19th European Congress of Endocrinology 2017

PRIZE LECTURES AND BIOGRAPHICAL NOTES
The European Journal of Endocrinology Prize Lecture ......................................................... EJE1
The Geoffrey Harris Prize Lecture ......................................................................................... GH1
European Hormone Medal Lecture ...................................................................................... EHM1
Clinical Endocrinology Trust Lecture ................................................................................ CE1
IPSEN1

PLENARY LECTURES
The fantastical world of hormones ......................................................................................... P1
The secret life of FGF21 ............................................................................................................ P2
Update on regulation of steroidogenesis by aberrant hormone receptors ........................ P3
The role of brain insulin resistance for the development of prediabetic phenotypes .......... P4
Browning of adipose tissue and metabolic regulation .......................................................... P5
Thyroid oncology in the crossroads of precision and narrative medicine ........................... P6

SYMPOSIA
Clinical Updates in Hypoparathyroidism .............................................................................. S1.1–S1.3
Evolving diagnostics in adrenal and neuroendocrine tumours .......................................... S2.1–S2.3
From the pituitary to the periphery ....................................................................................... S3.1–S3.3
2nd Joint Global Symposium on Obesity – The Many Dimensions of the Childhood Obesity Problem S4.1–S4.3
Turn your face to the sunshine .............................................................................................. S5.1–S5.3
Treatment of hypothyroidism: what have we learned? ....................................................... S6.1–S6.3
Crosstalk between bone & other organ(isms) ...................................................................... S7.1–S7.3
Predictors of therapeutic response in functioning pituitary tumours ............................... S8.1–S8.3
Novel type 2 diabetes treatment: Beyond glycaemic control .............................................. S9.1–S9.3
The Challenges of Male Fertility .......................................................................................... S10.1–S10.3
New Roles for Nuclear Receptors ......................................................................................... S11.1–S11.3
New development in Graves' Orbitopathy ........................................................................... S12.1–S12.3
Challenging pituitary diseases ............................................................................................... S13.1–S13.3
Searching for the cause and approach in ectopic hormone syndromes ............................ S14.1–S14.3
Metabolic surgery mechanisms to clinical results (Endorsed by the European Journal of Endocrinology) S15.1–S15.3
Late-breaking: the PCSK9 revolution ................................................................................... S16.1–S16.3
What endocrinologists should know about the genomics of endocrine tumors .......... S17.1–S17.3
Hyperandrogenism: challenges in clinical management ..................................................... S18.1–S18.3
How to incorporate the new guidelines for thyroid cancer in my clinical practice .......... S19.1–S19.3
Beta cell replacement and plasticity (Endorsed by Endocrine Connections) .................. S20.1–S20.3
Environmental influences on endocrine systems ............................................................. S21.1–S21.3
Rare bone diseases (Endorsed by the European Journal of Endocrinology) ................. S22.1–S22.3
Endo Oncology: prolactin, GH and metabolic hormones in oncology pathogenesis (Endorsed by Endocrine Connections) S23.1–S23.3
Obesity: Pharmacological solutions ..................................................................................... S24.1–S24.3
HPA axis regulation during a woman’s life: impact on metabolic outcomes .................. S25.1–S25.3
Tissue specific defects in thyroid hormone action .............................................................. S26.1–S26.3
Vitamin D beyond bone (Endorsed by Endocrine Connections) .................................... S27.1–S27.3
Sleep, love and reproduction (Endorsed by Endocrine Connections) ............................. S28.1–S28.3
Novel predictors of diabetes ................................................................................................. S29.1–S29.3
Moving away from old-fashioned steroidogenesis: what are the clinical implications? ..... S30.1–S30.3
Guided session 1 ........................................ GS1.1–GS1.6
Guided session 2 ........................................ GS2.1–GS2.6

**NEW SCIENTIFIC APPROACHES** ........................................ NSA1–NSA6

**DEBATES**

Is there a role for medical therapy for non-functioning pituitary adenomas? .......................................................... D1.1–D1.2
Incidentally discovered nonfunctioning pancreatic NETs: Surgery or not? (Endorsed by the European Journal of Endocrinology) .......................................................... D2.1–D2.2
Drug holiday in osteoporosis (Endorsed by the European Journal of Endocrinology) .................................................. D3.1–D3.2
Is cardiovascular risk increased in women with PCOS? .......................................................... D4.1–D4.2
Should we still ablate all patients undergoing total thyroidectomy for thyroid cancer? .................................................. D5.1–D5.2
Is it time for initial combination in type 2 diabetes? .......................................................... D6.1–D6.2

**MEET THE EXPERT SESSIONS** ........................................ MTE1–MTE16

**NURSE SESSIONS** .............................................................. N1.1–N1.4

**ORAL COMMUNICATIONS**

Adrenal—Basic & Clinical .................................................. OC1.1–OC1.5
Diabetes Prediction and Complications .................................................. OC2.1–OC2.5
Receptors & Signalling .................................................. OC3.1–OC3.5
Thyroid Disease 1 ........................................ OC4.1–OC4.5
Cardiovascular Endocrinology .................................................. OC5.1–OC5.5

*Endocrine Abstracts (2017) Vol 49*
Prize Lectures and Biographical Notes
European Journal of Endocrinology Prize Winner

The European Journal of Endocrinology Prize is awarded to a candidate who has contributed significantly to the advancement of knowledge in the field of endocrinology through publication. This year’s recipient is Dr Miguel Lopez who will receive his prize and deliver his lecture as part of the ECE 2017 Opening Ceremony on Saturday 20 May 2017. Further information on the prize can be found at http://www.ese-hormones.org/prizes/.

Dr. Miguel López received his PhD in Molecular Biology (2002) from the University of Santiago de Compostela (USC, Spain) and made his postdoctoral training (2002–2006) in the Department of Clinical Biochemistry in the University of Cambridge (UK). Currently, Dr. Miguel López is Associate Professor in Department of Physiology at the School of Medicine and the Research Centre of Molecular Medicine and Chronic Diseases (CIMUS) of USC. Since the beginning of his PhD, he has focussed his research on the regulation of energy balance and obesity, with his current interest on hypothalamic energy sensors in the modulation of energy balance and metabolism. He has published around 150 peer-reviewed papers. He currently serves on the editorial board of Endocrinology, Journal of Molecular Endocrinology, Molecular Metabolism, Journal of Endocrinology, several Frontiers journals and PLoS ONE, and as a reviewer for several international biomedical journals and funding agencies. For his work in this area, Dr. López received the awards for Basic Research in Obesity from Spanish Endocrinology and Nutrition Society (SEEN, 2006 and 2009) and the Spanish Society for the Study of Obesity (SEEDO, 2009), Spanish Award on Neuroendocrinology (2012), as well as the European Association for the Study of Obesity (EASO) Young Investigator Award for Basic Science (2008; first Spanish citizen to be awarded with that price) and the European Journal of Endocrinology Prize for the European Society of Endocrinology (2017). He has been PI of 12 national and international grants, among them an ERC Starting Grant. He teaches Endocrinology in the Schools of Medicine and Pharmacy of USC. He has supervised 14 Master Thesis and 10 PhD Thesis.
AMP-activated protein kinase (AMPK) is a cellular gauge that is activated under conditions of low energy, increasing energy production and reducing energy waste. Centrally, the AMPK pathway is a canonical route regulating energy homeostasis, by integrating peripheral signals, such as hormones and metabolites, with neuronal networks. Current evidence links hypothalamic AMPK with feeding, brown adipose tissue (BAT) thermogenesis and browning of white adipose tissue (WAT), as well as muscle metabolism, hepatic function and glucose homeostasis. The relevance of these data is interesting from a therapeutic point of view since several agents with potential anti-obesity and/or antidiabetic effects, some currently in clinical use, such as nicotine, metformin and liraglutide are known to act through AMPK, either peripherally or centrally. Furthermore, the orexigenic and weight-gaining effects of the worldwide use of antipsychotic drugs, such as olanzapine, are also mediated by hypothalamic AMPK. Overall, this evidence makes hypothalamic AMPK signaling an interesting target for drug development, with its potential for controlling both sides of the energy balance equation, namely feeding and energy expenditure via defined metabolic pathways.

DOI: 10.1530/endoabs.49.EJE1
Geoffrey Harris Prize Winner

The prestigious Geoffrey Harris Prize is awarded to an established researcher in the field of neuroendocrinology and is the first of its kind in Europe. This year’s recipient is Professor Matthias Tschöp who will receive his prize and deliver his lecture as part of the ECE 2017 Opening Ceremony on Saturday 20 May 2017. Further information on the prize can be found at [http://www.ese-hormones.org/prizes/](http://www.ese-hormones.org/prizes/).

Professor Matthias H. Tschöp received his M.D. from Ludwig-Maximilians Universität in Munich, where he also trained as a physician in internal medicine. In 1998 he accepted an invitation for a postdoctoral fellowship at the Eli Lilly Research Laboratories in Indianapolis, USA before returning to Europe in 2002 to establish his independent research laboratory at the German Institute of Human Nutrition (DIfE) Potsdam. He later returned to the United States where he joined the University of Cincinnati to ultimately serve as the Director of the Diabetes and Obesity Center of Excellence and Arthur Russell Morgan Endowed Chair of Medicine. In 2011 Prof. Tschöp accepted the position as Scientific Director of the Helmholtz Diabetes Center at Helmholtz Center München and was named Chair of the Division of Metabolic Diseases at Technische Universität München. Prof. Tschöp is the first German physician to receive the prestigious Alexander-von-Humboldt Professorship (2012). He was elected into the German National Academy of Science (Leopoldina) in 2013 and one year later was named adjunct Professor at Yale University, USA. He started the peer-reviewed open access journal Molecular Metabolism, which he leads as the Editor-in-Chief (first impact factor 2016: 5.4). In 2016 Matthias Tschöp received an honorary doctorate of the University of Leipzig and was named Director for Biomedicine of the Helmholtz Pioneer Campus in Munich, which he co-founded.
Toward hormone-based precision medicines for metabolic diseases
Matthias Tschöp
Germany.

After decades of research unraveling complex metabolic control networks, medicines capable of a safe reversal of morbid human obesity and type 2 diabetes are still not available. Historically, complex diseases have repeatedly proven to be defiant to the best mono-therapeutic approaches. Several examples of combination therapies have largely overcome such challenges, notably for the treatment of severe hypertension and tuberculosis. Obesity and its consequences, such as type 2 diabetes, have proven to be equally resistant to therapeutic approaches based on single medicines. Appropriate management of type 2 diabetes often requires adjunctive medications, and the recent registration of a few compound mixtures has set the precedent for combinatorial treatment of obesity. On the other hand, double or triple therapeutic combinations are more difficult to advance to regulatory approval. Following an improved understanding of the molecular basis for metabolic benefits following bariatric surgery interventions, several classes of novel unimolecular or independent combination therapeutics were discovered. These new classes of drug candidates are based on gastrointestinal hormones, offer efficacy superior to currently prescribed options and seem to have potential to fully reverse human obesity and type 2 diabetes. Moreover, gut peptide-based cell-specific targeted delivery of small molecules offer additional potential for novel metabolic precision medicines and reduced systemic side effects. In this presentation the discovery, pre-clinical validation and first clinical test of peptide hormone poly-agonist drug candidates as well as of combinatorial single molecule therapeutic candidates will be summarized, including previously unpublished observations.

DOI: 10.1530/endoabs.49.GH1
European Hormone Medal Lecture

The European Hormone Medal is awarded to an international scientist who has made significant contributions to the field of basic or clinical endocrinology. This year’s recipient is Professor Evi Diamanti-Kandarakis who will receive her prize and give her lecture as part of the European Congress of Endocrinology (ECE), beginning on the 20th May. Further information on the prize can be found at http://www.ese-hormones.org/prizes/.

Dr. Evanthia Diamanti-Kandarakis is professor of Internal Medicine-Endocrinology & Metabolism and Chairman of the Endocrine Department of Euroclinic Athens. She received her MD from Medical School of Athens and her PhD in experimental Endocrinology on the effects of androgens in hypophysectomised rats, from the same University. She was trained in Internal Medicine in England (1974–1980), and in Endocrinology-Diabetes, Metabolism & Obesity in USA (1980–1986). Her research interests have focused for the last 25 years on clinical, molecular and environmental aspects of metabolic & hormonal abnormalities in obesity Diabetes and Polycystic ovarian syndrome. This work has generated 181 publications and more than 12000 citations, classifying her among the 27 worldwide best Greek scientists and the first Greek woman endocrinologist with the greatest international contribution. In 2016 she has received the award of the best teacher in endocrinology in Greece. Dr. Diamanti-Kandarakis has been invited by the international academic community as a speaker and Tutor and has given more than 250 lectures, in Europe, Asia, Africa, North & South America.
The main achievement at present, on Endocrine-Disruptors (EDCs) effects on human health and disease development, is that it becomes a less ‘of a foreign language’ issue. The widespread distribution of environmental chemicals in the atmosphere and the detection of these substances within human body, converge to the concept that humans are continually exposed to EDCs. This presentation will focus on the possible role of the most common and studied environmental toxins in female reproductive disorders and especially in PCOS. Exposure to endocrine disrupting chemicals (EDCs) such as plasticizers, bisphenol A (BPA) or phthalates, and food toxins like advanced glycation end products (AGEs), which may affect women’s health in everyday, industrialized life, will be discussed. Acute or prolonged exposure to EDCs and AGEs may result in destabilization of the hormonal and metabolic homeostasis and lead to disruption of reproductive functions in females. Strategies and strong recommendations should be considered to protect present and future generations from their adverse health effects. Understandably, Rachel Carson, said in an international language: ‘In nature nothing exists alone.’

DOI: 10.1530/endoabs.49.EHM1
Clinical Endocrinology Trust Lecture

The Clinical Endocrinology Trust (CET) Award is given for clinical research that addresses aspects of endocrinology at the forefront of clinical practice. This year’s recipient is Professor Renato Pasquali who will receive his prize and give his lecture as part of the European Congress of Endocrinology (ECE), beginning on the 20th May. The award is sponsored by the Clinical Endocrinology Trust and further information can be found at http://www.ese-hormones.org/prizes/.

Renato Pasquali is full professor of Endocrinology at University Alma Mater Studiorum of Bologna (UNIBO), Italy. In the 90’s In 2000 he established the division of Endocrinology in the S. Orsola-Malpighi Hospital of Bologna (who was not present before), and served for a long period of time as Director. In addition, he was director of the School of Specialization in Endocrinology and Metabolism of UNIBO for fifteen years. Its clinical activity has covered over the years, all the major areas of Endocrinology and Metabolic diseases. He is a member of numerous national and international scientific societies and of the editorial boards of international journals. His scientific work was dedicated, in particular, to (i) the pathophysiology and treatment of the polycystic ovary syndrome, and (ii) the endocrinology of obesity (sex hormones, the hypothalamic-pituitary-adrenal axis, and the endocannabinoid system). He has authored 285 original papers and review articles published in international journals (PubMed) (HI 51) and 18 chapters in international textbooks. In particular, he participated as co-author, to the writing group of Clinical Guidelines in “Position” and “Consensus” statements.
Clinical Endocrinology Trust Lecture

CET1

Prospects for a new assessment of polycystic ovarian syndrome
Renato Pasquali
Italy.

PCOS is the most common hyperandrogenic disorder, with a high prevalence of metabolic comorbidities, including obesity and central fat distribution, insulin resistance and the metabolic syndrome. With this background, it should be accepted that androgen excess must be present in all women with PCOS. Thanks to the advance in measuring blood androgen levels by LC-MS/MS, it has become clear that almost all typical cases of PCOS have a variable pattern of androgen excess. An androgen profile including all major androgens should therefore be used for research purposes and clinical practice. The phenotype characterized by menses abnormalities and polycystic ovarian morphology but without androgen excess should be regarded as a separate entity. The presence of a dysmetabolic profile should also be used in the characterization of PCOS, specifically insulin resistance, which is commonly present in obese PCOS women but can also be detected in their normal-weight counterpart. In fact, there is evidence that androgen excess may play a crucial role in disrupting the metabolic pathway, in favouring aberrant visceral fat morphology and function, in favouring the development of insulin resistance and in increasing the susceptibility to develop glucose intolerance states and type 2 diabetes. Hirsutism is common in PCOS, however its correlation with blood androgen levels is weak or absent. Apart from the opportunity to use more objective methodologies to define it, much more research is needed on the potential role of cutaneous androgens. Finally, due to the relevant impact of obesity on PCOS and the fact that in many developed countries most PCOS women are obese, it can be suggested that a secondary form of PCOS related to obesity may exist. The concept of secondary PCOS can be extended to other pathological entities, particularly to the severe insulin resistant states, but also to other endocrinopathies and, finally, to specific drugs (particularly antiepileptics). As with other endocrine syndromes, we should therefore consider that PCOS, precisely because it is a ‘syndrome’, may include many different phenotypes, ranging from the classic to milder forms, and that a secondary PCOS may occur. Additional mild phenotypes without well defined androgen excess may have different pathophysiological mechanisms.

Plenary Lectures
The Fantastical World of Hormones

P1
The fantastical world of hormones
John Wass
USA.

We all know that endocrinology is the most amazing specialty. However although some of the discoveries in the last 3–400 years have been amazing, some of the wrong turns have exhibited opportunism and quackery. Perhaps we should start with testosterone and the effects of castration. We know that removal of the testes before puberty has irreversible affects and that in 16th and 17th centuries these were exploited for music. Popes did not come out of this covered in glory and the last papal castrato was singing in the Sistine Chapel choir in the early 1900s. In the late 1840s Berthold a German physiologist in Göttingen experimented on capons showing that if he removed their testes and transplanted them into the abdomen, where they regained their blood supply, the effects of castration were not seen. He did not recognize the importance of his observation. Later in the late 1880s Brown-Séquard, the famous French neurologist, reported at the French Royal Society injecting himself with a mixture of the bloods from the testes of dogs and guinea pigs. His reported marked improvement in strength and stamina was a placebo effect because of the shorter half-life of testosterone. Thyroxine from sheep given to patients with hypothyroidism, again in the late 1880s had a remarkable effect in women with hypothyroidism because of the longer half-life of thyroxine. In the late 1880s the ovary was thought to be part of the nervous system. Oophorectomy at that time was used to treat conditions in women including hysteria and anorexia and anxiety and even nymphomania. Ernest Starling was the first person to coin the term ‘hormone’ and ‘Ormao’ is the Greek word to ‘excite or stir up’. This was the founding of endocrinology. We have then gone from strength to strength with the discovery of insulin and more recent leptin, pioneered amongst others by Steve O’Rahilly and Sadaf Farooqi in Cambridge.

The Secret Life of FGF21

P2
The secret life of FGF21
David Mangelsdorf
USA.

Fibroblast growth factor 21 (FGF21) is an endocrine and paracrine factor that is produced in many tissues in response to metabolic stress, including several nutrient and dietary conditions. In addition to its physiologic role in regulating the adaptive response to these conditions, pharmacologic administration of FGF21 to obese animals causes weight loss and improves insulin sensitivity. The diverse actions of FGF21 are mediated through a unique receptor complex that is composed of a classic FGF receptor and the novel co-receptor, beta-Klotho. Investigation of the tissue-specificity of this FGF21 signaling pathway has revealed the existence of a complex peripheral and neural endocrine circuit that regulates metabolism, nutrient preference, and reward behaviors. We have also found an unexpected role for FGF21 in the exocrine pancreas as a secretagogue that protects acinar cells from proteotoxicity.

Update on Regulation of Steroidogenesis by Aberrant Hormone Receptors

P3
Update on regulation of steroidogenesis by aberrant hormone receptors
Andre Lacroix
Canada.

The mechanisms regulating cortisol production when ACTH of pituitary origin is suppressed in primary adrenal causes of Cushing’s syndrome (CS) include diverse genetic and molecular mechanisms. These can lead either to constitutive activation of the cAMP system and steroidogenesis or to its regulation exerted by the aberrant adrenal expression of several hormone receptors, particularly G-protein coupled hormone receptors (GPCR) and their ligands. Screening for aberrant expression of GPCR in bilateral macronodular adrenal hyperplasia (BMAH) and unilateral adrenal adenomas of patients with overt or subclinical CS demonstrates the frequent co-expression of several aberrant receptors. In addition, the aberrant GPCR can also exert their activity by regulating the paracrine secretion of ACTH or other ligands for those receptors in BMAH or unilateral tumors. The molecular mechanisms underlying the abnormal tissue-specific expression of the aberrant GPCR remains unclear but may be secondary to dedifferentiation of progenitor cells at the origin of hyperplasia or tumors or to specific genetic alterations. The aberrant expression of hormone receptors is not limited to primary adrenal CS but can be implicated in other endocrine tumors including primary aldosteronism (aldosteronoma or bilateral idiopathic hyperaldosteronism) and Cushings’ disease. Targeted therapies to block the aberrant receptors or their ligands have been effective in selected limited cases to date, but development of novel specific antagonists could become useful in the future.

Browning of Adipose Tissue and Metabolic Regulation

P5
Browning of adipose tissue and metabolic regulation
Jan Nedergaard
Sweden.

In most countries in the world, an increasing number of people suffer from the metabolic syndrome, normally defined as obesity, high blood sugar, high blood fats and high blood pressure. The new understanding that adult humans possess active brown adipose tissue has led to hope that a (re)activation of this tissue (browning) may be helpful in ameliorating the metabolic syndrome. Brown adipose tissue has the ability to combust (extra) food intake in a direct way, due to the unique presence of the Uncoupling-Protein-1 (UCP1). Thus, if activated – normally through the release of norepinephrine from the sympathetic nervous system – the tissue will burn away food energy, leaving only heat, water and CO2. Thus, it protects against the development of obesity. When the tissue is chronically activated, the stored lipid reserves in the tissue will not suffice for continued heat production, and the tissue will take up large amounts of sugar from the circulation, through a unique adrenergic mechanism, leading to lowering of blood sugar levels through a large glucose disposal. It will similarly activate the synthesis of lipoprotein lipase, leading in parallel to a large increase in lipid uptake from the circulation, diminishing blood triglyceride levels. During prolonged stimulation, the constant burning of food in the tissue will lead to the mobilization of the body’s lipid reserves (the white adipose tissue) that will be broken down and the released fatty acids will be transported to the brown adipose tissue for combustion, i.e. the brown adipose tissue is slimming (and all these effects together will likely also result in lowering of blood pressure). Although the acute activity of the tissue is determined by norepinephrine, it would seem that sex hormones (positively) and glucocorticoids (negatively) can affect the tissue. The tendency to a worsening of the metabolic syndrome with age could then partly be explained by a diminished sex hormone stimulation and an unaltered but increasingly dominating negative effect of glucocorticoids, together leading to brown adipose tissue inactivity, and thus to obesity.

Thyroid Oncology in the Crossroads of Precision and Narrative Medicine

Thyroid oncology in the crossroads of precision and narrative medicine
Manuel Sobrinho Simões
Portugal.

Thyroid cancers are the solid tumours of mankind with the lowest mutational load. This holds particularly true for papillary carcinomas (PTC) whose pathogenesis appears to be understandable by a limited number of genetic alterations (That is why they are so frequently multifocal). The utilization of NGS allowed the establishment of three molecular subtypes of well differentiated thyroid carcinomas: BRAF-life (Conventional and tall cell PTC, mainly), RAS-like (Follicular variant PTC and follicular carcinoma) and No BRAF/No RAS. Precision medicine is playing a major role in thyroid oncology but its shortcomings are becoming evident. Somatic copy number alterations play also a role in some tumour subtypes and, furthermore, one is progressively aware of the important role played by host factors: Stromal reaction (including extracellular matrix characteristics, subsets of fibroblasts and degree of desmoplasia), ‘social’ RNAs, immune cells, hormones, growth factors. The data brought in by the latter narrative medicine approach is turning easier the diagnosis and treatment of thyroid cancer patients.

Clinical Updates in Hypoparathyroidism

S1.1
Congenital hypoparathyroidism
Agnes Linglart
France.

The most common causes of hypoparathyroidism in children are the lack of or the impaired development of the parathyroid glands due to genetic/chromosomal alterations and the abnormal signaling of the CaC\(^{2+}\)-sensing receptor (CaSR).

The latter refers to autosomal dominant hypocalcemia (ADH) mainly caused by heterozygous activating mutations in CASR encoding CaSR (ADH type 1), and exceptionally caused by activating mutations of GNA11 encoding the Gq/11 protein (ADH type 2). Hypoparathyroidism can also be caused by an autoimmune process, mainly in the context of AIRE mutations. However, in many children, the origin of the hypoparathyroidism remains undiscovered. In a recent national French survey gathering 142 children affected with hypoparathyroidism performed by MAC, 43% of the patients were diagnosed before the age of 1 year. The main causes of the PTH insufficiency were 22q11 deletion (31%), ADH (13%), AIRE mutations (10%) and cervical surgery (7%). The etiology is still unknown in 23% of the children. Due to the high calcium needs of the skeleton during infancy and childhood, hypoparathyroidism in children is often symptomatic and is diagnosed because of the clinical symptoms of hypocalcemia (muscle spasms, laryngospasm, seizures). Children may present with unspecific features such as cognitive and or motor delay, slowness, ungueal, dental and skin anomalies. In addition, clinical characteristics due to the disease itself causing the hypoparathyroidism may be present such as candidosis, conotruncal cardiac defect, renal and/or uterine malformation. Once hypoparathyroidism has been diagnosed in a child, a comprehensive work-up should be performed to identify the disease-causing defect. The investigations depends on the age of the child (neonate, child, adolescent), and on the clinical features associated with the hypocalcemia. The diagnosis is of importance for the management of follow-up and treatment. The management of hypoparathyroidism in children relies upon calcium supplements and vitamin D analogs. Following the initial period of profound hypocalcemia which may require IV infusion of calcium and high doses of vitamin D analogs (up to 4 µg/day of alfacalcidol), the conventional therapy should aim at absence of clinical symptoms, low-normal level of serum calcium (2.2–2.2 mmol/l), avoiding hypophosphatemia and having normal urinary calcium excretion. In some children, this may be a challenging management requiring use of thiazide diuretics, phosphate binders, calcium supplements and in refractory cases, recombinant PTH. It has become obvious in the past ten years that we need to i) obtain more data on the long-term evolution of children affected with hypoparathyroidism, ii) adjust our decision rules for the identification of the cause of hypoparathyroidism in the context of next generation sequencing and gene panels or whole exome sequencing, and iii) develop guidelines for the management of hypoparathyroidism in children including the specificity of ADH.

DOI: 10.1530/endoabs.49.S1.1

S1.2
Acquired hypoparathyroidism
Fadil Hannan
Uk.

Hypoparathyroidism is characterized by absent or low circulating concentrations of parathyroid hormone (PTH), which results in hypocalcaemia, hyperphosphatemia and impaired renal reabsorption of calcium. Hypoparathyroidism has a prevalence of \(20–40\) cases per \(100 000\) individuals, and anterior neck surgery accounts for around \(75\%\) of cases. Postsurgical hypoparathyroidism may arise in patients undergoing total thyroidectomy, radical neck dissection for head and neck malignancies, and after total parathyroidectomy. Hypoparathyroidism following surgery is caused by intraoperative trauma, and inadvertent gland removal or devascularisation. Transient postsurgical hypoparathyroidism, defined as lasting \(<6\) months, affects \(25–30\%\) of patients following total thyroidectomy; whilst permanent postsurgical hypoparathyroidism, defined as lasting \(>6\) months, affects up to \(3\%\) of patients after total thyroidectomy. Decreases in pre-operative serum calcium and 25-hydroxyvitamin D concentrations, reduced intraoperative PTH concentrations, and longer duration of surgery represent independent predictors of transient hypoparathyroidism. Permanent hypoparathyroidism following thyroid surgery is associated with: inability to identify \(\geq 2\) parathyroid glands during surgery; hypocalcaemia at 24-h post-surgery; and reoperation for bleeding. Occasionally, postsurgical hypoparathyroidism may have a delayed-onset and present several years after neck surgery. Autoimmune-mediated destruction of the parathyroids represents the next most common cause of acquired hypoparathyroidism and is considered in patients with a personal or family history of autoimmune diseases. Autoimmune acquired hypoparathyroidism may be associated with the presence of anti-parathyroid gland antibodies, and some patients harbor antibodies against the calcium-sensing receptor (CaSR). Acquired hypoparathyroidism may also be caused by hypomagnesaemia, which impairs PTH secretion, and can rarely be due to exposure to ionizing radiation, or result from infiltrative diseases affecting the parathyroids such as metastases or iron/copper overload.

DOI: 10.1530/endoabs.49.S1.2

S1.3
Clinical updates in hypoparathyroidism
Erik Fink Eriksen
Norway.

The spectrum of symptoms associated with hypoparathyroidism span from virtually none to severely debilitating fatigue, memory loss, muscle cramps, and paresthesia. Until recently disease management has focused on securing stable serum calcium values at the lower end of the reference range using potent active vitamin D analogues like EtaIpha and RoCAltol, together with calcium supplementation. Recently maintenance of adequate levels of 25(OH)D have also been mentioned as being important. Adequate intracellular magnesium levels seem to be crucial for PTH secretion and action at the receptor level, and should therefore be kept at the upper end of the normal range if possible. It is one few endemic diseases where supplementation of missing hormone was impossible about 10 years ago. Now we have access to recombinant PTH(1-34) and PTH(1-84), and I will review the potential use of and differences between these analogues in the treatment of hypoparathyroidism. In terms of symptomatic relief the results of controlled studies using these analogues as sc. injections have been disappointing. A more physiological pattern can be achieved with continuous subcutaneous infusion using insulin pumps, and I will review the results obtained with this technique so far.

Evolving Diagnostics in Adrenal and Neuroendocrine Tumours

S2.1
Role of genetic and biomarker tests for diagnosis of neuroendocrine tumours (NETs)
Raj Thakker
UK.

Neuroendocrine tumours (NETs) are a heterogeneous group of neoplasms that occur in different organs and give rise to tumours including carcinoids, pancreatic tumours (PNETs), pituitary adenomas, medullary thyroid carcinoma, and pheochromocytomas. NETs usually occur as isolated non-familial tumours, but can also occur as hereditary and syndromic disorders, such as multiple endocrine neoplasia (MEN) types 1–4, Von Hippel Lindau (VHL) and pheochromocytoma/paraganglioma. Patients with NETs such as PNETs that do not secrete hormones (referred to as non-secreting or non-functioning PNETs) are often asymptomatic, and this may result in late diagnosis and presentation with metastases. Thus, there is an unmet need for new, reliable and specific biomarkers for early diagnosis that would improve patient survival and quality of life. Biomarkers, which are defined by the World Health Organisation as a substance, structure or process that can be measured in the body or its products and influence or predict the incidence of outcome or disease, for non-secreting NETs include pancreatic polypeptide, chromogranins, carcinoembryonic antigen, α-fetoprotein, neuron specific enolase and synaptophysin. However, these current biomarkers have poor sensitivity and specificity for non-secreting NETs thereby limiting their use for clinical decision making. Recently, detection of germline mutations of the \(MEN1\) and \(VHL\) genes have been established as useful predictive biomarkers for the development of PNETs in families with these disorders. However, such familial mutations account for only approximately \(3\%\) of NETs. Additional biomarker development has also focussed on studying altered expression of the epigenome, transcriptome, proteome and metabolome, as well as circulating DNA, microRNAs and tumour cells that can be released from tumours into the vasculature. These advances will be reviewed. Dr Kate E Lines, Dr Mark Stevenson & Professor Rajesh V Thakker.

**Current status in morphological imaging in adrenal and gastrointestinal neuroendocrine tumours**

Sundin Anders

Sweden.

Computed Tomography (CT) constitutes the basic technique for imaging of adrenal tumours and neuroendocrine tumours (NETs). The major workload in adrenal imaging is characterisation of adrenal incidentalomas, i.e. adrenal tumours diagnosed on imaging performed for other reasons than adrenal disease. Myelolipomas, which have a typical appearance with areas of macroscopic fat, and simple cysts are easy to characterize and require no follow-up. Morphologically benign adrenal tumours (rounded, sharply delineated, homogenous internal structure) with an attenuation of \( \leq 10 \text{HU} \) in the native CT images are characterized as benign adrenocortical adenomas and require no additional imaging. With an attenuation \( \geq 10 \text{HU} \), follow-up of tumour size is recommended for 6 months. In young (\(<40\) years) patients this should preferably be performed by MRI. Calculation of contrast medium wash-out is no longer applied. For tumours \( >4 \) cm surgical resection is recommended unless in cases of a typical myelolipoma or cyst. CT is for NETs used for the initial localization of the primary tumour, for staging of the disease, detection of recurrence and for monitoring of therapy. It is also used in hybrid imaging in conjunction with PET (PET/CT) and SPECT (SPECT/CT). MRI is superior for imaging of liver, pancreas, brain and bone. In metastatic NETs, \( 68\text{Ga-DOTA-somatostatin} \) analogue PET/CT generally shows several additional lesions as compared to CT/MRI and small lesions such as lymph nodes may be characterized as metastatic/not metastatic lesions. Contrast-enhanced US is excellent for CT/MRI and small lesions such as lymph nodes may be characterized as metastatic/not metastatic lesions. Contrast-enhanced US is excellent for monitoring of therapy. It is also used in hybrid imaging in conjunction with PET (PET/CT) and SPECT (SPECT/CT). MRI is superior for imaging of liver, pancreas, brain and bone. In metastatic NETs, \( 68\text{Ga-DOTA-somatostatin} \) analogue PET/CT generally shows several additional lesions as compared to CT/MRI and small lesions such as lymph nodes may be characterized as metastatic/not metastatic lesions. Contrast-enhanced US is excellent for diagnosis and characterization of liver lesions and to guide the biopsy needle for the histopathological NET diagnosis. Endoscopic US is the best method for detection of pancreatic NETs.

**Implication of the prolactin receptor in humans**

Nadine Binart

France.

While prolactin (PRL) is known as the pituitary hormone of lactation, accumulating evidence shows that PRL acts on many tissues and in many pathophysiological conditions. The major isoform, 23 kDa PRL, acts via a membrane receptor, the prolactin receptor (PRL-R), a member of the hematopoietic cytokine superfamily, and for which the mechanism of activation has been elucidated. The aim of this symposium is to present and discuss data supporting actions of PRL in hyperprolactinemia in the context of gonadotropin deficiency. High levels of PRL in humans may interfere with reproductive function mainly by actions at the hypothalamus. Our data suggest that Kisspeptin neurons appear to be the missing link between hyperprolactinemia and GnRH deficiency. Otherwise, germline PRLR mutations have been suspected to be a specific genetic cause of prolactinoma in humans. This will be discussed in light of our recent results.

**Efficacy and effectiveness of physical activity and nutrition interventions in childhood obesity treatment**

Hollie Raynor

USA.

While several organizations have recommended that multicomponent, behavioral family-based programs delivered at a moderate- to high-intensity contact frequency have a moderate to high rating of efficacy for improving weight status in children, these types of programs are difficult to translate into many practice-based settings. This presentation will review areas that have been identified within childhood obesity treatment programs that may assist with translation to practice-based settings, and discuss research that has been conducted that examine these factors. An example of a current randomized trial translating a multi-component,
behavioral family-based program into an integrated primary care setting in the USA will be provided.

**Can we prevent childhood obesity?**  
Tim Lobstein  
UK.

Childhood obesity prevalence continues at a high level in most developed economies and is rising strongly in emerging middle-income countries. This rise in prevalence shows strong links to the exposure of populations to mass-marketed foods and beverages and the use of motorised transport. In Europe the prevalence tends to be higher, and rising faster, among children from lower-income households. The prevention of obesity is essential but clearly we are not doing very well – no country in Europe has successfully and sustainably reduced childhood obesity prevalence. We need to ask: What are the major social, commercial and political barriers which need to be overcome? What steps can we take to overcome these barriers and create a truly health-promoting society?

**Effects of maternal thyroid function on infant neurodevelopment**  
Tim Korevaar  
The Netherlands.

In this talk I aim to provide a helicopter view of clinical studies on maternal thyroid function and child neurodevelopment and use this to pin-point out how different viewpoints on the results can help to interpret the clinical relevance of the currently available data and provide handles to make personal but informed clinical decisions. It is well-established that thyroid hormone plays an important role during early stages of fetal brain development. Thyroid hormone-dependent stages of brain development occur from the 5th week of pregnancy onwards while the fetal thyroid is not functionally matured until week 18–20. This implicates that adequate maternal thyroid hormone concentrations are important for achieving optimal early fetal brain development. After the initial link between iodine deficiency and cretinism was first identified, a wide range of experimental studies further established underlying (patho)physiological mechanisms. Subsequently, clinical studies were set-up to translate these findings and quantify the extent of effects in humans. During this presentation I aim to take the audience through a brief timeline of clinical studies published since the late 1990s until this day. The interpretation of clinical outcomes used to study the hypothesis that maternal thyroid hormones are important for fetal brain development, such as child IQ, will be discussed. The timeline of clinical studies together with the interpretation of the results of recent studies, including clinical trials, could help to weigh the potential clinical benefits and harms, and make for a better informed decision making.

**Vitamin D and rickets in African children**  
Vickie Braithwaite  
UK.

Rickets is the most common non-communicable disease in low and middle income countries and is re-emerging in countries such as the UK where it was once thought to be eradicated. Rickets is a bone disease which affects growing children and is caused by the undermineralisation of the growth plate of long bones. Rickets can lead to osteomalacia, disabling bone deformities of the lower limbs, stunting, increased fracture risk and in severe cases circulating bone mineral disturbances can result in hypocalcaemic seizures and death. The majority of nutritional rickets worldwide is thought to be driven by vitamin D deficiency due to inadequate skin exposure to UVB-containing sunshine. In many countries in Africa however, 25-hydroxyvitamin D concentrations (the status marker for vitamin D) are above those generally associated with vitamin D deficiency thus indicating alternative causes of rickets. This presentation will explore some of our work on the role of the vitamin D-calcium-phosphate axis on nutritional rickets in a selection of African countries; highlighting the potential roles of calcium and iron deficiency. This presentation will also explore whether aetiology may differ depending on setting i.e. urban vs rural and the various treatment methods for rickets including surgical correction of bone deformities, nutritional supplementation and prophylactic treatment strategies for rickets prevention.

**Carbohydrate metabolism in patients with Cushing disease: a glance at the incretin system**  
Lubov Matchekhina  
Russia.

The relevance of carbohydrate metabolism studying in patients with Cushing disease (CD) and acromegaly can be explained by frequent occurrence of glucose metabolism disturbances on the one hand, and difficulties in glucose-lowering therapy in these patients on the other. The effectiveness of hyperglycaemia treatment may be reduced due to difficulties in remission/cure of the underlying disease, as well as to the use of specific drug-therapy, leading to hyperglycaemia. There is a growing interest in research aimed at studying the role of incretin system in the pathogenesis of secondary hyperglycaemia associated with neuroendocrine diseases recently.  

**Aim of the study**  
To analyze the rhythm and levels of incretins and neuropeptides secretion in patients with CD and acromegaly and therefore to specify the pathogenesis of carbohydrate metabolism disturbances.  
**Methods**  
42 patients with Cushing disease and acromegaly were included; the mean age was 37.5 years. All of the patients were newly diagnosed with Cushing disease (using urinary free cortisol levels, evening saliva cortisol levels and low-dose dexamethasone suppression test) and acromegaly (in absence of GH suppression during OGTT and high IGF1 levels); none of them had a history of previous drug therapy, radiotherapy or pituitary surgery. All patients underwent OGTT, during which glucose, glucagon, GLP1, GLP2, GIP, ghrelin were measured at 0, 30 and 60 minutes. All patients with CD and acromegaly and therefore to specify the pathogenesis of carbohydrate metabolism disturbances.  
**Results**  
During OGTT glucose levels were not significantly different in all groups. The mean HbA1c level was 5.8% (5.3–6.2). However the prevalence of prediabetes was significantly higher in CD patients. In CD patients glucagon levels were significantly higher at all cut off points compared to controls (P<0.001). In acromegaly patients, no significant differences were found. GIP secretion was slightly lower in CD patients; in acromegaly patients, no differences were found. Acromegaly group was characterized by inverse rhythm of GIP secretion, with no peak level at 30’: GIP 0 min – 194.2 pg/ml, GIP 30 min – 178.8 pg/ml. GLP-1 levels were significantly higher in CD patients compared to acromegaly and controls (P<0.001). Ghrerin levels were significantly higher in CD patients (P<0.013) and acromegaly (P=0.023) patients.  
**Conclusion**  
More pleotropic actions of glucocorticoïds can possibly explain higher relevance of carbohydrate metabolism disturbances in CD patients. This can be also explained by higher levels of glucagon secretion, which does not depend on type
of carbohydrate metabolism disorder and is stimulated by a direct action of glucocorticoids on glucagon receptor. GIP and GLP-1 secretion in CD and acromegaly patients are characterized by inverse rhythm with no peak levels which means that these hormones are not playing the crucial role in carbohydrate disturbances development in these patients. On the contrary, GLP-2 and ghrelin seem to influence and potentially regulate glucose homeostasis in CD and acromegaly patients.

**S6.2**

**T4/T3 combination therapy: is there a true effect?**

Wilmar Wiersinga

The Netherlands.

L-T4 monotherapy remains the standard treatment of hypothyroidism, as RCTs comparing T4 and T4 + T3 did not indicate superiority of the combination therapy. However, the issue is far from settled, as these RCTs can be criticized and 5–10% of patients on T4 have persistent complaints.

1) Has T4 + T3 therapy a true effect on serum thyroid hormones? Under T4 monotherapy serum FT4 is higher and serum FT3 is lower than in healthy subjects, giving rise to abnormal T3/T4 ratio’s in 29% of patients. T4 + T3 therapy produces lower FT4 and higher FT3 values, and thereby T3/T4 ratio’s are closer to normal values. There is conflicting data whether T3/T4 ratio’s are related to SNPs (e.g. in DIO2) and to persistent complaints.

2) Has T4 + T3 therapy a true effect on thyroid-hormone dependent actions? There is emerging but weak evidence that markers of thyroid hormone action (such as LDL-cholesterol, SHBG, bone alkaline phosphatase) are closer to normal under T4 + T3 therapy than under T4 monotherapy.

3) Has T4 + T3 therapy a true effect on the clinical condition? Patients were asked for their preference in 4 RCTs. Preference for T4 was 28% and for T4 + T3 48%; no preference was expressed by 27%. Preference has been related to loss of body weight and to combined SNPs in MCT10 and DIO2.

4) Has T4 + T3 therapy a true effect on clinical practice? Yes, absolutely. Many patients demand T4 + T3 therapy, sometimes in a aggressive manner. Prescription of T3 tablets have increased, and pharmacy has discovered the potentially big market for T3, among others resulting in a steep price increase of T3 tablets but also in availability of 5 microgram T3 tablets. Only the ETA published detailed guidelines how to start the still experimental T4 + T3 regimen (Eur Thyroid J 2012;1:55). The many unresolved issues call for many more clinical trials of different designs.

**Immune system**

Patrizia D’Amelio

Italy.

The immune system has been recognized as one of the most important regulators of bone turnover and its de-regulation is implicated in several bone diseases as post-menopausal osteoporosis and inflammatory bone loss. The study of the relationship between immune system and bone metabolism is generally indicated under the term ‘osteimmunology’, the vast majority of these studies have been performed in animal models, however several data have been confirmed also in humans. Post-menopausal osteoporosis (POM) is the most frequent metabolic skeletal disease, it is characterized by reduced bone mineral density and micro architectural deterioration of bone with increased fracture risk. In POM the uncoupling between osteoblast (OB)-mediated bone formation and osteoclast (OC)-mediated bone resorption results in bone loss. Estrogen deficiency is the main driver of post-menopausal bone loss: during estrogen depletion OCs formation and activity are increased, this increase is partially mediated trough the effect of estrogen deficiency on immune system. Estrogen deficiency influences immune response, in particular T cells, become more active and able to produce inflammatory and pro-osteoclastogenic cytokines as TNFα and RANKL. Despite of some inverse reports, the main body of literature firmly supports the essential role of activated T cells in regulating bone loss induced by estrogen deficiency, both in animal models and in humans. We recently demonstrated that immune system, and in particular T cells mediate the effect of PTH on bone turnover, in particular we demonstrated that during treatment with teriparatide for POM T cells mediates osteoblastogenesis trough the production of Wnt10b, whereas primary hyperparathyroidism do not increase this molecule. Moreover we demonstrated that, both in mice and humans, continuous infusion of PTH and primary hyperparathyroidism increases the differentiation of T helper (TH) cells in TH17. These cells are responsible for increased OCs formation and activity both in inflammatory diseases and in PO. In conclusion The interactions between immune system and bone are complex and play significant role in both health and disease, nevertheless not all the pathways discovered in animal models have been fully demonstrated in humans, and several challenging questions remains unsolved.

**Osteocalcin signaling in myofibers is necessary and sufficient to increase exercise capacity**

Gerard Karsenty

USA.

The observation that circulating osteocalcin levels double during exercise in young mice suggests that this hormone might be a long sought after endocrine regulator of exercise capacity. We addressed this question by analyzing mice lacking either osteocalcin or its receptor in myofibers only. This analysis showed that osteocalcin signaling in myofibers enhances adaptation to exercise because it increases uptake and utilization of triglycerides into the tricarboxylic acid cycle and promotes fatty Osteocalcin signaling in myofibers favors adaptation to exercise through a second mechanism. Indeed it up-regulates the expression of Interleukin-6 a myokine that favors adaptation to exercise in part by signaling in bone to promote the production of bioactive osteocalcin. Acids utilization. In the course of these studies we noticed that circulating osteocalcin levels decline sharply before mid-life and do not increase during exercise in older mice. This observation raised the prospect that osteocalcin may also be sufficient to correct the age-related decline in muscle function. In support of this hypothesis, our experiments show that exogenous osteocalcin increases the exercise capacity of young wilt-type mice and confers to 15 month-old mice the exercise capacity of 3 month-old mice. This study uncovers an osteocalcin-interleukin-6 axis that increases muscle function during exercise and can reverse the age-induced decline in exercise capacity.

DOI: 10.1530/endoabs.49.S7.2
The gut microbiota (GM), the commensal bacteria living in our intestine, performs numerous useful functions, including modulating host metabolism and immune status. Our recent studies demonstrate that the GM is also a regulator of bone mass and we propose that the effect of the GM on bone mass is mediated via effects on the immune system, which in turn regulates osteoclastogenesis. A role of the GM in bone metabolism is further supported by studies demonstrating that antibiotic, probiotic, and prebiotic treatments that impact GM composition regulate bone metabolism. Collectively, these studies suggest that the GM may be a novel therapeutic target for osteoporosis. Treatment with probiotics has already been shown to improve bone mass in rodent models of bone loss, but future randomized clinical trials are required to determine the possible effect of probiotics and other novel therapies modulating the GM composition on bone mass and fracture risk in patients with osteoporosis. Access to cheaper sequencing and improved bioinformatics tools will allow metagenomic sequencing for the analysis of the GM composition in large prospective clinical cohort studies. This can be used to evaluate the predictive value of the GM composition as a biomarker for low bone mass and fracture risk. In addition, metatranscriptomics and metaproteomics will most likely be used to identify the microbial genes and proteins that have an impact on bone mass and fracture risk. We propose a new cross-disciplinary GM–bone research field called 'osto-microbiology', bridging the gaps between bone physiology, gastroenterology, immunology, and microbiology. Future studies are clearly warranted in this new research field to determine if the GM composition might be used as a biomarker for fracture risk prediction and to validate the GM as a possible novel therapeutic target for osteoporosis.

Clinical studies on GLP-1 - cardiovascular outcomes
Baptist Gallwitz
Germany.

The incretin hormone Glucagon-like peptide-1 (GLP-1) has various non-glycaemic properties. Among those, cardiovascular effects have been described in animal studies and in clinical studies in patients with type 2 diabetes that have been treated with GLP-1 receptor agonists (GLP-1RA). In animal studies, GLP-1 and GLP-1RA have lead to a decrease in ischemic areas in artificial myocardial infarct models. Additionally, in some clinical studies, an improvement in left ventricular function was observed as well as a decrease for catecholamine requirement in post-surgical patients after coronary bypass graft surgery. The pathophysiologic explanations for these effects are a possible improvement in substrate utilization of the myocardium as well as vascular effects mediated by the activation of cardiovascular GLP-1 receptors and a consecutive amelioration of hypertension. In recent years, randomized, prospective cardiovascular safety trials have been initiated or performed with GLP-1RA in patients with type 2 diabetes and concomitant cardiovascular disease or cardiovascular risk factors. Results from three of these studies have been published so far. In the ELIXA trial, the short acting GLP-1RA lixisenatide was given as add on to a standard antidiabetic therapy in patients after an acute cardiovascular event. In comparison to an established diabetes therapy, lixisenatide demonstrated non-inferiority and cardiovascular safety. The LEADER study performed with liraglutide in patients with type 2 diabetes and concomitant cardiovascular risk or disease showed a highly significant 13% relative risk reduction in the 3-point MACE (MACE = multiple adverse cardiovascular events; combined endpoint of cardiovascular death, non-fatal myocardial infarction and non-fatal stroke) after 54 months. This result was primarily driven by a significant reduction of cardiovascular death by 22%. Semaglutide, a long-acting GLP-1RA for once weekly injection that is not a substrate utilization of the myocardium as well as vascular effects mediated by the activation of cardiovascular GLP-1 receptors and a consecutive amelioration of hypertension. In recent years, randomized, prospective cardiovascular safety trials have been initiated or performed with GLP-1RA in patients with type 2 diabetes and concomitant cardiovascular disease or cardiovascular risk factors. Results from three of these studies have been published so far. In the ELIXA trial, the short acting GLP-1RA lixisenatide was given as add on to a standard antidiabetic therapy in patients after an acute cardiovascular event. In comparison to an established diabetes therapy, lixisenatide demonstrated non-inferiority and cardiovascular safety. The LEADER study performed with liraglutide in patients with type 2 diabetes and concomitant cardiovascular risk or disease showed a highly significant 13% relative risk reduction in the 3-point MACE (MACE = multiple adverse cardiovascular events; combined endpoint of cardiovascular death, non-fatal myocardial infarction and non-fatal stroke) after 54 months. This result was primarily driven by a significant reduction of cardiovascular death by 22%. Semaglutide, a long-acting GLP-1RA for once weekly injection that is not approved yet, lead to a significant 26% relative risk reduction in the 3-point MACE in its clinical phase III study programme. From these data, the hypothesis that the activation of the GLP-1 receptor has beneficial cardiovascular effects, is strongly supported and it has now been demonstrated in two studies, that patients with type 2 diabetes and cardiovascular disease may profit from a therapy with GLP-1RA regarding their cardiovascular outcomes.

Pubertal induction and hormone replacement in young males
Nelly Pitteloud

Congenital gonadotropin-releasing hormone deficiency is a rare disorder characterized by incomplete or absent puberty and infertility. This condition is both clinically and genetically heterogeneous and presents with a broad spectrum of phenotypes ranging from mild to severe. This presentation will provide a review of hypogonadotropic hypogonadism, including the clinical presentation of HH, a rational approach to evaluating HH patients, and an update on treatment options. In particular, the speaker will focus on the choice of the most appropriate treatment in hypogonadotropic hypogonadism based on clinical presentation including the use of rFSH to enhance treatment outcome.

New Roles for Nuclear Receptors

S11.1
Identification of nuclear receptors network in male fertility
David Volle
France.

Male fertility is controlled by complex interactions among the hypothalamus, pituitary, and testis. The major functions of the testicles include production of spermatozoa (male gametes) and synthesis of testosterone. Testosterone is produced by the testicular Leydig cells and is responsible for the development of gonad, the attainment of puberty, and the maintenance of secondary sexual characteristics. It is also involved in the maintenance of spermatogenesis and thus ensuring male fertility. Many studies have highlighted the complexity of the regulations of testicular homeostasis at both tissue and cellular levels. Among the involved molecular mechanisms, several nuclear receptors (NRs) have been identified as key regulators of testicular physiology. NRs are a family of transcription factors with a conserved structure that within testis control steroidogenesis and germ cell differentiation. Since several years, using both genetic and pharmacologic strategies, we have been implicated in the identification of the multiple roles of particular members of the NR superfamily. Here we will give an overview of our research highlighting the identification of a complex network showing the interactions of these NRs in the regulation of the exocrine and endocrine functions of the testis.

DOI: 10.1530/endoabs.49.S11.1
Graves’ orbitopathy (GO) is characterized by orbital tissue inflammation, expansion, remodelling and fibrosis. Although the initiating trigger of GO is still indistinct, excessive orbital fibroblast activity is at the heart of its pathogenesis. Orbital fibroblasts are activated by cellular interactions with immune cells and the soluble factors they secrete as well as autoantibodies (e.g. TSH-receptor autoantibodies). Activated orbital fibroblasts produce inflammatory mediators thereby contributing to the inflammatory process in GO. Moreover, orbital fibroblasts exhibit robust proliferative activity and extracellular matrix (especially hyaluronan) synthesizing capacity and can differentiate into adipocytes and myofibroblasts with disease progression, thereby contributing to tissue expansion/remodelling and fibrosis in GO. Orbital fibroblasts, especially those from GO patients, exhibit a hyper-responsive phenotype when compared to fibroblasts from other anatomical regions, which may further contribute to GO pathogenesis. This presentation will address our current view on the role that orbital fibroblasts fulfill in GO pathogenesis as well as the potential of direct targeting of the orbital fibroblast in the treatment of GO.

DOI: 10.1530/endoabs.49.S12.1

Management of Graves’ orbitopathy
Luigi Bartalena
Italy.

Management of Graves’ orbitopathy (GO) depends on the severity and activity of the disease. Guidelines for the management of GO have recently been published by EUGOGO (European Group on Graves’ Orbitopathy) (European Thyroid Journal 2016 8:9-26). Assessment of GO by standardized criteria is fundamental to determine the type of intervention. General measures for all patients with GO, irrespective of the degree of severity and activity, include restoration and stable maintenance of euthyroidism, refrain from smoking, use of local measures (e.g. artificial tears, ocular gels). All GO patients, except for the mildest cases, should be referred to specialists. Mild GO is not treated actively, except for a 6-month course of selenium supplementation, shown in a randomized clinical trial (RCT) to be more effective than placebo also in terms of prevention of progression to more severe forms of GO. Sight-threatening GO, due to dysthyroid optic neuropathy and/or corneal breakdown, is an endocrine emergency and should be treated immediately with very high doses of intravenous glucocorticoids (ivGCs) and measures to protect the corneal surface. If, however, response is absent or poor within 2 weeks, the patient should be promptly submitted to orbital decompression. Treatment of moderate-to-severe GO depends on disease activity. If GO is stably inactive, there is no place for medical treatment, and rehabilitative surgery (orbital decompression, squint surgery, eyelid surgery) can be performed, as needed. For moderate-to-severe AND active GO, ivGCs represent, for the time being, the first-line treatment. ivGCs are given as 12 weekly, slow infusions of methylprednisolone (MP). Most commonly, the cumulative dose of MP is 4.5 g, but the dose should be tailored to the patient conditions, avoiding a cumulative dose > 8 g and a single dose > 0.75 g, to minimize the risk of toxicity. If response is not satisfactory in terms of regression and inactivation of GO, second-line therapies include a second course of ivGCs, a course of oral glucocorticoids combined with either orbital radiotherapy or cyclosporine, treatment with rituximab. The choice of second-line treatments should be part of a shared decision-making process with the informed patient. In addition to rituximab, the effectiveness and safety of which should be confirmed in larger RCTs, ongoing studies are investigating the effectiveness and safety of other biologics, including teprotumumab and tocilizumab. Results of these studies are not available yet.

DOI: 10.1530/endoabs.49.S12.2

How to predict progression in Graves orbitopathy?
Petros Petros
UK.

Graves’ orbitopathy (GO) is a relatively rare condition, but can cause significant morbidity, poor quality of life, socioeconomic cost and occasionally impaired vision. Some studies indicate that nearly all patients with Graves’ hyperthyroidism, even those without overt GO, have subclinical eye disease. It is becoming increasingly evident that early recognition of GO and early interventions can affect the long-term outcome favourably. Predicting which patients will develop clinical manifestations of GO is therefore important. Clinical tools for early recognition of GO in a population of patients with Graves’ hyperthyroidism attending endocrine clinics have been developed and are being further validated. A number of clinical and biochemical parameters have been shown to be associated with progression of GO and can be used clinically to identify such cases. They include age, gender smoking status, severity of thyrototoxicosis, dysthyroid status, use of radioiodine and the level of TSH receptor antibodies.

DOI: 10.1530/endoabs.49.S12.3

Crosstalk between estrogen signalling and DNA damage repair
Simak Ali
UK.

Estrogen receptors (ER) are expressed in the majority of breast cancers, are key drivers of breast cancer development and progression and hence therapies to inhibit their activities are a mainstay of treatment for breast cancer. A large proportion of patients develop resistance to these therapies, so determining the mechanisms of ER action is important for improving patient management and for identifying new therapies. In defining the mechanisms by which ER regulates gene expression, we and others find that proteins involved in DNA damage recognition and repair (DDR), including components of base excision repair (BER) and non-homologous end-joining (NHEJ) are central to the promotion of gene expression by ER. Most recently, we have demonstrated that the cytosine deaminase APOBEC3B (A3B) is recruited to the regulatory regions of estrogen-responsive genes in an ER-dependent manner. We have shown that A3B recruitment promotes transient C-to-U changes at ER/A3B binding regions, repaired by BER/NHEJ pathways, with the cytosine deamination and its repair facilitating chromatin remodeling that aids expression of ER target genes. Importantly, we have now extended these studies to demonstrate an important role for A3B in transcription regulation in ER-negative, as well as ER-positive breast cancer cell lines, indicating that A3B has a general role in regulating gene expression in human cells. These findings highlight the therapeutic potential of A3B inhibitors for the treatment of ER+ and ER-negative breast cancer. Recent reports have implicated A3B as the enzyme responsible for acquisition of mutations and tumour evolution in diverse cancer types, highlighting the inherent dangers associated with the cellular role of DNA damage and repair in the regulation of gene expression. These findings also raise the question of whether targeting of A3B to gene regulatory regions might promote non-coding mutations that modify gene enhancer function and provide further impetus for the development of A3B inhibitors for cancer.

**Challenging Pituitary Diseases**

**S13.1**

**Hypophysitis**

Niki Karavitaki
UK.

Hypophysitis is a rare inflammatory condition of the pituitary gland. Its pathogenesis is poorly understood and new variants have been recently described. It can be primary (isolated inflammation of the gland, not related with medications, systemic inflammatory disorders, infections, or other diseases), or secondary (associated with systemic inflammatory processes (as sarcoidosis, Wegener’s granulomatosis, Crohn’s disease, Takayasu’s arteritis, Cogan’s syndrome), inflammatory cell proliferative disorders (Langerhans cell histiocytosis, Erdheim-Chester disease), infections (as tuberculosis, syphilis), tumour-associated inflammatory infiltrate (as in germinoma), immunotherapy (as medications targeting cytotoxic T-lymphocyte antigen-4 (CTLA-4) or programmed cell death 1 (PD-1)), rupture of sellar cysts (Rathke’s cleft cysts and craniopharyngiomas)). The histological subtypes are lymphocytic, granulomatous, xanthomatous, and plasmacytic (also termed IgG4-related hypophysitis which is often a manifestation of systemic disease). The inflammation may involve the anterior pituitary gland (adenohypophysitis), posterior gland and stalk (infundibulo-neurohypophysitis), or entire gland (pan-hypophysitis). Patients with hypophysitis present with manifestations related to mass effect from the gland enlargement and hypothalamo-pituitary dysfunction. The severity of hormone deficiencies may be out of proportion to imaging findings. Radiological findings include homogenous enhancement of the pituitary, diffuse symmetric gland enlargement, midline stalk thickening, and absence of a posterior pituitary bright spot. The diagnosis is established by biopsy and pathological examination. There are no prospective controlled studies on the optimal management of hypophysitis and treatment remains controversial; potential options include surgery (if visual deterioration), glucocorticoids (at variable dosages and duration), immunosuppressive agents and radiotherapy. Spontaneous resolution of pituitary enlargement has been observed in a number of cases and improvement of pituitary hormone deficits may occur after the resolution of hypophysitis.

**Empty sella**

Laura De Marinis
Italy.

Empty Sella (ES) represents a heterogeneous syndrome, with a completely unknown pathogenesis. Defects in the organogenesis or hypoplasia of the sellar diaphragm (associated with stable or intermittent variation of intracranial pressure and/or with pituitary volume variation) can facilitate the herniation of the arachnoid space into pituitary fossa and the consequentially pituitary compression. ES can be the sequel of necrosis of pituitary adenomas, of hypophysitis or of brain/head trauma. In these condition, ES is defined secondary. In cases with unknown aetiology ES is defined Primary. However, actually, obesity, systemic hypertension, multiple pregnancies, diabetes mellitus and pseudotumor cerebri are considerate factor risks for the occurrence of primary ES (PES). In 50% of cases with PES a coexistent intracranial hypertension is associated, with the occurrence of neurological signs and symptoms. The clinical manifestation of PES can be insidious, with subclinical or severe symptoms, as headache or papilledema, as visual disturbance or diplopia or optic neuritis, as partial or complete hypopituitarism, also associated inflammatory infiltrate (as in germinoma), immunotherapy (as medications targeting cytotoxic T-lymphocyte antigen-4 (CTLA-4) or programmed cell death 1 (PD-1)), rupture of sellar cysts (Rathke’s cleft cysts and craniopharyngiomas)). The histological subtypes are lymphocytic, granulomatous, xanthomatous, and plasmacytic (also termed IgG4-related hypophysitis which is often a manifestation of systemic disease). The inflammation may involve the anterior pituitary gland (adenohypophysitis), posterior gland and stalk (infundibulo-neurohypophysitis), or entire gland (pan-hypophysitis). Patients with hypophysitis present with manifestations related to mass effect from the gland enlargement and hypothalamo-pituitary dysfunction. The severity of hormone deficiencies may be out of proportion to imaging findings. Radiological findings include homogenous enhancement of the pituitary, diffuse symmetric gland enlargement, midline stalk thickening, and absence of a posterior pituitary bright spot. The diagnosis is established by biopsy and pathological examination. There are no prospective controlled studies on the optimal management of hypophysitis and treatment remains controversial; potential options include surgery (if visual deterioration), glucocorticoids (at variable dosages and duration), immunosuppressive agents and radiotherapy. Spontaneous resolution of pituitary enlargement has been observed in a number of cases and improvement of pituitary hormone deficits may occur after the resolution of hypophysitis.

**Imaging of sellar masses**

Michael Buchfelder
Germany.

To date, magnetic resonance tomography is generally considered the imaging method of choice for its premium resolution of lesions and surrounding anatomic structures. This is mainly due to the improved soft tissue contrast this method offers. Other advantages are the possibility of direct multiplanar imaging in sagittal, coronal, and axial orientations and the avoidance of ionizing radiation. The goal of all imaging studies in this region is to indicate precisely the location, extent, and size of a sella region tumor. These features, along with signal characteristics, frequently not only allow us to determine the presence of a lesion but also indicate the nature of the lesion. For this purpose, its extension in relation to the various surrounding structures, its structure, and its enhancement pattern must be recognized in order to help in differential diagnosis and in treatment planning. A proper set of images is required. A stepwise analysis of the images is suggested. For various types of lesions, typical examples are shown. In this context, monitoring of treatment effects is shown by using repeat imaging with comparable data acquisitions. The common artifacts are discussed as well as enhancement of depiction of minute tumours. Of course, the common features that allow differential diagnosis, are presented.

**Searching for the Cause and Approach in Ectopic Hormone Syndromes**

**S14.1**

**Rare Cushing’s**

Stephen Petersenn
Germany.

Ectopic ACTH syndrome accounts for approximately 20% of all cases of ACTH-dependent Cushing’s syndrome. The most common causes are oat cell carcinomas, bronchiol and foregut carcinoid tumors, pancreatic islet cell tumors and pheochromocytomas. Rarely, ectopic CRH-secretion occurs by peripheral carcinoids. Whereas the screening for hypercortisolism followed by analysis of ACTH is well established, the distinction between pituitary adenomas and ectopic sources in ACTH-dependent Cushing’s syndrome is more challenging. Ectopic tumors producing ACTH with already suppressed pituitary ACTH levels do generally not respond even to high doses of glucocorticoids. Measuring response to CRH or vasopressin may also be useful in the differential diagnosis. Inferior petrosal sinus venous sampling allows definite identification of a pituitary source of ACTH, especially in combination with a CRH-test administered during catheterization. Localization of the source of ectopic ACTH secretion may be especially difficult. In addition to CT, MRI and endoscopic ultrasound, nuclear medicine techniques can help greatly in identifying the source of ectopic ACTH production. Treatment often requires a combination of different approaches, including surgery, medical therapies to control hypercortisolism and/or proliferation, local ablation techniques, and PRRT. As hypercortisolism may cause more clinical problems than the underlying tumor itself, bilateral adrenalectomy is performed in selected cases.

Searching for the cause and approach in ectopic hormone syndromes: rare acromegaly
Françoise Borson-Chazot
France.

Acromegaly secondary to ectopic growth hormone-releasing hormone (GHRH) is rare accounting for less than 1% of cases of acromegaly. Less than 100 cases have been reported in the literature mainly as case reports, except for a nationwide French series of 21 cases. Ectopic acromegaly occurs more frequently in women who represent 2/3 of cases. Median age at diagnosis is 41 years but ranges from adolescence to elderly. GHRH secreting neuroendocrine tumors are usually well differentiated, originating in 90% of cases from pancreas or lung. Pheochromocytomas or paragangliomas have been reported in a small proportion of cases. Positive immunoexpression for GHRH is found in most tumors. Clinical and hormonal features of ectopic acromegaly are very similar to that of somatotropic adenomas and differentiating between both may be challenging. Pituitary may be normal or enlarged at MRI which may be difficult to interpret especially in MEN1 patients where the association of a microprolactinoma to a pancreatic tumor secreting GHRH may be misleading. Pituitary may be localized by conventional imaging or somatostatin receptor scintigraphy. Prognosis is usually favorable, even in metastatic forms which represent 50% of cases. Surgical approach is recommended and, when a complete tumoral resection is feasible, results, in most patients, in long-lasting remission. In such cases, GHRH concentration is normalized and its increase is an accurate indicator of recurrence. In uncured patients, somatostatin analogs control GH secretion but inhibit, only partially, GHRH secretion. MEN1 mutation should be systematically investigated in patients with a pancreatic tumor.

The role of bile in metabolic surgery
Gilles Mithieux
France.

Gastric bypass surgery (GBP) promotes early benefits in energy homeostasis in obese diabetic patients, including decreased hunger and improved glucose control. A suggested mechanism associates a decrease in hepatic glucose production (HGP) with an enhanced intestinal gluconeogenesis (IGN), the latter promoting metabolic benefits in energy homeostasis. In addition, bile acids (BA) have emerged as key metabolic regulators, which might account for several anti-diabetic effects. Moreover, plasma bile acids are elevated after GBP and are known to inhibit gluconeogenesis. Bile diversions mimicking GBP in lean rats (re-insertion of bile in the mid-jejunum or the mid-ileum) promote an increase in plasma bile acids and a marked improvement in glucose control. Bile bioavailability modification is causal since a bile acid sequestrant suppresses the beneficial effects of bile diversions on glucose control. In agreement with the inhibitory role of bile acids on gluconeogenesis, bile diversions promote a blunting in HGP, whereas IGN is increased in the gut segments devoid of bile. In obese rats fed a high fat-high sucrose diet, bile diversions improve glucose control and dramatically decrease food intake. This is due to an acquired disinterest for fatty food, leading the animals to prefer starch-enriched diet. These data suggest a key role of bile and of gluconeogenesis in the favorable outcomes of metabolic surgery.

Clinical consequences of the recent genomics findings in thyroid cancer
Thomas Giordano

Abstract unavailable.
Paragangliomas and pheochromocytomas (PPGL) are neuroendocrine tumors with a very strong genetic component. A germline mutation in one of the different susceptibility genes identified so far explains about 40% of all cases. Genetic testing is recommended in every affected patient and next-generation sequencing (NGS) is the ideal technology to screen the high number of PPGL susceptibility genes (1). The interpretation of genetic variants identified by NGS can be guided by the clinical presentation as well as by the secretory phenotype and by the immunohistochemical analysis of tumors (2). The diagnosis of an inherited form drives clinical management and tumor surveillance of the patient and relatives (1). While whole-exome sequencing studies showed that PPGL is characterized by a low mutation rate of 0.5 mutations per megabase similar to other neural crest-derived tumors, the first integrative genomic analysis of a large collection of 202 PPGL, carried out by the French COMETE network, demonstrated that mutation status in PPGL susceptibility genes is strongly correlated with multi-omics data and revealed the crucial role of predisposing mutations as being the main drivers of PPGL (3). PPGL subtypes can be defined by a set of unique genomic alterations that represent different molecular entities. Transcriptomic studies identified two main molecular pathways, activating either the hypoxic pathway (cluster C1) or the MAPkinase/mTOR signalling (cluster C2). This comprehensive analysis illustrated the functional interdependence between genomic and epigenetic dysregulations. Indeed, DNA methylation profiling uncovered a hypermethylator phenotype specific to the tumors related to a mutation in one of the PPGL susceptibility genes encoding for a protein of the tricarboxylic cycle. Besides, we demonstrated that succinate is acting as an oncometabolite, inhibiting 2-oxoglutarate-dependent dioxygenases, such as HIF prolyl-hydroxylases and histone/DNA demethylases, explaining noreadregenic secretory and metastatic phenotypes of PPGL classified in cluster 1A (4). A recently published novel comprehensive multi-platform analysis of 173 PPGLs led by TCGA has confirmed the COMETE data and identified recurrent fusions genes by RNA sequencing. Altogether those data suggested new therapeutic targets for patients with a metastatic PPGL as well as novel diagnostic and prognostic biomarkers. New ‘omics’-based tests for PPGL are likely to be transferred from research laboratories to clinical practice in order to give the access to a precise molecular classification of every PPGL, after surgery, to practicing clinicians with the goal of establishing a personalized medical management.

Hyperandrogenism: Challenges in Clinical Management

Hyperandrogenic states: pitfalls in diagnostic approach
Michel Pugeat
France.

Measuring total testosterone level is the first line approach to assess androgen excess in women. Most laboratories in Europe use direct testosterone immunoassay without prior extraction. In the near future, liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS) will be commonly used for measuring testosterone, providing the best accuracy with low limit of detection. In all cases, testosterone norms must be standardized for normal premenopausal women values. Where testosterone is twice the upper limit of normal, it is recommended that DHEAS assay be performed. DHEAS is primarily of adrenal origin in women. Thus, a DHEAS level of over 600 μg/dl indicates a diagnosis of androgen-secreting adrenal carcinoma (often associated with hypercorticism). In this case, abdominal scan must be performed rapidly. Where testosterone is just above the normal upper limit, the most likely diagnosis is polycystic ovary syndrome (PCOS). However, screening should be performed for the nonclassic form of 21-hydroxylase deficiency (assay of 17OHP-progesterone) and depending on the clinical setting, Cushing disease must be ruled. Normal testosterone levels in patients with clear clinical symptoms of hyperandrogenism must be interpreted with care. Indeed, T circulates in the blood tightly bound to sex-hormone binding-globulin (SHBG). Low SHBG is typically observed in overweight PCOS patients, in association to inflammatory state and metabolic syndrome, and contributes to lower total testosterone by increasing its clearance from the blood. Therefore, it is recommended, to measure SHBG for correct interpretation of total testosterone by calculating free testosterone index, awaiting direct free-T assay that is still not available. Δ4-Androstenedione (A) has been studied comparatively with testosterone, and dissociations exist, with isolated elevation of A but no elevation of testosterone, particularly in the incident of reduced SHBG. In unusual circumstances, dexamethasone test to suppress androgens arising from a functional adrenal source and gonadotropin-releasing hormone (GnRH) agonist in identifying ovarian androgen secreting tumor and hyperthecosis, could be helpful. All these pitfalls should not discourage endocrinologist to challenge the diagnosis of hyperandrogenic states. Decision trees for evaluating the origin of androgen excess will be suggested and discussed during the session.

DOI: 10.1530/endoabs.49.S18.1
patients with NCAH. Polycystic ovarian morphology is recorded in at least 25% of the patients. The data regarding insulin resistance, diabetes, obesity and abdominal visceral adiposity in NCAH patients is scarce. Chronic androgen excess around puberty may favor abdominal visceral adiposity, insulin resistance and its metabolic consequences. Hyperinsulinemia and insulin insensitivity associated with high androgen levels were reported in untreated newly diagnosed patients with NCAH. Chronic glucocorticoid administration in a limited number of patients may also favor metabolic abnormalities. The frequency of type 2 diabetes was reported to be increased in NCAH patients. It seems that NCAH is associated with increased cardiovascular and metabolic morbidity. Therefore, screening metabolic abnormalities may be required in patients with NCAH.

DOI: 10.1530/endoabs.49.S18.2

Hyperandrogenism is the main characteristic of PCOS therefore hyperandrogenism in women is best addressed when studying this highly prevalent syndrome. Besides the clinical features of oligomenorrhea, hirsutism and infertility, PCOS patients are often insulin resistant (IR), obese, they have arterial hypertension, dyslipidemia, an increased pro-thrombotic state, impaired glucose tolerance or frank type 2 diabetes (T2D). The prevalence of metabolic syndrome is doubled as compared to non-PCOS population. Obesity, particularly of visceral origin, plays a crucial role in both the development and maintenance of PCOS and significantly influences the severity of cardiovascular risk profile. At least 30% of women with PCOS are obese, and in some series, up to 75% are obese. About 50-60% of women with PCOS have central body fat distribution. Metabolic disease in PCOS should be considered as a continuous variable, with metabolic dysfunction worsening with severity of androgen excess. Increasing androgen burden is associated with an adverse metabolic phenotype. Androstenedione (A) has been shown to be in better correlation with IR than testosterone (T) in PCOS women. Recent data suggest that biochemical androgen excess poses a higher risk of liver disease, IR and subclinical atherosclerosis in PCOS compared with those women with anovulation and polycystic ovaries alone. Serum A is a more sensitive indicator of PCOS-related androgen excess than serum total T concentrations. Concurrent measurement of both A and T discovers a PCOS cohort that appears to be at the highest metabolic risk. The analysis of 2543 pre- and perimenopausal women in their 40s originally included in the SWAN study indicated that hyperandrogenemia but not oligomenorrhea was independently associated with the risk of prevalent metabolic syndrome. High prevalence of cardiovascular risk factors in PCOS is assumed to be associated with accelerated cardiovascular disease (CVD). However, clear data from large end point trials about cardiovascular morbidity and mortality in PCOS is currently lacking. Though, there is plenty of data on early occurrence of subclinical, potentially reversible atherosclerosis in women with PCOS. Endothelial dysfunction is associated with higher levels of androgens and with insulin resistance. This was observed even at very early ages, and with a trend of deterioration of endothelial function from lean to overweight and obese PCOS women. Recent systematic review has confirmed that androstenedione intima-media thickness was thicker in women with PCOS in comparison to controls. PCOS women have a greater prevalence and extent of coronary artery calcification, and that is independent of age and BMI.

In the last 20 years, the incidence of thyroid cancer (TC) has more than doubled. Since 50% of the increase is related to papillary microcarcinomas (mPTC, < 1 cm), it appears that an increased detection, due to the wide use of neck ultrasound (US), is the major factor driving this dramatic rise. Autopic and histological studies after thyroidectomy (TX) show that 10 to 30% of adults harbor an undiagnosed mPTC. The disease-specific mortality of patients treated by surgery for mPTC is <1% and loco-regional and distant recurrence rates are 2-6 and 1-2%, respectively. Furthermore, 2 Japanese prospective clinical trials demonstrated a good outcome in more than 1,300 patients with biopsy-proven mPTC who were not submitted to TX. Thus, since only a minority of mPTC progress to a clinically overt disease, it is critical to re-evaluate the current management strategy that indiscriminately recommends thyroid surgery that is, although infrequently, burdened by complications. We retrospectively evaluated clinical data of 293 consecutive patients with mPTC, surgically treated at our Department. After 6 years of follow-up no patient had evidence of structural disease. This prompted us to obtain the approval by the ethical committee of our center for patients an active surveillance instead of immediate surgery, when they had an intrathyroid nodule with a Thy4 or a Thy5 cytology, less than 1.3 cm of diameter, with no evidence at US of extrathyroid extension and cervical lymphnodes suspicious for metastasis. Out of 163 patients who choose active surveillance, 97 (59.5%) did not satisfied the inclusion criteria and 66 (40.5%) were enrolled in the protocol. With a median follow-up of 12 months (6-28) only 3/66 (4.5%) were addressed to surgery for the appearance of neck metastatic lymphnodes or an enlargement of the nodule. 7/66 (10.6%) patients withdrew from the study. In conclusion, the results of prospective studies will provide more precise data to build up a patient tailored approach for the management of mPTC.

When and how should we perform extensive surgery?
Electron Kebebew
USA.

Thyroid cancer is one of the most rapidly increasing cancer diagnoses worldwide. Thyroid cancers exhibit the full range of cancer behavior from the relatively indolent occult papillary thyroid cancer to the uniformly aggressive and lethal undifferentiated thyroid cancers. Surgical resection is the principal treatment for thyroid cancer and there are several important areas of controversy in the surgical management of thyroid cancer. Some of these controversies have arisen due to the increasing incidence of thyroid cancer, the variable biologic behavior of low-risk differentiated thyroid cancer, and because of the improved detection of persistent/recurrent disease. International Surgical and Medical Societies and Association have proposed guidelines to the surgical management of thyroid cancer and the level of evidence for these guidelines will be reviewed. Three critical areas in the surgical management of differentiated thyroid cancer remain controversial: the extent of thyroidecomy for differentiated thyroid cancer, need for prophylactic central neck lymph node dissection in patients with papillary thyroid cancer, and the need for completion thyroidectomy in patients who initially undergo hemithyroidectomy. A clinical, pathologic and molecular based approach to address these three controversial areas in the surgical management of differentiated thyroid cancer will be proposed to personalize surgical management decisions in patients with differentiated thyroid cancer.

Dynamic risk stratification in low-risk vs high-risk patients
Miguel Melo
Portugal.

In recent years, an increasing interest in an individualized approach for the care of patients with differentiated thyroid cancer has occurred. The cornerstone of individualized treatment is the existence of a proper risk stratification system that supports physicians’ options regarding the treatment and follow-up of patients. Considering that the initial risk stratification systems account for only about 15–20% of the variability in the outcome they are trying to predict, it is now well recognized that risk stratification is a dynamic process. The input of clinical, biochemical and imaging data collected during follow-up, notably the response to the initial treatment, can dramatically change risk estimation and significantly improve its accuracy in predicting long-term outcomes. The use of this approach faces different problems in patients with low/intermediate risk and in patients with high risk of recurrence. Regarding the low/intermediate risk group, dynamic risk stratification was based in the assessment of response to an initial treatment that consisted in total thyroidecomy followed by radiodine (RAI) treatment. However, lobectomy is now considered a reasonable approach for some low risk patients and the role of postsurgical RAI in the low/intermediate risk group is currently under debate. As a consequence, there are no well-established thyroglobulin (Tg) cut-off points to define categories (e.g. excellent response, biochemical incomplete response) in patients treated with lobectomy or total thyroidecmy without postsurgical RAI treatment. Nonetheless, different

Induction of pancreatic beta-like cell neogenesis
Patrick Collombat
France.

The recent discovery that genetically-modified α-cells can regenerate and convert into β-like cells in vivo holds great promise for diabetes research. However, to eventually translate these findings to humans, it is crucial to discover compounds with similar activities. Herein, we report the identification of GABA as an inducer of α-to-β-like cell conversion in vivo. This conversion induces α-cell replacement mechanisms through the mobilization of duct-lining precursor cells that adopt an α-cell identity prior to being converted into β-like cells, solely upon sustained GABA exposure. Importantly, these neo-generated β-like cells are functional and can repeatedly reverse chemically-induced diabetes in vivo. Similarly, the treatment of transplanted human islets with GABA results in a loss of α-cells and a concomitant increase in β-like cell counts, suggestive of α-to-β-like cell conversion processes also in humans. This newly discovered GABA-induced α-cell-mediated β-like cell neogenesis could therefore represent an unprecedented hope towards improved therapies for diabetes.

Evidence on reproductive disorders through endocrine disruption in-utero

Jorma Toppari

Finland.

Differentiation of male reproductive system is guided by testicular hormones and growth factors secreted during fetal development under gonadotropin control. Disruption of testicular hormone production or action leads to gonadal dysgenesis and maldevelopment of external genitalia. Cryptorchidism and hypospadias are the most common birth defects in boys, and both conditions can arise as a consequence of anti-androgenic disturbance during development. Both of them are also associated with poor semen quality and testicular cancer, suggestion similar pathogenetic pathways. Animal experiments show robust evidence that inhibition of androgen synthesis or action causes abnormalities in testicular and genital development. Chemicals with different mechanisms of action towards declined androgen activity work in an additive fashion. Therefore even small amounts of anti-androgens can add a critical dose to the total anti-androgenic load. While this is well documented in experimental animals, there is limited evidence on human harm. This is due to challenges in epidemiology to demonstrate causal relationships, albeit there are many examples of associations of chemical exposures with reproductive disorders.

Approach for clinicians

Maria-Luisa Brandi

Italy.

Rare skeletal metabolic diseases comprise a group of diseases commonly associated with severe clinical consequences. In recent years, the description of the clinical phenotypes and radiographic features of several genetic bone disorders was paralleled by the discovery of key molecular pathways involved in the regulation of bone and mineral metabolism. Including this information in the description and classification of rare skeletal diseases may improve the recognition and management of affected patients. In a recent effort to recognize the rare skeletal diseases based on their metabolic pathogenesis 116 OMIM phenotypes with 86 affected genes related to bone and mineral homeostasis were recognized. The diseases were divided into four major groups, namely, disorders due to altered osteoclast, osteoblast, or osteocyte activity; disorders due to altered bone matrix proteins; disorders due to altered bone micro-environmental regulators; and disorders due to deranged calcitropic hormonal activity. This publication provides the first comprehensive taxonomy of rare metabolic skeletal diseases based on deranged metabolic activity. This classification will help in the development of common and shared diagnostic and therapeutic pathways for these patients and also in the creation of international registries of rare skeletal diseases, the first step for the development of genetic tests based on next generation sequencing and for performing interventional studies to assess efficacy of orphan drugs. For their metabolic nature, the interest of endocrinologists towards this disorders is very high. The clinical management of these diseases from a metabolic point of view will be illustrated during the presentation.

Euthyroid: towards a euthyroid Europe

Henry Volzke

Germany.

Despite the fact that iodine deficiency (ID) can easily be prevented by iodine fortification of table salt, industrial salt and cattle food, Europe belongs to the worst regions in terms of access to iodized salt and is seriously iodine deficient, resulting in the perpetuation of the single most important, preventable cause of brain damage. Up to an estimated 360 million European citizens are exposed to ID, which is not only due to variable iodine provision, it is also rooted in significant heterogeneity of prevention and monitoring activities, leading to inappropriate interventions, health inequalities and increased disease burden with substantial impact on health-care costs. A major concern remains the large number of pregnant women exposed to ID, which results in a measurable decrease in cognitive potential of their children. The effects of ID in total cause significant, preventable costs in health-care systems of affected regions. More than 30 countries contribute to the EUthyroid consortium, which is funded by the EC Horizon2020 programme. The overall aims of EUthyroid are to evaluate ID prevention programmes in European countries, to initiate capacity building for integrated activities in Europe. Coordinated measures at national and EU level are a long-term goal, which will be worked towards by targeted communication activities of project results. EUthyroid has established a meta-platform for collaborative data collection and use. National and regional registry data are collected to gain an overview over prevalent and incident thyroid diseases and treatments in European nations. In parallel, EUthyroid improves the data quality of ID monitoring studies by providing infrastructures for training and standardization of interviews, laboratory measurements and thyroid ultrasound. All data will be used to provide a European map of iodine status and subclinical disorders and to relate the iodine status of populations to thyroid-related outcomes for the evaluation of ID prevention programmes. In addition, thyroglobulin, a novel and promising biomarker for the iodine status will be evaluated using biomaterials collected in ID monitoring studies and three mother-child cohorts from regions with different iodine status. The latter cohorts will investigate the important association between the iodine status in pregnant women and the neurocognitive function in their children. Combining findings from all studies, health-economic analyses will be conducted to investigate benefits and harms as well as cost-effectiveness of IDD prevention. Potential barriers against harmonized IDD prevention and monitoring programmes will be explored by collecting information from national and European ministries.

Fibrous dysplasia of bone/McCune-Albright syndrome

Roland Chapurlat

France.

Fibrous dysplasia of bone/McCune-Albright syndrome (FD/MAS) is due to a somatic activating GNAS mutation. Patients may be asymptomatic in monostotic forms, which represent two thirds of cases. In those forms, the diagnosis is often incidental. But these monostotic FD may also be revealed by bone pain, bone deformity or fracture. The diagnosis is generally made in childhood or in young adults. Polyostotic FD is often more severe, with a higher incidence of fragility fracture. It is also commonly associated with renal phosphate wasting. About 5% of patients with FD also suffer from endocrine complications, including precocious peripheral puberty, growth hormone excess and hyperthyroidism. These endocrine conditions have to be treated as early as possible. For example, the precocious puberty generally responds well to an aromatase inhibitor, letrozole. Bisphosphonates have been used to treat bone pain and reduce bone turnover for more than two decades with satisfactory outcomes in most patients. This treatment can often be tapered after 2–3 years. Preventive surgery is often advised in children to avoid fracture and deformity of lower limbs. This kind of approach is also warranted in adults. A multidisciplinary management is necessary, involving specialists of bone diseases, endocrinologists, orthopedic surgeons, and sometimes cranio-facial surgeons along with neurosurgeons, both in children and adults. New therapies e.g., denosumab and tocilizumab are currently being studied to improve bone pain in those patients who do not adequately respond to bisphosphonates. An international collaboration is currently developing a framework that would be applicable around the world to improve the care of this rare disease, in particular to avoid delays in treatment.

Prolactin regulation of prostate stem cells: potential implications in prostate cancer
Vincent Godin
France.

Prostate stem cells have been proposed to participate in prostate cancer initiation. Furthermore, based on their androgen-independence, they are suspected to trigger prostate cancer recurrence when the tumor is no longer responsive to anti-androgens. Therefore better understanding the regulation of this particular cell pool may have important therapeutic relevance. In the human prostate, expression of prolactin (PRL) and activation of its major downstream signaling effector Stat5, have been correlated to prostate cancer progression and relapse. To understand these effects, we use the probasin (Pb)-PRL transgenic mouse model which involves prostate-specific expression of PRL. Pb-PRL mice recapitulate many pre-neoplastic features of the human prostate including focal areas of epithelial dysplasia, prostate intra-epithelial neoplasia and moderate inflammation (‘reactive stroma’), together with hypertrophy and ductal dilatation of all prostate lobes. Using various cell lineage-specific markers coupled to immunohistochemistry and cell sorting (FACS), we showed some years ago that the p63+/basal/stem cell compartment (which contains ‘tumor-initiating’ cells) was highly enriched in Pb-PRL prostate tumors (Rouet et al, PNAS 2010). Subsequent studies revealed enrichment of another cell population that we discovered and named ‘LSCmed’ based on its FACS profile (Sackmann Sala et al, Am. J. Pathol 2014). LSCmed are luminal progenitors that exhibit stem-like properties in vitro (prostasphere assay, gland formation in transplantation assays) and importantly, resistance to androgen deprivation in vivo. Transcriptomic profiling showed that LSCmed is a distinct cell entity that differs from the well-known basal and luminal cell populations and that can be identified using a specific gene expression signature. LSCmed are rare in the normal prostate and their amplification in Pb-PRL prostate tumors more likely results from paracrine signals downstream of PRLR/Stat5 signaling than from a direct PRL effect. Strikingly LSCmed represent the major cell component of aggressive, castration-resistant prostate tumors driven by Pten loss, both before and after castration. This is particularly relevant since loss of PTEN is frequently observed in the human prostate oncogene. In summary, LSCmed represent a newly-identified prostatic cell population that is a strong candidate for mediating cell resistance to androgen-deprivation therapy. Ongoing studies aim to elucidate the mechanisms that regulate these luminal progenitors and to identify LSCmed(-like) cells in the human prostate.

Is GH a cancer growth factor?
Silomo Melmed
USA.

Acromegaly is associated with increased soft tissue neoplasms, while GH deficient patients are protected from cancer development. Both environmental and age-related signals lead to cellular senescence and cell cycle dysregulation. We have shown that DNA damage-induced cellular senescence increases GH by inducing p53. GH, in turn, suppresses tumor suppressor proteins in both pituitary and nonpituitary cells. These observations led us to propose that intracelular epithelial GH in the mucosal microenvironment may enable neoplastic growth. Mechanisms underlying pro-neoplastic GH actions include: knockdown or suppressing either GH or GHR mRNA induces p53; GH suppresses p53 by inhibiting PTEN, a p53 acylatyor, which protects p53 from ubiquitination, and up-regulates TRIM29, which also destabilizes p53. Thus, p53 ubiquitination and altered acetylation underlie suppression of p53 mediated by GH. GH also induces mTOR, EMT transcription factors and enhanced cell motility. In vivo epithelial p53 is markedly induced in GH-deficient Prop1−/−, and in GH receptor deficient GHR−/− mice, and in mutant GH receptor (Laron syndrome) fibroblasts. In mutant-treated mice with DNA damage, GH is induced in colon epithelial cells. Doubly mutant Prop1−/− (GH-deficient) and Apcmin+/− (develop intestinal tumors) mice exhibit high colon p53 and markedly decreased intestinal tumor number and size compared to single mutant APC min+/− mice GHR blockade induced by pegvisomant treatment of acromegaly patients leads to increased colon mucosal p53 and its transcriptional target p21. Overexpressing intracellular GH, or re-introducing WT GHR to mutant human fibroblasts, suppresses p53 thereby evading cellular senescence.

Obesity: Pharmacological Solutions

S24.1

MSH analogs
Peter Kühn
Germany.

The leptin-melanocortin signaling pathway plays a pivotal role in the regulation of body weight under the hypothalamus. Leptin, secreted by the adipose tissue, activates the leptin receptor at the arcuate nucleus, which in turn leads to the production of proopiomelanocortin (POMC) derived peptides as melanocorty stimulating hormone (MSH). MSH activates the melanocortin 4 receptor (MC4R), regulating thereby satiety and energy expenditure. Mutations within this pathway are leading to severe early onset obesity based on severe hyperphagia. After the discovery of MSH, different approaches have been made to generate MC4R agonists. Unfortunately, most of the studies were not successful either due to ineffectiveness of the drug to reduce body-weight or due to severe side-effects as e.g. increased blood pressure. However, recently the development of new MC4R agonists as setmelanotide (RM-493), which is leading to severe weight loss in POMC deficient patients, has open new perspectives for the treatment of monogenic obesity forms. Future studies will elucidate whether this new compounds will be of advantage and a new treatment option for obesity in these rare diseases.

The future drugs to come
Gema Frühbeck
Spain.

A complex interaction between environmental and genetic/epigenetic factors is driving the escalating obesity and diabetes epidemics together with a multitude of associated comorbidities. In the past decades the role of gastrointestinal signals in energy homeostasis and glucose control has made tangible progress mainly due to the findings derived from bariatric/metabolic surgery. In particular, incretin-based approaches in relation with glucagon-like peptide 1 and amylin have fostered the emergence of new treatment avenues. Interestingly, one of the most challenging obstacles in obesity treatment is maintaining a lower body weight after weight loss. It can be argued that weight loss and its maintenance may be uncoupled...
biological processes that require different pharmacological approaches. Thus, the reduction in metabolic rate triggered by a high calorie-restriction-induced weight loss, contributes to powerful counter-regulatory ‘homeostatic’ mechanisms leading to weight regain. Therefore, innovative strategies aimed at effectively minimizing these compensatory adaptations with combinations of drugs (comps) using different mechanisms of action may prove useful. Consequently, targeting of food hedonics in combination with the archetypical anorectic and thermogenic pathways will probably provide unparalleled pharmacological efficacy to combat obesity and prevent weight regain. Glucagon has reemerged in weight loss polypharmacy relevantly complementing thermogenic agents. Fibroblast growth factors (FGFs) are undoubtedly among a plethora of newly identified metabolic macromolecules. Evidence that brown adipose tissue exists in adult humans and is activated after cold exposure has opened the interest in the potential browning of adipose tissue and the quantitative contribution of BAT induction/activation towards energy expenditure in obesity. Novel insights that facilitate the design of refined polypharmacy that relevantly targets food hedonics at the same time as stimulates energy expenditure without severe off-target effects that are currently frequently linked to behavioral pharmacology are being pursued.

HPA axis, insulin resistance and adipocytokines in the fetal-maternal unit

George Mastorakos

Greece.

‘Stress’ is defined as a state of disharmony or threatened homeostasis. Pregnancy is a transient period of relative hypercortisolism. Chronic or acute stressors influence maternal and fetal Hypothalamus-Pituitary-Adrenal Axes (HPA) during pregnancy. Insulin sensitivity is a feature of normal pregnancy, possibly reflecting an adaptive phenomenon aiming at diverting maternal glucose towards fetal needs. We investigated the effect of maternal stress into maternal insulin sensitivity during pregnancy by employing state-trait anxiety inventory (STAI) trait and state questionnaires for stress assessment and we found that in normal pregnant women, enhanced long-term stress is associated with decreased insulin sensitivity. Both long- and short-term stress are associated with enhanced maternal HPA axis and increased placental CRH secretion. Furthermore the decrease in insulin sensitivity during pregnancy is paralleled by the progressive increase of maternal adipose tissue deposition. Throughout pregnancy maternal adipose tissue is metabolically active, producing adipocytokines involved in the process of insulin resistance. Visfatin concentrations in the 1st trimester positively predict insulin sensitivity during the 2nd trimester. Body fat mass during 1st trimester of pregnancy is negatively associated with insulin sensitivity during the 2nd trimester and should be kept under control. Furthermore, first trimester maternal BMI and serum visfatin seem to be strongly associated with fetal insulin secretion and final birth weight, respectively, suggesting a role of early-pregnancy maternal adipose tissue in the pregnancy metabolic environment. Interestingly, during pregnancy, maternal GLP1 might be involved in mechanisms that compensate for the pregnancy-related increase in glycemia and insulin resistance, suggesting a role of this peptide in maternal metabolism and weight and fetal growth. In conclusion, both maternal adipose tissue and stress-induced HPA activation influence directly and/or indirectly the development of insulin resistance during pregnancy.

HPA axis regulation during a woman’s life: impact on metabolic outcomes

Svetozar Damjanovic

Serbia.

Aging in both men and women is linked with a decline in diurnal variations in cortisol secretion. Cortisol secretion is increased during circadian nadir and possibly in total through the day. Reduced suppressibility of cortisol after dexamethasone (DEX) administration and increased ACTH secretion with aging are well documented. It appears that aging associates with the decrease in cortisol negative feedback efficacy on HPA axis due to underexpression of mineralocorticoid receptors (MRs) and imbalance of MRs to glucocorticoid receptors (GRs) in hippocampus (HC). Chronically elevated glucocorticoids (GCs) in mice, but not in the other species, lead to neuronal cell loss in the HC. In contrast to these results, an age-related decline in peripheral cortisol values from 30 to 60 years of age within the obese subjects has been observed. This may be explained by emotional eating which reduce HPA axis activity by CRF suppression. No such correlation was found in healthy individuals with normal body-mass-index (BMI). It seems that ‘healthy’ aging does not lead to enhanced HPA axis activity and peripheral cortisol levels rather decline with aging. Parental regulation of hippocampal GR expression as well as the priming effect of high GC concentrations on the future responses to stressors imprint life history through epigenetic changes within HC. Additionally, men and women tend to react differently with stress—both psychologically and biologically. Clinical significance of reduced adrenal androgen production (DHEA and DHEAS) with aging is not well established. Aldosterone secretion appears to be slightly reduced in elderly whereas sympathetic tone varies from organ to organ. Altogether aging associated changes in HPA activity only in a part depends on genetic background. Individual differences in stress reactivity might be important risk factor for gender-specific health problems in men and women.

11β-hydroxysteroid dehydrogenase activity, androgen excess, and metabolic outcomes in women

Jeremy Tomlinson

UK.

