, Gyeonggi-do, South Korea; [5]Pusan National University Hospital, Endocrinology and Metaboliam, Busan,, South Korea; [6]Ajou University School of Medicine, Endocrinology and Metaboliam, Suwon-si Gyeonggi-do, South Korea; [7]Yonsei University Severance Hospital,, Endocrinology and Metaboliam, Seoul, South Korea; [8]Kangbuk Samsung Hospital, Endocrinology and Metaboliam, Seoul, South Korea; [9]The Catholic University Bucheon St. Mary's Hospital, Endocrinology and Metaboliam, Bucheon-si, Gyeonggi-do, South Korea

Background and aims
The efficacy and safety of dapagliflozin as add-on therapy in patients with type 2 diabetes mellitus (T2DM) and inadequate glycemic control with evogliptin and metformin combinations was investigated.
Materials and methods
Patients with HbA1c of 7.0% to 10.5% receiving evogliptin 5mg and metformin ≥1000 mg were randomized to receive dapagliflozin 10 mg/day ($n=99$) or placebo ($n=99$) for 24 weeks. The primary endpoint was change from baseline in HbA1c at week 24. Prespecified subgroup analyses of the change in HbA1c were performed in patients with screening HbA1c values <8%, ≥8%. Secondary endpoints were changes from baseline in 2hr-postprandial plasma glucose, body weight, uric acid, liver function and lipid parameters.
Results
HbA1c (baseline mean±SD: dapagliflozin 7.87±0.72%; placebo 7.77±0.68%) decreased significantly from baseline with dapagliflozin (placebo-subtracted least square [LS] mean change±SE: –0.70±0.11%, $P<0.0001$). In patients with higher screening HbA1c values (≥8%), placebo-subtracted LS mean decreases in HbA1c seen with dapagliflozin were numerically greater (–0.79±0.20% compared with –0.65±0.12% in patients with lower HbA1c values (<8%)). LS mean difference in 2hr-postprandial plasma glucose after breakfast at week 24 with dapagliflozin vs placebo was -27.48±7.63 mg/dl($P=0.0004$). Significant reductions in uric acid and body weight were observed with dapagliflozin relative to placebo at week 24 [(LS mean difference± SE: -0.38±0.11 mg/dl ($P=0.0007$), -1.79±0.29 kg ($P<0.0001$), respectively). Compared to placebo, dapagliflozin treatment significantly reduced ALT, r-GT and hepatic steatosis index (HIS) at week 24 (placebo-subtracted LS mean change –2.77±1.37 U/l, $P=0.0444$; -9.46±3.56 U/l, $P=0.0085$; -0.91±0.33, $P=0.0062$). Patients receiving dapagliflozin showed placebo-subtracted LS mean increases in total and HDL cholesterol (6.73±2.82 mg/dl, $P=0.0179$; 2.78±0.87 mg/dl, $P=0.0016$, respectively). Adverse events occurred in 27.55% of patients receiving dapagliflozin and 27.27% receiving placebo. Adverse events were similar across treatment groups with a low overall risk of hypoglycemia (~3%).
Conclusions
Dapagliflozin improves hyperglycemia and fatty liver and well tolerated over 24 weeks as add-on to patients with type 2 diabetes inadequately controlled by metformin plus evogliptin combination.

Oral Semaglutide Improves Metabolic Outcomes in Type 2 Diabetes: A Spain-based Study

Carlos Casado[1], Jersy Jair Cardenas Salas[1,2], Roberto Miguel Sierra Poyatos[1,3], Teresa Montoya Alvarez[2], Diego Meneses González[1], Jorge Gabriel Ruiz Sánchez[1], Bogdana Luiza Luca[1], Begoña Sánchez Lechuga[1], María de los Angeles Velez Romero[1] & Clotilde Vazquez Martinez[1,2,3]
[1]Fundación Jiménez Diaz, Endocrinology and Nutrition, Madrid, Spain; [2]Hospital Universitario Infanta Elena, Valdemoro, Spain; [3]General Hospital Villalba, Collado Villalba, Spain

Objectives
To evaluate the changes in HbA1c, basal glucose, weight, and lipid profile in patients with type 2 diabetes after starting oral semaglutide.
Methods
This study was conducted in Madrid, Fundación Jiménez Díaz, Infanta Elena and General de Villalba hospitals. A total of 75 patients with type 2 diabetes were

	Comparison		
	Basal	**6 months**	**Differences**

included. The mean age was 62.0 ± 10.5 years and 60% were men. The mean duration of diabetes was 7.3 ± 6.6 years, and 66.7% had hypertension, 67.6% had dyslipidemia, 14.9% were smokers, 23.0% had sleep apnea, and 26.4% had microvascular disease. Basal treatment included insulin in 12.0%, metformin in 86.7%, SGLT2i in 48%, DPP4i in 41.9%, GLP1-Ra in 1.3%, repaglinide in 8.1%, and Sulphonylurea in 2.7%. A total of 58.3% of patients reached a dose of 7 mg, and 41.7% reached 14 mg. 4 patients discontinued the treatment, 2 due to adverse effects and 2 due to administrative problems. Gastrointestinal adverse effects were reported in 16% of patients. The study had a follow-up period of 7.3 ± 6.6 months. Paired T-Student test for parametric data (α), Wilcoxon test for non-parametric data (β), and McNemar test for proportions (ϕ) were used for statistical analysis.
Results
The following changes were observed after starting oral semaglutide:
Conclusions
Oral semaglutide was associated with significant improvements in HbA1c, fasting glucose, weight, and lipid profile in patients with type 2 diabetes. The treatment was well tolerated, with a low incidence of adverse effects. The results of this study support the use of oral semaglutide.

PDE4 Inhibitors Act in The Brain to Ameliorate Metabolic Parameters in Diet-Induced Obesity

Hellen da Silva[1], Luiza Mendonça Duarte[2], Michele De Souza Seixas[2], José Antunes Rodrigues[2], Francisco de Paula[1] & Lucila Elias[2]
[1]Faculdade de Medicina de Ribeirão Preto, Internal Medicine, Ribeirão Preto, Brazil; [2]Faculdade de Medicina de Ribeirão Preto, Physiology, Ribeirão Preto, Brazil

Obesity is associated with peripheral and central low grade inflammation characterized by the increase in pro-inflammatory cytokines, such as tumor necrosis factor alpha (TNF). Phosphodiesterase 4 (PDE4) modulates the inflammatory responses and its inhibitor can strongly reduce TNF release and inflammation. Additionally, PDE4 knockout mice were shown to be resistant to diet-induced obesity (DIO). The aim of this study was to investigate the role of central and peripheral effects of PDE4 in DIO. To attain this purpose, mice treated were treated with rolipram, a PDE4 inhibitor capable of crossing the blood brain barrier, or YM-976, a brain-impermeable inhibitor. All experimental protocols were approved by the Ethics Committee for Animal Use of the Ribeirao Preto Medical School. Male C57Bl6 mice were fed with either chow or high-fat diet (HFD; 60% fat) for 10 weeks and in the 8th week they received daily subcutaneous injections vehicle (VEH), rolipram (2mg/kg) or YM-976 (2mg/kg). During the experimental period, food intake and body weight were monitored and at the end of the study inguinal, retroperitoneal and brown fat pads were collected for analysis. Rolipram decreased the absolute value and change in body weight in the HFD group, which was associated with a decrease in epididymal and retroperitoneal fat pad weight, with no effect in the chow group. Remarkably, rolipram was able to decrease energy intake and energy efficiency, as well as increase energy expenditure in the HFD-treated animals. Consistent with these results, histological analysis showed that rolipram decreased the adipocyte size of inguinal adipose tissue and reduced the whitening of brown adipose tissue in the HFD group. In contrast to rolipram, YM-976 inhibitor was unable to ameliorate the metabolic changes in DIO. These results indicated that mechanisms in the brain are required to the beneficial metabolic effects of PDE4 inhibitors on DIO and reinforce PDE4 as a potential target for the treatment of obesity.

High-fat diet causes transgenerational alteration in the expression of Obesity-related genes in mouse seminal vesicles

Beatriz Rodrigues[1,2], Sara C. Pereira[2,3], Marco Alves[2,3,4], Pedro F. Oliveira[5] & Raquel Bernardino[2,3]
[1]Universidade de Aveiro, Department of Medical Sciences, Aveiro, Portugal; [2]ICBAS, UMIB - Unit for Multidisciplinary Research in Biomedicine, Clinical and Experimental Endocrinology, Porto, Portugal; [3]University of Porto, Laboratory for Integrative and Translational Research in Population Health (ITR), Porto, Portugal; [4]ICBAS - School of Medicine and Biomedical Sciences, Department of Imuno-physiology and Pharmacology, Laboratory of Physiology, Porto, Portugal; [5]University of Aveiro, LAQV-REQUIMTE and Department of Chemistry, Aveiro, Portugal

Obesity incidence is increasing globally at an alarming rate, particularly amongst children and young adults. Male obesity has been linked with a reduction in sperm quality and consequently decreased fertilization rates. Seminal vesicles are considered fundamental for male fertility and though for men's health. Vesicle seminal secretion contributes to a significant volume of seminal fluid, being extremely important for semen coagulation and sperm motility. Recent studies suggest that an obesity-inducing lifestyle combined with genetic changes can cause epigenetic mutations. Obesity-related genes (ORG) have been pointed out as causes for an overweight, suggesting that children born from obese parents could have a genetic predisposition to develop metabolic disorders. This project aimed to unveil molecular mechanisms related with the inheritance of an overweight through seminal vesicles. We hypothesized that ORG, Fat mass and obesity (FTO), Melanocortin-4 receptor (MC4R), Glucosamine-6-phosphate deaminase 2 (GNPDA2), and Transmembrane protein 18 (TMEM18) were present and could have a role in seminal vesicles and consequently in production of seminal fluid over three generations. Samples of seminal vesicle tissue were selected from mice included in the following experimental design: the first generation (F0) was divided into 3 groups ($n = 6$ per group) according to administered diet. Mice are randomly fed after weaning with standard chow (CTRL); HFD for 200 days or transient HFD(HFDt) (60 days of HFD + 140 days of standard chow). Subsequent generations (F1 and F2; 6 mice per generation) are fed with chow diet. Mice are euthanized 200 days post-weaning. RNA was extracted from the seminal vesicles of the 54 animals and used to evaluate the mRNA abundance of MC4R, FTO, GNPDA2 and TMEM18 through quantitative Polymerase Chain Reaction (qPCR) in the 3 groups of the 3 generations of mice. Early results suggest a significative abundance increase in all ORG genes analysed in generation F1 for all diet groups. We observed a tendency to increase the abundance of ORG from the F0 generation to the F1 generation and a further decrease in the F2 generation. Our results suggest that a high-fat diet is capable of causing changes in the expression of ORGs in the seminal vesicles of offspring of parents with poor eating habits. That is, HFD is capable of causing transgenerational damage that may manifest itself in children and grandchildren who may be more predisposed to obesity and possible fertility problems.

Therapy of overweight and obesity resistant to behavioral treatment in the adult population with metabolic comorbidities. A network meta-analysis

Irene Samperi[1], Agnese Persichetti[2], Roberto Attanasio[3], Luca Busetto[4], Michela Cinquini[5], Agostino Paoletta[6], Enrico Papini[7], Roberto Novizio[8], Alessandro Scoppola[9], Roberto Vettor[10] & Marco Chianelli[7]
[1]ASL Novara, Endocrinology, Novara, Italy; [2]IRCCS-Regina Elena National Cancer Institute, Rome, Italy, Service of Pharmacovigilance, Rome, Italy; [3]AME Scientific Committee; [4]University Hospital of Padua, Center for the Study and the Integrated Management of Obesity, Padua, Italy; [5]Laboratory of systematic review methodology and guidelines production, Istituto di Ricerche Farmacologiche Mario Negri IRCCS, Milan, Italy; [6]6ULSS6 Euganea of Padua, Padua, Italy; [7]Regina Apostolorum Hospital, Endocrinology and Metabolism, Albano Laziale, Italy; [8]Fondazione Universitaria Policlinico A. Gemelli, Catholic University of the Sacred Heart, Endocrinology and Metabolism, Rome, Italy; [9]Ospedale Santo Spirito, Endocrinology, Rome, Italy; [10]University of Padua, Department of Medicine, Padua, Italy

Background
Overweight and obesity are an increasing concern for public health worldwide. Obesity is a chronic, progressive and relapsing disease associated with the development of several comorbidities which may improve after weight loss. The first step in the management of weight excess includes life-style modifications but, in the long-term, obesity is frequently resistant to life-style changes only. Surgical procedures and medical treatments have, therefore, been developed for improving the outcomes of this chronic disease.
Aim
Of the study was to identify the best treatment for weight loss, and their timely use, as add-on to lifestyle intervention for adults with resistant overweight and obesity complicated by metabolic comorbidities: pre-diabetes, type 2 diabetes mellitus, hypertension, hyperlipidemia, and non-alcoholic fatty liver disease.
Methods
This systematic review and network meta-analysis (NMA) included searches of Medline/PubMed, Embase and Cochrane Library from inception to May 16, 2022, for randomized controlled trials (RCTs) of weight-lowering drugs that are available in Italy (Naltrexone/Bupropione-N/B, Orlistat, Liraglutide 3 mg/daily, Semaglutide 2.4 mg/weekly) and of bariatric surgery procedures (Sleeve gastrectomy, Roux en Y Gastric Bypass (RYGBP), Gastric Banding, and other

modalities of Gastric Bypass). Target population were adults with overweight or obesity (BMI 27-40 kg/m2) and at least one of the above reported comorbidities. The study was registered with PROSPERO (CRD42022351409). From the retrieved 2928 studies, this NMA included 45 RCTs on pharmacological and 20 RCTs on surgical treatments. Weight loss. As compared with lifestyle intervention, the add-on effect of the different evaluated interventions was (mean, CI 95%):

- Orlistat, -2.93 kg (4.34 lower to 1.52 lower) (mixed evidence, certainty of the evidence moderate)
- Liraglutide, -3.85 kg (6.19 lower to 1.52 lower) (direct evidence, certainty of the evidence high)
- Semaglutide, -9.83 kg (14.12 lower to 5.5 lower) (direct evidence, certainty of the evidence high)
- N/B, -4.5 kg (8.17 lower to 0.84 lower) (mixed evidence, certainty of the evidence moderate)
- Gastric banding, -12.26 kg (15.55 lower to 8.96 lower) (mixed evidence, certainty of the evidence moderate)
- Sleeve gastrectomy, -18.05 kg (21.66 lower to 14.44 lower) (mixed evidence, certainty of the evidence moderate)
- RYGBP, -24.71 kg (27.96 lower to 21.46 lower) (mixed evidence, certainty of the evidence moderate)
- Other gastric bypass, -21.74 kg (26.96 lower to 16.52 lower) (indirect evidence, certainty of the evidence moderate).

Conclusion

This NMA quantifies the effect of drugs and surgical treatments on weight loss that improved outcomes compared to lifestyle changes only. Surgeries were more effective than pharmacological treatments.

The Effect of Foot Care Protocol Applied to Individuals with Type 2 Diabetes on Foot Health Problems and Foot Care Behaviors

Aslı Kahraman[1] & Emine Kir Biçer[2]
[1]Ministry of Health, Hatay Training and Research Hospital, Hatay, Turkey; [2]Hatay Mustafa Kemal University, Demartment of Internel Medical Nursing, Hatay, Turkey

Aim

The research was conducted as a randomized controlled experimental study to determine the foot health status of individuals with type 2 diabetes and the factors affecting them, to use a protocol to protect and improve foot health for individuals with diabetes, and to determine the effects of this protocol on foot health problems (regarding dermatology, orthopedics, circulation, sensory, footwear and self-care skills), foot health knowledge and foot care behaviors.

Materials and Methods

The population of the study consisted of patients with type 2 diabetes who applied to Hatay Training and Research Hospital Endocrinology, Metabolism and Diabetes Polyclinic. A total of 70 individuals with diabetes who met the research criteria were randomized to intervention and control groups at the start of the study. Data were collected using Diabetes Information Form, Foot Examination Form, Foot Care Knowledge Level Form, Nottingham Assessment of Functional Footcare (NAFF) and Foot Care Protocol Satisfaction Level Form. Four interviews were conducted with the intervention group while two were conducted with the control group. In the power analysis performed at the end of the study, the results of the comparisons were computed at 95%, 99% confidence interval, and $P<0.05$, $P<0.01$ significance level.

Results

As a result of the intervention in the study, a statistically significant difference was found between the groups regarding dermatological problems related to the feet, burning sensation in the feet, footwear and problems related to self-care ($P<0.01$). In addition, a statistically significant difference was found in the pretest-posttest scores of the intervention group regarding foot care knowledge level and Nottingham Assessment of Functional Footcare scores ($P<0.01$).

Conclusion

As a result, it was determined that the foot care protocol applied to individuals with type 2 diabetes increased the level of foot care knowledge and consequently reduced foot health problems.

Prevalence and Impact of Diabetes Mellitus in Adult Tuberculosis Patients;A Cross-Sectional Study

Elona Xhardo Hysenbelli[1], Bledar Hysenbelli[2], Dorina Ylli[3] & Genta Smaja[4]
[1]University Hospital "Shefqet Ndroqi", Tirana, Albania, Internal Medicine, Tirana, Albania; [2]University Hospital Center "Mother Teresa", Emergency Medicine, Tirana, Albania; [3]University Hospital Center "Mother Teresa", Endocrinology, Tirana, Albania; [4]University Hospital Center "Mother Teresa", Pulmonary Diseases, Tirana, Albania

Background

Both diabetes mellitus (DM) and tuberculosis (TB) are major public health problems and among the leading causes of morbidity and mortality worldwide. The TB-DM coexistence is known to complicate TB care, control and prevention. Globally, 10.4 million TB cases exists, of them 10 % are linked to DM. People with DM are at four to five times higher risk of getting infected with tuberculosis and evidence show poor TB treatment outcomes. This study purposed to evaluate the impact of diabetes mellitus on treatment outcomes in patients with active tuberculosis.

Materials and methods

A cross-sectional study was conducted in a tertiary health care center in Tirana, Albania. We analyzed the medical records of 140 patients hospitalized during in 2018–2019 with a diagnosis of pulmonary tuberculosis. Study subjects were adult tuberculosis patients hospitalized in our hospital and undergoing antituberculosis treatment. Data from study subjects were obtained by interview method using semistructured questionnaire consisting of socio-demographic and clinical parameters. To determine DM risk factors, one variable and multivariable logistic regression analysis was done with 95% confidence interval and P-value <0.05 considered significant.

Results

Out of 140 patients, the prevalence of DM was found to be 9.3 % ($n=13$) with average glucose values X = 145 mg/dl (min 120 — max 175 mg/dl), SD = 30. No significant differences were found between sex, residence, type and site of TB. Increasing age ($P<0.02$), male sex ($P=0.04$), and clinical manifestations like type of TB ($P=0.82$), multilobe involvement ($P=0.243$), other lung diseases ($P=0.154$) are not significantly associated with DM-TB comorbidity.

Conclusion

The prevalence of DM among TB patients in this study is high. The expanding burden of diabetes is increasing the risk of contracting tuberculosis and has a strong impact on TB treatment outcomes. The results of our study show that patients with TB-DM were at higher risk of treatment failure and mortality compared to those with TB without diabetes. Bidirectional screening for TB and DM along with planning and implementation of preventive and curative strategies will help early detection and prevent complications of comorbidity.

Characteristics of components of metabolic syndrome in patients with diabetic kidney disease depending on the phenotype of latent autoimmune diabetes in adults

Iryna Tsaryk & Nataliia Pashkovska
Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Background

Metabolic syndrome is a cluster of conditions (abdominal obesity, atherogenic dyslipidemia, hypertension, insulin resistance with or without glucose intolerance) that occur together, increasing risk of cardiovascular diseases.

The objective

Of the study was to determine components of metabolic syndrome in patients with diabetic kidney disease (DKD) depending on the phenotype of LADA.

Methods

42 patients with LADA (19 patients with LADA1, 23 with LADA2) and DKD were examined, as well as 25 representatives of the control group. We studied blood pressure indicators, lipid profile, HOMA-IR index and anthropometric indicators: body mass index (BMI), waist circumference (WC) and waist circumference to hip circumference ratio (WC/HC).

Results

Arterial hypertension was found in 73,7% of patients with LADA1 and 78,3% of patients with LADA2 phenotype. HOMA-IR index was higher than normal in 26,3% of LADA1 patients and 91,3% of LADA2; it was increased in patients with LADA2 phenotype by 66.8% compared to control ($P<0.001$) and 2.8 times compared to LADA1 ($P<0.01$). Hypertriglyceridemia was registered in 31.6% patients with LADA1 and 56.5% of LADA2 patients; the indicator was higher by 84% ($P<0,05$) and 48.1% ($P<0,01$) compared to control group level respectively. High-density cholesterol level was abnormal in 26.3% of LADA1 patients and 43.5% of LADA2 patients; it was lower by 19.8% ($P<0.05$) and 43.9% ($P<0.001$) respectively compared to control. Abdominal obesity was registered in 47,8% of patients with LADA2; 42,1% patients with LADA1 and 39,1% with LADA2 have metabolically

unhealthy overweight phenotype. BMI in LADA2 group was 24.4% higher than the control indicator and 22.4% higher than the value in LADA1 group ($P<0.001$). WC was higher by 14.1% comparing LADA1/control ($P<0.05$), by 34.6% comparing LADA2/control ($P<0.001$) and by 18% in LADA2/lADA1 ($P<0.01$). The WC/HC ratio was the highest in the LADA2 group: by 31.3% compared to the control ($P<0.001$) and by 23.9% compared to the LADA1 group ($P<0.01$). In patients with LADA1 moderate positive relationships were found between fasting plasma glucose levels and BMI ($r=0.514$; $P<0.05$), HOMA-IR index and albumin-creatinine ratio ($r=0.479$; $P<0.05$); in LADA2 phenotype – between fasting plasma glucose and systolic blood pressure ($r=0.432$; $P<0.05$); negative correlations of medium strength – between glomerular filtration rate by the formula MDRD and BMI ($r=-0.485$; $P<0.05$) and WC/HC ($r=-0.483$; $P<0.05$).

Conclusion

The degree of insulin resistance, arterial hypertension, dyslipidemia and abdominal obesity as main components of metabolic syndrome significantly increase in patients with LADA2 phenotype which indicates the higher cardiovascular risk in this category of patients.

Prevalence of mutations in cublin-megalin receptor genes in Diabetis Mellitus: Subset analysis of an Indian NGS (Next Generation Sequencing) study

Ramesh Bangaraiahgari[1], Ramakanth Bhargav Panchangam[2], Udaya Kumar N[3], Rajesh Bangaraiahgari[1,4], Sabaretnam Mayilvaganan[5] & Chakrapani Bangaraiahgari[6]

[1]Arundathi Institute of Medical Sciences, Biochemistry, Hyderabad, India; [2]Bhargav Endocrine Hospital, Endocrine and Metabolic Surgery, India; [3]AIMS, Pediatrics; [4], Anatomy; [5]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Endocrine and Metabolic Surgery, India; [6]Chakri Neuro Hospital, Neurology, India

Background

Diabetes mellitus (DM) is the commonest endocrinopathy, Worldwide. Amongst the protean complex genetic variations, cubulin gene and megalin gene mutations in diabetes are important in dictating genotype-phenotypic correlations and natural clinical course of diabetes. The genetic studies in this area are especially very sparse from Indian sub-continent. In this context, we analyzed the prevalence of cubulin (CBN) and megalin (LRP2) gene mutations, as part of NGS (Next-generations sequencing) in diabetes patient's visavis controls.

Methods

This is inter-disciplinary case control study conducted by collaboration between biochemistry department of a teaching medical institute, a tertiary care endocrinology hospital, and genetics lab. Institutional ethical committee approval was obtained. In this prospective study, CUBN gene polymorphisms and megalin (LRP2) gene polymorphisms in subjects with type 2 diabetes mellitus using real-time PCR and ThyroSeq v2 on the Ion Torrent PGM sequencer was employed. Mutations were also manually checked using the Integrated Genomics Viewer v2.4.10 to filter out false positives.

Results

The percentages of AA, AG and GG in cases were 12.5, 62.5 and 25 while in controls it was 70, 20 and 10 respectively. The allele frequencies of A and G alleles in patients are 0.44 and 0.56, while in controls were 0.80 and 0.20 correspondingly. The percentages of CC, CT and TT in cases were 47.5, 50 and 2.5 while in controls it was 60, 30 and 10 respectively. The allele frequencies of A and G alleles in patients are 0.73 and 0.27 while in controls were 0.75 and 0.25 correspondingly. The difference was statistically significant (P -value <0.05) for CUBN gene and non-significant for LRP2 gene.

Conclusions

The rs622342 polymorphism of SLC22A1 appears to be the commonest mutation in South Indian T2DM patients. Cubulin gene mutation was significantly and megalin gene was insignificantly associated with DM. However, it needs validation in larger cohort studies through assessing the additional variants of SLC22A1 gene at the mRNA levels. NGS helps in patient management, providing risk stratification and sub-classification of DM.

Changes in Glycemic Risk Index (GRI) and its Association with other Continuous Glucose Monitoring (CGM) Metrics after Automated Insulin Delivery System Initiation in Adults with Type 1 Diabetes

Halis Akturk[1], Kagan Karakus[2], David Klonoff[3,4] & Viral Shah[1]

[1]Barbara Davis Center, Aurora, United States; [2]Koc University, Istanbul, Turkey; [3]Diabetes Technology Society, San Francisco, United States; [4]Diabetes Research Institute, San Francisco, United States

Objective

To evaluate the GRI and its association with other CGM metrics after initiation of automated insulin delivery (AID) system in adults with type 1 diabetes (awT1D).

Methods

Up to 90 days of CGM data before and after initiation of an AID system from 185 awT1D were collected. GRI with hypoglycemia and hyperglycemia components and other CGM metrics were calculated using cgmanalysis R software and analyzed for 24-hour, nighttime, and daytime. GRI values were assigned to 5 GRI zones as zone A (0-20), zone B (21-40), zone C (41-60), zone D (61-80), zone E (81-100).

Results

After AID initiation, GRI, its two components and other CGM metrics improved significantly (Table-1). The percentage of people in each zone changed as follows: A: 10.8% to 24.7%; B: 23.8% to 58.4%; C: 36.2% to 15.1%, D: 20.5% to 0.5%, and E: 8.7% to 0%. GRI was correlated with time between 181-250 mg/dl before ($r=0.691$, $P<0.001$) and after ($r=0.818$, $P<0.001$) and time above 250 mg/dl before ($r=0.925$, $P<0.001$) and after ($r=0.920$, $P<0.001$). GRI was not correlated with time between 54-70 mg/dl before ($r=-0.029$, $P=0.698$) and after ($r=0.038$, $P=0.611$), and with time below 54 mg/dl before ($r=0.123$, $P=0.096$) and after ($r=0.140$, $P=0.058$). Improvement in nighttime, compared to daytime, was superior; as seen in increased TIR and decreased GRI ($P<0.001$ for both). GRI improved by 19.7 percentiles and TIR improved by 14.6 percent.

Conclusion

GRI was highly correlated with various CGM metrics above (but not below) target range, both before and after AID initiation. Improvement in GRI was greater than improvement in TIR, and both were significant, GRI, compared to TIR, was a better indicator for improved glycemia after AID initiation.

Table 1 Comparison of CGM metrics before and after AID initiation, n=185

	Before AID Initiation	After AID Initiation	P value

Vitamin D deficiency and gestational diabetes

Edward Jude, Navin Sugathan & Susan Mathew

Tameside and Glossop Integrated Care NHS Foundation Trust, Ashton under Lyne, United Kingdom

Introduction

Vitamin D deficiency is known to cause adverse outcomes in pregnancy and has shown to have an association with Gestational Diabetes Mellitus (GDM)

Aim

To evaluate the relationship between GDM and Vitamin D

Materials and Methods

In a retrospective study we explored the Vitamin D levels (Sufficient >50nmol/l - G1, Insufficient 25-50nmol/l - G2, Deficient <25nmol/l - G3), GTT results, diabetes status and pregnancy outcomes of 250 pregnant women of multiple ethnicities who attended the antenatal clinic between 2018 and 2022. Blood tests and glucose tolerance tests (GTT) were performed at 26-28 weeks of pregnancy. All patients were on Pregnacare (multivitamin tablets including Vitamin D 400IU from booking).

Results

Mean Vitamin D in G1 was 64.13 ±10.27 nmol/l, in G2 was 38.39 ± 7.26 nmol/l and in G3 was 20.15 ± 3.37 nmol/l. The mean fasting sugar in G1 was

5.00 ± 0.70 nmol/l, G2 was 5.13 ± 0.82 mmol and G3 was 5.73±1.24 mmol; $P=0.003$ for G3 vs G2 +G1, $P=0.005$ for G3 vs G2. Caucasian group had a mean Vitamin D of 45.15 ±16.75 nmol/l and in South Asian (SA) group 41.17± 18.03 nmol/l. GTT in the two groups were: 0 min –5.05 ± 0.82 mmol and 5.28 ± 0.92 mmol ($P=0.05$), and GTT 2 h –7.03 ± 2.20 mmol and 8.11 ± 2.17 mmol ($P=0.0007$) respectively. Mean BMI in Caucasian and SA group was 31.24 ± 7.25 and 28.64 ± 5.08 ($P=0.01$) and baby birth weight was 3.30 ± 0.48 kg and 3.05 ± 0.60 kg ($P=0.004$), respectively.

Conclusion

Pregnant women with low Vitamin D were found to have elevated fasting sugars irrespective of the ethnicity and South Asians are more prone to have GDM. Caucasians had higher BMI and larger babies.

Sex-driven factors associated with anxiety and depression in Type 1 Diabetes Mellitus (T1DM) and Latent Autoimmune Diabetes in Adults (LADA)

Enrico Saudelli[1,2], Simona Moscatiello[1], Michele Baldari[1,2], Claudio Bongiorno[1,2], Stefano Zucchini[3], Giulio Maltoni[3], Alessandro Agostini[4], Danilo Ribichini[1], Alessia Bruco[1,2], Valentina Lo Preiato[1], Gilberto Laffi[1], Uberto Pagotto[1,2] & Guido Di Dalmazi[1,2]

[1]S. Orsola-Malpighi Polyclinic, Division of Endocrinology and Diabetes Prevention and Care, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [2]S. Orsola-Malpighi Polyclinic, Department of Medical and Surgical Sciences (DIMEC), Alma Mater Studiorum University of Bologna, Bologna, Italy; [3]S. Orsola-Malpighi Polyclinic, Pediatric Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [4]Alma Mater Studiorum - Università di Bologna, Department of Experimental, Diagnostic and Specialty Medicine (DIMES), Alma Mater Studiorum University of Bologna, Bologna, Italy

Aim

To analyze the prevalence of anxiety and depression in a large cohort of adults affected by autoimmune diabetes and to identify the associated factors, stratifying them according to sex.

Methods

We administered to 553 patients with autoimmune diabetes the questionnaires: Hospital Anxiety and Depression Scale (HADS), Diabetes Distress Scale, Diabetes-related Quality of Life and Diabetes Treatment Satisfaction Questionnaire. We excluded 119 patients with missing HbA1c ±4 months from HADS administration or incorrect HADS compilation (final cohort, $n=434$).

Results

Anxiety was reported in 132/434 subjects (30.4%), depression in 47/434 (10.8%). The group with anxiety had a larger proportion of females, higher HbA1c (median 56 mmol/mol [IQR 49-63] *vs* 59 [IQR 52-66]; $P=0.006$), higher average HbA1c in the previous 36 months (56 mmol/mol [IQR 50-63] *vs* 59 [IQR 54-66]; $P=0.002$), more individuals with HbA1c >48 mmol/mol (76.8% *vs* 90.2%; $P=0.001$), more CGM users (61.3% *vs* 71.2%; $P=0.046$) and lower Time in Range (60.1% *vs* 54.8%; $P=0.043$). The group with depression showed higher median age (47 years [IQR 33-59] *vs* 53 [IQR 42-59]; $P=0.015$) and superior prevalence of cardiovascular diseases (3.1% *vs* 12.8%; $P=0.002$) and retinopathy (31% *vs* 46.8%; $P=0.029$). There was greater emotional distress, and lower quality of life and treatment satisfaction (P equal or inferior to 0.005, for all), irrespective of sex. In females, CGM use was and independent risk factor for anxiety and older age for depression; in males elevated levels of Hb1Ac (a worse glycemic control) were an independent risk factor for both anxiety and depression. No differences in CGM-derived metrics were observed stratifying results by sex.

Conclusion

Nearly 1/3 of the patients with autoimmune diabetes suffers from anxiety and nearly 1/10 from depression. These conditions are associated with independent modifiable and non-modifiable characteristics, which are different between females and males.

Maharashtra, Pune, India; [7]MGM Medical College Mumbai, Mumbai, India; [8]Rajiv Gandhi Medical College, Thane, Maharashtra, Mumbai, India

Introduction

US Food and Drug Administration (FDA) has recently approved bexagliflozin, a new SGLT2 inhibitor. We examined the outcomes and metabolic effects of Bexagliflozin across the published Randomised Controlled Trials (RCCTs)

Methods

A comprehensive literature search was done to extract publications from Medline-PubMed and Cochrane library, since inception till January 20, 2023, then screened and reviewed by two independent reviewers. Data including, study title, year of publication, name of the journal, study design, and the evaluated outcomes were charted for evidence synthesis. Scoping review was performed according to PRISMA-SR checklist. We included only the RCCTs for evaluation.

Results

We analysed 12 publications, and evaluated five RCCTs, with 1704 T2DM cumulatively contributing to the evidence base for Bexagliflozin. The mean duration of the trials (weeks) was 50(±42, minimum 12, maximum 96, 95% CI -1.6 to 102). The mean number of T2DM evaluated across RCCTs were 341(±62, minimum 288, maximum 426, 95% CI 264 to 418). Each of the RCCT has been distinct from each other for comparison with glimepiride, dose finding study, evaluation as monotherapy, comparison with sitagliptin and evaluation in patients with CKD stage 3a or 3b. The findings include, that bexagliflozin was noninferior to glimepiride in lowering HbA1c, was superior to glimepiride for decreases in body mass and SBP, and was associated with significantly fewer hypoglycaemic events than glimepiride; bexagliflozin confers substantial and dose-dependent benefits, is non-inferior to sitagliptin and provides benefits over sitagliptin in FPG and body mass. The results support the usage in patients with CKD stage 3a/3b CKD. The initial results of the Bexagliflozin Efficacy and Safety Trial (BEST) support the benefits in patients with high cardiovascular risk

Conclusions

The synthesis of the evidence from our analysis reflects that bexagliflozin has durable, clinically meaningful improvement in glycaemic control.

Non Interventional Weight Changes are Associated with Alterations in Lipid Profile and in Trigycerides to Hdl-Cholesterol Ratio

Shiri Weinstein[1,2], Elad Maor[2,3], Alon Kaplan[1,2], Avshalom Leibowitz[1,2], Ehud Grossman[1,2] & Gadi Shlomai[1,2,4]

[1]The Chaim Sheba Medical Center, Department of Internal Medicine D and Hypertension Unit, Ramat Gan, Israel; [2]Tel-Aviv University, Sackler School of Medicine, Tel Aviv, Israel; [3]The Chaim Sheba Medical Center, Leviev Heart Center, Ramat Gan, Israel; [4]The Chaim Sheba Medical Center, The Institute of Endocrinology, Diabetes and Metabolism, Ramat Gan, Israel

Background and aims

Obesity is associated with dyslipidemia through insulin resistance and adipokines secretion, and weight loss can improve obese patients' lipid profile. Here we aimed to assess whether non interventional weight changes are associated with alterations in the lipid profile, particularly the triglycerides (TG) to high density lipoprotein (HDL) cholesterol ratio (TG/HDL) which is an emerging marker for insulin resistance, the metabolic syndrome and an elevated risk for coronary artery disease.

Methods

This is a retrospective analysis of subjects referred to annual medical screening. BMI, low density lipoprotein (LDL)- cholesterol, TG and HDL levels were measured annually. Patients were divided according to the change in BMI between visits: reduction of > 5% ("large reduction"), reduction of 2.5-5% ("moderate reduction"), reduction of <2.5% or elevation of <2.5% ("unchanged"), elevation of 2.5-5% ("moderate increase") and elevation of >

5% ("large increase"). The primary outcomes were the change in LDL, TG, HDL and TG/HDLbetween visits.
Results
The final analysis included 18,828 subjects. Mean changes in LDL (mg/dl), TG (mg/dl), HDL (mg/dl) and TG/HDL (%) were associated with BMI changes and were -3.89, -11.00, +5.76, -13.20 for "large reduction" BMI group, -0.96, -0.91, +2.99, -1.71 for "moderate reduction" BMI group, +1.30, +5.36, +1.93, +5.26 for "unchanged" BMI group, +2.91, +12.50, +1.30, +13.00 for "moderate increase" BMI group, and +3.91, +17.70, +0.43, +19.70 for "large increase" BMI group, respectively ($P > .01$). The proportion of patients with > 10% rise in TG/HDL progressively increased with the relative change in BMI (20.6%, 30.2%, 37.5%, 46.2%, and 50.2% for "large reduction", "moderate reduction", "unchanged", "moderate increase", and "large increase" groups, respectively, $P > .01$). Compared to the "unchanged" group, the odds ratio for TG/HDL rise of > 10% was 0.43, 0.72, 1.43 and 1.68 for "large reduction", "moderate reduction", "moderate increase", and "large increase" groups, respectively ($P > .01$). Subgroups analysis by gender, initial TG/HDL and initial BMI revealed that the trends of TG/HDL change by BMI did not change significantly, albeit the association of TG/HDL by BMI was mildly mitigated in females.
Conclusions
Non-interventional weight changes, even modest, are associated with alterations in lipid profile.

Loss of visceral adipose tissue may lead to a shortened aortomesenteric distance in congenital generalized lipodystrophy

Mehmet Çağrı Ünal[1], Furkan Uncuoğlu[2], Gökçen Güngör Semiz[1], Mehmet Emin Arayici[3], Serkan Yener[1], Canan Altay[2] & Barış Akıncı[1]
[1]Dokuz Eylul University, Endocrinology and Metabolism, Izmir, Turkey; [2]Dokuz Eylul University, Radiology, izmir, Turkey; [3]Dokuz Eylul University, Department of Preventive Oncology, Izmir, Turkey

Introduction
Superior mesenteric artery (SMA) syndrome is a rare cause of abdominal pain due to proximal intestinal obstruction which is characterized by compression of the third portion of the duodenum secondary to the narrowing of the space between the superior mesenteric artery and aorta. The development of the SMA syndrome is primarily attributed to the loss of the intervening mesenteric fat. Lipodystrophy is a rare clinical syndrome characterized by the loss of adipose tissue that can affect the amount of visceral and mesenteric fat.
Method
We measured aortomesenteric distance (AOM) in patients with various forms of lipodystrophy. Sixty patients with lipodystrophy (11 males; 49 females; mean age 38 ± 13 years; 20 congenital generalized lipodystrophy, 30 familial partial lipodystrophy, and 10 acquired partial lipodystrophy) were included. An age-, gender- and BMI-matched control group (1:2) was generated from a cohort of subjects with hormone inactive adrenal incidentalomas. The AOM distance was measured on MR images.
Results
Median AOM distance was 10.8 mm (25-75 percentiles: 7.1-16.1 mm) in patients with lipodystrophy and 11.0 mm (25-75 percentiles: 8.0-15.5 mm) in the control group ($P=0.311$). Patients with congenital generalized lipodystrophy had lower AOM distance (8.2 mm [25-75 percentiles: 6.0-12.4 mm]; $P=0.024$) compared to controls and patients with familial partial lipodystrophy (vs. 12.4 mm [25-75 percentiles: 7.2-18.0 mm]; $P=0.059$). Twelve of 20 patients (60%) with congenital generalized lipodystrophy had an AOM distance of less than 10 mm, a risk factor that may predispose patients to develop SMA syndrome. Body mass index was positively correlated with AOM distance, both in the overall sample ($r=0.397$, $P<0.001$) and in patients with lipodystrophy ($r=0.485$, $P<0.001$). BMI was found to be a significant predictor of AOM distance in multivariate linear regression analysis including age, sex, and BMI ($r^2= 0.27$, $P<0.001$).
Conclusion
Visceral fat loss in lipodystrophy syndromes may pose a risk to SMA syndrome that is likely to only affect patients with generalized lipodystrophy. Abdominal pain is a common symptom in lipodystrophy mostly attributed to episodes of acute pancreatitis secondary to severely elevated triglycerides. SMA syndrome should be kept in mind in patients with generalized lipodystrophy who presented with abdominal pain, nausea, and vomiting, especially when the initial workup does not support a diagnosis of acute pancreatitis.

High-fat diet promotes 3'mt-tiRNA-Met epididymosome enrichment which correlates to lower spermatozoa mitochondrial translation

Sara C. Pereira[1,2,3,4,5], Laís Freire-Brito[1,2], Bárbara Guerra-Carvalho[1,2,3,4,5], David F. Carrageta[1,2,5], Raquel Bernardino[1,2], Luís Crisóstomo[6], Simona Terzo[7], Mariana P. Monteiro[1,2], Pedro F. Oliveira[3], Mario Allegra[7] & Marco Alves[1,2,5]
[1]School of Medicine and Biomedical Sciences (ICBAS), University of Porto, 4050-313 Porto, Portugal, Endocrine and Metabolic Research, Unit for Multidisciplinary Research in Biomedicine, Porto, Portugal; [2]University of Porto, Laboratory for Integrative and Translational Research in Population Health (ITR), Porto, Portugal; [3]University of Aveiro, LAQV-REQUIMTE and Department of Chemistry, Aveiro, Portugal; [4]Faculty of Medicine, University of Porto, Department of Pathology, Porto, Portugal; [5]School of Medicine and Biomedical Sciences (ICBAS), University of Porto, Laboratory of Physiology, Department of Imuno-Physiology and Pharmacology, Porto, Portugal; [6]Institute of Biomedicine, University of Turku, Turku, Finland; [7]University of Palermo, Department of Pharmaceutical, Toxicological and Biological Chemistry, Palermo, Italy

Metabolic and endocrine dysregulation induced by high-fat diet (HFD) can lead to decreased male fertility potential and have a negative impact on the offspring's metabolic health. Small non-coding RNAs (sncRNAs) were proposed as being potential mediators of metabolic queues across transgenerational inheritance. During development and epidydimal transit, spermatozoa become enriched with tRNA-derived stress-induced RNAs (tiRNAs). This sncRNAs class appears to be particularly important for sperm quality and embryo development, through processes that are now starting to be unveiled. Herein, we hypothesized that mitochondrial tiRNAs (mt-tiRNAs) are integrated into the spermatozoa through epididymosomes. Further, we propose that HFD can alter the mt-tiRNAs carried by epididymosomes, which can then impact sperm quality. To test our hypothesis, 4-week-old male C57BL mice were fed *ad libitum* with an HFD or standard diet (control) for 14 weeks. Size characterization showed no significant difference between epididymosomes vesicle size from the two groups, although the HFD group presented a tendency for a greater epididymosome concentration (nearly 2-fold). We also found an increased abundance of 3'mt-tiRNA^{Met} in epididymosomes from the HFD group. Under stressful conditions, tiRNAs expression often becomes upregulated at different somatic cell lines. Additionally, higher tiRNAs expression is usually correlated to decreased translation. To explore spermatozoa mitochondrial translation function, we assessed mitochondrial 12S rRNA abundance. HFD mice presented lower 12S rRNA levels on spermatozoa, as well as higher 3'mt-tiRNA^{Met} levels on epididymosomes when compared to the control group. A positive correlation between spermatozoa 12S rRNA expression levels and normal sperm morphology was also found. Concurrently, higher 12S rRNA expression levels were negatively correlated with spermatozoa tail defects. Our results suggest that mt-tiRNAs have an important role in spermatozoa HFD-induced stress (dys)regulation. Most particularly 3'mt-tiRNA^{Met}, expressed by the epididymis, carried by epididymosomes, and integrated into the spermatozoa, might take part in the molecular mechanisms by which the HFD induces deleterious effects on sperm quality with a potential negative impact on male fertility.

Obesity in pediatric patients with Bardet - Biedl Syndrome – diagnostic hint and therapeutic challenge

Maria Nowak[1], Michał Ciołek[2], Maria Szczepańska[3], Agnieszka Tomaszewska[4], Friedhelm Hildebrandt[5] & Agnieszka Zachurzok[3]
[1]Medical University of Silesia, Students' Scientific Association at the Department of Pediatrics, Zabrze, Poland; [2]Medical University of Silesia, Students' Scientific Association at the Department of Psychiatry and Psychotherapy of Developmental Age; [3]Medical University of Silesia in Katowice, Department of Pediatrics, Faculty of Medical Sciences, Zabrze, Poland; [4]Prenatal Diagnostics and Genetic Clinic, Public Hospital No.1, Zabrze, Poland; [5]Harvard Medical School, Boston Children's Hospital, Division of Nephrology, Boston, United States

Introduction
Bardet-Biedl Syndrome (BBS) is an autosomal recessive disease and one of the most common causes of syndromic obesity. An excessive weight usually appears at an early age and affects almost 90% of patients. Mutations in BBS genes have been found to disrupt the function of the cilia, leading to disturbances of transduction satiety and hunger signals in hypothalamus and increased adipogenesis in the fat tissue.

Methods
We present a case series of eight pediatric patients (P1 to P8) with BBS (six boys and two girls) observed in one Medical Centre including two pairs of siblings.
Results
The age range at the moment of diagnosis was 1 month to 4 years (average 20 months). At presentation obesity was present only in four patients, whereas polydactyly and urinary system disorders was observed in six patients, psychomotor development delay in two patients. In two patients with kidney disorders and polydactyly, the genetic tests were ordered at the age of 2 and 6 months due to having ab older sibling with the diagnosis of BBS. Their weight-for-length z-scores at the age of one year were above 3.0 (P3 = 3.1, P5 = 3.7). The mutations in the following genes were confirmed: BBS10 (1), MKKS (P2, P3 – sibling, the same mutations), BBS7/BBS10 (P4, P5 - sibling, the same mutations), BBS7 (P6, P7, different mutations), BBS9 (P8). The duration of the follow up varied between 6 months to 9 years. All patients' parents received diet training and lifestyle intervention at every office visit. During follow up seven out of eight patients developed obesity at some point. Only P7 had never developed excessive weight (the highest BMI z-score 0.55). In six patients an excessive increase of body weight was observed, only in one case BMI z-score decreased (P8) and in another one remained stable during observation (P7). In P1 the obesity class 3 (BMI z-score 4.37) was diagnosed with multiple metabolic disorders (MAFLD, hypertension, insulin resistance, dyslipidemia). In the other one patient hypertriglyceridemia with increased LDL-cholesterol was found and in another three – isolated hypertriglyceridemia was present.
Conclusion
Obesity is one of the main therapeutic challenges while handling patients with BBS, even though it is not often the reason for starting diagnostics for this disease. It is necessary to bring awareness about this syndrome among pediatricians in order to allow for earlier diagnosis and ensure patients' better prognosis.

P353

Real-life outcomes of semaglutide therapy for weight loss

Ploutarchos Tzoulis[1,2]
[1]EBCED, Evidence-Based Care in Endocrinology & Diabetes, Marousi, Greece; [2]University College London, Department of Experimental and Translational Medicine, London, United Kingdom

Background
Obesity, a chronic relapsing disease, has become a global public health challenge**.** Semaglutide, a weekly glucagon-like peptide-1 (GLP-1) agonist which has shown unprecedentedly high efficacy in randomised controlled trials, was recently approved in Europe for weight loss. There is paucity of real-life data about its effectiveness and safety for weight management.
Methods
Our aim was to evaluate the changes in weight and metabolic parameters as well as the side effects of semaglutide use for weight management in a real-life clinical setting. Retrospective review of data on off-label semaglutide use in a weight management clinic in Athens, Greece, for adults with body mass index (BMI) > 30 kg/square meter with at least 3-month follow-up. Patients with diabetes mellitus were excluded. All patients received standard advice about reducing calorie intake and regular physical activity.
Results
Real-world data analysis included 25 patients (19 females, 6 males) with median age 46 years, weight 106.9 kg and BMI 38. Amongst those, eight patients had BMI 30-35, six 35-40, five 45-50, and six > 45. Four individuals had undergone bariatric operation in the past, while four had received medications for obesity. The most common weight-related comorbidities were dyslipidaemia (19/25), prediabetes (15/25), non-alcoholic fatty liver disease (12/25), obstructive sleep apnoea (5/25), depression (5/25) and hypertension (4/25). The median 12-week percentage weight loss was 7.1%, with 72% and 12% of patients achieving > 5% and > 10% weight loss, respectively. The median 24-week percentage weight loss was 13.5% with loss exceeding 5% and 10% of the baseline weight in 87% and 68% of cases, respectively. At week 24, half patients received weekly semaglutide dose of 2.0 mg and the remaining 1.0 mg due to cost reasons. The median percentage weight loss was similar, 12.7% for 2.0 mg and 13.8% for 1.0 mg dose. After 24-week semaglutide therapy, median fasting glucose decreased from a median baseline of 5.7 mmol/l to 5.0 mmol/l. The discontinuation rate was 5%, with only one case of semaglutide withdrawal due to protracted vomiting, while pancreatitis and gallbladder disease were excluded. All other patients had no or minor gastrointestinal symptoms.
Discussion
Real-world data confirm the effectiveness and safety of semaglutide for weight management. Semaglutide could herald a new era in the treatment of obesity, provided public funding ensures wide patient access. This case series reports great potency of semaglutide at the lower dose of 1.0 mg which needs to be explored further.

P354

Chronic inflammation linked to obesity has a negative impact on serum glycated albumin levels, but not glycated hemoglobin levels

Subhash Kumar[1] & Surendra Prasad Singh[2]
[1]Diabetes & Obesity Care Center, Patna, India; [2]Patna Medical College Hospital, Patna, India

Background
Glycated albumin (GA) and glycated haemoglobin (HbA1c) measurements have been used to track the long-term glycemic management of diabetic patients. Other than glycemia, there are known influences on both glycated proteins. In obese, non-diabetic children, GA levels have been found to be low, while in adult diabetic patients, GA levels have been found to be adversely correlated with body mass index (BMI). The causes of the link between obesity and GA are still unknown, though.
Objectives
This research aimed to see if GA and HbA1c were independently correlated with BMI and the inflammation-related inflammatory marker plasma high-sensitivity C-reactive protein (hs-CRP), which is related to obesity.
Material and Methods
This study included 215 non-diabetic participants, of which 150 had normal glucose tolerance and 65 had impaired glucose tolerance. Age, BMI, 2-hour glucose, fasting plasma glucose (FPG), oral glucose tolerance test (OGTT), and hs-CRP impacts on HbA1c and GA were examined. Unpaired Student's t tests or Fisher's exact tests, if applicable, were utilised in statistical analyses to compare two groups. With the help of the StatView software, stepwise multivariate regression analysis as well as univariate regression analysis were carried out to examine the impact of explanatory variables on HbA1c, GA, and the GA to HbA1c ratio (for correction). The F-value for the variables' inclusion in the stepwise multiple regression analysis was set at 2.0, and a P value of less than 0.04 was regarded as statistically significant.
Results
Significant correlations were found between FPG and HbA1c as well as between GA and FPG. While BMI and HbA1c exhibited a substantial positive connection, GA and BMI showed a negative correlation. Plasma hs-CRP was inversely correlated with GA while weakly positively correlated with HbA1c. BMI and hs-CRP were found to be negatively linked with GA but not with HbA1c by stepwise multivariate regression analysis.
Conclusion
This research indicate that in nondiabetic patients, BMI and hs-CRP were independent unfavorable hazards for GA but not for HbA1c. Lower blood GA levels in proportion to glycemia are caused by obesity and the associated chronic inflammation, but not by HbA1c levels.

What role does the Very Low-Calorie Ketogenic Diet (VLCKD) in obesity-related kidney complications?

Ludovica Verde[1], Annamaria Docimo[2], Giovanni Chirico[2], Nicola Tecce[2], Annamaria Colao[2], Luigi Barrea[3] & Giovanna Muscogiuri[2]
[1]Federico II University, Public Health, Naples, Italy; [2]Federico II University, Clinical Medicine and Surgery, Endocrinology, Diabetology and Andrology Unit, Naples, Italy; [3]Pegaso Telematic University, Naples, Italy

Background
Obesity can damage kidney via directly, through the production of pro-inflammatory adipocytokines, and indirectly due to systemic complications. Several strategies are available for weight loss (lifestyle, anti-obesity drugs and surgery therapy), but there are no guidelines to manage subjects with obesity and chronic kidney disease. Very low-calorie ketogenic diet (VLCKD) is an increasingly used tool for weight loss in subjects with obesity. Thus, we aimed to investigate the effects of VLCKD on subjects with obesity and mild kidney failure (MKF).
Methods
A cross-sectional study was conducted on 92 subjects with obesity (35.85 $\pm$ 4.61 kg/m^2; 27M/65F aged 52.03 $\pm$ 11.41 years) that underwent to a VLCKD. Anthropometric parameters and biochemistry data were collected before and at the end of active phase of VLCKD. Glomerular Filtration Rate (GFR) was calculated with the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation. Forty-nine subjects had MKF (GFR 60-89 ml/min/1.73m^2) and 43 had

normal kidney function (NKF) (GFR≥90 ml/min/1.73m^2) and were therefore designated as control.

Results

In the entire study population, the average weight loss was -10.67 ± 4.29 % of initial weight, with significant reductions in BMI (from 35.85 ± 4.61 to 32.50 ± 4.35 kg/m^2, $P<0.001$) and waist circumference (from 107.01 ± 11.32 to 99.98 ± 11.42 cm, $P<0.001$) at the end of the active phase of VLCKD. We also reported an improvement of several metabolic parameters: fasting blood glucose, insulin, HOMA-IR, total cholesterol, LDL and triglycerides ($P<0.001$ for all). No clinically relevant variation regarding liver and kidney function were detected. Of note, at the end of the active phase of VLCKD we found out significant reduction of GFR in subjects with NKF (from 104.53 ± 7.30 to 100.76 ± 11.39 ml/min/1.73m^2; $P=0.031$) while a significant increase in subjects with MKF (from 79.33 ± 7.82 to 84.61 ± 11.65 ml/min/1.73m^2; $P=0.001$). Finally, 30.6% of patients with MKF reported normalization of glomerular filtrate after the VLCKD.

Conclusion

Obesity can damage the kidney through alterations in the hemodynamics resulting in glomerular hyperfiltration, proteinuria and, finally, impairment of the GFR. VLCKD on the one hand reduced glomerular hyperfiltration in subjects with obesity with still NKF, and on the other hand improved filtration in those subjects who have already suffered a reduction in GFR. Consequently, VLCKD is a safe and effective tool for obesity-related kidney complications.

Managing stigma of Adolescents Diabetes in developing nations

S Pal & T Roy
SFCCP, Med, Meerut, India

Issues

Adolescent diabetes social stigma in India. Such diabetics needs proper guidance/information/treatment-counselling outlets. This is burning issue in developing-nations like India. Hence we all need to unite & form a comprehensive diabetes care & counselling policy plan at ECE conference. Treatment options must be suitable for developing-nations considering cost of Rx. Incorporating NGO's in such efforts is very effective.

Our Project Methodology

This is a policy paper. Our 10 year-old-NGO started Diabetes education-project in rural India from 2014. we started s education & surveillance project to analyze social & anthropological issues facing those affected by adolescent diabetes. Total 162 adolescents subjects enrolled by Feedback questionnaires to get their feedback on special needs, perceptions, social attitude on diagnosis of diabetes. Factors like community-inhibition, social-ostracism, economic-difficulties, marital discord, non-availability of treatment-guidance centres, lack of trained-staff analysed & draft policy is recommended to Govt-agencies.

Lessons learned

Adolescent diabetes management must include care of nursing & psycho-social needs. Here role of NGO's in diabetes education is very effective in terms of cost-management, better impact & better-compliance of young diabetics. Community mass intervention projects has proven useful in rural communities of resource poor-nations. ECE participants can collaborate with NGO-activists to address this issue. Uniform public health policy needed to implement & expand newer strategies to include broader range of diabetes care-issues.

Recommendations

Promoting dialogue between Government-health-services & NGO's accelerates diabetes education/awareness programs. NGO participation improves cost-efficacy of such initiatives in economically poor populations. This would reduce difficulties faced by young diabetics from Asian countries. It is essential that WHO/ESE makes common guideline manual on this issue affecting developing-countries. We graphically present our NGO's project on diabetes patients education project in four phases to ECE participants.

Assessment of Western dietary patterns in Georgian population with prediabetes

Nino Gvajaia, Nana Kvinikadze, Elene Pestvenidze & Mariam Tkeshelashvili
Tbilisi State Medical University, American MD Program, Tbilisi, Georgia

A Western dietary pattern, characterized by high consumption of red and processed meat, soft drinks, refined grains, fats and sweets, has frequently been associated with an increased disease risk. However, the distinct association between the nutritional habits and prediabetes has only been scarcely investigated in Western populations. The aim of this study is to underline the relationship and suggest the possible causality between the two. We conducted descriptive survey and formulated specific questionnaire with which we collected the responses of 160 participants BMIs of participants are as follows: 15-18 are 6%; 19-25 are 42%; 26-30 are 22.7%; 30+ are 29.3%. Out of 160 participants 25% eat processed meat twice a week, 14.3% - once a week, 16.25% rarely, 3.12% never, 15.62% every day and 25.62% every other day. 21.9% of the participants consume dairy products everyday, 21.2% every other day, 38.4% twice a week, 8.6% once a week and 7.9% seldom, 2% - never. Regarding seafood 62.3% consumes less than one portion (100-150 grams) during the week, 23.2% consumes 1 portion, 11.3% 2 portions, 2% 3 portions and the remainder 2% more than 3 portions.4.6% of participants consume junk food every day, 25.8% every other, 29.8 % once a week, 8.6% more than once in a month, 18.5% once in a month and 12.6% don't consume at all. About the fruit consumption 31.8% of the participants consume fruit everyday, 32.5% every other day, 17.9% twice a week, 9.3% once a week and 8.6 % seldom. As for portions (200 grams) of vegetables consumed in a day, 9.9% consume more than two portions of vegetables 16.6% 2 portions of vegetables, 38.4% consume one portion, and the remainder 35.1% consume less than one portion of vegetables. 41.7% state that they consume carbonated drinks often; 34.4% consume sometimes, 19.2% consume seldom, and 4.6% never. As for the desserts/pastries, 41.7% of participants consume it every day, 34.4% every other day, 11.3% consume twice a week, 6.6% - once in a week and 6% consume desserts seldom. Given results are suggestive that western dietary patterns (heavily carbonated drinks, processed meats, increased carbohydrates and fats) increase the likelihood of the development of prediabetes.

Vitamin B12, lipid profile and peripheral diabetic neuropathy in type 2 diabetic patients on Metformin: any association?

Meriem Adel[1], Manel Jemel[1], Radhouen Gharbi[1], Asma Kardi[1], Brahim Khalfa[2], Hajer Kandara[1], Ines Kammoun[1], Rahma Mahjoub[2] & Emna Talbi[2]
[1]Nutrition, Endocrinology, Tunis, Tunisia; [2]Nutrition, Biochemistry, Tunis, Tunisia

Introduction

Several studies have evaluated the prevalence and impact of metformin induced vitamin B12 deficiency in type 2 diabetes patients. On the other hand, low vit B12 was associated with adverse lipid profile.

Aim

To evaluate the relationship between vitamin B12 deficiency and the lipid profile in patients with neuropathy.

Patients and methods

A cross-sectional study included 123 type 2 diabetic patients treated with metformin. The presence of distal symmetrical polyneuropathy (DSPN) was determined by Toronto Clinical Neuropathy Score (TCSS). Vitamin B12 levels and lipid profile were measured for all participants.

Results

The mean age of participants was 60.99 ± 6.85 years. About 70% were female. The mean duration of metformin use was 14.6±7.27 years with a mean dose of 1923±575.4 mg/day. The mean total cholesterol level was 4.68 mmol/l ±1.2 mmol/l. The mean triglyceride level was 7.71 mmol/l ±0.96. The mean HDL cholesterol level was 1.11mmol/l ± 0.2 mmol/l and the mean LDL cholesterol level was 1.07 mmol/±0.41. There was a difference between the two sexe in the lipid profile ($P<0.005$). Eighty three and a half percent of patients were on statins. The mean dose was 24.13 mg/day with extremes ranging from 10 to 80 mg/day. The mean serum Vitamin B12 level was 353.77 ± 178.22 pg/ml with extremes ranging from 64.47 to 918.4 pg/ml. Eighteen and a half percent of the population had a vitamin B12 deficiency (level <200 pg/ml). There was no correlation between vitamin B12 level and lipid profile. Fifty seven percent of patients have mild neuropathy, 23.5% moderate neuropathy and 19.5% severe neuropathy. There was no correlation between TCSS and Lipid profile. There was no correlation between TCSS and statin dose ($P=0.79$). The mean dose of statins was 23.82 ± 16.75 mg/ day in patients with mild neuropathy,23.10 ± 18.72 mg/day in patients with mild neuropathy and 26.25 ±18.13 mg/day in patients with severe neuropathy.

Conclusion

This study shows no correlation of lipid profile and vitamin B12 level. Statin dose was not associated with the severity of DSPN. Larger studies are needed to clarify the relationship between vitamin B12 and lipid profile.

Puberty and staturoponderal development in type 1 diabetec patients

Dorra Ben Salem, Olfa Lajili, Selma Mohsen, Hana Ben Jemâa, Chaima Jemai & Feika Ben Mami
Tunisia, National institute of Nutrition, tunis, Tunisia

Introduction
Type 1 diabetes affects the puberty and staturopondral development of young diabetics.
Objective
Assess pubertal status in young DT1 patients and determine factors influencing pubertal development.
Materiel and method
Retrospective study involving 89 type 1 diabetics aged $\leq$ 18 years hospitalized in the department C of the National Institute of Nutrition of Tunis between January 2022 and October 2022.
Results
The mean age was 17.5 $\pm$ 5 years with a female predominance of 61%, the onset of diabetes was 9 $\pm$ 2 years. The average HbA1c level was 10.8%. Pediatric transition was noted in 15% of patients. Pubertal delay was observed in 12 girls (15%) and 6 boys (7.5%). The average age at menarche was 12.5 years (10-16), 47% of girls had irregular cycles. A statural delay was reported with 9 boys and 4 girls. Underweight was noted in 18.7% of patients, and overweight in 12% of girls. Pubertal delay was related to glycemic variability ($P=$ 0.02), diabetes seniority ($P<0.02$), and the frequency of hypoglycemia ($P<0.01$). No significant association with insulin regimen and microangiopathies ($P=$ 0.13).
Conclusion
Previous poorly controlled diabetes and hypoglycemia were predictors of delayed puberty. Puberty coincides with the transition period. Pediatrician-diabetologist coordination is needed to limit loss of sight and minimize the impact on growth and puberty.

Consensus Towards Reassessing Gliclazide for the Place in Therapy Based on Novel Cluster Classification of Diabetes

Bipin Sethi[1], Unnikrishnan A G[2], Usha Ayyagari[3], Prem Narayanan[4], Raviraj Acharya[5], Karthik Balachandran[6], Adlyne Reena[7] & Tejal Lathia[8]
[1]CARE Hospitals, Hyderabad, India; [2]Chellaram Diabetes Institute, Pune, India; [3]Apollo Speciality Hospital, Chennai, India; [4]Ahalia Diabetes Hospital, Palakkad, India; [5]Kasturba Medical College, Manipal, India; [6]Sri Ramachandra Medical College and Research Institute, Chennai, India; [7]Sri Ramachandra Medical College and Research Institute, Chennai, India; [8]Fortis Hospitals, Mumbai, India

Introduction
A novel classification of adult onset DM into five subgroups: Severe Autoimmune Diabetes (SAID); Severe Insulin-Deficient Diabetes (SIDD); Severe Insulin-Resistant Diabetes (SIRD); Mild Obesity-Related Diabetes (MOD); and Mild Age-Related Diabetes (MARD) has been postulated. We aim to formulate a consensus statement towards reassessing gliclazide use based on cluster classification of diabetes mellitus
Methods
A virtual collaborative educational initiative was convened from November-December 2022, through a series of 10 nationwide virtual interactive meetings by leading diabetologists-endocrinologists ($n=150$) at the forefront of diabetes care (RECLIDE Study Group). The cumulative clinical experience was approximately 4,000-man-years, who rated their level of agreement for 13 questions with each item on a 5-point Likert scale. This was preceded by a contemporary evidence-based discussion on the contemporary updates for gliclazide and novel cluster based definition of diabetes. Weighted mean for the Likert scale was calculated and consensus was pre-defined as a score $>$ 50. GraphPad 9.4.0 and ANOVA were used for statistical analysis
Results
The highest agreement score was as follows for the consensus statements: early intervention with gliclazide is associated with reduction in risk factors and better self-management of T2DM (124), gliclazide differs from other sulfonylureas (SUs) in several respects and may provide a suitable option for some patients with T2D (124), gliclazide, among SUs has minimal risk of hypoglycemia (124). This was followed by that, gliclazide is relevant for maturity-onset diabetes of the young (MODY) (115), gliclazide is a relevant SU in T2DM who are inclined to fasting during Ramadan, the distinctive "Structure Activity Relationship' of gliclazide contributes to determine its clinical characteristics (114), gliclazide is relevant for mild age-related diabetes (MARD, cluster 5) (98), relevant for mild obesity-related diabetes (MOD, cluster 4) (62). The highest mean response scores ($\pm$SD, 95% CI) for consensus were for agree (54.7 $\pm$ 19.2, 95% CI 43.1 to 66.4) followed by strongly agree (27.6 $\pm$ 19.7, 95% CI 14.3 to 40.9), neither agree nor disagree (23 $\pm$ 21.5, 95% CI 10 to 36.1), disagree (14.1 $\pm$ 13.5, 95% CI 4.3 to 23.8), and strongly disagree (4.5 $\pm$ 5, 95% CI -3.4 to 12.4).
Conclusions
We observed a high preference for the usage of gliclazide in mild age-related diabetes cluster and mild obesity-related diabetes cluster. Despite the evolution of wide therapeutic armamentarium for management of T2DM, gliclazide still holds a distinctive place in clinical practice. Gliclazide has stood the test of time and it appears that gliclazide would continue to contribute towards the patient-oriented diabetes care.

Urinary tract infections in patients with diabetes mellitus

Rahma Khalaf, Zohra Hadj Ali, Yosra Htira, Hedfi Imene, Chaima Jemai & Feika Ben Mami
National Institute of Nutrition, Department C, Tunis, Tunisia

Background and Aim
Patients with diabetes mellitus(DM) are at increased risk of infections, with the urinary tract being the most frequent infection site. High rates of antibiotic prescription, including broad-spectrum antibiotics, for urinary tract infection (UTI) in these patients may further induce the development of antibiotic-resistant urinary pathogens. The aim of our study is to determine the epidemiology of UTI and resistance patterns of bacterial isolates in patients with DM.
Methods
A total of 70 patients with DM presenting UTI admitted to a Tunisian university hospital from 2018 to 2020 were studied retrospectively. Socio-demographic and clinical data, urin culture results and antimicrobial susceptibility patterns of the isolates were collected.
Results
Mean age was 48 years $\pm$15 with female predominance (80%). In female subgroup,57.14% were postmenopausal. Mean body mass index (BMI) was 27.95 $\pm$ 10.5 kg/m^2. Mean HbA1C was 11.3% $\pm$ 3.6. Diabetes was insulin-treated in 70% of cases. Mean duration of diabetes was 10 years $\pm$ 3.7. Of our study population, 68.57% and 11.42% had lower and upper UTI, respectively. UTI was asymptomatic in 50% of cases. The predominant isolate was Escherichia coli (55.71%) followed by klebsiella Pneumoniae (14.28%), Enterobacter cloacae (2.85%), Entercoccus fecalis (1.42%), Acinetobacter (1.42%), Coagulase negative Staphylococcus (1.42%) and Raoutella terrigena (1.42 %). Extended Spectrum Beta-Lactamase Escherichia coli was isolated in 22% of cases and 70% of Klebsiella pneumoniae isolates were resistant to amoxicillin-clavulanic acid, ceftazidime, nitrofurantoin, ceftiraxone, ticarcillin, and piperacillin. The rate of resistance to two or more antimicrobials was 40%. UTI was significantly more prevalent in type 2 DM(67,14% vs 32,86%; $P=$0,04). Upper UTI was significantly associated with female sex (8.5% vs 5.1%; $P=0.002$) and with shorter duration of DM (6.5 years $\pm$5.1 vs 11.5 years $\pm$8.81; $P=0.04$) while age, DM type and treatment and BMI were not significantly associated with upper UTI.
Conclusion
Escherichia coli was the most frequent isolate in both symptomatic and asymptomatic DM patients. More resistant pathogens are a commun finding. Our results are in line with other studies. Investigation of bacteriuria in diabetic patients for UTI is important for treatment and prevention of the development of renal complications.

Estimation of "Physical Activity Level Equivalence" of Energy Expenditure in Adults with Severe and Complicated Obesity

Sian McGarel[1,2], Sadhbh O'Connor[1,2], Aisling McGrath[2] & Francis Finucane[1,2]
[1]University of Galway, Galway, Ireland; [2]University Hospital Galway, Ireland

Obesity is often framed as a consequence of inadequate physical activity, and patients with severe obesity sometimes attribute their weight gain to immobility and reduced exercise. We sought to compare Total Daily Energy Expenditure (TDEE) in adults with severe obesity to what their predicted TDEE would be at

their Ideal Body Weight (IBW). We conducted a cross-sectional analysis of the Croí CLANN prospective cohort study of patients with severe obesity attending our regional bariatric service. Data on weight, height, age and sex were used to estimate Basal Metabolic Rate (BMR) using the Mifflin-St Jeor formula. A conservative Physical Activity Level (PAL) estimate of 1.4 was used to estimate actual TDEE. Then, the hypothetical PAL required in order for IBW TDEE to match actual TDEE was derived – the "physical activity level equivalent" (PALE). Of 1,102 patients recruited, 67% were female, with a mean age of 46.8 ± 11.9 years, total weight 130.6 ± 25.6 kg, excess body weight was 60.7 ± 22.6 kg, IBW was 69.9 ± 7.7 kg and BMI was 46.7 ± 7.8 kg/m^2. The average theoretical PAL required for patients to achieve their current TDEE if they were at their IBW was 2.03 ± 0.25 units. Estimates of current TDEE in patients with severe obesity, even when conservative estimates of actual physical activity are assumed, suggest that if they were to try to match that TDEE at their IBW, they would need to have long periods of sustained and vigorous physical activity. Whether discussing the "PALE" with patients is helpful or effective in motivational interviewing remains to be determined.

Bulimia Investigatory Test of Edinburgh (BITE) use in an endocrinology outpatient clinic

Gabriela Alexandra Zapata Maldonado, María González-Villa, Pedro Luis Talledo Madrid, Gabriela Ines Simbaña Aragón & Valeria Alcantara-Aragon
Hospital Universitario Marques de Valdecilla, Endocrinology and Nutrition Department, Santander, Spain

Objectives
To evaluate the prevalence of eating disorders (ED) at an Endocrinology outpatient clinic (EOC); with the use of Bulimia Investigatory Test of Edinburgh (BITE).
Methods
Descriptive analysis of clinical characteristics and BITE scores from patients with suspicion of ED at a first appointment in an EOC with an average of 128 new patients/year. Data was collected from January-2021 to December-2022. The main suspicion criteria were: self-reported anxiety toward food or eating, and/or body dissatisfaction. Results are expressed as means and proportions.
Results
Sixty patients performed a BITE test: 78.33% women, 34.38 ± 14.87 years old, mean body mass index 38.26 ± 5.72 kg/m^2. The vast majority consulted for obesity (88.33%), followed by thyroid pathology (6.66%) and diabetes mellitus (5.01%). More than half (68.33%) received pharmacological treatments: GLP1-R analogues (51.22%), SGLT-2-inhibitors (29.27%), metformin (14.63%), orlistat (2.44%) and others (2.44%). BITE symptom scores were: 20% had an absence of abnormal behaviors (< 10pts), 26.67% had abnormal behaviors, not necessarily bulimia (10-15pts), 18.33% had possible subclinical bulimia (15-20pts) and 35% had possible bulimia nervosa (>20pts). Thirty-seven percent used fasting to attempt weight control, 33.33% used over-the-counter weight-loss pills more than once a day, 6.67% used diuretics, 5% used laxatives, and 3.33% used auto-induced vomiting. Seventy-five percent admitted suffering from binge eating; from occasionally up to several times per day. Regarding severity of abnormal behaviors: 78.33% of patients reported no severity (< 5pts), 18.33% clinically significant severity (5-10pts) and 3.33% a high degree of severity (>10pts). A subgroup analysis for adolescents 16-21 years old ($n = 16$), showed similar results for general clinical characteristics and BITE symptom scores but with higher severity scores: low in 62.5%, significant in 31.25% and severe in 6.25%. Twenty-nine (48.33%) patients were referred to a psychiatry ED unit for diagnosis and treatment. Twenty-two received a psychiatric diagnosis: binge-eating disorder 11.67%, adaptive disorder 10%, major depression 8.33%, not-otherwise-specified ED 5% and bulimia nervosa 1.67%. The referral was proposed and refused by 19.44% of patients.
Conclusions
A high frequency of anxiety related to food or eating and body dissatisfaction were present in this sample. After BITE screening about half of these patients were referred to an ED unit. A significant number of patients refused the referral, possibly in relation to stigma. These results highlight the importance of ED screening at EOCs and the need for multidisciplinary care teams. Prospective studies are required to evaluate the best practices for screening protocols and patient outcome optimization.

Metformin Ameliorates Fatty Liver Disease in A High-Fat Diet-Induced Obese FVB/N Mouse Model

Samanta Lozano de la Haba[1,2,3,4], Natalia Hermán-Sánchez[1,2,3,4], Betsaida Ojeda Pérez[1,2,3,4], Antonio Garcia-Estrada[1,2,3,4], André Sarmento-Cabral[1,2,3,4], Raul M Luque[1,2,3,4] & Manuel D. Gahete[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain; [2]University of Córdoba, Department of Cell Biology, Physiology and Immunology, Córdoba, Spain; [3]Reina Sofia University Hospital (HURS), Córdoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Córdoba, Spain

Objectives
Previous studies have shown that metformin can reduce high-fat diet (HFD)-induced body weight gain and fat accumulation in the liver. However, the results obtained in animal models regarding the implication of metformin in the modulation of other whole-body and tissue-specific parameters, are controversial or need to be further explored. Consequently, we aimed to explore the capacity of metformin in modulating glucose/insulin metabolism, liver function, adiposity, circulating hormones and lipids, food intake and energy expenditure in HFD-induced obese mice using a different inbred strain, FVB/N, which has been demonstrated to be a suitable and complementary model for diet-induced obesity (DIO) studies.
Materials and methods
Orally administered metformin (250 mg/kg/day) was used in HFD-induced obese FVB/N mice. The effects of metformin on body weight gain and composition, glucose/insulin metabolism, liver physiology, growth hormone and IGF1 axis and hepatic transcriptional regulation were analyzed using animals fed a low-fat diet (LFD) as control.
Results
HFD-fed mice exhibited significantly increased body weight compared to LFD mice, which was accompanied by the proportional increase in total fat mass as assessed by NMR. The observed increase in body weight was due to higher caloric intake. HFD consumption led to an increase in insulin and a non-significant increase in glucose. HFD-fed mice also exhibited impaired glucose tolerance, although no alterations in insulin tolerance were observed. Metformin treatment induced unexpected metabolic effects in HFD-fed mice, with no significant impact on LFD-fed mice. Specifically, metformin treatment did not induce changes in body weight, food intake, body composition, or fasting glucose under HFD or LFD conditions, whereas only a decrease in insulin was observed in metformin-treated HFD mice. However, a substantial effect was observed at the hepatic level as metformin-treated HFD mice exhibited a significantly lower proportion of hepatic steatosis, inflammation and necrosis, while LFD mice exhibited a more inconsistent role. These changes were accompanied by changes in the expression of genes involved in the control of gene expression, suggesting possible biomarkers in the development of steatosis and/or response to metformin.
Conclusion
In animal models, metformin exerts a potent role in the prevention and/or development of liver pathologies, although its effect on other metabolic parameters is highly dependent on the genetic background of the animals and their metabolic state.

Metabolic abnormalities in adult population with spinal muscular atrophy

Matej Rakusa[1,2], Dejan Firbas[2], Tjasa Rudolf[2], Katja Goricar[3], Andrej Janez[1,2] & Mojca Jensterle[1,2]
[1]Department of Endocrinology, Diabetes and Metabolic Diseases, University Medical Centre Ljubljana, Ljubljana, Slovenia; [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia; [3]University of Ljubljana, Faculty of Medicine, Institute of Biochemistry, Pharmacogenetics Laboratory, Ljubljana, Slovenia

Background
Spinal muscular atrophy (SMA) is hereditary, degenerative, neuro-muscular disease of lower motor neurone that leads to muscle weakness and atrophy. Several metabolic disturbances such as impaired glucose tolerance (IGT), insulin resistance (IR), hypoglycaemia and dyslipidaemia can be present. Most studies were done in children, with more severe forms of SMA. We aimed to assess body composition, IR, glucose and lipid metabolism in adult patients with SMA type 2 and 3.

Material and methods
We designed a cross sectional study consisting of 29 SMA type 2 and 3 (18 (62.1 %) males and 11 (37.9%) females) of median age 44 (30-51.5) years. Anthropometric measurements were performed. Morning blood samples for total cholesterol, LDL, HDL, TG, ApoB, Lp(a), HbA1c and IGF-1 were collected. Blood glucose and insulin were measured during 75 g oral glucose tolerance test (OGTT). Body mass index (BMI) and HOMA-IR were calculated. Body composition was measured with bioimpedance.
Results
BMI was <30 kg/m2 in 25 (86.2%), 30-35 kg/m^2 in 3 (10.3%), >35 kg/m^2 in 1 (3.4%). Increased body fat (women >35%, men >25%) was present in 22 (75.9%) patients. 18 (81.8%) patients with BMI <30 kg/m2 had increased body fat. Normal glucose metabolism was present in 8 (28.6%), isolated IGT in 9 (32.1%), impaired fasting glucose and IGT in 2 (7.1%), diabetes in 9 (32.1%). Fasting hypoglycaemia was recorded in 1 patient (3.6%). Insulin resistance (HOMA-IR>2) was present in 16 (55.2%) patients. Only 1 (3.6%) patient had HbA1c>6.0%. Total cholesterol was increased in 20 (69.0%), LDL in 24 (82.8%), TG in 10 (34.5%), HDL was low in 12 (41.4%). ApoB and Lp(a) were increased in 3 (10.7%) and 8 (28.6%) respectively. IGF-1 correlated with body fat (Spearman's rho -0.547, $P=0.002$ and -0.582, $P=0.001$ respectively).
Conclusions
BMI is not suitable for assessing obesity. Body composition should be measured, as in our population 81.8% of patients with BMI <30 kg/m^2 had increased body fat. Majority of patients have glucose metabolism abnormalities, almost a third fulfils criteria for diabetes. OGTT should be done in all patients with SMA. In children hypoglycaemia is common and usually asymptomatic. Continuous glucose monitoring could add additional information to hypoglycaemia in adults. The most common dyslipidaemia is increased LDL cholesterol. Emerging treatments such as nusinersen, risdiplam and onamsenogene abeparvovec will change course of the SMA, so interdisciplinary approach with inclusion of endocrinologists and appropriate assessment of cardiometabolic risk factors is necessary.

