Introduction

The role of interpersonal factors in determining Female sexual dysfunction (FSD) has been increasingly recognized. Among male sexual dysfunctions, the adverse effects of erectile dysfunction and premature ejaculation on the partner’s sexual experience have been widely investigated. In contrast, male hypactive sexual desire disorder is largely ignored, especially in the context of FSD.

Objectives

The present study aimed to evaluate the role of the male partner’s sexual function and of the relational factors, as perceived by women, in determining female sexual dysfunctions, using a structured interview and the Female Sexual Function Index (FSFI; Rosen et al., 2000).

Methods

A consecutive series of 156 heterosexual women consulting our clinic for FSD was retrospectively studied. All patients underwent a structured interview and completed the FSFI (Rosen et al., 2000).

Results

FSFI total score decreased as a function of partner’s age, conflicts within the couple, relationship without cohabitation and the habit of engaging in intercourse to please the partner. FSFI total score increased as a function of frequency of intercourse, attempts to conceive and fertility-focused intercourse. FSFI total score showed a negative, stepwise correlation with partner’s perceived hypactive sexual desire (r=−0.327; p<0.0001), whereas no significant correlation was found between FSFI and erectile dysfunction, premature and delayed ejaculation. In an age-adjusted model, partner’s HSD was negatively related to FSFI total score (Wald=8.196, p=0.002), *arousal* (Wald=7.893, p=0.005), *lubrication* (Wald=5.042, p=0.025), *orgasm* (Wald=9.293, p=0.002), *satisfaction* (Wald=12.764, p=0.0001) and *pain* (Wald=6.492, p=0.011) domains. Partner’s HSD hypactive sexual desire was also significantly associated with somatized anxiety, low frequency of intercourse, low partner’s care for the patient’s sexual pleasure and with a higher frequency of masturbation, even after adjusting for age. In patients not reporting any reduction of libido, FSFI total score was significantly lower when their partner’s libido was low (p=0.041), the correlation disappeared if the patient also experienced HSD.

Conclusions

In conclusion, the presence of erectile dysfunction, premature and delayed ejaculation of the partner may not act as a primary contributing factor to FSD, as determined by FSFI scores; conversely, women’s sexuality seems to be mostly impaired by the perceived reduction of their partner’s sexual interest.