Steroid hormones have potent metabolic effects. Glucocorticoid excess is characterized by central adiposity, insulin resistance, type 2 diabetes and increased cardiovascular risk. Whilst endogenous glucocorticoid excess is rare, local tissue-specific availability of glucocorticoid is controlled by a series of enzymes that are, at a pre-receptor level, able to regulate cortisol’s ability to bind and activate the glucocorticoid receptor. 11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) converts inactive cortisone to active cortisol, and therefore amplifies local glucocorticoid action. It is highly expressed in key metabolic target tissues including liver, fat and muscle and is dysregulated in metabolic disease including polycystic ovarian syndrome. It has been a target for therapeutic intervention and selective 11β-HSD1 inhibitors provide modest metabolic improvements in patients with type 2 diabetes. In parallel, 4α-reductases, (5α- and 5β-reductase), inactivate glucocorticoids, but importantly, the isoforms of 5α-reductase convert testosterone to the more potent androgen, dihydrotestosterone. 5α-reductase activity is increased in patients with PCOS and may contribute significantly to the androgen excess observed in these patients and fuel their adverse metabolic phenotype. In addition, adipose tissue is able to generate androgens through the activity of 17β-hydroxysteroid dehydrogenase type 5 (AKR1C3), and activity and expression are increased in patients with obesity and PCOS. In *in vitro* data suggest that AKR1C3 may drive lipid accumulation locally within adipocytes through enhanced androgen generation. In conclusion, pre-receptor steroid hormone metabolism has a powerful role to play in the regulation of metabolic phenotype in patients with PCOS and offers significant potential as a target for therapeutic intervention.

DOI: 10.1530/endoabs.49.S25.3
Tissue Specific Defects in Thyroid Hormone Action:

**S26.1**

Mouse models to study tissue specific hypothyroidism

Heike Heuer

Germany.

Thyroid hormone (TH) actions and metabolism are intracellular events that require the transport of TH across the plasma membrane in target cells. Consequently, impaired uptake of TH can lead to tissue-specific TH deprivation independent of the TH concentrations in the circulation. A prominent example for such a scenario represents the Allan-Herndon-Dudley syndrome (AHDS). This syndrome is caused by inactivating mutations in the X-linked Slc16a2 gene encoding the monocarboxylate transporter MCT8, a highly specific TH transporter widely expressed in CNS and peripheral tissues. Patients with inactive MCT8 display severe neurological symptoms and signs of brain hypothyroidism despite highly elevated serum T3 concentrations. Likewise, Mct8 ko mice exhibit abnormal TH serum values together with complex tissue-specific changes in the TH status ranging from hypothyroidism (brain, pituitary) to hyperthyroidism (liver, kidney, skeletal muscle). In order to define the tissue-specific function of Mct8 we recently started to generate mouse mutants that lack Mct8 in defined cell types only. In my presentation, I will report on our studies demonstrating pronounced cell-specific alterations in the TH status upon deletion of Mct8 at the blood-brain barrier (BBB), in hypothalamic tanycytes as well as in thyrocytes while absence of Mct8 in forebrain neurons or hepatocytes did not compromise proper tissue-specific TH action. Overall, our data clearly underscore the importance of Mct8 and other TH transporters in mediating TH transport thereby influencing tissue-specific TH homeostasis.

**S26.2**

Syndromes of decreased sensitivity to thyroid hormone

Nadia Schoenmakers

UK.

Disorders of thyroid hormone action are classified broadly, to encompass conditions with defective cellular uptake, metabolism or nuclear action of thyroid hormones. Genomic thyroid hormone action is mediated via receptor subtypes (TRalpha, TRbeta) with differing tissue distributions. TRbeta-mediated Resistance to Thyroid Hormone (RTH) is characterised by elevated thyroid hormones, raised metabolic rate and cardiac hyperthyroidism but hepatic resistance (dyslipidaemia, steatosis). In contrast, TRalpha1-mediated RTH patients exhibit growth retardation, skeletal dysplasia and constipation together with reduced metabolic rate and cardiac hypothyroidism, with near-normal thyroid hormone levels. The contrasting phenotypes of TRalpha1 and beta-mediated RTH exemplify the differing importance of receptor subtypes in tissues, providing a rational basis for receptor-specific drug development. Mutations in SECISBP2 and TRU/-TCA1-1 cause a multisystem disorder of defective selenoprotein synthesis, with features attributable both to tissue-specific selenoprotein deficiencies (e.g. male infertility, muscular dystrophy) and raised cellular reactive oxygen species due to lack of antioxidant selenoenzymes (e.g. photosensitivity, increased adipose mass and function). Additionally, patients have a characteristic biochemical signature resulting from impaired conversion of T4 to T3 via selenium-containing deiodinases. This presentation will describe clinical features of these conditions, which increase our understanding of thyroid hormone action and inform potential future therapeutic developments.

Restoring TH action in patients with transporter defects: the triac trial

Stefan Groeneweg

The Netherlands.

Mutations in the thyroid hormone (TH) transporter MCT8 result in the Allan–Herndon–Dudley syndrome (AHDS), which is characterized by severe intellectual and motor disability and high serum T3 levels inducing thyrotoxicity in peripheral organs. At present, no effective treatment is available. Preclinical studies suggest that the T3 analogue Triac is a promising candidate to i) normalize serum T3 levels and thus alleviate the thyrotoxicosis and ii) restore TH signaling in the brain.

Methods

We conduct a world-wide prospective interventional trial in which about 45 AHDS patients receive 1 year Triac treatment. The primary end-point is the reduction of serum T3 levels, and secondary end-points include normalization of heart rate (HR), improvement of body weight (BW) and serum parameters that reflect TH action in peripheral tissues. Neuro(psycho)logical functioning is assessed before and after 1 year of Triac treatment.

Results

Currently, 41 patients (age: 1–66 years) have been enrolled (median (IQR) follow-up time: 8 (3–12) months) of whom 18 have completed 1 year of follow-up. Triac treatment effectively suppressed serum TSH levels (2.3 (1.6–3.9) to 0.9 (0.2–1.9) mIU/l; P < 0.001), resulting in a strong reduction of T3 levels (5.0 (3.9–6.5) to 1.7 (1.4–2.2) nmol/l; P < 0.001). Importantly, BMI, serum HDL cholesterol, creatinine and CK levels significantly increased, whereas basal heart rate and serum SHBG levels significantly decreased.

Discussion

Triac treatment effectively normalizes serum T3 levels. This interim analysis suggests that Triac treatment has beneficial effects on the peripheral phenotype of AHDS, which will be further substantiated upon completion of the follow-up period by the other participants.

Vitamin D Beyond Bone (Endorsed by Endocrine Connections)

**S27.1**

Heart & Vessels

Klaus Witte

UK.

Vitamin D is a recognised important factor in bone health but in recent years is receiving much attention for its role in multiple other systems. The enthusiasm with which it is embraced as an elixir vitae especially in cancer, cardiovascular disease and neurodegenerative diseases is overwhelming and matched only by the skepticism from other quarters, since solid evidence is largely lacking. I will review the pleiotropic effects of vitamin D and how they may be of relevance to the specific syndrome represented by chronic heart failure and the evidence generated to date by, amongst others, the VINDICATE program at Leeds.

DOI: 10.1530/endoabs.49.S27.1

**S27.2**

Fertility

Elisabeth Lerchbaum

Austria.

Accumulating evidence from animal and human studies suggests that vitamin D is involved in many functions of the reproductive system in both genders. In women, vitamin D status has been associated with in vitro fertilization (IVF) outcome, features of polycystic ovarian syndrome (PCOS), endometriosis, and sex hormone steroidogenesis. In detail, cross-sectional data suggest a regulatory role of vitamin D in PCOS-related aspects such as ovulatory dysfunction, insulin resistance as well as hyperandrogenism. Moreover, results from randomized controlled trials (RCTs) suggest that vitamin D supplementation may be beneficial for follicular development and menstrual cycle regulation in PCOS women. Although several data converge towards a beneficial effect of vitamin D supplementation in metabolic disturbances in women with PCOS, this remains to be demonstrated in high-quality RCTs. Regarding assisted reproductive techniques, recent studies suggest that vitamin D supplementation might be beneficial for couples undergoing IVF. In men, vitamin D status has been associated with semen quality and sperm count, motility and morphology as well as with androgen levels in both fertile and infertile men. Further, there is evidence for a favourable effect of vitamin D supplementation on semen quality, fertility outcomes as well as on testosterone concentrations. In summary, vitamin D deficiency may be a risk factor for adverse fertility outcomes, there is, however, insufficient evidence to establish causality. High quality RCTs are needed to further evaluate the effects of vitamin D supplementation on fertility and sex hormone steroidogenesis in women as well as in men.

**Muscles**  
Roger Bouillon  
Belgium.

The vitamin D endocrine system (D-endo) is essential for calcium and bone homeostasis. The vitamin D receptor, VDR, is ubiquitously expressed and about 3% of the mouse or human genome is regulated by D-endo. VDR knock-out mice show impaired striated muscle maturation and selective VDR deficiency in heart muscle cause cardio-myopathy. Muscle weakness may be severe in patients with severe chronic renal failure combined with vitamin D deficiency or in subjects with congenital CYP27B1 deficiency. Muscle strength and function may be impaired in elderly vitamin D deficient elderly subjects and result in increased risks of falls. The final proof of causality is hotly debated but meta-analyses of supplementation studies suggest a modest reduction in falls in elderly subjects with severe vitamin D deficiency. All cells of the immune system express VDR. A large number of immune-related genes are coherently controlled by 1,25(OH)2D. The native immune system is stimulated by 1,25(OH)2D. A low vitamin D status is associated with an increased risk for all types of infections. Human intervention studies however are equivocal. The acquired immune system is suppressed by vitamin D deficiency which gives this hormone the title of social hormone. First it became clear that it was responsible for the strong bonds between mother and child but in the recent years it was investigated in relation to other types of pair bonding, the development of monogamous relations, and even the relation between different species (like between humans and dogs). Its role in sexual orgasm was also recognized. Its secretion can be influenced by a hug or a simple conversation when feelings of trust are present. Indeed, Oxytocin could be responsible for social behaviour as it facilitates the development of trust and empathy between individuals, strengthening relationships. This neuropeptide seems to facilitate security in human relations thus being supportive of positive social interactions. For all of these discoveries it became known as the love hormone. However other roles have also been attributed to Oxytocin: decreasing levels of stress, fear and pain, and also a sort of selective influence on memory (allowing the individual to keep some memories while eliminating others). The therapeutically potential of oxytocin has already started to be studied in diseases like autism spectrum disorder, schizophrenia and depression. Lab tools like measurements of oxytocin in plasma, brain imaging (f-MRI/SPET) and genetic/epigenetic assays bring new opportunities to explore the oxytocin pathway and will continue to help us to understand how to live a healthy life in a love ambience.

**Kisspeptin and neurokinin B – novel reproductive hormones with therapeutic potential**  
Waljit Dhillo  
UK.

Kisspeptin and neurokinin B are 2 novel key hypothalamic hormones which are vital in normal reproductive function. Inactivating mutations for the gene or the receptor for either of these peptides will cause a failure of puberty due to hypogonadotrophic hypogonadism. In this talk I will present evidence to suggest that kisspeptin is important in sexual and emotional processing in humans (1). In addition I will present evidence which suggests that NK3R (the receptor for NKB in humans) is important as a mediator of menopausal flushing and this has potentially practice changing therapeutic potential (2).

**Sleep, Love and Reproduction (Endorsed by Endocrine Connections)**

S28.1  
**Candidate mechanisms underlying the association between poor sleep and obesity**  
Christian Benedict  
Sweden.

An increasing proportion of people living in our 24/7 culture complain about insomnia symptoms, i.e., they experience problems to fall and/or stay asleep. As demonstrated by epidemiological studies, chronic sleep loss is correlated with weight gain. To investigate whether sleep loss would alter energy metabolism in favour of weight gain, my lab therefore performed a series of sleep loss experiments in metabolically healthy normal-weight subjects. These studies demonstrated that acute sleep loss alters circulating levels of appetite-modulatory metabolites (e.g. higher levels of the hunger-promoting hormone ghrelin), impairs the ability to control food impulses, and increases metabolic efficiency. In the setting of chronically insufficient sleep, such behavioral and metabolic effects may predispose normal-weight individuals to gain weight.

**Oxytocin: from biology to love**  
Susana Guerreiro  
Portugal.

Oxytocin was discovered by Henry Dale in 1906 and synthesized in the early 50’s by Vincent du Vigneaud and coworkers. It is secreted by axonal terminals in the hypothalamic paraventricular nucleus of the hypothalamus. This hormone similarly to others is secreted in a pulsatile way and, classically, in relation to labor (uterine contractility), lactation and to the maternal behaviour. After the initial identification of its role in labor induction and lactation it became clear that Oxytocin plays other very important roles in human life namely in the creation of bonds which gave this hormone the title of social hormone. First it became clear that it was responsible for the strong bonds between mother and child but in the recent years it was investigated in relation to other types of pair bonding, the development of monogamous relations, and even the relation between different species (like between humans and dogs). Its role in sexual orgasm was also recognized. Its secretion can be influenced by a hug or a simple conversation when feelings of trust are present. Indeed, Oxytocin could be responsible for social behaviour as it facilitates the development of trust and empathy between individuals, strengthening relationships. This neuropeptide seems to facilitate security in human relations thus being supportive of positive social interactions. For all of these discoveries it became known as the love hormone. However other roles have also been attributed to Oxytocin: decreasing levels of stress, fear and pain, and also a sort of selective influence on memory (allowing the individual to keep some memories while eliminating others). The therapeutically potential of oxytocin has already started to be studied in diseases like autism spectrum disorder, schizophrenia and depression. Lab tools like measurements of oxytocin in plasma, brain imaging (f-MRI/SPET) and genetic/epigenetic assays bring new opportunities to explore the oxytocin pathway and will continue to help us to understand how to live a healthy life in a love ambience.

**Novel Predictors of Diabetes**

S29.1  
**Novel predictors of type 1 diabetes**  
Mikael Knip  
Finland.

Inlet autoantibodies are strong predictors of type 1 diabetes (T1D), as positivity for multiple, i.e. is two or more, autoantibodies is associated with a risk of around 70% of progression to clinical disease over the next 10 years. Autoantibodies do not, however, predict when T1D will present clinically. We have assessed the utility of signs of dysglycemia for the prediction of the time of disease manifestation and observed that an increase in HbA1c of 10% over 3–12 months provides a 50% likelihood of disease presentation within 1.1 year after the observed increase. When the HbA1c value was 5.9% (41 mmol/mol) in two consecutive samples, the median time to diagnosis was 0.9 years. The median time to diagnosis after the detection of impaired glucose tolerance on OGTT was 0.7 years. After the detection of an increased random plasma glucose (≥ 7.8 mmol/l) the median time to diagnosis was 1.0 years. The omics technologies have raised the issue, whether there is a possibility to identify high risk individuals before the appearance of the first autoantibodies. We have looked at markers generated by transcriptomics. We observed that genes and pathways related to innate immunity functions, such as the type 1 interferon (IFN) response, were active, and IFN response factors were identified as central mediators of the IFN-related transcriptional changes. In a proteomics study we found that when including the total observation time from birth to diagnosis we were able to classify the participants into disease progressors and non-progressors.
with a success rate of 91%. The classification was based on the combination of the relative levels of APOC4 (decreased) and afamin (AFAM, increased). Lipidomics and metabolomics analyses showed that individuals who developed T1D had reduced serum levels of succinic acid and phosphatidylcholine (PC) at birth, reduced levels of triglycerides and antioxidant ether phospholipids throughout the follow up, and increased levels of proinflammatory lysophosphatidylcholine (LPC) several months before seroconversion to autoantibody positivity. The appearance of insulin and glutamic acid decarboxylase autoantibodies was preceded by diminished ketone urine and elevated glutamic acid. Another study focusing on the lipidome/metabolome in cord blood revealed that those children, who progressed quickly to clinical T1D, were characterized by a distinct cord blood lipidomic profile that includes reduced major choline containing phospholipids, including sphingomyelins and phosphatidylcholines. Risk children, who progress to clinical T1D are characterized by a decreased microbial diversity, an increased abundance of potentially pathogenic bacteria and a reduced functional gene content in their intestinal microbiome. These changes, can however, not be seen before seroconversion to autoantibody positivity. To summarize, metabolic markers help in the estimation of time to diagnosis in prediabetic individuals. The potential predictive markers generated by omics technologies have to be validated.

Clinical and genetic indicators for diabetes prediction
Valeriya Lyssenko
Denmark.

Worldwide diabetes epidemic leads to exponential increase in incidence and prevalence of associated co-morbidities and mortality. During the last 10 years we have devoted to investigate how clinical and genetic biomarkers can be used to facilitate prediction of these life-threatening hazards. Accumulating evidence from our large prospective studies indicate that decline in insulin secretion adjusted for the degree of insulin sensitivity is the key factor contributing to overt type 2 diabetes. Furthermore, genetic data indicate that risk alleles in genetic loci for type 2 diabetes influenced changes in pancreatic beta-cell function over time, while having no effect on changes in body mass index. Presently, genetic information has insufficient power to predict common type 2 diabetes. However, our follow-up studies on variants in TCF7L2, MTRNR1B, GIPR, GRB10 genes unravelled multiple and pleiotropic mechanisms of genetic loci which significantly contributed to our understanding of pathogenesis of type 2 diabetes including effects on insulin-incretin axis (GIP/GLP-1 and glucagon) and hepatic glucose production in the liver. We and others have also reported α-hydroxybutyrate, linolesoy glycerophosphocholine, and copetin as novel biomarkers to be associated with increased risk of type 2 diabetes. However, these new biomarkers require a systematic evaluation and validation across different studies and populations before their actual diagnostic and prognostic value is confirmed.

Moving Away from Old-fashioned Steroidogenesis: What Are the Clinical Implications?

S30.1
Clinical relevance of alternative synthesis of androgens
Hans Hofland
The Netherlands.

Recent years have seen many exciting developments in the field of steroidogenesis. These include improved diagnostics through mass spectrometry, novel clinical relevance attributed to steroids previously deemed irrelevant and successful implementation of new anti-cancer treatments. Prostate cancer is a prime example of the latter with the recent confirmation that castration-resistant disease is still androgen-dependent and susceptible to hormonal manipulation with next generation steroidalgenic enzyme inhibitors and anti-androgens. In advanced stages of prostate cancer hormonal treatment leads to complex and incompletely understood changes in circulating steroid hormones levels. CYP17 inhibitors like abiraterone acetate lead to accumulation of mineralocorticoid precursors and pregnosterone metabolites. This ensues a steroid flux into the alternative pathway to 5α-dihydrotestosterone (DHT) with intermediates such as allopregnanolone and androstanediol. Our data in parental and abiraterone-resistant prostate cancer cells show a functional block at the level of CYP17 in prostate cancer cells, preventing de novo steroid synthesis and local activation of CYP17 precursors. However, accumulation of other steroid hormones intratumorally could affect nuclear receptor activation. Concurrently, interaction with supplemented glucocorticoids leads to a complex interaction between wild type, mutant and splice variants of nuclear receptors and DNA regulatory elements. Further research into pre-receptor regulation of steroid hormones combined with innovative genome-wide receptor-DNA binding analyses will pave the way towards comprehensive understanding of their effects. In turn, this could secure efficient targeting of the detrimental sequelae of steroid hormones in prostate cancer and other endocrine diseases.

S30.2
Clinical relevance of steroid precursors in adrenocortical tumors
Vasileios Chortis

Adrenal incidentalomas represent an increasingly common diagnostic problem facing clinical Endocrinologists. Swift and accurate differentiation of benign from malignant disease is essential, but the diagnostic performance of current imaging modalities is sub-optimal and often leads to ill-advised management decisions. Urinary steroid profiling by modern mass spectrometry-based techniques can provide a comprehensive profile of steroidogenesis, quantifying both precursor molecules and end products. Adrenocortical carcinomas display a premature pattern of steroidogenesis, dominated by precursor hormone synthesis, which can be captured in the urinary profile. Emerging evidence highlights the unique diagnostic opportunities presented by this feature. The combination of high-sensitivity biochemical analysis and computational data processing is expected to transform the management of adrenal tumours, from the diagnostics of adrenal incidentalomas to the post-operative surveillance of adrenocortical carcinomas.

Glucocorticoid production in primary aldosteronism – from mechanisms to clinical implications
Felix Beuschlein
Germany.

Adrenal aldosterone excess is the most common cause of secondary hypertension and is associated with increased cardiovascular morbidity and mortality. However, adverse metabolic risk in primary aldosteronism extends beyond hypertension, with increased rates of insulin resistance, type 2 diabetes, and osteoporosis, which cannot be easily explained by aldosterone excess but would rather be associated with oversecretion of glucocorticoids. Over the last years, exome sequencing has provided new insights into the genetic setup of adrenal adenomas highlighting the concept of calcium dependent signalling being the main driver for aldosterone secretion while the cAMP/PKA pathway can be considered of particular importance for cortisol production. In rare examples somatic mutations in genes involved in cAMP signalling could be identified. However, in the majority of cases the contribution of glucocorticoid oversecretion in patients with primary aldosteronism has remained uncertain. Recently, we have performed mass spectrometry-based steroid metabolome profiling in 24-h urines from consecutively recruited patients with primary aldosteronism. Comparisons were made with healthy controls, patients with endocrine inactive adrenal adenoma, and patients with mild subclinical and clinically overt adrenal cortisol excess. Based on these measurements, patients with primary aldosteronism had significantly increased cortisol and total glucocorticoid metabolite excretion, only exceeded by glucocorticoid output in patients with clinically overt adrenal Cushings syndrome. Several surrogate parameters of metabolic risk correlated
New international clinical practice guidelines for the care of girls and women with Turner syndrome
Claus H Gravholt
Denmark.

Turner syndrome (TS) affects 25–50 per 100,000 females and can involve multiple organs through all stages of life, necessitating a multidisciplinary approach to care. Previous guidelines have highlighted this, but numerous important advances have been noted since their publication. These advances cover all specialty fields involved in the care of girls and women with TS. This new international guideline is based on an international effort that started with exploratory meetings in 2014 in both Europe and the USA, and culminated with a Consensus Meeting held in Cincinnati, Ohio, USA in July 2016. Prior to this meeting, five groups each addressed important areas in TS care: i) diagnostic and genetic issues, ii) growth and development during childhood and adolescence, iii) congenital and acquired cardiovascular disease, iv) transition and adult care, and v) other comorbidities and neurocognitive issues. These groups produced proposals for the new guidelines. Additionally, four pertinent questions were submitted for formal GRADE (Grading of Recommendations, Assessment, Development and Evaluation) evaluation with a separate systematic review of the literature. These four questions related to the efficacy and most optimal treatment of short stature, infertility, hypertension, and hormonal replacement therapy. These guidelines were initiated and developed by the European Society of Endocrinology (ESE) in Europe, and by the Pediatric Endocrine Society (PES) in USA, with important contributions from the European Society of Human Reproduction and Embryology (ESHRE), the Endocrine Society (ES), the European Society for Cardiology (ESC), the American Heart Association (AHA), and the European Society for Pediatric Endocrinology (ESPE). Several delegates from other societies also participated. Advocacy groups appointed representatives who participated in pre-meeting discussions and in the consensus meeting. Here, we will present the most important new advances in the care of Turner syndrome.

Cardiovascular health issues in Turner syndrome
Philippe Backeljauw

Individuals with Turner syndrome (TS) have an increased risk for congenital and acquired cardiovascular disease (23–50%). This results in increased morbidity and mortality throughout the TS lifespan. There is an increased prevalence of bicuspid aortic valve malformation, coarctation of the aorta, elongation of the transverse aortic arch, and partial anomalous venous return. In addition, TS females may develop aortopathy that may result in clinically significant aortic dilatation, which occasionally leads to dissection or rupture. Other cardiovascular conditions such as hypertension, coronary heart disease, and cerebrovascular disease (stroke) further reduce the lifespan of TS individuals. Because of this high prevalence of cardiovascular disease, any care provider should have some familiarity with the non-invasive cardiac imaging techniques required for diagnosis and management. Imaging modalities include transthoracic echocardiography and cardiac magnetic resonance imaging. Echocardiography is useful in the diagnosis of a bicuspid aortic valve and other congenital heart diseases, and can be used for surveillance of aortic dilatation. Some abnormalities, such as elongation of the transverse aortic arch and partially anomalous pulmonary venous return, are not as readily ascertained by ultrasound however; and cardiac magnetic resonance imaging is now commonly used as a screening and surveillance tool, especially in adult TS patients. The newly developed clinical care guidelines for girls and women with TS include very specific recommendations on which aortic dimensions may warrant consideration for close monitoring and possible operative intervention. They also provide guidance in decision-making regarding participation in various sports disciplines, and greatly clarify when more frequent cardiovascular health monitoring may be beneficial. It is important that both pediatric and adult endocrinologists, as well as reproductive endocrinologists, are familiar with the updated recommendations for cardiovascular health management in TS, in order to coordinate care with the cardiologists and to facilitate thorough health maintenance of girls and women with TS.

Guidance and recommendations about growth and induction of puberty will be reported and discussed.

New Scientific Approaches
NSA1
Identifying molecular signatures for cancer patient stratification via metabolomics and integrative bioinformatics
Hector Keun
UK.

Altered metabolism in tumor cells is required for rapid proliferation but also can influence other phenotypes that affect clinical outcomes such as metastasis and sensitivity to chemotherapy. Integration of metabolome and transcriptome data for the NCI-60 panel of cancer cell lines allowed us to identify cco-5'-nucleotidase (NT5E or CD73) and miRNA-22 as a major determinants of metabolic phenotypes in cancer cells. NT5E expression and associated metabolome variations were also correlated with sensitivity to several chemotherapeutics including platinum-based treatment. We observed that tumor NT5E levels were prognostic for outcomes in ovarian cancer and were elevated after treatment with platinum, supporting the translational relevance of our findings. The cancer-associated and cardioprotective miR-22 was shown to repress fatty acid synthesis and elongation in tumour cells by targeting ATP citrate lyase and fatty acid elongase 6, as well as impairing mitochondrial one-carbon metabolism, and enabling the transfer of carbon from methylene tetrahydrofolate dehydrogenase/cyclohydrolase (MTHFD2). Importantly, a beneficial effect of miR-22 on clinical outcomes in breast cancer was shown to depend on the expression levels of the identified target genes, demonstrating the relevance of miRNA/miRNA interactions to disease progression in vivo. These studies illustrate one route towards patient stratification based the rational combination of different types of molecular biomarkers for metabolic processes.

NSA2
Exosome profiling: potential in cancer diagnosis and stratification
Juan Falcon-Perez
Spain.

In the last decade, cell-secreted extracellular vesicles (EVs) have been isolated from most of the fluids of the body. There are many different types of EVs that include different subpopulations of exosomes, microvesicles and apoptotic bodies, all of them varying in size, composition and intracellular origin. Many laboratories around the world have shown that its composition of lipids, proteins, messenger and micro RNAs is cell-type specific, and subject to changes in pathological scenarios, consequently these vesicles are being actively studied as a source to identify disease biomarkers. Metabolic syndrome is a clinical condition affecting up to 25% of all adults worldwide. It influences many cellular systems including adipose tissue, macrophages and hepatocytes compromising most of the time the hepatic function that is essential for homeostasis of the organism. Apart of metabolic syndrome, liver injury ranging from mild infection to life-threatening liver failures constitute by itself a serious worldwide health issue. Consequently, a major goal in liver pathology is the identification of molecular markers for its early detection, i.e. before clinical manifestations are produced. In this context, by applying metabolomics, proteomics and transcriptomics technologies as well as specific biochemical tools, our group is studying the physiological role of extracellular vesicles in the hepatic function in normal and pathological conditions to identify novel low-invasive markers for liver injury. During last years, our group has demonstrated that hepatocytes are able to secrete exosomes-like vesicles enriched in metabolic enzymes. Now, we are currently achieving a thorough qualitative and quantitative analysis by proteomics, transcriptomics and metabolomics of extracellular vesicles secreted by hepatocytes obtained from experimental models of drug-induced liver injury and metabolic syndrome. Our work provides a repertoire of low invasive candidate markers to evaluate hepatic function in a low invasive manner. Furthermore, our results also support a physiological role of hepatic exosomes in different patho-physiological processes.

Mitochondrial epigenetics in obesity and its co-diseases
Ana Belén Crujeiras

The biological regulatory system through which the organism responds to environmental pressures is mediated by epigenetic modifications of the genome without altering the DNA sequence. Among the epigenetic processes, DNA methylation is perhaps the best understood epigenetic adaption and most common DNA modification. This mechanism plays an important role in regulating the gene expression of many biological processes and has wide-ranging effects on health. Aberrant epigenetic regulation has been described in many human diseases. Concretely, there is growing body of evidence that shows a relevant role of epigenetic marks with obesity and its co-disease susceptibility. However, while nuclear DNA methylation is a well-stablished feature, very little attention has been devoted to mitochondrial epigenetics. Obesity is often associated with a state of mild chronic inflammation characterized by an abnormal production of proinflammatory and prooxidant mediators. This proinflammatory condition has been linked to a mitochondrial dysfunction. In fact, an energy restriction therapy devised to lose weight induces an increase in the intracellular ATP content and mitochondrial-related gene expression, concomitantly with a decrease oxidative stress and inflammatory markers. Mitochondrial dysfunction and the increment of mitochondrial Reactive Oxygen Species (ROS) production are important benchmarks of the aging and metabolic disturbances development. Therefore, the mitochondrial dysfunction might be critically involved in the pathogenesis of obesity. However, the molecular mechanisms leading to mitochondrial dysfunction in metabolic diseases are still unknown. In this context, mitochondrial epigenetics is a novel mechanism to understand the pathobiology of diseases with a mitochondrial dysfunction involvement. Epigenetic regulation of mtDNA has received increasing attention in the last years due to its implication in clinically relevant disease. Variations in mtDNA methylation were associated with exposure to pollutants and Nonalcoholic fatty liver disease (NAFLD) and were proposed to have a role in mitochondrial gene expression regulation. mtDNA methylation was reported to be induced by hyperglycaemia in retinal endothelial cells and to negatively regulate mitochondrial gene expression. Moreover, mitochondrial epigenetic can modulate nuclear DNA and nuclear DNA epigenetic may affect mtDNA. Hence, abnormal mtDNA methylation is attracting increasing attention as potential biomarker and might have therapeutic potential for metabolic diseases management. DOI: 10.1530/endoabs.49.NSA6

Is There a Role for Medical Therapy for Non-Functioning Pituitary Adenomas?

D1.1

Is there a role for medical therapy for non-functioning pituitary adenomas? - FOR
Yona Greenman
Israel.

In this debate I will make an overview of outcomes of NFPA patients with post-operative remnants, who were treated conservatively after surgery. In view of the high rates of tumor progression with consequent need for repeated surgery and radiation therapy, we propose the use of dopamine agonists in these patients. Recent data showing that preventive treatment with dopamine agonists significantly reduces the rate of tumor progression during brain imaging. When symptomatic, primary therapy for NFPA is surgery most commonly by the trans-sphenoidal (TSS) approach. Medical therapy is not generally recommended in this setting, particularly when immediate decompression of the optic chiasm is needed. Despite the debulking efficacy of TSS, in many occasions only partial tumor resection is achieved. Recurrence rates are high in partially resected tumors. Although less frequently, even completely resected tumors may also recur. Therefore, there is a need for post-surgical surveillance and intervention in order to prevent recurrence. The current practice in most centers is to follow-up the pituitary lesion by MRI-imaging and offer additional therapy, usually in the form of radiotherapy (RT), in case of recurrence. RT, either conventional or stereotactic, is effective in controlling further tumor growth but its use is compromised by significant side effects. Based on findings that many NFPA's demonstrate expression of dopamine and somatostatin receptors, medical therapy with dopamine agonists (DA) and somatostatin analogues (SSA) has been used after surgery in order to prevent recurrence. So far, DAs have been more widely tested showing some promise in several small-scale case series. In a recent larger study, introduction of DA immediately after surgery led to a lower number of recurrences compared to a control group that did not receive DA therapy. However, since not all patients will recur, such a strategy exposes a substantial number of patients to unnecessary long-term DA therapy. Unfortunately there are no robust predictors for tumor recurrence. In fact, the best predictor of tumor growth itself. However, DA therapy was less effective when introduced later in patients that already demonstrated a tendency for tumor regrowth. Surprisingly the beneficial effect of DA therapy does not correlate with dopamine receptor expression. This finding raises concerns about the pathophysiological background of the observed DA benefit. Moreover, there are no solid data on hard end points e.g. prevention of visual fields defects and avoidance of second surgery. Although early initiation of treatment may be preferable, dosage and duration of treatment are largely empirical. The need for higher doses and long treatment periods raises some safety concerns. Definitely a well-designed randomized control trial will resolve many of these issues. However, the lack of industrial interest and the long time-length required to obtain valid data, limits the feasibility of such a perspective. To summarize, the promise of most medications is limited by imprecisions regarding the final outcome and uncertainties on dosing and duration of preventive therapy. So far, effective medications have rendered prolactinomas and acromegaly well manageable disorders. For NFPA's such a possibility still remains elusive.

Incidentally Discovered Nonfunctioning Pancreatic NETs: Surgery or Not? (Endorsed by the European Journal of Endocrinology)

D2.1

Incidentally discovered nonfunctioning pancreatic NETs: Surgery or not? - FOR
Ulrich Knigge
Denmark.

Pancreatic incidentalomas are defined as asymptomatic pancreatic lesions, discovered incidentally by imaging for an unrelated indication. A significant proportion of these tumors may be malignant or have a malignant potential. As the use of improved cross sectional imaging increases incidentalomas are becoming more common. In the ENETS guidelines it is proposed that selected patients with incidentally found sporadic, asymptomatic, non-functioning (NF) pancreatic neuroendocrine neoplasms (pNEN) less than 2 cm in size may be followed with repeated imaging instead of resected. However, this conclusion is based on limited data as only few and retrospective studies with a heterogeneous design have investigated the safety of active surveillance. Only few patients had histological or cytological diagnosis and the Ki67 proliferation index, which is the most powerful prognostic marker in NF pNEN, was only determined in 10% of the patients. Up to 20% (in a single study 50%) of the patients had significant tumor growth although regional lymph node metastases developed in few patients. In a recent study, 38% of pNEN < 2 cm displayed malignant features. Hence, it cannot be predicted which patients will progress during observation. Accordingly, active surveillance is a doubtful approach and resection should be offered patients with small NF pNEN, if not contraindicated by age, severe co-morbidity and poor performance status. Surgical procedures for small NF pNEN are safe when performed in high-volume centers. In contrast, in MEN-1 patients NF pNEN ≤ 2 cm are generally indolent tumors with low malignant features and surgical treatment is rarely indicated.

**Is Cardiovascular Risk Increased in Women with PCOS?**

**D4.1**

Is cardiovascular risk increased in women with PCOS? - FOR

Harpal Randeva

UK.

Polycystic ovary syndrome (PCOS) is the most common endocrine disorder amongst women of reproductive age and is associated with various cardiometabolic perturbations, in addition to chronic anovulation and factors related to androgen excess. Indeed androgen excess has been associated with increased cardiovascular risk in women; serum testosterone correlates with indices of subclinical atherosclerosis and cardiovascular disease (CVD). Moreover, women with PCOS, as compared with age- and body mass index-matched women without the syndrome, appear to have a higher risk of insulin resistance, hyperinsulinemia, glucose intolerance, dyslipidemia, and an increased prothrombotic state, possibly resulting in a higher rate of type 2 diabetes mellitus, fatty liver disease, subclinical atherosclerosis, vascular dysfunction, and potentially cardiovascular disease and mortality. Obesity, an independent risk factor for CVD, is also more prevalent in PCOS women as compared to age-matched controls, and is aggravated by androgen excess and has a detrimental android pattern of distribution. Further alterations in PCOS include an increased prevalence of sleep apnoea, as well as various changes in the secretion and/or function of adipokines and adipose tissue-derived pro-inflammatory factors, all of them with direct or indirect influences on the complex signaling network that regulates metabolism, insulin sensitivity, and energy homeostasis. The literature is full of conflicting data and this is partly due to the definition(s) used to identify women with PCOS and also the phenotypic variability of PCOS, which in itself generates significant influence on the cardiometabolic risks.

**D4.2**

Is cardiovascular risk increased in women with PCOS? – AGAINST

Enrico Carmina

Italy.

Young women with PCOS presents a severe risk of developing type II diabetes, cardiovascular diseases, chronic liver disease and endometrial cancer. However, in term of events, there is proven evidence only for type II diabetes and for endometrial cancer. In particular, it is still unclear whether CV events are increased in women with PCOS. Completely different data have been published and the quality of many studies is relatively low. Some recent evidence suggests a larger number of cardiovascular events (4 fold) in young population with PCOS. However, studies at this age present an inherent difficulty linked to the low number of CV events in young population. In addition, these data are based on hospitalized population and this approach may have some biases because it may exclude the less affected population. In our large follow up of unslected PCOS patients, no increase of CV events was noted. In aged PCOS patients the data are also contrasting with some studies showing a slight increase of CV diseases and others reporting normal prevalence of CV events. Large follow up studies are missing and are urgently needed to solve this important issue. However, it is clear that the number of events in aged women, who had PCOS during their reproductive age, is much lower than that expected on the basis of risk calculation during young adult age. The mechanisms of the discrepancy between CV risk and late events in PCOS are unclear but a progressive normalization of CV risk during late reproductive age may have a main role.

Germany.

Abstract Unavailable.

**D5.2**

Should we still ablate all patients undergoing total thyroidectomy for thyroid cancer? - AGAINST

Sophie Lebouilleux

France.

Regarding the debate about whether we should still ablate all patients undergoing total thyroidectomy, the answer is no. Most thyroid cancer patients have an excellent prognosis with a normal life expectancy and among them most of them have a low risk of recurrence. The absence of ablation in patients with thyroid cancer of 1 centimeter or less (pT1a) is already widely applied, so, we are used not to ablate all thyroid cancer patients treated with total thyroidectomy. The question, indeed, is whether the group of patients not undergoing systemic ablation can be extended beyond pT1aN0X patients. The selection of patients to be spared from ablation can indeed be based on pathology examination, on tumour size, on lymph node involvement and since some of these patients are now recognized as low risk patients. The selection can also be based on postoperative thyroglobulin level because of its excellent negative predictive, whether measured after TSH stimulation or measured under levothyroxine treatment with ultrasensitive method, and on neck ultrasonography. However, prospective randomized trials are needed in order to answer this question of ablation. This will allow reinforcing the strength of recommendation that can be done.

**D6.2**

Is it time for initial combination in type 2 diabetes? - AGAINST

Didac Mauricio

Spain.

Type 2 diabetes mellitus is a heterogeneous disease with multiple pathophysiological pathways contributing to hyperglycemia, and also resulting in a variable clinical picture. Thus, individualization of hypoglycemic therapy is a mainstay of current clinical guidelines. Several factors should be considered for a given treatment choice. These include the characteristics related to a given medication (efficacy, hypoglycemia, effect on weight, other safety issues, the mechanism of action), and other factors, like costs related to each treatment, convenience for the patient, etc. Initial combination therapy may be considered as a suitable choice for some patients/circumstances. However, the evidence favoring this combinatory initial option has not been clearly established. Different issues concerning the convenience of using either initial combination therapy vs sequential addition of hypoglycemic drugs will be addressed during the discussion. The following aspects will be dealt with: long term efficacy of combination therapy vs sequential titration/addition of hypoglycemic agents; durability; overall cost and cost-effectiveness; safety issues, including hypoglycemia and weight changes; advantages/disadvantages in terms of treatment adherence; effects on patient-oriented outcomes, including long-term morbidity and mortality; effect on clinical inertia; what is the best combination of hypoglycemic agents; individualization vs combination for every patient. To conclude, the question about the implementation of initial combination therapy as a strategy in usual clinical practice is still open.

Meet The Expert Sessions
How to manage diabetes in the elderly?
Leocadio Rodriguez-Manus
Spain.

The prevalence of diabetes and glucose intolerance is close to 50% in people older than 65. At the same time, near 30% of people with type 2 diabetes are ≥ 85 years old. But being these figures relevant enough to raise a special consideration about how to manage diabetes in this population, there are other reasons supporting the need of that a special consideration. These other needs are not quantitative but qualitative ones, making older people with diabetes a particular group of patients with different characteristics, different aims and, as a consequence, different management compared to adult non-older patients with type 2 patient and, of course, younger patients with both type 1 and type 2 diabetes. These differences range from differences in the pathophysiology of diabetes, that although stemming from insulin resistance have a different origin of this insulin resistance, to the mechanisms underlying the development of vascular and other complications of diabetes, the impact of the disease in the several classical target organs (in people older than 80 diabetes does not increase the risk of blindness), the clinical manifestations of the disease, the diagnostic approach or the general management of the patient. Among all of those, and some others, differences, perhaps the most relevant is the focus on function. While in younger populations, the focus is usually centered in preventing or treating vascular disease (both micro- and macroangiopathy) and other complications of diabetes, when people is older the main focus is to avoid, delay or, if possible, reverse functional (both physical and cognitive) impairment. It is quite clear that diabetes increases less significantly the risk of death in this population, reaching relative risks as low as 1.2 in people older than 80 years old. However, diabetes is one of the chronic diseases increasing the risk of mobility disability, dependency for instrumental or basic activities of daily living, falls and cognitive impairment/dementia in more than twice. In addition, the role of functional status inconditioning the prognosis (both functional and vital, plus other outcomes like hospitalization) is increasingly higher as patient is getting older, substituting the classical role of the comorbidities (both those related and those non-related to diabetes). Finally, the functional impact of the disease is also the main factor explaining the costs of the disease, reaching figures of 78% of the costs. As a consequence, the management of diabetes in older people should be based in functional status as the main factor in the decision-making process, but also as the main therapeutic target. This change in the focus is crucial to get the best benefits when facing older people with diabetes.

Hormone-secreting adrenal tumours in pregnancy
Catherine Williamson
UK.

Hormone-secreting adrenal tumours are rare occurrences in women or reproductive age. The commonest is phaeochromocytoma, followed by primary aldosteronism and Cushing’s syndrome. The shared maternal phenotypic feature of these tumours is marked hypertension. They may be difficult to diagnose as many of the clinical features are mimicked by pregnancy, e.g. flushing, weight gain, palpitations. Furthermore hypertensive disease occurs in approximately 5% of pregnant women. However, there are specific clinical features associated with each tumour type that aid diagnosis; the hypertension in phaeochromocytoma may be paroxysmal; primary aldosteronism is often accompanied by hypokalaemia and the striae in Cushing’s syndrome are usually more purple and marked than in normal pregnancy. It is important to know the normal ranges for the specific endocrine tests used to diagnose each hormone-producing tumour, and once a diagnosis has been made a multidisciplinary team should be involved with clinical management. This should include endocrinologists with an understanding of gestational disease, obstetricians, specialist anaesthetists, midwives and neonatologists. Individualised decisions should be made with regard to treatment with surgery or drugs. All hormone-secreting adrenal tumours are associated with increased rates of adverse pregnancy outcome, including preterm labour and stillbirth. This talk will summarise current knowledge about the management of these rare, and potentially life-threatening tumours in pregnant women and will consider the merits of prospective population cohorts to improve our understanding of the optimal management strategies to improve maternal and offspring outcomes.

Diagnosis and management of GH deficiency - from childhood to adulthood
Jens Jorgensen
Denmark.

Pituitary dwarfism has been known for many decades, originally as a component of organic panhypopituitarism. GH for clinical use was purified by Maurice Raben from human cadaveric pituitaries and tested for the first time and with success in 1957 in a patient with childhood onset disease. Moreover, pivotal short term studies on the metabolic effects were performed in both healthy and hypopituitary adults. The concomitant introduction of immunossays for GH led to the introduction of GH stim tests and recognition of isolated and idiopathic GHD. But the scarcity of GH for clinical use was a major limitation until the 1980s when biosynthetic GH became available. This opened the possibility of novel indications including GHD in adults (GHDA). The two first placebo-controlled studies in 1989 reported positive effects in both childhood- and adult-onset GHDA in terms of body composition and exercise capacity. This has since been corroborated in numerous trials, and it is also documented that discontinuation of GH in the transition from child to adulthood is unfavorable. Finally, there is indirect evidence to suggest that GH replacement in adults may reduce mortality and does not associate with increased cancer risk. Still, GH therapy in adults is by no means a fountain of youth, and there is no evidence to suggest that it is of any meaningful use in either normal or frail aging. This MTE will discuss this exiting journey from a personal point of view.

Modern spectrum of bone turnover markers – are they clinically useful?
Richard Eastell
UK.

Bone turnover markers reflect the work of the osteoblast and the osteoclast. They can be measured in blood or urine and allow for an inexpensive and non-invasive way to study bone metabolism. They have been evaluated for their use in
Graves’ disease (GD) is a heterogeneous autoimmune disorder affecting, with varying degrees of severity, the thyroid, eyes and skin. GD is the most common cause of hyperthyroidism. The incidence peaks between 30 and 50 years of age, but people may be affected at any age. Hyperthyroidism is caused by autoantibodies stimulating the TSH receptor on thyroid cells. The severity of thyrotoxicosis in GD is variable and the response to anti-thyroid drugs is difficult to predict. Graves’ orbitopathy (GO) is the most common and serious extrathyroidal manifestation of GD, significantly impairing the quality of life of affected patients. Clinically apparent orbitopathy occurs in 25%–50% of patients. The treatment selection must also take into account the patient’s preference. Before deciding on a treatment plan, the treating physician and patient should discuss each of the treatment options, including the logistics, local availability, advantages, disadvantages, potential side effects and costs.

How best to manage neuroendocrine tumours? - Towards a new algorithm
Alicja Hubalewska-Dydejczyk
Poland.

During the last couple of years an essential increase of newly diagnosed NENs has been observed, however it should be underlined that many cases represent new challenges for the medical staff. Development of personalized approach to NEN patients on the basis of knowledge rapidly coming from genetic/molecular research, improvement of biochemical/imaging diagnostic methods and availability of more efficient therapeutic options, means that existing guidelines are still being changed. However, the questions: ‘what of the future hold for NEN?’ and ‘how will future achievements influence the new algorithm?’ remain open. In the majority of patients the overall prognosis depends on the grade (G) and stage (TNM) of the tumour. Recently proposed classification of NENs divides additionally G3 NENs into NET G3a and G3b neuroendocrine cancers. Ki-67 is currently the main prognostic index which drives the management of all NENs, nevertheless it should be stressed that very often patient outcomes are difficult to foresee and the lack of response to therapeutic treatment regiments remains unpredictable so the identification of other prognostic factors would be of great help and it would make diagnostic and therapeutic decisions more appropriate. At present chromogranin A, urinary 5-HIAA and tumour specific hormones in secreting NENs are widely used as biomarkers. One should bear in mind that surgery is the only possible curative method in NENs however, half of the patients have metastases at presentation and unknown primary focus can also be challenging. Therefore, the development of fast and accurate imaging procedures (endoscopies, USG, CT/MRI) and the implementation of the different radionlabelled compounds targeting various membrane/intracellular receptors/metabolic pathways (PET/SPECT-CT/MRI) is necessary. Antiproliferative therapy with SSA, TKI, PRRT and cytotoxic therapy should be given rather as sequential pathways (PET/SPECT-CT/MRI) is necessary. Antiproliferative therapy with SSA, TKI, PRRT and cytotoxic therapy should be given rather as sequential monotherapy than a combination one. Based on clinical cases of patients with NENs in different locations and at a different stage of the disease the different diagnostic/therapeutic options will be discussed during the Meeting.

What can new insulins provide for management of diabetes?
Jean François Gautier
France.

The major abnormality in type 1 diabetes is insulin deficiency. Type 2 diabetes is also characterized by an insulin secretory defect so that many patients are on insulin therapy. Methods of replacing insulin have improved throughout the decades, but there are still limiting factors that prevent the achievement of a better HbA1c levels such as hypoglycemic events and glycemic variability, weight gain and fatty liver. Additionally, most patients wish to do less insulin injections and less blood glucose self-monitoring! New insulins and newer delivery systems are being developed that can improve some of the limitations of current insulins or make the delivery of insulins more acceptable for some patients. Extending the duration of action of basal insulins (glargine U300, Insulin degludec, PEGylated insulin Lispro) may have advantages in reducing risk of hypoglycemia (and especially nocturnal hypoglycemia) and weight gain. PEGylated insulin Lispro is no more in development for safety reasons (high triglycerides and liver enzymes) and there is still no head-to-head comparison between glargine 300 U/ml and degludec. Shortening the peak of fast-acting insulins in order to mimic the physiological first phase insulin secretion (bioD-090, rHuPH20, Ultra-fast-acting insulin aspart, BioChaperone lyspro) may also have advantages. However, peer-reviewed evidence to date remains scarce. Biosimilars are developed to minimize insulin cost but do not bring something new for the patients. Combination of new long acting insulins with a short acting insulin or with a GLP-1 analogue are available in some countries. These combinations reduce the number of injections. Different delivery systems may make insulin more acceptable to patients. Whether these innovations permit a better glycemic control will be discussed. Lastly, we will see whether ‘smart’ insulin, that is glucose-responsive insulin, the Holy Grail promise, will be available in the next future.

Thyroid carcinoma: complicated cases
Valeriano Leite
Portugal.

Thyroid neoplasias show a wide range of biological behaviours from indolent to highly aggressive, invasive and metastatic cancers. The great majority of thyroid carcinomas are successfully treated with surgery, radioactive iodine and TSH suppressive therapy. However, a subset of tumors can behave aggressively, with distant metastasis and/or local invasion. These patients have a poor prognosis and a shorter survival, remaining a challenging task in treatment options. Cytotoxic chemotherapy has only limited effect, without clear evidence that benefit outweighs risk of toxicity. Radiotherapy is an option for surgically unresectable neck recurrences and for bone and brain metastases. Recently, interest rose on tyrosine kinase inhibitors (TKI) and, currently, there are several TKIs that have been approved for advanced thyroid cancers either from follicular or parafollicular origin. A judicious use of different treatment modalities in advanced thyroid carcinoma may improve patients’ outcome and prolong survival. Illustrative cases of advanced thyroid cancer patients will be presented and discussed in this MTE session.

MTE15
Gaucher disease: interdisciplinary management
Milan Patakov
Serbia.

Gaucher disease (GD) is a rare, genetic, autosomal recessive lysosomal storage disease with multi-system manifestations caused by a deficiency of the lysosomal enzyme glucocerebrosidase, which leads to an accumulation of its substrate glucosylceramide (glucocerebroside) in macrophages of various tissues with an inflammatory response and a release of cytokines. In general population its incidence is approximately 1/40 000 to 1/60 000, rising to 1/800 in Ashkenazi Jews. Clinical features comprise cytopenias, splenomegaly, hepatomegaly, and bone lesions. Non-neuronopathic type-1 Gaucher disease, which affects the majority of patients (90% in Europe and USA), is characterized by visceral effects, whereas neuronopathic types 2 and 3 are dominantly associated with neurological impairment. The diagnosis of GD can be confirmed by the deficient acid glucocerebrosidase activity in peripheral blood leukocytes. Patients with type 1 GD, and even carriers of one gene mutation have predisposition to develop Parkinson’s disease, and there is increased risk of some neoplasia in GD patients. Disease-specific treatment of type 1 GD consists of intravenous enzyme replacement therapy (ERT) with one of the available enzymes (imiglucerase, velaglucerase, or taliglucerase) or orally administered substrate reduction therapy (SRT) with inhibitors of glucocerebrosidase biosynthesis (miglustat or eliglustat). Currently there is no treatment for type 2 disease which is lethal early in the life.

New treatment approaches in dyslipidemia
Luis Masana
Spain.

The introduction of PCSK9 inhibitors has changed the paradigm of dyslipidemia treatment. These monoclonal antibodies produce an incremental LDL reduction of about 60% add-on current therapy. Achieving LDL concentrations below 40 mg/dl is usual. The recent publication on the effect of very low LDL concentrations on atherosclerotic plaque burden (Glagov study) and on cardiovascular outcomes (Fourier and Spire) show the impact of this therapy in cardiovascular prevention. In the other hand these treatments seem to be pretty safe: Ebbinhouse study has demonstrated no impact on neurocognitive function. Price of therapy is the main limiting factors and several scientific societies have issued recommendation for use. The aim of this meeting is discussing about the new approaches of dyslipidemia therapy.

MTNE1
A paediatric perspective of endocrine late complications following childhood cancer
Tanya Urquhart
UK.

Dramatic improvements in cancer survival over the past four decades means that greater than 80% of children diagnosed with cancer can expect to survive for more than five years. For some cancers, such as acute lymphoblastic leukaemia and Hodgkin’s disease, cure rates exceed 90%. Currently, there are over 26000 young adults living in the UK, 600 000 across France, Italy, Switzerland, Netherlands and the Nordic countries and 363 000 in the US, who are survivors of childhood cancer (CCS). A late effect (LE) is the term used to describe any physical, psychological or social consequence of the disease itself or the disease treatment. The consequence of cytotoxic effects on maturing tissues may only become apparent many years following completion of treatment and with subsequent development, hence the term LE. Treatment for childhood cancer...
usually involves chemotherapy, radiotherapy (including radiosurgery) and surgery. These treatments can occur in isolation or in any combination, and can affect almost any system in the body. The most common effect of these treatments is on growth, endocrine function, fertility, neuropsychology and the cardiac systems. Two-thirds of childhood cancer survivors will experience at least one LE and the endocrine system is commonly involved. Another third of patients will develop two or more LE which may be severe or life threatening. Therefore this session will explore the endocrinopathies associated with the treatment for cancer in childhood using case studies to provide examples from practice. Knowledge of oncology and endocrinology are paramount for nurse specialists working with this patient cohort to ensure accurate education for young people about their past treatment and its implications for their future health. Transition will also be considered as these young people grow, develop and require continuing care from adult healthcare professionals.

Regulation and dysregulation of appetite and satiety

Patricia Iozzo
Italy.

The modulation of appetite, satiation and food intake stems from the interplay of central mechanisms of homeostasis, hedonism and cognitive control, receiving and integrating information on energy balance and feeding status of the body from peripheral organs, including dietary and gut-related signals. Obesity is a phenotype, likely resulting from the dysregulation of one or more of the above mechanisms. Different mechanisms may prevail in different people, though leading to a similar phenotype. The recognition of such diversity would offer opportunities for personalized treatment. This lecture will present data from a study conducted in well characterized overweight women, undergoing brain imaging of glucose metabolism to detect cerebral reactions to sensory food stimuli. The study suggests that women with food addictive behavior have a specific pattern of activation, which implicates cognitive control and diet-related factors (hormones, substrates, and possibly microbiota) in their food seeking behavior. This hypothesis is supported by the characterization of feeding behavior and brain and brown adipose tissue (BAT) metabolism in mice models of neurodegenerative disease and/or high-fat feeding, also in combination with intranasal insulin therapy. In order to better define the sequence of events linking brain function and feeding behavior, studies in the offspring of obese mothers are addressed, since maternal obesity represents a preventable condition, in which the factors above are affected since early life in the offspring. Results in humans, and animal models will be presented. Cumulatively, our studies suggest that a hypermetabolic brain, deriving from metabolic disturbances or high-fat dietary exposure may be an early detrimental factor, and a hypometabolic brain reflecting neuronal loss may enhance food intake, but also BAT browning. Substrates, hormones and gut microbes can promote a vicious cycle.

Clinical practice overlap and seamless care – diagnosis and management of hypothyroidism in patients with diabetes mellitus
Elena Shelestova

Today diabetes (DM) is one of the largest global health emergencies. Each year a large number of people live with this condition. Currently there are more than 422 million people with DM worldwide. DM is one of the major public health problems in Georgia. Number of people with DM is on the rise, though no exact statistical data for Georgia exist. Diabetes Atlas (International Diabetes Federation, 2015) gives diabetes prevalence for Georgia of 7.9%, though these data are extrapolated from other countries. On the other hand, hypothyroidism (HOT) is believed to be a common health issue worldwide. The prevalence of HOT in the developed world is about 4–5%, and the prevalence of subclinical HOT is about 4–15%. Both HOT and subclinical HOT are thought to be risk factors for T2DM development. In our patients approximately 30% of women and 15% of men have both conditions. Prevalence of both conditions increases with the age of the patients (age 35–74 years, prevalence range 7–5%).

Materials and methods

HOT and subclinical HOT are diagnosed in 2010. Treatment with L-thyroxine was performed (biopsy performed) and are managed at the National Centre for Diabetes Research. Case #1 – pt. E.G., 49 years old, female, T2DM since 2008, HOT – since 2015. Pt. was treated with oral hypoglycaemic agents (OHAs) – SU and Metformin (Met), in 2017 pt. was transferred to DPP-4 and Met. DM control is satisfactory, clinical and laboratory tests were tested. L-thyroxine therapy was initiated (50 mg, then elevated to 100 mg). Since treatment initiation pt. condition is satisfactory, clinical and laboratory tests have improved. Pt. control every 3 months. Prescribed treatment is continued, Case # – pt. K.N., 65 years old, female, HOT and goiter with thyroid nodules (no biopsy performed) were diagnosed in 2010. Treatment with l-thyroxine was initiated. No follow-up was carried out though the drug (50 mg) was used regularly. In 2017 pt. came to our Centre for the 1-st time. Ultrasound of the thyroid gland and hormone tests was performed that revealed thyroid nodules (TSH was within the n range). Nodule biopsy was carried out, colloid goiter was diagnosed. Pt. had following DM risk factors – family history of DM, obesity, arterial hypertension, HOT. Thus, she was screened for DM. HbA1c was 7.0% indicating to T2DM. Met. (500 mg) was initiate. Treatment with l-thyroxine at selected dose is continued. Diet and physical activity recommendations were selected individually. At present both pts are regularly followed-up (every 3 months). Doses and treatment are adjusted based on the results achieved.

Conclusion

Combination of the conditions is globally widely spread, it needs serious attention, knowledge and experience to manage. Proper management permits pts to live long and productive life and avoid complications caused by the conditions.

Clinical practice overlap and seamless care – challenges in the management of patients with Cushing’s syndrome and diabetes
Mies Kerstens

The Netherlands.

This lecture focuses on, a patient with Cushing’s syndrome case by bilateral adrenal hyperplasia. After adrenalectomy, there are major challenges in the care for this patient, that will be addressed: challenges in medical treatment (cortisol withdrawal and change of medication in hypertension en diabetes mellitus) as well as challenges in coaching (misconceptions in diabetes mellitus treatment, fears, educational needs with respect to hypercortisolism and hypocortisolism, withdrawal complaints).

DOI: 10.1530/endoabs.49.N1.3

Clinical practice overlap and seamless care – at risk of two endocrine emergencies: the patient with type 1 diabetes and Addison’s disease
Sofia Sjöberg
Sweden.

Patients diagnosed with Addison’s disease and diabetes mellitus type 1, has a rare combination of two autoimmune conditions. Two diagnosis that requires a great deal of self-care. Patients have a potential risk to induce endocrine emergencies such as diabetic hypoglycemia, adrenal crisis and diabetic ketoacidosis. The lack of lifesaving hormones can put the patient in potential life threatening situations. I’ll share my experience in meeting these patients. Brief physiology how the lack of hormones affects the glucose metabolism and what aid the patient need to handle the two disorders in daily life.

DOI: 10.1530/endoabs.49.N1.4

Clinical practice overlap and seamless care – links between hypogonadism, the metabolic syndrome and type 2 diabetes
Andrew Dwyer
Switzerland.

There is a bi-directional relationship between hypogonadism and type 2 diabetes and the metabolic syndrome (T2DM/MetS). Studies show that up to 50% of men with MetS/T2DM have testosterone deficiency. Moreover, both hypogonadism and MetS confer increased health risk for morbidity and mortality. Men with MetS are twice as likely to develop cardiovascular disease and have a fivefold higher risk for developing T2DM. Notably, the inverse relationship between testosterone and MetS is consistently observed across racial and ethnic groups. Therefore, in the setting of ever increasing obesity rates, the relationship between the reproductive endocrine axis and metabolism warrants renewed attention. Using a case-based approach, this presentation will provide an overview of the pathophysiologic basis for the relationship between hypogonadism and MetS/T2DM. Male patients may be trapped in the vicious cycle of hypogonadism-obesity-insulin resistance. We will review an evidence-based approach to the patient including the appropriate evaluation and treatment based on existing guidelines and recommendations. This presentation will have a particular focus on the role of the endocrine nurse in managing patients who present with this confluence of endocrine disorders. Current challenges in the field will be highlighted and we will touch on some yet unanswered questions as well as envisioned future directions. At the conclusion of this session participants will be able to:

- describe the interrelationship between hypogonadism and MetS/T2DM
- identify those patients who warrant screening for androgen deficiency
- recognize barriers to providing integrated care for these patients
- examine how their nursing care for these patients may be improved

DOI: 10.1530/endoabs.49.N1.2

Nurses professional development and networking session – obstructive sleep apnea and comorbidities in patients with pituitary adenomas
Christine Yedinak
USA.

Short sleep duration and insomnia have been linked to higher risk of cardiovascular disease and CVD related mortality. Likewise, obstructive sleep apnea has been shown to confer a higher cardiovascular risk and is reported to be associated with 52–70% of acute myocardial infarctions and strokes. Hypertension (HTN), diabetes (DM), weight gain, sleepiness, fatigue and depression have all been correlated with obstructive sleep apnea (OSA). Patients with pituitary adenomas (PA), particularly those with Cushing’s disease and acromegaly, often present with reported sleep dysfunction, fatigue and metabolic risk factors, diabetes, hypertension and cardiovascular disease and depression. The prevalence of sleep apnea in patients with pituitary hypersecretion at diagnosis has not been clearly quantified in patients as it may not be recognized and may go undiagnosed at the time of presentation. Additionally, the correlation with diabetes and other cardiovascular risk factors is not clear in these disorders. There is little data regarding the impact of treatment and disease remission on both OSA and persistent risk factors. The aim of this presentation is to explore the prevalence and correlation between sleep disturbance (SD), depression, BMI, HTN, diabetes

Endocrine Abstracts (2017) Vol 49

Nurses professional development and networking session – utilising the competence framework to develop the role of endocrine nurses in adrenal insufficiency
Janina Kirchner
Germany.

The competence of endocrine nurse in the treatment of adrenal insufficiency (AI) is defined by the competence framework. Here is distinguished into Competent, proficient and expert. In these points, the nurse’s knowledge is presented and gives a good overview of already acquired knowledge and things to be learned. With the acquired knowledge the endocrine nurse is intended to treat, train and support patients with AI as far as possible. Due to differences in the health systems of the countries in Europe, not all approaches are possible. Here the example of Germany is shown how patients with AI are provided with a national training program and the competence framework is also applied.

DOI: 10.1530/endoabs.49.N2.2

N2.3
Nurses professional development and networking session – hybrid training of nurses in the endocrinology; train the trainer with help of e-learning modules
Johan Beun
The Netherlands.

Adrenal insufficiency is a rare adrenal disorder that can be made more complicated by an adrenal crisis even to a life-threatening situation. An adrenal crisis occurs when the body has a shortage of the hormone cortisol. If the patient does not receive the correct treatment an adrenal crisis can be fatal. This can be avoided by correctly and carefully following the ‘stress instructions’ (also known as ‘sick day rules’). A significant percentage of patients have insufficient knowledge of these stress instructions or are not able to put them into practice themselves. In addition, it has become evident that the stress instructions vary between the different hospitals. For that reason, AdrenalNET has drawn up uniform stress instructions. These form part of the Quality of Care Standard for Adrenal Disorders, which sets out quality criteria (as applicable in the Netherlands) for the care of patients with adrenal insufficiency. One important quality criterion for the proper care of patients with adrenal insufficiency is that the hospital must have a nurse who has successfully completed this training course.

Objective
The objective of this training course is to offer nurses the essential theoretical and practical knowledge that they need if they are to provide adrenal patients with optimum care and instruct them how to apply the stress instructions for themselves. Indirectly, this will also help to promote the principle of co-management when patients with adrenal insufficiency find themselves in stressful situations. We are, in fact, training the trainers first via e-learning modules (4×) later one day at the university incl. a test at the end.

Update on diet and lifestyle throughout lifespan to improve health – prevalence and treatment of vitamin D deficiency in children
Pauline Musson
UK.

A number of factors have been associated with the apparent increase in children with vitamin D deficiency (VDD) in developed countries: increased awareness, increased migration, children living with chronic illness or disabilities, effects of medication (e.g. glucocorticoids, anticonvulsants), use of sunscreen, changes in lifestyles and a rise in childhood obesity. The clinical features of VDD vary with age and degree of deficiency and importantly, calcium deficiency is now recognized as a key factor in symptomatic VDD. At presentation, children may be asymptomatic or, have musculoskeletal pain; and in severe cases hypocalcaemic seizures, rickets and life threatening cardiomyopathy may occur. Evaluation of children should include careful assessment of dietary intake, previous medical history, medication review (including use of complementary alternative medicines), growth and puberty, and systemic enquiry of symptoms suggestive of malabsorption.Biochemical investigations are merited in symptomatic cases and there are important rare diagnoses that should be considered when interpreting results. There are a variety of treatment regimens for VDD. Typically treatment is with cholecalciferol, administered in daily, weekly, monthly or 12 weekly doses. Oral doses are considered as effective as intramuscular injections in children with normal intestinal absorption. Potential side effects from treatment should be communicated to the family and are rare. Calcium supplements should be considered in those with inadequate dietary intake. The family should be made aware of the reasons for intervening, the differences between treatment versus supplement doses of vitamin D, and how to optimize diet and additional lifestyle factors. Some licensed products are not palatable for children and achieving adherence can be challenging. Poor medicine adherence may be further aggravated by confusion regarding the doses required and inconsistent information given to families by health care professionals. I will review the contemporary multidisciplinary approach to the child presenting with vitamin D deficiency with illustrative clinical cases.

N3.2
Update on diet and lifestyle throughout lifespan to improve health – sexual hormones and bone, a close link throughout lifespan
Georgios Papadakis
Switzerland.

Bone health is increasingly recognized as a crucial factor for quality of life. Osteoporosis, defined as bone impairment leading to an increased risk of fracture, is an important source of morbidity and even mortality in later life. Both male and female achieve the peak bone mass at around the age of 25 years. This peak is significantly lower in case of puberty and/or growth disorders, thus increasing the risk of osteoporosis later in life.

Discussion
Our Reproductive Division of Endocrinology in Lausanne University Hospital specializes in Congenital Hypogonadotropic Hypogonadism (CHH), a disorder characterized by absent puberty and infertility due to complete or partial deficiency of GnRH, the hypothalamic hormone that initiates the reproductive cascade. When CHH is accompanied by anosmia, it is called Kallmann syndrome (KS). In our cohort of KS and CHH patients, there is an important decrease of bone density, which is more significant when the disease was diagnosed late in life, resulting in long periods without hormonal replacement. On the contrary, as our clinical cases illustrate, when diagnosis of these rare disorders is performed promptly and adequate treatment is followed, the patients maintain a near-normal bone density and avoid fractures later in life. In a different approach to the relation between bone and sexual hormones, using data from the Osteo.Laus population-based study, a large cohort of post-menopausal women, we recently showed that menopausal hormone treatment (MHT) is associated with enhanced bone density and structure. Interestingly, the bone benefit seems to persist for at least 2 years after its withdrawal. These results corroborate other studies outlining that in young postmenopausal women aged 50 to 60 years old the ratio benefit/risk is clearly in favor of the benefits in terms of bone health, cardiovascular outcomes and even mortality. We should reconsider MHT for recently postmenopausal women with menopausal symptoms such as hot flashes and/or increased risk of fractures. In new unpublished data, we detected that MHT users have significantly lower visceral fat mass, an important element with potential bone and systemic implications.
Conclusion
Sexual hormone deficiency throughout lifespan severely impairs bone quantity and quality leading to bone fragility. Increased awareness of the link between bone and gonadal function is mandatory among endocrine physicians and nurses in order to promote early diagnosis and avoid lack of treatment. The risk of bone morbidity later in life can be an important argument to increase patient’s adherence to therapy.

N3.3
Update on diet and lifestyle throughout lifespan to improve health – osteoporosis and prevention of fractures: nurses can a play key role
Marsha Van Ooswaard
The Netherlands

Treatment of osteoporosis is all about prevention of fractures. It relies on a combination of approaches, including adjustments to the patient’s diet and lifestyle, pharmacological therapy, and patient education. Changes to the patient’s diet and lifestyle typically involve: optimizing calcium and vitamin D intake and exercise levels, cessation of smoking and reducing alcohol consumption. Pharmacological therapies used to treat osteoporosis by reducing the fracture risk include bisphosphonates or the RANK ligand inhibitor denosumab. Nurses have an important role in educating patients about fracture risk, the benefits of lifestyle modifications for maintaining bone health and the treatment options available, including side effects and the importance of adherence. In the current Dutch osteoporosis guidelines, it is recommended that hospitals appoint a specialised fracture nurse for the organisation and coordination of osteoporosis care. These specialised nurses provide care relating to case finding, risk evaluation, prevention, diagnosis, treatment and follow up. Each of these steps is essential and an insufficient implementation can result in suboptimal fracture prevention. Their main area of expertise is the recognition of risk factors. These risk factors can be related to the bone itself, a fall or the patient’s lifestyle. Some of these factors can be influenced, some cannot. Patients need to have a good understanding of their diagnosis and fracture risk to make informed choices with regard to pharmacological treatment and/or lifestyle change.

High resolution tissue mass spectrometry imaging: a new tool for identification of prognostic markers in adrenocortical carcinoma

Thomas Kunzke1, Na Sun1, Silviu Sieraca2, Vanessa Wild1, Michaela Aichler1, Cristiano Ronchi1, Nicolas Schlegel1, Andreas Rosenwald1, Martin Fassnacht1, Axel Walch1 & Matthias Kroiss2,3

1Helmholtz-Center Munich, Munich, Germany; 2University Hospital Würzburg, Würzburg, Germany; 3University of Würzburg, Würzburg, Germany.

Adrenocortical carcinoma (ACC) is an orphan tumor entity the pathogenesis of which is poorly understood. In advanced tumour stages, prognosis is unfavorable, but biomarkers for early diagnosis are lacking. MALDI-Mass Spectrometry Imaging (MALDI-MSI) enables semi-quantitative detection of a broad spectrum of analytes including endogenous cell metabolites in tissue sections. MALDI-MSI was used as a discovery approach to analyse tissue specimens of 72 ACC patients in FFPE tissue arranged in tissue microarrays to identify pathways of pathophysiological relevance and histologic markers related to patient prognosis. We focused on steroid hormones and their metabolites which might also serve as tumour-derived blood biomarkers in the future. 3843 individual endogenous m/z species were obtained of which five were identified as known components of steroid hormone synthesis and metabolism. 2/5 steroid hormone metabolites showed differential abundance between ACC samples. Their low abundance in 5 and 6 of the 72 ACC samples was associated with poor overall survival in Kaplan-Meier analyses (Log rank P = 0.0030 and 0.0045, respectively). Based on the type of the steroid hormone modification present, mass spectra were screened for related m/z species. An unusual steroid hormone metabolite (M) was identified and validated by tandem mass spectrometry. After multivariable adjustment for age, tumor stage and sex by using the Cox proportional hazards model, presence of M was associated with poor overall survival (HR 4.54, 95%CI 1.56–13.22, P = 0.0056). By using immunohistochemistry we analysed protein expression of two related enzymes which was correlated with metabolites abundance. In conclusion, we demonstrated the utility of MALDI-MSI in detecting and identifying small molecule markers in FFPE tissue samples of ACC. A limited number of compounds related to steroidogenesis with strong prognostic value could be detected. One steroid hormone metabolite and related enzymes were of outstanding prognostic value. The potential of these metabolites as blood biomarkers remains to be investigated.

EZH2: a master regulator of adrenal cortex homeostasis and zonation

Mickael Mathieu1, Coralie Drelon2, Houda Tabbal1, Stephanie Rodriguez1, Bertrand Ménard1, 2, Jane E Gligorov1, 2, Annemieke Vercruysse1, 2, ministre d’État, Wilfried Martens4, 5, 6, 7, a \’leun2, 8, Thomas Maillet1, 2, 5, 7, a \’leun, and 1, 2, 3, 5, 7, a \’leun

1Laboratoire GReD, Clermont-Ferrand, France; 2Albert Einstein College of Medicine, Bronx, New York, USA; 3National Institutes of Health, Bethesda, Maryland, USA; 4Harvard Stem Cell Institute, Boston, Massachusetts, USA; 5University of Würzburg, Würzburg, Germany; 6University of Würzburg, Würzburg, Germany; 7University of Würzburg, Würzburg, Germany.

In adult mice the adrenal cortex is divided, in two distinct functional zones, outermost zona glomerulosa (ZG) and innermost zona fasciculata (ZF), encapsulated by a thin layer of mesenchymal cells (capsule). The adrenal cortex undergoes constant centripetal cell renewal, relying on recruitment of progenitors located within an outer cortex niche. Progenitors initially differentiate as ZG cells and undergo lineage conversion to ZF as they move within the cortex. This relies on a subtle balance and trans-inhibition between WNT and PKA signalling pathways. Epigenetic histone modifiers are prototypical factors that play essential roles from embryonic development to carcinogenesis. We have recently shown that the histone methyltransferase EZH2 is overexpressed in adrenal cortex carcinomas where it is associated with poor prognosis and tumour aggressiveness. In order to understand EZH2 function in adrenal physiology, we have developed a mouse model of EZH2 inactivation relying on a floxed allele of EZH2 and the S11-Cre driver (EZH2KO). Our analyses show adrenal hypoplasia and primary corticosterone insufficiency, associated with expansion of ZG at the expense of ZF and aberrant mixed ZG/ZF differentiation. Consistent with the role of PKA and WNT signalling in establishment and maintenance of zonation, WNT pathway is increased whereas PKA activity is decreased in EZH2KO adrenals. In addition to zonation defects, EZH2KO present abnormal accumulation of ‘stress progenitors’. Recruitment of these particular progenitors is under control of WT1 and GATA4. Our in situ ChIP and expression data show that these two transcription factors are direct targets of the inhibitory action of EZH2 in the adrenal. Altogether, these data suggest completely unanticipated functions of EZH2 in the control of stress progenitors homeostasis through WT1 and GATA4 and adrenal cortex zonation, which rely on a novel interaction between EZH2 and PKA signalling pathway.

Steroid metabolomics for accurate and rapid diagnosis of inborn steroidogenic disorders

Elizabeth Baranowski1,2, Kerstin Bunte1,3, Cedric H L Shackleton1, Angela E Taylor1,2, Beverley A Hughes1, Michael Biehl3, Peter Tino1,4, Tulay Gurun5 & Wielke Arlt1

1Institute of Metabolism and Systems Research, University of Birmingham, Birmingham, UK; 2Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, UK; 3Johann Bernoulli Institute for Mathematics and Computer Science, University of Groningen, Groningen, The Netherlands; 4School of Computer Science, University of Birmingham, Birmingham, UK; 5Department of Pediatric Endocrinology and Diabetes, Marmara University, Istanbul, Turkey.

Background

Urinary steroid metabolite profiling is an accurate reflection of adrenal and gonadal steroid output and metabolism in peripheral target cells of steroid action. Measurement of steroid metabolite excretion by gas chromatography–mass spectrometry (GC–MS) is considered reference standard for biochemical diagnosis of steroidogenic disorders. However, performance of GC–MS analysis and interpretation of the resulting data requires significant expertise and age- and sex-specific reference ranges. Here we developed novel computational approaches for rapid interpretation of GC–MS data for diagnosis of inborn steroidogenic disorders.

Materials and Methods

We analysed the urinary steroid metabolome by GC–MS in 829 healthy controls (302 neonates and infants, 167 children and 360 adults) and 118 untreated patients with genetically confirmed inborn disorders (21-hydroxylase deficiency, 17-hydroxylase deficiency, 21-hydroxylase deficiency, 17β-hydroxylase deficiency, 3β-HSD2 deficiency, 17β-HSD3 deficiency, 5α-reductase type 2 deficiency, cytochrome b5 deficiency). We calculated age-related normative values for established metabolite ratios representing distinct enzymatic functions. We developed a novel interpretable machine learning technique, Angle Learning Vector Quantisation (ALVQ), which looks at all possible metabolite ratios, computationally reduces these to the most relevant for discrimination, and differentiates disease states by comparison to a representative prototype. The method runs independent of sex and age information, units of measurement and method of urine collection.

Results

Conventional biochemical ratios had 100% sensitivity but only very poor specificity. By contrast, ALVQ predicted ‘affected urine’ vs ‘healthy urine’ with 100% sensitivity and 97% specificity. For our three most prevalent conditions (PORD, SRDS2A and CYP21A2), the specific condition was identified correctly in 96% of cases.

Conclusion

We developed a novel Steroid Metabolomics approach to automatically diagnose inborn steroidogenic disorders with very high sensitivity and specificity, superior to current methods, and with high potential for implementation in routine clinical care.

The epidemiology of pheochromocytoma: increasing incidence and changing clinical presentation. A population-based retrospective study 1977–2015

Andreas Ladebofeg Ebbehoj1,2,2, Esben Sondergaard3, Christian Trolle1, Kirstine Stochholm1 & Per Logstrup Poulsen1

1Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; 2Department of Clinical Medicine, Aarhus University, Aarhus, Denmark.

Phaeochromocytoma is a rare disease but frequently poses a diagnostic dilemma due to the unspecific symptoms and its potentially life-threatening nature. There is a perception of an increase in the incidence of phaeochromocytomas in recent years, but no data on time trends exist. We obtained data from The Danish National Registry of Patients, The Danish Registry of Causes of Death, and The National...
Remains unknown. Whether surgical treatment provides a health benefit in this group appears to represent a new group of pheochromocytomas not previously diagnosed. The incidence of pheochromocytoma has increased compared to 1977–2006. No changes were observed in duration of symptoms or level of catecholamines. Therefore, these incidentaloma patients are getting older. Thus, incidental pheochromocytoma should be considered when older patients present with symptoms and have normal blood pressure.

The diagnosis of primary aldosteronism: a prospective study and systematic review
Qifan Li, Ying Song, Shumin Yang & Aipin Zhang
Department of Endocrinology, Chongqing, China.

Background Confirmed aldosteronism is a sodium-retaining condition caused by excess aldosterone production. The most common diagnosis is primary aldosteronism (PA), which is divided into two subtypes based on lesion location: adrenal adenoma and idiopathic hyperaldosteronism (IHA). This study aimed to evaluate the diagnostic accuracy of three tests in a prospective study.

Methods
Five hundred and thirty-one patients with overt hypertension were enrolled. Plasma aldosterone-renin ratio (ARR) was used for screening. Hypertensive patients tested positive at PA screening (ARR > 5.0 µg/l per µU/ml), one in every three consecutive patient tested negative (ARR < 3.7 ng/dl per µU/ml) and patients who tested negative but PA was strongly suspected (ARR > 3.7 ng/dl per µU/ml) and patients who tested negative but PA was strongly suspected were selected for further examination. Area under receiver operator characteristic curve (AUC), sensitivity and specificity were calculated. A systematic review and meta-analysis of relevant studies were performed to place our results in context.

Findings
Finally, 132 patients diagnosed as PA and 104 diagnosed as essential hypertension completed three tests. AUC of CTR, CIT and FST were 0.97 (95% CI 0.95–0.99), 0.97 (0.95–0.99) and 0.98 (0.97–0.99), respectively, with post-test plasma aldosterone concentration (PAC) was used to confirm PA. But AUC of CIT significantly decreased to 0.76 (0.69–0.82) if PAC suppression ratio was used to confirm PA. When PAC cutoffs of CIT and FST was set at 8 ng/dl, and CIT at 1 ng/ml, the sensitivity was 87.9%, 93.2%, 92.4% and specificity were 93.3%, 90.4%, 90.4% respectively. No significant difference of synthetic AUC, pooled sensitivity or specificity between CIT and CTR was found in the meta-analysis. Only one study of FST fulfilling the criteria of the systematic review was included, reporting a sensitivity of 0.87 and a specificity of 0.95.

Interpretation
CIT, CIT and FST has comparable diagnostic accuracy. Based on their pros and cons, it is reasonable to recommend CIT as the first choice to confirm PA in clinical practice. When interpreting the results of CIT, PAC post-CCT is recommended.

Diabetes Prediction and Complications

OC2.1
microRNA expression profile in plasma from patients with type 1 diabetes: a case–control study and bioinformatics analysis
Tais Silveira Assmann1,2, Mariana Recamonde-Mendoza3, Luísa Puentes3, Baldinno Tschiedel3, Luis Henrique Canani1,2 & Daisy Crispim1,2
1Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; 2Postgraduate Program in Medical Sciences: Endocrinology, Faculdade de Medicina, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; 3Instituto da Criança com Diabetes, Porto Alegre, Brazil; 4Institute of Informatics, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Context Since the exact cause of type 1 diabetes mellitus (T1DM) remains unclear, the detection of novel biomarkers is necessary to complement the information obtained from the presence of autoantibodies together with genetic and environmental risk factors. MicroRNAs (miRNAs) are a class of small noncoding RNA molecules that negatively regulate gene expression. Changes in their expression were described in several pathological conditions, including autoimmune diseases. Circulating miRNAs are attractive biomarker candidates as they can be easily collected, are stable under different storage conditions and can be measured using specific assays.

Objective
To investigate a miRNA expression profile in plasma from patients with T1DM and non-diabetic controls and suggest their targets using bioinformatics analysis.

Design
Expressions of 48 miRNAs were investigated in the plasma from 33 T1DM patients and 26 age-and gender-matched controls using Stem-loop RT–PreAmp Real-time PCR and TaqMan Low Density Array cards (Thermo Scientific Inc). Five dysregulated miRNAs were chosen for validation using RT-qPCR in an independent sample (27 T1DM patients and 14 age-and-gender-matched controls).

Results
Nine miRNAs were differentially expressed between controls and T1DM patients with <5 years of diagnosis: 1 miRNA was downregulated (has-miR-146a-5p) while 8 miRNAs were upregulated (hsa-miR-101-3p, hsa-miR-103a-3p, hsa-miR-1275, hsa-miR-146a-5p, hsa-miR-148b-3p, hsa-miR-155-5p, hsa-miR-200a-3p, hsa-miR-210-5p and hasa-miR-21-5p) in patients with <5 years of T1DM diagnosis compared to controls. In contrast, no differences were detected between controls and T1DM patients with >5 years of diagnosis. Bioinformatics analysis evidenced that hasa-miR-103a-3p, hasa-miR-148a-5p, hsa-miR-155-5p, hasa-miR-200a-3p and hasa-miR-210-5p participate in pathways associated with T1DM pathogenesis, such as apoptosis, insulin and immune system.

Conclusions
Our data demonstrate that 9 miRNAs are differentially expressed in T1DM patients in the first years of the diagnosis. Our study also provided novel information about biological pathways implicated in T1DM. Ongoing studies will further explore the role of these miRNAs as possible novel biomarkers for T1DM prediction.

OC2.2
Effectiveness of complex therapy in patients with comorbidity of type 2 diabetes and essential hypertension depending on genetic polymorphism PPARα2
Anna Shalimova, Oleksandr Bilovol & Lesya Bobronnikova
Kharkiv National Medical University, Kharkiv, Ukraine.

The aim
To evaluate effectiveness of complex therapy in patients with comorbidity of type 2 diabetes (DM2) and essential hypertension (EH) depending on genetic polymorphism peroxisome proliferator-activating receptor-γ2 (PPARγ2). Before and after 3 months of treatment we examined 145 patients with EH stage II, grade DM2 moderate, subcompensated aged 45–60 years: group 1 (71 patients) received standart therapy (telmisartan, indapamide, metformin, gliclazide, lipoic acid (LA)). Both groups were matched for age, sex, EH stage and grade, the degree of compensation DM2. Methods: biochemical blood analyses, echocardiography evaluation of mitral diastolic blood flow and tissue Doppler spectral modes, reactive hyperemia, color Doppler mapping, enzyme immunoassay. We conducted genotyping of Pro12Ala polymorphism of PPARα2.

Results
Patients with genotype Pro/Pro of PPARα2 had significantly higher levels of total cholesterol, LDL, proinflammatory cytokines (TNF-α and IL-6), the values of intima-media thickness and significantly lower degree of endothelium-dependent vasodilatation as compared to genotype Pro12Ala/Ala12Ala. After standart therapy in patients with EH and concomitant DM2 (in all PPARγ2 genotypes) metabolic and hemodynamic parameters were improved. More pronounced dynamics was in patients with genotype Pro12Ala/Ala12Ala. Additional appointment of α-LA impacted more to vascular remodeling and levels of
Effect of alive probiotic on insulin resistance in type 2 diabetes patients: randomized clinical trial

Nazarii Kobyliak1, Kateryna Kondratuik1, Dmytro Kyriienko2 & Galyna Mykhailchyshyn1
1Bogomolets National Medical University, Kyiv, Ukraine; 2Kyiv City Endocrinology Center, Kyiv, Ukraine.

Background
Probiotics have beneficial effect on obesity related disorders in animal models. Despite a large number of animal data, randomized placebo-controlled trials (RCT) concluded that probiotics have a moderate effect on glycemic control-related parameters. However, effect of probiotics on insulin resistance are inconsistent.

Aim
In a double-blind single center RCT, effect of alive multistrain probiotic vs placebo on insulin resistance in type 2 diabetes patient were assessed.

Methods

Probiotic therapies modestly improved insulin resistance in patients with type 2 diabetes. Modulation of the gut microbiota represents a new treatment for diabetes and should be tested in larger studies.

Conclusions

A total of 53 patients met the criteria for inclusion. They were randomly assigned to receive multiprobiotic ‘Symbiter’ (concentrated biomass of 14 probiotic bacteria genera Bifidobacterium, Lactobacillus, Lactococcus, Propionibacterium) or placebo for 8 weeks administered as a sachet formulation in double-blind treatment. The primary main outcome was the change HOMA-IR (homeostasis model assessment-estimated insulin resistance) which calculated using Matthews et al.’s equation. Secondary outcomes were the changes in glycemic control-related parameters, anthropomorphic variables and cytokines (TNF-α, IL-1β, IL-6, IL-8, INF-γ) levels. ANCOVA was used to assess the difference between groups.

Results
Supplementation with alive multiprobiotic for 8 weeks was associated with significant reduction of HOMA-IR from 6.85 ± 0.76 to 5.13 ± 0.49 (P = 0.047), but remained static in the placebo group (7.24 ± 0.74 to 7.95 ± 1.01; P = 0.573). With respect to our secondary outcomes, HbA1c insignificantly decreased by 0.09% (P = 0.383) and 0.24% (P = 0.068) respectively in placebo and probiotics groups. However, in probiotic responders (n = 22, patient with decrease in HOMA-IR after supplementation a significant reduction in HbA1c by 0.39% (P = 0.022) as compared to non-responders was observed. In addition, from markers of chronic systemic inflammatory state only TNF-α (15.8%, P < 0.001), and IL-1β (14.4%, nonspecific and somewhat delayed manifestations of renal damage. Thus, earlier DKD new biomarkers are strongly warranted.

Objective
To investigate the urinary peptidomics profile of type 2 diabetes mellitus (DM) patients with different stages of DKD.

Methods
Casual urine samples were collected from 66 type 2 DM patients matched by age, gender and time of diabetes duration. Urine natural occurring peptides were purified by ultrafiltration under denaturing conditions and analyzed by LC-MS/MS. UAE was assessed by immunoturbidimetry and GFR was estimated by CKD-EPI equation. Kruskall–wallis, Mann–Whitney and χ² tests were performed when appropriate; Perseus software was used to perform hierarchical clustering of significantly up- and down-regulated proteins.

Results
Type 2 DM patients (mean age = 61.5 ± 9.7 years; males = 47.1%) were stratified by the levels of albuminuria (normal (n = 27), moderately increased (MI, n = 18) and severely increased (SI, n = 21)). A total of 116 urinary proteins were detected by LC/MS/MS. A distinct proteomic profile was identified in patients with SI albuminuria, represented by 11 proteins. When GFR values were analyzed, we observed that 13 urinary proteins differed significantly in the 9 patients with GFR < 60 ml/min per 1.73 m² when compared to 57 patients with GFR ≥ 60 ml/min per 1.73 m². Among the most remarkably different urinary protein profile, alpha-1 type 1 collagen was around 10% less expressed in SI patients, while alpha-1 antitrypsin, plasma protease C1 inhibitor and apolipoprotein-1 were twofold increased in these patients.

Conclusions
LC-MS/MS analysis revealed that at least 11 urinary proteins were differentially expressed in type 2 DM patients according to DKD severity. This study confirms the previously described findings in other populations and also detected novel proteins commonly altered in patients with GFR impairment and increased albuminuria.

DOI: 10.1530/endoabs.49.OC2.5
**OC3.1 Epigenetic regulation of aldosterone synthase gene, CYP11B2 by potassium**

Yoshiyuki Takeda, Masashi Demura, Takashi Yoneda, Yoshimichi Takeda, Mitsuhiro Kometani, Seigo Konishi & Toshitaka Sawamura
Kanazawa University, Kanazawa, Japan.

**Purpose**

We found the hypomethylation status of CYP11B2 gene in the aldosterone-producing adrenals compared with normal adrenal glands or non-functioning adrenal adenomas and reported that the methylation of promoter region of this gene influenced the mRNA expression in the adrenal cells. Angiotensin II or potassium regulates CYP11B2 gene expression in the adrenal cells. In order to clarify the acute effect of potassium on the methylation status of CYP11B2 gene, Human adrenal cells rats were treated with potassium and the methylation status of CYP11B2 gene in the adrenal cells was examined.

**Methods**

H295R cells were treated with potassium for 28 days. The gene expression of CYP11B2 was measured by real time quantitative PCR in the adrenal cells. ChiP assay and methylation activity were measured. Isolated DNAs from adrenal cells were treated with bisulfite and amplified using primers specific for the human CYP11B2 promoter regions.

**Results**

CYP11B2 mRNA levels were increased from 4th day to 7th day by the treatment with potassium. The methylation ratio was decreased from 4th day. The expression of CREB1 and NR4A1 were increased from 4th day. The methylation activity was increased from 7th day. The chromatin accessibility was increased from 4th day to 7th day.

**Conclusions**

Aldosterone biosynthesis may be reversibly regulated by the epigenetic mechanism.

DOI: 10.1530/endoabs.49.OC3.1

**OC3.2 Elucidating the role of Liver X receptors (LXRs) in the testis using lipid systems biology**

Sheba Jarvis1, Lee Gettings2, Raffaella Gadaleta1,1, Lord Robert Winston3, Catherine Williamson1 & Charlotte Bevan1
1Department of Surgery and Cancer, Imperial College London, Hamme-smith Hospital, London, UK; 2Waters Corporation, Wilmslow, UK; 3Department Interdisciplinare di Medicina, University of Bari, Bari, Italy; 4Womens Health Clinical Academic Group, Kings College London, Guys Campus, London, UK.

**Introduction**

The importance of the liver-X receptors (LXRs) in the maintenance of cholesterol homeostasis within the testis has yet to be fully characterised. By 7 months of age, Lxrα knockout male mouse (Lxrα/ DKO) develops sterility with aberrations in testosterone production and lipid homeostasis. However, the underlying testicular LXR-regulated pathways are not well understood.

**Aim**

The aim of this study was to further understand the importance of LXRs in the testis by investigating disruption of candidate genes and networks of cellular lipids and steroid metabolites in Lxrα/ DKO mice.

**Methods**

We used RNA-seq and quantitative mass spectrometry to study whole testicular tissues from 6-month old Lxrα/ DKO mice alongside age-matched littermate controls. cDNA libraries were prepared followed by sequencing using NextSeq 500. Lipid extracts from mouse testes were prepared for LC-MS analysis using SONAR acquisition, based on an m/z isolation range of the quadrupole. Results were analysed using LipidMaps and Progenesis QI for normalized quantitation.

**Results**

Histological assessment of testicular tissues from Lxrα/ DKO mice confirmed abnormal seminiferous tubules, germ-cell loss and lipid deposition. Quantitative lipidomic analysis confirmed statistically significant differences in 53 lipid species including triglycerides and cholesterol esters (notably 20:4 cholesterol ester) in the Lxrα/ DKO mice. Sphingolipid species (e.g. ceramide 18:0/2:0) were also altered. The retrieved curated targets were mapped onto KEGG pathways analysis, identifying key changes in steroid hormone biosynthesis and sphingomyelin metabolism. RNA-seq analysis revealed 1161 differentially expressed genes (log2 fold change in gene expression of −3.49 to +2.17, P < 0.01) in Lxrα/β DKO. Androgen biosynthesis genes (Cyp17a1, Hsd3b2, Hsd17b3), triglyceride synthesis (Acsl, Aco7) as well as genes involved in sphingolipid metabolism were altered correlating with lipidomic data.

**Discussion**

Our integrative approach using lipidomic analysis with mRNA transcript studies provides novel data, implicating LXRs in pathways such as sphingolipid metabolism, critical for successful spermatogenesis.

DOI: 10.1530/endoabs.49.OC3.2

**OC3.3 AKR1C3-mediated adipose androgen generation drives lipotoxicity in polycystic ovary syndrome**

Michael O’Reilly1, Punith Kempegowda1, Mark Walsh2, Angela Taylor3, Konstantinos Manolopoulos1, William Allwood1, Robert Semple2, Daniel Hebenstreit1, Warwick Dunn1, Jeremy Tomlinson2 & Wiebke Arlt1
1University of Birmingham, Birmingham, UK; 2University of Oxford, Oxford, UK; 3University of Cambridge, Cambridge, UK.

Polycystic ovary syndrome (PCOS) is a prevalent metabolic disorder in women, associated with androgen excess and insulin resistance. These two major features are closely correlated, but the direction of causality remains unclear. Aldoketoreductase type 1C3 (AKR1C3) converts the androgen precursor androstenedione to testosterone (T), and is highly expressed in subcutaneous (SC) adipose tissue. We hypothesised that adipose tissue represents an important site linking androgen activation and metabolic dysfunction in PCOS. We undertook metabolic phenotyping in 10 PCOS women and 10 age- and BMI-matched controls. Participants underwent an oral challenge with the androgen precursor DHEA, alongside adipose tissue microdialysis, with measurement of metabolic markers and adipose androgens in microdialysate fluid. Non-targeted serum metabolome analysis was performed before and after androgen exposure. SC adipose tissue biopsies were collected for RNA-sequencing. Complementary in vitro experiments in primary SC adipocytes and a preadipocyte cell line were performed to examine the effects of insulin and androgens on AKR1C3 expression and de novo lipogenesis, respectively. PCOS women had higher adipose T (P < 0.0006) and dihydrotestosterone (DHT, P = 0.01) than controls as measured by liquid chromatography-tandem mass spectrometry. Non-targeted serum metabolomics and adipose microdialysis revealed pro-lipogenic effects of androgens at baseline and after DHEA in PCOS. AKR1C3 mRNA expression was increased in PCOS SC adipose tissue (P = 0.04). Transcriptional profiling revealed dysregulation of mitochondrial and inflammatory pathways in PCOS SC adipose tissue. In vitro studies showed that insulin upregulates adipose AKR1C3 expression and activity, and androgens enhance adipose de novo lipogenesis. Pharmacological inhibition of AKR1C3 decreased adipose tissue androgen generation and androgen-mediated de novo lipogenesis. Complementary in vivo and in vitro studies highlight that AKR1C3-mediated intra-adipose androgen activation drives lipotoxicity and adverse metabolic risk in PCOS, fuelling a vicious circle of androgen generation and androgen-mediated de novo lipogenesis. Selective inhibition of AKR1C3 holds promise as a novel therapeutic approach in PCOS.

**OC3.4 Treatment with thyroid hormone metabolite 3,5-T2 alters cholesterol and sex steroid metabolism in mouse liver**

Julika Lietzow1, Janine Golcher2, Georg Homuth3, Wenke Jonas3, Claes Ohlsson1, Andreas Landin1, Matti Poutanen3 & Josef Köhrle1
1Institute of Experimental Endocrinology, Charité Universitätmedizin Berlin, Berlin, Germany; 2Interfaculty Institute for Genetics and Functional Genomics, Ernst-Moritz-Arndt-University Greifswald, Greifswald, Germany; 3Department of Experimental Diabetology, German Institute of Human Nutrition, Nuthetal, Germany; 4Institute of Medicine, The Sahlgrenska Academy, Gothenburg University, Gothenburg, Sweden; 5Department of Physiology, Institute of Biomedicine, University of Turku, Turku, Finland.

Recent findings revealed 3,5-diiodo-L-thyronine (3,5-T2) as a metabolically active iodothyronine affecting hepatic energy and lipid metabolism. Therefore, 3,5-T2 has been proposed as a potential hypolipidemic agent for treatment of obesity and its hepatic aftermath. So far only limited data exists relating to the effects of 3,5-T2 on metabolism in euthyroid mammals maintained on high-fat.
diet from the day of weaning onwards. Therefore, we performed a study in which 20-week old diet-induced obese male mice in comparison to lean animals received either 3.5-T2 (2.5 g/kg body weight) or saline over a four-week period. To identify new target genes and signaling mechanisms of 3.5-T2 which are distinct from established hepatic T3 action we performed microarray-based transcriptome analyses of liver tissue. The transcriptome as well as qPCR data demonstrated higher hepatic expression of genes involved in cholesterol biosynthesis (e.g. Srele 4.8-fold, Cyp51 2.8-fold, Hsd17b7 1.8-fold) and bile acid formation (Cyp7a1 2.0-fold, Cyp9a1 2.9-fold) in obese but not in lean mice treated with 3.5-T2. In contrast to the elevation of hepatic cholesterol biosynthesis, serum cholesterol concentration was reduced by up to 57% with 3.5-T2 administration. In addition, 3.5-T2 modulated expression of genes important for sex steroid biosynthesis and inactivation (e.g. Cyp17a1 3.5-fold, Hsd11b2b -7.8-fold). GC-MS/MS analysis of the hepatic sex steroid hormone profile indicated higher progesterone and androstenedione content in livers of obese mice treated with 3.5-T2, whereas no such changes were observed in 3.5-T2-treated lean mice. These results suggest a diet-dependent role of 3.5-T2 in modulating local cholesterol as well as sex steroid biosynthesis and androgen homeostasis in mouse liver. Such actions of thyroid hormone metabolites have not been reported elsewhere up to date and might help to explain liver-targeting effects of T3-receptor beta-selective ligands.