Assessing Foundation Doctors knowledge on the use of Sodium-glucose cotransporter 2 (SGLT2) Inhibitors: A Quality Improvement Project

Aiman Haddad, Angelica Sharma, Tsz Lee Tse, Bara Taufik & Ian Seetho
Northwick Park Hospital, London Northwest NHS Trust, Department of Endocrine and Diabetes, London, United Kingdom

Introduction
Sodium Glucose Co-transporter 2 inhibitors (SGLT2i) are a novel class of glucose-lowering therapies that have demonstrated prognostic benefit in the management diabetes, heart failure and renal impairment. National Institute for Health and Clinical Excellence (NICE) guidance recommends offering SGLT2i, in addition to metformin, first-line in individuals with type 2 diabetes (T2D) and chronic heart failure/ established atherosclerotic cardiovascular disease. However, SGLT2i require close monitoring and rarely can result in life-threatening complications including euglycaemic diabetic ketoacidosis. Therefore, foundation doctors (FDs) (Newly graduated Doctors undertaking the two years foundation training programme) should be competent in their use and early identification of side effects.
Aim
We conducted a quality improvement project to assess FDs' knowledge on the use of SGLT2i, provide educational material and thus improve patient care at Northwick Park Hospital (NPH).
Method
A questionnaire was designed within the department of Endocrinology encompassing 4 key domains including initiation, indications, benefits, and side effects of SGLT2i. FDs (FY1/ FY2) were invited to complete the initial questionnaire between October-November 2022. Within the second cycle, we designed and delivered educational material. This was by a re-audit.
Results
Of 80 FDs at NPH, 32 individuals completed the initial questionnaire. 40%($n=13$) were able to recall the indications of SGLT2i and 44%($n=14$) were well-informed on cardiovascular and renal benefits. 56%($n=18$) were aware of the appropriate eGFR prior to initiation. 56% ($n=18$) could recollect stopping SGLT2 inhibitors during acute illness whilst only 16%($n=5$) were aware of management of euglycaemic ketoacidosis. 59%($n=19$) appreciated the low incidence of hypoglycaemia. Overwhelmingly, 75%($n=24$) of individuals received no prior formal education on SGLT2i. Therefore, we delivered a formal teaching session specifically targeted at FDs. Individuals completed the same questionnaire post-teaching, and 38 responses were collated. Ability to recall indications for use of SGLT2i increased to 74%($n=28$) and 66%($n=25$) were now aware of the beneficial cardiovascular and renal outcomes. 74%($n=28$) could identify the safe eGFR range for commencing SGLT2i. 95%($n=36$) appreciated importance of stopping SGLT2i in periods of acute illness whilst 74%($n=28$) were confident on management of euglycaemic ketoacidosis.
Conclusion
This quality improvement project demonstrated a significant knowledge gap amongst FDs on SGLT2i. By providing focused and targeted educational initiatives, we have demonstrated an improvement in knowledge across all four essential domains. To ensure sustainability, we propose FDs nationally should receive bi-annual teaching sessions on the ever-evolving field of managing T2D.

Diabetic keto-acidosis secondary to sodium glucose co-transporter inhibitors: single-centre experience

Mikhail Nozdrin[1], Maria Selyanina[2], suhier elshowaya[1], Ghada Ahmed[1], Blazej Rzeszowski[3], Rafael Abreu[4], Simona Mihalikova[2] & Gideon Mlawa[1]
[1]Queen's Hospital, United Kingdom; [2]St Bartholomew's Hospital, United Kingdom; [3]Imperial College London, London, United Kingdom; [4]Hialeah Hospital, Hialeah, United States

Background
SGLT-2 inhibitors (SGLT-2i) are used in treatment of type 2 diabetes mellitus (T2DM) through increasing urinary glucose secretion. Cases of euglycemic and hyperglycaemic diabetic ketoacidosis (DKA) have been reported in literature in patients using SGLT-2i. Increased glucose urinary excretion promoted by SGLT2i, decreases the production of insulin. In turn, lipolysis and ketone production increase predisposing the patient to developing DKA. It is

hypothesised that SGLT2i, stimulate a cells of the pancreas, increasing the release of glucagon. The increased glucagon levels, further stimulate B-oxidation and ketone body production. In our case series we aim to describe the risk factors, demographics associated with development of SGLT-2i associated DKA and the course of disease in such patients.

Methods

All the T2DM patients with diabetic ketoacidosis on SGLT-2i who presented to the emergency department of a large hospital between Dec 26th 2018 and Jan 1st 2023 were included in the study.

Results

Ten patients were included in the study. Patient demographics are summarised in Table 1. All patients had confirmed T2DM, with negative GAD and anti-islet antibodies. Five patients were taking Canagliflozin, four-Empagliflozin, one-Dapagliflozin. Mean blood ketone level on admission was 4.18 mmol/l (2 St.Dev. $\pm$0.274) and venous blood gas pH was 7.088 (2 St. Dev. $\pm$0.155). Blood glucose on admission ranged from (4.7 to 28 mmol/l). Most common symptom at presentation was vomiting ($n=5$). Other common symptoms at presentation were abdominal pain ($n=2$), shortness of breath ($n=2$) and lethargy ($n=2$). Four patients had concurrent illness at presentation: urosepsis, recent knee surgery, community acquired pneumonia and acute coronary syndrome. All patients were treated with sliding scale, 1 patient was transferred to ITU, 1 required HDU support and 1 passed away from a cardiac arrest in ED. Mean duration of hospital stay was 5.3 days (2 St. Dev: 2.46 days).

Discussion

Diabetic ketoacidosis secondary to SGLT2i is a known side effect. In our cohort, we found 3 patients presenting with hyperglycaemia. DKA with SGLT2i is not uncommon, especially with intercurrent illness. Therefore patients on this therapy should be encouraged to monitor their blood ketone levels even if their blood glucose levels are within range.

LMF1-associated Chylomicronemia Syndrome

Michal Yacobi Bach[1,2], Merav Serebro[1], Hagit Baris Feldman[2] & Yona Greenman[1]

[1]Tel Aviv Medical Center, Endocrinology Institute, Tel Aviv, Israel; [2]Tel Aviv Medical Center, Genetics Department, Tel Aviv, Israel

Introduction

Familial Chylomicronemia-FC syndrome is characterized by severely elevated triglyceride levels, i.e., levels of TG above 1000 mg/dl. Monogenic etiology is associated with a small but a significant fraction of Familial Chylomicronemia (FC) Syndrome cases, which is mainly attributed to a few genes, that are involved in Lipoprotein Lipase activity *(LPL / LMF1 / APOC2 / GPIHBP1 / APOA5)*. Bi-allelic variants in these genes cause this rare Autosomal Recessive disorder with a prevalence of ~1 to a million. We herein report a case of a 51year old male, diagnosed with FC syndrome due to a homozygous pathogenic variant in the *LMF1* gene, and the clinical implications of this diagnosis.

Case description

A 51 years old male of consanguineous Jewish Yemenite ancestry, has been investigated in the Endocrinology Clinic due to recurrent pancreatitis. He was diagnosed with severe hypertriglyceridemia (TG levels up to 2300 mg/dl). His past medical history includes type 2 diabetes mellitus and complex PTSD. No family history could be retrieved. Initial treatment included a combination of fibrates, statin, ezetimibe and omega3 fatty acids. The patient was instructed to avoid alcohol, and a strict dietary-fat restriction. Despite good adherence to this treatment, triglyceride levels remained high, around 700mg/dl, and he continues to suffer from mild episodes of pancreatitis that reduce his quality of life.

Molecular investigation

Homozygous *LMF1* c.1391G>A p.Trp464* (RefSeq NM_022773), classified as "Pathogenic" according to the ACMG guidelines.

Discussion

Involvement of LMF1 gene by loss-of-function mechanism has been initially reported in 2007 [Péterfy *et al*]. *LMF1* gene encodes a transmembrane protein, which is involved in the maturation of lipoprotein lipase (LPL) and hepatic lipase in the endoplasmic reticulum. The *LMF1* variant diagnosed in our patient, was previously described (doi: 10.1210/jc.2009-0594). Functional analysis of this variant revealed significantly reduced expression and activity of LMF1 protein. The clinical presentation of our patient is consistent with the molecular diagnosis of Lipase Deficiency (OMIM #246650). Due to lack of improvement on current available treatments, he is a candidate for treatment with Volanesorsen-, a second-generation 2'-*O*-methoxyethyl (2'-MOE) chimeric antisense therapeutic oligonucleotide, that decreases plasma apolipoprotein C3 and triglycerides (TG) levels through LPL-independent pathways. We suspect that the rarity of this syndrome is partly due to underdiagnosis, and the availability of Next generation sequencing will improve our diagnosis and treatment options for our patients. Our hope is to offer personalized treatment based on the specific molecular diagnosis.

Background

Hyperphagia leading to craniopharyngioma-related obesity (CRO) is a common and serious sequel of treatments of craniopharyngiomas. The few therapeutic approaches that have been tested until now for the control of eating behaviour and weight have poor efficacy. Glucagon-like peptide-1 (GLP-1) analogues might be an option.

Methods

This multicentre, randomised, double-blind superiority trial was conducted in France. Adults with CRO (BMI $>$ 30 kg/m^2) without sign of recurrence in the past year were included. After a 4-week run-in period with a lifestyle intervention, participants were randomized (1:1) to receive exenatide 5 µg x 2/day for 4 weeks increased to 10 µg x 2/day for the following 22 weeks or placebo injected subcutaneously twice a day, using a computer-generated randomisation sequence. The lifestyle intervention (hypocaloric diet and regular physical activity) was maintained during the 26-week follow-up. The primary outcome was mean change in body weight (kg) at week 26 in the intention-to-treat population. This trial is registered with ClinicalTrials.gov, NCT02860923.

Findings

Between January 2017 and February 2018, 41 participants were subjected to an intensive lifestyle intervention and randomly assigned to exenatide ($n=20$) or placebo ($n=20$). At week 26, weight decreased from baseline by a mean of - 3.8 (SD 4.3) kg for exenatide and -1.6 (3.8) kg for placebo. Adjusted mean treatment difference was -3.1 kg (95% CI -7.0 to 0.7, $P=0.11$) in favor of exenatide. The estimated treatment difference from baseline to week 26 was -2.3 (95% CI -4.5 to -0.2) for reduction of hunger score, -1.2 (95% CI -3.2 to $+0.8$) for reduction of disinhibition score and – 8.1 cm (95% CI -21.1 to 4.9) for reduction of waist circumference in favor of exenatide. Restriction score and quality of life did not significantly differ between groups. A heterogeneity in the response to therapeutic intervention was observed. Adverse events occurred in 19 (95%) participants in the exenatide group vs 14 (70%) in the placebo group.

Interpretation

The results of our study show that both lifestyle intervention and exenatide have an impact on body weight. Exenatide was not demonstrated superior to placebo, when combined with intensive lifestyle interventions. The heterogeneity in response suggest that GLP-1 receptor agonists might be an additional option in targeting both body weight loss and eating behavior, in a subset of CRO population.

Characteristics of carbohydrate metabolism and insulin resistance in patients with chronic pyelonephritis depending on the phenotype of latent autoimmune diabetes in adults

Nataliia Pashkovska & Iryna Tsaryk
Bukovinian State Medical University, Clinical Immunology, Allergology and Endocrinology, Chernivtsi, Ukraine

Background
Chronic pyelonephritis (CP) is a common kidney infection complication in patients with diabetes mellitus and one of the main reasons of chronic kidney disease in diabetic patients.
The objective
Of the study was to determine the features of the carbohydrate metabolism and insulin resistance in patients with CP depending on the phenotype of latent autoimmune diabetes in adults (LADA).
Methods
28 patients with LADA and CP were examined, as well as 25 representatives of the control group. The patients were divided into two groups by the phenotype of LADA: 19 patients with LADA1 and 9 with LADA2. We studied fasting plasma glucose levels, glycated hemoglobin (HbA1c), HOMA-IR index and anthropometric indicators: body mass index (BMI), waist circumference (WC) and waist circumference to hip circumference ratio (WC/HC).
Results
Fasting plasma glucose level was 40.3% higher in patients with LADA1 than in the control group ($P<0.001$), in LADA2 it was 2 times higher ($P<0.01$). The HbA1c indicator was 83.6% higher in LADA1 and 55% higher in LADA2 compared to the control ($P<0.001$), respectively. HOMA-IR index was registered 1.6 times lower in LADA1 group compared to the control ($P<0.05$), but 2.2 times and 3.4 times higher in LADA2 compared to the control and LADA1 ($P<0.001$). BMI in LADA1 was lower than in the control group by 11% ($P=0.001$); in LADA2 it was higher by 17.8% ($P<0.01$) than in the control group and by 32.5% in relation to LADA1 ($P<0.001$). The WC was lower by 1.3% when comparing the LADA1 and control group ($P<0.05$), in LADA2 – by 34.6% and by 36.4% higher than in the control and LADA1 group respectively ($P<0.001$). The WC/HC was found to be higher by 20.5% in individuals with LADA2 compared to control and by 25% compared to LADA1 ($P<0.001$). In patients with LADA1 positive relationships were recorded between the HbA1c and the age of manifestation of diabetes ($r=0.489$; $P<0.05$). In the LADA2 group negative correlations were found between the fasting plasma glucose and the duration of diabetes ($r=-0.725$; $P<0.05$); HbA1c level and the age of manifestation of diabetes ($r=-0.788$; $P<0.05$); HbA1c and the duration of diabetes ($r=0.690$; $P<0.05$).
Conclusion
Insufficient compensation of diabetes is noted in patients with LADA1 and LADA2 without differences in intergroup comparison, however the degree of insulin resistance and abdominal obesity as main components of metabolic syndrome prevalence in patients with LADA2 which indicates the higher cardiovascular risk in this category of patients.

Prevalence and Predictive Factors of Painful Diabetic Peripheral Neuropathy in The Department of Endocrinology and Metabolic Diseases of The Uhc Ibn Rochd In Casablanca: About 623 cases

Amine Gueddari, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
Peripheral neuropathy is one of the most common complications of diabetes. Its prevalence is very different according to the studies ranging from 8 to almost 60%. The symptomatology can be very polymorphic. Its painful form, painful diabetic neuropathy (PDN), is the most common cause of peripheral neuropathy.
Objective of the study
Our objective was to determine the prevalence and factors associated with PDN.
Material and methods
This is a descriptive cross-sectional observational study including 623 patients followed in the endocrinology and metabolic diseases department of the Ibn Rochd University Hospital in Casablanca in a day hospital or in conventional hospitalization between January 2021 and July 2022. The painful diabetic neuropathy was assessed by the DN4 score. Statistical analysis of the data was performed using SPSS version 25.
Results
We included 623 patients, 63.4% of whom were women. The average age of the patients was 51.4 $\pm$ 16.1 years. Diabetes was type 2 for 79.9% of patients. The mean HbA1c was 10.22 $\pm$ 2.53%. Among our patients, 30.8% were obese. The prevalence of PDN was 22.2%. Diabetic retinopathy was the most frequent complication with a percentage of 24.2%. In bivariate analysis, the risk factors associated with PDN were: age $>$ 69 years ($P<0.001$), arterial hypertension ($P=0.005$), dyslipidemia ($P=0.001$), duration of diabetes $>$ 10 years ($P<0.001$), HbA1c $>7\%$ ($P<0.001$), retinopathy ($P<0.001$), nephropathy ($P<0.001$), autonomic neuropathy ($P<0.001$), coronary artery disease ($P<0.001$) and obliterating arteriopathy of the lower limbs ($P<0.001$). In multivariate analysis, the predominant risk factors for PDN were: HbA1c$>$ 7% ($P=0.01$ and Odds ratio at 3.7), retinopathy ($P<0.001$ and Odds ratio at 3.37), autonomic neuropathy ($P<0.001$ and odds ratio at 3.23) and coronary artery disease ($P=0.005$ and odds ratio at 3.47). All of the patients with PDN were put on pregabalin with a good evolution.
Conclusion
Diabetic neuropathy can have an impact on the quality of life of patients, prompting its detection by the DN4 score. Its management must include good glycemic control, management of risk factors and symptomatic treatment of pain.

Diabetic ketoacidosis as first presentation of diabetes mellitus in a subject with Friedreich' ataxia. A case report and review of literature

Marjeta Kermaj, Olta Zeneli, Violeta Hoxha, Klodiana Poshi, Dorina Ylli & Agron Ylli
UHC "Mother Tereza", Endocrinology, Tirana, Albania

Introduction
Friedreich ataxia (FA) is a multisystem autosomal recessive disease with progressive clinical course involving the neuromuscular and endocrine system. Individuals with FA have an increased risk of developing diabetes. In FA-associated diabetes, both insulin deficiency and insulin resistance have been reported. We present a case with FA, presented with diabetic ketoacidosis (DKA) as the first presentation of diabetes mellitus.
Case Presentation
We present a case of 40-years-old male who presented to emergency unit with DKA. It was not known to be diabetic before. He had a 6months history of physical weakness, weight loss, polyuria-polydipsia syndrome, dry mouth. For the last 3 days, he complained of constipation, chesty cough, dyspnea, abdominal pain, vomiting-after having a viral infection. The patient was diagnosed with FA, muscular dystrophy at the age of 15. No family history of diabetes mellitus. His physical examination revealed, coma, dry and pale mucous membranes and skin, bilateral basal crepitant rales, on lungs auscultation. Abdomen soft but painful on palpation, peripheral edema more pronounced in superior extremities. Laboratory tests showed: Hyperglycemia, severe metabolic acidosis, urinary ketones. Leukocytosis with neutrophilia. Hyperuricemia, hypoalbuminemia. Increased level of urea and creatinine. Very low C-Peptide level, but the immune markers typical of type 1 diabetes were negative. High level of HbA1c. We concluded with the diagnosis: DKA and diabetes mellitus for the first time in a subject with FA. He was treated with insulin, liquids and electrolytes, nasal oxygen, diuretics, antibiotics, vitamins, anticoagulant until the stabilization of acid basebalance, glycaemia and lungs infection. After that, the patient was noted to have difficulties with standing, inability to walk, difficulty in speaking and reduced hearing because of FA. The ECG showed sinus rhythm, T waves negative in almost connections. Head MRI: atrophic changes of the brain. The patient discharged after 12 days, keeping diabetes under a good control with insulin, helped by his family members.
Conclusion
The association of diabetes mellitus with Friedreich's ataxia has been reported from time to time in the literature. DKA can be the presentation of diabetes mellitus in a patient with FA. The physicians must be aware about it to diagnose diabetes in time and to treat it early without reaching DKA, this life-threatening situation.

Glycemic control in Type 1 Diabetes patients using multiple daily insulin injections (MDII) vs continuous subcutaneous insulin infusion (CSII)

Anastasios Tsitsimpis[1], Helen Cherolidi[1], Nikolaos Kalogeris[1], Loukia Spanou[1], Tzant Mouslech[2], Maria Somali[2], Georgios Georgiopoulos[3] & Andromachi Vryonidou[1]

[1]General Hospital "Korgialenio-Benakio", Department of Endocrinology & Metabolism – Center of Diabetes, Athens, Greece; [2]Euromedica, General Clinic of Thessaloniki, Department of Endocrinology & Metabolism – Center of Diabetes, Thessaloniki, Greece; [3]General Hospital "Alexandra", Department of Clinical Therapeutics of the School of Medicine of the National and Kapodistrian University of Athens, Athens, Greece

Objective
Glycemic control of patients with type 1 diabetes is mainly based on insulin administration. The ongoing technological developments in continuous glucose monitoring (CGM) and continuous subcutaneous insulin infusion (CSII) provide new treatment strategies, with better glycemic control. This study assessed the clinical impact of two treatment strategies in adults with type 1 diabetes (T1D): multiple daily insulin injections (MDII) vs continuous subcutaneous insulin infusion (CSII).
Material and methods
This is a retrospective cohort study of 70 patients with type 1 diabetes (PWT1D), after their care has been transferred to two Diabetes centers, one in Athens and one in Thessaloniki, between January 2017 and May 2021. PWT1D were divided according to insulin administration mode i.e. MDII ($n=40$) or CSII ($n=30$). They were trained in carb counting and were offered continuous glucose monitoring (CGM), either real-time (rtCGM), or intermittently scanned (isCGM). Among patients on CSII, 43.3% used rtCGM and all the other patients used isCGM, due to prescription restrictions. HbA1c was measured at the beginning of patient care and after 6 to 12 months of monitoring. CGM data were analyzed according to predefined glycemic indices: percentage of time within range (TIR), below range (TBR), and above glucose target range (TAR), also at the beginning and after 6 to 12 months of follow-up.
Results
Baseline characteristics of the two groups of PWT1D did not differ in median age and duration of disease ($P>0.05$), except for BMI which was lower in those using MDII (25.05 ± 5.97 vs 28.28 ± 5.92 kg/m^2, $P=0.028$). Baseline HbA1c was 8.3% for MDII users and 8.34% for CSII ($P=0,863$). After 6-12 months of monitoring, HbA1c decreased to 7.5% in both groups, with a non-significant difference ($P=0.863$). TIR was also similar for both groups (MDII 55.58%, SD=0.95 vs CSII 58.94% SD=16.64, $P=0.418$). Conversely, TBR was significantly lower for patients on CSII (2.64 ± 3.80 vs 5.66 ± 4.94%, $P=0.001$). CGM use was more consistent in CSII users than in MDII (58.94 ± 1.10 vs 55.58 ± 17.04, $P<0.001$).
Conclusions
Care of patients with type 1 diabetes in Diabetes Centers combined with continuous glucose monitoring results in HbA1c decrease. The utilization of MDII or CSII does not seem to impact HbA1c reduction degree or TIR. Patients on CSII exhibit fewer hypoglycemic episodes and TBR compared to those on MDII.

The Effect of Diabetes Mellitus on the Outcome of Sars-Cov-2 Infection

Theodoros Moschopoulos[1,2], Panagiotis Athanassiou[2,3] & Kostoglou Athanasiou Ifigenia[2,4]
[1]Peripheral Medical Center of Archanes, Ano Archanes, Heraklion, Crete, Greece; [2]Hellenic Open University, Patras, Greece; [3]St. Paul's Hospital, Department of Rheumatology, Thessaloniki, Greece; [4]Asclepeion Hospital, Voula, Department of Endocrinology, Athens, Greece

Introduction
Infection from the severe respiratory distress syndrome coronavirus 2 (SARS-CoV-2) virus may present as mild disease or as severe disease with high mortality. Although the majority of patients infected by the virus have a good prognosis, chronic diseases, such as diabetes mellitus (DM), especially in older adults may be a risk factor for a worse outcome. DM is a frequent comorbidity in patients with COVID-19.
Aim
The aim of the present work was to study the relationship between DM and SARS-CoV-2 infection and the effect of DM on disease outcome and the duration of hospitalization.
Methods
A cohort of patients were studied with confirmed COVID-19 infection examined at the Department of Emergency Medicine, Venizelion General Hospital, Heraclion, Crete during the days on duty (15 days/month) from the 1st of March until the 31st of August 2021.
Results
A cohort of 776 adult patients, 384 female and 391 male, medial age 47 years were included in the study. Within the group of patients examined at the Department of Emergency Medicine 129 (16.62%) had DM. Within the cohort of 129 DM patients, 70 (54.26%) male 59 (45.74%) female, with acute SARS-CoV-2 infection 106 survived and 23 died (17.83%, $P<0.001$). Within the group of DM patients examined at the Department of Emergency Medicine with acute COVID-19 infection 80% needed hospitalization. Within this group of patients with DM and acute COVID-19 infection who were admitted to the hospital 23 patients (17.83%) were transferred to the Acute Care Unit and all unfortunately succumbed to the infection. Mean number of days of hospitalization of the diabetic group in the COVID-19 department was statistically significantly higher as compared to that of the group without DM (10.2 vs 6 days, $P<0.001$).
Conclusions
It appears that DM significantly adversely affects the duration of hospitalization and the outcome of COVID-19 infection. The results of our study are in accordance with those of the literature regarding the effect of DM on the outcome of SARS-CoV-2 infection. Chronic hyperglycemia significantly affects innate and humoral immunity. It appears that DM is an independent risk factor for severe COVID-19 infection.

Reduction in Diabetes Distress and Improvement in Sleep Quality correlating with Better Glycemic Control Within 90 Days on Fitterfly Diabetes Program

Tejal Lathia[1], Neha Verma[2], Nishul Gupta[3], Priyadarshini Rajawat[3], Ankita Srivastava[3], Ritika Verma[4], Gaurav Chhaya[5], Nitin Ghaisas[6], Ila Samar[7], Bharat Agarwal[8] & Arbinder Singal[9]
[1]Apollo Hospital, Department of Endocrinology and Diabetology, Navi Mumbai, India; [2]Fitterfly HealthTech Pvt Ltd, Department of psychology and wellbeing, Navi Mumbai, India; [3]Fitterfly Healthtech Pvt Ltd, Department of psychology and Wellbeing, Navi Mumbai, India; [4]Fitterfly Healthtech Pvt Ltd, Scientific Writing and Research, Navi Mumbai, India; [5]Shivam Clinic, Department of Endocrinology and Diabetology, Ahmedabad, India; [6]Siddhi Hospital, Department of Cardiology, NASHIK, India; [7]Ila Samar Clinic, Department of Internal Medicine, Gurgaon, India; [8]Apollo Hospitals, Department of Diabetology, Navi Mumbai, India; [9]Fitterfly HealthTech Pvt Ltd, Chief Executive Officer, Navi Mumbai, India

Background
Managing the relentless requirements of diabetes management can lead to an increase in distress among people with diabetes. There is a need for feasibility studies to understand the effectiveness of multi-disciplinary care delivered using digital therapeutics interventions to provide effective glycemic control along with improved overall well-being of individuals. The study aims to evaluate the feasibility and effectiveness of the Fitterfly diabetes program to improve diabetes distress and sleep quality during the 90 days period of lifestyle change.
Methods
175 participants with T2DM enrolled in Fitterfly diabetes program for 90 days across India (74 females and 101 males with mean age $=49.79\pm12.2$ years) were analyzed. Virtual consultations with psychologists were provided to each participant along with expert-led care including nutritionists and physiotherapists. Diabetes Distress Scale (DDS) and Pittsburgh Sleep Quality Index (PSQI) were used to assess diabetes distress and sleep quality respectively. All the outcomes were assessed at the beginning and end of the program. Data was analyzed on SPSS. Unadjusted correlation analysis was done using the spearman method.
Results
Diabetes distress was reported in 46.28% (81/175) of participants. Sleep quality was poor among 80.00% (140/175). Towards the end of the program, a significant median reduction was seen in DDS score by 0.50 (0.20, 1.20) from a baseline score of 1.90 (1.40, 2.60) ($P<0.01$). PSQI score significantly reduced by 3.00 (1.00, 6.00) from a baseline score of 5.00 (3.00, 8.00) ($P<0.01$). HbA1c levels significantly reduced by 1.20 % (0.50, 2.30) from 8.00% (7.20, 9.70) ($P<0.01$). Fasting blood sugar levels also significantly reduced by 25.00 (7.00, 55.00) mg/dl from a baseline score of 142.00 (121.00, 177.00) mg/dl ($P<0.01$). Reduction in DDS score was found to be significantly correlated with reduction in HbA1c ($r=0.193$, $P=0.01$) and reduction in fasting blood sugar ($r=0.238$, $P=0.001$). After completion of the program, improvement in PSQI score was found to be correlated with reduction in fasting blood sugar ($r=0.178$, $P=0.01$).
Conclusion
Significant reduction in diabetes related distress and improvement in glycemic control and sleep quality was observed after completion of the Fitterfly diabetes program. Reduction in DDS might play a role in improvement of glycemic control. The study showed that holistic management using a multidisciplinary team through digital therapeutics can help in improved health outcomes in people with diabetes.

Transition to adult care in type 1 diabetes. A single center retrospective study

Alessia Bruco[1,2], Simona Moscatiello[1,2], Giulio Maltoni[3], Stefano Zucchini[3], Anna Malaguti[1,2], Enrico Saudelli[1,2], Uberto Pagotto[1,2] & Guido Di Dalmazi[1,2]
[1]Division of Endocrinology and Diabetes Prevention and Care, IRCCS Sant'Orsola-Malpighi Polyclinic, Bologna, Italy; [2]Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; [3]Pediatric Unit, IRCCS Sant'Orsola-Malpighi Polyclinic, Bologna, Italy, Bologna, Italy

Background
Moving from childhood to adulthood is a challenging process for individuals with type 1 diabetes (T1D), transition has been defined as the planned movement from pediatric to adult department.
Aim
To assess glucometabolic control, prevalence of autoimmune disorders, and use of glucose sensors in patients with type 1 diabetes after transition to adult care.
Methods
We retrospectively evaluated HbA1c, prevalence of patients using real-time (rt) or intermittently-scanning (is) continuous glucose monitoring (CGM) and prevalence of autoimmune diseases at the time of first evaluation in the adult clinic (baseline) and at the last follow-up. HbA1c values were additionally analyzed in a subgroup of patients at 1 and 3 years after transition.
Results
A total of 132 patients were enrolled between January 2017 and January 2023. We excluded patients without T1D and HbA1c at first visit (final cohort $n=102$). Median age at transition was 21 years (interquartile range-IQR 20-22 years) and age of diabetes onset was 9 years (IQR 6-11 years). Sex was evenly distributed (50% females). At baseline, the median HbA1c was 56 mmol/mol (IQR 51-67 mmol/mol). The prevalence of autoimmune diseases was 32% for autoimmune thyroiditis, 16% for celiac disease and 5% for other autoimmune disorders. Multiple daily injection therapy was prevalent (69% of the patients), as opposed to insulin pump (31%). Among those, 13% had advanced hybrid closed loop system. With regard to glucose monitoring, 48% of patients were under capillary monitoring, 18% had isCGM, and 34% rtCGM. After baseline visit, 87% of patients had at least one follow-up visit and the median duration of follow-up was 30.4 months (16.7-46.7 months). At the last follow-up, the median HbA1c was 57 mmol/mol (49-64 mmol/mol) and 37% of patients had HbA1c $\leq$ 53 mmol/mol, while 21% had HbA1c $\leq$ 48 mmol/mol. The analysis of the subgroup of patients at 1 ($n=60$) and 3 years ($n=28$) showed no significant difference in HbA1c compared with baseline HbA1c. An increase in sensor use was found, with 20 new CGM devices positioned, against 3 CGM removed. Autoimmune screening at last follow-up resulted in new diagnosis of 5 autoimmune thyroiditis and 2 autoimmune atrophic gastritis.
Conclusion
Patient with type 1 diabetes showed a stable metabolic control of diabetes after transition to adult care, which occurred in spite of an increase in prescription of CGM devices.

"Skewing of Antimony Mediated Therapy for an Optimal Insulin Secretion During Visceral Leishmaniasis

Sukrat Sinha
Nehru Gram Bharati University, Department of Zoology, Prayagraj, India

Objective
Visceral Leishmaniasis is a macrophage associated disorder for the treatment of which antimony based drug like Sodium Antimony Gluconate has been the first choice in the recent past. About 5 percent of the patients may develop insulin dependent diabetes mellitus. It appears to have a direct action on pancreatic beta cells, resulting in initial insulin release followed by impaired insulin secretion. Within this context we looked into alternate therapies of treatment along with SAG on triggering the CD2 epitope.
Methods
We have evaluated the effect of combining CD2 with conventional antimonial (sb) therapy in protection in BALB/c mice infected with either drug sensitive or resistant strain of Leishmania donovani with 3 million parasites via-intra-cardiac route. Mice were treated with anti CD2 adjunct SAG sub-cutaneously twice a week for 4 weeks. Assessment for measurement of weight, spleen size, anti-Leishmania antibody titer, T cell and anti-leishmanial macrophage function was carried out day 0, 10, 22 and 34 post treatments. Insulin levels were also determined on the same intervals.
Results
The combination therapy was shown boosting signicant proportion of T cells to express CD25 compared to SAG monotherapy. Although, the level of IFN-γ was not statistically different between combination vs monotherapy ($P=0.298$) but CD2 treatment even alone signicantly influuenced IFN- γ production than either SAG treatment ($P=0.045$) or with CD2 adjunct SAG treatment ($P=0.005$) in Ld-S strain as well as in Ld-R strain. The influence of CD2 adjunct treatment was also documented in anti-leishmanial functions in macrophages. Interestingly insulin levels were observed to be optimal on supplementing SAG along with CD2.
Conclusion
SAG along with CD2 could be used as a potential therapy to overcome incidences of Diabetes mellitus during Visceral Leishmaniasis.

Impact of Setmelanotide Treatment on Weight- and Body Composition–Related Outcomes in Pediatric and Adult Patients With Hypothalamic Obesity

Jennifer Miller[1], Ashley H. Shoemaker[2], M. Jennifer Abuzzahab[3], Michael Gottschalk[4], Guojun Yuan[5], Sonali Malhotra[5,6,7], Cecilia Scimia[5] & Christian L. Roth[8,9]
[1]University of Florida College of Medicine, Pediatric Endocrinology, Department of Pediatrics, Gainesville, FL, United States; [2]Vanderbilt University Medical Center, Ian Burr Division of Endocrinology and Diabetes, Nashville, TN, United States; [3]Children's Minnesota, Pediatric Endocrinology and Diabetes, Saint Paul, MN, United States; [4]University of California San Diego/Rady Children's Hospital, Pediatric Endocrinology, San Diego, CA, United States; [5]Rhythm Pharmaceuticals, Inc., Boston, MA, United States; [6]Massachusetts General Hospital, Boston, MA, United States; [7]Harvard Medical School, Boston, MA, United States; [8]Seattle Children's Research Institute, Seattle, WA, United States; [9]University of Washington, Division of Endocrinology, Department of Pediatrics, Seattle, WA, United States

Background
Hypothalamic obesity (HO) is an acquired form of severe obesity that can occur following surgical resection of or radiotherapy for brain tumors and is often unresponsive to lifestyle modifications or traditional obesity pharmacotherapies. Here, we report weight- and body composition–related findings from a Phase 2 trial of setmelanotide, a melanocortin-4 receptor agonist, in patients with HO.
Methods
A Phase 2, open-label, 16-week trial of setmelanotide in patients aged $\geq$6 to $\leq$ 40 years with HO caused by hypothalamic damage secondary to brain tumor, surgical resection, and/or chemotherapy was performed. Setmelanotide was initiated at 1 or 2mg and increased to 3mg once daily over 2-4 weeks. The primary endpoint was the proportion of patients reaching $\geq$5% body mass index (BMI) reduction from baseline at Week 16. Secondary and exploratory endpoints included changes from baseline in BMI Z score (patients aged $\geq$6 to 18 years), body weight, and waist circumference. Change in body composition, measured by dual-energy x-ray absorptiometry was also assessed.
Results
Eighteen (13 pediatric, 5 adult) patients were included. Tumor types leading to HO included craniopharyngioma, astrocytoma, and hamartoma. All patients adhering to treatment ($n=17$) experienced weight loss, including 2 patients who discontinued because of an adverse event (AE). At Week 16, most (16/18) patients met the primary endpoint (88.9%[90% confidence interval(CI), 69.0%-98.0%]; $P<0.0001$), with mean (standard deviation[SD]) percent changes in body weight of -12.6%(9.1%) and BMI of -14.5% (9.5%); mean(SD) BMI percent change for patients adhering to treatment ($n=17$) was -15.4%. Of 18 patients, 14 achieved $\geq$10% BMI reduction. The mean(SD) BMI Z score change in pediatric patients was -1.3(1.0), and 12 of 13 pediatric patients (92.3% [90% CI, 68.4%-99.6%]; $P<0.0001$) reached $\geq$0.2-point reduction. Across all patients, weight loss was primarily due to reduction in fat mass (mean [SD] change from baseline at Week 16, -7.7 [5.3]kg; -16.4%) rather than lean mass (-3.4 [5.5] kg; -6.5%). The mean(SD) waist circumference change from baseline was -12.0 (5.8)cm (mean[SD] percent change, -10.4%[5.2%]). Treatment-related AEs occurred in 15 patients (83.3%); nausea ($n=11$; 61.1%), skin hyperpigmentation ($n=6$; 33.3%), vomiting ($n=5$; 27.8%), and diarrhea ($n=4$; 22.2%) were the most frequently reported.
Conclusions
Setmelanotide improved BMI, weight, and waist circumference in a heterogeneous population with HO secondary to treatment of 3 different tumor types.

Body composition also improved, with relatively larger reductions in fat vs lean mass.

The new anthropometric indices and atherogenic indices are correlated with glucose status in women with PCOS

Justyna Nowak[1], Marzena Jabczyk[2], Paweł Jagielski[3], Bartosz Hudzik[1,4], Karolina Kulik-Kupka[2] & Barbara Zubelewicz-Szkodzińska[2,5]

[1]Medical University of Silesia, Department of Cardiovascular Disease Prevention, Department of Metabolic Disease Prevention, Faculty of Health Sciences in Bytom, Poland; [2]Medical University of Silesia, Department of Nutrition-Related Disease Prevention, Department of Metabolic Disease Prevention, Faculty of Health Sciences in Bytom, Poland; [3]Jagiellonian University Medical College, Department of Nutrition and Drug Research, Institute of Public Health, Faculty of Health Sciences, Poland; [4]Medical University of Silesia, Third Department of Cardiology, Silesian Center for Heart Disease, Faculty of Medical Sciences in Zabrze, Poland; [5]District Hospital, Department of Endocrinology, Poland

Introduction

Polycystic ovary syndrome is complex endocrine disorders, characterized by ovulatory dysfunction, hyperandrogenism and polycystic ovarian morphology. Those are lipid abnormalities, hyperinsulinemia, insulin resistance, impaired glucose metabolism, type 2 diabetes mellitus, metabolic syndrome, hyperandrogenism, oxidative stress and infertility. The visceral adiposity index (VAI) is a reliable marker of adipose tissue abnormalities in women with PCOS. A body shape index (ABSI), body adiposity index (BAI) are the other anthropometric indices which have shown correlation with cardiovascular diseases risk and metabolic syndrome risk such as glucose metabolism abnormalities and obesity.

Aim

The aim of this study was to investigate the usefulness of new anthropometric indices such as BAI, VAI, LAP, BRI, ABSI and new atherogenic indices such as TyG index, TyG-BMI index, TyG-WC index in evaluation of glucose parameters in patients with PCOS.

Material and methods

To the study was enrolled of 49 woman with diagnosed PCOS based on the Rotterdam criteria from 2003. Blood samples were taken from patients in the morning, before breakfast. Biochemical parameters (fasting glucose and fasting insulin, glucose and insulin after 60 and 120 minute OGTT, HbA1c, HOMA-IR index) were determined. Anthropometric parameters were measured with the use of standard methods in the morning. These measurements included body weight, height, waist circumference, and hip circumference. After this step anthropometric indices such as BAI (Body Adiposity Index), VAI (Visceral Adiposity Index), LAP (Lipid Accumulation Product), BRI (Body Roundness Index), ABSI (A Body Shape Index), AIP (Atherogenic Risk of Plasma) were calculated. The study conformed to the Declaration of Helsinki and was reviewed by the local bioethics committee

Results

There was observed positive correlation between fasting glucose and analyzed parameters: BAI, VAI, LAP, BRI, TyG index, TyG-BMI index, TyG-WC index ($P<0.05$). There was reported significant positive relationship between glucose after 60 minutes and VAI, LAP, BRI, ABSI, TyG index, TyG-BMI index, TyG-WC index ($P<0.05$). There was observed positive correlation between glucose after 120 minutes and VAI, LAP, BRI, TyG index, TyG-BMI index, TyG-WC index ($P<0.05$). HOMA-IR index was strongly correlated among group of women to all analyzed anthropometric parameters and atherogenic indices ($P<0.05$).

Conclusion

Analyzed newanthropometric indices and new atherogenic indices have demonstrated significant relationship with glucose profile in women with PCOS. These indices may be useful tool in assessing of metabolic disorders in women with PCOS.

Mitochondrial fitness in mouse Leydig cells is imbalanced by liraglutide upon glucose stimuli

Bruno Lopes[1,2], Patricia Braga[1,2,3], Pedro F. Oliveira[4], Marco Alves[1,2,3] & Raquel Bernardino[1,2]

[1]Unit for Multidisciplinary Research in Biomedicine (UMIB), Institute of Biomedical Sciences Abel Salazar (ICBAS), University of Porto, Porto, Portugal; [2]ITR- Laboratory for Integrative and Translational Research in Population Health, Porto, Portugal; [3]Institute of Biomedical Sciences Abel Salazar (ICBAS), Department of Imuno-physiology and Pharmacology, Porto, Portugal; [4]University of Aveiro, LAQV-REQUIMTE and Department of Chemistry, Aveiro, Portugal

Metabolic diseases represent a threatening worldwide epidemic that affects the entire body. It is known that metabolic diseases, namely diabetes, and obesity affect spermatogenesis via suppressing testosterone synthesis, inducing oxidative stress and other changes that lead to decreased male fertility. Glucagon-like peptide 1 (GLP1) receptor agonists, like liraglutide, are pharmacological agents recommended to normalize glucose levels in patients with type 2 diabetes mellitus. Recently, these agonists have been approved for the treatment of obesity to reduce body weight in patients without elevated blood glucose levels. However, the effects of liraglutide on male fertility are not fully understood. The main objective of this study was to understand the effect of liraglutide on the function of Leydig cells (LCs) exposed to conditions of hyperglycemia and normoglycemia. For this purpose, we exposed cell cultures of a LCs (BLTK1 cell line) to increasing concentrations of liraglutide (25, 50 and 100 nM), under conditions of normoglycemia (glucose 5 mM) and hyperglycemia (glucose 22 mM). Cellular viability, proliferation, and ROS production were accessed after 48 h treatment. Mitochondria function was accessed by Seahorse XF Cell Mito Stress assay. We observed that none of the concentrations of liraglutide alter the cell proliferation of LCs or induce cytotoxicity, however it induces an increase in the metabolic viability of cells under normoglycemic conditions. Nonetheless, we also observed an increase in oxidative stress caused by all liraglutide concentrations on 5 mM glucose LCs. In addition, mitochondrial bioenergetics is affected, in which liraglutide decreases basal respiration rate, maximal respiration rate, ATP production and proton leak in LCs exposed to hyperglycemic conditions compared to the group of LCs exposed to 22 mM glucose without exposure to any concentration of liraglutide. In conclusion, these results indicate that liraglutide alters the mitochondrial performance of LCs exposed to high glucose concentrations and increases the metabolic viability of cells in normoglycemia. Since mitochondria are essential for cell bioenergetics and for the steroidogenesis that occurs in LCs, it is extremely important in the future to understand the effect of mitochondrial fitness caused by liraglutide on testosterone production and male fertility.

Development of Exogenous Insulin Antibody Syndrome in a Patient with Type 1 Diabetes Mellitus Using Insulin Analogues

Buket Durmaz[1], Tuana Berivan Butun[1], Kenan Sakar[2], Gulhan Akbaba[2] & Nese Cinar[2]

[1]Mugla Sitki Kocman University Faculty of Medicine, Department of Internal Medicine, Mugla, Turkey; [2]Mugla Sitki Kocman University Faculty of Medicine, Department of Endocrinology and Metabolism, Mugla, Turkey

Introduction

Insulin antibodies, developed in patients treated with exogenous insulin, might affect glycemic control due to their tendency to bind and/or release insulin in an unpredictable fashion. It is reported to be caused by immunoglobulin G-derived insulin antibodies. Insulin antibodies induced by exogenous insulin in diabetic patients is associated with hypersensitivity reactions, glycemic variability mainly with insulin resistance/ hyperglycemia or hypoglycemia. We reported a case of Type 1 diabetes mellitus (T1DM) who developed exogenous insulin antibody syndrome (EIAS) to insulin analogues during follow-up.

Case presentation

A 20 year-old female patient diagnosed as TIDM three months before, had been using insulin aspart and glargine for three months. She weighed 42 kg. Her blood glucose levels were under control and her HbA1c level decreased from 13.9% to 8.6% in two months. Although she followed her diet and increased daily activity, her need for insulin aspart increased (3 U at each meal to 9-12 U), insulin glargine (7 U/d to 16 U/d) in a month. Her blood sugar levels still remained high (fasting plasma glucose were around 200 mg/dl and posprandial glucose levels were around 300 mg/dl). Her insulin regimen was transitioned to insulin detemir and glulisine but, her glucose control could not be achived despite using 2 U/kg of insulin. In suspicion of developing antibodies against insulin analogues, insuline glulisine was changed to regular insulin. Also, the patient's anti-insulin antibody levels were found to be increased than that at the time of diagnosis [30.93→44.62 IU/ml (0-20 IU/ml)]. After this treament regimen, her glucose levels were controlled in doses 0.95 U/kg (8 U regular insulin at each meal and 20 U/d detemir).

Conclusion

The majority of EIAS is reported in patients with type 2 DM and is very uncommon in patients with TIDM. Insulin analogues are known to have lower immunogenicity than animal/human insulin; accordingly, replacement with an insulin analogue is suggested to be an effective treatment of EIAS. However, a recent study by Hattori

et al., found that glargine and aspart were more antigenic than other insulin analogues. Recommended other regimens include glucocorticoids, immunsuppresants and plasmapheresis. Glucocorticoids may induce or worsen ketoacidosis in patient with TIDM. Interestingly, changing insulin regimen to human regular insulin is sufficient to achieve glucose control for our patient.

Effect of Origanum vulgare L. essential oil on insulin-induced PI3K/Akt signaling and glucose uptake in human adipocytes treated with palmitic acid

Alexis Cerda[1], Gabriela Yuri[1,2], Isidora Villagrán[2], Andrea Müller[3], Claudia Foerster[3] & Paulina Ormazabal[2]
[1]Laboratory of Obesity and Metabolism in Geriatrics and Adults (OMEGA), Institute of Nutrition and Food Technology (INTA), Universidad de Chile, Santiago, Chile; [2]Institute of Health Sciences, Universidad de O'Higgins, Rancagua, Chile; [3]Institute of Agrifood, Animal and Environmental Sciences (ICA3), Universidad de O'Higgins. Campus Colchagua, San Fernando, Chile

Background
Obesity is strongly associated with insulin resistance (IR). IR at the molecular level may be defined as a diminished activation of PI3K/Akt signaling and its related molecules (IRS-1/Akt/AS160) as well as reduced glucose uptake. Subjects with obesity have elevated plasma levels of saturated fatty acids, such as palmitic acid (PA), which triggers insulin signaling disruption *in vivo* and *in vitro*. Oregano (*Origanum vulgare* L.) is a plant used as a food component worldwide. Interestingly, the main constituents of oregano have shown protective effects on obesity-related dysfunctions. The *Origanum vulgare* L. essential oil (O-EO) contains considerable amounts of phenolic monoterpenes, such as carvacrol and thymol, which may explain the biological activity of the plant. The aim of this study was to assess whether O-EO exposure protects against PA-induced disruption of IRS-1/Akt/AS160 signaling and glucose uptake in human adipose cells.
Methods
Cytotoxicity of a range of O-EO concentrations (0.01–20 µg/ml) was evaluated by MTS assay in *in vitro* differentiated adipocytes from the adipose cell line SW872. Adipocytes were incubated or not with PA for 24 h in the presence or not of O-EO (2-h preincubation), and thereafter stimulated with insulin or vehicle. Thereby, experimental conditions were: control (untreated cells), 0.4 mM PA, 0.1 µg/ml of O-EO, 10 µg/ml of O-EO, 0.1 µg/ml of O-EO (2 h before) + 0.4 mM PA for 24 h, 10 µg/ml of O-EO (2 h before) + 0.4 mM PA for 24 h, and incubated with 100 nM insulin for 10 min. Phosphorylation of Tyr-IRS-1, Ser-Akt and Thr-AS160 were evaluated by Western blot and glucose uptake was assessed using the 2-NBDG analogue.
Results
In SW872 adipocytes, O-EO was not cytotoxic at any concentration assessed. Insulin-stimulated phosphorylation of IRS-1, Akt, AS160 and glucose uptake were not affected by treatment with 0.1 and 10 µg/ml O-EO compared with vehicle-treated cells. PA-treated adipocytes showed a reduction in insulin-stimulated phosphorylation of IRS-1, Akt, AS160 and glucose uptake compared to control ($P<0.05$). Interestingly, these effects were prevented by O-EO treatment.
Conclusion
These findings give new insights into the effect of O-EO ameliorating PA-impaired insulin signaling and glucose uptake in adipocytes. More studies should focus on *Origanum vulgare* L., since might represent a preventive approach in individuals whose circulating PA levels contribute to IR.

Strategic Designs to identify the best housekeeping genes for the characterization of biomarkers in adipose tissue of patients with obesity and cancer

Jesus Perez Gomez[1,2,3,4], Francisco Porcel-Pastrana[1,2,3,4], Marina de la Luz Borrero[1,2,3,4], Manuel D. Gahete[1,2,3,4], Rocío Guzmán[1,2,3,4], Maria Malagon[1,2,3,4] & Raul M. Luque[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba, GC27 - OncObesity and Metabolism, Córdoba, Spain; [2]University of Córdoba, Department of Cell Biology, Physiology and Immunology, Córdoba, Spain; [3]Reina Sofia University Hospital, HURS - Urology Service, Córdoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition, CIBERobn, Córdoba, Spain

Obesity (OB) is caused by an energy imbalance that finally leads to adipose tissue dysfunction, and the appearance of multiple comorbidities, such as certain cancer types, including prostate cancer (PCa), which is one of the leading causes of cancer-related death in men population worldwide. In this context, periprostatic adipose tissue (PPAT) has recently gained increased attention as a key regulator of the pathophysiological relationship between OB and PCa. However, it has been very challenging to identify suitable and useful housekeeping genes (HKGs) in adipose tissue as reference genes for expression analyses in such pathological conditions (OB and cancer) probably due to the constant dynamic state of the adipose tissue. Therefore, the objective of the present work was to identify a set of HKGs in PPAT samples useful in studies focused on the pathophysiological relationship between OB and cancer using PCa as a cancer model. To that end, 15 potential HKGs were bibliographically selected to evaluate their expression levels by quantitative real-time PCR in a PPAT-screening cohort of normoweight (NW)/obese patients with and without PCa (discovery-cohort; $n=20$; 5/group). Then, results were validated using an ample set of samples [validation-cohort; $n=76$; 20/35 PCa patients (with NW/OB), and 6/15 patients without PCa (under NW and OB state), respectively] using a microfluidic quantitative-PCR array (Fluidigm). Stability and HKG suitability were assessed using different software (GeNorm, BestKeeper, and NormFinder). Our results demonstrate that *LRP10*, followed by *PGK1* and *RPLP0* exhibits the lowest variability in expression levels across the discovery-cohort using the two methodological approaches mentioned above. Furthermore, the expression of these three genes ranked with the best scores as HKGs using all the programs by discriminating the samples according to the BMI and the presence/absence of tumors. The same results were obtained when using the validation-cohort. Additionally, the validation of these genes was corroborated by the analysis of genes typically altered in OB and PCa conditions and previously reported to be highly dysregulated in PPAT (e.g., *MMP2, MMP9, LEP*, and *ANGPT1*). Our analyses revealed that the genes with the highest variability were *HMBS*, *PPIG*, and *GUSB* when the pathophysiological relationship between OB and PCa was studied, but these HKGs were valid to discriminate between non-tumor and PCa conditions. Altogether, we can conclude that *LRP10*, *PGK1*, and *RPLP0* should be used as optimal HKGs for gene expression analyses in PPAT from patients with OB and/or PCa.

Time In Range and Triglyceride/Glucose Index In Type 2 Diabetes with Mafld

Giovanni Ragozzino[1], Igea Martina Madonna[1], Nadia Maria Venere Cristiano[1] & Edi Mattera[2]
[1]University of Campania, Environmental Biological and Pharmaceutical Sciences and Technologies, Caserta, Italy; [2]University of Campania, Precision Medicine, Naples, Italy

Background and Aims
The metabolic-associated fatty liver disease (MAFLD) is a fatty liver accumulation with metabolic dysfunction (diabetes, overweight/obese, insulin-resistance), a definition more practical for identifying patients with fatty liver disease with high risk of disease progression. The triglyceride-glucose (TyG) index is a marker of insulin resistance. Long-term fasting plasma glucose (FPG) variability is associated with fatty liver content (FLC). Continuous glucose monitoring (CGM)-derived time in range (TIR) is a valuable blood glucose metric and the concept of TIR has emerged from the efforts of diabetes experts to discover a reliable parameter, "beyond HbA1c" to assess glycemic control. Hence, an effective treatment should always target to increase TIR vs Time-below-range (TBR).
Methods
18 Type 2 diabetic patients (M/F:9/9; aged 56 ± 8yr; BMI: 28.3 ± 2.4; duration: 10.2 ± 4,5 yr; FPG: 8.5 ± 1.5 mmol/l; HbA1c:7.9 ± 0.6%) treated with DPPIV/metformin with proven MAFLD were recruited. Antidiabetic therapy was shifted to dulaglutide/pioglidazone. The TyG index was calculated as ln [fasting triglyceride level (mg/dl) × fasting plasma glucose level (mg/dl)/2] and TIR/TBR by real-time (GlucoMen® Day CGM). The primary endpoint was percentage of TIR and TyG index score after 90 days.
Results
A mean TIR (73.1% dulaglutide/pioglidazone vs 68.8% DPPIV/metformin, respectively) or estimated treatment difference (2.96% or 60.9 min/d) and reduced nocturnal TBR (<3.9mmol/l) were observed. TyG index was positively

correlated with HbA1c and negatively with TIR and is a useful tool for assessing glycemic control in T2D patients.
Conclusions
These evidences supported % TIR as an important outcome variable of glycemic control in treatment practice. Compared with HbA1c, CGM-TIR may better capture risk of MAFLD worsening and lower TIR was associated with MAFLD evolution. The TyG index was correlated with the severity of hepatic steatosis (FLC). Dulaglutide/pioglidazone compared with DPPIV/metformin, provided more TIR and time in tight glycaemic range, and reduced TyG in type 2 diabetes.

A new referral pathway to the multidisciplinary team for inpatients with diabetic foot pathology
Madeline Brazell, Muzammil Nahaboo Solim, Natalia Rios Turek & Simon Ashwell
The James Cook University Hospital, Middlesbrough, United Kingdom

Background
In any given week, 2.5% of diabetic patients have a foot ulcer. In the United Kingdom (UK), there are 7000 lower limb amputations in people with diabetes every year and the annual NHS expenditure on diabetic foot-related healthcare amounts to £1 billion. As per the National Institute for Health and Care Excellence guidelines in the UK, a person with diabetes needs to be referred to an MDT within 24 h of finding a foot ulcer. The National Diabetes Footcare Audit demonstrates better outcomes at 12 weeks for patients with a new diabetic foot ulcer referred early for MDT input. The early identification of patients with a diabetic foot ulcer and a timely referral to the MDT is therefore vital.
Methods
A two-cycle quality improvement project, with retrospective data collection before and after our intervention, was carried out at our hospital with the aim of improving identification of patients and quality of referrals. Those information mainly included ulcer charateristics, past medical history and investigations. An online referral system with a pre-set questions was then introduced along with teaching sessions delivered to the acute medical team. The results were analysed and presented to the endocrinology and diabetes department.
Results
Our results showed that the average monthly number of referrals was 10.3 for the first cycle and 12.5 for the second cycle. The average referral time was 8.3 days for the first cycle and 4.2 days for the second cycle. Size of ulcer reporting improved from 6.5% to 64%, depth of ulcer from 9.7% to 12.0% and position of ulcer from 74.19% to 80.0%. Mention of peripheral vascular disease improved from 9.7% to 20.0%, presence of pulse from 12.9% to 100% and presence of neuropathy from 12.9% to 100.0%. For investigations, mention of microbiology culture results improved from 12.9% to 40.0% and imaging from 22.6% to 60.0%.
Conclusion
There has been an improvement in the time from admission until referral although more work needs to be done to improve the time to within the 24 hour window. The online referral system helped to improve the quality of information of the referral with regards to information on ulcer characteristics, past medical history and investigations. Improved quality of referrals allow for a more efficient MDT functioning and more timely management strategies for patient outcomes. We intend to further continue this project to look at the effect of the referral system on patient outcomes.

Characteristics of patients admitted to the hospital with diabetes and frailty: preliminary data of an audit in a UK teaching hospital
Eka Melson[1], Mohamed Fazil[1], Meri Davitadze[2], Hnin Lwin[1], Kath Higgins[1] & Alison Gallagher[1]
[1]University Hospitals of Leicester, Diabetes, United Kingdom; [2]Clinic NeoLab, Endocrinology, Tbilisi, Georgia

Introduction
Older age and diabetes are both risk factors for frailty. Functional decline and disability in older, frail adults with diabetes results in an increased susceptibility to falls and hospital admission. Hypoglycaemia is common and more likely to result in hospital admission in older adults with diabetes and frailty. An Hb_{A1c} of below 7% (53 mmol/mol) is likely to represent overtreatment of hyperglycaemia. JBDS has recommended a review of Hb_{A1c} in the previous 6-12 months for patients with diabetes and frailty. Hospital admission presents an opportunity for clinical evaluation including medication review to deintensify blood glucose lowering treatment. This audit aimed to assess the prevalence and characteristics of patients with type 2 diabetes (T2DM) and frailty admitted to the hospital as an emergency.
Method
We collected data on frailty using the Clinical Frailty Scale (CFS) in older adults with and T2DM admitted to the acute medicine unit(AMU). Their Hb_{A1c} prior and upon admission were noted. Data including gender, body mass index (BMI), medications, and co-morbidities were also collected. Patients were categorized as overtreated if they had an Hb_{A1c} prior to admission of $\leq$ 7%. Chi-squared test, t-test and Mann-Whitney U-test were used to compare categorical data and continuous data between groups, respectively.
Results
Out of 667 patients admitted to the AMU, 67 patients with T2DM and CFS of $\geq$6 were identified representing a prevalence of 10% of acute medical admissions. Fifty-four percent (n=36/67) were female and mean age was 78.3$\pm$9.6 years. The median BMI was 27.5kg/m2 (23.5-32.8) with 36.7%(n=22/60) of normal weight and 63.3%(n=38/60) overweight/obese. Median Hb_{A1c} prior to admission was 6.9%;52mmol/mol (6.0-7.7%;42-61mmol/mol) whilst56.7% (n=38/67) had Hb_{A1c} >7.0% upon admission. Sixty-five percent(n=44/67) had their Hb_{A1c} checked in the last 6 months. Of the older adults with an Hb_{A1c} of <7.0%, 13%(n=5/38) were treated with insulin or sulphonylurea therapy. The overtreated group had lower BMI, required less medications, and had less co-morbidities, compared to patients who were not overtreated.
Conclusion
Our preliminary results showed that older adults with T2DM and frailty represent a high proportion of older adults admitted to hospital acutely. Despite recommendations, one third of patients had not had their Hb_{A1c} measured in the preceding 6 months. Those patients who had an Hb_{A1c} of below 7% whilst taking insulin or sulphonylureas could be considered overtreated and at risk of severe hypoglycaemia. Admission to the hospital presents an opportunity for deintensification of blood glucose lowering treatment in this group.

SIMBA for Students – teaching endocrinology to pre-clinical medical and pharmacy students through online simulation- a pilot study
Fatema Rezai[1], Isabel Allison[2], Aditya Swaminathan[1], Tamzin Ogiliev[3], Haaziq Sheikh[4], Georgia Morgan[5], Dengyi Zhou[6], Jameela Sheikh[1], Alice Yip[1], SIMBA and CoMICs Team[7] & Punith Kempegowda[7,8]
[1]University of Birmingham, College of Medical and Dental Sciences, Birmingham, United Kingdom; [2]West Middlesex University Hospital, London, United Kingdom; [3]Lancaster University Medical School, Lancaster, United Kingdom; [4]Haberdashers' Adams Grammar School, Birmingham, United Kingdom; [5]Princess of Wales Hospital, Princess of Wales Hospital, Cwm Taf Morgannwg University Health Board, Bridgend, United Kingdom; [6]Imperial College Healthcare NHS Trust, London, United Kingdom; [7]Institute of Metabolism and Systems Research, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom; [8]Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Introduction
Simulation via Instant Messaging – Birmingham Advance (SIMBA) for Students is an online education model used to teach endocrine topics to pre-clinical medical and pharmacy students using simulated clinical cases delivered through WhatsApp and Zoom. In this study, we investigated the efficacy and acceptability of SIMBA for students compared to traditional small-group teaching (SGT).
Methods
These SIMBA sessions were conducted from 2020 to 2022 covering adrenal, metabolic bone, thyroid, diabetes, and reproductive endocrinology. Medical students in year 1 and year 2 medical and year 3 pharmacy students were invited to participate in the session. Cases used for SGT were converted to SIMBA transcripts. These transcripts were reviewed and approved by clinicians and teachers involved in SGT with a focus on curriculum learning objectives and equivalence between SIMBA and SGT transcripts. On the day of the simulation, participants solved three interactive clinical cases during each session, followed by a Q& A session with an expert to resolve any queries participants had during the simulation. All students were invited to complete a survey following SIMBA which included 12-15 multiple-choice questions (MCQs) depending on the session. All SGT participants were also invited to complete the same survey. This resulted in three groups- those who attended SIMBA only, SGT only and those who attended both SIMBA and SGT. Median MCQ results as percentages were compared between groups using Wilcoxon signed rank test. The answers to Likert

scale questions were expressed as percentages. Open-ended questions from surveys underwent content analysis.
Results
130 students attended 15 SIMBA sessions during the study. The median MCQ result was significantly higher in the SIMBA-only group than in the SGT-only group ($P < .0001$). A large proportion of students agreed that SIMBA was easy to follow (91%), engaging and interactive (82%), stimulated their interest in endocrinology (82%), promoted new knowledge (90%), and provided an in-depth understanding of the topic (94%). 89% enjoyed the session overall and 83% would like to have SIMBA alongside SGT. Content analysis revealed themes of knowledge application through case-based learning, a deeper understanding of the topic, and instantaneous feedback.
Conclusions
SIMBA is a good alternative model for SGT to teach endocrinology to pre-clinical medical and pharmacy students by providing engaging, interactive, and interesting sessions. A future study focusing on cost-effectiveness analysis between the two models is underway to identify if SIMBA can replace SGT or be delivered in addition to SGT.

Intestinimonas butyriciproducens improves glucose metabolism in subjects with obesity and prediabetes: preliminary data from a randomized controlled trial

Valentina Antoniotti[1], Marina Caputo[2], Sabrina TIni[3], Alessandro Antonioli[3], Tommaso Daffara[2], Silvia De Marchi[2], Elisa Bona[4], Angela Amoruso[5], Marco Pane[5], Sahin Gul[6], Gianluca Aimaretti[2], Jos Seegers[6] & Flavia Prodam[2]
[1]SCDU of Pediatrics, Department of Health Sciences, Novara, Italy; [2]Endocrinology, Department of Translational Medicine, Novara, Italy; [3]Department of Health Sciences, Novara, Italy; [4]University of Piemonte Orientale, Department of Sustainable Development and Ecological Transition, Vercelli, Italy; [5]Research & Development, Probiotical Research srl, Novara, Italy; [6]Caelus Health, Amsterdam, Netherlands

As the prevalence of type 2 Diabetes Mellitus (T2D) is constantly increasing and the current prevention is not enough, new effective strategies are necessary, in particular in high-risk individuals. Therapeutic microbiology is one of further proposed targets, and, in particular, butyrate-producing bacteria can improve metabolic parameters in obese patients. Our study aims to evaluate the effect of *Intestinimonas butyriciproducens* as a preventive therapy for T2D in prediabetes, since it is able to decrease Advanced Glycation End Products (AGEs), convert sugars and proteins in butyrate, and increase insulin sensitivity. The trial is a double-blind, randomized, placebo-controlled (phase 1) and open label pilot study with two different doses (phase 2). *I. butyriciproducens* (10^5 CFU/day) or placebo were given for 12 weeks, then subjects in placebo will start the treatment (10^5 CFU/day), while the other group will increase the dose (10^8 CFU/day) for 14 weeks. We included overweight/obese patients with impaired fasting glucose (IFG) or impaired glucose tolerance (IGT). Patients were assessed for clinical, biochemical and microbiota parameters at the time of recruitment (V1), after 12 weeks (V7) and 26 weeks of treatment (V10), during which the eating and lifestyle habits were also evaluated. Fourteen out of the 26 patients programmed, have been closed phase 1 and/or 2. In the first 7 patients who completed the study, those who have taken the probiotic since the beginning of the study had a significant improvement in the fasting and post-OGTT glucose-insulin metabolism. In particular, HOMA-index decreased over time in treated patients (V1: 3.3 $\pm$ 1.3; V7: 2.6 $\pm$ 1.5, V10: 2.5 $\pm$ 1.3), whereas remained about unchanged in placebo group (V1: 3.2 $\pm$ 1.1, V7: 3.5 $\pm$ 1.0, V10: 3.4 $\pm$ 1.3). Flash glucose monitoring data were stable. These findings were confirmed in the other 7 patients who completed phase 1. Serum AGE concentrations showed a trend towards a decrease in treated patients. Microbiota analyses are ongoing. In conclusion, *Intestinimonas butyriciproducens* seems to improve insulin resistance and inflammation in patients treated for a longer period, likely due to the time or dose. Since the study is still ongoing, the data should be confirmed. *Intestinimonas butyriciproducens* could be a new strategy in the work-up of T2D prevention.

Introduction
Simulation via Instant Messaging – Birmingham Advance (SIMBA) is a simulation-based training model shown to have increased clinicians' confidence in managing cases in diabetes and endocrinology, as well as sustained clinical knowledge.[1] Traditional simulation models have typically focussed on a specific group of healthcare professionals. We evaluated if there is a difference in performance between different training groups during SIMBA.
Methods
All participants who completed both pre-and post-SIMBA surveys in 17 SIMBA sessions between May 2020 and June 2022 were included in this study. Participants' performance was assessed using the Global Rating Scale (GRS), which was adapted for each session and scored the participant on a scale of 1 (poor) to 5 (excellent) in 6 domains: History Taking, Physical Examination, Investigations, Result Interpretation, Clinical Judgement, and Management. Participants were grouped as junior grade (foundation year trainees, internal medical trainees and equivalent), middle grade (specialty training years 3 to 7 and equivalent) and senior grade (consultants and equivalent). Adjusted means and 95% confidence intervals of the scores for the six GRS domains were calculated using multiple linear regression models, adjusting for sex, country, training, and number of WhatsApp messages. The mean difference of the pairwise comparisons between each of the performance scores was calculated using a paired t-test.
Results
A total of 207 (junior grade – 59 (28.5%), middle grade – 116 (56.0%), and senior grade – 32 (15.4%)) from 49 countries were included in this analysis. Except for history taking where junior grade participants scored higher than the other two groups (junior vs middle vs senior: 4.2 vs 3.7 vs 3.7; $P = .0055$), there were no significant differences between the three groups on other GRS domains (Physical Examination (4.0 vs 3.7 vs 3.4; $P = .0688$), Clinical Interpretation (2.6 vs 2.6 vs 3.0; $P = .244$), Investigation (3.5 vs 3.4 vs 3.6; $P = .5573$)), Clinical Judgement (3.4 vs 3.3 vs 3.4; $P = .7891$), Management (2.8 vs 2.7 vs 2.7; $P = .8459$).
Conclusions
SIMBA provides equivalent simulation-based learning experiences irrespective of training grade. Combining these results with our previously published data on sustained improvement in clinical knowledge makes SIMBA an effective medium of teaching and learning for endocrinology.

A Case Report: Rapidly Onset Fournier'S Gangrene In Empagliflozin Treatment for Type 2 Diabetes

Melek Avci[1], Kenan Sakar[2], Nese Cinar[2] & Gulhan Akbaba[2]
[1]Faculty of Medicine, Mugla Sitki Kocman University, Department of Internal Medicine, Mugla, Turkey; [2]Faculty of Medicine, Mugla Sitki Kocman University, Department of Endocrinology and Metabolic Diseases, Mugla, Turkey

Introduction
Sodium/glucose co-transporter 2 (SGLT2) inhibitors are a relatively new group of antihyperglycaemic medications for type 2 diabetes mellitus (T2DM). Euglycemic diabetic ketoacidosis (EDKA) and Fournier's gangrene (FG) are uncommon advers effects of SGLT2 inhibitors. We report a case of a 52-year-old man who developed FG and EDKA after starting the SGLT2 inhibitor empagliflozin.
Case Presentation
A-52 years old male patient attended to the emergency department with bilateral red-swollen perineal lesion of one day evolution. Patient had a history of T2DM

under poor glycemic control for 10 years. He was using glyclazide 30 mg/d. He started to use empagliflozin treatment for his high HbA1c levels (12.2 %) two days before the development of the lesion. In suspicion of FG, pelvic CT scan was taken and severe subcutaneous air was reported in the lesion consistent with FG. Emergent surgical debridement was performed and after surgery he was followed in surgical ICU. During follow-up, the patient became tachypneic, lethargic and he had no response to verbal stimulus. The patient had severe acidosis, low bicarbonate level and euglycemia (pH:6.90, bicarbonate 4.9 mEq/l, lactate:1.7 mmol/l, plasma glucose: 189 mg/dl). After diagnosis of EDKA, continuous intravenous regular insulin and saline infusion was started. After 20 h of treatment, patient's plasma pH level increased to 7.26 and bicarbonate level increased to 19.9 mEq/l. His state of counciousness improved and GCS scored 15. The patient is still under intensive insuline therapy, antibiotherapy and negative pressure dressing for FG.

Conclusions

FG is a necrotizing infection of the tissue under the skin of the perineum. The incidence is 1.6 cases per 100×000 population. Poorly controlled diabetes, obesity, chronic alcoholism and immunosuppression are risk factors for FG. The duration of FG development after the use of SGLT2 inhibitors varies between 10 days and 6 years in the literature. In our patient, FG developed in a very short time, 2 days after starting SGLT2 inhibitor. EDKA is a clinical feature in which blood sugar is within normal limits, accompanied by acidosis and ketosis. In the perioperative setting, typical signs and symptoms of EDKA can confound the diagnosis and mistakenly be attributed to clinical presentations during the postsurgical state. EDKA, should be considered in the differential diagnosis and treatment should be started without delay. It is imperative that clinicians evaluate the benefits and risks associated with SGLT-2 inhibitors in diabetic patients at high risk of FG who do not use insulin.

Gaucher Disease Type 3c: A Rare Metabolic Disease Diagnosed In Adulthood

Fatma Tuğçe Şah Ünal & Özgür Demir
Ankara University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Background

Gaucher disease (GD) is the most prevalent lysosomal disorder caused by *GBA* mutations and abnormal glucocerebrosidase function, leading to glucocerebroside accumulation mainly in the liver, spleen, bone marrow, lungs, and occasionally in the central nervous system. Gaucher disease type 3c (GD3c) is a rare subtype of the subacute/chronic neuronopathic GD3, caused by homozygosity for the *GBA* p. Asp448His (D409H) mutation.

Case Report

A 24-year-old male patient. He first applied to neurology with the complaint of spasms in the hands and neck. In the evaluation, hepatosplenomegaly and mild pancytopenia were detected. His cytopenia, eye and neurological findings have been present since early childhood. In the family history, his father died at the age of 35 and his brother at the age of 19 due to cardiac reasons. On physical examination, the patient's vertical eye movements were limited and bradykinesia was detected. In addition, the patient had brown macules scattered on his trunk, diagnosed as tinea versicolor. Bilateral hallux valgus was detected in the orthopedic evaluation. In the complete blood count, the white blood cell count was $3.39x10^9$/l(4.5-11), the hemoglobin level was 8 g/dl(13.2-17.3), and the platelet count was $35x10^9$/l(150-400). In addition, his transferrin saturation was 25%(13-45), total iron binding capacity was 302 mg/dl (250-450), serum iron level was 77 mg/dl(37-145), ferritin level was 987ng/ml(30-400), B12 level was 216 pg/ml(197-771), HDL cholesterol level was 27 mg/dl(40-60). In the MRI volumetric evaluation, the liver volume was 1300cc and the spleen volume was 9959cc. The patient has had no complain of chest pain or exertional dyspnea. In the echocardiographic examination, the aortic and mitral valves were thick. Aortic valve opening was found to be slightly restricted. On MRI of bones, heterogeneous bone marrow intensity was detected in both femur and pelvic bones, there was no osteonecrosis. In bone mineral densitometry, the femoral neck Z score was- 0.2 and the lumbar total Z score was -2.2. Orbital and cranial MRI revealed hydrocephaly, partial empty sella, hyperintense signal foci in T2AG and FLAIR sequences in periventricular and subcortical areas, and thickening in the calvarium. In the psychiatric evaluation, no pathological findings were detected, except for the anxiety. Genetic examination was performed with the preliminary diagnosis of GD. NM-000157.4 c.1342G>C(p.Asp448His) homozygous mutation was detected in the GBA gene compatible with the diagnosis of Gaucher disease type 3c. Thereupon, the patient was started with enzyme replacement treatment as velagluceridase alfa at a dose of 60 U/kg once every 15 days.

Conclusions

Although clinic presentation is variable, heart valve diseases, aortic calcification, oculomator apraxia, abnormal eye movements, corneal opacities, pancytopenia, hepatosplenomegaly, hydrocephalus are the main findings of GD3c.GD3c should definitely be considered in patients with these findings.

Obesity-Associated Hepatic Steatosis, Somatotropic Axis Impairment and Ferritin Levels are Strong Predictors of COVID–19 Severity

Davide Masi[1], Elena Gangitano[1], Luca Marino[1], Anna Criniti[1], Laura Ballesio[2], Antonella Anzuini[1], Antonio Angeloni[3], Lucio Gnessi[1], Orietta Gandini[4] & Carla Lubrano[1]
[1]Sapienza University, Department of Experimental Medicine, Section of Medical Pathophysiology, Food Science and Endocrinology, Italy; [2]Sapienza University, Department of Radiology, Anatomo–Pathology and Oncology, Italy; [3]Sapienza University, Emergency Medicine Unit, Department of Emergency-Acceptance, Critical Areas and Trauma, Italy; [4]Sapienza University, Department of Molecular Medicine, Italy

Purpose

From a clinical perspective, the full spectrum of Sars–CoV–2–infected patients has not yet been defined. This study aimed to evaluate whether liver density on computed tomography (CT) scan and serum insulin-like growth factor 1 (IGF1) values can explain the clinical variability of COVID–19 cases.

Methods

We performed a retrospective study including SARS–CoV–2–infected patients hospitalized from March 2020 to May 2021 at Umberto I Polyclinic of Rome. Patients were divided into four groups (0–mild, 1–moderate, 2–severe, and 3–critical) according to respiratory failure. Routine laboratory examinations, BMI, liver steatosis indices, CT quantification of hepatic attenuation, and IGF1 serum levels have been assessed and correlated with COVID–19 severity. Hepatic attenuation was defined as the mean density of three regions of interest expressed in Hounsfield (HU).

Results

Mean liver density was 50.7 ± 9.5 HU, whereas mean GH and IGF1 were 0.92 ± 1.06 ng/ml and 97.2 ± 63.4 ng/ml, respectively. Analysis of variance between groups showed that patients with worse prognoses had higher BMI, lower liver density, and significantly lower concentrations of albumin, GH, and IGF–1. ROC analysis confirmed the prognostic accuracy of serum IGF1 in discriminating patients with the occurrence of death/severe respiratory failure. (AUC 0.688, CI: 0.587 to 0.789, $P < 0.001$). A multivariate analysis considering the degrees of severity of the disease as the dependent variable and ferritin, liver density, and the standard deviation score of IGF1 as regressors showed that all three parameters were significant predictors ($B = 0.37$, $P < 0.001$; $B = -0.36$, $P < 0.001$ and $B = -0.21$, $P = 0.03$ respectively).

Conclusions

IGF-1 and liver steatosis account for the increased risk of poor prognosis in COVID-19 patients with obesity.

Objective
Ideally, treatment strategies designed to reduce weight or body mass index in patients with obesity should reduce fat mass while preserving lean mass because reduced lean mass can negatively impact overall health and energy expenditure, thus favoring weight regain. In Phase 3 trials, 1 year of treatment with the melanocortin-4 receptor agonist setmelanotide led to weight reduction in patients with obesity due to biallelic variants in the genes encoding proopiomelanocortin (POMC)/proprotein convertase subtilisin/kexin type 1 (PCSK1; mean −25.6% change from baseline) or leptin receptor (LEPR; mean −12.5% change). The current analysis assesses changes in total fat and lean mass over 2 years in adult and pediatric patients who achieved beneficial weight loss at 1 year of treatment.
Methods
Patients with POMC, including PCSK1, or LEPR deficiency aged ≥6 years who demonstrated clinical benefit and acceptable safety after treatment with setmelanotide in a prior (index) trial continued treatment in a long-term extension trial (NCT03651765). Body weight measures and safety were assessed. Body composition was measured by dual-energy x-ray absorptiometry and reported as percent change in total fat and lean mass from index trial baseline in patients who achieved ≥10% weight reduction (≥18 years old) or ≥0.3-point body mass index Z score reduction (<18 years old) after 1 year of treatment.
Results
Across all patients ($n=24$), mean (standard deviation [SD]) percent changes in total fat mass were −37.2% (13.0%; $n=22$) at Month 12 and −32.4% (16.7%; $n=17$) at Month 24. Smaller mean (SD) percent changes were seen in lean mass at Month 12 (−7.8% [10.8%]) and 24 (−6.5% [16.2%]). No new safety issues were observed during long-term treatment.
Conclusions
Setmelanotide demonstrated clinical benefit in total fat mass reduction while achieving a relative maintenance of lean mass over 2 years of treatment.

Serum Vitamin B12 Levels and Diabetic Retinopathy in Type 2 Diabetes

Meriem Adel[1], Manel Jemel[1], Radhouen Gharbi[1], Anis Grassa[1], Yasmine Chaari[2], Hajer Kandara[1], Ines Kammoun[1], Rahma Mahjoub[2] & Emna Talbi[2]
[1]Nutrition, Endocrinology, Tunis, Tunisia; [2]Nutrition, Biochemistry, Tunis, Tunisia

Introduction
Diabetic retinopathy (DR) is a serious microvascular complication of type 2 diabetes and the leading cause of blindness worldwide. Several studies have reported the association between metformine-induced vitamin B12 deficiency in type 2 diabetic patients. However, the association between vitamin B12 and DR has only been investigated in few studies.
Materials and methods
A cross-sectional study was carried out on 123 type 2 diabetic patients treated with metformin. One hundred and four patients had a fundus examination: sixty eight patients with DR, 36 patients without DR. Vitamin B12 levels were measured in all participants.
Results
The mean age of the subjects (DR+) was 61.34±6.62 years vs 60.61±6.79 years in patients (DR-). In the patients (DR+) 30.9% were male vs 33.3% (DR). The mean duration of diabetes was 17.72 ±4.1 years in (DR+) and 13.92 ±7.57 years in (DR-) with a significant difference ($P=0.01$). The mean FBG was 12.53 ± 4.53 mmol/l and 10.58 mmol/l ± 4.53 mmol/l respectively with significant difference ($P=0.039$). However, there was no difference in mean HbA1c between the 2 groups. Blood levels of vitamin B12 were comparable between patients (DR+) (360.76 ± 165.12) and (DR-) (350.26 ± 219.20). There was no correlation between cobalamin levels and retinopathy ($P=0.78$). Mean metformin dose was 1908.82 ±606.79 in patients (DR+) and 1984.72±538.36 in patients (DR-). There was no correlation between metformin dose and DR $P=0.5$. The mean folate level was 7.82±3.19 in patients (RD+) and 8.41±4.25 in patients (DR-). There was no correlation between folate levels and retinopathy.
Conclusion
This study shows that vitamin B12 deficiency does not seem to play a role in DR. Further studies are needed to assess the real impact of vitamin B12 deficiency on DR and to evaluate the Impact of supplementation.

Association between diabetic peripheral neuropathy (DPN) and Hypertiglyceridemia in patients with type 2 diabetes in Georgia

Tamar Maghradze, Ramaz Kurashvili & Elena Shelestova
National Center for Diabetes Research, Endocrinlogy, Tbilisi, Georgia

Background
Diabetic neuropathy is the most prevalent chronic complications of diabetes. This heterogeneous group of conditions affects different parts of the nervous system and presents with diverse clinical manifestations. Diabetic peripheral neuropathy (DPN) is one of the common complication of type 2 diabetes and can lead to foot ulcer, gangrene or amputation. The risk of developing diabetic neuropathy increases with age, diabetes duration and poor control of blood glucose. About 60% to 70% of all people with diabetes will eventually develop DPN. Hypertiglyceridemia is a typical lipid disorder in patients with poorly controlled diabetes mellitus.
The Aim
Of this study was to assess the effect of hypertiglyceridemia on peripheral neuropathy in patient with type 2 diabetes(T2DM).
Methods
62 T2DM patients with peripheral neuropathy were enrolled in this study; among them, 33 men and 29 women (Study Group/SG). Their mean age was 56±7 yrs and diabetes duration varied from 5 to10 yrs. In all SG patients hypertiglyceridemia was diagnosed. 50 patients with the same age, sex and diabetes duration, but without DPN and normal triglycerides (TG) were used as controls (CG). HbA1c in SG was 8,1±1,2% and in CG - 7,7±1,1%. According to current Guidelines, to assess DPN, following neuropathy tests were performed in all patients: 10-g monofilament test, tip-term/temperature test, vibration test with the 128-Hz tuning fork, pick tests and neurological examination with Sudoscan. Results of all neurological tests in SG patients (monofilament test, tip-term/temperature test, vibration test) were positive, Sudoscan examination revealed presence of small fiber neuropathy. In CG patients all tests, except Sudoscan, were negative, while Sudoscan revealed small fiber damage. Association between hypertiglyceridemia and DPN was assessed. Serum triglyceride levels in SG patients were elevated(mean TG level 299± 45mg/dl, while in CG patients - 100±20mg/dl).
Results
According to neurological examinations prevalence of DPN in SG patients comprised 64,5% (40 cases). TG concentration was significantly elevated in T2DM patients with DPN when compared to patients without DPN and normal TG levels($P=0,005$). Elevated serum triglyceride levels were associated with DPN($P<0,044$).
Discussion
This study shows that increased levels of serum triglycerides may play important clinical role in development of DPN in T2DM patients in Georgia. The problem needs further investigation with other important parameters.

