Next Generation Sequencing Approach for Molecular Genetic Diagnosis of Familial Partial Lipodystrophy

Nihal Thomas , H.S.Asha, Aaron Chapla, Manika. V, Shrinath Shetty

Department of Endocrinology, Diabetes and Metabolism, Christian Medical College, Vellore, India.

BACKGROUND

- Lipodystrophies are a heterogeneous group of diseases characterized by abnormal fat distribution.
- Familial partial lipodystrophy 2 (FPLD2) is autosomal dominant condition due to mutations in the LMNA gene.
- It is characterized by selective loss of subcutaneous adipose tissue from the limbs and trunk, and accumulation of fat in the neck and face.
- Usually associated with a variety of metabolic disorders including insulin resistance, diabetes mellitus, dyslipidemia, hepatic steatosis and high blood pressure.

OBJECTIVES

To study the clinical and molecular features of 2 subjects with FPLD.

SUBJECTS AND METHODS

Utilizing Next Generation Sequencing (NGS) we carried out mutational analysis of LMNA gene in a woman and her daughter with FPLD phenotype

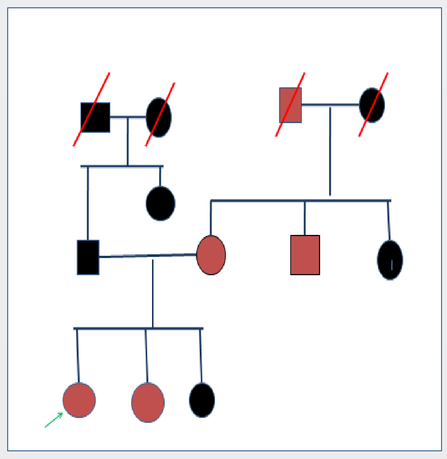
CLINICAL PRESENTATION

MOTHER AND DAUGHTER

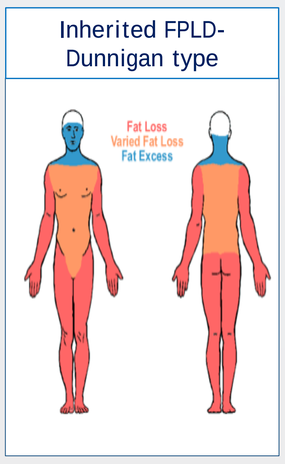
- Diabetes detected less than 30 years of age.
- On insulin from the time of diagnosis
- No history of Diabetic ketoacidosis
- Hypertriglyceridemia

Family history :

Maternal uncle and younger sister with similar fat distribution



Inherited FPLD-Dunnigan type



Examination: In both mother and daughter

- Cushingoid facies
- Acanthosis nigricans
- Prominent veins – UL>LL
- Calf muscles and deltoid appear prominent
- Vulval fat appears hypertrophic
- Hepatomegaly

BODY COMPOSITION

Body composition was assessed by DXA scan

REGION	FAT (gm)	% FAT
Lt Arm	249.6	13.7
Rt Arm	295	15
Trunk	3361.2	14.2
Lt Leg	837.7	12.0
Rt Leg	1053	14.3
Head	**833**	**20.3**
Total	6629.7	14.4

Limbs and trunk had very less fat with increased fat in the head

INVESTIGATIONS

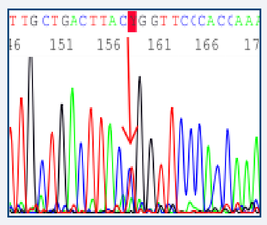
Parameters	Mother	Daughter
C-peptide (ng/ml) Fasting 2h Post-meal	3.2 3.6	1.43 3.67
Fasting insulin (µIU/ml)	52.5	6.99
HOMA-IR	23.33	3.11
Triglycerides (mg/dl)	118 (on treatment)	1070

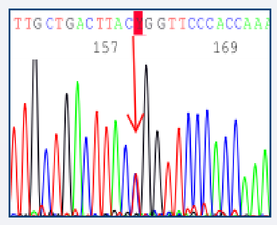
HOMA-IR- Homeostatic model assessment of Insulin resistance

RESULTS OF GENETIC TESTS

The NGS of LMNA gene showed that mother and daughter were both heterozygous for a reported c.1444C > T missense mutation which causes the substitution of the Arginine at residue 482 by a Tryptophan. This identified mutation was confirmed by Sanger sequencing.

LMNA Mutation in the mother and daughter





DISCUSSION

- The subject and her mother were diagnosed to have diabetes mellitus at young age, never had keto-acidosis, had cushingoid appearance of face, features of insulin resistance, fat atrophy in the limbs with prominent muscle contours, and hepatomegaly consistent with familial partial lipodystrophy.
- Both subjects also had elevated C-peptide levels and HOMA-IR suggestive of insulin resistance, and Dual energy X-ray absorptiometry showed increased fat in the face with decreased limb fat confirming fat redistribution. Further, genetic testing helped in confirming the diagnosis.
- With this diagnosis, Metformin was added and better glycaemic control was achieved.

CONCLUSIONS

Our subjects had a clinical form of FPLD2 due to a mutation affecting LMNA gene. A high index of clinical suspicion based on the phenotype, followed by appropriate biochemical and genetic testing led to the diagnosis in this family. A clear understanding of the disease process is very important to choose the right treatment modalities, predict the natural history of the disease and to determine the prognosis.