Hypothyroidism in pregnancy is associated with twin pregnancies and with adverse obstetric outcome: Analysis of 142,277 deliveries data from a single center

Ort Barenholz-Goulltschin1,2, Rivka Farkash1,2, Arnon Samuolloff1,2 & Gabriel Munter3

1Shaare Zedek Medical Center, Jerusalem, Israel; 2Hebrew University, Jerusalem, Israel.

Introduction

Many studies have examined maternal and fetal complication rates in treated and untreated overt and subclinical hypothyroidism. Maternal hypothyroidism may adversely affect the development of the fetal pituitary-thyroid axis. It has also been reported to be closely related to adverse pregnancy outcome.

Aim

To study the prevalence and outcome of hypothyroidism in pregnancy during the last decade in a high volume obstetric center in Jerusalem.

Methods

A retrospective study of the obstetric database between August 2005 and December 2015 in Shaare Zedek Medical Center, Jerusalem.

Results

During the study period there were 142,277 deliveries of singleton or twin pregnancies (1.9% twin deliveries). The medical files of 4042 (2.8%) deliveries (group A) included a diagnosis of maternal hypothyroidism. Women giving birth with the diagnosis of hypothyroidism were older (31.1 ± 6 years 28.8 ± 5.6 y, P < 0.0001). Gestational diabetes was more prevalent (7.3% vs 3.3%, P < 0.0001) in group A as were hypertensive disorders (3.7% vs 2.3%, P < 0.0001). Higher rate of assisted reproduction techniques were used in group A (5.3% vs 3.7%, P < 0.0001). Although not previously reported, the incidence of twin pregnancies was higher in group A (3.8% vs 1.8% P < 0.0001) and this association remained significant in a multivariate analysis with IVF as a co-variate (OR 1.43 95%CI[1.20–1.71], P < 0.0001). Obstetric complications including preterm deliveries (7.8% vs 5.2%, P < 0.0001), cesarean sections (20.6% vs 11.4%, P < 0.0001), any obstetric hemorrhage and prolonged hospitalization were more frequent in group A. The incidence of adverse neonatal outcome including low birth weight (7.3% vs 5.4%, P < 0.0001) and NICU admission (5.1% vs 3.6%, P < 0.0001) was higher in group A but there was no difference in fetal macrosomia and apgar scores.

Conclusions

In this large database, hypothyroidism is associated with adverse obstetric outcome. This is the first study to describe a higher incidence of hypothyroidism in twin pregnancies. TSH screening should be considered in twin pregnancies.

Inducible thyrocyte-specific Gs alpha-deficient mice as a novel model for hypothyroidism

Konrad Patyra1, Holger Jaeschke1, Henriette Undeutsch1, Christoffer Löf1, Zaki Hassan-Smith1, Lorna Gilligan1, Matt Armstrong1, Philip Newsome1, Tahir Shah3, Wiebke Arlt2 & Jeremy Tomlinson1

1Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, UK; 2Centre for Endocrinology, Diabetes & Metabolism, Oxford University Hospitals, Oxford, UK; 3Centre for Liver Research, University of Birmingham, Birmingham, UK.

Aim

We have previously demonstrated that a single two-stage feeding regimen during lactation, which increased the thyroid hormone metabolite 3,5,3'-triiodothyronine (3,5-T2) during the first stage, resulted in the induction of a Gsα-/- phenotype in the offspring. Furthermore, unbiased GMLVQ analysis of the urinary steroid metabolome appears robust in differentiating healthy controls from cirrhosis and warrants further exploration as a novel non-invasive biomarker tool to assess the severity of NAFLD.

Methods

Using gas chromatography / mass spectrometry, we analysed steroid metabolites in spot urine samples (corrected for creatinine) in patients with biopsy proven NASH (n=65), NAFLD cirrhosis (n=51), alcoholic cirrhosis (n=48) and in healthy controls (n=58). Additionally, we used machine learning-based analysis to investigate changes across 32 steroid metabolites.

Results

Cortisol regeneration (11β-HSD) activity: THF-5αTHF/THF ratio, was significantly increased in NAFLD cirrhosis (P = 0.0004), and alcoholic cirrhosis (P < 0.0001), compared to controls. Cortisol inactivation (A-ring reductase activity: THF-5αTHF ratio) was significantly reduced in NAFLD cirrhosis compared to controls (P = 0.0004), but not between controls and alcoholic cirrhosis (P > 0.099) nor NASH (P = 0.332). Machine learning-based analysis by generalised matrix-learning vector quantisation (GMLVQ) achieved excellent separation of control and NASH groups (AUC-ROC = 0.87). Furthermore, there was near perfect separation of controls from NAFLD cirrhosis (AUC-ROC = 0.99) and controls from alcoholic cirrhosis (AUC-ROC = 0.98).

Conclusion

This data is consistent with our previous findings that identified differentially regulated steroid metabolic pathways across the spectrum of NAFLD.

Endocrine Abstracts (2017) Vol 49
a thyrocyte-specific tamoxifen-inducible Gs deficient mouse line (iTGKO). Mice were injected with tamoxifen at P28 and phenotypic characterization was carried out by performing thyroid function tests at different ages. iTGKO mice showed hypothyroidism at P56, four weeks after induction with tamoxifen. Furthermore, a decrease in thyroid weight and an increased pituitary weight support the conclusion of hypothyroidism in these mice. Morphometric analysis of the thyroid histology of iTGKO mice with an age of 6 months (P168) showed that the thyrocyte layers between adjacent follicles and the follicle areas were significantly reduced when compared with controls. Interestingly, despite of an identical thyroid hormone status we observed a clear sex difference. In iTGKO males, the body weight was significantly decreased at P70 when compared with control males but no weight difference was seen in females over the investigated time period of 6 months (P168). The lower body weight in iTGKO males was associated with reduced fat mass. In summary, we show that iTGKO mice are a useful tool for understanding the role of G-protein signaling in the thyroid as well as investigating the metabolic consequences in hypothyroidism.

The TSH receptor reaches the trans-Golgi network to induce PKA activation and trigger gene transcription

Amol Godbole1,2, Sandra Lyga1, Martina Les1,2 & Davide Calebio1,2

1Institute of Pharmacology and Toxicology, University of Würzburg, Würzburg, Germany; 2Bio-Imaging Center/Rudolf Virchow Center, University of Würzburg, Würzburg, Germany.

Whereas G-protein coupled receptors (GPCRs) have long been believed to signal via cyclic AMP (cAMP) exclusively at the cell surface, our group has shown that GPCRs also stimulate cAMP production from the cell interior once internalized together with their ligands. This phenomenon, which we originally described for the thyroid stimulating hormone receptor (TSHR) in thyroid follicles, has now also been shown for several other GPCRs. However, the involved subcellular compartment(s) and the mechanisms linking signalling by internalized GPCRs to downstream biological effects are largely unknown. The aim of this study was to follow the trafficking of internalized TSHRs and involved signalling proteins in living primary thyroid cells by highly inclined thin illumination (HILO) microscopy as well as to monitor cAMP production and protein kinase A (PKA) activation by real-time fluorescence resonance energy transfer (FRET) microscopy. Importantly, using a biosensor nanobody that is specific for the active Gs-protein, we were able to directly demonstrate that the internalized TSHR activates an endogenous pool of Gs-protein located on membranes of the Trans Golgi Network (TGN). Direct monitoring of PKA activation with a Golgi-localized FRET sensor (AKAR2) showed a delayed PKA activation (approx. 10 min) after TSH stimulation, which is compatible with the time required for TSH/TSHR complexes to reach the Golgi/TGN. Moreover, our results also indicate that Gs-protein mediated signalling by internalized receptors at the TGN and the resulting PKA activation at a critical position near the nucleus are required for the efficient induction of CREB phosphorylation and gene transcription. These findings provide a mechanism to explain the biological relevance of GPCR signalling at intracellular sites, which might help explaining the pathogenesis of endocrine disorders such as Graves’ disease and might pave the way to innovative pharmaceutical therapies.

Levothyroxine replacement therapy: once treatment is started, should it last indefinitely?

Sarantis Livadas1, Christina Bothou1, Ioannis Androulakis1, Anastasios Boniakos1, Nicholas Angelopoulos1 & Leonidas Duntas2

1Endocrine Unit, Metropolitan Hospital, Athens, Greece; 2Unit of Endocrinology, Diabetes and Metabolism, Evgenideion Hospital, University of Athens, Athens, Greece.

Background
Levothyroxine (LT4) is one of the most prescribed drugs worldwide. Once started, about 90% of patients continue LT4 treatment long-term.

Aim of the study
To evaluate the necessity of long-term thyroxine supplementation and to determine the prognostic factors that could identify which patients may discontinue LT4 treatment.

Design and methods
LT4 replacement therapy was paused for at least six weeks in all patients consecutively visiting our department, excluding those who have a definite need for l-thyroxine use (replacement after total thyroidectomy), those on thyroid-altering medication, women wishing to conceive and those who gave birth last year. 231 individuals were assessed (84% females), aged 48 years (SD 15), who were categorized into the following categories: a) unknown reason for LT4 treatment, those on thyroid-replacement therapy was paused for at least six weeks in all patients (n = 62), b) presence of thyroid nodules (n = 44), over 10 years’ use of LT4 (n = 10), therapy initiated post-pregnancy (n = 20). Thyroid function was evaluated before and after the thyroxine pause. A value of TSH ≥ 4.5 IU/ml post treatment discontinuation was considered as ‘relapse’ and LT4 was reinstituted in those individuals. The potential prognostic factors analyzed were family history of thyroid dysfunction, sex, age, dose per BMI and dose per kg, thyroid volume, thyroid ultrasound characteristics, positivity of thyroid autoantibodies, basal TSH values and reason for the initial treatment indication.

Results
25.5% (83% females) of the studied subjects relapsed. Of the above-described factors, only diffuse inhomogeneous echogenicity was tentatively identified as the only predictive factor for relapse (71% vs 57%, P = 0.001). The age (47.27 ± 15.45 vs 48.17 ± 16.98 years, P = 0.072), the positivity of TPOAb (69% vs 54%, P = 0.064) and basal TSH values (1.51 ± 0.96 mIU/l vs 1.57 ± 0.84, P = 0.81) did not differ significantly among the two groups.

Conclusions
One out of four individuals evaluated required thyroxine treatment. The need for a patient-centered approach regarding l-thyroxine supplementation and for a thorough review of patient history was evident.

DOE: 10.1530/endoabs.49.OC4.5
Arterial hypertrophy is a major health problem affecting 1.13 billion people worldwide, of which 10% could be due to endocrine pathologies related to the mineralocorticoid receptor (MR) (i.e. primary aldosteronism, 11β-hydroxysteroid dehydrogenase type 2 enzyme (HSD11B2) deficiency). The MR pathway is expressed mainly in placenta, kidney and colon epithelial cells. Current research highlights potential epigenetic regulatory mechanisms for the MR pathway. Here, specific miRNAs are being studied as epigenetic regulators, either present in cells or exosomes (nanovesicles of 40–150 nm diameter) carrying miRNA, RNA, lipids and proteins. Those miRNAs could dynamically influence the onset and progression of the mineralocorticoid arterial hypertrophy (Ah).

To isolate exosomes from polarized epithelial cells and to identify in their cargo miRNAs affecting HSD11B2 and MR gene expression.

Methods

The bioinformatic tool mirWalk2.0 was used to determine miRNAs capable to interact with HSD11B2 and MR RNAs. The cell line derived from colon epithelia (Caco-2) was cultured and polarized in Transwells. MR pathway genes and miRNAs targeting the MR and HDS11B2 were measured by qPCR. Exosomes from apical and basolateral culture medium were isolated at 24 h of incubation in basal conditions, quantified with NanoSight-NS300 and their specific miRNA content was determined.

Results

We identified bioinformatically that miRNA 135b, 644a and miRNA 488, 1205 could interact with the MR and HSD11B2, respectively. Caco-2 cells polarize after 21 days of culture (trans-epithelial resistance (TEER): 114.18 cm²), expressing polarization genes (SLC11A2, SLC11A1, SLC12A2, SLC12A1, SLC12A5, SLC12A7, SLC12A6, SLC12A8) with a combination of miRNA 135b, 644a and miRNA 488, 1205. We identified that Caco-2 release 21×10⁹±0.69×10⁹ (apical) and 4.1×10⁹±0.0029×10⁹ (basolateral) extra-cellular vesicles per ml of which a 36.8 and 38.5% are exosomes with a modal range in 124–125 nm diameter respectively. Preliminary results show expression of miRNA 135b, 644a, 488 and 1205 in apical and basolateral exosomes.

Conclusion

Caco-2 cells release five-times more exosomes in the apical than basolateral side, both carrying miRNAs that could interact HSD11B2 and MR gene.

DOI: 10.1530/endoabs.49.OC5.1
Conclusion
The non-R482 presented more arrhythmias than the R482-carriers, who were twice more often diabetic with more coronaryopathies. The frequency of diabetes reached, however 40% in non-R482 mutations. The follow-up of laminopathies should be adjusted to the genotype. Arrhythmias, especially associated to diabetes or medical device family history should lead to LMNA genetic testing.

Food history characterization of Portuguese centenarians, nutritional biomarkers and cardiovascular risk: case control study
Alda Pereira da Silva1,2, Catarina Chaves1, Andreia Matos1,3, Angela Gil1,4, Carolina Santos1,5, Ana Valente1, Manuel Bicho1,6 & João Gorjão Clara1
1Genetics Laboratory, Environmental Health Institute – ISAMB, Faculty of Medicine, University of Lisbon, Lisbon, Portugal; 2Geriatric Universitary Unit of Faculty of Medicine, University of Lisbon, Lisbon, Portugal; 3Centro Hospitalar de Lisboa Central, Lisbon, Portugal; 4Department of Nutritional Science, Atlantic University, Barcarena, Portugal; 5Instituto de Investigac¸a˜o Cientı´fica Bento da Rocha Cabral, Lisbon, Portugal.

Introduction
Eating habits may contribute to longevity. Consumption of red meat, source of saturated fatty acids and cholesterol may be associated with increased risks of diabetes, cardiovascular disease (CVD), and mortality risk.

Methods
We studied 521 subjects, both genders, 253 centenarians (CENT) (100.26 ± 2.19 age) and 268 controls (67.51 ± 3.25 age), both low (LCR) and high cardiovascular risk (HCR), calculated based on QRISK algorithm. SBP (95.71 ± 11.7 vs 99.2 ± 1.0 mmHg, P < 0.0001) and HR (662 ± 3 vs 687 ± 4 bpm, P < 0.0001) were significantly lower in females compared to males. This was accompanied by a sex and tissue-specific expression of MR signaling pathway from fetal stage (E18) to adulthood, notably for GR (Nsr3c1) and Gilz renal mRNA expression which was twofold-lower in adult females mice compared to males (P < 0.01). Moreover, 11βHSD2 mRNA and protein expression was found significantly increased in females (P < 0.05), with a statistically different ratio of corticosterone/dehydrocorticosterone between sexes (P = 0.012). Finally, the implication of sex hormones in this sex-specific expression profile was confirmed in vitro, most notably for Gilz mRNA expression. We demonstrate a tissue-specific, sex-dependent and developmentally-regulated pattern of expression of MR signaling that could have important implications in physiology and pathology, particularly in the development of essential hypertension in men.

A passe-PAR2 for β-cell regeneration and protection
Ron Piran1 & Fred Levine2
1Bar Ilan University’s Faculty of Medicine, Safed, Israel; 2Sanford Children’s Health Research Center, Sanford Burnham Prebys Medical Discovery Institute, La Jolla, California, USA.

Cell and tissue damage, particularly to pancreatic β-cells, is an essential characteristic of diabetes mellitus, triggered by autoimmune destruction of β-cells in type-1 (T1D) and by obesity associated factors or insulin resistance in type 2. Thus, stimulating β-cell regeneration has long been a most important goal of diabetes research. Recently, we have shown that pancreatic injury consisting of acinar cell inflammation and β-cell destruction led to islet cell transdifferentiation. In this work, we report that the molecular mechanism for this process requires the activation of the protease-activated receptor-2 (PAR2), a G-protein-coupled receptor. PAR2 modulation was sufficient to induce islet cell transdifferentiation in the β-cells ablated animals as PAR2 Knock out mice and mice injected with PAR2 pharmacological activator showed that it was necessary and sufficient for the induction of islet cell transdifferentiation in the settings of β-cell ablation. PAR2 expression was modulated in an islet cell type-specific manner in murine and human T1D. In addition to transdifferentiation, PAR2 regulated β-cell apoptosis in caerulein-mediated pancreatitis, demonstrating that PAR2 was required for β-cell survival and protection during inflammation.

Sex dimorphism of renal corticosteroid signaling during development and long term consequence on blood pressure
Laurence Dumeige1, Caroline Storey1,2, Lyvianne Decourtye3, Mélanie Nehlich1,4, Christophe Lhadj1,4, Say Viengchareun1, Laurent Kappeler1, Marc Lombes1,2 & Laëtitia Martinere1,2
1INSERM 1185, Le Kremlin Bicêtre, France; 2Service d’endocrinologie pédiatrique, hôpital Robert Debré, APHP, Paris, France; 3INSERM UMR-S 938, Paris, France; 4Prem Up foundation, Paris, France.

Sex differences have been demonstrated in various biological processes such as arterial blood pressure. However, the potential sex dimorphism of the renin-angiotensin-aldosterone system and, by extension, the mineralocorticoid receptor (MR) signaling pathway, major regulators of blood pressure, has only been poorly studied, notably in the kidney. Basal systolic blood pressure (SBP) and heart rate (HR) were measured in adult male and female mice. Renal gene expression studies of major players of MR signaling were performed at different developmental stages in male and female mice using RT-qPCR, and were compared to that of the same genes in the lung, another mineralocorticoid epithelial target tissue. The potential role of sex hormones in the regulation of these genes was also investigated in differentiated KC3AC1 renal cells. Additionally, renal expression of the 11βHSD2 protein, a regulator of mineralocorticoid specificity, was measured by immunoblotting and its activity was indirectly assessed in the plasma using LC-MSMS method. SBP (91.7 ± 1.1 vs 99.2 ± 1.0 mmHg, P < 0.0001) and HR (662 ± 3 vs 687 ± 4 bpm, P < 0.0001) were significantly lower in females compared to males. This was accompanied by a sex and tissue-specific expression of MR signaling pathway from fetal stage (E18) to adulthood, notably for GR (Nsr3c1) and Gilz renal mRNA expression which was twofold-lower in adult females mice compared to males (P < 0.01). Moreover, 11βHSD2 mRNA and protein expression was found significantly increased in females (P < 0.05), with a statistically different ratio of corticosterone/dehydrocorticosterone between sexes (P = 0.012). Finally, the implication of sex hormones in this sex-specific expression profile was confirmed in vitro, most notably for Gilz mRNA expression. We demonstrate a tissue-specific, sex-dependent and developmentally-regulated pattern of expression of MR signaling that could have important implications in physiology and pathology, particularly in the development of essential hypertension in men.

DOI: 10.1530/endoabs.49.OC5.5

Endocrine Abstracts (2017) Vol 49
It has been suggested that the selective m-TOR inhibitor, Rapamycin, has been improved the success pancreatic islet allotransplantation (ITx) in type 1 diabetic patients (TIDM). Forty-one ITx were studied. Thirteen TIDM in poor glycemic control underwent a 45-days Rapamycin before ITx followed by standard Edmonton Protocol (EP, group 1, Milan), and they were compared to 28 TIDM patients undergoing EP (group 2, Miami). Outcome measures were daily insulin requirement (DIR), HbA1c, C-peptide and the SUITO index of cell-beta function before and 1 year after ITx. Four patients from group 1 underwent euglycemic-hyperinsulinemic clamp with 6.6-d2-glucose infusion before and after ITx. We found a significant reduction in DIR after Rapamycin pre-treatment (< 8 ± 6 U/day, mean ± s.d., P < 0.001). Nine patients from group 1 fulfilled follow-up. One year after ITx, DIR significantly decreased (< 37 ± 15 U/day, P < 0.001) and six patients became insulin independent. We observed greater DIR reduction in group 1 as compared to group 2 at 1-year follow-up (< 37 ± 15 vs. < 19 ± 13 U/day, P = 0.005), which remained significant after adjusting for gender, age, glucose and baseline HbA1c (beta coefficient of multivariate regression analysis ± s.e. 18.2 ± 5.9, P = 0.006). In patients from group 1, HbA1c significantly decreased 1 year after ITx (< 2 ± 1.4%, P = 0.002), while C-peptide (< 1.5 ± 0.9, P = 0.002), and SUITO index increased (+ 57.4 ± 39.7, P = 0.016). We did not observe differences in change between group 1 and 2 as far as HbA1c, C-peptide and SUITO index are concerned before and after ITx. Hepatic glucose production during the insulin clamp decreased after Rapamycin pre-treatment (< 1.1 ± 1.1 mg/kg per min, P = 0.04) and after ITx (< 1.6 ± 0.6 mg/kg per min, P = 0.015), while no changes in peripheral glucose disposal were observed during Rapamycin treatment. In conclusion, Rapamycin contributes to improve metabolic control also enhancing hepatic insulin sensitivity after ITx. Rapamycin pre-treatment may improve ITx success rate by reduction of pre-transplant DIR and increase of hepatic insulin sensitivity.

Alterations in DNA methylation from peripheral blood cells in humans treated with metformin
Janis Klovins1, Ilze Elbere1, Raatis Peculis1, Ineta Kalnina1, Linda Zaharenko1, Ilze Konade1 & Valdis Pirts1
1Latvian Biomedical Research and Study Centre, Riga, Latvia; 2Department of Endocrinology, Pauls Stradins Clinical University Hospital, Riga, Latvia, 3Riga Stradins University, Riga, Latvia
Metformin is a biguanide class agent widely used as a first-line treatment for type 2 diabetes, however the detailed mode of action and exact pharmacodynamics has not been clarified. Moreover there is no studies in humans displaying the effect of metformin on DNA methylation. We therefore performed a clinical study involving twelve healthy nondiabetic individuals who were subjected to the 1 week of metformin (2 x 850 mg/day) treatment. Peripheral blood for DNA isolation was drawn at three time points during metformin treatment: i) right before metformin treatment, ii) 10 hours after the first metformin dose and iii) after a week-long metformin administration. DNA methylation was estimated using genome-wide Illumina Infinium HumanMethylation450 BeadChip (Illumina), which allows interrogation of 485 512 CpG dinucleotides. Analysis global methylation data displayed predominance of demethylated CpGs over the methylated as the result of metformin treatment. In order to identify differentially methylated gene promoter regions we filtered all CpGs located in 5000 bp proximity of the transcription start site and having the methylation change across all samples larger than 3% with Bonferroni corrected P values. This stringent approach resulted total in 35 genes with differentially methylated CpG regions near the promoters. Five genes, considered most likely biologically relevant to have impact in diabetes were those involved in processing of energy molecules, differentiation and formation of adipocytes and exhibiting GTF-ase activities. Eighteen regions included genes with known specific functions that are not directly linkable to influencing diabetic phenotype. Finally 12 genes where either pseudogenes or had unknown function. In conclusion this is the first study that shows influence of metformin in altering DNA methylation in humans and identified markers may prove to be valuable biomarkers for the understanding of the molecular basis of metformin action and may lead to the identification of new drug targets.

DOI: 10.1530/endoabs.49.OC6.3

Insulin-mimetic effects of short-term Rapamycin in type 1 diabetic patients prior islet transplantation

It has been suggested that the selective m-TOR inhibitor, Rapamycin, has been improved the success pancreatic islet allotransplantation (ITx) in type 1 diabetic patients (TIDM). Four-ten ITx were studied. Thirteen TIDM in poor glycemic control underwent a 45-days Rapamycin before ITx followed by standard Edmonton Protocol (EP, group 1, Milan), and they were compared to 28 TIDM patients undergoing EP (group 2, Miami). Outcome measures were daily insulin requirement (DIR), HbA1c, C-peptide and the SUITO index of beta-cell function before and 1 year after ITx. Four patients from group 1 underwent euglycemic-hyperinsulinemic clamp with 6.6-d2-glucose infusion before and after ITx. We found a significant reduction in DIR after Rapamycin pre-treatment (< 8 ± 6 U/day, mean ± s.d., P < 0.001). Nine patients from group 1 fulfilled follow-up. One year after ITx, DIR significantly decreased (< 37 ± 15 U/day, P < 0.001) and six patients became insulin independent. We observed greater DIR reduction in group 1 as compared to group 2 at 1-year follow-up (< 37 ± 15 vs. < 19 ± 13 U/day, P = 0.005), which remained significant after adjusting for gender, age, glucose and baseline HbA1c (beta coefficient of multivariate regression analysis ± s.e. 18.2 ± 5.9, P = 0.006). In patients from group 1, HbA1c significantly decreased 1 year after ITx (< 2 ± 1.4%, P = 0.002), while C-peptide (< 1.5 ± 0.9, P = 0.002), and SUITO index increased (+ 57.4 ± 39.7, P = 0.016). We did not observe differences in change between group 1 and 2 as far as HbA1c, C-peptide and SUITO index are concerned before and after ITx. Hepatic glucose production during the insulin clamp decreased after Rapamycin pre-treatment (< 1.1 ± 1.1 mg/kg per min, P = 0.04) and after ITx (< 1.6 ± 0.6 mg/kg per min, P = 0.015), while no changes in peripheral glucose disposal were observed during Rapamycin treatment. In conclusion, Rapamycin contributes to improve metabolic control also enhancing hepatic insulin sensitivity after ITx. Rapamycin pre-treatment may improve ITx success rate by reduction of pre-transplant DIR and increase of hepatic insulin sensitivity.

Copeptin and its association to cardiovascular dysfuntion in type 2 diabetes
Simona Ioana Chisalita1, Lee Ti Chong2, Fredrik Nyström3, Carl Johan Östgren4 & Toste Länne5
1Department of Endocrinology and Department of Medicine and Health Sciences, Linköping University, Linköping, Sweden; 2Department of Emergency and Department of Medicine and Health Sciences, Linköping University, Linköping, Sweden; 3Department of Medical and Health Sciences (IMH)/Division of Community, Linköping, Sweden; 4Department of Thoracic and Vascular Surgery, and Department of Medicine and Health Sciences, Linköping University, Linköping, Sweden.
Background
We aim to test whether plasma copeptin (copeptin), the C-terminal fragment of vasopressin, has predictive value of cardiovascular events in patients with type 2 diabetes without previous cardiovascular disease who were treated in primary care.

Methods
We measured copeptin in 697 patients who participated in the epidemiological study CARDIPP (Cardiovascular Risk Factors in Patients with Diabetes – a Prospective Study in Primary Care; ClinicalTrials.gov identifier NCT01049737) and who did not have previously known myocardial infarction or stroke. The outcome variable was a composite endpoint consisting of cardiovascular mortality, hospitalization for myocardial infarction and hospitalization for stroke.

Results
During a median follow-up time of almost 7 years, the unadjusted HR per each increment of Copeptin by 1 pmol/l was 3.5 (95% CI 1.7–7.1, P < 0.001) for the primary endpoint. Following adjustments for age, sex, HbA1c, arterial stiffness (PWV) as well as atherosclerosis plaque the adjusted hazard ratio was 2.4 (95% CI 1.1–5.2, P = 0.03).

Conclusions
In primary preventive patients with type 2 diabetes treated in primary care, copeptin predicted a composite outcome of incident cardiovascular events independently of age, sex, HbA1c, arterial stiffness as well as atherosclerosis plaque.

Insulin resistance and type II diabetes (T2D) are associated with activation of the Renin-Angiotensin-Aldosterone-System (RAAS) in part via regulation of its principal effector molecule, Angiotensin II (AngII). Endothelial cell activation leads to, among other factors, increased

DOI: 10.1530/endoabs.49.OC6.5
extracellular protein disulfide isomerase (PDI), a multifunctional protein that is critical to thrombus formation and regulation of reactive oxygen species. However, the effects of RAAS on PDI are unknown. We studied the in vivo effects of AngII on EA.hy926 human endothelial cells and measured PDI activity. Our results show that AngII (10 nM), dose- and time-dependently, increased PDI activity (P < 0.05, n = 6); an event that was blocked by pre-incubation with 0.5 μM losartan, an AngII Type I receptor antagonist (ARB). Western blot analyses showed increased PDI following AngII that was likewise reduced by losartan. In normal in Sprague–Dawley rats, we studied the in vivo effects of exogenous AngII infusion and observed significant increases in plasma PDI levels (P < 0.05, n > 5) that were blunted by ARB treatment. We then studied the obese Otsuka Long Evans Tokushima Fatty (OLETF) (n = 6/group) rats, a model of naturally increased AngII and RAAS-mediated insulin resistance and hypertension. Our results show that OLETF rats had increased insulin resistance and greater circulating PDI activity than lean control rats (P < 0.05) and was reduced by ARB treatment to baseline levels (P < 0.05). To assess the clinical relevance of our findings, we measured circulating PDI in subjects with and without T2D. PDI activity correlated with measures of insulin resistance in our cohort (HOMA2-IR, Spearman P = 0.496, P < 0.001, n = 134) and was significantly greater in T2D patients than healthy controls (P < 0.01, n = 56 vs 78, respectively). Our data in human and animal models suggest that RAAS activation represents a novel mechanism for PDI secretion. Thus we posit that PDI may contribute to the deleterious effects of RAAS-mediated vascular disease.

Background
Adrenocortical cancer (ACC) is an aggressive tumour with heterogeneous prognosis. Recently integrated genomics reported distinct genomic alterations: transcriptome “C1A” (high expression of proliferation/cell cycle-related genes) vs “C1B”, “CIMP” (CpG islands hypermethylation) vs “non-CIMP”, chromosome alterations “Noisy” (numerous and anarchic alterations) vs “Chromosomal” (extended patterns of loss of heterozygosity) and “Quiet” (limited alterations), and recurrent somatic mutations in 20 genes. These alterations converge into a single three-groups classification, correlating with outcome. The aim was to develop and validate targeted molecular markers reflecting these genomic groups. Patients and methods Two hundred and forty five ACC were included from 21 ENSAT (European network for the Study of Adrenal Tumors) centers. Tumor RNA was assessed by RT-qPCR for BUB1B-PINK1 expression (n = 135). Tumor DNA was studied by SNP array for chromosomal alterations (n = 238), targeted NGS for mutations of 20 driver genes (n = 251), and MS-MLPA for CpG islands methylation of four genes -PAX5, GSTP1, PYCARD, PAX6- (n = 221).

Results
Gene expression levels identified “C1A”, “C1B” and “undetermined” ACC in 50, 38 and 12% of cases respectively. Methylation assay identified “CIMP” and “non-CIMP” ACC in 44 and 56% of cases respectively. Chromosomal alteration profiles identified “chromosomal”, “noisy” and “quiet” ACC in 55, 32 and 13% of cases respectively. Recurrent mutations or deletions were found in ZNF63, CDKN2A, TP53 and CTNNB1 in 21, 17, 15 and 11% of cases respectively, in agreement with previous exome studies. All molecular statuses were available for 107 tumors. 87/107 (81%) concordantly recapitulated the 3 main ACC subgroups previously identified by genomic classifications: 37 were “C1A/CIMP”, 18 were “C1A/non-CIMP”, and 32 were “C1B/non-CIMP”. Death events occurred in 34/37, 7/18 and 1/32 patients respectively (Fisher exact P < 0.10–15).

Conclusion
Targeted molecular measures can recapitulate the genomic classification of ACC, giving original and useful prognostication information for patient management. DOI: 10.1530/endoabs.49.OCT7.2

A novel insight into the anticancer mechanism of metformin in Pancreatic Neuroendocrine Tumor cells
Eleonora Vitali1, Sara Piccinini1, Ilena Boemi1, Alberto Tresoldi1, a, Alessandro Zerbi2, Carlo Carnaghi3, Anna Spada4 & Andrea Lania1, a
1Laboratory of Cellular and Molecular Endocrinology, IRCCS Humanitas Research Hospital, Rozzano, Italy; 2Pancreas Surgery Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; 3Endocrinology Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; 4Endocrinology and Diabetology Unit, IRCCS Ospedale Maggiore Policlinico, Milano, Italy; 5Department of Biomedical Sciences, Università Humanitas, Rozzano, Italy.

Metformin (1,1-dimethylbiguanide hydrochloride), a widely used antidiabetic drug, has been reported to display potent anticancer properties in various types of cancers, including neuroendocrine tumors. Recently, a potential synergistic activity between metformin and octreotide (SSA) in Pancreatic Neuroendocrine Tumors (P-NETs) has been proposed. AIP (aryl hydrocarbon receptor-interacting protein) acts as tumor suppressor gene in neuroendocrine tumors at pilatory level and it is up-regulated by SSA. We investigated the effects of metformin on P-NETs cell proliferation, apoptosis and colony formation, the potential synergistic effect between metformin and octreotide and the possible role of AIP pathway in mediating these effects. We found that in QGP-1 cells metformin significantly inhibited cell proliferation (~37±2% P<0.001 vs basal at 10 mM). We showed no additive effect between Metformin and Octreotide on P-NETs cell proliferation. Moreover, metformin incubation reduced colony formation, cells amount after 7 days (~66±6% P<0.001 vs basal) and it promoted apoptosis (~150±8% P<0.05 vs basal). As expected, octreotide induced AIP up-regulation (~+60±11% P<0.05 vs basal), and surprisingly, AIP expression levels were also increased by metformin (~+90±13% P<0.05 vs basal). In addition, AIP silencing abolished the antiproliferative and proapoptotic effects of metformin, confirming its involvement in mediating metformin effects. Interestingly, metformin decreased HSP70 expression, increased Zca1 and AhR expression levels. These effects were totally abolished in QGP-1 cells lacking AIP. In conclusion, metformin acts as an anticancer agent in P-NET cells, its activity is mediated by AIP and its interacting proteins, HSP70, AhR and Zca1. These findings provide a novel insight into the antitumorigenic mechanism of metformin.

Regulation of steroid receptor signalling by tumor suppressor INPP4B
Manqi Zhang1, Egla Suarez2, Lubov Nathanson3, Michael Ittmann3, a, Nancy Weigel4 & Irina Agoulnik5
1Florida International University, Miami, FL, USA; 2Nova Southeastern University, Ft. Lauderdale, FL, USA; 3Baylor College of Medicine, Houston, TX, USA.

Androgen receptor (AR) signaling is the main driver for prostate cancer progression and androgen ablation is the treatment of choice for tumors that spread beyond the prostate. Efficient at first, androgen ablation fails due in part to altered cell signaling and expression of AR splice variants. Cell signaling in prostate cancer is regulated by dual specificity phosphatases and tumor suppressors INPP4B and PTEN that are lost with prostate cancer progression. Loss of PTEN destabilizes AR and alters AR transcriptional output. We investigated how loss of INPP4B affects AR signaling. We have previously shown that AR induces expression of INPP4B in prostate cancer. Intriguingly, AR splice variant AR-V7, which also contributes to ADT resistance, was unable to induce INPP4B expression. We performed microarray analysis of changes in gene expression caused by INPP4B knockdown. Gene expression clustering and GSEA analysis revealed that the INPP4B loss significantly altered AR transcriptional activity. Using immunofluorescent labeling with 3D rendering we determined that INPP4B localizes to cellular and endoplasmic membranes. We and others have shown that INPP4B suppresses PI3K/Akt and PKC pathways. We show that INPP4B specifically inhibits PKCa and Jii in multiple prostate cancer cells. The analysis of PI3K, Akt and PKC specific inhibitors, LY294002, AZD5363, and BIM-I, showed that Akt and PKC signaling did contribute to the changes in AR signaling. We investigated INPP4B functions in prostate of Inpp4b−/− mice. AR expression in mouse prostate was not affected by the loss of INPP4B. Remarkably, expression of several direct AR target genes like Msmb, Apsd, and Nkx3.1 was significantly reduced in Inpp4b−/− mice, while some others were not altered. AR expression in mouse prostate was not affected by the loss of INPP4B. However, expression of some direct AR target genes like Msmb, Apsd, and Nkx3.1 was significantly reduced in Inpp4b−/− mice. Taken together, full length AR, but not AR-V7 induce INPP4B expression. INPP4B reciprocally modulates AR transcriptional activity without altering AR protein level in both normal prostate and prostate cancer cells and suppresses Akt and PKC signaling and the suppression is required for optimal AR transcriptional activity.

Knocking down/out the prokineticin pathway during zebrafish development results in the GnRH neurons axons misguiding
Ivan Bassi1, Federica Marello1, Valeria Vezzoli2, Luca Persani1,2, Yoav Gothilf1 & Marco Bononni1,2

Wise Faculty of Life Sciences and Sagol School of Neuroscience, Tel-Aviv, Israel.

Studies conducted using knockout mouse model revealed that defects of PROKR2 affect the correct ontology of GnRH neurons and, by consequence, neuroendocrine control of reproduction. Nevertheless its exact role during these processes and in the pathogenesis of congenital hypogonadotropic hypogonadism (CHG) remains elusive due to the phenotypic differences observed between mouse and human. Zebrafish (ZF) has emerged in the last ten years as a reliable model system for studying the GnRH neuronal development and the neuroendocrine control of reproduction. Previous results obtained in our lab identified two well-conserved loci in the ZF genome, on chr1 and chr13, respectively named prokr1a and prokr1b. Whole mount in situ hybridization (WISH) and qRT-PCR experiments conducted at different developmental stages of ZF revealed distinct patterns of expression for prokr-receptors suggesting prokr1b as the potential candidate involved in the GnRH-secretory neurons migration process from olfactory placode to their final hypothalamic destination. To verify these indications and better elucidate the function of both prokinetics receptors we recently conducted knockdown experiments using morpholino oligonucleotides sequences. Our results display an alteration of the GnRH fibers network architecture at 48 hours post fertilization (hpf) after downregulation of prokr1b that appeared misguided and reduced in numbers especially at level of pallium commissure and optic chiasma. Moreover, we also generated in ZF the prokr1b knockout model and our preliminary data are confirming the knockdown model observations. On the contrary, the downregulation of prokr1a does not affect GnRH fibers architecture. Taken together these results confirm the role of prokr1b during GnRH neurons migration establishing it as the ZF orthologous of human PROKR2. A deeper characterization of ZF prokr1b KO model could provide new information regarding the early establishment of the forebrain GnRH system, the factors controlling this complex developmental event, and its functional significance.

Cerebrovascular stroke incidence in GH-treated adults: experience from KIMS (Pfizer International Metabolic Database)
Cecilia Camacho-Hubner1, Jose Cara1 & Anders Mattsson2
1Endocrine Care, Pfizer Inc, New York, NY, USA; 2Endocrine Care, Pfizer Health AB, Sollentuna, Sweden.

Background and aim
Patients with GH deficiency (GHD) have increased risk of cerebrovascular events. The aim of this study was to evaluate the rate and factors associated with the occurrence of stroke, a major cause of death and disability, in adults with GHD.

Patients and methods
Data from 15,188 GHD patients treated with GH replacement therapy (GHT) enrolled in KIMS were analyzed. Stroke incidence rates were compared to rates from the Oxford Vascular Study (Lancet, 2004; 363:1925–33) by standardized incidence ratios (SIRs). Age at first radiotherapy (RT) corrected for attained age and sex, was analyzed with Poisson regression.

Results
Causes of GHD comprised pituitary adenoma 42.9%, craniopharyngioma 10.8% and idiopathic GHD 15.6%. Mean age at KIMS entry was 43.7 (range 17–75) years. Mean GH dose was 0.42 mg/day and number of patient treatment-years was 81,086. Mean age at first radiotherapy (RT) was 34.5 (range 3–72) yrs. First-ever stroke was reported in 155/7667 (M) and 123/7521 (F) patients. The crude incidence was 377 (M) and 308 (F) per 100,000 patient-years and overall SIR was 2.51 (95% CI: 2.22–2.82). SIR ranged between causes of GHD from 1.02 (0.41–2.64) to 19.3 (11.6–30.1) in patients with GH deficiency secondary to a malignant cranial tumor. RT was reported in 3866 patients and 146 reported a stroke (SIR: 3.96; 3.35–4.66). Rates were increased in all ages at first exposure (P<0.01), especially in younger patients

1Section of Specialized Endocrinology, Department of Endocrinology, Oslo University Hospital, Oslo, Norway; 2University of Southern Denmark, Odense, Denmark; 3Department of Medical Genetics, Oslo University Hospital, Oslo, Norway; 4Faculty of Medicine, University of Oslo, Oslo, Norway; 5Research Institute for Internal Medicine, Oslo University Hospital, Oslo, Norway; 6Latvian Biomedical Research and Study Centre, Riga, Latvia; 7Department of Endocrinology and Metabolism, Odense University Hospital, Odense, Denmark.

Conclusion
Non-functioning pituitary adenomas (NFPAs) necessitate prolonged clinical, biochemical and radiological observation, constituting a significant burden in terms of medical resources and societal costs. Reliable biomarkers associated with aggressiveness and recurrence of NFPAs are lacking. As the growth of tumor remnants is highly variable, molecular markers that can predict growth potential and tumor behavior are necessary.

Aim
To identify target genes in fast- and slow-growing NFPAs estimated by postoperative initial tumor volume doubling time (TVDT), and to find reliable biomarkers predicting the growth potential of the remnant tumor, focusing on the specific role of epithelial-mesenchymal transition (EMT) process.
The pituitary progenitors are responsible for generating a fully functional endocrine organ during embryonic development. They also preserve potency, to maintain the homeoeostasis in the adult pituitary, being able to respond to endocrine challenges, such as pregnancy or obesity. But the main players of this complex process remain elusive. Eph-Ephrins have been implicated in an increasing number of physiological functions such as axon-guidance, eye field segregation from neural plate, tissue boundary formation, cell migration, angiogenesis, and more recently stem cell maintenance and differentiation in the colon and mammary gland. However, the EphrinB2/EphB signalling pathway in hypothalamic-pituitary function is not known. Using a transgenic line that expresses GFP under the EphrinB2 (Efnb2) genetic locus we observed that cells expressing Efnb2 are localised in the pituitary progenitor of the anterior pituitary. We found Efnb2 co-expressed with known PPSCs markers Sox2/Sox9 during embryogenesis and this expression continues in adulthood, suggesting a role in adult pituitary homeoaeostasis. Conditional genetic removal of Efnb2 in the undifferentiated precursor using a Cre-pituitary line, results in significant pituitary abnormalities, comprising multiple bifurcations hyperplasia of the anterior pituitary gland. These data suggest for the first time, that Efnb2 is a critical regulator of pituitary development and could have an effect on hypothalamic-pituitary body endocrine regulations. Interestingly a proportion of Efnb2 Knockout animals exhibit features of congenital hypopituitarism, such as dwarfism and infertility. These data suggest that Efnb2 is a critical regulator of pituitary development, and could have an effect on hypothalamic-pituitary body endocrine regulations. Interestingly a proportion of Efnb2 Knockout animals exhibit features of congenital hypopituitarism, such as dwarfism and infertility. Previous studies have suggested that Efnb2 may play a role in the regulation of cell migration and differentiation during early development. Here, we provide evidence that Efnb2 is expressed in the pituitary progenitor of the anterior pituitary. These data suggest for the first time, that Efnb2 is a critical regulator of pituitary development and could have an effect on hypothalamic-pituitary body endocrine regulations. Additionally, the expression of Efnb2 in the undifferentiated precursor suggests a role in the regulation of cell migration and differentiation during early development.

**Conclusions**

Levels of CIT, but not FT3, were inversely associated with all components of the metabolic syndrome in men, and with elevated TG, waist, and overall MetS in women.

**Methods**

This was a prospective observational study. We recruited 40 patients presenting to a University hospital out-patient endocrine clinic with subclinical or overt hypothyroidism, and in whom thyroid hormone replacement was planned. Currently, 24 patients completed the study. Thyroid hormone concentrations were measured during a 90 min period before and after a mild cold stimulus of 90 min, both during the hypothyroid state and at least 3 months of sufficient thyroid hormone replacement. CIT was considered as the difference between resting energy expenditure (REE) during cold (REEcold) and warm (REEwarm) conditions. Additionally, skin temperature was measured using wireless probes in one-minute intervals in the supraclavicular region adjacent to the major human BAT depot. The primary endpoint was CIT in the hypothyroid vs euthyroid state. Data were analysed by non-parametric tests and are given as mean ± S.D.

**Results**

CIT increased from 73 (± 103) kcal/day during the hypothyroid state (CIThypothyroid) to 160 (± 143) kcal/day in the euthyroid state (CITEuthyroid), P = 0.0007. REEwarm was 1324 (± 120) kcal/day during hypothyroidism and rose slightly to 1395 (± 140) kcal/day, P = 0.0137. REEcold rose profoundly from 1396 (± 157) kcal/day to 1555 (± 178) kcal/day, P = 0.0001. While the inter-individual variability of CIT was large, the correlation between CIThypothyroid and CIT euthyroid was moderate, r = 0.657, P = 0.001. The change in supraclavicular skin temperature during cold exposure correlated with CIT in the euthyroid (r = 0.389, P = 0.067), but not in the hypothyroid state (r = 0.041, P = 0.853).

**Conclusion**

Cold induced thermogenesis is blunted in hypothyroid patients and increases markedly after restoration of euthyroidism. The difference in CIT is larger than the difference in resting energy expenditure during warm conditions.

**OC9.1 Thyroid function and metabolic syndrome: results from the population-based LifeLines Cohort study**

Bruce Wolffenbuttel, Hanneke Wouters, Sandra Slagter, Robert van Waereling, Jana van Vliet-Ostaptchouk, Thera Links & Melanie van der Klauw
University of Medical Center Groningen, Groningen, The Netherlands.

**Background**

The metabolic syndrome (MetS) is a combination of unfavourable health factors including abdominal obesity, dyslipidaemia, hypertension and impaired fasting glucose. Several small-scale studies have reported a relationship between thyroid function and some MetS components or suggested that serum FT3 levels within the normal range were independently associated with insulin resistance. We assessed how thyroid function relates to the prevalence of MetS in a large population-based study.

**Methods**

Data of 26,719 western European participants aged 18-80 years from the Dutch LifeLines Cohort study, all with normal TSH, FT4 and FT3 levels (electrochemiluminescent immunoassay, Roche Modular E170 Analyzer), were available. MetS was defined with the revised NCEP ATP III criteria. We calculated prevalence of all MetS components according to FT4 and FT3 quartiles.

**Results**

At similar TSH levels and age (mean 45 yrs), men had significantly higher levels of FT4, FT3, blood pressure (BP), heart rate, total and LDL-cholesterol, triglycerides (TG), and creatinine, but lower HDL-cholesterol compared to women (all P < 0.001). In total, 9.1% of women and 10.2% of men were treated with BP-lowering agents. In men, lower FT4 levels were associated with higher prevalence of all MetS components. The lowest FT4 quartile was associated with the highest prevalence of elevated BP (60%), elevated glucose (22%), waist circumference (33.4%) and TG (30.2%), low HDL-cholesterol (26.5%), and MetS (27.6%). In women, the lowest FT4 quartile was only associated with elevated TG (11.2%), waist circumference (47.4%), and MetS (13.8%). In contrast, higher FT3 levels were associated only with low HDL-cholesterol in both sexes, and with a higher percentage of participants with ≥ 3 MetS components (21.6% in men, 12.4% in women).

**Conclusions**

The prevalence of MetS was positively associated with FT in all studied ages, with younger patients at first RT showing a higher risk.

**OC9.2 Effect of restoration of euthyroidism in patients with hypothryroidism on cold induced thermogenesis**

Claudia Maushart, Rahel Loeliger, Cemile Bathelt, Nina Hutter, Mirjam Christ-Crain & Matthias Betz
Department of Endocrinology, Diabetes and Metabolism, University Hospital Basel, Basel, Switzerland.

**Background**

Thyroid hormones have been shown to be necessary for proper function of brown adipose tissue (BAT) and cold induced thermogenesis (CIT) in rodents. However, the data on CIT in humans in the hypothyroid vs. the euthyroid state are limited and conflicting.

**Methods**

This was a prospective observational study. We recruited 40 patients presenting to a University hospital out-patient endocrine clinic with subclinical or overt hypothyroidism, and in whom thyroid hormone replacement was planned. Currently, 24 patients completed the study. Thyroid hormone concentrations were measured during a 90 min period before and after a mild cold stimulus of 90 min, both during the hypothyroid state and at least 3 months of sufficient thyroid hormone replacement. CIT was considered as the difference between resting energy expenditure (REE) during cold (REEcold) and warm (REEwarm) conditions. Additionally, skin temperature was measured using wireless probes in one-minute intervals in the supraclavicular region adjacent to the major human BAT depot. The primary endpoint was CIT in the hypothyroid vs euthyroid state. Data were analysed by non-parametric tests and are given as mean ± S.D.

**Results**

CIT increased from 73 (± 103) kcal/day during the hypothyroid state (CIThypothyroid) to 160 (± 143) kcal/day in the euthyroid state (CITEuthyroid), P = 0.0007. REEwarm was 1324 (± 120) kcal/day during hypothyroidism and rose slightly to 1395 (± 140) kcal/day, P = 0.0137. REEcold rose profoundly from 1396 (± 157) kcal/day to 1555 (± 178) kcal/day, P = 0.0001. While the inter-individual variability of CIT was large, the correlation between CIThypothyroid and CIT euthyroid was moderate, r = 0.657, P = 0.001. The change in supraclavicular skin temperature during cold exposure correlated with CIT in the euthyroid (r = 0.389, P = 0.067), but not in the hypothyroid state (r = 0.041, P = 0.853).

**Conclusion**

Cold induced thermogenesis is blunted in hypothyroid patients and increases markedly after restoration of euthyroidism. The difference in CIT is larger than the difference in resting energy expenditure during warm conditions.

**OC9.3 How much of the genetic predisposition to Hashimoto’s thyroiditis can be explained by genes commonly associated with the disease?**

1. Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; 2. Endocrinology Department, University Hospital in Krakow, Krakow, Poland; 3. Center for Medical Genomics OMICRON, Jagiellonian University Medical College, Krakow, Poland.

**Background**

Hashimoto’s thyroiditis (HT) is a common autoimmune disorder of the thyroid (AITD) which affects about 1-2% of the European population. The disease often
clusters in families, which is why many attempts have been undertaken to find the genetic background that would underly the predisposition to HT. In contrast to another AITD - Graves' disease, results of genetic analyses have been ambiguous and have failed to find a major genetic locus that would be essential for HT development.

Aim
To assess the joint impact of disease loci associated in the literature with HT predisposition.

Methods
One hundred and forty seven HT fully-symptomatic patients and 147 healthy controls (matched for age, gender, incomes, education, marital status and place of descent), unrelated to each other, were genotyped for 40 polymorphisms (Illumina GoldenGate, custom panel), which were located in genes most often tested in literature for association with AITD, or typed out by genome-wide association studies. All polymorphisms were confirmed to be in Hardy-Weinberg equilibrium in the control group ($P>0.05$). Variations in the HLA-DRB1 gene were analyzed by Sanger sequencing. A genetic model for HT predisposition was obtained with use of stepwise logistic regression. Biostatistical analyses were performed with the programs Statistica v12, Plink v1.9, and GCTA v1.02.

Results
The model which best explained the predisposition to HT contained seven polymorphisms in the genes PTPN22, IFIH1, CTLA4, RGS6, TNMD, NOX1, and the promoter region of FAM155A. The model was able to classify correctly 67% of all cases, similarly for both groups. Such a model explained only 5.12% of the between-group variance. This value is in agreement with a model published lately for another autoimmune disorder.

Discussion
Our data confirm that there seem to be no genes that are per se crucial for HT development. Future analyses on HT predisposition should focus on the joined influence of many polymorphisms in different genetic regions.

Thyroid dysfunction during the use of PD-1/PD-L1 blockade predicts its therapeutic response in the patients with advanced non-small cell lung cancer

Hye In Kim1, Tae Hyuk Kim1, Hye Won Jang2, Young Nam Kim1, Hosi Kim3, So Young Park1, Sun Wook Kim1 & Jae Hoon Chung1
1Samsung Medical Center, Seoul, Republic of Korea; 2Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Background
PD-1/PD-L1 blockade is one of the promising drugs in the treatment of advanced non-small cell lung cancer (NSCLC). and predicting drug effect is important due to unique pattern of response. Immune-related adverse event (IRAE) might be associated with favorable clinical outcome. Thyroiditis is the most common IRAE which can be easily detected with the measurement of thyroid hormone levels. However, the relationship between thyroid dysfunction during the use of PD-1/PD-L1 blockade and its therapeutic response has not been well demonstrated in advanced NSCLC patients.

Methods
A total 53 patients with stage IV NSCLC treated with PD-1/PD-L1 blockade were enrolled. Patients were categorized into thyroid dysfunction and euthyroid group. Overall survival (OS) and progression free survival (PFS) of two groups were compared. Hazard ratio (HR) adjusting patients, tumor, and drug factors were analyzed using Cox proportional hazard model. Response rate (RR) and durable RR were assessed according to thyroid dysfunction and its severity.

Results
OS (mean 148.5±26.2 vs 82.0±65.1, log-rank $P=0.003$) and PFS (143.2±88.2 vs 68.0±50.0, log-rank $P=0.001$) were significantly longer in the thyroid dysfunction group. After adjustment for age, sex, smoking status, tumor stage, and drug type, adjusted HR (95% CI) for overall death and progression disease were 0.08 (0.01-0.65) and 0.29 (0.12-0.69) compared with euthyroid group. RR (36.0 vs 10.7%, $P=0.028$) and durable RR (28.0 vs 6%, $P=0.003$) were more frequent in the thyroid dysfunction group. Severity of thyroid dysfunction was also associated with RR ($P$ for trend = 0.018) and durable RR ($P$ for trend = 0.001).

Conclusions
Thyroid dysfunction during the use of PD-1/PD-L1 blockade and its severity predict its favorable disease outcome in NSCLC patients. Therefore, regular measurement of thyroid hormone levels during the use of PD-1/PD-L1 blockade could be the good biomarker of immune monitoring.

Selenium supplementation in the management of thyroid autoimmunity during pregnancy: results of the ‘Serena Study’ a randomized, double-blind, placebo-controlled trial

Carla Di Dato1, Giovanna Mantovani2, Costanzo Moretti3, Ermanno Greco4, Marco Bonomi5, Antongiulio Faggiano2, Stefania Di Sante1, Vincenzo Giannetta1, Luisa Petrone1, Angela Fumarola2, Annamaria Colao3, Andrea Lenzi1, Andrea M. Isidori1 & Elisa Giannetta1
1Department of Experimental Medicine - Sapienza University of Rome, Rome, Italy; 2Endocrine Unit, Department of Clinical Sciences and Community Health, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; 3Unit of Endocrinology, Section of Reproductive Endocrinology, Department of Systems’ Medicine, University of Rome Tor Vergata, Rome, Italy; 4Centre for Reproductive Medicine, European Hospital, Rome, Italy; 5Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; 6Thyroid and Parathyroid Surgery Unit, Istituto Nazionale per lo Studio e la Cura dei Tumori-IRCCS, Fondazione G. Pascale’, Naples, Italy; 7Endocrinology Unit, Careggi Hospital and University of Florence, Florence, Italy; 8Endocrinology Unit, Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy.

Autoimmune thyroiditis and related complications represent a growing concern during pregnancy. Selenium is frequently present in nutraceuticals recommended for thyroiditis and pregnancy, given its advocated role in immunity, fertility and thyroid function. However, most evidences come from non-controlled studies.

Materials and Methods
We designed a multicenter, randomized, double-blind, placebo-controlled trial (Serena Study: NCT01465867) to evaluate the effects of L-selenomethionine (Se) supplementation on antibodies title in euthyroid women with positive anti-thyroid antibodies that are pregnant or undergoing in-vitro fertilization. Secondary outcomes included: implantation rates, pregnancy rate, delivery, obstetrical, fetal and neonatal complications. Ten endocrinology and gynecology Italian referral centers participated. The study was promoted and supported by EnGiol Club (Italian Young Endocrinology).

Results
56 women were randomly assigned to placebo (PLB) or Se 83 mcg/die. Thyroid hormones, TgAbs, TPOAbs, selenium concentration were measured during pregnancy and after labor (months 3 to 6). All analysis were centralized. Of the enrolled women, 45 (80.3%) were pregnant and 11 (19.6%) embryo transferred. A significant reduction of TgAb was observed in Se-treated women after labor: treatment effect $d=10.67$ (95%CI: −1.3, 21.86; $P=0.03$). The change in antibodies was paralleled by a significant increase in selenium serum concentration measured already at 36 ± 2 weeks: (PLB: $-11 ± 23.76$, Se: $30.5±17.63$; treatment effect $d=35.57$ 95% CI:14.9, 62.3; $P=0.004$) and confirmed after labor: treatment effect $d=17.56$ (95% CI: 3.9, 31.2; $P=0.014$). Post-labor rebound in antibodies’ title of PLB treated, as compared to Se-treated women was paralleled by a trend toward TSH rise (PLB: $+0.56 ± 17.33$, Se: $-1.7±0.28$; treatment effect $d=-3.57$ 95% CI:14.9, 62.3; $P=0.004$) and confirmed after labor: treatment effect $d=-11.75$ (95% CI: 0.7, 22.5; $P=0.044$). Safety analysis showed no discontinuation in the Se-treated subjects. Two miscarriage occurred in PLB vs 0 in Se-treated. No differences were found in fetal and maternal complications. The pregnancy rate after embryo transfer was 3/5 (60%) in Se-treated vs 1/6 (16.6%) in PLB. Conclusion
SERENA Study demonstrated a beneficial effect on the title of TgAb with a safety profile. Larger studies are needed to confirm the trends observed on post-partum thyroiditis recurrence and hypothyroidism, miscarriage and pregnancy rate in in vitro-fertilization.

Treatment of 711 patients with hypoparathyroidism: a retrospective study in 3 German endocrine centres
Martin Grussendorf1, Bettina Stamm2, Niklas Stamm1, A & Heide Siggelkow1
1Endocrine Centre, Stuttgart, Germany; 2MVZ Endokrinologikum, Saarbrücken, Germany; 3Endocrinology and Metabolism, University Medicine, Mainz, Germany; 4Clinik of Gastroenterology and Gastrointestinal Oncology, University Medical Center, Göttingen, Germany; 5MVZ Endokrinologikum, Göttingen, Germany.

Care of patients (pts.) with hypoparathyroidism (HypoPT) is a challenge, because pts. are usually not treated with the absent hormone, but with several forms of vitamin D. We retrospectively evaluated the data of pts. with HypoPT in three endocrine centres in Germany.

Methods
Records of 711 pts. with HypoPT (Centre 1 (C1): n=381, C2: n=253, C3: n=77) were reviewed (female: 592, male: 119). The following data under treatment (time range 2–199 months) were evaluated: medication, Calcium (C) – values, tingling sensations (paresthesia), and cramps.

Results
Of these 711 pts. 29 had idiopathic HypoPT, 10 HypoPT after parathyroidectomy, 669 after thyroid operation (Tx): subtotal Tx: 471, HemiTx: 12, totalTx: 186 pts. Age of pts. at first visit (V1): 49.85 years (mean), time between Tx and V1: 76.85 months (mean, range 0–733 months). Mean values of Ca (mmol/l), PO4 (mg/dl) in serum, Ca in urine (Ca U; mmol/24 h); % of patients with paresthesia (par.) and cramps under different therapies (mean daily dose in brackets): as follows:

<table>

</tbody>
</table>

Conclusion
As expected monotherapy with high doses of calcium was not sufficient. The combination of 1-Alphacalcidol and Calcium was the best regimen for treating HypoPT and improving complaints. Further correlations between different treatment regimen and parameters of renal and bone metabolism will be calculated.

Evaluation of bone quality, measured by trabecular bone score (TBS) in patients with primary hyperparathyroidism (PHH) with and without surgery
Isabel Huguet, Miguel Sampredo-Núñez, Jose Luis Muñoz De Nova, Ana Ramos-Levi, Sandra Campos, Eugenio Escolano & Mónica Marzuela Hospital La Princesa, Madrid, Spain.

Evaluation of bone quality represents a challenge since the analysis by bone mineral density (BMD), provides useful but incomplete information. New tools are arising, and among them, TBS is emerging as a new surrogate marker of bone texture and microarchitecture which may be useful to potentially evaluate the risk of bone fracture and can be obtained from already existing BMD scans. Retrospective study of 23 patients with PHH. Clinical, analytical and BMD data were collected form clinical records. TBS was calculated by reevaluating the already existing BMD images. Patients were classified into two different groups according to their treatment: 1) 13 patients who underwent surgery, in whom TBS was evaluated before surgery (B-S) and one year after surgery (A-S), and 2) 10 patients who received standard medical treatment, in whom TBS was evaluated with a time-lapse of 1 year. Basal age, body mass index (BMI), serum calcium, vitamin 25-OH-D levels and T-Scores were not significantly different between the two groups. Only PTH levels (82 vs 110 pg/ml, p = 0.04) presented differences. We observed a significant improvement of TBS one year after surgery in the first group (1,244 ± 0.11 vs 1,311 ± 0.1 P = 0.08). A subtle deterioration on TBS was observed one year after standard treatment in the second group (1,249 ± 0.06 vs 1,223 ± 0.07 P = 0.124). Overall, surgical patients experienced a TBS increase 5.8% whilst a decrease of – 2.04% was observed in the second group (P = 0.02).

In the multivariate correlation analysis, the percentage of variance in TBS was negatively correlated with the level of PTH and calcium at the moment of the second BMD (0.04 and 0.03 respectively). Bone microarchitecture, measured by TBS, improves after surgery in patients with PHH and has been shown to be sensitive to changes developed during only one year time-lapse in bone. This parameter is a promising tool in the evaluation of bone status in PHH.

High prevalence of radiological vertebral fractures in patients with differentiated thyroid carcinoma undergoing i-thyroxine TSH-suppressive therapy
Anna Maria Formenti1, Gherardo Mazzotti2, Stefano Frazza3, Filippo Maffezzoni1, Mauro Doga3, Francesco Bertagna4, Roberto Maroldi5, Maurizio Memo6, Raffaele Giubini7 & Andrea Giustina1
1Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy; 2Department of Internal Medicine, Mantua Hospital, Mantua, Italy; 3Chair of Endocrinology, Vita-Salute San Raffaele University, Milan, Italy; 4Chair of Nuclear Medicine, University of Brescia, Brescia, Italy; 5Chair of Radiology, University of Brescia, Brescia, Italy.

Thyroid hormones play a central role in the regulation of bone turnover and thyrotoxicosis is an established cause of secondary osteoporosis. Increased prevalence of reduced bone mineral density (BMD) has been reported even in patients with subclinical thyrotoxicosis such as those with differentiated thyroid carcinoma undergoing long-term i-thyroxine (i-T4) TSH-suppressive therapy. Morphometric vertebral fractures (VFs) are an early and clinically crucial marker of bone fragility but they have never been investigated so far in this setting. In this cross-sectional study, we evaluated the VF prevalence (DXA quantitative morphometry) and BMD (DXA Hologic 4500 W, at lumbar spine, total hip and femoral neck) in 53 consecutive patients with differentiated thyroid carcinoma (two males, 51 females; median age 61 years, range: 42–82; 45 with papillary carcinoma and eight with follicular carcinoma; median duration of therapy (two males, 51 females; median age 61 years, range: 42–82; 45 with papillary carcinoma and eight with follicular carcinoma; median duration of therapy 5 years, range: 1–45) and 75 control subjects (72 females and three males; median age 62 years, range: 42–83) with normal thyroid function attending an outpatient bone clinic. VFs were significantly more prevalent in patients with thyroid carcinoma as compared to the control subjects (30.2 vs 9.3%; P = 0.002) without significant (P = 0.21) differences in BMD at either skeletal sites. BMD was not significantly different TBS than fractured and non-fractured TSH suppressed patients at either skeletal site. Prevalence of VFs was not significantly (P = 0.29) different among patients with normal BMD (11.1%), osteopenia (39.1%) and osteoporosis (28.6%). In patients under TSH-suppressive therapy, VFs were significantly associated with age (OR 1.1, CI 95% 1.01–1.12; P = 0.03) but not with duration of i-T4 therapy (OR 1.03; CI 1.05% 0.96–1.11; P = 0.34). This is the first study showing high prevalence of VFs in patients with thyroid carcinoma undergoing i-T4 TSH-suppressive therapy likely due to an impairment in bone quality. Vertebral morphometry should be performed at baseline and during follow-up of TSH-suppressed patients to assess their skeletal health.

OC10.4
The effect of denosumab or bisphosphonates in women with severe postmenopausal osteoporosis after completion of teriparatide treatment
Tomaz Kocjan1, Antonela Sabati Rajic 1, Mojca Jensterle Sever 1, Gaj Vidmar1, Barbara Ostanek3, Janja Marc3, Nina Orehek3 & Marija Pfeifer1

Endocrine Abstracts (2017) Vol 49
The ideal antiresorptive agent to preserve or further increase bone mineral density (BMD) following teriparatide treatment is not known. We aimed to compare BMD changes after one year of therapy with denosumab or bisphosphonates in osteoporotic patients who had completed treatment with teriparatide. We retrospectively analyzed 140 women (age 74 years, 26 years from menopause, BMI 27 kg/m² on average) with severe postmenopausal osteoporosis who had been treated between 2006 and 2014 with teriparatide for 18–24 months at our outpatient clinic. After stopping teriparatide, they continued with a bisphosphonate (alendronate, risedronate, ibandronate or zoledronic acid) or with denosumab in standard doses per physician’s and/or patient’s preference. All patients were prescribed with vitamin D3 1000 IU daily and were instructed to ingest 1200 mg of calcium daily. BMD was measured at lumbar spine (LS), total hip (TH) and femoral neck (FN) by DXA when teriparatide was stopped and after 12 months of further treatment. The data were analyzed using multiple linear regression to adjust the comparison between groups for age, BMI, 25-hydroxyvitamin D, serum urate, procalcitonin type 1 N-terminal propeptide (PINP) at baseline and BMD gain on teriparatide. Seventy patients continued treatment with a bisphosphonate and 70 received denosumab. The results indicate a lower BMD increase (especially at LS) in patients on bisphosphonates when compared to denosumab; a lower BMD increase at FN and LS in patients who had a larger BMD increase on teriparatide (i.e. regression to the mean); a lower BMD increase at FN and a higher BMD increase at LS in patients with higher baseline PINP; and a higher BMD increase at FN in patients with higher baseline PINP. Twelve months after stopping teriparatide, sequential osteoporosis treatment with denosumab yields higher additional BMD gain as compared to a bisphosphonate. The effect is more pronounced at LS.

G11-Phe220Ser loss-of-function mutation causes familial hypocalciuric hypercalcemia type-2 (FHH2) by disrupting a hydrophobic cluster critical for G-protein signaling

Caroline M. Gorvin1, Treena Cranston2, Fadil M. Hannan1,3, Helena Valta4, Outi Makitie5, Camilla Schalin-Jantti6 & Rajesh V. Thakker7

1Academic Endocrine Unit, Radcliffe Department of Medicine, Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, UK; 2Oxford Molecular Genetics Laboratory, Churchill Hospital, Oxford, UK; 3Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, UK; 4Children’s Hospital, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; 5Division of Endocrinology, Abdominal Center, University of Helsinki, Helsinki, Finland.

Mutations of the calcium-sensing receptor (CaSR), G-protein alpha-11 subunit (G11), and adaptor protein-2 sigma subunit (AP2σ) resulting in a loss-of-function, cause familial hypocalciuric hypercalcemia types 1-3 (FHH1-3), respectively. We investigated a family with FHH4 (four affected and two unaffected members) for CaSR, G11 and AP2σ mutations, and identified a heterozygous G11 missense mutation, Phe220Ser, which is predicted to disrupt a cluster of hydrophobic residues that are important for G-protein/G-protein coupled receptor interactions. G11, which acts downstream of the CaSR, activates phospholipase C (PLC) leading to two predominant signal outputs: intracellular calcium (Ca2⁺i) release; and activation of the extracellular-signal regulated kinase (ERK) mitogen-activated protein kinase (MAPK) pathway. We assessed the effects of the G11 mutation on signalling by expressing G11-wild-type Phe220 and three G11-mutants: Ser220, detected in the FHH2 kindred; and Glu220, which acts downstream of the CaSR, activates phospholipase C (PLC) leading to two predominant signal outputs: intracellular calcium (Ca2⁺i) release; and activation of the extracellular-signal regulated kinase (ERK) mitogen-activated protein kinase (MAPK) pathway. We assessed the effects of the G11 mutation on signalling by expressing G11-wild-type Phe220 and three G11-mutants: Ser220, detected in the FHH2 kindred; and engineered mutants, Ala220 (a hydrophobic residue); and Glu220 (a non-hydrophobic residue), in HEK293 cells stably expressing CaSR. Ca2⁺i responses to extracellular calcium (Ca2⁺i) were assessed using a Fluo-4 fluorescent assay and an NFAT-response element-containing luciferase reporter that measures Ca2⁺i-induced gene expression; and MAPK responses assessed using a phospho-ERK (pERK) AlphaScreen assay and a serum-response element (SRE)-containing luciferase reporter that measures ERK-induced gene expression. Mutation of Phe220 to the non-hydrophobic Ser220 and Glu220 residues, but not the hydrophobic residue, Ala220, significantly impaired G11 signalling via PLC-Ca2⁺i and ERK/MAPK pathways. Thus, Ser220 and Glu220, when compared to Phe220 and Ala220 led to a rightward shift of the dose-response curves of Ca2⁺i responses to Ca2⁺i + with increased maximal concentration (EC50) values; reductions in NFAT reporter responses; impaired pERK responses; and reductions in SRE reporter activity. Thus, we have identified a novel G11 mutation, Phe220Ser, causing FHH2, and have demonstrated the importance of the hydrophobic Phe220 residue, which forms part of a cluster, for G-protein signaling via PLC-Ca2⁺i + and ERK/MAPK pathways.

Role of Extracellular vesicles in the crosstalk between adipocytes and pancreatic beta-cells

Jacopo Gesmundo1, Eleonora Gargantini1, Enrica Favaro2, Lorenzo Piemonti1, Giovanni Camussi2 & Riccarda Granata1

1Division of Endocrinology, Diabetology and Metabolism, Department of Medical Sciences, University of Torino, Torino, Italy; 2Department of Medical Sciences, Torino, Italy; 3San Raffaele Diabetes Research Institute, IRCCS San Raffaele Scientific Institute, Milano, Italy.

Obesity is characterized by insulin resistance and pancreatic β-cell dysfunction; moreover, secretion of adipokines from adipocytes may affect metabolic functions in several tissues, including pancreatic β-cells. Extracellular vesicles (EVs) released by cells as exosomes or shedding vesicles, play a key role in cell-to-cell communication, modifying the phenotype and function of recipient cells by delivering proteins, RNAs and microRNAs. The crosstalk between adipocytes and β-cells in the regulation of glucose and lipid metabolism is still unclear. We hypothesized that EVs derived from adipocytes are able to influence the survival and function of β-cells in pathophysiological conditions. In this study, the role of EVs released by murine 3T3-L1 adipocytes was evaluated on cell viability and proliferation, apoptosis and function of rat INS-1E β-cells and human pancreatic islets. INS-1E β-cells and human pancreatic islets were treated for 24 and 72 hours, respectively, with EVs in either presence or absence of CKs or palmitic acid and high glucose (P/G). Our results show that EVs derived from untreated adipocytes promote cell survival and proliferation, inhibit apoptosis in β-cells and pancreatic islets treated with CKs and P/G, and stimulate glucose-induced insulin secretion. Conversely, EVs derived from adipocytes treated with CKs enhanced the detrimental effects of CKs and P/G. These results suggest a functional crosstalk between adipose tissue and β-cells/pancreatic islets. Furthermore, the protective effects of EVs derived from adipocytes on survival and function of β-cells exposed to stress, such as inflammatory CKs or glucolipotoxicity, suggest possible therapeutic implications in pathological conditions like diabetes and obesity.

Three year prospective study in morbidly obese patients between longitudinal gastrectomy and gastric bypass based on a composite outcome combining weight loss efficacy and surgery related complications (PHRC SLEEVE K060213 / IDRC B2007-A0373-50)

Jean Marc Catheline1, Marinos Fysekidis2, Yasmina Bendacha2, Najib Bdeoui1, Vidhya Raghavan3, Sophie Gérard3, Jean Jacques Portal1, Kami Dhouk4, Jean Michel Fabre5, Gilles Fourtier5, Jean Gugesheim6, Noël Hutin7, Maxime Sodji8, Simon Msika9, Michel Scott10, Eric Vicaut11 & Regis Cohen1

1Centre coordinateur du PHRC, Centre Hospitalier de Saint-Denis, Saint-Denis, France; 2CHU Bobigny, Bobigny, France; 3Unite´ de Recherche Clinique Lariboisie`re-St Louis Hoˆpital Fernand Widal, Paris, France; 4CHU de Montpellier, Montpellier, France; 5CHU Toulouse, Toulouse, France; 6CHU Nice, Nice, France; 7CHU Tours, Tours, France; 8Clinique Emileau, Limoges, France; 9Hôpital Louis Mourier « APHP », Colombes, France; 10CHU Rouen, Rouen, France.

Since its first description in 2000, Longitudinal Gastrectomy (LG) has become the first surgical procedure in the treatment of morbid obesity in the world, exceeding in numbers Gastric Bypass (GB). GB is considered to have better results regarding long-term weight loss and improvement in co-morbidities. We aimed to demonstrate that LG is non inferior to GB for a composite end point that included more than 50% excess weight loss from the baseline and surgery related complications after a mean follow-up of 36 months. This is a prospective study in
morbidly obese patients that tested a two hypotheses composite outcome: the first hypothesis was that after 36 months LG was non-inferior to GB regarding EWL, (the predefined margin of non-inferiority was 20%), and the second hypothesis was the presence of significant difference in post-operative morbidity and mortality. From February 2008 to March 2015 we included 277 patients (91 GB vs 186 LG). The mean age was 41.1 years, 19.2% had a previous bariatric operation, 85.9% were women and the average pre-intervention BMI was 45.3 kg/m². At baseline there were no significant differences between the GB and LG for age, sex and BMI. The % of patients with EWL for age, sex and BMI was 50% at 18 months for 82.1% (GB) vs 84.5% (LG), and 79.1 vs. 79.5% respectively at 36 months. The estimated difference in EWL was [95% CI 10.5% to 9.8%], confirming the non-inferiority of LG compared to BP. Finally there was a significant less morbidity and mortality for the LG group (GB vs LG, 12.1 vs. 4.8%, one death for LG, \(P = 0.01\)). This is the first prospective study demonstrating that LG is not inferior to GB for an estimated 10% difference in EWL but with less surgical complications. These results reinforce the choice of LG as surgical procedure for obesity.

Results

The primary endpoint was change in morning cortisol from baseline to after 38.7, 95% CI −6.0 to −13.4, \(P = 0.0019\). Similar effects were found for salivary cortisol levels (−2.8, 95% CI −4.4 to −1.3, \(P = 0.0007\)), ACTH levels (−2.2, 95% CI −4.2 to −0.1, \(P = 0.038\)), systolic blood pressure (−5.2, 95% CI −8.5 to −1.8, \(P = 0.0006\)) and heart rate (−2.9, 95% CI −4.7 to −1.0, \(P = 0.0029\)).

Conclusion

IL-1 antagonist in obese individuals with features of the metabolic syndrome leads to a decrease in serum cortisol, salivary cortisol and ACTH-levels along with a reduction in systolic blood pressure and heart rate. IL-1 antagonism could thus be a novel treatment option to improve cortisol levels and associated comorbidities in obesity.

Comparing effects of weight loss by liraglutide with intensive lifestyle modification on hepatic steatosis, inflammation and stiffness, and insulin resistance in obese Asians with non-alcoholic fatty liver disease (NAFLD)

Joan Khoo, Ngai-Moh Law, Johan Hsiang, Jessica Tan & Tiang-Leong Ang Changi General Hospital, Singapore, Singapore.

Background and Aims

Non-alcoholic fatty liver disease (NAFLD), a leading cause of cirrhosis and liver cancer, is increasing worldwide due to rising obesity rates, particularly in Asia. Weight loss induced with diet and exercise decreases hepatic steatosis and inflammation, but requires greater efforts to sustain compared to medication. We therefore aimed to compare the effects of liraglutide, a glucagon-like peptide-1 agonist, which induces weight loss, on hepatic steatosis and inflammation in obese Asian adults with NAFLD with intensive lifestyle modification.

Methods

22 abdominally obese Asian (mean BMI 33.6 ± 3.9 kg/m², mean waist circumference WC 108.5 ± 10.6 cm) non-diabetic normotensive adults with NAFLD, as diagnosed by a hepatologist based on elevated serum alanine transaminase (ALT) and aspartate transaminase (AST) levels and liver fat fraction >5% using magnetic resonance imaging (MRI) in the absence of other causes of hepatic steatosis and transaminasits, were randomized to supervised dieting (restriction by 400 kcal/day) plus moderate-intensity exercise (200 minutes/week) to induce ≥5% weight loss (DE group, \(n = 11\)) or liraglutide 3 mg daily (LI group, \(n = 11\)) for 26 weeks. Insulin resistance was estimated by homeostasis model assessment (HOMA-IR) and liver shear stiffness with MRI elastography.

Results

At 26 weeks, both DE and LI groups had significant (\(P < 0.01\)) and similar reductions in weight (−3.1 ± 2.9 vs −3.6 ± 2.4 kg), WC (−4.4 ± 3.2 vs −5.7 ± 3.9 cm), liver fat (−9.5 ± 13.8 vs −7.7 ± 7.3%), liver stiffness (−0.22 ± 0.20 vs −0.32 ± 0.25 kPa), ALT (−42 ± 34 vs −43 ± 59 U/L), AST (−21 ± 16 vs −26 ± 25 U/L) and HOMA-IR (−2.87 ± 2.67 vs −3.12 ± 2.40).

Conclusion

Once-daily liraglutide is as effective as intensive lifestyle modification for decreasing hepatic steatosis, inflammation and stiffness in obese Asian adults with NAFLD.

Differentiating constitutional thinness from anorexia nervosa in DSM 5 era

Bruno Estour1,2, Nesrine Marouani1, Torrance Sigaud2,3, Francois Lang2,3, Eric Fakra2,3, Aurelie Diamonde2, Bogdan Galusci1,2 & Natacha Germain1,2

1Endocrinology Department, University Hospital of Saint Etienne, Saint Etienne, France; 2EA 7423, Jean Mouret University of Saint Etienne, Saint Etienne, France; 3Psychiatry Department, University Hospital of Saint Etienne, Saint Etienne, France.

Introduction

Constitutional thinness (CT) is an overweight state characterized by normal metabolic and somatic functions and no change in feeding behaviour. Thinness is the only resemblance between Anorexia Nervosa (AN) and CT. Removal of anorexia nervosa in the new DSM 5 definition of AN might lead to misdiagnosis between these two populations. The objective of this study was to compare CT, AN and Control subjects in terms of biological, anthropometric, and psychological markers in order to better distinguish AN from CT subjects.

Patients and method

This retrospective study conducted from 2000 to 2015 included three groups of young women: fifty-six CT, forty restrictive-type AN and fifty-four control subjects were included in the study. Basal evaluation was made in all groups with any intervention. Body composition, nutritional markers, pituitary hormones, bone markers and psychological scores were evaluated in three groups. For every markers, a receiver Operator Characteristics (ROC) curve was calculated to evaluate the accuracy of differentiation between AN and CT groups.

Results

For the majority of the studied parameters, CT subjects were similar to controls but dramatically different from AN subjects. According to ROC data, while psychological scores were unsuccessful to differentiate AN from CT, except for DEBQ Restraint Eating item, free-T3 and Leptin were strong tools for AN and CT distinction as they displayed high sensitivities and specificities with low P values (<0.0001). The goal is to avoid social stigmatization and excessive useless therapies for CT women.

T2-Weighted signal intensity of functional pituitary adenomas: correlation with clinicopathological findings and response to treatment
Sema Ciftci Dogansen1, Seher Tanrikulu1, Gulsah Yenidunya Yalin1, Sakin Tekin1, Nihan Nizam1, Bilge Bilgic2 & Sema Yarman1
Division of Endocrinology and Metabolism, Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey; 2Department of Pathology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Purpose
Somatotrophinomas have been shown to demonstrate T2-weighted signal intensity (WSI) on MRI that is correlated with clinicopathological findings and response to treatment. Therefore, we aimed to investigate these correlations in functional pituitary adenomas, including prolactinoma and corticotrophinoma.

Material and Methods
Patients with somatotrophinoma (n=87), prolactinoma (n=78) and corticotrophinoma (n=33) were involved in this study. The initial T2-WSI findings (grouped into hypo-, iso- and hyperintense) were compared with hormone levels, tumor diameter, granulation pattern and treatment response.

Results
While most of somatotrophinomas were hypointense, most of prolactinomas and corticotrophinomas were hyperintense. Tumor diameter was significantly larger in hyperintense somatotrophinomas than in hypointense group (P=0.007), but the tumor diameter in the isointense group did not show any difference when compared to the others. IGF-1% ULN (upper limit of normal) was higher in hypointense somatotrophinomas than the other two groups (P=0.02). Sparsely granulation pattern in hyperintense somatotrophinomas and densely granulation pattern in hypointense somatotrophinomas are more frequent (P=0.035), whereas the granulation pattern distribution in isointense group did not differ from the other two groups. The hormonal response to somatostatin analogs (SSA) treatment (percentage of IGF-1 reduction) was higher in the hypointense group than in the other two groups (P=0.04). The tumor diameter was smaller in the hyperintense prolactinomas than in the other groups (P=0.039), but the basal PRL levels were not different between the groups. The response to dopamine agonist (DA) treatment of iso- and hyperintense prolactinomas is much better than the hypointense group (P<0.001). Tumor diameter was larger in hyperintense corticotrophinomas than the other two groups (P=0.012), but there was no difference between the baseline cortisol and ACTH levels of the groups. Sparsely granulation pattern was higher in hyperintense corticotrophinomas and densely granulation pattern in hypointense corticotrophinomas (P=0.029), whereas granulation pattern distribution in isointense group was not different from the other two groups. There was no difference between the groups in terms of remissions and recurrences.

Conclusion
Hyperintense somatotrophinomas support literature knowledge with increased tumor diameter, sparsely granulation pattern and less responsiveness to SSA treatment. The response to DA treatment of iso- and hyperintense prolactinomas is much better, but there was no difference between the groups in terms of remissions and recurrences in corticotrophinomas. Our results in prolactinomas and corticotrophinomas should be supported by further studies.

Design
Cohort study based on an electronic survey open for participation to ESE members Dec 2015-Nov 2016.

Results
Reports on 167 patients, 40 pituitary carcinomas, and 127 aggressive pituitary tumours were obtained. Median age at diagnosis was 43 (range 4–79) years. 59% of tumours were clinically functioning at presentation, and the most frequent were corticotroph tumours. TMZ was the first line chemotherapy in 157 patients. At the end of TMZ treatment (mean 9.92 cycles) radiological evaluation showed complete response in 6%, partial response in 31%, stable disease in 33% and progressive disease in 30%. Progression occurred more often in pituitary carcinomas (40%) than in aggressive adenomas (26%), P=0.05. Clinically silent tumours showed less regression compared with secreting tumours, 17 vs 45%, P=0.01 (overall χ² test). Median follow-up after TMZ treatment was 21 months. Of patients with complete response, partial response and stable disease 22, 34 and 40% respectively showed progression during further follow-up. Twenty five patients received a second course of TMZ, 3 had a partial response. Overall mortality was 33%, and highest in patients with progression after TMZ treatment (54%).

Conclusion
TMZ was accompanied by tumour regression in 37% of patients, documenting its value in the management of these aggressive tumours. The high recurrence rate following TMZ cessation highlights the need to identify additional effective therapies.

Recombinant Growth Hormone added to physical therapy in GH-deficient adults with complete (ASIA A) Spine Injury
Guillem Cuatrecasas1, Hatice Gumrukçu2, M’Josep Covés1, Ioana Patrascuioiu1 & Josep Vidal2
1Department of Endocrinology, Hospital Quiron-Teknon, Barcelona, Spain; 2Fundacíon Institut Guttmann, Badalona, Spain; 3Institut Universitari de Neurorehabilitacio´ (UAB), Badalona, Spain.

Introduction
Although in-vitro models suggest GH-induced differentiation, migration and survival of astrocytes and oligodendrocytes, no studies had been published in-vivo. We want to evaluate the efficacy and safety of GH associated with physical therapy compared to placebo in patients with complete spine injury (SI) and associated GH deficiency (GHD).

Methods
Eighteen Patients with complete SI were screened for GH (glucagon test). 12 severe (GH<3 ng/ml) or partial (<10 ng/ml) GHD were randomized in a double-blind placebo-controlled study. Motor and sensory ASIA scale, SCIM-III (spinal cord injury independence measure), Ashworth (spasticity), Neuropathic Pain Scale and Quantitative Sensory tests were assessed. Patients received subcutaneous injections of placebo or GH (Natur opin®) 6 days/week IGF1-adjusted, in addition to intensive physical therapy 2/h/day, for 6 months. Both groups were similar according to age, sex, BMI, waist circumference.

Results
Significant (P=0.05) improvement was observed in SCIM-III score at 3 months: 55.6 (14.4 S.D.) vs 74 (2.8 S.D.) and 6 months: 55.4 (14.2 S.D.) vs 73.5 (2.1 S.D.), comparing GH-treated group with placebo. A significant improvement in the electrical perception threshold from the 1st up to the 5th metamera below the SI site was observed on both sides after 6 months of treatment in the GH, but not in the placebo group. These differences were observed intra-individually (P=0.04 Friedman’s test) and between groups (5th left level (P=0.023) and 5th right level (P=0.031), mixed linear model). No correlations with IGF1 were observed. No GH-related adverse events were reported.

Conclusions
Not studied so far, GHD seems very prevalent in SI. This is the first trial with complete SI and concomitant GHD. GH added to intensive physical rehabilitation improved functional parameters (SCIM) and changes in sensory quantification up to 5 levels below SI. Larger studies should be performed to confirm a GH beneficial effect on sensitive pathways in SI.

Subclinical cardiovascular system dysfunction in the patients with Cushing’s disease
Przemysław Witęś1, Beata Uzielbo-Zyczkowska2, Paweł Krzesiński3, Agnieszka Jurek2, Grzegorz Zielinski1, Andrzej Skrobowski3 & Grzegorz Gierlarz1
1Department of Endocrinology and Isotope Therapy, Military Institute of Medicine, Warsaw, Poland; 2Department of Cardiology and Internal Medicine, Military Institute of Medicine, Warsaw, Poland; 3Department of Neurosurgery, Military Institute of Medicine, Warsaw, Poland.

Background
Hypercortisolism in Cushing’s disease (CD) is associated with high cardiovascular risk. Hemodynamic disturbances, especially excessive vasoconstriction and elevated blood pressure (BP), may contribute to accelerated myocardial remodeling. Early identification of subclinical left ventricular (LV) dysfunction may be crucial for optimizing treatment and reducing mortality in patients with CD.

Methods
In 171 subjects (CD – 22, AH – 114, HV – 35), without any symptoms of heart failure, the echocardiographic assessment of LV systolic and diastolic function and non-invasive hemodynamic assessment by impedance cardiography (ICG) were performed. Statistical comparison included separate analysis for women and men.

Results
CD revealed good BP control (82% below 140/90 mmHg). However, in comparison to AH and HV they presented: 1) significantly lower LV contractility expressed by global longitudinal strain (GLS: –17.7% vs −19.2 vs −20.0; P<0.004); 2) higher prevalence of LV diastolic function (45.0% vs 14.2% vs 0.0%; P<0.0001); 3) lower impedance indices of LV performance: stroke index (51.39.8 vs 52.2 vs 49.9 mm2/ml; P<0.0001) cardiac index (CI: 2.86 vs 3.54 vs 3.27 l/min/m2; P<0.0001) and 4) higher afterload: systemic vascular resistance index (SVRI: 2560 vs 1901 vs 1907 dyn*s*cm⁻²; P<0.0001). Men with CD distinguished with lower CI (P<0.0001) and SVRI (P<0.0001), as though worse LV diastolic function (e': P=0.0002; GLS: P=0.052). In women hypercortisolism was more related to impaired LV systolic function (GLS: P=0.010; e': NS).

Conclusions
Cushing’s disease, even with well-controlled BP, is associated with LV systolic and diastolic dysfunction and pronounced vasoconstriction which individual presentation depends on sex. These hemodynamic alterations can be detected by modern non-invasive diagnostic tools and became potential therapeutic objectives.

Effects of pegvisomant and somatostatin receptor ligands on risk of vertebral fractures in patients with Acromegaly
Sabrina Chiloiro1, Gherardo Mazziotti3, Antonella Giampietro1, Anna Maria Formentini2, Antonio Bianchì2, Marilda Mornando1, Alfredo Pontecorvi1, Andrea Giustina4 & Laura De Marinis 1
1Pituitary Unit, Catholic University of the Sacred Heart, Rome, Italy; 2Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy; 3Department of Internal Medicine, Mantua Hospital, Mantua, Italy; 4Chair of Endocrinology, Vita-Salute San Raffaele University, Milan, Italy.

Acromegalic osteopathy is an emerging complication of chronic GH excess characterized by increase in bone turnover, deterioration in bone microarchitecture and high risk of vertebral fractures (VF s). Medical therapies may exert direct effects on peripheral targets leading to improvement of clinical outcomes regardless of biochemical control of acromegaly. In this longitudinal study, we compared the effects pegvisomant (PegV) and somatostatin receptor ligands (SRLs) on VF risk in 80 acromegaly patients (47 females, 33 males; mean age 53 years, range 24–86 years) who were prospectively evaluated by quantitative vertebral x-ray morphometric approach. During the 30 month study period, 39 patients (48.8%) were treated with PegV, 33 (41.2%) with SRLs and 8 (10%) showed a controlled disease after neurosurgery. At follow-up, 23 patients (28.8%) experienced incident VFs which were significantly correlated with persistently active disease (OR 4.9, 95% CI 1.95–17.22; P=0.003) and preexisting VFs (OR 2.79, CI 1.95–10.76; P=0.004). By contrast, no significant differences in incident VFs were found between patients receiving PegV and those treated with SRLs alone, either when disease was persistently active (58.3% vs 60.0%; P=0.94) or when disease was controlled by treatment (20.0 vs 27.0%; P=0.67). In conclusion, this longitudinal study showed that PegV and SRLs had comparable effects on VF risk in acromegaly. Biochemical control as well as early diagnosis of the disease are the main endpoints for fracture prevention in acromegaly.

Thyroid peroxidase antibodies do not predict outcome in 900 women with recurrent pregnancy loss
Sofie Bliddal1, Henriette Svarre Nielsen 2, Aase Krogh-Rasmussen3, Astrid Marie Kolte2, Ole Bjarne Christiansen2, Claus Henrik Nielsen3 & Ulla Feldt-Rasmussen3
1Department of Medical Endocrinology, Copenhagen University Hospital (Rigshospitalet), Copenhagen, Denmark; 2Recurrent Pregnancy Loss Unit, Copenhagen University Hospital (Rigshospitalet), Copenhagen, Denmark; 3Institute of Inflammatory Research, Copenhagen University Hospital (Rigshospitalet), Copenhagen, Denmark.

Introduction Thyroid autoimmunity has been associated with pregnancy loss. A possible mechanism is an overactive maternal immune system leading to rejection of the fetal allograft. In women with recurrent pregnancy losses (RPL), we investigated the association of thyroid peroxidase antibodies (TPOAbs) with number of losses and outcome of first pregnancy after referral.

Methods
Prospective study of women with RPL (≥3) followed at the RPL Unit, Copenhagen University Hospital, from 2011 to 2016. Upon first visit, all women were screened for TSH (Roche Modular E170 electrochemiluminescence immunoassays) and TPOAbs (automated Kryptor immunofluorescent assay). TPOAb-positivity >60 kU/l. We performed test for trends by chi-square or independent t-tests as appropriate, and adjusted regression analyses with covariates: maternal age, TSH (logtransformed), number of losses, immunotherapy, thyroxine replacement therapy. The National Data Protection Agency approved the project.

Results
We included 5219 pregnancies (76.6% spontaneous) in 900 women; 119 (13.2%) women were TPOAb-positive. TPOAb-positivity was neither associated with number of losses (P=0.87, aOR 0.004 (-0.3-0.3), P=0.98), nor number of pregnancies (P=0.62, aOR 1.02 (0.92-1.11) P=0.76). Among TPOAb-positive women, TPOAb-concentration was not associated with number of losses (B=0.75 (-0.12-0.27), P=0.45). In women with a registered first pregnancy after referral, TPOAb-positivity (72 of 557 (12.9%)) was not associated with live birth rate (54.4 vs 60.6%, P=0.35, aOR 0.78 (0.42-1.43) P=0.38). However, live birth rate was significantly associated with total number of losses (aOR 0.53 (0.45-0.61) P=0.000). TSH-levels were positively associated with TPOAb-positivity (P=0.00), but not with any investigated outcome. Immunoglobulin therapy or thyroxine replacement did not alter results.

Conclusion
In a large cohort of women with RPL, we found no association between TPOAbs and pregnancy outcome. TSH-levels were significantly increased in TPOAb-positive women and screening according to guidelines should be performed. However, if RPL is caused by an immunological reaction, thyroid autoimmunity does not seem to be a sensitive marker hereof.

Sertoli cell expressed hydroxysteroid (17beta) dehydrogenase 1 is required for male fertility
Janne Hakkarainen1, Heiti Jokela1, Fuping Zhang1, Noora Kotaja1, Petra Sigila2 & Matti Putanen1
1Department of Physiology and Turku Center for Disease Modeling, Institute of Biomedicine, University of Turku, Turku, Finland; 2Institute of Medicine, Sahlgrenska Academy, Gothenburg University, Gothenburg, Sweden.

Hydroxysteroid (17beta) dehydrogenase 1 (Hsd17b1) is a steroidogenic enzyme catalyzing the conversion of estrone (E1) to estradiol (E2), and androstenedione (A-dione) to testosterone (T). We have shown that the deletion of Hsd17b1 gene in mice resulted in the failure of ovarian estradiol production and subfertility. In this study, we clarified the role of Hsd17b1 in male reproduction. The data revealed that in mice Hsd17b1 mRNA is highly expressed in the Sertoli cells at the fetal age. The Sertoli cell function is critical for normal spermatogenesis, and their action is dependent on the pituitary gonadotropins and testosterone. The breeding tests revealed that the Hsd17b1 knockout male mice (Hsd17b1KO) were infertile. Because the Hsd17b1 is part of the steroid synthesis machinery, we analyzed the in vivobiomarkers for androgen action, while no changes were observed in fetal masculinization or in onset of puberty. Furthermore, the weights of androgen-dependent tissues in HSD17B1KO males, with minor changes in the E1/E2 and A-dione/T ratios. Interestingly, several steroidogenic genes, Hsd17b3, Star, Cyp11a1 and Hsd3b3, were significantly upregulated in HSD17B1KO testes, suggesting a functional compensation due to the lack of Hsd17b1 activity. Although marked changes were observed in the hormonal environment, histological analysis of HSD17B1KO testis revealed defects in the organization of differentiating germ cells in the seminiferous epithelium, and major defects in the haploid germ cell differentiation, particularly in the head shaping of elongating differentiating germ cells in the seminiferous epithelium, and major defects in the histological analysis of HSD17B1KO testis revealed defects in the organization of spermatids. Consequently, the epididymal sperm count was dramatically reduced in the HSD17B1KO males, and the remaining spermatozoa were morphologically abnormal. These results revealed a novel role for Hsd17b1 in the control of spermatogenesis and male fertility, and suggest that Hsd17b1 is required for a proper function of Sertoli cells.

Diabetes mellitus: a new cause of male infertility
Rosaria Angela Condorelli, Sandro La Vignera, Rossella Cannarella, Laura Maria Mongioi & Aldo Eugenio Calogero
Unit of Andrology and Endocrinology, Department of Clinical and Experimental Medicine, Catania, Sicily, Italy.

Introduction
Diabetes mellitus (DM) may cause male infertility acting with pre-testicular, testicular and post-testicular mechanisms.

Aim
To evaluate the presence of male infertility and the mechanisms of sperm damage in diabetic patients in childbearing age.

Patients and methods
Thirty-four patients with DM1, 55 with DM2 and 100 healthy fertile men (controls) were enrolled. Diabetic patients were further divided into three groups based on their glycometabolic status and illness duration. Conventional and biofunctional sperm parameters were evaluated by standard semen analysis and flow cytometry. This latter included sperm DNA fragmentation, vitality, early and late apoptosis, chromatin condensation, mitochondrial membrane potential (MMP), leukocyte subpopulations, lipid peroxidation (PL) and sperm mitochondrial superoxide. In addition, all patients and controls underwent testicular ultrasound scan and sperm LH and testosterone measurements.