Gender differences in lower limb amputations among persons with diabetes

Trine Elisabeth Finnes[1,2], Susanna Valland[1], Ove Talsnes[3], Sindre Eik-Nes[1] & Kristin Holvik[4]
[1]Innlandet Hospital Trust, Internal Medicine, Hamar, Hamar, Norway; [2]University of Oslo Faculty of Medicine, Institute of Health and Society, Oslo, Norway; [3]Innlandet Hospital Trust, Orthopedic Surgery, Elverum, Norway; [4]Norwegian Institue of Public Health, Physical Helath and Ageing, Oslo, Norway

Background and Aim
Recent international studies indicate a secular decrease in the proportion of patients with diabetes who undergo lower limb amputations (LLA). However, our findings suggest that the proportion of diabetics among patients undergoing non-traumatic, non-cancer related lower limb amputations has increased over the past decades despite comprehensive preoperative investigations and other surgical interventions. To further explore the underlying reasons for this, we aimed to explore any gender differences in the preoperative treatment and assessment regarding indication for vascular surgery.
Methodes
Medical records for all patients identified with LLA by the electronic discharge registers at Innlandet Hospital, Elverum, from 2013 through 2019 were retrieved. Traumatic and cancer-related amputations were excluded. All codes for amputations and exarticulations were included, and amputations were verified by manual review by two of the authors. Only the first minor or major amputation in an individual were included in further analyses. Diabetes was defined by the

WHO criteria. Descriptive statistics and chi-square tests were performed using the SSPS TM version 26
Results
We identified 190 persons undergoing non-traumatic, non-cancer related amputations of the lower limb. Of the 120 men 70 % had type 1 or 2 diabetes. 50% of the women had diabetes. 66 % of the persons with diabetes and 72 % of the persons without diabetes had a vascular angiography (CT, MRI or conventional) preoperative. The proportion of amputees who underwent an angiography of the lower limbs were higher in men than in women ($P=0.048$). When stratifying in groups with and without diabetes, this difference was found only in the non-diabetes group ($P=0.004$). No statistical differences were found regarding other markers or risk factors of vascular disease, such as smoking, use of statins or anti-platelet agents.
Conclusion
The gender difference in favour more investigations with preoperative angiography before LLA in men, was not found in persons with diabetes, indicating equal treatment across the genders in this group.

Case Report: Atypical presentation of central pontine myelinolysis in hyperglycemia

Paloma González Lázaro[1], Cristina Contreras Pascual[2], Antonio Moreno Tirado[1], Maria Zhao Montero Benítez[1], Pedro Jimenez Torrecilla[1] & Ines Gomez García[1]
[1]Hospital General La Mancha Centro, Alcázar de San Juan, Spain; [2]Hospital Santa Barbara, Soria, Spain

Central pontine myelinolysis (CPM) is a neurological disorder typically caused by rapid correction of severe chronic hyponatremia. Conditions causing a hyperosmolar state can also cause CPM, but it is rarely seen in diabetes. We report the case of a 33-year-old woman with personal history of Type 1 Diabetes since she was 9 years old with very poor metabolic control (A1hbC 15%) and microvascular complications, who attended the emergency department due to left hemicranial headache for the past 2 days that subsided with the analgesia prescribed in the emergency room. As an incidence laboratory result showed a glycemia of 676mg/dl without ketoacidosis, increased serum osmolality, and normal sodium, so insulin therapy was started in the emergency room and she was discharged the next day asymptomatic with a glycemia of 183mg/dl. She went back to the emergency room 24 h later due to language impairment with difficulty in issuing words. MRI brain demonstrated a symmetric lesion in the central pons with increased signal intensity on T2- and diffusion-weighted images. After neurological consultation and MRI confirmation, the patient was diagnosed with CPM secondary to hyperosmolar hyperglycemia. Twelve-week-follow up with neurology was notable for near-complete resolution of symptoms and MRI alterations. The patient is currently undergoing Endocrinology check-ups with good metabolic control (A1HbC 6.7%) This is a case report of central pontine myelinolysis (CPM) associated with hyperglycemia, which is unique in several aspects: CPM occurred in the setting of uncontrolled hyperglycemia with normal corrected serum sodium and no other electrolyte abnormalities. The presentation was atypical with intermittent symptoms and patient remained alert without corticospinal involvement. Despite the pronounced fluctuations in serum osmolality, central pontine myelinolysis (CPM) is rarely seen in diabetics. This case report of CPM associated with hyperglycemia highlights the importance of adequate blood glucose control in diabetics. CPM can present atypically in diabetics and is only diagnosed in the presence of a high index of clinical suspicion.

Oxidative Stress and Biochemical Indicators In T2DM

Maria Trapali, Theodora Mavrogianni, Dimitrios Chaniotis & Petros Karkalousos
University of West Attica, Biomedical Sciences, Athens, Greece

Introduction
Many complications of T2DM, including retinopathy and renal failure, have been associated with glucose and triglyceride metabolism. Hyperglycemia causes oxidative stress mainly due to the enhanced production of mitochondrial reactive oxygen species ROS, non-enzymatic protein glycosylation and glucose autoxidation. Elevated levels of free fatty acids can contribute to oxidative stress by promoting mitochondrial oxidation. Furthermore, oxidative stress caused by hyperglycemia and free fatty acids leads to the activation of stress-sensitive signaling pathways, which impair both insulin secretion and action and promote the development of T2DM.
Aim
The aim of this study is to determine the possible correlation of glucose Glu, cholesterol Chol, HDL-Chol, LDL-Chol, triglycerides TG, plasma uric acid UA and glycosylated hemoglobin HbA1c with the levels of oxidized lipids in plasma and in red blood cells, diabetics and normal patients.
Materials and Methods
The study included 30 T2DM volunteers with plasma Glu levels $>$ 125mg% and HbA1c $>$ 7.0% and 30 normal volunteers who were the control group. Oxidative damage was determined by the thiobarbituric acid TBA method. The assay photometrically measures the malondialdehyde MDA contained in the sample as well as the MDA generated by lipid hydroperoxidases under the hydrolytic reaction conditions. Glu, HDL-Chol, LDL-Chol, TG, UA and HbA1c determinations were performed on a biochemical analyzer.
Results
In the control group, Glu levels were 84 ± 8 mg%, TG 78 ± 28 mg%, HDL 57 ± 8 mg%, LDL 115 ± 27 mg%, UA 5.6 ± 1.5 mg%, HbA1c 5.4 ± 0.2%, plasma TBA 0.023 ± 0.013 μmol/l and hemolysate TBA 0.017 ± 0.005 μmol/l. In the diabetic patient group, Glu levels were 152 ± 25mg%, TG 185 ± 50mg%, HDL 40 ± 10mg%, LDL 100 ± 40mg%, UA 6.1 ± 1.5mg%, HbA1c 7.8 ± 0.2%, plasma TBA 0.112 ± 0.043μmol/l and blood plasma TBA 0.015 ± 0.005μmol/l. TBA levels in the control group were statistically significantly lower than those in the diabetic group. In the group of diabetic patients, a positive correlation was found with Glu -HbA1c ($r=0.889$, P-value <0.001), LDL–Chol ($r=0.686$, P-value $=0.01$), LDL–HDL ($r=0.649$, P-value $=0.016$), TG–Glu($r=0.548$, P-value $=0.042$), plasma TBA–HbA1c($r=0.549$, P-value $=0.023$), plasma TBA-Glu ($r=0.593$, P-value <0.001) and negative correlation HDL-TG ($r=-0.684$, P-value $=0.01$), LDL-TG ($r=-0.72$, P-value $=0.006$). In the control group, a positive correlation was found between LDL – Chol ($r=0.964$, P-value <0.001) and plasma TBA-TG ($r=0.773$, P-value $=0.009$).
Conclusions
The present study in the Greek population showed increased TBA levels in the T2DM group and a positive correlation with Glu and HbA1c levels. Further correlation with other markers would complete the study.

Pancreatic autoimmunity in the diagnosis of type 1 diabetes: usefulness of zinc transporter 8 and proposal for stepwise assessment

Raúl Rodríguez Escobedo[1,2], Silvia González Martínez[1,2], Carlos Alonso Felgueroso[2,3], Paula Morales Sánchez[2,4], Lucía Díaz Naya[2,3], Elias Delgado[2,4,5,6] & Edelmiro Luis Menendez Torre[2,4,5,6]
[1]Hospitales Universitarios San Roque, Endocrinology and Nutrition, Maspalomas, Spain; [2]Instituto de Investigación del Principado de Asturias (ISPA), Endocrinology, Nutrition, Diabetes and Obesity Research Group (ENDO), Spain; [3]Hospital Universitario de Cabueñes, Endocrinology and Nutrition, Gijon, Spain; [4]Centro de Investigación Biomédica en Red en Enfermedades Raras (CIBERER), Madrid, Spain; [5]Hospital Universitario Central de Asturias, Endocrinology and Nutrition, Oviedo, Spain; [6]Universidad de Oviedo, Departamento de Medicina, Oviedo, Spain

Introduction
Zinc transporter 8 (ZnT8) autoimmunity has been established as one of the markers for the diagnosis of type 1 diabetes (T1D) along with glutamate decarboxylase (GAD) and tyrosine phosphatase IA-2 (IA-2) antibodies. The aim of this study is to understand the status of pancreatic autoimmunity in the diagnosis of T1D, with special attention to the usefulness of ZnT8. In addition, as a second objective, we study the proposal to perform the assessment of pancreatic autoimmunity using a stepwise approach.
Methods
We studied all ZnT8 tests performed in Asturias (Spain) since the introduction of ZnT8 analysis in April 2017 until December 2020 and how many of the 304 new diagnoses of T1D in this period had ZnT8, GAD or IA2 as the only positive antibody. Autoinmunity was considered positive if GAD>10, IA2>10 and ZnT8>20 units/ml. Finally, the proposed stepwise assessment is determined with initial analysis of GAD, subsequent study of IA2 if GAD negative and final evaluation of ZnT8 if the previous two were negative.
Results
Since the introduction of ZnT8 in our laboratory, 2388 studies have been performed in a total of 2096 patients, with a duplication in 188 patients. Of these

2096 patients, 266 patients (12.69%) had anti-ZnT8. Of these, 146 were new diagnosis of T1D in this period. In the 304 patients diagnosed with T1D included, the prevalence of anti-GAD was 74.01%, anti-IA2 45.07% and anti-ZnT8 48.03%. Of these patients, 5.59% had ZnT8 as the only positive antibody, while in the case of GAD and IA2 it was 31.58% and 6.91%, respectively. Regarding the stepwise study proposal, of the 304 patients diagnosed with T1D, 225 had anti-GAD and therefore no IA-2 or ZnT8 study would be performed in them. Of the remaining 79 patients, 45 were positive for IA2 and would not need to be tested for ZnT8. Therefore, if the analysis would have been performed in a staggered manner, 74.01% of the IA2 and 88.82% of the ZnT8 studies would have been avoided.

Conclusions

The frequency of GAD is higher than IA2 and ZnT8 and may serve as the first antibody to be requested in case of suspected T1D. ZnT8 is useful in a limited number of patients so measures should be sought to increase the effectiveness of the technique. The assessment of pancreatic autoimmunity in a stepwise manner may be a useful strategy to reduce unnecessary testing and consequently reduce healthcare costs.

Mutation in MT-TV gene – a novel etiology of mitochondrial diabetes?

Mariana Ornelas, Eduarda Resende, Pedro Gouveia, Elena Maritza Pontes Santos Sa & Margarida Maria Morna Ferreira
Hospital dos Marmeleiros, Funchal, Portugal

Mitochondrial diseases are rare conditions with a wide phenotypic range. The inability of dysfunctional mitochondria to produce sufficient ATP results in multi-organic defects dependent on high aerobic such as pancreas. The most common endocrine disease related to mitochondrial diseases is diabetes *mellitus* and it is thought to be secondary to insulin deficiency. A 26-year-old pregnant patient with 26 weeks gestational age was referred to an Endocrinology appointment due to diagnosis of diabetes *de novo* in pregnancy (oral glucose tolerance test - OGTT: fasting plasma glucose 187 mg/dl; 2-hour plasma glucose 417 mg/dl). The patient had no relevant past medical history or diabetes history in family and her regular medication were pregnancy vitamins. She denied catabolic symptoms. The actual HbA1C was 7.3% and pancreatic autoantibodies were negative. Before pregnancy, body index mass was normal. She was started on basal-bolus insulin therapy (insulin detemir 8 units plus insulin aspart 2+2+2). During medical follow-up, insulin aspart was suspended due to overall good postprandial glucose levels and basal insulin was maintained. Two weeks later the patient had a preterm delivery (36 weeks and 6 days); birth weight was 2.25 kilograms (4.94 lb). By this time, she discontinued insulin therapy and was started on metformin 700 mg b.i.d. and a genetic panel was conducted. It was identified a m.1644G>A variant in Mitochondrially Encoded tRNA Valine gene (MT-TV) with 82% heteroplasmy. This gene encodes transfer RNA that attaches specifically to valine ($tRNA^{Val}$) and therefore assists in protein synthesis involved in oxidative phosphorylation. *ClinVar* and *Mitomap* databases consider this variant as probably pathogenic and it has been associated to Leighs' syndrome, hypertrophic cardiomyopathy and mitochondrial encephalomyopathy, lactic acidosis and stroke-like episodes (MELAS). Nevertheless, it has never been reported as a diabetes causative gene. Since this variant may reduce the amount of $tRNA^{Val}$ available and impair mitochondrial function, the authors speculate if this mutation may be associated with diabetes surge.

Asymptomatic Pyuria/Bacteriuria and Urinary Tract Infection Risk in Women Initiated SGLT2 Inhibitors

Erman Akkus[1], Asena Gökçay Canpolat[2], Özgür Demir[2], Demet Çorapçıoğlu[2] & Mustafa Sahin[2]
[1]Trabzon Arakli Bayram Halil Public Hospital, Internal Medicine, Trabzon, Turkey; [2]Ankara University, Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey

Objective

The study aims to investigate the association between asymptomatic pyuria/bacteriuria at the initiation of SGLT2 inhibitors (SGLT2i) and urinary tract infection (UTI) risk in a cohort of women with type 2 diabetes mellitus (T2DM) (NCT05520684).

Methods

The female outpatients with T2DM under follow-up in the department of internal medicine and initiated SGLT2i (dapagliflozin/empagliflozin) were included between February and September 2022. Exclusion criteria were; being symptomatic for UTI or genital infection at the initiation, being treated for UTI or genital infection in the past 3 months or having a high risk for UTI (any urological disease/catheter use, cancer, immunodeficiency, bedridden). Hospitalization and antibiotic use for indications other than UTI were exclusion criteria during follow-up. Automated urinalysis and urine culture were obtained on the SGLT2i initiation day. Pyuria was defined as ≥ 3 white cells per high-power field. Any bacterial growth in the culture reported by the microbiology laboratory was defined as bacteriuria. All patients were followed up for 3 months after SGLT2i initiation. UTI diagnosed or treated by any physician was recorded as the outcome. Cumulative incidence and relative risk of UTI were analyzed for pyuria and bacteriuria.

Results

143 female patients were included. 13 patients were excluded during follow-up (antibiotic use $n=7$, hospitalization for CABG $n=1$, DHF $n=1$, NSTEMI $n=1$, CVA $n=1$, acute pancreatitis $n=1$, PTE $n=1$). The median age was 62 (range 34-87). 20.8% of the patients ($n=27$) had cardiovascular disease. Median HbA1c was 9.1%(range 5.9-13.9). Median creatinine and eGFR were 0.79 mg/dl (range 0.4-1.77) and 80 ml/min (range 32-120), respectively. 41.5% of the patients ($n=54$) had pyuria and 28.5% ($n=37$) had bacterial growth in urine culture. The most common microorganisms were E. coli ($n=13$, 35%) and S. agalactiae ($n=7$, 19%). Dapagliflozin was initiated in 70% of patients ($n=91$). The cumulative incidence of the UTI was 20%($n=26/130$) in the whole cohort, 25,9% ($n=14/54$) in the pyuria group and 18.9% ($n=7/37$) in the bacteriuria group. The relative risk of UTI was 1.64 (95% CI: 0.82-3.26) for pyuria, 0.92 (95% CI: 0.42-2.01) for bacteriuria and 1.2 (95% CI: 0.47-3.08) for pyuria plus bacteriuria. Multiple logistic regression analysis including the variables of age, HbA1c, CVD as comorbidity, eGFR, pyuria, bacteriuria and SGLT2i type did not reveal any statistical significance.

Conclusions

In this pragmatic practical cohort study, pyuria or bacteriuria at the initiation of SGLT2 inhibitor are not risk factors for UTI for female patients with type 2 DM in a 3-month-follow-up.

Hybrid Closed Loop in obesity: to each his own (algorithm)!

Nicola Tecce[1], Ludovica Verde[2], Annamaria Docimo[1], Giovanni Chirico[1], Luigi Barrea[3], Annamaria Colao[1] & Giovanna Muscogiuri[1]
[1]Clinical Medicine and Surgery, Endocrinology, Diabetology and Andrology Unit, Napoli, Italy; [2]Federico II University, Public Health, Naples, Italy, Napoli, Italy; [3]Pegaso Telematic University, Napoli, Italy

Introduction

Currently, patients with type 1 diabetes (T1D) have the option of being treated with Hybrid Closed Loop (AHCL) systems, which allow insulin delivery to be modulated according to glycemic values. These systems do not allow any kind of anthropometric or laboratory characteristics to be used to enhance the devices' capabilities. Thus, the aim of our study was to investigate the efficacy of AHCL systems in subjects with T1D and with obesity compared to normal-weight subjects in terms of metabolic control.

Methods

Forty-one subjects with T1D and normal weight (BMI 18.8-24.9 Kg/m^2) or obesity (BMI 30.3-36.6 Kg/m^2) were treated with AHCL and were enrolled in this retrospective observational study. BMI, fasting plasma glucose, Hba1c, lipid profile, creatinine, Time In Range 70-180mg/dl (TIR), Time above range with glycemia 180-250mg/dl ($TAR^{180-250}$), Time above range >250mg/dl ($TAR^{>250}$), Time Below range with glycemia 70-54mg/dl (TBR^{70-54}), Time Below range <70mg/dl ($TBR^{<54}$) and glycemic variability were assessed.

Results

We enrolled 41 subjects (13M/28F; age:47 $\pm$ 12 years; BMI: 26.7 $\pm$ 4.9 kg/m2; mean duration of T1D: 26 $\pm$ 12 years). Hba1c (8.6 $\pm$ 2% vs 7.4 $\pm$ 0.8 %, $P=0.021$) and TG (122 $\pm$ 70mg/dl vs 73 $\pm$ 29mg/dl, $P=0.012$) were shown to be significantly higher in patients with obesity when compared to normal weight subjects while there were no differences in terms of fasting plasma glucose, total cholesterol, HDL, LDL and creatinine. AHCL prediction algorithms showed different efficacy in patients with obesity when compared with normal weight patients: although the TIR (mean 63.1 $\pm$ 16.4), $TAR^{>250}$ (mean 9.2 $\pm$ 10.5) and both TBR^{70-54} (mean 1.1 $\pm$ 1.1) and $TBR^{<54}$ (mean 0,4 $\pm$ 1) did not show statistically significant differences, patients with obesity when compared to normal weight patient showed higher $TAR^{180-250}$ (23.9 $\pm$ 8.3% vs 34.3 $\pm$ 10.1%,

$P=0.003$) and higher prevalence of high (>36%) glycemic variability (33.3% vs 66.7% $P=0.05$).
Conclusions
T1D subjects with obesity had worse glycemic control, evidenced not only by laboratoristic parameters such as higher levels of Hba1c and triglycerides but also by the higher TAR $^{180-250}$ and greater presence of patients with high glycemic variability when compared with normal weight. This suggests that AHCL algorithms should also take into account the anthropometric characteristics of the subjects in order to better tailor insulin treatment.

Hirata disease: a rare cause of hypoglycemia

Eva Rusu[1], Oana Stanoiu- Pinzariu[2] & Carmen Emanuela Georgescu[1,2]
[1]Clinical County Emergency Hospital, Endocrinology Department, Cluj-Napoca, Romania; [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania

Introduction
Hirata disease (or Insulin autoimmune syndrome) is characterized by the presence of high concentrations of insulin autoantibodies leading to hyperinsulinemic hypoglycemia in individuals with no history of prior exposure to exogenous insulin. Etiopathogenesis is not completely elucidated, it's considered to result from the interaction of genetic predisposition and environmental triggers such as: medications (methimazole, carbimazole, alpha-lipoic acid, captopril, diltiazem, clopidogrel, diclofenac, pantoprazole, omeprazole), viral infections (mumps, rubella, varicella zoster, hepatitis C virus), and hematological disorders (multiple myeloma, monoclonal gammopathy).
Case report
A 67-year-old female was referred to our clinic with frequent, daily episodes of unpredictable hypoglycemia (fasting, postprandial, and during physical activity) with autonomic and neuroglycopenic symptoms for about six months. Hypoglycemia (capillary blood glucose 42-55 mg/dl) was documented during these episodes with remission of symptoms and signs of hypoglycemia after glucose administration. She had a history of toxic multinodular goiter treated by surgery, prediabetes treated with lifestyle change, arterial hypertension, chronic ischemic heart disease, and old myocardial infarction. She was taking Indapamide, Amlodipine, Valsartan, Betaxolol, Clopidogrel and Pantoprazole. In addition, the patient did not previously use oral hypoglycemic drugs or exogenous insulin. Laboratory tests revealed normal thyroid and adrenal function, and normal chromogranin A (with prior interruption of Pantoprazole). We observed normal basal glucose level, HbA1c 6.99%, and very high insulin levels (19600 uU/ml). After 72-h fasting test, results revealed low glucose (55 mg/dl) with high insulin levels (8673 uU/ml), elevated C-peptide levels (9.44 ng/ml, NR: 0.8-3.85), high insulin/peptide-C molar ratio (>1), and high level of proinsulin (31 pmol/l, NR<11). Measurement of anti-insulin antibodies revealed high titers (>100 U/ml, NR<10). Abdominal CT scan showed no pancreatic or extra-pancreatic lesions. Regarding the presence of hypoglycemic hyperinsulinemia, high titers of insulin autoantibodies, and the use of medications associated with this disease, the diagnosis of insulin autoimmune syndrome was established. The treatment with Pantoprazole was stopped and Clopidogrel was switched to another drug, and the patient was advised to eat frequent and small meals with low carbohydrate content. After six months, our patient reported a decrease in the frequency of hypoglycemic episodes until complete remission.
Conclusions
Hirata disease is still an underdiagnosed condition with increasing incidence. Diagnosis of the disease is a challenge and differential diagnosis from other forms of hypoglycemia is mandatory to avoid unnecessary and high costs imaging examinations. In most cases is self-limited, but in severe cases, pharmacologic therapy is indicated.

Changes of Cholesterol and Cardiovascular Risk Before and After Initiation of Statin Therapy

Gyorgy Simon[1], M. Regina Castro[2] & Pedro Caraballo[2,3]
[1]University of Minnesota, Institute for Health Informatics, Minneapolis, United States; [2]Mayo Clinic, Internal Medicine, Rochester, United States; [2]Mayo Clinic, Internal Medicine, Rochester, United States

Introduction
Cholesterol management is essential to prevent coronary artery disease (CAD) and related complications. Lifestyle changes are first treatment, followed by statin therapy. Multiple studies have shown statins to effectively reduce the risk of cardiovascular complications. LDL cholesterol is the main measure to assess impact of statin therapy. However, CAD risk also depends on other often neglected risk factors. We present preliminary data of the evaluation of the simultaneous effect of statins on LDL cholesterol and CAD risk.
Methods
Retrospective cohort evaluation of Olmsted County residents (Minnesota, USA) seen at Mayo Clinic. Clinical data were collected searching electronic medical records. The cohort was divided based on statin treatment or not during the study period, and if they developed CAD or not 1 year after the index date. The index date (time=0) was the date of the first statin prescription, with follow-up of quarterly LDL levels and CAD risk scores (Framingham) between -10 and +10 years. An AI model to predict CAD and tailored to our population was used to validate the Framingham Risk score with similar results.
Results
Contrary to expectations, in the general sample the prediction model showed that LDL was a negative predictor (-0.0052) and statin a positive predictor (0.4670) of CAD. Subjects who developed CAD vs. those without CAD had lower LDL in the group without statins (mean 110.3 vs. 115.3 mg/dl) and in the group with statins (126.7 vs 135.2). Framingham risk score showed expected results, being higher in subjects who developed CAD vs. those without CAD, without statins (.079 vs .050) and with statins (.084 vs .067). Quarterly follow-up of those that received statin therapy, before and after the first statin prescription, showed a significant LDL reduction (approximately 30mg/dl) after statin initiation, being always higher in the group without CAD. However, the CAD risk showed no significant changes in either group at the time of statins initiation.
Conclusion
Our results support current practice of initiating statins based on calculated overall cardiovascular risk rather than LDL value alone. Despite a significant drop in LDL levels with statin therapy, the cardiovascular risk showed negligible changes, remaining higher in subjects who developed CAD. It is difficult to have a position on the statin mechanism impacting CAD based on the nature of our study. However, it seems evident that LDL reduction is insufficient, and better management of additional cardiovascular risk factors is critical and needed to prevent CAD complications.

Biomarkers of prostate cancer transgenerational transmission risk in the progeny of obese fathers subjected to dietary correction

Mariana Pereira[1,2,3,4], Sara C. Pereira[1,2,4,5,6], Luís Rato[7,8], Pedro F. Oliveira[5] & Marco Alves[6,9]
[1]School of Medicine and Biomedical Sciences (ICBAS), University of Porto, Endocrine and Metabolic Research, Unit for Multidisciplinary Research in Biomedicine, Porto, Portugal; [2]University of Porto, Laboratory for Integrative and Translational Research in Population Health (ITR), Porto, Portugal; [3]Faculty of Sciences, University of Porto, Porto, Portugal; [4]School of Medicine and Biomedical Sciences (ICBAS), University of Porto, Laboratory of Physiology, Department of Imuno-Physiology and Pharmacology, Porto, Portugal; [5]University of Aveiro, LAQV-REQUIMTE and Department of Chemistry, Aveiro, Portugal; [6]Faculty of Medicine, University of Porto, Department of Pathology, Porto, Portugal; [7]University of Beira Interior, CICS-UBI-Health Sciences Research Centre, Covilhã, Portugal; [8]Polytechnic Institute of Guarda, Health School, Guarda, Portugal; [9]School of Medicine and Biomedical Sciences (ICBAS), University of Porto, Endocrine and Metabolic Research, Unit for Multidisciplinary Research in Biomedicine, Porto, Portugal

Metabolic disorders, such as overweight and obesity, are serious health societal challenges due to their high incidence rates. Obesity leads to metabolic dysregulation, promoting hormonal imbalance, oxidative stress, and a chronic inflammation state. Eating habits towards the intake of highly caloric fat-rich regimes induce epigenetic changes in the information transgenerationally transmitted. Furthermore, obesity promotes carcinogenesis. It is known that the prostate is sensitive to the metabolic and hormonal alterations promoted by obesity. Prostate Cancer (PCa) is the second most common cancer and the fifth leading cause of death among men. The diagnosis is generally based on the detection of PSA (prostate-specific antigen) and digital rectal examination. Further, PCa biomarkers, like homeobox Hox-B13 (HOXB13), are used for tissue diagnosis. Due to the close relationship between obesity and PCa development, as well as the emerging evidence on the inheritance of obesity-related factors, it has been debated if there are inheritable obesity-related changes that trigger

PCa. Still, to date, no data has been clearly reported showing the inheritance of obesity-related factors that could also promote the development of PCa. In this work, we studied the expression of HOXB13, a PCa biomarker, on the prostate of the progeny of fathers lean, obese, and subjected to diet correction after high-fat diet. To test this, a transgenerational animal model (*Mus musculus*) was established, where F0 mice were exposed to three different diets: standard, high-fat (HFD), and diet correction (60 days HFD, plus 120 days standard diet), *ad libitum* for 200 days post wearing. Two more generations were bred, F1 and F2, between males and lean females. We evaluated several PCa biomarkers expression on the prostates (Androgen receptor, HOXB13, Ki-67). Among these, HOXB13 presented a decreased expression on the prostates of F1 mice whose diet was corrected from HFD to standard. HOXB13 decreased expression is associated with carcinogenesis since it promotes lipid accumulation, which is a carcinogenesis hallmark. Obesity has already been correlated to altered DNA methylation patterns in several tissues, including the prostate. Concurrently, *HOXB13* promoter hypermethylation decreases *HOXB13* expression. These results suggest that the offspring of obese fathers subjected to diet correction have an increased risk of developing PCa. We propose that a diet correction from HFD to a standard diet may not be sufficient to revert the effects of HFD on DNA methylation and that this epigenetic alteration is being transmitted from the F0 to F1 animals as detected in *HOXB13* expression.

Comparison of the Effects of a Ketogenic Diet and an Isocaloric Balanced Diet administered to Obese patients on Quality of Life and Sleep: a Randomized Clinical Trial

Elena Gangitano[1,2], Maria Elena Spoltore[2], Andrea Lenzi[2], Lucio Gnessi[2] & David Ray[1]
[1]University of Oxford, Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, United Kingdom; [2]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy

Introduction
The prevalence of obesity and metabolic disturbances is worryingly increasing worldwide, therefore the study of their pathophysiology is extremely important to find new strategies for their treatment. Obesity has an impact not only on the metabolism of the patients, but also profoundly influence their daily life, and potentially affect the quality of life and the quality of sleep. These latter are strictly related to the circadian rhythm of the individuals that, accordingly to animal models, can be influenced by the diet composition.
Aim
The aim of our research project is to study the effects of a ketogenic diet in comparison with an isocaloric balanced diet on quality of life and sleep quality in obese individuals.
Methods
24 obese patients referred to the CASCO centre (High Specialization Centre for the Care of Obesity) in Sapienza University, Umberto I Polyclinic, Rome, Italy, were enrolled and completed the study. The enrolled patients were randomly divided in 2 branches and prescribed a ketogenic diet or an isocaloric balanced diet (1200 Kcal per day, protein content 1.2-1.4 g/Kg of ideal body weight for each patient), for 30 days. Patients were encouraged to walk 30 minutes every day. Questionnaires for assessing quality of life and quality of sleep were administered at baseline and at the end of the study. In a subgroup of 20 patient, an actigraphy study for assessing sleep parameters was performed.
Results
Quality of life was significantly ameliorated after both diets, and ketogenic diet had a greater positive effect. We observed a reduction of daily sleepiness in both diets. The ketogenic diet was more effective in achieving better-quality sleep, but this may be related to the greater weight loss seen. Total sleep time was insufficient in both groups.
Conclusion
A hypocaloric balanced diet and an isocaloric ketogenic diet are both able to induce a significant amelioration of the quality of life of obese patients even in the short-term, and the ketogenic diet has a greater beneficial effect. Improved quality of life, and in particular of the physical function and self-esteem domains, may act as a motivating factor for adherence to the diet. Diurnal sleepiness was ameliorated after both diets, and sleep quality significantly improved after the ketogenic diet, which induced a greater weight loss. As good quality sleep is important for healthy metabolism, measures aimed to a better sleep hygiene should be encouraged as part of weight-loss programs.

Impact of Bariatric Surgery in Metabolic-Associated Fatty Liver Disease

David Veríssimo, Joana Vinhais, Vânia Machado, Sandra Silva, Catarina Ivo, Ana Cláudia Martins, Joao Silva, Dolores Passos, Luis Lopes, J Jácome Castro & Mafalda Marcelino
Hospital das Forças Armadas, Serviço de Endocrinologia, Portugal

Introduction
In 2020, a group of experts proposed to change the term "non-alcoholic fatty liver disease" (NAFLD) to "metabolic-associated fatty liver disease" (MAFLD), which includes hepatic steatosis (HS) (using imaging or analytical scores) associated with overweight or obesity, type 2 diabetes (T2D), or the presence of two other metabolic disorders.
Objectives
Analyse the impact of bariatric surgery on MAFLD.
Methods
A total of 43 patients with obesity diagnosed with MAFLD were analysed before and 12 months after bariatric surgery. We compared body mass index (BMI), abdominal perimeter, body fat, HS, and liver fibrosis. HS was diagnosed using abdominal ultrasound and/or NAFLD Liver Fat Score (NAFLD-LFS: metabolic syndrome, T2D, plasma insulin, AST, and ALT). Liver fibrosis risk was assessed using NAFLD Fibrosis Score (NAFLD-FS: age, BMI, fasting glucose, AST, ALT, platelets, and albumin).
Results
Median pre-surgery age was 52 years (44-57), 51% were female. Median BMI was 42kg/m2 (40-43), median abdominal perimeter and body fat were 130 cm (122-139) and 37% (34-38) in males, and 123 cm (116-134) and 49% (45-50) in females. Regarding comorbidities, 72% had MS, 56% had T2D, 93% had HS identified with abdominal ultrasound and 98% using NAFLD-LFS. Hepatomegaly was observed in 56%. A high risk of fibrosis was calculated in 25%, no fibrosis risk in 19% and an indetermined score in 56%. Laboraty result revealed increased transaminases In 21%, increased gamma-GT in 30%, 2% thrombocytopenia, 5% hypoalbuminemia, and 2% hyperalbuminemia. After surgery, we observed 60.5% remission of MAFLD, with reduction in BMI (-13.2kg/m2, $P<0.001$), abdominal perimeter (-28cm in males and -25cm in females, $P<0.001$) and body fat (-19% in males and -15% in females, $P<0.001$). There was also 50% and 79% remission of MS and T2D, as well as 58% and 88% regression of steatosis and hepatomegaly in abdominal ultrasound, and 82% reduction of NAFLD-LFS steatosis. NAFLD-FS showed an overall reduction, with 60% at no risk and 40% with indeterminate scores after surgery. There was a significant reduction in platelet count (244x109/l (191-278), $P=0.002$), ALT (20U/l (14-33), $P<0.001$), gamma-GT (15U/l (11 -22), $P<0.001$) and insulin (6mU/ml (4-8), $P<0.001$), but no change in AST (19U/l (16-29), $P=0.125$), nor albumin levels (44g/l (43-46), $P=21$).
Conclusions
Following bariatric surgery, we observed similar outcomes in MAFLD as those described for NAFLD (66% remission). These results are associated with a significant improvement in comorbidities, with an overall reduction in liver fibrosis risk.

Features of the Course of Covid-19 in Patients With Metabolic Syndrome

Umida Mirzaeva
Tashkent Pediatric Medical Institute, Endocrinology, Tashkent, Uzbekistan

The COVID-19 pandemic has forced the dispatch of significant efforts to identify prognostic factors development of critical conditions and death. Elderly age, cardiovascular disease (CVD), blood sugar diabetes, chronic lung disease, arterial hypertension was associated with an increased risk of death with COVID-19. Metabolic syndrome is a significant comorbid pathology, which increases the risk of developing life-threatening complications and unfavorable outcome of the coronavirus infection. Due to this patient with metabolic syndrome and COVID-19 deserve especially close attention. One of the main constituents of MS are abdominal obesity. Obesity potentiates multiple cardiovascular risk factors, underlying clinical cardiovascular continuum, leading to the development of CVD and adverse cardiovascular outcomes. This association between obesity and severe COVID-19 infection may be due to increased expression of ACE-2 in overweight individuals, making it more likely that SARS-CoV-2 enters the body of obese individuals compared to non-obese individuals. ACE-2 is present in lung alveolar epithelial cells, small intestine epithelial cells, vascular endothelial cells, and adipose tissue, and its expression is increased due to obesity. Increased expression of ACE-2 can cause greater penetration of SARS-CoV-2 into the body, which can significantly increase the release of cytokines and lead to a fatal

outcome of COVID-19. Obese patients are more active nuclear transcription factor (NF) and higher RNA expression of proinflammatory cytokines such as tumor necrosis factor-α (TNF-α), interleukin-1(IL-1) and interleukin-6 (IL-6), which are key in the pathogenesis of the metabolic syndrome [15]. Also, the pro-inflammatory role of IL-6 is often described in the pathogenesis of lung diseases, especially in asthma and in patients with acute respiratory distress syndrome (ARDS). Understanding the relationship between obesity and severe course of COVID-19 may suggest some therapeutic interventions to potentially reduce the risk of developing adverse outcomes of COVID-19. This issue becomes especially relevant weight gain and changes in food intake.

The new anthropometric indices and atherogenic indices are correlated with lipid status in women with PCOS

Justyna Nowak[1], Marzena Jabczyk[2], Paweł Jagielski[3], Bartosz Hudzik[1,4], Karolina Kulik-Kupka[2] & Barbara Zubelewicz-Szkodzińska[2,5]
[1]Medical University of Silesia, Department of Cardiovascular Disease Prevention, Department of Metabolic Disease Prevention, Faculty of Health Sciences in Bytom, Bytom,; [2]Medical University of Silesia, Department of Nutrition-Related Disease Prevention, Department of Metabolic Disease Prevention, Faculty of Health Sciences in Bytom, Bytom, Poland; [3]Jagiellonian University Medical College, Department of Nutrition and Drug Research, Institute of Public Health, Faculty of Health Sciences, Cracow, Poland; [4]Medical University of Silesia, Third Department of Cardiology, Silesian Center for Heart Disease, Faculty of Medical Sciences in Zabrze, Zabrze, Poland; [5]District Hospital, Department of Endocrinology, Piekary Slaskie, Poland

Introduction
Polycystic ovary syndrome (PCOS) contributes to endocrine and metabolic complications. Cardiovascular disease (CVD) is a leading cause of mortality and morbidity worldwide. Identification of the subpopulations with a higher risk of developing CVD and lipid metabolic disorders is crucial, particularly in PCOS patients.
Aim
The aim of this study was to investigate the usefulness of new anthropometric indices such as BAI, VAI, LAP, BRI, ABSI and new atherogenic indices such as TyG index, TyG-BMI index, TyG-WC index in evaluation of lipid parameters in patients with PCOS.
Material and methods
To the study was enrolled of 49 woman in aged 18-39. Criteria for selecting the subjects were as follows: diagnosed PCOS based on the Rotterdam criteria from 2003. Blood samples were taken from patients in the morning, before breakfast. Biochemical parameters (total cholesterol, HDL, LDL, TG) were determined and used for the calculation atherogenic indices. Anthropometric parameters were measured with the use of standard methods in the morning. These measurements included body weight, height, waist circumference, and hip circumference. After this step anthropometric indices such as BAI (Body Adiposity Index), VAI (Visceral Adiposity Index), LAP (Lipid Accumulation Product), BRI (Body Roundness Index), ABSI (A Body Shape Index), AIP (Atherogenic risk of plasma) were calculated. The study conformed to the Declaration of Helsinki and was reviewed by the local bioethics committee
Results
There was observed significant positive relationship between BAI, VAI, LAP, BRI, ABSI, TyG index, TyG-BMI index, TyG-WC index and LDL cholesterol and triglycerides ($P<0.005$). Also, there was observed strong negatively correlation between HDL cholesterol and analyzed parameters/indices ($P=0.000$) excluding ABSI ($P>0.05$).
Conclusion
Analyzed new anthropometric indices and new atherogenic indices have demonstrated significant relationship wtl lipid profile in women with PCOS. These indices may be useful tool in assessing of metabolic disorders in women with PCOS.

Urinary C-peptide to creatinine ratio (UCPCR) as indicator for metabolic risk in apparently healthy adults - a BioPersMed cohort study

Sharmaine Reintar[1], Magdalena Pöchhacker[2], Anna Obermayer[1], Katharina Eberhard[3], Andreas Zirlik[4], Nicolas Verheyen[4], Christoph Haudum[1], Thomas Pieber[1], Harald Sourij[1] & Barbara Obermayer-Pietsch[1]
[1]Medical University of Graz, Department of Internal Medicine, Division of Endocrinology and Diabetology and Endocrinology Lab Platform, Austria; [2]University of Vienna, Austria, Department of Food Chemistry and Toxicology, Faculty of Chemistry, Austria; [3]Medical University of Graz, Center for Medical Research, Core Facility Computational Bioanalytics, Austria; [4]Medical University of Graz, Department of Internal Medicine, Division of Cardiology, Austria

Background
C-peptide consists of 31 amino acids, synthesized in the beta cells of the pancreas and co-secreted along with insulin. Hence, serum C-peptide may be the preferred diagnostic biomarker for evaluating beta cell function compared to insulin. The urinary C-peptide to creatinine ratio (UCPCR) recently gained attention as a non-invasive biomarker for evaluating and monitoring metabolic risk. In this study, we aimed to characterize guiding values of UCPCR in healthy individuals based on American Diabetes Association (ADA) criteria and follow-up outcomes in a large longitudinal cohort study.
Methods
Cross-sectional and longitudinal clinical and laboratory phenotyping including body composition and oral glucose tolerance tests of participants from the BioPersMed cohort (Biomarkers in Personalized Medicine) were evaluated. Our study population was based on ADA (American Diabetes Association) criteria defining non-diabetic subjects via fasting plasma glucose (FPG) $\leq$ 126 mg/ml ($\leq$ 7.0 mmol/l), 2-hour plasma glucose (2-h PG) of $\leq$ 200 mg/dl ($\leq$ 11.1 mmol/l) during 75-g oral glucose tolerance test (oGTT), and an HbA1c of $\leq$ 6.5% ($\leq$ 48mmol/mol). A two-site chemiluminescent sandwich immunoassay was used to detect urinary C-peptide levels, which were normalized by individual urinary creatinine values to obtain the ratio. Subjects were followed for 4.2 ± 0.62 years from baseline to their first and second biannual follow-up.
Results
Out of all BioPersMed participants ($n=1022$), 317 individuals were non-diabetic according to ADA criteria (female $n=198$ (62,5%), male $n=119$ (37,5%)) with a median age of 56 ± 8 years. In our study, we found no significant differences of UCPCR values between gender (*P*-value 0,997). During follow-up, initially healthy participants progressed by 25% to prediabetes and by 1% to type 2 diabetes mellitus (T2DM), predicted by UCPCR values.
Conclusion
UCPCR provides a valuable diagnostic biomarker for a non-invasive estimation of endogenous insulin production, which can be used to monitor and guide individual subjects over time for their potentially increased metabolic risk. A risk assessment graph for UCPCR ranges provides a useful screening and monitoring tool. UCPCR applications are not limited to T2DM but could further be used in other settings such as hyperinsulinemia in obesity or polycystic ovary syndrome (PCOS) and gestational diabetes

Using digital technology to improve understanding and adherence of clinical guidelines for diabetic emergencies

Tanya Chopra, Monali Patel, Hugh Furness & Elaine Hui
Northwick Park Hospital, Department of Diabetes & Endocrinology, London, United Kingdom

Background
Diabetic ketoacidosis (DKA) and hyperosmolar hyperglycaemic state (HHS) are common diabetic emergencies. However, the associated morbidity and mortality remains substantial. Non-specialist trainee healthcare professionals (HCPs) are usually the first point of contact in managing these patients in the acute medical setting. It is therefore essential that these trainees are confident in the management of these emergencies.
Aims
Our aim was to use digital technology to establish how confident trainee HCPs felt in managing diabetic emergencies, DKA and HHS, at a large university hospital Trust accepting unselected emergency cases. Digital platforms were utilised to assess trainees' understanding and access to national-based Trust guidelines for DKA and HHS.
Methods
An online survey was carried out between December 2022 and January 2023. A QR code was utilised to allow easy access to the survey. The code was disseminated via email, posters, and messaging platforms within our Trust.

Results
Data was gathered from 45 HCPs; 38% were foundation year 1 doctors, 42% were senior house officers, and the remainder were nursing staff, medical support workers or higher speciality trainees. 82% of the responders had managed DKA or HHS in the last 6 months. 91% of the HCPs knew where to access the online Trust guidelines and 85% of the responders regularly used these trust guidelines. However, the survey found that only 49% of responders felt confident in the management of DKA, and 31% felt confident in the management of HHS. With regards to insulin prescription, 31% did not follow guidelines in prescribing regular basal insulin alongside fixed-rate insulin in the management of DKA. Moreover, the vast majority (62%) were not confident at all with initiating basal insulin.
Conclusions
Digital technologies such as online surveys and QR codes allowed quick feedback to be gathered to assess the competency of non-specialist healthcare professionals in managing DKA and HHS. This survey showed that the majority of non-specialist trainee HCPs were aware of the guidelines for DKA and HHS, but were not confident in managing these diabetic emergencies. More than half of these trainees did not follow the guidelines especially in prescribing regular basal insulin. The results were used to improve the way guidelines are presented to non-specialist HCPs and to tailor teaching sessions for these trainees to improve their confidence in managing diabetic emergencies.

Changing clinical features of diabetic ketoacidosis: any impact of SGLT2 inhibıtors is there?

Selin Genc[1], Bahri Evren[1], Onur Selçuk Yiğit[2] & İbrahim Şahin[1]
[1]Inonu University, Faculty of Medicine, Department of Endocrinology and Metabolism, Malatya, Turkey; [2]Inonu University, Faculty of Medicine, Department of Internal Medicine, Malatya, Turkey

Aims
Sodium-glucose cotransporter-2 inhibitors (SGLT2i) increase the risk for diabetic ketoacidosis, particularly in patients with type 1 diabetes (T1DM). We aimed to determine whether SGLT2i use increase the risk of euglycemic diabetic ketoacidosis (euDKA) and to indicate its demographic, clinical features.
Methods
We performed a retrospective cohort study of 51 patients over 18 years-old admitted to emergency unit at a tertiary care hospital from 2018-2022. The data were collected by communicating with the hospital network system, national health registry, and personnel communication. Fisher's exact, Yates's chi-square, and Mann-Whitney-U tests were used to identify variables associated with euDKA initiation using SPSS-version23.
Results
We included 51 DKAs, of whom 33 (64.7%) were female out of 508 patients with hyperglycemia in the emergency department. T1DM, type 2 DM and latent autoimmune diabetes in adults (LADA) were present in 25 (49%), 22 (43.2%), and 4 (7.8%), respectively. 156 (30.7%) patients used SGLT2 and 19 (37.3%) of these patients were diagnosed with DKA. Regarding SGLT2i use there was no significant correlation between DKA and patients with non-DKA hyperglycemia ($P=0.364$). 15 and 4 patients with DKA had T2DM and LADA. SGLT2i use was significantly higher in patients with type 2 DM ($P<0.05$). All patients with LADA were using the SGLT2i which prescribed at different centres. The median age of patients using SGLT2i was 59.16 $\pm$ 17.63, BMI 25.09$\pm$4.80, plasma glucose 397.89$\pm$191.07, HbA1C 11.24$\pm$2.51, pH 7.17$\pm$0.16, HCO3 12.02$\pm$5.56. The mean age of patients using SGLT2i was significantly higher, plasma glucose levels were lower ($P<0.05$). There is a significant correlation between euDKA ($n=5$, 9.8%) and SGLT2i use ($P=0.005$). All 5 patients were using SGLT2i. There were 13 (25.4%) patients with urinary tract infection (UTI) of which 9 (69.2%) were female. The number of patients with any genitourinary infection (GUI) in women was 15 (45.5%). There was also a significant correlation between the use of SGLT2i and urinary tract infection (UTI), vulvavaginitis ($n=6$, 18.2%), GUI in women and in general ($n=19$, 37.3%) ($P=0.050$, $P=0.002$, $P=0.013$, $P=0.008$), respectively. In the euDKA group, 3 out of 5 patients required intensive care and one patient was dead.
Conclusions
We observed euDKA, DKA in T2DM and GUI (UTI or vulvavaginitis) cases were more common in patients using SGLT2i. Furthermore, we suggest that LADA should be excluded before starting SGLT2i. In sum, SGLT2i may increase the risk of the serious adverse events that should not overshadow the significant cardioprotective benefits and therefore carefully prescribed.

The prevalence of vitamin D deficiency in hospitalized patients with COVID-19 decreased significantly during the pandemic in Slovakia between the years 2020-2022

Juraj Smaha[1], Peter Jackuliak[1], Martin Kužma[1], Filip Max[2], Neil Binkley[3] & Juraj Payer[1]
[1]Faculty of Medicine, Comenius University and University Hospital Bratislava, 5th Department of Internal Medicine, Bratislava, Slovakia; [2]Faculty of Pharmacy, Comenius University, Department of Pharmacology and Toxicology, Bratislava, Slovakia; [3]Geriatrics Faculty, Medical Sciences Center, University of Wisconsin, Department of Medicine, Madison, Wisconsin, United States

Background
The coronavirus disease 2019 (COVID-19) pandemic led to changes in lifestyle, which could influence vitamin D status on a population level. The purpose of our study was to compare 25-hydroxyvitamin D (25[OH]D) levels in patients hospitalized because of severe COVID-19 during two waves of the pandemic (2020/21 vs. 2021/22).
Materials and methods
We analyzed 101 patients (61 males/ 40 females) hospitalized in the internal medicine department of University Hospital Bratislava during the third wave of COVID-19 pandemic (Group 2). The patients from the third wave of the pandemic were compared to 101 (61 males/ 40 females) sex and age-matched subjects from the second wave of the COVID-19 pandemic (Group 1). Patients were first matched for sex, then for age +/- 1 year. If several options were available for the match, patients with the closest value of BMI were chosen. Patients from both waves were hospitalized during the winter season: the second wave was considered from 1 December 2020 to 28 February 2021, and the third wave from 1 December 2021 to 28 February 2022. Both sexes were analyzed together, as well as separately. Analyses were also performed according to the age of the participants. Younger age was defined as <65 years, and older age was defined as $<$ 65 years. Serum 25(OH)D concentration $>$ 30 ng/ml was considered vitamin D sufficiency and concentration <20 ng/ml deficiency.
Results
The mean concentration of 25(OH)D on admission during the second wave of the pandemic (Group 1) was 17.76 ng/ml, which increased to 25.21 ng/ml during the third wave (Group 2) ($P<0.0001$). On admission, 82% of patients from Group 1 were 25(OH)D deficient, and 10% were 25(OH)D sufficient. In Group 2, 54% of patients were 25(OH)D deficient, and 34% of patients were 25(OH)D sufficient ($P<0.0001$). The proportion of patients with a history of vitamin D supplementation increased from 18% to 44% ($P<0.0001$). The most significant absolute change of 25(OH)D concentration between waves was observed in younger males (10,70 ng/ml, $P=0.002$), and the smallest absolute change of 25(OH)D concentration was observed in younger females (2,49 ng/ml, $P=0.676$). Serum 25(OH)D concentration higher by one ng/ml was associated with a ~ 7% increase in the chance of survival for given age and sex category.
Conclusions
The prevalence of inadequate vitamin D status in hospitalized patients with COVID-19 in Slovakia decreased significantly due to a higher rate of vitamin D supplementation during the COVID-19 pandemic.

DOI: 10.1530/endoabs.90.P633

Adverse impact of Covid-19 pandemic on the glycemic status of persons with diabetes: Experience from a large Indian cohort

Manash Baruah & Seema Bhuyan
Apollo Excelcare Hospital, Endocrinology, Guwahati, India

Introduction
There is a general assumption that glycemic control in persons with diabetes(PWD) has deteriorated since the onset of COVID-19 pandemic. We conducted this to compare the glycemic status of a very large cohort of PWD prior to COVID-19 outbreak with that of a similar cohort post onset of the outbreak.
Methods
This was a retrospective study wherein entire data of glycated hemoglobin (HbA1c)% available in the hospital database since 3rd October, 2017 till 31st Dec, 2021 were collected and segregated into two cohorts-one on or prior to 31st May, 2020(i.e., pre COVID-19) and another after 1st June (i.e., post COVID-19)
Results
Total 20575 HbA1c values (12081 in the pre COVID-19 arm and 8494 in the post COVID-19 arm) were used for analysis. Mean ($\pm$SD) HbA1c% in the post

COVID-19 arm (8.28 ± 1.9, 8) was significantly higher($P < 0.05$) than that of the pre COVID-19 arm (7.74 ± 1.33). The trend was consistent in various subgroup analyses such as males (8.33 ± 1.9 vs 7.73 ± 1.3)), females(8.21 ± 1.9 vs 7.75 ± 1.2), age <65 years (8.23 ± 1.9vs 7.72 ± 1.2) and age >65 years (8.13 ± 1.8 vs 7.9 ± 1.5). The main driver for such a difference was significantly higher numbers in the subcategory of HbA1c >10% ($P < 0.05$ compared to other categories) as clearly indicated in Table 1

Table 1 Total subjects in 5 different categories of HbA1c. Significance of each category is indicated in terms of *P*values.

HbA1c category	Pre Covid 19, n (%)	Post Covid 19, n (%)	P value
6%-6.9%	4170 (34.54)	2542 (29.96)	0.3 (NS)
7%-7.9%	3368 (27.9)	2061 (24.27)	0.4 (NS)
8%-8.9%	2204 (18.26)	1365 (16.07)	0.2 (NS)
9%-9.9%	1565 (13)	959 (11.3)	0.4 (NS)
≥ 10%	763 (6.3)	1562 (18.4)	≥ 0.05

Discussion
Our study and others suggested that the lockdown situation worsened the glycemic status of PWD.[1] Forced nationwide lockdowns could produce acute panic, anxiety and stress which may also lead to worsened glycemic status. [2]
Conclusion
COVID-19 pandemic has adversely impacted glycemic control in general amongst PWD in general.

Assesment the effects of long-term leptin replacement therapy on ocular structures in the patients with congenital leptin deficiency: a case-control study

Sevde Nur Firat[1] & Özlem Candan[2]
[1]University of Health Sciences, Ankara Training and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]University of Health Sciences, Ankara Training and Research Hospital, Department of Ophthalmology, Ankara, Turkey

Purpose
Congenital leptin deficiency (CLD) is an extremely rare condition. The effects of the disease and leptin treatment on ocular structures are unknown in this patient group. In our study, we planned to compare the ocular findings of patients who received leptin replacement therapy due to leptin deficiency with the control group
Methods
In this prospective, cross-sectional comparative study, six patients with a diagnosis of congenital leptin deficiency and fifteen healthy controls were included. All participants underwent optical coherence tomography (OCT) and optical coherence tomography angiography (OCTA) imagining. Measurements of axial length, central corneal thickness, thickness of subfoveal choroid, retinal nerve fiber layer (RNFL) and macular vessel densities of the superficial capillary plexus and deep capillary plexus were compared.
Results
In the leptin group, 4 patients were on leptin replacement therapy for 23 years and two patients were on leptin replacement therapy for 4 years. The mean axial length ($P = 0.23$), anterior chamber depth ($P = 0.011$), and central corneal thickness ($P = 0.000$) measurements were significantly lower in the leptin group than the control group. The mean of subfoveal choroidal thickness (EDI) ($P = 0.002$), and nasal RNFL thickness ($P = 0.008$), were significantly increased in the leptin group. Perifovea superficial capillary plexus density were significantly decreased in the leptin group (45.02 ± 3.12) compared to controls (48.44 ± 3.61, $P = 0.005$).
Discussion
In this study, the ocular findings of patients with CLD and the effect of long-term leptin replacement therapy on ocular structures were evaluated for the first time in the literature. In our study, mean superficial retinal capillary plexus values of patients with congenital leptin deficiency were significantly lower than controls. The possible explanation for this result may be chronic hypoxia caused by inappropriate vascular structure and impaired angiogenesis due to leptin deficiency. In addition, the mean of EDI and nasal RNFL thickness measurements were significantly higher in leptin patients compared to controls. These results may be due to the effects of leptin on angiogenesis, cell proliferation, endothelial dysfunction, inflammatory and vascular smooth muscle proliferation. In addition, the increase in the nasal region RNFL layer thickness in the patient group, especially in those using leptin replacement therapy for more than 5 years, compared to the controls suggests the neuroprotective effect of leptin.
Conclusions
This study revealed that CLD can bring about developmental and pathological structural changes in anterior segment of eye and in vessel formation of retinal and choroidal vasculature.

Time restricted feeding is a non-pharmacological strategy against diet induced obesity

Nazmin Fatima & Gyanendra Kumar Sonkar
King George's Medical University, Biochemistry, Lucknow, India

Background
Obesity is the major health problem in both developed and developing countries, due to increasing its rate there is a new strategy to prevent obesity by time restricted feeding (TRF). The aim of our study is the effect of TRF intervention on diet induced obese rats and their association with circadian gene expression.
Method
Total 15 Wistar rats were included in our study and divided into two groups. Control group and High Fat diet (HFD) group which consist of six rats and nine rats respectively. HFD group was fed fatty diet for two months to developed obesity. These rats were shifted to TRF with HFD for three months, after which they were again put back on *ad lib* (24 hr feeding). These rats were sacrificed and samples collected. Body weight was measured monthly, with blood glucose, Insulin, melatonin lipid profile and RNA expression estimated after sacrifice.
Results
The body weight and blood glucose level of HFD group were significantly increased as compared to control rats ($P = 0.0263$) and ($P = 0.0089$) respectively. The level of insulin, melatonin ($P = 0.006$) and HDL were reduced in rats fed with HFD whereas total cholesterol, TG and LDL were increased. TRF intervention reduced body weight, blood glucose level, TG, LDL Per1 expression and elevated the level of insulin, melatonin, total cholesterol, HDL and Bmal1 expression. TRF in HFD induced obesity showed its legacy effect when put on *ad lib.*
Conclusions
TRF is a potential behavioural intervention which is easily adaptable in lifestyle modification. TRF intervention can prevent and treat obesity and their associated disorders.

Non-invasive methods of assessment of liver fibrosis in patients following chemotherapy

Oksana Prokopchuk, Ihor Hospodarskyy, Svitlana Danchak, Olha Kozak & Nadiia Havrulyuk
Ternopil National Medical University, Ternopil, Ukraine

Toxic hepatitis is a diffuse inflammatory process in the liver which is caused by the impact of industrial poisons of hepatotoxic action in doses exceeding the maximum allowable concentration. Given the complexity of differentiation, in fact, the symptoms of the disease from possible side effects of treatment, the statistics of the prevalence of the disease in this profile is quite ambiguous. Data from clinical studies show that in the structure of acute and chronic liver disease the drug lesions range from 0.7% to 20% and the percentage of all adverse reactions associated with the use of drugs ranges from 2% to 28%, 10% of which are cytostatic.
Aim
Of the work is to improve the possibility of diagnosing liver fibrosis due to its toxic lesion after chemotherapy in patients with normal weight and overweight by analyzing serum markers of fibrosis.
Materials and Methods
In dynamics, 88 people aged from 31 to 74 years with toxic liver damage without symptoms of cirrhosis and concurrent pathology of the liver and biliary tract were studied.

Results
All subjects were female (100%). The Fibrotest method was used to diagnose the stages of liver fibrosis. Analyzing the level of profibrogenic cytokine TGF-β_1 it was noted that the lowest value was 6123 ng/ml, the highest level was noted at 19746 ng/ml, with the average value for all examined patients was 12758 $\pm$ 3518.3. It was found to increase significantly with increasing stage of fibrosis and BMI with maximum values in the group of patients with toxic liver disease and obese. With the progression of liver fibrosis, the concentration of TGF-β_1 ($r=0.83$, $P<0.05$) in the blood increases, which confirms the role of TGF-β_1 in the activation of liver stellate cells and stimulation of collagen and other extracellular matrix synthesis and is likely a marker of the progression of fibrosing reactions. Also, direct strong correlations of TFG-β_1 with the stage of liver fibrosis according to the fibrotest ($r=0.88$, $P<0.05$).
Conclusions
The presence of excess body weight in cancer patients in stable remission correlates with the severity of liver fibrosis and may be an important factor in predicting the development of severe fibrosis in patients in the long term due to breast cancer treatment. The level of profibrogenic cytokine TFG β_1 correlates with the severity of liver fibrosis according to fibrotest and may be a sensitive predictor of fibrosis progression.

Intake of Fruit and Glycemic Control in Korean Patients with Diabetes Mellitus

Eunju Yoon[1] & Sunghwan Suh[2]
[1]Dong-A University, Department of Food Science and Nutrition, Busan, South Korea; [2]Samsung Changwon Hospital, Department of Internal Medicine, Changwon, South Korea

Background
Despite the well-recognized health benefits of fresh fruit consumption, substantial uncertainties remain about its potential effects on glycemic control in patients with type 2 diabetes mellitus (T2DM).
Methods
We examined the association of fresh fruit consumption and glycemic control in patients with T2DM using data from the 7th Korea National Health and Nutrition Examination Survey. Study samples were divided into 3 groups based on the weekly fruit consumption frequency for the analysis.
Results
Patient with highest fruit intake were older compared to the other two groups and women were more likely to consume fruits. Fruit consumption was positively correlated with better HbA1c levels in these patients. Currents smokers and weekly alcohol intake also showed negative correlation according to the fruit intake tertiles. Moreover, patients with highest tertile of fruit intake were 3.63 times more likely to be in good glycemic control, meaning HbA1c <7% as shown in **Table 1**.

Table 1 Odds ratios for patients in good glycemic control (HbA1c <7%)

	Tertile 1	Tertile 2	Tertile 3
Crude model	1.00 (reference)	0.77 (0.45 – 1.34)	1.46 (0.84 – 2.55)
Model 1	1.00 (reference)	0.78 (0.45 – 1.35)	1.42 (0.81 – 2.48)
Model 2	1.00 (reference)	1.49 (0.62 – 3.59)	1.94 (0.79 – 4.77)
Model 3	1.00 (reference)	1.59 (0.67 – 3.81)	2.28 (0.88 – 5.89)
Model 4	1.00 (reference)	1.83(0.69 – 4.88)	3.63 (1.20 – 11.03)

Model 1 is adjusted by sex and age Model 2 is adjusted by sex, age, body mass index, systolic blood pressure, Triglycerides, LDL-C, current smoking and alcohol intake Model 3 is adjusted by Model 2 plus total energy intake Model 4 is adjusted by Model 3 plus walking per week and dietary fiber intake

Conclusion
In this study, we observed a significant beneficial impact of fruit consumption on glycemic control in Korean patients with T2DM.

Angiotensin-Converting Enzyme (ACE) Level, But Not ACE Gene Polymorphism, Is Associated with Prognosis of COVID-19 Infection: Connection Between Type 2 Diabetes, Hypertension and Renin-Angiontensin-Aldosteron System

Onur Elbasan[1], Feyza Bayram[2], Ceyda Dinçer Yazan[3], Tugce Apaydin[3], Saida Dashdamirova[3], Hamza Polat[2], Ebru Arslan[2], İpek Yılmaz[2], Nastaran Karimi[2], Buket Ertürk Şengel[4], Sultan Yılmaz[5], Ömer Faruk Çelik[5], Pınar Ata[2], Goncagül Haklar[5] & Hülya Ilıksu Gözü[3]
[1]Sinop Ataturk State Hospital, Endocrinology and Metabolism, Sinop, Turkey; [2]Marmara University School of Medicine, Medical Genetics, İstanbul, Turkey; [3]Marmara University School of Medicine, Endocrinology and Metabolism, İstanbul, Turkey; [4]Marmara University School of Medicine, Infectious Diseases and Microbiology, İstanbul, Turkey; [5]Marmara University School of Medicine, Biochemistry, İstanbul, Turkey

Introduction
Renin-angiotensin-aldosterone system was shown to be activated in severe COVID-19 infection. We aimed to investigate the relation between angiotensin converting enzyme (ACE) levels, *ACE* gene polymorphism, type 2 diabetes (T2DM), and hypertension (HT), and the prognosis of COVID-19 infection.
Methods
Clinical features of adult patients with SARS-CoV-2 infection diagnosis were analyzed. *ACE* gene analysis and ACE level measurements were performed. The patients were grouped according to *ACE* gene polymorphism (DD, ID or II), disease severity (mild, moderate, or severe), and the use of dipeptidyl peptidase-4 enzyme inhibitor (DPP4i), ACE-inhibitor (ACEi) or angiotensin receptor blocker (ARB). Intensive care unit (ICU) admissions and mortality were also recorded.
Results
A total of 266 patients were enrolled. Gene analysis detected DD polymorphism in *ACE I* gene in 32.7% ($n=87$), ID in 51.5% ($n=137$), and II in 15.8% ($n=42$) of the patients. *ACE* gene polymorphisms were not associated with disease severity, ICU admission, or mortality. ACE level was higher in patients who died ($P=0.004$) or admitted to ICU ($P<0.001$), and in those with severe disease in comparison to mild ($P=0.023$) or moderate ($P<0.001$) cases. HT, T2DM, and ACEi/ARB or DPP4i use were not associated with mortality or ICU admission. ACE levels were similar in patients with or without HT ($P=0.374$) and with HT using or not using ACEi/ARB ($P=0.999$). It was also similar in patients having T2DM or not ($P=0.062$) and in those with T2DM under DPP4i or not ($P=0.427$) . ACE level was a weak predictor of mortality, but an important predictor of ICU admission. ACE level predicted ICU admission in total (cut-off value >37.092 ng/ml, AUC:0.775, $P<0.001$).
Conclusions
Our findings suggest that higher ACE levels, but not *ACE* gene polymorphism or ACEi/ARB or DPP4i use, were the associated with the prognosis of COVID-19 infection. Presence of HT and T2DM, and ACEi/ARB or DPP-4i use was shown not to be associated with mortality or ICU admission.

Cancer, cardiovascular disease and all-cause mortality in Iraqi- and Swedish-born individuals in Sweden - the MEDIM cohort study

Nadine Fadhel Dhaher[1,2,3], Miriam Pikkemaat[4], Nael Shaat[2,3], Anton Nilsson[5] & Louise Bennet[6,7]
[1]Trelleborg Hospital, Department of Medicine, Trelleborg, Sweden; [2]Lund University, Genomics, Diabetes and Endocrinology, Department of Clinical Sciences, Malmö, Sweden; [3]Skåne University Hospital, Department of Endocrinology, Malmö, Sweden; [4]Lund University, Center for Primary Health Care Research, Department of Clinical Sciences Malmö, Malmö, Sweden; [5]Lund University, Department of Laboratory Medicine, Lund, Sweden; [6]Lund University, Department of Clinical Sciences in Malmö, Malmö, Sweden; [7]Lund University Hospital, Clinical Research and Trial Center, Lund, Sweden

Background
Immigrants from the Middle East to Sweden have a twice as high prevalence of type 2 diabetes (T2D) and obesity as native-born Swedes. Both obesity and T2D have been linked to increased incidence of cancer, cardiovascular disease (CVD) and all-cause mortality (ACM); however, data on differences between ethnicities are scarce.
Aims
In a population-based cohort we aimed to study the impact of Middle Eastern and European ethnicity on ACM, cancer- and CVD related mortality, incidence of cancer and CVD in an eight-year follow-up study. Methods: People born in Iraq or Sweden, who were 30-75 years of age, were invited from 2010-2012 to participate in the population based MEDIM study. A total of 1398 Iraqi- and 757 Swedish-born residents participated in the study, which consisted of a health exam, fasting blood sampling, assessment of insulin secretion and action (through oral glucose tolerance test) and questionnaires assessing history of CVD, cancer and T2D. Register data were retrieved until the 31st of December 2018 from the Swedish National Patient Register and Cause of Death register regarding CVD diagnosis, cancer diagnosis and cause of death. Information regarding diabetes (DM) diagnosis was retrieved from the National Diabetes Register. Individuals with a history of cancer or CVD at baseline were excluded. Cox regression analysis was assessed to study the adjusted hazard ratios (HR) for the relationships between ethnicity and ACM, cancer events, CVD events, death from cancer, and death from CVD, with adjustments for age, sex, anthropometrical measures, DM, and lifestyle.
Results
The HR for ACM was 0.35 (95% CI .14-.86) (p0.05) were observed for CVD related morbidity and mortality between Iraqi- and Swedish-born.
Conclusion
In this 8-year follow-up study, our data show that despite the high burden of cardiovascular (CV) risk factors and T2D, ACM, cancer morbidity and mortality rates were lower in Iraqi-born immigrants compared to native Swedes.

Abdominal pain in pediatric diabetic ketoacidosis: a single center study

Svitlana Suchok & Oleksandr Yakymenko
National Pirogov Memorial Medical University, Pediatric Surgery, Vinnytsia, Ukraine

Background
Despite typical constitutional findings (polyuria, weight loss, and polydipsia), clinical presentation of diabetic ketoacidosis also includes nausea, frequent vomiting and abdominal pain. Moreover, diffuse abdominal tenderness and diminished or absent peristalsis might mimic acute abdomen in pediatric patients. There is paucity of published data regarding prevalence, dynamics and associated laboratory findings in pediatric patients with abdominal pain in DKA.
Aim
To evaluate prevalence of abdominal pain in pediatric DKA; compare and correlate clinical and laboratory findings between children with and without abdominal pain in DKA.
Materials and methods
Ninety-nine pediatric patients' records with diagnosis "diabetic ketoacidosis" on admission from January 2016 to December 2021 were screened for this retrospective single center study. Primary inclusion criteria of DKA were met by 58 pediatric patients (pH $<$ 7,3; blood sugar $\geq$ 11mmol/l; urine ketones $>++$; negative diagnostic abdominal ultrasound). Additionally we included 22 patients transported from the low resource hospital settings (pH was not measured initially) according to the standard patient pathway. These patients had already received initial resuscitation upon admission to our settings and showed improved blood sugar and pH levels. Thus, exclusion criteria of this subgroup included pH>7,35, urine ketones $<++$, with no regards to blood sugar upon secondary check-up. All patients (age range -3-17 yo) were divided into two groups: control – patients without abdominal pain ($n=53$), study grou*P*– patients with abdominal pain ($n=27$). Initial work-up included HbAc1, pH, electrolytes, CBC etc. The local institutional bioethics committee approved the study design.
Results
Prevalence of abdominal pain was 36% (13/36) and 32% (14/44) in new onset T1DM and previously confirmed diabetes (OR: 1.2112; CI 95% [0.4779 - 3.0699], $P=0.6864$. Tenderness upon palpation of the LUQ and periumbilical region was elicited among 59% (16/27) and 18.5% (5/27) of patients, respectively. Mean pH upon admission was 7.16 ± 0.15 and 7.19 ± 0.11 among the controls and the study group, respectively ($P=0.2901$). HbAc1 ranged from 7 to 17,5% (controls – $12.62\pm2.09\%$; the study group $-12.41\pm2.4\%$, $P=0,6998$). Leukocytosis was found in both groups (controls $-16.09\pm8.81*10^9$/l; the study group $-15.85\pm6.75*10^9$/l, $P=0,9013$). 71% (5/7) of patients with severe DKA, 31% with moderate (12/39) and 35% (7/20) with mild DKA suffered from abdominal pain. No significant associations between DKA severity and presence of abdominal pain were observed.
Conclusions
One in three pediatric patients experience abdominal pain in DKA. This clinical finding is not associated with severity of DKA, pH level, WBC count and HbAc1 in children with negative diagnostic abdominal ultrasound.

Physical activity assessment is crucial for obesity risk prediction in adolescent patients

Tzvetelina Totomirova[1], Mila Arnaudova[2], Ivanina Arabadzhieva[3] & Teodor Badarov[4]
[1]Military Medical Academy, Clinic of Endocrinology and Metabolism, Sofia, Bulgaria; [2]MBAL VITA, Sofia, Bulgaria; [3]V MBAL, Sofia, Bulgaria; [4]Military Medical Academy, Clinic of Thoracic Surgery, Sofia, Bulgaria

Physical activity is assumed to be a factor of great importance for weight maintenance. Assessment of physical activity in childhood should be done for identifying patients at risk and predicting obesity development. The aim of our study was to assess physical activity's importance as a risk factor for weight changes in boys and girls 8-18 years aged. The study include 262 subjects (128 boys, 134 girls) in single country region in Bulgaria (mean age 12.02 ± 3.03 years, mean BMI 20.38 ± 4.36 kg/sq.m). Children were asked to answer unified questions considering information about physical activity (time spent in sport, open air activities and before screen time). The information was assessed regarding BMI and weight problems. Results show that 26.87% of girls and 17.19% of boys have previous problems with body weight and 10.45% of girls and 10.93% of boys have increased body weight at the moment. Two girls (1.49%) and six boys (6.25%) were diagnosed with obesity. BMI showed negative correlation with average time spent in physical activity ($r=-0.301$) and open-air activities ($r=-0.321$) and positive correlation with before screen time ($r=0.274$). No other correlations between healthy and unhealthy activity habits were established. No differences in gender and age were found. Based on our data we found out that physical activity assessment is of great importance for adolescent weight gain and risk of obesity. The increase in active sport activity and decrease of before screen time is crucial for weight maintenance and should be focused by parents in establishing of daily child's habits

Evaluation of the Frequency of Exocrine Pancreatic Insufficiency in Patients With Diabetes Mellitus

Sadi Furkan Engürülü[1], Nilüfer Özdemir[2], Sedat Can Güney[2], Serkan Erdal[3], Fatma Taneli[3], Elmas Kasap[4] & Zeliha Hekimsoy[2]

[1]Manisa Celal Bayar University, Faculty of Medicine, Department of Internal Medicine, Manisa, Turkey; [2]Manisa Celal Bayar University, Faculty of Medicine, Department of Endocrinology and Metabolism, Manisa, Turkey; [3]Manisa Celal Bayar University, Faculty of Medicine, Department of Medical Biochemistry, Manisa, Turkey; [4]Manisa Celal Bayar University, Faculty of Medicine, Department of Gastroenterology, Manisa, Turkey

Introduction and Aim
In our study, the frequency of exocrine pancreatic insufficiency, and its relationship with the duration of diabetes and the level of glycemic control and other complications of diabetes were investigated in patients with diabetes mellitus.
Materials and Methods
This paper was supported by Manisa Celal Bayar University Scientific Research Projects Coordination Unit, Project Number 2021-086. A total of 249 diabetic patients, 21 with type 1 diabetes mellitus, 2 with MODY, and the remaining 226 with type 2 diabetes mellitus, were included in this prospective study, between 15 September 2021 and 20 September 2022. The frequency of exocrine pancreatic insufficiency was investigated using fecal elastase-1 measurements in stool. Statistical evaluations were made with T test, Chi-square test and Kruskal Wallis test.
Results
In 20 patients, fecal elastase-1 levels were below 100 mg/ml and this was considered as severe exocrine pancreatic insufficiency. In 57 patients, fecal elastase-1 levels were found to be between 100-200 mg/ml and it is evaluated as mild-moderate exocrine pancreatic insufficiency. In total, exocrine pancreatic insufficiency was detected in 77 patients (30.9%). While mean duration of diabetes mellitus in 77 patients with exocrine pancreatic insufficiency was 11.34 ± 9.42 years, the mean disease duration of 172 patients with normal fecal elastase levels was 9.06 ± 7.81 years. The difference was found to be statistically significant ($P = 0.047$). When glycemic control, duration of diabetes mellitus and exocrine pancreatic insufficiency were evaluated, exocrine pancreatic insufficiency was found more frequently in patients with HbA1c level above 8.5% ($P = 0.007$) and in patients with diabetes mellitus for more than 15 years ($P = 0.018$). In addition, when diabetes mellitus complications and exocrine pancreatic insufficiency were evaluated, exocrine pancreatic insufficiency was found more frequently in patients with diabetic retinopathy ($P = 0.033$). No relation was found between neuropathy, nephropathy and coronary artery disease.
Conclusions
In our study, it was revealed that exocrine pancreatic insufficiency was more common as the duration of diabetes increased and glycemic control worsened. Exocrine pancreatic insufficiency was also found more frequently in patients with diabetic retinopathy. Although it is thought that exocrine pancreatic insufficiency may be one of the chronic complications of diabetes mellitus, further studies with more patients are needed.

Epidemio-clinical and microbiological profile of Staphylococcus aureus bacteremia in diabetics

Nabil Lachiheb[1], Bougharriou Ichrak[1], Gargouri Omar[2], Bartegi Ines[1], Mnif Khouloud[1], Hammami Adnene[2], Mezghani Senda[2] & Ben Jemaa Mounir[1]
[1]Hedi Chaker-Department of Infectious Deseases, Sfax, Tunisia; [2]Habib Bourguiba Laboratory Of Microbiology, Sfax, Tunisia

Purpose
Diabetes is a major risk factor for Staphylococcus aureus (SA) bacteremia. The purpose of this work is to study the epidemiological, clinical and microbiological profile of SA bacteremia in diabetics.
Patients and methods
Retrospective study conducted in the infectious diseases department of Sfax between January 2003 and April 2022 (19 years), including all diabetics admitted for SA bacteremia (at least one positive blood culture).
Results
Among 166 patients admitted for SA bacteremia, 72 were diabetic (43.3%). They were 38 men and 34 women, with an average age of 53 ± 19 years. Associated risk factors were catheterism ($n = 27$) and surgery ($n = 8$). Bacteremia was community-acquired ($n = 38$) and nosocomial ($n = 34$). The portal of entry was mainly endovascular ($n = 29$) and cutaneous ($n = 28$). Septic localizations were noted in 37 cases (51.4%), mainly bone ($n = 17$), muscle ($n = 10$), lung ($n = 7$), joint ($n = 7$), kidney ($n = 6$) and neurological ($n = 6$). Community strains and nosocomial strains were resistant to methicillin in 18% and 29% respectively. Antibiotic susceptibility was for fusidic acid (81%), rifampicin (80%), gentamicin (80%), ciprofloxacin (78%) and cotrimoxazole (69%). The mean duration of antibiotic therapy was 54 ± 30 days. The evolution was favorable in 96%.
Discussion
SA bacteraemia is frequent in diabetics and is characterized by the multitude and variety of septic localizations. SA meti-R is relatively common in nosocomial and community settings. Early and appropriate antibiotic therapy often guarantees a good evolution.

A Case of Diabetes Mellitus Following the COVID-19 Vaccine

Murat Calapkulu
Igdır State Hospital, Endocrinology and Metabolism, Turkey

A Case of Diabetes Mellitus Following the COVID-19 Vaccine
Background
Coronavirus disease-2019 (COVID-19) is a public health issue worldwide. Although COVID-19 vaccines are one of the most effective strategies against COVID-19, it has been reported in recent publications that they can trigger endocrine diseases. Herein, we aimed to present a 37-year-old male patient who had polydipsia, polyuria, thirst, fatigue, and loss of appetite a month after the first dose of the COVID-19 RNA-based vaccine without a prior history of diabetes mellitus.
Case report
A 36-year-old male patient was admitted to the emergency department with complaints of polyuria, polydipsia, thirst, anorexia, and fatigue, which occurred a month after the first dose of the COVID-19 RNA-based vaccine. He had no medical history. Hyperglycemia (645 mg/dl), metabolic acidosis (pH 7.3), and ketonuria were detected in laboratory analysis. The glycated hemoglobin (HbA1c) level was elevated (Table 1). He was diagnosed with diabetic ketoacidosis and management was initiated with intravenous fluid replacement and insulin infusion. When ketoacidosis resolved, subcutaneous multiple daily injections of insulin was initialized. In the follow-up, the patient's insulin therapy was discontinued, and he was discharged with vildagliptin 100/mg/day and metformin 2000 mg/day treatment. The HbA1c level was 10.4%, and the c-peptide level was 4.04 ng/ml six months after the diagnosis. Pioglitazone 30mg/day was added to the patient's treatment. The patient's follow-up continues in our center.
Conclusions
Recent studies have been reported that COVID-19 vaccination induced hyperglycemia and related complications. In general, the majority of patients presented with common osmotic symptoms of hyperglycemia. In most cases, good glycemic control was attained in patients on oral antidiabetic medication after discharge. As the vaccination of the global population accelerates, there must be an investigation of the side effects of COVID-19 vaccines. So that subjects at risk for diabetes can be predicted and appropriate treatment initiated without severe complications.

