Comment and p-values

INTRODUCTION

Type 2 diabetes (T2D) comprises a spectrum from thinner patients who may be more insulin deficient to those who are overweight/obese and insulin resistant.

METHODS

To compare management between these phenotypes, we reviewed 1007 T2D patients attending annual review.

Patients were divided into quartiles by body mass index (BMI) and those in the lowest and highest quartiles were compared. Phenotypic and biochemical data were compared using t tests while chi-square-test was used to compare proportions on different treatments.

RESULTS

Table 1 details the comparison between these groups:

- Highest BMI quartile had significantly higher mean HbA1c, and were slightly younger
- Greater proportion of patients in the highest BMI quartile were on insulin, sulphonylurea, biguanide and GLP-1 analogues (p<0.05 respectively)
- However, DPPIV inhibitor usage was similar (p=0.271)

Systolic blood pressure, total and LDL cholesterol and eGFR, were not different between the groups.

CONCLUSION

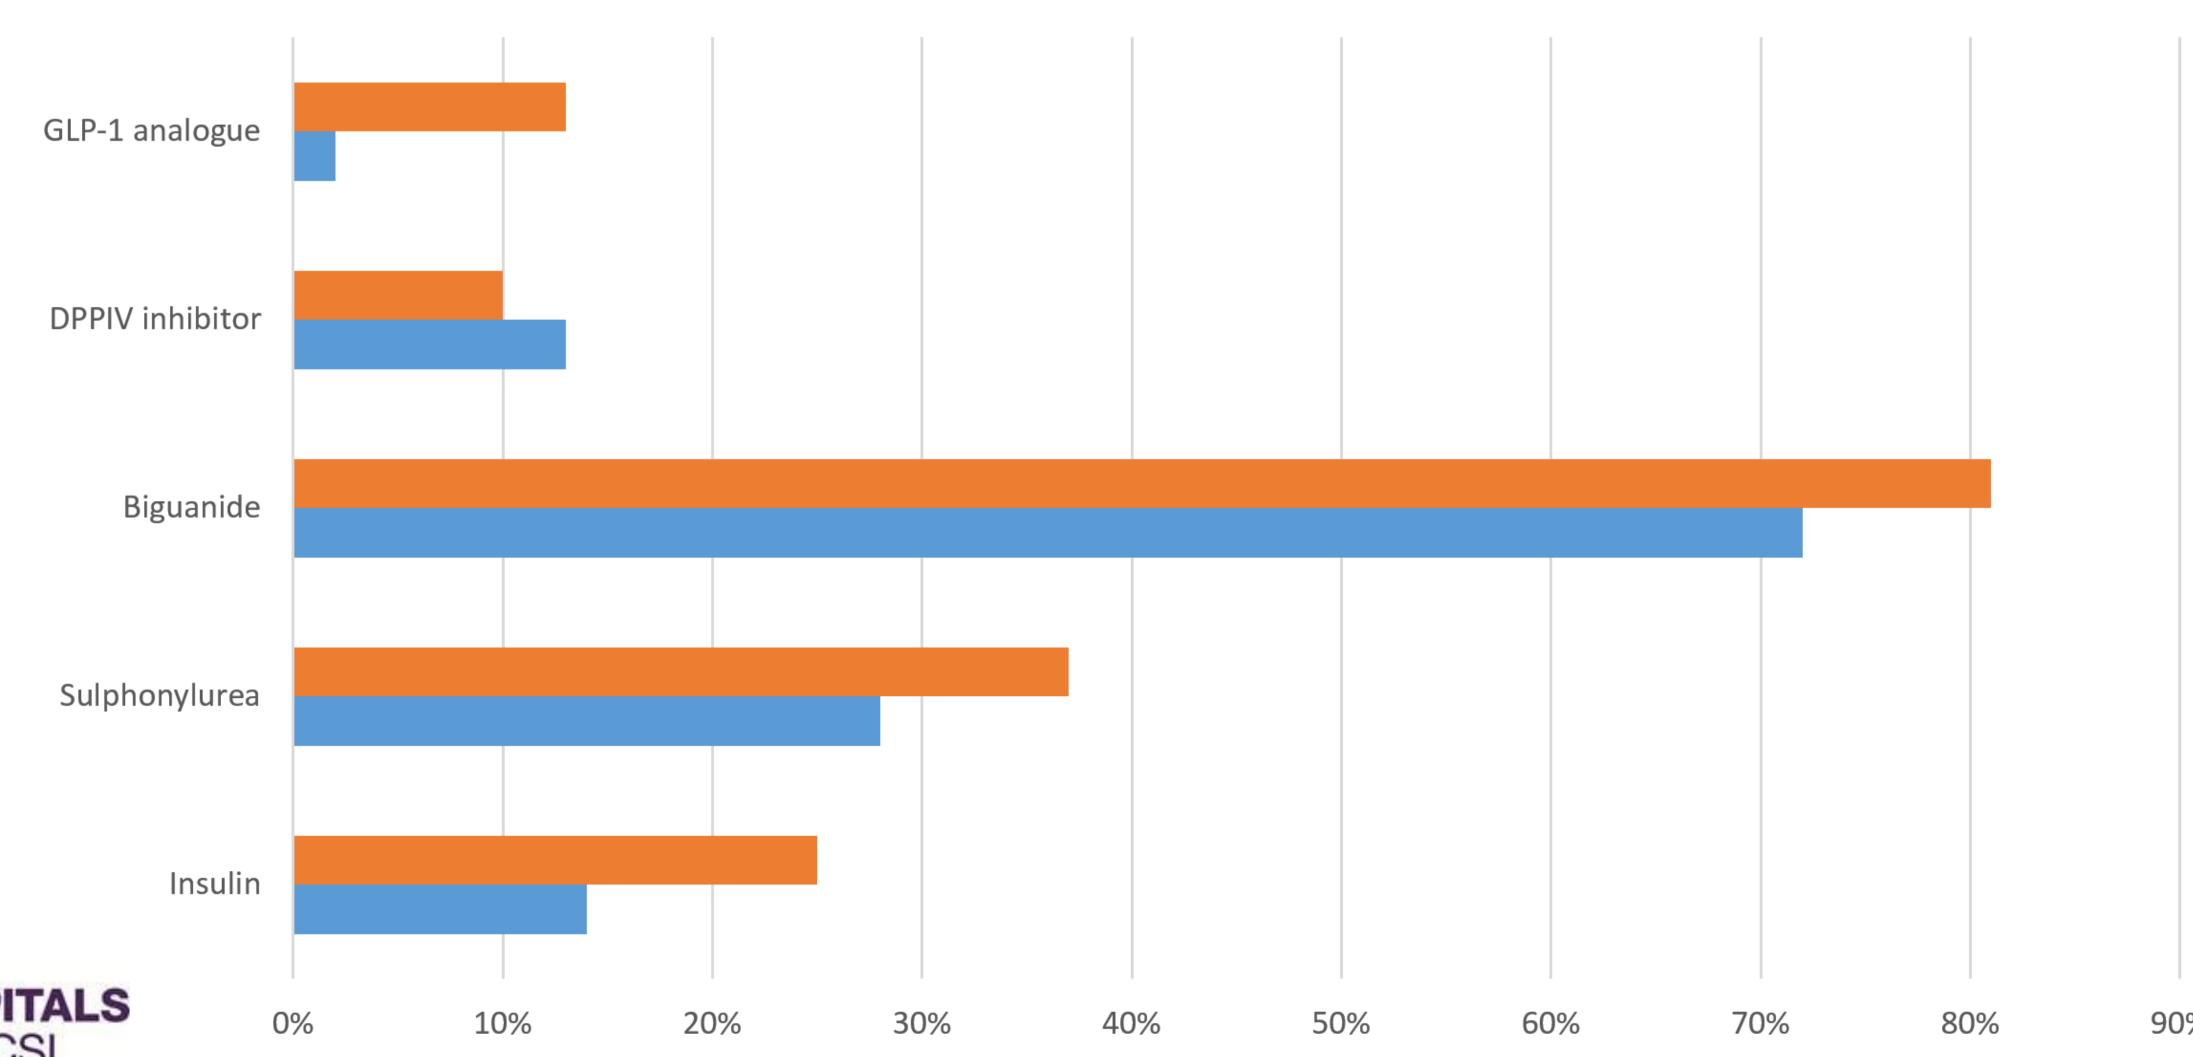

summary, thinner patients slightly older and had slightly better control, despite glycemic less aggressive glycemia management. We believe that this reflects a different underlying pathophysiology of diabetes these phenotypes between and highlights the need for a personalised management approach.