Results
Diabetic patients had lower sperm concentration, progressive motility and morphology vs controls (P<0.05). The ejaculate volume is significantly lower in patients with DM1 vs controls (P<0.05). Leukocyte concentrations were higher in patients with DM2 (P<0.05), showing a statistically significant reduction in the percentage of T helper cells and an increase of the suppressor T lymphocytes compared to controls (P<0.05). The analysis of the biofunctional sperm parameters showed worsening MMP in diabetic patients (P<0.05). Patients with DM2 showed a significant decrease in the degree of sperm vitality and increased spermatozoa in late apoptosis vs Controls and of the DNA fragmentation compared to the other two groups (P<0.05). Moreover, patients with DM1 had a lower progressive motility when the disease duration was >10 years vs the other two groups, and lower MMP after 5 years of disease (P<0.05). The degree of PL was higher in DM2 patients compared to the other two groups (P<0.05), while the contributions of mitochondrial supersorption was greater in DM2 patients compared to DM1 and control group (P<0.05). The ultrasound data showed that the diameter of the epididymal head and tail after ejaculation were greater in patients with DM1 long term than those of short duration compared to controls (P<0.05). Testosterone levels were lower in DM2 patients vs controls (P<0.05).

Conclusion
Patients with DM1 have low ejaculate volume for an altered epididymal emptying and a mitochondrial damage that anticipates the later decline of sperm motility. DM2 is instead characterized by an inflammatory condition with increased leukocyte and oxidative stress and elevated levels of sperm DNA fragmentation and decreased sperm vitality.

Urinary cadmium excretion is associated with increased synthesis of cortico- and sex steroids in a family-based Swiss population study
Murielle Bochud1, Judith Jenny-Burri2, Menno Fruijn3, Belen Ponte4, Idris Guesous1, Georg Ehret5, Dusan Petrovic1, Vincent Dudler2, Max Holdmann1, Genevieve Escher7, Bernhard Dick7, Markus Mohaupt7, Michel Burnier7, Antoine Pechere-Bertschi7, Pierre-Yves Martin8, Bruno Vogt9 & Daniel Ackermann9
1Institute of Social and Preventive Medicine (IUMSP), Lausanne, Switzerland; 2Federal Food Safety and Veterinary Office, Bern, Switzerland; 3Service of Nephrology, Lausanne, Switzerland; 4Service of Nephrology, Geneva, Switzerland; 5Cardiology, Department of Specialities of Internal Medicine, Geneva, Switzerland; 6Endocrinology, Department of Specialities of Internal Medicine, Geneva, Switzerland; 7University Clinic for Nephrology and Hypertension, Bern, Switzerland.

Background: Cadmium (Cd) is considered as a human carcinogen. A potential intermediate mechanism could be hormone-related by disturbing steroidogenesis in gonads and adrenal glands. We tested whether urinary Cd excretion, as a marker of long-term exposure, is associated with the urinary steroid profile in the general adult population.

Methods and findings
The Swiss Kidney Project on Genes in Hypertension (SKIPGH) is a multicentric family-based population study with a response rate of 25.6%. We measured 24-h urinary excretions of Cd and steroid hormone metabolites by gas chromatography and mass spectrometry in 1000 participants (473 men, 527 women), with separate day and night collections. Mixed linear models were used to analyse the associations of each steroid metabolite with Cd excretion.

Cortisol and testosterone excretions were positively associated in men (β(SE, P): 1.378[0.242, <0.00001] and 1.440[0.333, 0.00002] for day and night, respectively), but not in women (0.333[0.257, 0.2] and 0.674[0.361, 0.06] for night and day, respectively). There was a strong positive association of the urinary excretion of Cd and cortisol (0.475[0.157, 0.0025] and 0.877[0.194, 0.00001]) for day, and 0.875[0.253, 0.00053] and 1.183[0.277, 0.00002] for night and day, respectively). Cd excretion was not associated with the excretion of tetrahydroaldestosterone, the major metabolite of aldosterone, but with other mineralocorticoid metabolites (P<0.01 in men and women).

Further adjustment revealed an independent effect between the synthesis of sex hormones and corticosteroids and an interdependent effect of Cd on gluco- and mineralocorticoid synthesis.

Conclusions
Our findings provide evidence for a global stimulating effect of low-dose Cd exposure on sex and corticosteroid synthesis in the general adult population. Further studies are needed to explore the health consequences of chronic low-dose exposure to Cd on selected diseases such as steroid-sensitive cancers or metabolic disorders.

Thyroid Cancer

Anti-Müllerian hormone (AMH) in pre-menopausal females after ablative radioactive iodine (RAI) treatment for differentiated thyroid cancer (DTC): single-center study

Miranda Mittle1, Paola Comite2, Claudia Camba1, Stefano Gay1, Michele Mussap2 & Massimo Giusti1

1UO Clinica Endocrinologica, Azienda Ospedaliera Universitaria San Martino – IST, Genoa, Italy; 2UO Laboratorio Analisi, Azienda Ospedaliera Universitaria San Martino – IST, Genoa, Italy.

Background

It is generally reported that female fertility is not affected by high-dose RAI treatment. AMH has been considered a reliable and accurate index of ovarian reserve. There are few data on AMH values in thyroid diseases. Recently, in DTC women who had undergone RAI ablation treatment, Acibucu et al. (2016) reported low AMH levels without significant impairment of fertility.

Aim

The aim of this single-center study was to evaluate AMH levels in association with the characteristics of spontaneous menstrual cycles and the levels of pituitary–gonadal hormones in our cohort of pre-menopausal women with a history of low-risk DTC.

Subjects

From a group of 68 women, 39 who were not on oral contraceptive therapy were enrolled. All hormonal evaluations were performed on chemiluminescence assays. AMH, FSH, 17β-estradiol (E2) were assayed on day 2 and PRL and progesterone (P) levels on day 21–24 of the same menstrual cycle. Twenty-seven women (aged 40 ± 6 years) were studied 7 ± 4 years after primary DTC treatment, which included at least one RAI treatment (median activity 80 mCi). As a control group, 12 female DTC patients (aged 40 ± 8 years) who had undergone only thyroidectomy were used.

Results

All women were free from DTC. Pregnancy (study group 62%; control group 50%) and abortion rates (17 and 33%) were similar. TSH and f-T4 were similar in the study group (33%), while a high incidence of oligomenorrhea was noted in the control group (50%). Ovulatory cycles (72 and 40%) and abortion rates (17 and 33%) were similar. AMH levels were 2.0 ± 0.4 ng/ml and 2.3 ± 1.5 ng/ml in the study and control groups, respectively.

Limitations

These data are preliminary, as data collection is still ongoing.

Conclusions

AMH should replace FSH in the evaluation of gonadal reserve in pre-menopausal DTC women. At present, age is the only predictor of AMH levels. About one out of two women with a history of DTC suffers from menstrual dysregulation, but infertility must be considered a low risk.

Suppression of heme oxygenase-1 inhibits growth and invasion of thyroid cancer

Shih-Ping Cheng1,2, Jie-Jen Lee1,2, Ming-Jen Chen1,2, Chien-Liang Liu1,2, Po-Sheng Yang1,2 & Yi-Chiung Hsu3

1MacKay Memorial Hospital, Taipei, Taiwan; 2MacKay Medical College, Taipei, Taiwan; 3National Central University, Taoyuan City, Taiwan.

Oxidative stress generated in the process of iodide metabolism and thyroid hormone synthesis may play a role in thyroid tumorigenesis and progression of thyroid cancer. The transcription factor Nr2f2 is the most important regulator of antioxidant responses. It has been shown that Nr2f2 expression is upregulated in papillary thyroid cancer. In response to oxidative stress, nuclear Nr2f2 activates antioxidant-responsive elements and induces the expression of stress-responsive genes, including heme oxygenase-1 (HO-1). Previously we have demonstrated that HO-1 overexpression was associated with advanced tumor stage in thyroid cancer. Therefore, we hypothesize that HO-1 may represent a potential target for cancer therapy. HO-1 inhibitors have been clinically used in patients with hyperbilirubinemia and hereditary porphyria. In the present study, thyroid cancer cells were treated with two different classes of HO-1 inhibitors: metalloporphyrin and imidazole-dioxolane compound. We found that treatment with HO-1 inhibitors suppressed cell growth, colony formation, cell migration, and invasion of thyroid cancer cells in a dose-dependent manner. Cell cycle analysis by flow cytometry revealed that growth arrest in the G0/G1 phase. However, there was no synergistic effect of HO-1 inhibitors in combination with doxorubicin or sorafenib. Our results suggest a modest susceptibility of thyroid cancer cells to HO-1 inhibitors. Nonetheless, HO-1 inhibition may not act as a sensitizer to chemotherapy in thyroid cancer.

João, Porto, Portugal; 12Department of Pathology and Oncology, Medical Faculty, University of Porto, Porto, Portugal.

Context

Little is known about the frequency of key mutations in thyroid cancer metastases and its relationship with the primary tumor genotype.

Objectives

To evaluate the frequency of TERT promoter (TERTp), BRAF and NRAS mutations in metastatic thyroid carcinomas, analyzing primary thyroid tumors, lymph node metastases (LNM) and distant metastases.

Material and Methods

Mutation analysis was performed in 437 tissue samples from 204 patients, mainly with papillary thyroid carcinomas (PTC) (n = 180), including 196 LNM and 56 distant metastases. All the distant metastases included corresponded to radioiodine-refractory metastatic tissue.

Results

We found the following mutation frequency in primary thyroid tumors, LNM and distant metastases, respectively: TERTp- 15.9, 10.8, and 52.4%; BRAF (PTC-only)- 44.6, 41.7, and 23.8%; NRAS- 1.7, 1.3, and 11.9%. In the subgroup of patients with PTC, the TERTp mutation frequency in primary tumors, LNM and distant metastases was 12.9, 10.5, and 52.4%, respectively. There was a significant concordance between the primary tumor genotype and the corresponding LNM, in particular for BRAF-mutated PTC. The overall concordance between primary tumors and respective distant metastases was low. In the group of patients with PTC, we found a high frequency of TERTp mutations and a low frequency of BRAF mutations in distant metastases, in comparison to the paired primary tumors.

Conclusions

The frequency of BRAF, NRAS and TERTp mutations is similar in primary tumors and matched LNM, whereas distant metastases show an enrichment in TERTp mutations and a decrease in BRAF mutations. TERTp mutations seem to play an important role in distant metastases.

Endocrine Abstracts (2017) Vol 49
Inverse relation between thyroid cancer incidence and threshold for thyroid surgery: a national population-based retrospective study
Brigitte Decallonne1, Van den Brul Annick2, Elaau Nathalie3 & De Schutter Harlinde2
1KU Leuven, Leuven, Belgium; 2Belgian Cancer Registry, Brussels, Belgium; 3General Hospital Sint Jan, Bruges, Belgium.

Background
In Belgium, lower thyroid cancer incidence – most pronounced for microcancers (T1a) – is present in the North compared to the South. This variation is paralleled by differences in clinical practice: in the North less thyroid surgery is performed, more surgery is preceded by fine needle aspiration (FNA), and more patients with a final cancer diagnosis (2004–2006) underwent a presurgical FNA or a lymph node dissection (LND) at fist surgery.

Aim
To study 1/ the evolution in the use of FNA and LND, and 2/ the weight of T1a non-thyrotoxic thyroid glands in a recent thyroid cancer cohort.

Methodology
Population-based retrospective study, using data from the Belgian Cancer Registry (including case-by-case study of pathology protocols) and Belgian Healthcare Insurance database for differentiated thyroid cancer (DTC) cases diagnosed between 2009 and 2011 (n = 2659).

Results
Linkage of both databases resulted in 2557 DTC cases (96%). In the North a higher proportion of DTC cases underwent FNA before surgery: 62.3% [95%CI 58.3;66.3] compared to 33.6% [95%CI 29.3;39.9] in the South (P < 0.0001), confirming geographical differences. A positive trend for FNA was observed in the period 2004–2012, at national and regional level, especially in the South. The execution of LND during first thyroid surgery was proportionally higher in the North (24.3% [95%CI 20.6;28.0]) compared to the South (15.3% [95%CI 12.0;18.7], P < 0.0001), without temporal trend. Finally, in the subgroup of 121 T1a DTC cases – considered to be mainly incidental findings – the mean thyroid weight was 57.7 ± 52.1 g in the North, compared to 37.9 ± 29.1 g in the South (P < 0.0001).

Conclusion
In the present cohort, more FNA precedes thyroid cancer diagnosis, according to international guidelines. However, geographical differences clearly persist. A lower thyroid weight is present in DTC T1a in the South. These findings support the alignment of a higher thyroid cancer incidence with a lower threshold for thyroid surgery in case of nodular disease, strongly suggesting overdiagnosis.

Dose aggressive variants of papillary thyroid carcinoma have worse clinical outcome than classical papillary carcinoma?
Eyun Song1, Min Ji Jeon2, Hyemi Kwon1, Suyeon Park1, Hye-Seon Oh1, Jin-Sook Ryu1, Dong Eun Song1, Eui Young Kim1, Tae Yong Kim1, Young Kee Shong1, Won Bae Kim1 & Won Gu Kim1
1Asan Medical Center, Seoul, Republic of Korea; 2Dongnam Institute of Radiological & Medical Sciences Cancer Center, Busan, Republic of Korea.

Background
Unlike excellent prognosis of classical papillary thyroid carcinoma (cPTC), certain pathological subtypes of aggressive variants of PTC (AV-PTC) are considered to have poor clinical outcome. However, the evidence of unfavorable outcome of AV-PTC is not clear because previous studies did not control other confounding factors contributed to clinical outcomes.

Methods
This retrospective cohort study initially included 4339 patients with cPTC and 121 patients with AV-PTC including tall cell, columnar, hobnail, solid and diffuse sclerosing variants. Dynamic risk stratification (DRS) and recurrence free survival (RFS) between the two groups were compared after two-to-one individual risk factor matching by age, sex, tumor size, and initial surgical extent.

Outcome
AV-PTC was associated with larger tumor size (P < 0.001) and higher rates of cervical lymph node (LN) metastasis (P < 0.001) compared to cPTC. A total of 121 patients with AV-PTC and 242 patients with cPTC were evaluated after individual risk factor matching. There were no significant differences in the tumor size and cervical LN metastasis between the two groups after mating. When we compared the proportion of patients according to the DRS, there was no significant difference between patients with cPTC and those with AV-PTC (P = 0.14). There was also no significant difference in RFS (hazard ratio [HR] 1.93, 95% confidence interval [CI] 0.68–5.47, P = 0.23) between the two groups.

In subgroup analysis including patients with tall cell, columnar, and hobnail variants of PTC, there were no significant differences in DRS (P = 0.68) and RFS (HR 2.04, 95% CI 0.56–7.41, P = 0.29) compared with matched patients with cPTC.

Conclusion
The clinical outcome of patients with AV-PTC was not different with those with cPTC when their other clinicopathological risk factors were similar. Therapeutic and follow-up strategies for PTC might not need to be modified according to presence of AV-PTC.

Previously, we identified seven mutations in the main catalytic subunit of protein kinase A (PKA C) to be responsible for cortisol-secreting adrenocortical adenomas (CPAs): L206R, L199_C200_insW, S213R, L212_K214insIILR, C200_GlyinsV, W197R, del244-248+E249Q, E32V. Here we performed a functional characterization of these mutants. Specifically, we evaluated the association between PKA regulatory and catalytic subunits using co-immuno- precipitation and PKA activity using a kemptide assay and a western blot analysis. Our results show that four mutations (L206R, L199_C200_insW, W197R, del244-248+E249Q) directly demonstrated altered substrate specificity for three mutants (L206R, del244-248+E249Q, C200_GlyinsV). Taken together, these findings suggest that the PKA C mutations found in CPAs alter substrate specificity and that interference with the formation of a stable PKA holoenzyme is probably just one of the mechanisms through which these mutations affect PKA signaling, ultimately leading to increased cortisol production and cell proliferation. The results of the phosphoproteomics analysis might lead to the identification of new PKA targets involved in the pathogenesis of CPAs.

Background

Extracellular vesicles (exosomes, microvesicles) shed from tumor cells containing microRNAs can be exploited as markers of malignancy. The preoperative diagnosis of adrenocortical malignancy is difficult and microRNAs have proved useful in the diagnosis of many tumors, including adrenocortical cancer (ACC), but there have no studies to date on extracellular vesicle associated microRNAs in ACC.

**Aim**

To evaluate the diagnostic potential of extracellular vesicle-associated (exosomal) microRNAs in human adrenocortical tumors.

**Methods**

Isolation of extracellular vesicles (EV) was performed by differential centrifugation/ultracentrifugation or by using Total Exosome Isolation Kit. The significantly differentially expressed microRNAs were validated in a mouse xenograft model. The disruption suggested could contribute to normal adrenal cell proliferation in the adrenal cortex, creating a permissive environment for the emergence of specific driver mutations in APA.

Background

Extracellular vesicles (exosomes, microvesicles) shed from tumor cells containing microRNAs can be exploited as markers of malignancy. The preoperative diagnosis of adrenocortical malignancy is difficult and microRNAs have proved useful in the diagnosis of many tumors, including adrenocortical cancer (ACC), but there have no studies to date on extracellular vesicle associated microRNAs in ACC.

**Aim**

To evaluate the diagnostic potential of extracellular vesicle-associated (exosomal) microRNAs in human adrenocortical tumors.

**Methods**

The isolation of extracellular vesicles (EV) was performed either by differential centrifugation/ultracentrifugation or by using Total Exosome Isolation Kit. EV preparations were also assessed by transmission electron microscopy and flow cytometry. 6 adrenocortical adenomas (ACA) and 6 histologically verified ACC samples were profiled by Taqman Human Microarray A-cards in the discovery cohort. The significantly differentially expressed microRNAs were validated in 13 ACAs and 12 ACCs by targeted quantitative real-time PCR.

**Results**

Significant overexpression of EV-associated hsa-miR-101 and hsa-miR-483-5p was measured in ACC vs ACA samples in the microRNA profiling. We could confirm the overexpression of these microRNAs in the validation cohort, too. dCThSA-miR-483-5p normalized to cel-mir-39 showed the highest area under curve (AUC) value (0.96), with 91.67 sensitivity and 92.33 specificity.

**Conclusions**

Extracellular vesicle-associated (exosomal) hsa-miR-483-5p might be a promising minimally invasive biomarker in the preoperative diagnosis of ACC.

**Androgen receptor signalling is essential for regression of the adrenal x-zone and regulation of the adrenal cortex in the male mouse**

Anne-Louise Gannon, Laura O’Hara, Rod Mitchell, Ian Mason & Lee Smith
University of Edinburgh, Edinburgh, UK.

Introduction

Androgens have long been known to play an important role in health and wellbeing. A range of clinical disorders in males and females can arise due to disruption to production and action of androgens. Androgen receptor (AR) is widely expressed throughout the adrenal cortex, yet the wider role for androgen signalling in the adrenal remains underexplored due to the lack of suitable animal models.

Methods

An adrenal-specific androgen receptor knockout mouse model was created by targeting GFP-Cre-GC to the mouse Cyp11a1 locus to drive Cre Recombinase expression in steroidogenic cells. Males were then mated to C57BL/6 female homozygous AR<sup>−/−</sup> mice. C57BL/6 mice were also used to investigate normal adrenal function. Tissue was analysed through qRT-PCR and statistical analysis by one way ANOVA. Immunohistochemistry was used to determine changes in protein localisation.

Results

Results highlight that androgens signalling through AR is essential for the regression of the foetal ‘X-zone’ during puberty in male mice. Loss of androgens (through castration) or AR results in significant morphological differences in the adrenal cortex and X-Zone cells. However, interestingly, loss of androgens or AR impact cortex structure, gene expression and protein localisation differently.

Conclusions

We show that androgen signalling through AR is essential for removal of X-zone cells during puberty. We also demonstrate that androgens can act independently of AR to modulate cortex function. Additionally, the loss of androgen signalling results in a decrease in apoptotic cells, suggesting the adrenal has become more resistant to cell death. Improper removal of cortical cells and loss of apoptosis could have serious implications for adrenal function and disease progression. The impacts of this are undergoing further investigation.

Background

Androgen receptor (AR) is widely expressed in the male mouse adrenal cortex and X-Zone during puberty. We show that androgen signalling through AR is essential for removal of X-zone cells during puberty. Androgens have long been known to play an important role in health and wellbeing. A range of clinical disorders in males and females can arise due to disruption to production and action of androgens. 

Methods

We investigated the correlation between catalytic subunit adrenocortical adenomas (CPA) heterozygous activating somatic mutations in the and the underlying regulation mechanisms in CPA and the adrenal cell line NCI-H295R. 

Results

For example, the L206R mutation led to full degradation of RII<sup>b</sup> in H295R cells, transfection with the L206R mutant led to full degradation of RIβ, which could not be rescued by different degradation mechanisms, suggesting another mechanism that can be abrogated by stimulating PKA signaling. LC-MS/MS revealed putative RIβ interaction partners affecting its stability in the presence of Cα-L206R only after stimulation of PKA signaling.

Conclusions

We confirm the role of ARMC5 as a pro-apoptotic protein and its importance in the steroidogenesis related to PMAH, as previously described in H295R cells. We also report for the first time the involvement of ARMC5 in proliferation control of PMAH mutated cell cultures, decreasing cell viability.

DOI: 10.1530/endoabs.49.GP5

**Involvement of ARMC5 in proliferation and cell cycle control of human cell cultures from adrenal nodules of primary macronodular adrenocortical hyperplasia (PMAH)**

Isadora Cavalcante<sup>1</sup>, Mirian Nishi<sup>2</sup>, Maria Claudia Zerbini<sup>3</sup>, José Luiz Chambo<sup>1</sup>, Madison Almeida<sup>2,3</sup>, Clairemaria Lotti<sup>2</sup> & Maria Candida Fragoso<sup>2,3</sup>

<sup>1</sup>Institute of Biomedical Sciences, São Paulo, Brazil; <sup>2</sup>Laboratory de Medical Investigation LIM 42, São Paulo, Brazil; <sup>3</sup>Department of Urology, São Paulo, Brazil; <sup>4</sup>Department of Pathology, São Paulo, Brazil; <sup>5</sup>Adrenal Unit, São Paulo, Brazil.

Methods

Cell cultures obtained from nodules of 13 unrelated patients with PMAH ARMC5 mutated or not were analyzed for: i) Morphological and functional characterization; ii) ARMC5 sequencing; iii) ARMC5 silencing through shRNA in non-mutated PMAH cells for steroidogenic and proliferative functional studies; iv) ARMC5 overexpression through transient transfection in mutated PMAH cells and viability analyses.

Results

i) The cell cultures demonstrating presence of steroidogenic cells, ectopic/aberrant receptors and functional intra-adrenal ACTH, ii) ARMC5 mutations were located mostly in exons 1, 2 and 3, responsible for protein-protein interactions of ARM repeat family; ARMC5 germline mutations identified in seven samples were associated or not to somatic mutations or LOH. In six samples, ARMC5 mutation was not identified; iii) ARMC5 silencing in non-mutated PMAH cell cultures decreased StAR, CYP17A1, CYP11A1, NR5A1 and MC2R, increased CCNE1 mRNA expression and its proliferative capacity, but without interference in cell viability. iv) ARMC5 overexpression induced apoptosis and necrosis after 8h in PMAH mutated cell cultures, decreasing cell viability.

Conclusions

We confirm the role of ARMC5 as a pro-apoptotic protein and its importance in the steroidogenesis related to PMAH, as previously described in H295R cells. We also report for the first time the involvement of ARMC5 in proliferation control and cell cycle regulation of PMAH cell cultures, which needs to be further explored.

Identification of a new glucocorticoid receptor mutation underscores the substantial prevalence of genetic NR3C1 alterations in adrenal hyperplasia: the French National Research Program MUTA-GR

Geraldine Villénius1, Brigitte Delemer2, Philippe Caron3, Antoine Benuën1, Jerome Bouligand4, Anne Guichaud-Mantel5, Say Viengchareun6, Christian Dani1, Severine Trabado1, Marc Lombes1,5
1Inserm UMR S 1185, Kremlin Bicêtre, France; 2Service d’Endocrinologie, Hopital Robert Debré, CHU de Reims, REIMS, France; 3Service d’endocrinologie, maladies métabolique et nutrition, CHU Larrey, TOULOUSE, France; 4Service de Génétique moléculaire, pharmacogénétique et hormonologie, KREMLIN BICETRE, France; 5Service d’Endocrinologie et des Maladies de la Reproduction, KREMLIN BICETRE, France; 6Université Côte d’Azur, CNRS, Inserm, iBV, NICE, France.

Primary generalized glucocorticoid resistance is characterized by glucocorticoid excess without any Cushing syndrome. Patients exhibit variable clinical presentation including arterial hypertension, hirsutism or adrenal hyperplasia. Although glucocorticoid resistance has been associated with glucocorticoid receptor (GR) mutations (encoded by NR3C1 gene), only 23 mutations have been reported so far. We have conducted a French National Research Program, referred to as MUTA-GR that aims at determining the prevalence of NR3C1 genetic alterations in patients with adrenal masses associating by glucocorticoid resistance. In this context, we have recently identified a novel GR stop mutation in a 43-year-old man presenting with glucocorticoid resistance, bilateral adrenal hyperplasia and biological hypercortisolism (1.5 to 3-fold increased in 24 urine free cortisol; negative response to dexamethasone suppression test and normal plasma ACTH concentrations). Alteration of GR signaling is currently validated by transient transfection assays, binding studies, subcellular trafficking, Chromatin Immunoprecipitation experiments, stability investigation, three-dimen- sional modeling and gene expression studies. More than 120 patients have been enrolled and five original GR heterozygous mutations (two missense and three false sense including R469X, R477S, Y478C, L672P) were discovered. Each original mutation impaired a different step of GR functional modeling and gene expression studies. Interestingly, all mutated patients present with metabolic disorders (high BMI, metabolic syndrome, …), supporting the essential role played by glucocorticoid signaling in adipocyte physiology that we are currently exploring. Altogether, GR mutations are not such an uncommon event given that 5% of our patients carried NR3C1 alterations. Collectively, GR defects are not a rare cause of glucocorticoid resistance, an incidence initially minimized. We propose that genetic screening of NR3C1 alterations. Collectively, GR defects are not a rare cause of glucocorticoid metabolism, adrenal masses, and metabolic syndrome, phenotypes with a decreased response in glucocorticoid-dependent target gene signaling in adipocyte physiology that we are currently exploring. Altogether, GR defects are not a rare cause of glucocorticoid resistance, an incidence initially minimized. We propose that genetic screening of NR3C1 alterations. Collectively, GR defects are not a rare cause of glucocorticoid resistance, an incidence initially minimized. We propose that genetic screening of NR3C1 alterations. Collectively, GR defects are not a rare cause of glucocorticoid resistance, an incidence initially minimized. We propose that genetic screening of NR3C1 alterations.

Clinical and translational relevance of circulating miR483 in adrenocortical cancer

Letizia Cani1, Francesca Salvianti2, Giada Poli1, Roberta Armignacco1, Giulia Cantini1, Alessandra Di Franco1, Stefania Gelmini1, Tonino Ercolino1, Massimo Terzolo2, Gabriella Nesi1, Pamela Pinzani1, Massimo Mannelli1 & Michaela Luconi1
1University of Florence, Florence, Italy; 2University of Turin, San Luigi Gonzaga Hospital, Orbassano, Turin, Italy.

Adrenocortical cancer (ACC) is a rare aggressive malignancy, with poor prognosis when metastatic at diagnosis. Recent ACC pan-genomics analysis contributed to redefine the risk groups on molecular bases, including tumor micro RNA (miR), which can be detected not only in the primary lesion but also in the bloodstream.

We develop a quantitative real-time assay for the measurement of absolute levels in plasma samples of miR483 and its mature miR483-5p form. miR483/miR483-5p levels were evaluated in plasma samples of 27 patients with ACC before surgery and at follow up, and in an independent validation cohort of 21 metastatic ACC. Statistically significant difference in miR483-5p and miR483 levels of pre-surgery and post-surgery samples was found between low (stage 1/2) and high (stage 3/4) risk groups. Moreover the mean levels of both miRs were significantly higher in plasma of patients belonging to the high risk group compared to stage 1/2.

Cut-off value for miR483-5p (0.221 ng/ml) significantly predicted overall and recurrence-free survival. miR483-5p was the only variable that significantly predicts recurrence, but not overall survival, in a multivariate Cox analysis (HR 16.2, 95% CI [1.39–188.6], P < 0.026). In addition, miR483-5p levels significantly correlated with the number of circulating tumor cells in the same blood samples, independently of the timing of sampling. Analysis of an independent cohort of metastatic ACC (n = 21) revealed that miR483 negatively correlated with mutan levels.

In conclusion, we demonstrated that miR483 and miR483-5p absolute plasma levels in ACC patients are powerful molecular markers that may help to follow patients after surgery and chemotherapy, and contribute to better classify and predict tumor evolution.

DO: 10.1530/endoabs.49.GP8

Mortality is increased in patients with Cushing’s disease in long-term remission: A nation-wide study

Dimitrios Chantzichristos1, Eleni Papakokkinou1, Per Dahlqvist2, Elin Segerstedt1, Tommy Olsson3, Katarina Berinder1, Charlotte Höbye1, Sophie Bensing1, Britt Eden Engström2, Pia Burman1, Cecilia Folin1, Eva Marie Erfurth1, Jeanette Wahlberg1, Bertil Ekman1, Erik Schwarzkopf2, Ing-Liss Bryngelsson3, Eva Andersson2, Gudmundur Johansson1, Daniel S Olsson1 & Oskar Ragnarsson1

Background
It is still undetermined whether patients with Cushing’s disease (CD) in remission have an increased mortality. Most previous studies are limited by small numbers of patients and/or short follow-up time. Objective
To study mortality in a nation-wide cohort of patients with CD during long-term follow-up.
Methods
Patients with ICD codes for Cushing’s syndrome and/or CD, between 1987 and 2013, were identified in the Swedish National Patient Registry. Medical records of the patients were reviewed (clinical, biochemical, imaging and histopathological data) to verify the diagnosis, and to determine remission status. All other forms of Cushing’s syndrome than CD were excluded from the study. Standardized mortality ratios (SMRs) with 95% confidence intervals were calculated using the Swedish general population as reference.

Results
Out of 1252 identified patients, 502 (387 women (77%)) had a confirmed CD diagnosis. Of these, 411 (82%) were in biochemical remission. The mean ± s.d. age at diagnosis was 46 ± 16 years. The median (interquartile range) follow-up time was 13 (6–23) years, resulting in 7165 patient-years of follow-up. Of the 502 patients, 364 (73%) had been treated with pituitary surgery, 129 (26%) with radiotherapy and 102 (20%) with bilateral adrenalectomy. The observed number of deaths was 133 vs 54 expected, resulting in an overall SMR of 2.46 (95% CI 2.06–2.91). SMR in patients not in remission (n = 91) was markedly increased, SMR 8.23 (95% CI 5.42–12.8). Mortality in patients in biochemical remission was lower (P < 0.0001), but increased compared to the general population, SMR 1.80 (95% CI 1.44–2.23).

Conclusion
This large nation-wide study demonstrates that patients with CD have an excess mortality, irrespective of remission status. The findings emphasize the importance of curative treatment as well as continued active surveillance after remission has been achieved.

Background

Recently, GATA transcription factors have been linked to the development of Testicular Adrenal Rest Tumours (TART), benign adrenal-like testicular tumours that frequently occur in male patients with congenital adrenal hyperplasia (CAH). The objective of this study is to determine GATA expression in TART and other steroidogenic tissues, examining their discriminative potential and their possible role in the aetiology of TART.

Methods

GATA1-6 expression was determined in TART, Leydig cell tumour (LCT), adult tests, adult adrenal, foetal tests, and foetal adrenal tissues. In addition, GATA1-6 gene expression was measured in Hs181tes cells after induction with dibutyryl cAMP (dbcAMP).

Results

In TART, tests-like GATA4 gene expression, but higher compared to adult adrenal, was found. In contrast, GATA5 and GATA6 expression in TART is similar to adrenal, but higher compared to adult tests or LCT. GATA3 and GATA6 could discriminate between TART and tests (AUC of 0.982 and 0.920, respectively). ACTH is a line with 0.1 mM dbcAMP for 4 hours increased gene expression of both potential stimulator of TART differentiation in CAH. Stimulation of the Hs181.tes cell adrenal characteristics. Additionally, gene expression of GATA transcription factors in TART shows both testicular and steroidogenic tissue, examining their discriminative potential and their possible role in the aetiology of TART.

Conclusions

The maintenance doses of hydrocortisone observed in this study are in line with international guidelines in all four countries. The country difference in maintenance doses in DRHC is consistent with data showing that mean daily doses of hydrocortisone tend to be higher in Sweden than in other countries.

Activation of the cAMP/PKA transduction system triggers abnormal expression of the serotonin signaling pathway in human adrenocortical cells

Julie Le Mestre1, Céline Duparc1, Zakariae Brum1, Yves Reznik2, Jérôme Berthet3, Philippe Touraine2, Jacques Young4, Olivier Chabre2, Constantine A. Stratakis5, Hervé Lefebvre6,7 & Estelle Louiset1
1Normandie University, UNIROUEN, INSERM, U1239, Rouen, France; 2Department of Endocrinology-Diabetology, Caen University Hospital, Caen, France; 3Department of Endocrinology and Metabolic Diseases, Assistance Publique des Hôpitaux de Paris, Hôpital Cochin, Paris, France; 4Department of Endocrinology and Reproductive Medicine, Assistance Publique-Hôpitaux de Paris, Hôpital Pitié Salpêtrière, Paris, France; 5Department of Endocrinology, Assistance Publique-Hôpitaux de Paris, Hôpital Bicêtre, Kremlin-Bicêtre, France; 6Department of Endocrinology, CHU de Grenoble, Grenoble, France; 7Section of Endocrinology and Genetics, PFDEGEN, NICHD, Bethesda, Maryland, USA; 8Department of Endocrinology, Rouen University Hospital, Rouen, France.

**Introduction**

In human adrenals, serotonin (5-HT), released by subcapsular mast cells, increases aldosterone secretion through activation of type 4 serotonin receptors (5-HT4R) but only exerts a modest control on cortisol production. Interestingly, illicit synthesis of 5-HT in adrenocortical cells as well as overexpression of the 5-HT receptor (5-HT4R) have been observed in bilateral macronodular adrenal hyperplasia responsible for hypercortisolism. In this study, we have investigated the expression of the key enzyme of 5-HT synthesis tryptophan hydroxylase (Tph) and 5-HT1A, 5-HT1B, 5-HT1D, 5-HT1F, 5-HT2C, 5-HT3, 5-HT4, and 5-HT7 receptors (5-HT4R) in this adrenocortical cell line with clinical and biochemical data from patients in the four countries were compared. 1798 patients (626 PAI, 1172 SAI) were included in the current analysis of data collated until November 2016. Patients with congenital adrenal hyperplasia or primary AI were excluded.

**Results**

We found that dbcAMP can induce GATA3 and GATA6 gene expression, which might indicate that ACTH can stimulate tests-like cells to become more adrenal like and eventually TART cells. To confirm this, we are pending on the results of stimulation experiments with dbcAMP or ACTH in ACTH-responsive H295RA cells.

**Conclusion**

We are pending on the results of stimulation experiments with dbcAMP or ACTH in ACTH-responsive H295RA cells.

A country comparison of glucocorticoid replacement therapy in patients with primary and secondary adrenal insufficiency: data from the EU-AIR

Bertil Ekman1, Marcus Quinkler2, Pinggao Zhang3, Pierre Zelissen4 & Robert D. Murray5
1Linköping University, Linköping, Sweden; 2Endocrinology in Charlottenburg, Berlin, Germany; 3Shire, Lexington, Kentucky, USA; 4University Medical Center Utrecht, Utrecht, The Netherlands; 5St James’s University Hospital, Leeds, UK.

**Introduction**

The daily maintenance dose of conventional hydrocortisone currently recommended by international guidelines for the management of primary adrenal insufficiency (PAI) or secondary adrenal insufficiency (SAI) is 15 – 25 mg/day, in 2 – 3 divided doses. The aim of this analysis was to investigate inter-country differences in glucocorticoid replacement doses in patients with PAI and SAI.

**Design**

EU-AIR (ClinicalTrials.gov identifier: NCT01661387) with 20 contributing centres across Germany, the Netherlands, Sweden and the UK started enrolling patients with AI in August 2012. Baseline clinical and biochemical data from patients in the four countries were compared. 1798 patients (626 PAI, 1172 SAI) were included in the current analysis of data collated until November 2016. Patients with congenital adrenal hyperplasia or primary AI were excluded.

**Results**

No major differences between countries were seen in disease duration, BMI, blood pressure or blood lipids in patients with PAI and SAI. However, BMI was generally higher in patients with SAI than PAI. Most patients were treated with conventional hydrocortisone, with similar mean doses administered in Germany, the Netherlands, Sweden and the UK (PAI: 24.7 ± 8.4 mg/day, 22.2 ± 5.7 mg/day, 21.6 ± 10.0 mg/day, 21.0 ± 9.3 mg/day; SAI: 20.0 ± 6.4 mg/day, 20.8 ± 6.1 mg/day, 21.6 ± 9.4 mg/day, 18.9 ± 5.2 mg/day). Cortisone acetate was most commonly used in the Netherlands (PAI: 23%; SAI: 27%). No difference was observed in fludrocortisone dosing in patients with PAI between countries (0.1 ± 0.07 mg/day, 0.1 ± 0.04 mg/day, 0.1 ± 0.05 mg/day, 0.1 ± 0.12 mg/day). Patients with PAI treated with dual-release hydrocortisone (DRHC) were treated with lower doses in Germany 21.3 ± 2.3 compared with those in Sweden 28.0 ± 6.0 mg/day.

**Conclusions**

The maintenance doses of hydrocortisone observed in this study are in line with international guidelines in all four countries. The country difference in maintenance doses in DRHC is consistent with data showing that mean daily doses of hydrocortisone tend to be higher in Sweden than in other countries.

**PRKARIA (Carney complex gene)** is a major regulator of the tight link between cell cycle phases and steroidogenesis in the adrenocortical tumor cells H295R

Marthe Rizk-Rabin1, Bruno Ragazzon1 & Jeroˆme Bertherat1,2
1INSERM U1016, CNRS UMR6104 Paris Descartes University, Paris, France; 2Center for Rare Adrenal Diseases, Department of Endocrinology, Hôpital Cochin, Paris, France.

The cyclic AMP/PKA signalling cascade is involved in the pathogenesis of cortisol-secreting adrenocortical tumors (ACT). Defects in cell cycle checkpoints play a major role in oncogenesis. The PKA regulatory subunits \textit{PRKARIA} and \textit{PRKARIIb} are involved in cell survival and steroidogenesis in the adrenocortical carcinoma H295R cell line. We have previously shown that their inactivation enhances the accumulation of cells in the G2 phase and activates PKA and MAPKinas pathways.

This study investigates the correlation between the cell cycle phases and the adrenal steroid secretion, as well as their control by PKA.

Methods

Using pharmacologic drugs, H295R cells were synchronized at specific cell cycle check point (G1 phase), (S phase) and (G2 phase). The cell cycle distribution (Cytometry), the expression of cyclins, PKA subunits, cell signalling pathways, StAR and steroidogenic enzymes were analysed. The effect of PKA activation either by the different PKA subunits, or cAMP, PKA inactivation by H89 and PKI along the cell cycle synchronization were studied.

Results

Cells synchronized at G2 phase increased the expression of the steroidogenic enzymes and steroid secretion. Arresting H295R in G1 phase decreased the steroidogenic enzymes expression and cortisol secretion. PKA subunits distribution and PKA activity modulation were cell cycle dependent. PKA activation by \textit{PRKARIA} inactivation counteracted specifically the decrease of steroidogenesis in cells arrested in G1 phase: StAR/luc reporter gene activity and cell progression in G2 phase were stimulated. \textit{PRKARIIb} inactivation and \textit{PRKACA} overexpression or cAMP increased the StAR/luc reporter gene activity, independently of the cell cycle check point arrest. The H89 and PKI differentially reduced StAr/luc reporter gene activity, and both reversed the cell cycle in the G2 arrested cells.

Conclusion

Inactivation of the Carney complex gene stimulates steroidogenesis in the low steroidogenic G1 phase arrested cells. This study shows a link between the cell cycle check points and the regulation of steroidogenesis, in which the \textit{PRKARIA} subunit is a key regulator of both cell cycle and steroidogenesis.

Simultaneous assays of aldosterone and renin concentrations in just ten minutes could change the clinical assessment for the diagnosis of primary aldosteronism

Fumitoshi Satoh1,2, Mamuto Kudo2, Yoshikazu Inoue1, Yuta Tazuka1,2, Kei Ono2,2, Masahiro Nuzi2, Yoshitsugu Iwakura3, Yoshuhiro Igarashi2, Masatake Kudo1 & Sadayoshi Ito3
1Tohoku University Graduate School of Medicine – Division of Clinical Hypertension, Endocrinology and Metabolism, Sendai, Japan; 2Tohoku University Hospital – Division of Nephrology, Endocrinology and Vascular Medicine, Sendai, Japan.

Measurement of plasma aldosterone and renin concentration, or activity, is useful for selecting antihypertensive agents as well as detecting hyperaldosteronism in hypertensive patients. However, it takes several days to get results when measured by radioimmunoassay and development of more rapid assays has been long expected. We have developed chemiluminescent enzyme immunoassays enabling the simultaneous measurement of both aldosterone and renin concentrations in ten-minutes by a fully automated assay using antibody-immobilized magnetic particles with quick aggregation and dispersion. We performed clinical validation of diagnostic ability of this newly developed assay-based screening of 125 patients with primary aldosteronism from 97 patients with essential hypertension. Results of this novel assay significantly correlated with the results of radioimmunoassay (aldosterone, active renin concentration and renin activity) and liquid chromatography-tandem mass spectrometry (aldosterone). The analytical sensitivity of this particularly novel active renin assay was 0.1 pg/ml, which was better than that of radioimmunoassay (2.0 pg/ml).

Using Bland-Altman plots with the mass-spectrometry values, both bias and limits of agreement with 95% confidence interval of the automated aldosterone assay were smaller than those of the radioimmunoassay, indicating smaller systemic errors in the novel measurement. The ratio of aldosterone-over-renin concentrations of 11.2 (ng/dl per pg/ml) provided 80.8% sensitivity and 94.9% specificity as a cut-off for differentiating primary aldosteronism from essential hypertension. This novel measurement is expected to be a clinically reliable alternative for conventional radioimmunoassay and to provide better throughput and cost-effectiveness in diagnosis of hyperaldosteronism from larger numbers of hypertensive patients in clinical settings.

Integrated genomic and phenomic analysis reveals key molecular pathways of aldosterone producing adenoma

Fabio Fernandes-Rossa1,2, Sherazad Boukroun3, Feltpe Golib Dzib3, Georgios Dami1, Laurence Amar2,4, Bastien Rance2,4, Benoit Samson-Coutriere1, Xavier Jeunemaître1,2,1, Tchao Meatchi1,6, Arndt Benecke7,8, Tim Strom10,10 & Maria-Christina Zennaro1,2
1INSERM, UMR8970, Paris Cardiovascular Research Center, Université Paris Descartes, Sorbonne Paris Cité, Paris, France; 2Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Service de Génétique, Paris, France; 3Institut des Hautes Etudes Scientifiques, Bures sur Yvette, France; 4Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Unité Hypertension artérielle, Paris, France; 5Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Département d’Informatique Hospitalière, Paris, France; 6Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Service d’Anatomie Pathologique, Paris, France; 7Université Pierre et Marie Curie, Paris, France; 8CNRS UMR 7224, Paris, France; 9Institute of Human Genetics, Helmholtz Zentrum München, Munich, Germany; 10Institute of Human Genetics, Technische Universität München, Munich, Germany.

Primary aldosteronism is the most common form of secondary hypertension. Somatic mutations in \textit{KCNJ5}, \textit{ATP1A1}, \textit{ATP2B1} and \textit{CACNAID} have been described in 50% of aldosterone producing adenomas (APA). To identify genetic alterations in new genes, we performed whole exome sequencing in 23 patients with APA negative for recurrent mutations in known driver genes. A low number of somatic variations were identified per patient, ranging from 1 to 22. No somatic variations were identified in two patients. Somatic mutations in \textit{KCNJ5} and \textit{CACNAID} were identified in 12 APA. These mutations were not observed or were present at very low levels on previous Sanger sequencing, indicating tumor heterogeneity. Two patients harbored mutations in genes involved in the Wnt/\(\beta\)-catenin pathway, which represents, together with the membrane ion transporter activity, the two significantly overrepresented pathways in gene ontology analysis. Sequencing of \textit{CTNNB1} in somatic DNA from 150 subjects with APA identified additional variants in 13 subjects, including 2 APA harboring also a \textit{KCNJ5} mutation. Transcriptome data obtained from 123 APA and 11 control adrenals did not show differences on the expression levels of \textit{Wnt4}, an activator of the Wnt/\(\beta\)-catenin pathway, and \textit{LEF1} and \textit{Axin2}, two \(\beta\)-catenin target genes, as a function of the mutation status. Hierarchical clustering of transcriptional profiles at a genome-wide scale was not associated to the APA mutation status, supporting a model whereby all recurrent mutations converge upon activation of calcium signaling and increased aldosterone production. In addition, \(\beta\)-catenin activation was observed by immunohistochemical analysis in two thirds of APA independently of \textit{CTNNB1} mutations, suggesting the involvement of additional mechanisms promoting cell proliferation. Using transcriptome affinity-propagation-based analysis we identified 15 different clusters of APA. These clusters are not associated with demographic or clinical data, highlighting additional molecular pathways underlying APA development and identifying subgroups to be targeted for gene discovery.

Cardiovascular features of autonomous cortisol secretion in patients with adrenal incidentalomas
Emilia Sbardella1, Marianna Minnetti1, Laura Rizza1, Maria Rosaria Di Giorgio2, Valeria Hasenmajer1, Denise D’Aluisio2, Sergio Morelli2, Andrea Lenzi2 & Andrea M Isidori1
1Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; 2Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Rome, Italy.

Background
Possible Autonomous Cortisol Secretion (pACS) is a condition found in 1-29% of patients with adrenal incidentalomas. The diagnosis of pACS has been variably associated with an increased risk of cardiovascular events and mortality. However, dedicated studies describing the morphologic and functional cardiac alterations in these patients are lacking.

Aim
To compare the cardiovascular features of patients with pACS to those with nonfunctioning (NF) adrenal masses.

Materials and methods
Fifty-eight patients with adrenal incidentaloma without the classic signs or symptoms of overt hypercortisolism were prospectively enrolled. Anthropometric, metabolic and hormonal parameters, adrenal magnetic resonance, echocardiography B-mode ultrasound and arterial stiffness calculated with oscillatory method were assessed in all patients. We diagnosed patient with pACS after 1mg overnight dexamethasone suppression test (1 mg-DST), confirmed by traditional 48-h Liddle tests, if post-test serum cortisol fell between 51 and 138 nmol/l.

Results
Overall 30 patients had pACS and 28 NF adrenal masses. No differences in gender, smoke habits, hypertension, obesity and diabetes prevalence were observed between pACS and NF patients. Mean left ventricular (LV) mass index was increased in the pACS compared to the NF group (112.6±29.2 vs 94.8±31 g/m²; P=0.032). We also detected a significantly higher prevalence of LV hypertrophy in pACS than NF group (35.7% vs 14.3%; P=0.007). Furthermore, there was a negative correlation between the post-dexamethasone cortisol levels and ejection fraction (r = −0.26; P = 0.041). The assessment of arterial stiffness showed a higher pulse wave velocity in pACS compared with the NF group (11.3±1.4 vs 10.2±0.6 m/s; P = 0.048).

Conclusions
Autonomous Cortisol Secretion (pACS) can lead to early cardiac and vascular dysfunction even in apparently asymptomatic patients. These results underline the need for further studies, including second line cardiovascular assessment, to correctly define the management of pACS and allow early recognition of possible complications.

DOI: 10.1530/endoabs.49.GP16

Hypercortisolism is prevalent in newly diagnosed type 2 diabetes: a prospective study of 384 consecutive patients
Charlotte Steffensen1, Olaf M Dekkers2,3, Johanne Lyhne1, Per L Poulsen1, Jørgen Runghy1, Henrik T Sorensen1 & Jens Otto L Jørgensen1
1Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; 2Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark; 3Department of Epidemiology, Leiden University Hospital, Leiden, The Netherlands; 4Department of Clinical Pharmacology, Aarhus University, Aarhus, Denmark.

Background
Cross-sectional studies in small and selected populations indicate a relatively high prevalence of incident and/or subclinical Cushing’s syndrome (CS) in patients with type 2 diabetes (T2D), which could have therapeutic implications.

Aim
To estimate the prevalence of CS in a large, unselected cohort of recently diagnosed T2D patients.

Methods
A total of 384 consecutive out – patients with T2D diagnosed after 1 January 2009 were investigated by means of an overnight dexamethasone (1 mg) suppression test (DST). Patients who failed to suppress to ≤50 nmol/l after the DST were further examined with 48 h low dose dexamethasone suppression test (LDDST) and 24-h urinary free cortisol collection (UFC). Patients with elevated cortisol levels according to LDDST or UFC underwent ACTH measurements and imaging.

Results
85 (22%) patients had elevated cortisol after DST of whom 20 (5%) failed to suppress after LDDST and/or had elevated UFC. No significant difference in age, BMI, HbA1c, T-score, Total Body Fat or blood pressure were recorded between the two groups. Among the 20 patients with biochemical CS subsequent imaging with either pituitary MR or abdominal CT, according to suppressed (n=10) or unsuppressed (n=10) ACTH levels, revealed adrenal adenoma(s) in nine cases and a pituitary macroadenoma in one case.

Conclusion
i) The prevalence of hypercortisolism is high in T2D, also in unscreened newly diagnosed patients, ii) Hypercortisolism was not associated with a persuasive phenotype, iii) The clinical implications remain uncertain but continued interest is justified, preferably in terms of randomized intervention trials.

Effects of two mineralocorticoid receptor antagonists on the morphology of the adrenal cortex
Sofia S Pereira1,2, Madalena M Costa1, Angela Moreira1, Liliana Carvalho3, Mariana Monteiro1, Gavin Vinson4 & Duarte Pignatelli2,5
1Department of Anatomy and UMB (Unit for Multidisciplinary Biomedical Research) of ICBAS, University of Porto, Porto, Portugal; 2IPATIMUP/IES, Porto, Portugal; 3Department of Experimental Biology, Faculdade de Medicina, University of Porto, Porto, Portugal; 4The School of Biological and Chemical Sciences Queen Mary University of London, London, UK; 5Department of Endocrinology, Hospital S.João, Porto, Portugal.

Arterial hypertension usually results from the deregulation and hyperactivity of the renin angiotensin-aldosterone system. One of the available therapeutic approaches for its treatment is the use of mineralocorticoid receptor (MR) antagonists, thus blocking aldosterone action. The aim of this study was to characterize the effects of spironolactone and eplerenone, on the morphology of the adrenal gland of spontaneously hypertensive (SHR) and normotensive (Wistar-Kyoto) rats.

Results
SHR (n=18) and Wistar-Kyoto (n=18) rats were exposed, for 1 month, to spironolactone (100 mg/kg per day, n=6), eplerenone (50 mg/kg per day, n=6); or not exposed to either drug (n=6) and at the end of this period their adrenal glands were collected and we evaluated the percentage of the stained area (%SA) of CytoP1B1, CytoP1B2, the adrenal inner zone antibody (IZAb), a proliferation marker (ki-67), β-catenin and finally the percentage of cellular area occupied by lipid droplets as well as the capsular width. SHR hypertensive rats presented higher area of lipid droplets in all layers of the adrenal cortex, an effect that was even further increased by the exposure to eplerenone, in the fasciculata and reticularis zones. In the normotensive rats it was only spironolactone that elicited this effect, being significant only in zona reticularis. Both drugs also increased Ki-67 expression in the hypertensive rats, but only eplerenone increased it on normotensive rats. Finally, spironolactone decreased the capsular size but only in the normotensive rats. No significant differences were found for the % SA of CytoP1B1, CytoP1B2, IZAb or β-catenin.

In conclusion, we have found that, morphologically the adrenal glands of normotensive and SHR only differed in number of lipid droplets. Exposure to the MR antagonists had significant consequences on the capsular size, lipidic depots and on the cellular proliferation of both normotensive and SHR adrenal glands.

Plasma cortisol and aldosterone responses to insulin tolerance test and sodium depletion in women with non classic 21-hydroxylase deficiency caused by bi-allelic CYP21A2 mutations (NC-CAH)
Peter Kamenicky1, Anne Blanchard2, Antonin Lamaziere2, Bruno Donadille3, Lise Duranteau1, Sylvie Salenay1, Laurence Piets3, Marie Laure Raffin-Sanson3, Jean-Francois Gautier2, Philippe Chanson1,2, Sophie Christin Maitre4, Veronique Tardy6, Yves Le Bouc7, Sylvie Brailly-Tabard1 & Jacques Young1,2
1APHP Hôpital Bicêtre, Paris, France; 2Université Paris Sud-Reproductive Endocrinology, Paris, France; 3APHP Hôpital Georges Pompidou, Paris, France; 4APHP-UMPC Hôpital Saint-Antoine, Paris, France; 5Hôpital Saint Joseph, Paris, France; 6APHP Hôpital Ambroise Paré, Paris, France; 7APHP Hôpital Lariboisière, Paris, France; 8Hôpital Nord-Hôpitaux Civils de Lyon, Lyon, France.

NC-CAH is diagnosed in pubertal/post-pubertal women because of androgen excess however, the risk of potential adrenal insufficiency is not known, and indication of systematic glucocorticoid replacement therapy is controversial.

Aim
To evaluate cortisol and aldosterone secretions in response to challenges tests.

Design
Prospective controlled clinical study in a tertiary referral center. 20 women with NC-CAH (serum stimulated 17-OHP > 10 nmol/250 μg, Synacthen) comparatively to matched healthy women, were included if they had not receive glucocorticoid treatment > 1 year and estrogen-based oral contraception stopped > 3 months. Each participant underwent sequentially two tests separated by a 2 to 7-days: insulin tolerance standard test (ITT) and a sodium depletion test (oral 40 mg furosemide under low sodium diet) to stimulate both endogenous active renin (AR) and aldosterone. Steroid levels measured by LC-MSMS.

Results
NC-CAH had lower pic plasma cortisol concentrations during ITT than healthy women: 17.2 μg/dl (13.1–22.8) vs 21.2 μg/dl (17.1–33.5), P=0.0002. A peak plasma cortisol above 17.0 μg/dl was obtained in all controls but only in 60% NC-CAH women. NC-CAH had higher baseline ACTH and AR levels. 24-h after sodium depletion, mean plasma aldosterone levels were comparable between the two groups, but NC-CAH women had higher (P=0.003) stimulated AR levels than healthy women: 67 μg/l (15–156) vs 39 μg/l (6–87).

Conclusions
Forty percent women with NC-CAH have subnormal glucocorticoid adrenal function. Their aldosterone secretion was maintained normal by increased AR levels. Besides androgen excess therapy, clinical management of NC-CAH women should include assessment of their cortisol and aldosterone secretion; systematic chronic replacement therapy is still an open question, but transient glucocorticoid supplementation and rehydration during periods of stress should be considered.

Which are the factors and causes of death in patients with adrenal insufficiency? Mortality data from EU-AIR
Marcus Quancker1, Bertil Ekman2, Pinggao Zhang2, Pierre Zelissen3 & Robert D Murray4
1Endocrinology in Charlottenburg, Berlin, Germany; 2Linköping University, Linköping, Sweden; 3Shire, Lexington, Kentucky, USA; 4University Medical Center Utrecht, Utrecht, The Netherlands; 5St James’s University Hospital, Leeds, UK.

Introduction
If untreated, adrenal insufficiency (AI) leads to premature death. Hospital record data suggest mortality associated with primary (PAI) and secondary AI (SAI) to be 2-3-fold higher than in the general population. Major causes of death include cardiovascular disease, Addisonian crises, brain tumours and infections; however, there is little further characterisation of patients who died.

Design
We analysed real-world data from the European Adrenal Insufficiency Registry (EU-AIR; NCT01661387) with centres across Germany, the Netherlands, Sweden and the UK. Clinical and biochemical data at enrolment were compared for patients who had died and those alive for each AI subset. Patients with congenital adrenal hyperplasia or tertiary AI were excluded. 1798 patients were included (626 PAI, 1172 SAI) in the current analysis.

Results
To November 2016, 21 deaths had occurred (7 PAI, 14 SAI). Causes of death were cardiovascular (n=8), infection (n=3), unclear (n=3), Addisonian crisis (n=1), suicide (n=2), renal failure, drug-induced hepatitis, cachexia and brain tumours (each n=1). Patients who died were significantly older at enrolment than those alive (PAI, 63.4±13.4 vs 50.0±15.8 years, P=0.0253; SAI, 64.0±16.6 vs 54.3±16.2 years, P=0.0250). Interestingly, duration of AI was shorter in patients with PAI who died versus alive patients (6.5±5.7 vs 16.3±13.1 years, P=0.0035), whereas the reverse was true for SAI (20.4±13.2 vs 13.7±11.1 years, P=0.0257). There were no significant differences in sex, BMI, blood pressure, triglycerides, LDL-cholesterol, cholesterol or HbA1c between the deceased and alive cohorts. Patients who died were generally more likely to have hypertension (PAI, 57.1% vs 21.8%, P=0.0007; SAI, 71.4% vs 33.9%, P=0.0076) and diabetes mellitus (PAI, 57.1% vs 14.4%, P=0.0112; SAI, 28.6% vs 11.5%, ns) at study inclusion.

Conclusions
This is the first study providing detailed characteristics of AI patients who died. Hypertension and diabetes, as well as infectious diseases, appear to play a major role in mortality.

Is diabetes mellitus associated with catecholamine-secreting tumours always a secondary diabetes?
Mara Baetu1, Ana Maria Stefănescu1, Simona Jercalau1, Victor Tomulescu2, Anna-Maria Tinu1 & Corin Badiu1,4
1C.I. Parhon’ National Institute of Endocrinology, Bucharest, Romania; 2Punenci’ Clinical Institute, Bucharest, Romania; 3N.C. Paulescu’ National Institute of Diabetes, Nutrition and Metabolic Diseases, Bucharest, Romania; 4Carol Davila’ University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Hyperglycaemia occurs frequently in catecholamine-secreting tumours due to insulin suppression or induced insulin resistance. These changes can be reversible postoperatively (postOp).

Objective
Our study aims to establish the impact of surgery in patients with catecholamine-secreting tumours upon glucose metabolism disorders, as well as the predictive factors for postOp diabetes-free patients.

Methods
We retrospectively analysed 72 patients (46 women-26 men), mean age 48 years (9–82), median body mass index 24.5 kg/m 2 (16–36.19), 66 with pheochromocytoma, 6 with paraganglioma, 3 malignant, 12 known with genetic syndromes.

Results
We found preOp diabetes mellitus (DM) in 32 patients (44.4%). We identified significant glycaemic changes in older patients, with longer hypertensive period, androgen excess however, the risk of potential adrenal insufficiency is not known, and indication of systematic glucocorticoid replacement therapy is controversial. We found preOp diabetes mellitus (DM) in 32 patients (44.4%). We identified significant glycaemic changes in older patients, with longer hypertensive period, androgen excess however, the risk of potential adrenal insufficiency is not known, and indication of systematic glucocorticoid replacement therapy is controversial.

Conclusions
Our study found that DM is associated frequently with catecholamine-secreting tumours and 2 thirds disappear postOp. Remnant DM suggests that DM associated with catecholamine-secreting tumours is not always a secondary DM. A longer duration of preOp DM and the fact that the glycaemic control is obtained with insulin upon tumour diagnosis are predictive factors for remnant DM.

Epithelial to mesenchymal transition in adrenocortical tumours: focus on FGF-FGFR pathway and c-MET
Iuliu Shibera1, Barbara Alfteri1-2; Annette Feuchttinger3, Kerstin Höfner1, Axel Walch4, Martin Fassnacht4, Cristina L Ronchi3, Matthias Kroiss1, Silvia Shibera1,4
1Division of Endocrinology and Diabetes, University Hospital, University of Würzburg, Würzburg, Germany; 2Division of Endocrinology and Metabolic Diseases, Catholic University of the Sacred Heart, Rome, Italy; 3Research Unit Analytical Pathology, Helmholtz Zentrum München, Oberschleissheim, Germany; 4Comprehensive Cancer Center Mainfranken, University of Würzburg, Würzburg, Germany; 5Clinical Chemistry and Laboratory Medicine, University Hospital, University of Würzburg, Würzburg, Germany.

Ad Adrenocortical carcinoma (ACC) is an aggressive tumour and treatment remains unsatisfactory in advanced disease. Activation of epithelial to mesenchymal transition (EMT) is considered causative for metastatic spread in a variety of human cancers. Accordingly, new drugs were developed specifically targeting EMT with a focus on hepatocyte growth factor (HGF)/HGF receptor (c-MET) and fibroblast growth factor (FGF)/FGFR signalling. We here asked whether EMT is relevant to ACC progression to evaluate the therapeutic potential of small molecule drugs targeting EMT. Expression of FGFR family members and c-MET was analysed in 20 normal adrenal glands (NAG), 23 adrenocortical adenomas(ACA) and 27 ACC at mRNA and protein level. Expression of FGFR1-4 was quantified in FFPE tumour tissue using RNAscope mRNA in situ hybridization technique. c-MET mRNA was quantified by qRT-PCR. In a subset of 40 samples we quantified expression of 92 different genes involved in FGF-FGFR pathway signalling. FGFR2 mRNA was lower in ACC compared to ACA (3.1 ±2.1 vs 6.5 ±2.3 mRNA copies/cell, P = 0.0005) whereas FGFR1 (7.5 ±5.3 vs 4.5 ±2.9, P = 0.09) and FGFR4 (5.1 ±2.3 vs 2.6 ±1.3, P =0.002) were higher in ACC. FGFR4 expression was higher in advanced vs localized tumor (6.2 ±1.6 vs 3.9 ±2.7, P = 0.03). Pan-FGF-FGFR pathway qRT-PCR confirmed differential FGFR expression and revealed decreased expression of FGFR7, FGFR17 and mitogen associated protein kinases in tumours compared with NAG. In advanced ACC protein kinase c PRKCA was decreased but PRKCC increased. c-MET mRNA expression was significantly higher in ACC compared to ACA and NAG (0.03 ±0.05 vs 0.01 ±0.03 and 0.01 ±0.02, respectively, P = 0.02). Considering median expression as a cut-off, high c-MET expression in ACC was associated with decreased overall survival (HR =8.8, P =0.02).

In conclusion, EMT appears to be relevant for adrenocortical tumourigenesis and progression. PRKCC may be involved in EMT signalling in advanced ACC. EMT-related kinases such as c-MET and FGFR4 may be suitable treatment targets in advanced ACC.

Clinical features and treatment outcomes in a group of SDHx-related pheochromocytoma/paraganglioma patients
Helder Simoes, Pedro Antunes, Ana Pinto, Sara Donato, Valeriano Leite & Branca Cavaco
Portuguese Oncology Institute, Lisbon Centre, Lisbon, Portugal.

Introduction
Germline mutations in succinate dehydrogenase complex (SDHx) are a risk factor for developing Pheochromocytoma (Pheo) and/or Paragangliomas (PGL) (named together PPGL), being responsible for approximately 30% of cases. The precise genotype-phenotype correlations and best management strategies are still uncertain.

Objective
To characterize the clinical features and genotype-phenotype associations in a group of SDHx-mutated PPGL patients.

Methods
Retrospective analysis of all germline SDHx-mutated PPGL cases followed in a reference centre.

Results
Total PPGL patients with SDHx-mutation: 30 (16 female). SDHB-related: 18(60%); SDHD-related: 9(30%); SDHC-related: 3(10%). Mean age at diagnosis: 36.8 ±15.4 years. Median follow-up: 94.8 months. Twenty nine patients had symptoms at diagnosis. Cathecholamine secretion was detected in 9(30%). Nine cases (30%) were malignant. Anatomical distribution: SDHB: 9 head and neck Pheo (9/16 PGL). SDHD: 5 Pheo and 5 thoraco-abdominal PGL (TAPGL) cases; SDHC-9 HNPGL, 1 Pheo and 1 TAPGL cases. All SDHC were single non-metastatic HNPGL. Malignancy: SDHB = 44.4%; SDHD = 11.1%. Multiple PPGL: SDHB = 16.7%; SDHD = 55.6%. Family history of SDHx-related PPGL was present in 20%. Deletions in SDHB exon-1 were the most frequent genetic defect. Complete resection was achieved in 7(33.3%) and pre-surgery vascular embolization was performed in 10(47.6%) of HNPGL patients. Radiotherapy was used in 12(40%) patients (mainly unresectable HNPGL) achieving partial response/stabilization. 177Lu-DOTATOC or 131I-MIBG were used in 4. Overall, remission was observed in 33.3%, stable disease in 53% and progression in 13.3% of patients. Related morbidity was observed in 66.6% of patients, and one death occurred.

Conclusion
SDHC and SDHD patients are prone to develop single and multiple HNPGL, respectively, and SDHB patients carry increased risk of malignancy, as suggested in other studies. SDHB patients and HNPGL had the worse prognosis, the former related to malignancy, and the last to cranial nerve deficits, unresectable disease and multimodality interventions. Radiotherapy represented a good alternative in unresectable HNPGL.

Increased exosomes in endogeneous Cushing syndrome
Gloria Aranda1, Gemma Xifra1, Jose Manuel Fernandez-Real2, Guillermo Garcia-Eguier3, Gregori Casals1, Adriana Pane1, Mireia Mora1, Irene Halperin4 & Felicia A Hanzu5
1Group of Endocrine Disorders, Department of Endocrinology Hospital Clinic Barcelona, IDIBAPS, CIBERDEM, Barcelona, Spain; 2Department of Endocrinology, Hospital de Girona 'Dr Josep Trueta'; IIBiG Girona, CIBERObn, Girona, Spain; 3Biochemistry and Molecular Genetics, Hospital Clinic Barcelona, Barcelona, Spain.

Exosomes are nano-sized vesicles secreted by the cells in the extracellular fluids representing a novel way of intracellular communication. Exosomes secreted from blood cells like monocytes and platelets have been reported to be checkpoints involved in haemostatic and thrombotic response. Glucocorticoids are inducing a profound alteration of blood cells homeostasis with atherothrombotic, bleeding and immune response alterations. Hereby we quantified for the first time circulating exosomes in overt Cushing syndrome (CS) patients.

Methods
Cross sectional study in CS patients and controls. Diagnosis of CS was performed following ECE and Endo guidelines. Blood samples from active, drug naïve CS patients (n=20) were obtained after overnight fast. Peripheral blood cells, biochemical and hormonal parameters were analyzed using standard methods. Circulatory exosomes were quantified in plasma by a sandwich enzyme-linked-immuno-sorbent assay (EsoTEST) employing a monoclonal antihuman CD9 antibody. Further exosome phenotyping and analysis is ongoing.

Results
CS patients present as compared to controls a significant increased number of CD9 positive exosomes (2.35 ±105 vs 7.74 ±107 μl, P = 0.005**). Absolute monocytes (MN) number and 24 h urinary free cortisol (UFC) level correlates with the number of exosomes, respectively P = 0.022* with r=0.391 for MN and P = 0.005** with an r=0.467 for UFC.

Conclusion
Circulatory exosomes are increased in the hypercortisolecime state of Cushing syndrome.

Tumor microenvironment increases migration/invasion of murine pheochromocytoma SDHB silenced spheroids
Vanessa D’Antongiovanni1, Serena Martinelli1, Susan Richter1,2, Letizia Canu1, Daniele Guasti2, Paolo Romagnoli2, Karel Pacák2, Graeme Eisenhofer4,5, Massimo Mammeli1 & Elena Rapizzi1
1Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; 2Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; 3Institute of Clinical Chemistry & Laboratory Medicine, Dresden, Germany; 4Department of Medicine III, Technische Universitat Dresden, Dresden, Germany; 5Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, USA.

Pheochromocytomas (PHEOs) and paragangliomas (PGLs) are rare neuroendocrine tumors. About 30-40% of Pheo/PGLs are due to a germ-line mutation in one
of the 13 main susceptibility genes which include the genes encoding the four subunits of the succinate dehydrogenase (SDH - mitochondrial complex II). In PHEO/PGL due to SDHB mutations up to 80% of affected patients develop metastatic disease and no successful cure is at present available. To obtain an experimental model resembling the in vivo conditions of the SDHB-mutated PHEO, we used multicellular tumor spheroids (3D culture) of a murine cell line cultured alone or in co-culture with mouse primary fibroblasts, evaluating the effects of SDHB silencing and microenvironment on invasion and migration properties. The growth of spheroids is linear with clear edges. When the spheroids are treated with conditioned medium of cancer-associated fibroblasts (CAF), we observe an evident detachment of clusters of viable cells in the surrounding space. SDHB silenced cells show a greater migratory capability than negative control (NC) cells. In particular, SDHB silenced cells invade the surrounding space moving collectively, unlike the NC spheroids where cells tend to move individually. This difference was even more evident when spheroids were co-cultured directly with mouse primary fibroblasts. Using electronic microscopy on spheroids, we observed that SDHB silenced cells show swollen mitochondria and, alterations of mitochondrial crests (similarly to mitochondria of patients with SDHB mutations) while SDHB mutated spheroids show borders that are more fraying than those of NC spheroids. In conclusion, SDHB silencing strongly increased the invasion/migration capabilities, and these changes are more evident in SDHB spheroids co-cultured directly with primary fibroblasts. Further studies on these mechanisms may suggest new therapeutic targets.

Metformin reduces viability and proliferation of pheochromocytoma cells in vitro
Cinthia Meireles, Francisco Neves, Luiz Simeoni & Adriana Lofrano-Porto

Background
Pheochromocytomas (PHEO) are rare neuroendocrine tumors derived from chromaffin cells of the adrenal medulla. Catecholamin's secretion is associated with a high risk of cardiovascular complications. Malignancy is rare, but still demands effective treatment. Metformin has been shown to have antiproliferative properties in several cancer cell lines, possibly related to its ability to inhibit cell peroxidation, while decreased O2 consumption in PC12-Adh PHEO cells. Metformin at 20 mM induced an inhibition of 60% of cell viability after 48 h treatment, as compared to untreated controls, and increased cellular lipid peroxidation, while decreased O2 consumption in PC12-Adh PHEO cells. Moreover, metformin treatment reduced the activation of proteins of the AMPK/PTEN/AKT/mTOR pathway, which suggests growth and cell proliferative effects, as compared to untreated controls. Metformin treatment induced a positive modulation of the AMPK/PTEN/AKT/mTOR pathway, which suggests growth and cell proliferative abilities in several cancer cell lines. Our results suggest that metformin has a moderate inhibitory effect on the viability of PC12-Adh PHEO cells. This effect is associated with enhanced lipid peroxidation and decreased O2 consumption by these cells, which are both suggestive of increased cellular stress. Moreover, metformin treatment induced a positive modulation of the AMPK/PTEN/AKT/mTOR signaling pathway. Altogether our results corroborate the hypothesis of an inhibitory effect of metformin on PHEO cellular proliferation in vivo.

The role of in vivo metabolomics using H-MRS in SDH deficient disease
Ruth Casey 1, Mary McLean 2, Madha Bassetti 2, Ben Challis 2, Helen Simpson 2, Mark Garnell 1,2, Ramesh Bulusu 1, Alison Marker 1, Olivier Giger 1, Kieran Allinson 1, Krishna Chatterjee 1, Eamonn Maher 1,6, & Fergal Gallagher 1,6

1Cambridge University, Cambridge, UK; 2Cancer Research UK, Cambridge, UK; 3Cambridge University Hospital NHS Foundation Trust, Cambridge, UK.

Tumours caused by mutations in the SDH enzyme complex have a unique tumour metabolism due to a truncated citric acid cycle. The accumulation of the onco-metabolite succinate is believed to drive tumourigenesis. The aim was to investigate the role of MRI spectroscopy (H-MRS) to detect in vivo succinate elevations in suspected SDH deficient tumours including GIST, pheochromocytoma/paraganglioma (PPGL) and pituitary adenomas (PA). Suitable patients were identified based on SDH germline status, clinical phenotype and/or tumour SDHB immunoregativity. A minimum tumour size of 1.5 cm was applied. H-MRS was performed on a 3T MRI scanner and spectra with and without water suppression, was obtained. Succinate when detected, was visible on the spectra at a frequency of 2.4 ppm and a succinate to choline ratio of >0.1 was deemed confirmatory of succinate detection. H-MRS was performed on nine patients to date including four patients with GIST, 4 with PPGL and 1 with a PA. A succinate peak was detected in 7/9 patients and correlated with the immunohistochemistry (IH) and or germline status in all seven cases. H-MRS of a PA in a patient with a germline mutation in SDHB demonstrated no succinate peak and this correlated with the tumour SDHB immunopositivity. H-MRS successfully detected a succinate peak in a patient with a metastatic GIST and a somatic mutation in SDHC. This is the first study to investigate the use of in vivo metabolomics in SDH deficient GIST and pituitary adenomas and has proven efficacy as a non-invasive test for the identification of in vivo succinate peaks and detection of SDH deficient tumours. It may be particularly useful for the detection of somatic SDH mutations and to clarify the role of SDH mutations in newly identified phenotypes. Future application includes the use of in vivo succinate detection as a biomarker for therapeutic response.

Introduction
Alterations of the cAMP signaling pathway are described in adrenal tumors causing Cushing syndrome, specifically mutations in the gene coding for the protein kinase A (PKA) catalytic subunit alpha (PRKACA) in cortisol producing adrenocortical adenomas (CPA) with overt Cushing syndrome. Material and Methods
Eight CPAs without PRKACA mutations were analyzed by whole exome sequencing. Direct sequencing of PRKACB encoding for the catalytic subunit type 1 (RIb) was performed in 21 cases. Interaction of WT or mutant CB with the PKA-regulatory subunits was studied by bioluminescence resonance energy transfer and surface plasmon resonance analysis. To study the PKA activity, phosphorylation of the synthetic PKA-substrat Kemptide was analyzed in celluare in HEK293 cells transfected with a combination of RIz and CB in vitro with purified proteins.

Results
A PRKACB somatic mutation p.S54L was found in one CPA, from a 41-year-old patient presenting with a severe form of Cushing syndrome. Direct sequencing of PRKACB encoding for the catalytic subunit beta (CB) of the CPA was performed in 21 others. Interaction of WT or mutant CB with the PKA-regulatory subunits was studied by bioluminescence resonance energy transfer and surface plasmon resonance analysis. To study the PKA activity, phosphorylation of the synthetic PKA-substrat Kemptide was analyzed in celluare in HEK293 cells transfected with a combination of RIz and CB and in vitro with purified proteins.

Conclusions
PRKACB is a new gene responsible for at least one CPA, mutated in the somatic state. This finding suggests that the CB subunit of the PKA, too, may have specific functions in the adrenal cortex. Particularly, the role of the residue Ser54 (as was previously suggested) may be very important for PKA function in the adrenal cortex.

DOI: 10.1530/endoabs.49.GP28
Germline mutations in the succinate dehydrogenase subunit-B gene (SDHB) are well recognised for predisposing to head and neck parangangioma, sympathetic parangangioma,phaeochromocytoma and renal cell carcinoma. The co-existence with pituitary adenomas remains uncommon. We report a 31-year-old female who presented at age 29 years old with 9 months of secondary amenorrhoea. Prolactin was 3000 mIU/l and a 1.7-cm macroprolactinoma revealed on MR pituitary. Taking prolactin-lowering therapy, she achieved normal menses and subsequent MRI imaging demonstrated reduction in the size of this macroprolactinoma. At age 30 years, she was found to have a parangangioma in the aortic–pelvic region. On reflection, she had noticed anxiety, sweating, palpitations and extreme exercise intolerance for the 2 years preceding diagnosis, which resolved following surgical resection. She was screened for familial parangangiomas, which revealed she was a carrier of the SDHB mutation. Interval screening MRI neck to pelvis has since demonstrated no evidence of recurrent or new disease. Plasma metanephrines have subsequently remained normal. Her father, aged 64 years old, was referred for genetic counselling and testing. He too is an SDHB mutation carrier. His plasma metanephrines are normal and MRI neck to pelvis has not revealed a parangangioma or phaeochromocytoma. Both the index case and father will remain under lifelong specialist care in a Neuroendocrine Tumours Clinic. Family members have been advised to seek genetic counselling.

Although uncommon, increasing incidence of pituitary adenomas in carriers of SDH mutations are being reported. These pituitary adenomas tend to be larger with macroprolactinomas commoner than other pituitary adenomas. Screening programmes vary widely for carriers of SDH mutations and tend not to involve pituitary imaging. However, given the association with pituitary lesions, screening imaging might need to include the pituitary. At present, however, it is thought that this is likely to be a low-yield strategy.

Long-term treatment of acute ectopic ACTH syndrome with Etomidate

Zydrune Visockiene1,2, Vilija Guntaite3, Vigantas Dunauskas3, Donatas Vajauskas1,2, Gintautas Kekstas1,2 & Giedre Vasyliene4

1 Vilnius University Faculty of Medicine, Vilnius, Lithuania; 2 Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania; 3 Republican Siauliai Hospital, Siauliai, Lithuania; 4 Republican Panevezys Hospital, Panevezys, Lithuania.

Case description

A 25-year-old male was admitted to the Intensive Care Unit due to progressive muscle weakness, difficulty walking, weight loss, headache, chest discomfort, type 1 diabetes for few months. He was confused and irritated, with “moon” face, facial plethora, acne, and hyperpigmentation of the skin, few obscure red-bluish striae and significant wasting of proximal and distal muscles of lower limbs. Cortisoldiabetesreduction due to ectopic ACTH production was confirmed by plasma ACTH (>1250 ng/l) and cortisol (1120–2145 nmol/l), 24-hour free cortisol (14 726 nmol/24 h), failure to suppress cortisol on a high dose intravenous and 16 mg oral 2 days dexamethasone suppression tests. Severe hypercortisolemia resulted in critical fluid and electrolyte imbalance, deterioration in physical and mental state. Daily Etoxidate infusion 20-60 mg for 14 days stabilized condition and later was used for treatment on alternate days in the dose of 20–40 mg for 10 months in day care clinic. Alternative treatment with Ketoconazole induced hepatic injury. Etoxidate was ineffective, Metyrapone was not available. Following Etoxidate infusions, plasma cortisol decreased to 280–560 nmol/l, potassium – 3.7–4.3 mmol/l with oral supplementation of KCI 3 g/day and Spironolactone 50 mg, glucose became normal without insulin. In 10 months Metyrapone became available and 1 g/day was used to achieve control. Patient refused from adrenalectomy.

Pituitary MRI, chest and abdomen CT, somatostatin receptor scintigraphy, bronchoscopy, esophagogastroduodenoscopy, colonoscopy revealed no potential source of ectopic ACTH production. Further assessment by whole body 18F-FDG PET-CT and 68Ga-DOTATATE PET-CT scans, selective sinuses petrosum inferior sampling and enteroscopy failed to detect the source of ACTH. Thoracic CT and colonoscopy was performed three times, abdominal CT and pituitary MRI – twice during 16 months. Primary tumour was not detected.

Conclusion

Etoxidate infusion could be used for long term treatment of ectopic ACTH syndrome when other options are ineffective or unavailable.

Multiple pathologic fractures as the presenting manifestation of Cushing’s syndrome in patients with vitamin D receptor FokI gene polymorphism

Vasiliki Daraki1, Paraskevi Floroskoufi 1, Theodoros Liarigkovinos1, Maria Chrysoulaki1, Vasilios Tsamadou2, Emmanuel Economou2 & Stathis Papavasiliou1

1 Department of Endocrinology Diabetes and Metabolic Diseases, University Hospital of Crete, Heraklion, Greece; 2 Laboratory of therapeutic individualization, University of Athens, Aretaieio University Hospital, Athens, Greece.

Rare cases of Cushing’s syndrome have been diagnosed only based upon bone manifestations. Fracture risk is related to individual susceptibility to glucocorticoids that is genetically determined by several factors, including VDR gene polymorphism.

We report three patients with VDR FokI gene polymorphism and multiple non-traumatic pathologic fractures as the presenting manifestation of Cushing’s syndrome.

Case reports

The first case is a 55-year-old man who presented with pain in the right hip. CT scan revealed fracture in the right femur. Additionally bone scintigraphy revealed non-traumatic micro-fractures in ribs and pelvis.

The second case is a 44-year-old woman who presented with pain in the left hip. She reported weight gain (25 kg) in the last 6 years, depression, fatigue, and muscle weakness. MRI revealed fracture in the left hip, while bone scintigraphy showed multiple non-traumatic micro-fractures in ribs and right femur.

The third case is a 64-year-old woman presented with recurrent rib and low extremities fractures the last 10 years. She also suffered from depression and hypercholesterolemia.

The aim of the present study was to evaluate the phenotype of PHPT, the adherence to International Guidelines and the rate of surgical cure of PHPT in Italy. From January 2014–January 2016, we conducted a prospective, multicenter (54 centers) Italian tertiary referral centre study on patients with PHPT, recording clinical and biochemical data, parathyroid imaging and therapy choice at baseline and at last follow-up. The study group included 604 patients with PHPT, with a mean age of 61 ± 14 yrs (F: M = 5:1). Most patients had sporadic PHPT (n = 556 (93.7%), mean age 63 ± 13 yrs); the remaining 38 (6.3%, mean age 41 ± 17 yrs) were familial forms. Follow up data were available in 345 patients: 158 (45.8%) with symptomatic and 187 (54.2%) with asymptomatic PHPT. Eighty-six patients (54.4%) of the former group underwent PTX, mainly for symptomatic nephrocalcinosis (n = 71, 82.6%). One hundred twenty-one asymptomatic patients (64.7%) met at least one criterion for PTX according to the 2008 International guidelines for parathyroidectomy and 65 patients (53.7%) underwent surgery. Criteria for PTX were: serum calcium levels 1 mg above the upper normal limit (n = 37, 56.9%), osteoporosis (n = 35, 53.8%) and age < 50 yrs (n = 14, 21.5%). Surgery was not performed in the remaining patients (n = 56, 46.3%) despite the presence of serum calcium levels 1 mg above the upper normal limit (n = 12, 21.4%), osteoporosis (n = 44, 78.6%) and age < 50 yrs (n = 11, 19.6%). Surgery was also performed in 16 of the 66 (25.7%) patients who did not meet the criteria for surgery. A total of 168 patients underwent PTX. The histological diagnosis was single adenoma in 89% of cases, hyperplasia in 9%, atypical adenoma in 1%, and carcinoma in 1%. The large majority (n = 158, 94%) of patients were cured. Persistence of PHPT was observed in the remaining 10 patients, who were apparently sporadic. Patients followed without surgery showed a stable clinical and biochemical disease, after one year of follow-up. This is the first multicenter Italian study with the specific aim of evaluating PHPT phenotype and therapeutic approach. International guidelines recommendations for surgery were observed in half of cases, either for symptomatic or asymptomatic patients.

Spiridon” Hospital, Iasi, Romania; 4Immunology Department, “Gr. T. Popa” University of Medicine and Pharmacy, Iasi, Romania; 5Nephrology Clinic, “Dr. C.I. Parhon” University Hospital, Iasi, Romania; 6Nephrology Department, “Gr. T. Popa” University of Medicine and Pharmacy, Iasi, Romania.

Introduction

Body weight and lean mass (LM) are classic bone mass determinants. However, the association between total fat mass (FM), regional FM and bone remains controversial, especially as fat is a source of adipocytokines, with both positive and negative bone consequences.

Materials and methods

Anthropometric, bone mass (assessed by Dual X-Ray Absorptiometry; DXA) and body composition parameters (assessed by DXA) and also serum adipocytokine (leptin, adiponectin, resistin) levels were determined from 93 female volunteers (38 premenopausal and 55 postmenopausal women). Correlation analysis was performed in order to assess the association between body mass index (BMI), body composition parameters, adipocytokines and bone mass. Multivariable and hierarchical regression models were used to determine which of the above factors are independent predictors of bone mass.

Results

In correlation analysis, BMI, total LM, total FM and regional FM (trunk FM and lower limbs FM) were positively associated with bone mass in both groups. Correlations between adipocytokines and bone were found only in the postmenopausal group. In multivariable regression analysis, only LM remained an independent predictor of bone mass in premenopausal women, explaining 38.1% (P < 0.001) of femoral neck, 24.5% (P = 0.002) of total hip and 20% (P = 0.005) of whole-body bone mineral density (BMD) variance; in postmenopausal women, LM, trunk-to-lower limbs FM ratio (together explaining 30.9% of the variance of total hip BMD, P < 0.001) and resistin (adipokine known to regulate bone cell proliferation and bone turnover) remained independent positive predictors of bone mass. Hierarchical regression showed no additional effect of BMI or of total FM to that of total LM in predicting bone mass in both groups.

Conclusions

LM independently predicts bone mass in premenopause, while after menopause FM distribution becomes an important factor in regulating bone mass together with total LM and resistin. These parameters may find their place for fine tuning the evaluation of fracture risk.

Aldosterone and parathyroid hormone – is there a connection?

Mara Ventura, Miguel Melo, Diana Oliveira, Diana Martins, Adriana Lages, Nelson Cunha & Francisco Carrilho

University and Hospital Center of Coimbra, Coimbra, Portugal.

Introduction

Recent studies seem to support a bidirectional positive interaction between aldosterone and parathyroid hormone (PTH). Understanding the normal physiological relationship between renin-angiotensin-aldosterone system (RAAS) and PTH is of clinical interest because their inappropriate activity may negatively impact cardiovascular and skeletal health.

Objective

To evaluate the presence of an interaction between aldosterone and PTH in a cohort of patients assessed for suspected hyperaldosteronism or hyperparathyroidism.

Material and Methods

We retrospectively evaluated consecutive patients followed in our Endocrinology Department between January 2014 and December 2016. We collected data about renin-angiotensin-aldosterone system and calcium metabolism from clinical and laboratorial records and selected patients whenever both data were available.
Relationship between circulating microRNAs and bone mineral density in patients with active acromegaly
Elena Valassi¹, Natalia García-Giralt², Jorge Malouf³, Iris Crespo¹ & Susan M. Webb¹
¹Endocrinology/Medicine Department, Hospital Sant Pau, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER 747), II-B Sant Pau, ISCIII, Universitat Autònoma de Barcelona (UAB), Barcelona, Spain; ²URFOA, IMIM (Institut Hospital del Mar d’Investigacions Mèdiques), Universitat Autònoma de Barcelona, Barcelona, Spain; ³Mineral Metabolism Unit, Medicine Department, Hospital Sant Pau, Barcelona, Spain.

Objective
Acromegaly (ACRO) is associated with abnormal bone remodeling and reduced volumetric bone mineral density (vBMD) at the lumbar spine and proximal femur. Circulating microRNAs (miRNAs) modulate the activity of osteoblasts and osteoclasts, and are currently being investigated as potential biomarkers of osteoporosis. The aims of our study were: 1) To identify differentially expressed miRNAs in the serum of five patients with active ACRO vs. healthy controls, and 2) To correlate selected miRNAs concentrations with altered bone parameters in 11 ACRO patients.

Patients and methods
Eleven patients with active ACRO (six females; mean age, 47.5 ± 6.7 years; BMI, 27.2 ± 3.8 kg/m²) and 11 age-, gender-, and BMI-matched controls were recruited. Analysis of differential expression of miRs was performed in 5 of them (5 males; mean age, 44.3 ± 4.3; BMI, 26.2 ± 2.8). Areal BMD (aBMD) at lumbar spine and femur was assessed through dual energy X-ray absorptiometry (DXA); vBMD was measured by quantitative computed tomography (QCT). Serum miRNA levels were assessed by qPCR. Osteocalcin (OC), type 1 amino-terminal propeptide of P1NP and carboxy-terminal collagen crosslinks (CTX) were measured using electrochemiluminescent immunoassay.

Results
Expression of miR-885-5p, miR-99a-5p, and miR-29a-3p was significantly higher, while that of miR-7-1-3p and miR-335-3p was significantly lower in the ACRO patients. Both miR-885-5p and miR-7-1-3p were inversely associated with femoral aBMD (r = -0.64, P = 0.034 and r = -0.73, P = 0.009, respectively), and trocantheric vBMD (r = -0.66; p = 0.038 and r = 0.67; P = 0.023) in ACRO but not in the controls. They were also positively associated with P1NP (r = 0.82, P = 0.002 and r = 0.79, P = 0.004, respectively) and CTX (r = 0.73, P = 0.010 and r = 0.68, P = 0.019) in ACRO. MiR-99a-5p was inversely associated with femoral aBMD (r = -0.66, P = 0.26) and positively associated with P1NP (r = 0.83, P = 0.001) and CTX (r = 0.88, P = 0.001) in ACRO only. The relationship between femoral aBMD and miR-99a-5p remained significant after adjusting for age and IGFe-SDS (β = -0.52, P = 0.012).

Conclusions
Circulating miRNAs may be one of the mechanisms whereby BMD is impaired, mainly at the femoral level. Further larger studies are needed to confirm these preliminary data.

DOI: 10.1530/endoabs.49.GP36

Decreased trabecular bone score but not bone mineral density in patients with acromegaly and concurrent hypogonadism: cross-sectional study with healthy controls
Martin Kažmařík¹, Dušan Pavá¹, Ivana Ságová¹, Zdenko Killinger¹, Peter Jackulík¹, Anton Valtuša², Peter Valtuša² & Juraj Payer³
¹Comenius University Faculty of Medicine, Fifth Department of Internal Medicine, University Hospital Bratislava, Bratislava, Slovakia; ²National Institute of Endocrinology and Diabetology, Lobuchna, Slovakia; ³Comenius University Jessenius Faculty of Medicine, First Department of Internal Medicine, University Hospital, Martin, Slovakia.

Introduction
Acromegaly is associated with higher prevalence of vertebral fractures (VFx) and bone microarchitecture potentially play a role in fracture development. Trabecular bone score (TBS), a novel indicator of bone microstructure could provide additional information.

Objectives
Assessment of BMD, TBS and bone turnover markers (BTM) in acromegaly patients in comparison to healthy controls with regard to gender, hypogonadism and disease activity.

Patients and methods
A cross-sectional study of acromegaly patients with age-, gender- and BMI-matched healthy controls was conducted. Study group consisted from all acromegaly patients (regardless age, gender, disease duration or activity) which came for follow-up visit during period 6/2016 – 12/2016 and the control group consisted of healthy subjects. In all subjects a single measurements of all pituitary axis hormones levels, BTM, BMD of total hip (TH) and lumbar spine (LS) and TBS was performed. N-terminal type 1 procollagen (P1NP) – marker of bone formation and C-terminal telopeptide (CTX) – marker of bone resorption were analyzed.

DOI: 10.1530/endoabs.49.GP38
Results
Thirty Seven acromegaly patients (12 males/25 females with mean age 56.7 years,
mean BMI 29.8 kg/m²) and 27 of control group subjects (seven males/20 females
with mean age 59.5 years, mean BMI 30.9 kg/m²) were included. TBS was signifi-
cantly lower in patients in comparison to controls (1.16 vs 1.22; P <0.05),
but no BMD and BTM difference was observed. Hypogonadal patients had lower
TBS in comparison to patients without hypogonadism (TBS 1.13 vs 1.20;
P <0.05) and no BMD difference. BTM were increased in hypogonadal patients
(CTx 0.67 vs 0.38 ng/ml; P1NP 75.5 vs 47.5 ng/ml; both P <0.05). No difference
in TBS, LS BMD and BTM with regard to gender was observed.
Conclusion
This study indicates that patients with acromegaly, especially those with
hypogonadism, despite unchanged BMD, may have impaired trabecular bone
microstructure, which can lead to increased prevalence of fractures.

Association of changes in serum urate level and bone mineral density
during treatment with teriparatide: a retrospective observational study
Tomaz Kocjan1, Gaj Vulinar2, Antonela Sabati Rajic3, Mojca Jensterle Sever1, Marija Pfeifer1, Janja Marc1, Nina Orehek1 & Barbara Ostanek3
1University Medical Centre Ljubljana, Ljubljana, Slovenia; 2University
Rehabilitation Institute, Ljubljana, Slovenia; 3Faculty of Pharmacy,
University of Ljubljana, Ljubljana, Slovenia.

Serum urate level has recently been associated with increased bone mineral
density (BMD). Teriparatide, an osteocalcinic medication for osteoporosis,
is associated with increased incidence of hyperuricemia. Hence, we hypothesized
that changes in serum urate are associated with changes in BMD and procollagen
II type N-propeptide (P1NP) during treatment with teriparatide.
We collected data from 151 women (mean age 72 years, mean BMI 26.6 kg/m²)
with severe postmenopausal osteoporosis who had been treated with teriparatide
for 2 years at our outpatient clinic. They were prescribed with vitamin D3
1000 IU daily and were instructed to ingest 1200 mg of calcium daily. BMD was
measured at the three standard sites by DXA at baseline, after 12 and 24 months
treatment. Routine laboratory parameters (including serum urate), 25-hydro-
xysteroid 1,25-D and P1NP were measured at the same time-points. Estimated
glomerular filtration rate (eGFR) was calculated. The associations were assessed
using univariate correlations and multiple linear regression models (each fitted
using casewise deletion of records with missing data as well as missing data
imputation). Repeated-measures analysis of variance was used to verify the
increase in serum urate level and stability of eGFR.
During the 2-year treatment with teriparatide, we observed no notable univariate
association between change of serum urate level and change of BMD. When
adjusting for basal eGFR, vitamin D sufficiency, previous bisphosphonate
treatment, change of serum and of urinary calcium during the same period, we
observed a weak positive association of serum urate level change with change of
BMD at lumbar spine. Conversely, change of serum urate level tended to be
weakly positively univariately associated with change of P1NP, but the
association vanished when adjusting for the confounders listed above.
Our results may indicate that the effect of teriparatide on bone might be partly
mediated by changes in serum urate level.

Coexistence of primary hyperparathyroidism with papillary thyroid
carcinoma: a case series
Panagiotis Anagnostis1, Athanasios Panagiotou1, Fotini Adamidou1, Savvas Rafailidis2 & Marina Kita1
1Department of Endocrinology and Diabetes, Hippokration Hospital of
Thessaloniki, Thessaloniki, Greece; 2Euromedica Kyanous Stavros,
Thessaloniki, Greece.

Introduction
Primary hyperparathyroidism (PHPT) may rarely coexist with non-medullary
thyroid carcinoma (NMTC). We report the clinical manifestation and
management of nine cases of synchronous PH and NMTC.
Cases
Eight women and one man were included (mean age at diagnosis: 64 ± 6.6 years).
In all cases, PH was the initial diagnosis, whereas NMTC was detected
incidentally, after ultrasound assessment for PH. The histological diagnosis of
NMTC was classical papillary thyroid carcinoma (PTC) in all cases, with
follicular subtype in four cases. In one patient, medullary carcinoma was also
detected and a diagnosis of multiple endocrine neoplasia type 2B syndrome was
set. In three cases (33.3%), NMTC was multifocal. Extrathyroidal extension was
detected in one case, but without metastatic disease. In seven cases (78%),
maint maximal NMTC diameter was <10 mm (mean diameter: 7.6 ± 4.4 mm).
Thyroid autonomy was present in two cases.
The histological diagnosis of PHPT was single parathyroid adenoma (mean
diameter: 15.4 ± 19.3 mm, in six cases on the right side) in all cases. In one case,
the adenoma was intrathyroidal. Nephrolithiasis was diagnosed in one case,
hypercalciuria in two, whereas low bone mass in eight patients. Preoperative
mean parathyroid hormone (PTH) and total calcium concentrations were 133.5 ±
43.9 and 11.3 ± 0.8 mg/dl (corrected calcium: 11 ± 0.78 mg/dl, respectively).
Cardiovascular risk factors, such as arterial hypertension, dyslipidemia and/or
hyperglycemia were diagnosed in six cases (66.7%).
PH and NMTC were successfully managed with thyrosidectomy and total
thyroidectomy (mean post-operative PTH concentrations: 33.3 ± 24.7 pg/ml). No
case developed post-operative hypocalcemia. Prophylactic central lymph node
resection was performed in one patient. No recurrence of either PH or NMTC has
been reported (mean follow-up time: 3.8 ± 5.1 years).
Conclusions
NMTC may rarely be incidentally detected in patients with PH. It is usually
unifocal microcarcinoma of classical PTC subtype, without extrathyroidal
extension. The pathogenetic mechanisms linking these two endocrine entities
are currently unknown.

Follow-up of patients with surgical hypoparathyroidism: unknown
cause of renal function decline?
Tess van de Meerhaeghe, Sergie Bukowski, Elien Coudenys, David Uvaune,
Brigitte Velkeniers & Bert Bravenboer
UZ Brussels, Brussels, Belgium.