Table 1 Laboratory analysis of patient at the time of admission

	Values	Reference range
Fasting plasma glucose (mg/dl)	645	74-100
HbA1c (%)	18.1	3.5-5.6
Creatinine (mg/dl)	0.75	0.7-1.2
C-reactive protein (mg/l)	1.72	0-5
Sedimentation rate	13	0-20
Sodium (mmol/l)	120	136-146
Potassium (mmol/l)	4.34	3.5-5.1
Calcium (mg/dl)	9.58	8.6-10.2

New onset diabetes mellitus and thyroid dysfunction following Prembolizumab – a case report

Tânia Matos, Daniela Dias, Catarina Silvestre, Filipa Serra & Inês Sapinho
Hospital CUF Descobertas, Endocrinology, Lisboa, Portugal

Introduction
Prembrolizumab, a programmed cell death protein 1 (PD-1) inhibitor, is one of the immune checkpoint inhibitors (ICI) that have revolutionized cancer therapy. However, ICIs can also trigger immune-related adverse events (irAEs) in different organ systems, including endocrine glands. While thyroid dysfunction is among

the most common endocrinopathies reported, ICI-induced diabetes mellitus (DM) is extremely rare, with an overall incidence ranging from 0.9 to 2%.
Case report
We report the case of 76 years-old woman, with past history of hypertension and dyslipidemia. She was diagnosed in August/20 with an endometrial adenocarcinoma with peritoneal dissemination. In September/21, due to disease progression, she started treatment with Prembolizumab. A month later she developed a transitory thyrotoxicosis, followed by permanent hypothyroidism, most likely caused by silent inflammatory thyroiditis and is currently being treated with levothyroxine. About 6 months later, her fasting blood glucose levels (108 – 119mg/dl) and her A1c levels started to rise (5.8 - 6.3%). Since she was asymptomatic, she was started on SGLT2 inhibitor treatment. Nevertheless, two months later, she suddenly started to lose weight and complaining of polyuria and polydipsia. At observation, she had a blood glucose level of 477mg/dl, positive ketones (4.5mmol/l) and a metabolic acidosis. A diabetic ketoacidosis (DKA) was admitted, and she was treated accordingly. Her laboratory results at that time revealed an A1c level of 9.6% and a low C-peptide (0.44ng/ml). ICI-induced DM was admitted, and a basal-bolus insulin scheme was started. Prembolizumab treatment was never stopped, and she has been gradually improving her metabolic control.
Conclusion
ICIs are associated with significant endocrine irAEs, that can appear at anytime throughout the course of ICI treatment. In the case reported, two endocrinopathies appeared progressively, with a thyroiditis presenting right after the beginning of ICI treatment and a DM appearing about 6 months later. The majority of patients with ICI-induced DM presents in a fulminant way and DKA is frequent at diagnosis, seen in up to 70% of cases. In the reported case, both the high A1c level at DKA diagnosis and the previous signs of glucose metabolism dysfunction, suggest a slower DM development than what is usually described. Nevertheless, our patient ended up presenting with DKA and will probably need lifelong insulin replacement. Although rare, ICI-induced DM can be life-threatening, and a prompt diagnosis is essential. This reinforces the importance of patient education and regular endocrine dysfunction monitoring as a key to reduce irAEs impact.

Objective
Establishing good metabolic control is essential to prevent morbidity and mortality in patients with type 2 diabetes (T2DM). This nationwide survey is performed five years after the first national TEMD study, to search for any improvement in attaining glycemic and metabolic targets in Turkish patients with T2DM.
Methods
The nationwide, multicenter survey consecutively enrolled patients who were under follow up for at least a year in tertiary centers specialized for diabetes care. Optimal control was defined as HbA1c $<7\%$, home arterial blood pressure (ABP) $<135/85$ mmHg, or LDL-C <100 mg/dl or <70 mg/dl or <55 mg/dl according to the risk factors of patients.
Results
A total of 4956 patients (female 2965 (59.8%); median age (IQR) 59(13) years) were enrolled. The clinical and sociodemographic characteristics of patients in previous and current surveys are given in table. The recent survey showed that HbA1c levels are significantly higher, and the HbA1c target attainment rates are poorer ($P<0.001$ for both). Also, mean BMI, systolic and diastolic ABP, and LDL-C levels were significantly lower ($P<0.05$ for all). Macrovascular complication rates were similar while nephropathy rates increased and retinopathy and neuropathy rates decreased in the recent survey ($P<0.001$ for all).
Conclusion
The results of the TEMD-2 Survey show that the glycemic control rates were poorer while other metabolic parameters (BMI, blood pressures, LDL-C) were better five years after the first TEMD survey.

Table Comparison of clinical and sociodemographic characteristics of patients with Type 2 diabetes of TEMD-1 Study (2017) and TEMD-2 Study (2022)

Variable	TEMD-1 ($n=4756$)	TEMD-2 ($n=4956$)	p
Age, years, mean±SD	58.5±10.5	58.9±10.0	**0.030**
Gender (female), n (%)	2799 (58.9)	2965 (59.8)	0.332

Serum Follistatin-Like-1(FSTL-1) Levels in Gestational Diabetes and The Role of FSTL-1 Gene Polymorphism in the Development of Gestational Diabetes Mellitus

Ender Celik[1], Gulhan Akbaba[2], Tuba Edgünlü[3], Eren Akbaba[4], Fatih Pirincci[4] & Nese Cinar[4]
[1]Muğla Sitki Kocman University Faculty Of Medicine, Internal Medicine, Turkey; [2]Muğla Sitki Kocman University Faculty Of Medicine, Endocrinology, Turkey, [3]Muğla Sitki Kocman University Faculty Of Medicine, Medical Biology, Turkey, [4]Muğla Sitki Kocman University Faculty Of Medicine, Obstetrics And Gynecology, Turkey

Introduction
Gestational Diabetes Mellitus (GDM) is associated with maternal and perinatal morbidity. Follistatin-like 1 (FSTL-1), also known as TGFB-beta-stimulated clone 36 (TSC-36), is a glycoprotein cardiokine reported to be associated with insulin resistance and inflammatory processes. To date, there is no study evaluating the effect of FSTL-1 gene polymorphism on the development of GDM in the literature. In this study, we aimed to investigate the effect of serum FSTL-1 level and FSTL-1 gene rs12173 and rs869247 polymorphism in the development of GDM.
Material and Method
Demographic characteristic sand metabolic parameters (FSTL-1, fasting plasma glucose, fasting insulin, HbA1c) of all participants were evaluated. DNA was isolated from peripheral blood. Genotype and allele frequencies were determined by PCR-RFLP method. The prevalences of FSTL-1 polymorphism of the patient sand controls were compared.
Results
72 patients with GDM (meanage: 29.54±4.56 years) and 79 healthy pregnant women (meanage: 28,27±4,47 years) were included in the study. GDM patients had significantly higher BMI than the control group (27.44±5.46 kg/m2 vs. 25.39±2.96 kg/m2, $p<0.001$). The mean HbA1c % in the GDM group was found to be higher than in the control group (5.11±0.42% vs. 4.92±0.30%, p=0.002).There was no significant difference in the serum FSTL-1 levels between the groups (339.35±293.59 ng/mL for GDM and 414.53±364.09 ng/mL for control group; p=0.917). 11 GDM patients (15.3%) had CC genotype, 22 (30.6%) had CT genotype, and 39 patients (54.2%) had TT genotype of FSTL-1 gene rs12173 polymorphism. The prevalence of CC-, CT- and TT- genotypes, in the control group was 11.4, 20.3, and 68.4% respectively-similar prevalences as in the patient group (p:0.097). 24 GDM patients (33.3.%) had CC genotype, 38 (52.8%) had CT genotype, and 10 patients (13.9%) had TT genotype of FSTL-1 gene

rs869247 polymorphism. There was no difference in the distribution of the genotypes of FSTL-1 gene rs869247 polymorhism between the groups (24.1, 65.8, and 10.1%forCC-, CT- and TT- genoypes, in the control group, p: 0.264). There was no difference in the allele frequencies of FSTL-1 gene rs12173 and rs869247 polymorphism between the groups (p=0.086 andp=0.627, respectively).
Conclusion
FSTL-1 gene rs12173 and rs869247 polymorphism seemed to have no effect on the development of GDM. Large-scale studies are needed to find out the molecular mechanisms of FSTL-1 on metabolic diseases

Insulin adherence in type 1 diabetes: about 69 cases (Preliminary results)

Amine Gueddari, Nassim Essabah Haraj, Siham El Aziz & Asma Chadli
UHC Ibn Rochd, Endocrinology and Metabolic Disorders, Casablanca, Morocco

Introduction
Insulin, an essential treatment for type 1 diabetes, must be implemented as soon as diabetes is discovered. It helps to ensure glycemic control. Poor therapeutic compliance may be responsible for the development and progression of complications related to glycemic disorders.
Objective of the study
Assess insulin adherence in type 1 diabetes and study the consequences on glycemic control.
Materials and methods
This is a descriptive prospective study in a group of type 1 diabetic patients followed in the endocrinology and metabolic diseases department at the UHC Ibn Rochd in Casablanca from September 2022. The evaluation of therapeutic compliance was evaluated by the Morisky-Green questionnaire "high adhesion if the score is greater than or equal to 8, medium adhesion between 6 and 7 and low adhesion if <6". Statistical analysis was performed using SPSS 25.
Results
We included 69 patients. The average age was 25 years (+-6.7 years). There is a male predominance with 38 patients (55.1%). Among these patients, 39.1% had a college education level, 29% a high school education level and 7.2% university. The socio-economic level was low in 62 patients (89.9%). The average duration of diabetes was 11.51 years (+-6.4 years). Almost all of our patients were on a basal-bolus regimen (91.3%) including 52 patients (75.4%) on human insulins and 17 patients (24.6%) on insulin analogues. The average number of injections per day was 4.7. The average HbA1c was 10.32% (+- 2.4%). Adherence to insulin was good in 52.2% of cases, medium in 27.5% of cases and low in 20.3% of cases. In bivariate analysis, patients with good treatment compliance had an A1c within the target ($P=0.005$). In multivariate analysis, patients with poor adherence to treatment were more at risk of microangiopathic complications ($P=0.038$).
Conclusion
Therapeutic compliance was low in 20.3% of cases, which suggests the importance of therapeutic education of these patients and the need to create specialized education units.

Ectopic Cushing syndrome due to a late metastatic recurrence of a salivary gland carcinoma: a new therapeutic approach

Maria Claro[1], Neus Baste[2], Gregori Casals[3], Nuria Sanchez[4], Mireia Mora[1,5] & Felicia Alexandra Hanzu[1]
[1]Hospital Clinic Barcelona, Endocrinology, Barcelona, Spain [2]Hospital Clinic Barcelona, Oncology, Barcelona, Spain; [3]Hospital Clinic Barcelona, Hormonal Laboratory, Barcelona, Spain; [4]Hospital Clinic Barcelona, Nuclear Medicine, Barcelona, Spain; [5]Hospital Clinic Barcelona, Barcelona, Spain

Background
Acinic cell carcinoma of the parotid gland is a rare cancer, and metastatic (M1) disease is uncommon, occurring in around 10% of cases, with ectopic paraneoplastic Cushing being described in only few cases.
Clinical case
A 58-year-old woman, with a history of dedifferentiated parotid acinar cell carcinoma, underwent surgery and adjuvant radiotherapy in 2005. In February 2019 the disease recurred with pulmonary, bone and lymph node metastases. Despite further 4 lines-oriented chemotherapies disease showed liver progression. April 2022, facial edema, asthenia, muscle weakness, skin fragility and hyperpigmentation and worsening of blood pressure control with abdominal obesity and hypokalemia established. Clinical suspicion of ACTH dependent Cushing's syndrome was confirmed by the biochemical studies: ACTH 1174pg/ml, plasma cortisol 59 mg/dl, urinary free cortisol (UFC) 2046 mg/24h (1633 mg/24h by mass spectrometry), 8 mg dexamethasone test: cortisol: 27 mg/dl. Pituitary MRI was negative for adenoma and 68Ga-DOTATE- PET scan was positive for all M1, suggesting positive somatostatin receptors. PET-FDG showed similar distribution of the radiotracer. Biopsy of the new liver M1 shows a high-grade carcinoma, Ki80%, and a positive ACTH in 10%, as well as positive expression of somatostatin receptors 2 and 5. Treatment of the hypercortisolism with the steroid inhibitor Osilodrostat was started in rapidly ascending doses to 10mg c/12h, with rapid and stable decrease of cortisol at basal values of 26 mg/dl with a UFC of 416 mg/24 h after 4 weeks of treatment with control of hypertension and of the Cushing phenotype. K and oedema were controlled by adding mineralocorticoid antagonists. Two doses of PRRT with Lu177-DOTATATE were administrated at external center with significant reduction of the liver M1. Intercurrence of urinary sepsis with hypotension in context of self-overdosing of analgesic treatment required parenteral glucocorticoid administration, and finally block and replace treatment was selected (UFC at hospital discharge was of 268 mg/24 h with cortisol of 7 mg/dl y under concomitant dexamethasone 2 mg/day). Unfortunately, despite biochemical stability during 3 months of Osildrostat and partial response to the PRRT the clinical condition acutely worsted due to spinal cord compression and palliative treatment was initiated.
Conclusion
Hereby we show the clinical case and therapeutic approach of a salivary carcinoma with metastatic late recurrency after more than one decade with ectopic ACTH secretion.

Congenital craniopharyngioma – Cases recruited in the German Kraniopharyngeom trials and review of the literature

Julia Beckhaus[1], Svenja Boekhoff[1], Brigitte Bison[2], Carsten Friedrich[1] & Hermann Müller[1]
[1]Klinikum Oldenburg AöR, Oldenburg, Germany; [2]University Hospital Augsburg, Augsburg, Germany

Background
Craniopharyngiomas (CP) are rare malformational tumors. Clinical presentation and outcome of patients with congenital CP (cCP) are not clear and refer mainly to few case reports in the literature. The aim of this study was to analyze clinical presentation and outcome in patients with cCP.
Clinical cases
Seven hundred and nine patients diagnosed with adamantinomatous CP were recruited 1999-2021 in HIT-ENDO, KRANIOPHARYNGEOM 2000 / 2007 / Registry 2019 and prospectively observed. In 3 cases, cCP was diagnosed prenatally and in one case at the 2nd day of life. Pre- and perinatal diagnostic findings, postnatal evaluation, therapeutic interventions and outcome in these 4 cases of cCP were analyzed. When compared to cases of cCP reported in the literature, more recent cases like our reported cCP have an overall better prognosis with regard to survival and sequelae. Two of our 4 cCP suffered from hemiparesis and one patient presented with mild motor retardation. In contrast to historical reports (lethal rate of $>50\%$), all patients in our report recruited after 2000 survived. Prenatal routine ultrasound examination was the usual diagnostic procedure leading to diagnosis of cCP. Tumor resection was performed during early postnatal period (range: 11 - 51 days of age). Complete resection of the mostly large sized tumors could be achieved in two of four patients with cCP.
Conclusions
Based on improvements of diagnostic and therapeutical methods and techniques, earlier prenatal diagnosis of cCP should lead to intrauterine transfer of cCP patients to a specialized center for postnatal treatment of newborns with sellar masses by a multidisciplinary team to secure an improved prognosis of these patients.

Hypothalamic-pituitary endocrine surveillance among childhood and young-adult cancer survivors

Yaasir Mamoojee[1], Salman Hossen[2] & Muhammad Hassaan Pervez[2]
[1]Royal Victoria Infirmary, Endocrine and Diabetes(on behalf of the Late Effects Endocrine Multidisciplinary Team), Newcastle Upon Tyne, United Kingdom; [2]Royal Victoria Infirmary, Endocrine and Diabetes, Newcastle Upon Tyne, United Kingdom

Introduction
Survivors of childhood, adolescent or young adult cancers are at risk of endocrine dysfunction from their tumours, surgery, chemotherapy and/or radiotherapy treatment. The hypothalamic pituitary axes and gonads are at risk of dysfunction depending on a number of risk factors. Endocrine dysfunction can occur from before diagnosis of cancer, soon after but mostly a number of years later, even after survivors have been discharged from oncology follow-up. We aim to evaluate the burden of endocrinopathies and tempo of hormonal losses during long-term follow-up in survivors.
Methods
All patients currently attending our Late Effects Endocrine Clinic (LEEC) were included and following data extracted from notes: demographics, primary tumour, cancer therapy received, endocrinopathies along with year of diagnosis.
Results
137 patients are currently under long-term follow-up in LEEC, with a F:M of 1:2. 75% of patients had previous solid intracranial tumours and 15% suffered from haematological malignancies. Mean age at diagnosis of cancer was 17 years with 80% diagnosed before 20 years of age. Mean duration of follow-up is 18 years. Treatment modalities for cancer included surgery (50%), cranial radiotherapy (85%), spinal radiotherapy (25%) and chemotherapy (60%). 7% of patients had four anterior pituitary hormone deficiencies (thyroid, steroid, gonadal and growth hormone). 70% of patients had up to 3 hormone deficiencies and 23% had none. Notably 36% of eugonadal patients had steroid and/or adrenal deficiency. Overall hormonal losses mostly occur between 6 and 15 years post cancer treatment. Adrenal deficiency occurred mostly soon after cancer treatment with no further loss after 10 years of follow-up. Thyroid deficiency occurs progressively during the first 15 years of follow-up. In contrast, gonadal hormones were progressively loss throughout the 30 years of follow-up available.
Conclusion
Gonadotrophin-sparing pituitary deficiency is not infrequent in our LEEC cohort. Tempo of hormonal losses suggest that surveillance for steroid and thyroid axes can be stopped after 15 years but surveillance for gonadal axis should continue beyond 20 years.

Clinical implications of splicing machinery alteration in Pheochromocytomas and Paragangliomas

María Trinidad Moreno Montilla[1,2,3], Víctor García Vioque[1,2,3], Ricardo Blázquez Encinas Rey[1,2,3], Angel Mario Martinez Montes[4], Emilia Alors-Pérez[1,2,3], Federica Mangili[1,2,3,5], Sergio Pedraza-Arevalo[1,2,3], Mercedes Robledo[4,6], Justo P. Castaño[1,2,3,7] & Alejandro Ibañez Costa[1,2,3]
[1]Maimonides Biomedical Research Institute of Cordoba, Cordoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, Cordoba, Spain; [3]Reina Sofia University Hospital, Cordoba, Spain; [4]Hereditary Endocrine Cancer Group, Human Cancer Genetics Program, Spanish National Cancer Research Centre (CNIO), Madrid, Spain; [5]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [6]Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERer), Madrid, Spain; [7]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain

Pheochromocytomas and paragangliomas (PPGL) are infrequent neuroendocrine neoplasms, which develop metastases or aggressive behaviour in 25 % patients. They can be classified into three clusters according to their molecular features; nevertheless, these differences may not stratify patients according to their prognosis. The dysregulation of the splicing process has emerged as a novel feature shared by most cancers, which is associated with an aggressive phenotype in several tumours, including NETs, but it has not been explored in PPGL. The purpose of this study was to determine the splicing machinery profile in PPGL, its relationship with clinical/molecular features, and to investigate the functional role of splicing inhibitors in vitro. We investigated the expression of 310 splicing-related genes in a dataset of 196 PPGL and analysed their relationship with clinical features of patients and tumor phenotypes, which was validated using the TCGA dataset. SK-N-AS (WT and *SDHB* knock-down), and PC12 cell lines were used to perform in vitro assays testing the effects of the SF3B1 inhibitor Pladienolide B. Pheochromocytomas and paragangliomas show clearly distinct profiles of splicing machinery components. Interestingly, clear differences were observed among the molecular clusters. Furthermore, the expression levels of certain splicing-related genes were associated to metastasis, aggressiveness, and low survival. The *in vitro* blockade of the splicing process reduced functional parameters of aggressiveness as proliferation, colony formation, migration, and sphere formation. Finally, our findings revealed that the splicing machinery is severely altered in PPGL, which may be associated with key clinical features, and its modulation may improve tumour aggressiveness.

Keywords
pheochromocytoma, paraganglioma, splicing dysregulation, splicing machinery, pladienolide B.

Should patients with incomplete microscopic resection of papillary thyroid carcinoma be classified as high-risk ones for the recurrence/-persistent disease?

Artur Kuchareczko[1,2], Iwona Palyga[1,2], Agnieszka Walczyk[1,2], Danuta Gasior-Perczak[1,2], Janusz Kopczyński[2], Izabela Płachta[2], Magdalena Chrapek[1], Stanislaw Gozdz[1,2] & Aldona Kowalska[1,2]
[1]Jan Kochanowski University, Kielce, Poland; [2]Holycross Cancer Centre, Endocrinology, Kielce, Poland

Introduction
In recent years the growing rate of newly diagnosed papillary tyroid cancers (PTC) has been observed. Nowadays most of PTC are small (mostly $<$2cm in diameter) with no unfavourable patomorphological features, although the cases of incompletely resected PTC can still be encountered. Incomplete tumour resection, regardless of the presence of microscopic (R1) or macroscopic (R2) disease, after operation, is considered as a high-risk factor for PTC recurrence/persistent disease both by American Thyroid Association (ATA) and European Society for Medical Oncology (ESMO) recent guidelines.
Aim
The aim of our study was to assess the relationship between resection margin status (R0 vs R1) and the clinical outcomes (response to therapy, recurrence presence) in Polish patients with PTC.
Materials and Methods
A retrospective analysis of 2674 patients, who were enrolled to the study, from a single tertriary oncologic referential centre, operated between 2000-2021, was performed. From this group 1975 patients were further qulified for study: 1819 who had R0 resection status and were assessed as having low-risk cancer according to ATA guidelines (ATA-LR) and 156 who were treated as high-risk cancer (HR-ATA) only due to incomplete microscopic tumor resection (R1).
Results
In the group with R0 resection the excellent response to therapy, at the end of follow-up, was observed in 1738 (95.55%) patients and indeterminate response was observed in 76 (4.18%) cases. The biochemical incomplete response to therapy, during last follow-up, was detected in 1 (0.05%) patient. Structural incomplete response was stated in 4 cases (0.22%). There were 11 cases of reccurence (definied as diagnosing cancer after achieving so-called ''no evidence of disease'' due to prior treatment) of which 10 (90.91%) were treated succesfully and excellent response was achieved. In total, the risk of recurrence/persistent disease in patients with R0 resection was 5.24% (91/1738). In the group with R1 resection the excellent response to therapy was observed in 139 (89.1%) patients and indeterminate in 11 (7.05%) cases. The biochemical incomplete response to therapy was detected in 3 (1.92%) patient. Structural incomplete response was stated in 3 cases (1.92%). There were 2 cases of reccurence of which none achieved excellent response. In total, the risk of recurrence/persistent disease in patients with R1 resection was 10.9% (17/156).
Conlusions
Due to lower risk of unfavourable outcomes when incomplete microscopic resection is observed in differentiated thyroid cancer the consideration of treating cases with R1 feature as ''intermediate cancer'' for recurrence/persistent disease should be made.

Instituto de Investigación Sanitaria de Santiago de Compostela (IDIS), Endocrinology and Nutrition, Santiago de Compostela, Spain

Introduction / Background
Patients with advanced GEP-NENs often present with metabolic disorders and oncological treatments may increase malnutrition risk as well as alterations on body composition. Several studies have suggested that sarcopenia is independently associated with a worse prognosis in oncological patients. Sarcopenia predicts survival regardless of body weight; moreover, a reduced muscle mass is not only observed in cachectic individuals but also in overweight patients.
Aims
The aim of this study is to describe body composition and to evaluate functionality of patients with advanced GEP NENs in Spain.
Materials and Methods
Cross-sectional study including patients with GEP-NENs at a metastatic/unresectable stage and active oncological treatment. Patients had a complete demographic evaluation, physical examination, anthropometry, bioelectrical impedance, dynamometry, laboratory analysis, and nutritional risk assessment. Malnutrition was defined according to GLIM criteria and sarcopenia according EWGSOP criteria. The study plans to include 400 patients; Accrual is open. Pearson's $\chi 2$ test with α 0.05.
Results
284 patients were included. Median age was 63 years (24-83). The most frequent tumor location was small bowel (44.7%) and pancreas (43%). 94.7% were metastatic, 88.4% grade 1-2 and 83.8% had ECOG 0-1, and 23.6% were functioning. The most common previous/current treatments were somatostatin analogues (89.8%), targeted therapy (29.9%), peptide receptor radionuclide therapy (28.9%) and chemotherapy (19.7%). 50% of the patients were on first line treatment, 23.9% on second line and 26% were on more than two lines. Malnutrition prevalence was 62% ($n=176$) being severe in37.7%($n=107$). Low muscle mass was the most common GLIM phenotypic criteria, present in 139 patients (48.9%), being severe in 25.7%. Mean calf circumference was 34.2(4.8)cm and 36.5(5.5)cm, free fat mass of 41.4(10.6)kg and 56.1(11.8)kg and handgrip strength of 19.2(6.9)kg and 36.3(9.5)kg in females and males respectively. Mean phase angle was 7(9.3)° and 7(8.9)° in females and males respectively. Sarcopenia was present in 22.5%. Patients with malnutrition showed decreased handgrip strength ($P<0.001$).
Conclusions
Malnutrition among patients with advanced GEP-NENs is high, being low muscle mass the most frequent phenotypic criteria in patients with GEP-NENs present in half of the patients. One every five patients with GEP-NENs had sarcopenia.

The involvement of endocannabinoid system in Multiple Endocrine Neoplasia type 1 (MEN1)

Cinzia Aurilia[1], Simone Donati[1], Gaia Palmini[1], Irene Falsetti[1], Gianna Galli[1], Roberto Zonefrati[1], Teresa Iantomasi[1] & Maria Luisa Brandi[2]
[1]University of Florence, Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [2]Fondazione Italiana Ricerca sulle Malattie dell'Osso (F.I.R.M.O Onlus), Italy

Background
Multiple endocrine neoplasia of type 1 (MEN1) is a rare heritable endocrine tumor syndrome that results from biallelic inactivation of the MEN1 gene and the loss of menin protein, that was characterized by a susceptibility to the development of multiple endocrine neoplasms within a single patient. The MEN1 gene screening is helpful in the clinical practice for early genetic diagnosis. Unfortunately, the lack of genotype-phenotype correlation doesn't allow to foresee the syndrome's clinical course, consequently, reducing the possibility to develop a personalized diagnostic and therapeutic plan. Recently, it has been reported that menin is capable to suppress the Hedgehog signalling pathway (Hh) MEN1-dependent tumors and its loss might cause the over-activation of this proliferative and oncogenic pathway. Moreover, emerging evidence highlight that Hh pathway and MEN1 tumorigenesis could be under the control of epigenetic mechanisms, including miRNAs. In addition, results obtained over the last years demonstrated that cannabinoids regulate miRNA expression in BV-2 microglial cells and are endogenous conserved inhibitors of the Hedgehog (Hh) pathway. However, no data are currently available on the relationship between the endocannabinoid system (ES), Hh pathway, and miRNAs in MEN1 syndrome.
Materials and methods
First, in silico analyses, using TargetScan, miRanda, and miRNet software, were performed to find the possible binding between miRNAs and different factors involved in the Hh pathway. Next, cell biology analyses were carried out for a preliminary assessment of the ES components expression in different neuroendocrine tumor cells (i.e., insulinomas, gastrinomas, and prolactinomas) derived from MEN1 patients. Finally, we observed the effects of Anandamide (AEA) on insulinoma cells proliferation.
Results and future perspective
In silico analysis indicated the 3' untranslated region (3'UTR) of human Dual specificity tyrosine phosphorylation regulated kinase 2 (DYRK2) mRNA as potential target of miR-24-1-3p, which was deregulated in MEN1 parathyroids and pancreas tumors. Then, PCR analysis showed the presence in the neuroendocrine tumor cells of both receptors (i.e., CNR1, CNR2, GPR55, GPR6, and TRPV1) and enzymes (i.e., FAAH, NAPE e DAGLα) involved in ES. Finally, we observed that treatment with different concentrations of AEA on insulinoma cells led to a decrease in their proliferative capacity, especially with 10 μM and 100nM concentrations. Further studies are needed to validate the latter finding and to subsequently establish the relationship between ES, miRNAs, Hh pathway, and MEN1 tumorigenesis. In conclusion, this project could pave the way for the possible future endocannabinoid-based drug development against MEN1 syndrome.

In silico neoantigen prediction - a forceful avenue to improve immunotherapy in human adrenocortical carcinoma

Laura-Sophie Landwehr[1], Silke Appenzeller[2], Laura Ölsner[2], Isabel Weigand[3], Silviu Sbiera[1,2], Martin Fassnacht[1,2,4] & Matthias Kroiss[2,3]
[1]University Hospital Würzburg, Department of Internal Medicine I, Division of Endocrinology and Diabetes, Würzburg, Germany; [2]University of Würzburg, Comprehensive Cancer Center Mainfranken, Germany; [3]LMU Klinikum München, Medizinische Klinik und Poliklinik IV, München, Germany; [4]University Hospital Würzburg, Clinical Chemistry and Laboratory Medicine, Würzburg, Germany

Introduction
Adrenocortical carcinoma (ACC) is one of the most aggressive endocrine malignancies and confers a poor prognosis in advanced stages. Effective treatments are lacking. The results of immune checkpoint inhibition were disappointing with few responders only deriving clinical benefit. For the development of novel immunotherapies such as tumor vaccines and T cell-based treatments, target identification is essential. Tumor-specific mutant

neoantigens that may be recognized by T cells in the context of major histocompatibility complex (MHC) I are promising candidates.
Methods
We performed whole exome-sequencing in 10 ACC samples with matched blood controls. Somatic mutations were identified using an in house bioinformatics pipeline. By coupling POLYSOLVER for HLA typing with netMHCpan, *in silico* binding affinity of tumor-specific neoantigens to MHC was calculated taking into account both peptide and HLA sequence information. Strong binding (SB) was defined as $<0.5\%$ rank, weak binding (WB) as 0.5-1.9% rank and no binding (NB) as $>2.0\%$ rank of all peptides to MHC.
Results
Across 10 ACC patients, we identified 1067 unique somatic mutations (median 49.5, ranging from 15-590), affecting 989 different genes. Binding affinity changed for 414 predicted neoantigens from NB to WB, 80 from NB to SB and 82 from WB to SB. The mutant neoantigen load per patient ranged from 10 to 235 (mean 66.2) and was positively correlated to the total number of non-synonymous single nucleotide variants (R^2 0.8977, 95% CI 0.79-0.99; $P<0.0001$).
Discussion
This is the first study that demonstrates successful *in silico* neoantigen profiling in ACC. Mutant neoantigens were predicted to be present both in ACC with high and low tumor mutational burden. These data will pave the way for *in vitro* validation and hold potential to develop therapeutic cancer vaccines and T cell-based cancer immunotherapy in ACC.

Hyperandrogenism in menopause: whose fault?

Ilaria Bonaventura[1], Alessandra Tomaselli[1], Marianna Minnetti[1], Dario De Alcubierre[1], Chiara Tarantino[1], Alessia Cozzolino[1], Riccardo Pofi[2], Daniele Gianfrilli[1], Andrea Isidori[1] & Carlotta Pozza[1]
[1]Sapienza University of Rome, Department of Experimental Medicine, Rome, Italy; [2]Oxford Centre for Diabetes, Endocrinology and Metabolism and NIHR Oxford Biomedical Research Centre, Department of Endocrinology, Oxford, United Kingdom

Background
Hyperandrogenism in postmenopausal women is extremely rare and requires exclusion of malignancy.
Case reports
1. A 65-year-old woman was referred to our Department of Endocrinology for appearance of hirsutism and alopecia for about 2 years. Abdomen-pelvis CT scan showed a 2-cm lesion (45 HU) at the left adrenal gland, confirmed by MRI scan, without loss of signal intensity in opposed-phase sequences. In addition, in the right ovary, a 3-cm lesion with progressive enhancement was found, suspected for malignancy. Hormone assays detected increased levels of adrenal and ovarian androgens (DHEAS 107.7 µg/dl, Delta 4-Androstenedione 401 ng/dl, Testosterone, Te, 5.97 nmol/l), Estradiol (40 pg/ml) and Urinary Free Cortisol (298 mg/24h) with normal to low values of ACTH (14.5 pg/ml) and inappropriately normal for age LH values. She therefore performed a 18F-FDG PET scan, which showed uptake in the left adrenal (SUVmax 6.5) and a focal and inhomogeneous distribution of the tracer in the right ovary (SUVmax 4.1). She then underwent left adrenalectomy, with normalization of adrenal androgen levels but persistence of elevated Te levels post-surgery (8.69 nmol/l). She therefore performed bilateral oophorectomy, with subsequent normalization of Te levels (1.19 nmol/l). Histological examination showed left adrenal adenoma and steroid cell tumor of the right ovary.
2. A 73-year-old woman was referred for clinical hyperandrogenism (alopecia and hirsutism for about 20 years, with worsening in the last 4 years) with increased Te levels (5.5 nmol/l). She performed adrenal-pelvis MRI scan, which found two lesions in both adrenal glands (9 mm in the right and 13 mm in the left), referable to adrenal cortical nodular hyperplasia. In addition, both ovaries were enlarged, but free from lesions. Basal hormone assessment showed a marked increase in serum Te (6.58 nmol/l), 17-OH-Progesterone (2.4 ng/ml) and gonadotropin levels (FSH 76.22 mUI/ml, LH 24.99 mUI/ml). A normal short Synacthen test for 17-OH-Progesterone excluded congenital adrenal hyperplasia, while a prolonged Dexamethasone test for androgens failed to suppress Te levels. Ovarian hyperthecosis was hypothesized. The patient was, thus, addressed for bilateral oophorectomy.

Conclusions
The coexistence of adrenal and ovarian androgen-secreting lesion, although rare, is a possibility and a challenge for the endocrinologist in the differential diagnosis of hyperandrogenism.

Hand-foot syndrome: a frequent but rarely severe adverse event in patients with thyroid cancer treated with lenvatinib

Elisa Minaldi, Virginia Cappagli, Carlotta Giani, Laura Valerio, Loredana Lorusso, Antonio Matrone, Carla Gambale, Alessandro Prete, Luciana Puleo, Valeria Bottici, Eleonora Molinaro, Laura Agate & Rossella Elisei
University Hospital of Pisa, Department of Clinical and Experimental Medicine, Endocrine Unit, Pisa, Italy

Introduction
Hand-foot syndrome (HFS), or palmo-plantar erythrodysplasia, is an adverse event related to lenvatinib therapy. In the clinical trial (SELECT study) HFS was reported in 32% of patients, but only 3% was grade ≥ 3. In real-life studies the frequency was variable: between 8 and 55%.
Patients
We collected clinical and pathological data about 165 patients with thyroid cancer treated with lenvatinib, followed up between 2012 and 2022 at the Endocrinology Unit of the University Hospital of Pisa.
Results
Fortythree out of 165 (26.7%) developed HFS during lenvatinib treatment after a median time of 2.9 months (IQR 1.14-6.79) from the beginning of the treatment. Among these 43 cases of HFS, 24 (55.8%) were classified as grade 1, 16 (37.2%) as grade 2, 3 (7%) as grade 3/4. Because of the HFS, in 2 patients drug dose reduction was required, while in one patient a transient discontinuation of lenvatinib was necessary. All patients were treated with topical therapy. Grade ≥ 3 cases required podiatrist intervention and specific footwear. The comparison between those patients who developed HFS and those who did not developed HFS showed a significant association with age (mean 63 ± 8.97 years vs 66.61 ± 10.14; $P=0.032$) and duration of lenvatinib therapy [median 15.96 months (IQR 8.47-46.72) vs median 12.68 months (IQR 4.48-27.23); $P=0.039$]. No significant association was found concerning sex (females 29.62% vs females 23.75%), presence of distant metastasis (M1), thyroid carcinoma histotype, the starting dose of lenvatinib (mean $21.12 \pm$ 4.79 mg/die vs mean $19.46 \pm$ 6.04 mg/die), and prior treatments (131-I, chemotherapy, external radiotherapy, other multikinase inhibitors).
Conclusions
HFS is a frequent adverse event related to lenvatinib but rarely of grade ≥ 3, such as to require reduction or discontinuation of the drug. In our series, HFS was more frequent in younger patients and those who was using Lenvatinib since more time. Further studies are needed to understand the pathogenesis and risk factors related to the occurrence of HFS.

Impact of Gender on Treatment Decisions and Outcome in Patients with Neuroendocrine Neoplasms

Julia Beck[1], Alexander Siebenhüner[2], Damian Wild[1], Emanuel Christ[1] & Julie Refardt[1]
[1]University Hospital Basel, ENETS Center of Excellence for Neuroendocrine and Endocrine Tumors, Basel, Switzerland; [2]Hirslandenklinik Zürich AG, Medical Oncology, Zürich, Switzerland

Introduction/Background
Gender differences affect the treatment of several diseases in both male and female patients. However, the influence of gender on treatment decisions and outcome in neuroendocrine neoplasms (NENs) has scarcely been investigated.
Aims
Comparison of tumor characteristics, treatment decisions and outcome of patients with NENs, stratified by gender
Material and Methods
Retrospective analysis of the SwissNET cohort involving NENs of gastroenteropancreatic, pulmonal or unknown origin from 07/14 – 09/21. Site of origin, tumor grading, time to first treatment, choice of treatment and overall survival was assessed.
Results
2329 patients were included in the analysis with 54% being male and 46% female patients. No significant difference in site of origin, tumor grading and staging was found between male and female patients. There was also no difference in time of symptoms onset until diagnosis and first treatment intervention. Surgery was performed in 66.3% of male and 71% of the female patients, $P=0.016$. Meanwhile, male patients received more often PRRT (22% vs 19.3%, $P=0.007$) and chemotherapy (15.9% vs 12.7%, $P=0.032$). Despite the similar tumor characteristics, the median overall survival of male patients was significantly lower compared to female patients (Male: 124.8 months, Female: 158.5 months, $P<0.001$). Interestingly, this difference was most pronounced in patients with

lung NENs (Male: 142 months, Female: not reached) and cancer of unknown origin (Male: 18.5 months, Female: 35 months).
Conclusions
Male gender seems to be a risk factor for worse outcome, specifically for lung NENs and NENs of unknown origin. The underlying mechanisms of these findings remain to be established.

Pivotal phase III COMPOSE trial to compare lutetium (177Lu) edotreotide with best standard of care in patients with well-differentiated aggressive grade 2 and grade 3 gastroenteropancreatic neuroendocrine tumors

Jaume Capdevila[1], Daniel Halperin[2], Diane Reidy-Lagunes[3], Grace Kong[4], Thorvardur R Halfdanarson[5], Josh Mailman[6], Ken Herrmann[7], Rajaventhan Srirajaskanthan[8], Thomas Thevenet[9] & Philip Harris[9]
[1]Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology, Barcelona, Spain; [2]Anderson Cancer Center, Houston, United States; [3]Memorial Sloan Kettering Cancer Center, New York, United States; [4]Peter MacCallum Cancer Centre, Melbourne, Australia; [5]Mayo Clinic, Rochester, United States; [6]NorCal CarciNET Community, Oakland, United States; [7]University Hospital Essen, Essen, Germany; [8]Kings College Hospital, London, United Kingdom; [9]ITM Oncologics GmbH, Garching/Munich, Germany

Background
Gastroenteropancreatic neuroendocrine tumors (GEP-NETs) represent an estimated 70% of NETs. GEP-NETs frequently develop metastatic disease with limited treatment options. For well-differentiated high grade 2 and 3 GEP-NETs, current therapies include peptide receptor radionuclide therapy (PRRT), somatostatin analogues, chemotherapy, cytoreduction, and molecular targeted therapies (everolimus, sunitinib). PRRT uses radiolabeled somatostatin analogues to selectively target somatostatin receptor expressing (SSTR+) tumor cells. The radiolabeled somatostatin analogue lutetium (^{177}Lu) edotreotide has shown promising efficacy and a favorable safety profile. Retrospective data in patients with metastatic GEP-NETs treated with two or more lutetium (^{177}Lu) edotreotide cycles demonstrated nearly 30 months progression-free survival (PFS). COMPOSE (NCT04919226), a prospective, randomized, controlled, open-label, multi-center Phase III study, aims to extend therapeutic options for patients with well-differentiated aggressive grade 2 and grade 3, SSTR+, GEP-NETs. Furthermore, functional imaging and genetic profiling analysis as part of COMPOSE plans to guide detection of specific traits in NET patients, to potentially improve treatment and surveillance strategies.
Trial design
COMPOSE evaluates efficacy, safety, and patient-reported outcomes of first- or second-line treatment with lutetium (^{177}Lu) edotreotide PRRT. At least 202 patients with SSTR+ disease will be randomized 1:1 to up to six cycles of lutetium (^{177}Lu) edotreotide, given at 6- to 8-week intervals, or to an active comparator (CAPTEM, FOLFOX or everolimus, according to investigator's choice). PFS, the primary endpoint, will be assessed every 12 weeks until disease progression (RECIST v1.1) or death, whichever occurs earlier. Overall survival, assessed up to 2 years after disease progression, is a secondary outcome. In addition, baseline fluorodeoxyglucose and SSTR positron emission tomography imaging, full exome sequencing and gene expression analysis of tumor histology and longitudinal blood samples will be studied. DNA will be assessed to determine the impact of different types of mutations; mRNA will be assessed to confirm and quantify these assumptions and compare gene expression at different treatment phases. COMPOSE recruitment commenced in September 2021 and comprises of 40 study sites in the United States, Europe, India and Australia.
Conclusion
COMPOSE results are expected to inform about optimal treatment options for patients with well-differentiated aggressive grade 2 and grade 3 SSTR+ GEP-NETs. Moreover, the genetic profiling analysis may assist in developing predictive models that would integrate genetic data with functional and structural imaging, histopathology and phenotype information for implementation into clinical practice.

Survival, obesity and quality of life after childhood-onset craniopharyngioma: The role of age at diagnosis and hypothalamic damage

Julia Beckhaus[1], Carsten Friedrich[1], Svenja Boekhoff[1], Gabriele Calaminus[2], Brigitte Bison[3], Maria Eveslage[4], Beate Timmermann[5], Jörg Flitsch[6] & Hermann Müller[1]
[1]Klinikum Oldenburg AöR, Department of Paediatrics and Paediatric Heamtology/Oncology, University Children's Hospital, Oldenburg, Germany; [2]University Hospital Bonn, Bonn, Germany; [3]University Hospital Augsburg, Augsburg, Germany; [4]University of Münster, Institute of Biostatistics and Clinical Research, Münster, Germany; [5]Essen University Hospital, Department of Particle Therapy, Essen, Germany; [6]University Medical Center Hamburg-Eppendorf, Department of Neurosurgery, Hamburg, Germany

Background
Adamantinomatous craniopharyngiomas (CP) are rare malformational tumors. The association between age at diagnosis and the outcome, clinical presentation and treatment of pediatric CP patients is not clear. The aim of this cohort study was to determine clinical presentation, outcome and quality of life in CP patients diagnosed at different AaD.
Methods
Seven hundred and twenty-two patients diagnosed with CP were recruited 1999-2021 in HIT-Endo, KRANIOPHARYNGEOM 2000/2007/Registry2019 and prospectively observed. AaD was categorized as infants and toddlers (<2y), early childhood (2–<6y), middle childhood (6–<12y) and early adolescence (12–<18y). After median follow-up of 8.4 years, overall and event-free survival (EFS), functional capacity (FMH) and quality of life (QoL) (PEDQOL) were assessed. Multivariable cox regression was applied to compare the survival of three age groups in dependence of HI and HL. Multivariable logistic regression was used to determine potential risk factors for obesity (BMI SDS >3) at last visit.
Results
In this cohort, the prevalence of severe obesity (BMI >3SDS) was 45.4%. No differences regarding surgical approach were determined between the age groups. Lower EFS but better QoL was observed in children with AaD <6y compared to □6y. Reduced functional capacity (FMH) percentiles were associated with increased BMI-SDS at last visit (rho = -0.125, 95% CI [-0.21; -0.04]) and AaD < 2y. Posterior HI and HL are independent risk factors for events (HR = 1.59, 95% CI [1.12;2.26]) and obesity at last visit (OR = 2.94, 95% CI [1.73;5.08]). Patients with posterior HI and HL report worse scores on PEDQOL body image domain.
Conclusions
Severe obesity is a frequent sequela in nearly half of all pediatric CP patients. Diagnosis of CP at an age <6 years, enables patients to adapt earlier to disabilities, but increases the probability of CP relapse. Posterior HI and HL can lead to obesity (BMI SDS >3), which reduces the functional capacity and self-evaluation on body image. Therefore, GTR should be viewed critically.

Improvement of Lung NET Management through standardized Care – a Swiss nationwide observational Study

Moira Schmidlin[1], Samira Sadowski[2], Alexander Siebenhüner[3], Damian Wild[4], Emanuel Christ[1] & Julie Refardt[1]
[1]Universitätsspital Basel, Basel, Switzerland; [2]National Cancer Institute, NIH, Bethesda, United States; [3]Hirslanden Klinik Hirslanden, Zürich, Switzerland

Introduction/ Background
Typical (TC) and atypical carcinoids (AC) are the most common neuroendocrine tumors (NETs) of the lung. Being a rare disease, the management of these tumors varies widely among Swiss centers. The impact of guidelines introduced in 2015 is unknown.
Aims
Comparison of the management of Swiss patients before and after the publication of the expert consensus of the European Neuroendocrine Tumor Society (ENETS) in 2015.
Material and Methods
Retrospective analysis of patients with TC and AC using data from the Swiss NET registry from 2009 to 2021, focusing on diagnostic evaluation and treatment before and after 2016. Survival analysis was performed using the Kaplan Meier method and log-rank test.
Results
Overall 238 patients were included, thereof 75,6% (180) with TC and 24,4% (58) with AC, with 155 patients included before and 83 patients after 2016. An increase in the use of functional imaging was observed, 10,3% (16) before and 22,8% (19) after 2016 respectively, $P<0{,}001$. In histopathological evaluation, the presence of SST2A-receptors was determined more often; 14,8% (23 times) before 2016 and 26,5% (22 times) after, $P<0{,}001$. Concerning the therapeutic approach, higher removal of lymph nodes after 2016 was observed, 53,5% (83) before compared to 78,3% (65) after, $P<0{,}001$. No difference in mortality was seen before and after 2016. Generally, median overall survival for patients with

AC was significantly shorter with 89,5 months compared to 156,9 months for patients with TC, $P<0{,}001$.
Conclusions
The ENETS guideline recommendations have ameliorated the management of TC and AC, however there is still room for further standardization and improvement.

Risk of Bilateral Testicular Germ cell Tumors: a single center long-term experience
Marta Tenuta[1], Paola Mazzotta[1], Franz Sesti[1], Francesco Angelini[1], Valentina Di Vito[1], Alain J. Gelibter[2], Donatella Paoli[1], Daniele Gianfrilli[1], Andrea M. Isidori[1] & Carlotta Pozza[1]
[1]Sapienza University, Experimental Medicine, Rome, Italy; [2]Sapienza University, Oncology, Rome, Italy

Background
Bilateral testicular germ cell tumors (B-TCGT) are reported as rare findings (incidence 1-8%) and can be distinguish in synchronous (sB-TCGT) (recurrence within 3 months) and metachronous (mB-TCGT) (recurrence after 3 months). Risk factors of relapse are still underexplored. The aim of our study was to identify clinical, biochemical and radiological risk factors for the onset of a second tumor in a wide cohort of TGCT patients.
Materials and Methods
This is a retrospective, monocentric case-control study including TGCT-patients who performed regular ultrasound (US) follow-up at the *TestisUnit* of Policlinico Umberto I, Rome, Italy, from 2006 to 2021. Testicular US, post-orchiectomy hormones and semen analysis were all performed in our institution. Data from serum tumor markers (STM), histological examination, post-orchiectomy treatments and follow-up time were recorded. Patients with mB-TGCTs were compared with unilateral TGCT patients with a follow-up greater than the median time-to-onset of the second tumor, which represented our control group (u-TGCT). The statistical analysis was carried out with non-parametric tests.
Results
The final population included 243 patients with TGCT: 158 (65%) with seminoma, 85 (35%) with non-seminoma. Among B-TGCT, 11 were sB-TGCT and 36 mB-TGCT. Among mB-TGCT, the median time-to-onset of the second tumor was 56.5 months [IQR 28;138 (range 8-211)]. u-TGCT group included 100 patients. mB-TGCT compared to u-TGCT showed a residual testicle with lower volume [10.4mL (8.9;13) vs. 16.3mL (12.0;19.1), $P<0.001$], more inhomogeneous echotexture [27/36 (75%) vs 50/100 (50%), $P=0.003$] and testicular microlithiasis (TML) [28/36 (77.7%) vs 24/100 (24%), $P<0.001$]. mB-TGCT presented higher gonadotropin values [FSH 12.1 mIU/ml (6.0;34.5) vs 5.9 mIU/ml (2.8;9.3), $P=0.003$; LH 6.5 mIU/ml (2.8;13.4) vs 3.4 mIU/ml (1.9;5.2), $P=0.014$] with similar testosterone levels ($P=0.862$) and lower sperm concentration [$6x10^6$/ml (0.1-32) vs $21x10^6$/ml (5.7-48), $P=0.045$]. No differences were found in the two groups for clinical history, histological features, STM and post-orchiectomy treatments. Kaplan-Meier curves confirmed that patients with contralateral testicular volume <12 mL ($P=0.023$), inhomogeneous echotexture ($P=0.011$) and TML ($P<0.001$) had a higher cumulative risk of development of a second tumor. Logistic regression analysis showed that the presence of TML was the best independent predictor (OR 13.992, 95%CI:1.96-99.897, $P=0.009$).
Conclusions
B-TCGT is not such a rare event. Patients with a low volume surviving testicle, with inhomogeneous echotexture or TML have a cumulative increased risk of developing a second tumor. US follow-up is mandatory and a complete morpho-functional evaluation of the contralateral testis is essential to set up a personalized program.

Thymic Neuroendocrine Tumor Presenting as Cushing's Syndrome
Adela Krausova[1], Zdenka Límanová[1], Eva Sedláčková[2], Jan Schutzner[3], David Michalský[4], Vaclav Hana[1] & Jan Jiskra[1]
[1]General University Hospital and 1st Faculty of Medicine, Charles University in Prague, 3rd Department of Internal Medicine, Prague, Czech Republic; [2]General University Hospital and 1st Faculty of Medicine, Charles University in Prague, Department of Oncology, Prague, Czech Republic; [3]Motol University Hospital and First Faculty of Medicine, Charles University in Prague, 3rd Department of Surgery, Prague, Czech Republic; [4]General University Hospital and 1st Faculty of Medicine, Charles University in Prague, 1st Department of Surgery, Prague, Czech Republic

Introduction
Cushing's syndrome (CS) is a rare disease with incidence estimated 2-4 cases per million inhabitants per year. ACTH-dependent forms comprise up to 80% of all cases, of which 80% are central and 20% are ectopic, paraneoplastic forms of ACTH-dependent CS. Thymic neuroendocrine tumors (NET) are accounting for 0,4 - 3% of all NET's with incidence of 0.02/100 000 inhabitants/year. Up to one third of them are hormonally active (secrete adrenocorticotropic hormone - ACTH, antidiuretic hormone, growth hormone releasing hormone and other hormones).
Clinical case report
A 39-year-old man presented with a rapid development of CS. CS was only partially expressed due to its relatively short history - discrete Cushingoid facies, hyperpigmentation, hypertension, sleep disorders, decreased libido, depression and also complaints of intermittent retrosternal pressure and mild cough. Examination proved highly active ACTH-dependent paraneoplastic hypercortisolism (ACTH 247 ng/l, free urinary cortisol 3220 nmol/day, unsuppressed cortisol in 1mg dexamethasone test: 1110 nmol/l) with hypokalemia and glucose intolerance. CT showed an anterior mediastinum tumor 69x47x64mm. Tumor was resected. Histopathology revealed a thymic atypical carcinoid - neuroendocrine tumor grade 2, however, a resection margin was positive for tumor cells. Postoperatively, the symptoms of hypercortisolism vanished and a central hypocortisolism was proved. As a postoperative OctreoScan examination was negative, no adjuvant therapy was started. Thirteen months after the surgery, laboratory markers suggested recurrence of hypercortisolism. Two tumor masses close to the pulmonary veins found on imaging were considered inoperable. Therefore, cyber knife irradiation was applied, and lanreotide and everolimus were initiated. The effect was insufficient and new metastases appeared in spine, lymphatic nodes, myocard and lungs. Palliative chemotherapy was started - using dacarbazine, subsequently capecitabine and oxaliplatin. What is more, hypercortisolism was not sufficiently suppressed by pharmacotherapy (ketoconazole, metyrapone), which necessitated palliative bilateral adrenalectomy. Later, due to metastatic disease, the patient suffered from malignant pericardial and pleural effusions, both of which required repetitive drainage (in spite of application of cisplatin for pericardial one), and obstructive jaundice caused by tumorous infiltration of gall bladder and pancreas. He died 42 months after the first surgery.
Conclusion
Thymic neuroendocrine tumors are very rare. One third of them manifests itself by paraneoplastic secretion of hormones. Finding the origin of hormone production in ectopic CS can be very challenging but is pivotal for the causal resection of the tumor. The other therapy options include somatostatin analogues, everolimus or chemotherapy.

Early calcitonin levels in medullary thyroid carcinoma: prognostic role in patients without distant metastases at diagnosis
Clotilde Sparano[1], Virginia Adornato[1], Matteo Puccioni[1], Elena Zago[1], Mario Maggi[1] & Luisa Petrone[2]
[1]University of Florence, Department of Experimental and Clinical Biomedical Sciences "Mario Serio', Florence, Italy; [2]Careggi Hospital, Endocrinology Unit, Florence, Italy

Introduction
Calcitonin (CT) is the most specific marker for medullary thyroid carcinoma (MTC), thus, even low detectable values can conceal persistent disease. Current guidelines suggest performing an early CT evaluation three months after surgery. However, this timing may be too premature to evaluate the CT nadir, since different isoforms or aggregates from tumour deposits may persist in the bloodstream and require additional time to be cleared. The present study aimed to explore the prognostic role of pre-operative and *early* CT levels, in MTC patients without distant metastases at diagnosis.
Methods
A retrospective cohort of patients suffering from medullary thyroid carcinoma without distant metastases at diagnosis was considered ($n=55$). The final disease status, i.e. *complete response* (undetectable CT levels and negative radiological assessments) or *persistent disease* (detectable CT levels and/or positive radiological assessments), was deduced from the last available follow-up. Pre-operative and *early* CT levels (i.e. six months after surgery) have been correlated to several clinical and histological features, according to the final disease status.
Results
Persistent disease patients ($n=27$) showed higher pre- and *early* CT values ($P=0.028$ and $P<0.001$, respectively), compared to *complete response* sub-cohort ($n=28$). After a median follow-up of 39.2 months [16.3-83.7], six patients died, while 12 patients (21%) developed distant metastases. A pre-surgical CT value of 284 pg/ml

showed a sensitivity of 69.2% and a specificity of 68.0 % in predicting the final outcome (AUC= 0.679, CI95:0.525-0.833, $P=0.028$). In a similar ROC model, the lowest detectable CT value at six months follow-up (i.e. 0.7 pg/ml) of the present cohort was able to predict the final outcome with a sensitivity and a specificity of 95.8 % and 80.0%, respectively (AUC= 0.958, CI95: 0.900-1.0, $P<0.001$). In fact, only five patients (9.1% of the population) with a final *complete response* status showed *early* detectable CT values. The cox-regression model shows that early detectable CT levels increase up to 18-fold the risk of persistent disease, independently from tumour size and pre-operative calcitonin levels (O $r=18.53$, CI95%: 2.25-152.8, $P=0.006$). Of note, when considering only patients who finally developed distant metastasis, ROC curve analysis shows that an *early* CT level ≥ 16 pg/ml predicts the final disease status with a sensitivity of 89% and a specificity of 82% (AUC=0.911, CI95%: 0.819-1000, $P<0.001$).

Conclusions

CT levels six months after surgery are an easy and effective predictor of persistent disease for medullary thyroid carcinoma without distant metastases at diagnosis.

Urea for treatment of hyponatremia in SIADH – an old treatment for a current problem

Sara Santos, Pedro Souteiro, Joana Oliveira, Isabel Inácio, Ana P Santos & Isabel Torres

Portuguese Institute of Oncology of Porto, Endocrinology, Porto, Portugal

Introduction

There are several endocrine causes of hyponatremia. SIADH is perhaps the most challenging, as patients do not always respond to initial correction measures and pharmacological treatment options are scarce. Urea is a viable option, but not commonly used.

Methods

Analysis of patients with SIADH-induced hyponatremia (<135mEq/l) treated with urea *per os* in the Portuguese Institute of Oncology of Porto between August 2021 and October 2021.

Results

Seventeen patients were included, with median age of 61 (19,5) years. In 15 patients, SIADH had a neoplastic etiology, mostly in the context of small cell lung carcinoma, and in 2, several factors, including pharmacological ones, contributed to the syndrome. Serum sodium nadir was 117 (11) mEq/l. Most patients received treatment with 0,9% saline, hypertonic saline, water restriction and/or increased protein/salt consumption before starting urea. They presented a pre-therapeutic sodium of 123 (5,5) mEq/l, plasmatic and urinary osmolality of $261\pm9,74$ and 558 (263,5) mOsm/kg, respectively, and urinary sodium of 97 (102). Urea was started orally at a dose of 10mg bid. Fourteen out of 17 patients were reevaluated 48-72h later, showing a statistically significant rise in plasma sodium [127 (4,5) ($P=0,009$)]. Patients continued treatment for a median of 96 (196) days, and plasma sodium continued to improve until their last bloodwork [sodium 134 (7) mEq/l; $P<0,001$)]. There was no clinically relevant change in renal function [(pre and post treatment creatinine $0,55\pm0,17$ vs. $0,65\pm0,2$, respectively ($P=0,007$)], and no other adverse effects were recorded.

Conclusions

Urea appears to be a safe and effective treatment for patients with SIADH-induced hyponatremia refractory to the usual initial correction measures.

Exploring the interplay of RNA methylation and alternative splicing machineries in lung carcinoids

Sergio Pedraza Arévalo[1], Alejandro Ibañez Costa[1], Víctor García Vioque[1], Ricardo Blázquez Encinas Rey[1], María Trinidad Moreno Montilla[1], Antonio Agraz-Doblas[1], Matthieu Foll[2], Lynnette Fernandez-Cuesta[2] & Justo P. Castaño[1]

[1]Maimónides Institute for Biomedical Research at Córdoba, University of Cordoba, Reina Sofia University Hospital, Department of Cell Biology, Physiology and Immunology, Cordoba, Spain; [2]International Agency for Research on Cancer, Section of Genetics, Lyon, France

Lung carcinoids are slow-proliferating neuroendocrine neoplasms commonly showing low mutational burden but a high heterogeneity and difficult clinical management. Despite valuable advances in their molecular characterization, some aspects remain still unknown. Recent studies have shown that alternative splicing is severely dysregulated in lung carcinoids, where it could promote tumoral features. In contrast, the role of some molecular systems closely related to splicing and other RNA processing mechanisms has been poorly explored in these rare tumors. An emerging example of this is the machinery that regulates the methylation of RNA (N6-methyladenosine or m6A), the most usual internal modification of RNA, which is largely understudied in this pathology. We hypothesized that m6A processing machinery may be altered in lung carcinoids and linked to splicing dysregulation, thus RNA metabolism would be severely modified in these tumors. Our main aim was to identify alterations in the m6A process coupled to RNA splicing changes that may interfere with lung carcinoid development and aggressiveness. To this end, we have carried out a pilot analysis on 16 atypical carcinoids, and, through biocomputational analyses, we have assessed the expression of 13 m6A regulators, exploring their putative associations with clinical features and splicing alterations. Remarkably, we observed a clear relationship between the expression levels of several m6A readers and patient survival, highlighting the relevance of these factors. Interestingly, we found a strong link between abnormal m6A-related gene expression and cellular functions and pathways associated with carcinoids tumorigenesis, development, and aggressiveness features. Among them, the more remarkable ones were related to key metabolic pathways, including cellular adhesion, ionic transport, and tumor-related features, such as proliferation, differentiation, and increased sensitivity to growth factors. Altogether, our preliminary results suggest that lung carcinoids also possess another level of RNA processing dysregulation involving m6A alteration, which would be linked to tumor development and aggressiveness and may be useful in the future to improve the clinical management of this disease.

Audit of Incidence and Management Practices of Endocrinopathies due to Immunotherapy and introducing a new locally adapted Guidelines for better monitoring and Management

Amrita Solanki[1,2], Simon Grumett[3] & Harit N Buch[4]

[4]Queen Elizabeth Hospital Birmingham, Internal Medicine Trainee IMT2, Birmingham, United Kingdom; [2]Former Clinical Fellow, New Cross Hospital, Royal Wolverhampton NHS Trust, Medical Oncology, Wolverhampton, United Kingdom; [3]Consultant Medical Oncology, Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; [4]Consultant Endocrinology, New Cross Hospital, Royal Wolverhampton NHS Trust, Wolverhampton, United Kingdom

Background

Immune related adverse events (iRAEs) of the endocrine system are commonly recognised in Checkpoint Inhibitor (CTLA-4 and PD-1 inhibitors) Therapy. Clinically, endocrinopathies can present with symptoms of hormone deficiency, hormone excess or both (in the same or different glands).

Aim

Audit of Incidence and Management (detection, investigation, referral and management) practices of Endocrinopathies due to Immunotherapy in Oncology department for the duration of six months January-June 2019. We aimed to improve management of endocrinopathies through peer led education and new locally adapted guidelines.

Methods

A retrospective anonymised audit of all patients receiving immunotherapy was done. Data sources included outpatient clinic letters, electronic prescriptions, biochemistry results and multidisciplinary team meeting summaries. Analysis of quantitative data was in percentages and proportions. The detection, investigation, referral and management was assessed on a two point criteria stating adequate or inadequate /appropriate or inappropriate taking UK Oncology Nursing Society (UKONS) Endocrinopathies with Immune Check Point Inhibitors (ICPi) Guidelines as standard. Thereafter with multidisciplinary input from Endocrinology team, a locally adapted new guidelines were written and implemented. The process was re-audited and using the two point assessment and the results will be available for presentation at the conference. The knowledge attitude and practice of doctors in oncology was also assessed with a 10 question questionnaire.

Results

Total number of patients receiving immunotherapy, ipilumab, nivolumab, atezolizumab and pembrolizumab alone or in combination were 101. Total number of patients with endocrinopathies either single or multiple were 37. Total number of endocrinopathies detected(symptomatic/asymptomatic) were 50. Total Incidence of endocrinopathies was found to be 36.6%. Thyroid disorders detected were 16/50(32%), hypoglycemia-2/50(4%), diabetes mellitus(DKA)-1/50(2%).) Hypocortisolism(Biochemical asymptomatic + symptomatic) was 6/50(12%).

Symptomatic hypocortisolism was 5/50(10%) and low testosterone was found in 2/50(4%). Endocrinopathies were detected in first line therapy in 17/37(45%) and in second line therapy in 20/37(54%). The endocrinopathies were distributed amongst cancer sites as lung -29, melanoma-2, colon-2, renal-2, hypopharynx-1, Transitional cell carcinoma-1. The maximum number of endocrine aberrations were found between 3weeks-3months-29/37(78%). The process was re-audited after educational sessions and measurable improvement was achieved in clinical practise.

Conclusions

Total Incidence of endocrinopathies was found to be 36.6%. Most of the management was by individual teams and there was knowledge gap and co ordination identified amongst doctors managing these patients since immunotherapy a new and developing area of practice. KAP questionnaire was used to assess the knowledge gap amongst staff members. Shared learning and multidisciplinary approach can go a long way in management of endocrine side-effects of these novel therapies.

Carcinoembryonic antigen role in the assessment of neuroendocrine tumors

Ramona Dobre, Iulia Florentina Burcea, Cristina Capatana & Catalina Poiana
Carol Davila University of Medicine and Pharmacy, Endocrinology, Bucharest, Romania

Background

The importance of carcinoembryonic antigen (CEA) assessment in the evaluation of medullary thyroid carcinoma is well known. The role of CEA in the assessment of other neuroendocrine tumors (NET) is not clear. We aimed to evaluate a possible correlation between CEA measurements and the aggressivity of NETs.

Methods

We evaluated 56 (36 women) NETs followed in a tertiary center (23 gastrointestinal, 12 pancreatic, 10 pulmonary, 7 without primary tumor localization, 1 urinary bladder and 3 neuroendocrine carcinomas (NEC)). We evaluated a possible correlation with the CEA measurements (absolute values and dichotomic values, larger than the upper normal cutoff value, UNV) and ki67% values, type of NET, the presence of metastases, hepatic or all other types and newly imagistic evaluation suggestive of progressive metastatic disease. All CEA measurements were done using the same technique. Patients with medullary thyroid carcinoma were excluded.

Results

Three patients (5.35%) had values 10 times higher than the UNV, 23 patients (41%) had levels above UNV. Ki67% values were available only for 45 patients, no correlation was found between ki67% and CEA values, correlation coefficient -0.03, $P=0.07$. Also, we didn't find a correlation between abnormal CEA values and the presence of metastatic disease other than hepatic (23 patients), hepatic metastasis (18 patients), gastrointestinal type of NET and newly diagnosed progressive disease (13 patients), with correlation coefficients between 0.13-0.2, p>0.05. The newly diagnosed progressive disease was mainly observed on hepatic metastases. Thirty-eight patients were currently on somatostatin analog (SSA) treatment, no correlation being found between CEA values and the presence SSA treatment (0.12, $P=0.36$).

Conclusion

Data presented does not support a role of CEA in the algorithm assessment of NETs. In the same time, a large number of patients had abnormal values, raising the question of a possible importance of CEA evaluations in this patients, further studies with higher number of patients and correlation with other neuroendocrine markers are warranted.

Severe ectopic Cushing syndrome in a transgender male with metastatic gastrinoma and adrenal tumor - a case report

Karolina Cylke-Falkowska[1], Arnika Wydra[2], Maria Stelmachowska-Banaś[2], Izabella Czajka-Oraniec[3], Agnieszka Kolasińska-Ćwikła[4], Jarosław Ćwikła[5,6] & Wojciech Zgliczyński[2]
[1]Bielański Hospital, I Department of Internal Medicine, Warsaw, Poland; [2]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [3]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland; [4]Curie National Research Institute of Oncology, Department of Oncology and Radiotherapy - The Maria Skłodowska-Curie, Warsaw, Poland; [5]Medical School University of Warmia and Mazury, Department of Cardiology and Internal Medicine; [6]Diagnostic and Therapy Center – Gammed, Warsaw, Poland

Background

Gastrinoma is a functional neuroendocrine neoplasm (NEN) most commonly located in the duodenum (70%) and the pancreas (25%). The initial confirmation of NEN's secretion profile does not exclude the possibility of a new hormonal activity of the tumor occurring in the course of the disease. Ectopic Cushing syndrome has been described in up to 5% of gastrinoma cases and hypercortisolemia may worsen the patient's prognosis.

Case presentation

A 38-year-old transgender male with advanced metastatic functional PanNEN - gastrinoma was admitted to the Department of Endocrinology due to new symptoms and signs of severe ACTH-dependent hypercortisolemia. The patient's medical history included non-functional adrenal adenoma and chronic gender-affirming hormone treatment with testosterone after the female-to-male surgical intervention at the age of 28 years. Two years before the admission an advanced pancreatic gastrinoma with liver metastases (NET G2, with Ki-67 4-5%) was diagnosed. The patient was disqualified from surgical intervention and the disease was initially managed with somatostatin receptor ligand. Later he was shortly treated with everolimus but it was ceased due to drug-induced interstitial pneumonia. After the diagnosis of ACTH-dependent ectopic hypercortisolemia the patient was qualified for bilateral adrenalectomy after preoperative treatment with metyrapone. Finally, the patient underwent a resection of the left adrenal gland with the tumor, as the right adrenal was surgically inaccessible. Surprisingly, that resulted in a significant decrease in ACTH and cortisol levels leading to clinical remission of Cushing syndrome. Pathology report revealed an adenoma of the adrenal cortex with positive ACTH staining. The result of the simultaneous liver lesion biopsy confirmed a metastatic NEN G2 with positive ACTH immunostaining as well. Subsequently, due to progression of liver metastases in CT and somatostatin receptor scintigraphy, and further increase in gastrin and chromogranin A levels, the patient was qualified for a temozolomide and capecitabine chemotherapy. Although the therapy was discontinued after 4 courses, due to life-threatening anaemia, the patient's NEN is stable and normalisation of ACTH and cortisol levels persists after a one year follow-up.

Conclusion

We present a rare case of the ectopic Cushing's syndrome complicating metastatic gastrinoma. Hypercortisolemia significantly worsens the prognosis of patients with NEN, thus a multimodal approach might be needed, as in presented case. We found it very unusual that the remission of ACTH-dependent hypercortisolemia was noted after removal of one adrenal gland with previously non-functioning adenoma. Furthermore, it is interesting if the gender-affirming hormone treatment influence the neuroendocrine tumor development and progression.

Association between diabetes mellitus and reduced efficacy of pembrolizumab in non-small cell lung cancer

Yasmin Leshem[1], Yardena Dolev[1], Nava Siegelmann-Danieli[2], Sarah Sharman Moser[2], Lior Apter[2], Gabriel Chodick[2], Alla Nikolaevski-Berlin[1], Sivan Shamai[1], Ofer Merimsky[1] & Ido Wolf[1]
[1]Tel Aviv Medical Center, Oncology, Tel Aviv, Israel; [2]Maccabi Healthcare Services, Maccabitech, Tel Aviv, Israel

Introduction

Type 2 diabetes mellitus (T2DM) and cancer commonly occur together, either because of direct association or merely as both diseases are common among the elderly. The presence of either T2DM itself, or its treatment may affect cancer progression outcomes and response to cancer therapy. Immune-checkpoint inhibitors (ICIs) have become the cornerstone of treatment of several malignancies, including non-small cell lung cancer (NSCLC). As T2DM has been shown to suppress activity of the immune system, we hypothesized that it will impair the activity of ICIs.

Methods

Medical records of all consecutive patients with advanced NSCLC, treated with first-line pembrolizumab either alone or in combination with chemotherapy at Tel Aviv Medical Center (TLVMC) were reviewed. Data on a similar group of patients was extracted from the computerized data of a large Israeli HMO, from Maccabi Healthcare Services (MHS), with over 2.5- million-member.

Results

Two hundred and three eligible NSCLC patients were identified, 51 of them (25%) had T2DM. Compared to patients without DM, patients with DM had a significantly shorter median progression-free survival (PFS; 5.9 vs. 7.1 months,

$P=0.004$) and overall survival (OS; 12 vs. 21 months, $P=0.006$). The differences in OS were significantly more pronounced for patients being treated with pembrolizumab as single agent (12 vs. 27 months, for DM vs. Non-DM, $P=0.03$) but was of borderline significance for those receiving immunotherapy and chemotherapy (14.3 vs. 19.4 months, for DM vs. Non-DM, $P=0.06$). Multivariate analysis indicated DM as an independent risk factor for lower PFS (HR 1.67, 95% CI 1.11−2.50, $P=0.01$) and lower OS (HR 1.73, 95% CI 1.09−2.76, $P=0.02$). A cohort of 452 metastatic NSCLC patients was identified at MHS database. Similarly to the TLVMC cohort, shorter time on treatment was noted for DM compared to non-DM patients, with only 19.6% of patients remaining on treatment at 12 months compared to 31.7% of the non-diabetic patients ($P=0.025$).

Conclusions

These data indicate an adverse effect of T2DM on the efficacy of pembrolizumab in patients with advanced NSCLC. While additional studies are required to better define this association, it is possible that our observation is relevant to other malignancies, as well as other types of ICIs.

Treatment of childhood-onset craniopharyngioma patients using proton beam therapy vs photon-based radiation therapy in the prospective Kraniopharyngeom 2007 trial

Carsten Friedrich[1], Svenja Boekhoff[1], Panjarat Sowithayasakul[1,2], Maria Eveslage[3], Julia Beckhaus[1], Brigitte Bison[4], Beate Timmermann[5] & Hermann Müller[1]

[1]Klinikum Oldenburg AöR, Oldenburg, Germany; [2]Srinakharinwirot University, Thailand; [3]University of Münster, Münster, Germany; [4]University Hospital Augsburg, Augsburg, Germany; [5]Essen University Hospital, Essen, Germany

Background

Proton beam therapy (PBT) compared to photon-based radiotherapy (XRT) offers the benefit to administer lower radiation doses to critical organs thereby possibly minimizing the risk of sequelae in patients with residual craniopharyngiomas (CP) after hypothalamus-sparing surgery. The validation in large CP patient cohorts is still pending.

Methods

Of 290 childhood-onset CP patients included 2007-2019 in the prospective multicenter trial Kraniopharyngeom 2007, 99 (34%) received external RT (65% PBT, 35% XRT). Outcome was compared between the different groups in terms of overall (OS) and event-free survival (EFS), quality of life (QoL using PEDQOL), functional capacity (FMH), and auxological data (BMI and height SDS) one, three and five years after irradiation/CP diagnosis.

Results

PBT became the predominant irradiation technique during the study period (used in 23% and 77% of all irradiated patients registered within the first and second half of the enrollment period, respectively). PBT as well as XRT were associated with high ($P<0.001$) EFS (PBT: 0.917 ± 0.040; XRT: 0.940 ± 0.041) compared to non-RT (EFS: 0.669 ± 0.044). OS was similar in all groups. No differences between PBT, XRT and non-RT CP patients concerning functional capacity and anthropometric parameters (height SDS, BMI SDS) have been obtained. Only in the PEDQOL domain "physical function", proxy-assessed QoL was lower one year after PBT when compared to XRT treated and non-irradiated CP patients. PBT is similar efficient in preventing relapses in childhood-onset CP patients. During follow-up, clinically relevant differences between PBT and XRT in terms of QoL, functional capacity and degree of obesity as a marker of hypothalamic syndrome were not detectable.

Conclusions

While PBT is increasingly applied, studies on larger CP cohorts with longer follow-up after RT are warranted to analyze, whether it can prevent sequelae such as hypothalamic syndrome and severe obesity compared to XRT.

The incidence of Neuroendocrine Neoplasm (NEN) and related carcinoid syndrome (CS) increased markedly in recent decades, and women appear to be more at risk than men. As per other tumors, gender may be relevant in influencing the clinical and prognostic characteristics. Unfortunately, there are no studies designed to answer this question in the literature. The present multicentric study was designed to evaluated gender differences, if any, in clinical presentation and outcomes of CS. For this purpose, 144 patients affected by CS were enrolled from 18 Italian high-volume centers following the Neuroendocrine Tumors, Innovation in Knowledge and Education (NIKE) project. Clinical characteristics and treatment were collected. Outcomes were evaluated by progression free survival (PFS) and disease specific survival (DSS). The 144 patients diagnosed were 90 (62.5%) men and 54 (37.5%) women. Age at CS diagnosis was no different between the two sexes (median age 61 years, range 26-83, in men and 60 years, range 23-84, in women, $P=0.28$). No differences were observed in the site of the primary NEN, with NEN of the intestinal tract being more prevalent in both sexes (80% and 77.8% in men and women, respectively; $P=0.74$). Patients of both genders differed in clinical manifestations for the occurrence of abdominal pain (53.3% vs 70.4%, $P=0.044$) and tachycardia (6.7% vs 31.5%, $P=0.001$), that were significantly more often found in women, and for the presence of lymph node metastases at CS diagnosis, that was higher in men than in women (80% vs 64.8%; $P=0.04$). Moreover, considering comorbidities and risk factors according to gender, men were more frequently smokers (37.2%) and alcohol drinkers (17.8%) than women (9.5%, $P=0.002$, and 3.7%, $P=0.004$, respectively). Women did not suffer from cardiovascular disease compared to men (0 vs 12.2%, $P=0.0008$). No significant differences emerged in treatment response, prognosis, and overall survival. However, men presented a slightly trend to a shorter PFS (median PFS of 24 months, range 17.1-30.9) than women (PFS 32 months, range 16.7-47.3; $P=0.34$). This study is the first designed to analyze the impact of the gender on CS. The preliminary analysis showed that, in Italy, the prevalence of CS is higher among men (62.5%), unlike the literature. We found that the clinical presentation of CS was different between the two genders, but no clear differences emerged in outcomes of treatment and survival. The characterization and evaluation of the clinical impact of gender-related differences in CS could improve the treatment and the prognosis.

Decision making, patient involvement and a rare form of thyroid cancer

Aaisha Saqib[1], Ricard Simo[2] & Carroll Paul[1]

[1]Guy's and St Thomas' NHS Foundation Trust, Diabetes and Endocrinology, London, United Kingdom; [2]Guy's and St Thomas' NHS Foundation Trust, Head and Neck Surgery, United Kingdom

In 2022, a 63 year old woman was referred for assessment of a six month history of gastro-oesophageal reflux symptoms and dysphagia. Upper gastrointestinal (GI) endoscopy was normal apart from mild reflux oesophagitis. A computerized tomography (CT) scan demonstrated a 2 cm nodule medial to the caudate lobe of the liver, a 1.5 cm nodule in the right lung base and two further sub cm nodules in the right lung lobe. In terms of background, the patient had a benign breast lump under surveillance and she had undergone a right sided salpingo-oophorectomy in 2008. Following discussion in the upper GI multi-disciplinary team (MDT) meeting she was referred for biopsies of lung nodule and caudate lobe lesion. The paravertebral biopsy of lung nodule was non-diagnostic and an endoscopic biopsy of caudate lobe lesion was suggestive of metastatic thyroid carcinoma (TTF-1 and

thyroglobulin immunostain positive). FDG and DOTATATE positron emission tomography (PET) scans showed no evidence of uptake in thyroid gland but there was uptake in the lung node and in the nodule medial to the caudate lobe. Serum thyroglobulin was 43.1 ug/l with negative anti-thyroglobulin antibody. Thyroid ultrasound showed a 6 x 8 mm exophytic (BTA class U2 i.e. benign) nodule, FNAC confirmed benign cytology (Thy2). Her case was discussed in our central thyroid cancer MDT meeting where it was suggested to review histopathology of the right sided ovary and tube from 2008. This confirmed a large cystic teratoma (weighing 1368 gm) with well-formed thyroid tissue of fetal origin which showed thyroglobulin and TTF1 marker positivity on immunohistochemistry. The patient has undergone total macroscopic removal of the thoracic metastasis and laparoscopic excision of the nodule medial to the caudate lobe of the liver. Histopathology of these samples was similar to the previous atypical thyroid lesion within the mature teratoma of the right ovary, consistent with a diagnosis of metastatic struma ovarii. Although the metastatic disease has progressed slowly, after careful consideration the patient will have thyroidectomy to facilitate radioiodine treatment with a proposed dose of 3.7 GBq. Struma ovarii is a rare ovarian germ cell tumour and comprises only 1.4-2.7% of ovarian tumours. 5-15% of teratomas contain thyroid tissue. The vast majority of struma ovarii are benign, with malignant disease found in less than 5-6% of cases. As struma ovarii is a rare tumour, there is an absence of consensus and guidelines on the management of metastatic disease.

Prostate cancer (PCa) is one of the most common causes of cancer-related deaths in men worldwide. Therefore, more specific non-invasive diagnostic biomarkers with potential therapeutic use are urgently needed. As miRNAs have been proposed as promising elements for the identification of novel diagnostic and therapeutic tools for different pathologies, including different cancer types, we investigated herein the miRNA landscape in PCa patients and explored their putative diagnostic/therapeutic utility. Specifically, the miRNome of plasma samples from healthy ($n=18$) and PCa patients ($n=19$) was initially determined using an Affymetrix-miRNA array (discovery-cohort). The main changes were validated in an independent and ample validation-cohort [$n=202$: healthy ($n=91$) and PCa patients ($n=111$] by quantitative real-time PCR. Additionally, *in silico* and *in vitro* assays in normal (RWPE-1 and PNT-2) and tumor (LNCaP, DU145, and PC-3) prostate cell lines were performed. Results from the discovery-cohort revealed that the expression of 104 miRNAs was significantly altered ($P<0.01$) in plasma samples from PCa patients vs. healthy controls. Of note, 6 of these miRNAs also exhibited a significant ROC curve to distinguish between healthy and PCa patients with an AUC=1. The analyses in the validation-cohort demonstrated that miR-191-5p was one of the most profoundly altered miRNAs in PCa ($P<0.0001$) exhibiting an AUC=0.67. Remarkably, miR-191-5p significantly outperformed the ability of prostate-specific antigen (PSA) to distinguish between control and PCa patients, especially in the "grey zone", which represents the range where PSA levels are less accurate to diagnose PCa. Interestingly, the diagnostic capacity of miR-191-5p was even higher in obese patients (BMI>30). Furthermore, we found that miR-191-5p levels were also dysregulated in PCa cells (vs. non-tumor cells). Moreover, *in vitro* overexpression of miR-191-5p significantly decreased cell proliferation and migration in LNCaP, DU145, and PC-3 PCa cells line. An *in silico* approach using diverse bioinformatics tools was performed to discriminate possible targets that may be regulated by miR-191-5p, finding 13 oncogenic targets, which were further explored in response to mimic overexpression. Of all the targets evaluated, *TMOD2*,a migration-related gene in PCa, was the most consistently decreased, whose levels were also confirmed to be modulated by miR-191-5p. Altogether, our data demonstrate that miR-191-5p might represent a novel and useful personalized diagnostic biomarker in PCa, especially in patients with obesity, as well as a potential therapeutic tool in PCa.

Introduction

In multiple endocrine neoplasia 1 (MEN1), the decreased life expectancy is related especially to pancreatic neuroendocrine tumors (panNETs). Timely diagnosis of potentially aggressive panNETs is the cornerstone of the follow-up in MEN1. Somatostatin receptor positron emission tomography (SSTR PET/CT) has a high accuracy in the detection of neuroendocrine tumors. The role of this imaging modality in early diagnosis and follow-up of MEN1-related panNETs is unclear.

Patients and methods

We compared SSTR PET/CT and conventional imaging in 58 patients with MEN1 (median age 40 (range 16–72) years) in Helsinki University Hospital, Helsinki, Finland and in Turku University Hospital, Turku, Finland. SSTR PET/CT was used either as a screening tool in patients without pancreatic NET or in the follow-up of known panNETs. SSTR PET/CT and matched magnetic resonance imaging (88%) or computed tomography (12%) images (median difference between images 3.0 months, IQR 1.2-7.8) were blindly analyzed by two experts. We also assessed the impact of SSTR PET/CT on the management of MEN1 patients during a median follow-up of 46 months.

Results

SSTR PET/CT detected 1.57 ($\pm$2.19) more panNETs per patients than conventional imaging. Significantly more lesions were found in the entire pancreas ($P<0.001$), locating particularly in the head ($P<0.001$) and in the body-tail ($P=0.001$) regions. SSTR PET/CT detected lymph node metastases not identified on conventional imaging in four patients (three abdominal and one mediastinal metastases). There was no statistically significant difference in the amount of suspected hepatic lesions (13 vs 23, $P=0.54$). The SSTR PET/CT changed the management of 27/58 (47%) patients: 7/58 (12%) were referred for surgery, 5/58 (9%) received systemic treatment, and in others the follow-up was intensified. In 15/25 (60%) patients with either no previous panNET ($n=22$) or in remission after surgery ($n=3$), SSTR PET/CT identified a panNET ($n=14$) or recurrence ($n=1$). In eight patients, SSTR PET/CT revealed a panNET not immediately visible on conventional imaging. During a median follow-up of 47 months, three became visible on conventional imaging, but none required intervention. When SSTR PET/CT was negative, no panNETs were identified on conventional imaging during the 38 months of follow-up.

Conclusions

SSTR PET/CT has high accuracy in the detection of MEN1-related panNETs and changes the disease management in nearly half of the MEN1 patients.

Characterization of telomerase/shelterin system in endocrine intracranial tumors at clinical, transcriptomic, and functional levels

Miguel E. G-Garcia[1,2,3,4], Álvaro Flores-Martínez[1,2,3], Ana S. De la Rosa-Herencia[1,2,3,4], David Cano Gonzales[5], Eugenio Cardenas[5],

Juan Solivera[1,3,6], Manuel D. Gahete[1,2,3,4], Alfonso Soto-Moreno[7], María Ángeles Gálvez-Moreno[1,6,8], Antonio C. Fuentes-Fayos[1,2,3,4] & Raul M Luque[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), 14004 Cordoba, Spain; [2]Department of Cell Biology, Physiology and Immunology, University of Cordoba, 14004 Cordoba, Spain; [3]Reina Sofia University Hospital (HURS), 14004 Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), 14004 Cordoba, Spain; [5]Department of Neurosurgery, Hospital Universitario Virgen del Rocío (HUVR), 41013 Seville, Spain; [6]Service of Neurosurgery, HURS, 14004 Cordoba, Spain; [7]Metabolism and Nutrition Unit, HUVR, Instituto de Biomedicina de Sevilla (IBIS), 41013 Seville, Spain; [8]Service of Endocrinology and Nutrition, HURS, 14004 Cordoba, Spain

Intracranial tumors (IT) comprise a heterogenous group of neoplasias (e.g., pituitary/brain tumors and craniopharyngiomas), characterized by difficult diagnosis based on MRI, challenging prognostic predictors and lack of effective therapeutic strategies. In addition, these tumors are usually associated with neurological disorders and severe comorbidities (e.g., those associated with Cushing syndrome, Acromegaly, etc.), worsening the quality life of patients. In this context, several elements of the telomerase/shelterin system, a macromolecular machinery responsible for maintenance of telomers and genomic stability, have been suggested to exert an important role in different endocrine IT (i.e., *TERC* in pituitary tumors, *TERT* promoter in craniopharyngiomas, and *TRF1* in glioblastomas). However, the information about the presence, clinical relevance and potential functional role of the telomerase/shelterin system is still quite limited, fragmentary, and unclear in IT. Therefore, our aim was to extensively characterize the expression levels and clinical/functional relevance of the components of this system in endocrine IT. To that end, expression levels of 17 telomerase/shelterin components were analysed by microarray technology based on qPCR-methodology in different cohorts of IT *vs*. control samples: 1) Pituitary [10 Normal Pituitary (NPs) *vs*. 83 Non-Functioning Pituitary Tumors (NFPTs), 50 GHomas, 19 ACTHomas and 6 PRLomas samples], 2) Brain [7 Normal Brain (NBs) *vs*. 69 brain tumor samples], and 3) 60 Craniopharyngioma *vs*. NP/NB samples. Moreover, several bioinformatic analyses (PLSDA/heatmap/k-means clusterization) with molecular/clinical features, and different functional approaches [e.g., treatment with etoposide (telomerase inhibitor) in selected primary derived cell-cultures and cell line models] were performed. Results revealed an alteration of telomerase expression levels in brain-tumor *vs*. NB samples (e.g., TREF2IP and 4 splicing-variants of *TERT* gene were found to be downregulated in tumor samples, having a diagnostic/prognostic potential). Dysregulation of the telomerase/shelterin system was also observed in different pituitary-tumors *vs*. NPs, being some of these changes common across pathologies (i.e., TERF2, TREF2IP, and TINF2). Interestingly, two different subtypes in NFPTs and GHomas could be identified based on their telomerase/shelterin component profile reinforcing the heterogeneity of pituitary-tumors. A clear dysregulation of the telomerase/shelterin system was also observed in craniopharyngiomas, highlighting again the TERF2IP as a potential biomarker in this pathology. Finally, the antiproliferative effect of etoposide was dependent on the tumor type analysed. Altogether, our study revealed a profound dysregulation in the shelterin/telomerase complex in IT wherein some of the components might be clinically and functionally relevant, opening new avenues to improve the management of these pathologies.

Elderly Male with Multiple Endocrine Neoplasia Type 2A: A Diagnostic Journey

Rok Vrckovnik[1] & Tomaž Kocjan[1,2]
[1]UMC Ljubljana, Department of Endocrinology, Diabetes and Metabolic Diseases, Ljubljana, Slovenia; [2]Faculty of medicine University of Ljubljana, Department of internal medicine, Ljubljana, Slovenia

Background
Multiple endocrine neoplasia type 2A (MEN2A) is a rare genetic tumor syndrome due to germline mutations of the RET proto-oncogene, which is characterized by medullary thyroid cancer (MTC), pheochromocytoma (PHEO), and primary hyperparathyroidism (PHPT). The age at onset, aggressiveness of MTC, and the penetrance of other components depend on the genotype. Early prophylactic thyroidectomy and life-long screening for PHEO from childhood are recommended in most cases.
Clinical case
A 73-year-old male was found to have progressively increasing PSA levels during routine check-ups. Prostate biopsy confirmed a prostatic adenocarcinoma (Gleason 3+4 and 4+4). 18F-Choline PET/CT was done next; however, this imaging did not only exclude metastatic disease, but also showed a highly metabolically active thyroid nodule. An ultrasound-guided fine needle biopsy of the nodule confirmed MTC (Bethesda 6). Calcitonin level was high at 1290 ng/l (ref. 8.3 – 14.3 ng/l). Catecholamines and nor/metanephrines were routinely measured in a 24h urine sample before thyroidectomy and were positive. Abdominal CT scan showed a 44 mm partially cystic formation of the left and an 11 mm nodule of the right adrenal gland, both with CT characteristics of PHEO. Laboratory testing for PHPT was negative. After a course of phenoxybenzamine, the patient was planned for laparoscopic total left and partial right adrenalectomy, however, bilateral total operation was finally done due to technical issues. Histopathological report confirmed bilateral PHEO with a PASS score of 8/20 on the left, and 3/20 on the right side. Total thyroidectomy and laparoscopic radical prostatectomy followed in the next weeks. Genetic testing was consistent with MEN 2A (NM_020975.6(RET):c.1900T>G (p.Cys634Gly)). Currently, the patient is doing well on hydrocortisone, fludrocortisone, and levothyroxine supplementation. The family history for MEN2A-related manifestations was negative. Genetic testing results of patient's close relatives are pending.
Discussion
Genetic testing classified our patient as high risk MEN2A-MTC (Level C American Thyroid Association Risk Level) where prophylactic thyroidectomy should be performed before age of 5 and yearly screening for PHEO commenced at eight. The presented patient experienced an indolent, incidentally diagnosed disease, which might be in line with a recent finding that considered age at diagnosis as the most important marker of MTC outcome in MEN2A. Additional yet to be determined factors may enable better understanding of such phenotypic variability.

Don't let your guard down – aggressive, hereditary paraganglioma associated with SDHD gene nonsense variant: c.33C>A (p.(Cys11Ter))

Alicja Szatko, Dorota Leszczynska, Beata Woźniak, Lucyna Papierska, Wojciech Zgliczyński & Piotr Glinicki
Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland

Introduction
Paragangliomas belong to the neuroendocrine tumours arising from autonomic nervous system. Various localizations, symptoms that can mimic a wide range of diseases and often unpredictable ability to metastasize are the reasons why paragangliomas pose a significant diagnostic challenge. More than one third of paragangliomas is associated with germline mutations –succinate dehydrogenase (SDH) subunit genes are among the most common susceptibility genes. SDHD was the first among SDH genes identified as being involved in pheochromocytoma/paraganglioma pathogenesis. SDHD mutations are inherited as autosomal dominant trait with a paternal transmission, affected patients usually develop multiple cervical paragangliomas. However, mutations in the SDHD gene do not often predispose to a metastatic evolution.
Case Presentation
We report a case of a 48-year-old woman admitted to the Department of Endocrinology due to suspicion of bilateral cervical paraganglioma – two lesions were visualised on ultrasonography, performed because of concomitant Graves disease. Remarkably, the only sister of the patient died at the age of 47 due to metastatic paraganglioma, 14 years after the diagnosis (SDHD gene mutation was identified), patients' father was diagnosed with bilateral cervical lesions, died suddenly at the age of 39. Laboratory tests revealed slightly elevated free plasma metanephrine concentration 72,1 pg/ml (reference range $<$62 pg/ml), free plasma normetanephrine, plasma 3-metoxytyramine and serum chromogranin A concentrations were within reference range. The result of head and neck CT scan confirmed the presence of two carotid lesions: on the right side measuring 21 x 20 x 32 mm, on the left side measuring 13 x 16 x 18 mm (grade I according to the Shamblin classification). Furthermore, the result of thorax CT scan revealed the suspected lesion below the aortic arch, adjoining the aorta, measuring 10 x 15 mm. All three described lesions showed the pathological tracer uptake in somatostatin receptor scintigraphy (99mTc HYNICTOC 720MBq). The molecular analysis revealed pathogenic SDHD gene nonsense variant: c.33C>A (p.(Cys11Ter)). The patient was referred to the Vascular Surgery Department, where two-stages cervical paraganglioma removal was performed. Other family members also underwent the screening for pheochromocytoma/paraganglioma.
Conclusions
Presented case highlights the importance of molecular testing of patients with pheochromocytoma/paraganglioma and the necessity for long-term follow-up. Furthermore, reported case may hint that the clinical course and risk of

malignancy is not universal for all SDHD pathogenic mutation carriers, and should be stratified in relation to the carried variant, which may improve the accuracy of genetic counselling, clinical screening, and follow-up strategies.

PRRT 177Lu-DOTA-TATE in pancreatic neuroendocrine tumors – When to initiate?

Sara Franco[1], Inês Lucena Sampaio[2], Gonçalo Ferreira[2], Daniel Barbosa[2], Sara Gil-Santos[3], Henrique Vara Luiz[1], Ana Paula Santos[3], Isabel Torres[3] & Hugo Duarte[2]
[1]Hospital Garcia de Orta, Endocrinology, Almada, Portugal; [2]IPOFG Porto, Nuclear Medicine, Porto, Portugal; [3]IPOFG Porto, Endocrinology, Porto, Portugal

Introduction
The best timing for PRRT (*peptide receptor radionuclide therapy*) in the case of pancreatic neuroendocrine tumors (panNETs) is still to define, as randomized prospective trials are lacking. Recent studies suggest that some systemic therapies can affect response to PRRT, favoring an earlier use of the latter.
Objective
To determine the efficacy and toxicity of PRRT, comparing its results when used as a second line systemic therapy (after somatostatin analogs) (Group 1) and as a third or fourth line (after chemotherapy, sunitinib or everolimus) (Group 2).
Methods
A real-world, retrospective study of well-differentiated nonfunctioning panNETS, metastatic and/or unresectable, that completed 3 cycles of PRRT with 177Lu-DOTA-TATE at a tertiary center between 2011 - 2018. The data was collected from clinical records. The statistical analysis was performed in SPSS.
Results
We reviewed a population of 29 patients with a mean age of 55 ± 11 years (52% males). Median time since diagnosis until PRRT was 38 (range: 14-95) months. The majority had grade 2 tumors (64%). Around 89% of patients had hepatic metastasis, 61% lymph node metastasis and 29% other metastases. Median cumulative activity of 19,61 (range: 17-22,2) GBq. A total of 16 patients received PRRT as a 2nd line systemic therapy (Group 1), while 13 patients previously received other systemic therapies (Group 2). Median follow-up time after the first cycle was 31,3 (range: 22-55) months. Median progression-free survival (PFS) was 24,5 (CI 95%: 17 – 32) months and median overall survival (OS) was 46,6 (CI 95%: 20 - 73) months. There was no statistically significant difference of PFS (Group 1: 22,3 (CI 95%: 11-34) Group 2: 24,5 (CI 95%: 15-34); $P = 0{,}95$) and OS (Group 1: 54,8 (CI 95%: 29 - 81); Group 2: 43,3 (CI 95%: 15-72); $P = 0{,}39$) between the 2 groups. Around 90% of patients that reported symptoms before treatment, had symptomatic improvement. One patient had clinically significant hepatic toxicity (G3) after the 1st cycle, partially reversible before the 3rd cycle. There were no cases of clinically significant (grade 3/4) hematological or renal toxicity.
Conclusion
PRRT is a safe treatment, associated with symptomatic improvement. PFS was similar between groups, suggesting that PRRT efficacy is not influenced by previous systemic therapies. However, patients receiving PRRT earlier had the longest OS, although not statistically significant. These data can indicate a potential benefit of using PRRT earlier in the treatment sequence. Randomized prospective studies with larger samples are needed to confirm these results.

Therapeutic potential of the splicing factor SRSF6 as a novel regulator of the Androgen Receptor in prostate cancer

Antonio J. Montero-Hidalgo[1,2,3,4], Enrique Gómez-Gómez[1,3,4,5], Prudencio Sáez-Martínez[1,2,3,4], Antonio C. Fuentes-Fayos[1,2,3,4], Rafael Sánchez-Sánchez[1,3,4,6], David Olmos[7], Antonio Jesús Martínez-Fuentes[1,2,3,4], André Sarmento-Cabral[1,2,3,4], Manuel D. Gahete[1,2,3,4], Juan Manuel Jiménez Vacas[1,2,3,4] & Raul M Luque[1,2,3,4]
[1]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; [2]University of Cordoba, Department of Cell Biology, Physiology and Immunology, Cordoba, Spain; [3]Reina Sofia University Hospital (HURS), Cordoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Cordoba, Spain; [5]Reina Sofia University Hospital (HURS), Urology service, Cordoba, Spain; [6]Reina Sofia University Hospital (HURS), Anatomical Pathology service, Cordoba, Spain; [7]Hospital Universitario 12 de Octubre, Madrid, Spain

Background
Prostate cancer (PCa) is the fifth leading cause of cancer-related death worldwide. The main pharmacological strategy for this pathology is the blockade of the androgen receptor signalling pathway, commonly known as androgen-deprivation therapy. However, some of the patients does no longer respond to this hormonal therapy. Therefore, finding novel therapeutic strategies to tackle PCa, especially its most advanced phenotype [i.e., castration-resistant prostate cancer (CRPC)], is urgently needed. In this sense, although the dysregulation of the splicing process has emerged as a distinctive feature of advanced PCa, the potential role that splicing regulators may play in this disease remain poorly explored. In this study, we aimed to analyse the levels, pathophysiological role, and associated molecular features of the splicing factor SRSF6 in PCa.
Methods
SRSF6 levels (copy-number, mRNA, and protein) were interrogated in seven well-characterized cohorts of PCa patients and in the Hi-MYC transgenic model. The functional/molecular effects of SRSF6 overexpression and silencing were evaluated *in vitro* [using different PCa-derived (LNCaP, 22Rv1, DU145, and PC-3) and non-tumour prostate (RWPE-1) cells] and *in vivo* (tumour growth in xenograft models). RNAseq was performed in 22Rv1 cells to analyse splicing and gene expression alterations in response to SRSF6 silencing.
Results
Our results showed that SRSF6 levels (mRNA/protein) are upregulated in PCa vs. non-tumour prostate samples, linked to clinical parameters of tumour-aggressiveness (e.g., Gleason score, T-stage, perineural infiltration, metastasis at diagnosis), and associated with poor prognosis (i.e., shorter disease-free survival) in PCa patients. Moreover, SRSF6-overexpression increased, while SRSF6-silencing decreased, functional parameters of aggressiveness *in vitro* (proliferation, migration, colonies- and tumorspheres-formation) and tumour growth *in vivo*. Mechanistically, SRSF6 modulation resulted into a dysregulation of Androgen-Receptor (AR) activity through transcriptional control of the AR-coregulators APPBP2 and TOP2B.
Discussion
SRSF6 could represent a new therapeutic target to inhibit persistent AR-signalling in advanced PCa.

Efficacity of combination of Lenvatinib and PPRT in severe hypersecretion of VIP

Natalia Raluca Mitru, Julien Hadoux, Livia Lamartina, Fabiana Pani, Eric Baudin & Sophie Moog
Gustave Roussy, Service d'Oncologie Endocrinienne, Département d'Imagerie, Villejuif, France

Introduction
VIPomas are rare neuroendocrine tumors (NET), usually located in the pancreas that secrete vasoactive intestinal polypeptide (VIP) leading to high-volume watery diarrhea and complications such as hypokalemia, acidosis and dehydration. The management of VIPoma symptoms is often challenging when surgical resection of all the lesions is not feasible. Treatments are then based on somatostatin analogs (SSA) and may also include hepatic chemoembolization, systemic chemotherapy, targeted therapies, with reported efficacy of sunitinib on hormonal secretion or Peptide Receptor Radionuclide Therapy (PPRT). The combination of these treatments on anti-secretory effects is unknown.
Clinical case
A 61 years-old woman had a non-functioning metastatic grade 2 (Ki67 = 15%) well differentiated pancreatic NET, misdiagnosed during the first 2 years of management as hepatocellular carcinoma (HCC). Therefore, she received Sorafenib and Lenvatinib according to HCC guidelines. After expert pathological review and final diagnosis of NET, she was started on SSA. Six months after SSA initiation, metachronous VIP secretion appeared, contemporary with diffuse liver progression and VIPoma symptoms: severe watery diarrhea leading to continuous hospitalization during four months. Symptoms management required high doses of *I.V.* SSA (octreotide 2400 µg/day). The patient was not eligible for locoregional treatment due to diffuse hepatic miliary invasion. Sunitinib lead to rapidly controlled symptoms but required dose adjustments due to hematological toxicity, and disease progression occurred after 2 months. Chemotherapy with 5FU-Oxaliplatin and the anti VEGF agent Bevacizumab was ineffective. At that time, the 68Ga-DOTATOC PET showed avidity for all lesions. Due to the previously symptomatic response to Sunitinib, Lenvatinib was initiated at reduce dosage (10 mg/day) for hormonal secretion control, together with 2 cycles of 177-Lu-Dotatate (7,4 GBq). This combination resolved rapidly, completely and sustainably VIPoma symptoms, associated with a massive decreased of plasma VIP level after one month (from 20 to 3 times over the upper limit normal) and a morphologic partial response after three months. Lenvatinib led to constipation and, whenever, the patient stopped taking the drug, the diarrhea recurred.

Therefore, maintenance Lenvatinib alone is ongoing with no functional symptoms since four months.
Conclusion
Urgent management of severe uncontrolled VIP secretion can lead to unusual treatment combinations in order to control both hormonal secretion and tumor growth. The anti VEGF activity may not be the only mechanism of VIP secretion inhibition of Sunitinib owing to the lack of efficacy of Bevacizumab in our case. The long-term toxicity of the combination reported here is unknown and remains to be studied.

Urinary free cortisol is an independent predictive factor for early distinction between ectopic ACTH secretion and pituitary Cushing's disease

Furnica Raluca[1], Alix Collard[1], Cornelis Frank[2], Orsalia Alexopoulou[1] & Dominique Maiter[1]
[1]Cliniques Universitaires Saint-Luc (UCLouvain), Endocrinology, Bruxelles, Belgium; [2]Cliniques Universitaires Saint-Luc (UCLouvain), Oncology, Bruxelles, Belgium

Introduction
The poor prognosis of patients with Cushing's syndrome due to ectopic ACTH secretion (ECS) requires prompt diagnosis and management of the disease.
Objectives
To find clinical and biological differences between ECS and pituitary Cushing's disease (CD) at diagnosis and to determine whether any of them may be a potential predictor for early suspicion of ECS.
Methods
This was a retrospective case-nested study of 18 patients with ECS diagnosed and treated between 1993 and 2017, compared with 36 patients with proven CD and matched for the time of diagnosis.
Results
ECS occurred more frequently in men (13/5 vs. 10/26) and at an older age (53.4 $\pm$ 17.3 vs. 43.1 $\pm$ 13.9) than CD. In most patients (89%) the source of ectopic ACTH secretion was identified by thoraco-abdominal CT. No significant difference was found in the prevalence of symptoms and signs of hypercortisolism between the two groups. We found that potassium level $\leq$ 3.65 mmol/l had sensitivity and specificity of 77%, and LDH level greater than 1.28xULN had a sensitivity of 69% and a specificity of 68% for the diagnosis of ECS. Both parameters were correlated with 24-hour urinary-free cortisol (UFC) which was higher in the ECS group (median: 1127 µg/24h) compared to the CD group (216 µg/24h, $P<0.05$). On univariate analysis, an older age at diagnosis, male sex, lower serum potassium, higher LDH and higher UFC values were significant predictors of ECS. Male sex increased the relative risk of ECS by 6.8 times and hypokalemia increased this risk by 52 times for each 1.0 mmol/l-decrease in serum potassium. However, only UFC (expressed as $\log_{10}$) was kept as an independent predictive factor in the multivariate analysis ($P=0.0009$), and a discriminant decision-tree approach showed that a UFC level $\geq$ 633 µg/24h (10.5-fold the upper limit of normal) was the best cut-off with a sensitivity of 87% and a specificity of 92% for the diagnosis of ECS. There was no difference between the two groups in terms of complications related to hypercortisolism but patients with ECS had a lower remission rate and a higher mortality.
Conclusions
While severe hypokalaemia and higher LDH values translate a more severe degree of hypercortisolism in patients with ECS, 24h UFC at diagnosis appears to be the main independent predictor of ECS, with the best cut-off value determined at 10.5-fold the ULN, above which clinicians should rapidly suspect ECS and perform the appropriate work-up including thoraco-abdominal CT.

Influence of CaSR in testicular germ cell tumors

Jasmin Hjerresen[1], Gustav Gøbel Nielsen[1], Christine Hjorth Andreassen[1,2,3], Anders Juul[1,4] & Martin Blomberg Jensen[1,5]
[1]Rigshospitalet, Department of Growth and Reproduction, Copenhagen, Denmark; [2]Copenhagen University Hospital - Rigshospitalet, Group of Skeletal, Mineral, and Gonadal Endocrinology, Department of Growth and Reproduction, Copenhagen OE, Denmark; [3]Copenhagen University Hospital – Rigshospitalet, International Centre for Research and Research Training in Endocrine Disruption of Male Reproduction and Child Health (EDMaRC), Copenhagen OE, Denmark; [4]University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark; [5]HSDM/HMS Harvard University, Boston, MA, US, Division of Bone and Mineral Research, Boston, United States

More than 90% of malignant testicular tumors arise in the germ cells and are denoted testicular germ cell tumors (TGCTs). TGCTs are one of the most common cancers among men between 15 to 40 years of age and arise from a common precursor cell, the germ cell neoplasia in situ (GCNIS), an arrested and transformed fetal gonocyte that become invasive after puberty. TGCTs are divided into seminomas and nonseminomas based on histology. Fortunately, TGTCs are highly sensitive to cisplatin-based chemotherapy and therefore the survival rate is high. However, adverse effects involve an increased risk of infertility and other comorbidities, highlighting the importance of chemotherapy-reducing strategies. The calcium sensing receptor (CaSR) is a key player in the regulation of calcium homeostasis, exerting its primary function in the parathyroid gland and the kidneys. CaSR has been implicated in the pathogenesis of various cancers including colorectal- and breast cancer, exerting both oncogenic- and tumor suppressor functions. However, the role of CaSR in TGCTs have not previously been described. CaSR can be targeted using the negative allosteric modulator, NPS-2143, and the FDA-approved positive modulator, Cinacalcet. Therefore, we investigated the influence of CaSR in TGCTs as a potential target for chemotherapy-reducing treatment. The expression of CaSR was investigated by qPCR, western blot, and immunohistochemistry (IHC) in TGCT cell lines and human samples of normal testis, GCNIS, and TGCTs. The effect of treatment of TGCT-derived cell lines with Cinacalcet, NPS-2143, or calcium was assessed in vitro using proliferation assays. Finally, the effect of positive allosteric modulation of CaSR using Cinacalcet was determined *in vivo* using TGCT xenograft mouse models. CaSR was expressed in normal testis, GCNIS, TGCTs, and TGCT cell lines. mRNA levels of CaSR were correlated with markers of pluripotency, NANOQ and Oct-4. Additionally, expression levels of CaSR were strongly correlated with PTHrP in GCNIS and embryonal carcinoma tissue suggesting a link between these two factors. Western blot and IHC demonstrated expression of CaSR in normal testis, GCNIS, and TGCTs. In vitro experiments revealed a slight increase in proliferation of embryonal carcinoma-derived NTera2 cells treated with cinacalcet and a corresponding decreased proliferation when treated with NPS-2143. Accordingly, treatment with Cinacalcet increased tumor volume in an NTera2 xenograft mouse model. This study indicates potential growth regulating effects of CaSR in TGCTs and suggests that cellular calcium homeostasis in TGCTs may be a promising target for developing novel chemotherapy-reducing strategies.

Hypogonadism as a first manifestation of Poems Syndrome

Esther Serisuelo Meneu, Begoña Pla Peris, Mayet Roxana Padilla Segura, Pablo Abellán Galiana, Sara Franch Salvador & Agustín Angel Merchante Alfaro
Hospital General Universitario de Castellón, Servicio de Endocrinología y Nutrición, Castellón de la Plana, Spain

Introduction
Poems Syndrome is a rare multisystem disorder characterized by polyneuropathy, organomegaly, endocrinopathy, monoclonal plasma-proliferative disorder and skin changes, among other features. Literature describes endocrine abnormalities at least in 93% of patients with Poems Syndrome during the diagnosis as well as during the follow-up. The most common deficiencies ranked by their frequency are hypogonadism, hyperprolactinemia, hypothyroidism, abnormal glucose metabolism and in rare cases adrenal insufficiency and elevated IGF-1 levels.
Case Presentation
67-year-old man with history of right occipital stroke and 1-2 pack a day smoker with pulmonary disease with severe obstruction in spirometry is referred to endocrinology consultations because of erectile dysfunction with decreased libido and asthenia. At physical examination he presented with a group of cervical adenopathies and paresthesia in palms and soles that prevent walking of about one year of evolution. No mucosal hyperpigmentation but presence of hyperpigmented lesions in thorax and abdomen. Normal testicular size and presence of secondary sexual characteristics. No other relevant associated symptoms. Laboratory parameters confirmed by two determinations revealed: Hb 18.1 g/dl (12,0-18,0), Hematocrit 59% (37,0-52,0), HbA1c 5,73% (4,0-6,5); TSH 0,459 mU/l (0,380-5,330); T4L 1,22 ng/dl (0,54-1,24); Prolactine 14,7 ng/ml (2,6-13,1);

GH 0,386 ng/ml (1,0-3,0); IGF-1 94,9 ng/ml (67,0-141,0). FSH 2,31 UI/l (1,27-19,26); LH 2,48 UI/l (1,2-8,6); Testosterone 1,42 ng/ml (1,75-7,81); establishing the diagnosis of secondary hypogonadism. Corticoid axis was not valuable due to chronic corticoid treatment for respiratory disease. Pituitary MRI was performed with no findings. The electromyogram showed polyneuropathy in palms and soles with axonal and demyelinating involvement. Hematology completed examination with lymph node biopsy resulting in plasmocellular variant of Castleman disease with low HHV-8 expression and monoclonal spike IGG Lambda (6,8% 0,4 g/dl). Diagnosis of Poems Syndrome was done following the diagnostic criteria:

- Mandatory criteria: monoclonal spike and sensory-motor polyneuropathy.
- Mayor criteria: Castleman disease.
- Minor criteria: secondary hypogonadism, cutaneous hyperpigmented lesions and polyglobulia.

The patient was discharged after clinical stability and improvement of symptoms. He continues with chemotherapy treatment in Hematology outpatient clinics and follow-up by Neurology and Endocrinology. Testosterone treatment was not started due to severe polyglobulia secondary to hematological disease.

Conclusions

Poems Syndrome involves multiple organs, and a multidisciplinary approach should include an endocrinologist. Patients should be systematically assessed for endocrinopathy and treated as indicated. Long-term follow-up is recommended since the appearance of new endocrinopathies as well as the remission of others.

Investigating the risk of metabolic and cardiovascular comorbidities among patients with parathyroid cancer: a nationwide representative cohort study in Taiwan

Ming-Chieh Tsai[1,2], Kuo-Liong Chien[3] & Po-Jung Tseng[4]
[1]Mackay Memorial Hospital, Division of Endocrinology and Metabolism, Department of Internal Medicine, Taipei, Taiwan; [2]National Taiwan University, Institute of Epidemiology and Preventive Medicine, College of Public Health, Taipei, Taiwan; [3]National Taiwan University College of Public Health, Institute of Epidemiology and Preventive Medicine, Taipei, Taiwan; [4]Hsin Chu Armed Force Hospital, Division of Cardiovascular Surgery, Department of Surgery, Hsinchu, Taiwan

Background

This study aimed to determine whether primary parathyroid cancer patients were associated with increased metabolic and cardiovascular comorbidities in comparison to the general population

Method

We used the National Taiwan Cancer Registry Database to construct a cohort of patients with parathyroid cancer from January 1, 2004, to December 31, 2019. We compared the incidence of hypertension, diabetes mellitus, hyperlipidemia, atrial fibrillation, coronary heart disease, and heart failure with the general population matched based on a propensity score in a one-to-five fashion.

Results

A total of 72 parathyroid cancer patients and 360 matched general population (mean age: 55 years; 59% women) were included, with different exclusive numbers for each metabolic and cardiovascular comorbidity cohort. The number of cases based on a total of 2347.7 person-years of observation, included 53 deaths, 29 hypertension, 9 diabetes, 13 hyperlipidemia, 10 atrial fibrillation, 18 coronary artery disease, and 13 heart failure. According to multivariate analysis, parathyroid cancer remained significantly associated with diabetes [Hazard ratio (HR): 9.28; 95% confidence interval (CI): 1.72-50.07], hyperlipidemia (HR: 5.86; 95% CI: 1.61-21.31), and heart failure (HR: 4.46; 95% CI: 1.18-16.84). Sub-distribution of competing mortality events and subgroup analysis showed robust evidence of metabolic and cardiovascular comorbidities. Model were estimated by years since cancer diagnosis and the highest odds appeared within six years and dramatically dropped after the sixth year. However, the long-term trend for an association between parathyroid cancer and comorbidities persisted for decades. The national cohort study demonstrated that adult parathyroid cancer patients had a significantly higher incidence of diabetes mellitus, hyperlipidemia, and heart failure than the general population.

Conclusion

An increased risk of metabolic and cardiac comorbidities among parathyroid cancer patients required great caution.

Key words

Parathyroid cancer' cardiovascular disease' diabetes mellitus

Selective Arterial Calcium Stimulation Test In Two Cases With Occult Insulinoma

Gökhan Baykal[1], Berna Evranos Ogmen[2], Mustafa Özdemir[3], Birol Bostancı[4], Şefika Burçak Polat[2], Oya Topaloglu[2], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yıldırım Beyazıt University, Faculty of Medicine, Ankara Bilkent City Hospital, Endocrinology and Metabolism, Ankara, Turkey; [3]Ankara Bilkent City Hospital, Radiology, Ankara, Turkey; [4]Ankara Bilkent City Hospital, General Surgery, Ankara, Turkey

Introduction

Insulinoma is a rare neuroendocrine tumor that is difficult to diagnose due to its obscure location. Conventional radiographic methods have low sensitivity and are inadequate to detect insulinoma. Selective arterial calcium stimulation test (SACST) is 95–100% sensitive in the diagnosis of insulinomas. Here, we presented two cases of insulinoma that could not be located by radiographic methods and evaluated them with SACST.

Case 1

A 48-year- old woman who had dizziness was referred to our endocrine clinic with a suspicion of insulinoma. A 72-hour fasting test was performed to establish a diagnosis of endogenous hyperinsulinemia. After 19 h hypoglycemic symptoms emerged and fasting serum glucose (FSG) was 27 mg/dl, insulin 6,5 mU/l, and C-peptide 2 µg/l. MRI of the abdomen, Galium-68 Dotatate scintigraphy, and endoscopic ultrasonography (EUS) failed to detect the tumor. SACST was performed to localize the tumor. Calcium injection of the gastroduodenal artery caused a more than 11-fold increase in hepatic insulin above baseline indicating a lesion in the head region of the pancreas. Intraoperative ultrasonography of the pancreas revealed a 1 cm nodular lesion in the head. Proximal pancreatectomy was performed. Histopathological findings were consistent with well-differentiated neuroendocrine tumor showing positive staining with synaptophysin and chromogranin. After surgery, the patient was free of all previous symptoms.

Case 2

A 67-year- old woman was admitted to the clinic due to dizziness and diaphoresis. She applied to the emergency department once with a loss of consciousness. There was a weight gain of 4-5 kg during this period. After 12 h of the 72-hour fasting test, hypoglycemic symptoms emerged, and FSG was 36 mg/dl, insulin 6,9 mU/l, and C-peptide 1,7 µg/l. MRI of the abdomen, Galium-68 Dotatate scintigraphy, and EUS failed to demonstrate the tumor. SACST was performed and calcium injection of the splenic artery caused a more than 9-fold increase in hepatic insulin above baseline which was suggestive of an insulinoma lesion in the tail of the pancreas. Intraoperative ultrasonography of the pancreas revealed a 1 cm nodular lesion in the tail. Distal pancreatectomy was performed. No hypoglycemia has occurred since the surgery.

Conclusions

The localization of insulinoma is critical for curative surgery and might be problematic. Because of the low sensitivity of non-invasive imaging procedures in tumors smaller than 2 cm, invasive methods can be used for the localization like in our cases.

Therapeutic Efficacy of the Combination of Braf and Mek Inhibitors in Erdheim-Chester Disease (EEC)

Sharona Azriel, Gema Garcia Romero De Tejada & Virginia Martin Borge
Infanta Sofia University Hospital, Madrid, Spain, Endocrinology and Nutrition, Madrid, Spain

EEC is a multisystemic disease secondary to a clonal histiocyte proliferation of non-Langerhans cells due to hyperactivation of the MAPK/ERK signaling pathway, with somatic BRAF V600E mutation present in 50% of cases with therapeutic implications. Between 50% of patients develop endocrinopathies, the most frequent being central diabetes insipidus (CDI). We present the case of a 42-

year-old woman, diagnosed with CDI in 1998 without family history, treated with DDAVP [MRI: absence of neurohypophysis, normal pituitary stalk), negative AVP gene and hypergonadotropic hypogonadism since the age of 39 years. In 2019 she developed acute renal failure (GFR 20 ml/min/1.73 m^2) and HTA, bilateral grade IV hydronephrosis due to bilateral perirenal infiltrative process. She required a double J catheter and subsequent bilateral nephrostomy without improvement of renal function. She had associated blastic bone lesions in axial and appendicular skeleton. During the diagnostic process she developed gait ataxia, dysarthria and dysphagia. In view of the suspicion of multisystemic disease of histiocytic origin, a bone biopsy of the sacral lesion (not profitable) was conducted and biopsy of the perirenal infiltrative tissue showed proliferation of histiocytes (CD68 positive, S100 and CD1 negative, no Langerhans phenotype) compatible with EEC and presence of BRAF V600E mutation in molecular analysis. The PET-CT extension study (18FDG) showed cerebral hyperenhancement predominantly in the posterior fossa, generalized bone involvement and pathological uptake in bilateral perirenal fat, retroperitoneal, left adrenal, gonads, pulmonary artery, interatrial septum and pericardial thickening. Bone marrow biopsy showed grade 3 myelofibrosis without myeloproliferative syndrome criteria. The presence of BRAFV600E mutation allowed treatment with Vemurafenib without side effects despite renal failure, with clinical improvement and reduction of lesions in PET-CT at 8 weeks of treatment. At the 5th month, after worsening of the neurological symptoms (pyramidocerebellar syndrome), she was treated with IV dexamethasone and second line with Drabrafenib-Trametinib was started (2020). Clinical neurological improvement was confirmed a few weeks after initiation, her nystagmus, dysarthria, dysmetria, and gait improved remarkably, and progressive reduction of pathological uptakes at brain and renal level during follow-up with FDG-F18. In 2021 she was diagnosed with central hypothyroidism and somatotropic deficit, renal function has remained stable and nephrostomies have been closed (2022). The patient continues with the combination of BRAF and MEK inhibitors. She has also developed several endocrinopathies over time: CID as first manifestation 21 years earlier, adenohypophyseal deficits, gonadal involvement with amenorrhea and unilateral adrenal involvement. Prognosis depends on the neurological and cardiological evolution.

Severe insulin secretion by an inoperable metastatic insulinoma can be controlled by 177-Lu-DOTA-TATE radionuclide therapy: a case report

George Riley[1], Cécile Creton[1], Léa Demarquet[1], Perrine Raymond[1], Elodie Chevalier[1,2], Aurélien Lambert[3], Bruno Guerci[1], Marc Klein[1] & Nicolas Scheyer[1]

[1]University Hospital of Nancy, Endocrinology, Diabetology and Nutrition, Vandœuvre-lès-Nancy, France; [2]University Hospital of Nancy, Nuclear Medicine, Vandœuvre-lès-Nancy, France; [3]Lorraine Institute of Oncology, Vandœuvre-lès-Nancy, France

Introduction

Metastatic insulinoma is an extremely rare form of malignant insulinoma involving metastatic growth where classical surgical treatment is often impossible. Medical therapies are widely considered and reserved for those especially with inoperable insulinoma with the goals of reducing tumor size, but also of reducing hypoglycemic events either by acting directly on the insulinoma cells (reducing excess insulin secretion from the insulinoma cells or reducing tumor volume), by decreasing sensitivity to insulin or by directly increasing blood sugar levels (glucose perfusion, enteral nutrition). Ga-DOTATOC radionuclide imaging is widely used for insulinoma diagnosis, however, the equivalent therapeutic radionuclide Lu-DOTATATE is less commonly used.

Observation

We report the case of a 58 yo patient with no previous medical history hospitalized in our department for treatment of a malignant symptomatic secreting insulinoma with bone, liver and lymphatic metastasis. The patient presented a severe excess of insulin secretion leading to a rapid escalation in conventional therapy (DIAZOXIDE, calcium channel blockers, corticotherapy, mTOR inhibitors, second-generation somatostatin analogs, continuous enteral nutrition and continuous glucose perfusion) that struggled to maintain blood sugar levels above 50 mg/dl. Tests for germline mutations and somatic mutations were negative and four months of intensive conventional treatment lead to no clinical or morphological success. However, after observing good 68-Ga-DOTATOC uptake, peptide receptor radionuclide therapy was proposed using 177-Lu-DOTA-TATE. The first single dose of 7400 MBq was extremely effective on insulin secretion allowing the discontinuation of DIAZOXIDE, mTOR inhibitors and G30% glucose perfusion as well as significant reduction in enteral nutrition and corticotherapy. The clinical tolerance of the treatment was excellent and did not cause initial excess insulin release.

Discussion

Radionuclide therapy by 177-Lu-DOTA-TATE was an effective and well tolerated treatment in this patient presenting secreting inoperable malignant insulinoma and could be considered in other patients in similar situations presenting hypoglycemia despite conventional treatment.

Impact of vascular invasion on otherwise low-risk papillary thyroid carcinomas: a retrospective and observational study

Francisca Marques Puga[1,2], Abir Al Ghuzlan[3], Dana M. Hartl[4], Mohamed-Amine Bani[3], Sophie Moog[2], Fabiana Pani[2], Ingrid Breuskin[4], Joanne Guerlain[4], Matthieu Faron[4], Desirée Denadreis[5], Eric Baudin[2], Julien Hadoux[2] & Livia Lamartina[2]

[1]Centro Hospitalar Universitário do Porto, Department of Endocrinology, Diabetes and Metabolism, Porto, Portugal; [2]Gustave Roussy, Département d'Imagerie, Service d'oncologie endocrinienne, Endocrine Oncology Unit, F-94805 Villejuif, France; [3]Gustave Roussy, Département de biologie et pathologie médicale, Department of Biology and Pathology, F-94805 Villejuif, France; [4]Gustave Roussy, Département Anesthésie Chirurgie et Interventionnel, Department of Anesthesia, Surgery, and Interventional, F-94805 Villejuif, France; [5]Gustave Roussy, Département d'Imagerie, Service de Médecine Nucléaire, Nuclear Medicine Unit, F-94805 Villejuif, France

Background

Presence of venous vascular invasion is a criterion of intermediate risk of recurrence in papillary thyroid carcinoma (PTC). However, the presence and type of vascular invasion (lymphatic or venous) is often underreported and its impact on PTCs without other risk features remains unknown.

Objective

To evaluate the impact of both lymphatic and venous invasion on the risk of recurrence/persistence on otherwise low-risk PTCs.

Methods

Retrospective study including patients with otherwise low-risk PTCs but with vascular invasion, diagnosed between 2013 and 2019. The persistence/recurrence during the follow-up was evaluated. Pathology was reviewed to confirm the presence of vascular invasion and determine the type of invasion.

Results

A total of 141 patients were included. Vascular invasion was confirmed in 20.6%. After surgery, 48.9% ($n=69$) of the patients received radioactive iodine (RAI). The median follow-up time was 4 [3-6] years. Overall, 6 (4.2%) patients experienced persistent/recurrent disease in the neck, including 3 with vascular invasion, confirmed as "only lymphatic". Overall, patients with tumors harboring vascular invasion had significantly more persistent/recurrence disease compared with those without vascular invasion (10.3% vs 2.7%, $P=0.1$), especially in the subgroup of patients not treated with RAI (20% vs 1.6%, $P=0.049$) [OR 15.25, 95% CI 1.24-187.85, $P=0.033$].

Conclusions

Vascular invasion, including lymphatic invasion only, is associated with a sensibly higher risk of persistent/recurrent disease in otherwise low-risk PTCs, namely in patients not treated with RAI. Lymphatic invasion could have a role in risk-stratification systems for decision making.

Luque[1,2,3,4] & Antonio Jesús Martínez-Fuentes[1,2,3,4]

[1]Maimónides Institute for Biomedical Research of Córdoba (IMIBIC), 14004 Córdoba, Spain, Córdoba, Spain; [2]University of Córdoba, Department of Cellular Biology, Physiology and Immunology, Córdoba, Spain; [3]Reina Sofía University Hospital (HURS), Córdoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Spain; [5]Hospital Virgen del Rocío, Servicio de Endocrinología y Nutrición, Seville, Spain; [6]Instituto de Investigaciones Biomédicas "Alberto Sols", Consejo Superior de Investigaciones Científicas, Madrid, Spain

Emerging evidence indicates that the cellular machinery controlling the splicing process (spliceosome) is altered in several tumour types, leading to oncogenic

splicing events associated with tumour progression and aggressiveness. However, whether this molecular phenomenon also occurs in thyroid cancer has not been yet explored. Therefore, our main aim was to explore the potential dysregulation of the expression of relevant spliceosome components and splicing factors in clinically well-characterized human thyroid cancer samples (papillar, follicular and medullary), compared to its adjacent non-tumour tissue, and whether these alterations might be associated with relevant clinical parameters. Results revealed a clear dysregulation of several components of the splicing-machinery in thyroid cancer samples compared to its adjacent non-tumoral tissue, wherein the expression of specific components was associated with key clinical parameters. Based on these results, we next explored different functional (e.g. proliferation, migration, and tumour-spheres and colonies formation) and mechanistic (gene expression/signalling pathways) assays in human thyroid cancer cell models (TCP1 and Cal62) in response to the inhibition of the splicing machinery activity [i.e. using the splicing-factor-3B-subunit-1 (SF3B1; a core component of this machinery) inhibitor pladienolide B] and SF3B1 silencing (using an specific siRNA). These *in vitro* studies revealed that pladienolide-B significantly decreased cell aggressiveness parameters (proliferation, migration, formation of tumour-spheres and colonies) in thyroid cancer cells through the modulation of the expression levels of different component of key oncogenic signalling routes. Similarly, SF3B1 silencing also reduced the above-mentioned tumour-related features, thus confirming the critical role of SF3B1 and consequently, of the splicing machinery, in thyroid pathophysiology. Altogether, our data demonstrate a drastic dysregulation of the splicing-machinery in thyroid cancer tissues that might be associated to its tumorigenesis, paving the way to explore the use of specific splicing-machinery components as novel diagnostic/prognostic and therapeutic targets in this pathology. In particular, the genetic and/or pharmacological inhibition of SF3B1 may represent a promising novel therapeutic strategy worth to be explored through randomized controlled trials that could improves the outcome of patients affected by clinically aggressive thyroid cancer.

Innate differences in the molecular signature of inferior and superior human parathyroid glands: potential implications for parathyroid adenoma

Shipra Agarwal[1], Parmita Kar[2], Monikongkhona Boruah[1], Soma Saha[2], Tabin Millo[3], Chitresh Kumar[4], Seenu Vuthaluru[4] & Ravinder Goswami[2]
[1]All India Institute of Medical Sciences, Department of Pathology, New Delhi, India; [2]All India Institute of Medical Sciences, Endocrinology and Metabolism, New Delhi, India; [3]All India Institute of Medical Sciences, Department of Forensic Medicne, India, India; [4]All India Institute of Medical Sciences, Department of Surgery, New Delhi, India

Primary hyperparathyroidism (PHPT) is a common endocrine disorder characterised by hypercalcemia, skeletal fragility, and renal stones with majority (75%) of parathyroid tumours localized to the inferior parathyroid glands. The reasons for this natural bias are not known till date. A probable reason may be due to inherent differences in the molecular milieu of normal superior and inferior parathyroid glands. Such questions cannot be answered using superior and inferior parathyroid adenoma tissues from different patients due to the confounding effect of inter-individual differences. Comparison of inferior parathyroid adenoma tissue with normal superior gland from the same patient would also be inappropriate, as any differences observed could be secondary to tumorigenesis. Thus, the ideal approach would be comparison of normal superior and inferior parathyroid glands from the same individual. However, it is difficult to obtain normal parathyroid tissue. To overcome this limitation, we assessed the global gene expression profile of superior and inferior glands obtained from forensic autopsies. Genes with significant differential expression between superior and inferior parathyroids were further confirmed by RT-PCR in 19 pair of glands. As an iterative approach, additional genes with an established role in parathyroid disorders, i.e., *CASR*, *MAFB*, *PAX9*, *TBCE*, *TBX1*, *VDR*, *MEN1*, *CCND1*, and *CDC73* were also evaluated by RT-PCR in all 19 pairs of superior and inferior parathyroid glands. Seven homeobox genes, namely *HOXA4*, *HOXA5*, *HOX-BAS3*, *HOXB4*, *HOXB6*, *HOXB9*, *IRX1*, and one encoding for *ALDH1A2* showed a lower expression in the inferior parathyroid glands than the superior. Conversely, *SLC6A1* showed a higher expression in the inferior glands. Of the nine genes with significant differential mRNA expression among superior and inferior glands HOXB9, HOXB4 and IRX1 could be detected by western blotting/mass spectrometry. The study is the first to provide novel clues for the differential expression of seven Homeobox genes *HOXA4*, *HOXA5*, *HOX-BAS3*, *HOXB4*, *HOXB6*, *HOXB9*, *IRX1 along with ALDH1A2*, and *SLC6A1* in inferior vs the superior parathyroid glands. The Homeobox genes are evolutionarily conserved family of transcriptional-factors essential for embryogenesis and tumorigenesis. The above results suggest that the first hit in parathyroid oncogenesis might be developmental. The mutations in *MEN1*, *CDC73*, or *CCND1* in the inferior gland may be a second hit. This study suggests potential clues for the preferential localization of parathyroid tumours to the inferior glands as in primary hyperparathyroidism. Future studies on identification of methylations of homebox genes may also help elucidate the underlying mechanisms of primary hyperparathyroidism.

Intermediate-risk Differentiated Thyroid Cancer with Stimulated Thyroglobulin or N1b Needs High Adjuvant Radioactive Iodine Dose

Xue Li[1], Wei Zheng[1], Yanhui Ji[1], Danyang Sun[2] & Xuan Wang[1]
[1]Tianjin Medical University General Hosipital, Department of Nuclear Medicine, Tianjin, China; [2]Tianjin Medical University General Hosipital Airport Hospital, Department of Nuclear Medicine, Tianjin, China

Background
There are no definite recommendations on the optimal dosage of initiating adjuvant radioactive iodine (RAI) therapy for intermediate-risk differentiated thyroid cancer (DTC) patients in current relevant guideline. This study aimed to investigate the response of intermediate-risk DTC patients with a low (3.7GBq) or high RAI dose (5.55GBq).
Methods
Propensity score matching was performed to control for baseline characteristics. A total of 476 patients with intermediate-risk DTC were retrospectively reviewed. 238 patients received RAI of 3.7GBq (Group 1), and the other 238 patients received RAI of 5.55GBq (Group 2). Then patients were further divided into 4 subgroups: Subgroup 1: stimulated thyroglobulin (sTg) <10ng/ml, Subgroup 2: sTg ≥ 10ng/ml, Subgroup 3: N0 + N1a, Subgroup 4: N1b. We compared the response to different RAI dose in subgroups. The univariate and multivariate logistic regression were conducted to screen out factors associated with excellent response (ER). Finally, the prognostic nomogram was used to explain ER rates as a useful tool in clinical practice.
Results
Before dividing the subgroups, The ER rate in Group 1 was higher than Group 2 (65.1% vs 47.1%, $P<0.05$). There was no significant difference of response to different RAI dose in subgroup 1. Group 1 has significantly higher incomplete response (IR) rates in Subgroup 2 and 4(71% vs 41.5%, 24.1% vs 10.9%, all $P<0.05$ respectively). However, in Subgroup 3, the ER rate in Group 1 and the IR rate in Group 2 were relatively higher. (69.2% vs 53.2%, 7.5% vs 15.6%, all $P<0.05$ respectively). By univariate and multivariate logistic regression analysis, N1b (OR:0.158, 95%CI: 0.034-0.736, $P=0.019$), sTg> 10ng/ml (OR:0.048, 95%CI: 0.022-0.104, $P<0.001$), and T2 (OR: 0.472, 95%CI: 0.228-0.981, $P=0.044$) were manifested to be independent risk factors for ER. The nomogram showed that sTg, N status and T status were the top 3 contributors to the ER.
Conclusions
Higher RAI dose should be considered for intermediate-risk DTC patients when sTg ≥ 10ng/ml or with N1b status.

Asfendiyarov", Tole bi 88, Kazakhstan; [3]JSC "Scientific Center of Pediatrics and Pediatric Surgery", department of oncology, Almaty, Kazakhstan; [4]city polyclinic No2, Aktobe, Kazakhstan; [5]NAO "Kazakh National Medical University named after S.D. Asfendiyarov", Almaty, Kazakhstan

Introduction
A rare cause of hyperparathyroidism in pediatric is parathyroid carcinoma. The variety of clinical manifestations of hyperparathyroidism and the associated hypercalcemia slows down the verification of its primary nature.
Material and methods
Medical records of an inpatient 13y.o child.
Results
Child from 5 pregnancies, 1 delivery. Pregnancy was accompanied by endemic goiter. Delivery at 39-40weeks, physiological. Previous pregnancies-miscarriages. The child was ill during the last year of life. In the debut of the disease, arthralgia of the knee joints, gait disturbance. In the dynamics for 9 months, there is an increase in

the deformity of the knee joints, he received inpatient treatment with a diagnosis of "Bilateral dysplastic coxarthrosis with juvenile epiphysiolysis of the femoral heads. Pathological fracture of the upper and middle third of the diaphysis of the left femur with angular displacement between the fragments against the background of fibrous dysplasia". 10th month of illness, the condition worsened, complained of abdominal pain, thirst, vomiting, weakness, pallor. Urgently hospitalized with a hypercalcemic crisis. In the clinic of the disease there were bone, renal, cardiovascular, gastrointestinal forms, laboratory hyperparathyroidism (up to21448ng/dl), metabolic disorders (hypokalemia, hyponatremia, hypercalcemia up to3.76mmol/l, hyperglycemia, hypoproteinemia, high alkaline phosphatase up to1597.4u/l, alpha-amylase up to318.7u/l, hypercreatininemia, anemia. Instrumental studies confirmed the volumetric formation of the parathyroid gland. Ultrasound of the thyroid gland-hyperplasia and diffuse changes in the parenchyma of the thyroid gland. Node (adenoma?) of the right lobe of the thyroid gland. Adenoma of the parathyroid gland on the right; MRI of the neck and mediastinum-a picture of the neoplasm soft tissues of the neck on the right (adenoma of the parathyroid gland (size3.1-2.0-2.0cm). The child underwent surgery to remove the adenoma of the parathyroid gland, hemithyroidectomy on the right. Cytology (material of the parathyroid gland): corresponds to parathyroid adenoma. Histology (microscopy): parathyroid tumor, nodular structure, with a well-defined fibrous capsule and fibrinous septa dividing the tumor into lobes and trabeculae. Tumor cells with signs of moderate polymorphism. There is a focus of invasion of tumor cells into the capsule. IHC study: Cyclin D1, P53-positive, Ki-67-5%. Conclusion: morphological picture and immunophenotype of parathyroid carcinoma. There are no tumor elements in the thyroid tissue, ICD-0 Code8140/3(Ki-67-5%).

Conclusion

Parathyroid adenoma can be clinically asymptomatic, as well as under the masks of other diseases. In the case of extremely high levels of calcium in the blood and the presence of pronounced symptoms by pediatricians should be alert to hyperparathyroidism.

Introduction

The management of patients with neuroendocrine neoplasms (NEN) has been revolutionised since the introduction of radiolabelled somatostatin analogues targeting overexpressed somatostatin receptors (SSTR). Accurate assessment of SSTR status of primary focus/metastases is crucial to determine the choice of the treatment method. Recently it has been shown that novel molecular probes, SST_2-antagonists, recognize more binding sites in comparison to the widely used $SSTR_2$-agonists and hence improve diagnostic efficacy, especially when the density of SSTR is low. The aim of the project is to develop a novel 99mTc-labelled $SSTR_2$-antagonist as a sensitive probe to assess the SSTR status in NEN patients.

Material and Methods

In frame of the first, extensive preclinical studies the most promising SSTR antagonist N4-LM-3 (p-Cl-Phe-cyclo(D-Cys-Tyr-DAph(Cbm)-Lys-Thr-Cys)-D-Tyr-NH_2 (TECANT-1) was selected for clinical translation to initiate a clinical feasibility study including the development of a robust, reproducible quantitative imaging method of SSTR assessment in NEN tissues[1]. The clinical study is a phase I multicentre trial. Ten patients with advanced NEN and SSTR positivity confirmed by routinely used SSTR imaging based on a radiolabelled agonist will be enrolled in the study. Safety, tolerability, human pharmacology, dosimetry and NEN targeting properties of the compound tested will be assessed. Comparability of clinical and imaging data collected at imaging centres will be ensured through an established, centralized secured database also providing standardized image analysis protocols and integrated statistical tools.

Results

Within the TECANT project, the preselected ^{99m}Tc-labelled $SSTR_2$-antagonist TECANT-1 was successfully developed into a kit formulation amenable for use in a hospital radiopharmacy setting. Together with the favourable toxicological and promising pharmacological profile, [^{99m}Tc]Tc-TECANT-1 is ready to be advanced into first-in-human multicentre clinical trial (EudraCT no: 2019-003379-20). After receiving positive opinion from the national authorities, the clinical part of the study has been initiated. No clinical side effects were observed after the first [^{99m}Tc]Tc-TECANT-1 application; a very good visualization of NEN metastases was obtained.

Conclusions

The first obtained images with radiolabelled $SSTR_2$-antagonist appear to be of great clinical significance. The 99mTc-labelled $SSTR_2$-antagonist is expected to enable a reliable and widely available method for quantitative assessment of SSTR status and to improve the decision-making diagnostic and therapeutic algorithm as one of the key elements in a personalised approach to the management of NEN patients.

Neuroendocrine tumors (NETs) and carcinomas (NECs) are a heterogeneous group of malignances whose incidence is increasing worldwide. First-line approach is represented by surgery, whereas an effective pharmacological treatment for disseminated and relapsing disease is still needed. Somatostatin (SS) receptors (SSTs) constitute the main suitable pharmacological targets for NETs therapy with SS analogs (SSAs). Nevertheless, a large proportion of NETs and most NECs, are unresponsive or resistant to SSAs and the causes that underline resistance still remain poorly understood, highlighting the need of alternative strategies. Recently, the neuropeptide cortistatin (CST), that shares with SS actions and affinity to SSTs, emerged as an anti-inflammatory player, showing potential antitumoral behavior. The aim of this study was to characterize the SS and CST system in different NETs and NECs cell models. More precisely, the effects of SS/CST and selected analogs were tested on cell proliferation and apoptosis on classical (BON-1, QGP-1) and novel Pan-NETs (NT-18P, NT-18LM) and Pan-NEC (NT-38) cell lines. Our data shows that SSAs exerted limited actions on cell proliferation in novel cell lines. On the other hand, CST treatment induced dose and time-dependent effects: while it caused limited actions in BON-1 and QGP-1 cells, it exerted significative inhibition of cell proliferation, and induced apoptosis in NT-18P, NT-18LM, and NT-38 cells. Interestingly, each model used displayed a unique SSTs expression profile, which may underlie their different response to treatments. Our study provides an initial characterization of novel Pan-NETs and Pan-NECs cell models, more accurately resembling human tumors behavior, in response to various drugs, paving the way for novel original avenues to explore new therapeutical approaches for NETs/NECs treatment.

Medicine, Florence, Italy; [4]University of Florence, Experimental and Clinical Medicine, Florence, Italy

Parathyroid carcinoma (PC) is an extremely rare endocrine malignancy of the parathyroid glands, representing less than 1% of all parathyroid neoplasms. PC is characterized by an excessive secretion of parathyroid hormone (PTH) and severe hypercalcemia. In contrast to parathyroid adenoma, the prognosis for patients with PC is poor, with an overall survival rate of 78-85% and 49-70% respectively at 5 and 10 years after diagnosis, due to the commonly unmanageable hypercalcaemia, which is the cause of death in most cases. There are currently no decisive therapies available for PC. The main treatment for PC remains surgical removal of the tumour gland(s), but persistent, or recurrent post-surgical disease is reported in about 50% of patients. A better understanding of the biology and pathophysiology of PC is necessary to advance is not only too better in distinguishing PC from benign counterpart, but also to develop novel targeted and effective therapies. The principal aim of this research is to establish an *in vitro* model of human primary cell line of PC, to evaluate the presence of cancer stem cells (CSCs), and to isolate and characterize them. We established a primary cell culture of from a primary sporadic PC lesion. Hence, the PC phenotype was evaluated by immunofluorescence staining for PTH, ki67, Desmin, CaSR protein, parafibromin, and by evaluation of PTH release. We evaluated the ability of PC cells to form spherical colonies under non adherent conditions to identify and isolate PC cancer stem cells (PC-CSCs). Cells isolated through this particular assay were then characterized by: 1) immunofluorescence staining for mesenchymal stem cell (MSC) markers, 2) immunofluorescence staining for PTH, ki67, Desmin, CaSR protein, parafibromin, 3) quantitative RT-PCR analyses of gene expression of the embryonic stem cell (ESC) marker genes (i.e., *KLF4*, *POU5F1*, Nanog and *SOX2*) and of the *PTH* gene, and 4) ELISA dosage of the PTH extracellular release. The obtained preliminary results showed that we established a primary human PC cell line and that we isolated, for the first time, a PC-CSCs line, presenting the phenotypic characteristics typical of CSCs and the classical features of parathyroid principal cells, such as CaSR expression and PTH expression and release. Further investigations are ongoing to completely characterized both the primary PC cell line and the PC-CSCs. In conclusion, these established cell models could pave the way to better understand the biology of PC cells, and the basis of parathyroid malignant carcinogenesis and aggressiveness of PCs.

Two cases of paraneoplastic hypoglycemia

Sara Santos, Raquel Calheiros, Joana Oliveira, Pedro Souteiro, Isabel Inácio, Ana P Santos & Isabel Torres
Portuguese Institute of Oncology of Porto, Endocrinology, Porto, Portugal

Introduction
Nonislet cell tumour hypoglycemia (NICTH) is a rare complication of malignancy. The most common cause is overproduction of IGF2, which activates insulin receptors, resulting in hypoinsulinemic hypoglycemia. When a solitary fibrous tumor is responsible, it is called Doege-Potter syndrome.
Case 1
58-year-old woman, with a history of gastrointestinal stromal tumor and pleural solitary fibrous tumor with pulmonary and lymph node metastases. She presented in the ER with altered mental state and hypoglycemia (minimum glucose value of 32mg/dl). Bloodwork showed: glucose 34 (76-115) mg/dl, C peptide 0.294 (1.1-5.0) ng/ml and insulin <0.400 (2.6-24) uUI/ml. The patient was started on therapy with corticosteroids and was later discharged with prednisolone 60mg daily. Further bloodwork showing IGF2 639 (230-970) ng/ml and IGF1 20.3 (63.3-190) ng/ml, with an IGF2/IGF1 ratio of 31.5 (>10) confirmed the diagnosis of Doege-Potter syndrome. The patient improved significantly after treatment with chemotherapy, with progressive tapering of prednisolone.
Case 2
55-year-old man, with a history of diabetes mellitus type 2. He was admitted after he presented in the ER with acute confusional state in the context of hypoglycemia (minimum glucose value of 25mg/dl). Physical examination showed an abdominal mass. An abdominal MR confirmed the presence of an abdominopelvic mass, with 27x13cm, and a biopsy was performed, suggestive of lipossarcoma. Bloodwork showed: glucose 58 (76-115) mg/dl, C peptide 0.10 (1.10 – 4.40) ng/ml, insulin <0.40 (2.6-24.9) U/ml and IGF1 30.1 (67.0-195) ng/ml. Due to a laboratorial mistake, IGF2 was not measured. However, after mass excision, bloodwork showed normal IGF1 [220 (67.0-195) ng/ml], C peptide [2.30 (1.1-5.0) ng/ml] and insulin [8.35 (2.6-24.9) uUI/ml] values, and so IGF2 tumor production was assumed. After surgery, no further hypoglycemia events were detected.
Conclusão
NICTH must be considered, even when IGF2 measurement isn't possible, in the presence of low glucose values and suppressed C peptide/insulin and IGF1 values.

Objective
Carney Complex (CNC) is a rare hereditary genetic syndrome, mostly due to inactivating pathogenic variants of the tumor suppressor gene *PRKAR1A*. It has a wide spectrum of manifestations with frequent pigmented skin lesions, cardiac myxomas, primary pigmented nodular adrenocortical dysplasia, acromegaly and thyroid cancers. Breast benign tumors (fibroadenomas, ductal adenomas and myxoid lesions) have been associated with CNC, but so far, association with malignancy has not been investigated.
Methods
The present study was designed to describe the characteristics of breast tumors diagnosed in CNC patients and their association with other manifestations of CNC and *PRKAR1A* genotype. Since breast cancer is the most frequent cancer in women, malignant breast lesions were carefully analyzed. This cohort comes from a 3 years' follow-up multicenter French prospective study of CNC patients (Espiard, JCEM 2020). The 50 included women were investigated for CNC manifestations and particularly breast tumors, with breast echography, genetic and hormonal investigations, in order to characterize them and assess the frequency and average age of breast cancer.
Results
Among the 38 women with breast imaging, 14 had breast tumors (50% bilateral). Ten women (20%) presented with benign tumors. Six women presented (12%) with breast carcinomas: five had invasive cancer under 50 years of age (4 ductal adenocarcinomas and one solid intracystic papillary carcinoma) and one had ductal carcinoma *in situ.* The occurrence of breast cancer was more frequent in the CNC women with *PRKAR1A* pathogenic variants than in the general population (OR = 6.2[1.58-17.31]; $P = 0.006$). The mean age at breast cancer diagnosis was 44.7 years old, 17 years younger than in the general population. Cumulative risk of developing breast cancer in our cohort was higher if compared to French women under 40 (OR = 30.25[6.06-93.06]; $P = 1{,}67^{-4}$) or 50 years old (OR = 116,90[19,14-1246,78]; $P = 8{,}17^{-8}$). Breast cancer had good prognosis factors: 5 out of 6 tumors were T1N0M0. One woman had metastatic breast cancer, alive after 15 years follow up. All breast cancers were negative for HER2, with positivity for estrogen receptor(100%) and progesterone receptor(50%). They all occurred in individuals with familial CNC and *PRKAR1A* pathogenic variants. Loss of heterozygosity at the *PRKAR1A* locus observed in 2 investigated breast carcinomas tissues suggests that *PRKAR1A* bi-allelic inactivation could promote breast cancer development.
Conclusions
Breast carcinoma occurs frequently and prematurely in women with CNC, suggesting that CNC predisposes to breast carcinoma. This suggests that adequate screening strategy (starting around 40 years old) and follow up should be discussed in CNC women.

Revealing the anti-cancer region within KL1 subunit of the hormone klotho

Marana Abboud[1,2], Keren Merenbakh-Lamin[1], Shira Ben-neriah[1], tami rubinek[1,2] & Ido Wolf[1,2]

[1]Tel Aviv Sourasky Medical Center - Ichilov, Oncology, Tel Aviv-Yafo, Israel; [2]Tel Aviv University, Sackler Faculty of Medicine, Tel Aviv-Yafo, Israel

Background
Klotho is a 1012 amino acids transmembrane protein, composed of two internal repeats, KL1 and KL2, that can be cleaved, shed and act as a circulating hormone. Klotho regulates several pathways, including fibroblast growth factor 23 (FGF23), Wnt-β/catenin and the cation channels TRPV and TRPC. Our group and other labs identified klotho as a potent tumor suppressor in breast and pancreatic cancers and that KL1 domain is responsible for this activity. Yet, the mechanism mediating this activity remains unresolved.
Aim
Reveal the role of C-terminal and N-terminal parts within KL1 and understand their association to the tumor suppressor activity.
Methods
Expression vectors of truncated KL1 included C-terminal truncations: KL340, KL320, and N-terminal truncation: KL88-340. We assessed their anti-cancer activity or regulation of the Wnt-β/catenin pathway by colony formation assay and co-expression in cancer cells. We used MCF-7, MDA-MB-231, PANC1, MIAPaca-2, HCT116. We then performed RNA seq analysis on MCF7 cells over-expressing either KL1 or one of the C-terminal truncated KL340, KL320 to decipher global transcriptome differences.
Results
Over expression of C-terminal truncated protein KL340 inhibited colony formation, unlike KL320 in pancreatic and colon cancer. In breast cancer KL340 partially inhibited colony formation. N-terminal truncated proteins lost the ability to inhibit colony formation. Investigation of the Wnt-β/catenin signaling showed that only KL1 and KL340 decreased the levels of wnt3a in all cancer cell lines. Gene expression profile in MCF7 cells overexpressing KL1 and KL340 reflected their tumor suppressor activity.
Conclusions
This study reveals that klotho's anti-cancer effect may be mediated by an N-terminal sequence. KL340 is the shortest truncation that retains the significant tumor suppressor activity of KL1. KL340 and KL1 induce a wide systemic transcriptome change in breast cancer, affecting cell survival. The structural features of the protein gained by the N-terminus remains questionable. Moreover, the 20 amino acids missing in KL320 compared to KL340 are critical for the tumor suppressor function and require further investigation.

Vision-related Quality of Life in Patients with Childhood-onset craniopharyngioma – Results of HIT-Endo and KRANIOPHARYN-GEOM 2000/2007

Panjarat Sowithayasakul[1,2], Svenja Boekhoff[1], Julia Beckhaus[1], Carsten Friedrich[1] & Hermann Müller[1]
[1]Klinikum Oldenburg AöR, Oldenburg, Germany; [2]Srinakharinwirot University, Thailand

Background
Quality of life (QoL) has become a critical component of therapeutic outcomes in the survivors of childhood-onset craniopharyngioma (CP). Visual deficiency adversely affects daily functioning and QoL in childhood CP. This cohort study aimed to report the vision-related QoL in CP patients.
Methods
120 patients with CP were included in this study and prospectively observed. The primary outcome measure was pediatric QoL (PEDQOL score) in patients with and without visual impairment from presentation at the time of CP diagnosis to three-year follow-up. Potential risk factors associated with visual impairment were analyzed using multivariable logistic regression.
Results
The most common presenting symptoms at the time of CP diagnosis were headache (42%), visual impairment (20%), and growth retardation (12%). Visual impairment was found in 87 patients (70%). Ophthalmologic examination and PEDQOL scores, which were grouped into seven domains: physical functioning, cognition, social functioning friends, social functioning family, and body image, were evaluated at the third month, first-year, and third-year after diagnosis. Parents of children with visual impairment report worse social functioning in their families than parents of children without visual impairment, one ($P=0.017$) and three years ($P=0.011$) after diagnosis. After three years, children with visual impairment were found to have worse quality of life in the autonomy domain of self- ($P=0.029$) and parental assessment ($P=0.048$). High tumor volume (>21 cm^3), radiation therapy and extrasellar tumor location were identified as potential risk factors for visual impairment.
Conclusions
We conclude that visual impairment has a negative impact on QoL after CP. Early detection of visual impairment, regular QoL assessment, and risk-appropriate follow-up care are recommended.

High diagnostic yield of multigene panel testing in patients with endocrine tumors

Henriett Butz[1,2,3,4], Petra Nagy[1,5], János Papp[1,5], Anikó Bozsik[1,6], Vince Grolmusz[1,5], Tímea Pócza[1,3] & Attila Patócs[4]
[1]National Institute of Oncology, Department of Molecular Genetics and the National Tumor Biology Laboratory, Budapest, Hungary; [2]National Institute of Oncology, Department of Oncology Biobank, Budapest, Hungary; [3]Eötvös Loránd Research Network, Hereditary Tumours Research Group, Budapest, Hungary; [4]Semmelweis University, Department of Laboratory Medicine, Budapest, Hungary; [3]Eötvös Loránd Research Network, Hereditary Tumours Research Group, Budapest, Hungary; [6]Eötvös Loránd Research Network, Hereditary Tumours Research Group

Hereditary genetic variants are common among patients with endocrine tumours. Some specific clinical conditions are informative for certain monogenic syndromes (i.e., Carney complex, MEN1, MEN2, von Hippel Lindau syndrome) but manifestations characteristic for these syndromes occur more commonly as apparently sporadic. Other tumours, i.e., pheochromocytoma/paragangliomas (PPGL) are linked to multiple genes, hence a multigene approach in molecular genetic testing strategy is recommended. As a national reference centre for molecular genetic testing of patients with hereditary cancer, we prospectively tested a multigene panel's diagnostic utility which covers 113 genes associated with various tumours. The most common genes responsible for hereditary endocrine tumours are also included in this panel. Between October 2021 and December 2022, we analysed 97 patients as part of their routine clinical and molecular genetic diagnostic workup. All pathogenic/likely pathogenic variants with unknown significance were validated from a second DNA sample using gold-standard Sanger sequencing or multiplex ligation-dependent probe amplification. Patients with primary hyperparathyroidism, gastro-pancreatic neuroendocrine tumours, pheochromocytoma, paraganglioma, adrenocortical cancer, medullary thyroid cancer, neurofibromatosis, etc. were referred for testing. Of 97 patients, in 24 cases the relevant P/lP variants were identified (24/97; 25%). Of these, the most common variants were detected in *MEN1, SDHx*, and *NF1* genes. In 8 cases secondary findings were reported in *BRCA2, ATM, CHEK2, MSH6* and *NF1* genes (8/96; 8%). Our data show that using a comprehensive multigene panel as a routine diagnostic tool for testing patients with endocrine tumours yields a high diagnostic benefit in a short turnaround time. Incidentally identified variants may serve as a potential therapeutic target (such as *BRCA2* or *MSH6*) in tumours where therapeutic possibilities are limited (i.e., adrenocortical cancer).

Mutational profiles of typical and atypical bronchial carcinoids

Irene Gagliardi, Patricia Borges de Souza, Lucrezia Rossi, Maria Rosaria Ambrosio & Maria Chiara Zatelli
University of Ferrara, Department of Medical Sciences, Ferrara, Italy

Introduction
Typical and Atypical bronchial carcinoids (TBC and ABC) are rare neuroendocrine neoplasms (NEN). TBC are low grade and well-differentiated NEN often with indolent clinical behavior, slow growth, rare extra-thoracic metastases, and with a long survival following surgical resection. Conversely, ABC have often a worse prognosis with a greater tendency to metastasize and recur. A better understanding of TBC and ABC genetic background would help in evaluating prognosis, especially in advanced BC resistant to treatment.
Aim
Investigate by whole-genome sequencing the mutational profile in TBC vs. ABC using a multigenic panel previously employed in pancreatic NEN.
Materials and methods
Genomic DNA was isolated from 25 TBC and 13 ABCs frozen samples. 11 genes (MEN1, DAXX, ATRX, MUTYH, SETD2, DEPDC5, TSC2, ARID1A, CHECK2, MTOR, PTEN) were sequenced by Next Generation Sequencing (NGS).
Results
TBC more frequently presented alterations vs. ABC in TSC2, ARID1A and DEPDC5 genes (OR 5.4, 3.7 and 3.7, respectively). Specifically, 32% of TBC

samples showed alterations in the DUF3384 domain of TSC2 gene, 24% in ARID1A and/or DEPDC5 genes. TSC2, ARID1A and DEPDC5 were altered in 8% of ABC samples, respectively.
Conclusions
The present study suggests that TBC are more frequently mutated in TSC2, ARID1A and DEPDC5 genes as compared to ABC. Interestingly, preliminary studies indicate that TGF-B and mTOR crosstalk might contribute to resistance to everolimus (an mTOR inhibitor) in advanced TBC, which might be explained by altered TSC2 gene (involved in mTOR signalling) in our study. In light of these findings, further studies with larger and balanced groups are needed to confirm these observations and to investigate the clinical significance of these mutations in TBC and ABC, as well as to explore the potential therapeutic implications of targeting TSC2 and other genes identified in our study in TBC and ABC.

A rare cause of bilateral adrenal masses

Sara Santos, Raquel Calheiros, Pedro Souteiro, Joana Oliveira, Isabel Inácio, Ana P Santos & Isabel Torres
Portuguese Institute of Oncology of Porto, Endocrinology, Porto, Portugal

Introduction
Bilateral adrenal masses may appear in the context of metastatic disease, adrenal congenital hyperplasia, primary tumors or infections, among others. Primary adrenal lymphoma is rare, accounting for approximately 1% of cases of non-Hodgkin lymphoma.
Clinical case
47-year-old woman, with a history of *erythema nodosum* and left hemithyroidectomy in the context of benign nodular disease. She presented with persistent fever and tiredness. An abdominal ultrasound showed bilateral adrenal nodular lesions. An abdominal CT confirmed the presence of bilateral adrenal masses, the one on the right with 129x63mm and the one the left with 113x63mm, with relative and absolute washouts of 16% and 40%, respectively. Suspicious retroperitoneal adenopathies were also present. The patient presented no signs or symptoms suggestive of pheochromocytoma, hypercortisolism or hyperandrogenism and physical examination showed cutaneous hyperpigmentation. Bloodwork revealed: ACTH 1964 (7.2-63.3) pg/ml, plasma cortisol 6.03 (5.0-25.0) ug/dl, immeasurable levels of testosterone and estradiol, DHEA-S 3.16 (35-256) ug/dl, and normal urinary metanephrines and 17-OH progesterone. She started therapy with 20mg of hydrocortisone daily. In order to study the possibility of adrenal metastasis of a primary occult tumor, an 18F-FDP-PET/CT was performed, that showed bilateral malignant involvement of the adrenal glands as well as pelvic and axillary lymph node metastasis. Given the absence of a primary occult tumor and hormonal hypersecretion, and taking into account the rarity of bilateral adrenal carcinomas, primary adrenal lymphoma presented as a possible diagnosis. Additional bloodwork showed elevated β2-microglobulin [6.03 (<3) ug/dl], LDH [421 (67-248) U/l] and ferritin [293 (10-120) ug/l]. A left adrenal biopsy confirmed the diagnosis of large cell diffuse B lymphoma. The patient was started on chemotherapy, with significant improvement.
Conclusions
Although rare, adrenal lymphoma, whether primary or secondary, must be thought of as a possible diagnosis in the presence of bilateral adrenal masses with suspicious characteristics on imaging studies. Clinical and analytical evaluation is essential.