Background
Hypoparathyroidism is a rare endocrine disease with low calcium and insufficient
parathyroid hormone levels. In most cases it is caused by thyroid surgery. The
objective of this retrospective cohort study was to evaluate if the typical therapy
regimens of postsurgical hypoparathyroidism with calcitriol have a negative
effect on renal function.
Methods
We performed a chart analysis of patients that were seen in a tertiary care hospital
in Brussels, Belgium. A total of 101 patients were identified as patients with
permanent post-surgical hypoparathyroidism, based on the hospital records of
patients who underwent a total thyroidectomy between 1996 and 2016, while still
being treated with calcitriol. Patients with pre-existing renal insufficiency and/or
active malignancy were excluded. The cohort was predominantly female of
Caucasian origin. Kidney function was evaluated before and after surgery (with a
maximum follow-up of 12 years), using the CKD-EPI equation.

Results
A multivariate linear regression model was used to correlate kidney function
decline with the duration of calcitriol treatment, while accounting for the mean
calcium-phosphate product and age. We found a statistically significant
(Z=0.027) relation between the duration of calcitriol treatment and renal
function decline at a rate of 1.06 ml/min/1.73 m² per year of calcitriol
therapy. Conclusions
Renal abnormalities are frequent finding in patients with hypoparathyroidism.
Our study, although being retrospective, is the first one to demonstrate a
relationship between the duration of calcitriol therapy and progressive renal
insufficiency.

Expression of hypoxia-inducible factor-1z in Calbindin-DKa Knockout mice
Song Ai Kang, Seon Young Park, Jin Yong An & Eui-Bae Jeung
Chungbuk National University, Cheongu, Chungbuk, Republic of Korea.

Introduction
Hypoxia-inducible factors (HIF) are the key transcription factor induced by hypoxic condition, which regulate expression of specific target genes including angiogenic factors, erythropoietin, glucose transporters, and glycolytic enzymes.

Results
8–10 weeks old C57BL/6 mice and calbindin-DKa knockout mouse were exposed to hypoxia (12 ± 2% O2) for 3 weeks in closed polycarbonate chamber with nitrogen described as normoxic condition. Expression of HIF-1α in and glucosé transporter 1 (GLUT1, a downstream gene of HIF-1α) was analyzed in mRNA or protein level.

Conclusions
These results suggest that calbindin-DKa can regulate expression of HIF-1α in protein level.

Chromosome 2q37 microdeletions in two cases of sporadic PHP-1B with broad GNAS imprinting defects
Arianna Pirelli1, Francesca Marta Elli1, Paolo Bordogna1, Luisa de Sanctis2, Damiano Terenzi3, Laura Arosio4 & Giorgia Maggiore Poli2
1Department of Clinical Sciences and Community Health, Endocrinology and Metabolic Sciences, University of Milan, Milan, Italy; 2Endocrinology and Metabolic Diseases Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy; 3Department of Public Health and Pediatrics, University of Turin, Regina Margherita Children’s Hospital, Turin, Italy.

Pseudohyoparathyroidism type 1B (PHP-1B) is a rare, familial or sporadic, imprinting disorder due to the epigenetic dysregulation of the GNAS locus, whose main product is the α subunit of the stimulatory G protein (Gαs). Sporadic PHP-1B cases (spor-PHP-1B) display broad methylation abnormalities at multiple GNAS DMRs, but the underlying molecular mechanism is still unknown.

Classically, PHP-1B patients show PTH and TSH resistance, but, in the past years, also physical features of Albright hereditary osteodystrophy (AHO) were reported in small subsets of clinically diagnosed PHP patients with no detectable GNAS defects, highlighting the clinical overlap with diseases in 2q37 deletions. In the present study, we screened our series of spor-PHP-1B pts with (n = 21) or without AHO (n = 33) for BDMR-associated deletions to find modifier genes possibly involved in the phenotypic heterogeneity observed in PHP-1B, and we detected 2 different deletions (ranging from 2.83-Mb up to 4.5-Mb) in 2 unrelated pts with AHO. Additional analysis confirmed rearrangements and allowed to roughly delineate the genetic defects extension.

Deletions overlapped with previously described rearrangements and included several genes already proposed as causative for BDMR. Interestingly, our mutated patients displayed molecular (GNAS loss of imprinting) and endocrine characteristics (overt PTH resistance) usually absent in BDMR, although so far only one BDMR patient with raised PTH levels was described (Powell et al. 1997)

GP44
Investigation of total and free 25OHD vitamin levels in patients with chronic renal failure on different dose of cholecalciferol
Ezsebet Tolasy1,2, László Kovács3,4, Reka Nemeth3, Gyuláne Szakács4, Imre Kulsár5,6 & Zoltán Locsei1
1Institute of Diagnostics-Faculty of Health Science, University of Pécs, Pécs, Hungary; 2Central Laboratory, Markósványossy University Teaching Hospital, Szombathely, Hungary; 3Department of General Internal Medicine of Markósványossy University Teaching Hospital, Szombathely, Hungary; 4B. Braun Avitum 6th Dialysis Centre, Szombathely, Hungary.

The total 25-hydroxy-vitamin-D (t-25OHD) level reflects the vitamin-D supply, but it is also influenced by the levels of vitamin-D-binding-proteins (DBP) and albumin. The type of dialysis influences the levels of serum proteins. The ‘free-hormone hypothesis’ states that only the free molecules (f25OHD) can diffuse intracellular. Our aim was to evaluate the total, calculated (c-f25OHD) and direct measured (dm-f25OHD) 25OHD levels in patients with chronic renal disease on cholecalciferol.

Methods
100 patients (45 men; 55 women; 69 ± 14 years: 40 on haemodialysis (HD), 26 chronic renal failure (CRF) both on 1000 IUD/day; 34 on peritoneal dialysis (PD) on 3000 IUD/day) were investigated. Their sera were analysed for DBP (Dako), albumin, Ca, PTH, t-25OHD (Roche), dm-f25OHD (DIAsource).

Results
Albumin levels were significantly lower (PD:38 ± 5; HD:40 ± 5; CRF:43 ± 3 g/l; P < 0.001) and DBP concentrations higher (390 ± 55; CRF:352 ± 42; HD:323 ± 61 mg/l; P < 0.001) were in PD group. The t-25OHD and c-25OHD were the lowest in PD (t-25OHD: 65 ± 30; CRF:78 ± 13; HD:79 ± 45 nmol/l, c-25OHD: 14 ± 7; CRF:18 ± 9; HD:20 ± 11 nmol/l, P < 0.05). There were no significant differences among dm-f25OHD levels (PD:16 ± 5; CRF:16 ± 6; HD:15 ± 6 nmol/l). The highest incidence of suboptimal vitamin-D supply was found in PD patients on the bases of t-25OHD (PD:65%; CRF:42%; HD:43%) and also in c-25OHD levels. These incidences decreased significantly into 15%–23% when dm-25OHD was taken into consideration. Out of the three 25OHD fractions only dm-f25OHD levels gave the opportunity to prove significant relationship between PTH/Ca and 250HDL level (OR = 3.8; 95%CI:1.024-14.4; P = 0.036).

Conclusions
t-25OHD and c-25OHD values underestimate the vitamin-D supply particularly in PD patients. Patients on PD need much higher doses of cholecalciferol, without any differences from other two groups in dm-f25OHD levels either. Patients, who have higher dm-f25OHD level have 3.8 times higher chance for normal Ca/PTH levels. In case of dm-f25OHD there was a significant relationship proven between 25OHD level and related biomarkers. The dm-f25OHD seems to be a reliable marker for estimation of vitamin-D supply in patients with chronic renal disease.

Methylation patterns at the novel DMR of GNAS (GNAS-AS2) in pseudohyoparathyroidism 1B (PHP1B or iPPSND1) subtypes
Patrick, Hanna1, Anne Koch2, Hui-Chen Hsu1, Deborah Mackay2, Bruno Francou3, Jérôme Bouligand4, Anne Mantel5, Elli Anagnostou6, Dominique Guillard1 & Agnès Linglart1
1INSERM U1169, Bicêtre Paris Sud, France; 2University of Leuven, Leuven, Belgium; 3Massachusetts General Hospital and Harvard Medical School, Boston, USA; 4University of Southampton, Southampton, UK; 5APHP, Pharmacoendocrinology and Hormone, Bicêtre Paris Sud, France; 6Obstetrics and Gynecology, Alexandria Hospital, Athens, Greece.

1Génétique et Biologie de la Reproduction, Centre Hospitalier Universitaire, Reims, France; 8APHP, CMR Calcium-Phosphore, Bicètre Paris Sud, France.

PHP1B -iPPSND3 per the new proposed classification- is a rare disorder characterized in most patients by proximal tubular resistance to PTH resulting in hypocalcemia, hyperphosphataemia and elevated PTH. Loss-of-methylation (LOM) at the Differentially methylated Region (DMR) at GNAS exon A/B occurs in all PHP1B patients, but methylation changes at other DMRs within GNAS
occur in some familial and most sporadic PHP1B cases. All patients with autosomal dominant PHP1B (AD-PHP1B) due to a maternal deletion that comprises the STX16 region (delSTX16+) present with LOM at the GNAS-A/B DMR, while sporadic cases (sporPHP1B) with both GNAS methylation defects, including LOM at a novel, recently identified DMR within the GNAS locus referred to as antisense DMR2 (GNAS-AS2).

Objectives and patients

To characterize the methylation pattern at the GNAS-AS2 DMR in AD-PHP1B and sporPHP1B patients and quantify PCR of the GNAS and STX16 regions.

Results

1. The mean methylation index at the GNAS-AS2 DMR was significantly higher in delSTX16+ patients (32.2 ± 14%) than in controls (24.5 ± 6%), delSTX16+ (5.2 ± 2%) and sporPHP1B patients (3% + 1%) (P < 0.0001).

2. Bisulfite-treated DNA of PHP1B patients with delSTX16+ was PCR amplified across the GNAS-AS2 DMR and products were cloned into pCNA3A1. First, we identified 2 CG-rich subdomains (SD1 and SD2) within the GNAS-AS2 DMR that are separated by 184 bp. Second, in delSTX16+ patients we observed a unique pattern of methylation including gain of methylation at SD1 and a methylation pattern at SD2 similar to that of controls, whereas both delSTX16+ and sporPHP1B patients displayed full LOM at SD1 and SD2.

Conclusion

We have further refined the GNAS-AS2 DMR and identified a subgroup of PHP1B patients with a specific pattern of methylation at the GNAS-AS2 DMR. Our findings reinforce the hypothesis that delSTX16+ patients carry a defect in an element that controls the methylation both at the GNAS-A/B DMR and at the GNAS-AS2 DMR.

Vitamin D correction elevates apolipoprotein levels in a sex-specific manner

Nasser Al-Daghri1, Spiros Garbis2, George Chrousos2, Shaun Sabico1, Najj Aljohani3 & Yousef Al-Saleh2

1King Saud University, Riyadh, Saudi Arabia; 2University of Southampton, Southampton, UK; 3University of Athens, Athens, Greece; 4King Fahad Medical City, Riyadh, Saudi Arabia; 5King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.

Numerous studies have identified several extra-skeletal health outcomes to be associated with vitamin D deficiency, yet a definitive causal link is yet to be discovered. Our recent 3D LC-NESI-FTMS proteomic analysis among normal and overweight but apparently healthy adult Saudis identified apolipoproteins, a known independent cardiovascular risk factor, as one of the serological molecular signatures that modulate vitamin D levels. The present interventional study aims to compare and validate the identified apolipoproteins among vitamin D deficient subjects that have achieved full vitamin D status correction. 199 Saudi adults (89 males, mean age 42.0 ± 10.4; BMI 28.2 ± 4.4 kg/m²; 110 females, mean age 39.1 ± 12.0; BMI 30.7 ± 5.3) (with vitamin D deficiency [25(OH)D < 50 nmol/l]) were recruited and given 50,000 IU cholecalciferol (VitaD50000®) weekly for 2 months, then twice a month for 2 months, followed by daily, high dose IU (VitaD10000®) until month 6. Blood samples were taken at baseline and after 6 months. Serum 25(OH)D was measured using electrochemiluminescence and apolipoproteins (Al, AII, B, CI, CIII, CII and E) using commercially available kits. In all subjects, serum 25(OH)D increased significantly from baseline and after 6 months (32.6 ± 11.1 vs 63.4 ± 16.4 nmol/l, P < 0.001). In parallel, a significant increase in apolipoproteins B, CI, CIII, CII and E (P-values < 0.05) after 6 months compared to baseline was observed. After stratification according to sex, only apolipoproteins CII and CIII were significantly increased in males (P-values < 0.001), and only apolipoprotein CI was significantly increased in females (P < 0.001), showing sexual dimorphism in the effects of vitamin D with regards to apolipoprotein levels. The rest of the apolipoproteins were not significantly different pre- and post-vitamin D correction. The present study partially explains the effects of vitamin D correction in the reduction of cardiovascular risk through significant modification of apolipoproteins, particularly the apolipoprotein C class. These effects differ according to sex.

Recombinant human parathyroid hormone (rhPTH[1-84], parathyroid hormone rDNA) improves hypercalcemia in patients with hypoparathyroidism: 3-year analysis from RACE study

Bart L Clarke1, Tanara J Vokes2, John P Bilezikian3, Henry G Bone4, Douglas S Denham5, Hak-Myung Lee6, Michael A Levine7, Michael Mannstadt8, Munro Peacock9, Jeffrey G Rothman10, Dolores M Shobak11, Mark L Warren12, Nelson B Watts13 & Alan Krasner9

1Mayo Clinic, Rochester, Minnesota, USA; 2University of Chicago Medical Center, Chicago, Illinois, USA; 3College of Physicians and Surgeons, Columbia University, New York, New York, USA; 4Michigan Bone and Mineral Clinic, PC, Detroit, Michigan, USA; 5Clinical Trials of Texas, Inc, San Antonio, Texas, USA; 6Shire Human Genetic Therapies, Inc., Lexington, Massachusetts, USA; 7Children’s Hospital of Philadelphia, Philadelphia, Pennsylvania, USA; 8Massachusetts General Hospital and Harvard Medical School, Boston, Massachusetts, USA; 9Indiana University School of Medicine, Indianapolis, Indiana, USA; 10State Island University Hospital, Staten Island, New York, USA; 11Endocrine Research Unit, Department of Veterans Affairs Medical Center, Department of Medicine, University of California, San Francisco, California, USA; 12Physicians East, PA, Greenville, North Carolina, USA; 13Mercy Health, Cincinnati, Ohio, USA.

Hypoparathyroidism (HPT) is characterised by hypocalcaemia and impaired renal phosphate excretion and calcification conservation. Oral calcium supplements and calcitriol can improve serum calcium levels but lack the pharmacological effects of PTH on renal reabsorption of calcium. RACE is an ongoing open-label study evaluating the long-term safety of recombinant human parathyroid hormone 1-84 (rhPTH[1-84], parathyroid hormone rDNA) in adults with HPT (NCT01297309). In this interim analysis, we report the 3-year treatment effect with 25–100 μg/day rhPTH(1-84) on 24-h urinary calcium levels, with or without thiazide diuretics. All data are presented as mean (SD). The study cohort comprised 49 patients enrolled at 12 USA centres; 38 (78%) completed 36 months of rhPTH(1-84) treatment. Baseline demographics were as follows: 82% women, aged 48 (9.8) years, HPT duration of 16 (12.5) years, 100% taking prescribed calcium supplements and calcitriol. In response to rhPTH(1-84), albumin-corrected serum calcium remained within the target range over the 3 years; 2.1 (0.17) mmol/l at baseline (i.e., start of rhPTH[1-84], n = 49) and Month 36 (n = 36). Treatment with rhPTH(1-84) also led to a reduction in urinary calcium, from baseline 8.9 (5.0) mmol/24 h to 6.5 (2.8) mmol/24 h (n = 35; P < 0.05). Urinary calcium excretion at Month 36 was similar for men compared with women, and in patients taking or not taking thiazide diuretics. Overall, 71% of rhPTH(1-84)–treated patients with baseline hypercalcemia had normal 24-h urinary calcium excretion at Month 36 (n = 12/17). Treatment with rhPTH(1-84) improved calcium–phosphate product from baseline 3.4 (0.5) mmol/L7 (n = 49) to 2.9 (0.5) mmol/L7 (n = 36) (P < 0.0001). eGFR was baseline 108.2 (36.4) ml/min (n = 41) and 115.7 (47.3) ml/min (n = 36) at Month 36 (P < 0.0772). Over 3 years, rhPTH(1-84) maintained target levels of serum calcium and reduced urinary calcium to normal levels in HPT patients. More information is needed to understand the timing of the beneficial effect on urinary calcium excretion.

Vitamin D levels after 4 weeks of very low calorie diet (VLCD)

M` Angeles Bennasar Remolar, Ignacio Pérez Catalán & María Guinot Soler

Hospital General Universitario, Castellón, Spain.

Introduction

Vitamin D is a liposoluble molecule which takes part in calcium–phosphorous homeostasis of the human body. Its optimum levels according to SEIOMM range between 30 and 75 ng/ml. Being liposoluble substances they require the presence of bile salts for their absorption; 80% is absorbed in the yeyune and in a lesser extent in the duodenum. The correct concentration of vitamin D is of key significance in obesity, particularly its visceral type. An excessive body weight is thought to represent a significant determinant of a reduced vitamin D concentration in serum. Due to its high metabolic activity, visceral adipose tissue promotes sequestration and alterations in turnover of the vitamin resembling hormone. Care for elimination of the factors which promote deficiencies is particularly essential in obese persons in whom degree of adiposity correlates with reduced concentrations of this vitamin in blood. Given the
Upper gastrointestinal symptoms, endoscopic and pathological features, and serum gastrin and chromogranin A levels in patients with primary hyperparathyroidism

Introduction

Upper gastrointestinal (UGI) symptoms are frequently encountered in patients with primary hyperparathyroidism (PHPT). Some of these symptoms may improve after PHPT treatment, while hypercalcemic state may also cause permanent effects. We aimed to evaluate UGI symptoms, UGI endoscopic and pathologic features and determine the relationship between these features with serum chromogranin A (CgA) and gastrin in PHPT patients.

Methods

Seventy-one patients diagnosed with PHPT were included in the study after exclusion of patients who refused UGI endoscopy, had an UGI surgery or used drugs that affect serum chromogranin A or gastrin. Patients were questioned regarding UGI symptoms. Serum CgA and gastrin were measured. Endoscopy was performed and gastric biopsy specimens were taken to evaluate atrophic gastritis.

Results

There were 60 females and 11 males, and median age was 52 years. Mean serum CgA and gastrin levels were 134.10±49.43 ng/ml (28-620) and 219.39±35 kg/m² with associated comorbidity or IMC ≥ 35 kg/m² with associated comorbidity or IMC ≥ 40 kg/m², between 18 and 60 years old, candidate for bariatric surgery with laparoscopic gastric by-pass. Vitamin D concentrations were monitored at two different moments: 1 month before surgery and at the moment of surgery, 4 weeks after the VLCD.

Objective

To establish whether there are statistically significant variations in the values of vitamin D before and after following a VLCD.

Results

We obtain an average level of vitamin 25 (OH) D of 16.31 ng/ml in the analytical evaluation 1 month before surgery and 21.32 ng/ml at the time of the surgery, which takes place at the end of the VLCD. Statistically significant differences are observed between the levels of vitamin 25 (OH) D 1 month before surgery and at the time of the chirurgical act.

Conclusions

According to the results, patients that follow a 4-week VLCD significantly improve the levels of vitamin 25 (OH)D in blood. Those levels do not reach a normal level after the diet, however it is evident the benefit of the recommended process, and it would be interesting to evaluate in the long term if such a tendency remains.

GP49
Background
Primary hyperparathyroidism (HyperPT) and primary hypoparathyroidism (HypoPT) are often underdiagnosed. Several strategies have been investigated in the past in order to identify diagnostic parameters, although the diagnosis of both HyperPT and HypoPT remains challenging so far, especially in asymptomatic patients. Calcium (Ca) and phosphorus (P) are inversely related together, thus the Ca/P ratio could be an useful tool to define these conditions. Recently, we proposed for the first time a cut-off of 3.5 for Ca/P ratio for the diagnosis of HyperPT. Aim
To evaluate the diagnostic value of the Ca/P ratio for HyperPT and HypoPT through a big-data approach.
Methodology
A retrospective, observational, case-control study on big-data was carried out. All examinations of parathyroid hormone (PTH), Ca and P performed at the laboratory of Modena Hospital from 2010 to 2016 were consecutively included. We considered only patients between 18 and 90 years of age. Laboratory ranges of normality for both PTH and Ca were used to divide records in HyperPT, HypoPT and controls.
Statistical analysis
The diagnostic accuracy of Ca/P ratio was investigated using receiver operator characteristics (ROC) curves in order to define cut-off points, which show higher sensitivity and specificity for the identification of affected patients. Results
46,597 records were considered. 576 HyperPT (1.2%), 323 HypoPT (0.7%) and 45,698 controls (98.1%) were found. Ca/P ratio was significantly different among groups (P < 0.001). In particular, Ca/P ratio was significantly higher in HyperPT than controls (P < 0.001). For the diagnosis of HyperPT, the threshold of 3.17 for Ca/P ratio was obtained by means of the ROC curve analysis, with 85% of both sensitivity and specificity. HypoPT showed lower Ca/P ratio compared to controls (P < 0.0001), although no useful threshold for the diagnosis was found at ROC curve because of the low sensitivity.
Conclusions
We confirm the high sensitivity and specificity of Ca/P ratio for the diagnosis of HyperPT using the largest cohort of patients available so far in the literature. On the contrary, Ca/P ratio does not contribute to identify patients with HypoPT and further researches are needed to better describe this condition. In conclusion, Ca/P ratio is a simple and inexpensive diagnostic tool to recognize HyperPT.

Cardiovascular & Lipid Endocrinology

Liraglutide prevents right ventricle hypertrophy by avoiding ACE1 & ACE2 reduction in an experimental model of idiopathic pulmonary fibrosis
Juan Fandino, Laura Toba, Hugo Ogando, Yolanda Doz, Lucas Gonzalez & Federico Mallo
Biomedical Research Centre (CINBIO, Vigo, Galicia, Spain.

The Glucagon-like peptide-1 (GLP-1) receptor is expressed in the lung having a very important role in the modulation of the Angiotensin Converting Enzymes (ACE) system. ACE1 cleaves angiotensin-I into angiotensin-II, which is converted by ACE2 to Ang(1-7). Ang(1-7) has vasodilating effects. The Idiopathic Pulmonary Fibrosis (IPF) is characterized by excessive extracellular matrix deposition disrupting the alveolar architecture and physiology. IPF develops by a sequence of events leading to fibrosis. IPF presents pulmonary hypertension and right ventricle hypertrophy. The aim of this study is to elucidate the effect of precocious treatment with LIR during the inflammatory phase of IPF in ACE1 & ACE2 in the late fibrotic phase in an experimental model of IPF.
IPF was induced in rats by a single intra-tracheal instillation of Bleomycin (BLM, 2.5 mg/kg) on day 0 (D0). From day −1 to day 6, animals were treated with Liraglutide (LIR, 100 µg/kg/12 subcutaneous). On D21 rats were sacrificed.
Heart ventricles and lungs were isolated, weighted and frozen. Histology of lungs confirmed interstitial lung fibrosis in all BLM-treated rats.
The real time-PCR levels of ACE1 & ACE-2 were lower in lungs of BLM-IPF than in controls (40% and 48% reduction, respectively). Right ventricle weight was markedly increased in BLM-IPF rats (+66%). The treatment with LIR at the beginning of the inflammatory phase completely restored the levels ACEs at the fibrotic phase (21D), and prevented the right ventricle hypertrophy.
In conclusion BLM instillation causes local injury with inflammation and alteration of lung vasculature with pulmonary hypertension reflected by right ventricle hypertrophy and related to a reduction in the expression levels of ACEs in the lung, especially ACE2. The precocious LIR treatment in the inflammatory phase prevented all these pathogenic alterations.

Clinical, laboratory and cardiac parameters in overt primary hypothyroidism versus overt central hypothyroidism
Melania Balas1, Florina Parv1, Mihaela Vlad1, Ioana Golu1, Daniela Amzar1 & Ioana Zosin1
1Department of Endocrinology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; 2Department of Cardiology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania.

Background
Hypothyroidism affects cardiac function, leading to cardiomyopathy, pericarditis, left lower ventricular performance, etc. The present study investigates different parameters (clinical, hormonal, biochemical, echocardiographic) in overt primary hypothyroidism (OPTHypo) and overt central hypothyroidism (OCHypo).

Material and methods
The study included 33 untreated patients with OCHypo (5 with empty sella, 3 with idiopathic hypopituitarism, 7 with Sheehan’s syndrome, 18 with different types of pituitary macroadenomas, before or after surgery) and 67 cases with OPTHypo, respectively with chronic autoimmune thyroiditis. Among the patients with OCHypo, 4 presented partial pituitary insufficiency (2 cases on gonadotropins and TSH secretion and 2 cases on growth hormone and TSH secretion), the rest of the cases showing global pituitary insufficiency. Patients with acromegaly and Cushing’s disease were excluded.

Results
The clinical picture was more severe in OPTHypo as in OCHypo (dominated by fatigue, edema, dry skin, neurological alterations). The values of serum thyroxin were significantly lower in OCHypo (P < 0.0001). 40% of OPTHypo patients presented pericarditis, as compared to OCHypo (2 cases, P = 0.0003). No statistical differences were noted between the two groups, regarding heart rate, systolic and diastolic blood pressure values, isovolumic contraction time. Nonetheless, the isovolumic relaxation time was significantly higher in OCHypo group (91.8 ± 8.5 ms), as in OCHypo (80.2 ± 9.9 ms, P < 0.0001). Coronary artery disease was more common in OPTHypo group (21 cases, 31.3%), as compared to OCHypo (5 cases, 15.1%, P = 0.095). Hyponatremia was recorded in 4 patients with OPTHypo and in 3 cases with OCHypo (P = 0.68). The values of serum total cholesterol, LDL-cholesterol, glycemia, creatin-kinase, transaminases, creatinine were significantly higher in OCHypo group, correlated to lower values of serum thyroxin. The incidence of anemia was similar in both groups (18 cases in OPTHypo group, 6 cases in OCHypo group, P = 0.456).

Conclusion
The metabolic and cardiac parameters were more pronounced altered in primary hypothyroidism, as compared to central hypothyroidism.

Correlation between triglyceride glucose index (TyG) and coronary artery calcification in Korean adults
Jihong You, Kahui Park, Jung Hye Kim, Sang Bae Lee, Yusik Kim, Ji sun Nam, Jong Suk Park & Chul Woo Ahn
Gangnam Severance Hospital, Seoul, Republic of Korea.

Objective
Triglyceride glucose (TyG) index is considered a surrogate marker of insulin resistance, and insulin resistance is known risk factor of cardiovascular disease. Until now, few studies have investigated the relationship between TyG index and coronary artery calcification (CAC). The present study investigated the correlation between TyG index and CAC in healthy Korean Adults.

Methods
A total of 4,463 participants underwent cardiac computed tomography in health promotion center were enrolled. TyG index was calculated as ln(fasting triglycerides [mg/dl] x fasting glucose [mg/dl]/2]. Multi-detector CT was used to measure coronary artery calcium score (CACS) and CACS > 0 was defined as the presence of CAC.

DOI: 10.1530/endoabs.49.GP54

Endocrine Abstracts (2017) Vol 49
Results
There were significant differences in cardiovascular parameters among the groups and the prevalence of CAC significantly increased with TyG index levels. In the logistic regression analysis after adjusted for multiple risk factors, the odds ratios (95% CI) for the prevalence of CAC were 1.0, 1.03 (0.72–1.45), 1.23 (0.85–1.74), 1.68 (1.15–2.44) for increasing TyG index level (P < 0.05).

Conclusion
There was a significant association between TyG index and prevalence of CAC. TyG index, a simple measure reflecting insulin resistance, might be useful to the indicator of atherosclerosis. TyG index is even simple to calculate and seems a useful marker of atherosclerosis, and reflect cardiovascular risk.

DOI: 10.1530/endoabs.49.GP54

GP57
Clinical significance and hormonal relationships of visceral adiposity index (VAI) in independently living old subjects
Mireia Mora1,2, Elisabet Palomera1, Mateu Serra-Prat1 & Manel Puig-Domingo4
1Department of Endocrinology and Nutrition, Hospital Clinic i Universitari of Barcelona, Barcelona, Spain; 2Group of Endocrine Disorders, IDIBAPS, Barcelona, Spain; 3Research Unit and Ciberhep, Hospital de Matarrà, Matarrà, Spain; 4Department of Endocrinology and Nutrition, Hospital Universitar de Germans Trias i Pujol, Badalona, Spain.

Introduction
The Visceral Adiposity Index (VAI) has been proven to be an indicator of adipose distribution and function that indirectly expresses cardiometabolic risk, in particular in specific populations such as women with polycystic ovary syndrome, acromegaly or type 2 diabetes. Little information is known about its usefulness in the definition of cardiometabolic risk in ageing population.

Objective
To study VAI in relation to metabolic and hormonal data, frailty and mortality in non-institutionalized people more than 70 years old of the Matarrà Ageing Study.

Methods/Design
289 participants (142 men/147 women) were included. Individuals were characterized by anthropometric variables, metabolic syndrome (MS) parameters by IFG and ATP-III as well as hormonal factors (TSH, free-T4, growth hormone, IGF-I, ghrelin, cortisol, dehydroepiandrosterone –DHEA-, DHEAs, testosterone, SHBG, estradiol, estrogen, cortisol/DHEA and cortisol/DHEAs), grip strength, Barthel and assessment of cognitive impairment (MiniCognitive Examination –MCOE- Spanish version) and frailty by Fried criteria. VAI was calculated according to Amato et al.

Results
The whole cohort showed a statistically significant association of the individual components of MS with VAI. However, the trend association was observed between the prevalence of diabetes and VAI categorized in quartiles. However, VAI showed no association in our sample population with the presence of cardio or cerebrovascular disease. The multiple regression analysis showed that ghrelin (B = −0.024, P = 0.020) and SHBG (B = −0.019, P = 0.034) were the only hormonal variables independently associated to VAI in women, while no associations were found in men. After a prospective follow-up of 2 years, those individuals with higher VAI at basal time point were associated to frailty condition at two years (media (SD): 2.47 (2.19) in frail vs 1.71 (0.97) in non-frail, P = 0.064). No significant association was found between VAI and mortality 2 and 8 years follow-up.

Conclusions
VAI does not provide additional information to MS criteria in ageing individuals in relation to cardiovascular risk or mortality in our population. However, VAI was associated to frailty in the whole cohort, and in women, with diabetes and ghrelin.

GP56
PCSK9 in relation to coronary damage severity in patients with cardiovascular disease
Nan Hee Cho, Kwi Hyun Bae, Gwon Soo Jung, Mi Jin Kim, Yeon Kyung Choi, Jung Beom Seo & Keun Gyu Park
Kyungpook National University Hospital, Daegu City, Republic of Korea.

Proprotein convertase subtilisin/kexin type 9 (PCSK9), a circulating protein that promotes degradation of the low density lipoprotein (LDL) receptor, has been emerged as a novel therapeutic target for the dyslipidemia. It is well known that the pathogenesis of cardiovascular disease (CVD) involves lipid metabolism alteration, but the predictive value of circulating PCSK9 level concerning coronary disease severity is largely unknown. The main objective of this study is to determine whether circulating PCSK9 concentration is linked to coronary damage severity in patients with acute coronary syndrome (ACS). We studied 137 patients with ACS who underwent coronary angiography. The study population was divided into two groups according to the SYNTAX score (lesion (+): n = 112, lesion (−): n = 25). Baseline characteristics and PCSK9 levels were measured and coronary lesions were evaluated using the SYNTAX scoring system. After adjustment for established CVD risk factors including age, body mass index (BMI), total cholesterol and low-density lipoprotein-cholesterol (LDL), ACS patients with coronary artery lesion have significantly higher PCSK9 levels than patients without lesion (178.2± 26.9 mg/ml vs. 223.0± 76.1 mg/ml, P = 0.026). Spearman’s correlations revealed that PCSK9 was positively associated with the number of involved coronary artery (Pearson coefficient, 0.034; P = 0.01) and the global registry of acute coronary events (GRACE) risk score which is a risk prediction tool applicable for ACS patients (Pearson coefficient, 0.209; P = 0.015). Furthermore, we found that plasma PCSK9 level was positively correlated with SYNTAX score (Spearman’s R = 0.115, P = 0.048). In the present study, we show that Serum PCSK9 concentration is associated with angiographic severity of ACS and GRACE score after adjustments for established CVD risk factors. Further studies are needed to confirm this observation.

Both oral and vaginal combined hormonal contraceptives induce unfavourable metabolic effects in women with PCOS: a randomized study
Maria-Elina Mosorin1,2, Terhi Piltonen1,2, Juha Tapanainen3,4 & Laure Moir-Morn-Papunen1,2
1Department of Obstetrics and Gynecology, Oulu University Hospital, Oulu, Finland; 2Department of Obstetrics and Gynecology, PEDEGO, MRC, University of Oulu, Oulu, Finland; 3Department of Obstetrics and Gynecology, University of Helsinki, Helsinki, Finland; 4Department of Obstetrics and Gynecology, Helsinki University, Helsinki, Finland.

Oral combined hormonal contraceptives (CHCs) have been suggested to induce more unfavourable metabolic effects than vaginal CHCs. CHCs are used routinely to treat the clinical symptoms of polycystic ovary syndrome (PCOS), but there are no studies investigating whether the vaginal route is safer in women with known metabolic risks.

Twenty-five women with PCOS defined according to the Rotterdam criteria were randomized to use either oral contraceptive pills (desogestrel-ethinylestradiol) (n = 14) or contraceptive vaginal rings (etonogestrel-ethinylestradiol) (n = 11) continuously for 9 weeks. Blood samples were drawn and OGTT performed at baseline and at 9 weeks.

Serum levels of SHBG increased and consequently the free androgen index (FAI) decreased in both study groups from baseline to 9 weeks of treatment [oral: 3.2 (95% confidence interval, CI: 2.2; 4.3) to 0.7 (0.5; 1.0); vaginal: 3.8 (1.8; 5.8) to 0.6 (0.5; 0.8), P ≤ 0.003 in both groups]. Insulin sensitivity was reduced at 9 weeks according to the Matsuda index [oral: 2.5 (0.1; 4.8) to 0.2 (0.2; 0.3), P = 0.035]; vaginal: 3.0 (0.4; 4.4) to 0.2 (0.1; 0.2), P = 0.366]. Serum levels of triglycerides [oral 0.9 (0.7; 1.2) to 1.3 (0.8; 1.8) mmol/l, P = 0.132; vaginal 0.8 (0.6; 1.0) to 1.3 (0.9; 1.7) mmol/l, P = 0.003] hs-CRP [oral = 0.034] and the AuG glucose during the OGTT (P = 0.017) rose significantly only in the vaginal group. The AUICinsulin (oral: P = 0.36; vaginal: P = 0.16) increased non-significantly from baseline to 9 weeks in both treatment groups. There were no differences in serum levels of glucose, insulin, hs-CRP, lipids or testosterone between the treatment groups at baseline or after 9 weeks.

Against our hypothesis, vaginal CHCs were not metabolically safer than oral CHCs. These results emphasize the importance of monitoring glucose metabolism during CHC use regardless of the route of administration, especially in PCOS women displaying typically risks of type 2 diabetes or cardiovascular diseases.

**Circulating levels of miR24-1 cluster microRNAs are increased in primary aldosteronism**

Josie van Kralingen1, Cali Anderson1, E. Marie Freelf, John M. Connelly2, Scott M. MacKenzie1 & Eleanor Davies1

1University of Glasgow, Glasgow, UK; 2University of Dundee, Dundee, UK.

**Introduction**

Measurement of microRNA (miRNA) in aldosterone-producing adenoma (APA) tissue from primary aldosteronism (PA) patients show levels of the miR24-1 cluster miRNAs (i.e. miRNAs 24-1, 27b and 23b) are significantly reduced relative to normal adrenal tissue. Our previous studies also show that miRNA-24 directly targets CYP11B2 (aldosterone synthase) gene expression. Circulating miRNAs released into the bloodstream may be diagnostic biomarkers or signalling molecules. Here, we assessed whether circulating levels of miR24-1 cluster miRNAs differ significantly between PA patients and essential hypertensives, and whether they correlate with relevant phenotypic traits.

**Methods**

Patients with essential hypertension patients (n = 18) were drawn from the British Genetics of Hypertension (BRIGHT) study and matched with 18 confirmed PA patients for age, gender and systolic blood pressure. Circulating miRNA was isolated from 200 µL EDTA plasma and analysed using quantitative real-time assays for miRNAs 24, 27b and 23b.

**Results**

PA patients had significantly increased circulating levels of miRNAs 24 (P < 0.05) and 23b (P < 0.0001) relative to primary hypertensive patients; there were also trends towards higher miRNA 27b but this was not significant. MiRNA-23b negatively correlated with diastolic pressure (P < 0.05), left ventricular mass (P < 0.01) and age (P < 0.05). MiRNAs 27b and 23b positively correlated with BMI (P < 0.05).

**Conclusions**

We have identified and validated increased circulating miR24-1 cluster miRNA levels in PA patients. These contrast with the significantly reduced levels of these miRNAs observed in APA tissue. Interestingly, miR-24 has been proposed to act as a feedback signal, repressing CYP11B2 expression when aldosterone levels are high. Therefore, increased secretion of these miRNAs into the circulation may be the result of high aldosterone levels and be intended to suppress its release. Future studies will examine the role of these miRNAs in the aetiology and pathology of PA.

**Body composition and testosterone determined VO2max in 780 young men – results from the Odense Androgen Study**

Louise Lehmann Christensen, Torben Leo Nielsen, Pernille Herrmann, Dorte Glintborg & Marianne Andersen

Odense University Hospital, Odense C, Denmark.

**Background**

Cardiorespiratory fitness is a measure for physical activity and a prognostic health indicator. However, measurement of maximal oxygen consumption (VO2max) is not possible in clinical practice.

**Aim**

We hypothesized that body composition and testosterone levels could be used as possible determinants of VO2max in young men.

**Participants and design**

The Odense Androgen Study, a population-based, observational study including 780 men aged 20–30 years. VO2max (ml/min/kg 0.73) was indirectly measured by a mechanically braked cycle ergometer. Fat mass (%) and lean body mass (%) were assessed by whole-body DXA scans. Total testosterone levels (nmol/l) were measured (RIA using extraction and chromatography). SHBG levels (nmol/l) were determined by immunoluminometric assay. Bioavailable and free testosterone were calculated.

**Results**

Descriptive data of the subjects were BMI 24.4 kg/m² (22.4–26.6), waist 88 cm (82–94), percentage lean body mass 79.1% (75.6–82.5), percentage fat mass 17.2% (18.8–21.1), total testosterone 20.7 nmol/l (17.0–25.4), SHBG 27 nmol/l (21–34) and VO2max 160.3 ml/min/kg 0.73 (143.3–177.6) (median (interquartile range). In bivariate analysis, lean body mass (%) (r = 0.62), SHBG (r = 0.26), total testosterone (r = 0.24), and free testosterone (r = 0.13) were positively associated with VO2max, whereas fat mass (%) (r = −0.63) and waist (r = −0.47) were negatively associated with VO2max (all P < 0.001). Fat mass (%) and lean body mass (%) were closely associated (r = −0.998, P < 0.001). In multivariate regression analysis, models with VO2max as the dependent variable and lean body mass (%) or fat mass (%) as independent variables were the best predictors of VO2max (both models R² = 0.47), whereas the models including testosterone (total, free or bioavailable testosterone) or SHBG as independent variables had lower R² values (R² = 0.09–0.13). All models were adjusted for age and smoking.

**Conclusion**

Body composition measures were the best predictors of VO2max in young men. VO2max was more closely associated with waist than testosterone or SHBG.

**Probiotics and nutraceuticals as a new frontier in obesity prevention and management**

Nazarii Kobylaik1, Tetyana Falalyeyeva3, Petro Bodnar4 & Tetyana Beregovsa3

1Bogomolets National Medical University, Kyiv, Ukraine; 3Taras Shevchenko National University of Kyiv, Kyiv, Ukraine.

**Introduction**

The beneficial interaction between the microbiota and humans is the way how bacteria contained within the gut ‘talk’ to the immune system. Into this landscape probiotics and nutraceuticals play a major role. The study aims to determine whether probiotics plus nutraceuticals such as smectite or omega-3 are superior to probiotic alone on the monosodium glutamate (MSG) induced obesity model in rats.

**Methods**

Totally 75 rats divided into five groups were included (n = 15, in each). Rats of group I were intact. Newborn rats of groups II–V were injected with MSG. The III (Symbiter) group received 2.5 ml/kg of multiprobiotic “Symbiter” containing concentrated biomass of 14 probiotic bacteria genera. The IV (Symbiter-Omega) and V (Symbiter +Smectite) groups received combination of probiotic biomass supplemented with flax and wheat germ oil (250 mg of each, concentration of omega-3 fatty acids 1–5%) or smectite gel (250 mg) respectively. Anthropometric, biochemical parameters of lipid and carbohydrate metabolism, and level of proinflammatory cytokines (IL-1), IL-12, Tumor Necrotizing Factor (TNF-α) and anti-inflammatory cytokines (IL-4, IL-10, TGF-β) were measured.

**Results**

In all interventional groups significant reduction of total body and VAT weight as compared to MSG-obesity were observed. However, the lowest prevalence of obesity was noted for Symbiter-Omega (20% vs 33.3% as compared to other interventional groups). Moreover, supplementation of probiotics with omega-3 lead to more pronounced decreasing of HOMA-IR (2.31 ± 0.13 vs 4.02 ± 0.33, P < 0.001) and elevation of adiponectin level (5.67 ± 0.39 vs 2.61 ± 0.27, P < 0.001) as compared to obesity group. Both nutraceuticals combination with probiotic and probiotic alone equally attenuated inflammation that was confirmed by the decrease of the pro-inflammatory and the activation of anti-inflammatory system.

**Conclusion**

Probiotics and nutraceuticals led to a significantly lower prevalence of obesity, reduction of insulin resistance, total and VAT weight. Our study demonstrated that supplementation of probiotics with omega-3 may have most beneficial antiobesity properties.

DOI: 10.1530/endoabs.49.GP60
Introduction
Leptin is a 16-kDa peptide hormone secreted by adipose tissue and acts as a sensor for energy stores. It feedback at the hypothalamic arcuate nucleus to suppress appetite. Leptin treatment has been highly effective in suppressing appetite in the rare cases of leptin-deficient obesity and improving the metabolic profile in congenital generalised lipodystrophy. These patients require 2.5–10 mg once daily recombinant leptin treatment. We hypothesised that prolonged constant exposure to leptin with a long acting leptin may have a more potent metabolic action and appetite suppression and therefore we designed a long acting leptin molecule.

Aim
To construct, express, purify and test for bioactivity a long acting leptin.

Methods
We have previously demonstrated that a fusion of growth hormone to growth hormone binding protein (GHBP) generated a long acting GH. In this project we utilise GHBP as a fusion partner with leptin the concept being that linking a fusion protein to the C-terminus will decrease clearance through reduced proteolysis and renal clearance. We further modified this molecule by introducing a W104A (Tryptophan-Alanine amino acid substitution) in the GHBP to prevent GHBP binding to GH in the circulation.

Results
GHBP(W104A)-leptin fusion was cloned in a modified invitrogen pSecTag plasmid with the secretion sequence for leptin. This plasmid was transfected into CHO Flp-In cells by reagent-mediated transfection. Protein was expressed in CHO cells grown in roller bottles in the presence of valproic acid at a set temperature of 31°C and purified by antibody affinity chromatography. In vitro bioactivity was assessed by luciferase expression induced by leptin. Approximately two times fold induction was achieved.

Conclusion
We have demonstrated it is possible to generate a fusion of leptin to GHBP and that this fusion retains bioactivity. Future studies will assess pharmacodynamic and pharmacokinetic properties of this molecule.

Effects of prenatal dexamethasone on fetal rat ovary
Natasa Ristic1, Lazo Pendovski2, Milica Manojlovic-Stojanoski1, Dragana Miljic1, Marko Miler1, Vladimir Ajdzanovic1, Svetlana Trifunovic1 & Natasa Nestorovic1 & Verica Milosevic1
1Hacettepe University Department of Endocrinology and Metabolism, Ankara, Turkey; 2University of Sheffield Department of Oncology and Metabolism, Sheffield, UK.

Glucocorticoids affect the growth and maturation of fetal organ systems, but overexposure to exogenous glucocorticoids retard fetal growth and may alter developmental process in sensitive tissues. On the other hand, fetal ovary is not a target organ for glucocorticoids. Dexamethasone (Dx) altered normal structure and development of ovary in 19 day old rat fetuses. Pregnant females in the experimental group received subcutaneous injections of 1.0, 0.5 and 0.5 mg Dx /kg body weight on days 16–18 of pregnancy. Control mothers were injected with the same amount of saline. On day 19 of pregnancy, the dams and their fetuses were sacrificed under ether anesthesia and the fetuses were referred to as 19-day-old fetuses. Fetal ovaries were prepared for further stereological examination.

The volume of the fetal ovary estimated using Cavalieri’s principle was significantly reduced after exposure to Dx by 22% (P<0.05) in comparison with control ovary. Using a fractionator-physical disector method, a reduction in total number of germ cells in meiotic prophase by 43% (P<0.05) was observed, while total number of germ cells with sign of degeneration increased by 54% (P<0.05), when compared with control values.
utilization of the agonists of TRs could be the meaningful strategy in liver relative to HCC.

3-year safety and efficacy Update of the VERTICAL & VISTA trials of somavaratan (VRS-317), a long-acting rhGH in children with Growth Hormone Deficiency (GHD)

Bradley S. Miller1, Wayne V. Moore2,3, Patricia V. Fechner4,5, Quentin L. Van Meter2, John S. Fuqua1, David Ng4, Eric Humphris5,
R. William Charlton1 & George M. Bright

1University of Minnesota Masonic Children’s Hospital, Minneapolis, MN, USA; 2Children’s Mercy Hospital, Kansas City, MO, USA; 3University of Missouri-Kansas City, Kansas City, MO, USA; 4Seattle Children’s Hospital, Seattle, WA, USA; 5University of Washington, Seattle, Seattle, WA, USA; 6Van Meter Pediatric Endocrinology, P.C., Atlanta, GA, USA; 7Indiana University School of Medicine, Indianapolis, IN, USA; 8ResearchPoint Global, Inc., Austin, TX, USA; 9Versartis, Inc., Menlo Park, CA, USA.

Requirement for daily rhGH injections is a treatment burden that can compromise adherence and efficacy in patients with GHD. Somavaratan is a novel long-acting rhGH fusion protein in clinical development for pediatric and adult GHD. In a multicenter, randomized Phase Ib/2a study, somavaratan significantly improved height velocity (HV) and IGF-I in pre-pubertal children with GHD. Preliminary efficacy and safety in subjects who have completed 3 years of somavaratan treatment are presented. Of 64 subjects randomized in the Phase 2a VERTICAL study to receive 5.0 mg/kg/month (weekly/twice-monthly/monthly dosing) for 6 months, 60 elected to continue treatment in the long-term safety study, VISTA. Initial IGF-I response supported a dose increase, and all subjects transitioned to somavaratan 3.5 mg/kg twice-monthly by the 2nd treatment year. Data cutoff was December 8, 2016. Of 48 subjects (24 males, 24 females), the mean ± SD age was 7.6 ± 2.4 years, and mean IGF-I SDS was −0.8 ± 1.6 at baseline. In Year 3, IGF-I SDS increased to 1.2 ± 1.7 at peak (3–5 days post-injection) and −0.3 ± 1.0 at trough (end of dosing cycle). Mean HV remained consistent during Years 1, 2, and 3, at 8.4 ± 2.0, 8.3 ± 1.6, and 7.8 ± 1.6 cm/year, and height (HT)/SDS continued to increase from −2.6 ± 0.6 at baseline to −2.1 ± 0.6, −1.7 ± 0.7, and −1.2 ± 0.8; delay in bone age (years) was −1.48 ± 0.81 at baseline, −1.34 ± 0.89 (Year 1, n = 48), −1.09 ± 1.02 (Year 2, n = 47), and −0.66 ± 0.82 (Year 3, n = 25). Treatment-related AEs were generally transient and mild. Overall, IGF-I, HV, HT-SDS, and bone age showed continued improvement through 3 years of somavaratan treatment in pre-pubertal children with GHD. Dose increase to somavaratan 3.5 mg/kg twice-monthly resulted in consistent growth rates through 3 years of treatment, and overall Year 3 growth was consistent with daily rhGH from US registries. A Phase 3 study of somavaratan 3.5 mg/kg twice-monthly in treatment-naive GHD children is ongoing.

Achievement of a suitable basis of comparison in phase 2 and 3 clinical trials (VERTICAL-VISTA, and VELOCITY) comparing somavaratan vs daily rhGH for pediatric GHD deficiency

Philippe Backeljauw1, Bradley S Miller2, Nancy Wright3, Aristides Maniatis4, Michael Stalvey5, Eric Humphris6, R. William Charlton1 & George M Bright

1Cincinnati Children’s Hospital Medical Center, Cincinnati, OH, USA; 2University of Minnesota Masonic Children’s Hospital, Minneapolis, MN, USA; 3Nancy Wright MD p.a., Tallahassee, FL, USA; 4Rocky Mountain Pediatric Endocrinology, Centennial, CO, USA; 5University of Alabama at Birmingham, Birmingham, AL, USA; 6Versartis, Inc., Menlo Park, CA, USA.

Efficacy of rhGH for treatment of pediatric GHD deficiency (PGHD) may depend on several variables at treatment initiation (age, body weight, height velocity (HV), IGF-I SDS, skeletal maturation, GHmax), but may be compromised by poor adherence to required daily injections. Somavaratan is a novel, long-acting rhGH fusion protein that demonstrated clinically meaningful improvements in HV and IGF-I concentration in PGHD patients. Over 200 pre-pubertal GHD subjects have enrolled in somavaratan trials to date, including 137 in the Phase 3 non-inferiority VELOCITY trial comparing somavaratan vs daily rhGH. In the randomized Phase Ib/2a VERTICAL study in pre-pubertal children with GHD, primary determinants of Year 1 HV included age at treatment initiation and GH severity. To achieve a valid basis of comparison of efficacy outcomes across trials (VELOCITY, VERTICAL, VISTA (long-term safety)), distribution of clinical characteristics known to affect HV should be similar between treatment arms (somavaratan vs daily rhGH) and between trials. The same primary efficacy endpoint (HV) and similar eligibility criteria were used across trials. Stratification for Phase 3 randomization (somavaratan vs daily rhGH) was based on region, expected age, and expected baseline IGF-I SDS. In VELOCITY (n = 104 somavaratan; n = 32 daily rhGH), baseline ages were 7.07 ± 2.0 vs 7.03 ± 2.4 years, respectively, mean GHmax 5.77 ± 2.6 vs 5.87 ± 2.5 ng/ml, mean height-SDS −2.76 ± 0.7 vs −2.64 ± 0.7, mean IGF-I SDS -1.72 ± 0.7 vs −1.87 ± 0.9, and mean bone ages 5.28 ± 1.9 vs 5.29 ± 2.2 years. In VERTICAL (N = 64), mean age was 7.8 ± 2.4 years, mean height-SDS −2.6 ± 0.6, mean IGF-I SDS −1.7 ± 0.8, and mean bone age 6.4 ± 2.4 years. No clinically meaningful differences in baseline characteristics were noted between trials, or between VELOCITY treatment arms. Collectively, similar populations were achieved between trials by use of consistent eligibility and stratification procedures. This allowed balanced treatment arms for clinical characteristics that may influence the primary efficacy outcome, thereby achieving a valid basis of comparison between trial populations.

Karyotype and mid-childhood gonadotropin concentrations in prediction of spontaneous puberty in Turner syndrome patients

Aneta Gawlik1, Magdalena Hunka2, Kamil Soltysak1, Kamila Szeliga3 & Ewa Malecka-Tendera1

1Department of Pediatrics and Pediatric Endocrinology, School of Medicine in Katowice, Medical University of Silesia, Katowice, Poland; 2Department of Pediatrics and Pediatric Endocrinology, Upper-Silesian Pediatric Health Center, Katowice, Poland; 3Department of Anatomy and Molecular Cell Biology, Nagoya University Graduate School of Medicine, Nagoya, Japan.

Gonadotropin levels in all Turner syndrome (TS) patients present a diphasic pattern: highest in early childhood, declining at 6–10 years of age, and then increasing again. Here, we have investigated whether karyotype or FSH&LH can be used as indicators of spontaneous puberty in TS. From a consecutive group of 139 TS girls treated at one clinical center (1996–2015) the clinical and biochemical data were finally analyzed in 110 TS patients (110 of the clinical study population was divided into two subsets based on karyotype type A = 45X, 54%; type B-others excluding 45X/46XY). The mean diagnosis age and duration of follow-up were 10.7 ± 4.0 and 5.9 years, resp. The average number of visits was 10.4. Spontaneous puberty was confirmed in 48.2% and menarche in 20%, both less common in group A than B (31.1% and 9.8% vs 69.4% and 32.6%, resp., P < 0.05). The mean age of Tanner B2 and menarche in all girls were 13.7 ± 2.4 and 14.2 years, no difference between the groups (13.5 ± 2.5 and 13.2 ± 1.0 years (A) vs 13.8 ± 2.3 and 14.6 ± 1.7 years (B), P > 0.05). The median FSH and LH values in all patients at the age of 6–10 were 8.16 and 0.35 IU/l resp., significantly lower comparing to younger (44.6 and 0.76 IU/l) and older (93.0 and 16.1 IU/l) age (P < 0.0001). LH were similar in both groups, whereas in group B FSH values were significantly higher only in the older age. At the age of 6–10 FSH and LH levels were higher than 6.7 and 0.2 resp. decrease the chance of spontaneous menarche (33.3% vs 13.9% and 28.6% vs 11.8%). Conclusion: Nearly half of our TS patients showed spontaneous puberty symptoms and every fifth had spontaneous menarche with higher frequency in non-45,X girls. The diphasic pattern of FSH&LH was confirmed, however using their cut-off values one can predict the chance for spontaneous menarche.

Assessment of reports of behaviour by patients and their parents in pediatric Cushing disease

Margaret Keil, Elena Belyavskaya, Charalampos Lyssikatos, Maya Lodish & Constantine Stratakis

NIH, NICHD, Bethesda, MD, USA.

Context

Prior studies of children with endogenous Cushing syndrome (CS) have identified cognitive decline despite reversal of brain atrophy after remission as well as residual impairment of quality of life measures. Although parental observations support personality changes with CS, significant psychopathology has not been described. We investigated the feasibility of using paediatric Patient-reported

Endocrine Abstracts (2017) Vol 49
outcomes (PROMIS) using a computer interface to assess patient perception of burden of illness and correlation with parent proxy report using Child Health Questionnaire (CHQ).

Setting
Subjects were enrolled in a clinical protocol at the National Institutes of Health Clinical Center in Bethesda, MD, USA.

Method
We report 9 children (6F, 12 ± 3.5 years) diagnosed with Cushing disease (CD). Prior to surgical treatment, subjects completed paediatric PROMIS measures and parents completed CHQ using an online secure website.

Results
PROMIS measures scores (mean ± S.D.): anxiety (54 ± 9, depression (55 ± 11), anger (50 ± 9), and emotional support (52 ± 10) (higher scores indicate more of the concept being measured); CHQ total Psychosocial score (mean ± S.D. (43 ± 10) (lower values are associated with a greater deficit in functioning). A significant correlation was found between Psychosocial summary score of CHQ and paediatric PROMIS measures of anxiety (r = -0.70; 5, P < 0.03) and depression (r = -0.9; P < 0.002). No correlation was found between urinary free cortisol level or midnight serum cortisol and PROMIS measures.

Conclusion
Prior to treatment for CS, a significant correlation was found between children’s endorsement of anxiety and depression symptoms and parental proxy report of psychosocial function. Our findings support that paediatric PROMIS measures represent feasible and potentially valuable instruments for future studies to assess behavioural symptoms in children diagnosed with CS prior to and after treatment.

The adverse effects of prescribed glucocorticoids are worsened by co-administration of 5α-reductase inhibitors
Tom Marjot, Nantia Othonos, Conor Woods, Jonathan Hazelehurst, Ahmad Moola, Leanne Hodson & Jeremy Tomlinson

Introduction
Glucocorticoids (GC) are prescribed to 2-3% of the population of the UK and USA. Their use is associated with a significant side effect profile that includes the development of central obesity, insulin resistance and type 2 diabetes. 5α-reductase (5αR) inhibitors (Finasteride and Dutasteride) are also commonly prescribed in the context of prostate disease, where they inhibit the conversion of testosterone to dihydrotestosterone. Additionally, they have a role to inactivate and clear GC. We have therefore hypothesised that 5αR inhibitors have the potential to exacerbate the adverse metabolic effects of GC.

Methods
We conducted a prospective, randomised, study in 19 healthy male volunteers (age: 45±8.5 years, BMI: 27.1±3.1 kg/m²). Participants underwent detailed metabolic assessments including a 2-step hyperinsulinaemic euglycaemic clamp incorporating stable isotopes, adipose tissue microdialysis and biopsy. They were then randomised to receive either prednisolone (10 mg OD) or prednisolone (10 mg OD) and a 5αR inhibitor (finasteride 5 mg OD or dutasteride 0.5 mg OD) for 7 days, metabolic assessments were then repeated.

Results
We have previously shown that high dose parenteral GC administration decreases glucose utilization (M value; 3.1±0.4 vs 1.6±0.1 mg/kg per min, P=0.001) and 5αR inhibitors alone are without effect (M value; 3.5±0.4 vs 3.3±0.4 mg/kg per min, P=0.42). In this study, prednisolone only did not alter glucose utilization (M value; 3.2±1.3 vs 2.8±1.6 mg/kg per min, P=0.37), however, co-administration of prednisolone and 5αR inhibitors significantly decreased it (M value; 4.0±2.0 vs 2.6±1.3 mg/kg per min, P=0.02). Similarly, high dose GC, but not 5αR inhibitors alone, impair insulin-mediated suppression of circulating non-esterified fatty acids (NEFA). Prednisolone 10mg OD did not alter insulin-mediated suppression of NEFA (0.15±0.27 vs 0.13±0.13, P=0.88), however, co-administration with 5αR inhibitors impaired the ability of insulin to suppress NEFA (0.15±0.1 vs 0.29±0.18, P=0.01).

Conclusion
5αR inhibitors exacerbate the adverse metabolic effects of prescribed GCs. This has significant translational implications, not only with regards to the need to consider steroid dose reductions, but also the necessity for increased vigilance for the development of adverse effects.

Carbohydrates metabolism and H. pylori: case-control study
Israel Ma Cornejo-Fajre1, M Mar Roça-Rodriguez2, Leticia Coint-Aragüez2, Araaceli Muñoz-Garach1, María Molina-Vega1, Cristina Díaz-Perdigones1, Carmen Hernández-García1, Juan Alcaide-Torres1, Carlos Clu-Fernández1, Laura Viituela-González4, Laura Mora-Nava4, Isabel Mancha-Doblas1 & Francisco J Tinahones-Madueño1
1Endocrinology and Nutrition Department. Virgen de la Victoria Hospital, Málaga, Spain; 2Endocrinology and Nutrition Department Puerta del Mar Hospital, Cádiz, Spain; 3Research Laboratory IBIMA; Málaga, Spain; 4Microbiology Department. Virgen de la Victoria Hospital, Málaga, Spain.

Introduction
H. pylori infection has been related with extragastric diseases such as type 2 diabetes.

Aim
To evaluate changes in carbohydrate metabolism induced by 75g oral glucose tolerance test (OGTT), before and after antibiotic eradication treatment in patients colonized by H. pylori compared to healthy controls.

Materials and methods
A prospective case-control study. Biochemical parameters, carbohydrate profile, ghrelin and GLP1 levels before and after antibiotic eradication treatment were analyzed.
Results
We studied 40 cases and 21 controls (60% and 57.1% women, respectively). Mean age: 46.95 ± 2.02 vs 44.52 ± 2.73 years, family history of digestive disorders: 70% vs 57.1% and clinical history of gastrointestinal disease: 57.5% vs 42.9%, respectively. After antibiotic treatment, significant improvements in HbA1c (P = 0.014), glucose levels post OGTT at 60’ and 120’ (P = 0.018 and P = 0.019, respectively) and HDL Cholesterol (P = 0.021) were observed. Somatostatin levels in basal ghrelin levels (P = 0.05) were found, but ghrelin levels did not change. We observed differences between infected population by H. pylori and healthy people: lower post OGTT insulin levels at 30’, 60’,80’ and 120’ (P = 0.042 and P = 0.03, respectively) in infected patients. Those differences disappeared after treating the infection. In cases and controls, we found significant positive correlations in carbohydrate metabolism, and significant negative correlations in controls between ghrelin with basal insulin and C peptide. No significant correlations respect to GLP1 were found. 90% of patients completed correctly the treatment, 31.6% needed ranitidine and 97.5% eradicated H. pylori after conventional antibiotic treatment.

Conclusion
1) H. pylori eradication improved carbohydrate metabolism. 2) Significant positive correlations in carbohydrate metabolism in cases and controls were found. 3) Negative correlations between ghrelin and pancreatic reserve were observed in cases. 4) Carbohydrate metabolism differences between healthy and infected people disappeared after eradication treatment. 5) More than 95% of patients achieved H. pylori eradication with conventional antibiotic treatment.

Specific plasma amino acids alternations associated with metabolic syndrome
Marta Siomkajło1, Jacek Rybka1, Andrzej Gamian2,3, Joanna Stankiewicz-Olczyk1, Marek Bolanowski1 & Jacek Daroszewski1
1Department of Endocrinology, Diabetes and Isotope Therapy, Wroclaw Medical University, Wroclaw, Poland; 2Department of Medical Biochemistry, Wroclaw Medical University, Wroclaw, Poland; 3Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland.

Objectives
Amino acids (AA) plasma profile is associated with cardiometabolic diseases (CMD), predicts diabetes mellitus type 2 (DM2) and cardiovascular diseases (CVD) many years in advance. Metabolic syndrome (MS) defines the area of metabolic disturbances that precede DM2 and CVD development. The primary objective of the study was to examine the association between BCAA (branched chain amino acids), AAA (aromatic amino acids) profile and MS’s phenotype and to evaluate its clinical utility for MS diagnosis.

Methods
263 healthy, professionally active men, with and without MS (MS+, n = 165; MS−, n = 98) were included into the study. Anthropometric, biochemical and AA measurements were performed. AA were tested for the ability to discriminate subjects with MS and insulin resistance irrespectively. Based on logistic discrimination multivariate early MS diagnostic model was built and its discrimination properties were evaluated.

Results
2 functionally independent AA clusters were identified. BCAA and phenylalanine differed strongly between MS+ and MS- participants (p = 0.003), appeared as significant indicator of MS+ individuals (AUC 0.66; 95% CI: 0.5757–0.7469) and correlated with cardiometabolic factors. No statistical significant differences in AAs concentrations between IR + and IR – groups were noted and none of the AA group appeared as meaningful IR+ indicator. Proposed MS multivariate diagnostic model consisted of phenylalanine, insulin, leptin, adiponectin and had good discrimination properties – AUC 0.79; (95% CI: 0.7239–0.8646).

Conclusions
MS is associated with selective hiperaminoacydemia that could be a part of CMD pathogenesis. Present study suggests that AA disturbances do not derive directly from insulin sensitivity impairment nor obesity or muscle mass. AA utility for MS diagnosis needs further evaluation. The original outcome of the study became MS diagnostic model creation – MS screen test, with good discrimination properties and that could be validated in the next coming studies.

Permanent neonatal diabetes in a 24 year old Spanish patient
Milagros Sierra, Elena Garcia, David Males, Juan Carlos Romero, Carlos Silva, Gonzalo Allo & Guillermo Martinez
12 De Octubre University Hospital Endocrinology and Nutrition Department, Madrid, Spain.

Introduction
Neonatal diabetes mellitus is a rare form of diabetes, diagnosed within the first six months of life. We report a case of a 24-year-old patient with permanent neonatal diabetes.

Case Report
The patient had no relevant family history. Her mother had no gestational diabetes. Personal history included: Normal birth weight, poylcsytic ovarian syndrome and ovarian teratomas. She was diagnosed of diabetes at 3 months of age, starting immediately with insulin treatment. Glucose control had always been optimal (HbA1c 1 < 6.7%). Acute diabetic complications included: symptomatic hypoglycemias every 3 days, usually after dinner and, less frequently nighttime hypoglycemias. No hyperglycemias that required in hospital management. No chronic metabolic complications. The patient came to our clinic to continue follow up. We completed her work up doing islet antibodies detection (anti GAD65, anti tyrosine phosphatase IA2, anti insulin and anti zinc transporter), and as expected the results were negative. Considering the age of the diagnosis, genetic testing for monogenic forms of diabetes was performed. discovering a heterozygous mutation c.323Ag (pY108C) in INS gene. Family genetic mutation are still pending.

Discussion
Neonatal diabetes mellitus have an incidence of 1 in 500000 live births. Most common genes are KLF11, ABC8 and less frequently INS gene (30%, 19% and 14% respectively). Depending on the severity of the mutations insulin bioactivity will be affected, ranging from a decreased biosynthesis to altered transcription. Clinical implications include transient requirement of insulin, later switching to sulfonylureas or even completely stopping hypoglycemic treatment; and permanent insulin treatment. In the latter, the risk of ketoacidosis also depends and the recessive or dominant inheritance.

Conclusions
Monogenic forms of diabetes are uncommon, however it is important to consider them in the differential diagnosis of particular cases. Genetic mutation study is important to assess future treatment options and the risk of ketoacidosis.

Rescue study of trapped AVPR2 mutants with chemicals
Beril Erdem, Emel Saglar, Tugce Karaduman, Merve Ozcan, Dilara Sahin & Hatice Mergen
Department of Biology, Faculty of Science, Hacettepe University, Ankara, Turkey.

Diabetes insipidus (DI) is a disorder that characterized by producing large volume of urine for daily due to the problems at the arginine vasopressin (AVP-NP), aquaporin 2 (AQP2) and arginine vasopressin receptor 2 (AVPR2) genes. These problems can be inherited or acquired. Among these genes, AVPR2 is a G protein coupled receptor and most of the inherited type of DI are caused by mutations in AVPR2 gene. Mutations can cause improper folding of the receptor protein and this situation causes to retention of the protein in cellular compartments such as endoplasmic reticulum (ER) or Golgi apparatus. For treatment strategies, researchers try to use chemicals to rescue of mutant proteins from the control mechanisms to make them at least functional. In this study, we aimed to do pre-research for the rescuing mutant receptors (R68W, V162A, T273M, R67_G69del/G107W, V88M, R106C, G12E). We performed functional characterization of these mutant receptors in our previous study and they were observed as trapped in the ER or Golgi apparatus. In the present study, COX-7 cells were transfected with mutant and wild type AVPR2s. 48 hours after the transfection, different concentrations of DMSO and glycerol were performed to the cells. 16–18 hours after the treatment of DMSO and glycerol, cell surface ELISA were performed to understand cell surface expression of the mutant proteins when they were treated with different concentrations of DMSO and glycerol. According to the ELISA results, mutant receptors showed different rescue profile compared to the wild type receptor. As a result, we can say that rescued trapped mutant receptors from ER or Golgi apparatus can control mechanisms using with chemicals could be a forward step for the treatment of DI. Receptors that have mutations which cause retention in ER or Golgi apparatus may be functional if they are rescued by chemicals. For further studies, instead of chemicals, pharmacochaperons could be use. We can conclude that, rescue
studies of mutated proteins by using chemicals or pharmacochaperons shed light to the treatment strategies of DI. This work was supported by The Scientific and Technological Research Council of Turkey (Project Numbers: 216S304 and 12ES513).

GLP-1 acutely regulates carbohydrate and lipid metabolic routes in the liver
Lauri Toba, Yolanda Diz-Chaves, Juan Fanditto, Hugo Ogando, Lucas González-Matías & Federico Mallo
University of Vigo, Vigo, Spain.

The Glucagon-like peptide-1 receptor is widely expressed in diverse tissues including the liver. GLP-1 contributes itself to the regulation of glucose homeostasis and has important effects in lipid metabolism even preventing liver steatosis induced by high-fat diets.

The aim of this study was to analyse the short-term effects of lepirudin on key enzymes of the hepatic energy metabolism.

Thirty-six Sprague-Dawley young adult male rats were studied (weight range 350–400 g). Control rats were fed ad libitum, while the fast group (F) were deprived of food for 48 hours, and treated with lepirudin (100 µg/Kg/12 h). CT/LIR; F/LIR or vehicle (CT/VEH; F/VEH) for 48 hours. Rat body weight was measured at 0, 24 and 48 hours. At 48 h, rats were sacrificed and liver samples were collected and stored at −80°C until analysis. mRNA expression of G6P, PCK-1, DGAT-1, GPIAT, CPT1a and ACACA in the liver were assessed by real time PCR.

CT/LIR rats gained less body weight (∼6.4 g/100 g, P < 0.0001) than CT/VEH at 24 h and still less at 48 h (∼2.9 g/100 g, < 0.0001). The expression levels of G6P and PCK-1, key enzymes in gluconeogenesis, decreases in rats treated with lepirudin by a 5% (P < 0.05) and 75% (P < 0.01) respectively. On the other hand, DGAT-1 and GPIAT4 levels, involved in synthesis of triacylglycerol, were not modified by LIR. In addition, CPT1a and ACACA, enzymes implicated in the synthesis & metabolism of fatty acids, yielded no significant differences. Fasting just increased CPT1 levels (27% F/VEH vs CT/VEH, P < 0.01), and LIR treatment reduced them (92% F/LIR, P < 0.01 vs F/VEH).

In conclusion, Liraglutide modifies the metabolism of energy substrates in the liver reducing glucose production in normal feeding and CPT1a specially in fasting, limiting lipid access to mitochondria. These metabolic changes may underlie the prevention of liver steatosis attributed to GLP-1 analogues.

Increased risk of diabetes and hyperglycaemia associated with treatment with statins, beta-blockers and diuretics: the PPP-Botnia study
Lisa Hakaste1,2, Teo Helkkula1, Bo Isomaa1, Marija-Riitta Taskinen3,4, Liisa Hakaste1,2, Teo Helkkula2, Bo Isomaa2, Marja-Riitta Taskinen3,4, Leif Groop5,6 & Tiinamaija Tuomi1,2
1Folkhalsan Research Center; Diabetes and Obesity Research Program, University of Helsinki, Helsinki, Finland; 2Research programs Unit, Diabetes and Obesity, University of Helsinki, Helsinki, Finland; 3Heart and Lung Center, Helsinki University Hospital, Helsinki, Finland; 4Land University Diabetes Center, Malmo, Sweden; 5Finnish Institute for Molecular Medicine, University of Helsinki, Helsinki, Finland.

Background
Statin medication is commonly used in prevention of cardiovascular diseases. Pooled evidence shows that statin therapy is associated with increased risk of incident diabetes, but studies vary in results and there is no consensus of the diabetogenic mechanism of statins. Beta blockers and diuretics are commonly used antihypertensive agents that also have been shown to increase the risk of incident diabetes. Our objective was to examine the effects of statins, beta blockers and diuretics on glucose metabolism and the risk of incident diabetes.

Methods
5208 subjects from western Finland identified through the Population registry participated in the baseline PPP-Botnia Study, and 3,614 subjects participated in the follow-up study after a mean time of 6.7 years. Participants underwent oral glucose tolerance tests (OGTT) and gave information about their use of medication. Insulinogenic index (IGI) and corrected insulin response (CIR) were calculated from the glucose and insulin response during OGTT.

Results
After controlling for confounding factors, the group treated with statins during the entire follow-up had a, nominally significant, 7% (95% CI 1.16, 2.76 P = 0.008) increased risk of developing incident diabetes, compared to the group without statins, and statin use was significantly associated with higher levels of fasting plasma glucose (FPG) and 2 hour plasma glucose (2hPG). Statin therapy was associated with a reduced CIR30, but not IGI30. Beta blocker therapy was associated with a nominally significant 6% increased risk of developing incident diabetes.

Conclusion
Statin treatment is associated with an increased risk of incident diabetes, higher levels of FPG and 2hPG, and reduced insulin secretion. Beta blocker therapy is associated with an increased risk of incident diabetes.

Susceptibility to type 2 diabetes may be modulated by haplotypes in G6PC2, a target of positive selection
Mario Clerici1, Nassir Al-Daghiri2, C Pontremoli3, R Cagliani1, Diego Foroni1, Majed Alakawi2, Omar Al-Attar2, Shaun Sabico2, S Riva1 & M Sironi3
1University of Milano, Milan, Italy; 2King Saud University, Riyadh, Saudi Arabia.

Introduction
The endoplasmic reticulum enzyme glucose-6-phosphatase catalyzes the common terminal reaction in the gluconeogenic and glycogenolytic pathways and plays a central role in glucose homeostasis. In most mammals, different G6PC subunits are encoded by three paralogous genes (G6PC, G6PC2, and G6PC3). Mutations in G6PC and G6PC3 are responsible for human Mendelian diseases, whereas variants in G6PC2 are associated with fasting glucose (FG) levels.

Methods
We analyzed the evolutionary history of G6Pase genes in mammals. Results indicated that negative selection was the major force shaping diversity at these genes. Nonetheless, site-wise estimation of evolutionary rates at corresponding sites revealed weak correlations, suggesting that G6Pas have evolved different structural features over time. We also detected pervasive positive selection at mammalian G6PC2 genes. Most selected residues are located in the C-terminal protein region, where several human variants associated with FG levels also map. This region was thus re-sequenced in a cohort of ~560 subjects from Saudi Arabia, 185 of whom suffering from type 2 diabetes (T2D).

Results
The frequency of rare missense and nonsense variants was not significantly different in T2D and controls. Association analysis with two common missense variants (V219L and S342C) revealed a weak but significant association for both SNPs when analyses were conditioned on rs560887, previously identified in a GWAS for FG. Two haplotypes were significantly associated with T2D with an opposite effect direction.

Conclusion
These results, although preliminary, suggest that distinct haplotypes at the G6PC2 locus modulate susceptibility to T2D.

Contribution of genetic predisposition and lifestyle to gestational diabetes risk
Polina Popova1,2, Alexandra Tkachuk1, Yana Bolotko1, Andrei Gerasimov1, Alexandra Klyushina1, Anna Kostareva1 & Elena Grineva1,2
1Almazov Federal North-West Medical Research Centre, Saint-Petersburg, Russia; 2Saint Petersburg Pavlov State Medical University, Saint-Petersburg, Russia.

Aim
The aim of our study was to assess the contribution of genetic variation in some previously reported gestational diabetes mellitus (GDM) susceptibility loci and lifestyle parameters to GDM risk.

Endocrine Abstracts (2017) Vol 49
Methods
We performed a case-control study of 278 GDM cases and 179 controls who had filled up special questionnaires concerning their lifestyle habits during the oral glucose tolerance test (OGTT) on the 24–32 week of gestation. The questionnaire consisted of the following sections, stratified in a semi-quantitative manner: the consumption of major food groups and drinks, the amount of physical activity and smoking before and during pregnancy. GDM was diagnosed according to the IADPSG criteria. Maternal blood was sampled for further genotyping of single nuclear polymorphisms (SNPs) in MTNR1B (rs10830963 and rs1387153), GCK (rs1799884), KCNJ11 (rs5219), IGF2BP2 (rs4402960), TCF7L2 (rs7903146), CDKAL1 (rs7758480) and RS1 (rs1801278). Binary logistic regression (forward conditional) was accomplished to identify the contribution of «classical» risk factors for GDM (advanced maternal age, higher body mass index (BMI), history of GDM, impaired glucose tolerance, arterial hypertension, family history of diabetes), lifestyle parameters and the above mentioned SNPs to the assessment of GDM risk.

Results
After automatic lineal modeling the following factors proved to be associated with the increased GDM risk: age (OR = 1.11, 95% CI = 1.06–1.16, P = <0.001), BMI (OR = 1.09, 95% CI = 1.05–1.14, P = <0.001), the presence of G allele of rs10830963 (OR = 2.1, 95% CI = 1.4–3.1, P = <0.001), T allele of rs799884 (OR = 2.1, 95% CI = 1.3–3.4, P = 0.003) and consumption of sausage > 3 times a week (OR = 2.55, 95% CI = 1.36–4.78, P = 0.004) compared to less consumption. Legumes consumption 1–2 times a week was associated with the decreased risk of GDM, when compared to less consumption (OR = 0.95, 95% CI = 0.36–0.97, P = 0.036).

Conclusion
MTNR1B and GCK variants, some eating habits along with an increment in maternal age and BMI were associated with the increased risk of GDM.

The rs2292239 polymorphism in the ERBB3 gene is associated with risk for type 1 diabetes mellitus
Daisy Crispim1, Cristina Dieter1,2, Natalia Lemos1,2, Tais Assmann1,2, Guilherme Duarte1,2, Luiza Dorfman3 & Andrea Bauer1,2
1Endocrine Division, Hospital de Clinicas de Porto Alegre, Porto Alegre, Rio Grande do Sul, Brazil; 2Post-graduation Program in Medical Sciences: Endocrinology, Faculdade de Medicina, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil; 3Universidade do Vale do Rio dos Sinos - UNISINOS, Sao Leopoldo, Rio Grande do Sul, Brazil.

Background and Aim
Type 1 diabetes mellitus (T1DM) is an autoimmune disease resulting from the complex interaction among multiple genes, environmental factors and the immune system. Genome-wide association studies identified ERBB3 (Erb-b2 receptor tyrosine kinase 3) gene as a main susceptibility locus for T1DM. This gene encodes a member of the family of intracellular receptors of protein tyrosine kinases, which activates multiple signaling pathways including P38, Akt and MAPK; thus, regulating cell survival and proliferation. Moreover, ERBB3 seems to contribute to T1DM pathogenesis by modulating antigen-presenting cell function and autoimmunity as well as beta-cell apoptosis and insulin production. Therefore, the aim of this study was to investigate the association of the rs2292239 (C>A) polymorphism in the ERBB3 gene with susceptibility to T1DM in a Brazilian population from Southern-Brazil.

Methods
Frequencies of the rs2292239 polymorphism were analyzed in 461 T1DM patients (cases) and 570 non-diabetic subjects (controls). Genotyping was performed using Real-Time PCR and TaqMan MGB probes (Thermo Scientific).

Results
Genotype distributions of the ERBB3 rs2292239 polymorphism were in agreement with those predicted by the Hardy-Weinberg Equilibrium in the control group (P = >0.05), with the A/A genotype being more frequent in T1DM patients compared with non-diabetic subjects (P = <0.001). The A allele frequency was 39.7% in the T1DM group and 32.8% in the control group (P = 0.008). Moreover, the A allele was significantly associated with T1DM risk when taking into account additive (OR = 1.67, 95% CI 1.07–2.61; P = 0.023) and recessive (OR = 1.58, 95% CI 1.04–2.40; P = 0.031) inheritance models, adjusting for

Trace elements as an oxidative stress marker in women with gestational diabetes and their neonates
Georgios Boutzios1, Eleni Koukoulioti1, Ioannis Papoutsis2, Sotiros Athanaselis2, Gerassimos Tsouroufis1 & Evangelia Zapantii
1Endocrine Unit, Department of Pathophysiology, Laiko University Hospital, Medical School, University of Athens, Athens, Greece; 2Department of Toxicology, Medical School, University of Athens, Athens, Greece; 3Endocrine Unit, Alexandra Maternity Hospital, Athens, Greece.

Background and aims
Gestational diabetes (GD) is closely related to unbalanced zinc (Zn) and copper (Cu) serum levels. The aim of this study was to investigate serum zinc and copper levels in relation to the metabolic profile, and the impact on fetal development in a cohort of gestational diabetes GD(N) neonates and their mothers GD(M) compared to normal pregnancies.

Material and Methods
Prospective controlled study in a tertiary Academic medical center. The study population included 101 mother/neighbor pairs; 50 control group (C) and 51 GD group. Intervention: Diet and/or insulin administration in GD(M). Anthropometric, metabolic parameters, and trace elements serum levels were assessed.

Results
Age and body weight change during pregnancy (ΔBW) were similar in both groups. HbA1c was comparable between C and GD group (5.37 ± 0.34 and 5.39 ± 0.48%, for C and GD respectively, P = 0.844). Mean serum Cu levels were (150.1 ± 45.85, 32.16 ± 43.37) µg/dl in C and (203.53 ± 65.63, 23.62 ± 13.42) µg/dl in GD, mean Zn levels (87.8 ± 17.48, 120.47 ± 37.16) µg/dl in C and (88.1 ± 27.1, 113.76 ± 36.77) µg/dl in GD, for mothers and neonates, respectively. Neonates had statistically significantly lower serum Cu levels but higher Zn levels compared to their mothers (P < 0.001). Serum copper levels in mothers (Cu(M)) levels were statistically significantly higher in GD(M) compared to C(M) (P < 0.0001). There was a negative correlation between Zn(M) and insulin levels (M) in C (r = -0.264, P = 0.045), between Zn(M) and insulin(N) in GD (r = -0.372, P = 0.012), and between Zn(N) and head circumference in C group (r = -0.423, P = 0.013). There was a positive correlation between Cu(N) and insulin(N) in GD (r = 0.365, P = 0.019), and between Cu (M) and birth weight in C (r = 0.304, P = 0.042).

Conclusions
Serum copper levels are higher in women with gestational diabetes and independently of diabetes control. Both serum trace element levels in neonates seem to correlate with neonatal head circumference and birth weight only in control group.

Reduced level of soluble TLR2 in type 2 diabetes despite increased TLR2 monocyte expression

Emanuela Zaharieva1, Tsvetelina Velikova2, Elena Vikentieva3, Dora Popova1, Adelina Tsakova2 & Zdravko Kamenev1
1Medical University Sofia, Alexandrovska University Hospital, Clinic of Endocrinology, Sofia, Bulgaria; 2Medical University Sofia, St Ivan Rilski University Hospital, Laboratory of Clinical Immunology, Sofia, Bulgaria; 3Military Medical Academy, Department of Clinical Laboratory and Immunology, Sofia, Bulgaria; 2Medical University Sofia, Alexandrovska University Hospital, Central Clinical Laboratory, Sofia, Bulgaria.

Background
Chronic low-grade inflammation is a major factor in the pathogenesis of type 2 diabetes. One way for promoting inflammatory cytokines secretion is through activation of toll-like receptors (TLR). Their overexpression on monocytes has been demonstrated in insulin resistance and type 2 diabetes. Soluble forms of toll-like receptors (sTLR) are considered a regulatory mechanisms of their activation. Their role has been described in modulation of bacteria-induced infective diseases but has not been analysed in diabetes. The aim of the study was to evaluate the place of sTLR2 in type 2 diabetes and compare it with monocyte expression.

Subjects and methods
We performed a cross-sectional study that included 63 patients with type 2 diabetes and 25 controls. All were assayed for soluble forms of TLR2 through Enzyme-Linked Immunosorbent Assay. We evaluated monocyte expression of TLR2 in 28 diabetic patients and 14 control subjects through direct Immunofluorescence with conjugated monoclonal antibodies. All participants were assessed for interleukin 6 (IL-6) through Electro-Chemiluminescent Immunoassay and high sensitivity C-reactive protein (hs-CRP) through Particle Enhanced Immunoturbidimetric Assay.

Results
TLR2 expression in patients with type 2 diabetes was higher compared to controls (89.85 ± 9.66% vs. 50.20 ± 36.91% for CD14+ + CD16+ monocytes, P = 0.003 and 34.54 ± 12.38% vs. 17.12 ± 15.39%, P = 0.011 for CD14+ + CD16+ monocytes) but sTLR2 was significantly lower in diabetic subjects (1.15 ± 0.65 ng/ml vs 1.44 ± 0.60 ng/ml, P = 0.019). Inflammatory status between groups was confirmed significantly different concerning hs-CRP (2.79 ± 2.89 mg/l vs. 0.70 ± 0.89 mg/l, P = 0.000) and IL6 (2.65 ± 2.46 ng/ml vs 1.44 ± 0.22 ng/ml, P = 0.005) with higher values in diabetic group, although correlations with TLR2 expression were not established (P > 0.05).

Conclusion
Type 2 diabetes-associated chronic inflammatory state is characterised by elevated monocyte expression of TLR2 but decreased serum sTLR2 level. This poses the question about presence of an impaired immunomodulation of TLRs’ activation in diabetes.

Diabetes & complications 2

Vitamin D metabolites and IL1β RS16944 polymorphism in type 2 diabetes patients: evidence for functional interaction

Nojan Nejatian, Marissa Pena-Martinez & Klaus Badenhoop
Division of Endocrinology, Diabetes and Metabolism, University Hospital Frankfurt, Frankfurt am Main, Hessen, Germany.

We investigated the SNP rs16944 in German type 2 diabetes (T2D) patients and healthy controls (HC) and correlated the findings with concentrations ofVD metabolites.

Methods
504 T2D patients and 447 HC were genotyped by a Taqman assay. Additionally 25(OH)D3 and 1,25(OH)2D3 plasma levels of 76 T2D patients and 267 HC were measured by radioimmunoassay.

Results
The AA genotype was significantly less frequent in T2D compared to HC whereas GG and AG genotypes were more frequent in T2D (AA: 48.5 vs 37.95%; AG 40.4 vs 49.7%; GG: 11.4 ± 12.4%; P = 0.003). Furthermore the allele A was less frequent (63.6 vs 62.7% OR = 0.77; 95% CI: 0.64-0.93) and allele G more frequent (31.4 vs 37.3% OR = 1.3 95% CI: 1.07-1.57, P = 0.006) in T2D patients compared to HC. Both T2D patients and HC with IL1β genotypes AA and AG did not differ for the VD metabolites. However T2D patients with the GG genotype showed significantly lower levels of 25(OH)D3 (median 34.95 vs 13.7 ng/ml

Antidiabetic medication use and the risk of fracture in type 2 diabetic patients: a nested case-control study

Eladio Losada1, Berta Soldevilla2,3, M. Sanni Ali4, Daniel Martinez-Laguna2, Xavier Nogué6,7, Adolfo Diez-Perez8, Manel Puig-Domingo3,5, Didac Mauricio17 & Daniel Prieto-Alhambra2,3
1Section of Endocrinology, Hospital Can Misses, Ibiza, Spain; 2Department of Endocrinology and Nutrition, University Hospital & Health Sciences Research Institute “Germans Trias i Pujol”, Badalona, Spain; 3CIBER of Diabetes and Associated Metabolic Diseases (CIBERDEM). Carlos III Institute of Health, Madrid, Spain; 4Oxford NIHR Musculoskeletal Biomedical Research Unit. Nuffield Department of Orthopaedics. Rheumatology and Musculoskeletal Sciences. University of Oxford., Oxford, UK; 5GREMPAL Research Group. IDIAP Jordi Gol Primary Care Research Institute. Autonomous University of Barcelona, Barcelona, Spain; 6Internal Medicine Department. IMIM (Hospital del Mar Research Institute). Autonomous University of Barcelona, Barcelona, Spain; 7Cooperative Research Network on Aging and Fragility (Spanish acronym: RETICEF). Carlos III Institute of Health, Madrid, Spain.

Background
Patients with type 2 diabetes mellitus (T2DM) have an increased risk of fragility fractures. Anti-diabetic oral agents and insulin may also impact on fracture risk. There is however scarce data available on the effect of such therapies combined as usually prescribed in real-life practice conditions.

Objectives
The objective of this study was to compare the risk of fracture among T2DM patients who are users of different antidiabetic treatments.

Methods
A nested case-control study was conducted using incident T2DM patients registered in computerised primary care records in the Sistema d’Informació per al Desenvolupament de la Investigació en Atenció Primària (SIDIAP) between 2006–2012, with follow-up available until end/2013. Each case (incident fractures of the hip, spine, wrist, or proximal humerus in 2006–2013) was risk-set matched with five controls of the same gender, calendar year of T2DM diagnosis and age at index date (± 10 years). Study exposure included metformin mono-therapy (reference category) and other antidiabetic medications (alone or in combination as prescribed in actual practice) in the 180 days before the index date. Conditional logistic regression analysis was used to estimate odds ratios and 95% confidence interval adjusting for the following confounders: age, gender, HbA1c level, body mass index, history of fracture, co-morbidities, and concomitant medication use.

Results
Data on 12,277 T2DM patients (2,049 cases and 10,2280 controls) was analysed. Insulin use was associated with increased fracture risk (adj OR 1.63 [95%CI 1.30–2.04]), as was the combination of metformin + sulphonylureas (adj OR 1.29 [1.07–1.56]). No significant association was found with other antidiabetic medications and/or combinations.

Discussion
Insulin and sulphonylureas appear to be associated with an increased fracture risk when compared to metformin amongst recently diagnosed T2DM patients. Residual confounding cannot be ruled out, and more studies are needed to confirm these findings. Given their impact, risk of fracture should be taken into account in the management of T2DM patients.

Increased incidence of diabetes mellitus 30 years after the radiation impact in persons exposed to ionizing radiation during the Chernobyl NPP accident

Oleksii Kaminskyi, Dmitrii Afanasiev, Olga Kopilova, Irina Chikalova, Irina Muravyova, Olena Tepla, Oleksii Pronin, Irina Kiselova, Natalia Dombrovsk&á & Dimitrii Bazyla

National Research Center for Radiation Medicine of NAMS of Ukraine, Kiev, Ukraine.

Several million people in Ukraine and other countries had been exposed to ionizing radiation during the Chernobyl nuclear power plant accident (ChNPPA) on April 26, 1986. The ChNPPA clean-up personnel involved in emergency and recovery works in the 30-kilometer exclusion zone of power plant in the nearest days or months and/or for a long time had received the highest radiation doses due to external gamma-exposure and from incorporated radioactive isotopes with high affinity to endocrine organs, including the thyroid, pancreas, and cerebral endocrine structures. Consequently a dramatic elevation in non-cancer endocrine morbidity emerged due to thyroid disease, pre-diabetes, diabetes mellitus, and obesity. Despite pancreas was previously considered resistant to ionizing radiation the recent research however suggests high sensitivity of endocrine cells, particularly pancreatic beta cells to radiation exposure. It just explains a high prevalence of diabetes mellitus (up to 23%) in the ChNPPA survivors, whilst the respective value for population of Ukraine is much lower, i.e. from 3 to 7% depending on data source. According to retrospective review of endocrine system data from the ChNPPA clean-up workers (n=13,158) the prevalence of pre-diabetes and diabetes mellitus had increased dramatically 10 years upon the accident and continues to increase 30 years later. Now it is in average ~16% and ~12% respectively. At that not only a radiation dose but also the duration of moderately intensive gamma-exposure, namely 0.082 ± 0.01 Gy, is critical for the onset of type 2 diabetes mellitus. Persons involved in recovery operations for more than 4-6 months are of concern here. Survey results in the ChNPPA emergency workers demonstrate an increased incidence of latent autoimmune diabetes in adults (LADA).

Baicalin lowers glucose intolerance by controlling pancreatic hormone in high fat-induced obese diabetic rats

Kahui Park, Jung Hye Kim, Sang Bae Lee, Jong Hye You, Yusik Kim, Ji sun Nam, Jong Suk Park & Chul Woo Ahn

Gangnam Severance Hospital, Seoul, Republic of Korea.

Objective

Baicalin was known as an allosteric modulator of the benzodiazepine sites of the γ-aminobutyric acid A receptor (GABA<sub>A</sub>R), which produce anxiolytic effects in mice without myorelaxant or sedative effects. Baicalin occur flavonoid found in naturally in the genus Scutellaria. It has been recently shown to exert metabolic effects by attenuating hyperglycemia-induced mitochondrial damage in β-cells in diabetic rats, high-fat diet (HFD)- induced body weight gain, and lipid deposits in the liver and systemic inflammation in mice. This study investigated the effects of baicalin on islet functions and diabetic status in HFD-induced obese diabetic mice.

Methods

C57BL/6 mice were grouped into normal control, HF control, HF sham, and 4 different baicalin dose-administered groups (25, 50, 100, and 150 mg/kg). HFD containing 60% fat and water were fed ad libitum for 24 weeks. Designated doses of baicalin or 0.9% saline were administered intraperitoneally 5d/wk. Body weight (BW) and conventional glucose homeostasis parameters (FPG, FPI, AUC-glucose, AUC-insulin, and etc.) were monitored; in addition, ex vivo glucose-stimulated insulin secretion (GSIS) and glucagon secretion (GSGS) with isolated islets were performed.

Results

Insulin secretion in response to high glucose stimulation (16.7 mM) was significantly higher in islets isolated from the groups administered 50, 100, 150 mg/kg baicalin compared to HF control; glucagon secretion was significantly suppressed by high glucose stimulation in islets from the same groups.

Conclusion

This study showed that baicalin had positive effects on glycemic control by regulating secretion of insulin and glucagon, possibly through GABA<sub>A</sub>R mediation.

Effect of insulin on neurotrophins' levels in the muscular wall of mice intestine and colon

Mohammad Alqudah, Ayman Mustafa, Mohammad Allouh, Othman Alshboul & Ahmad AlDwairi

Jordan University of Science and Technology, Irbid, Jordan.

Background

Neurotrophins are implicated in the physiology and pathophysiology of the mature gastrointestinal tract (GIT) such as motility and inflammatory bowel disease. Moreover, GIT disturbances has been attributed to hyperinsulimia. Insulin-neurotrophins interactions in the (GIT) have not been investigated yet.

Aim

To test the effect of Insulin on the expression of neurotrophins in the muscular wall of mice intestine and colon.

Methods

Total protein extracts from intestinal and colonic muscular wall treated for 24 hours with insulin were subjected to ELISA assays specific for different neurotrophins and data were analyzed using suitable statistical test with graph pad.

Results

Insulin treatment resulted in significant reduction of neurotrophin-3 (NT-3) protein levels in the muscular wall of both mice intestine and colon. Moreover, neurotrophin-4 (NT-4) levels were significantly reduced in response to insulin treatment in muscular tissue from both intestine and colon as well. Interestingly the effect of insulin was more profound in the colon on NT-3 and NT-4.

Conclusion

These results indicate that changes in GIT structure and function seen in hyperinsulimia might be due to the effect of insulin on neurotrophins expression levels. However, functional studies are needed to elucidate the exact interactions between insulin and neurotrophins in the GIT.

Clinical assessment of trabecular bone microstructure in type 2 diabetes mellitus with Trabecular Bone Score (TBS)

María Dolores Avilés Pérez, Antonia García Martín, Cristina Novo Rodríguez, Rafael Nieto Serrano, Elena Torres Vela & Manuel Muñoz Torres

Hospital Campus de la Salud, Granada, Spain.

Introduction

Type 2 diabetes mellitus (T2DM) is a risk factor for osteoporotic fractures although bone mineral density is increased. As such, there is a need for improved approaches to estimate fracture risk in such individuals. The Trabecular Bone Score (TBS) is a new technique to determine the trabecular bone micro-architecture.

Objective

Our aim was to evaluate the usefulness of TBS in T2DM patients.

Methods

We compared TBS values in T2DM group (n: 31) and control group (n: 25) and we analyzed its relationship with bone mineral density (BMD), history of prior fractures and glycemic control. BMD was evaluated by conventional bone densitometry (DXA) and 3D (3D-DXA). TBS values were determined using TBS InSight® software.
Results
T2DM patients had lower TBS than controls \((1.14 \pm 0.17\) vs \(1.25 \pm 0.16, P = 0.013\). However, there were no differences in the densitometric or volumetric parameters measured by conventional DXA and 3D-DXA. In T2DM group, TBS at the lumbar spine showed degraded microarchitecture \((TBS \leq 1.2)\) in 16 patients \((51.6\%); 13\) patients \((41.9\%\) had partially degraded structure \((TBS \leq 2.5\) s.d.) or history of prior fracture in either group. We found a significant correlation of TBS with age, body mass index and lumbar spine BMN both in diabetic patients and controls \((P < 0.05)\). Finally, we did not observe relationship with glycemic control or duration of diabetes in T2DM group.

Conclusion
TBS is shown as a promising method in the clinical assessment of trabecular bone microstructure in T2DM.

The G allele of the BDKRB1 rs12050217 polymorphism is associated with protection for diabetic retinopathy
Leticia A. Brondani1, Julia Pisco1, Jorge A. Guimarães1,2, Daisy Crispim1,2, & Markus Berger1
1Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; 2Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Background
Diabetic retinopathy (DR) is a chronic diabetic complication occurring in most diabetic patients after 20 years of disease progression. Development of DR to its sight threatening stages is usually associated with worsening of underlying retinal vascular dysfunction and disease. The plasma kallikrein kinin system is activated during vascular injury, mediating important functions in inflammation, blood flow, and coagulation. Bradykinin B1 receptor (B1R) is expressed in human retina, and retinal B1R levels are increased in murine models of diabetes. Furthermore, experimental studies reveal that B1R antagonists ameliorate retinal functional abnormalities caused by diabetes in rodents. Thus, B1R gene (BDKRB1) is a candidate gene for DR.

Objective
To investigate the association between rs12050217G polymorphism in the BDKRB1 gene and DR in patients with type 2 diabetes mellitus (T2DM).

Methods
We analyzed 1129 T2DM patients and 416 non-diabetic subjects. T2DM patients were categorized by the presence of non-proliferative DR (NPDR, \(n = 476\)), proliferative DR (PDR, \(n = 275\)) and absence of DR \((n = 200)\). The local ethic committee approved the study, and all subjects signed a consent form. The genotype frequencies of the BDKRB1 rs12050217G polymorphism was genotyped by Real-Time PCR using TaqMan MGB probes.

Results
The genotype frequencies of the BDKRB1 rs12050217G polymorphism are in Hardy-Weinberg equilibrium, and did not differ between T2DM patients and normoglycemic subjects \((P > 0.05)\). The presence of the minor G allele of the rs12050217 polymorphism was less frequent mainly in patients with PDR when compared to patients with NPDR and without DR \((31.5, 41.8\) and 41.2\%, \(P = 0.034\); respectively). Interestingly, we observed that the presence of the G allele was associated with protection for PDR, which was confirmed after correction for the presence of hypertension, ethnicity, diabetes duration and age \((95\% CI 0.580 (0.398–0.843); \(P = 0.0044)\).

Conclusions
The BDKRB1 rs12050217 G allele is associated with protection for the advanced stage of DR in T2DM patients.

Dipeptidyl peptidase-4 inhibitor therapy and risk of diabetic retinopathy: a population based study
Nam Hoon Kim1, Hye Suk Kim2, Hye Jin Yoo1, Ji A Seo1, Nan Hee Kim1, Kyung Mook Choi1, Sei Hyun Baik1, Junyeong Lee1, Jung Hyun Nohl1 & Goon Kim1
1Korea University College of Medicine, Seoul, Republic of Korea; 2Anyang SAM Hospital, Anyang, Republic of Korea; 3Inje University College of Medicine, Ilsan, Republic of Korea.

Background
Given the possible association between dipeptidyl peptidase-4 (DPP-4) inhibitor and risk of diabetic retinopathy (DR), we examined whether DPP-4 inhibitors are beneficial or harmful for DR compared with other glucose-lowering agents. Methods From a Korean population-based cohort, we identified 67,743 adults with type 2 diabetes treated with oral glucose-lowering agents between 2008 and 2013. Matching (1:1) was done for comparative groups: ever-used (case) and never-used (control) DPP-4 inhibitors \((n = 14,522\) each group). Cox regression analyses assessed the risk of DR events: vitreous hemorrhage, vitrectomy or photocoagulation, intravitreal agent use, and blindness.

Results
During a median follow-up of 28-4 (14.0–45.2) months, there were 305 (control group) and 342 (case group) composite DR events, respectively. Use of DPP-4 inhibitors was not associated with overall risk of composite DR events \((adjusted hazard ratio [HR] 1.08, 95\% CI 0.93–1.26)\). Each DR events including vitreous hemorrhage, vitrectomy or photocoagulation, use of intravitreal agents, and blindness were also not increased with DPP-4 inhibitor therapy. The results were consistent according to baseline retinopathy. However, in the analyses by duration of treatment, a DPP-4 inhibitor treatment duration of <12 months was associated with increased risk of composite DR events \((adjusted HR 1.95, 95\% CI 1.61–2.36)\).

Conclusion
DPP-4 inhibitor treatment did not increase the overall risk of DR compared with other oral glucose-lowering agents. Given that short-term DPP-4 inhibitor use was associated with increased risk of DR, the need to assess the aggravation of retinopathy in the early phase of DPP-4 inhibitor use is warranted.

Non-genetic rat model of nephropathy in type 2 diabetes with attenuated streptozotocin-induced tubular alteration
Valentina Bayrachev1,2, Alina Babenko1,2, Ivan Pehelin1,2, Anna Arefjeva1,2, Svetlana Chefu1,2, Ivan Shatalov3, Yuriy Dmitriev4, Alexandra Ivanova1,2, Pavel Andoskin1, Parvis Aliiev1 & Elena Grineva1,2
1Federal Almazov North-West Medical Research Centre, Saint Petersburg, Russia; 2Pavlov First Saint Petersburg State Medical University, Saint Petersburg, Russia; 3Saint Petersburg State University, Saint Petersburg, Russia; 4Saint Petersburg National Research University of Information, Technologies, Mechanics and Optics, Saint Petersburg, Russia; 5Komarov Botanical Institute of the Russian Academy of Sciences, Saint Petersburg, Russia.

Non-genetic animal models of diabetic nephropathy (DN) are most commonly reproduced by using streptozotocin (STZ) which preferentially gets into β-cells via GLUT2 transporters. However, STZ administration results in nephrotic effects as well, due to expression of GLUT2 by renal tubular epithelial cells. We hypothesized that nicotinamide (NA), which is considered to attenuate the severity of STZ-induced β-cell damage, could also prevent tubular alteration. Starting at 3 weeks after unilateral nephrectomy, thirty adult male Wistar rats were fed the high-fat diet for 5 weeks and then successively received either NA \((230 \text{ mg/kg})\) and STZ \((65 \text{ mg/kg}, \text{NA-STZ-group})\) or STZ in a low dose \((40 \text{ mg/kg, LD-STZ-group})\) intraperitoneally in 15-min interval. Control nondiabetic uninephrectomized rats received vehicle and were fed normal chow \((\text{C-group})\). At weeks 10, 20, and 30 (the end of the study), metabolic parameters, creatinine clearance, albuminuria, and urinary tubular injury markers (NGAL, KIM-1) were evaluated as well as renal ultrastructural and light microscopic changes at weeks 20 and 30. NA-STZ group showed higher increase in insulin resistance (HOMA-IR 3.2 ± 0.39 vs 1.93 ± 0.29), and
dyslipidemia (total cholesterol 2.89 ± 0.25 mmol/l vs 1.55 ± 0.35; triglycerides 1.05 ± 0.18 mmol/l vs 0.57 ± 0.1), P < 0.05 each, that were observed until the end of the study. At 20 weeks, development of early stage of DN was confirmed by glomerular basement membrane thickness, gradual decline in creatinine clearance, and mild albuminuric status (478.4 ± 63.3 μg/24 h vs 35.8 ± 3.6 μg/24 h), with progression by week 30, when light microscopic features of DN were observed. Morphofunctional renal changes in NA-STZ appeared to be more pronounced than those in LD-STZ despite lower levels of KIM-1 and NGAL (2535.8 ± 303.9 ng/24 h (LD-STZ) at week 30) vs 1704.2 ± 444.7 ng/24 h in NA-STZ, P = 0.037. We have described a model of type 2 diabetes and DN with attenuated STZ-induced tubular alteration in rats that is characterized by relatively early stages of human DN.

**microRNA expression profile in plasma from patients with diabetic kidney disease**

Tais Silveira Assmann1,2, Marcia Punales3, Baldhuino Tschiedel4, Luis Henrique Canani1,2, Andrea Carla Bauel1,2 & Daisy Crispim1,2

1Hospital de Clínicas de Porto Alegre, Porto Alegre, Rio Grande do Sul, Brazil; 2Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; 3Instituto da Criança com Diabetes, Porto Alegre, Brazil.

**Introduction**

Diabetic kidney disease (DKD) is the major cause of end-stage renal disease; however, the pathogenesis of this disease is not fully understood. Currently available therapies are not totally efficacious in the treatment and prognosis of DKD, suggesting that further understanding of the molecular mechanisms underlying the pathogenesis of this disease is necessary to improve its management. Recently, research on microRNAs (miRNAs) has become a hotspot because of their critical role in regulating posttranscriptional levels of protein-coding genes. Several miRNAs were found to participate in DKD pathogenesis; nevertheless, results are still conclusive. Therefore, the identification of miRNAs involved in DKD may help in the diagnosis and treatment of this disease.

**Objective**

To identify a miRNA expression profile associated with DKD in plasma from patients with type 1 diabetes mellitus (T1DM) with different degrees of this diabetic complication.

**Design**

Expression of 48 miRNAs were investigated in the plasma from 46 T1DM patients: 24 patients in group 1 [patients with T1DM for more than 10 years, with urinary excretion of albumin (UEA) < 30mg/g and estimated glomerular filtration rate (eGFR) ≥ 60 ml/min/1.73 m²] and 11 in group 2 (patients with T1DM with UEA 30–300mg/g or eGFR 45–59 ml/min/1.73 m²) and 11 in group 3 (patients with T1DM with UEA ≥ 300 mg/g or eGFR 15–29 ml/min/1.73 m²), using Stemloop RT-PreAmp Real-time PCR and TaqMan Low Density Array cards (Thermo Scientific Inc).

**Results**

Eighteen miRNAs were differently expressed between T1DM patients without DKD (controls) and T1DM patients with different levels of DKD (cases). Seventeen miRNAs were downregulated (miR-126, miR-146a, miR-155, miR-192, miR-200a, miR-200b, miR-204, miR-216a, let-7b, miR-29c, miR-200a, miR-208, miR-216a, miR-25, miR-320, miR-92a and miR-638) and one miRNA was upregulated (miR-124) in cases compared to controls. In addition, miRNAs let-7b, miR-155, miR-200a, miR-208, miR-216a, miR-25, miR-320, miR-92a were downregulated in T1DM patients with severe DKD (group 3) compared to controls.

**Conclusion**

Our preliminary results show that some circulating miRNAs are differentially expressed between T1DM patients with and without DKD.

The A allele of the -866G/A polymorphism in UCP2 gene decreases high glucose-induced UCP2 expression in HUVECs

Tais Assmann1,2, Daisy Crispim1,2, Michella Rodrigues2, Liana Silva2, Ana Paula Bouças1,2, Rodrigo Carlessi2, Leticia Brondani2, Luis Henrique Canani1,2 & Bianca Souza1,2

1Postgraduate Program in Medical Sciences: Endocrinology, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil; 2Endocrine Division, Hospital de Clínicas de Porto Alegre, Porto Alegre, Rio Grande do Sul, Brazil.

Uncoupling protein 2 (UCP2) is a mitochondrial protein located in the mitochondrial inner membrane, and it uncouples substrate oxidation from ATP synthesis, thereby dissipating the membrane potential energy and consequently decreasing reactive oxygen species (ROS) formation by mitochondrial respiratory chain. ROS overproduction is related to diabetic retinopathy (DR), a chronic complication of diabetes mellitus (DM). Recently, our group reported that the -866A/55Val/Ins haplotype (-866GA, Ala55Val and Ins/Del polymorphisms) of the UCP2 was associated with risk for proliferative DR in both type 1 and type 2 diabetic patients. Additionally, this haplotype influenced UCP2 expression in human retina samples. Indeed, some studies suggest that the -866G/A polymorphism directly affect UCP2 expression; however, its effect on endothelial cells under different glucose concentrations is not well defined.

**Objective**

To investigate the effect of -866G/A polymorphism on UCP2 expression in an endothelial cell line under different glucose concentrations.

**Methods**

HUVECs cells were transfected with pGL3 plasmids containing the promoter region of UCP2 gene and the coding sequence of firefly luciferase, using LTX Lipofectamine (Life Technologies). The test conditions were: 1) transfection with the wild-type allele-containing plasmid (pGL3-UCP2-G); and 2) transfection with the mutated allele (pGL3-UCP2-A), under conditions of normoglycemia (4 mM) or hyperglycemia (25 mM) after 24 h and 48 h. Plasmid pCMV encoding renin luciferase and pEGFP were co-transfected as internal control and transfection control, respectively. Luciferase levels were measured with Luminescent Dual-luciferase Assay (Promega).

**Results**

HUVECs cells transfected for 24 h and 48 h with the plasmid containing the -866A allele under normal glucose conditions had 47% and 37% decrease in UCP2 expression than cells transfected with the plasmid containing the G allele (P = 0.011 and P = 0.0001, n = 3). Interestingly, under high glucose conditions, cells containing the A allele had a more drastic decrease in UCP2 expression (70% and 54%) compared to cells with the G allele (P = 0.0001 and P = 0.028; n = 3) after 24 and 48 h.

**Conclusion**

Our preliminary results demonstrate that the UCP2 -866A allele decreases UCP2 expression in HUVEC cells, which is exacerbated under high glucose conditions. The -866G/A polymorphism of the UCP2 gene is associated with increased UCP2 protein concentrations in human retina, which may explain the previous reported association between -866A/55Val/Ins haplotype and risk for DR.

The relation between PON-1 activity and 25-OH hydroxyvitamin D3 levels and other biochemical parameters in diabetic patients with respect to obesity and diabetic complications

Pinar Karakaş1, Meral Mert1, Hamide Karagöz2 & Bahar Ozdemir2

1Bakırköy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Turkey; 2Department of Internal Medicine, Bakırköy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Turkey.

**Objective**

To evaluate the relation of mean platelet volume (MPV) levels with serum paraoxonase-1 activity in diabetic patients with respect to obesity and diabetic complications.

**Methods**

A total of 201 diabetic patients grouped with respect to obesity (n = 89) and non-obese (n = 112) and diabetic complications with (n = 50) or without (n = 150) microvascular complications and with (n = 91) or without (n = 108) macrovascular complications groups were included. Data on demographic and lifestyle characteristics of patients, anthropometric measurements, diabetes related microvascular and macrovascular complications, Correlation of MPV values to paraoxonase and arylesterase activities.

**DOl**: 10.1530/endoabs.49.GP95

---
Results
Mean(SD) paraoxonase and arylesterase values were 119.8±37.5 U/l and 149.0±39.9 U/l respectively in the overall population, with no significant difference with respect to obesity and macrovascular diabetic complications, whereas significantly lower values for paraoxonase 107.5±30.7 vs. 123.9±38.8 U/l, (P = 0.007) and arylesterase 132.1±30.2 vs. 154.4±41.2 U/l (P = 0.001) were noted in patients with than without diabetic microvascular complications. Mean(SD) MPV values were 9.10±0.87 1L in the overall population, with no significant difference with respect to obesity and diabetic complications. No significant correlation of MPV values to paraoxonase and arylesterase activities. A significant positive correlation was determined with plasma 25-(OH) hydroxyvitamin D3 values, r=0.398, P=0.001 and r=0.484, respectively (P=0.001). HOMA-IR exhibited a significant negative correlation with PON and arylesterase in the groups.

Conclusion
In conclusion, our findings revealed a significant decrease I PON-1 activity in diabetic patients with microvascular rather than macrovascular complications, whereas regardless of obesity and diabetic complications, no increase in thrombogenic activity and no relation of thrombogenic activity with PON-1 activity. PON-1 activity exhibited a significant negative correlation, independent of obesity, sex and age, with plasma glucose, HBAlc and HOMA-IR values in all patients and a significant positive correlation with 25-OH vitamin D3 values. Low PON-1 activity and 25 OH vitamin D3 levels may be a marker of inadequate glycemic control independent of obesity in diabetic patients. They may play an important role for early atherosclerosis who had only in obese diabetic especially with Type 2 diabetes.

Methods
A total of 1360 patients with type 2 diabetes mellitus involved in an epidemiological study received an examination of CPT measured by Neumometer® CPT/C (Neurotron, Inc., Baltimore, Maryland, USA) on a supine position. The measurement was taken for three frequencies, i.e. 5, 250 and 2000 Hz at three sites; the preauricular area (trigeminal nerve), the index finger (median nerve) and the great toe (superficial peroneal nerve) on both sides. The three frequencies measure small unmyelinated C fiber (5 Hz), small myelinated Aβ fiber (250 Hz), and large myelinated Aδ fiber (2000 Hz), respectively. The normative data from 75 normal individuals were used as control and an “abnormal CPT” was defined as a value greater than the normal mean plus 3 standard deviations derived from the normal individuals. Age, sex, body height and body weight were treated as potential confounders. Student’s t test, Chi-square test, correlation coefficient and stepwise regression were used for statistical analyses and a P value <0.05 was considered as statistically significant.

Results
Accept for a significantly older age in the diabetes group, the distribution of sex, body height and body weight were not different significantly. CPT measurements on the right and left sides correlated significantly with correlation coefficients mostly > 0.7 (P < 0.0001) in the diabetes patients. The trigeminal nerve had the most commonly reported “abnormal CPT” that involved approximately 60% of the diabetes patients, followed by the superficial peroneal nerve (50%) and the median nerve. The median nerve showed frequency-dependent abnormality with higher proportion of “abnormal CPT” involving lower frequency. For the frequency of 2000, 250 and 5 Hz, “abnormal CPT” was observed in 15~20, 30~33 and 56~99%, respectively. In stepwise regression analyses, diabetes and age were consistently predictive for CPT.

Conclusions
Patient with type 2 diabetes mellitus have higher CPT values than normal individuals in all anatomical sites. The application of Neumometer® for screening of diabetes neuropathy awaits further confirmation.

Gestational diabetes mellitus: the new screening criteria and its outcomes
Pedro Gouveia, Maritza Sá, Eduarda Resende, Margarida Ferreira & Silvestre Abreu
Centro Hospitalar do Funchal, Funchal, Portugal.

Background
Gestational Diabetes Mellitus (GDM) is one of the most common illness of pregnancy. Despite its frequency, there’s no worldwide accepted screening criteria for GDM. In 2011, Carpenter and Coustan (CC) screening (50-g glucose challenge test (GCT) followed by 100-g glucose tolerance test (OGTT) if GCT screen was positive) was abandoned and began the implementation of the screening of the International Association of Diabetes and Pregnancy Study Group (IADPSG) 2010 (75-g OGTT).

Aims
Asses and compare perinatal outcomes of these two screening criteria.

Materials and methods
We undertook a retrospective study, of gestational diabetes followed on Endocrinology department. Two groups were constituted: CC (followed in 2009 and 2010) and IADPSG (followed in 2014 and 2015). All patients were treated with nutrition and exercise. When target glucose levels were not met, insulin was initiated, no oral antidiabetic agents were used. Analysed data included birthweight, prematurity delivery, macrosomia, mode of delivery, maternal parity, body mass index (BMI) and insulin treatment.

Results
In 2009 and 2010, of 4705 childbirths in the hospital, 259 (5.5%) women met the CC criteria, of which 134 were included in this study. In 2014 and 2015, of 3496 childbirths in the hospital, 348 (9.9%) women met the IADPSG criteria, of which 221 were included in this study. Those with GDM per IADPSG criteria had more

Comparison of current perception threshold measured by Neurometer in patients with type 2 diabetes mellitus to a group of normal individuals
Chin-Hsiao Tseng1
1National Taiwan University College of Medicine, Taipei, Taiwan;
2National Taiwan University Hospital, Taipei, Taiwan.

Purpose
To determine the proportion of abnormal current perception threshold (CPT) in patients with type 2 diabetes mellitus.

Methods
A total of 1360 patients with type 2 diabetes mellitus involved in an epidemiological study received an examination of CPT measured by Neumometer® CPT/C (Neurotron, Inc., Baltimore, Maryland, USA) on a supine position. The measurement was taken for three frequencies, i.e. 5, 250 and 2000 Hz at three sites; the preauricular area (trigeminal nerve), the index finger (median nerve) and the great toe (superficial peroneal nerve) on both sides. The three frequencies measure small unmyelinated C fiber (5 Hz), small myelinated Aβ fiber (250 Hz), and large myelinated Aδ fiber (2000 Hz), respectively. The normative data from 75 normal individuals were used as control and an “abnormal CPT” was defined as a value greater than the normal mean plus 3 standard deviations derived from the normal individuals. Age, sex, body height and body weight were treated as potential confounders. Student’s t test, Chi-square test, correlation coefficient and stepwise regression were used for statistical analyses and a P value <0.05 was considered as statistically significant.

Results
Accept for a significantly older age in the diabetes group, the distribution of sex, body height and body weight were not different significantly. CPT measurements on the right and left sides correlated significantly with correlation coefficients mostly > 0.7 (P < 0.0001) in the diabetes patients. The trigeminal nerve had the most commonly reported “abnormal CPT” that involved approximately 60% of the diabetes patients, followed by the superficial peroneal nerve (50%) and the median nerve. The median nerve showed frequency-dependent abnormality with higher proportion of “abnormal CPT” involving lower frequency. For the frequency of 2000, 250 and 5 Hz, “abnormal CPT” was observed in 15~20, 30~33 and 56~99%, respectively. In stepwise regression analyses, diabetes and age were consistently predictive for CPT.

Conclusions
Patient with type 2 diabetes mellitus have higher CPT values than normal individuals in all anatomical sites. The application of Neumometer® for screening of diabetes neuropathy awaits further confirmation.

High prevalence of lower extremity peripheral artery disease in type 2 diabetes patients with diabetic nephropathy and the role of netrin-1 levels
Ahmet Kor, Suleyman Baldane, Suleyman Hilmi Ipekci, Kamile Marakoglu, Ali Altinok, Ali Uulu, Fatih Colkesen, Bahadur Ozturk, Cem Omur Kirac & Levent Kebapcilar
Selcuk University, konya, Turkey.

Background
Netrin-1 is an early biomarker of acute kidney injury. Besides, recent studies have showed that netrin-1 promotes angiogenesis; but its usefulness for peripheral artery disease (PAD) in type 2 diabetes patients is unknown. This study aimed at investigating whether netrin-1 levels are increased in peripheral artery disease among patients with type 2 diabetes and also investigating possible associations between diabetic nephropathy (DN) and PAD.

Material and Methods
This was a cross-sectional observational clinical study. This study involved a total of 84 adults with type 2 DM, who underwent ABI (low ankle-brachial index) measurement in an outpatient clinic. PAD was defined as ABI < 0.9 in either leg. ABI of 42 patients with PAD were compared with 42 non-PAD patients. Diabetic nephropathy was evaluated by estimated glomerular filtration rate and urinary albumin-creatine ratio (ACR).

Results
Compared with control group, the levels of Netrin-1 levels and diabetic nephropathy subjects were significantly increased in the PAD group. As regards similar GFR values, patients with higher urinary albumin-creatinine ratio (ACR) values had significantly lower ABI parameters than the patients without albuminuria. (Right: 0.96 ± 0.1 vs. 1.05 ± 0.01, Left: 0.94 ± 0.1 vs. 1.04 ± 0.01, P < 0.01) Binary logistic regression analysis revealed that diabetic nephropathy (vs non-DN) was associated with PAD (OR = 2.94, 95% CI: 1.2-7.1; P = 0.017).

In multivariate models, adjusted additionally for the mean duration of diabetes, gender, BMI, HBAlc, hyperlipidemia and hypertension, the associations with netrin-1 and PAD persisted (beta: 0.238, P = 0.042).

Conclusion
Our study in patients with type 2 DM demonstrated that PAD was associated with diabetic nephropathy and netrin-1 levels. In conclusion, changes in netrin-1 levels are likely to be used as a biomarker for monitoring the risk of PAD in patients with Type 2 diabetes.

DOI: 10.1530/endoabs.49.GP96
Results
Fifteen articles fulfilled the inclusion criteria and passed the quality control evaluation. In most studies, hearing loss (HL) was defined as pure tone greater than 25 dB in the worse ear of at least one frequency. The incidence of HL ranged between 0 and 48% for diabetics, which was higher than in controls (OR=12.43 95% CI 3.09–49.95). The tendency of mean PTA (pure tone audiometry) thresholds were higher in diabetics than in controls for higher frequencies, however the results were not significant. Auditory brainstem response (ABR) latencies were longer in diabetic patients compared to controls. Statistical significance was obtained in wave III and V (Z = 3.18, P = 0.001 I2 = 82%; Z = 2.55, P = 0.001 I2 = 89% respectively).

Conclusions
Patients with type 1 diabetes have a significantly greater incidence of HL compared to the control group. However, hearing thresholds seems to be not significantly different from control subjects. Mean PTA thresholds were greater at 6000 and 8000 Hz. Despite a trend of higher threshold difference at higher frequencies tested, the mean differences between groups at any frequency were not statistically significant. A significant prolonged ABR of waves III and V latencies in the diabetic group suggest a retro-cochlear involvement in hearing damage in type 1 diabetes.

Comparison of the effects of combinations of different antihypertensive therapies on microalbuminuria and renal functions in type 2 diabetic patients

Muge Erek1, Alparslan Ersoy1 & Canan Ersoy2
1Uludag University Medical Faculty, Department of Nephrology, Bursa, Turkey; 2Uludag University Medical Faculty, Department of Endocrinology and Metabolism, Bursa, Turkey.

Renin angiotensin system blockers are currently used in the treatment of diabetic nephropathy. Carvedilol, 3. generation beta-blockers, may provide additional benefits in diabetic patients. Its antiproteinuric activity is not investigated in patients with diabetic nephropathy. We try to compare short-term additive effects of losartan with cilazapril or carvedilol combination on blood pressure, proteinuria and renal functions in microalbuminuric patients with type 2 diabetes mellitus and hypertension.

Methods
Thirty patients with type 2 diabetes, stage 1 hypertension and albuminuria of 30–300 mg/day, were enrolled in the study. After the 2 week follow-up period, all patients were started on losartan 50 mg/day for 6 weeks. Then, they were randomized to three groups for 6 weeks: 1st group (n:10) on losartan 100 mg/day, 2nd group (n:10) on carvedilol 25 mg/day + losartan 50 mg/day and 3rd group (n:10) on cilazapril 5 mg/day + losartan 50 mg/day treatment.

Results
Characteristics of groups were similar. In all groups, systolic and diastolic blood pressures (BP) were significantly decreased. Greatest decrease in systolic (16.5 ± 7.4 mmHg) and diastolic (10.5 ± 2.8 mmHg) BPs were seen in group 3 and smallest decreases were seen in group 1 (systolic BP: 9 ± 6.1 mmHg, diastolic BP: 3 ± 4.8 mmHg). Microalbuminuria levels in all groups decreased significantly when compared to the period of 50 mg losartan alone (P < 0.05). Renal functions of the groups did not change significantly. But creatinine clearances significantly increased in all groups after the randomization, although there was no significant difference between groups.

Conclusion
We observed that the combination of carvedilol in hypertensive type 2 diabetics patients with microalbuminuria safely controlled blood pressure more effectively without additional benefit in reducing microalbuminuria.

Non-stimulated c-peptide is independently associated with requirement at 1 year for insulin therapy in patients with diabetes: a retrospective cohort study of 872 patients
Emma Leighton1, Karen Smith1, Christopher Samsbury1 & Gregory Jones 1Gartnavel General Hospital, Glasgow, UK; 2Glasgow Royal Infirmary, Glasgow, UK.

Introduction
C-peptide is frequently used in clinical practice to estimate insulin secretion, and guide need for future insulin treatment. Present practice is based on studies with small patient numbers.

Aim
To explore the association between non-stimulated c-peptide and progression to insulin therapy in patients with diabetes.

Patients and Methods
1971 patients with c-peptide measurements were identified (February 2007–December 2016) within a single health board. 940 individuals also appeared on the national diabetes database. 872 individuals within this dataset have a defined diabetes diagnosis and were analysed. The date of first encashed insulin prescription for each individual was extracted from the national diabetes dataset. Insulin-free survival (time to first insulin prescription or end of follow-up) in individuals who were insulin-naive at the time of c-peptide measurement was investigated using survival analysis. Individuals with c-peptide values below median were compared with those above median value. Time to insulin prescription was analysed using cox proportional hazard model with age and BMI as covariables. The positive predictive value (PPV) of c-peptide for predicting insulin use at 1 year was calculated in 0.2 nmol/l increments.

Results
458 individuals had BMI data available, and were insulin-naive at the time of c-peptide measurement. In this cohort a c-peptide in the lower half of the range of observed values (<0.76 nmol/l) is associated with a significantly decreased insulin-free survival time (P<0.001, HR 3.0). PPV for initial c-peptide(nmol/l) increments were: c-peptide 0.01-0.2 PPV =0.95, 0.2-0.4 PPV =0.67, 0.4-0.6 PPV =0.6, 0.6-0.8 PPV =0.43, 0.8–1.0 PPV =0.3.

Conclusion
Unstimulated c-peptide is independently associated with increased probability of requiring insulin at 1 year. This is a simple test which offers potentially useful information allowing patients to plan for future treatment.

Ceramide synthase 6 inhibition as a novel therapeutic approach for obesity and type 2 diabetes
Maximilian Bielohuby1, Surya Prakash1, Bodo Brunner1, Anja Pfenninger1, Ulrich Werner1, Sarah Turpin-Nolan2, Jens Brüning2 & Norbert Tengnagels1 1Sanofi-Aventis Deutschland GmbH, R&D Diabetes Division, Industriepark Höchst, Frankfurt am Main, Germany; 2Max Planck Institute for Metabolic Research, Cologne, Germany.

Excess consumption of saturated fatty acids may lead to an increased production of ceramides that contribute to development of insulin resistance and type 2 diabetes. Substantial research demonstrated that inhibition of ceramide biosynthesis ameliorates atherosclerosis, hepatic steatosis, insulin resistance and obesity. However, as ceramides and their sphingolipid products are involved in multiple fundamental cellular processes, concerns exist about possible risks or adverse effects resulting from overall inhibition of sphingolipid synthesis for treatment of chronic diseases. Therefore, the inhibition of specific ceramide species represents a new strategy for pharmaceutical intervention. Recent research demonstrated that specifically CerS6 mediated C16 ceramide synthesis plays a key role in the development of obesity mediated insulin resistance.

In the current study, we investigated the effects of specifically knocking-down CerS6 in ob/ob mice using ASO. In this animal model, CerS6 expression is significantly higher vs. lean control mice (~2 fold in the liver and BAT) which correlates with a 4-fold increase of C16 ceramide in the plasma and a 2-fold increase in the liver. CerS6 ASO treatment led to selective and significant ~80% knockdown of the CerS6 expression in the liver and correlated with a significant 50% reduction of C16 ceramide in the liver and plasma compared to control ASO-treated ob/ob mice. CerS6 knockdown protected against body weight gain and was associated with a significant reduction in fat mass and blood glucose levels. Moreover, insulin resistance was significantly improved by ASO treatment as evidenced by oral glucose tolerance and insulin tolerance tests (~50% reduction in AUC during oGTT).

In conclusion, CerS6 dependent C16 ceramide synthesis represents a distinct sphingolipid species, which contributes to the development of obesity and insulin resistance and therefore may represent a unique and attractive novel target to treat obesity and type 2 diabetes.

Outcomes of integrating personal continuous glucose monitors with insulin pumps in a University Diabetes Unit
Ali Rizvi & Kyoka Smith
University of South Carolina School of Medicine, Columbia, SC, USA.

Objective
Personal continuous glucose monitoring (pCGM) with interstitial fluid glucose sensing is rapidly becoming the standard of care for real-time, intensive insulin therapy of diabetes. We report our experience of glycemic control in patients in an academic setting using minimally invasive pCGM with continuous s.c. insulin infusion (CSII, or insulin pump) vs CSII alone.

Methods
Over a two-year period, we reviewed all patients treated with insulin pumps at the Diabetes Unit of the Palmetto Health-University of South Carolina Medical Group. Group A (CSII alone) used only meters to self-monitor blood glucose, and while Group B additionally used pCGM integrated with CSII to adjust pump settings, including basal rate and/or short-acting bolus insulin doses, and change insulin-to-carbohydrate ratio and supplemental factor. The data was analyzed with respect to age, gender, glucose control as assessed by glycosylated hemoglobin (HbA1c), and severe hypoglycemia.

Results
There were 54 patients in group A and 59 in group B. They were comparable in mean age and gender breakdown (47.3 vs 45.2 years, and 66.8% vs 62.7% females, respectively). The average glycosylated hemoglobin (HbA1c) changed from 8.8% to 8.2% and from 8.2% to 7.3% from baseline to the end of one year in the two groups respectively. The number of severe hypoglycemic episodes per patient during the one year was 0.2 and 0.07 respectively.

Discussion
CSII patients who used pCGM were similar in demographics to those who used insulin pumps alone, but had a lower baseline A1c, exhibited a larger decrease in A1c at one year (0.9% vs 0.6%), and had fewer severe hypoglycemic events.

Conclusions
The better outcomes with pCGM-integrated pump therapy may be explained by a higher motivation ability for self-monitoring and care, and by the pCGM being a valuable informational tool in assessing glucose trends when used in properly chosen insulin pump patients who are managed by qualified experts.

**Specific Oct1 gene variants are associated with changes in the risk of cardiovascular death in metformin users**

Natascha Schweighofer1,2, Bernd Genser1,2, Winfried Marz3,5, Marcus E Kleber1, Thomas R Pieber1 and Barbara Obermayer-Pietsch1,3

1Division of Endocrinology and Diabetology, Department of Internal Medicine, Medical University Graz, Graz, Austria; 2BG Statistical Consulting, Vienna, Austria; 3Institute of Public Health, Social and Preventive Medicine, Medical Faculty of Mannheim, University of Heidelberg, Mannheim, Germany; 4Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University Graz, Graz, Austria; 5Synlab Center of Laboratory Diagnostics, Heidelberg, Germany; 6Vth Department of Medicine (Nephrology, Hypertensionology, Endocrinology, Diabetology, Rheumatology), Medical Faculty Mannheim, Heidelberg University and Competence Cluster of Nutrition and Cardiovascular, Heidelberg/Halle-Jena-Leipzig, Germany; 7CBmed GmbH, Center for Biomarker Research in Medicine, Graz, Austria.

**Aim**

Increased cardiovascular incidents and a high risk for microvascular complications are associated with type 2 diabetes. Worldwide, metformin is the most commonly prescribed antidiabetic drug. Polymorphisms in the Oct1 gene can alter the function or activity of organic cation transporter 1 (Oct1), thus changing metformin efficacy (Oct1 acting as its main transporter) as well as influencing the actions of Oct1 physiological substrates. In the past, polymorphisms in Oct1 were associated with cardiovascular risk factors, thus they might contribute to cardiovascular risk development.

We investigated, whether the Oct1 polymorphism rs3777392 is associated with increased risk for cardiovascular death in a cohort of patients with and without type 2 diabetes (T2DM) on various therapies.

**Methods**

Data from the LURIC study (n = 3316), a prospective cohort study of Caucasians scheduled for coronary angiography were analysed. We identified 1820 non-diabetics, 1220 T2DM patients, including 73 metformin users (Met), 154 sulfonylurea users (SF) and 967 T2DM individuals without medication.

Cardiovascular mortality was assessed in all groups according to Oct1 rs3777392 genotypes using Cox proportional hazard models and associations with cardiovascular biomarkers were investigated.

**Results**

Cardiovascular mortality risk for each minor allele copy was HR 2.08 (95% CI: 1.01, 4.28) only in metformin users. Variants of rs3777392 were associated with BMI, baseline insulin values and triglyceride levels in all T2DM patients (P = 0.016, P = 0.048 and P = 0.007, respectively), patients without medication (P = 0.006, P = 0.041, P = 0.008, respectively) and non-diabetics (P = 0.021, P = 0.074, P = 0.125, respectively) but not in the Met and SF groups.

**Conclusion**

In our study, the minor allele of rs3777392 in the Oct1 gene was associated with an increased cardiovascular mortality risk in T2DM patients on metformin therapy, which might be due to loss of association with cardiovascular parameters. Besides very positive effects in the majority of metformin users, some individuals may profit from a pre-treatment genotyping and careful monitoring.

**Liraglutide improves carotid intima-media thickness in pre-elderly and elderly patients with type-2 diabetes: an 18-month prospective, real life study**

Ali Rizvi1, Angelo Maria Patti2, Giuseppa Castellino2, Carlo Mannina2, Dragana Nikolic2, Rosaria Vincenza Giglio2, Roberta Chianetta2, Giuseppe Montalici2 & Manfredi Rizzo1

1University of South Carolina School of Medicine, Columbia, SC, USA; 2University of Palermo, Palermo, Sicily, Italy.

**Introduction**

Liraglutide exerts cardio-protective effects beyond those on glucose metabolism, affecting several cardio-metabolic parameters, such as subclinical atherosclerosis. However, it is not known if those effects differ in the long-term between pre-elderly and elderly subjects with type-2 diabetes (T2DM).

**Methods**

We included 135 subjects with T2DM divided in 2 groups: i) 71 pre-elderly subjects (46 men and 25 women, 55 ± 7 years), and ii) 64 elderly subjects (33 men and 31 women, 70 ± 5 years). All subjects were naive to incretin-based therapies and treated with liraglutide as add-on to metformin, 0.6 mg/day for two weeks, followed by a dose of 1.2 mg/day. At baseline and every 6 months fasting samples were taken for laboratory analyses and carotid-intima media thickness (cIMT) was assessed by B-mode ultrasound. Statistical analysis was performed by ANOVA and the Spearman correlation method.

**Results**

After 18 months of liraglutide therapy HbA1c reduced significantly in both groups (from 9.02 ± 1.06 to 6.93 ± 1.25 and from 8.59 ± 0.71 to 6.74 ± 0.90%, respectively) as well as fasting glycaemia (from 9.57 ± 3.33 to 7.16 ± 2.83 mmol/l; and from 9.14 ± 3.71 to 7.28 ± 2.29 mmol/l, P < 0.0001 for all. Anthropometric parameters changed although not significantly. Lipids, with the exception of HDL-cholesterol, reduced significantly only in pre-elderly subjects (triglycerides from 1.94 ± 1.48 to 1.57 ± 0.80 mmol/l, P = 0.0458; total cholesterol from 4.90 ± 1.57 to 4.27 ± 1.04 mmol/l, P = 0.0025; LDL-cholesterol from 2.92 ± 1.44 to 2.34 ± 0.91 mmol/l, P = 0.0054). cIMT significantly decreased in both groups (from 0.96 ± 0.18 to 0.78 ± 0.20 mm; and from 0.99 ± 0.17 to 0.79 ± 0.20 mm, respectively; P < 0.0001 for both). Changes in cIMT were positively associated only with changes in triglycerides in both pre-elderly (r = 0.245, P = 0.0398) and elderly (r = 0.506, P = 0.0001) groups.

**Conclusion**

Liraglutide significantly reduced cIMT in both pre-elderly and elderly subjects with T2DM, beyond glycemic control.

**Introduction**

Diabetic ketoacidosis (DKA) is an endocrine emergency and the leading cause of morbi-mortality in children with type 1 diabetes mellitus (1DM). DKA treatment is still controversial, mainly regarding hydroelectrolytic replacement and insulin dose.

**Aims**

To evaluate effectiveness and safety of our tertiary centre protocol in DKA treatment, which included initial volume expansion with isotonic saline in the first two hours followed by 0.45% sodium chloride with 5% glucose and insulin infusion (0.1 U/kg per h). Potassium replacement with potassium phosphate in the first 12 h.

**Methods**

Retrospective study of all children with moderate and severe DKA 1DM presented from 2004 to 2016. Data collected: insulin infusion dose, glycaemia, pH, Osmolarity, corrected sodium, potassium and phosphate along the first 12 h of treatment. Statistical analysis with SPSS21 (P < 0.05).

**Results**

179 new cases of 1DM were admitted and 45 (25%) had DKA at presentation (15 severe, 12 moderate and 18 mild DKA). Within moderate and severe DKA (N = 27), 1867% were female and mean age at diagnosis was 8.5 ± 3.8 years. Means at admission were: 528 ± 138 mg/dl glycaemia, 310 ± 12 mosm/kg osmolality, 146 ± 5 mmol/l corrected sodium, 4.5 ± 0.73 mmol/l potassium and 1.5 ± 0.5 mmol/l phosphate. Mean insulin infusion dose at treatment start was 0.08 ± 0.03 U/kg per h. Along the first 12 h mean replacement doses were 4.3 ± 1.3 gr/l per h of glucose, 0.13 ± 0.04 mmol/kg per h of potassium, 0.33 ± 0.1 mmol/kg per h of sodium and 0.06 ± 0.02 mmol/kg per h of phosphate. There were 12(4%) cases of hypokalemia and 10(37%) of hypophosphatemia. There was no hypoglycaemia nor cerebral edema. There was statistical significance in variation regarding glucose, pH, corrected sodium and osmolality along the 12 h (P < 0.0001). Sodium decreased in the first 8 h. Potassium decreased along the first 4 h and rose from 8 h forwards.

**Conclusions**

Our protocol allowed a safe treatment of DKA at 1DM presentation, with gradual correction of dehydration and acidosis. However, sodium and potassium replacement should be adjusted, leading to our actual protocol.

The method of reporting hypoglycemia in Randomized Controlled Trials (RCTs): a systematic review on RCTs conducted for SGLT-2 inhibitors

Noor Kassir1, Sarah Medeiros2 & Pendar Farahani3

1National University of Ireland, Galway, Ireland; 2University of Western Ontario, London, Ontario, Canada; 3McMaster University, Hamilton, Ontario, Canada.

Background
Hypoglycemia is an important side effect in pharmacotherapy of patients with diabetes mellitus. Medical organizations have tried to define hypoglycemia in clinical practice and RCTs with scientific standards and guidelines.

Objective
To explore the method of reporting hypoglycemia conducted on SGLT-2 inhibitor RCTs.

Methods
A systematic review using PubMed to find data on RCTs conducted for SGLT-2 inhibitors, limited to English language.

Results
Of 155 RCTs, 95(61.3) (n(%)) were found to have defined and reported hypoglycemia. The results showed that 8(5.2) RCTs were reported as event/arm, 15(9.7) as event/combined all arms, 69(44.5) as event/patient/arm and 3(1.9) RCTs reported as both event/arm and event/combined all arms. Additionally, 3(1.9) RCTs defined hypoglycemia but did not report it. Hypoglycemia was neither defined nor reported in 57(36.8) of the RCTs. In addition, 41(26.5) RCTs had hypoglycemic episodes that were confirmed, by glucose threshold, whereas only 24(15.5) RCTs had episodes that were reported as symptoms from patients. Hypoglycemic episodes were reported and confirmed in 5(3.2) of the RCTs and 27(17.4) showed that the episodes were reported or confirmed.

Conclusion
This study illustrates that around 40% of RCTs on SGLT-2 inhibitors did not define and report hypoglycemia. The method of reporting hypoglycemia was variable among the RCTs. Almost half the RCTs reported as event/patient/arm. Additionally, a quarter of RCTs only reported hypoglycemic episodes with confirmation of glucose threshold. Future RCTs should unify the reporting of hypoglycemia for safety assessment of diabetic medication.

Hepatic effects of GLP-1 receptor agonist Liraglutide in patients with type 2 diabetes

Marta Hayon1, Marta Fernandez1, Silvia Maraver2, Teresa Muros1, Daniel Cepero1, Martín Lopez1, Miguel Quesada1 & Gonzalo Piedrola1

1Complejo Hospitalario Universitario de Granada, Granada, Spain; 2Clínico de Vírgenes de la Victoria Hospital, Malaga, Spain; 3Torrecardenas Hospital, Almeria, Spain; 4Endocrinology Private Office, Granada, Spain.

Introduction
The aim of this study was to analyze the effects of Liraglutide in hepatic steatosis as well as clinical and biochemical data before and after 6 months.

Methods
We have retrospectively analysed epidemiological, anthropometric and laboratory data of 83 type 2 diabetic patients treated with Liraglutide and followed at different endocrinology units across east Andalusia. We have evaluated nonalcoholic fatty liver disease using liver enzymes and hepatic steatosis index (HSI). HSI > 36 reflects fatty liver, < 30, absent, and intermediate values are considered indeterminated.

Results
Of the 83 cases evaluated, 54.2% were male, mean age 56.76 ± 9.87 years, time from diagnosis 9.46 ± 5.46 years. Prior to treatment, patients had BMI 37.68 ± 6.82 kg/m², blood pressure 138.80/82.87 mmHg, fasting glucose 187.33 ± 55.11 mg/dl, glycaemic hemoglobin (HbA1C) 8.62 ± 1.33%, total cholesterol 178.73 ± 55.11 mg/dl, triglycerides 197.64 ± 24.19 mg/dl, AST 29.20 ± 23.11 U/l, ALT 39.98 ± 31.31 U/l, and HSI 46.44 ± 6.48.

Clinical and biochemical figures at 6 months were: BMI 36.08 ± 6.32 kg/m², blood pressure 132.76/77.41 mmHg, fasting glucose 185.16 ± 56.56 mg/dl, HbA1C 7.73 ± 1.33%, total cholesterol 170.6 ± 39.19 mg/dl (c-HDL 46.25 ± 15.03 mg/dl, c-LDL 87.74 ± 30.53 mg/dl), triglycerides 198.29 ± 22.29 mg/dl, AST 24.97 ± 12.49 U/l, ALT 32.76 ± 18.24 U/l, and HSI 43.98 ± 6.38.

Statistically significant differences were found regarding several variables, such as BMI, HbA1C, fasting glucose, blood pressure and c- LDL, as well as in ALT and HSI, showing an amelioration in hepatic steatosis. No differences were found in total cholesterol, c-HDL, triglycerides and AST.

Exenatide treatment causes suppression of serum fasting ghrelin levels in patients with type 2 diabetes Mellitus

Metin Gucul1, Sinem Kiyici2, Zulfiya Gu2 & Sinan Cavun2

1Department of Endocrinology and Metabolism, Health Sciences University, Bursa Yuksek Ihtisas Education and Training Hospital, Bursa, Turkey; 2Uludag University Medical Faculty, Department of Pharmacology, Bursa, Turkey.

Aim
Ghrelin plays an important role in the stimulation of food intake and long-term regulation of body weight. In present study we investigate the long term effect of exenatide treatment on serum fasting ghrelin levels in patients with type 2 diabetes mellitus.

Methods
Type 2 diabetic patients who were using metformin with and without the other oral antihyperglycemic drugs on a stable dose for at least 3 months were enrolled in the study. Body mass index (BMI) > 35 kg/m² and hemoglobin A1c (HbA1c) > 7.0% were the additional inclusion criteria. Oral antihyperglycemic drugs other than metformin were stopped and metformin treatment was continued at 2000 mg per day. Exenatide treatment was initiated at 5 mcg per dose twice daily and after one month the dose of exenatide was increased to 10 mcg twice daily. Changes in anthropometric variables, glycemic control, lipid parameters, and total ghrelin levels were evaluated at baseline and following 12 weeks of treatment.

Results
Thirty-eight patients (male/female = 7/31) with type 2 diabetes mellitus entered to the study. Mean age of patients was 50.3 ± 8.4 years with mean diabetes duration of 8.5 ± 4.9 years. Mean BMI was 41.6 ± 6.3 kg/m² and mean HbA1c of patients was 8.9 ± 1.4%. Percentage change in weight of patients was −5.2 ± 3.7% following 12 weeks of treatment. BMI and HbA1c levels of patients were decreased significantly (P < 0.001) and P < 0.001, respectively) while there was no change in lipid parameters. Serum fasting ghrelin levels were suppressed significantly after 12 weeks of exenatide treatment compared with baseline values (328.4 ± 166.8 vs 245.3 ± 164.8 pg/ml) (P = 0.024).

Conclusion
These results suggest that the effect of exenatide on weight loss may be related with the suppression of serum fasting ghrelin levels, which is an orexigenic peptide.

Impact of the socio-economic level on the management in type 2 diabetes

Bouhbaba Kolsi1, Mouna Elleuch1, Rihab Ben Abdallah2, Feten Haj Kacem1, Fatma Mufli1 & Mohamed Abid1

1Hedi Chaker Hospital, SFax, Tunisia; 2Faculty of Sciences of sfax, Sfax, Tunisia.

Diabetes is a chronic disease whose associated comorbidities are largely influenced not only by pathology but also by socio-economic conditions. The aim of this study is to investigate the influence of social conditions on the evolution of diabetes. A retrospective, comparative study of 111 patients with type 2 diabetes Follow-up in the Endocrinology-Diabetology department in hospital Hedi Chaker of Sfax. Patients were divided into two groups with unfavorable (G1) and good (G2) socio-economic conditions, both groups had 58 and 53 patients, respectively. The average age of our patients was 54 in G1 and 49 in G2 (P = 0.07). A female predominance was noted in the G1 by 64% while the male sex was predominant in the G 2: 80%. The age of diabetes was comparable between the two groups (12.5 years vs 11 years, P = 0.09). Fasting glucose was significantly higher in G 1 (15 mmol/l) versus 9 mmol/l in G2 (P < 0.0001). The number of hospitalizations was higher in G1: 2.8 versus 1.3 in G2 (P = 0.005).

The food investigation showed a higher caloric intake in G2 estimated at

Endocrine Abstracts (2017) Vol 49
Endocrine Abstracts (2017) Vol 49

2615 Kcal/d versus 2184 Kcal/d for the G1. Infectious complications and amputation were significantly more frequent in G 1 compared to G2. Similarly, microangiopathic complications were more frequent in G1 patients. This imbalance was related to management difficulties, so no patient of G1 was placed under insulin analogs versus 23% of G2 patients. Socioeconomic status seems to play a crucial role in the glycemic balance and the occurrence of chronic complications of diabetes. This is mainly due to the restriction of access to health care structures and therapeutic, sometimes expensive, and the level of instruction of these disadvantaged classes.

Outcomes of a nurse-led thyroid clinic at a tertiary-care endocrine centre
Violet Fazal-Sanderson1, Niki Karavitaki2, Ashley Grossman3 & Atul Kalhan4
1Royal Berkshire Hospital, Reading, UK; 2Queen Elizabeth Hospital, Birmingham, UK; 3Oxford University Hospitals NHS Foundation Trust, Oxford, UK; 4Royal Glamorgan Hospital, Wales, UK.

Introduction
A Nurse-led Thyroid Clinic (NLTC) in a tertiary-care Endocrinology centre (EC) in Oxford was set up in 2005. The patients were managed by an Endocrine Advanced Nurse Practitioner.

Aims
To evaluate standard of clinical care (SOCC) quality of service provision (QOSP) and cost effectiveness (CE) of the NLTC.

Methods
Three aspects of service were assessed:

a) SOCC: Data were collected for patients managed over 12 months between 1/2014 and 1/2015. Diagnosis, investigations and management plans for individual patients were compared against accepted regional and national guidelines.

b) QOSP was evaluated from standardised patient feedback questionnaires (PFQ) that were anonymised for confidentiality.

c) CE was assessed through collection of retrospective data of filed patients clinic lists between 1/2014 and 1/2015. A new patient (NP) tariffed at £120, follow-up at £90 per visit according to department protocol. Annual data was recorded of non-face-to-face-telecommunication (NFTFT) costed at £30 per call.

Results

a) SOCC: 214 patient appointments for 134 patients were reviewed; 112 patients had Graves’ disease, 10 subacute thyroiditis, 10 toxic nodular diseases and two subclinical thyrotoxicosis. Patients were managed with a departmental protocol based on British Thyroid Association guidelines 2006.

b) QOSP: 50 out of 60 PFQ were returned (34 women/16 men, median age 52.3 years, range 21–85). Majority of the patients expressed high satisfaction with the quality of services provided, with 86% “Extremely Likely” to recommend the TNLC to friends and family.

c) CE: New and follow-up patients generated an annual income of £20,490. NFTFT calls (908 patients) generated an income of £27,240. 41 empty NP clinic slots, 22 follow up cancellations and 19 patients who failed to attend the clinic, amounted to a loss of £6160.

Conclusions
The audit supports the value of NLTCs in EC’s with a significant thyroid dysfunction workload. These clinics can provide high quality of clinical care and potentially be cost-effective.

Education, patient empowerment and admission avoidance
Anna Hawkins, Edel Casey & Khash Nikookam
Barking, Havering & Redbridge University NHS Trust, ESSEX, UK.

It is paramount to educate our patients, thereby empowering them to manage their chronic conditions. This is an evidence based fact. As healthcare professionals our challenge is to provide and ensure patients have been well informed in order to understand and manage their condition successfully on a daily basis.

In today’s healthcare service patient education has become a casualty of the reduced resources; there are ever increasing restrictions on both the length and frequency of consultations.

Endocrine teams and in particular the specialist nurses role involves teaching patients with new diagnosis as well as building on information they have gained from their consultations etc. We wanted to see how many patients with pituitary/adrenal failure have gaps in the understanding of their condition, particularly in relation to their sick day rules.

We surveyed 18 patients on hydrocortisone replacement who completed a questionnaire assessing their knowledge and understanding of their condition. When asked what action they would take if they had flu and a high temperature, nine would double their steroid dose, three would triple it. This leaves six patients at potential risk of admission. When asked about vomiting and/or diarrhea, six said they would double their dose, one would triple it and one would take their emergency hydrocortisone injection, potentially leaving ten patients at risk of an Addisonian crisis. Within this group of patients seven had been given intra muscular hydrocortisone, but only four had been shown how to use it.

The national annual admission rate for patients with Addison’s disease/syndrome is 8%. Within this sample group the admission rate was 27.2%.

We need more resources to build on our initial and ongoing education/teaching programme to work on patient awareness of their condition as a whole, including sick day rules.

Recovery of the hypothalamus-pituitary-adrenal axis after transsphenoidal surgery for pituitary adenomas
Erasmus Medical Center, Rotterdam, The Netherlands.

Purpose
Hypopituitarism is frequently associated with lifelong replacement therapy. However, it has been suggested that recovery from hypopituitarism after transsphenoidal surgery (TSS) for pituitary adenomas may occur during follow up. The aim of this study was to assess the frequency of hypothalamus-pituitary-adrenal (HPA) axis recovery after TSS in patients with non-functioning pituitary adenomas and acromegaly.

Methods
Over the 3-year observational study period, 146 patients underwent transsphenoidal pituitary surgery. The metyrapone test was used to assess the HPA-integrity after 1 week and after 3–12 months after TSS. The pituitary-thyroid-, gonadal and growth hormone axis were measured one week after TSS.

Results
Patients with Cushings’s disease and panhypopituitarism were excluded from the study. 44 subjects had a sufficient HPA-axis one week after surgery. 14 subjects with an insufficient HPA-axis were excluded, as the 11-deoxycortisol after metyrapone was <100 nmol/l. Eighteen patients were eligible to reassess the HPA-integrity. In 10 out of 18 patients, insufficiency of the HPA-axis appeared to be reversible. Eight patients had persistent secondary adrenal insufficiency. The number of other pituitary hormone insufficiencies one week after TSS was associated with recovery of the HPA-axis after TSS.

Conclusion
After TSS, recovery of the HPA-axis over time does occur in a proportion of subjects. Therefore it is recommended to re-assess the HPA-integrity during follow up to prevent unnecessary glucocorticoid replacement therapy. Pituitary adenoma, reversible hypopituitarism, recovery HPA-axis, pituitary surgery, adrenal insufficiency.

Key words
Pituitary adenoma, reversible hypopituitarism, recovery HPA-axis, pituitary surgery, adrenal insufficiency.

The role of luteinizing hormone (LH) and its receptor (LHICGR) signaling in the adrenal gland remains unknown. Gonadectomy-induced chronically elevated LH levels trigger neoplastic transformation in genetically susceptible mouse strains (DBA/2J) or transgenic mice expressing the Simian Virus 40 T antigen (SV40Tag) oncogene under inhibin-x promoter (intra/Tag). In order to study the functional role of LHR and GATA4 in the onset and progression of adrenocortical tumors in ovarioectomized (OVX) intra/Tag females in vivo and in vitro, we crossed the intra/Tag with LHR knockout (LuRKO) mice. Additionally we knocked out Lhr (Lgr-ko) and Gata4 (Gata4-ko) in the Cx1 cell line derived from an adrenal tumor of intra/Tag mice. In intra/Tag mice, we identified two distinct types of SV40Tag expressing neoplastic cells. The first type, subcapsular non-steroidogenic spindle-shaped A-like cells, which never developed to tumors, were found in both intact and OVX intra/Tag females. The second type, parenchymal tumor cells in the topmost layer of zona fasciculata, later forming tumor foci, were found only in OVX intra/Tag mice. Lack of LHR in OVX intra/Tag/LuRKO mice adrenal prevented tumor formation. Histological and immunohistochemical analyses revealed the presence of hyperplastic cells expressing SV40Tag in parenchyma. These cells were devoid of GATA4 and showed signs of apoptosis. In vitro, a complete inactivation of Gata4 significantly decreased cell proliferation, expression of tumor markers (intra, SV40Tag, Lhgr and Esr1) and gonadal-like steroidogenic phenotype of Cx1 cells. Our results suggest that at first, the tumor formation was LH-dependent, but later on became LH-independent. GATA4 is responsible for the intra/SV40Tag expression, gonadal steroidogenic phenotype and possibly pro-survival pathways. Identifying GATA4 downstream targets in the adrenocortical tumors in both, intra/Tag and human could be of importance to find potential therapeutic targets for human adrenocortical tumors.

GP119 Targeted molecular analysis in adrenocortical carcinomas: a way towards personalized medicine

Cristina L. Ronchi1, Juliane Lippert2, Silke Appenzeller3, Silviu Sibira1, Sonja Steinheuer4, Raimunde Liang1, Andrea Gehrig5, Matthias Kross1, Simone Kost1, Andreas Rosenwald1, Clemens Müller-Reible5 & Martin Fassnacht1

1Division of Endocrinology and Diabetes, University Hospital of Wuerzburg, Wuerzburg, Germany; 2Institute of Human Genetic, University of Wuerzburg, Wuerzburg, Germany; 3Core Unit Bioinformatics, Comprehensive Cancer Center Mainfranken, University Hospital of Wuerzburg, Wuerzburg, Germany; 4Department of Pathology, University of Wuerzburg, Wuerzburg, Germany.

Adrenocortical carcinoma (ACC) is a rare tumor with heterogeneous outcome and no available targeted therapy. The aim of the study is to identify prognostic molecular markers and novel potential drug targets. A total of 43 FFPE tumor samples were retrospectively investigated for somatic mutations and copy number variations (CNV) by next-generation sequencing (160 cancer-related genes, Qiagen). Gene expression was evaluated by quantitative RT-PCR in a subgroup of 25 ACC samples (84 cancer drug targets, Qiagen). The major clinical endpoint was progression free survival (PFS). We observed 123 protein-altering mutations in 47 genes (median 2 per sample), with the most frequent known to be ACC-related: TP53 (28% of samples), CDKN1A (16%), ZNF531 (19%), NF1 (16%) and GNAS (14%). Notably, we also detected recurrent mutations in genes previously not clearly associated with ACC (i.e. ABLI, KDM6A, TSC1, FBXW7, DNM3TA, BRCA1, BRCA2). Some focal CNV were found in >30% samples (i.e. gains of CDK4, MDM2, I2R, and losses of TNFRSF14). A nosy pattern was associated to a shorter median PFS than others (P = 0.067, HR = 1.78). At mRNA level, most frequently overexpressed genes (>2.5 fold change) were IG2Z (92%), TOP2A (92%), CDK1 (72%) and PLK1 (60%). Tumors with increased BUB1B/PINK1 (>5.9) were associated with a trend to worst PFS (P = 0.16, HR = 1.98).

This pilot study demonstrates the feasibility of molecular analysis in FFPE samples. We identified some genetic variants previously not associated with ACC and new potential drug target genes. These results will be validated in a larger series in order to path the way to a personalized medicine in ACC.

Endocrine Abstracts (2017) Vol 49

19th European Congress of Endocrinology 2017

continuous quality assessment and improvement work within the Swedish health care system.

The Swedish Pituitary Register Nursing Group (SPRING) was formed by nurses at the University Hospitals, working with the register, in 2011.

Purpose

To increase the coverage rate and improve the data quality in the register.

To strengthen the endocrine nurse role and encourage and promote the nurses to own their register projects.

Methods

The SPNRG, consisting of endocrine nurses, one responsible for the register at each University Hospital. Meetings are performed 1–2 times/year. The SPNRG is working for the same routines considering the register and is actively working with projects in the SPR.

Results

Since the SPRNG was started the coverage rate and the reporting speed in the SPR have increased. Several nurse projects during 2016. Implement PREM and disease-specific PROM variables. User Survey in the register. Register data template for the hospitals operations managers and for the public to increase the knowledge of this patient group.

A study ‘Time from first symptoms to diagnosis’, where approximately 600 patients with pituitary tumours (Acromegaly, Mb Cushing, NFPA and Prolactinomas) are included, will be compiled. 2017. This purpose is to find these patients earlier and to identify how we can do that.

The SPRNG have been active at international conferences with several abstracts. Material and sharing experiences of the register with finish endocrine nurses.

Conclusion

Meeting and sharing experiences of the register with finish endocrine nurses.

is to find these patients earlier and to identify how we can do that.

The Sprng has contributed to increase the data quality and coverage rates in the SPR.

The SPRNG is a good example of how nurses can be supported by each other and share experiences, skills and knowledge but also operate their own project.

Introduction
The Carney Complex is a multiple endocrine and non endocrine neoplasia mostly due to PRKAR1A mutations. Spectrum of manifestations and genotype-phenotype correlations have been previously described by retrospective studies. A prospective study evaluating the occurrence of the different manifestations was needed to precise the optimum follow-up.

Methods
Multi-center national prospective study (Clinical Trials NCT00668291) including 767 patients mutated or wild-type for PRKAR1A followed prospectively during 3 years with screening of the different manifestations by annual clinical, biological and radiological evaluation.

Results
The cohort was composed of 50 females and 20 males with a mean age at 35.4-years +/– 16.7. Prevalence of cardiac myxomas at the end of the follow-up was 22.9% with newly diagnosis during the study period for 3 patients. Forty-four% of patients with myxomas had related stroke attack and 56% had recurrences. Median delay between recurrences was 3.8-years (minimum-maximum: 0.8-24). Primary pigmented adenal nodular disease was diagnosed in 57.1%. Skin manifestations, abnormal somatotroph hormonal tests and thyroid tumors were observed respectively in 58.6, 21.4 and 12.9%. Four% had melanotic schwannomas confirmed by histology. Spinal magnetic resonance imaging revealed lesions for 8.6%. Characteristic multiples calcified tumors on testicular ultrasonography were present in 35% of male patients. Ten% of female patients had surgery for breast myxoma or adenaibroma. Forty% had lesions classified ACC2-3 at mammography. Interestingly, four patients (8%) had breast adenocarcinomas (11.1% of female older than 30years). Eighty-three% of patients had PRKAR1A mutations. Patients carrying the mutation c.709-7del6 (34% of the cohort) had no manifestation or phenotype restricted to adrenal, lentigines and abnormal somatotroph test.

Conclusion
The penetrance of the disease is high after screening except for patient carrying the c.709-7del6 mutation. This study highlights the importance of an annual follow-up, with especially annual cardiac imaging for patients with history of cardiac myxomas and earlier and regular senologic evaluation.

Immunity in adrenocortical carcinoma patients – interplay between anti-cancer immunity and steroid hormones
Silviu Sbiera1,2, Thomas Drexneit1,3, Iuliu Sbiera1, Jochen Schreiner1, Cristina L. Ronchi1, Matthias Kroiss1,2* & Martin Fassnacht1,3
1Division of Endocrinology and Diabetes, University Hospital, University of Würzburg, Würzburg, Germany; 2Comprehensive Cancer Center Mainfranken, University of Würzburg, Wuerzburg, Germany; 3Department of Neurosurgery, University Hospital, University of Würzburg, Wuerzburg, Germany.

Adrenocortical carcinoma (ACA) is one of the most aggressive endocrine malignancies. By applying a ‘multiple omics’ approach, we recently identified two distinct subgroups of ACC patients, a good prognosis “immune” and bad prognosis “steroid” phenotype. We hypothesized that the steroid phenotype is associated with glucocorticoid-resistant tumour free PBMCs from blood of 19 healthy controls.

To assess changes induced by ACC on circulating immune cells we isolated GP121 helper and cytotoxic T-cells, B-cells, monocytes, naive and memory T-cells, NK-cells, and platelets from blood of 40 ACC patients and 19 healthy controls. Using immunofluorescence, we analysed the presence of tumour infiltrating T-cells, B-cells, dendritic cells (CD209+), B-cells (CD19), monocytes (CD14), regulatory T-cells (T-reg) and macrophages (CD68+). Of 40 ACC patients, 23 (58%) had a strong CD68+ macrophage infiltration, 57% of the total tumour volume. Using Flow Cytometry, we showed decreased B-cells, CD56+ NK-cells and increased CD4+ T-cells, CD3+ T-cells. Furthermore, expression of immune checkpoint markers programmed death 1 (PD1) and its ligand PDL1 was analysed by IHC. Presence of CD4+ T-cells infiltrating tumour correlated significantly with tumoral and steroid secretion status. Programmed death 1 (PD1) and its ligand PDL1 was analysed by IHC. Present and cortisol excess.

1Department of Clinical and Biological Sciences, University of Turin, Turin, Italy; 2Institute of Metabolism and Systems Research, University of Birmingham, Birmingham, UK; 3University of Turin, Turin, Italy; 4Waweterski University Medecynzy, Warszawa, Poland; 5Universitatsklinikum Würzburg, Würzburg, Germany; 6Klinikum der Ludwig-Maximilian-Universität München, München, Germany; 7Antiko University Hospital, Athens, Greece; 8Charitè Universitätsmedizin Berlin, Berlin, Germany; 9University Hospital Zagreb, Zagreb, Croatia; 10Institute of Applied Health Research, University of Birmingham, Birmingham, UK.

Background
Adrenal masses are discovered in 5% of abdominal imaging scans. Work-up aims at exclusion of malignancy and hormone excess. However, estimates of these risks derive from retrospective studies only, mostly small and with significant selection bias.

Methods
Prospective multi-centre study (2011–2016) in 14 centres (11 countries) of the European Network for the Study of Adrenal Tumours (ENSAT) with prospective consecutive enrolment of patients with newly diagnosed adrenal mass. Extra-adrenal malignancy and phaeochromocytoma were exclusion criteria. Diagnosis was confirmed by histology or imaging follow-up.

Results
We enrolled 1994 patients. 1746 (87.6%) with a benign adrenocortical adenoma (ACA), 83 (4%) with other benign masses (e.g. adrenomyelolipoma, cyst), 105 (5.3%) with adrenocortical carcinoma (ACC) and 59 (3%) with other malignant masses (e.g. metastases, sarcoma). Risk of ACC was highest in young patients (<40yrs; 13%–40–60yrs:6%≥60yrs:3%; P<0.0001) and in large masses (>4 cm; 21%, <4 cm; 0.4%, P<0.0001). Of 1746 patients with ACA, imaging for exclusion of malignancy included unenhanced CT in 1301 patients, with tumour density <10HU indicative of a benign tumour in 69%, with 16% borderline (10–20HU) and 15% suspicious (>20HU). Results. MRI with chemical shift results in 271 ACA patients were indicative of a benign lesion in 79%. In 829/1746 (47%) ACA patients, two or more imaging studies were performed; 19% underwent three or more. Upon re-imaging after ≥6 months, the adrenal mass appeared stable in size 601 of 629 ACA patients (96%). Mild autonomous cortisol excess (MACE) was detected in 547/1316 (42%) patients with ACA. Adrenalectomy was performed in 21% (370/1746) of ACA patients. Of those, 222 (60%) had overt hormone excess and 64 (17%) had MACE (70%; 18%); the remaining 84 patients (23%) had non-functioning ACA.

Conclusions
Overall risk of ACC is 5.3% and is highest in young patients with adrenal mass size >4 cm. ACAs are frequently misclassified as malignant by routine imaging, resulting in a high rate of interval imaging and unnecessary adrenalectomies.

In conclusion, ACC patients are characterized by increased circulating immune inhibitory Tregs and tumour infiltrating CD4+ T-helper cells have a positive influence on patient survival.

DOI: 10.1530/endoabs.49.GP123
Background
Adjuvant mitotane therapy is frequently used in Europe following surgery for adrenocortical carcinoma (ACC). Management of adjuvant mitotane is mainly empirical and a major open question is the optimal duration of therapy, because no study has ever addressed this issue.

Objective
We aimed to assess the outcome of ACC patients who were treated with adjuvant mitotane for at least one year following surgery and then discontinued therapy for other reasons than ACC recurrence.

Design
We did a retrospective analysis of 132 patients (91 F, 41 M; median age 44 years) with histologically confirmed ACC who were treated at 9 European centres and 1 centre in Canada since 1999.

Results
Tumour stage was ENSAT I, 11%; ENSAT II, 79%; ENSAT III, 20%; hormone secretion was present in 44% and resection status was R0, 83% and Rx, 17%. Median Ki-67 was 10% and Weiss 6. Duration of adjuvant mitotane therapy was 34 months (12–141). Median duration of follow-up was 79 months (31–280), including 34 months after discontinuation (1–263). Seventeen patients (13%) recurred after treatment discontinuation with a recurrence-free survival from surgery of 74 months (31–277) and tumour-free survival after mitotane discontinuation of 32 months (1–263). The only difference in prognostic characteristics between patients with recurrent ACC and the remainders was a higher number of secreting tumours. Interestingly, no recurrence was observed among the 41 patients (31%) treated for >48 months; such patients had similar prognostic characteristics and follow-up duration after mitotane discontinuation than the remainders.

Conclusions
These first results suggest that a prolonged duration of adjuvant mitotane therapy may be associated with better recurrence-free survival.

GP125
GPER-stimulation increases proliferation in colorectal cancer via the Hippo signalling pathway
University of Birmingham, Birmingham, West Midlands, UK.

Colorectal cancer (CRC) is the 2nd most commonly diagnosed cancer in Europe. Previously, we have shown steroid sulphatase (STS), the enzyme that converts conjugated oestrogens to their active forms, is significantly upregulated in human CRC tissue. Furthermore, increased STS activity substantiates greater CRC tumour burden in mouse models. Here we demonstrate that this oestrogen-induced increase of CRC proliferation is mediated by G-protein coupled oestrogen receptor (GPER) via Hippo pathway signalling through the yes-associated protein 1 (YAP1), transcriptional coactivator with PDZ-binding motif (TAZ), and connective tissue growth factor (CTGF).

To examine how GPER effects CRC proliferation we employed in vitro BrdU proliferation assays and in vivo mouse models of CRC treated with G1, a GPER agonist, oestrogens and G15, a GPER antagonist. To investigate whether YAP1, its target gene CTGF, and its transcriptional co-activator TAZ, were altered by oestrogen-induced GPER signalling, we used immunoblotting and immunohistochemistry. YAP1 knockdown cells were also examined by treating them with G1, oestrogens and verteportin, a YAP1 inhibitor, to assess the role of YAP1 on proliferation.

GPER-stimulation by G1 and oestrogen increased CRC proliferation in a dose-dependent manner, with this effect inhibited by G15 in vitro and in vivo CRC xenografts. YAP1 mediated this pro-proliferative response in CRC cells in contrast to colon adenoma cells. These findings were underpinned by increased phosphorylation of YAP1 and increased protein expression of TAZ and CTGF after oestrogen and G1 treatment. Intriguingly, CTGF up-regulation correlated with elevated GPER in human CRC tissue. In line with the above results, pharmacological inhibition of YAP1 and YAP1 knockdown blocked G1-induced cellular proliferation supporting the functional pro-proliferative role of YAP1 in CRC.

Taken together, our results propose a new oestrogen-driven pro-proliferative GPER-stimulated pathway through Hippo signalling in CRC. Further studies are required to establish whether this early metabolic response translates into increased cellular viability and cancer development.

Inhibition of hRAS and CDK4/6 leads to an antiproliferative activity, blocks cell cycle and induces cell death in anaplastic thyroid cancer cell lines
Marta Pojo1, Sara Lopes-Ventura1, Ana Matias1, Valeriano Leite1,2 & Branca Cavaco1

The unresponsiveness of anaplastic thyroid carcinomas (ATCs) to multimodal therapy represents the major challenge in thyroid cancer treatment. Our group previously showed that genes involved in cell cycle are differentially expressed in ATCs compared to normal thyroid, and that the most common mutations found in

Endocrine Abstracts (2017) Vol 49
these tumours are related with proliferation and cell cycle genes, namely TP53, RAS, CDKN2A and CDKN2B. Therefore, these genes are promising new targets in ATCs.

Here, we investigated if the inhibition of HRAS by Tipifarnib (TIP) and CDK4/6 by Palbociclib (PD) could be an option in ATC treatment. Different ATCs cell lines with distinct mutational patterns for RAS, CDKN2A and CDKN2B were used to evaluate the cytotoxic effects of these drugs. The IC50 for TIP and PD were determined, and the effect of these compounds in cell cycle, cell death and cell proliferation were analysed.

Cell culture studies demonstrated that low doses of TIP, at 48 h, induced cell cycle arrest in G2/M phase (50%, P < 0.01), cell death (20%), and inhibition of cell viability (P < 0.001), only in the HRAS mutated cell line. PD at low concentration increased significantly cell cycle arrest on G0/G1 phase (80%, P < 0.05), only in cell lines with deletion/mutation in CDKN2A or CDKN2B genes, however only higher doses induced more than 50% of cell death. The inhibition of cell viability was more pronounced in cell lines with deletion/mutation in CDKN2A or CDKN2B genes than in wild type thyroid cancer cell lines or in normal thyroid cells (P < 0.05).

In conclusion, this study suggests that TIP and PD, which are currently in clinical trials for other types of cancer, could play a relevant role in inhibiting the progression of ATC, depending on the specific molecular profile of the tumour.

Benign prostatic hyperplasia is associated with liver inflammation: it’s time for prevention?

Giorgio Ivan Russo1, Aldo E. Calogero1, Giuseppe Morgia2, Rosìa Angela Contordelli1 & Sandro La Vignera2

1Andrology Center of Catania University, Catania, Italy; 2Urology Center of Catania University, Catania, Italy.

Metabolic Syndrome (MetS) has been frequently associated with an overall inflammation status, called “metflammation”, including atherosclerosis and non-alcoholic steatohepatitis (NASH). In this study we aimed to evaluate the relationship between intra-prostatic inflammation and NASH in a cohort of patients affected by BPH. Between January 2012 and January 2016, 132 consecutive patients with BPH-related lower urinary tract symptoms (LUTS) who underwent transurethral resection of the prostate were prospectively enrolled. The presence of NASH was evaluated using the NASH score: 1.18*MetS (yes = 1) + 0.45*Diabetes (yes = 2) + 0.15*fasting serum insulin + 0.04*serum AST – 0.94*(AST/ALT) – 2.89. A cut-off of 1.05 was set to predict NASH (AUC: 0.94). Prostate samples were anlaysized for the evaluation of inflammation and considering patients with MetS and/or presence of NASH was evaluated using the NASH score: 1.18*MetS (yes = 1) + 0.45*Diabetes (yes = 2) + 0.15*fasting serum insulin + 0.04*serum AST – 0.94*(AST/ALT) – 2.89. A cut-off of 1.05 was set to predict NASH (AUC: 0.94). Prostate samples were analyzed for the evaluation of inflammation and considering patients with MetS and/or presence of NASH was evaluated using the NASH score: 1.18*MetS (yes = 1) + 0.45*Diabetes (yes = 2) + 0.15*fasting serum insulin + 0.04*serum AST – 0.94*(AST/ALT) – 2.89. A cut-off of 1.05 was set to predict NASH (AUC: 0.94).

Prostate samples were analyzed for the evaluation of inflammation and considering patients with MetS and/or presence of NASH was evaluated using the NASH score: 1.18*MetS (yes = 1) + 0.45*Diabetes (yes = 2) + 0.15*fasting serum insulin + 0.04*serum AST – 0.94*(AST/ALT) – 2.89. Peptides derived from the sst5TMD4 extracellular domain increase malignancy of endocrine-related cancer cells

Manuel D Ghate, Mercedes del Rio-Moreno, Emilia Alors-Perez, Patricia Borges de Souza, Maria E Prados-Gonzalez, Justo P Castaño & Raúl M Luque

Maimonides Institute of Biomedical Research of Cordoba; Reina Sofia University Hospital; Department of Cell Biology, Physiology and Immunology, University of Cordoba; CIBER Physiopathology of Obesity, Cordoba, Spain.

A growing number of studies suggest that extracellular fragments derived from plasma membrane receptors can play relevant functional roles in the development and progression of certain tumoral pathologies which might, therefore, serve as novel tools in the diagnostic and prognostic of such pathologies. In this scenario, the truncated somatostatin receptor sst5TMD4, which is overexpressed in various endocrine-related cancers (i.e. breast, prostate, neuroendocrine, liver and pituitary), is an aberrant splicing variant with only 4 transmembrane domains, wherein its C-terminal tail is exposed towards the extracellular matrix and could, therefore, be the substrate for proteolytic enzymes. Thus, to explore the plausible generation of soluble peptides derived from the sst5TMD4 extracellular domain and their potential patho-physiological implications, in silico and in vitro approaches were implemented using several cancer-derived cell lines (i.e. breast, prostate, neuroendocrine and liver). Firstly, in silico analysis predicted the existence of two cleavage sites for metalloproteases (MMP). 2, 9, 14 and/or 16, which could generate the release of three possibly soluble peptides. We, then, chemically synthesized these sst5TMD4-derived peptides and demonstrated that they were able to enhance malignancy features (proliferation, migration and dedifferentiation processes) in all the tumoral cell lines tested, probably acting through PI3K/Akt and/or MEK/ERK signalling pathways. Moreover, treatment with sst5TMD4-derived peptides altered the expression pattern of several genes involved in cancer development and progression (e.g. certain MMPs, Kef7, AR/P23 or CD24/44). Therefore, based on these results, it is possible that sst5TMD4-derived peptides could be linked to the pathological role of sst5TMD4 previously observed in these tumoral pathologies. Altogether, these studies provide new information about the patho-physiological role of this truncated variant of sst5 and suggest that sst5TMD4-derived peptides could be potential candidates for future studies aimed to identify novel diagnostic, prognostic and/or therapeutic targets in certain endocrine-related cancers.

Androgen receptor activation inhibits endothelial cell proliferation through an extra-nuclear signaling pathway

Yen-Nien Huo1, Shauh-Der Yeh2, Chih-Ming Chou3 & Wen-Sen Lee4

1Graduate Institute of Medical Sciences, Medical College, Taipei Medical University, Taipei 110, Taiwan; 2Departments of Urology, Taipei 110, Taiwan; Departments of Biochemistry and Molecular Cell Biology, Taipei 110, Taiwan; 3Departments of Physiology, School of Medicine, Medical College, Taipei Medical University, Taipei 110, Taiwan.

The effect of androgen on angiogenesis has been documented. However, its molecular mechanisms underlying has not been well illustrated. Here, we show that treatment with an androgen receptor (AR) agonist, metribolone (R1881) at a range of concentrations (0.05–5 nM) or dihydrotestosterone (DHT) at a range of concentrations (0.4–40 nM) caused concentration-dependent inhibition of proliferation in human umbilical venous endothelial cells (HUVEC). The R1881-induced proliferation inhibition was also observed in human dermal microvascular endothelial cells (HDMVE). Blockade of the AR activity by pre-treatment with HF (5 nM), an AR antagonist, or knockdown of AR expression using the shRNA technique abolished the R1881-induced proliferation inhibition in HUVEC, suggesting that AR receptor activation can inhibit endothelial cell proliferation. To further delineate the signaling pathway involved in the AR activation-induced proliferation inhibition, our data indicate that R1881 inhibited proliferation in vascular endothelial cells through activating the AR/serdeK/AKT/p38/ERK/NFκB signaling pathway, which in turn up-regulated the expression of p53, p21 and p27 protein, and finally reduced endothelial cell proliferation. Using the zebrafish model, we also demonstrate that R1881 inhibited angiogenesis through the AR-mediated pathway in vivo. The findings of the present study highlight the molecular mechanisms underlying AR activation-induced proliferation inhibition in vascular endothelial cells.

DOI: 10.1530/endoabs.49.GP129
LncRNAs deregulation in PAds may be modulated by the genetic background, clusters of parathyroid tumors with different clinical activity. Moreover, conclusion, LncRNAs are deregulated in parathyroid tumors and identify 30.08 mmol/l; MEN1 including miR-296-5p, previously identified significantly downregulated in PCas. A similar analysis was applied to LncRNAs on 11p15.5 and KCNQ1OT1 unmapped on chromosome 11:

1Laboratory of Investigative Medicine, Imperial College, London, UK; 2Department of Investigative Medicine, Imperial College, London, UK; 3Milenio Therapeutics, Inc., Michigan, USA; 4Department of Gynecology, Queen Charlotte’s & Chelsea Hospital and Chelsea & Westminster Hospital, London, UK; 5Institute of Reproductive and Developmental Biology, Imperial College London, London, UK; 6Institute of Psychiatry, Psychology and Neuroscience, King’s College, London, UK; 7Mayo Clinic, Minnesota, USA; 8Scientific Partnering & Alliances, Innovative Medicines & Early Developmental Biotech Unit, Astrazeneca, Melbourne, UK; 9Division of Experimental Medicine, Imperial College, London, UK.

Aberrent epigenetic signatures have been previously determined in parathyroid tumors, in terms of microRNAs (miRNAs) and methylome deregulation. In this study, we profiled the expression of 90 long non-coding (Lnc) RNAs in 4 parathyroid carcinomas (PCas), 12 parathyroid adenomas (PAds) and 2 parathyroid glands from normocalcemic patients (PaNs). Matched mRNA profiles were available for a subset of cases. Unsupervised clustering distributes samples in two groups clearly distinguishing PCas from PaNs. Further analyses identified 9 LncRNAs significantly deregulated between PCas and PaNs, 12 LncRNAs between PAds and PaNs, and 23 LncRNAs between PAds and PCas. Five LncRNAs with a fold change > 2, namely MEG3, SGNH6 and KCNQ1OT1 downregulated in PCas, NEAT1 and HARP upregulated in PAds, were validated by qPCR in an independent series of 3 PCas, 4 atypical PAds, 22 PAds and 2 PaNs. LncRNAs and mRNA profiles showed similar expression levels of the 5 LncRNAs, whereas PAds were distinguished in two clusters with 10 PAds similar to PaNs. Clinically, PAds with the LncRNA profile similar to normal glands had lower mean serum calcium and ionized calcium than PAds with the LncRNA profile similar to PCas and PAds with intermediate profile (0.2 ± 0.5 vs 12.1 ± 0.2 vs 11.5 ± 0.8 mg/dl; P = 0.006 and 1.36 ± 0.06 P = 1.81 ± 0.11 vs 1.51 ± 0.08 mmol/l; P = 0.0001). Correlating LncRNA and mRNA profiles, we detected an association between the 5 deregulated LncRNAs and a set of miRNAs, including miR-296-5p, previously identified significantly downregulated in PCas. Finally, 10 PAds were characterized for the MEND1 gene expression level: PAds with lower nuclear menin expression had decreased expression of two LncRNAs mapping on chromosome 11: KCNQ1OT1 on 11p15.5 and NEAT1 on 11q13.1. In conclusion, LncRNAs are deregulated in parathyroid tumors and identify 3 clusters of parathyroid tumors with different clinical activity. Moreover, LncRNAs deregulation in PAds may be modulated by the genetic background, while they may be involved in miRNAs deregulation.

Findings

MEL4901 significantly reduced weekly hot flush severity, bother, and interference compared to placebo by 41% (P < 0.0001), 45% (P < 0.0001), and 58% (P < 0.0001) respectively. Treatment was well tolerated.

Interpretation

Treatment with a neurokinin 3 receptor antagonist (MEL4901) could be practice changing as it safely and effectively relieves hot flush symptoms without the need for oestrogen exposure. Larger scale studies of longer duration are now indicated. 

DOI: 10.1530/endoabs.49.GP130

Neurokinin 3 receptor antagonism as a novel treatment for menopausal hot flushes: a phase 2, randomised, double-blind, placebo-controlled trial

Julia Pragle, Rachel Roberts, Alexander Conninos, Sophie Clarke, Channa Jayasena, Zachary Nash, Chedie Doyle, Deborah Papadopoulou, Stephen Bloom, Pharis Mohidien, Nicholas Panay, Myra Hunter, Johannes Veldhuis, Lorraine Webber, Les Hounson & Waljit Dhillon

1Department of Investigative Medicine, Imperial College, London, UK; 2Milenio Therapeutics, Inc., Michigan, USA; 3Department of Gynecology, Queen Charlotte’s & Chelsea Hospital and Chelsea & Westminster Hospital, London, UK; 4Institute of Reproductive and Developmental Biology, Imperial College London, London, UK; 5Institute of Psychiatry, Psychology and Neuroscience, King’s College, London, UK; 6Mayo Clinic, Minnesota, USA; 7Scientific Partnering & Alliances, Innovative Medicines & Early Developmental Biotech Unit, Astrazeneca, Melbourne, UK; 8Division of Experimental Medicine, Imperial College, London, UK.

Background

Hot flushes affect 70% of menopausal women, can be long-lasting, and often severely impact on physical, psychosocial, sexual, and overall wellbeing. Hormone replacement therapy is effective but not without risk. Neurokinin B is an important mediator of hot flushes in rodents and elevated hypothalamic expression occurs in menopausal women. Neurokinin B acts via the neurokinin 3 receptor. Neurokinin 3 receptor antagonism could be a novel treatment for menopausal hot flushes.

Methods

This phase 2, randomised, double-blind, placebo-controlled, crossover trial assessed the effectiveness of an oral neurokinin 3 receptor antagonist (MEL4901) on menopausal hot flushes in a double-blind, placebo-controlled trial, and were included in an ITT analysis. Twenty-eight participants (aged 49–62 yrs, experiencing > 7 hot flushes/24 h some of which were reported as bothersome or severe), completed the trial, and were included in a Per-Protocol analysis. They received 4 weeks of MEL4901 and placebo in random order separated by a washout period. Randomisation was completed by a central computer, and participants were allocated to treatment number in numerical order. Primary outcome was total number of hot flushes during the final week of both treatment periods.

Findings

MEL4901 significantly reduced total weekly number of hot flushes by 45% compared to placebo (adjusted means: placebo 49.01 (SE 8.01–58.56), MEL4901 19.35 (SE 15.99–23.42), P < 0.0001) (ITT). MEL4901 also significantly reduced weekly hot flush severity, bother, and interference compared to placebo by 41% (P < 0.0001), 45% (P < 0.0001), and 58% (P < 0.0001) respectively. Treatment was well tolerated.

Different animal models have been used to study the postnatal effect of a prenatal exposure to an androgen excess on the female offspring. We have established a sheep model to test the hypothesis that the intrauterine environment of the PCOS mother may play a role in the etiology of the PCOS. In this regard, our sheep model for the study of PCOS has the advantage that provides mainly an androgenized milieu to the fetus in comparison to pregnant PCOS women who offers a hyperandrogenic and hyperinsulinemic intrauterine environment to the fetus. Previous results from our laboratory have demonstrated that female sheep born to mothers receiving testosterone (T) during part of their pregnancy exhibit features from early postnatal life until adulthood resembling those of PCOS women. In the present work the programming effect of prenatal T on the IS was explored in adult females born to T treated mothers (T-females), and born to untreated mothers (C-females). Our aim was to establish if exogenous T may exacerbate the insulin resistance due to programming effect of prenatal exposure to T. Both groups were injected with T, twice weekly (40 mg per dose), for 8 weeks, beginning at 30 weeks of age. Females were estrous synchronized with progesterin and 48 hours after the last T dose, an IVGTT was carried out. On the day of the IVGTT, there was no difference in plasma concentration of estradiol, progesterone and T between groups. IS indexes were calculated with the plasma insulin and glucose concentrations during the IVGTT. Plasma levels of glucose were not different during the IVGTT but T-females secreted more insulin (P < 0.005) than C-females. The ratio insulin/glucose before the IVGTT tends to be higher in T-females (P = 0.054) and the IS Index-C tended to be lower in T-females compared to C-females (P = 0.054). Results show that T administration to T-females amplifies the effect of a glucose challenge on the insulin secretion compared to C-females, suggesting an exacerbation of the insulin resistance induced by fetal programming.

Influence of BMI on AMH levels in non-PCOS women
Joana Simões-Pereira, Joaquim Nunes, Ana Aguiar, Sandra Sousa, Cátia Rodrigues, J Sampaio Matias & Carlos Calhaz-Jorge
1Endocrinology Department, Instituto Português de Oncologia de Lisboa, Francisco Gentil, Lisbon, Portugal; 2Reproductive Medicine Unit, CHLN-Hospital de Santa Maria, Lisbon, Portugal; 3Clinic Pathology, CHLN-Hospital de Santa Maria, Lisbon, Portugal.

Introduction
Anti-Mullerian Hormone (AMH) is a useful marker of ovarian reserve (OR); since it remains stable inter/intra-cycles and presents a good correlation with ultrasonographic antral follicular count. Obesity/overweight are increasing and may affect the reproductive health. However, previous studies regarding the effect of body mass index (BMI) on AMH levels are discordant. Our main goal was to evaluate the influence of BMI in AMH levels in women with infertility.

Methods
Revision of medical records of 995 women who performed AMH determinations as part of their fertility workup, between 2011–2016. Women diagnosed with polycystic ovarian syndrome (Rotterdam criteria) were excluded. We analysed the influence of BMI, age, ethnicity, smoking and previous ovarian surgery on AMH levels.

Results
Median AMH concentration was 1.750 (0–26) mg/dL and median age at AMH determination was 35 (19–40) years. These women evidenced a median BMI of 23.15–39 kg/m² and had been struggling with infertility for 60 (7–432) months. The majority [700 (70.4%)] presented primary infertility. Caucasian women were more represented [889/893 (3.5%)].

Smoking habits (present/past) were present in 359 (36.1%), and 147 (14.8%) harboured a history of ovarian surgery. On univariable analysis AMH was not correlated with BMI (r = 0.52, p = 0.10); the only factors influencing AMH were age (p = 0.001), ethnicity (p = 0.005) and previous surgery (p < 0.001). On multivariable analysis, age was the only variable significantly associated with AMH, evidencing a reduction of 6.2% for each additional year (p < 0.0001). Furthermore, we verified a trend suggesting an AMH reduction of 22% (p = 0.08) in melanodermic patients comparing with the caucasian ones, when controlling for the other variables.

Conclusion
We report one of the largest series evaluating the influence of BMI on AMH levels and, consequently, on OR. BMI does not seem to affect AMH levels. The reported concerns on infertility in overweight/obese women may be related to follicular development/endothelial disorders, rather than decreased OR.

Relugolix, an oral gonadotropin-releasing hormone (GnRH) receptor antagonist, in women with endometriosis (EM)-associated pain: Phase 2 safety and efficacy 24-week results
Yutaka Osugi1, Yoshifumi Seki1, Masataka Tamimoto2, Takero Kusumoto2, Kentaro Kudo1 & Naoki Terakawa1
1The University of Tokyo, Tokyo, Japan; 2Takeda Pharmaceutical Company Limited, Osaka, Japan; 3Tottori University Faculty of Medicine, Yonago, Japan.

Objective
The objective of this Phase 2 study was to evaluate the safety of relugolix when administered for 24 weeks in women with EM-associated pain. Efficacy was exploratory assessed using leuprorelin as a reference.

Design
This was an open-label extension study evaluating safety of 3 doses (10 mg, 20 mg, and 40 mg) of relugolix administered orally once daily for a period of 24 weeks in women with EM-associated pain, who had participated in a preceding 12-week study.

Materials and methods
Premenopausal women with EM-associated pain who completed a preceding 12-week study and were eligible to continue for an additional 12-week treatment were enrolled. The primary endpoint was the safety including assessment of change in bone mineral density using dual energy x-ray absorptiometry. Analysis sets were defined as all patients who were administered the study drug.

Results
Among the randomized patients in the preceding study (N = 487), 397 were enrolled in this extension study; 77 to placebo, 78 to 40 relugolix groups, and 69 to leuprorelin. Baseline characteristics were similar between randomized patients and all patients who entered the extension study. The incidences of adverse events including metrorrhagia, menorrhagia, and hot flush in the relugolix 40 mg group were similar to those in the leuprorelin group. Dose-dependent bone density loss was observed with relugolix treatment, with the relugolix 40 mg result consistent with the leuprorelin result. The change from baseline in mean visual analogue scale score for pelvic pain (in mm) during the last 4 weeks of treatment period was −3.222 in the placebo group, −6.849, −9.032, and −11.924 in relugolix 10 mg, 20 mg and 40 mg groups, respectively, and −12.552 in the leuprorelin group. Estradiol levels decreased with increasing dose of relugolix and were maintained below the postmenopausal levels throughout the 24-week relugolix 40 mg treatment period.

Conclusion
Treatment with relugolix for 24 weeks was generally well tolerated and demonstrated similar pelvic pain reduction as leuprorelin in women with EM. Relugolix, a once-daily oral nonpeptide GnRH receptor antagonist, demonstrated similar benefit to injectable leuprorelin in this Phase 2 study.

Brown adipose tissue thermogenesis in women with polycystic ovary syndrome
Soulmaz Shorakae1,2, Eveline Jona1, Barbara de Courten1,2, Gavin Lambert1, Elisabeth Lambert, Sarah Phillips, Iain Clarke4, Helena Teele1,2 & Belinda Henry
1Monash Centre for Health Research and Implementation, Monash University, Melbourne, Australia; 2Diabetes and Vascular Medicine Unit, Monash Health, Melbourne, Australia; 3Human Neurotransmitters Laboratory, Baker IDI Heart & Diabetes Institute, Melbourne, Australia; 4Department of Physiology, Monash University, Melbourne, Australia; 5Neuroscience Program, Monash Biomedicine Discovery Institute, Department of Physiology, Melbourne, Australia; 6Obesity Program, Monash Biomedicine Discovery Institute, Department of Physiology, Melbourne, Australia.

Polycystic ovary syndrome (PCOS) is the most common endocrinopathy of reproductive age women and is characterized by reproductive, metabolic and psychological features exacerbated by weight gain. Weight management in PCOS is challenged by propensity to weight gain and lack of sustainable dietary interventions. Body weight is regulated by calorie intake and the rate of energy expenditure. Metabolically active brown adipose tissue (BAT), contributing to energy dissipation, has been described in humans. The thermogenic activity of BAT is controlled by the sympathetic nervous system (SNS). Sex hormones also play a role in modulating BAT. Human studies confirm association of supraclavicular skin temperature, where most human BAT is located, with BAT activity. This observational study aimed to explore BAT thermogenesis and its associations, for the first time, in PCOS. Cutaneous wireless temperature probes (2 cm diameter, 0.5 depths) were taped to supraclavicular (BAT) and upper arm (muscle) regions of 49 premenopausal women with PCOS, over 96 hours, (mean age: 29.85±5.93, mean BMI: 29.02±5.43), recruited from community. Multimodal muscle SNS activity (by microneurography) and plasma noradrenaline levels were measured as markers of SNS activity. Fasting lipids, serum androgens, markers of insulin resistance and inflammation were measured. Recorded temperature data from both regions were available in 41 participants. Supraclavicular temperature was significantly higher than arm temperature (33.87±0.65 vs 32.23±0.85, P < 0.0001). Supraclavicular temperature correlated with testosterone (r = −0.410, P = 0.011), noradrenaline (r = −0.488, P = 0.005) and triglycerides (r = −0.393, P = 0.015) which remained significant after adjustment for BMI. Arm temperature did not correlate with testosterone, noradrenaline and triglycerides. This is the first study of BAT thermogenesis in PCOS using cutaneous temperature probes. The negative correlation of BAT temperature with noradrenaline levels could implicate a maladaptive thermogenic response to chronic SNS activation in PCOS. Chronic sympathoexcitation and hyperandrogenism play potential roles in modulation of BAT thermogenesis in PCOS.

Dipeptidyl peptidase-4 (DPP-4) inhibitor sitagliptin improved beta cell function and prevented a conversion rate to MTG and DM2 in metformin intolerant PCOS with high metabolic risk
Andrea Janez, Simona Ferjan & Mojca Jensterle
University Medical Center Ljubljana, Ljubljana, Slovenia.

Objective
Metformin is the first-line therapy for PCOS with high metabolic risk, yet a large proportion of patients cannot tolerate it due to associated gastrointestinal adverse events. The alternative pharmacological strategy when metformin cannot be tolerated is not well established in this population. Our aim was to evaluate whether sitagliptin (SITA) preserves metabolic profile in metformin (MET) intolerant PCOS with high metabolic risk.

Design and methods
A 12-week prospective randomized open-label study was conducted with 30 obese MET intolerant women with PCOS (aged 35.0±7.2 years, BMI 36.9±5.5 kg/m²). They were randomized to lifestyle intervention and SITA 100mg QD or lifestyle intervention alone as controls (CON). All participants underwent standard anthropometric, endocrine measurements and OGTT. Model derived indexes of insulin resistance (IR) and β-cell function were calculated.

Results
SITA improved beta cell function as assessed by HOMA beta for 45.9±35.8 (P=0.001), modified beta cell function index (MBCI = 10×G0/G(120)+G(60)-7) for 7.9±7 (P=0.002) and QUICKI for -0.03±0.03 (P=0.002) and increased IR as assessed by HOMA-IR and insulin action index (IAI = 1/G0XIR) for 1.8±1.7 (P=0.002) and -0.01±0.01(P=0.003). By contrast, beta cell function decreased in CON arm. The between group differences were significant for HOMA-beta (P=0.000), MBCI (P=0.010) and QUICKI (P=0.025). The conversion rate from normal glucose tolerance to impaired glucose tolerance (IGT) or T2DM was prevented in SITA (3/15 of subjects with MTG before and after the study). In CON 4 women had IGT at the beginning. After 12 weeks IGT was observed in 2 and T2DM in 3 subjects.

Conclusion
SITA improved beta cell function and prevented a conversion rate to IGT and T2DM in metformin intolerant PCOS with high metabolic risk when compared to lifestyle alone.