P666

A rare case of immunotherapy related adrenalitis

Shawg Ganawa, Chiedza Mashamba, Waqas Ilyas, Claire Higham, Tim Cooksley, Jan Hoong Ho, Safwaan Adam & Shaishav Dhage
The Christie NHS Foundation Trust, Endocrinology, Manchester, United Kingdom

Introduction
Immunotherapy has transformed the outcomes of various cancers. Monoclonal antibodies against cytotoxic T lymphocyte antigen 4 (CTLA4), programmed cell death 1 (PD1) and its ligand, PDL1 target mainly T cells, unleashing the immune system against tumour cells. Immune checkpoint inhibitor therapy results in a variety of immune related adverse events, including various endocrinopathies. Thyroid disorders, pituitary disorders are relatively more common compared to primary adrenal insufficiency and diabetes mellitus. Immune therapy related primary adrenal insufficiency is rare and can present acutely. Its incidence ranges from 1 to 2 % with monotherapy to 5 to 8 % with combination regimens. Presenting symptoms are usually like secondary adrenal insufficiency or can be completely nonspecific. We present a rare case of primary adrenal insufficiency caused by combination immunotherapy.
Case Presentation
A 72-year-old male with a history of hypertension, Type 2 Diabetes and Atrial fibrillation was treated with combination ipilimumab and nivolumab for metastatic melanoma. Following the second cycle, he developed immune-checkpoint inhibitor (ICPi) induced dermatitis which was treated with high dose glucocorticoids (which were subsequently weaned off) and ICPi treatment was held for 2 months. Following cycle 3, the patient developed acute kidney injury which improved with oral glucocorticoid but there was persistent hyperkalaemia which was disproportionate to the creatinine. The patient's cortisol was unremarkable [444 nmol/l] and due to the ongoing hyperkalaemia, he was commenced on mycophenolate mofetil. He was also treated with sodium zirconium and sodium bicarbonate for the ongoing hyperkalaemia. As an investigative screen renin 19.5 nmol/l(0.3-2.2), aldosterone <50 pmol/l(0-630), sodium (130 mmol/l) and potassium (7.1 mmol/l) were in keeping with hyper-reninaemic hypoaldosteronism. His urea (10 mmol/l), creatinine (117 umol/l) were disproportionate to the electrolyte imbalance, but he maintained satisfactory random cortisol readings of 314 nmol/l. Treated with fludrocortisone which resulted in normalisation of the potassium. Two months later he had further screening bloods and his cortisol was undetectable. He was referred to endocrinology where hydrocortisone was added to his therapy. His ACTH was markedly raised at a value of 1009 ng/l (0-46) in keeping with ICPi-induced adrenalitis and Adrenal antibodies were negative. In retrospect, it was felt that his mineralocorticoid deficiency preceded the glucocorticoid deficiency by at least 2 months representing an earlier presentation of adrenalitis. Clinicians should be aware of the possibility of ICPi-induced adrenalitis in patients who present with refractory hyperkalaemia and hyponatraemia, even in the setting of a normal cortisol measurement.

Introduction
Paragangliomas and pheochromocytomas (PGGs) are infrequent tumors of the autonomic nervous system that represent a diagnostic and therapeutic challenge. Management and follow-up of PGGs requires specialized knowledge and solid experience, which, given the rarity of these diseases, is available only in highly specialized centers. University Hospital La Fe (Spain) was designated a reference unit on Neuroendocrine Tumors by local sanitary authorities in 2018. The aim of this study is to describe multidisciplinary management of PGGs in our center from Nov 2021-Nov 2022.
Material and Methods
Descriptive and unicentric study that includes 173 patients with PGG evaluated at Hospital Universitari i Politècnic La Fe in Valencia, Spain.
Results
173 patients have been evaluated (27 pediatric age) during the period november 2021-2022, 27 of them in a first evaluation. Mean adult age at visit 45.6 years (SD). 66% ($n=114$) of the totality of patients were known germline mutation carriers: 28% MEN 2A, 22% SDHD, 27% SDHB, 3.5% SDHA, 1.7% SDHC, 9.7% VHL, 2.6% FH, 3.5% MEN 2B, MAX 0,5% and 1.7% NF1. 43 (24.8%) were mutation carriers non-affected and 14 (8%) had metastatic disease. During this year all of the patients have been followed in the Endocrinology department (adult or pediatrics), 48%($n=83$) of the patients have required follow-up from more than one speciality. Patients have required evaluation during this year by the following specialists: Oncology 14 (8%), Endocrine Surgery 10 (7.5%), Pediatric Surgery 2 (1.1%), Head-neck surgeon 44 (25.4%), Radiotherapy 16 (9.2%). A

new diagnosis of PGG tumor was made in 26 patients. All patients have performed urine catecholamine and metanephrine analyses, and 17% were functioning tumors. Imaging tools have included: 27 total body MRI, 30 head-neck MRI, 18 abdominal MRI, 60 PET/CT 68Ga-DOTATOC, 11 123-I-MIBG, 3 PET/CT 18F-DOPA, 56 PET/CT 18F-FDG. Surgical procedures during this period included: 10 adrenalectomies, 8 head and neck surgeries, 1 complex peritoneal surgery of PGG implants. 9 patients required presurgical medication with alpha and beta blockade. Nuclear medicine treatment included: 5 I131-MIBG and 3 Lu-DOTA-TATE. Other treatments include: 4 radiotherapy, 2 chemotherapy and 10 others.

Conclusions

All patients with PGG must be followed by the Endocrinology department following current clinical guidelines. Patients with PGG often require evaluation by more than one specialist and require multidisciplinary management in highly specialized centers which offer surgical, medical and imaging technique expertise.

MEN1 and Liposarcomas: Report of three cases

Bélyne ISHIMWE[1], GOUDET Pierre[2] & Bruno Verges[1]
[1]University Hospital F.mitterand Dijon-Bourgogne, Endocrinology Department, Dijon, France; [2]University Hospital F.mitterand Dijon-Bourgogne, Surgery Department, Dijon, France

Introduction

Multiple endocrine neoplasia type 1 is a rare inherited tumor syndrome defined most frequently by the association of primary hyperparathyroidism, gastro-entero-pancreatic tract endocrine neoplasia and anterior pituitary gland adenoma and less commonly by neuroendocrine tumor of the adrenal cortex, thymus and bronchis. Association to non-endocrine tumors affecting the skin, glial cell, smooth muscle or breast cancer has been described. As far as we know, only one case of liposarcoma associated with MEN1 has been reported. Herein, we report data from the French MEN-1 Register showing 3 cases of liposarcoma.

Case 1

Male patient born in 1973.

-Personal medical history:Removal of a cervical lipoma.

-2001:Surgery for a **well differentiated liposarcoma** of the left hip that was growing gradually for years.

-2007:Genetic diagnosis of **MEN1** (Father with MEN1).

-2015:Subtotal parathyroidectomy after a **primary hyperparathyroidism** known since 2007.

The histological analysis found an aspect of hyperplasia with predominance of clear cells and presence of oncocytic foci, no suggestive sign of malignancy.

-2014:Ulcerative duodenitis due to **Zollinger-Ellison Syndrom**.

-2016:Right middle lobectomy for a **very well-differentiated neuroendocrine carcinoma**. Immunohistochmistry testing:Synaptophysin+, Chromogramine A+, TTF1-, Ki67<3%.

-No new tumor(pancreatic, pituitary, etc) at the last follow-up.

Case 2

Male patient born in 1937.

-Family history of MEN1.

-2005: **Primary hyperparathyroidism** treated by Subtotal parathyroidectomy(-hyperplasia), removal of the fat tissue surrounding the left thymic horn and right thyroid lobectomy. **Confirmation of MEN1 germline mutation**.

-No MRI was performed because of claustrophobia. Normal pituitary gland function.

-August 2011:Weight loss and asthenia revealing a 16cm **well differentiated retroperitoneal liposarcoma** after a distal pancreatectomy, a splenectomy and a splenic flexure colectomy was performed. Discovery at the same time of a **pancreatic well-differentiate endocrine tumor** and a stomach stromal tumor.

-July2012:Local and regional recurrence(lung, pleura, liver).

Case 3

Female patient born in 1944 carrying a **MEN1 mutation**.

-1990: **Primary hyperparathyroidism** initially treated by a resection of the two lower parathyroid in 1990 then by a complete parathyroidectomy(Hyperplasia) followed by a parathyroid gland reimplantation on the left arm in 1994.

-2004:Distal spleno-pancreatectomy(**Well-differentiated pancreatic neuro-endocrine tumor**) and left adrenalectomy(Hyperplasia).

-2010:Discovery of lower-grade astrocytoma. Unremarkable pituitary MRI.

-2012:Quick appearance in 3 weeks of a tumor on the rooth of the left thigh. The biopsy showed an **undifferentiated pleomorphic liposarcoma** stage II.

Conclusion

These 3 cases from the French MEN-1 Register(1570 cases) show that liposarcoma is not rare within MEN1 population compared to the general population (1/100000 person/year). Thus the association of the two entities may not be fortuitous. Further research is warranted and more cases are needed to establish that liposarcoma might be a new tumor type in patients with MEN1.

Clinical findings, treatment modality and outcomes of adrenocortical carcinoma: a retrospective review of single tertiary center experience

Alev Selek, Damla Köksalan, Mehmet Sözen, Emre Gezer, Özlem Alkan, Zeynep Cantürk & Berrin Cetinarslan
Kocaeli University, Endocrinology, Kocaeli, Turkey

Background & Aim

Adrenocortical carcinoma (ACC) is an extremely rare malignancy usually with poor outcomes, although the prognosis varies greatly depending on the initial tumor stage. Here we present clinical and outcome diversity of the patients in a single center.

Methods

We retrospectively analyzed 16 patients with ACC diagnosed between 2000 and 2022. Demographical findings, hormonal status, radiological findings, ENSAT stage, weiss score and Ki67 levels, multidisciplinary treatment modalities and prognostic outcomes were evaluated.

Results

There were 8 (50%) women and men with a mean age of 56 (±12) years. Mean follow-up was 88 (±66) months, 11 (69%) patients were still alive without any metastasis and local recurrence. 5 patients died during follow-up, 4 of them were due to disease progression however one patient with complete remission were died due to myocardial infarction. Disease specific mortality was 25% with a mean survival of 69 months of these four patients. 25% of the patients were hormonally active predominantly hypercortisolism. The mean tumor size was 93.5±56.8 mm (range, 30-250 mm), 3 (18%) patients had local invasion and 3(18%) patients had distant metastasis including thorax, bone and liver metastasis. 16 patients (94%) underwent surgery, 5 of them had laparoscopic adrenalectomy, 2 patients had also metastasectomy and lymphnode dissection. Postoperative pathology revealed 4 (25%) oncocytic, 2 (12,5%) sarcomatoid, 2 (12,5%) mixoid and 8 (50%) clasiccal subtype ACC. 4 (25%) patients had venous and 12 (75%) had capsule invasion, mean Ki 67 score was 16 (range,2-90). According to ENSAT staging, two (12,5%) patients were stage 1, nine (56%) patients were stage 2, one was stage 3 and four (25%) were stage 4 disease. Six patients had adjuvant mitotane treatment and two patients had mitotane and EDP treatment. 2 of 6 patients on mitotane treatment had disease progression and added on EDP treatment. 2/6 patients were still on adjuvant mitotane and remaining 2/6 had remission and treatment stopped. All patients had drug toxicities in variable levels, majority of them were mild GIS symptoms and liver function test alterations, however one patient had moderate dermatological toxicity and one had neurologic toxicity necessitating dose decrement but recovered without any sequelae.

Conclusion

ACC has wide range of clinical course; therefore ACC management has to be patient specific. Mitotane is an effective treatment in properly selected patients and may be a curative treatment. Careful monitoring is mandatory to achieve disease control.

Incidental Metastases of Medullary Thyroid Carcinoma in a Patient with Multiple Endocrine Neoplasia Type

GEMA GARCIA ROMERO DE TEJADA[1], Virginia Martín Borge[1], Sharona Azriel[1], Sagrario García Sánchez[2], Irene Ortega Vazquez[3], Ana Jiménez Gordo[4], Antonio Picardo[3] & José Antonio Balsa Barro[1]
[1]Infanta Sofia University Hospital, Endocrinology, San Sebastián de los Reyes, Spain; [2]Infanta Sofia University Hospital, Pathology, San Sebastián de los Reyes, Spain; [3]Infanta Sofia University Hospital, Surgery, San Sebastián de los Reyes, Spain; [4]Infanta Sofia University Hospital, Oncology, San Sebastián de los Reyes, Spain

Introduction

Multiple endocrine neoplasia type 1 (MEN1) is a rare hereditary tumour syndrome inherited in an autosomal dominant manner and characterized by a predisposition to a multitude of endocrine neoplasms primarily of parathyroid, enteropancreatic, and anterior pituitary origin, as well as nonendocrine neoplasms. However, thyroid cancer is not part of this syndrome.

Case details
We report the case of a 36-year-old man diagnosed with primary hyperparathyroidism after being referred for mild asymptomatic hypercalcemia. Genetic testing for MEN1, CDKN1B, CDC73 and CASR were requested and an heterozygous variant c.415C>T (p.His139Tyr) classified as pathogenic variant of MEN1 in ClinVar database was detected. The patient underwent subtotal parathyroidectomy and removal of the entire thyrothymic space. The pathology report confirmed three parathyroid glands compatible with hyperplasia and thymic remains. In addition, two of the three incidentally excised nodes were reported as microscopic metastases from medullary thyroid cancer (MTC) based on their morphologic and immunohistochemical profile (positive for CKPan and calcitonin). Serum chromogranin A and calcitonin were normal. After confirming that 24-h urine catecholamines and metanephrines were normal, total thyroidectomy and prophylactic central-compartment neck dissection were performed. The pathology study showed focal parafollicular cell hyperplasia without histological findings of malignancy and ruled out additional nodal metastasis. An additional molecular genetic study of the RET proto-oncogene ruled out germline mutations. Thoracoabdominal CT and hepatic MRI showed new findings of MEN1 related-conditions such as numerous millimetric hypervascular pancreatic nodules in head, body and tail, as well as one adrenal lesion of 16x15 cm with radiological characteristics of adenoma. A 68Ga-DOTATOC PET was ordered and pancreatic foci of pathological overexpression of somatostatin receptors were confirmed, but no other foci suggestive of possible metastasis from MTC. Additional hormonal studies ruled out secretory activity of both pancreatic and adrenal lesions, and a pituitary MRI was normal.
Conclusions
To best of knowledge this is the first case reported in the literature of a patient with MEN1 who has been affected by a concomitant MTC.

Assessment of oxidative stress, neurotoxicity, genotoxicity and prey-predator interactions in freshwater snails exposed to microplastics

Dipak Sapkale & Sangeeta Pandit
Savitribai Phule Pune University, Department of Zoology, Pune, India

Microplastics are one of the major pollutants over the globe jeopardising the health of aquatic life. The ecotoxicological effects of microplastics are well investigated in marine organisms, however, their impact on freshwater ecosystem remain unnoticed. Gastropod molluscs serve as good bioindicators for environmental toxicology. Therefore, we studied two commonly found freshwater snails, *Lymnaea acuminata* and *Indoplanorbis exustus* and checked the effect of microplastics obtained from 3 polymers; polypropylene, polystyrene and polyvinyl chloride. The aim of our study was to prepare microplastics, their characterization and to examine the oxidative damage caused by them. Also, the neurotoxicity and genotoxicity caused due to microplastics were assessed. The behavioural assay was performed to scrutinize the predator-prey interactions. Lipid peroxidation levels, catalase activity and superoxide dismutase activity were elevated in the intestine and ovotestis after microplastic exposure. It was found that, polypropylene caused less oxidative damage than polystyrene, while, highest damage was caused by polyvinyl chloride. Acetylcholinesterase (AChE) inhibition and DNA damage was maximum in polyvinyl chloride exposure as compared to polypropylene and polystyrene. Variations in the antioxidant enzyme level, acetylcholinesterase activities and DNA damage are indicative of oxidative stress, neurotoxicity and genotoxicity in snails. Microplastic exposure also disrupted their ability to detect the presence of predator in their surroundings. Physiological and behavioural parameters of these organisms can reveal the consequences of environmental toxicity.

Thyroid cancer diagnostics related to occupational and environmental risk factors: an integrated risk assessment approach

Cozma Andreea[1], Socaciu Andreea-Iulia[2], Socaciu Mihai Adrian[3], Petre Gabriel Emil[4], Berinde Gabriela Maria[5], Rajnoveanu Armand Gabriel[5] & Piciu Doina[6]
[1]Medisyn Medical Clinic, Endocrinology, Cluj-Napoca, Romania; [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, Occupational Health, Cluj-Napoca, Romania; [3]"Iuliu Hatieganu" University of Medicine and Pharmacy, Radiology and Imaging, Cluj-Napoca, Romania; [4]"Iuliu Hatieganu" University of Medicine and Pharmacy, Surgery, Cluj-Napoca, Romania; [2]"Iuliu Hatieganu" University of Medicine and Pharmacy, Occupational Health, Cluj-Napoca, Romania; [6]"Iuliu Hatieganu" University of Medicine and Pharmacy, Doctoral School, Cluj-Napoca, Romania

There are still many questions remaining about the etiopathogenesis of thyroid cancer, themost common type of endocrine neoplasia. Numerous occupational and environmental exposureshave been shown to represent important risk factors that increase its incidence. Updated informationabout thyroid cancer diagnostics related to occupational and environmental risk factors is reviewedhere, considering an integrated risk assessment approach; new data concerning thyroid canceretiology and pathogenesis mechanisms, diagnostic biomarkers and methodologies, and risk factorsinvolved in its pathogenesis are presented. A special emphasis is dedicated to specific occupationalrisk factors and to the association between environmental risk agents and thyroid cancer development.The occupational environment is taken into consideration, i.e., the current workplace and previousjobs, as well as data regarding risk factors, e.g., age, gender, family history, lifestyle, use of chemicals,or radiation exposure outside the workplace. Finally, an integrative approach is presented, underlyingthe need for an accurate Risk Assessment Matrix based on a systematic questionnaire. We proposea complex experimental design that contains different inclusion and exclusion criteria for patientgroups, detailed working protocols for achieving coherent and sustainable, well-defined researchstages from sample collection to the identification of biomarkers, with correlations between specificoncometabolites integrated into the Risk Assessment Matrix.

Tributyltin exposure during gestation and lactation changes the hormone profile of the offspring in a sex- and age-dependent manner

Egberto Gaspar de Moura, Patricia Cristina Lisboa & Rosiane Aparecida Miranda
State University of Rio de Janeiro, Physiology, Rio de Janeiro, Brazil

The ingestion of marine foods is a potential route of contamination by tributyltin (TBT), a biocide organotin used as an antifouling in boat paints. TBT causes a phenomenon known as imposex, that induces, for instance, the irreversible appearance of male sexual characteristics in gastropod females. In mammals, TBT also directly impairs the sexual development. In fact, it is known that TBT can affect women in reproductive age. Our aim was to study whether the maternal exposure to TBT, in a high dose, during pregnancy and lactation can cause long-term hormonal dysfunctions in male and female offspring. Experimental design was approved by the Ethics Committee (protocol: CEUA/010/2019). Wistar rats were mated and after pregnancy detection, females were randomly separated into 2 groups: dams received vehicle (0.1% ethanol; Control group) or TBT (1000 ng/kg of body weight, bw). Exposure occured from the 7th gestational day until the end of lactation (21 days of lactation period) by gavage. We evaluated plasma hormones of male and female offspring at puberty (45 days old) and adulthood (180 days old) by enzyme-linked immunosorbent assay (ELISA). Data were analyzed by Student's t test ($n=7$/group). During puberty, male TBT offspring showed a significant reduction of plasma follicle stimulating hormone (FSH) (-42%), luteinizing hormone (LH) (-51%), testosterone (-70%), estradiol (-39%), insulin (-30%) and corticosterone (-78%) levels. No differences were observed in plasma thyroid-stimulating hormone (TSH), thyroxine (T4), triiodothyronine (T3) and leptin. Female TBT offspring presented increase in plasma testosterone and reduction of corticosterone levels (2-fold and -43%, respectively), without changes of other hormones. On the other hand, at adulthood, TBT males displayed higher plasma T3 (2.7-fold), insulin (1.8-fold), corticosterone (3.8-fold) and leptin (+56%) levels when compared to control ones. Adult TBT females only displayed lower plasma corticosterone level (-45%). Taken togheter our data indicate that perinatal exposure to TBT causes endocrine dysfunctions during puberty period and adult life. Interestingly, in this model we evidence a sex dimorphism, since male offspring seem to be more affected than females.

Endocrine disrupting chemicals and thyroid hormone patterns during gestational periods: a systematic review approach

Isabel Forner, Asma Baig & Andreas Kortenkamp
Centre for Pollution Research and Policy, Department of Life Sciences, College of Health, Medicine and Life Sciences, Brunel University London, Uxbridge, United Kingdom

The Hypothalamic Pituitary Thyroid (HPT) axis is well-known as a classic endocrine negative feedback loop: increased levels of thyroxine (T4) in the blood are associated with a reduction of thyroid stimulating hormone (TSH) production and vice versa. However, the thyroid hormone (TH) system is sensitive to alterations by a number of endocrine disrupting chemicals (EDCs). Intriguingly, exposure to specific EDCs can decrease the levels of T4 but this might be not followed by the expected increase of TSH. The reasons for such patterns are still unclear. The aim of the present evidence mapping was to obtain a comprehensive picture of T4/TSH patterns evoked by EDC exposures in rodent models. We conducted an extensive systematic literature search of peer-reviewed articles in which we collected studies that met the following criteria: experimental data (T4, TSH) for rodent models (pups and/or dams) exposed during perinatal periods through the diet to different chemical doses. Our results show that the idealized view of the HPT axis is not supported by the evidence when EDCs are involved. When administered during gestation, some EDCs induced reductions of T4 serum levels in pups followed by increased TSH levels. These chemicals often disrupted the synthesis of THs and the hepatic metabolism. However, with others, the expected TSH increase did not materialise, and these chemicals often interfered with the removal of T4 via up-regulated conjugating enzyme systems in the liver.

Maternal caffeine intake at low doses causes hormonal and metabolic changes in the offspring in a sex-dependent manner

Patricia Cristina Lisboa, Luana Lopes de Souza, Rosiane Aparecida Miranda & Egberto Gaspar de Moura
State University of Rio de Janeiro, Physiology, Brazil

Caffeine crosses the placenta and mammary barrier and can affect the offspring metabolism and endocrine system from heavy caffeine users. Here, we tested the impact of a safe dose of maternal caffeine (200-300 mg/day) on plasma hormone of offspring from both sexes at different ages (weaning, puberty and adulthood). For this, pregnant Wistar rats received caffeine (25mg/kg/day) by gavage or vehicle during gestation (GEST group), lactation (LACT group) or both periods (G + L group). Litters were adjusted to 8 pups per dam. Biometric parameters were recorded in dams and offspring. Milk was collected at weaning. Oral glucose tolerance test (OGTT) was performed in offspring at postnatal (PN) days 45 and 180; hormones were measured at PN21 and PN180 by ELISA. Data were analyzed using one way ANOVA followed by the Newman-Keuls post-test (Ethical committee 26/2019). At delivery, dams of GEST and G + L groups showed lower food intake and body weight (-18% and -12%; respectively, $P < 0.05$). At the end of lactation, all dams' caffeine groups had no change of leptin and insulin in plasma and milk; showed lower plasma total T3 (GEST = -70%, LACT = -52% and G + L = -56%; $P < 0.05$), although no differences of free T4 and TSH. Regarding the offspring at birth, only GEST and G + L females showed lower body weight (-6%; $P < 0.05$). At weaning, all males' caffeine groups showed lower T3 (G = -75%, LACT = -80% and G + L = -58%; $P < 0.05$), without changes of T4 or TSH, while females had no changes of these hormones. At weaning, G + L females presented hyperinsulinemia (+100%; $P < 0.05$) despite normoglycemia. From weaning until adult life, GEST and G + L females showed lower body weight (-6%; $P < 0.05$), whereas GEST and LACT males had higher body weight (+6%; $P < 0.05$). At puberty, only LACT females showed hyperglycemia at 30 and 120 minutes after glucose overload, characterizing a glucose intolerance. At adulthood, GEST and LACT females displayed glucose intolerance. Males had no differences in glycemia in the OGTT at PN45 and PN180. Plasma insulin, leptin, T3 and T4, TSH and estradiol were not altered in adult female offspring. However, plasma testosterone was higher in LACT females (+152% $P < 0.05$). Adult male offspring from all caffeine groups did not show changes of these hormones. We suggested that perinatal caffeine exposure, even at a safe dose, induces short- and long-term hormonal changes and metabolic disturbances in offspring especially in females. Thus, during the critical periods of pregnancy and breastfeeding, the consumption of caffeinated beverages and foods should be avoided.

Asymptomatic Familial Hyperprolactinemia Caused by a Unique bi-Allelic Variant in the Prolactin-Receptor Gene

Yoav Natif[1], Matan M. Jean[1,2], Ohad S. Birk[2,3], Marina Eskin-Schwartz[2,3], Merav Fraenkel[1,4] & Uri Yoel[1,4]
[1]Ben Gurion University of the Negev, Faculty of Health Sciences, Be'er Sheva, Israel; [2]Soroka Medical Center, Genetics Institute, Be'er Sheva, Israel; [3]Ben Gurion University of the Negev, Human Genetics, NIBN, Be'er Sheva, Israel; [4]Soroka Medical Center, Endocrinilogy, Be'er Sheva, Israel

Introduction
Hyperprolactinemia is usually an acquired condition. Typical clinical manifestations include hypogonadism, infertility, and galactorrhea. Rarely, hyperprolactinemia has been attributed to a variant in the prolactin receptor gene (*PRLR),* presenting as agalactia, without hypogonadism, infertility, or galactorrhea.
Aim
In the current study we aimed to delineate the clinical phenotype and the genetic basis of marked hyperprolactinemia found in few females from one large kindred.
Methods
We have ascertained extended inbred kindred with multiple female subjects displaying presumably asymptomatic hyperprolactinemia. The family members underwent clinical, laboratory and imaging assessment. Whole exome sequencing has been used to obtain genetic molecular diagnosis of the proband. Segregation analysis was performed by Sanger sequencing.
Results
Fourteen family members, 7 females and 7 males of 3 different branches and of 2 generations were evaluated. Ethylene glycol precipitation and pituitary Magnetic Resonance Imaging revealed no evidence of macroprolactin or pituitary adenoma, respectively. Four females of reproductive age with elevated prolactin levels (X6-10 of the upper limit of norm), harbored a homozygous PRLR(NM_000949.7):c.1750del (p.Glu584AsnfsTer49) variant, predicted to change the amino acid (aa) sequence of the last 39 aa of the encoded PRLR, elongating it by additional 13 aa, thereby affecting its intracellular domain. All 4 had regular ovulatory cycles and no galactorrhea. Of these, 3 homozygous females conceived spontaneously. Of 3 who gave birth, only one nursed without difficulties, while 2 reported "lack of milk' and did not have breast engorgement after stopping breastfeeding. All three postmenopausal women (one homozygous, one heterozygous, and one wildtype of the *PRLR* gene) had prolactin levels within the normal range. However, the homozygous postmenopausal woman had prolactin level X2 of ULN at menopause transition. She had 5 spontaneous pregnancies and successfully nursed all her children. All seven males (2 homozygous and 5 heterozygous) had prolactin level within the normal range and did not demonstrate any signs or symptoms related to hyperprolactinemia.
Conclusions
We describe a novel homozygous *PRLR* p.Glu584AsnfsTer49 variant predicted to affect the intracellular domain of the PRLR, resulting in significant, apparently asymptomatic hyperprolactinemia among females in their reproductive age, with a possible mild lactation difficulty. It might be suggested that the hyperprolactinemia largely compensate for the lower activity or stability of the PRLR.

Increased Plasma Leptin and Agouti-Related Peptide May Be Related To Sleep Alterations In Patients With Active Cushing's Syndrome

Cem Sulu, Hande Mefkure Ozkaya & Pinar Kadioglu
Istanbul University-Cerrahpasa, Endocrinology, Metabolism, and Diabetes, Istanbul, Turkey

Aim
To evaluate sleep architecture of patients with Cushing's disease (CD) and to explore whether agouti-related peptide (AgRP) leptin, and interleukin-6 (IL-6) play a permissive role in sleep alterations.

Methods
We performed polysomnography on 26 patients with active CD and age 26 age- and sex-matched control subjects. Blood samples were obtained from all participants for the analyses of AgRP, leptin, and IL-6. The laboratory and sleep-related parameters were compared.
Results
The groups were similar in age, gender, and body mass index. Plasma AgRP (13.2±7.4 pg/ml vs 9±3.1, $P=0.029$), leptin (59.5 mg/l, [IQR] 32.6-94.6)vs 25.3 mg/l, [IQR] 12.9-57.5, $P=0.007$) and IL-6 levels (1.2 pg/ml, [IQR] 0.5-2.7 vs 0.6 pg/ml, [IQR] 0.5-2.7, $P=0.058$) were higher in CD group. The CD group had reduced sleep efficiency (71.6±12.1% vs 78.8±12.6%, $P=0.042$) and increased wake after sleep onset % (WASO%) (24.7±13.1% vs. 17.4±11.6%, $P=0.040$) as compared to control group. AgRP and leptin correlated negatively with total sleep time, sleep efficiency, N2%, and positively with WASO%. In multiple regression analyses, AgRP emerged as a significant predictor of sleep efficiency ($\beta=0.481$ and $P<0.05$) and WASO% ($\beta=0.452$ and $P<0.05$) among other confounders. Seventeen patients with CD and 18 control subjects had obstructive sleep apnea (OSAS).
Conclusion
Active CD hampers sleep efficiency and continuity which may be associated with increased plasma AgRP. Leptin may correlate negatively with sleep efficiency and continuity. More than half of patients with CD may suffer from OSAS. Therefore, patients with CD who complain of impaired sleep or have symptoms attributable to OSAS should undergo polysomnographic evaluation.

Somatostatin receptor expression in pituitary tumours according to the 2022 WHO classification: An insight into the rarer morphological subtypes

Prishila Fookeerah[1,2], Winny Varikatt[3,4] & Mark McLean[1,2,4]
[1]Westmead Hospital, Department of Diabetes and Endocrinology, Sydney, Australia; [2]Western Sydney University, School of Medicine, Sydney, Australia; [3]Institute of Clinical Pathology and Medical Research, Tissue Pathology and Diagnostic Oncology, Sydney, Australia; [4]University of Sydney, Faculty of Medicine, Sydney, Australia

Introduction
Pituitary tumours may express somatostatin receptors (SSTR), which are a potential drug target to achieve tumour reduction and control of hormone secretion. There is a well-established role for somatostatin analogues in the management of acromegaly and Cushing's disease. The recent 2022 WHO classification of pituitary tumours provides a comprehensive approach to the diagnosis of pituitary tumours, allowing identification of additional morphological subtypes. Our aim is to assess SSTR expression in a large cohort of pituitary tumours and to determine patterns of expression in the rarer morphological subtypes identified under this new classification system.
Methodology
We conducted a retrospective study of pituitary tumours archived at the Institute of Clinical Pathology and Medical research at Westmead Hospital from 2011 to 2018. Immunohistochemistry was performed on each tumour to evaluate for expression of pituitary hormones, transcription factors (PIT1, TPIT, SF1), co-factors (GATA3, oestrogen receptor), somatostatin receptors (SSTR2A, SSTR5) and cytokeratin (CK 8/18). After reclassification according to the 2022 WHO classification of pituitary tumours, expression of SSTR 2 and 5 in each morphological subtype was assessed.
Preliminary Results
208 of 284 available pituitary tumours have been assessed and classified according to the 2022 WHO classification. SSTR2 expression was positive in 72.2% of PIT1 tumours, 43.9% gonadotroph (SF1) tumours and 33.3% corticotroph (TPIT) tumours. The corresponding expression of SSTR5 was 69.4% of PIT1 tumours, 1% gonadotroph (SF1) tumours and 18.2% corticotroph (TPIT) tumours. Among corticotroph tumours, expression of SSTR2 and SSTR5 was higher in Crooke cell tumours. In the PIT1 group, 100% of mature plurihormonal tumours and immature PIT1 lineage tumours expressed both SSTR2 and SSTR5. Densely granulated (DG) somatotroph tumours preferentially expressed SSTR2 (100%) over SSTR5 (33.3%), whereas their sparsely granulated (SG) counterpart showed high expression of both SSTR2 (87.5%) and SSTR5 (100%). SG lactotroph tumours showed no immunoreactivity for either form of SSTR; while 50% of DG lactotroph tumours expressed either SSTR2 or 5. We identified 5 plurihormonal tumours which co-expressed PIT1 and SF1 and all were positive for both SSTR.
Conclusion
This is the first study to systematically assess SSTR expression in all subtypes of the 2022 WHO classification. We have demonstrated that mature plurihormonal PIT1, immature PIT1, SG somatotroph and plurihormonal PIT1+SF1 highly express both types of SSTR. Our findings may be useful in predicting therapeutic response to somatostatin analogues in the future.

Comparative Efficacy and Safety of Osilodrostat Vs Metyrapone for the Treatment of Cushing's Syndrome – a Matching-Adjusted Indirect Treatment Comparison

Emma Tyas[1], Conor Hickey[1], Matthew Hemstock[1], Grzegorz Binowski[2], Carl Rios[3] & Fabian Schmidt[4]
[1]Lumanity, Sheffield, United Kingdom; [2]MAHTA Intl., Warsaw, Poland; [3]Recordati AG, Basel, Switzerland; [4]Recordati Rare Diseases, Puteaux, France

Objectives
Endogenous Cushing's Syndrome (CS) is a rare, chronic condition that results in high morbidity, caused by prolonged exposure to elevated levels of circulating free cortisol levels. Osilodrostat, a newly approved steroidogenesis inhibitor, has been shown to achieve fast and high rates of cortisol normalization, improving manifestations of hypercortisolism in patients with Cushing's Disease (CD), a form of CS. We evaluated relative complete response (CR) outcomes at Weeks 12 and 36, and two discontinuation outcomes at Week 24 for osilodrostat vs metyrapone for patients with CS.
Methods
The LINC-4 and PROMPT clinical trials investigated osilodrostat and metyrapone, respectively, in patients with CS. All LINC-4 patients and 90% of PROMPT patients had CD; remaining PROMPT patients had other endogenous CS aetiologies. Efficacy endpoints of CR (mean urinary free cortisol [mUFC] $\leq$ 1.0 x the upper limit of normal) at Weeks 12 and 36, and safety endpoints of all cause discontinuation and discontinuation due to lack of efficacy or any adverse event at Week 24 were analysed. Unanchored matching-adjusted indirect comparisons were performed using LINC-4 patient-level data and published summary data for PROMPT. Four baseline characteristics identified as potential prognostic factors were adjusted for: age, sex, time since diagnosis, and mUFC. Estimated weights were applied to logistic regression models providing relative effect estimates through weighted odds ratios (ORs). Scenario analyses investigated a trade-off between the effective sample size of the matched population and inclusion/exclusion of baseline mUFC as a matching variable, a plausible but unconfirmed prognostic factor. For CR endpoints, two methods of imputing missing response observations were investigated: non-response imputation and last observation carried forward (LOCF).
Results
Non-response imputation results suggested treatment with osilodrostat was associated with significantly increased odds of CR compared with metyrapone at Week 12 (OR: 3.43; 95% confidence interval [CI]: 1.10, 10.65) and Week 36 (OR: 7.57; 95% CI: 2.22, 25.77). This implies osilodrostat patients have 3.43 and 7.57 times greater odds of experiencing normalized cortisol levels at Weeks 12 and 36, respectively. No significant differences between treatments were found for the discontinuation endpoints. Scenario analyses investigating the exclusion of baseline mUFC as a matching variable and the LOCF imputation method for missing observations had consistent results.
Conclusions
Our analyses suggest osilodrostat significantly increases the odds of achieving CR at Weeks 12 and 36 compared with metyrapone, implying osilodrostat is a more efficacious treatment option than metyrapone for reducing cortisol levels in patients with CS.

Rare adverse event of treatment with somapacitan after switch from somatotropine

Matej Rakusa[1,2], Andrej Janez[1,2] & Mojca Jensterle[1,2]
[1]Department of Endocrinology, Diabetes and Metabolic Disease, Ljubljana, Slovenia; [2]Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Introduction
Somapacitan is 23.3-kDa human GH derivate linked to small noncovalent albumin binding moiety that facilitates reversible endogenous albumin binding to delay somapacitan elimination. The longer half-life and improved pharmacodynamics allow injections once per week. Some patients find a daily regimen with established treatment difficult, especially because treatment may be lifelong or at least for several years. Poor adherence with medication can lead to poorer clinical outcomes. In studies somapacitane was well tolerated and no safety issues were identified.
Case report
We report a case of 38 years old women with congenital panhypopituitarism with pituitary dysplasia, posterior pituitary ectopy and disconnected pituitary stalk. Diagnosis of hypopituitarism was established when she was 8 years old. In the past PROP1 and LHX3 mutations were excluded. Patient received treatment with hydrocortisone 20 mg QD in divided doses, levothyroxine 100 µg QD, somatotropine 0.4 mg sc. QD, norgestrel/estrogen. Because she was not adherent to somatotropine treatment we started treatment with somapacitan 4 mg sc. QW. At the start of treatment, she was educated from nurse educator about correct handling and application of medication. She followed the recommendation to administer somapacitan by subcutaneous injection to the abdomen or thigh with regular rotation of injection sites. Before switch from somatotropine to somapacitan IGF-1 was 72 µg/l (69.0 – 227.0 µg/l), IGF-1 SDS was -1.825. Three days post second injection IGF-1 was 140 µg/l, IGF-1 SDS was 0.143. Approximately 4 weeks after start of treatment, she reported reduced subcutaneous tissue on the site of application. On evaluation lipoatrophy of diameter of about 10 cm were present at two sides of lower abdomen and in left and right tight. The reduction of fat tissue was confirmed with DXA. Otherwise, she reported more energy, improved quality of life and treatment satisfaction. IGF-1 SDS was in target range. We discontinued treatment with somapacitan and re-started treatment with somatropine. On follow-up visit 1 month after discontinuation of somapacitan partial improvement in lipoatrophy was noted.
Discussion and conclusion
To our knowledge this is the first case of lipoatrophy in adult during treatment with somapacitan. Until today, lipoatrophy, which was reversable with change of application site, was described in 2 children in randomised control trial REAL 3.

Efficacy and Safety Analysis of Setmelanotide As a Novel Treatment for Hypothalamic Obesity

Christian L. Roth[1,2], Ashley H. Shoemaker[3], Michael Gottschalk[4], Jennifer L. Miller[5], Guojun Yuan[6], Evan Chen[6], Cecilia Scimia[6] & M. Jennifer Abuzzahab[7]
[1]Seattle Children's Research Institute, Seattle, WA, United States; [2]University of Washington, Division of Endocrinology, Department of Pediatrics, Seattle, WA, United States; [3]Vanderbilt University Medical Center, Ian Burr Division of Endocrinology and Diabetes, Nashville, TN, United States; [4]University of California San Diego/Rady Children's Hospital, Pediatric Endocrinology, San Diego, CA, United States; [5]University of Florida College of Medicine, Pediatric Endocrinology, Department of Pediatrics, Gainesville, FL, United States; [6]Rhythm Pharmaceuticals, Inc., Boston, MA, United States; [7]Children's Minnesota, Pediatric Endocrinology and Diabetes, Saint Paul, MN, United States

Background
Hypothalamic injury and impaired melanocortin-4 receptor (MC4R) pathway signaling, often a result of surgery or radiation for a benign tumor, may lead to hypothalamic obesity (HO). After injury, sudden weight gain and appetite changes unresponsive to existing therapies develop. Setmelanotide, an MC4R agonist, is approved for chronic weight management in patients with certain MC4R pathway–associated diseases. We report interim results of a Phase 2 study of setmelanotide in HO (NCT04725240).
Methods
Patients aged 6-40 years with body mass index (BMI) $\geq$95th percentile (children 6 to $<$18 years) or $\geq$35 kg/m^2 (adults $\geq$18 years) and HO caused by structural hypothalamic damage secondary to craniopharyngioma or other benign brain tumor, surgical resection, and/or chemotherapy were enrolled. The setmelanotide dose was initiated by age, with 2-4 weeks of titration to 3.0 mg once daily, followed by 12-14 weeks at the target dose. The primary endpoint was the proportion of patients achieving $\geq$5% BMI reduction at Week 16. A key secondary endpoint was the composite proportion of children with $\geq$0.2-point reduction in BMI Z score and adults with $\geq$5% weight loss. Hunger was assessed daily using a numerical rating scale, where 0 = not hungry at all and 10 = hungriest possible.
Results
Eighteen patients were included (baseline mean [standard deviation (SD); range] age, 15.0 [5.3; 6-24] years and mean [SD] BMI, 38.0 [6.5] kg/m^2). A statistically significant proportion of patients achieved $\geq$5% reduction in BMI (88.9%; 90% confidence interval [CI], 69.0%-89.0%; $P<0.0001$); 72.2% experienced $\geq$10% reduction at Week 16. Mean (SD) change in BMI was $-$14.9% (9.6%; $n=17$). Mean (SD) percent change in hunger score was $-$45% (36.4%; $n=11$), a reduction of $-$2.9 (2.3) points from baseline. Frequent adverse events included nausea (61.1%), vomiting (33.3%), skin hyperpigmentation (33.3%), diarrhea (22.2%), and COVID-19 (22.2%). Two patients discontinued because of adverse events.
Conclusions
These early results warrant continued evaluation of setmelanotide in this population with a high unmet medical need and no approved therapies.

Prolactinomas under high doses cabergoline in portuguese patients: The Resistant Prolactinoma Study

Inês Manique[1], Vânia Benido Silva[2], Davide Carvalho[3], Olinda Marques[4], Ema Nobre[5], Maria João Bugalho[5], Ana Palha[1], Isabel Ribeiro[6], Josué Pereira[7], Rui Almeida[8], Amets Sagarribay[9], Luís Cerqueira[10] & Cláudia Amaral[11]
[1]Centro Hospitalar Universitário de Lisboa Central, Endocrinology, Lisboa, Portugal; [2]Centro Hospitalar Universitário do Porto, Endocrinology, Portugal; [3]Centro Hospitalar Universitário de São João, Endocrinology, Portugal; [4]Hospital de Braga, Endocrinology, Braga, Portugal; [5]Centro Hospitalar Universitário Lisboa Norte, Endocrinology, Lisboa, Portugal; [6]Centro Hospitalar Universitário do Porto, Neurosurgery, Porto, Portugal; [7]Centro Hospitalar Universitário de São João, Neurosurgery, Porto, Portugal; [8]Hospital de Braga, Neurosurgery, Braga, Portugal; [9]Centro Hospitalar Universitário de Lisboa Central, Neurosurgery, Lisboa, Portugal; [10]Centro Hospitalar Universitário de Lisboa Central, Neuroradiology, Lisboa, Portugal; [11]Centro Hospitalar Universitário do Porto, Endocrinology, Porto, Portugal

Background
In 15% of prolactinomas there is dopamine agonist(DA) resistance. The clinical characteristics, the best diagnostic and therapeutic management of these cases have not been established so far.
Aim
To characterize patients taking a high dose cabergoline($\geq$ 3mg/week) and then describe clinical, biochemical and imaging features of cabergoline-resistant cases.
Methods
Retrospective study with 5 centers representing the contribution of Pituitary Study Group of SPEDM to "RESISTANT PROLACTINOMA STUDY"(ENEA Workshop and Study Committee). Clinical, biochemical and imaging data, diagnostic approaches, treatment options and outcomes were assessed. Cabergoline-resistant prolactinoma was defined as tumors treated with $\geq$3mg/week cabergoline for at least 6 months without achieving prolactin level normalization.
Results
Twenty patients, 55%($n=11$) males with a median age at diagnosis of 29 years(Interquartile range[IQR]:13) were included. Median initial prolactin level was 2117ng/ml(IQR:4005) and largest tumor dimension 28mm(IQR:25.3). All prolactinomas were macroadenomas. Parasselar, suprasselar and infrasellar intraesphenoidal growth was verified in 80%($n=16$), 80%($n=16$) and 60%($n=12$) respectively, and optic chiasm compression in 20%($n=4$). At diagnosis, 40%($n=8$) presented visual disturbances and 15%($n=3$) pituitary apoplexia. Hypogonadotropic hypogonadism was established in 85%($n=17$), central hypothyroidism in 30%($n=6$) and secondary adrenal insufficiency in 20%($n=4$). Cabergoline was the first treatment in 80%($n=16$). Eighteen prolactinomas(90%) were defined as cabergoline-resistant, and 75%($n=15$) did not decrease their size by $\geq$50%. Fifteen patients(75%) did an alternative treatment, achieving prolactin normalization in only 6,7%($n=1$) and decrease in $\geq$50% of tumor size in 33%($n=5$). Cabergoline median dose needed to decrease $\geq$50% of tumor was 4mg(IQR:0.5), the maximum median dose prescribed $>$3months without prolactin normalization was 3.25mg(IQR:1) and without tumor reduction was 3mg(IQR:0.5). One patient had metastasis and 30%($n=6$) had tumor relapse.

Conclusions
The male sex, tumor invasiveness and the magnitude of hyperprolactinemia are known predictors DA-resistance, and our results are consistent with that. The efficacy of alternative treatments in this type of lesions was scarce, either in prolactin normalization or tumor shrinkage. This study will contribute, we hope, to improve the understanding of the natural history of cabergoline-resistant prolactinomas.

Characteristics of follicular-stellate cells in newborn pituitary gland

Valeria Nicoleta Nastase, Alina Barb, Andrei Cosma, Amalia Raluca Ceausu & Marius Raica
Piaţa Eftimie Murgu, Department of Microscopic Morphology/Histology and Angiogenesis Research Center, Timi?oara, Romania

Introduction
The development of pituitary gland is orchestrated by genetic signals, transcription factors and signaling molecules with a crucial role in cell proliferation and differentiation. Anterior pituitary gland is formed by both granular (secretory) and agranular cells represented mainly by follicular-stellate cells. It is known that these cells form a supporting network around secretory cells and produce many kind of growth factors, but their major function remains unknown. Development of follicular-stellate cells and their implications in pathological processes of the adenohypophysis is scarcely covered in the literature.
Material and methods
54 newborn pituitary glands obtained from autopsy (ages between 0 days and 6 months) were evaluated using morphological (hematoxylin and eosin) and immunohistochemical staining (glial fibrillary acidic protein and S100 protein).
Results
The histopathological examination of the anterior pituitary gland revealed acidophilic-basophilic differentiation starting with 0 days. Pituitary anterior cells are distributed in nests and cords in first month after birth. The nests became dominant, starting one month, like in normal adult gland. Follicular-stellate cells, evaluated using GFAP and S100 protein, presented isolated IHC expression during first month, morphologically having oval and round shape. The follicular-stellate cells density increased progressively starting with five-seven days, with a more relevant IHC cytoplasmic reaction. The one-month specimens present follicular-stellate cells having star-like appearance with a strong IHC expression, being predominantly located in perivascular areas. Compared to S100 protein, GFAP analysis revealed more details about cell morphology (shape, orientation, tendency to form a network).
Conclusions
Few data regarding newborn pituitary gland morphological and immunohistochemical characteristics are found in the literature, even less about follicular-stellate cells. Their role is incompletely described, and it may be associated with normal and pathological development of pituitary gland. Newborn pituitary gland shows different microscopical aspect compared to adult. Follicular-stellate cells density increases with age, starting one week after birth.

The Effect of Dual-release vs Conventional Hydrocortisone on the Metabolic Profile in Secondary Adrenal Insufficiency

Nanna Thurmann Jørgensen[1,2], Victor Brun Boesen[1], Stina Willemoes Borresen[1], Thea Christoffersen[2,3], Niklas Rye Jørgensen[2,4], Torquil Watt[1,2], Ulla Feldt-Rasmussen[1,2] & Marianne Klose[1]
[1]Copenhagen University Hospital, Rigshospitalet, Department of Endocrinology and Metabolism, Copenhagen, Denmark; [2]Faculty of Health and Medical Sciences, Copenhagen University, Department of Clinical Medicine, Copenhagen, Denmark; [3]Copenhagen University Hospital, Bispebjerg and Frederiksberg Hospital, Department of Clinical Pharmacology, Copenhagen, Denmark; [4]Copenhagen University Hospital, Rigshospitalet, Department of Clinical Biochemistry, Copenhagen, Denmark

Background and aim
The dual-release hydrocortisone Plenadren® has shown promising results of improved cardiovascular and metabolic profiles after treatment of adrenal insufficiency, possibly due to an improved circadian profile of cortisol, but results are ambiguous.
Aim
To further investigate the potential effect of dual-release hydrocortisone on the metabolic profile as compared to conventional hydrocortisone in patients with secondary adrenal insufficiency.
Material and methods
Design
An investigator-initiated 21 week open-label switch trial studying the effect of dual-release hydrocortisone vs conventional hydrocortisone on fatigue measured by ecological momentary assessments. In the present study, the metabolic outcome assessments at baseline on conventional stable hydrocortisone therapy and 16 weeks after switch to dual-release hydrocortisone were analysed.
Participants
Patients with adrenal insufficiency due to hypopituitarism and without diabetes (N = 27, 24 men/3 postmenopausal women). Outcomes: 24-h ambulatory blood pressure, body mass index (BMI), body composition assessed by Dual-Energy X-ray absorptiometry scan, blood samples for lipids, fasting glucose, and glycated haemoglobin, and markers of bone turnover (type 1 procollagen, collagen type 1 cross-linked C-telopeptide, osteocalcin, receptor activator kappa-B ligand, osteoprotegerin, and sclerostin).
Results
Median age[range] was 62 years[38–73]. The dose of conventional hydrocortisone and dual-release hydrocortisone did not differ significantly (median[range]: 20[10–35] mg and 25[10–35] mg, respectively, P= 0.1). Ten patients above the age of 50 years had osteopenia at baseline while none were diagnosed with osteoporosis. After 16 weeks of treatment with dual-release hydrocortisone, no change in mean BMI was observed (difference(sem): -0.2(0.2) kg/m^2, P = 0.2), whereas mean total fat mass was reduced (difference(sem): -1.4(0.4) kg, P = 0.003). Mean total lean mass increased, however, non-significantly (difference(sem): +0.6(0.5) kg, P = 0.3). Mean glycated haemoglobin was reduced (difference(sem): -1.1(0.4) mmol/mol, P = 0.02), but the mean of fasting glucose and lipids did not change. Mean osteocalcin significantly decreased (difference(sem): -7.0(3.1) µg/l, P = 0.03), but the levels of the remaining bone markers were unchanged. No difference was observed in 24-h ambulatory blood pressure.
Conclusions
We observed an improved metabolic profile with reduced total fat mass and glycated haemoglobin as well as a non-significant increase in total lean mass after 16 weeks of treatment with the dual-release hydrocortisone Plenadren® compared to stable conventional hydrocortisone replacement therapy that could be explained by the more physiological circadian profile of dual-release hydrocortisone. However, we also found a decrease in osteocalcin concentrations indicating an inhibition of bone formation which contradicts previous findings.

Post operative copeptin does not predict occurrence of the syndrome of inappropriate antidiuresis (SIAD) after pituitary transsphenoidal surgery

Agatholklis Efthymiadis[1], Hussam Rostom[2], Tim James[2], Brian Shine[2], Nishan Guha[2], Simon Cudlip[3], Mirjam Christ-Crain[4] & Aparna Pal[5]
[1]Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [2]Department of Clinical Biochemistry, John Radcliffe Hospital, Oxford, United Kingdom; [3]Department of Neurosurgery, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom; [4]Division of Endocrinology, Diabetes and Metabolism, University Hospital Basel, Basel, Switzerland; [5]Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Introduction
The incidence of the syndrome of inappropriate antidiuresis (SIAD) post pituitary surgery is estimated at 3-20% with the condition potentially leading to significant morbidity and prolonged admission. Copeptin, a surrogate marker for vasopressin activity, has been shown to be a diagnostic tool in the diagnosis of AVP deficiency (formerly known as diabetes insipidus) post pituitary surgery. There is limited data regarding the utility of copeptin in predicting SIAD post pituitary transsphenoidal surgery (TSS). The aim of this study was to evaluate the predictive value of copeptin for SIAD post TSS.
Methods
Retrospective analysis of copeptin measured at day 1, day 2 and day 8 post pituitary surgery where data available in consecutive patients undergoing TSS (November 2017 to October 2022). All patients were fluid restricted to 1.5L post TSS except for patients who developed AVP deficiency. Incidence of post TSS SIAD was noted from the electronic patient records and defined as Na < 135 mmol/l with serum osmolality < 275 mOsm/kg, urine osmolality > × 100 mOsm/kg, urine sodium > × 30 mmol/l, normal adrenocortical and thyroid function or replaced postoperatively, in euvolemic patients not on diuretics. Logistic regression and Receiver Operating Characteristic (ROC) curves were performed to investigate the value of copeptin in predicting SIAD.

Results
Post TSS copeptin was measured in 133 patients; mean age 34 years (SD = 17 years) ; 45% (60/133) female. Sixteen patients (12%) had SIAD within 8 days of surgery. Copeptin results were available in 123, 53 and 89 patients for day 1, day 2 and day 8 post TSS, respectively. Logistic regression for day 1 copeptin to predict SIAD gave odds ratio (OR) of 0.98 (95%CI 0.85-1.14, $P=0.82$) and an area under ROC curve (AUC) of 0.49; day 2 copeptin OR was 0.96 (95%CI 0.73-1.26, $P=0.76$) with AUC of 0.57; day 8 copeptin OR was 0.98 (95%CI 0.85-1.12, $P=0.73$) with AUC of 0.44. Logistic regression for day 1 sodium to predict SIAD revealed OR of 0.81 (95CI% 0.69-0.95, $P=0.01$) with AUC of 0.70, which remained unchanged after addition of day 1 copeptin to the day 1 sodium regression model.
Conclusions
Incidence of SIAD in our cohort is comparable to published data. We find that post operative copeptin is not helpful in predicting post TSS SIAD and hence would not recommend its use for this purpose.

Patients with acromegaly continue to derive clinical benefit from pasireotide long-acting release (LAR) for up to 12 years of treatment: Follow-up analysis of patients who received pasireotide during the clinical trial programme

Monica Gadelha[1], Elena Grineva[2], Jesus Miguel Escalante Pulido[3], Guilherme Rollin[4], Rattana Leelawattana[5], Christophe De Block[6], Andrea Piacentini[7], Fabian Schmidt[8], Alberto M Pedroncelli[9] & Nitin Kapoor[10]
[1]Medical School and Hospital Universitário Clementino Fraga Filho, Universidade Federal do Rio de Janeiro, Neuroendocrinology Research Center, Rio de Janeiro, Brazil; [2]VA Almazov National Medical Research Centre, Saint Petersburg, Russia; [3]Hospital de Especialidades, Centro Médico Nacional de Occidente (CMNO), Instituto Mexicano del Seguro Social (IMSS), Departamento de Endocrinología, Guadalajara, Mexico; [4]Hospital Moinhos de Vento, Porto Alegre, Brazil; [5]Prince of Songkla University, Songkhla, Thailand; [6]University of Antwerp, Department of Endocrinology-Diabetology-Metabolism, Antwerp, Belgium; [7]Recordati SpA, Milan, Italy; [8]Recordati Rare Diseases Sarl, Puteaux, France; [9]Recordati AG, Basel, Switzerland; [10]Christian Medical College and Hospital, Department of Endocrinology, Diabetes and Metabolism, Vellore, India

Introduction
Acromegaly is associated with significant morbidity and reduced quality of life. A robust clinical programme (14 trials) established pasireotide as an effective second-generation somatostatin receptor ligand for the treatment of various endocrine conditions, including acromegaly. Patients who completed a previous pasireotide trial and continued to receive clinical benefit, according to the parent study investigator, could continue treatment in the B2412 rollover study, which assessed long-term safety and clinical benefit.
Methods
This ongoing, open-label, multicentre, Phase IV study allows continued treatment for patients with acromegaly, Cushing's disease or other endocrine disorders who completed a pasireotide parent trial (NCT01794793). Here, we analysed patients with acromegaly who received pasireotide LAR in four parent studies (B2219, C2305, C2402, C2413) and ≥ 1 dose during the rollover, including cumulative data from parent study baseline to rollover interim data cut-off (1 November 2021). The B2412 study primary objective was to evaluate long-term safety, determined by adverse event (AE)/serious adverse event (SAE) frequency.
Results
Overall, 211 patients from 23 countries entered the rollover from four parent studies. At data cut-off, 59.2% of patients ($n=125$) were continuing treatment, 24.2% ($n=51$) had completed the study and 16.6% ($n=35$) had discontinued the study. The most common reason for study discontinuation was AEs ($n=12$; 5.7%). Median (min − max) exposure from first dose in the parent study to rollover data cut-off was 64.0 months (9–148), with a median (min − max) average dose of 44.8 mg/month (6–69). The most common AEs considered by the investigator to be treatment related from the first dose in the parent study to rollover data cut-off ($\geq 10\%$ of patients) were hyperglycaemia (34.1%), cholelithiasis (25.6%), diabetes mellitus (not further specified; 25.1%) and diarrhoea (16.6%). The most common AE leading to treatment discontinuation was hyperglycaemia (1.9%). AEs that most frequently required additional therapy ($\geq 20\%$ of patients) were hyperglycaemia (28.9%) and diabetes mellitus (not further specified; 26.5%). SAEs were reported by 29.4% of patients ($n=62$), most commonly cholelithiasis (6.2%) and COVID-19 (3.3%); all other SAEs were reported with $<1\%$ frequency. Altogether, $>94\%$ of patients were assessed as deriving clinical benefit from pasireotide LAR treatment at all study visits.
Conclusions
Pasireotide is well tolerated and provides clinical benefit for up to 12 years of treatment in patients with acromegaly. Hyperglycaemia, an AE often reported during the first 3 months of pasireotide treatment, is manageable, usually without the need for treatment discontinuation.

Molecular and clinical relevance of the somatostatin system in brain tumors

Ana S. De la Rosa-Herencia[1,2,3,4], Miguel E. G-Garcia[1,2,3,4], Mari C. Vázquez-Borrego[1,2,3,4], Cristobal Blanco Acevedo[2,3,5], Juan Solivera[2,3,5], Manuel D. Gahete[1,2,3,4], Antonio C. Fuentes-Fayos[1,2,3,4] & Raul M Luque[1,2,3,4]
[1]University of Cordoba, Department of Cell Biology, Physiology and Immunology, Córdoba, Spain; [2]Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain; [3]Reina Sofia University Hospital (HURS), Córdoba, Spain; [4]CIBER Physiopathology of Obesity and Nutrition (CIBERobn), Córdoba, Spain; [5]Reina Sofia University Hospital (HURS), Service of Neurosurgery, Córdoba, Spain

High-grade astrocytomas (HGAs) remain the most prevalent and malignant brain tumor based on its locally aggressive behavior, being glioblastoma (grade-IV astrocytoma) the most lethal. The current standard treatment for glioblastomas consists of surgery followed by radiotherapy and/or chemotherapy. However, the average period of survival is about 14 months after the first intervention. Therefore, there is a clear clinical need for the identification of novel diagnostic, prognostic and therapeutic tools to manage and treat these brain pathologies. In this context, somatostatin analogues (SSAs) are efficacious and safe treatments for a variety of endocrine related tumors, but the presence of somatostatin receptors (SSTRs) and pharmacological effects of SSA on HGAs are poorly known. Specifically, we have recently reported that the truncated splicing variant of SSTR5, sst5TMD4, is overexpressed and associated with increased aggressiveness in glioblastomas. In this study, we demonstrated that the expression levels of the 5 canonical receptors (SSTR1-5) were significantly down-regulated in HGAs compared to non-tumor samples using different human cohorts (both internal and external cohorts). Notably, SSTRs expression levels were inversely correlated with the tumoral grade, and, consequently, with the aggressiveness of HGAs. Moreover, ROC curve and survival analysis demonstrated the potential value of SSTRs, mainly SSTR1 and SSTR2, as novel diagnostic and prognostic biomarkers. Additionally, lower expression levels of SSTRs were associated with aggressive parameters (i.e., IDH wildtype status, classical/mesenchymal subtypes, etc.) showing a potential pathophysiological role of the somatistatin-system in HGAs. Notably, treatment with different SSAs (octreotide, pasireotide) and specific receptor-agonists (SSTR1/SSTR2/SSTR5 agonists) significantly reduced cell proliferation in primary patient-derived glioblastoma cell cultures. Altogether, this study demonstrated that SSTRs expression is dysregulated in HGAs vs. control brain tissues and could represent a novel souse of diagnostic and prognostic biomarkers, since their expression is associated with critical clinical and pathological features. Moreover, our data unveil clear antitumoral effects of SSAs on HGAs, opening new avenues to explore their potential as targeting therapy for these devastating brain pathologies.

177Lu DOTATATE Peptide Receptor Radionuclide Therapy (PRRT) in advanced Phaeochromocytomas and paragangliomas (PPGL) – a single centre experience at a ENETS Centre of Excellence

Kalyan Mansukhbhai Shekhda[1], Eleni Armeni[2], Aimee Hayes[2], Martyn Caplin[2], Christos Toumpanakis[2], Dalvinder Mandair[2], Ann-Marie Quigley[3], Shaunak Navalkissoor[3], Ashley Grossman[2] & Bernard Khoo[1,2]
[1]Royal Free Hospital, Department of Endocrinology, London, United Kingdom; [2]Royal Free Hospital, Neuroendocrine Tumour Unit, ENETS Centre of Excellence, London, United Kingdom; [3]Royal Free Hospital, Department of Nuclear Medicine, London, United Kingdom

Introduction
Phaeochromocytomas and paragangliomas (PPGL) are rare neuroendocrine tumours with no standardised protocol for treatment. ^{177}Lu-DOTATATE peptide receptor radionuclide therapy (PRRT) is an emerging treatment option for patients with metastatic and/or inoperable PPGL, and with low toxicity. We

present our experience with PRRT in advanced PPGL, treated in a ENETS *Centre of Excellence*.
Materials and Methods
165 patients with PPGL were screened retrospectively to identify cases with progressive disease and/or inoperable PPGL, treated with 2 or more cycles of ^{177}Lu-DOTATATE. Clinical (changes in antihypertensive medications or catecholaminergic features), radiological response rate (assessed by review of radiology reports and a formal RECIST assessment will be completed) and biochemical (plasma free metanephrines) responses were evaluated 8-12weeks after the last cycle of PRRT. Toxicity was assessed according to CTCAE v5.0. Progression Free Survival (PFS) was estimated using Kaplan Meier Survival analysis. Median Overall Survival (OS) was not reached.
Results
A total of 19 patients (4 phaeochromocytoma, 15 paraganglioma) were included (age range: 35-84 years, germline SDHx pathogenic variant found in 53%, elevated normetaphrines in 53% at baseline). Median duration of follow up was 30 months(range: 5-114) from the date of cycle 1 of PRRT. Patients received PRRT due to radiological progression 15(79%) or inoperable disease with metastases at baseline 4(21%) (median cycles: 4; median cumulative dose: 24.5 GBq). Radiological response was evaluable in 17 patients with PPGL, which confirmed stable disease in 11 patients (65%), and progressive disease in 6 patients (35%). Of the total cohort, median PFS from the date of the first cycle of PRRT was 32 months (95% CI, 4.61-59.39). Median PFS for the paraganglioma subgroup and inoperable disease at baseline was 30 months (95% CI, 3.67-56.33), 12 months (95% CI, 9.45-14.55) respectively. Median PFS for the patients with progressive disease at baseline, phaeochromocytoma subgroup and OS could not be assessed due to the relatively small patient numbers. Of patients with elevated metanephrines at baseline (10, 53%), anti-hypertensive doses were unchanged in 6 (60%), increased in 2 (20%), and increased transiently in 1 (10%). No CTCAE grade 3/4 cytopenia or nephrotoxicity was seen. One patient received 2 cycles of half standard dose PRRT due to baseline thrombocytopenia but therapy was then suspended due to progressive disease.
Conclusion
PRRT is an effective treatment option for patients with metastatic PPGL with encouraging PFS and low toxicity. It is a feasible alternative to chemotherapy and ^{131}I-MIBG but prospective and comparative studies are needed.

Characterization of a large cohort of patients with "micromegaly": long-term follow-up and preliminary data on treatment response

Giulia Carosi[1,2], Alessandra Mangone[1,3], Elisa Sala[1], Giulia Del Sindaco[1,3], Roberta Mungari[1], Arianna Cremaschi[1,3], Emanuele Ferrante[1], Maura Arosio[1,3] & Giovanna Mantovani[1,3]
[1]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Endocrinology Unit, Milano, Italy; [2]Sapienza University of Rome, Department of Experimental Medicine, Roma, Italy; [3]University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Background
In a previous study, we retrospectively analysed a group of patients with high insulin growth factor 1 (IGF1) but normal growth hormone (GH) suppression, identifying among them a subgroup of "micromegalic" patients presenting with clinical features of acromegaly and high rate of comorbidities. We therefore expanded our cohort of patients, extended the follow-up time and collected preliminary data on treatment response aiming to better characterize this condition.
Patients and methods
We enrolled 86 patients (53 included in our previous study, mean age 48 ± 17 years, 56 females and 30 males) referred to our Endocrinology Unit between 2008 and 2022, presenting with persistently high IGF1 and adequate GH nadir after glucose load (<0.4 ng/ml according to most recent guidelines). We divided them in two groups: with (G1, "micromegaly", $n=28/86$) or without (G2, 58/86) clinical features of acromegaly. We performed systematic clinical-instrumental screening of acromegaly-related comorbidities (arterial blood pressure and glucose metabolism evaluation, thyroid ultrasound for goitre, colonoscopy and/or faecal occult blood for colonic polyposis, echocardiography for cardiopathy, polysomnography and ESS questionnaire for OSAS). We recorded biochemical and clinical data from diagnosis to the last available follow-up. Finally, we collected preliminary data of a small subgroup of patients who underwent medical or surgical treatment.
Results
In G1 group ("micromegaly") we confirmed a higher prevalence of comorbidities vs G2 (median comorbidities for each patient 4 vs 3, $P=0.001$), especially goitre ($P=0.009$), carpal tunnel ($P=0.003$) and malignant neoplasms ($P=0.03$). During a mean follow-up time of 6 ± 3 years, IGF1 and GH nadir levels did not significantly change, whilst we observed an increase in random GH values in G1 vs G2 patients ($P=0.03$). Four patients with highly suggestive clinical features of acromegaly and typical comorbidities were selected for treatment: two were treated with somatostatin analogues and two underwent transsphenoidal surgery (1 micro and 1 macroadenoma, both histologically proven GH+). All treated patients showed normalization of IGF1 values and referred subjective improvement in clinical symptoms.
Conclusions
Our preliminary data suggest that "micromegalic" patients present typical comorbidities of acromegaly and can benefit from either medical or surgical therapy.

Role of fT4 and TSH-index fluctuations as early diagnostic tools in milder forms of central hypothyroidism: data from 221 patients with pituitary lesions from a single tertiary center

Silvia Carrara[1], Elena Galazzi[2], Federico Nicoli[1], Mirella Moro[2], Letizia Fatti[2], Biagio Cangiano[1,2] & Luca Persani[1,2]
[1]University of Milan, Department of Medical Biotechnology and Translational Medicine, Italy; [2]Italian Auxological Institute San Luca Hospital, Department of Endocrine and Metabolic Diseases, Milano, Italy

Diagnosis of Central Hypothyroidism (CeH) is commonly given when FT4 concentrations are below the lower limit of normal range. A reduction in FT4 concentrations greater than 20% was proposed in ETA 2018 Guidelines as an unphysiological fluctuation indicating the onset of milder forms of CeH with FT4 still within the normal range. Similarly, TSH-index was proposed to quantify thyrotrope reserve, hence as a tool to detect patients at risk of CeH. Here we verified the performance of these parameters for the diagnosis of CeH in 221 patients with pituitary lesions – 127 adenomas and 94 empty sellas – and at least three evaluations of Thyroid Function Tests (TFTs, i.e. paired detection of TSH and FT4) during a median follow-up of 4 years. We also studied TFTs of 42 matched controls, selected from a cohort of euthyroid patients (TSH 0.5-4.5 mU/l) with multinodular goiter and negative thyroid autoimmunity followed up during the same period. We evaluated FT4 concentrations, TSH, TSH-index and defined two derived parameters, FT4var and ΔTSH-index, which were respectively the greatest reduction of FT4 and TSH-index compared to their median value for each patient (FT4var=FT4 nadir – median FT4; ΔTSH-index = TSH-index nadir – median TSH-index). The diagnosis of CeH+ was made according to ETA 2018 Guidelines. In CeH- patients, FT4var did not differ statistically in patients with adenomas, empty sellas and controls (varying from 15 to 25%; P=n.s.). Consistently, in patients diagnosed with CeH+, FT4var (and its percentage value FT4var%) was able to distinguish patients harbouring adenomas or empty sellas with and without CeH [CeH+ vs CeH-: FT4var -3.1 ± 1.9 vs -1.4 pmol/l (IQR-2.1; -0.7), $P=0.03$; FT4var% -28% ± 15 vs -8% (IQR -14; -5), $P<0.001$]. Moreover, in our cohort, TSH-index allowed in distinguishing patients harbouring a pituitary lesion CeH+ vs CeH-, at baseline [CeH+ vs CeH– 1.8 (IQR 0.8; 2.2) vs 2.5 (IQR 2; 2.9); $P<0.001$]) and during follow-up [CeH+ vs CeH–: 1.3 ± 1.3 vs 2.5 ± 0.7, $P<0.001$]. In conclusion, both patients with pituitary lesions and controls show fluctuations of TFTs around an individual set-point. In patients with pituitary lesions such as adenomas and empty sellas, FT4var, FT4var% and TSH-index are useful tools able to highlight milder forms of CeH. We found that a fluctuation of FT4 value (FT4var) or FT4var% respectively greater than 3.1 pmol/l or 28% indicated the onset of mild CeH. The coexistence of a TSH-index lower than 1.3 may be useful to support this challenging diagnosis.

Glucocorticoid Resistance Syndrome: a Rare Disorder that we Must not Forget. A Clinical Case

Iciar Martín Timón, Inmaculada Moreno-Ruiz, Olalla Meizoso-Pita, Isabel Huguet, Maria Llavero Valero, Vanessa Triviño Yannuzzi & Cristina Sevillano-Collantes
Hospital Universitario Infanta Leonor, Endocrinology, Madrid, Spain

Primary generalized glucocorticoid resistance or Chrousos syndrome is a rare disorder, which affects all tissues expressing the human glucocorticoid receptor. It has been defined by an absence of overt Cushing's syndrome (CS) signs (no skin weakness, muscle atrophy, or osteoporosis) associated with biological

hypercortisolism consisting of high urinary free cortisol (UFC) and an absence of negative feedback loop of cortisol on HPA, defined as 8-AM cortisol level >50 nmol/l after overnight 1 mg DXM suppression test. It is characterized by tissue insensitivity to glucocorticoids caused by genetic defects in the NR3C1 gene. To date, 31 NR3C1 loss-of-function mutations have been reported

Case Report

A 31-year-old woman was referred to our hospital to continue monitoring and treatment of ACTH-dependent CS. When she was 26-year-old an analysis was performed for a hormonal study prior to laser treatment for hirsutism, where elevated cortisol was evidenced, being referred to an outpatient clinic of endocrinology. An increased UFC was found of 2 times over the upper limit of normal (234 and 248 mg/dl), a disturbed 1-mg and 2-mg dexamethasone suppression test with a cortisol value of 8,14 and 14 µg/dl respectively and a high normal ACTH level of 136 pg/ml where evidenced. Pituitary imaging with magnetic resonance imaging (MRI) showed no pituitary adenoma. A bilateral petrosal sinus sampling was performed showing a lack of ACTH gradient. A whole-body CT was performed to evaluate tumors suggestive of ectopic ACTH secretion with no findings. In 2021 she arrived at our hospital. At physical examination her blood pressure was 110/70mmHg, her body mass index was 23.5 kg/m2. She hadn't plethoric facial appearance, no central obesity, no muscle atrophy, no ecchymoses and no hirsutism. She had regular menses. No osteoporosis. Levels of UFC (243 mg/dl), ACTH (147pg/ml), DHEAS (675 mg/dl), androstenedione (6.9ng/ml), testosterone (0.59ng/ml) and 17OHprogesterone (3.90ng/ml) where similar than five years ago. Aldosterone concentration and ratio aldosterone/DRC were normal. A CT scan shows bilateral adrenal hyperplasia. With a suspected diagnosis of glucocorticoid resistance syndrome, we proposed a NR3C1 sequencing study in which no pathogenic variants were identified

Conclusion

In patients with biological hypercortisolism without signs and symptoms of CS we must think in a GC resistance syndrome. There had been several cases reports of patients with clinical and/or biochemical glucocorticoid resistance without alterations in glucocorticoid receptor gene NR3C1

Somatostatin receptor type 2 (SSTR2) expression regulation by miR-375 in a murine pituitary corticotroph tumor cell model

Claudia Pivonello[1], Roberta Patalano[2], Tatiana Montò[2], Mariarosaria Negri[2], Feliciana Amatrudo[2], Donatella Paola Provvisiero[2], Chiara Simeoli[2], Nicola Paola[2], Angelica Larocca[2], Erminio Massimo Crescenzo[2], Annamaria Colao[2,3] & Rosario Pivonello[3,4]
[1]Università Federico II di Napoli, Dipartimento di Sanità Pubblica e medicina Preventiva, Naples, Italy; [2]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Naples, Italy; [3]Università Federico II di Napoli, UNESCO Chair for Health Education and Sustainable Development, Naples, Italy; [2]Università Federico II di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Naples, Italy

Cushing's disease (CD), caused by an adrenocorticotropic hormone (ACTH)-secreting pituitary tumor, is the most common form of hypercortisolism. Pituitary surgery is the first-line treatment of CD and medical treatment is an alternative second-line approach to control cortisol excess. Long-term exposure to glucocorticoids (GC) downregulates the expression of somatostatin receptor type 2 (SSTR2) but not type 5 (SSTR5) in human and mouse ACTH-secreting tumor cell cultures; thus octreotide, the somatostatin receptor ligand (SRL) with high affinity for SSTR2, failed to show any significant decrease neither in circulating ACTH and, consequently, cortisol levels, nor on tumor growth in CD patients. A recent study showed that in vitro dexamethasone treatment of a murine corticotroph tumor cell model induces an increase in miR-375 expression. The sequence analysis of SSTR2 revealed a binding site for miR-375. This finding supports the hypothesis that GC excess might downregulate SSTR2 expression through an epigenetic mechanism. The aim of the current study was to evaluate whether miR-375 is involved in the regulation of SSTR2 expression in a murine corticotroph tumor cell model AtT20. SSTR2 gene and miR-375 expression levels were evaluated by RT-qPCR in murine corticotroph (AtT20) and compared with somatotroph (GH3) cell lines. To evaluate the involvement of miR-375 in the regulation of SSTR2 protein expression, 24h miR-375 knocking-down was performed in AtT20 and SSTR2 protein levels were evaluated by western blot (WB) and immunofluorescence (IF). Moreover, miR-375 expression levels were also evaluated in 6 human corticotroph pituitary tumors and 2 normal pituitaries, whereas miR-375 circulating levels were evaluated in 21 CD patients and 19 healthy subjects by RT-qPCR. The results demonstrated an inverse SSTR2 and miR-375 expression in AtT20 and GH3 cells, with low levels of SSTR2 messengers and high levels of miR-375 in AtT20 and an opposite expression pattern in GH3 cells. After 24h of miR-375 knocking-down, induced by miR-375 inhibitor, SSTR2 protein expression, evaluated by WB and IF, was significantly increased in AtT20 ($P=0,0310$ and $P=0,0154$, respectively), compared to the control. Furthermore, miR-375 showed a higher expression in human corticotroph pituitary tumors than in normal pituitaries, as well as a higher and significant miR-375 circulating levels were observed in CD patients ($P<0.0001$) compared to healthy subjects. In conclusion, these data suggested that SSTR2 protein expression might be epigenetically downregulated by miR-375 in corticotroph pituitary tumors. Functional assays are mandatory to evaluate the role of SSTR2 in the condition of miR-375 knock-down.

Dopamine agonist-resistance in patients with macroprolactinoma: prevalence and predictive factors

Ameni Terzi, Ibtissem Oueslati, Bel Hadj Sliman Chayma, Arige Abid, Meriem Yazidi & Melika Chihaoui
La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction

Dopamine agonists, mainly cabergoline and bromocriptine, represent the first-line treatment option in the management of prolactinomas. They allow prolactin normalization and tumor shrinkage. However, a subset of individuals with macroprolactinoma could exhibit a varying degree of resistance to dopamine agonists. The aim of this study was to determine the prevalence of dopamine agonist-resistance in patients with macroprolactinoma and to assess its predictive factors.

Methods

This was a single-center, retrospective study including 52 patients with macroprolactinoma. All enrolled patients were treated with dopamine agonists (cabergoline or bromocriptine). Resistance to dopamine agonists was defined as failure to achieve normoprolactinemia and/or 30% tumor shrinkage. Age, gender, epidemiological parameters, medical history, and clinical and paraclinical data were collected from medical records.

Results

Twenty-seven men and 25 women were enrolled in this study. Their mean age at the diagnosis of macroprolactinoma was 34.7 ± 14.9 years. The median baseline prolactin level was 1879 µg/l. The mean baseline macroprolactinoma size was 35 ± 17 mm (extremes: 11-77 mm). Macroprolactinoma was invasive in 73% of cases, with hemorrhagic or necrotic components in 52% of cases. Dopamine agonist resistance was observed in 16 patients (31%). Univariate analysis showed that age at diagnosis <30 years (OR=5, 95%-confidence interval (95%-CI):1.13-14.29, $P=0.011$), baseline prolactin level > 7000 µg/l (O $r=4.86$, 95%-CI:1.14-20.63, $P=0.035$), invasive adenoma (OR=10.26, 95%-CI: 1.20-87.55, $P=0.018$), presence of hemorrhagic or necrotic components (OR=28.5, 95%-CI: 3.27-248.17, $P=10^{-3}$), and tumor size > 40 mm (OR=7, 95%-CI: 1.71-28.54, $P=0.004$) were associated with dopamine agonist-resistance. In multivariate analysis, the presence of hemorrhagic or necrotic components was the only independent predictor of dopamine agonist-resistance (adjusted-O $r=28.68$, $P=0.005$).

Conclusion

Dopamine agonist-resistance was frequent in patients with macroprolactinoma. Its predictive factors included young age, invasive tumor, high baseline prolactin levels, tumor size, and the presence of hemorrhagic or necrotic components. The latter was the only independent predictor of treatment resistance.

Baseline clinical and treatment characteristics of dopamine agonist treated patients in a Dutch national cohort of patients with prolactinoma

Ingrid Zandbergen[1,2], Iris Pelsma[1], Wouter van Furth[2] & Nienke Biermasz[1]
[1]Leiden University Medical Center, Deparment of Medicine, Division of Endocrinology, Leiden, Netherlands; [2]Leiden University Medical Center, Deparment of Neurosurgery, Leiden, Netherlands

Introduction

Dopamine agonists (DA) are first-line treatment for prolactinomas and effectively control hyperprolactinemia in most patients. However, side effects may negatively impact health-related quality of life; and post-withdrawal remission rates are low, resulting in prolonged DA treatment.

Methods

Dutch multicenter prospective observational cohort study mapping standard care for 316 prolactinoma patients. Baseline clinical characteristics and treatment outcomes of 210 DA treated (DAT) patients are described (mean age 49.4±15.4 years; females $n=122$, 58.1%). 106 patients were not treated with DA at inclusion.

Results
Current prolactin levels -available for 155 patients- were elevated above the sex specific upper limit of normal in 54 (34.8%) patients, not different between males and females. Imaging data -available for 60 patients- showed 21 (35.0%) microprolactinomas, 23 (38.3%) macroprolactinomas, 1 (1.7%) giant prolactinoma, whereas in 10 (16.7%) patients no adenoma was visible, and 5 (8.3%) had a postoperative remnant. Males had more macroprolactinomas (15 (62.5%) vs 8 (22.2%), $P<0.001$). Galactorrhea was reported by 15/119 (12.6%) patients (males $n=1/50$ (2.0%) vs females $n=14/69$ (20.3%), $P=0.004$). Hypogonadism was reported by 42/153 (27.5%) patients, and subfertility by 10/118 (8.5%) patients, not different between males and females. DA side effects -measured using the PROCTCAE questionnaire ($n=155$)- were gastro-intestinal tract symptoms (e.g. diarrhea, constipation, nausea) in 63 (40.6%) patients (males $n=14/68$ (20.6%) vs females $n=49/87$ (56.3%) $P<0.001$). 77 (50.0%) patients reported fatigue (males $n=22/68$ (32.4%) vs females $n=55/86$ (64.0%) $P<0.001$). 41 (26.6%) patients reported concentration loss (not different between males and females).
Conclusions
In this Dutch national cohort of patients with prolactinoma, 210 DA treated patients were identified. We describe baseline clinical characteristics and significant sex differences for most outcomes of interest, which need to be taken in to account when interpreting treatment outcomes of prolactinoma patients.

Uncontrolled Acromegaly, Diabetes Mellitus and Metabolic Syndrome are the Main Risk Factors of Colon Polyposis Recurrence in Patients with Acromegaly

Rosa Pirchio, Renata Simona Auriemma, Alice Vergura, Rosario Pivonello & Annamaria Colao
Università "Federico II" di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy

Colon polyps represent a frequent complication of acromegaly. Knowledge about prevalence and risk factors of polyps' recurrence in acromegalic patients is still limited. The current retrospective study aimed at investigating polyps' prevalence and recurrence risk factors in acromegalic patients. One hundred and forty-three patients (73 males, 70 females) referring to "Federico II" university diagnosed with acromegaly from 2000 to 2022 who underwent at least one colonoscopy have been considered in the present study. Hormonal, metabolic parameters and colonoscopy result were evaluated. Colonoscopy was performed at diagnosis in 104 (72.7%) and after a disease duration of 9.6 ± 5.5 years in 39 patients (27.3%). Polyps were found in 39.4% and 38.5 %, respectively ($P=0.91$). At diagnosis, polyps were found more frequently in older ($P=0.09$), diabetic ($P=0.007$) patients, with higher number of systemic complications ($P=0.004$). Prevalence of polyps at diagnosis was significantly higher in patients with presumed disease onset greater than 5 years (median, $P=0.013$). Patients with IGF-I ($P=0.003$) and fasting glucose (FG, $P=0.01$) above the median showed significantly higher prevalence of polyps than those below. In patients who underwent colonoscopy after the diagnosis, age at diagnosis of acromegaly ($P=0.03$), FG ($P<0.001$), HbA1c ($P=0.001$), HOMAIR ($P=0.05$), and number of systemic complications ($P=0.02$) were significantly higher in patients with polyps than those with a normal colonoscopy. Overall among diabetic patients, polyps prevalence was significantly higher in patients administered with insulin than in those treated with oral antidiabetic drugs (35% vs 6.25%, $P=0.04$). Forty-nine patients (34.2%) underwent multiple evaluations with 10-years median of colonoscopy follow-up. Among patients with polyps at first colonoscopy, recurrence was present in 41.6% at the second evaluation, particularly in patients with uncontrolled acromegaly ($P=0.06$), glucose metabolism alterations ($P=0.002$), metabolic syndrome (MS, $P=0.04$), and diabetes treated with insulin therapy ($P=0.02$). In patients treated with SRLs polyps recurrence was lower than those treated differently (29.4% vs 66.6%, $P=0.07$). 30.4% of patients with first negative colonoscopy had polyps at the second evaluation, particularly those with uncontrolled acromegaly ($P=0.03$), smoking habit ($P=0.002$) and MS ($P=0.06$). Overall, five patients (3.5%) had colon cancer, diagnosed in two cases at acromegaly diagnosis and in three during the follow-up, after a mean disease duration of 18 years. Colonic polyposis is a major concern in patients with acromegaly. Regular colonoscopy is mandatory in this population. Recurrence is more common in patients with uncontrolled acromegaly, glucose metabolism alterations, and MS, requiring frequent colonoscopy evaluations.

Is a 20% decrease in free T4 (fT4) levels a reliable marker of secondary hypothyroidism in patients with non-functioning pituitary macroadenoma (NFPA)?

David McLaren[1], Ellen Mitchell[1], Nawaz Z Safdar[1,2], Stephen Gibbons[1] & Robert D Murray[1]
[1]Leeds Centre for Diabetes and Endocrinology, Department of Endocrinology, St James's University Hospital, Diabetes and Endocrinology, Leeds, United Kingdom; [2]University of Leeds, School of Medicine, Leeds, United Kingdom

Background
Central hypothyroidism can be difficult to diagnose as TSH values often reside within the normal range. The Endocrine Society clinical guideline for hormone replacement in hypopituitarism suggests levothyroxine is indicated for treatment of secondary hypothyroidism where fT4 levels decrease by $\geq$20%. To determine the reliability of this biochemical marker of secondary hypothyroidism we evaluated evolution of TFTs over time within a cohort of NFPA.
Methods
A retrospective review of TFTs was undertaken during 2000 to mid-2019 whilst using the Siemen's Centaur assay to measure fT4 levels. Patients with NFPA were identified from the departmental database. Patients with a history of CNS/pituitary irradiation; more than one pituitary surgery; on levothyroxine or identified with primary or secondary hypothyroidism at their first assessment during the study period, were excluded from analysis. Demographic, adenoma characteristics, treatment and hormone data were collected from primary and secondary care records.
Results
A total of 67 patients were identified, 39 male and 28 female with a mean age 58.0 (range 29.0-89.7) years. 34 patients underwent surgery and 33 patients did not. Mean follow-up was 5.2 (range 0.25-15.1) years. The indication for surgery in the majority of patients was visual compromise from optic chiasm compression. A total of 22/67(32.8%) patients experienced a drop of $\geq$20% in their fT4 levels from baseline (either first thyroid function test at diagnosis or first post-operative result in those who underwent surgery). Of the 22 patients, 12 showed subsequent recovery in their fT4 levels, whereas 10 did not recover during follow-up. In those who showed recovery 7, 2 and 3 had no, one or two hormone deficits. Similarly in those who did not recover 6, 2 and 2 had no, two or three additional hormone axis deficits. 12/67 patients saw a drop in their fT4 to below the reference range (10-20pmol/l), of whom 7 also showed a $\geq$20% decrease in fT4 values. 5 showed recovery of their fT4 levels and 7 a temporary decrease.
Conclusions
Variations of $\geq$20% in fT4 values occur in around a third of operated and non-operated NFPA on long-term follow-up. Around 50% of these episodes resolve spontaneously. Current guidelines may therefore lead to over diagnosis of secondary hypothyroid in patients with pituitary adenoma. Surveillance of repeated fT4 levels and symptoms is indicated before a diagnosis of secondary hypothyroidism can be established.

DOI: 10.1530/endoabs.90.P149

Epidemiology, clinical presentation, treatment and outcome of acromegaly in the island of Crete, Greece. 27 years of follow up study

Maria Chrysoulaki[1,2], Stavrina Vergou[1], Artemis Maria Makri[1], Elpida Mpouhlaki[1], Stefanos Michailidis[1], Vasiliki DARAKI[1,2], Maria Sfakiotaki[2], Grigoria betsi[1,2], Kalliopi Kontolaimaki[1,2], Rodanthi Vamvoukaki[1,2], Dimitra Sifaki-Pistola[1], Christos Lionis[1], Georgios Goulielmos[1] & Paraskevi Xekouki[1,2]
[1]University of Crete, School of Medicine, Heraklion, Greece; [2]University General Hospital of Heraklion, Endocrinology & Diabetes Clinic, Iraklio, Greece

Background
Acromegaly is a rare endocrine disorder due to growth hormone excess attributed to a pituitary tumor, in most cases. Epidemiological data of acromegaly are derived from national tumor registries or population studies while there are no published data in the Greek population except for a few small studies regarding treatment outcome.
Methods
We carried out a retrospective ongoing observational study to determine the epidemiology, presentation and outcome in patients with acromegaly in University Hospital of Heraklion, Crete, Greece, referal center for acromegaly, from years 1995 to 2022. Age at diagnosis, estimated delay in diagnosis, clinical, biochemical and imaging data at presentation and post treatment were recorded.
Results
Forty-two patients were included in the analysis (28 females, 14 males). The mean age at diagnosis was 45.5 $\pm$17 years and the mean follow-up time was 12,5$\pm$ 14 years. Nine patients (21.4%) presented before the age of 30 years. The time lag from the onset of symptoms to diagnosis was 5,2 years. The three most common clinical features at diagnosis were acral changes (88%), coarse facial features (75%), headache(47,5%,). Nine patients (21.4%) had a microadenoma while 24 (57.1.%) harbored a pituitary macroadenoma. No size data were

available for 21.5% patients. In our series, 10 patients (23.8%) had a family history of pituitary adenoma including a family with Familial Isolated pituitary adenoma (FIPA) due to *AIP* mutation. Musculoskeletal manifestations were present in 46.4%, diabetes mellitus in 26.8% and hypertension in 16%. Fifteen patients (36.5%) declined surgery and were given medical treatment (somatostatin analogues in 31,7%, dopamine agonist in 2.4%, and combination therapy in 2,4%). Twenty seven patients (63,5%) underwent transsphenoidal surgery (TSS); two of them (5.4%) had a second surgery, Six patients (14.6%) received radiotherapy. Histology was available for 11 patients; densely granulated tumors were 1,7 times more frequent than sparsely granulated (26.3 vs 15.7%), whereas 10,4% were mixed mamosomatotrophs. There was one case of mixed gangliocytoma/sparsely-granulated somatotrophinoma. Disease remission was obtained in 14 patients (34%) and almost 50% had stable disease. The mean time interval from start of treatment till achievement of biochemical control was approximately 2 years. Seven patients (16%) remained biochemicaly uncontroled.

Conclusions

This is the first epidemiological study for acromegaly in Greece. Our results are similar to those of other international reports. We also confirm the data, of international registries that almost a third of all patients remain undertreated which underlies the importance for a better management.

Novel provocation test with MDMA (“ecstasy’) reveals oxytocin deficiency as a new pituitary entity in patients with central diabetes insipidus – a randomized placebo-controlled trial

Cihan Atila[1], Friederike Holze[2], Rakithan Murugesu[1], Nikki Rommers[3], Nina Hutter[1], Nimmy Varghese[4], Sailer Clara Odilia[1], Anne Eckert[4], Markus Heinrichs[5], Matthias Liechti[2] & Mirjam Christ-Crain[1]

[1]University Hospital Basel, Department Endocrinology, Basel, Switzerlan; [2]University Hospital Basel, Department of Clinical Pharmacology, Basel, Switzerland; [3]University Hospital Basel, Department of Clinical Research, Basel, Switzerland; [4]University Psychiatry Hospital Basel, Basel, Switzerland; [5]University of Freiburg, Department of Psychology, Laboratory for Biological Psychology, Clinical Psychology and Psychotherapy, Freiburg, Germany

Introduction

Patients with arginine vasopressin deficiency (AVP-D), known as central diabetes insipidus (cDI), often report psychological symptoms such as heightened anxiety levels, difficulties describing emotions, and depressed mood despite adequate treatment with desmopressin. Given the anatomical proximity, disruptions of the hypothalamic-pituitary axis causing an AVP-D could also disturb the oxytocin (OXT) system. OXT regulates socio-emotional functioning, including fear reduction, attachment, emotion recognition, and empathy. Therefore, these psychological symptoms may be caused by an additional OXT deficiency. However, OXT deficiency has not been established as a pituitary entity, as no provocation test for OXT is currently available. Here, we aimed to investigate the OXT system stimulator 3,4-Methylenedioxymethamphetamine (MDMA, “ecstasy’) as a novel biochemical and psychoactive provocation test to reveal an OXT deficiency in patients with cDI.

Methods

Randomized, placebo-controlled, double-blind, cross-over study in 15 patients with cDI and 15 matched healthy controls. Participants underwent a psychological baseline evaluation, including the assessment of anxiety levels using the State-Trait Anxiety Inventory (STAI), mood using the Beck’s Depression Inventory (BDI), and alexithymia using the Toronto Alexithymia Scale (TAS). Participants were randomized to receive either a single oral dose of MDMA (100 mg) or placebo first. OXT samples were collected at 0, 90, 120, 150, 180, and 300 minutes after drug intake. Subjective effects in response to MDMA were assessed throughout the experiment. The primary outcome was the area under the plasma OXT concentration curve (AUC) after MDMA intake.

Results

Already at baseline, patients compared with healthy controls, showed significantly higher scores in anxiety (STAI: 41 points [IQR 34-48] vs. 28 points [24-31]; $P=0.02$), alexithymia (TAS: 47 points [38-59] vs. 30 points [29-37; $P=0.04$), and depression symptoms (BDI: 6 points [3-17] vs. 1 point [0-2]; $P=0.04$). In response to MDMA stimulation, in patients, there was only a minimal OXT change with 66 pg/ml [16-94], while in healthy controls, OXT increased by 658 pg/ml [355-914]. The AUC was 15.8 times (1485%), i.e., 85,678 pg/ml (95%-CI [-10,800 to -63,356], $P<0.001$), lower in patients compared with healthy controls. This lack of OXT in patients was associated with lower subjective effects such as “good drug effect,’ “feeling high,’ “satisfaction,’ “happy,’ “trust,’ “talkative,’ “openness,’ and “fear reduction’ compared with healthy controls.

Conclusion

These results lay the groundwork for OXT deficiency as a hypothalamic-pituitary entity. In patients with cDI, this lack in OXT was associated with reduced pro-social, empathic, and anxiolytic effects.

Protein tyrosine phosphatase receptors N and N2 regulate gonadotropin-releasing hormone neuron function

Srdjan Sokanovic[1], Stephanie Constantin[1], Aloa Lamarca Dams[1], Yuta Mochimaru[1], Kosara Smiljanic[1], Ivana Bjelobaba[2], Rafael Maso Previde[1] & Stanko Stojilkovic[1]

[1]The Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Section on Cellular Signaling, Bethesda, United States; [2]Institute for Biological Research “Sinisa Stankovic” National Institute of the Republic of Serbia, Department for Neurobiology, Belgrade, Serbia

Simultaneous knockout of the neuroendocrine marker genes *Ptprn* and *Ptprn2*, which encode the protein tyrosine phosphatase receptors N and N2, respectively, causes infertility of female mice while males are fertile. To clarify the mechanism of sex-specific roles of *Ptprn* and *Ptprn2* in mice reproduction, we analyzed the effects of their double knockout (DKO) on the hypothalamic-pituitary-gonadal axis. In DKO females, a delay in puberty and lack of ovulation were observed, supplemented by changes in ovarian gene expression and steroidogenesis. In DKO males, the testicular gene expression, steroidogenesis, and development of reproductive organs were not affected. However, in both sexes, pituitary luteinizing hormone (LH) beta gene expression and LH levels were reduced, while the calcium-mobilizing and LH secretory actions of gonadotropin-releasing hormone (GnRH) receptors were preserved. The expression of hypothalamic *Gnrh1* and *Kiss1* genes were also reduced in DKO females and males. The density of immunoreactive GnRH fibers was decreased in the median eminence in DKO females and males. The density of immunoreactive kisspeptin fibers was also decreased in the rostral periventricular region of the third ventricle of females and in the arcuate nucleus of females and males. Therefore, infertility in DKO females cannot be explained only by sex-specific gonadotroph impairment. Instead, changes in hypothalamic gene expression, specifically *Kiss1* in the rostral periventricular region of the third ventricle, might provide an alternative hypothesis due to its sexual dimorphism and involvement in puberty onset and ovulation.

Objective

Data on gender comparisons of diagnosis, management and prognostic factors in Cushing’s disease are very limited, however, there is no such a comparison in

ectopic ACTH syndrome (EAS) in the literature. The aim of this study is to compare clinical and hormonal data, neuroendocrine tumor (NET) localization, treatment and survival outcomes in Cushing's syndrome due to EAS by gender.
Material-Methods
Eleven experienced centers from our country participated in this retrospective study. Clinical and hormonal features, tumor imaging, pathological results, treatment modalities and disease courses of the patients were evaluated.
Results
Fifty-four EAS patients (28 female and 26 male) were reviewed. The mean age at diagnosis is similar as 43 ± 18 years for females and 41 ± 14 years for males. Results of clinical characteristics and hormonal evaluations (ACTH, basal cortisol and 24-h UFC levels and results of dexamethasone suppression test) did not differ in both gender. However, insulin-requiring diabetes mellitus ($P=0.04$) and osteoporosis with fractures were more common in males ($P=0.03$). While number of patients with increased DHEA-S levels than upper limit of normal was found to be significantly higher in females ($P=0.002$), suppressed freeT4 and TSH levels consistent with central hypothyroidism were higher in males ($P=0.02$). At the diagnosis, 36 NETs (68% of females and 69% of males) were localized. Small cell lung carcinoma was higher in females than in males ($P=0.02$), the frequency of other NETs (typical/atypical bronchial carcinoid, thymic carcinoid/thymic neuroendocrine carcinoma-NEC, medullary thyroid carcinoma, pancreatic G1-G2 NET/pancreatic NEC and pheochoromocytoma) was not different. Curative surgery was performed on 61% of females and 46% of males. Tumor size, ki-67 labelling index and presence of local lymph node metastasis in pathological examination and distant metastasis rates were similar in both gender. In the follow-up, tumor became visible in 7 of 10 females and 4 of 8 males after medical treatment and/or bilateral adrenalectomy. Tumor could not be detected in 7 patients (3 females, 4 males) during a mean follow-up of 58 months. The overall remission rates (65% of females, 62% of males) and NET-related death rates (14% of females, 30% of males) at the last visit were similar.
Conclusions
While EAS has a similar disease course in many aspects in males and females, hyperglycemia and osteoporosis are more severe in males. Their severity may be due to the reduced beneficial effects of adrenal androgens on bone due to low DHEA-S level and the difficulty of glycemic control by central hypothyroidism.

Clinical utility of the Octreotide Challenge Test in Acromegaly

Irfan Khan, Muna Guma, Yaasir Mamoojee & Andy James
Royal Victoria Infirmary, Endocrinology and Diabates, Newcastle upon Tyne, United Kingdom

Background
Acromegaly is a rare condition characterised primarily by tumourous production of excess Growth Hormone (GH) from a pituitary adenoma. The Octreotide Challenge Test (OCT) has been used in the RVI to predict short term efficacy of long-acting Somatostatin Analogue (SSA) therapy.
Aims
We retrospectively reviewed the OCT results of all patients with acromegaly treated at RVI from 2005 to 2021 to evaluate its clinical utility.
Methods
OCT protocol: blood sampling for GH is undertaken at baseline and then hourly for 6 h after SC administration of 100 mg of short-acting Octreotide. Data extracted: patient demographics, baseline GH and nadir GH on OCT, IGF1 level at presentation and after long-acting SSA therapy, follow-up MRI findings after SSA therapy.
Results
46/79 patients diagnosed with acromegaly had OCT. Female to male ratio was 3:2, with a mean age of 49 years and mean IGF1 of 3xULN at diagnosis. All patients demonstrated a reduction in GH on OCT, with a mean reduction of 72%. 25 patients received SSA pre-surgery or as long-term medical therapy. There was no relationship between reduction of GH on OCT and IGF1 suppression on SSA. Females were more likely to experience $>50\%$ reduction in IGF1 on SSA compared to males (78% vs. 56%, $P=0.04$). 18 patients underwent repeat imaging >6 months after SSA initiation and/or before surgery. Tumour shrinkage were demonstrated in 67% of cases. Shrinkage was most likely to be observed in females (66% vs. 33%, $P<0.05$). Average GH reduction on OCT was 68% in patients who demonstrated tumour shrinkage compared to 83% in those who did not ($P<0.05$).
Conclusions
OCT does not predict biochemical response to SSA therapy in our cohort. Female patients are more likely to have a better reduction in IGF1 and tumour shrinkage on SSA therapy compared to males. Tumour shrinkage is inversely related to GH reduction on OCT in our cohort.

Development of a new score to predict dopamine agonist resistance in patients with macroprolactinoma

Ameni Terzi, Ibtissem Oueslati, Bel Hadj Sliman Chayma, Sabrina Ayari, Meriem Yazidi & Melika Chihaoui
La Rabta University Hospital, Department of Endocrinology, Tunis, Tunisia

Introduction
Surgical treatment is indicated in patients with dopamine agonist-resistant macroprolactinoma. However, the resection of the tumor is usually partial because of fibrotic changes under long-term dopamine agonist therapy. Thus, early identification and management of patients at high risk of dopamine agonist resistance is crucial to a complete resection outcome and a better remission. The aim of this study was to develop a score predicting dopamine agonist resistance in patients with macroprolactinoma.
Methods
This was a single-center, retrospective study including 52 patients with macroprolactinoma. All enrolled patients were treated with dopamine agonists (cabergoline or bromocriptine). Resistance to dopamine agonists was defined as failure to achieve normoprolactinemia and/or 30% tumor shrinkage. Univariate and multivariate logistic regression analyses were performed to assess predictive factors of dopamine agonist resistance.
Results
Dopamine agonist resistance was observed in 16 patients (31%). Its predictive factors were age at diagnosis <30 years (Odds Ratio (OR):5, 95%-confidence interval (CI):1.39-18.41, $P=0.011$), baseline prolactin level $>$ 7000 µg/l (OR:4.861, 95%-CI:1.145-20.632, $P=0.035$), invasive adenoma (OR:10.263, 95%-CI:1.203-87.550, $P=0.018$), presence of hemorrhagic or necrotic components (OR = 28.5, 95%-CI:3.273-248.175, $P=10\text{-}3$) and tumor size $>$ 40 mm (OR = 7, 95%-CI:1.717-28.545, $P=0.004$). In multivariate analysis, the presence of hemorrhagic or necrotic components was the only independent predictor of resistance. We developed a new score to predict dopamine agonist resistance based on five items including age <30 years (5 points), prolactin level >7000 (4 points), invasive adenoma (10 points), tumor size $>$ 40 mm (7 points) and hemorrhagic or necrotic components (28 points). The total score was 54 points. The mean total score was 45.2 ± 8.4 in patients with dopamine agonist resistance and 17.5 ± 17.3 in patients responding to treatment ($P=10^{-3}$). This score had an area under the ROC curve of 0.902 (95%-CI: 0.816-0.987, $P<10^{-3}$). A total score $>$ 39 points predicted the risk of resistance with a sensitivity of 87% and a specificity of 88%.
Conclusion
We developed in this study a new score for the prediction of dopamine agonist resistance in patients with macroprolactinoma. This new tool would have a decisive impact on surgery timing for better management of macroprolactinomas.

P156

Incidence of complications of acromegaly 10 years after achieving biochemical control of GH – a single centre retrospective observational study

Sarah Mulholland, Richard Clayton, Biju Jose & Lakshminarayanan Varadhan
University Hospitals of North Midlands NHS Trust, Diabetes and Endocrine Department, Stoke on Trent, United Kingdom

Aim
Acromegaly is associated with multiple co-morbidities including diabetes mellitus (DM), obstructive sleep apnoea (OSA), arthropathy, cardiovascular events and malignancies. Early diagnosis and treatment, with an intention to cure or control the growth hormone (GH) exposure can reduce risk of these complications. The aim of this study is to assess the development of acromegaly-related complications amongst patients who have completed at least 10 years of follow up after achieving disease control.
Methods
167 patients who were treated for acromegaly in our tertiary pituitary referral centre (1940 -2012) were included in this retrospective observational study. 81/167 had achieved disease control. 31/81 had been discharged back to the care of the peripheral district general hospitals from which they were referred and hence were not included in the analysis (due to inaccessibility of case files). The case notes, general practice summary care records of 50/81 were subsequently included in the analysis and reviewed for development of any new complications after 10 years of cure and follow up thereafter.

Results
$n=50$: 30 patients remain under follow up and 20 patients had died. The mean duration of follow up was 291 months among patients on follow up and 259 months for those who had died. 21/50 patients did not develop any new complications throughout their follow up. 21/50 developed at least one complication of which 18 developed their complication after 10 years follow-up after cure: HT ($n=9$), DM ($n=7$), malignancy ($n=9$; one patient developed two malignancies), OSA ($n=2$), CCF ($n=3$), TMJ joint pathology ($n=1$) and dementia ($n=1$). [A further 9 patients had developed HT and 5 developed DM within 10 years after control]. On comparing the patients who remained normal ($n=21$) with those who developed complications after 10 years ($n=18$), there was no statistical difference in age at diagnosis (40.7 $\pm$ 14.6 vs. 45.4 $\pm$ 10.2 years), GH at diagnosis (23.4 $\pm$ 36.2 vs. 14.2 $\pm$ 16.5 mg/l), time to achieve control (55 $\pm$ 55 vs. 38 $\pm$ 46 months), modalities to achieve cure, total treatments required to achieve cure or the proportion of macroadenomas (17/21 vs. 13/18)
Conclusions
Our observational analysis of clinical practice demonstrates significant acromegaly–related complications developing during long term follow up of acromegaly despite achieving biochemical control. Though this study did not involve multivariate analysis and adjustment for other relevant risk factors for the comorbidities, it reemphasizes the need for continued monitoring and need for analysis of larger databases

Various cut-off points for paradoxical increase of growth hormone after glucose load in patients with acromegaly and their clinical implications

Magdalena Godlewska[1], Anna Bogusławska[1], Anna Grochowska[2], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]
[1]Jagiellonia University Medical College, Department of Endocrinology, Cracow, Poland; [2]Jagiellonia University Medical College, Department of Radiology, Cracow, Poland

Introduction
Paradoxical increase of growth hormone after glucose load (PR) and its clinical significance remain the focus of researchers. Different cut off points for diagnosis of PR are used in the literature.
Aim
Our aim was to investigate 3 different definitions of PR and their clinical implications.
Material and Methods
We analyzed 116 consecutive patients diagnosed with acromegaly in 2012-2022. We included 89 patients with available pituitary MRI, results of at least 3 GH values in the OGTT and hormonal evaluation before treatment. We used 3 definitions of PR. Definition 1(D1): increase of of GH at any time point of OGTT compared to baseline GH concentration. Definition 2 (D2): increase of at least 25%. Definition 3 (D3): increase of at least 50% occurring earlier than in 120'. For each definition, patients were divided into groups: with PR (PRpos), without PR (PRneg) and compared in terms of: GH concentrations during OGTT, IGF-1 and PRL and their upper limit of normal ratios, tumor volume, Signal Intensity Ratio (SIR) of the tumor and temporal grey matter. Response to SSA was assessed after 3-6 months of presurgical treatment in 69 patients, as the frequency of normalization of IGF1/ULN ratio and IGF1/ULN ratio decrease by $\geq$ 50%. This study was approved by the local Bioethics Committee (1072.6120.72.2020) and is part of statutory research of the Jagiellonian University Medical College (N41/DBS/000407).
Results
According to D1 60.7% of patients were PRpos, PRneg and PRpos differed in median nadir GH (15.05 uIU/ml IQR 23.6 vs. 26.4 I uIU/ml QR 49.2, $P=0.012$) and IGF1/ULN ratio (1.85 IQR 0,46 vs 2.44 IQR 1.05, $P=0.002$). Using D2, PRpos constituted 37.1% of patients. Median fasting GH concentration was higher in PRneg than in PRpos (10.23 ug/ml, IQR 14.19 vs 7.46 ug/ml, IQR 7.96, $P=0.011$). Using D3, 18% patients were PRpos, with no statistically significant differences between groups. The frequency of achieving normalization of IGF1 or decrease by at least 50% did not differ between PRpos and PRneg according to D1, D2, D3.
Conclusions
Even though we used 3 cut off points of PR, we observed no differences in responsiveness to presurgical treatment with SSA between PRpos and PRneg. However, further evaluation is required to understand the significance of PR and precise its exact definition.

Expression of omentin in the porcine anterior pituitary and action on cell proliferation, cell cycle, and secretion of FSH, LH, PRL, GH, TSH and ACTH

Natalia Respekta[1,2], Karolina Pich[1,2], Ewa Mlyczyńska[1,2], Kamil Dobrzyń[3], Małgorzata Opydo[4], Tadeusz Kamiński[5], Nina Smolińska[5], Joëlle Dupont[6] & Agnieszka Rak[1]
[1]Jagiellonian University, Institute of Zoology and Biomedical Research, Laboratory of Physiology and Toxicology of Reproduction, Kraków, Poland; [2]Jagiellonian University, Doctoral School of Exact and Natural Sciences, Faculty of Biology, Kraków, Poland; [3]University of Warmia and Mazury, Department of Zoology, Faculty of Biology and Biotechnology, Olsztyn, Poland; [4]Jagiellonian University, Institute of Zoology and Biomedical Research, Laboratory of Experimental Hematology, Kraków, Poland; [5]University of Warmia and Mazury, Department of Animal Anatomy and Physiology, Faculty of Biology and Biotechnology, Olsztyn, Poland; [6]INRAE, UMR85, Unité Physiologie de la Reproduction et des Comportements, Nouzilly, France

Background
Omentin, also known as intelectin-1, is a member of the family of adipose tissue-related hormones known as adipokines, that exert anti-inflammatory, anti-atherosclerotic, and cardiovascular protective effects. Omentin expression has been detected in adipocytes as well as in a variety of extra-adipose tissues, including the ovary. Interestingly, omentin expression in the pituitary has been shown to be regulated by pituitary hormones. These observations led us to investigate whether omentin, like the other adipokines, including leptin or adiponectin, regulates pituitary cell proliferation and hormone production. Disturbances of pituitary endocrinology lead to many pathologies. Therefore, the aim of the present study was to investigate i) omentin mRNA and protein expression as well as immunolocalization in the anterior pituitary cells (APc) of sows, ii) in vitro effect of omentin on proliferation, cell cycle, and hormone secretion by pig APc.
Methods
Anterior pituitaries were collected from mature Large White sows on days 2-3, 10-12, 14-16, and 17-19 of the estrous cycle ($n=6$). Omentin mRNA and protein expression as well as immunolocalization in APc were determined by real-time PCR, Western Blot, and immunohistochemistry, respectively. Next, in in vitro experiments, we investigated the time- (4-72 h) and dose- (10-100 ng/ml) dependent effect of omentin on APc proliferation (alamarBlue), cell cycle (flow cytometry), and hormones' secretion (FSH, LH, PRL, GH, TSH, ACTH). Statistical analysis was performed using the Student's t-test, one-way ANOVA, and Tukey's post-hoc test.
Results
Results showed fluctuations of omentin expression in AP during the estrous cycle: mRNA abundance increased from days 10-12 to 17-19, whereas protein concentration was highest on days 10-12, and lowest on days 17-19. We observed colocalization of omentin with FSH and LH in gonadotropes, with PRL in lactotropes, with GH in somatotropes, with TSH in thyrotropes, but not with ACTH in corticotropes. Interestingly, we noted the stimulatory effect of omentin on APc proliferation and an increase in the percentage of cells in the M phase of cell cycle. Additionally, we demonstrated a dose-dependent action of omentin on pituitary hormone secretion: decrease of FSH, increase of LH, GH, TSH, and no effect on PRL and ACTH.
Conclusion
Taken together, our data indicate that omentin, either locally produced or from other sources, may regulate porcine pituitary cells' functions. Funding: National Science Centre, Poland, 2020/37/B/NZ9/01154; Excellence Initiative – Jagiellonian University "Visibility and Mobility Module".

Mild Autonomous Cortisol Secretion May Be Related To Decreased Thalamic Volume

Cem Sulu, Pinar Kadioglu & Hande Mefkure Ozkaya
Istanbul University-Cerrahpasa, Endocrinology, Metabolism, and Diabetes, Istanbul, Turkey

Aim
To investigate the volumetric changes in cortical and subcortical deep gray matter (GM) structures and cognitive alterations in patients with mild autonomous cortisol secretion (MACS). We also sought to assess whether the anticipated changes in brain volume and cognitive functions of the patients with MACS differ from the changes in patients with overt Cushing's Syndrome (CS).
Methods
In this cross-sectional study, volumes of the cortex, hippocampus, amygdala, thalamus, caudate, and putamen were examined using 3T magnetic resonance

imaging and a voxel-based morphometry approach in 23 patients with MACS, 21 patients with active CS, 27 patients with CS in remission, and 21 controls. Cognitive functions were assessed using validated questionnaires.
Results
Patients with MACS had smaller volume of left thalamus (F = 3.8, $P=0.023$), left posterior thalamus (F = 4.9, $P=0.01$), left medial thalamus (F = 4.7, $P=0.028$), and right lateral thalamus (F = 4.1, $P=0.025$) than controls. Patients with active CS also had smaller volume of the left thalamus (F = 3.8, $P=0.044$), left posterior thalamus (F = 4.9, $P=0.007$), left medial thalamus (F = 4.7, $P=0.006$), and right lateral thalamus (F = 4.1, $P=0.042$) in relation to controls. Furthermore, patients with active CS and MACS had smaller volumes belonging to the pulvinar and mediodorsal nuclei of the left hemisphere in comparison to controls. Patients with CS in remission showed smaller volumes only in left medial (F = 4.7, $P=0.030$) and right lateral thalamus (F = 4.1, $P=0.028$) when compared with controls. Neuropsychological tests showed no difference between the groups.
Conclusion
MACS may be related to reduced volumes of the whole thalamus and thalamic nuclei similar to patients with overt hypercortisolism.

Multimodal therapy for the management of an aggressive corticotroph tumour after bilateral adrenalectomy

Prishila Fookeerah[1,2], Winny Varikatt[3,4] & Mark McLean[1,2,4]
[1]Westmead Hospital, Department of Diabetes and Endocrinology, Sydney, Australia; [2]Western Sydney University, School of Medicine, Sydney, Australia; [3]Institute of Clinical Pathology and Medical Research, Department of Tissue Pathology and Diagnostic Oncology, Sydney, Australia; [4]University of Sydney, Faculty of Medicine and Health, Sydney, Australia

Background
Rapid progression of corticotroph tumours can occur after bilateral adrenalectomy for treatment of Cushing's disease. There are currently no guidelines to assist with management of aggressive cases of Nelson's syndrome, particularly after surgery and radiotherapy.
Clinical case
A 53 year old woman presented with classic clinical features of hypercortisolism. Initial investigations showed a markedly elevated 24 hour urine cortisol level of 2426 nmol/day (<250), unsuppressed cortisol after 1mg dexamethasone and ACTH 22.6 pmol/l (0-12). High dose dexamethasone and CRH tests confirmed a pituitary cause of ACTH-dependent Cushing's syndrome. MRI of the pituitary fossa revealed a pituitary macroadenoma, maximum dimension 14 mm, without compression of the optic chiasm but extension into the right cavernous sinus. Surgical resection of the tumour could not be completed due to an intraoperative complication of internal carotid artery rupture and haemorrhagic stroke. Consequently, the patient opted for radiotherapy, achieving clinical remission after 2 years. Tumour regrowth 3 years later necessitated treatment with further radiosurgery (2200 cGy). Laparoscopic bilateral adrenalectomy was eventually performed after 2 years due to further relapse. Postoperative ACTH level was 195pmol/l (0-12). 15 months later she was diagnosed with Nelson's syndrome after significant progression of tumour with a maximum dimension now of 36mm and ACTH level of 2053 pmol/l. Urgent surgical debulking was undertaken via craniotomy. Histopathological evaluation confirmed a pituitary tumour expressing TPIT and ACTH, consistent with a densely granulated corticotroph tumour. Ki67 was elevated around 12-15%. Postoperative ACTH declined to 1190 pmol/l. She completed an 18 month course of temozolamide and capecitabine without progression (ACTH 603 pmol/l). At that point, due to modest tumour growth she received further radiotherapy followed by monthly pasireotide LAR 30mg. ACTH level 9 months after pasireotide is stable at 228 pmol/l, similar to her baseline level before developing Nelson's syndrome.
Conclusion
We employed a multimodal therapeutic approach including surgery, radiotherapy, temozolamide and pasireotide to successfully manage an aggressive corticotroph tumour. There has been adequate tumour control for up to 3 years since development of Nelson's syndrome.

Neurosarcoidosis Presenting with Panhypopituitarism

Amina Al-Qaysi & Shanthi Chandran
Milton Keynes University Hospital, Endocrinology & Diabetes Department, Milton Keynes, United Kingdom

Introduction
Sarcoidosis is a multisystem inflammatory disorder that affects the lungs and the lymph nodes commonly. The involvement of the nervous system in this disease is infrequent with prevalence lower than 10%. The diagnosis could be challenging when the neurologic disease presents in a patient without previously known sarcoidosis.
Case Report
A 39-year-old Caucasian gentleman was brought to the Emergency department with a one week's history of worsening confusion and headache on the background of nine months of intermittent headache, fatigue, weight gain and erectile dysfunction. The non-contrast CT scan of the head showed an infundibular pituitary lesion and he had raised opening pressure (33.5 cm H2O) on lumbar puncture. The cerebrospinal fluid (CSF) studies showed lymphocytic pleocytosis, high protein with normal glucose. He had negative blood cultures, negative CSF BioFire PCR, bacterial and mycobacterial cultures, and negative CSF TB PCR. He also had negative HIV and cryptococcal serology. His serum Angiotensin-Converting Enzyme (ACE) level was 42 U/l (reference range 18 - 55 U/l) and CSF ACE was raised at 4.78 U/l (normal value <1.20 U/l). The patient had panhypopituitarism (central hypothyroidism, hypogonadotropic hypogonadism and hypocortisolaemia) with a mild hyperprolactinaemia of 531 µg/l. He was commenced on oral Hydrocortisone and Levothyroxine was added later. The contrast MRI of the brain showed profuse enhancement of the thickened nodular pituitary infundibulum. There was also widespread profuse enhancement of the leptomeninges particularly around the brainstem and extension of the enhancement along the perivascular spaces of the cerebral hemispheres. The radiologic appearance was suspicious of neurosarcoidosis, and other differential diagnoses were tuberculosis and carcinomatosis. The patient was found to have mediastinal and bilateral hilar lymphadenopathy on CT scan of the chest, abdomen and pelvis. He was commenced on intravenous Methylprednisolone after an ultrasound-guided left inguinal lymph node biopsy showed non-caseating granulamatous changes in keeping with sarcoidosis. The patient improved clinically and he was discharged home to be followed up in the Endocrinology and Sarcoidosis clinics.
Conclusion
Neurosarcoidosis manifests with cranial neuropathy in up to 50% of the cases with the involvement of the hypothalamus and the pituitary gland being infrequent and reported in 2% of the cases only. The diagnosis is generally guided by clinical findings and imaging investigations, supported by extra-neural tissues biopsy. Systemic steroids remain the mainstay of treatment in neurologic disease, as the spontaneous improvement is unlikely to happen.

An unusual sellar dermoid cyst

Shahzad Akbar[1], Muhammad Taqi[1], Najeeb Shah[2], Shiva Mongolu[1] & Mo Aye[1]
[1]Hull University Teaching Hospitals NHS Trust, Diabetes and Endocrinology, Kingston upon Hull, United Kingdom; [2]York and Scarborough NHS Foundation Trust, Diabetes and Endocrinology, York, United Kingdom

Introduction
Dermoid cysts are rare (0.5% of intracranial tumours). They are best considered a spectrum: from epidermoid cysts containing desquamated squamous epithelium to teratomas containing all three embryonic tissues. Sellar dermoid cysts are even rarer [Orpha.net ID: ORPHA:91351].
Case
A 47-year old white British male was referred following incidental discovery of bitemporal field defect on routine eye test. He was otherwise completely asymptomatic. A 27mm x 24 mm x 27 mm intra-/suprasellar lesion was found on orbital MRI. A pituitary MRI with contrast showed the same mass with a small left lateral extension, superomedial to the proximal middle cerebral artery. The tumour was heterogeneous with areas of high T1 and T2 signal. The bulk of the tumour showed low signal on the fat-suppressed sequences. The suprasellar component displaced the optic chiasm and stretched the pre-chiasmatic segments. The pituitary gland was separate from the tumour. Numerous T1 hyperintense foci were found in the third and left lateral ventricles and in subarachnoid spaces overlying the frontal lobes and the cerebellar hemisphere. The radiological diagnosis was either a craniopharyngioma or a dermoid cyst that has ruptured with intracranial dissemination. Baseline pituitary function was normal: cortisol 477nM/l, testosterone 12 nmol/l, FSH 4.1 IU/l, LH 2.8 IU/l, IGF-1 16.8 nmol/l (ref 7-28), free T4 12 pmol/l, TSH 4.2 mU/l, prolactin 270 mU/l. OCT-RNFL analysis showed deteriorating fibre loss and thinning. Endoscopic transsphenoidal debulking was done. Histology showed keratinous material with a basket weave appearance. Cam5.2 stain showed <20 cells. Reticulin staining and immunohistochemistry for synaptophysin, p53, Ki-67, pituitary hormones and

transcription factors were negative. Visual fields improved. Postoperative endocrine function showed suboptimal cortisol (402 nmol/l) and GH (2.0) on insulin tolerance test. A 3-month postoperative scan showed extensive debulking with a 11 mm residuum. Optic chiasm was decompressed. The patient further scans at 6 monthly intervals. The first showed no change. The second showed increase in the residuum with no immediate pressure on the chiasm. Further proactive surgery is being offered to patient.

Discussion points

- This was an unusual presentation of a very rare condition. Despite rupture of the cyst, the patient was asymptomatic and the field defect was an incidental finding.
- The pituitary function was preserved at presentation despite a large tumour, possibly indicating slow growth over time.
- Histologically, the lesion was closer to the epidermoid end of the spectrum but it is difficult to prognosticate regrowth. Close monitoring is advisable.

Pituitary apoplexy as the first manifestation of non-functioning pituitary neuroendocrine tumor

Lukasz Działach[1], Joanna Sobolewska[1], Wioleta Respondek[2], Agnieszka Wojciechowska-Luzniak[1] & Przemysław Witek[1]
[1]Medical University of Warsaw, Department of Internal Medicine, Endocrinology and Diabetes, Warsaw, Poland; [2]Mazovian Brodnowski Hospital, Department of Internal Medicine, Endocrinology and Diabetes, Warsaw, Poland

Introduction

Pituitary apoplexy (PA) is a rare but potentially life-threatening complication that may occur in pituitary neuroendocrine tumors (PitNETs). Non-functioning PitNETs (NF-PitNETs), specifically macroadenomas, seem to have a higher risk of apoplexy.

Case description

A 45-year-old male presented to the emergency unit with a one-week history of binocular visual deterioration (blurred vision, diplopia, visual field defect) with left-side predominance, dull headache and nausea. His past medical history was significant for arterial hypertension. The ophthalmological examination showed that visual acuity was limited to hand motion in the left eye with visual field impaired in all directions and a decrease of visual acuity to 0.5 in the right eye without visual field deficits. Vital signs were normal. Apart from the visual impairment, the neurological examination was normal. Initial laboratory tests showed mild hyponatremia (Na^+: 131 mmol/l). A computed tomography of the brain was performed and revealed a haemorrhagic sellar mass with suprasellar extension. The subsequent magnetic resonance imaging confirmed a large pituitary lesion measuring 20x27x29 mm with signs of intratumoral bleeding, compressing and displacing the optic chiasm, compressing posterobasal part of the frontal lobes, and reaching the floor of the third ventricle. The hormonal evaluation showed central hypothyroidism (TSH: 0.761 μIU/ml, FT4: 0.65 ng/dl, FT3: 1.21 pg/ml) and hypogonadotropic hypogonadism (LH: 1.8 mIU/ml, FSH: 4.26 mIU/ml, testosterone: 0.69 nmol/l); the corticotroph axis was preserved (ACTH: 25.3 pg/ml, random cortisol: 25.30 μg/dl). The patient received hydrocortisone intravenously and underwent endoscopic endonasal transsphenoidal surgery. A total resection of the pituitary lesion was achieved. Postoperatively, the ophthalmological deficits improved, however, due to panhypopituitarism, the patient continued oral hydrocortisone. Additionally, levothyroxine, testosterone, and growth hormone replacement therapy were introduced. Due to the transient diabetes insipidus, he required also temporary treatment with desmopressin which was discontinued 12 weeks after the surgery. Pathological examination revealed gonadotroph PitNET with tumor positive staining for FSH, LH and alpha-subunit. The patient is still followed up at our Department.

Conclusions

PA, although being a rare complication of PitNETs, is considered an endocrine emergency, requiring prompt diagnosis and appropriate treatment, especially in cases, when PA is the first manifestation of PitNET. Management of PA should be individualized, however, all patients should receive corticosteroids, regarding the coexistence of adrenal insufficiency. In the case of optic chiasm compression, a neurosurgical intervention should be urgently performed.

FTO gene polymorphisms and their role in acromegaly

Aleksandra Jawiarczyk-Przybyłowska, Justyna Kuliczkowska-Płaksej, Jowita Halupczok-Zyła, Katarzyna Kolačkov, Agnieszka Zembska, Aleksandra Zdrojowy-Wełna & Marek Bolanowski
[1]Wroclaw Medical University, Wrocław, Poland

Acromegaly is characterized by two-fold higher mortality than in the general population. The leading causes of morbidity and mortality in patients with acromegaly are cardiovascular diseases (CVD). Many population-based studies suggest a role of genetic background in CVD and associated metabolic disturbances. In 2007, *FTO* (fat mass and obesity associated) gene polymorphisms were discovered. According to a few studies, the polymorphisms of FTO gene are associated with obesity, as well as with an increased risk of CVD. It has been suggested that the GH / IGF-1 axis may be the mediator of the relationship between the *FTO* gene and BMI. The aim of our study was to determine the relationship of four risk alleles of selected FTO gene polymorphisms: rs1121980 (allele T), rs1421085 (allele C), rs9930506 (allele G), rs9939609 (allele A) with: selected parameters of lipid metabolism and IGF-1 and GH levels in the group of patients with acromegaly compared to control group. We showed that the distribution of the risk-alleles of the analyzed genotypes did not deviate between acromegaly and control group. The data revealed that homozygotes for risk allele carriers as well as only carrier of risk allele have lower IGF-1 (IGF-1 x ULN) concentrations. We did not find any association of *FTO* gene polymorphisms with lipid metabolism in the whole acromegalic group but found these when we analyzed acromegalic patients according to the activity of the disease. In controlled acromegaly group we showed that homozygotes for three risk alleles had lower HDL cholesterol concentration. Homozygotes for the rs1121980-risk allele (allele T) had lower HDL cholesterol concentration than carriers of the CC and CT genotypes ($P\times=\times0.037$). Homozygotes for the rs1421085-risk allele (allele C) had lower HDL cholesterol concentration than carriers of the TT and CT genotypes ($P\times=\times0.035$). Homozygotes for rs993609–risk allele (allele A) had lower HDL concertation than carriers of AT and TT genotypes ($P=0.09$). We observed a similar situation for total cholesterol and LDL cholesterol. What is important to note, we did not observe this association in the control group. Conclusion: There is an association between *FTO* gene polymorphisms and lipids metabolism suggesting *FTO* gene polymorphisms may be associated with higher CVD risk in patients with acromegaly. In addition, there is an association between *FTO* gene polymorphisms and IGF-1 concertation implying *FTO* gene polymorphisms may influence/modify IGF-1 synthesis. Further investigation on a larger scale is required to provide more precise evidence.

Longer surveillance period needed for Ectopic ACTH secretion and Cushing's syndrome – two unusual cases

Zin Htut, Fatima Bahowairath & Jeannie Todd
Imperial College Healthcare NHS Trust, Endocrinology and Diabetes, London, United Kingdom

Ectopic Cushing's syndrome is a rare condition accounting for 10–20% of all cases of ACTH-dependent Cushing. Neuroendocrine tumours (NETs), mainly bronchial carcinoids and small cell lung cancer, are the most frequent causes of ectopic ACTH secretion(1). Here we report two challenging cases with long duration of surveillance and monitoring.

Case 1

A 42-year-old lady with a florid Cushing syndrome underwent bilateral adrenalectomy in 2002. An IPSS in 2001 failed to demonstrate a central to peripheral ACTH gradient suggesting an ectopic ACTH secretion. Serial whole-body gallium 68 DOTATATE PET CT over a decade failed to reveal any tracer avid lesion. CT CAP did not identify any pathology. Since 2012, her ACTH level continued to rise and peaked at 3800 ng/l. Despite thorough radiological evaluation, the source remained unlocalised. In 2016, 16 years after her initial diagnosis, her CT CAP revealed a 13 mm right perihilar nodule with a positive FDG-PET in the perihilar region. She underwent right middle lobectomy. Histology showed a typical bronchial carcinoid with positive ACTH stain and low proliferation index (Ki-67 1%). Post operative ACTH level was 12 ng/l and she is in remission.

Case 2

A 31 years old lady was diagnosed with ectopic Cushing's syndrome and required bilateral adrenalectomy in 1990 to ameliorate hypercortisolism. Surveillance imaging with CT and octreotide scans over the period showed two right lung nodules with marginal interval growth. The case was discussed in the lung MDT in 2006 and 2014. The nodules were not amenable for surgery. Her ACTH level during this time was between 1000 and 2800 ng/l. In 2015, the nodules increased in size with growth noted in proximity to the main vessels and bronchi. It was then decided to proceed with a right lung wedge resection. Histology confirmed bronchial carcinoids and stained positive for ACTH. The ACTH level fell from peak 2210 to 24 ng/l postoperatively with spontaneous remission of Cushing's syndrome.

Conclusion

We present two uncommon cases of ectopic ACTH secretion caused by bronchial carcinoid, which took nearly two decades for localisation. The cases highlight the fact that identifying the source of ectopic secretion is always challenging due to their small size and unpredictable anatomical location. It is of paramount importance for regular follow up with surveillance imaging.

Doege-Potter Syndrome, a case report

Alba Guerrero[1], Fabiola Romero[1], Helen Lopez[1], Chong Hun Lee[2], Alejandra Muller[1], Roque Rodriguez[1] & Elizabeth Valinotti[1]
[1]Institute of Prevision Social, Endocrinology, Asuncion, Paraguay; [2]Institute of Prevision Social, Surgery, Asuncion, Paraguay

Introduction
2 to 3% of the causes of hypoglycemia in the population without diabetes mellitus correspond to tumors of cells other than islets. Below is a rare case of hypoglycemia related to a pleural tumor.
Clinical case
A 65-year-old woman with arterial hypertension, psychiatric treatment for confusion and behavioral changes of 6 months of evolution, palpitations and night sweats, loss of 20 kg of weight, several admissions to the emergency room, until her hospitalization due to alteration of the sensory, where severe hypoglycemia is found. She denies using hypoglycemic agents, corticosteroids, and alcoholism. Physical examination: Diminished vesicular murmur in the middle and lower left lung fields. Laboratory tests: Plasma glucose: 30 mg/dl, serum insulin: less than 1 Uu/ml, C peptide: 0.17 ng/ml, anti-insulin antibodies: 1.8 negative, the rest in normal range including cortisol, normal thyroid, renal and hepatic function. Chest CT: left pleural tumor of 30 x 20 cm in the left hemithorax. Biopsy: spindle cell proliferation. Tumor excision and histology: well-defined stromal neoplastic proliferation, without atypia, suggestive of an intense, diffuse, cytoplasmic CD34+ solitary fibrous tumor. Desmin, pancytokeratin AE1/AE3 and S 100 negative, ki67 10%, resolved hypoglycemia after surgery.
Discussion
Doege- Potter syndrome is a rare cause of hypoglycemia, characterized by solitary fibrous tumors that are associated with hypoglycemia of non-islet cell tumors of the pancreas (NICTH). These are epithelial of mesenchymal tumors, of various locations, that produce IGF2, which bind to insulin receptors, increasing peripheral glucose consumption, decreasing glycogenolysis and gluconeogenesis. In general, hypoglycemia is fasting with confusional symptoms; as the case of our patient; in which it is confused with a psychiatric picture. Decreased peptide C and decreased insulinemia make it necessary to think about NICTH. In half of the cases, hypoglycemia precedes the discovery of tumors, as stated. Hypoglycemia is not related to aggressiveness or tumor size. Random IGF2 levels may be normal; in this case IGF2 dosing was not possible. Complete resolution of hypoglycemia after surgery supports the diagnosis of the syndrome. In conclusion, Doege- Potter syndrome, a rare and potentially reversible entity, should be evaluated in the differential diagnosis of hypoglycemia in the population without diabetes.

Somatostatin analogue treatment is associated with lack of progression of pNETs <20mm in size in patients with MEN1

Isolda Frizelle, Anand Velusamy, Barbara McGowan, Louise Breen, Emma Duncan, Louise Izatt, Dimitra Christodoulou, Mamta Joshi & Carroll Paul
Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom

Introduction
Pancreatic neuroendocrine tumours (pNETs) are the main cause of mortality in patients with multiple endocrine neoplasia type 1 (MEN1). The CLARINET study demonstrated that somatostatin analogue treatment improved progression free survival in patients with enteropancreatic NETs but little is known about the role of SSA in preventing progression of pNETs in MEN1 (1). Many centres have started using SSA treatment in MEN1 patients with enlarging pNETs or tumours >15 mm. This is current practice in our centre.
Objective
This observational study examined the effectiveness of somatostatin analogue (SSA) treatment in preventing progression of pNETS in MEN1.
Methods
Using our database of MEN1 patients, electronic patient records were individually reviewed to document the radiological, biochemical and clinical behaviour of pNETs over time. Patients were treated with SSA if tumours had documented growth, were > 15 mm in size or were associated with metastases. We compared pNET size/ growth in patients treated and untreated with SSA (overwhelmingly lanreotide autogel 120 mg 4 weekly).
Results

Demographics

	Total MEN1 cohort
n	57
Gender	37F: 20M
Age (y)	45 (16)
PNETs documented	44 (12 surgical)
Deceased (n)	8
Mean age of death, y (range)	59 (41-84)
SSA use (%)	35.1
Metastases N (%)	4 (7.02)
Surgical intervention? N (%)	16 (28.1)
Other Rx (n)	Peptide receptor radiotherapy (PRRT) ($n=2$)

Conclusion

Included patients treated with SSA compared with untreated patients

	MEN1 cohort with pNETs on SSA	MEN1 cohort with pNETs not on SSA
n	20	12
Gender	12F: 8M	8F:4M
Age (y)	42.2 (12.9)	41.6 (17.6)
Deceased (n)	3	2
Mean age of death (y)	56	51
Cause of deaths	Metastatic pNET x2, metastatic gastrinoma	ACC, metastatic pNET
Surgical intervention? (n)	3	1
PNET size (mm)(SD)	15 (8)	8 (4)
Stable disease	11	8
Progression	1	1
Improvement	4	0
Data unavailable	4	3
Duration of SSA use	4- 120 (mean: 48)(SD 24)	N/A
Duration of total surveillance (mths)	61.9 (25.2)	34.8 (24.6)
SEs reported	Minimal reporting-GI Symptoms, GB sludge, ?pancreatitis	N/A
Other Rx	1 patient had PRRT	

These data indicate that mean duration of 4 years SSA treatment is associated with stable size or reduction (20%) in pNETs averaging 1.5 cm in patients with MEN1. Multi-centre collaboration, including comparison of a larger untreated cohort would clarify the effectiveness of SSA preventing progression on pNETs in MEN1.

Quantitative assessment of the signal intensity of somatotropin pituitary tumors and its clinical implications in consecutive newly-diagnosed patients with acromegaly

Magdalena Godlewska[1], Anna Bogusławska[1], Anna Grochowska[2], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]
[1]Jagiellonian University Medical College, Department of Endocrinology, Cracow, Poland; [2]Jagiellonian University Medical College in Cracow, Department of Radiology, Cracow, Poland

Introduction
Somatotroph Pituitary Neuroendocrine Tumor's (sPitNET) signal intensity in T2-weighted MR images (SI) was reported as prognostic marker for tumor's aggressiveness and poor response to 1st generation somatostatin analogs (SSA). Tumors are arbitrary divided into 3 groups: hyperintensive (HYPER), isointensive (ISO) and hypointensive (HYPO).
Aim
Our aim was to quantitatively assess SI of sPitNETs and investigate its clinical implications.
Patients and methods
116 consecutive patients newly diagnosed with acromegaly between 01.01.2012 and 31.12.2022 at the Department of Endocrinology, Jagiellonian University Medical College were evaluated. Patients with available coronal T2-weighted pituitary MRI images were included. Exclusion criterion was tumor's cystic

component preventing from SI assessment. Finally, 67 patients were in the analysis. SI of the solid part of sPitNETs, grey and white matter of the temporal lobe were measured. Patients were divided into 3 groups: HYPER, with SI higher than grey matter, ISO with SI higher than white matter, but lower than grey matter and HYPO with SI lower than white matter. Baseline and nadir GH after glucose load; IGF-1 and upper limit of normal range for age, sex ratio (IGF%ULN) before and after SSA treatment, tumor volume measured by manual delineation of Volume of Interest (TV), and baseline GH concentration to TV ratio (GH/TV) were compared. This study was approved by the Bioethics Committee (1072.6120.72.2020) and is part of statutory research (N41/DBS/000407).
Results
Median TV was 1.38 cm3 (IQR 4.51) for HYPER, 1.83 cm3 (IQR 6.44) for ISO and (0.58 cm3 IQR 0.73) for HYPO ($P=0.005$). TV was higher in HYPER than in HYPO ($P=0.04$) and in ISO than in HYPO ($P=0.04$), with no differences between HYPER and ISO($P=1.0$). Differences in baseline GH, nadir GH in OGTT and IGF1%ULN before and after treatment with SSA, were not significant. GH/TV ratio was higher in HYPO (43.64 uIU/ml*cm^3 IQR 48.35) than in HYPER (11.78 uIU/ml*cm^3 IQR 15.75) ($P=0.037$) and higher in HYPO than in ISO (20.38 uIU/ml*cm^3; IQR 32.57) ($P=0.005$), with no significant differences between HYPER and ISO ($P=1.0$)
Conclusions
Both HYPER and ISO were larger than HYPO. HYPO may seem more biochemically active than HYPER and ISO tumors. In our cohort, no statistical differences were found between HYPER and ISO tumors. Whether HYPER and ISO tumors constitute two separate groups in terms of clinical significance, requires further research.

DOI: 10.1530/endoabs.90.P168

Lymphocytic Hypophysitis – many faces of the same disesase. Watchful waiting could be suggested therapeutic approach in majority of patients

Łukasz Kluczyński, Magdalena Godlewska, Alicja Hubalewska-Dydejczyk & Aleksandra Gilis-Januszewska
Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland

Introduction
Clinical manifestation of hypophysitis depends on presence of hormonal abnormalities and/or enlargement of pituitary structures. Both the diagnosis and treatment still remain challenging. Hormonal replacement is the basic therapy, while steroids are the first-line treatment in case of mass related symptoms. The course of the disease varies from spontaneous remission to atrophy of the pituitary gland.
Aim
To characterize and sum up clinical/hormonal/radiological findings and therapeutic approach in patients with probable lymphocytic hypophysitis.
Methods
A retrospective analysis of 12 patients (9W/3M) with probable lymphocytic hypophysitis hospitalized in our Department (2015-2022) was performed. Clinical, laboratory and imaging findings were assessed. The study is a part of a project "Assessment of the health condition of patients with hypopituitarism in Poland" (grant N41/DBS/000408).
Results
Mean age at diagnosis was 49.2 years (48.2 for W, 52.0 years for M). Headaches and diabetes insipidus were the first manifestation in 7/12 and 3/12 cases, respectively, while 2/12 patients presented with clinical symptoms of adrenal insufficiency. In one patient hypocortisolism was transient, in the second case reassessment is difficult due to inhaled and oral steroids used by patient in asthma exacerbations. 5/12 patients were diagnosed with diabetes insipidus (one temporary) and gonadal axis dysfunction was detected in 5/12 cases (one transient). Central hypothyroidism was found in 4/12 patients – in all cases permanent. Probable GH deficit (based on lower insulin-like growth factor 1 concentration) was suspected in 5/12 patients (one transient). One patient had no hormonal abnormalities. Magnetic resonance (MR) revealed thickened pituitary stalk (max. 11 mm) in all but one cases; in two – lack of the posterior lobe signal. In one patient the area of inflammation within the anterior pituitary lobe was described. The hormonal substitution was administered appropriately to the deficits; due to the severe headaches 3 patients were given steroids (2 in intravenous pulses, one orally) with subsequent reduction in the frequency and severity of complaints and stable/improved image of pituitary area in the control MR. One woman was operated due to the progression in the pituitary tumor size and mass effect-related symptoms – histopathological examination confirmed lymphocytic hypophysitis. In the remaining 8/12 patients watchful waiting approach allowed to obtain hormonal and radiological stabilization/improvement.
Conclusions
Non-specific, transient characteristic of the symptoms and hormonal deficits cause difficulties in establishing proper diagnosis. The treatment may vary depending on the clinical and hormonal status. Further research and long term observation might help in better understanding of the disease.

Mortality in acromegaly diagnosed in the elderly in Spain is higher in women compared to the general Spanish population

Betina Biagetti[1], Pedro Iglesias[2], Rocio Villar Taibo[3], María Dolores Moure[4], Miguel Paja Fano[5], Marta Araujo Castro[6], Jessica Ares Blanco[7], Maria Cristina Alvarez Escola[8], Almudena Vicente[9], Èlia Álvarez Guivernau[10], Iria Novoa-Testa[11], Fernando Cordido Carballido[11], Rosa Camara-Gómez[12], Beatriz Lecumberri[8], Carlos García Gómez[2], Ignacio Bernabeu[3], Laura Manjon Miguelez[7], Sonia Gaztambide[4], Susan Webb[10], Edelmiro Luis Menendez Torre[7], Juan Jose Diez[2], Rafael Simo Canonge[1] & Manel Puig-Domingo[13]
[1]Hospital Universitari Vall d'Hebron, Barcelona, Spain; [2]Puerta de Hierro Majadahonda University Hospital, Majadahonda, Spain; [3]Santiago Clinic Hospital CHUS, Santiago de Compostela, Spain; [4]University Hospital of the Crosses, Barakaldo, Spain; [5]Basurto University Hospital, Bilbo, Spain; [6]Ramón y Cajal Hospital, Madrid, Spain; [7]Central University Hospital of Asturias, Oviedo, Spain; [8]La Paz University Hospital, Madrid, Spain; [9]Hospital General Universitario de Toledo, Toledo, Spain; [10]Sant Pau Art Nouveau Site, Barcelona, Spain; [11][CHUAC] University Hospital of A Coruña, A Coruña, Spain; [12]Hospital la Fe, Valencia, Spain; [13]Germans Trias i Pujol Hospital, Badalona, Spain

Context
There is no data on mortality of acromegaly diagnosed in the elderly.
Objective
To compare clinical characteristics, GH-related comorbidities, therapeutic approaches and mortality of patients diagnosed before or after 2010 and to assess overall mortality compared with the general Spanish population.
Setting
Spanish tertiary care centers.
Design, Patients, and Methods
Retrospective evaluation of 118 patients diagnosed with acromegaly at or above the age of 65. Kaplan-Meier curves were constructed to trace survival, and Cox proportional hazard models were used to assess the risk factors associated with mortality. We also compared mortality with that of the Spanish population by using age- and gender-adjusted standardized mortality ratios (SMR)
Results
No differences were found in first-line treatment or biochemical control, between both periods except for faster biochemical control after 2010. Twenty-nine (24.6%) patients died, without differences between groups, median of follow-up 8.6 years [103, (72.3) months]. Overall SMR was 1.02 (95% CI: 0.57–1.54), [0.60 (95% CI: 0.35–1.06) for men] and [1.80 (95% CI: 1.07–2.94) for women]. The most common cause of death was cardiovascular disease (CVD).
Conclusions
The mortality in patients with acromegaly diagnosed in the elderly was no different between both periods and there was no overall SMR difference from the general Spanish population. However, the SMR was higher in women. As CVD is the leading cause of mortality, it seems advisable to initiate an intense CVD protective treatment as soon as acromegaly is diagnosed, particularly in women, in addition to tight acromegaly control in order to prevent excess mortality.

Treatment Patterns in Acromegaly: Analysis of Real-World US Insurance Claims from the MarketScan® Database

Thierry Brue[1], Maria Fleseriu[2], Ariel Barkan[3], Edouard Duquesne[4], Aude Houchard[4], Maria del Pilar Schneider[5], Antonio Ribeiro-Oliveira[6] & Shlomo K. Melmed[7]
[1]Aix-Marseille University, Marseille, France; [2]Oregon Health and Science University, Pituitary Center, Portland, United States; [3]University of Michigan, A. Alfred Taubman Health Care Center, Ann Arbor, United States; [4]Ipsen, Boulogne-Billancourt, France; [5]Ipsen, Les Ulis, France; [6]Ipsen, Cambridge, United States; [7]Cedars-Sinai Medical Center, Los Angeles, United States

Background
Medical treatment for acromegaly (characterized by excess growth hormone [GH] production) includes somatostatin receptor ligands (SRLs), dopamine

agonists (DAs), and GH receptor antagonists (GHRAs). However, recent real-world United States (US) treatment evaluations are few. We present treatment patterns for patients receiving medications for acromegaly (1/1/2010–31/7/2022).
Methods
De-identified data were extracted from MarketScan®, a US health insurance claims database. Eligible patients were ≥18-years-old at diagnosis; receiving monotherapy or combination therapy (≥2 treatments overlapping for >3 months) for ≥90 days without treatment gaps; had ≥2 claims associated with acromegaly; with data ≥3 months before and ≥6 months after diagnosis/first treatment claim (earlier date). Outcomes were: demographic characteristics; treatment frequency by line of treatment (LOT) and changes between LOTs (Sankey plot); treatment persistence for first LOT (LOT 1) monotherapies (Kaplan–Meier estimator); and treatment up-/downtitration (≥30% dose change, for octreotide long-acting release [OCT] and lanreotide depot [LAN]). Biochemical control values were unavailable.
Results
Of 882 patients, 50.1% were female; mean age at diagnosis was 48.6 years (standard deviation 13.6 years). Among patients, 59.4% had 1 LOT, 23.1% had 2 LOTs, and 17.5% had 3 LOTs. Most common LOT 1 medication class was first-generation SRLs: OCT (27.7%), LAN (21.1%). Other LOT 1 classes: DAs (cabergoline; 34.5%), GHRAs (pegvisomant; 10.5%). In LOT 1, only 7 patients received second-generation SRL pasireotide and no patients received oral octreotide. Most patients initiated treatment with monotherapies (94.6%). Among LOT 1 monotherapies, GHRAs had the longest median persistence (pegvisomant; 24.8 months; 95% confidence interval [CI]: 16.59–32.49 months; $n=93$), followed by first generation SRLs (OCT and LAN; 20.0 months; 95% CI: 16.98–23.87 months; $n=430$). DAs had the shortest persistence (cabergoline; 14.4 months; 95% CI: 12.23–16.82 months; $n=304$). Of patients receiving OCT or LAN, 67.6% had ≥1 dose uptitration; 45.0% had ≥1 dose downtitration.
Conclusions
Despite consensus guidelines recommending DA monotherapy for few select patients with acromegaly, our real world analysis found that approximately one third of patients initiated treatment with this class with the shortest persistence. OCT and LAN monotherapies were also commonly used as LOT 1 and had longer persistence. GHRAs, the class with the longest persistence, were not common monotherapy in LOT 1, possibly due to not targeting pituitary adenomas directly. Interestingly, only 5% of patients initiated treatment with combination therapies. Recommendations for individualized therapy should consider medication persistence and real-world treatment patterns.

Bilateral Inferior Petrosal Sinus Sampling and Utility of Maximum Stimulated Petrosal Sinus ACTH to Baseline ACTH ratio in Adrenocorticotropin-dependent Cushing's Syndrome

Aasim Maldar[1], Phulrenu Chauhan[1], Aniruddha Kulkarni[2], B. K. Misra[3], N. F. Shah[1] & Manoj Chadha[1]
[1]P. D. Hinduja Hospital and Medical Research Centre, Department of Endocrinology, Mumbai, India; [2]P. D. Hinduja Hospital and Medical Research Centre, Department of Interventional Radiology, Mumbai, India; [3]P. D. Hinduja Hospital and Medical Research Centre, Department of Neurosurgery and Gamma Knife Radiation, Mumbai, India

Methods
The diagnosis of Cushing's Syndrome (CS) was made as per the prevalent endocrine society guidelines. CS patients with serum ACTH>15 pg/ml were considered as ACTH-dependent CS. Baseline ACTH (both inferior petrosal sinuses and peripheral) values were obtained, and since 2014, stimulated ACTH values (5 and 10 minutes post one unit iv vasopressin) were obtained as standard protocol. Prolactin corrected ACTH ratios were additionally being calculated since 2016. The highest central to peripheral ACTH gradient >2 in baseline samples (bC:P), >3 in samples after vasopressin stimulation (sC:P), and >0.8 in PRL-corrected ratios (pC:P) was used as reference value indicative of Cushing's Disease (CD). An inter-petrosal gradient >1.4 was considered to be suggestive of an adenoma located on the side of the petrosal sinus with the higher ACTH concentration.
Results
Of the 51 patients with ACTH-dependent CS who underwent BIPSS, four patients with incomplete data, one patient with unilateral petrosal sinus catheterization, one patient with Cortisol Resistance Syndrome were excluded from the analysis. Mean age of our cohort was 37.5 years, with 77.8% females. 39 patients had CD, while six had ectopic CS. bC:P>2 ($n=45$) demonstrated 92.3% sensitivity, 83.3% specificity, 97.3% PPV and 62.5% NPV, while sC:P>3 ($n=31$) demonstrated 96.3% sensitivity, 100% specificity, 100% PPV and 80% NPV to diagnose CD. pC:P>0.8 ($n=20$) improved the sensitivity and NPV to 100%, with a 75% specificity and 94.1% PPV. On ROC analysis, cut-point ratio of 2.55 for bC:P value gave a sensitivity of 89.7% and specificity of 100% (AUC=0.964); sC:P ratio of 2.95 had 96.3% sensitivity and 100% specificity (AUC=0.991); 0.93 for pC:P ratio provided a sensitivity of 93.8% and specificity of 100% for diagnosis of CD (AUC=0.984). Maximum-stimulated petrosal sinus ACTH to baseline petrosal sinus ACTH ratio of <1.11 provided a 100% sensitivity, while a ratio >1.75 provided 100% specificity towards diagnosis of CD. 71.4% (10/14) patients with left sided adenoma, and 85% (17/20) patients with right sided adenoma were correctly lateralised on BIPSS. In patients whom adenoma was detected on pituitary MRI, 66.7% (6/9) were correctly lateralised to the left side, and 94.1% (16/17) to the right side.
Conclusions
BIPSS provides high sensitivity and specificity to diagnose CD. Vasopressin stimulation improves the sensitivity and specificity, while prolactin correction improves the sensitivity of BIPSS, as compared to baseline ratios. Maximum-stimulated petrosal sinus ACTH to baseline petrosal sinus ACTH ratio can be additionally used, especially in CD patients suspected of false negative localization.

Prevalence of transient and permanent diabetes insipidus after transsphenoidal pituitary surgery: A systematic review and meta-analysis

Athanasios Fountas[1,2,3], Amy Coulden[1,2,3], John Allotey[1] & Niki Karavitaki[1,2,3]
[1]Institute of Metabolism and Systems Research, College of Medical and Dental Sciences, University of Birmingham, Birmingham, United Kingdom; [2]Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, United Kingdom; [3]Department of Endocrinology, University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom

Introduction
Patients undergoing transsphenoidal pituitary surgery (TPS) may develop water balance disorders post-operatively, with diabetes insipidus (DI) being the most common. Nonetheless, data on the prevalence of post-operative DI are not consistent necessitating a systematic review of the literature.
Aim
To estimate the prevalence of DI following TPS in patients with pituitary adenomas (PAs), craniopharyngiomas and Rathke's cleft cysts (RCCs) by performing a systematic review and meta-analysis of published studies which have provided clear criteria of DI diagnosis.
Methods
Extensive literature search of Medline, Embase and Cochrane Library between 01/01/2000 and 31/12/2020 was conducted. Prevalence of postoperative DI, effect size (ES) and 95% confidence intervals (CIs) were estimated from each study and pooled using random effects meta-analysis model.
Results
From a total of 11,627 studies, 54 were finally included. Overall, 22% of patients who underwent TPS developed post-operative DI (ES 0.22; 95%CI, 0.17-0.27). In particular, DI was diagnosed in 19% (ES 0.19; 95%CI, 0.15-0.23), 61% (ES 0.61; 95%CI, 0.49-0.72) and 44% (ES 0.44; 95%CI, 0.27-0.61) of patients with PAs, craniopharyngiomas and RCCs, respectively. Data specifically on rates of transient and permanent post-operative DI were provided in 40 studies; prevalence of transient and permanent DI in total population was 17% (ES 0.17; 95%CI, 0.13-0.21) and 3% (ES 0.03; 95%CI, 0.02-0.05), respectively. Further subgroup analyses revealed prevalence of post-operative transient and permanent DI of 16% (ES 0.16; 95%CI, 0.12-0.20) and 2% (ES 0.02; 95%CI, 0.02-0.03) in patients with PAs, 31% (ES 0.31; 95%CI, 0.24-0.39) and 30% (ES 0.30; 95%CI, 0.22-0.39) in patients with craniopharyngiomas, as well as 35% (ES 0.35; 95%CI, 0.16-0.57) and 14% (ES 0.14; 95%CI, 0.06-0.23) in patients RCCs, respectively. Prevalence of DI was also affected by the diagnostic criteria used in each study. When hypotonic polyuria was sole criterion of diagnosis, post-operative DI was reported in 18% of patients (ES 0.18; 95%CI, 0.12-0.26), whilst in studies where both hypotonic polyuria and hypernatraemia were required as diagnostic criteria, prevalence was 29% (ES 0.29; 95%CI, 0.18-0.42). In those studies where diagnosis was based on desmopressin administration requirement, 26% of cases developed post-operative DI (ES 0.26; 95%CI, 0.09-0.48).
Conclusions
Overall, 22% of patients undergoing TPS for the above tumours will develop post-operative DI. This resolves in the majority of PAs and remains permanent in a significant number of craniopharyngiomas and RCCs. Diagnostic criteria for post-operative DI remain variable affecting the reported prevalence of this condition.

The TRH test is a valuable diagnostic test in central hypothyroidism with low T4

Liv Norma Smith*[1], Sara Ellegaard Christensen*[1], Christian Rosendal[1], Helga Angela Gulisano[2], Kåre Ettrup[2], Eigil H Nielsen[1], Jesper Karmisholt[1] & Jakob Dal[1,3]
[1]Aalborg University Hospital, Endocrinology, Aalborg, Denmark; [2]Aalborg University Hospital, Neurosurgery, Aalborg, Denmark; [3]Steno Diabetes Center North Jutland, Aalborg, Denmark

Objective
To evaluate the value of the thyrotropin-releasing hormone (TRH) test in the diagnosis of central hypothyroidism (CH) in patients with pituitary disease.
Methods
Systematic evaluation of 368 TRH tests including measurements of TBG corrected thyroxine ($T4_{corr}$), baseline TSH (TSH_0) and fold and absolute TSH increase (TSH_{fold}, $TSH_{absolute}$) in patients with pituitary disease.
Results
Patients diagnosed with CH ($n=40$) show comparable TSH_0 (P-value 0.57) but lower $T4_{corr}$ (P-value 0.001) and TSH_{fold} response (P-value 0.001) compared to patients without CH. In 54% (44 of 81 cases) of the patients with low $T4_{corr}$, the CH diagnosis was rejected based on a high TSH_{fold}. In these cases, a spontaneous increase and normalisation in $T4_{corr}$ (62 to 74nmol/l, P-value 0.001) was observed during the follow-up period (7.7 years, SD $\pm$4.9). Two of the 44 patients (4.5%) were started on replacement therapy due to spontaneous deterioration. In patients with normal $T4_{corr}$ ($n=258$), no patients were diagnosed with CH based on the TRH test. Patients diagnosed with CH reported significantly more symptoms of hypothyroidism (P-value 0.006), although, symptoms were reported in most patients with pituitary disease. There were only mild adverse effects related to the TRH test except for one case (0.3%) with a pituitary apoplexy.
Conclusions
The TRH test is a useful and safe diagnostic test but could be reserved for patients with pituitary disease and a low T4. Approximately 50 % of patients with a low $T4_{corr}$ were considered to have normal pituitary thyroid function based on the TRH test results.

Somatotroph Pituitary Neuroendocrine Tumors (Pitnets)/Adenomas Expressing Steroidogenic Factor (SF1)

Federica Guaraldi[1], Federico Roncaroli[2], Chiara Villa[3], Matteo Zoli[1], Mueez Waqar[2], Claire Higham[4], Imogen Lally[5], Bertrand Baussart[6], Guillaume Assié[7], Luca Morandi[8], Diego Mazzatenta[1] & Sofia Asioli[8]
[1]IRCCS Istituto delle Scienze Neurologiche di Bologna, Pituitary Unit, Bologna, Italy; [2]University of Manchester, Geoffrey Jefferson Brain Research Centre, Division of Neuroscience, Manchester, United Kingdom; [3]Hôpital Universitaire Pitié-Salpêtrière, APHP, Sorbonne Université, Department of Neuropathology, Paris, France; [4]Christie Foundation Trust, Department of Endocrinology, Manchester, United Kingdom; [5]Northern Care Alliance, Department of Cellular Pathology, Salford, United Kingdom; [6]Hôpital Universitaire Pitié-Salpêtrière, APHP, Sorbonne Université, Department of Neurosurgery, Paris, France; [7]Hôpital Cochin APHP, Department of Endocrinology, Center for Rare Adrenal Diseases, Paris, France; [8]University of Bologna, Department of Biomedical and Neuromotor Sciences (DIBINEM), Bologna, Italy

Rationale and aim
A recent pangenomic study documented a subset of somatotroph mostly GNAS-wildtype PitNET/adenomas co-express steroidogenic factor 1 (SF1). Aim of our study was to investigate clinical and molecular features of a cohort of these tumour subtype.
Study sample
We identified 20 cases of SF1-expressing somatotropinomas out of 173 (11.6%) operated via transsphenoidal endoscopic approach in 3 referral Pituitary Centers patients. Pre- and post-operative biochemical and imaging, histopathological data, and follow-up were available.
Results
The cohort included 10 male and 10 female patients with a mean age at surgery of 50.2$\pm$14.9 years (range 27-70.4; median 47.1). Eighteen patients (80%) presented with clinical and biochemical features typical of acromegaly. Mean tumor maximum size was 17.2 $\pm$ 7.5 cm; 17 (85%; 10 males) were macro PitNET/adenomas, of which 9 (45%) showed cavernous sinus invasion, and 2 (10%) with sphenoid sinus invasion. Resection was total in 14 patients (70%) and 6 had subtotal resection (30%) . At follow-up, acromegaly relapsed in 4 (20%). Molecular analysis identified a pathogenic mutation of *NOTCH* (p. N335K; VAF17%) and *GNAS* (p. R201C; VAF61%) in a male aged 50.8 years, with a non-invasive tumour and post-surgical disease relapse. No mutations were found in *KRAS*, *BRAF*, *TP53*, *PIK3CA*, *CDKN2A*, *TERT*, *PTEN*, *FBXW7*, *EP300*, *CASP8*, *AIP* and *USP8*.
Conclusions
Patients with somatotroph PitNET/adenomas expressing SF1 typically present with large and invasive tumours, with overt clinical and biochemical features of acromegaly. Most of the cases are GNAS-WT. The incidence of tumour recurrence and disease relapse is similar to the known relapse rate in acromegaly patients.

TGFβ1 and activins as new therapeutic targets for the treatment of dopamine-resistant prolactinomas

Milagros Peña-Zanoni[1], Alejandra Inés Abeledo-Machado[2], Dana Bornancini[2] & Graciela Diaz-Torga[1]
[1]Instituto de Biología y Medicina Experimental - CONICET, Laboratory of PItuitary Physiology and Pathology, CABA, Argentina; [2]Instituto de Biología y Medicina Experimental - CONICET, Laboratory of PItuitary Physiology and Pathology, CABA, Buenos Aires, Argentina

Background
Pituitary tumours are commonly benign adenomas, accounting for 10-15% of all intracranial neoplasms. Among functioning pituitary tumours, prolactinomas are the most frequently observed in the clinic (about 40%). Dopamine, acting through the dopamine type 2 receptor (Drd2), is the main inhibitor of lactotroph proliferation and prolactin secretion, therefore, these tumours are usually treated with dopaminergic agonists with a high efficiency. However, there is a subset of prolactinomas (15 and 20%) that do not respond to this treatment, named dopamine agonist resistant prolactinomas, which represent a major challenge for clinical management, because up to date, no alternative treatments have been found. Transforming growth factor β1 (TGFβ1) and activins are known inhibitors of lactotroph cell proliferation and prolactin secretion.
Aims
Study the role of TGFβ1 and activins in normal and tumoral pituitaries, in 3 animal models of prolactinomas.
Hypothesis
We postulate that, due to the inhibitory action on lactotroph functions exercised by the intra-pituitary members of the TGFβ-family, these factors represent novel targets to develop alternative treatments for resistant prolactinomas.
Results
We demonstrated, in 3 different animal models of prolactinomas, the Drd2 knock-out mice, the estrogen-treated rat and the hCGβ overexpressing mice, that:
1. Pituitary TGFβ1 activity, several components of the TGFβ1 system (LTBPs, TβRII, local activators), as well as activin and activin-receptors expression are reduced in prolactinomas vs normal pituitaries;
2. *in vivo* pharmacological treatments that recover pituitary TGFβ1 activity reduce the hyperprolactinemia and counteract the tumour growth;
3. TGFβ1 activity and activin expression are higher in male pituitaries (sex differences: protective factors?),
4. Ovariectomy in animal models of prolactinoma recovers pituitary TGFβ1 activity and activin expression preventing prolactinoma development.

Conclusion
These findings open new possible therapies in treatment for prolactinomas, especially in those that are resistant to dopaminergic drugs.