Genetic susceptibility for adrenal hyperandrogenism in polycystic ovary syndrome
Nicoleta Baculescu1,2, Sarah Haydar3, Monica Livia Gheorghiu1,2, Serban Radian1,2, Corinne Lautier3, Catalina Poiana1,2, Michel Pugeat4 & Florian Grigorescu1
1Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2C.I. Parhon Institute of Endocrinology, Bucharest, Romania; 3UMR-204 NUTRIPASS, University of Montpellier, Montpellier, France; 4Fédération d’Endocrinologie, Hôpital Neuro-Cardio, University of Lyon, Lyon, France.

Background
Hyperandrogenism is a main feature of the polycystic ovary syndrome (PCOS). Although its ovarian origin is well recognized, laboratory investigation suggested the contribution of adrenal gland, albeit of unknown mechanism.

Aim
To understand the contribution of genetic factors in adrenal hyperandrogenism (AH) we investigated genome wide SNPs in subgroups of PCOS patients stratified as function of DHEAS levels in two ethnic populations (Romanians and French).

Subjects and methods
Patients recruited during European MEDIGENE program (FP7-279171) with PCOS (n=307) of 18–42 years old were stratified in two groups as function of DHEAS level greater than 95th percentiles in age-matched controls. Genotyping was performed with customized MEDISCope microarray chip with 759 000 SNP. Influential SNPs were determined by correlation trend (CT) test and then by genetic association in two subgroups of patients.

Results
Despite no difference in total-testosterone levels, in PCOS with AH (n=58, 18.9%) the SHBG (27.6±3.6 vs 44.5±3.3 nmol/L, P=0.0002) was lower and FAI (14.0±2.2 vs 8.7±0.7, P<0.002), 2-h insulin in OGTT (111.2±26.0 vs 77.3±6.9 mU/L, P=0.044) and systolic BP (123.7±4.6 vs 114.4±4.4 mmHg, P<0.045) were higher than in PCOS without AH. SNPs corresponding to at least 15 genes were positive in CT test with DHEAS levels. Among them, INS1R and CDH13 were the most significant with numerous SNPs having a P value < 1.0X10-5 after Bonferroni correction. In genetic association by logistic regression between two groups, other genes were also confirmed, the most influential being IL2RA, PTER, SORCS1, LG4R and KR2. For instance, LG4R (Chr 11) was associated with P<0.005, OR 5.6, 95%CI [1.6–19].

Conclusion
These data indicated that, in PCOS patients, AH may be in part explained by genetic susceptibility. Despite a full array of genes involved, the insulin-resistance appears as potential actor of AH in PCOS.

DOI: 10.1530/endoabs.49.GP137

Turner’s syndrome and abnormal liver chemistry: relationship with karyotype in a large dedicated clinic
Matilde Calanchini1,2, Ahmad Moolla1, Jeremy W Tomlinson1, Jeremy Cobbold1, Andrea Fabbi1, Ashley Grossman1 & Helen Turner1
1Oxford Centre for Diabetes, Endocrinology and Metabolism – Churchill Hospital, University of Oxford, Oxford, UK; 2Department of Hepatology, John Radcliffe Hospital, Oxford, UK; 3Department of Endocrinology, CTO Alesini & S. Eugenio, University of Rome Tor Vergata, Rome, Italy.

Introduction
Abnormal liver function tests (ALT) are frequently observed in Turner’s syndrome (TS), although the aetiology is unclear. Obesity is reported as one of the causes; recently an increased prevalence of elevated GGT was found in TS patients with a ring X karyotype.

Aim
To analyse the association between abnormal LFTs and TS-related conditions, in particular their relationship with the different TS-karyotypes.

Methods
Data on adult TS-patients were collected. ALT was defined as elevated aminotransferases ± GGT and ALP, for more than 6 months. TS-karyotypes were classified in eight groups.

Results
109 TS women were studied: mean age 36(±13) y, BMI 28.3(±6.9) Kg/m², 45.X was found in 47 patients (46.1%), mosaicism 45,X/46,XX or 45,X/47,XXX in 15 (15.7%), 4 (3.9%) del(X)(p), 1 (1%) del(X)(q), 10 (9.8%) isochromosome(X)(q), 10 (9.8%) ring X, presence of Y in 4 (3.9%) and 10 (9.8%) other TS-karyotypes. 38/109 (35%) presented with ALTs, most frequently a GGT. Differences between the normal-LFTs-group versus the ALTs-group were found for age (33.8 vs 41y, P=0.008), Tot-Chol (4.9 vs 5.5 mmol/L, P=0.005), LDL-Chol (2.7 vs 3.2 mmol/L, P=0.006), and triglycerides (1.1 vs 1.5 mmol/L, P=0.02). No differences were noted analysing anthropometric values, HbAlc, history of diabetes, hypertension or autoimmunity.

The prevalence of ALTs was significantly higher in the isochromosome(X)(q)-group (P=0.0003); the mosaicism-group had a decreased prevalence of ALTs (P=0.0092). Using the stringent ALT cut-off of 19UI/L, this was commoner only in the isochromosome(X)(q)-group (P=0.0134). The (X)(q)-group showed a similar clinical phenotype compared to 45,X and no increased prevalence of autoimmune disease.

Conclusions
This study shows 1) ALTs are common in TS; 2) the prevalence of ALTs increases with age and is associated with increased cholesterol and triglycerides; 3) for the first time, a relationship between ALTs and karyotype was found, suggesting that liver biochemical abnormalities could be triggered by over-expression of Xq genes escaping inactivation.

Sensitivity of hypothalamo-pituitary-adrenal axis in women with PCOS

Djuro Macic1, Ivana Bozic-Antic1, Jelica Bjekic-Macic2, Dusan Illic1, Danijela Vojnovic-Milutinovic2, Olivera Stanojlovic2, Tamara Bogavac1, Bojana Popovic1, Tatjana Isailovic1, Valentina Elezovic1 & Sanja Ogjjanovic1

1Clinic of Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; 2CHC Bezanjska kosa, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction
Increased adrenal androgen production is present in 20–60% of women with polycystic ovary syndrome (PCOS). Possible mechanism is not clarified yet and could be related to altered hypothalamic-pituitary-adrenal-axis (HPA) activity or a consequence of adrenocortical steroidaligenic abnormalities. The aim of the study was to assess HPA sensitivity in PCOS women using different doses of dexamethasone.

Methods
We analyzed 359 women with PCOS diagnosed using ESHRE/ASRM criteria (age: 25.6±5.3 years, BMI: 25.1±6.4 kg/m²), and 58 BMI-matched healthy controls (age: 28.7±6.1 years, BMI: 23.7±6.1 kg/m²). In all subjects serum ACTH, morning serum cortisol (SC), and DHEAS were measured, and SC and DHEAS determined after overnight dexamethasone test with 0.5 mg (Dex0.5mg), and 1 mg (Dex1mg), and marked as SC_dex0.5, SC_dex1, DHEAS_dex0.5 and DHEAS_dex1, respectively. Differences between groups were age adjusted and data are presented as ANCOVA-mean (%±IC).

Results
SC was borderline higher [437.9(421.6–454.3) vs. 395.7(356.7–437.8)nmol/ml, P=0.052] and DHEAS significantly higher [7.7(7.3–8.2) vs. 5.6(4.6–6.7)nmol/l, P<0.001] in PCOS than in controls. There was no difference in ACTH among groups. After dexamethasone tests, both groups significantly lowered SC and DHEAS in comparison to basal analyses. In comparison to controls, PCOS had borderline higher SC_dex1 [49.9 (22.9–76.9) vs. 78.5(67.8–89.1)nmol/l, P=0.055] but similar percentage of SC suppression [86.5 (80.6–92.3) vs. 82.8(80.4–85.3)%, P=0.26]. PCOS had lower SC_dex0.5 [26.8 (23.5–30.2) vs. 29.9(26.5–34.2)mmol/l, P<0.051] and suppressed SC more than controls [92.5(90–95.5) vs. 94.5(94–97.5)%, P<0.001]. There were no differences in DHEAS_dex0.5, DHEAS_dex1 between groups. Suppression of DHEAS was similar after Dex0.5mg (P=0.92), but PCOS suppressed DHEAS after Dex1mg less than controls [32.1 (25.9–38.3) vs. 47.7(34.0–61.4)% P=0.04].

Conclusions
Our women with PCOS, in comparison to BMI-matched controls increased HPA axis sensitivity to 1 mg but not to 0.5 mg of dexamethasone. DHEAS production in PCOS seems to be more independent of ACTH than in controls.

Nonalcoholic fatty liver disease liver fat score (NAFLD-LFS) could be used for the assessment of NAFLD in women with PCOS

Jelica Bjekic-Macic1, Ivana Bozic-Antic2, Konstantinos Tziomalos3, Dusan Illic1, Danijela Vojnovic-Milutinovic2, Olivera Stanojlovic2 & Djuro Macic1

1CHC Bezanjska kosa, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; 2Clinic of Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; 3Department of Medicine, University of Thessaloniki, Thessaloniki, Greece.

Introduction
A relation between polycystic ovary syndrome (PCOS) and nonalcoholic fatty liver disease (NAFLD) was demonstrated recently. Both PCOS and NAFLD are associated with increased risk for type 2 diabetes and cardiovascular disease. NAFLD liver fat score (NAFLD-LFS) has been implicated as a non-invasive surrogate marker for NAFLD. The aim of this study was to identify the prevalence of NAFLD in different PCOS phenotypes using NAFLD-LFS.

Methods
We evaluated 489 obese PCOS women (PCOS: 33.2±5.7kg/m²; 25.6±6.2 years) diagnosed using ESHRE/ASRM criteria and BMI-matched obese healthy women (controls: 32.5±5.5kg/m²; 31.7±5.1 years). PCOS group was divided into 4 phenotypes: A (anovulatory (ANOV), hyperandrogenism (HA), polycystic ovary morphology (PCOM)), B (ANOV,HA), C (HA,PCOM) and D (ANOV,PCOM). NAFLD was assessed using NAFLD liver fat score (NAFLD-LFS) cutoff > −0.640. Differences between groups were age adjusted.

Results
NAFLD was more prevalent in PCOS in comparison to controls (59.7 vs 44.4%, P=0.009). Our PCOS group consisted of 268 women with phenotype A, 129 with phenotype B, 47 with phenotype C and 35 with phenotype D. Prevalence of NAFLD in phenotypes were: A: 59%, B:61%, C:53% and D:66%. There were significant differences in the prevalence of NAFLD between controls and phenotype A (P=0.015), phenotype B (P=0.015) and phenotype D (P=0.028). There were no significant differences between phenotypes.

Conclusions
NAFLD is more prevalent in obese PCOS women than in obese BMI-matched controls. All four phenotypes have the same risk for NAFLD which confirms susceptibility of PCOS as a whole to develop metabolic derangements.

Effects of central sympathoinhibition with moxidone on the elevated sympathetic nervous activity and downstream metabolic abnormalities observed in polycystic ovary syndrome

Soulimaz Shoraka1,2, Elisabeth Lambert1,4, Eveline Jona1, Carolina Ika Sari1, Barbora de Courten1,2, Gavin Lambert1,4 & Helena Teede1,2

1Monash Centre for Health Research and Implementation, Monash University, Melbourne, Australia; 2Diabetes and Vascular Medicine Unit, Monash Health, Melbourne, Australia; 3Human Neurotransmitters Laboratory, Baker IDI Heart & Diabetes Institute, Melbourne, Australia; 4Department of Physiology, Monash University, Melbourne, Australia.

The role of the sympathetic nervous system (SNS) in the pathophysiology of PCOS, a metabolic syndrome associated with increased risk for type 2 diabetes and cardiovascular disease, is an active area of interest. Our previous studies have demonstrated that increased SNS activity in PCOS, potentially contributing to metabolic features via multiple mechanisms including insulin resistance, may be driven by increased SNS activity, which may also be driven by increased SNS activity, which may also be driven by increased SNS activity.

Methods
We analyzed 359 women with PCOS diagnosed using ESHRE/ASRM criteria (age: 32.5±5.1 years). PCOS group was divided into 4 phenotypes: A: 32.1±5.1 years, mean BMI: 29.0±5.4 kg/m², P<0.001] in PCOS vs. 27.5±4.7 years, mean BMI: 26.3±4.5 kg/m², P<0.001] in controls. There were no differences in age, BMI, menstrual cycle, PCOM, or phenotype B (P<0.015), phenotype C (P<0.052) and phenotype D (P<0.056) between groups.

Conclusions
Our women with PCOS, in comparison to BMI-matched controls increased HPA axis sensitivity to 1 mg but not to 0.5 mg of dexamethasone. DHEAS production in PCOS seems to be more independent of ACTH than in controls.

Steroid receptors involvement in enamel hypomineralization resulting from exposure to low-dose DEHP and bisphenol A

Bui Ai Thu1,2, Sophia Houari1,2, Sophia Loiodice1,2, Katia Jedeon1,2, Ariane Berdal1,2 & Sylvie Babajko1,2

1University Paris Diderot, Paris, France; 2INSERM, Paris, France.

The environment has become increasingly contaminated by various pollutants including endocrine disrupting chemicals (EDCs). This has led to an increase in the incidence and gravity of known pathologies and the emergence of new ones, including dental pathologies as the Molar Incisor Hypomineralization (MIH).

The effects of low-dose DEHP and bisphenol A (BPA) on enamelogenesis have been investigated in vitro and in vivo. The aim of the study was to investigate the role of steroid receptors in enamel hypomineralization resulting from exposure to low-dose DEHP and bisphenol A (BPA).

Materials and Methods
The effects of low-dose DEHP and bisphenol A (BPA) on enamelogenesis have been investigated in vitro and in vivo. The aim of the study was to investigate the role of steroid receptors in enamel hypomineralization resulting from exposure to low-dose DEHP and bisphenol A (BPA).

Results
The results showed that low-dose DEHP and bisphenol A (BPA) exposure led to a decrease in enamel mineralization, as assessed by microradiography and microanalysis. The expression of steroid receptors, including estrogen receptors α and β, as well as androgen receptor (AR), was significantly increased in enamel exposed to low-dose DEHP and bisphenol A (BPA). The results suggest that steroid receptors play a crucial role in enamel hypomineralization resulting from exposure to low-dose DEHP and bisphenol A (BPA), and that these receptors may be targets for interventions aimed at reducing the incidence of MIH.

Conclusions
The results of this study suggest that low-dose DEHP and bisphenol A (BPA) exposure leads to a decrease in enamel mineralization, as assessed by microradiography and microanalysis. The expression of steroid receptors, including estrogen receptors α and β, as well as androgen receptor (AR), is significantly increased in enamel exposed to low-dose DEHP and bisphenol A (BPA). The results indicate that steroid receptors play a crucial role in enamel hypomineralization resulting from exposure to low-dose DEHP and bisphenol A (BPA), and that these receptors may be targets for interventions aimed at reducing the incidence of MIH.
We previously showed a link between experimental exposures to low-dose BPA and enamel defects similar to MIH (1). The characterization of enamel defects may be helpful to propose them as early markers of exposure to EDCs thanks to enamel unique properties.

The aims of the present work are 1) to compare mouse enamel defects resulting from exposure to low-dose BPA and/or DEHP and, 2) to approach the mechanism, of action of both EDCs during amelogenesis.

The study was carried out on mice exposed to 5 and 50 mg/kg per day DEHP with or without 5 μg/kg per day BPA. Exposed animals present enamel defects on their incisors with similar characteristics than those of MIH affected teeth. In addition, 11% of DEHP mice presented enamel breakdown suggesting a weak enamel structure. As both EDCs act through steroid receptors, their presence and expression levels were investigated in ameloblasts by immunofluorescent assays and RT-qPCR respectively. We found that dental epithelium express a specific combinatorial of steroid receptors (AR, ERs, ERRs, RARs/RXRα, VDR, GR, MR and PGR) depending on their stage of differentiation. These data suggest that depending on their nature and the time of exposure, pthialsates and BPA could affect enamel quality (and through AR) and/or quantity (through ERRy and ERRz).

Studies are currently driven to decipher the functional role of AR in the mechanism of action of both EDCs in ameloblasts.

Altered protein expression of cell cycle- and EMT-associated genes by bisphenol compounds in MCF-7 CV human breast cancer cells via estrogen receptor dependent pathway
Ana Patricia Ayala-Cuellar, Kyung-A Hwang & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Bisphenol-A (BPA) has been considered as an endocrine disrupting chemical (EDC) because it can exert estrogenic properties. For bisphenol-S (BPS) and bisphenol-F (BPF) that are BPA analogs and substitutes, their risk to estrogen-dependent cancer has been reported rarely compared with the numerous cases of BPA. In this study, we examined whether BPA, BPS, and BPF can lead to the proliferation, migration, and epithelial mesenchymal transition (EMT) of MCF-7 clonal variant (MCF-7 CV) breast cancer cells by expressing estrogen receptors (ERs). In a cell viability assay, BPA, BPS, and BPF significantly increased proliferation of MCF-7 CV cells compared to control (DMSO) as did 17β-estradiol (E2). In Western blot assay, BPA, BPS, and BPF enhanced the protein expression of cell cycle progression genes such as cyclin D1 and E1. In addition, MCF-7 CV cells lost cell to cell contacts and acquired fibroblast-like morphology by the treatment of BPA, BPS, or BPF for 24 h. In cell migration assay, BPA, BPS, and BPF accelerated the migration capability of MCF-7 CV cells as did E2.

In relation with the EMT process, BPA, BPS, and BPF increased the protein expression of N-cadherin, while they decreased the protein expression of E-cadherin. When BPA, BPS, and BPF were co-treated with ICI 182,780, an ER antagonist, proliferation effects were reversed, the expression of cyclin D1 and cyclin E1 was down-regulated, and the altered cell migration and expression of N-cadherin and E-cadherin by BPA, BPS, and BPF were restored to the control level. Thus, these results imply that BPS and BPF also have the risk of breast cancer progression as much as BPA in the induction of proliferation and migration of MCF-7 CV cells by regulating the protein expression of cell cycle-related genes and EMT markers via ER-dependent pathway. (This work was supported by a grant from the Next-Generation BioGreen 21 Program (no. PJ011355-2015), Rural Development Administration, Republic of Korea.)

Reproductive toxicity of low dose nonylphenol in mice: a two-generation study
Sung-Ho Lee, Yong Bin Kim & Hee Su Kim
Sangmyung University, Seoul, Republic of Korea.

Nonylphenol (NP), a member of alkylphenol family, has been widely used in both industry and household. NP is classified as an endocrine-disrupting chemical and is known to act as an agonist of the GPER (GPR30). The aim of this study was to address the two-generational effects of para-nonylphenol (NP) on the body weights, reproductive organ weights and histopathologies of ICR mice. We also test the potential reproductive toxicity of octylglucuronide (OG), a substitute candidate for NP. The testing drugs were administered as drinking water (50 and 500 μg/l) throughout the pre-mating period of P0 animals and lactation of F2 animals. Significant decreases were found in the weights of testis, prostate and seminal vesicle in the F1 NP50 group, in the weights of testis and epididymis in F2 NP50 and NP500 groups. There was no weight change in the OG-treated groups. In female, significant decreases in the weights of ovary and uterus in F1 NP50 group, uterus of F1 NP500 group, and F2 NP500 group were found. The weights of ovary in F1 OG50 and OG500 were also significantly decreased. Histopathological studies revealed that the numbers of Leydig cells were reduced in the testes of F1 and F2 NP50 groups. There were no changes in the Leydig cell numbers of OG groups. In F1 NP500 mice, the increased numbers of primary and secondary follicles and decreased number of corpora lutea were observed. There was no change in OG-treated group gonad. Finally, vaginal opening was delayed in F1 NP50 and NP500, and F2 NP50 animals. Present study demonstrated that the potential reproductive toxicity in animals long-term exposed to low dose NP (approximately 15–150 ng of daily intake). Our study also show that OG seems to be a promising alternative to NP, and further studies are warranted. This work was supported by the National Research Foundation of Korea Grant funded by the Korean Government (NRF-2016N004200).

Psychological rather than organic and/or relational components are involved in sexual dysfunction in Young/Middle aged human immunodeficiency virus (HIV)-Infected Men
Maria Chiara Decaroli1, Sara De Vincents1, Chiara Diazza1, Stefano Zona2, Giovanni Guaraldi1, Daniele Santi1 & Vincenzo Rocchic1
1Unit of Endocrinology, University of Modena and Reggio Emilia, Modena, Italy; 2Unit of Infectious Diseases, University of Modena and Reggio Emilia, Modena, Italy.

Background
HIV-infection is associated to an increased prevalence of erectile dysfunction (ED). In HIV-infected men ED seems to be less related to serum Testosterone (T), depending from other factors.

Aim
To investigate the role of different components (organic, relational, psychological) of erectile function by using validate questionnaires in HIV-infected men with normal serum T.

Methodology
Prospective, cross-sectional, observational study on eugonadal HIV-infected male patients with ongoing Highly Active Antiretroviral Therapy (HAART) attending the Clinic of Infectious Diseases. The International Index of Erectile Function (IIEF)-15, IIEF-5 and Structured Interview for Erectile Dysfunction (SIEDY) were used to assess sexual function. Sexual desire was further evaluated through a direct question during the visit. LC-MS/MS was used to assess gonadal status.

Results
225 HIV-infected patients were enrolled (mean age 45.19±5.36 years). SIEDY scores at appendix and scale 3 were significantly higher in patients with ED at IIEF-15 (n = 136, 60.4%) compared with those without ED (P < 0.001 and P = 0.015, respectively). Conversely, scale 1 (P = 0.448) and 2 (P = 0.503) of SIEDY did not differ between patients with or without ED, suggesting a predominance of the psychological basis of ED in our cohort. The erectile function domain at IIEF-15 was directly correlated with IIEF-5 score (0.778, P < 0.001). Similarly, the score at SIEDY appendix was significantly different among ED degrees at IIEF-15 (P < 0.001). In particular, lower score was found in HIV-infected men without ED compared to those with mild, moderate and severe ED (P < 0.001, P = 0.001, and P < 0.001, respectively), confirming the reliability of these tools. Sexual desire was impaired in 73 patients (31.33%) at interview with a good correlation with the specific item of IIEF-15 (P < 0.001).

Conclusions
The psychological component impacts in a significant manner on ED in HIV-infected context. Despite the high prevalence of comorbidities in these patients, the organic component does not affect erectile function. All the three validated questionnaires seem to be trustworthy in the diagnosis of ED in this setting.

Effects of physical exercise or metformin on testosterone deficiency and erectile dysfunction associated to metabolic syndrome
Linda Vignozzi1,2, Sandra Firmo1, Paolo Comeglio1, Ilaria Cellari1, Francesca Corcetto1, Chiara Cornò2 & Mario Maggi2
1Interdepartmental Laboratory of Functional and Cellular Pharmacology of Reproduction, Department of Neuroscience, Psychopharmacology, Drug Research and Child Care, University of Florence, Florence, Italy; 2Sexual Medicine and Andrology Unit, Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; 3INBB, Rome, Italy.

Metabolic Syndrome (MetS) is a cluster of clinical conditions, associated to an increased cardiovascular and metabolic risk, to hypogonadism and erectile dysfunction (ED). Lifestyle modification (including physical exercise, PhyEx) and metformin (MET) are well-known treatments for the condition. We established an animal model of MetS that recapitulates the human phenotype, including andrologic derangements.

The aim of this study was to investigate in experimental MetS the effect of PhyEx or MET on penile erection and on hormone and metabolic parameters. Control (RD) and MetS rabbits were treated with MET (the last 18 days) or exercise-trained to run on a treadmill for 12 weeks. Penile tissue was collected for in vitro contractility study or gene expression.

MET, but not PhyEx, induced a reduction in visceral adiposity, blood pressure, triglycerides, glucose level and tolerance. MET increased testosterone (T), whereas PhyEx completely restored it. Ach-induced relaxation, hampered in MetS rabbits, was significantly ameliorated by MET and completely normalized by PhyEx. HFD determined a net reduction of electrical field (EF)-vasorelaxation in CC. The relaxant response to sildenafil, abolished in HFD rabbit CC, was restored by PhyEx. PhyEx normalized sodium nitroprusside (SNP)-induced relaxation, that was enhanced in MetS rabbits. Genes related to NO signaling were up-regulated by PhyEx, but not by MET. Similar results were obtained for smooth muscle-related genes. PDE5 expression was decreased in MetS rabbits and completely restored by PhyEx. Accordingly, sildenafil-induced increase in SNP relaxation was completely normalized by PhyEx.

In conclusion, PhyEx more than metformin, completely restored T levels and responsiveness to Ach and sildenafil in experimental MetS, even though it was less effective than metformin in reducing metabolic abnormalities. The effect of exercise training is most probably related to an improved NO signaling, including PDE5. Hence, PhyEx can be considered a new strategy to treat hypogonadism and ED related to MetS.

Background
Radioactive iodine therapy (RAI) is a classical therapeutic approach in patients with differentiated thyroid carcinoma (DCT). Few data are currently available on RAI’s potential impacts on testicular function.

Design
A longitudinal prospective multi-center study (PHRC N°040419) included male patients before a single radioiodine dose of 3.7 GBq of I 131 (V0), at 3 months (V3) and 13 months (V13) post treatment.

Method and Patients
Hormonal assessments (FSH, LH, Testosterone, inhibin B) as well as sperm parameters (number, mobility and morphology), DNA fragmentation and sperm FISH analysis in order to detect chromosomal abnormalities were performed at V0, V3 and V13.

Results
Thirty six patients were included in the study. At V0, all patients had normal gonadal function. At V3, FSH median levels were significantly increased as compared to V0, respectively 9 UI/l ± 4 (6–17 UI/l) versus 4 UI/l ± 3 (P < 0.0001). Between V3 and V13, FSH levels decreased but remained higher than baseline levels. Inhibin B median levels decreased significantly at V3 (P < 0.001) and returned to V0 levels at V13. LH and T levels were not modified at V3 or V13. Median sperm concentration significantly decreased at V3 as compared to V0 (20 vs 48 million/ml; P = 0.0001) and returned to V0 levels at V13. In parallel, a statistically significant decrease in sperm morphology was observed at V3. Sperm mobility and DNA fragmentation were not modified after RAI. However sperm chromosomal abnormalities were increased at V3 (P < 0.0005) and V13 (P < 0.01), as compared to V0.

Conclusion
In this prospective study, RAI transiently altered FSH, inhibin B and sperm number. Furthermore, chromosomal abnormalities observed at V3 were found to persist 13 months after RAI. Therefore, our study illustrates that counseling about fertility could be interesting in male patients with DCT treated by a single dose of radioiodine.

Presentation, clinical features and long-term follow-up of Leydig cell tumours of the testis: 77 cases from a single center experience  
Andrea M. Isidori, Vincenzo Giammetta, Daniele Gianfrilli, Rosa Lauretta, Maria Grazia Tarstiano, Giorgio Fattorini, Riccardo Potì, Carlotta Pozza & Andrea Lenzi

Introduction  
With the improved imaging techniques, Leydig cell tumours (LCTs) are frequently found, accounting up to 22% of testicular tumours. The natural history of LCTs is relatively unknown, because of the small size and heterogeneity of available studies. Since LCTs are often removed, long-term follow-up is missing. The aim of this study was to report the experience with a large cohort of prospectively collected LCTs.

Materials and methods  
Patients with LCTs were enrolled from 2005 to 2016. Clinical and biochemical features of LCTs were compared with two matched cohorts: patients with seminomas and patients without testicular lesions (nol.) randomly selected among patients referred in the same period.

Results  
77 patients had LCTs, 90 had seminomas, and 1420 had no lesion (nol.). Groups were matched for age and BMI. Infertility was the reason for referral in more than half of LCTs. Testicular volumes (P < 0.002), sperm concentration (P < 0.001) and morphology (P < 0.001) were significantly lower in LCTs compared to nol.; gonadotropins were higher (P < 0.001) and testosterone was lower (P = 0.008) in LCTs vs nol. No differences were found in gonadal steroid after hCG test, between groups. When compared to seminomas, LCTs did not show differences in hormonal status except for higher SHBG levels (P = 0.04), LH/T ratio (P < 0.001), and lower sperm concentration (P = 0.04). LCTs lesions were smaller compared to Sem (P < 0.001); Cryptorchidism (χ² = 45.658 P < 0.001) and gynecomastia (χ² = 54.923, P < 0.001) were associated with a higher risk of LCTs. After a median follow-up of 32.5 months, no metastases have been detected. Non-operated LCTs developed subclinical hypogonadism (P = 0.018) compared to surgically removed LCTs.

Conclusions  
LCTs have a good prognosis when correctly recognized. Based on the largest existing series, we showed that infertility, gynecomastia, low testicular volume, and cryptorchidism are frequently associated with LCTs, supporting the hypothesis that testicular dysgenesis syndrome could play a role. Active surveillance, as an alternative to surgical removal, appears to be a safe option, but monitoring of Leydig cell failure remains necessary.

Semen quality in patients with adult-onset hypogonadotropic hypogonadism  
Mikkel Andreassen¹, Anders Juul², Ulla Feldt-Rasmussen¹ & Niels Jørgensen²

¹Department of Endocrinology, Rigshospitalet, Faculty of Health Science, University of Copenhagen, Copenhagen, Denmark; ²Department of Growth and Reproduction Rigshospitalet, Faculty of Health Science, University of Copenhagen, Copenhagen, Denmark.

Introduction  
Gonadotropins from the pituitary gland are essential for testosterone production and spermatogenesis. However, little is known about semen quality in patients with adult onset hypogonadotropic hypogonadism requiring testosterone replacement therapy.

Patients and method  
A single center study comprising all hypogonadal men with pituitary disease (year 2003–2016, n = 28, median(IQR) 30 (27–37) years), who accepted cryopreservation, reproductive hormone levels were measured. Semen parameters, hormones levels and size of testicles were compared to those of young men (n = 340, 19 (18–20) years) from the general population.

Results  
Patients vs controls had lower serum testosterone 5.6 (3.5–7.8) vs 19.7 (15.5–24.5) nmol/l (P < 0.001), free testosterone index 33.3 (18.1–55.1) vs 73.7 (57.8–91.7) (P < 0.001), luteinizing hormone 1.5 (1.1–2.1) vs 3.1 (2.3–4.0) IU/l (P < 0.001), and inhibin B 142 (126–187) vs 229 (176–285) ng/l (P < 0.001).

Levels of follicle stimulating hormone were unchanged 2.3 (1.4–4.4) vs 2.2 (1.5–3.3) IU/l (P = 0.47). There were no differences on semen volume 3.0 (1.5–5.0) vs 3.2 (2.3–4.3) ml (P = 0.33), sperm concentration 35 (6–62) vs 43 (22–73) mill/ml (P = 0.1), or total sperm count 102 (8.236) vs 126 (65–235) mill (P = 0.09).

Forty-seven percent of patients and 77% of controls had normal semen quality, WHO criteria (volume > 1.5 ml, concentration > 15 mill/ml and AB-motile sperm > 42%) (P = 0.001). Three had azoospermia. Testicular size was unchanged 18 (13–25) vs 20 (19–25) ml (P = 0.46).

Conclusion  
Patients with acquired pituitary insufficiency had reduced semen quality, supporting the need for early cryopreservation of semen in this group of patients. However, despite severe Leydig cell insufficiency almost half of patients had normal semen quality based on determination of three variables. This finding is in contrast to men with hypergonadotropic hypogonadism where spermatogenesis is often severely compromised before Leydig cell insufficiency occurs.

Growth hormone-releasing hormone (GHRH) antagonists, MIA-602 and MIA-690, inhibit survival and proliferation of human pleural mesothelioma cells  
Tania Villanovas¹, Iacopo Gesmundo¹, Marina Taliano¹, Ezio Ghigo¹, Andrew V Schally² & Riccarda Granata¹

¹Division of Endocrinology, Diabetology and Metabolism, Department of Medical Sciences, University of Torino, Torino, Italy; ²Endocrinology, Polypeptide, and Cancer Institute, Veterans Affairs Medical Center, Miami, Florida, USA; ³Department of Pathology and Department of Medicine, Divisions of Hematology, Oncology and Endocrinology, University of Miami Miller School of Medicine, Miami, Florida, USA.

Human malignant pleural mesothelioma (MPM) is a rare but aggressive neoplasm, arising from pleural mesothelial cells, generally due to asbestos exposure. Different growth factors are involved in the pathogenesis of MPM and in resistance to therapy; moreover, chemotherapy with cisplatin and antifolates, like pemetrexed (PEM), is the first-line treatment for inoperable MPM. Growth hormone-releasing hormone (GHRH), apart from stimulating GH secretion in the pituitary, exerts many extrapituitary functions, including stimulation of cell proliferation and survival. GHRH and GHRH receptor (GHRH-R) are expressed in different cancer cell types, where they modulate their proliferative effects. Moreover, GHRH-R antagonists were found to inhibit the proliferation of different cancer cells in vitro and in vivo; however, the role of GHRH antagonists in MPM remains unknown. Thus, in the present study, we investigated the effects of the GHRH antagonists MIA-602 and MIA-690 on survival and proliferation of MPM.

Results  
In vitro, MIA-602 and MIA-690 promoted apoptosis and reduced the expression of the antiapoptotic protein Bcl-2 in MPM cell lines. Cell cycle analysis of MPM cells treated with GHRH antagonists showed an increase in the Sub-G1 apoptotic phase and a decrease in the G2 pre-mitotic phase. Furthermore, MIA-602 and MIA-690 inhibited cell migration in MPM cells and increased the cytotoxic action of PEM in both MPM cell lines. These results suggest a novel therapeutic role for GHRH antagonists in the treatment of MPM, alone or in combination with standard therapies, by reducing the chemotherapy doses and their associated side effects.

Somapacatan expected to provide IGF-1 levels suitable for once-weekly dosing in children  
Rasmus Juul, Michael Rasmussen, Henrik Agero & Rune Overgaard

Somapacatan is a long-acting growth hormone (GH) intended for once-weekly subcutaneous administration. As for GH, the mechanism of action of somapacatan is either directly or indirectly via insulin-like growth factor 1 (IGF-I). A PK/PD model of somapacatan was developed from the pharmacokinetics (PK) and IGF-I levels from three phase 1 trials data: a single dose/multiple dose trial (0.02–0.24 mg/kg per week) in healthy adults, a multiple dose trial in adults with growth

Endocrine Abstracts (2017) Vol 49
hormone deficiency [GHD] (0.02–0.12 mg/kg per week) and a single dose trial in children with GHD (0.02–0.16 mg/kg). Somapacitan exposure-response was described with a non-linear relationship between dose and exposure and a delay in response observed between C_{min} and C_{max}. IGF-I. Somapacitan PK levels and IGF-I response was found to correlate to body weight bridging exposure and response between children and adults. The PK/PD model was based on goodness of fit judged adequate to describe somapacitan exposure and IGF-I levels and similar to the expected IGF-I profiles after multiple doses in children. Descriptive IGF-I exposure-response analysis of single dose data in GHD paediatric patients indicated that the dose range 0.04–0.16 mg/kg provided change in IGF-I comparable to daily hGH. Based on the PK/PD model of somapacitan, once-weekly dosing of 0.04 mg/kg per week are expected to provide C_{min} IGF-I levels that match the average daily hGH treatment; 0.08 mg/kg per week are expected to provide C_{avg} IGF-I levels that match the average daily hGH treatment; and 0.16 mg/kg per week are expected to provide higher IGF-I levels than with daily hGH, with average concentrations not exceeding +2 SDs. In conclusion, the PK/PD of somapacitan is well characterised in adults and children in GHD in support of once-weekly dosing.

Evaluating CHARGE syndrome in CHD7-positive CHH patients: clinical implications

Cheng Xu1, Daniele Cassatella1, Almer van der Sloot2, Michael Hauschild1, Richard Quinlon1, Christian De Geyter1, Christa Flück3, Katrin Feller3, Deborah Bartholdi1, Attila Nemeth1, Irene Halperin1, Sandra Pecak Djurdjevic1, Georgios Papadakis1, Andrew Deyser4, Laura Marino5, Duarte Pignatelli6, Carol Huang7, Nicolas Niederlander8, James Acier9 & Nelly Pitteloud1

1Lausanne University Hospital, Lausanne, Switzerland; 2Institute for Research in Immunology and Cancer, Quebec, Montreal, Canada; 3Institute for Genetic Medicine, University of Newcastle-on-Tyne, Newcastle-on-Tyne, UK; 4University Hospital, University of Basel, Basel, Switzerland; 5Inselspital, Bern, Switzerland; 6St John’s Hospital, Budapest, Hungary; 7Hospital Clinic, Universitat de Barcelona, Barcelona, Spain; 8Institute of Endocrinology, University Clinical Center, Belgrade, Serbia; 9University of Lausanne, Lausanne, Switzerland; 10Faculty of Medicine of the University of Porto, Porto, Portugal; 11Alberta Children’s Hospital, Calgary, Canada.

**Context**

Congenital hypogonadotropic hypogonadism (CHI) and CHARGE syndrome are clinically and genetically overlapping syndromes, with mutations in the CHD7 gene presenting in both disorders. However systematic evaluation of CHARGE features in CHD7-positive patients is seldom performed.

**Objective**

This study aims to systematically evaluate CHARGE features in CHD7-positive patients and explore the phenotype-genotype correlation.

**Design**

Whole exome sequencing was performed on 130 CHH probands to identify mutations in 24 CHH genes, including CHD7-positive CHH patients. Putative mutations were defined as heterozygous mutations (two PTVs and 14 missense mutations) that were either rare sequence variants (RSVs, minor allele frequency < 1%) that were either protein-truncating variants (PTVs) or missense variants predicted to be damaging by SIFT and/or PolyPhen2. Missense mutations were also evaluated using Bergman criteria, integrating computational algorithms, population and segregation data (Bergman, Human Mutation, 2012). CHD7-positive CHH patients were evaluated for CHARGE features.

**Results**

We identified 16 CHH patients harboring heterozygous mutations (two PTVs and 14 missense), of whom 14 were available for re-evaluation. After detailed phenotyping, three probands (one PTV and two missense) were re-classified as CHARGE syndrome. Four probands with missense mutations present additional CHARGE features, while the remaining seven probands exhibit no additional CHARGE feature (one PTV and six missense). Both the missense mutations underlying CHARGE syndrome were categorized as pathogenic using Bergman criteria, while the other missense mutations were classified as either benign or of unknown significance. Of note, 3/4 CHH patients with additional CHARGE features also had mutations in other CHI genes, contributing to the variable expressivity.

**Conclusions**

56% of CHD7-positive CHH patients exhibit additional CHARGE features, with 21% meeting the clinical diagnosis of CHARGE syndrome. While the Bergman criteria accurately predict the most severe mutations resulting in CHARGE syndrome, it is unable to distinguish isolated CHH from CHH with additional CHARGE features. The results of this study have diagnostic and genetic counseling implications for CHD7-positive CHH patients.

The effect of chronic hypothalamic-pituitary-adrenal axis activation on hypothalamic glucagon-like peptide-1 action in an animal model of depression and in vitro studies

Jan Detka, Anna Kurek, Mateusz Kucharczyk, Joanna Shurczyk, Katarzyna Glombik, Wladyslaw Lason & Boguslawa Budziszewska

Department of Experimental Neuroendocrinology, Institute of Pharmacology, Polish Academy of Sciences, 12 Słomnica Street, 31-343, Cracow, Poland.

Hypersecretion of hypothalamic-pituitary-adrenal (HPA) axis is considered to be an important factor in the pathogenesis of depression. Interestingly, glucagon-like peptide-1 (GLP-1) – an incretin hormone involved in the maintenance of glucose homeostasis in the periphery is known to activate HPA axis. The aim of the present study was to investigate whether prenatal stress (an animal model of depression) may influence levels of GLP-1 and GLP-1 receptor (GLP-1R) in the hypothalamus. Since prenatal stress may not change the level of the investigated factors in basal conditions, but may change the response to adverse factors in the adulthood, our studies were also conducted on animals subjected to acute stress and oral glucose administration (1 g/kg). In parallel in order to study the direct influence of GLP-1 receptor agonists on the activity of corticotropin-releasing hormone (CRH) promoter gene, a hypothalamic cell line mHypoA-2/12 was stably transfected with plasmid DNA containing the sequence (from −663 to +124 bp) of human CRH promoter gene conjugated with luciferase reporter gene. The cells were treated with GLP-1 and exenin-4 (20 and 200 nM) for 6, 24 and 48 h. The amount of GLP-1 in the hypothalamus was not altered by prenatal stress in basal conditions, however it was significantly lower in a group subjected to acute stress. Prenatal stress and glucose loading significantly decreased the concentration of GLP-1R in the hypothalamus. Obtained results suggest that attenuated central incretin hormone signaling may contribute to metabolic disturbances, evident in depression. In contrast, transfected mHypoA-2/12 cells treated with selected GLP-1R agonists displayed no significant differences in reporter gene activity, which may suggest that GLP-1R activation does not stimulate CRH expression in this experimental model.

A novel purified polyclonal antibody towards T-Pit is a reliable marker of corticotroph cell differentiation

Evelina Sjöstedt1, Jens Bollerslev2, 3, Fredrik Pontén1, 2 & Olivera Casar-Borot2

1Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; 2Department of Clinical Pathology, Uppsala University Hospital, Uppsala, Sweden; 3Department of Specialized Endocrinology, Rikshospitalet, Oslo University Hospital, Oslo, Norway; 4Faculty of Medicine, University of Oslo, Oslo, Norway.

Classification of pituitary neuroendocrine tumours (NETs) or pituitary adenomas is based on the expression of the anterior lobe pituitary hormones (FSH, LH, GH, Prolactin, TSH, ACTH and alpha-subunit of the glycoprotein hormones). Assessment of the transcription factors SF-1, Pit-1 and T-Pit has been a major focus in many studies. However, lack of sensitive and specific antibodies towards T-Pit has been a major challenge in the field. A novel purified polyclonal antibody (HPA072686) towards T-Pit was developed using selected GLP-1R agonists displayed no significant differences in reporter gene activity, which may suggest that GLP-1R activation does not stimulate CRH expression in this experimental model.

**Conclusions**

We present a novel purified polyclonal antibody towards T-Pit that is a reliable marker of corticotroph cell differentiation.

Liraglutide treatment prevented the increased expression of proinflammatory cytokines in the hippocampus of male pups in a perinatal stress model of food restriction

Yolanda Diz-Chaves1, Laura Toba1, Juan Fandiño1, Lucas González-Matias1, Luis Miguel García-Segura2 & Federico Mallo1
1University of Vigo, CINBIO, Vigo, Spain; 2CISC, Instituto Cajal, Madrid, Spain.

Adverse events during gestation in rodents, results in an enhancement of immune function, including elevated levels of inflammatory cytokines in the brain. Liraglutide is a GLP-1 receptor agonist known to exert neuroprotective effects in brain. The aim of this study was to elucidate if liraglutide given to food restricted (FR) pregnant rats may prevent the deleterious effects of FR in the hippocampal inflammatory status of male and female pups at 21 days of age (D21). 20 Sprague-Dawley pregnant rats were included. Controls (CT) were fed ad libitum, whereas dams in restricted group were fed with 50% (50FR) daily intake of control dams. Pregnant rats were treated with liraglutide (100 µg/kg per 12 h; 50FR/LIR, CT/LIR) or vehicle (50FR/VEH, CT/VEH) from gestational day 14 to 21. During lactation FR was increased to 30%. At D21 and before weaning, pups were sacrificed. The hippocampi were obtained and stored at −80°C until analysis. mRNA expression levels of IL1β, IL6, NFKB, IL10 and Arginase1 in the hippocampus were assessed by RT-PCR. Immunohistochemistry analysis for Iba1 (marker of microglia) was performed in dentate gyrus (DG). The FR-mothers model provided a proinflammatory state in the hippocampus just in male but not in female pups. 50FR male rats displayed increased mRNA expression of IL1β, IL6 and NFKB compared to control males. LIR treatment decreased the expression of these cytokines and increased IL6 in control males. Furthermore, LIRA treatment increased the anti-inflammatory cytokine IL10 in 50FR male and CT female rats and the mRNA expression of the arginase1 (marker of microglia M2-like phenotype) in 50FR male rats. The number of Iba1 immunopositive cells were increased in the DG of 50FR males compared to controls, and were reduced by the treatment with LIRA. In conclusion, LIRA prevents the proinflammatory status induced by FR in the mother in male pups and enhanced anti-inflammatory markers.

Predictors of permanent, transient and three-phase postoperative diabetes insipidus

Daria Mikhailova, Larisa Dzeranova, Ekaterina Pigarova, Ludmila Rozhinskaya, Andrey Grigoriev, Vilen Aziyan & Oksana Ivashenko
Endocrinology Research Centre, Moscow, Russia.

Objectives
To evaluate predictors of permanent, transient and three-phase diabetes insipidus (DI) in patients undergoing endoscopic endonasal transsphenoidal surgery.

Patients and methods
The study included 154 patients undergoing endoscopic endonasal transsphenoidal surgery (122 women and 32 men) age from 18 to 65 years (median 40 (31;52)), 73 patients with Cushing disease, 66 patients with acromegaly, four patients with prolactinomas, nine patients with non-functioning pituitary adenomas, one patient with thyrotrhina, one patient with Nelson’s syndrome and three patients with multihormonal secreting adenomas we examined. Patients were monitored for hormones, balance of fluids, serum electrolytes, plasma and urine osmolality. Results
Postoperative permanent DI occurred in 27 patients, among them four as three-phased disturbances. Transient DI occurred in 42 patients, among them nine as three-phased disturbances. Onset arised on the 1th day–2nd month after surgery (median 1 day (1.5)) for the permanent DI’s and on the 1th day–4th month for transient DI’s (median 1 day (1.5)). Duration for transient DI was 1 day–1 year and 3 month (median 2 (1.50)), in 38% patients transient DI occurred as single polyuria-polydipsia episode. Adrenal insufficiency increased risk of transient and three-phased DI development (RR 0.516 (0.287; 0.927), P = 0.02, RR 0.056 (0.008; 0.42), P = 0.0003, respectively), panhypopituitis decreased permanent DI onset risk (RR 0.264 (0.132; 0.53), P = 0.02). Patients with corticotropinomas and somatotropinomas had higher risk of transient and three-phased DI (RR 0.212 (0.061; 0.734), P = 0.02, RR 0.459 (0.311; 0.677), P = 0.04, for corticotropinomas, respectively; RR 4.559 (1.049; 19.813), P = 0.03, RR 1.977 (1.033; 3.803), P = 0.07 for somatotropinomas, respectively). Macroadenoma also increased risk of transient and three-phased DI (RR 5.739 (1.32; 24.962), P = 0.01, RR 2.593 (1.357; 4.955), P = 0.02, respectively).

Conclusions
ACTH- and GH-secreting adenomas, macroadenomas and postoperative adrenal insufficiency can be considered as predictors of transient and three-phased diabetes insipidus. Panhypopituitis decreased as a predictor of permanent diabetes insipidus.

GP158
The effect of chronic tianeptine administration on NLRP3 inflammasome pathway – study in an animal model of depression

Ewa Trojan, Anna Kurek, Katarzyna Chamera, Joanna Slusarczyk, Katarzyna Glombik & Agnieszka Basta-Kaim
Department of Experimental Neuroendocrinology, Institute of Pharmacology PAS, Cracow, Poland.

Introduction
Recently, the immune hypothesis of depression has gained a new dimension because of inflammasomes. NLRP3 inflammasome is a protein complex and its activation leads to stimulation of the enzyme caspase 1 responsible for generation of active form of pro-inflammatory cytokines: IL-1 β and IL-18. Recently postulated inflammasome theory of depression assumes that depression is based on a disturbance of the mechanisms regulating NLRP3 complexes and uncontrolled synthesis of IL-1β.

Aim
The aim of present study was to examine whether prenatal stress influence the inflammasome NLRP3 system (subunits: NLR, ASC, pro-caspase-1) in the frontal cortex and hippocampus of adult rats offspring. Furthermore the impact of chronic antidepressant drug – tianeptine administration on the above-mentioned parameters were evaluated.

Methods
Pregnant rats were subjected to restraint stress. At 3 months of age, control and prenatally stressed rats were tested for behavioural changes in forced swimming test. After that male offspring were administered i.p. for 14 days with tianeptine or vehicle. The animals’ behaviour were tested again and rats were sacrificed. The protein level of all NLRP3 inflammasome subunits was determined by Western blot analyses.

Result
Prenatal stress procedure cause long-lasting behavioral alterations expressed as an increase in immobility and a decrease in swimming and climbing time measured in the forced swim test. Chronic treatment of tianeptine normalized all above-mentioned changes in prenatally stressed offspring. Prenatal stress procedure increased concentration of all NLRP3 subunits in frontal cortex. In hippocampus prenatal stress affected caspase-1 levels but had no effect on the other NLRP3 inflammasome subunits. Chronic tianeptine treatment attenuated all evoked by stress changes.

Conclusion
Prenatal stress procedure leads not only to persistent behavioral disturbances but also malfunction in brain NLRP3 inflammasome pathway. NLRP3 pathway can be indicate as an potential attractive target for antidepressant drug action.

Pituitary androgen receptor signalling is a novel negative regulator of prolactin production

Laura O’Hara, Paul Le Tissier & Lee Smith
University of Edinburgh, Edinburgh, UK.

The classical paradigm of lactotroph prolactin production and release is based around tonic inhibition by hypothalamic dopamine and stimulation by factors such as estrogen. We have recently shown that conditional ablation of pituitary androgen receptor (Foxg1-Cre ARKO) surprisingly does not change the concentration of circulating gonadotrophins but increases circulating prolactin.
in male mice; highlighting androgen signalling as a novel negative regulator of prolactin production. We aimed to refine our knowledge of the site and mechanism of action of this control by performing further genetic, pharmacological and surgical experiments to ablate the production and/or action of prolactin and/or androgens. Male mice with a genetic ablation of AR in neurons (Nestin-Cre ARKO) do not have an increase in circulating prolactin, confirming that the increase in prolactin seen in the Foxg1-Cre ARKO mouse is not due to loss of hypothalamic AR, but specifically pituitary AR. However, Foxg1-Cre ARKO mice treated with the dopamine agonist bromocriptine show a decrease in circulating prolactin levels suggesting that the mechanism of prolactin increase originates with the hypothalamic dopamine system that normally controls prolactin. Male mice with postnatal AR ablation in ~50% lactotrophs (Prolactin-Cre ARKO) do not show an increase in circulating prolactin, suggesting that either the mechanism is not lactotroph-specific or that ablation of AR needs to occur earlier or in a greater number of lactotrophs to result in an increase in circulating prolactin. Mice castrated in adulthood do not show an increase in circulating prolactin which suggests that the control mechanism is not an acute response to changes in androgens but is programmed during the pre-adult development of the pituitary. Further experiments are currently being undertaken to ablate AR in other pituitary cell populations and at earlier time points with the aim of pinpointing the spatio-temporal mechanism of control of prolactin production by androgen receptor signalling.

Recent studies have reported a high prevalence of USP8 mutations in corticotroph adenomas causing Cushing’s disease. Nelson’s syndrome is a potentially life-threatening complication of bilateral adenocarcinoma in patients with refractory Cushing’s disease that is caused by the development of an ACTH-secreting tumor in the pituitary gland. Whether USP8 alterations are also present in Nelson’s tumors has not been studied in detail so far.

**Methods**

We have screened for mutations in the exon 14 of USP8 in tumors from 32 patients who were diagnosed with Nelson’s syndrome (28 females, four males). Genomic DNA was extracted from fresh-frozen or FFPE adenomas. The presence of mutations was analyzed by Sanger sequencing. Mutational status was correlated to clinical data.

**Results**

In our cohort, 15/32 tumors presented a mutation in the exon 14 of USP8, a prevalence similar to that reported in Cushing’s disease, with c.2159C>A (p.Pro720Gln) being the most frequent (8/32), followed by c.2155_2157delTCC (p.Ser718del; 4/32) and c.2152T>C (p.Ser718Pro; 3/32). Two USP8 WT cases were categorized as atypical pituitary tumors and excluded from subsequent analyses. Mutations were found exclusively in females (15/27, 55%; vs 0/5 males). Other variables, such as age at diagnosis of Nelson’s syndrome, BMI, hyperpigmentation, visual field defects, adenoma size or mortality did not significantly differ between patients with WT and mutant tumors. Regarding the hormonal status, patients with mutant tumors tended to exhibit higher levels of plasma ACTH at time of Nelson’s diagnosis (median WT 1335 pg/ml vs mutant 1668 pg/ml; P = 0.098; n = 25) and significant changes after surgery (median 131 vs 639, P = 0.043; n = 22). Postoperative normalization of plasma ACTH was reached more frequently in patients with WT tumors (4/12, 33% vs 1/10, 10%) but without statistical significance (P = 0.323). No differences were observed in tumor control after surgery.

**Conclusion**

Somatic mutations in the USP8 gene are common in Nelson’s syndrome and may be related to a more severe hormonal phenotype.

The association between olfaction and taste functions with serum ghrelin and leptin levels in obese women

Burçin Uygun1, Sinem Kiyici1, Suay Ozmen1, Zulfiye Gul1, Deniz Sigirli1 & Sinan Cavus1

1University of Health Sciences, Bursa Yuksek Ihtisas Education and Training Hospital, Department of Endocrinology and Metabolism, Bursa, Turkey; 2University of Health Sciences, Bursa Yuksek Ihtisas Education and Training Hospital, Department of Otorhinolaryngology, Bursa, Turkey; 3Uludag University Medical Faculty, Department of Pharmacology, Bursa, Turkey; 4Uludag University Medical Faculty, Department of Bio-statistics, Bursa, Turkey.

**Aim**

Olfaction and gustation have great importance on feeding behavior and food preferences. Recent published data suggest that olfaction and taste functions are modulated in response to changing levels of various molecules such as ghrelin and leptin which are play important roles on feeding and energy balance. We aimed to investigate the olfaction and taste functions in obese female patients and the association between serum ghrelin and leptin levels compared with healthy controls.

**Methods**

Fifty two obese women who have body mass index > 30 kg/m² and 15 healthy women were included in to the study. After 8 h of fasting, blood samples were taken for serum biochemical parameters, ghrelin and leptin levels measurement. For the quantitative assessment of olfactory function, all participants underwent on N-butanol threshold test and odor identification test by using 12 Sniffin’ Sticks ready-made fragrance sticks. The gustatory function was tested by administering a whole-mouth above-threshold test using sucrose solutions.

**Results**

The sucrose taste threshold score in obese women was significantly higher than the controls (P = 0.004). N-butanol smell threshold was not significantly different between the two groups (P = 0.149) while the Sniffin’ Sticks smell test scores were significantly lower in obese women compared with the controls (P = 0.007). Serum leptin levels were also significantly higher in obese women (P < 0.001) although there was no significant difference in serum ghrelin levels between the two groups (P = 0.768).

**Conclusion**

No significant association was observed between olfaction and taste functions and serum ghrelin levels of obese individuals. It was found that serum leptin levels were increased while taste and smell functions were decreased in obese women. These results might suggest that leptin, which is an anorexigenic peptide, may have a negative effect on taste and smell functions.

**Objective**

Sarcopenic obesity is a double burden for older people because it carries the cumulative risk of functional abnormality, metabolic, cardiovascular risk, and mortality compared to either sarcopenia or obesity alone. Diabetes is related to an increase in visceral adiposity and is associated with the risk of sarcopenia. The objective was to explore the association between sarcopenic obesity and diabetes and determine the associated factors with sarcopenic obesity in older people with diabetes.

**Research design and methods**

This study was based on data from the Korean National Health and Nutrition Examination Survey (KNHANES), conducted by the Korean Ministry of Health and Welfare, from 2009 to 2010. Out of 19,491 participants, the analysis included data for 3,206 older people. Multivariate logistic regression analyses were used to identify
Results
The Prevalence of nonsarcopenic nonobesity, nonsarcopenic obesity, sarcopenic nonobesity, and sarcopenic obesity were 43.2, 7.7, 23.5 and 25.6%, respectively, in all subjects. The prevalence of sarcopenic obesity in older people with diabetes was significantly higher than those without diabetes (33.9% vs. 23.4%, P-value < 0.001).

Diabetes was an independent associated factor with sarcopenic obesity after fully adjusting for confounding factors, including chronic disease, sociodemographic influences, and lifestyle. Among the older people with diabetes, undiagnosed diabetes, diabetes duration with more than 10 years, elevated diastolic blood pressure, known hypertension, increased intake of protein, and number of comorbidity were independent associated factors with higher risk of sarcopenic obesity. History of stroke and increased vitamin D level were independently associated with a lower risk of sarcopenic obesity.

Conclusion
Diabetes influenced the risk of sarcopenic obesity in older people. Undiagnosed diabetes, diabetes duration with more than 10 years, elevated diastolic blood pressure, known hypertension, increased intake of protein, number of comorbidity, history of stroke, and vitamin D level were independently associated with sarcopenic obesity in older people with diabetes.

Resistance training reduces skeletal muscle inflammation even after 4-week detraining in obese rats
Patricia Seraphim1, Marcelo Freitas1, Marcos Teixeira2, Giovana Teixeira2, Maria Tereza Nunes3 & José Carlos Camargo Filho1
1School of Sciences and Technology – Sao Paulo State University/UNESP, Presidente Prudente/SP, Brazil; 2Institute of Biomedical Sciences – University of Sao Paulo, Sao Paulo/SP, Brazil.

The ingestion of high-fat diet has been considered a crucial factor in the genesis of inflamed muscle in the soleus muscle. Additionally we analyzed the insulin sensitivity by GTT, and muscle fiber area by HE staining. The results showed that RTr (DH vs. DHD). RTr was performed for 12 weeks (wk), 3 sets of 12 repetitions per session. In the 8th wk, DHD group interrupted training for 4 wk. RT-PCR was performed to analyze gene code TNFα, AMPK, GLUT4 and MEF2A, and Western blotting was assayed to analyze the expression of TNFα in the soleus muscle. The purpose of the present study was to analyze the effects of RTr and cessation of training on muscle inflammation and expression of genes related to glucose metabolism in obese rats. Thirty male Wistar rats aged 2 months were subdivided into three groups: High-Fat Diet (DH), Trained High-fat Diet (DHT) and Detrained High-fat Diet (DHD). RTr was performed for 12 weeks (wk), 3 sets of 12 repetitions per session. In the 8th wk, DHD group interrupted training for 4 wk. RT-PCR was performed to analyze gene code TNFα, AMPK, GLUT4 and MEF2A, and Western blotting was assayed to analyze the expression of TNFα in the soleus muscle. Additionally we analyzed the insulin sensitivity by GTT, and muscle fiber area by HE staining. The results showed that RTr (DH vs. DHT) caused increase of muscle fiber area (P < 0.05), and insulin sensitivity by 31% (P < 0.05), increased AMPK gene levels by 23% (P < 0.05), GLUT4 by 24% (P < 0.05), and ME2A by 20% (P < 0.05), and reduced protein and gene levels by 51 and 28% of TNFα (P < 0.05), respectively. Detraining (DHD vs DH) increased body weight (P < 0.05), and provoked reduction of muscle fiber area (P < 0.05). However, TNFα expression remained reduced even after cessation of training. We conclude that RTr exerts positive effects on reduction of the local inflammation, and improves the expression of genes related to glucose metabolism in the oxidative skeletal muscle. These adaptations are maintained even after 4-week detraining.

miR-26b is decreased in obesity and is associated with insulin resistance and visfatin levels
Mitra Nourbakhsh1, Atieh Hooniah Farahan2, Farideh Yaghmaei4, Saeedeh Moradgholi4, Fatemeh Ahmadpour1 & Maryam Razzaghy-Azar2,3
1Department of Biochemistry, Faculty of Medicine, Iran University of Medical Sciences, Tehran, Iran; 2Metabolic Disorders Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; 3Department of Biology, Science and Research Branch, Islamic Azad University, Tehran, Iran; 4Department of Endocrinology, Diabetology and Isotope Therapy, Wroclaw Medical University, Wroclaw, Poland.

Obesity is one of the major causes of morbidity and mortality worldwide and is considered a risk factor for metabolic syndrome, type 2 diabetes and cardiovascular disease (CVD). miRNAS are epigenetic regulators of several aspects of metabolism and energy homeostasis and are involved in obesity and regulation of insulin sensitivity. miR26 is among the obesity-related miRNAs and is differentially expressed in predispoicytes and mature adipocytes in humans and is upregulated during adipocyte maturation. visfatin which is implicated in insulin resistance and metabolic syndrome is a target of miR-26b. The aim of this study was to investigate the levels of miR-26b levels in obesity and its association with insulin resistance and metabolic parameters.

Methods
Seventy children and adolescents (35 controls; 35 obese), between the ages of 8 and 18 years, were selected and clinically evaluated. The expression of miR-26b was measured after microRNA extraction from plasma samples. The extracted microRNAs were elongated using poly A polymerase reaction followed by cDNA synthesis. Real-time PCR was performed using SYBR green and delta Ct was calculated by the formula: Ct (reference gene)-Ct (target gene). miR-16 was used as the reference gene. Insulin and visfatin levels were measured using ELISA, and insulin resistance was calculated by the homeostasis model of assessment of insulin resistance (HOMA-IR). Fasting plasma glucose, triglyceride, total cholesterol, LDL-C and HDL-C were also measured colorimetrically. Results
miR-26b expression were significantly lower in obese subjects compared with control group and were also lower in subjects with insulin resistance compared to those without insulin resistance. miR-26b was significantly correlated with insulin levels and HOMA-IR. It also showed a significant negative correlation with visfatin which was higher in obese subjects compared with control subjects.

Conclusion
Decreased miR-26b expression in obese children and adolescents may be involved in insulin resistance and increased visfatin levels.

The effect of FTO polymorphism rs9939609 on obesity and metabolic disturbances in Polish people from Lower Silesia
Aleksandra Zdrojowy-Welna1, Grazyna Bednarek-Tupikowska1, Katarzyna Kolacki1, Katarzyna Zatonska2, Malgorzata Tupikowska-Marcze2, Marek Bolanowski1 & Grażyna Bednarek-Tupikowska1
1Department of Endocrinology, Diabetology and Isotope Therapy, Wroclaw Medical University, Wroclaw, Poland; 2Department of Social Medicine, Wroclaw Medical University, Wroclaw, Poland.

Background
The association between fat mass and obesity-associated gene (FTO) polymorphism rs9939609 and obesity was found in some European countries. However, the data concerning Polish population is insufficient. The relationship between FTO and metabolic disorders remains unclear.

Methods
The study group consisted of 686 women and 418 men from Lower Silesia in Poland, aged 30–80 years (mean age 54.2 ± 9.26 years). The examination included anthropometric measurements, blood pressure, lipid profile and fasting blood glucose analysis. The group was genotyped for FTO rs9939609 polymorphism.

Results
Mean BMI was 28.2 ± 5.0 kg/m² and was slightly higher in men. Prevalence of obesity (BMI >30 kg/m²) was around 31% with no sex differences. Minor allele frequency was 0.44. In whole study group, mean BMI was higher in risk allele carriers (AA, AT) than TT homozygotes (AA – 28.45 kg/m², AT – 28.41 kg/m² vs TT – 27.8 kg/m²), but the difference was not statistically significant. The association between FTO polymorphism and obesity traits were stronger in men than in women (p-values, respectively: for body weight 0.005 vs >0.1, for BMI <0.01 vs >0.1, for waist circumference 0.0005 vs >0.1 in co-dominant model). We did not observe any association between FTO polymorphism and dyslipidemia, hypertension or higher blood glucose concentration.

Conclusions
FTO polymorphism is one of many factors influencing body mass in Polish population. The effect on other metabolic disturbances is not significant. The reasons why the association between FTO and obesity were more pronounced in men than women remain unclear. Probably age, degree of obesity or other hormonal factors modify the clinical presentation of genetic predisposition.

Anti-obesity therapeutics based on increasing the amount of brown fat have received more attention from industry as the biology and regulation of brown fat are better understood than that of beige fat. Cold exposure and treatment with β3 adrenergic receptor agonist are known to activate brown/beige adipose tissue. Many transcriptional pathways regulating brown/beige adipose tissue have been identified, the role of lipid biosynthetic enzymes in brown/beige adipose tissue has been less investigated. In this study, we investigated the role of Elovl6, the enzyme responsible for converting C16 non-essential fatty acids (FAs) into C18 species, in brown/beige adipose tissue. We have observed upregulation of Elovl3, 4, 6 and 7 in BAT and inguinal WAT of mice treated with β3-adrenergic receptor agonist CL-316243 as well as cold-expose. These elongases are responsible for the conversion of C16 FAs into C30 saturated FAs, indicating the relevance of very long chain FAs in the activation process of brown/beige adipose tissue. It was reported that Elovl6 KO mice have impaired mitochondrial function and hence impaired thermogenic capacity of BAT when exposed to cold temperature (Cell Rep. 13:2039, 2015). When exposed to chronic CL-316243 treatment we observed that Elovl6 KO mice compensate its impaired BAT function by increased development of functional beige fat contributing to its increased energy expenditure. Interestingly, these metabolic changes are appearing to be mediated by increased type-2 cytokine signalling and macrophage polarization in the inguinal WAT of Elovl6 KO mice, as per our preliminary results. We have observed increased expressions of markers for cell proliferation (Ki67), macrophage (F4/80, CD68, Iga-1, Arg-1, Clec-10) in the beige fat of Elovl6 KO mice compared to WT mice stimulated with CL-316243. These results suggest that Elovl6-regulated FA chain length is important for beigeing and M2 macrophages are playing a mediator role in beige adipogenesis.

A link between sex hormones, obesity and gut microbiota
Gabriela Martı´ nez-Chaco´ n1,2, Eveliina Munukka2, Himanshu Kumar1, Arno Ha¨ nninen2, Leena Strauss2,3 & Sari Ma¨ kela¨ 1,2
1Department of Biomedicine, University of Turku, Turku, Finland; 2Turku Center for Disease Modeling, University of Turku, Turku, Finland; 3Turku Centre for Biotechnology, University of Turku, Turku, Finland; 4Abo Akademi, Turku, Finland.

Sex steroids are involved in the development of obesity and metabolic disorders. The interrelationship between sex steroid balance and metabolism is complex, and the underlying mechanisms are still unclear. The impact of gut microbiota in development of obesity, inflammation and metabolic dysregulation has been suggested in humans and demonstrated in mouse models. Less is known about the underlying mechanisms are still unclear. The impact of gut microbiota in development of obesity, inflammation and metabolic dysregulation has been suggested in humans and demonstrated in mouse models. Less is known about the interplay between sex steroid balance and gut microbiota. Based on available evidence, it is, however, pertinent to ask if sex steroids participate in the regulation of the composition or function of gut microbiota, or if gut microbes regulate sex steroid balance. The aim of the present study was to define the interplay between sex steroid balance and gut microbiota, in the context of obesity and metabolic dysregulation. First, we showed that non-obese human aromatase expressing (AROM+) male mice, with increased circulating estradiol to testosterone ratio and impaired liver lipid metabolism, have a female-type intestinal microbiota and higher ratio of Firmicutes to Bacteroidetes. Treatment with aromatase inhibitor restored estradiol/testosterone levels, followed by a slight improvement in their microbiota ecology. Second, in a mouse model reporting the expression of human aromatase (CYP19A1) gene (hARO-Luc mice), ovariectomy-induced obesity, accompanied with elevated Firmicutes to Bacteroidetes ratio, altered gut homeostasis and increased aromatase reporter gene expression in the mammary adipose tissue. In conclusion, by applying two genetically-modified mouse models, we showed that changes in sex steroid balance are linked to altered gut microbiota composition, and on the other hand, sex steroid-related obesity is linked to increased expression of human aromatase gene reporter. Further experiments, such as fecal transplantation from mice with altered sex steroid balance to WT mice, are needed to confirm the causality between sex steroids, gut microbiota and metabolic disorders.

Effects of short sleep duration on energy metabolism and energy balance in subjects with overweight and obesity
Eleonora Poggiogalle, Lorenzo Donini, Lucio Gnesi, Stefania Mariani, Marianna Calabretta, Federica Luisi, Andrea Lenzi & Carla Lubrano

Introduction
The chronic reduction of sleep duration is associated to an increased risk of weight gain, but mechanistic aspects remain to be fully elucidated. The aim of our study was to examine the relationship between short sleep duration and energy metabolism, fuel selection and energy balance in overweight and obesity. Methods: Inclusion criteria were: age 18-65 years, BMI ≥25 kg/m². Use of any CNS medications, any psychiatric disorders and night shift work were considered as exclusion criteria. Body composition was evaluated by DXA. All participants underwent indirect calorimetry. The respiratory quotient (RQ) was calculated from gas exchanges. The equations by Weir and by Froyln were used to calculate the resting energy expenditure (REE), and carbohydrate and fat oxidation, respectively. Sleep duration, total daily energy expenditure (TDEE) and the level of physical activity (METs/day) were objectively assessed (Sensewear Armband). A 3-day dietary record was administered. Participants were divided into two groups, “regular sleep” (RS): >300 min/day or “short sleep” (SS): ≤300 min/day. Results: 88 women and 30 men were included (age:49.6 ± 12.1 years), of whom 30.5% exhibited a short sleep duration. BMI (39.7 ± 7.1 vs. 36.2 ± 5.0 kg/m², P = 0.03) and trunkal body fat (18.7 ± 6.2 vs. 16.1 ± 4.6 kg, P = 0.04) were higher in the SS group than the RS group. Subjects with short sleep had a lower RQ (0.71 ± 0.12 vs. 0.76 ± 0.12, P = 0.004) and oxidized more fat (113 ± 55 vs. 95 ± 56 g/min, P = 0.006) than regular sleepers. The METs/day were higher in the SS group compared to the RS group (1.56 ± 0.55 vs. 1.35 ± 1.24, P = 0.04). RQ was positively associated to sleep duration (P = 0.04, adj. for age, sex, and body fat). No difference emerged in TDEE or energy intake (SS group: 23 ± 10 vs. RS group: 25 ± 6 kcal/kg/day, P = 0.05).

Conclusion
Short sleep affects energy substrate metabolism and adiposity distribution in overweight and obese subjects.

Blood mercury concentration in relation to overweight or obese among Korean children and adolescents: KNHANES 2009–2013
Kyung Hee Park1 & Jeong-Hyeon Kim2
1Hallym University Sacred Heart Hospital, Anyang, Republic of Korea; 2Chunchon Sacred Heart Hospital, Chunchon, Republic of Korea.

Background
Harmful effects of mercury on cardiovascular disease have been suggested in many epidemiologic studies. However, reports on harmful effect of mercury in relation to overweight or obesity have shown inconsistent findings. Methods
A total of 1577 children and adolescents (10–18 years of age) from the Korean National Health and Nutrition Examination Survey (KNHANES) 2009–2013. Overweight or obese group was defined as over the 85th percentile of the age- and sex-specific BMI norms or BMI over 25. Subjects were categorized into three groups by age and gender specific blood cadmium, lead, and mercury concentration. Multivariate logistic regression stratified by gender was performed to estimate the odd ratio (OR) and 95% confidence interval (CI) for the investigation of association. Results
Compared to non-obese group, blood mercury concentration of was higher in obese group. Blood levels of cadmium and lead were not significantly different according to obese status. After adjustment for confounders, subjects in the highest tertile group of blood mercury levels were more likely to have overweight or obesity (OR 2.65, 95%CI 1.13–6.26) compared to subjects in the lowest tertile group in girls. No significant association was found in boys. Conclusions
Blood mercury concentration is positively associated with overweight or obesity among Korean children and adolescents. Further longitudinal studies will be needed to confirm the causality.

Association of the FTO gene rs9939609 polymorphism with obesity in the Republic of Tatarstan
Kamilla Khasanova1, Tatjana Kiseleva2, Sabina Bogdanova1, Elena Valeyeva1, Svetlana Guibaidullina2, Ilshat Ahmetov3 & Farida Valeyeva1
1Kazan State Medical University, Kazan/Russian Federation, Tatarstan, Republic of Tatarstan, Russia; 2Volgograd Academy of Physical Culture and Sport, Tatarstan, Republic of Tatarstan, Russia.

Aim
To investigate the possible association of the rs9939609 polymorphism in the FTO gene with obesity in the Republic of Tatarstan (RT).

Materials and methods
The study involved 63 adult patients (21 men and 42 women; 38–77 years old) with overweight or obesity and 515 healthy young people (157 men and 358 women; 16–35 years old) with normal weight. We assessed clinical and biochemical parameters (blood lipid profile). The analysis of the rs9939609 T/A polymorphism of the FTO gene in buccal cells was performed using Sintol kits (Russia) for RT-PCR. All the patients were tested by bioelectrical impedance analysis.

Results
The distribution of genotypes of the FTO gene polymorphism (TT ~ 11%, TA ~ 65% AA ~ 24%) and alleles (T ~ 44% A ~ 56%) in the group of patients with overweight and obesity was significantly different from those of the control group (TT ~ 42.9%, TA ~ 45.4%, AA ~ 11.7%; T ~ 65.6%, A ~ 34.4%; OR = 2.43, P < 0.0001), confirming that the A allele is a risk factor for obesity. In the group of obese patients we found an additive effect of the A allele on the increase of the average waist-to-hip ratio (lowest value in TT carriers, maximum value in AA carriers). We found that the number of patients with arterial hypertension and dyslipidemia was higher in the group with AA and TA genotypes compared with group with TT genotype.

Conclusion
We found a significant association of the T/A polymorphism of the FTO gene with the obesity. Obese patients with the risk allele of the rs9939609 FTO gene polymorphism have significantly higher values of absolute and relative body fat mass and BMI, total cholesterol, low-density lipoprotein, and triglycerides.

Effect of bariatric surgery on sexual function and sex hormone levels in obese patients: a meta-analysis
Junping Wen1,2, Lingying Wen1, Wei Lin1,2, Liangtao Li1,2, Jixing Liang1,2, Huibin Huang1,2 & Gang Chen1,2
1Fujian Provincial Hospital, Fuzhou, China; 2Fujian Medical University, Fuzhou, China.

Objective
The aim of this meta-analysis is to evaluate the effect of bariatric surgery on sexual function and sex hormone levels in obese patients. The search was restricted to data from January 1, 1990 to December 1, 2016. The data were extracted and evaluated by two independent investigators. The inclusion and exclusion criteria were defined and the results were analyzed using RevMan 5.3.5 software for Meta-analysis.

Results
In all, 31 studies met all criteria, including 1150 patients. The types of bariatric surgery performed included laparoscopic Roux-en-Y gastric bypass, laparoscopic gastric banding surgery, laparoscopic adjustable gastric banding, laparoscopic sleeve gastrectomy, Roux-en-Y gastric bypass, sleeve gastrectomy, adjustable gastric banding, vertical gastric banding, biliopancreatic diversion. The time to follow-up after surgery varied from 1 months to 115 months. Of the 31 studies, 5 reported the IIEF in obese men in 154 of 1150 patients (MD = 4.84, 95%CI (2.92, 6.75), P < 0.0001); 7 studies reported the SFSE in obese women in 369 of 1150 patients (MD = 4.10, 95%CI (-0.28, 8.48), P = 0.07). The changes of sex hormone levels in obese male patients before and after bariatric surgery as following: total testosterone (MD = 8.55, 95%CI (6.59, 10.52), P < 0.0001); free testosterone (MD = 6.52, 95%CI (3.09, 9.94), P = 0.0002); estradiol (MD = -7.03, 95%CI (-11.05, -3.01), P = 0.0006); luteinizing hormone (MD = 0.92, 95%CI (0.64, 1.20), P < 0.0001); follicle-stimulating hormone (MD = 1.29, 95%CI (0.65, 1.94), P < 0.0001); sex hormone-binding globulin (MD = 23.85, 95%CI (18.44, 29.26), P < 0.0001). The changes of sex hormone levels in obese female patients before and after bariatric surgery as following: total testosterone (MD = -0.78, 95%CI (-0.84, -0.71), P < 0.0001); free testosterone (MD = -5.53, 95%CI (-10.47, -0.59), P = 0.03); estradiol (MD = -25.10, 95%CI (16.32, -36.92), P < 0.0001); luteinizing hormone (MD = 4.50, 95%CI (1.04, 10.05), P = 0.11); follicle-stimulating hormone (MD = 1.68, 95%CI (0.50, 2.86), P = 0.005); sex hormone-binding globulin (MD = 34.79, 95%CI (22.63, 46.96), P < 0.0001).

Conclusion
This meta-analysis indicates that bariatric surgery has a significant improvement on the sexual function in both genders.

Lipolytic effects of endogenous 3-iodothyronamine (T1AM) and synthetic analog SG-2 in vivo and in cultured adipocytes
Martina Sabatini1, Michael P Rogowski2, Ebru Selen Alpergin3, Fariba Assadi-Porter2, Riccardo Zacchini1 & Grazia Chiehelli1
1Department of Pathology, University of Pisa, Pisa, Italy; 2UAB School of Medicine-Caroldvascular Disease, Birmingham, AL, USA; 3Department of Zoology, University of Wisconsin-Madison, Madison, WI, USA.

3-Iodothyronamine (T1AM) is a hormone like molecule structurally similar to TH, that has been reported to modulate energy metabolism by favoring lipid over glucose catabolism. To better understand the role played by T1AM on the regulation of lipid metabolism, in the present study we administered spontaneously obese mice with T1AM at two different dosages (10 and 25 mg/kg per day) for 7 days and the effects on body weight (BW) and lipid profiles were examined. In addition a fluoro-labeled version of T1AM (FL-T1AM) was synthesized and utilized to assess T1AM intracellular localization in 3T3-L1 mouse adipocytes. Administration of 10 or 25 mg/kg per day T1AM showed a BW loss of 10% or 18% of initial BW by day 7 of treatment. T1AM treatment at both dosages produced a significant increase in total plasma triglycerides (P < 0.05) and a significant decrease in plasma cholesterol (P < 0.05), without any significant change in glycaemia. At present, the specific mechanism of T1AM entry into the cell, as well as its internal targets remains unknown. Cellular imaging revealed rapid intercellular uptake of FL-T1AM without localization to the lipid droplet or nucleus of mature adipocytes. This rapid rate of uptake was further evaluated via flow cytometry, with peak detection of FL-T1AM steadily rising until reaching peak signal and equilibrium at ~ 20 min. We also observed that when 3T3-L1 adipocytes were treated with T1AM or its synthetic halogen free analog SG-2 (1–10 M), both compounds decreased lipid accumulation in mature adipocytes, with SG-2 showing a potency significantly higher than T1AM (IC50, 0.25 ± 5 μM; IC50, T1AM = 20 μM).

In conclusion T1AM and its synthetic analog show a significant lipolytic activity, both in cultured adipocytes and in vivo.

A comparison of single-dose effects of short acting somatostatin analogs: octreotide vs pasireotide in patients with active acromegaly after surgical debulking
Agnieszka Majos, Maria Stelmachowska-Banas, Izabella Czajka-Oraniec & Wojciech Zagliczynski
Department of Endocrinology, Centre of Postgraduate Medical Education, Bielsk Hospital, Warsaw, Poland.

Acronegalmy is a rare endocrine disorder caused by growth hormone (GH) secreting pituitary adenoma. The treatment of choice is transphenoidal surgery. In patients with persistent disease after surgery medical therapy is recommended.
First-line medical treatment include first generation long-acting somatostatin analogs: octreotide LAR and lanreotide autogel. Recently, pasireotide – a second generation somatostatin analog has been investigated in patients with acromegaly. The aim of this study was to compare the effectiveness of the single-dose of short-acting somatostatin analogs: octreotide vs pasireotide in patients with active acromegaly after surgical debunking who were resistant to first generation long-acting somatostatin analogs.

Eighteen patients after debunking surgery without biochemical control of acromegaly on medical therapy were enrolled in the study. All patients had short-acting octreotide and pasireotide administered on different days. GH concentration was measured before and 60, 120 and 180 min after drug administration. Nadir GH concentrations and decreases in GH concentrations were compared.

Nadir GH values in octreotide test were reached 60 min after drug administration, while in pasireotide test – 180 min after drug administration. The median nadir GH concentration was 2.765 μg/l (IQR: 1.805–4.007) vs 1.51 μg/l (IQR: 0.95–2.555) respectively. $P<0.001$. The decrease in GH concentration was more significant after pasireotide administration compared to octreotide administration ($P<0.001$). The median decrease in GH concentration in octreotide test was 1.255 μg/l (IQR: 0.918–1.75) vs 2.605 μg/l (IQR: 1.523–5.043) after pasireotide administration. Octreotide was generally better tolerated than pasireotide.

Short-acting pasireotide is more effective than short-acting octreotide in GH supression in patients with uncontrolled acromegaly. Pasireotide may be a promising alternative for patients resistant to first-generation somatostatin analogs.

DOI: 10.1530/endoabs.49.GP173

**Resistance to somatostatin analogs is associated with GSTP1 gene methylation and AHR rs2066853 variant in acromegaly patients**

Francesco Ferrara¹, Petromilia Daniela Romeo², Soraya Puglisi³, Marta Ragonese¹, Federica Spagnolo¹, Riccardo Lentile², Isa Anna Maria Picerno², Monica Currò³, Giuseppa Visalli⁴, Angela Alibrandi⁵ & Salvatore Cannavo⁶

¹Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; ²Department of Biomedical Sciences, Dental Sciences and Morpho-functional Imaging, Messina, Italy; ³Department of Economics, Messina, Italy; ⁴Department of Human Pathology of Adulthood and Childhood, Messina, Italy.

Evidence suggest that environmental contaminants exposure and/or the impairment of intracellular xenobiotic metabolization system could affect pituitary pathophysiology. Glutathione-S-transferase-P1 (GSTP1) gene encodes for an enzyme that is involved in cellular detoxification mechanisms. GSTP1 altered activity or expression has been reported in some tumours.

We aimed to assess the GSTP1 gene promoter methylation status in acromegaly patients and its contribution to their clinical features.

Seventy-seven WT AIP gene acromegaly patients (50 women) have been screened for germline AHR rs2066853 variant and GSTP1 promoter methylation. Epide-

miologic, clinical, biochemical and radiological parameters at diagnosis have been compared after patients’ stratification according to GSTP1 methylation status and the presence of AHR rs2066853 variant. We also evaluated the response to somatostatin analogs (SSAs) administered either before or after surgery in 71 cases.

Seventeen patients were found to carry AHR rs2066853 variant and 26 methylated GSTP1 (GSTP1methyl). GSTP1methyl patients showed a higher prevalence of diabetes mellitus ($P=0.01$), colonic polyps ($P=0.05$), and were more resistant to SSA ($P=0.02$) as compared to GSTP1 unmethylated patients (GSTP1unmethyl).

On the basis of GSTP1 methylation status and the presence of AHR rs2066853 variant, we identified four groups: group 1, 40 patients GSTP1methyl and AHR WT; group 2, 20 patients only GSTP1methyl; group 3, 12 patients carrying only AHR rs2066853 variant; group 4, five patients with both GSTP1 methylation and AHR rs2066853 variant. Group 1 patients were more sensitive to SSA than other groups ($P=0.02$). Patients of group 4 were more resistant to SSA ($P=0.02$) and showed higher GH ($P=0.03$) and IGF1 ($P=0.04$) levels and lower percentage of GH decrease ($P=0.04$) after SSA than other groups.

In conclusion, GSTP1 methylation and AHR rs2066853 variant associate with resistance to SSA in acromegaly patients.

**Efficacy and safety of switching to pasireotide LAR alone or in combination with pegvisomant in acromegaly patients controlled with combination treatment of first-generation somatostatin analogues and weekly pegvisomant (PAPE study): a prospective open-label 48 week study, preliminary results 24 weeks**

Amnar Muhammad, Aart Jan van der Lely, Joop Janssen & Sebastian Neegers

Erasmus MC, Rotterdam, The Netherlands.

**Background**

Efficacy and safety of combination treatment of pasireotide LAR with pegvisomant (PEGV) has not been studied yet. Switching to Pasireotide LAR in patients previously controlled with long-acting somatostatin analogs (LA-SSAs) and PEGV could reduce the required PEGV dose to normalize serum IGF1 levels, while the effect on glucose metabolism is unknown.

**Methods**

We enrolled 60 acromegaly patients > 18 years with acromegaly who had normal IGF1 levels (≤1.2xUpper Limit of Normal (ULN)) using combination treatment of high dose LA-SSAs and weekly PEGV for ≥ 6 months. After enrollment LA-SSA treatment was continued, and the PEGV dose was reduced by 50% for 12 weeks. If IGF1 levels remained normal after 12 weeks, patients were switched to pasireotide LAR 60 mg monotherapy, every 4 weeks. If IGF1 levels > 1.2xULN patients were switched to pasireotide LAR 60 mg and continued with the 50% reduced PEGV dose. The primary endpoint was the percentage of patients achieving normal IGF1 levels at 24 weeks. The key secondary endpoint was the frequency diabetes at 24 weeks.

**Results**

At baseline, median IGF1 was 0.94xULN with a median PEGV dose of 80 mg/week, and 30.6% of patients had pre-existing diabetes. After the 50% dose reduction of PEGV, median IGF1 levels increased to 1.43 ULN, while IGF1 remained normal in 33% of patients. At 24 weeks, 73% of patients achieved normal IGF1 levels with a median IGF1 0.98xULN. Cumulative PEGV dose reduction between baseline and 24 weeks was 66%. At 24 weeks, IGF1 levels were normal in 88% of patients on pasireotide LAR monotherapy, and 68% of patients on combination treatment. Pasireotide LAR was well tolerated. At 24 weeks, the most common adverse event was diabetes which occurred in 70.2% of patients. Two patients withdrew prematurely due to hyperglycemia requiring insulin treatment.

**Conclusion**

Pasireotide LAR alone or in combination with pegvisomant controls IGF1 in 73% of patients after 66% reduction in cumulative dose of weekly pegvisomant. The frequency of diabetes was 70.2% and is in line with previous studies.

**Minimally Invasive Diagnosis and Direct Transnasal Surgery: a single centre series of 100 children with Cushing’s Disease with long term follow-up**

Patricia Crock1,², Dieter K Ludecke¹, Ulrich Knuppe³, Joerg Flitsch³ & Wolfgang Saeger²

¹Paediatric Endocrinology, John Hunter Children’s Hospital, Newcastle, NSW, Australia; ²University of Newcastle, Newcastle, NSW, Australia; ³Department Neurosurgery, University Hospital Eppendorf, Hamburg, Germany; ⁴Neurosurgical Clinic, Minden, Germany; ⁵Department Neuropathology, University Clinic Eppendorf, Hamburg, Germany.

**Introduction**

Trans-sphenoidal surgery (TSS) with minimally invasive techniques is the first choice in the treatment of paediatric Cushing’s disease (CD). The question is how can high remission rates be achieved with less invasive investigations and TSS. The developments in our centre treating 100 pediatric Cushing patients with long-term follow-up may add some helpful ideas.

**Material and methods**

Data from our first series 1 (n = 55) will be compared with new data from the recent series 2 (n = 45) until 2009. All patients were operated by one surgeon by direct transnasal microsurgery (TNS). Special diagnostic methods such as inferior petrosal sinus sampling (IPSS) were replaced by ACTH measurement from the cavernous sinus (CSS) restricted to unclear cases without increase of salivary cortisol in the CRH-test, difficult sella anatomy and/ or negative MRI. Multiple direct micro-cytology, micro-doppler and adequate visualization will be described.

**Results**

In our first series of 55 cases, IPSS was performed in 13 (24%) of whom 46% had false adenoma lateralization. All adenomas could be removed with extensive pituitary exploration and all had intraoperative pathology. Two patients had early successful re-surgery. Recurrence rate 15%. In the second series with more
refined MRI and endocrinology: easy repeat CRH saliva tests and CSS sampling used in only 7 patients (15%), all micro-adenomas were initially detected. Early repeat-TNS was necessary and successful in three. Recurrence rate 11%. Side effects of TNS were minimal, as such, children and parents readily accepted re-TNS. Thus, including re-TNS in recurrences, 98 of 100 patients had long-term remission. TNS in recurrences had a better outcome in the last series with less pituitary dysfunction using more intraoperative minute biopsies.

Conclusions

Invasive pre-surgical investigations could be reduced. 98% remission rate could be achieved with advanced investigations, refined TNS, early re-TNS and re-TNS in recurrences. Only two children (2%) were irradiated – only one was indicated by the senior surgeon.

Background

Octreotide s.c. depot is a novel, ready-to-use formulation administered via a thin needle, which may allow self-administration. In a phase 1 study in healthy volunteers, octreotide s.c. depot provided greater bioavailability with faster onset and greater IGF1 suppression than long-acting octreotide. Here, we present data from a phase 2 study evaluating pharmacokinetics (PK), efficacy, safety, and tolerability of octreotide s.c. depot in patients with acromegaly and neuroendocrine tumours (NETs).

Methods

Adult patients with acromegaly or functioning, well-differentiated NETs treated with long-acting octreotide 10 mg/20 mg every 4 weeks (q4w) for ≥ 2 months were randomized to receive octreotide s.c. depot 10 mg q2w or 20 mg q4w for 3 months (period 1 [P1]). Results

Twelve patients were randomized to receive octreotide s.c. depot 10 mg q2w (acromegaly, n = 3; NET, n = 1) or 20 mg q4w (acromegaly, n = 4; NET, n = 4). Acromegaly: steady state (SS) PK (for octreotide s.c. depot 10 mg, 20 mg vs long-acting octreotide 10 mg, 30 mg, respectively) – AUC0-28d(day*ng/l): 95.6, 78.5 vs 83.3, 135.0 vs 27.8, 39.9; Cmax(ng/ml): 5.61, 15.7 vs 0.35, 1.41. NETs: SS PK (for octreotide s.c. depot 10 mg, 20 mg vs long-acting octreotide 20 mg, 30 mg, respectively) – AUC0-28d(day*ng/l): 83.3, 135.0 vs 27.8, 39.9; Cmax(ng/ml): 10.6, 11.3 vs 0.35, 1.41. NETs: PK (for octreotide s.c. depot 10 mg, 20 mg vs long-acting octreotide 20 mg, 30 mg, respectively) – AUC0-28d(day*ng/l): 95.6, 78.5 vs 83.3, 135.0 vs 27.8, 39.9; Cmax(ng/ml): 5.61, 15.7 vs 1.68, 2.48. In acromegaly, control of IGF-1 and GH levels was maintained or improved in P1 vs P0. In NETs, symptoms of carcinoid syndrome were similar or improved in P1 vs P0. Symptoms disappeared in two patients in 20 mg group. Adverse events (all grade 1-2) were reported in six and eight patients during P0 and P1, respectively; most common in P1 were GI disorders.

Conclusions

Octreotide s.c. depot provided higher exposure than long-acting octreotide, maintained biochemical control in patients with acromegaly and symptom control in patients with functioning NETs, and was well tolerated with a safety profile consistent with long-acting octreotide.

Sleep patterns in patients with non-functional GHRH receptor

Francielle T Oliveira1, Roberto Salvadori1, José Marcondes2, Larissa B Macena1, Alecia A Oliveira-Santos3, Augusto C N Faro1, Viviane C Campos1, Carla R P Oliveira1, Ursula M M Costa1 & Manuel H Aguiar-Oliveira1

1Federal University of Sergipe, Aracaju/Sergipe, Brazil; 2The Johns Hopkins University School of Medicine, Baltimore, MD, USA; 3Instituto do Soto e Medicina Integrada, Aracaju/Sergipe, Brazil.

Hypothalamic GH releasing hormone (GHRH) has hypnotic actions by increasing slow wave sleep (SWS) (non-rapid eye movement sleep, non-REM), which account for about 75% of sleep. Conversely, GH may stimulate the rapid eye movement sleep (REM). Patients with GH deficiency (GHD) often exhibit sleep problems leading to daytime fatigue and reduced quality of life (QoL). We have described a cohort of patients with isolated GHD (IGHD) due to GHRH resistance caused by a homozygous null mutation (c.57+1G> A) in the GHRH receptor gene. They have normal QoL and no obvious complaints of chronic tiredness. The aim of this study was to determine objectively and subjectively the sleep quality in these subjects, who have never received GH therapy. A cross sectional study was carried out on 21 adult IGHD subjects, and 21 matched controls. Objective sleep assessment included polygraphic records of the stages wake (W), non-REM: N1 (drowsiness), N2 and N3 (already sleeping) and R (REM). Subjective evaluation included the Pittsburgh Sleep Quality Index, Insomnia Severity Index, and Epworth Sleepiness Scale. Compared to controls, IGHD subjects exhibited lower sleep efficiency (77.7 (27.5) vs 87.5 (10.1) %, P = 0.007), total sleep time (330.0 (127.5) vs 385.5 (56.0) min, P = 0.028) and higher percentage of the non-REM 1 stage (14.6 (18.9) vs 7.3 (8.1) %, P = 0.022). There was no difference between the groups in REM sleep and in quality questionnaires. These data show an extension of the drowsiness period, with a reduction in the total sleep time, suggesting a preponderant role of GHRH resistance over GHD in the sleep quality of these IGHD subjects. The objective reduction in the sleep efficiency and total sleep time seem have minimal subjective consequences, as it was not reflected in differences of quality sleep questionnaires.

Correction of sustained hyponatremia secondary to SIAD by the use of chronic tolvaptan therapy is associated with a reduction in Emergency Room visits, hospital admissions and days of hospitalization over a 3-year period

Martín Cuesta Hernández1, Irene Crespo Hernández2, Pablo Amich Alemany1, Emilia Gómez Hoyos3, Nancy Sánchez Gómez1, Alejandro Santiago1, Paz De Miguel Novoa1, Alfonso Luis Calle-Pascual1 & Isabelle Runkle de la Vega1

1Hospital Universitario Clínico San Carlos, Madrid, Spain; 2Hospital Universitario Clínico Universitario de Valladolid, Valladolid, Spain; 3Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain.

Introduction

Hyponatremia (HN) is associated with worse clinical outcomes, and longer hospital lengths-of-stay than seen in eunatremic patients. The Syndrome of Inappropriate Antidiuresis (SIAD) is the most common cause of hyponatremia in hospitalized patients. We studied the relationship between correction of sustained SIAD-induced hyponatremia and visits to the Emergency Room (ERs) as well as hospital admissions (HA) in a case series.

Methods

Retrospective, cross-sectional study of patients whose HN was corrected with chronic tolvaptan therapy (CTV) for a minimum of 3 years. Serum Sodium levels (SNa) in mmol/l. Descriptive statistics expressed as median (IQR). SPSS 15, non-parametric tests (Wilcoxon for paired data), univariate analysis. Results

16/25 (64%) patients fulfilled inclusion criteria. Nine patients not completing 1 year of follow-up were excluded. Median age: 82 (74–87). Women: 11/16 (69%). HN was first detected a median of 31 months (IQR 29–56) prior to initiation of therapy. SIAD etiology: 9/16 (56%) idiopathic, 3/16 (19%) due to drug-induced (19%), 2/16 (3%) respiratory, 1/16 (6%) abdominal, 1/16 (6%) cancer. The year before HN correction. Nadir SNa: 120 (115–125) mmol/l, with a median of 2 (1–4) ERs/patient, HA: 1 (1–2) with 18 (10–32) days of hospitalization (DH). During year 1 of CTV, Nadir SNa rose to 130 (37) mmol/l (P = 0.001), ERV dropped to 1 (0–3) (P = 0.03), HA to 0 (0–9) (P = 0.003), DH to 0 (0–10) (P < 0.001). The benefits were sustained when comparing the second and third years to the year prior to HN correction. Second year: ERV: 0 (0–1) (P = 0.004), HA: 0 (0–1) (P = 0.001), DH: 0 (0–1) (P < 0.001). Third year: ERV: 1 (0–2) (P = 0.05), HA: 0 (0–1) (P = 0.009), DH: 0 (0–1) (P = 0.009).

Outcome of non-functioning pituitary adenomas that regrow after primary treatment: a study from two large specialist UK centers
Metaxia Tampourliou1,2, Georgia Ntal1, Shahzada Ahmed3, Wiebke Arlt1, John Ayuk2, James Byrne2, Swarupshin Chavda3, Simon Cudlip3, Neil Griffoes1, Ashley Grossman1, Rosalind Mitchell1, Michael O’Reilly1,1, Alessandro Paluzzi1, Andrew Toogood3, John Waiss1 & Niki Karavitaki1,2
1Institute of Metabolism and Systems Research, College of Medical and Dental Sciences, University of Birmingham, Birmingham, UK; 2Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, UK; 3Oxford Centre for Diabetes, Endocrinology and Metabolism, Churchill Hospital, Oxford, UK; 4Department of Ear, Nose and Throat, Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; 5Department of Neuroradiology, John Radcliffe Hospital, Oxford, UK; 6Department of Radiology, Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; 7Department of Neurosurgery, John Radcliffe Hospital, Oxford, UK; 8Department of Neurosurgery, Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK.

**Introduction**
Despite the significant risk of regrowth of non-functioning pituitary adenomas (NFAs) after primary treatment, systematic data on the probability of further tumour progression and the effectiveness of management approaches are lacking.

**Aims**
Assess the probability of further regrowth(s), predictive factors and outcomes of management approaches in patients with NFA diagnosed with adenoma regrowth after primary treatment (surgery combined or not with radiotherapy) in two UK referral centers.