Endocrine Section, Rotterdam, Netherlands; [5]Universidade Federal do Rio de Janeiro, Neuroendocrinology Research Center, Endocrinology Section, Rio de Janeiro, Brazil; [6]Centre hospitalier de l'Université de Montréal, Montreal, Canada; [7]Medical University of Warsaw, Department of Internal Medicine, Endocrinology and Diabetes, Warsaw, Poland; [8]David Geffen School of Medicine, University of California, Division of Endocrinology, Diabetes and Metabolism, Department of Medicine, Los Angeles, United States; [9]Recordati SpA, Milan, Italy; [10]Recordati AG, Basel, Switzerland; [11]Massachusetts General Hospital, Neuroendocrine and Pituitary Tumor Clinical Center, Boston, United States

Introduction
In two Phase III studies (LINC3, NCT02180217; LINC4, NCT02697734), osilodrostat, (potent oral 11β-hydroxylase inhibitor), provided rapid, sustained reductions in mean urinary free cortisol (mUFC) and late-night salivary cortisol (LNSC), alongside improvements in clinical signs of hypercortisolism and health-related quality of life (HRQoL), in Cushing's disease (CD) patients. mUFC and LNSC are recommended for monitoring treatment response. We assessed whether patients with both controlled mUFC + LNSC experienced greater improvements in clinical signs of hypercortisolism and HRQoL, compared to control of mUFC alone.
Methods
LINC3 comprised a 48-week (W) core phase, including an 8W randomised-withdrawal period. LINC4 included a 12W, double-blind, placebo-controlled period followed by 36W of open-label osilodrostat. Both studies had an optional extension. mUFC (mean of 2–3 samples; normal range [NR] 11–138 nmol/24h) and LNSC (one sample; NR $\leq$ 2.5 nmol/l) were measured by liquid chromatography-tandem mass spectrometry. Changes in cardiovascular/metabolic-related parameters, physical manifestations of hypercortisolism and HRQoL were assessed in the pooled population by mUFC/lNSC control status: both controlled mUFC + LNSC (mUFC $\leq$ upper limit of normal [ULN] + LNSC $\leq$ ULN), controlled mUFC (mUFC $\leq$ ULN + LNSC>ULN) and both uncontrolled mUFC + LNSC (mUFC>ULN + LNSC>ULN). Patients with controlled LNSC (mUFC>ULN + LNSC $\leq$ ULN) were not analysed as few patients had LNSC control without UFC control. Patients in core and extension phases with both mUFC and LNSC assessments were included. Placebo treatment periods were excluded.
Results
Of evaluable patients at baseline (n = 160), 136 (85.0%) had both uncontrolled mUFC + LNSC. At W48 (n = 133) and W72 (n = 111), respectively, 59 (44.4%) and 54 (48.6%) patients had both controlled mUFC + LNSC, 49 (36.8%) and 44 (39.6%) had controlled mUFC, and 19 (14.3%) and 11 (9.9%) had both uncontrolled mUFC + LNSC. Patients with both controlled mUFC + LNSC had greater percentage improvements from baseline to W72 in cardiovascular/metabolic-related parameters than patients with controlled mUFC or both uncontrolled mUFC + LNSC, respectively: fasting plasma glucose, –5.0%, –4.8%, 1.9%; glycated haemoglobin, –5.1%, –4.8%, –1.3%; weight, –6.5%, –6.5%, –4.5%; waist circumference, –7.2%, –6.3%, –4.9%. Physical manifestations of hypercortisolism generally improved from baseline to W72 irrespective of mUFC/lNSC control. Patients with both controlled mUFC + LNSC or controlled mUFC had the greatest improvement from baseline to W72 in HRQoL.
Conclusions
Patients with both controlled mUFC + LNSC or controlled mUFC had the greatest improvements in cardiovascular/metabolic-related parameters and HRQoL. Improvements in most physical manifestations of hypercortisolism were observed irrespective of mUFC/lNSC control. Data are limited by small patient numbers in some groups. Both mUFC and LNSC normalisation can improve long-term treatment outcomes in CD patients.

Inflammatory infiltrate in wild-type and non-wild-type GNAS somatotropinomas

Sabrina Chiloiro[1,2], Martina Cicia[1,2], Antonella Giampietro[1,2], Marco Gessi[3], Liverana Lauretti[4], Pier Paolo Mattogno[4], Angela Carlino[3], Alessandro Olivi[4], Guido Rindi[3], Alfredo Pontecorvi[1,2], Laura De Marinis[1,2], Francesco Doglietto[4] & Antonio Bianchi[1,2]
[1]Fondazione Policlinico Universitario A. Gemelli, Endocrinology and Diabetology, Roma, Italy; [2]Fondazione Policlinico Universitario A. Gemelli, Traslational Medicine, Roma, Italy; [3]Fondazione Policlinico Universitario A. Gemelli, Women's and Children's health sciences and Public health, Roma, Italy; [4]Fondazione Policlinico Universitario A. Gemelli, Neurosurgery, Roma, Italy

Introduction
Somatotropinomas are benign pituitary tumors with heterogeneous biological and clinical behavior. The tumor microenvironment (TME) is an environment generated by the interaction between tumor cells and the host immune system. It affects both the behavior of the tumor and the outcome of the therapy. The GNAS gene encodes the alpha subunit of G proteins associated with hormone receptors such as TSH, PTH, GHRH, FSH/lH, ACTH. Mutation of this gene has been associated with more aggressive forms of acromegaly. We aim to investigate the presence of CD3+, CD20+, CD138+, CD4+, CD8+, CD68+ cells in the tumor inflammatory infiltrate and their correlation with GNAS mutations.
Material and methods
A retrospective, monocenter study was conducted on 36 acromegaly pts included according the following criteria: 1) age >18 at the diagnosis of acromegaly, 2) availability of tumor sample. Pts with history of radiotherapy of head/neck within 10 years before pituitary surgery, with immune-related disease were ruled out.
Results
Thirty-six patients (23 females) entered the study. Macro-adenomas were identified in 23 cases (12 with cavernous sinus invasion). The median value of tumor infiltrating CD3+ lymphocytes was 30/HPF (IQR: 41.7, range: 7-122), of CD20+ lymphocytes was 2.5/HPF (IQR: 2.75, range: 0.5-12), of CD138+ was 6.5/HPF (IQR: 7.75, range: 1-44), of CD4+ lymphocytes was 5/HPF (IQR: 5.5), of CD8+ lymphocytes was 21/HPF (IQR: 29.5) and of CD68+ macrophages was 50/HPF (IQR: 30). CD68+/CD4+ ratio was 2.4 (IQR: 4.8). Four patients carried GNAS mutations. The number of CD3+, CD20+, CD138+, CD4+, CD8+, CD68+ was similar among GNAS wild type and not-wild type patients.
Conclusion
According to our preliminary data, GNAS mutation do not modify TME in somatotropinomas.

Impact of Surgery or Medical Treatment with the Selective Glucocorticoid Receptor Modulator Relacorilant on Hypercoagulopathy in Patients with Cushing Syndrome

Chiara Simeoli[1], Nicola Di Paola[1], Antonio Stigliano[2], Pina Lardo[2], Tara Kearney[3], Emese Mezosi[4], Ezio Ghigo[5], Roberta Giordano[5], Cary N. Mariash[6], Diane Donegan[7], Richard Feelders[8], Austin Hand[9], Andreas G. Moraitis[9] & Rosario Pivonello[1]
[1]Università "Federico II" di Napoli, Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Naples, Italy; [2]Sant'Andrea University Hospital, Sapienza University of Rome, Endocrinology, Rome, Italy; [3]Salford Royal Foundation Trust, Manchester, United Kingdom; [4]University of Pecs, Ist Department of Internal Medicine, Clinical Center, Pecs, Hungary; [5]University of Turin, Division of Endocrinology, Diabetology and Metabolism, Turin, Italy; [6]Indiana University and Indiana University Health, Indianapolis, United States; [7]Indiana University School of Medicine, Indianapolis, United States; [8]Erasmus Medical Center, Department of Internal Medicine, Division of Endocrinology, Rotterdam, Netherlands; [9]Corcept Therapeutics Incorporated, Menlo Park, United States

In patients with Cushing syndrome (CS), hypercoagulability represents a significant concern, leading to elevated risk for thrombotic events. After curative surgery, hypercoagulability persists for several months; CS treatment guidelines recommend anticoagulation therapy for $\leq$ 3 months. In patients with Cushing disease, hemostatic parameters may even worsen after surgery, independent of surgical outcome; improvements begin ~3 months after successful surgery (Casonato *et al. Blood Coagul Fibrinolysis* 1999). This transient worsening may be due to increased inflammation—cortisol levels, and hence cortisol's anti-inflammatory effects, decrease after successful surgery, leading to increased coagulation cascade activity, which normalizes over time. We evaluated the impact of surgery or treatment with the selective glucocorticoid receptor modulator relacorilant on the coagulation state in patients with CS in a retrospective, longitudinal, monocentric, surgical cohort study and an open-label phase 2 study of relacorilant (NCT02804750). In the surgical study, coagulation markers were assessed in 30 patients before curative surgery and during remission. In the relacorilant study, patients received relacorilant 100–200 mg for 12 weeks or relacorilant 250–400 mg for 16 weeks; coagulation markers were assessed in 34 patients. In the surgical study, baseline mean 24-hour urinary free cortisol (UFC) was 615.6 mg/day (by immunoassay; 2.1× upper limit of normal [ULN]); mean and median time to hemostasis assessment after remission were 6.2 and 6 months. Significant mean changes from baseline were observed in activated partial thromboplastin time (aPTT; +2.0 seconds, P = 0.031), factor VIII (fVIII; 24.2%, P = 0.044), and von Willebrand factor (vWF; 20.6%, P = 0.018); platelet

count was unchanged. In the relacorilant study, baseline mean UFC was 211.9 mg/day (by tandem mass spectrometry; 4.2× ULN). Similar to the surgical study, significant mean changes from baseline to last observed visit were reported in aPTT (+1.5 seconds, $P=0.046$), fVIII (-18.9%, $P=0.022$), and platelet count ($68.8*10^9$/l, $P<0.0001$); vWF was unchanged. Significant improvements in other coagulation factors (eg, fIX and fX) were seen in patients with abnormal baseline values. These studies showed that coagulation markers in patients with CS improve 6 months after curative surgery, and relacorilant treatment may have similar effects after 3–4 months. Transient increases in fVIII immediately after surgery were absent with relacorilant, where negative mean changes from baseline were seen throughout the study. This is presumably due to the less abrupt reduction of cortisol activity with relacorilant compared to surgery. Relacorilant's effects on hypercoagulopathy support further investigation of preoperative use and in patients with CS who are ineligible for surgery.

We previously described a short version of the acute octreotide test (sAOT) for predicting somatostatin receptor ligands (SRLs) response in patients with acromegaly[1]. In the present work, we prospectively reassess the sAOT ability to identify SRLs response in patients from the ACROFAST study using the current GH standards and control criteria and we also correlate sAOT values with E-cadherin tumor expression.

Methods

Patients from the ACROFAST study evaluated with the sAOT before receiving any medications and treated with first generation somatostatin analogues. Response to SRLs was evaluated at 6 months of medical treatment in 47 participants: those patients whose IGF1 was <3SDS were considered *responders* and those with IGF1≥3SDS, *non-responders*. Additionally, E-cadherin immunohistochemistry expression was investigated in 22/43 patients. The value of GH 2 h after the administration of 100 mg of octreotide subcutaneous (GH_{2h}) was evaluated according to the IGF1 response and to the E-cadherin expression, in order to generate cut-off GH values predicting SRLs response.

Results

47 patients (30 responders, 17 non-responders) were analyzed. GH_{2h} was higher in non-responder patients (5.04 vs 1.17ng/ml; $P<0.01$). ROC analysis for predicting non-response with GH_{2h} cut-off showed an Area Under Curve of 0.832. A GH_{2h} value of 4.3ng/ml was the best cut-off for non-response prediction, with a Positive Predictive Value of 92% (Sensitivity 35%; Specificity 97%). The cut-off for GH_{2h} of 1.4ng/ml showed the highest ability to identify responders with a Negative Predictive Value for non-response of 92% (Sensitivity 94%, Specificity 73%). Patients with E-cadherin expression tumors presented a lower GH_{2h} compared with tumors with low or no E-cadherin expression (1.29 vs 5.69ng/ml; $P<0.01$).

Conclusions

The sAOT is a good predictor tool for assessing SRLs treatment response and correlates with E-cadherin tumor expression, thus being useful in clinical practice in patients with acromegaly for the medical therapeutic decision-process.

Copeptin levels increase in response to both insulin-induced hypoglycemia and arginine but not to clonidine – data from GH-stimulation tests

Jelena Stankovic, Kurt Kristensen, Niels Birkebæk, Jens Otto Jørgensen & Esben Søndergaard
Aarhus Universitetshospital, Aarhus, Denmark

Background

The differential diagnosis of the polyuria-polydipsia syndrome is challenging. The water-deprivation test is the current gold standard, but the test is cumbersome, and the diagnostic performance is poor. Copeptin, which is a split product of the vasopressin pre-propeptide, appears to be a robust biomarker in the circulation and a promising tool for the diagnosis of patients with polyuria and polydipsia, especially when measured in conjunction with intravenous infusion of arginine. With this study we aimed to clarify underlying mechanisms of copeptin secretion.

Methods

Using a cross-sectional study-design, we included patients referred to Aarhus University Hospital with suspicion of growth hormone deficiency, who underwent arginine ($n=16$), insulin tolerance test ($n=12$) or clonidine ($n=8$) stimulatory tests. Baseline copeptin was measured and repeated at 60, 105 and 150 minutes.

Results

Copeptin level increased significantly from baseline to 60 min after arginine ($P<0.01$) and ITT ($P<0.01$). By contrast, copeptin level tended to decrease after clonidine stimulation ($P=0.14$). Arginine and the ITT induced a similar response in copeptin level from baseline to 60 min ($P<0.01$).

Conclusion

The present data support that arginine infusion and the ITT induce a similar increase in plasma copeptin level after 60 min. Clonidine tended to decrease copeptin levels. We hypothesize that abrogation of somatostatin-induced copeptin-suppression could be a possible explanatin.

Sleep Disorders And Osas Risk in Patients with Prolactinoma: A Single Center Experience

Guendalina Del Vecchio[1], Federica Sorice[1], Roberta Scairati[1], Rosa Pirchio[1], Sara Di Meglio[1], Rosario Pivonello[1,2], Annamaria Colao[1,2] & Renata Simona Auriemma[1]
[1]Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Università Federico II di Napoli, Naples, Italy; [2]UNESCO Chair for Health Education and Sustainable Development, Federico II University, Naples, Italy

Purpose

Dopaminergic system is implicated in the development of sleep disorders, and dopaminergic agents are used in clinical practice to treat daytime sleepiness and sleep disorders. The present study aimed at investigating the effects of hyperprolactinemia and its control with dopamine-agonists (DA) on sleep quality, excessive daytime sleepiness (ESS) and risk of obstructive sleep apnea syndrome (OSAS) in prolactinomas.

Methods

A single-centre study was conducted from July to December 2022: 44 patients with prolactinoma (23 M, 21 W, aged 46,4±14,42 yrs), including 22 with

macroprolactinoma, 20 with microprolactinoma and 2 with empty sella, were sex- and BMI-matched with 80 healthy controls (32 M, 48 W, age 34,8 ± 11yrs). In all participants, 3 questionnaires were administered to investigate sleep disorders (Pittsburgh Sleep Quality Index, PSQI, normal score <5), daytime sleepiness (Epworth Sleepiness Scale, ESS, normal score <10) and OSAS risk (Berlin Questionnaire, BQ, normal score less than 2 categories). In all participants, height, weight and BMI were recorded. In patients, tumour size at diagnosis, PRL at evaluation, treatment duration (TD), CAB dose (CD), and fasting glucose and insulin were evaluated.

Results

Between patients and controls no significant difference was found in the prevalence of sleep disturbances, ESS and OSAS risk. According to patient age, a significant difference ($P=0.028$) in OSAS risk was found in older patients (age> 56y) as compared to other quartiles. Based on sex, BMI, PRL, TD and CD, no significant difference was found in the prevalence of sleep disturbances, ESS and OSAS risk. In patients, tumour size and BMI were significantly higher in men than in women ($P<0.001$; $P= 0.043$). In male patients, PSQI scores directly correlated with tumour size ($r=0.45$; $P= 0.029$), whereas ESS scores directly correlated with tumour size ($r=0.533$; $P=0.009$), BMI ($r=0.51$; $P=0.012$), PRL ($r=0.457$; $P=0.028$).

Conclusions

The results of the current study did not confirm an association between sleep disturbances, ESS and OSAS risk and treatment with DA in patients with prolactinomas, but ESS was associated with PRL levels. OSAS risk appeared to be influenced by age and daytime sleepiness by BMI. Interestingly, sleep quality was associated with tumour size, suggesting that the long-term effects of chiasm compression on sleep-wake rhythmicity, observed especially in patients with large pituitary tumours, might negatively impact sleep quality.

Assessment of adrenal axis function in patients with PROP1 mutation – longitudinal observation

Łukasz Kluczyński[1], Damian Rogoziński[1], Agata Zygmunt-Górska[2], Małgorzata Wójcik[2], Beata Piwońska-Solska[1], Jerzy Starzyk[2], Alicja Hubalewska-Dydejczyk[1] & Aleksandra Gilis-Januszewska[1]
[1]Jagiellonian University Medical College, Chair and Department of Endocrinology, Krakow, Poland; [2]Jagiellonian University Medical College, Department of Paediatric and Adolescent Endocrinology, Krakow, Poland

Introduction

Mutation in PROP1 gene is the cause of different forms of pituitary dysfunction. The assessment of the functioning of the adrenal axis still raises the most doubts.

Aim& methods

A retrospective longitudinal (mean 35 years, SD 16.24) analysis of 32 patients (19W/13M, including 5 families and sporadic cases) with PROP1 mutation was performed to define the optimal diagnostic approach in evaluation of adrenal axis. In the study morning cortisol and ACTH were assessed in 27/32 patients as well as tests with 1 ug of recombinant ACTH and 100 ug of CRH were conducted in 22/32 and 18/32 patients, respectively. Project grant number N41/DBS/000408).

Results

26/32 were diagnosed with adrenal gland insufficiency, not all family were affected. In majority of patients the disease was detected later than deficits in other hormones (mean delay 17.75 years). In 4 cases it was found at initial diagnosis of pituitary dysfunction. The youngest and oldest patients were diagnosed at the age of 7 and 60, respectively. 3 patients presented with transient adrenal insufficiency – the hydrocortisone substitution was withdrawn due to retesting in adulthood. The average dose of hydrocortisone is 15,7 mg/day. The mean morning cortisol and ACTH concentrations were 6,62 ug/dl (SD 5.12, min./max. 1,09/19.35 ug/dl) and 20.18 pg/ml (SD 7.49, min./max. 8.6/49 pg/ml), respectively. Test with ACTH confirmed adrenal dysfunction in 14/22 patients, while test with CRH was positive in 13/18 patients. In 14 patients tests findings were compatible. All patients with abnormal Synacthen test had positive CRH test results as well. CRH revealed adrenal insufficiency in 3 additional patients with normal ACTH stimulation test or correct morning cortisol. Surprisingly, significant rise in ACTH concentration was observed in the CRH stimulation test with mean maximum value 100,7 pg/ml (min./max. 26/260 pg/ml), both in adrenal sufficient and insufficient patients suggesting other than ACTH deficit mechanism of adrenal insufficiency.

Conclusions

Adrenal insufficiency in patients with PROP1 mutation may occur at any age. Usually is detected later than other hormonal deficits, some patients may present with transient abnormalities, some retain its proper function throughout whole life. Morning cortisol is not an sufficient marker of adrenal condition; stimulation tests are commonly required and test with CRH seems to be the most adequate. In the view of ACTH increase after stimulation further studies are needed to understand the underlying mechanism and find the best diagnostic algorithm for patients with pituitary function deterioration caused by PROP 1 mutation.

Synchronous multiple pituitary neuroendocrine tumors (PitNETs) consisting of a null cell and PIT-1 lineage adenomas: a peculiar acromegalic case report

Alessia Bruco[1,2], Matteo Zoli[3,4], Sofia Melotti[5], Danilo Ribichini[1], Gianmarco Pizza[1,2], Federico Mao[1,2], Diego Mazzatenta[3,4], Sofia Asioli[4,6] & Uberto Pagotto[1,2]
[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Division of Endocrinology and Diabetes Prevention and Care, Bologna, Italy; [2]Alma Mater Studiorum University of Bologna, Department of Medical and Surgical Sciences (DIMEC); [3]IRCCS Istituto delle Scienze Neurologiche di Bologna, Programma Neurochirurgia Ipofisi- Pituitary Unit, Bologna, Italy; [4]Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy; [5]School of Anatomic Pathology, Department of Biomedical and Neuromotor Sciences, Bologna, Italy; [6]Azienda USL di Bologna, Anatomic Pathology Unit, Bellaria Hospital, Bologna, Italy

Pituitary adenomas constitute the third most common intracranial neoplasm. Adenoma cells either express no hormone (null cell adenoma) or hormones of different cell lineage. About 1% of pituitary adenomas shows a plurihormonal expression pattern, which may either be attributed to one cell lineage or rarely to different cell lineages. In addition, the development of separate pituitary adenomas may be observed in 0.5–1.5% of surgical specimens and in up to 10% of autopsy cases. These lesions are termed synchronous multiple pituitary neuroendocrine tumors (PitNETs) and are traditionally known as difficult to be detected at preoperative imaging investigation. Synchronous multiple PitNETs clinical manifestations depend on the histological subtypes. Specifically, null cell adenomas are invasive at the time of presentation and have an aggressive clinical course with short progression-free survival. We present a case of a 45-years old woman in which, following the diagnostic investigations for a suspected Guillain-Barrè syndrome, a 13 mm pituitary lesion was found on brain MRI images. On T2-weighted images, the lesion was described as iso-hypointense in the peripheral edge and hyperintense in the central portion with mild compressive effect on the pituitary stalk and optic chiasm. Despite the absence of clinical acromegalic features, the blood tests showed an increased baseline GH and IGF-1 levels (4.9 ng/ml and 401 ng/ml respectively) and the lack of GH suppression during OGTT test (GH nadir 3.9 ng/ml) confirming the diagnosis of acromegaly. Transsphenoidal surgery was performed with a regular post-operative course, with disease remission confirmed by biochemical and radiological investigation at one- and three-months follow-up. At histology, a synchronous multiple PitNETs were found, consisting of a PIT-1 lineage and a null cell adenomas. The former was a mixed somatotroph-lactotroph PitNET with a low mitotic and proliferative index (<3 mitoses for 10 HPF, Ki67<3%). On the other hand, the latter was characterized by spindle cells, negative for all pituitary hormones and transcription factors (TTF-1, T-PIT, SF1, PIT1 and GATA3) with focal p53 overexpression and a high proliferative index (Ki67 5-6%). Given the ambiguous histological nature of this component, the case was discussed collectively, deposing for possible aggressive behavior of the null cell adenoma. In conclusion, this is a rare and incidentally discovered case of a synchronous multiple PitNETs, in which the absence of acromegalic features and the histological characterization may suggest an aggressive and rapidly growing neoplasm, that require careful clinical-radiological post-operative follow-up.

Treatment, complications and mortality of Cushing's Disease: twenty-year report from a referral Centre

Alessandro Mondin, Filippo Ceccato, Giacomo Voltan, Pierluigi Mazzeo, Irene Tizianel, Carla Scaroni & Mattia Barbot
University Hospital of Padua, Endocrinology Unit, Department of Medicine-DIMED, University-Hospital of Padova, Padova, Italy

Context

Cushing's disease (CD) is rare condition burdened by several systemic complications that in turn increase mortality. The main goal of CD treatment is

to promptly reduce cortisol excess, but whether remission can revert cortisol-related complications and guarantee a normal life expectancy remains debated.
Aim
To assess the prevalence of cortisol-related complications and mortality in a large monocentric cohort of CD patients followed at our centre.
Materials and methods
We reviewed clinical charts of patients with CD diagnosed between December 2001 and December 2021. Biochemical features, CD treatments history, comorbidities and deaths were recorded.
Results
126 CD patients, with a median follow-up of 10 years were included. Median age at diagnosis was 39 years, with a prevalence of females gender (F:M = 3:1), microadenomas (80.5%) and mild to moderate cortisol excess (77.5%). At last follow-up, 78/126 (61.9%) patients were in remission irrespective of previous treatment strategies. All but one patients with active CD at last follow-up were on medical treatment, achieving normalization of urinary free cortisol and circadian rhythm in about 75% and 25%, respectively. Remission proved a significant improvement in all cardiovascular (CV) comorbidities ($P<0.05$). Patients presenting multiple comorbidities (at least 3) at last follow-up had increased CV complications ($P=0.013$). CV events were also more frequent in older patients ($P=0.003$), smokers ($P=0.02$) and in persistent cases ($P=0.044$). Most of thromboembolic (TE) and infective events occurred during active disease. Older age ($P=0.04$) and dis-glycaemia ($P=0.035$) were related to TE events; whereas no predictors of infective complications were identified. CV events were the most frequent cause of death. SMR was increased in patients with persistent disease at last follow-up (SMR 4.99, 95%CI [2.15; 9.83], $P<0.001$), whilst it returns comparable to that of general population after remission (SMR 1.66, 95%CI [0.34; 4.85], $P=0.543$). This latter finding was confirmed irrespective of timing and number of treatments performed to achieve remission. Younger age at diagnosis ($P=0.005$), a microadenoma at first imaging ($P=0.002$) and remission status at last follow-up ($P=0.027$) increased survival. Conversely, an elevated number of CV risk factors at last follow-up ($P=0.0057$), especially arterial hypertension, increased mortality.
Conclusions
active CD patients present a poor survival outcome, but disease remission can restore life expectancy. This result seems independent of timing and modalities used to achieve remission. Nevertheless, adequate monitoring and management of persisting CD-related comorbidities is of the outmost importance to reduce both CV events and mortality

A negative association between growth hormone secretion and inflammation in adult patients with non-functioning pituitary mass

Yasufumi Seki, Kanako Bokuda, Satoshi Morimoto, Satoshi Watanabe, Kaoru Yamashita, Noriyoshi Takano, Daisuke Watanabe & Atsuhiro Ichihara
Tokyo Women's Medical University, Internal Medicine, Tokyo, Japan

Background
Growth hormone (GH) deficiency, which causes visceral obesity and non-alcohol fatty liver disease, increases cardiovascular event risks. High-sensitivity C-reactive protein (hs-CRP), an inflammatory marker associated with increased cardiovascular risk, reportedly decreased after GH supplementation in GH-deficient patients, however, the association between GH secretion and inflammation remains unclear.
Patients and Methods
We retrospectively investigated the association between GH secretion assessed using a GH-releasing peptide-2 (GHRP-2) test and serum hs-CRP level in the patients with non-functioning pituitary neuroendocrine tumor (NF-PitNET) and Rathke's cleft cyst (RCC). Patients with severe renal insufficiency, active inflammatory and malignant diseases, and a history of pituitary surgery, and under GH supplementation therapy were excluded.
Results
Among 171 patients (100 NF-PitNET and 71 RCC), 55 (32%) presented severe GHD. Serum hs-CRP levels were significantly higher in the patients with severe GHD than those without (754 [393-1330] vs 249 [113-537] ng/ml, $P<0.001$) and significantly correlated with peak GH response to GHRP-2 ($r=-0.50$, $P<0.001$). Peak GH response to GHRP-2 significantly estimated the hs-CRP levels independent of the atherosclerotic and metabolic parameters and other anterior hormone secretions ($\beta = -0.334$, $P = 0.001$). Severe GHD was significantly associated with high hs-CRP (> 1000 ng/ml) (adjusted odds ratio, 2.55; 95% confidence interval 1.15-5.70). In the 60 patients who received pituitary surgeries, the postoperative changes in peak GH response to GHRP-2 ($\beta = -0.320$, $P = 0.025$) significantly estimated those in serum hs-CRP levels independent of other anterior hormone secretions.
Conclusions
The negative association between GH secretion and serum hs-CRP levels suggested an important role of impaired GH secretion in the increased cardiovascular risks through the development of inflammation.

Search for new biomarkers of adult growth hormone deficiency metabolic syndrome: a comprehensive overview of a four peptides analysis

Antonio Mancini[1], Edoardo Vergani[1], Carmine Bruno[1], Alessandro Oliva[1] & Diego Currò[2]
[1]Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, Abdominal and Endocrine Metabolic Medical and Surgical Sciences, Rome, Italy; [2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, Safety and Bioethics, Section of Pharmacology, Rome, Italy

Adult growth hormone deficiency (aGHD) is characterized by an altered metabolic profile and increased cardiovascular risk. Neudesin is a newly discovered protein mainly secreted from adipose tissue and brain, under evaluation for its possible activity as negative regulator of energy expenditure. Liver expressed antimicrobial peptide (LEAP)-2 is a competitive antagonist of ghrelin on its receptor. Spexin is a polypeptide related to the galanin-kisspeptin family, secreted along with insulin by pancreatic beta cells with insulin secretion blunting effect. Given the role played in metabolism and energy balance, plasma evaluation of the four peptides was performed and any possible relationships between them and metabolic/anthropometric parameters were evaluated. Thirty-eight patients were included: 18 aGHD patients (7 females and 11 males, aged 59.7 ± 2.6 years, BMI 30.2 ± 2.2 kg/m^2); 20 healthy controls (12 females and 8 males, aged 47.1 ± 2.5 years, BMI 24.1 ± 0.9 kg/m^2). aGHD was diagnosed by a GHRH plus arginine test. They were evaluated for glucose and insulin, HOMA and QUICKI index, total/lDL/HDL cholesterol, triglycerides, uric acid and IGF-1. Plasma neudesin, LEAP-2, ghrelin and spexin were measured by ELISA, according to manufacturers' protocols. Fat mass percentage was evaluated by DXA. Data were expressed as Mean $\pm$ SEM. AGHD patients showed significantly higher HOMA index and triglycerides, and lower HDL cholesterol than controls. Age and BMI significantly differed between aGHD patients and controls; however, no correlation between peptides and age or BMI was detected in aGHD patients, controls, or the overall enrolled population. Fat mass percentage was significantly higher in aGHD than controls, as expected (44.41 ± 3.15 vs 32.2 ± 3.64). Neudesin plasma levels (ng/ml) were significantly higher in aGHD patients than in controls (2.83 ± 0.37 vs 1.55 ± 0.12). Ghrelin plasma levels (nM) were significantly lower (0.91 ± 0.08 vs 1.07 ± 0.09), LEAP-2 (nM) significantly higher (5.19 ± 0.42 vs 3.68 ± 0.49) and consequently LEAP-2/ghrelin ratio significantly higher (6.29 ± 0.84 vs 3.51 ± 0.53) in aGHD patients than in healthy controls. Spexin levels (ng/ml) were similar in the two groups (aGHD 1.17 ± 0.21 vs controls 1.25 ± 0.10). A significant and strong direct correlation between neudesin and LEAP-2 was found both in aGHD patients and in the overall analyzed population. A significant direct correlation between neudesin and uric acid in aGHD patients was also found. Negative correlations were found between neudesin plasma levels and plasma concentrations of glucose and HDL cholesterol. On the contrary, neudesin plasma concentrations appeared positively correlated with the plasma levels of triglycerides. Finally, in the whole population, a significant direct correlation between neudesin and fat mass percentage was pointed out.

Reference intervals for soluble alpha klotho and the impact of biological variables

Junia Ribeiro de Oliveira Longo Schweizer[1], Katharina Schilbach[1], Michael Haenelt[1], Anica Pauline Gagliardo[1], Anette Peters[2], Barbara Thorand[3], Sylvère Störmann[1], Jochen Schopohl[1] & Martin Bidlingmaier[1]
[1]LMU Klinikum; Med. Klinik und Poliklinik IV/ Endokrinologie, Munich, Germany, München, Germany; [2]LMU, Helmholtz Zentrum München, Institute of Epidemiology, Germany; [3]LMU, Institute of Epidemiology, München, Germany

Background
Alpha klotho is a transmembrane protein that regulates calcium metabolism. Its soluble portion has been linked to endocrine functions. We have recently shown high concentrations of serum soluble alpha klotho (sαKL) in active acromegaly. There is limited information about regulation of sαKL secretion. We aimed to gain insight about sαKL as a potential biomarker for H-related diseases.
Methods
SαKL was measured by ELISA (IBL, Hamburg, Germany) in healthy adults (A, $n=890$, ~120 subjects/decade) to calculate a reference interval for sαKL. It was compared to concentrations of patients with non-functional pituitary adenomas (NFPA, B, $n=18$) or prolactinomas (C, $n=66$). Moreover, we evaluated the potential impact of biological variables on sαKL concentrations.
Results
The reference interval (2.5-97.5 centile) for sαKL in healthy adults was 152-1303 pg/ml (median: 673 [IQR: 543-846]). SαKL was not different in NFPA (A vs. B, p>0.05), but higher in prolactinoma (902 [754-1228]; A vs. C, $P<0.0001$). SαKL in males was slightly lower than in females (651 [537-815] vs. 687 [546-881], $P=0.01$). As expected, IGF-I and IGFBP 3 significantly differed between age decades, while sαKL mainly differed between individuals <40 as compared to $\square 70$ years ($P<0.05$ for all comparisons). SαKL exhibited a weak negative correlation with age, BMI, waist-hip-ratio, ($r_s=-0.30$, -0.13, -0.12, respectively, $P<0.001$ for all) and a positive correlation with estimated glomerular filtration rate and IGF-I ($r_s=0.11$, 0.31, respectively, $P<0.001$ for all). These correlations were remarkably weaker than those observed for IGF-I and IGFBP 3. There was no correlation between sαKL and IGFBP 3 or parameters of glucose, liver and calcium metabolism ($P>0.05$ for all), while IGF-I and IGFBP 3 correlated with glucose and calcium metabolism. SαKL was slightly lower in individuals after $>$ 12h of fasting and on use of isolated estrogen ($P<0.05$ for all).
Conclusions
We provide a reference interval for sαKL from a large cohort of healthy adults. Furthermore, we show that many biological variables correlate only weakly with sαKL. Fasting and oral estrogens are associated with slightly lower sαKL, perhaps through induction of hepatic GH-resistance which was already described for IGF-I. In prolactinoma patients, sαKL concentrations were slightly higher, but within the reference interval. This could be due to the somatotropic activity of prolactin. Overall, our findings support the concept that sαKL might be a specific, GH-sensitive biomarker, and less impacted by biological variables as compared IGF-I and IGFBP 3. Our data could facilitate the use of sαKL as a biomarker in GH-related diseases.

Aim
This guideline (GL) is aimed at providing a reference for the management of prolactin (PRL)-secreting pituitary adenoma in non-pregnant adults.
Methods
For each question, the panel identified potentially relevant outcomes, which were then rated for their impact on therapeutic choices.
Results
The present GL provides recommendations about the roles of pharmacological and neurosurgical treatment for the management of prolactinomas. We recommend cabergoline (Cab) vs bromocriptine (Br) as the first-choice pharmacological treatment, to be employed at the minimal effective dose capable of achieving the regression of clinical picture. We suggest that medication and surgery are offered as suitable alternative first-line treatments to patients with non-invasive PRL-secreting adenoma, regardless of size. We suggest Br as an alternative drug in patients who are intolerant to Cab and are not candidates for surgery. We recommend pituitary tumor resection in patients 1) Without any significant neuro-ophthalmologic improvement within two weeks from the start of Cab, 2) Who are resistant or do not tolerate Cab (or other dopamine-agonist drugs, DA), 3) Who escape from previous efficacy of DA, 4) Unwilling to assume a chronic DA treatment. We recommend that patients with progressive disease notwithstanding previous tumor resection and ongoing DA should be managed in a multidisciplinary team with specific expertise in pituitary diseases with a multimodal approach that includes repeated surgery, radiotherapy, DA, and, possibly, temozolomide.
Conclusions
The present GL is directed to endocrinologists, neurosurgeons, and gynecologists working in hospitals, in territorial services or in private practice, and to general practitioners and patients.

Factors Affecting Quality of Life in Patients with Acromegaly: Single Center Experience

Ayşe Merve Ok[1,2], Fatih Bektaş[1], Gamze Bilik Oyman[1], Ümmü Mutlu[1,3], Hülya Hacişahinoğulları[1], Gulsah Yenidunya Yalin[1], Nurdan Gül[1],

Ayse Kubat Uzum[1], Ferihan Aral[1], Sema Yarman[1] & Özlem Soyluk Selçukbiricik[1]
[1]Faculty of Medicine, Istanbul University, Endocrinology and Metabolism, İstanbul, Turkey; [2]Şırnak State Hospital, Endocrinology and Metabolism, Şırnak, Turkey; [3]Van Training and Research Hospital, Endocrinology and Metabolism, Van, Turkey

Objective
Despite treatment, the quality of life in patients with acromegaly remains lower than in the healthy population due to the classical findings and complications related to the disease. Therefore, in the follow-up of acromegaly, evaluation of quality of life along with symptoms and biochemical parameters is recommended. The aim of our study was to evaluate the quality of life, anxiety and depression status of our acromegaly patients and to assess the factors affecting these.
Material and Methods
Ninety acromegaly patients (46 females, 44 males) followed in our center were included in the study. After completing the demographic information form, four questionnaires were applied to the patients; General Quality of Life Questionnare (EQ-5D-3L), Acromegaly Quality of Life Questionnare (AcroQoL), Beck Depression Inventory (BDI) and Beck Anxiety Inventory (BAI). Information about disease status, current complications, treatment were obtained from patient records.
Results
The mean age of the study group was 48 11.02 years. The median scores of AcroQoL, BDI, BAI, EQ-5D and EQ-5D/VAS were 76.7 % (61.93-85.5), 10.5 (4.75-15.25), 9 (4-18), 0.779 (0.69-1) and 80 (70-90) respectively. Female patients had higher BAI, BDI scores ($P<0.001$, $P=0.003$ respectively) and lower EQ-5D and AcroQoL scores ($P=0.004$, 0.002 respectively). Patients with elementary school/no education had lower AcroQoL, EQ-5D, EQ-5D/VAS scores and higher BDI score than high school/university graduates ($P=0.002$, 0.027, 0.037, 0.006 respevtively). There was no significant difference between patients who received replacement therapy for hypopituitarism and those who did not, but the AcroQol and EQ-5D, EQ-5D/VAS score was significantly better and BAI score was worse in those who received gonad replacement therapy ($P=0.019$, 0.015, 0.02, 0.013 respectively). In addition, patients with diabetes insipidus had higher BDI scores and lower EQ5D scores ($P=0.025$, 0.05 respectively). There was a negative correlation between follow-up time and AcroQol scores ($r=$-0.209, $P=0.048$). Educational status negatively correlated with BDI and BAI scores ($r=$-0.284, $P=0.007$; $r=$-0.267, $P=0.011$), and were positively correlated with EQ-5D, EQ-5D/VAS and AcroQol scores ($r=0.291$, $P=0.005$; $r=0.287$, $P=0.006$; $r=0.361$, $P<0.001$).
Conclusions
Gender and educational status are the main determinants of quality of life, depression and anxiety in acromegaly patients.

Effects of a GLP-1 agonist on consumption of alcohol in patients treated for smoking cessation

Leila Sofia Probst[1,2], Sophie Monnerat[1,2], Sophia Lengsfeld[1,2], Thilo Burkard[3,4], Andrea Meienberg[3,4], Cemile Bathelt[1,2], Mirjam Christ-Crain[1,2] & Bettina Winzeler[1,2]
[1]University Hospital Basel, Department of Endocrinology, Diabetology and Metabolism, Basel, Switzerland; [2]University of Basel, Department of Clinical Research, Basel, Switzerland; [3]University Hospital Basel, Medical Outpatient Department, Basel, Switzerland; [4]University Hospital Basel, Department of Cardiology, Basel, Switzerland

Introduction
Alcohol use disorder AUD causes high socio-economic costs and has a detrimental impact on health globally, being considered a key risk factor for non-communicable diseases. In Switzerland, four substances are currently approved for treatment of AUD, with varying effects. Taking into consideration the complex nature of the disease and the heterogeneity of affect patients, it becomes evident that there is need for new treatment targets. A body of preclinical studies provide evidence for the attenuating effects of GLP-1 agonists on addictive behavior in rodents and non-human primates. Furthermore, a few studies have shown a link between GLP-1 receptors and reward related processes in humans, however clinical data are scarce and results remain inconclusive.
Methods
This is a secondary analysis of the SKIP study, a double-blind, randomized, placebo-controlled trial to evaluate treatment with the GLP-1 agonist dulaglutide (Trulicy®) as a new therapy for smoking cessation. In the present analysis, the primary objective was to assess differences in alcohol consumption after 12 weeks of treatment with dulaglutide compared to placebo in smokers willing to quit smoking. We selected patients out of the cohort ($n=255$) who consumed alcohol at baseline and completed 12 weeks of treatment ($n=151$). The independent effect of dulaglutide on alcohol consumption was analysed by fitting a multivariable generalized linear regression model with quasipoisson distribution and adjustment for baseline alcohol intake.
Preliminary Results
One hundred and fifty-one patients (placebo $n=75$, dulaglutide $n=76$) were included in the primary analysis. Baseline patient characteristics were well balanced between groups. The median [IQR] age was 42 [33, 53] years with 61% ($n=92$) females. At baseline, patients in both treatment groups consumed 3 [IQR 2, 7] standard glasses of alcohol per week on average. At week 12, patients in the dulaglutide group drank an estimated 29% less (baseline alcohol intake adjusted IR$r=0.71$; 95% CI 0.52, 0.97; $P=0.04$) than patients in the placebo group.
Conclusions
These results suggest that participants treated for smoking cessation drink significantly less alcohol after 12 weeks of treatment with dulaglutide compared to placebo. Our data thus contribute to the growing evidence promoting the use of GLP-1 agonists in treatment of addictive disorders.

Context
Acromegaly is associated with several metabolic and cardio-respiratory comorbidities, with a relative increase in the last years of cancer mortality. Although the GH/ IGF-1 axis has long been supposed to play a role on immune modulation, immune function in acromegaly is poorly known.
Objective
This observational, prospective, single site, pilot study (NCT05069324) aims to analyse peripheral blood mononuclear cells (PBMCs) subpopulations in acromegalic patients and the potential impact of disease control and different medical treatments.
Methods
Twenty-nine patients with active acromegaly (16M and 13F, mean age 51.3 ± 15.6 years) (ACRO) have been enrolled - 4 naïve, 15 on somatostatin analogs (SSA), 10 on pegvisomant monotherapy or combined with SSA - and compared with 25 sex- and age-matched control subjects (CTRL). Anthropometric, metabolic, and hormonal parameters were recorded along with full quantification of PBMCs (monocytes, lymphocytes, and natural killer/NK cells) by flow cytometry. Monocytes (MONO) were further divided into classical (CD14++ CD16-), intermediate (CD14+CD16+) and non-classical (CD14+CD16++). NK cells were also divided into $CD56^{dim}$ and $CD56^{bright}$, which are respectively characterized by a relatively higher naturally cytotoxic activity or cytokine production. Data are expressed as median (IQR) and non-parametric tests were used for statistical analysis.
Results
Compared with CTRL, ACRO had higher levels of fasting blood glucose ($P=0.001$), HbA1c ($P=0.001$) and BMI ($P=0.015$) and a higher prevalence of cardio-metabolic comorbidities. ACRO had significantly lower total MONO [197 (101-355) vs 334 (279-411) cells/μL, $P=0.049$], with a lower percentage of intermediate [2.9 (1.5-4.8) vs 7.3 (5.5-10.4) %, $P<0.001$] but an increased percentage of non-classical MONO [7.9 (5.3-11.37) vs 1.7 (1.0-3.3) %, $P<0.001$]. Moreover, ACRO had a significantly lower total number of NK [123 (62-261) vs 279 (198-410) cells/μL, $P=0.003$], with a lower percentage of $CD56^{bright}$ [0.8 (0.1-2.9) vs 7.8 (6.9-10.2) %, $P<0.001$] but a higher percentage of $CD56^{dim}$ [99.0 (97.3-99.8) vs 91.3 (88.2-92.8) %, $P<0.001$], and similar T and B-lymphocytes. No significant differences were found according to disease control and medical treatment in ACRO.
Conclusions
To the best of our knowledge, this is the first evidence of a peculiar immunological fingerprint in acromegaly, with a reduced number of MONO and NK cells and an

imbalance of immune innate cells subsets. No major impact of disease control and treatment was found in this series. This suggests that immune function should be further investigated in acromegalics, particularly in view of their higher oncological risk.

The acro-TIME score: a new clinical, pathological and immune integrative approach to early identify acromegaly patients resistant to treatment with first generation somatostatin ligands

Sabrina Chiloiro[1,2], Antonella Giampietro[1,2], Marco Gessi[3], Liverana Lauretti[4], Pierpaolo Mattogno[4], Flavia Costanza[1,2], Angela Carlino[3], Alessandro Olivi[4], Guido Rindi[3], Alfredo Pontecorvi[1,2], Laura De Marinis[1,2], Francesco Doglietto[4] & Antonio Bianchi[1,2]
[1]Fondazione Policlinico Universitario A. Gemelli, Endocrinology and Diabetology, Rome, Italy; [2]Fondazione Policlinico Universitario A. Gemelli, Department of Translational Medicine and Surgery, Rome, Italy; [3]Fondazione Policlinico Universitario A. Gemelli, Department of Woman and Child Health Sciences and Public Health, Anatomic Pathology Unit, Rome, Italy; [4]Fondazione Policlinico Universitario A. Gemelli, Neurosurgery, Rome, Italy

Somatotropinomas are benign pituitary tumors, with a heterogenous biological and clinical behavior. Tumor microenvironment reflects the interaction between tumor cells and the host immune system and may regulate tumor behavior and therapy outcome. We develop a scoring system that includes clinical, pathological and immune markers to early identify fg-SRLs resistant acromegaly pts. 43 acromegaly pts were included according the following criteria (1) first line treatment with surgery, (2) post-surgical fg-SRLs therapy (3) availability of tumor sample. Pts not-naïve to acromegaly therapies before surgery, with history of radiotherapy of head/neck within 10 years before pituitary surgery, with immune-related disease were ruled out. Eighteen pts (41.9%) were fg-SRLs resistant: 14 were females (77.8%), with a median age of 36.5 (IQR:13) and with cavernous sinus invasion in 12 cases (66.7%). At histological examination, Ki-67 was $<$ 1.5% in 17 cases (39.5%). The SSTR2A Volante scores were 0-1 in 5 cases (11.6%) and 2-3 in 38 cases (88.4%). Tumour-infiltering CD4+ lymphocytes was 4.9/HFP (IQR: 8), CD8+ lymphocytes was 11/HFP (IQR:14) and CD68+ cells was 60/HFP (IQR:69). The ratio CD68+/CD8+ cells was 5.2 (IQR: 5). We analysed 18 clinical, pathological and immune features as possible predictors of fg-SRLs response. Fg-SRLs resistance was associated to age at acromegaly diagnosis $<$37 years (AUC: 0.72 OR: 2 95%IC: 1.1-4 $P=0.04$), cavernous sinus invasion (OR: 9.3 95%IC:1.4-61 $P<0.001$), Ki-67>1.5% (OR: 3.2 95%IC:1.2-13.1 $P=0.04$), score 0-1 of SSTR2A (OR: 2.7 95%IC: 1.7-4.1 $P=0.03$), ratio CD68+/CD8+ cells $<$5.7/HPF (AUC: 0.709 OR: 4.9 95%IC:1.2-19.2 $P=0.03$) and persistence of post-surgery residual tumour (OR: 2.5 95%IC:1.3-4.7 $P=0.004$). These variables were analysed in a logistic regression model, yielding a beta coefficient of 3.7 for age $>$37 years; of -3 for cavernous sinus invasion; of -0.2 for Ki-67>1.5%; of 20 for SSTR2A score 2-3; of -0.9 for CD68+/CD8+cells ratio $>$5.7/HFP; and of -0.9 for persistence of post-surgery residual. We assigned a score to each covariate proportional to its beta coefficient, yielding a cumulative score for each patient. The score values ranged from 18.5 to 24 in cases responsive to fg-SRLS and from -5.5 to 21.5 in fg-SRLs resistant cases. A score $<$19 was chosen as cut-point to identify fg-SRLs resistance (AUC: 0.059 $P<0.001$ 95%IC: 0.0-0.126). A score $<$19 was associated to fg-SRLs resistance in 84.6% of cases ($P<0.001$ OR: 3.7 95%IC:1.7-6.7). This new score integrates clinical, pathological, immunological data and may predict resistance to fg-SRLs and the need of second line treatments.

[1]Instituto Mexicano del Seguro Social, Unidad de Investigación Medica en Enfermedades Endocrinas, Mexico City, Mexico; [2]Instituto Tecnologico de Monterrey, Escuela de ingenieria y Ciencias, Monterrey, Mexico; [3]Ichan school of Medicine at Mount Sinai, Department of Neurology, New York, United States

Pituitary tumors (PT) represent 20% of all intracranial neoplasms. Some behave aggressively, growing rapidly and invading surrounding tissues, with high recurrence rates and are frequently resistant to conventional therapies. We performed exome and transcriptome sequencing, as well as methylation profiling of **primary and recurrent PT of the same patient**. The cohort consisted of patients with GH- and gonadotropin-producing PT and a patient with an ACTH carcinoma. We sought genome evolution as well as transcriptomic and methylomic changes trough time, trying to identify molecular markers of recurrence. We performed scRNAseq to identify tumor cell populations. Compared to the primary PT, recurrent lesions showed less than 5% genomic changes in the SNV profile. The gonadotrophinomas did not show common variants between patients or between primary and recurrent lesions. The ACTH-carcinoma showed USP8, TP53 and EGFR variants in both tumor samples, but no genomic changes between tumors despite a Ki67 of 80% in the recurrent lesion. A GH-tumor showed an AIP variant with high genetic heterogeneity. No CNV between the primary and recurrent tumors were observed. Regardless of their lineage, all PT showed different degrees of transcriptomic and methylomic heterogeneity between the primary and the recurrent lesions. Primary and recurrent tumors clustered separately from each other but together among themselves. Interestingly the differentially expressed and methylated genes in gonadotropin-producing PT are related to fatty acid biosynthesis and metabolism, GPI-anchor biosynthesis, and other metabolic pathways. ACTH-carcinoma differs significantly from the silent corticotrope in gene expression and methylation patterns. The ACTH-carcinoma showed alteration in N-Glycan biosynthesis, glycerophospholipid metabolism, purine and pyrimidine metabolism, whereas the silent corticotrope showed one carbon pool by folate, inositol phosphate metabolism, carbohydrate digestion and absorption and biosynthesis of unsaturated fatty acids. The GH-tumor showed alteration in pyruvate metabolism, propanoate metabolism, insulin secretion, and aldosterone synthesis and secretion. Our results suggest that there are several clones conforming a PT and some of them remain after surgical resection and can re-grow, this was confirmed by our scRNAseq analysis and immunofluorescence assays. We conclude that PT are genomically stable trough time, indicating that mechanisms other than somatic mutations are involved in pituitary tumorigenesis and that their biology could be driven by transcriptomically and epigenetically heterogeneous clones within the tumor itself.

Acromegaly in the elderly: additional challenges in timely recognizing

Sandra Pekic Djurdjevic[1,2], Marko Stojanovic[1,2], Mirjana Doknic[1,2], Dragana Miljic[1,2], Toplica Milojevic[3], Mihailo Milicevic[2,3], Aleksandar Stanimirovic[3], Vuk Scepanovic[3], Emilija Manojlovic Gacic[2,4], Sandra Banjalic[5], Marija Jovanovic[2,5], Zvezdana Jemuovic[1], Marina Nikolic Djurovic[1,2], Danica Grujicic[2,3], Vera Popovic[2] & Milan Petakov[1,2]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, University Clinical Center, Department of Neuroendocrinology, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [3]Clinic for Neurosurgery, University Clinical Center of Serbia, Belgrade, Serbia; [4]Institute of Pathology, Belgrade, Serbia; [5]Center for Radiology and Magnetic Resonance Imaging, University Clinical Center of Serbia, Belgrade, Serbia

Background
Increased life expectancy and wider availability of neuroimaging lead to increase in diagnosis of acromegaly in elderly patients, after the age of 70. Delay in diagnosis is attributable to milder symptomatology, higher prevalence of comorbidities and symptoms overlapping with normal aging process.
Objective
To investigate clinical characteristics, presenting symptoms, comorbidities and treatment modalities of acromegaly in patients diagnosed after the age of 70.
Methods
Eleven patients with acromegaly diagnosed after the age of 70 (9 females, 81.8%) were identified from the group of 121 patients with pituitary adenoma (PA) diagnosed after the age of 70 (9.1%), in the PA Database ($n=1442$, 0.76%) of the Department of Neuroendocrinology for the past 18 years. Gender, age at diagnosis, tumor size, presenting signs and symptoms, presence of comorbidities and treatment modality were analyzed.

Results
Mean age at diagnosis was 73.5 ± 0.8 years (range: 70-78). All patients had two or more comorbidities (median 4). Six patients (54.5%) had microadenomas, two (18.2%) had mesoadenoma, while three (27.3%) had macroadenomas. Ten patients (90.9%) had typical acromegalic clinical symptoms and signs, while one male with the largest PA (3cm in diameter) presented with neurologic symptoms (headache, instability, vertigo). Arterial hypertension was diagnosed in nine patients (81.8%), cardiomyopathy and valvular heart disease in six (54.5%), diabetes and dyslipidemia in five (45.5%). One patient had breast cancer. One patient with pituitary macroadenoma had hypopituitarism and was replaced with hydrocortisone and levothyroxine. Baseline IGF-1 was 594.7 ± 65.7 ng/ml. Five patients (45.5%) underwent transsphenoidal surgery, without complications, with significant IGF-1 decrease (573.6 ± 148.4 ng/ml preoperatively vs 159.1 ± 45.2 ng/ml postoperatively). Six patients (54.5%) were medically treated with long-acting somatostatin analogues, with favorable therapeutic response after 19.5 ± 9.6 months of therapy (IGF-1 612.3 ± 31.6 ng/ml before vs. 168.5 ± 30.3 ng/ml upon treatment).
Conclusion
Recognition of acromegaly in the elderly may be challenging and delayed due to milder symptoms overlapping with aging and comorbidities. The prevalence of the elderly among newly diagnosed acromegaly patients is expected to expand. Further studies are needed to define optimal diagnostic and therapeutic management appropriate to patients advanced average age.

Long-term Surgical Remission in Patients with Acromegaly in South-Eastern Norway

Camilla Maria Falch[1,2], Anne Kirstine Dupont[2], Cristina Olarescu[1,2], Jens Bollerslev[1,2], Jon Berg-Johnsen[2,3] & Ansgar Heck[1,2]
[1]Oslo University Hospital, Section of Specialized Endocrinology, Department of Endocrinology, Oslo, Norway; [2]University of Oslo, Institute of Clinical Medicine, Faculty of Medicine, Oslo, Norway; [3]Oslo University Hospital, Department of Neurosurgery, Oslo, Norway

Context
Immediate and sustained cure of acromegaly can only be achieved by surgery, however, most growth hormone (GH) producing adenomas are macroadenomas (≥ 10 mm) at diagnosis, with reported surgical cure rates of approximately 50% compared to microadenomas (<10 mm) with an expected higher cure rate (around 80%). Further, long-term data on remission rates after surgery are sparse.
Aim
Estimate short- and long-term surgical remission rates of patients with acromegaly and identify potentially predictive factors for long-term remission.
Methods
Patients who underwent surgery for a GH-producing pituitary adenoma between 2005-2020 were included from the local pituitary registry ($n=178$). Disease activity (GH and insulin-like growth factor 1, IGF-1), medical treatment, radiotherapy and reoperation were recorded at the short-term (one year postoperatively) and long-term (five year postoperatively) visit. Remission status was defined as IGF-1 ≤ 1.2 x upper limit of normal, without any additional surgical, radiation or pharmacological treatment for acromegaly. Baseline characteristics potentially predicting outcome (age, sex, GH and IGF-1 levels, tumor size (maximal diameter) and first treatment modality (preoperative with somatostatin analogues vs. direct surgery), were evaluated by multivariate regression models.
Results
Median age at diagnosis was 49 (IQR: 38-59) years, 46% were women. At diagnosis, 76% had macroadenomas and 24% microadenomas. Overall surgical remission rate at short-term was 54% and at long-term 41%. At short-term, 62% of patients with microadenomas and 52% with macroadenomas, obtained surgical remission. In patients who obtained persistent remission long-term, the remission rate was 58% for microadenomas and 37% for macroadenomas, with a trend towards higher remission rate in microadenomas ($P = 0.058$). In patients diagnosed in period 2005-2009, 2010-2013 and 2014-2020, the remission rates were 30%, 61% and 31%, respectively, at the long-term visit. Age, sex, GH and IGF-1 levels, tumor size and first treatment modality did not predict remission at long-term.
Conclusions
In unselected patients with acromegaly, the long-term remission rate after surgery was lower than expected and lower than the short-term outcomes. Our short-term outcomes are comparable to results of previous studies.

Effects of acromegaly treatment on left ventricular systolic function assessed by speckle tracking echocardiography: results from a prospective single-center study

Agata Popielarz-Grygalewicz[1], Maria Stelmachowska-Banaś[2], Dorota Raczkiewicz[3], Wacław Kochman[1] & Wojciech Zgliczyński[4]
[1]Centre of Postgraduate Medical Education, Department of Cardiology, Warsaw, Poland; [2]Centre of Postgraduate Medical Education, Department of Endocrinology, Warszawa, Poland; [3]School of Public Health, Centre of Postgraduate Medical Education, Department of Medical Statistics, Warsaw, Poland; [4]Centre of Postgraduate Medical Education, Department of Endocrinology, Warsaw, Poland

Background
Despite the preserved left ventricular(LV) ejection fraction, patients with acromegaly are characterized by subclinical systolic dysfunction, i.e. abnormal global longitudinal strain(GLS) assessed by speckle-tracking echocardiography(STE). The effect of acromegaly treatment on LV systolic function assesed by STE has not been evaluated so far.
Patients and methods
Thirty two naïve acromegaly patients with no detectable heart disease were enrolled in a prospective, single-center study. 2D Echocardiography and STE GLS was performed at the diagnosis, 3 and 6 months on preoperative somatostatin receptor ligand(SRL) treatment and 3 months after the transsphenoidal surgery(TSS).
Results
Treatment with SRL resulted in a significant reduction in median GH& IGF-1 levels after 3 months from 9.1(3.2-21.9) ng/ml to 1.8(0.9-5.2) ng/ml($P<0.001$) and from 3.2(2.3-4.3)xULN to 1.5(1.1-2.5)xULN($P<0.001$), respectively. Longer SRL treatment did not lead to further decrease in GH& IGF-1 levels. Biochemical control on SRL was achieved in 25.8% and complete surgical remission was achieved in 41.7% of patients. TSS resulted in a decrease in IGF-1 compared to IGF-1 levels on SRL treatment: from 1.5(1.2-2.5)xULN to 1.3(1.0-1.6)xULN ($P=0.003$). Females had lower IGF-1 levels at baseline, on SRL and after TSS compared to males. The majority of patients had normal end diastolic and end systolic LV volumes(median LVEDV 56.4mL/m^2 in males and 44.5mL/m^2 in females, median LVESV 23.4mL/m^2 in males and 16.7mL/m^2 in females). Almost half of the patients(46.9%) had abnormal LVMi, however the median value of LVMi was normal in both sex groups: 99g/m^2 in males and 94g/m^2 in females. Most of the patients(78.1%) had abnormal LAVi and the median was 41.8mL/m^2. At baseline 50% of acromegaly patients had abnormal GLS, i.e. higher than -20% and the majority constituted men (62.5% vs. 37.5%). There was a positive correlation between baseline GLS and BMI $r=0.446$($P=0.011$) and BSA $r=0.411$($P=0.019$). GLS significantly improved after 3 months of SRL treatment compared to baseline: -20.4% vs. -20.0%($P=0.045$). There was no further change in GLS after 6 months of SRL therapy and no significant change after TSS. The median GLS was significantly lower in patients with surgical remission compared to those who had elevated GH& IGF-1 levels: -22.5% vs. -19.8%($P=0.029$). There was a positive correlation between GLS and IGF-1 levels after TSS $r=0.570$($P=0.007$).
Conclusions
The greatest beneficial effect of acromegaly treatment on LV systolic function is visible already after 3 months of preoperative SRL treatment, especially in women. Patients with surgical remission have better systolic function as assessed by STE compared to patients with persistent acromegaly.

Clinicopathological aspects of growth-hormone and prolactin-producing pituitary neuroendocrine tumors

Roxana Dumitriu[1,2], Iulia Florentina Burcea[1,2], Valeria Nicoleta Nastase[3], Amalia Raluca Ceausu[3], Marius Raica[3], Anca Maria Cîmpean[3] & Catalina Poiana[1,2]
[1]Carol Davila University of Medicine and Pharmacy, Bucure?ti, Romania; [2]C.I. Parhon National Institute of Endocrinology, Bucure?ti, Romania; [3]Victor Babeş University of Medicine and Pharmacy, Timi?oara, Romania

Introduction
Pituitary neuroendocrine tumors (PitNET) are characterized by a heterogenous behavior. The immunohistochemical (IHC) staining of anterior pituitary hormones, along with that of pituitary transcription factors and with the clinical and biochemical characteristics of the patients can be integrated in a risk stratification system, which helps the therapeutic management.

Material and Methods
We analyzed 37 patients with confirmed diagnosis of acromegaly and 5 patients diagnosed with prolactinoma who underwent transsphenoidal pituitary surgery. The patient information was collected retrospectively. Using the postoperative tumour blocks, we performed morphological and IHC (anterior pituitary hormones: GH, PRL, TSH, FSH, LH, ACTH) analysis. Clinical data were extracted from medical charts. We correlated the IHC features of GH and PRL-secreting PAs with their clinical, laboratory and imaging data.
Results
Macroadenomas represented 88 % (37 cases) and the maximum mean diameter at diagnosis was 23,10 mm (the majority had Knosp grade II – 57%). Based on the morphological analysis (Hematoxylin and eosin method), histologically, the majority of tumors had diffuse growth pattern (80,95%). The intensity scores for anterior pituitary hormones were from 0 to 3+ (from absent to strong staining). We characterized the tumors according to the 2022 WHO classification. Immunohistochemistry showed 10 mixed mammosomatotroph PAs (GH/PRL) and 27 gonadotroph PAs. All of them showed intensive reaction for GH (3+). After surgery, only 2 patients were cured, 4 were in remission, 18 had controlled disease under medical treatment with somatostatin analogues and 10 under treatment with pegvisomant. Mean preoperative GH levels were 11.22 ng/ml (range: 0.97-44.7), and mean postoperative GH 4.82 ng/ml (range:0.09-30.5). Almost all patients diagnosed with prolactinomas (3 males and 1 female) had giant adenomas (maximum median tumour diameter was 43,6 mm), and after transsphenoidal surgery one patient was in clinical remission, 3 of them had controlled disease under treatment with dopaminergic agonists and one had uncontrolled disease under maximal doses.
Conclusions
The histopathological variability of pituitary adenomas (PAs) that cause growth hormone (GH) or prolactin (PRL) excess influences the clinical behavior, radiological characteristics and therapy response. The IHC classification and the radiological dimensions and extent influence disease control, and they are probably the best prognosis factors.

Menin, p27 and pAKT role in prolactinoma development
Milagros Peña-Zanoni, Alejandra Inés Abeledo-Machado, Dana Bornancini, Agustina Marcial-López, Susana Rulli & Graciela Diaz-Torga
Instituto de Biología y Medicina Experimental, Buenos Aires, Argentina

Molecular mechanisms involved in lactotrophs cell proliferation that led to prolactinoma development are not fully understood. Cyclin-dependant kinase (CDK) $p27^{Kip1}$ is a key cell cycle regulator, and it is regulated by Menin. The transgenic mice model *MEN1* $^{+/-}$, as the *p27* $^{-/-}$ knock-out mice, develop pituitary adenomas and other neuroendocrine tumours. Menin can also interfere with phosphorylated AKT (pAKT) function, known for its stimulatory action on cell proliferation. Additionally, PTEN is an inhibitor of AKT activation/phosphorylation. For better understanding, we studied these regulatory mechanisms in a mice model of prolactinoma that overexpress the human chorionic gonadotrophic hormone β-subunit (hCGβ), in which the transgenic female (hCGβ+), but not the transgenic male, develops lactotroph hyperplasia from 3-month of age onwards. We used 6 months old mice, and we analysed pituitary gene expression by Real-Time PCR and lactotroph protein expression by double indirect immunofluorescence detection (PRL+ protein+), comparing transgenic mice (hCGβ+) and wild-types (WT). We observed higher levels of *MEN1* gene expression in males vs females, without genotype differences. Male pituitaries presented similar levels of *p27* gene expression as WT females, without genotype differences. However, hCGβ+ females showed lower levels of *p27* compared to WTs. In addition, p27 protein expression was found to decrease in lactotrophs (PRL+) from hCGβ+ female pituitaries vs WTs. When Menin protein expression was analysed in female pituitaries, although no genotype differences were observed in the percentage of lactotrophs expressing Menin, important changes in its subcellular localization was observed: in lactotrophs from WT females Menin was expressed in cytoplasm and nuclei, while in hCGβ+ lactotrophs Menin was expressed mostly in cytoplasm. WT female lactotrophs showed low pAKT expression and it was most prevalent in cytoplasm while its expression was found increased in cytoplasm and nuclei in lactotrophs from hCGβ+ females. Additionally, lower levels of *PTEN* gene expression was observed in hCGβ+ pituitaries vs WTs. Pituitary *PTEN* gene expression was higher in males than females without genotype differences. We conclude that lower Menin expression in nulcei from hCGβ+ lactotrophs concomitant with lower *PTEN* expression could contribute to the decreased p27 and increased pAKT levels in transgenic females leading to tumour development. On the other hand, the higher levels of pituitary *MEN1* and *PTEN* observed in males could help to control the cell proliferation rate in this sex.

Morphological and functional parameters of the cardiovascular system in acromegalic patients: impact of body composition
Ivana Ságová[1,2], Milan Dragula[3], Marián Mokáň[4] & Peter Vanuga[5]
[4]National Institute of Endocrinology and Diabetology, Department of Endocrinology, L'ubochňa, Slovakia; [2]Comenius University Jessenius Faculty of Medicine, 1st Department of Internal Medicine, University Hospital Martin, Martin, Slovakia; [3]University Hospital Martin, Department of Cardiology, Martin, Slovakia; [2]Comenius University Jessenius Faculty of Medicine, 1st Department of Internal Medicine, University Hospital Martin, Martin, Slovakia; [1]National Institute of Endocrinology and Diabetology, Department of Endocrinology, L'ubochňa, Slovakia

Objective
Cardiovascular diseases are the most common comorbidities in acromegaly. Potential parameters in pathology of cardiovascular comorbidities are changes in levels of growth hormone (GH) and insulin-like growth factor 1 (IGF-1) as well as body composition parameters.
Purpose
The aim of this study was to examine morphological and functional parameters of the cardiovascular system by echocardiography and to assess its relationship with disease activity and body composition parameters.
Methods
We prospectively enrolled 129 acromegalic patients (82 females, 47 males) and 80 healthy controls (53 females, 27 males) matched for age, gender, and BMI. All patients underwent two-dimensional echocardiography. Body composition parameters were assessed by dual-energy X-ray absorptiometry.
Results
Acromegaly patients presented with higher left ventricle mass (LVM) compared to controls (LVMI: 123 $\pm$ 45 g/m^2 vs 83 $\pm$ 16 g/m^2, $P<0.001$). Prevalence of left ventricle hypertrophy in acromegaly patients was 67% (78% concentric, 22% eccentric). IGF -1 levels, BMI, and lean mass positively correlated with LVM in all acromegaly patients ($P<0.001$). Fat mass positively correlated with LVM in females ($r=0.306$, $P=0.005$), but this correlation was not found in males. We did not find any difference in size of the left and right ventricle between acromegaly patients and controls. Acromegaly patients presented with left atrium enlargement, diastolic dysfunction and low incidence of systolic dysfunction. Valvopathy was found in 43% of patients with predominant (31%) prevalence of mitral regurgitation.
Conclusions
Our study demonstrates higher prevalence of cardiovascular comorbidities in acromegaly patients and the impact of IGF-1 levels and body composition parameters in pathology in some of these comorbidities.

Design of the foresiGHt Trial: A Multicenter, Randomized, Placebo- and Active-Controlled Trial to Compare Once-Weekly Lonapegsomatropin to Placebo and Daily Somatropin in Adults with Growth Hormone Deficiency (GHD)
Aleksandra Gilis-Januszewska[1], Maria Fleseriu[2], Jens Otto Jørgensen[3], Kevin CJ Yuen[4], Charlotte Hoybye[5], Meng Mao[6], Jennifer Kang[6], Wenjie Song[6], Allison Komirenko[6], Aimee Shu[6] & Michael Beckert[7]
[1]Jagiellonian University, Medical College, Kraków, Poland; [2]Oregon Health & Science University, Portland, OR, United States; [3]Aarhus University Hospital, Aarhus, Denmark; [4]Barrow Pituitary Center, Barrow Neurological Institute and St. Joseph's Hospital and Medical Center, University of Arizona College of Medicine, Phoenix, AZ, United States; [5]Karolinska University Hospital, Stockholm, Sweden; [6]Ascendis Pharma, Inc, Palo Alto, CA, United States; [7]Ascendis Pharma A/S, Hellerup, Denmark

Background
Adult GHD results from insufficient growth hormone (GH) secretion from the anterior pituitary gland and may represent either a continuation of childhood-onset GHD or GHD acquired during adulthood. Clinically, adult GHD is associated with central adiposity, decreased lean muscle mass, increased fat mass,

decreased bone mineral density, and reduced quality of life. Current standard of care consists of GH replacement via daily injections. Lonapegsomatropin (SKYTROFA; TransCon hGH), a once-weekly prodrug of somatropin approved for the treatment of pediatric GHD by the FDA and EMA, uses TransCon technology to transiently link a parent drug to an inert carrier and achieve sustained release of active, unmodified somatropin under physiologic conditions. The safety and efficacy of lonapegsomatropin have previously been evaluated in three phase 3 trials in pediatric GHD. Change in body composition in both pediatric and adult GHD reflects biologic activity of GH and clinical efficacy of GH replacement.
Methods
The primary objective of the foresiGHt trial is to evaluate the efficacy of once-weekly lonapegsomatropin compared to placebo at 38 weeks in adults with GHD. The trial has been conducted at approximately 120 sites in North America, Europe, Asia, and Oceania. Approximately 240 subjects have been randomized 1:1:1 to once-weekly lonapegsomatropin, once-weekly placebo, or daily somatropin. Subjects will be treatment-naïve or without GH therapy for at least 12 months. Subjects with well-controlled non-insulin dependent diabetes mellitus (HbA1c $\leq$ 7.5%) will be eligible. Following screening, the 38-week treatment period will consist of a 12-week gradual dose titration period and 26 weeks of fixed dose maintenance. Fixed dosing will be used to ensure maximal comparability across the treatment arms in the trial. Three dosing groups per arm will be established to allow for differences in age and oral estrogen intake in women. The primary endpoint is change from baseline in trunk percent fat at week 38, as measured by dual energy X-ray absorptiometry (DXA). Secondary efficacy endpoints are change from baseline in trunk fat mass and change in total body lean mass at week 38. Exploratory efficacy endpoints include total body fat mass, trunk lean mass, visceral adipose tissue, and patient-reported outcomes.
Conclusion
The ongoing global Phase 3 foresiGHt trial is designed to assess the efficacy, safety, and tolerability of lonapegsomatropin by weekly administration, compared to weekly placebo and daily hGH replacement therapy in adults with GHD.

Lanreotide-Induced Acalculous Acute Pancreatitis in a Person with Acromegaly: an Unexpected Severe Side Effect

Diogo Ramalho, Helena Alves, Jorge Henrique Carmona Alexandrino, Nuno Jesus, Gustavo Melo & Maria João Oliveira
Centro Hospitalar de Vila Nova de Gaia / Espinho, Endocrinology, Vila Nova de Gaia, Portugal

Introduction
Somatostatin analogues (SA) are the first-line treatment for Acromegaly in patients whose surgery failed to achieve cure or it was contraindicated. The main reported adverse events of SA are mild and transient, and include nausea, abdominal cramps, diarrhea and flatulence. Other side effects are of rare occurrence.
Case report
The authors describe a case of a 44-year-old previously asymptomatic male patient with a growth hormone-secreting pituitary macroadenoma partially involving the left cavernous sinus who was submitted to debulking transsphenoidal surgery. Biochemical and imaging remission were not accomplished and adjuvant treatment was initiated with lanreotide 120 mg every 8 weeks. Three days after the first administration, the patient attended the Emergency Department complaining of general abdominal pain, along with fever *that resolved with* paracetamol, nausea and acholia. He denied choluria, jaundice and alcohol intake. Physical examination revealed a slight *right flank tenderness.* Biochemical analysis exhibited high C-reactive protein (10.69 [0-0.5] mg/dl) and high serum pancreatic amylase (178 [13-53] U/l) and lipase (259 [13-60] U/l) levels. The remaining analytical investigation was unremarkable. A transabdominal ultrasonography showed no lithiasis, a *non-dilated biliary* tract and a normal gallbladder. Acalculous acute pancreatitis was assumed, but the patient refused hospitalization for proper treatment and investigation. Therefore, he was actively monitored in the outpatient setting. He got hydrated, progressively reintroduced the diet and avoided alcohol intake, with clinical improvement after one week. One month later, serum pancreatic amylase (145 [13-53] U/l) and lipase (245 [13-60] U/l) levels persisted high, but C-reactive protein level dropped (0.13 [0-0.5] mg/dl) and transabdominal ultrasound remained unremarkable. Two months after the episode, C-reactive protein (0.05 [0-0.5] mg/dl) level persisted low, and serum pancreatic amylase (67 [13-53] U/l) and lipase (102 [13-53] U/l) levels dropped near to the upper normal limit, with no clinical relapse. Acalculous acute pancreatitis was assumed, and lanreotide was presumed as the culprit.
Conclusions
As far as the authors know, the association between acalculous acute pancreatitis and a SA was only reported once in the literature. This may be due to spasm of the sphincter of Oddi with subsequent biliary-pancreatic obstruction. This case report highlights the need to raise awareness on SA-induced acute pancreatitis and include it in the differential diagnosis of a patient who present abdominal complaints after initiating a treatment with a SA.

Awaken a sleeping giant: Incidentally discovered pituitary gigantism

Eva Rusu[1], Andreea Peica[2], Tudor Gliga[1], Ana Milea Gheorghe[1], Mircea Adrian Radu[1], Oana Stanoiu- Pinzariu[3] & Carmen Emanuela Georgescu[1,3]
[1]Clinical County Emergency Hospital Cluj-Napoca; [2]Clinical County Emergency Hospital Bistrita, Bistrita, Romania; [3]"Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania

Introduction
Pituitary gigantism is a rare disorder characterized by growth hormone (GH) excess that occurs before epiphyseal growth plates fusion leading to rapid and excessive linear growth in childhood and very tall adult stature. It can be sporadic or coexist with genetic disorders such as FIPA, X-LAG, McCune-Albright, Carney complex, MEN 1 or 4, and Neurofibromatosis type 1.
Case report
We present a case of a 12 years old boy with no medical history, who presented in our clinic with pituitary incidentaloma detected on head CT scan for craniocerebral injury due to falling from the same level. The patient complained of intermittent headaches for about three years, tall stature, and large hands and feet (the mother reported an increase in the size of his shoes from 35 to 43). On physical examination, his height was 173.5 cm (+ 3 DS), with proportionate growth, height velocity approximately 10 cm in 10 months (reported by his mother), predictive target height 195 cm, parenteral target height 179 cm, body weight 52 kg (+ 1.13 DS), Tanner stage II. Laboratory tests showed elevated levels of serum age-adjusted and sex-adjusted IGF-1 (647 ng/ml, NV: 49-487 ng/ml) and failure of GH suppression during an oral glucose tolerance test (nadir GH 35 ng/ml). The other pituitary hormones were within normal limits. Bone age was normal for chronological age. MRI of the sellar region showed pituitary macroadenoma with dimensions of 23/19/11 mm with bilateral extension but no cavernous sinus invasion or optic chiasm involvement. Visual field evaluation was normal. He underwent transsphenoidal surgery and the histopathology report revealed positive immunohistochemistry for GH and prolactin, high Ki67 (25%) and positive p53. Three months after surgery, IGF-1 level normalized (390 ng/ml, NV: 49-487 ng/ml), GH secretion decreased significantly, but without suppression on OGTT (nadir GH 2.57 ng/ml), and no residual tumor was detected on MRI. There was no hypopituitarism after surgery. Treatment with first generation somatostatin analogues was initiated without response. In the absence of disease control, Pegvisomant was prescribed with favorable outcomes (IGF-1 = 160 ng/ml and growth stagnation), but after three months of treatment the patient presented elevated liver enzymes. The treatment with Pegvisomant was stopped and Pasireotide was initiated.
Conclusions
Pituitary gigantism is a rare disease, caused by a growth hormone secreting pituitary adenoma. Management of the disease represents a real challenge due to the lack of experience in children. Close follow-up is mandatory to prevent complications and improve survival rates.

Osilodrostat as an effective and safe treatment for ectopic Cushing Syndrome- case report

Mari Minasyan, Anna Boguslawska, Ewelina Rzepka, Łukasz Kluczyński, Aleksandra Gilis-Januszewska & Alicja Hubalewska-Dydejczyk
Jagiellonian University, Endocrinology, Kraków, Poland

Osilodrostat as an inhibitor of adrenal 11B-hydroxylas, is an effective medication used in the management of endogenous hypercortisolism. There are limited data regarding usage of osilodrostat in ectopic Cushing Syndrome (CS). Surgery is usually the first line treatment in ectopic CS, however the source of ectopic hormonal production often remains undiscovered for a long period of time. Meanwhile dangerous state of severe hypercortisolism needs to be managed pharmacologically by steroidogenesis inhibitors. We present a case of a 72 year- old male patient with diabetes mellitus, hypertension, obesity, dyslipidemia who was admitted to Emergency Department due to Transient Ischemic attack (TIA), severe hypokalemia and hyperglycemia.

Physically patient presented Cushing Syndrome's features. Additional biochemical assesment showed ACTH dependent hypercortisolemia (ACTH 197 pg/ml, Cortisol 76 ug/dl). Patient was transferred to Endocrinology Department. Hormonal tests suggested ectopic Cushing Syndrome. Either 2-[18F]FDG PET/CT or [68Ga]Ga-DOTA-TATE PET/CT didn't show potential ectopic lesion. Pituitary MRI showed Rathe cyst. We put the patient on metyrapone (up to 2250 mg) and observed dropping of cortisol level. After 3 months of treatment metyrapone was withdrawn and osilodrostat was started 1mg BID, followed by dose reduction to 1mg per day. The Patient reached satisfactory clinical and biochemical control of Cushing Syndrome. Since cortisol levels dropped, we plan repetition of [68Ga]Ga-DOTA-TATE PET/CT. To sum up, osilodrostat seems to be an effective, safe and convenient treatment in management of severe hypercortisolism in patients with ectopic CS.

The Indian Male Aging Study Shows Differential Relationships Between Age and Modifiable Risk Factors for Hypothalamic-Pituitary-Testicular Axis Disruptions in Older Men

Abhishek Chandra[1] & Vijay Kumar Singh[2]
[1]Kurji Holy Family Hospital, Patna, India; [2]sri Krishna Medical College, Medicine, Muzaffarpur, India

Introduction
It is unknown what causes ageing men to have lower testosterone levels and how those levels relate to risk factors. Less research has been done on the health of ageing males than on postmenopausal women.
Objective
The aim was to look into how men-aging lifestyles and health related to their levels of reproductive hormones.
Method
A prospective cohort study in Indian men included 320 community-dwelling men between the ages of 41 and 78 for this baseline cross-sectional survey. Equal numbers of men were chosen from the general population to represent each of the four age groups: 41-48, 51-58, 61-68, and 71-78 year. As long as the person could respond to the mail invitation and give written informed consent, there were no particular exclusion criteria. As soon as the null hypothesis could be rejected at the 0.04 (two-tailed) level, the results were deemed statistically significant. SAS proc mixed and STATA version 9.2 were used for all data analyses.
Results