**Methods**
The records of the patients with NFA who during their follow-up had adenoma regrowth were reviewed. The period covered for the primary NFA surgery was between 1/1963 and 12/2011 and the follow-up period ended in 6/2016.

**Results**
We identified 237 patients (median follow-up after 1st regrowth of 5.9 years (range 0.4–37.7)). The 5-year 2nd regrowth rate was 35.3% (36.2% after surgery; 12.5% after radiotherapy; 12.7% after surgery combined with radiotherapy; 63.4% with monitoring). Of those managed by monitoring, 34.8% eventually were offered intervention. Type of management and sex were risk factors for 2nd NFA regrowth, whereas age at diagnosis of primary NFA and type of adenoma immunostaining were not. Amongst those with 2nd adenoma regrowth, the 5-year 3rd regrowth rate was 26.4% (24.4% after surgery; 0.0% after radiotherapy; 0.0% after surgery combined with radiotherapy; 48.3% with monitoring). Overall, patients with a NFA regrowth had probability of a 3rd regrowth 4.4% at 5 years, and 10.0% at 10 years, and the type of management of the 1st regrowth was the only risk factor. Malignant transformation was diagnosed in two of 237 patients (one gonadotroph and one silent ACTH adenoma).

**Conclusions**
Patients with regrown NFA after primary treatment continue to carry considerable risk of tumour progression necessitating long-term follow-up. Management approach of the regrowth is the major factor determining this risk; monitoring alone is associated with high progression rates and a substantial number of patients will ultimately require intervention.

Targeting either GH or IGF-I levels during somatostatin analogue treatment in patients with acromegaly: A randomized, investigator-initiated multicentre study
Jakob Dal1, Marianne Klose2, Ansgar Heck3, Marianne Andersen3, Caroline Kristorp4, Eijig Husted Nielsen5, Jens Børnberg5, Ulla Feldt-Rasmussen6 & Jens Otto Lunde Jørgensen7
1Aarhus University Hospital, Aarhus, Denmark; 2Aalborg University Hospital, Aalborg, Denmark; 3Odense University Hospital, Odense, Denmark; 4Herlev Hospital, Herlev, Denmark; 5Natural University Hospital, Copenhagen, Denmark; 6Oslo University Hospital and Faculty of Medicine, Oslo, Norway.

**Context**
Assessment of disease control in acromegaly depends on GH and IGF-I, but discordant values frequently occur. Further, the role of OGTT-suppressed GH (GH\textsubscript{OGTT}) in somatostatin analogue (SA) treated patients is debated.

**Objective**
To evaluate the effect of targeting either IGF-I or GH during SA treatment.

**Design**
A randomized, investigator-initiated, multicentre trial.

**Patients and methods**
84 patients controlled with either SA (n = 61) or surgery only (n = 23) underwent a 3 h GH profile including a 2 h OGTT at baseline, after 6 months (SA treated patients only) and after 12 months together with IGF-I. SA patients were randomized to be monitored by either IGF-I (n = 33) or GH\textsubscript{OGTT} (n = 28). SA dose increase was allowed at baseline and after 6 months. Symptoms and quality of life (QoL) were assessed by disease-specific questionnaires (PAQI2 and AcroQoL).

**Main outcome measures**
GH and IGF-I at baseline and 12 months, symptoms and QoL, and SA dose increases.

**Results**
IGF-I and fasting GH levels at baseline were comparable between the two groups, whereas GH\textsubscript{OGTT} (µg/l) was lower in the surgery group (GH\textsubscript{OGTT} 0.7 ± 0.1 (SA) vs 0.3 ± 0.1 (surgery), P<0.01). At baseline, 31% of SA patients had discordant controlled GH and IGF-I, 43% had elevated GH and 3% elevated IGF-I. Significantly more patients in the surgery group had discordant controlled values (65%), P<0.01. SA dose increase was performed in 20 patients in the GH target group as compared to eight patients in IGF-I target group (P=0.02) and resulted in a higher proportion of controlled patients (P=0.01). SA patients had suppressed insulin levels and elevated glucose and FFA levels during the OGTT compared to surgery. QoL was only mildly affected at baseline and did not change consistently.

**Conclusions**

i) Discordance between GH and IGF-I is more prevalent during SA treatment as compared to surgery, mainly due to elevated GH\textsubscript{OGTT} levels, ii) targeting discordant GH or IGF-I levels in SA patients translates into SA dose increase and a higher degree of concordance, iii) Our data suggest that a sizable proportion of SA patients are undertreated.

Brain white matter damage and volumes of hippocampus and hypothalamus correlates to cognitive function in craniopharyngioma
Sigridur Fjalldal1, Daniel Svärd1, Cecilia Follin1, Danielle Van Westen2, Sänaz Gabery3, Åsa Petersén1, Magdalena Jansson1, Pia Maly Sundgren2, Isabella Björkman-Burtscher1,3, Jimmy Lätt1, Peter Mannfolk1, Carl-Henrik Nordström1, Lars Rylander1, Bertil Ekman4, Aki Johansson4 & Eva-Marie Erfurth1
1Department of Endocrinology, Skåne University Hospital, Lund, Sweden; 2Department of Diagnostic Radiology, Clinical Sciences, Lund University, Lund, Sweden; 3Translational Neuroendocrine Research Unit, Department of Experimental Medical Science, Lund University, Lund, Sweden; 4Department of Psychology and Psychiatry, Skåne University Hospital, Lund, Sweden; 5Department of Medical Imaging and Physiology, Skåne University Hospital, Lund, Sweden; 6Department of Neurosurgery, Skåne University Hospital, Sweden, Lund, Sweden; 7Division of Occupational and Environmental Medicine, Lund University, Lund, Sweden; 8Department of Endocrinology and Medical and Health Sciences, Linköping University, Linköping, Sweden.

**Objective**
Despite the limited knowledge on cognitive symptoms in craniopharyngioma, the associations between brain white matter damage in the hypothalamus and corpus callosum and volumes of hippocampus and hypothalamus as well as the correlation to cognitive function are insufficiently studied.

**Methods**
We recruited 17 patients diagnosed with craniopharyngioma and treated with surgery and/or radiotherapy. All patients underwent cognitive testing, and we assessed by MRI the white matter damage in the hypothalamus and corpus callosum as well as the volumes of the left and right hippocampus and hypothalamus.

**Results**
We found that the patients with white matter damage in the hypothalamus and corpus callosum had a lower mean right hippocampus volume compared to the patients without white matter damage (p = 0.001). The patients with white matter damage in the hypothalamus and corpus callosum also had a lower mean left hippocampus volume compared to the patients without white matter damage (p = 0.001). Furthermore, we found that the patients with white matter damage in the hypothalamus and corpus callosum had a lower mean right hypothalamus volume compared to the patients without white matter damage (p = 0.001). The patients with white matter damage in the hypothalamus and corpus callosum also had a lower mean left hypothalamus volume compared to the patients without white matter damage (p = 0.001).

**Conclusions**
Our results suggest that the white matter damage in the hypothalamus and corpus callosum is associated with a lower mean volume of the hippocampus and hypothalamus. Furthermore, our results suggest that the white matter damage in the hypothalamus and corpus callosum is associated with lower cognitive function.

DOI: 10.1530/endoabs.49.GP182
Introduction
Adult patients with craniopharyngioma (CP) and hypothalamic (HT) damage have impaired cognitive function. The white matter (WM) changes behind these findings remain to be elucidated. Diffusion tensor imaging (DTI) is a MRI technique that quantifies microstructural damage in the WM. This is the first study of DTI, hippocampal (HC) and HT volume in relation to cognition in CP patients.

Methods
A cross-sectional study of childhood onset CP was performed at median 22 years after first operation. After exclusions, 36 patients and 31 controls remained in the MRI study. Main outcome measures were comparison of cognitive tests, volume measurements of HC and HT and the DTI parameters median diffusivity (MD) and fractional anisotropy (FA) between patients and controls.

Results
CP patients have WM damage in the left dorsal cingulum and right uncinate fasciculus. No significant difference was found on DTI measurements of the HC. Correlations were found between DTI results from the right uncinated fasciculus (MD, P = 0.035 and FA, P = 0.005) and the left HC (MD, P = 0.035 and FA, P = 0.001) with long term memory reflecting general knowledge. DTI in the cingulum correlated with visual memory (MD, P ≤ 0.04 and FA, P ≤ 0.04) and short term memory (MD, P = 0.004). DTI in the HC correlated with long term memory (MD, P = 0.03 and FA, P ≤ 0.04) and short term memory (FA, P = 0.02), HT volume correlated negatively with MD of right uncinate fasciculus (P = 0.015). The CP patients had a smaller HC volume which correlated with long term memory (P = 0.016).

Conclusions
A structure to function relationship is established between cognition and WM damage detected with DTI in CP. CP patients have a smaller HC compared to controls. Whether the cognitive deficits are a direct consequence of HT damage or an indirect effect on frontotemporal network remains to be elucidated.

Copeptin – a sensitive marker of an altered CRH-axis in pituitary disease
Krzysztof Lewandowski 1, Andrzej Lewinski 1, Elżbieta Skowronkska-Jozwiak 2, Katarzyna Malicka 2, Wojciech Horzelski 3, Georg Braissant 1
1 Department of Endocrinology and Metabolic Diseases, "Polish Mother" Memorial Research Institute and The Medical University of Lodz, Lodz, Poland; 2 Faculty of Mathematics and Computer Science, University of Lodz, Lodz, Poland; 3 Experimental and Clinical Endocrinology Med Clinic I, University of Luebeck, Luebeck, Germany.

Background
Copeptin (pre-proAVP) secreted in equimolar amounts with vasopressin (AVP) closely reflects AVP release. Previously it was shown that copeptin is stimulated in standard pituitary function tests acting through hypothalamic centres. Furthermore, copeptin has been shown to subtly mirror stress potentially mediated via CRH. To further test a potential direct interaction of CRH with copeptin release which could augment AVP effects on pituitary function, we investigated copeptin response in a standard CRH test, both in healthy controls and patients with pituitary disease.

Patients and methods
18 healthy controls and 29 subjects with history of pituitary disease were subjected to a standard CRH test and in addition to ACTH and cortisol we measured copeptin by standard assays (ThermoFisher).

Results
Patients with previous pituitary disease were subdivided in a group passing the test (P1) and failing (P2). The latter group included five patients with diabetes insipidus. The overall copeptin response was higher in controls than in subjects with pituitary disease (area under the curve. P = 0.04 for P1 + P2) with a maximum increase in controls from 3.84 ± 2.66 pmol/l to 12.65 ± 24.87 pmol/l, P = 0.04, at 30 min. In contrast, both groups of patients lacked a significant CRH response. The mean increase in P2 was from 1.93 ± 1.4 pmol/l to 3.37 ± 3.49 pmol/l, at 30 min, P = ns, and even in P1 where ACTH concentrations increased four-fold (mean 21.48 vs. 91.53 pg/ml, P < 0.001) copeptin did not respond (e.g. 4.35 ± 5.81 pmol/l vs. 5.36 ± 6.79 pmol/l, at 30 min, P = ns).

Conclusions
Copeptin release in healthy controls suggests a direct interaction of CRH and AVP/Vasopressin. Interestingly, this relation is altered already in the group of pituitary patients who pass the standard CRH test indicating i) that the CRH-ACTH-cortisol response is largely independent from the AVP system, but ii) the CRH-AVP interaction reflected by copeptin may be of much more sensitive to reveal subtle alterations in the regulation of pituitary function.

Purpose
We aim at prospectively comparing the detection rate of GLP1-R PET/CT vs GLP1-R SPECT/CT and PET/CT and MRI in a prospective clinical study.

Methods
27/40 patients. So far 29 patients have been operated. The histological diagnosis after surgery. Standard of comparison was the histological diagnosis after surgery.

Results
In conclusion, CAB discontinuation significantly worsens lipid profile and MetS prevalence in patients with prolactinomas.
GP186
24 hour urinary 5-hydroxyindoleacetic acid (5-HIAA) doubling-time (DT) is associated with disease-specific mortality (DSM) and progression-free survival (FPS) in patients with neuroendocrine tumors (NETs)

Amit Tirosh1,2, Niris Nilubol3, Dhaval Patel3 & Electron Kebebew3
1National Institutes of Health, Bethesda, Maryland, USA; 2Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; 3Endocrine Oncology Branch, National Cancer Institute, Bethesda, Maryland, USA.

Background
Biochemical biomarker DT is used clinically for prognosis prediction in several solid malignancies. The aim of the current analysis was to determine whether biomarker DT has any prognostic utility in patients with NETs.

Methods
Patients with NETs (n=184) were enrolled in a prospective study with comprehensive biochemical analysis. The current analysis included subjects with increasing 5-HIAA levels in at least two consecutive measurements. DTs for each biomarker were calculated using the formula DT = (log2[A2]/log2[A1]) × (time interval between tests)/(log2[A2]−log2[A1] × value). Log-rank test was used to assess differences in DSM or FPS risk by DT. The c-statistic of 5-HIAA predictive utility for DSM was calculated using receiver operating characteristic (ROC) curve analysis. DSM and FPS were compared by 5-HIAA DT using Kaplan-Meier survival analysis and multivariate analysis was performed using Cox regression.

Results
91 patients had increasing 5-HIAA levels. Four patients died during a median follow-up of 8 months (interquartile range, 12). The c-statistic for DSM prediction by 5-HIAA was 0.76 (95% CI 0.62–0.90), and 5-HIAA DT <434 days had positive and negative predictive values for DSM of 75 and 76%, respectively. Patients with a 5-HIAA DT <434 days had higher risk for DSM during follow-up (Log-Rank test, P=0.02). In sub-group analysis this difference was found only among patients with a non-pancreatic NET (P=0.002). In the entire cohort, FPS were comparable between patients with 5-HIAA DT longer vs. shorter than 434 days. However, patients with small-intestine NET with 5-HIAA DT <434 days had a higher risk for progression (P=0.006), also in multivariate analysis (Hazard Ratio 15.3, 95% CI 1.01–232.6, P=0.049).

Conclusions
Short 5-HIAA DT is associated with increased DSM and lower FPS in patients with NET, and specifically among those with SINET, and can be used as a prognostic measure in NET patients.

Ventral fractures are prevalent among patients with acromegaly in spite of normal bone mineral density reflecting overall duration of disease regardless of biochemical control or cure

Marko Stojanovic1,2, Dragana Miljic1,8, Sandra Pekic1,2, Mirjana Doknic1,2, Marina Nikolic Djurovic1,2, Zvezdana Jemuovic1, Vera Popovic1 & Milan Petakos1,2
1Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia; 2University of Belgrade, School of Medicine, Belgrade, Serbia.

Introduction
Skeletal complications of acromegaly are among its most persistent and invalidating impacts. Dual-X-ray absorptiometry (DXA) alone might be insufficient or even misleading for bone health assessment in acromegaly.

Patients and methods
Patients with acromegaly (N=170) were classified as active (N=104), operatively cured (N=34) or medically controlled (N=32). 57 males and 113 females were included, 52.8 (22.0–78.5) years old. Bone mineral density (BMD) was assessed at L1-L4 and Femoral neck (FN) using DXA Hologic Discovery-W-QDR. BMD results were expressed as Z score, accounting for age and gender. Vertebral fracture assessment (VFA) on Th4-L4 was performed in 71 patients (24 male, 47 female) to identify number, type, location and degree of severity of vertebral fractures (VFs).

Results
L1-L4 BMD was normal in all patients and not significantly different in active (Zsc: 0.61 ±0.13) cured (Zsc: 0.32 ±0.25) or controlled acromegaly (Zsc: 0.17 ±0.32). FN BMD was normal in all and not significantly different in active (Zsc: 0.61 ±0.11) cured (Zsc: 0.59 ±0.19) or controlled acromegaly (Zsc: 0.49 ±0.22). VFs were identified in 23.9% (1771) of patients. Prevalence in males was significantly higher than in females (33.3% vs. 19.2%, P<0.01). Patients with and without VFs did not differ in BMD L1-L4 Zsc (0.98 ±0.06 vs. 1.04 ±0.02) or FN Zsc (0.83 ±0.05 vs. 0.86 ±0.02). Duration of the disease in patients with VFs was significantly longer (14.1 ±1.9 vs. 9.6 ±1.2 yrs) than in those without VFs (P<0.05). Prevalence of VFs was significantly higher in controlled (62.5%) and cured (40.0%) compared to active (17.8%) acromegaly (P<0.01).

Conclusions
Considerable prevalence of vertebral fractures (24%) was identified in a large cohort of patients with acromegaly, irrespective of normal bone mineral density. Duration of the disease was the main determinant of VFs prevalence, regardless of the biochemical control or cure. VFs are important, persistent and invalidating yet often under-recognized complication of acromegaly.

**Evaluation of pituitary toxicity after radiotherapy for cerebral chondrosarcomas in adult patients**

Suzanne Laroche1, Loïc Feuverte1, Alain Beauchet2, Rémi Dendale3, Philippe Chanson4, Eric Brucker4 & Christel Jublan1

1Endocrinologie, Hôpital Pitié Salpêtrière, APHP, Paris, France; 2Unité de Recherche Clinique, Département de Sûreté Publique, Hôpital Ambroise Paré, APHP, Paris, France; 3Centre de Protonthérapie d’Orsay, Institut Curie, Orsay, France; 4Endocrinologie, Hôpital Bichèvre, APHP, Le Kremlin Bicêtre, France; 5Radiothérapie, Hôpital Pitié Salpêtrière, APHP, Paris, France.

Pituitary dysfunction can be a consequence of cranial radiotherapy. It usually occurs years after the treatment. However little is known on risk factors for pituitary dysfunction. The object of this study was to evaluate radiation induced pituitary toxicity of proton beam therapy in a cohort of adult chondrosarcoma patients. The files of 113 patients were reviewed. Mean age at the beginning of radiotherapy was 43 years old (18–76). Mean dose delivered to the tumor was 67 Gy and mean dose delivered to the pituitary gland was 59 Gy. Mean post-radiotherapy follow-up time was 7 years (4–17). Pituitary dysfunction was observed in 78 patients, within the delay of 4 years after radiotherapy. The prevalence of hypoprolactinemia was of 40%, thyrotrophic insufficiency was 36%, corticotrophic insufficiency 31%, and gonadotrophic insufficiency 25%. No significant differences were shown in the delay of dysfunction between the pituitary axes. In multivariate analysis, risk factors known to increase the risk of vascular side-effects of radiation (sex, age, smoking, high blood pressure, dyslipidemia and diabetes mellitus) were not associated with an increase of pituitary dysfunction.

Conclusions

Pituitary toxicity of radiotherapy is frequent after 4 years. The high prevalence of hypoprolactinemia pinpoint a possible hypothalamic origin of post radiotherapy pituitary insufficiency. A prospective follow up is necessary to complete these observations and propose relevant guidelines. Our study analyses the largest cohort of patients with chondrosarcomas after proton beam therapy. Our results emphasize the importance of careful and long term endocrine follow-up of these patients.

**Figure:** Kaplan-Meyer curve for pituitary dysfunction.

**Safety of long-term growth hormone (GH) treatment in adults with GH deficiency (GHD): an analysis from the NordiNet® International Outcome Study**

Jens Otto Jørgensen1, Vera Popovic-Brkic2, Efie Pourmara3, Birgitte Pedersen4, Anita Cledica5 & Christian Strasburger5

1Aarhus University Hospital, Aarhus, Denmark; 2University of Belgrade, Belgrade, Serbia; 3Novo Nordisk Health Care AG, Zurich, Switzerland; 4Novo Nordisk A/S, Sorø, Denmark; 5Charité Universitätsmedizin Berlin, Berlin, Germany.

Long-term safety data (1998 to mid-2016) are reported for adult patients with GHD treated with GH (Norditropin® somatropin, Novo Nordisk) as prescribed by treating physicians in the real-life clinical setting and enrolled in NordiNet® International Outcome Study (IOS) (NCT00960128), a non-interventional, multicentre study.

Objective and hypotheses

To describe and report safety data and incidence rates (IRs) (events/1000 patient-years) of adverse drug reactions (ADRs), serious adverse events (SAEs) and serious ADRs (SADRs).

**Method**

Events were classified by MedDRA Preferred Term/System Organ Class (SOC). IRs during GH treatment were calculated.

**Results**

Data for 2438 patients (adult-onset, 90.1%; female 44.0%; mean (s.d.) age at treatment start, 43.3 (17.8) years; duration of follow-up, 5.8 (4.7) years; GH dose, 0.41 (0.32) mg/day) were analysed. Overall, 197 adverse events (AEs) were reported in 150 patients. Among these patients, mean (s.d.) treatment duration to first AE was 4.7 (4.1) years and GH dose at AE onset was 0.36 (0.31) mg/day. After the first AE, GH dose was unchanged in 55.3%, discontinued in 26.4% and decreased in 7.6% of patients (not reported/other for 10.7%). IRs were 11.91 for SAEs, 1.89 for SADRs and 5.52 for ADRs. Most frequently reported (n ≥ 10) AEs by SOC (n, %) were nervous system disorders (n=43, 21.8%), neoplasms (benign, malignant and unspecified) (n=35, 17.8%), musculoskeletal and connective tissue disorders (n=20, 10.2%); general disorders and administration-site conditions or infections and infestations (each n=15, 7.6%); and cardiac disorders (n=14, 7.1%). Type 2 diabetes was reported as an AE in four patients. Twelve deaths (one possibly related) were reported.

**Conclusions**

IRs of SAEs, ADRs and SADRs were low. Data from NordiNet® IOS revealed no new safety signals, further supporting the favourable safety profile of GH replacement in adults with GHD.

**GH and IGF-1 levels at 12 weeks predict long-term responses to lanreotide Autogel in treatment-naïve acromegalic patients: post-hoc analyses from the PRIMARYS study**

Philippe Caron1, Stephan Petersen2, Aude Houchard3, Caroline Sert3 & John S Bevan4

1Department of Endocrinology, CHU Larrey, Toulouse, France; 2ENDOC Center for Endocrine Tumors, Hamburg, Germany; 3Ipsen Pharma, Boulogne-Billancourt, France; 4Department of Endocrinology, Aberdeen Royal Infirmary, Aberdeen, UK.

**Background**

In PRIMARYS, lanreotide Autogel (LAN) 120 mg/28 days reduced tumour volume (TV), and GH/IGF-1 levels in patients with GH-secreting macroadenomas. In post-hoc analyses, we investigated predictive factors for treatment responses.

**Methods**

PRIMARYS, a 48-week, international, open-label study, involved 90 treatment-naive patients with GH-secreting macroadenomas receiving LAN. Factors predictive for hormonal control (HC; GH ≤ 2.5 µg/L+ normal IGF-1) at last post-baseline value available (LVA) or ≥ 20% TV reduction (TVR) at week 48/LVA were investigated using univariate logistic regression. Week-12 GH, IGF-1 and TV cutoff values for predicting responses were obtained from ROC curves, maximising the Youden index. Analyses used intention-to-treat populations and P ≤ 0.05 as significant.

**Results**

From univariate analyses, HC was more likely in women (odds ratio: 2.9 times higher for women vs. men), and older patients (2.2 times higher for each 10-year higher age), and with lower baseline IGF-1 (1.1 times higher for each 10% lower IGF-1 level [% upper limit of normal, ULN]), but no association with GH levels was shown. HC was determined by week-12 hormonal response: optimal cut-offs were 1.19 µg/L for GH (sensitivity, 0.74; specificity, 0.67; AUC, 0.87) and 110% ULN for IGF-1 (0.89, 0.85 and 0.93, respectively).

Univariate analyses revealed no baseline factors influencing TVR. TVR was, however, determined by changes from baseline to week 12 in GH, IGF-1 and TV: optimal cut-offs were −69% for GH (sensitivity, 0.74; specificity, 0.67; AUC, 0.74), −61% for IGF-1 (0.58, 0.80, 0.75), and −21% for TV (0.81, 0.97, 0.93).

**Conclusions**

Based on post-hoc PRIMARYS data, treatment-naive patients with GH-secreting macroadenomas are more likely to achieve long-term hormonal control with LAN 120 mg/28 days if GH levels are < 1.2 µg/L and IGF-1 levels < 110% ULN at 12 weeks, and more likely to achieve clinically significant long-term reductions in TV with >60% reductions in GH/IGF-1 levels by week 12.

Long-term treatment with pegvisomant (Somavert®): Observations from 2090 acromegaly patients followed in ACROSTUDY

Aart Jan van der Lee1, Beverly Biller2, Thierry Brune3, Michael Buchfelder4, Ezio Ghigo5, Kajije Pan6, Peter Jonsson7, Joanne Lavenberg8, Christian J. Strasburger9, Susan Webb10, Cecilia Camacho-Hubner11 & Judith Hey-Hadavi12

1Erasmus University Medical Center, Rotterdam, The Netherlands; 2Massachusetts General Hospital, Boston, MA, USA; 3Université de la Méditerranée, Marseille, France; 4Università di Torino, Torino, Turin, Italy; 5University of Erlangen-Nürnberg, Erlangen, Germany; 6Charite-Universitätsmedizin, Berlin, Germany; 7Universitat Autonoma de Barcelona, Barcelona, Spain; 8Pfizer Inc Endocrine Care, New York-Collegeville, USA; 9Pfizer Inc ACROSTUDY Endocrine care, Solllentuna, Sweden.

Introduction

Pegvisomant (PEGV) is approved for the treatment of acromegaly since 2003. This is the second interim analysis of data from ACROSTUDY, with the majority of patients treated for at least five years (ys).

Methods/design

ACROSTUDY is an international, open-label, prospective, non-interventional, post-marketing surveillance study monitoring the long-term safety and efficacy of PEGV. Patients were enrolled in the study on an ongoing basis.

Results

As of May 31, 2016, data from 2090 patients (51% men) from 15 countries were available. Mean treatment duration was 7.6 yrs (median 8.1 range: 0.0–19.1 yrs). Patients were followed in ACROSTUDY for a mean of 6.3 yrs (median 6.8, range 0.1–12.1). At ACROSTUDY start, there were 12 patients in the 0–18 yrs category and 203 patients in the > 70 yrs category. At PEGV start, pituitary insufficiencies were observed for gonadotrophins (37.9%), TSH (29.1%) and ACTH (28.3%). 54.4% of patients experienced adverse events (AEs) with most common AE being headache (4.9%), vitamin D deficiency (4.6%) and arthralgia (3.7%). SAEs were experienced in 22% of patients (2.3% were treatment related, while 70% of patients discontinued treatment due to the SAE). A total of 78 deaths were reported (all non-treatment related).

Locally assessed MRIs showed that most patients (72.2%) had no change in tumour size relative to last exam; 16.8% had decrease in tumour size, 6.8% had an increase, and 4.3% had both increase and decrease. Shift analysis demonstrated that of the 1245 with reported normal LFTs (AST/ALT) at baseline, 3% had increase, and 4.3% had both increase and decrease. Shift analysis demonstrated that this second interim analysis of long-term follow up showed that PEGV is an effective and safe treatment in patients with acromegaly. Data indicate low occurrence of reported pituitary tumor changes, liver test elevations and site administration reactions.

Amenorrhea without vasomotor symptoms in women over 40: A sign of pathological hyperprolactinemia?

Irena Illovsayskaya, Alexader Dreval & Yulia Krivosheeva

Moscow Regional Research & Clinical Institute, Moscow, Russia.

Background

Hyperprolactinemia is often seen in women of reproductive age (20–35 years), most often due to microprolactinomas. However, prolactinomas do occur in older women.

Objective

To analyze clinical features of hyperprolactinemia in women >40 years.

Methods

Material and methods

Clinical and biochemical data of 185 women with pathological hyperprolactinemia were analyzed.

Results

Seventy (37.8%) patients had microprolactinomas (MI), 57 (30.8%) – macroprolactinomas (MA), and 58 (31.4%) – non-tumoural hyperprolactinemia (NT). Among them, 26 (36.1% of corresponding subgroup) with MI, 27 (46.6%) with NT and 37 (64.9%) with MA were >40 years of age. Menstrual disturbances and infertility issues are key factors for prolactin measurement but among these women, it was a reason to visit doctor only in few cases. In most cases with onset of hyperprolactinemia within 40–50 years of age, women themselves or their gynecologists considered amenorrhea as a natural postmenopause, missing the correct diagnosis. It was characteristic for hyperprolactinemic women that they did not experience vasomotor climacteric symptoms. Weight gain was common (68% women) but was also considered as climacteric and result of ageing. Headache and visual impairment were common causes for referral later on, and hyperprolactinemia was found due to hormonal investigation after MR-visualization of pituitary tumor. In some cases with prolactin levels 1300–1900 mIU/L, differential diagnosis was required between hyperprolactinemia due to pituitary stalk compression and prolactinomas with moderate secreting activity (“hook” phenomenon was excluded). However, significant tumor shrinkage and (in some cases) restoration of regular menstrual cycle after 3–6 months of cabergoline treatment confirmed prolactinoma.

Conclusion

If a woman over 40 has menstrual irregularity or amenorrhea and does not experience any vasomotor symptom, it is a reason to prove a natural menopause by measuring high FSH levels (>25 mIU/L). In cases of lower FSH levels it is reasonable to consider pathological hyperprolactinemia.

Serotonin, ATRX and DAXX as differential diagnostic markers of neuroendocrine tumours (NETs) in the sellar region. An immunohistochemical study in a large series of pituitary adenomas and in a non-pituitary NET

Olivera Casar-Borota1, Johan Botlin1,2, Dan Granberg3, Johan Wikström4, Frederik Pontén5 & Jacqueline Trouillas6

1Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; 2Department of Clinical Pathology, Uppsala University Hospital, Uppsala, Sweden; 3Department of Medical Sciences, Uppsala University, Uppsala, Sweden; 4Department of Surgical Sciences, Uppsala University, Uppsala, Sweden; 5Faculté de Médecine Lyon-Est, Université Lyon 1, Lyon, France; 6Centre de Pathologie et de Biologie Est, Groupeement Hospitalier Est, Hospices Civils de Lyon, Bron, Lyon, France.

We present a case of a patient with a locally invasive, serotonin- and ACTH-reactive tumour in the sellar region, filling the sphenoïd sinus and expanding into the epipharynx. Clinical examination completed by 68-Gallium-DOTA-TOC PET revealed tracer uptake in the sellar tumour as well as in a 7 mm lesion in the pancreatic tail. A differential diagnosis between silent corticotroph adenoma and another primary or secondary neuroendocrine tumour (NET) with ACTH-expression was difficult. As serotonin was strongly positive in the tumour cells and its expression in pituitary endocrine tumours has not been systematically studied, we performed immunohistochemical analysis of serotonin in a large series of pituitary adenomas of different hormonal types from 246 patients. In addition, ATRX and DAXX, which mutations are associated with a subset of pancreatic NETs have been studied by using immunohistochemistry in the same cohort of pituitary tumours.

None of the examined pituitary tumours expressed serotonin. There was normal expression of ATRX and DAXX corresponding to a lack of ATRX/DAXX mutations in the pituitary tumours. Thus, serotonin-immunolabelling tumours in the sellar region most probably represent primary or secondary neuroendocrine tumours of non-pituitary origin. ATRX and DAXX do not seem to be involved in the pathogenesis of pituitary adenomas. Demonstration of ATRX or DAXX mutations in a neuroendocrine tumour of the sellar region excludes pituitary adenoma and suggests a non-pituitary NET, probably of pancreatic origin.

Long-term follow-up of a family with a large AIP gene deletion: variable phenotypes and challenges in the management

Pedro Marques1, Mary Dang1, Arla Ogilvie1, Helen Store2, Michael Powell3, Joan Grieve4, Jane Evans5, Ajith Kumar6 & Marta Korbonits4

1Centre for Endocrinology, William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, London, UK; 2West Hertfordshire Hospitals NHS Trust, Watford, UK; 3Department of Paediatric Endocrinology, Royal London Hospital, Barts Health NHS Trust, London, UK; 4The National Hospital for Neurology and Neurosurgery, London, UK; 5Department of Radiology Barts Health NHS Trust, London, UK; 6North East Thames Regional Genetics Service, Great Ormond Street Hospital, London, UK.

Introduction

Germinal aryl hydrocarbon receptor-interacting protein (AIP) mutations are responsible for 15–30% of familial isolated pituitary adenomas (FIPA). We report

Endocrine Abstracts (2017) Vol 49
a 4-generation FIPA kindred with a heterozygous AIP gene deletion in exon 2, highlighting the benefits of genetic screening and management challenges in affected subjects and asymptomatic carriers.

Patients
A 45y woman died of a spinal epedymoma (obligate carrier). Her 18y son showed lethargy over the following months attributed to grief. However, investigations due to headache revealed hypothpituitarism and a clinically non-functioning PA was diagnosed. Two years later, his 185 cm 18y-brother was diagnosed with a sparsely-granulated PA co-expressing PRL/GH. Fourteen years after operation his IGF-1 was repeatedly raised with small increase in his tumour remnant. Lantrectide treatment was started and surgery is planned. A Rathke’s cyst was detected in a bulky gland in their eupituitar 17y mutation carrier sister when she was first screened, which is now is regressed. However, after 8y follow-up a 4 mm-microadeno was became visible, with normal PRL, IGF-1 and OGTT-GH nadir 0.38 µg/L. Their 27y second-cousin presented amenorrhoea after cessation of oral contraceptive, hyperprolactinemia and 2xULN IGF-1. Her MRI showed 2 pituiatory microadenomas, corresponding to a 6 mm-somatotropinoma on the right and a 4 mm-prolactinoma on the left, confirmed histologically.

Discussion
Of 14 subjects with AIP mutations, 4 have PA, 1 epedymoma and 7 are asymptomatic (penetrance 29%). Epedymomas were described with loss of genetic material at 11q13-locus, but has not been described in patients with AIP mutations. The slow regrowth of the tumor in the brother suggests that long-term monitoring of acromegaly. However, discrepancies between GH nadir and IGF-I concentrations were higher in patients (both HT(Se+)) and HT(Se-)) when compared to controls: (3.01 ± 1.66 and 3.01 ± 1.90 vs 1.77 ± 0.88 µU/L, P < 0.000), but FT4 concentrations were not different: (12.81 ± 4.01 vs 12.46 ± 2.64 vs 12.93 ± 2.88 µg/L, P > 0.05). TSH lab concentrations were different, both between HT(Se+ ) and HT(Se-), as well as between and patients and controls (1325 ± 25.98 vs 4200.96 ± 3177.13 vs 20.48 ± 30.73 µU/mL, P < 0.0001). Global cognitive function (MMSE, Visual- and Digit Span), attention span in visual and verbal modality (Numbers from WAIS and Visual span from WMS-R), conceptual tracking (TMT A and B), verbal divergent thinking (Phonemic fluency test, Listing of animals from BDEA, TMT B, Verbal fluency test).

Results
Selenium levels were within the normal range in all groups, but significantly higher in HT(Se-) vs controls (94.88 ± 20.63 vs 86.95 ± 14.95 µg/L, P < 0.05). TSH concentrations were higher in patients (both HT(Se+ ) and HT(Se-)) when compared to controls: (3.01 ± 1.66 and 3.01 ± 1.90 vs 1.77 ± 0.88 µU/L, P < 0.000), but FT4 concentrations were not different: (12.81 ± 4.01 vs 12.46 ± 2.64 vs 12.93 ± 2.88 µg/L, P > 0.05). TSH lab concentrations were different, both between HT(Se+) and HT(Se-), as well as between and patients and controls (1325 ± 25.98 vs 4200.96 ± 3177.13 vs 20.48 ± 30.73 µU/mL, P < 0.0001). Global cognitive function (MMSE, Visual- and Digit Span), attention span in visual and verbal modality (Numbers from WAIS and Visual span from WMS-R), conceptual tracking (TMT A and B), verbal divergent thinking (Phonemic fluency test, Listing of animals from BDEA, TMT B, Verbal fluency test).

Discussion
Selenium (Se) is a trace element that plays key roles in thyroid pathology. In patients with Hashimoto thyroiditis (HT), Se supplementation might reduce antibody levels and may provide additional beneficial effects, such as on cognition. Aim To evaluate cognitive function (cognitive decline) in patients on long-term levothyroxine replacement for primary hypothyroidism with and without selenium supplementation. Design Cross-sectional, case-control study. Patients and methods Sixty-nine patients with HT (mean age 43.52 ± 14.33 yrs) on long-term levothyroxine replacement and 57 euthyroid controls, matched for age, sex, and educational level, were included. HT patients were divided into 2 groups, 25pts with (Se+) and 44pts without selenium supplementation(Se-). Neuropsychochological evaluation assessed general cognitive function/cognitive screening: MMSE, Visual- and Digit Span, attention span in visual and verbal modality (Numbers from WAIS and Visual span from WMS-R), conceptual tracking (TMT A and B), verbal divergent thinking (Phonemic fluency test, Listing of animals from BDEA, TMT B, Verbal fluency test).

Results
Selenium levels were within the normal range in all groups, but significantly higher in HT(Se-) vs controls (94.88 ± 20.63 vs 86.95 ± 14.95 µg/L, P < 0.05). TSH concentrations were higher in patients (both HT(Se+) and HT(Se-)) when compared to controls: (3.01 ± 1.66 and 3.01 ± 1.90 vs 1.77 ± 0.88 µU/L, P < 0.000), but FT4 concentrations were not different: (12.81 ± 4.01 vs 12.46 ± 2.64 vs 12.93 ± 2.88 µg/L, P > 0.05). TSH lab concentrations were different, both between HT(Se+) and HT(Se-), as well as between and patients and controls (1399 ± 25.98 vs 4200.96 ± 3177.13 vs 20.48 ± 30.73 µU/mL, P < 0.0001). Global cognitive function (MMSE) was different between groups (29.16 ± 1.31 vs 29.16 ± 1.61 vs 29.54 ± 0.93, P > 0.05), but conceptual tracking and verbal divergent thinking was different between all groups (TMT-A:36.40 ± 12.85 vs 40.89 ± 21.89 vs 29.81 ± 11.57, P < 0.001, TMTB:89.00 ± 27.88 vs 103.93 ± 48.81 vs 73.02 ± 24.10, P < 0.001, KF:21.88 ± 5.61 vs 19.07 ± 5.65 vs 21.44 ± 5.11, P < 0.05, FF:11.28 ± 3.37 vs 9.22 ± 3.69 vs 11.05 ± 3.44, P < 0.05).

Conclusion
Patients treated for primary hypothyroidism according to routine clinical care guidelines show persistent impairments in cognitive functioning which were, in certain domains, improved with selenium supplementation. Future studies are still needed in order to provide reliable evidence to support selenium supplementation in a clinical practice.

Which is the best tool to use when initiating the differential diagnosis of a thyrotropic patient? A challenge to current guideline recommendations
Carolina Perdomo1, Elisa Gil Ramos1, Gila Gutiérrez Buey1, María Llavero1, Javier Gargallo1, Javier Arbizu2, Magdalena de la Higuera1
1Department of Endocrinology. University of Navarra, Pamplona, Spain; 2Department of Nuclear Medicine. University of Navarra, Pamplona, Spain.

Aim
Differential diagnosis (DD) of thyrotoxicosis is critical as the treatment of the three main causes of this condition (Graves' disease [GD], Toxic Multinodular

Endocrine Abstracts (2017) Vol 49
Goitre [TMG], and Thyroiditis [TS]) differs substantially. Recently published diagnostic algorithms investigating hyperthyroidism embrace the presence of thyrotropin receptor (TSH-R) antibodies (TRab) as the first and most crucial diagnostic step. Although TRab measurement has important limitations (some can block or be neutral to TSH-R, or pass undetected by the assay), Guidelines recommend thyroid radionuclide scan (TRS) when TRab are absent. Our objective was to compare the TRab vs. TRS values in the DD of hyperthyroidism.

We sought to analyse limitations of the current diagnostic Guidelines which could lead to misdiagnosis and improper treatment of thyrotoxicosis.

Methods
We conducted a retrospective study of 235 outpatients attended at our Centre from 2006 to 2016. Inclusion criteria were patients with overt or subclinical hyperthyroidism from whom TRab and TRS levels were taken at the time of diagnosis. SSPS 20.0 was used for statistical analysis. Pearson’s correlation was applied to quantify the relationship between the two diagnostic tools.

Results
We grouped the sample in Gr. A: 89 (37.8%) those with positive TRab; Gr. B: 102 (43.4%) those with diffuse TRS uptake; and Gr. C: 146 (62.2%) those with negative TRab. All groups were partially overlapped. In Gr. A, the TRS reported a diffuse increase uptake (consistent with GD) in 63 (70.8%), heterogeneous uptake consistent with TMG in 21 (23.6%), and absent or low uptake consistent with TRS in 5 (5.6%). In Gr. B, only 63 (61.8%) had positive TRab. In Gr. C, up to 39 (26.7%) of individuals had a diffuse increased uptake in TRS. Pearson’s r analysis between positive TRab and diffuse increased uptake was: 0.431 (P = 0.001).

Conclusions
Provided that a high diffuse uptake by TRS can only be associated with GD, our results support the value of thyroid scintigraphy as the first step in the DD of thyrotoxicosis.

Cardiovascular risk factors in patients with autoimmune thyroiditis
João Sérgio Neves1, Catarina Cunha1, Celestino Neves2, Sofia Castro Oliveira1, Oksana Sokhatska1, Camila Dias1, César Esteves2, Miguel Pereira1, José Luíz Medina1, Luís Delgado2 & Davide Carvalho1,3
1Faculty of Medicine, University of Porto, Portugal; 2Endocrinology Service, São João Hospital, Faculty of Medicine, University of Porto, Portugal; 3Department of Biostatistics and Medical Informatics, Faculty of Medicine, São João Hospital, University of Porto, Portugal

Background
Overt thyroid dysfunction is associated with an increased cardiovascular risk. The impact of subclinical hypothyroidism and autoimmune in the increased cardiovascular risk remains controversial. Aim: To evaluate the interrelations between thyroid function, thyroid autoimmunity and cardiovascular risk factors, in patients with autoimmune thyroiditis (AIT).

Methods
353 subjects with AIT were evaluated. We defined three groups based on TSH levels: TSH <2.5 µIU/ml, TSH 2.5–5.0 µIU/ml and TSH >5.0 µIU/ml. We recorded thyroid function tests, thyroid autoimmunity, insulin resistance markers including Homeostasis Model Assessment for Insulin Resistance (HOMA-IR), lipid profile, homocysteine, C-reactive protein (CRP) and vitamin B12 levels. Statistical analysis was performed using Kruskal-Wallis test and Spearman correlations.

Results
Our sample comprised 94% females with a mean age of 47 ± 16.3 years. The group TSH <2.5 µIU/ml presented higher levels of HOMA-IR when compared to the other two groups [2.96(1.76–4.59) in TSH>5.0 µIU/ml vs 1.86(0.97–2.56) in TSH 2.5–5.0 µIU/ml and 1.58(1.06–2.46) in TSH <2.5 µIU/ml, P = 0.002]. In the total group we observed positive correlations between free T3 (FT3) and both HDL (r = 0.118, P = 0.028) and ApoA1 (r = 0.129, P = 0.024); TSH was positively correlated with HOMA-IR (r = 0.146, P = 0.018) while free T4 (FT4) was negatively correlated with homocysteine (r = −0.119, P = 0.041). In the group TSH <2.5 µIU/ml, positive correlations were found between TSH and both FT3 (r = 0.136, P = 0.037) and homocysteine (r = 0.147, P = 0.028); FT4 and CRP (r = 0.136, P = 0.037) and also anti-thyroglobulin and ApoB (r = 0.165, P = 0.013); anti-thyroglobulin was negatively correlated with homocysteine (r = −0.186, P = 0.006). Negative correlations between anti-thyroglobulin, total cholesterol

(r = 0.371, P = 0.004), LDL (r = −0.325, P = 0.011), ApoB (r = −0.342, P = 0.022) and lipoprotein(a) (r = −0.470, P = 0.001) were revealed in the group TSH 2.5–5.0 µIU/ml. Regarding the group TSH > 5.0 µIU/ml, we found positive correlations between FT3 and HDL (r = 0.358, P = 0.030), vitamin B12 (r = 0.398, P = 0.024) and HOMA-IR (r = 0.424, P = 0.031); and between anti-thyroglobulin and homocysteine (r = 0.383, P = 0.033).

Conclusion
We observed significant correlations between thyroid function, thyroid autoimmunity, insulin resistance, lipid profile and homocysteine that may contribute to an increased cardiovascular risk in AIT.

Evaluation of the effectiveness of personalized radiiodine treatment in Graves' disease
Ana Fernandes1, Teresa Faria1, Ana Oliveira1, Jorge Pereira1 & Pedro Coelho2
1Centro Hospitalar São João, Porto, Portugal; 2Universidade Fernando Pessoa, Porto, Portugal

Aim
Radioiodine activities for the treatment of Graves’ disease hyperthyroidism are still subject to discussion, as is the use of a fixed approach over a dosimetric one. We aimed to evaluate our success rate using a personalized dosimetric approach: instead of the “(MBq I-131 x g gland mass x 100)/percentage uptake at 24 h” activity calculation, we further adjusted for factors such as gender, age, diagnosis, 2 h and 4 h radioiodine uptake, previous medication, and clinical history.

Materials and methods
We reviewed data from all patients treated with radioiodine therapy (RIT) for hyperthyroidism at our department (n = 179), from January 2008 to January 2016, selected those with Graves’ disease (n = 118), and excluded the ones without follow-up (n = 11). RIT was considered successful if either euthyroidism or hypothyroidism were achieved. We evaluated success rates differences between lower and higher activities. All statistical analyses were carried out using IBM SPSS version 21.0 for Mac. A type I error 0.05 was considered.

Results
107 patients were included (44.36 ± 13.07 years; 89 female). RIT was successful in 91.6% (n = 98), while 8.4% (n = 9) remained hyperthyroid. If we consider the success after the first RIT, 72.0% (n = 77) succeeded, while 28.0% (n = 30) remained hyperthyroid. 87 (83.1%) were submitted to a single therapy whereas 20 (18.7%) were subjected to multiple RIT. There were no significant outcome differences between the lower and higher activities used (P = 0.061).

The used activities ranged between 148 MBq and 703 MBq (335.92 ± 101.60 MBq).

Conclusion
Our results confirm RIT effectiveness in Graves’ disease hyperthyroidism treatment. Although using inferior activities to those generally prescribed (200–800 MBq), we achieved higher success rates – comparable to the best reported in the literature. There were no statistically significant outcome differences between the lower and higher activities used, highlighting the importance of tailored treatment approaches to warrant the best therapeutic outcome and while avoiding unnecessary exposure.

**Citrus flavanones naringenin and hesperetin induced mild functional alteration in thyroids of old-aged Wistar rats**

Marko Miler1, Vladimir Ajdzanovic1, Natasa Ristic1, Branko Filipovic1, Gordana Uscebrka2, Dragana Miljic1, Verica Milosevic1 & Branka Sosic-Jurjevic1

1Institute for Biological Research “Sinisa Stankovic”, University of Belgrade, Belgrade, Serbia; 2Department of Veterinary Medicine, Faculty of Agriculture, University of Novi Sad, Novi Sad, Serbia; 3Department of Neuroendocrinology, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia.

Aging is a complex process characterized by a progressive decline in cellular function, alterations of the endocrine system and the increased incidence of thyroid diseases. Citrus flavanones naringenin (NAR) and hesperetin (HES) may contribute to maintenance of health at old age however they may also affect thyroid hormone economy. The aim of this study was to test weather NAR or HES administration alter thyroid functioning. NAR or HES were administrated orally (15 mg/kg) to male 24-month-old Wistar rats during 4 weeks. Control groups received vehicle, sunflower oil. Immunohistochemical staining of thyroglobulin (Tg), thyroid (T3) and sodium iodide symporter (NIS) were performed. Immunopositivity of Tg or T3-Tg in thyroid follicles were measured as intensity of optical density (OD) or relative intensity of fluorescence (RF). Thyroid stimulating hormone (TSH) and total T4 concentrations were measured in serum. After citrus flavanones treatments, thyroids showed Tg and T3-Tg immunopositivity mainly in the colloid of the follicles. The obtained results showed increased (P < 0.05) OD of Tg and T3-Tg RI after both flavanones treatments, while NIS expression did not change. Serum TSH increased (P < 0.05) only after NAR, although T4 remained unchanged after both treatments. In conclusion, citrus flavanones induced stronger expression of thyroid-specific proteins in gland of aged males. However, only NAR elevated serum TSH, being more potent than HES. This alteration is in line with preserved capacity of the thyroid to compensate the mild interference of flavanones treatments with thyroid hormone production in old-aged males.

**The Oxford multidisciplinary thyroid eye disease (TED) clinic; can short waiting times and use of steroid sparing agents (SSA) reduce total steroid dose and requirement for surgery/radiotherapy?**

Helen Turner1, Joel David2 & Jonathan Norris1

1Department of Endocrinology, Churchill Hospital, Oxford, UK; 2Department of Rheumatology, Nuffield Orthopaedic Hospital, Oxford, UK; 3Oxford Eye Hospital, Oxford, UK.

Introduction

The Oxford multidisciplinary thyroid eye disease (TED) clinic comprising an oculoplastic surgeon, rheumatologist and endocrinologist with access to orthoptics, neuroradiology and radiotherapy was established in 2013. The aim was to facilitate rapid referral and treatment in a specialist centre in keeping with Amsterdam Declaration. Early use of steroid sparing agents (SSA) and recently rituximab forms part of the treatment regimen.

Methods

A retrospective, 4-year, single-centre, consecutive case series of patients with TED audited both outcomes (in terms of severity and activity) derived from the VISA classification and treatment modalities, at presentation and 1 year follow-up.

Results

104 patient records were analysed. Mean wait from referral to first review was 1 month with 42% of referrals originating from endocrinology departments. Mean age was 51.2 years. 26.0% (n=27) of patients were male and 35% were current/ex-smokers. Where thyroid biochemistry was available at referral (n=380): 51% were euthyroid, 45% hyperthyroid and 4% hypothyroid. Thyroid TSH was positive in 85% of patients checked compared to 62% of TPO Ab. Presenting signs included: ocular surface disease (68%), exophthalmos (53%), diplopia (45%), eyelid retraction (38%) and reduced vision (7%). Presenting activity was mild (VISA ≤3/10) in 69% and severe in 16% (≥7); severity mild in 47.1% and severe in 20.2%. 1 year data (n=36) showed mild activity at 1 year in 95% (38.9% at referral) and 0% severe disease (33% at referral). Intravenous methylprednisolone was administered to 30 patients; 47% required ≤1.5 g total with use of SSAs: methotrexate (n=30), azathioprine (n=6), ciclosporin (n=10) and Rituximab (n=8). Orbital decompression surgery was performed in 12.5% (n=13), squint surgery 12.5%, eyelid surgery 22% and orbital radiotherapy 8%.

Conclusion

Early use of SSAs has significantly reduced the overall steroid load in patients when compared to established European guidance (EUGOGO). This regimen confers a low orbital decompression and orbital radiotherapy rate.

**24-month efficacy of a single radiofrequency ablation on autonomously functioning thyroid nodules**

Stella Bernardi1,2, Fulvio Stacul2, Andrea Michelli1, Veronika Calabro1, Fabiola Giudici1, Chiara Dohrn1 & Bruno Fabris1,2

1Università degli Studi di Trieste, Trieste, Italy; 2ASUTS, Trieste, Italy.

Background

Radiofrequency ablation has been advocated as an alternative to radioiodine and/or surgery for the treatment of autonomously functioning benign thyroid nodules. However, only a few studies have measured radiofrequency ablation efficacy on autonomously functioning benign thyroid nodules. The aim of this work was to evaluate the 24-month efficacy of a single session of radiofrequency ablation (performed with the moving shot technique) on solitary autonomously functioning benign thyroid nodules.

Methods

Thirty patients with a single, benign autonomously functioning thyroid nodule, who were either unwilling or ineligible to undergo surgery and radioiodine, were treated with radiofrequency ablation between April 2012 and May 2015. All the patients underwent a single radiofrequency ablation, performed with the 18-gauge needle and the moving shot technique. Clinical, laboratory, and ultrasound evaluations were scheduled at baseline, and after 1, 3, 6, 12, and 24 months from the procedure.

Results

A single radiofrequency ablation reduced thyroid nodule volume by 51, 63, 69, 75%, and 76% after 1, 3, 6, 12, and 24 months, respectively. This was associated with a significant improvement of local cervical discomfort and cosmetic score. As for thyroid function, 33% of the patients went into remission after 3 months, 43% after 6 months, 50% after 12 months, and 70% after 24 months from the procedure. This study demonstrates that a single radiofrequency ablation allowed us to withdraw anti-thyroid medication in the majority of patients, who remained euthyroid afterwards.

Conclusions

This study shows that a single radiofrequency ablation was effective in 70% of patients with autonomously functioning benign thyroid nodules. Most importantly, patients responded gradually to the treatment, such that it is possible that longer follow-up studies might show greater response rates.

**Association of vitamin D levels with thyroid function and autoimmunity**

Luís Raposo1,2, SandraMartins3,4, Daniela Ferreira1, João Tiago Guimarães3,5 & Ana Cristina Santos1,2

1Grupo de Estudo da Insulino-Resistência da Sociedade Portuguesa de Endocrinologia, Diabetes e Metabolismo, Portugal; 2Instituto de Saúde Pública da Universidade do Porto - EPIUnit, Universidade do Porto, Porto, Portugal; 3Serviço de Patologia Clínica, Centro Hospitalar de S. João, Porto, Portugal; 4Departamento de Biomedicina, Faculdade de Medicina, Universidade do Porto, Porto, Portugal; 5Departamento de Epidemiologia Clínica, Medicina Preditiva e Saúde Pública, Faculdade de Medicina, Universidade do Porto, Porto, Portugal.

Association of vitamin D levels with thyroid function and autoimmunity is widely debated. Several studies have suggested that low levels of vitamin D are associated with various thyroid disorders, including autoimmune thyroiditis. Vitamin D is a steroid hormone that plays a crucial role in calcium homeostasis and bone health, but its role in thyroid function is not well understood.

Vitamin D deficiency has been linked to an increased risk of thyroid autoimmunity and thyroid-related disorders. Studies have shown that vitamin D levels are inversely correlated with the prevalence of thyroid autoantibodies, such as thyroid peroxidase (TPO) and thyroglobulin (Tg) antibodies. Low vitamin D levels have been associated with a higher likelihood of developing Hashimoto’s thyroiditis, a common autoimmune thyroid disease.

A number of studies have investigated the relationship between vitamin D and thyroid function. Some studies have reported that low vitamin D levels are associated with an impaired thyroid function, while others have found no significant association. The mechanisms by which vitamin D may affect thyroid function are complex and not fully understood.

In summary, there is evidence to suggest that vitamin D deficiency may contribute to the development of thyroid-autoimmunity and thyroid-related disorders. However, more research is needed to clarify the role of vitamin D in thyroid function and understand the underlying mechanisms.
Introduction
Vitamin D is a hormone that acts through the Vitamin D receptor (VDR) not only on the skeletal system but on a great number of target tissues, including thyroid gland. In recent years the association of vitamin D with autoimmune thyroid diseases (AITD), has been suggested. VDR gene polymorphisms had been associated with an increased risk of AITD. In addition a recent meta-analysis showed that AITD patients had lower level of 25-hydroxyvitamin D. However some studies have not confirmed the association between vitamin D levels and AITD. Furthermore, data on the effects of vitamin D in thyroid hormones and TSH serum levels are very poor.

The aim of our study was to evaluate the association of vitamin D levels with thyroid function and positivity for thyroid antibodies.

Material and methods
PORMETS is a nationwide, cross-sectional study in Portugal comprising a sample of 4095 adults. Five hundred participants were randomly selected to be included in the present study. A fasting venous sample was collected and serum calcium, PTH, 25-hydroxyvitamin D [25(OH)D], TSH, FT3, FT4 and thyroid antibodies were measured.

Results
Our study included 286 women and 214 men with a mean age of 53.4 years.
Free thyroxine (FT4), free triiodothyronine (FT3), TSH and thyroid antibody levels did not present any significant linear correlation with 25(OH)D levels. After adjustment for sex and age, TSH, FT4 and FT3 levels did not present any significant association with 25(OH)D levels or with low vitamin D status.

Logistic regression analysis did not show any significant association of low vitamin D status with thyroid antibodies positivity, even after adjustment for several possible confounding variables.

Conclusion
Our results do not confirm the association of vitamin D levels with thyroid function and positivity for thyroid antibodies.

Early use of steroid-sparing agents in treatment of moderate-to-severely active thyroid eye disease
Zuzana Sipkova1, Joel David2, Helen Turner3 & Jonathan Norris1

Introduction
The management of active thyroid eye disease (TED) remains controversial. High dose intravenous methylprednisolone (IVMP) is the current recommended first-line treatment based on EUGOGO guidance. Such therapy has the potential for serious adverse effects. We present the outcomes of an alternative approach in the management of moderate-to-severely active TED, using steroid-sparing agents (SSAs) in conjunction with IVMP. Methotrexate is used as the first-line SSA alongside ciclosporin and rituximab depending on activity score.

Methods
Presented is a retrospective, 4-year, single-centre, consecutive case series of patients with moderate-to-severely TED treated using the Oxford protocol. Treatment modality, disease activity (derived from the VISA classification) and adverse effects are reported at initial presentation, 6- and 12-month follow-up.

Results
104 consecutive case notes were reviewed of TED patients treated by the TED MDT. 24 patients with moderate-to-severely active disease were identified (mean age 46.8 years; 12 female) with a mean pre-treatment VISA activity score of 5.5/10 (s.d. = 2.3; range 1–9). IVMP and an SSA was commenced in all patients. Mean total steroid dose was 2.72 g (s.d. = 1.4; 1.0–6.9). 38% of patients (n = 9) received 1.5 g of IVMP or less. Only two patients required 4.5 g of IVMP. Two patients (n = 2) were defined as whether serum TSH normalized within 3 months. There were reported adverse effects including postural hypotension, nausea, joint pain and cheilitis.

Conclusion
Based on our experience and outcomes, the initiation of an SSA with limited dose intravenous methylprednisolone (IVMP) is as an effective and safe therapy for moderate-to-severely active TED. This approach results in a significant reduction in disease activity with reduced total steroid load.

Prediction of response to methimazole based on clinical symptoms in new onset Graves’ patients, using neural networks
Hoon Sung Choi & Won Sang Yoo
1Kangwon National University Hospital, Chuncheon-si, Republic of Korea; 2Dankook University Hospital, Cheonan-si, Republic of Korea.

Introduction
Anti-thyroidal drug (ATD) therapy is a treatment of choice for Graves’ disease because of its effectiveness and low rate of adverse effect. Response to ATD or remission rate varies among individuals, although there were few useful clues for prediction of treatment response. We applied neural network model to predict response to methimazole, based on clinical symptoms at initial clinical symptoms.

Methods & Design
We reviewed 20 new onset Graves’ patients and used their symptoms at initial diagnosis. A total of 12 symptoms were classified into 5 categories (general, cardiac, neuromuscular, psychologic, and gastrointestinal). In each category, the number of positive symptoms was considered the score of the category. Response to methimazole was defined as whether serum TSH normalized within 3 months. A total of six variables, 5 symptom categories and sex, were used for a 2-layer neural network model. Among 20 subjects, 15 subjects used in training set, and the other 5 subjects were used in model validation.

Results
The mean age of subjects was 49.3 ± 12.2 years and male subjects were 6 (30%). Our neural network model with 15 subjects as a training set showed sensitivity of 1.0 and specificity of 0.545 with AUC of 0.75 to predict normalization of serum TSH within 3 months. With same model, the estimated scores of the other 5 subjects corresponded to their actual outcomes.

Conclusion
Despite the limitation of small sample size, our neural network model showed promising performance to predict response to methimazole with patients’ clinical symptoms in new onset Graves’ patients.

Serum Interleukin-37 (IL-37) levels were increased and correlated with oxaliplatin stress parameters in Hashimoto’s Thyroiditis (HT) patients
Rosaria Maddalena Ruggeri1, Teresa Manuela Vicchio1, Angela Alibrandi2, Salvatore Giovinazzo3, Rosaria Certo4, Giuseppe Giaffreda4, Francesco Trimarchi5, Sebastiano Gangemi3 & Mariateresa Cristani5
1Division of Endocrinology, Department of Clinical-Experimental Medicine and Pharmacology, University of Messina, Messina, Italy; 2Department of Economy, University of Messina, Messina, Italy; 3University of Messina, Accademia Peloritana dei Pericolanti, Messina, Italy; 4Division of Clinical Immunology and Allergology, Department of Human Pathology, University of Messina, Messina, Italy; 5Department of Pharmaceutical Sciences and Health Products (SCIFAR), University of Messina, Messina, Italy.

Background
IL-37, member of the IL-1 family, is a natural suppressor of immune and inflammatory responses. Increased serum IL-37 levels were observed in several autoimmune diseases, including Graves’ disease. No data on TH are available from the literature.

Materials and methods
We enrolled 45 euthyroid HT patients (5 M e 40 F, mean age 38.5 ± 12.6) and 50 age- and sex-matched healthy controls. None was on LT-4 therapy. Smokers, subjects with kidney failure, history of cancer or autoimmune, inflammatory and infection comorbidities were excluded. Serum IL-37 levels were measured by ELISA (kit IL-37 DuoSet Elisa, R&D System, Minneapolis, USA; minimum detectable dose 10 pg/ml). Specific serum tests, such as d-ROMs (derived Reactive Oxygen Metabolites) test and BAP (Biological Antioxidant Potential) test (Diacon International, Italy), were performed in all patients.

Endocrine Abstracts (2017) Vol 49
subjects to investigate the changes in oxidative balance, and AGEs (Advanced Glycation End Products) were determined as a specific marker of oxidative stress.

Results
IL-37 levels were significantly higher in TH (mean ± s.d.: 999.59 ± 1064.93 pg/ml) than in controls (448.02 ± 498.96 pg/ml; \( P = 0.018 \)). In both groups, these values correlated negatively with age (TH, \( R_S = -0.377 \), \( P = 0.016 \); controls, \( R_S = -0.404 \), \( P = 0.006 \)) and were tendentially higher in men than in women (\( P = 0.063 \)). Furthermore, there was a positive correlation between serum IL-37 levels and TSH, statistically significant in TH (\( R_S = 0.412 \), \( P = 0.008 \); in controls, \( R_S = 0.418 \), \( P = 0.053 \)). The regression analysis showed a significant positive association between IL-37 and d-ROMs (\( P = 0.022 \)) and AGEs (\( P = 0.014 \)); if serum d-ROMs and AGEs levels increased, serum IL-37 levels also increased. A significant direct correlation between serum IL-37 levels and AGEs was also observed (\( R_S = 0.578 \), \( P = 0.006 \)).

Conclusion
Serum IL-37 levels were significantly increased in TH patients and correlated with oxidative stress parameters. Given the anti-inflammatory properties, IL-37 could be an innovative research strategy for TH pathogenesis and therapy.

The increased immunohistochemical expression of IL-23 in Hashimoto’s thyroiditis but not in Graves’ disease patients
Tatjana Zake1,2, Sandra Skuja3, Ieva Kalere2, Ilze Konrade1,2 & Valerija Groma1
1Riga East University Hospital, Riga, Latvia; 2Department of Internal Medicine, Riga Stradins University, Riga, Latvia; 3Institute of Anatomy and Anthropology, Riga Stradins University, Riga, Latvia.

Introduction
Recently, Th17 cells and their cytokines were identified to play an important role in the pathogenesis of thyroid autoimmunity. IL-23, produced by antigen presenting cells, is required for survival and differentiation of Th17 cells, and is known to guide T cells toward the Th17 phenotype. Its serum levels are increased in several autoimmune diseases, including Hashimoto’s thyroiditis (HT), however, the expression level of IL-23 within thyroid tissue assessed by immunohistochemistry has not been addressed thoroughly before. The aim of our study was to estimate the levels of immunoeexpression and distribution of IL-23 within thyroid tissue of patients with HT and Graves’ disease (GD) and compare them with controls.

Materials and Methods
Forty seven adult patients presenting 21 cases of HT, 8 of GD, and 18 cases of ordinary colloid goiter without autoimmune component, which served as control group, were enrolled in this study. Immunostaining was performed using an anti-IL-23 antibody (Santa Cruz Biotechnology, CA, dilution 1:50). Levels of immunopositivity for IL-23 were defined semiquantitatively.

Results
In HT patients the expression of IL-23 was detected both in the abundant inflammatory lymphocytic infiltrates characteristic of HT and follicular epithelial cells, whereas tissues obtained from GD patients demonstrated the weak thyrocytic expression predominantly. Majority of patients in controls showed negative or occasional expression of IL-23. The highest IL-23 immunopositivity was observed in HT patients, furthermore, it was significantly higher compared to the control group and GD (\( P<0.001 \), \( P=0.043 \), respectively). No difference was found between the expression of IL-23 in GD patients and the control group (\( P=0.324 \)). Additionally, weak expression of IL-23 was observed in connective tissue septae and blood vessels in most HT patients.

Conclusion
Overexpression of IL-23 might play a role in the pathogenesis of HT, guiding T cells towards the Th17 phenotype and promoting the autoimmune inflammation of the thyroid gland.

GP210

Laser ablation of benign thyroid nodules without anesthesia: clinical tolerance, hazards and complications
Pablo Vidal-Ríos, Teresa Jiménez, Antonio Rodríguez, Laura Villas & Sebastian Vidal-Ríos
Coruna Endocrinology Center, La Coruna, Spain.

Laser ablation of thyroid nodules has been used for the last two decades (Pacella et al, 2000). Surprisingly, complications are less frequent in patients treated without anesthesia, probably because eventual pain is an useful alarm symptom, leading the operator to repositioning the fiber during the procedure (Pacella et al., 2015).

Material and methods
A total of 32 patients were included, without using local anesthesia. Nodules were solid, 5–72 ml volume, age 36–84 years, gender female (84%). Procedure included three phases: (1) Preparation 30 min (informed consent and final decision about anatomic approach); (2) Laser ablation 30 min (usually 3–8 paths, 3–5 illuminations each and total energy of 50–500 joules2/3); and (3) Observation 60 min (with ice collar and vital constants monitoring). A 1064 nm Nd:YAG laser from an EchoLaser generator (Elesta, Florencia-Italy) was used. Triple thyroid image (Ultrasound, Doppler and Elastography) was monitored using an Acuson 2000 Helitrix platform (Siemens, Forchheim-Germany).

Results
30 of 32 patients (93.75%) would accept another ablation if necessary. Pain was referred as 1–6 of 10 (arithmetic mean 3.5; median 2). Difficulties were: cervical discomfort (4), excessive time of manipulation because short neck (1), transient mild hypertension (1), mild vasovagal reaction (1), small intra-thyroid hematoma (1) and a partial and transient Horner syndrome (1) resolved 3 months later.

Discussion
Clinical tolerance in general was spectacular. Major complaints were postural. Complications were mild and transient, although potentially risky. No cases of severe pain, voice change, fever, skin burn or cough were observed. In the future, preventive specific strategies (like careful identification of risky patients, laser cauteterization of large feeding vessels or protective hydrossection to protect vital organs) will be considered before laser ablation.

Conclusions
Clinical tolerance was very good. Complications were few, mild and transient, but potentially risky. This highlights the importance of identifying properly risky patients as well as the need of including preventive strategies.

Orbital ectopic thyroid mistaken for metastases
Greta Jaguciškaite1,2, Agne Petrenaitė1,2, Rasa Ziukaitė2 & Zydrune Visockiene1,2
1Vilnius University Faculty of Medicine, Vilnius, Lithuania; 2Vilnius University Hospital Santariskiu Klinikos, Centre of Endocrinology, Vilnius, Lithuania.

Introduction
Ectopic benign thyroid tissue outside the normal migration path of the thyroid is an extremely rare condition that, to our knowledge, has never been described in the orbit.

Clinical case
75-year-old woman with nodular thyroid was referred to Vilnius University Hospital Santariskiu Klinikos for fine needle aspiration biopsy. Her complaints were palpitations, difficulty swallowing, diplopia, 5.61 kU/l) on admission. Fine needle aspiration biopsy and histological examination revealed nodular thyroid hyperplasia and follicular adenoma. To exclude orbital malignancy head MRI was performed. Imaging
Biostatistics, Hacettepe University Faculty of Medicine, Ankara, Turkey; population expressing the GG genotype (OR = 1.83, CI: 1.04-3.20; \( P = 0.033 \)). No significant associations of genotypes were detected with the age of onset of disease, presence and severity of orbitopathy in GD and thyroid function status at diagnosis and daily dose of thyroxine per kg body weight in HT. AITD and control groups were similar in terms of mean IL-6 levels, but mean serum IL-6 level was significantly lower in the group with GA genotype than in the group with GG genotype in GD (\( P = 0.013 \)). Mean level of TNF-\( \alpha \) was significantly higher in patients with AITD compared with controls (\( P < 0.001 \)) but TNF-\( \alpha \) levels were not significantly different in the groups of different genotypes of the selected polymorphism of the Period3 gene.

Conclusion
This study provides the first evidence for a genetic association between AITD and the Period3 gene, highlighting the possible relevance of polymorphisms in clock genes in the etiopathogenesis of AITD.

GP213
IgG4-related fibrous variant of Hashimoto thyroiditis in a non-Asian woman
Sónia da Vale1,2, Ana Filipa Martins1, Cristina Costa1, Lucas Batista1 & Margarida Mendes de Almeida4
1Endocrinology Department, Santa Maria Hospital, North Lisbon Hospital Center, Lisbon, Portugal; 2Endocrinology Department, Lisbon Medical School, Lisbon, Portugal; 3Surgery Department, Santa Maria Hospital, North Lisbon Hospital Center, Lisbon, Portugal; 4Pathology Department, Santa Maria Hospital, North Lisbon Hospital Center, Lisbon, Portugal.

Introduction
First described in 2009, IgG4-related thyroid disease includes several subcategories: Riedel’s thyroiditis, fibrous variant of Hashimoto thyroiditis (FVHT), IgG4-related Hashimoto thyroiditis (HT) and Graves’ disease with elevated IgG4. It is rare, with most cases described in Japan and characterized by increased IgG4 plasma cells at immunostaining.

Case Report
A 59-year-old Caucasian woman, without known Asian ancestry, was observed at the endocrinology department due to neck swelling over the previous 4 months. She reported dyspnea at some neck positions, fatigue and constipation. She presented a diffusely enlarged very hard thyroid, with some nodules and reduced mobility. Laboratory evaluation revealed primary hypothyroidism, very elevated titres of anti-thyroglobulin and anti-peroxidase antibodies, elevated erythrocyte sedimentation rate and G immunoglobulins (3400 mg/dl, reference range, RR: 751–1560), elevated IgG4 (267 mg/dl, RR: 4–86) and k-dominant light chains. There was no monoclonal band; IgA and serum calcium levels were normal. Ultrasound confirmed an enlarged heterogeneous thyroid, with nodules and small calcifications. Cytology was compatible with lymphocytic thyroiditis. The CT scan additionally revealed multiple latero-cervical ganglia, esophageal diversion, airway impression and reduction of the nasopharynx lumen. There was no evidence of malignancy, infection, other autoimmune disorders or non-neck involvement. Euthyroid state was obtained with levothyroxine reposition and total thyroidectomy was performed. Histology revealed a FVHT with elevated IgG4-positive plasma cells and IgG4/IgG ratio. After surgery, serum IgG levels decreased and IgG4 levels became normal.

Discussion
The very hard rapidly enlarging thyroid, short disease duration, high antibody titers, hypothyroidism, diffuse thyroid involvement, no evident extrathyroidal invasion, increased inflammatory parameters, IgG and k dominant profile and elevated IgG4 that normalized after surgery, suggested a fibrous IgG4-HT. Histology and immunostaining confirmed an IgG4-related FVHT. Although very rare in non-Asian countries, it is important to suspect and confirm an IgG4-related thyroid disease, allowing an adequate diagnosis, treatment and follow-up.

Hypothyroidism and heart failure outcome: a study with a long-term follow-up

V Triggiani1, B Licchelli1, D Grande1, C Rizzo2, T Leopizzi1, I Gioia1, E Guastamacchia1, M.Iacoviello1 & M. Iacoviello3
1Endocrinology and Metabolic Diseases Unit, University of Bari, Bari, Italy; 2School of Cardiology, University of Bari, Bari, Italy; 3Cardiology Unit, Cardiothoracic Department, Polyclinic Hospital of Bari, Bari, Italy.

Aim of the study
To evaluate the impact of HT on the progression of HF during a long-term follow-up.

Methods
From 2006 to 2015, we evaluated 675 consecutive CHF outpatients (523 males, 64±13 years) in stable clinical conditions (>1 month) and in conventional therapy. They underwent a clinical evaluation, 12-lead ECG, echocardiogram, blood pressure measurement and a routine chemistry. They have been carefully evaluated for the presence of thyroid diseases. The follow-up was extended on a median value of 47 months, for a maximum of 123 months. Thyroid function has been evaluated every 4 months, more frequent (every 6 weeks) for patients receiving levothyroxine. The onset of HT during follow-up was defined as detection of TSH values above the upper limit. When HT was detected, thyroid replacement therapy was started according to guidelines. During follow-up were also evaluated hospitalizations related to exacerbation of HF and death.

Results
Four hundred and fifty-five patients (67.7%) were euthyroid at the enrolment and showed a normal thyroid function during the follow-up; in 80 patients (11.8%) there was a previous diagnosis of HT; in 40 patients (5.9%) the HT was detected at the time of enrolment; 52 patients (7.7%) developed HT during the follow-up. To avoid confounding factors, we compared patients in euthyroid status at the enrolment and during follow-up and patients with HT at the enrolment. At univariate Cox regression analysis, a significant association between HT and the events, i.e. mortality for all causes (HR: 1.60; 95% CI: 1.08–2.38; P=0.019) and hospitalization for HF worsening (HR: 2.13; 95% CI: 1.54–2.96; P<0.001) was found. At multivariate Cox regression analysis, HT remained associated only with HF hospitalization (HR: 1.58; 95% CI: 1.09–2.29; P=0.015), but not with mortality (HR: 1.05; 95% CI: 0.67–1.65; P=0.819), after correction to LVEF<35%, GFR<60 ml/min/m2, NTproBNP>1000 pg/ml, NYHAII, PA 95 mmHg.

Conclusion
In a long-term follow-up, HT is independently associated with hospitalization due to HF worsening, but not with mortality. We hypothesise that HT is able to induce hemodynamic instability leading to hospitalization, but, probably, its correction with thyroid hormone therapy could in part blunt its impact on patients’ survival.

Introduction
Thyroid hormones play a central role in the regulation of the cardiovascular system. Heart failure with preserved ejection fraction (HfPfEF) is responsible for more than 50% of all heart failure cases and its main pathophysiological alteration is diastolic dysfunction. Diminished thyroid function is known to predominantly impair diastolic function, however the thyroid hormone status in HfPfEF remains largely unknown.

Methods
We evaluated an animal model of HfPfEF, ZSF1 Obese rats (ZSF1-Ob, n = 13), and their control group, ZSF1 Lean rats (ZSF1-Ln, n = 11), with serial echocardiography followed by invasive hemodynamic recordings and tissue collections at 20 weeks. Serum TSH was quantified by ELISA. Thyroxine (T4) and triiodothyronine (T3) were quantified in serum, left ventricle and visceral adipose tissue by radioimmunoassay (RIA).

Results
At 20 weeks of age, ZSF1-Ob group developed HF with diastolic dysfunction, as shown by an increased E/E' on echocardiography, a prolonged time constant of end-diastolic pressure-volume relationship on invasive hemodynamic evaluation. Serum levels of thyroid hormones were significantly decreased in ZSF1-Ob rats compared with their control group, ZSF1-Ln (T3: 3.87 ± 0.85 vs 10.51 ± 7.91 ng/g in ZSF1-Ln, P < 0.012; T4: 0.99 ± 0.43 vs 2.02 ± 0.60 ng/g in ZSF1-Ln, P = 0.016). The levels of T3 and T4 in visceral adipose tissue were not significantly different between the two groups.

Conclusion
We observed a decrease in serum and myocardial thyroid hormone levels in an animal model of HfPfEF. This may contribute to impaired diastolic function and, therefore, may constitute an interesting therapeutic target in HfPfEF.

STAT6 deficiency ameliorates Graves’ disease severity by suppressing thyroid epithelial cell hyperplasia

Bingbing Zha

Department of Endocrinology, Fifth People’s Hospital of Shanghai Fudan University, Shanghai, China.

Signal transducer and activator of transcription 6 (STAT6) is involved in epithelial cell growth. However, little is known regarding the STAT6 phosphorylation status in Graves’ disease (GD) and its role in thyroid epithelial cells (TECs). In this study, we found that STAT6 phosphorylation (p-STAT6) was significantly increased in TECs from both GD patients and experimental autoimmune Graves’ disease mice and that STAT6 deficiency ameliorated GD symptoms. Autocrine IL-4 signalling in TECs activated the phosphorylation of STAT6 via IL-4R engagement, and the downstream targets of STAT6 were Bcl-xL and cyclin D1. Thus, the IL-4–STAT6–Bcl-xL/cyclin D1 pathway is crucial for TEC hyperplasia, which aggravates GD. More importantly, in vitro and in vivo experiments demonstrated that STAT6 phosphorylation, inhibited by AS1517499, decreased TEC hyperplasia, thereby reducing serum T3 and T4 and ameliorating GD. Thus, our study reveals that in addition to the traditional pathogenesis of GD, in which autoantibody TRAb stimulates thyroid-stimulating hormone receptors and consequently produces T3 and T4, TRAb could also trigger TECs producing IL-4, and IL-4 then acts in an autocrine manner to activate p-STAT6 signalling and stimulate unrestricted cell growth, thus aggravating GD. These findings suggest that STAT6 inhibitors could be potent therapeutics for treating GD.

Delayed TSH recovery after dose adjustment during TSH-suppressive levothyroxine therapy in patients with differentiated thyroid cancer

Hye In Kim, Tae Hyuk Kim, Young Nam Kim, Hou Kreased Tec, So Young Park, Yun Jae Chung, Jae Hoon Chung & Sun Wook Kim

1 Samsung Medical Center, Seoul, Republic of Korea; 2 Chung-Ang University Hospital, Seoul, Republic of Korea.

Background
Delayed thyroid-stimulating hormone (TSH) recovery during treatment of Graves’ disease is caused by long-term excessive thyroid hormone, which results in down-regulation of pituitary thyrotrophic cells. However, it is unknown whether delayed TSH recovery exists after levothyroxine (LT4) dose adjustment in patients with differentiated thyroid cancer (DTC) who are taking a suppressive dose of LT4.

Methods
We retrospectively reviewed 97 DTC patients who had a reduced LT4 dose while receiving excessive LT4 for TSH suppression. LT4 levels at baseline (point 1), 6 months (point 2), and 12-18 months (point 3) after LT4 dose adjustment were compared with each other. A delayed TSH recovery group whose TSH levels exceeded target TSH levels (according to recent guidelines) between points 2 and 3 was identified.

Results
In patients with LT4 reduction, the median TSH level at point 3 was significantly higher than that at point 2 (0.17 vs 0.09 mU/L, P < 0.001). The delayed TSH recovery group (44.3%, 43 of 97 patients) showed increased body weight during follow-up (60.84–62.73 kg, P = 0.01), although TSH levels remained in the target range. A lower LT4 dose per body weight (LT4 dose/weight) after reduction [HR (95% CI), 0.03 (0.00–0.54); P = 0.03], greater changes in the LT4 dose/weight (1.10 (1.00–1.22); P = 0.04), and higher BMI before surgery [1.19 (1.03–1.38); P = 0.01] predicted the occurrence of delayed TSH recovery.

Conclusions
Delayed TSH recovery was commonly observed after LT4 dose adjustment was performed as recommended by dynamic risk stratification. Six months may not be enough time to evaluate real thyroid hormone status by TSH levels.

Analysis of a large cohort of subjects with thyroid hemiagenesis (THA) reveals random seasonality in the dates of birth
Ewelina Szczepanek-Parulski1, Ariadna Zybek-Kocik1, Marek Niedziela2, Agata Czarnywojtek1 & Marek Ruchala1
1Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; 2Department of Paediatric Endocrinology and Rheumatology, Poznan University of Medical Sciences, Poznan, Poland.

Introduction
In the etiology of thyroid dysgenesis (TD) an interplay between genetic and environmental factors is thought to play a crucial role. Data from previous studies on association between the season of birth and the incidence of TD causing congenital hypothyroidism (mainly agenesis and ectopy) are conflicting. To date, seasonality of births have not been analysed yet in regard to congenital absence of one thyroid lobe (thyroid hemiagenesis, THA).

Patients and Methods
Dates of birth of 102 patients diagnosed with THA were analysed and compared to 102 control subjects with no thyroid pathology matched for age and gender. Both groups were subdivided according to the month of birth (I-XII), season of birth (spring, summer, autumn, winter) and quarter (1-4) of the year. The differences were analysed statistically.

Results
Distribution of the months of birth in the group of patients with THA was asymmetric; smaller number of patients were born in the 4th (X-XII) quarter of the year (19 patients) vs 1st (28 patients), 2nd (29 patients) and 3rd (26 patients). Similarly, smaller number of patients were born in autumn (IX-XI) – 19 patients, compared to other seasons of the year (winter – 27 patients, spring – 27 patients, summer – 29 patients). However, if the studied group was compared to the control group, the difference in the distribution of the months of birth was at the border of statistical significance (P<0.05).

Conclusions
An analysis of the largest so far reported cohort of patients with THA indicate that environmental factors including intrauterine exposure to maternal seasonal viral infections or variable vitamin D availability seem not to play a significant role in pathogenesis of THA.

Thyroid hormone T3 protects mice from fasting induced skeletal muscle atrophy by counteracting autophagy
Sarasoua Ucci1,2, Valentina Russo1, Maria Giulia Santaguida2, Marco Centannì3,4, Viviana Moreo1 & Cecilia Verga Falzacappa1,2,3,4
1Pasteur Institute, Rome, Italy; 2Sapienza, University of Rome, Medical Surgical Sciences and Biotechnologies Department, Rome, Italy; 3Sapienza, University of Rome, Department of Anatomy, Histology, Forensic Medicine and Orthopedic, Section of Histology, Rome, Italy.

Purpose
Skeletal muscle has been recognized as a thyroid hormones (THs) target for contractile function, regeneration, metabolism and glucose disposal. Despite a role in regulating muscle development has been described, little is known about the role of THs in regulating muscle homeostasis in a pathological state such as food deprivation induced atrophy. The purpose of this study is to evaluate whether thyroid hormones may hamper the fasting induced skeletal muscle atrophy and to investigate the mechanisms involved.

Methods
Preliminary data on C2C12 myotubes have suggested that T3 could counteract the starvation induced atrophy in vitro. Based on these results, BALB/c male mice (8-10 weeks) were used for in vivo experiments. Animals were food-deprived (STV) for 24 and 48 hours to induce muscle atrophy and daily injections intraperitoneally with T3 (100 µg/kgBW) or vehicle (NaCl 0.95%) were performed on hematoxylin/eosin stained sections. ATG7-Mrna was evaluated by Sybr-Green qRT-PCR and LC3II/Lc3I was evaluated by western blot.

Results and conclusions
As a sign of skeletal muscle atrophy, the STV group showed a significant (P<0.001) reduction in the Cross-Sectional Area of the myofibers, compared to the control group; on the contrary the T3 treated group (STVT3) ensures the maintenance of the fiber size. Protein degradation in skeletal muscle cells is mediated by the autophagic/lysosomal pathway. The core autophagic machinery is composed of ATG (autophagy-related) proteins. One ATG family member, Atg7, activates enzyme facilitating microtubule-associated protein-light-chain3 (LC3)-phosphatidylethanolamine conjugation. The presence of T3 was able to significantly reduce ATG7 mRNA expression, moreover the hormone significantly reduces LC3II/LC3 protein expression, when compared to STV mice (P<0.05). On the whole our results suggest that T3 treatment can reduce fasting induced skeletal muscle atrophy by counteracting the autophagic process.

Will it be useful to measure PTH at 4 hours post thyroidectomy to decide for calcium replacement? 1st result of a prospective study
Silvia Silva1, Ana Rafael1, Ricardo Marques1, Luisa Moniz2, Carlos Costa1, Ricardo Capitão2, Catarina Saravia1, Clotilde Limbert1, Luis Fernandes1 & Rogério Matias1
1Surgery, Egas Moniz Hospital, Lisboa, Portugal; 2Endocrinology, Egas Moniz Hospital, Lisboa, Portugal.

Introduction
Calcium replacement after Thyroid surgery has been changing along times. The aim for this replacement is to avoid hypocalcaemia effects after thyroid surgery but not all the patients seem to need it. Parathyroid hormone (PTH) has a short half-life after its release into the bloodstream, making it a good marker of calcium metabolism in short time after surgery.

Methods
Prospective study of Endocrine Surgery Multidisciplinary group of one Centre between March and December of 2016. Calcium replacement was done according to a protocol defined by multidisciplinary group after PTH measurement. PTH values were considered normal above 15 pg/ml. Data were analyzed using SPSS.

Results
96 patients underwent total thyroidectomy vs totalization of thyroidectomy. 5 were excluded since they were admitted at ICU and protocol was not implemented. PTH was measured 4 hours after surgery. From the 91 patients, 74 had normal PTH levels. The remaining patients (17) started calcium replacement according to established protocol and showed no symptoms of hypocalcaemia.

Conclusions
Our Sample has a significance of 0.05 in the non-parametric, Q-square and Kolmogorov-Smirnov test.

Endogenous TH metabolite 3-iodothyronamine (T1AM) and synthetic thyronamine-like analogues SG-1 and SG-2 induce autophagy in human glioblastoma cells (U-87MG)
Lorenza Bellusci1, Martina Sabatini1, Giulia Nesi1, Simona Rapposelli1, Leonardo Rossi1, Paola Lenzi2, Francesco Fornai3, Riccardo Zacchi1 & Grazia Chiellini1
1Department of Pathology, University of Pisa, Pisa, Italy; 2Department of Pharmacy, Pisa, Italy; 3Department of Clinical & Experimental Medicine, Pisa, Italy.

Endogenous TH metabolite 3-iodothyronamine (T1AM) and synthetic thyronamine-like analogues SG-1 and SG-2 have emerged as neuroprotective agents. Autophagy has proved to be an effective therapeutic approach for neurodegenerative diseases. Therefore we investigated whether these compounds can induce autophagy in human glioblastoma cells (U-87MG). Cultured U-87MG cells were initially treated with 1µM T1AM, SG-1, SG-2 or vehicle for 30’, 4, 8 and 24 h and autophagy was monitored morphologically by assessing the presence of autophagic vacuoles and LC3-II puncta formation with transmission electron microscopy (TEM) and immunofluorescence (IF) microscopy, respectively. In addition, cellular lysates were subjected to western
blooming to assess the accumulation of microtubule-associated protein 1 light chain 3 (LC3). This protein is widely used as a marker for autophagy because it is a structural protein vital in autophagosome formation. TEM and IF microscopy showed a significant time dependent increase of autophagy-like vacuoles density and LC3 puncta formation in U87MG cells exposed to the treatment with test compounds, with T1AM and SG-1 being the most effective. Along with extensive cytoplasmic vacuolization, western blotting analysis revealed significant up regulation of LC3-II expression (P<0.01). Finally, we extended our analysis to examine the role played by our test compounds on the PTEN→ Akt→ mTOR pathway that has been suggested to play an important role in the regulation of autophagy in mammalian cells. We carried out WB for Akt, phosphorylated Akt (pAkt) and we calculated the ratio pAkt/Akt in vehicle-treated cells following test compounds administration. We found that 1 μM T1AM, SG-1 and SG-2 decreased such a ratio after 30’ and 4 h treatment, suggesting that they might induce autophagy through the modulation of pAkt level. In conclusion, T1AM and synthetic analogues induce autophagy in a glioblastoma cell line. The potential pathophysiological and/or therapeutic implications of this finding remain to be determined.

Impact of chronic high fat diet consumption on the expression of organic nutrients carriers in the small intestine of mice: role of thyroid hormones in these processes
Mariana Losacco Cerqueira, Carolina Fernanda Theodora Almeida, Paula Bargi-Souza, Maria Tereza Nunes, Patricia Gama & Francemilson Goulart-Silva
Institute of Biomedical Sciences – University of São Paulo, São Paulo-SP, Brazil.

Products of carbohydrates, proteins and lipids hydrolysis are absorbed by specific carriers located at the enterocytes apical membrane, but little is known about the mechanisms related to their regulation by own nutrients, especially considering the high consumption of fats. Carbohydrates are transported by SGLT1, GLUT5 and GLUT2 and peptides are transported by PEPT1. Cholesterol is transported by NPC1L1 and long chain fatty acids occur through FAT-CD36 and FATP4. Thyroid hormones have important effects on organic nutrients metabolism, but little is known about their role on the intestine, which led us to evaluate thyroid hormone effects on intestine organic nutrients carriers of mice fed high fat diet (HFD) or standard diet. C57BL/6 mice were fed standard diet (control) or high fat diet (HFD) for 12 weeks. Afterwards, both mice were treated with saline, PTU (antithyroid drug) or T3 for 30 days. They were killed and the jejunum was removed for histological analysis or inverted for intestinal epithelium separation from the mucosa for protein analysis by Western blotting technique. SGLT1, PEPT1 and FATP4 remained unchanged among experimental groups. On the other hand, NHE3 protein content, which is important for sodium and peptides absorption, increased significantly in the small intestine of mice fed HFD. PTU or T3 treatment did not affect these parameters. High fat compared to standard diet did not show any alteration of the villus length, but mice fed standard diet and treated with PTU or T3 showed an increased villus length compared to treated vehicle mice, however this finding have no association with the changes of nutrient carriers described above. Thus, we can infer that HFD affects the expression of some organic nutrient carriers in the small intestine, independently of thyroid hormones treatment.

Prognostic factors for intrathyroidal papillary carcinomas – a multivariate analysis
Nada Santrać1,2, Ivan Marković1,2, Merima Goran1, Marko Buta1,2, Igor Djurisic1 & Radan Dzodic1,2
1Surgical Oncology Clinic, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; 2Medical Faculty, University of Belgrade, Belgrade, Serbia.

Introduction
The aim of this study was to examine prognostic significance of patient-related, tumor-related and treatment-related factors for intrathyroidal papillary thyroid carcinomas (PTC), via multivariate analysis.

Materials and methods
This study included 153 patients with intrathyroidal PTCs (pT1pT2pT3) surgically treated in our Institution during two-decade period. Patients with locally invasive tumors (pT4) and initial distant metastases (M1) were excluded. Parameters of interest were: gender (male; female), age (\(<45; >45\) years), tumor size (pTNM classification WHO 1984), multifocality (no; yes), histological type of PTC (pure; microcarcinoma; follicular; poorly differentiated), presence of lymphonodal metastases (pN1a; ipsilateral-pN1b; contralateral-pN1b; total), surgery extent (total thyroidectomy; total thyroidectomy with lymphonodal dissections). Univariate and multivariate analysis of all parameters was performed in order to distinguish factors of significance for disease-free (DFS) and cancer-specific overall survival (cs-OS).

Results
In the follow-up, 10% of patients had locoregional or distant relapse, while 5.2% died due to PTC. Univariate analysis distinguished older age, male gender, tumors over 4 cm in diameter, multifocality and poorly differentiated PTC-types as unfavorable prognostic factors for cs-OS. DFS was significantly shorter in males vs. females, as well as in patients with multifocal vs. solitary PTC. Tumor multifocality was unfavorable prognostic factor for both DFS and cs-OS. Independent prognostic factors for intrathyroidal PTCs, based on Cox multivariate analysis, were multifocality and gender for DFS, and multifocality and age at diagnosis for cs-OS.

Conclusion
Prognostic factors define risk groups within population of differentiated PTCs providing timely, adequate treatment and opportunity for longer quality life of patients with PTCs.

DOI: 10.1530/endoabs.49.GP225

GP226
Malignancy Rate in Thyroid Nodules: Cytology versus Histology in challenging categories
Catarina Silvestre, Rita Lúis, Maria João Bugalho, Margarida Meneses de Almeida & Raquel Carvalhalo
Santa Maria Hospital, Lisbon, Portugal.

Background
To stratify the risk of malignancy, thyroid fine-needle aspiration cytology (FNAC) is an important and cost-effective method to evaluate nodules. The Bethesda System for Reporting Thyroid Cytopathology III, IV and V categories are diagnostic challenges, falling between benign and malignant.

Objective
Determine the malignancy rates of thyroid nodules classified as Bethesda Categories III-V.

Methods
Retrospective study of patients’ records with thyroid nodules classified as III-V by the Bethesda system, between January 2014-June 2016.

Results
Of a total of 2791 cytologies, 176 (6%) were classified as III-V, with the following distribution: 93 (3%) atypia of undetermined significance (AUS, III); 50 (1,8%) suspicious for follicular neoplasm (SFN, IV) and 33 (1%) suspicious for malignancy – 33%, 50 repeated the FNAC and the remaining are under evaluation. Among patients in group III, 27% (10/37) and 85% (22/26), respectively. Among patients in group III, 27 patients underwent surgery after a single AUS report (final diagnosis of malignancy – 33%), 39 repeated the FNAC and the remaining are under surveillance. The second cytology report was as follows: 24 benign, 9 AUS, 4 SM, 1 SFN and 1 unsatisfactory; surgery was performed in 9 patients (5AUS + 1SFN + 3SM) and the final diagnosis of malignancy was 44%. The malignancy rate based on histology was not statistically different between patients with one or two cytologies (P=0.693).

Conclusions
Incidence of III-V diagnostic categories in our study resemble the predicted by the Bethesda System. The malignancy rate for the AUS category was higher than expected and similar to the one found in SFN. Repeating the FNAC in the former group offered minimal additional benefit.

Fine needle aspiration biopsy in pediatric patients with thyroid nodules

Maria Manuel Costa, Rita Santos Silva, Cintia Castro-Correia, Maria Bom Sucesso, Tiago Henriques Coelho, Helena Barroca & Manuel Fontes

1Department of Endocrinology, Diabetes and Metabolism of Centro Hospitalar de São João, Porto, Portugal; 2Faculty of Medicine, University of Porto, Porto, Portugal; 3Instituto de Investigação e Inovação da Saúde da Universidade do Porto, Porto, Portugal; 4Department of Pediatrics of Centro Hospitalar de São João, Porto, Portugal. Department of Pediatric Surgery of Centro Hospitalar de São João, Porto, Portugal. Department of Pathology, Centro Hospitalar de São João, Porto, Portugal.

Introduction

Although thyroid nodules (TN) are less common in children than in adults, the risk of malignancy is much higher in pediatric age and therefore representing greater concern in this age group.

Objectives

1. Evaluate a cohort of pediatric patients with TN and search differences between subjects with malignant and benign TN regarding sex, age, compressive symptoms, cervical ultrasound characteristics, family history of differentiated thyroid cancer (FDHTC), radiation exposure and previous/existing thyroid disease.

2. Retrospective review of patients under 18 years of age with the diagnosis of TN submitted to fine needle aspiration biopsy (FNAB) from 2010 to 2016.

Results

Seventy-three patients [21% males; mean age 13.8(3.2) years] were included. 46.6% had palpable nodules. 84.9% were euthyroid and 12.3% had hypothyroidism. 31.5% of the patients had positive anti-thyroid antibodies. Ultrasound showed that TN had a diameter range of 15.9 ± 9.8 mm. 47.9% patients had a solitary nodule, 31.5% TN were hypoechogenic, 5.5% had increased intranodular flow, 10.9% had microcalcifications and 5.5% had irregular margins. We found that 5.5% of patients had undergone previous cervical irradiation and 12.3% had FDHTC. 84.9% of the patients had a conclusive FNAB at first: benign in 39 (6% papillary microcarcinoma (n = 25), chronic lymphocytic thyroiditis (n = 12), granulomatous thyroiditis (n = 1), thymus tissue (n = 1)), PLUS in 4, suspected follicular neoplasia in 3, suspected malignancy in 1 and papillary carcinoma in 15 patients. Thyroidectomy was performed in 43.8% of the patients. In histology, 71.9% were malignant. In 5.5% of patients had undergone previous cervical irradiation and 12.3% had FDHTC. 46.6% had palpable nodules. 84.9% were euthyroid and 12.3% had hypothyroidism. 31.5% of the patients had positive anti-thyroid antibodies. Ultrasound showed that TN had a diameter range of 15.9 ± 9.8 mm. 47.9% patients had a solitary nodule, 31.5% TN were hypoechogenic, 5.5% had increased intranodular flow, 10.9% had microcalcifications and 5.5% had irregular margins. We found that 5.5% of patients had undergone previous cervical irradiation and 12.3% had FDHTC. 84.9% of the patients had a conclusive FNAB at first: benign in 39 (6% papillary microcarcinoma (n = 25), chronic lymphocytic thyroiditis (n = 12), granulomatous thyroiditis (n = 1), thymus tissue (n = 1)), PLUS in 4, suspected follicular neoplasia in 3, suspected malignancy in 1 and papillary carcinoma in 15 patients. Thyroidectomy was performed in 43.8% of the patients. In histology, 71.9% were malignant. In 5.5% of patients had undergone previous cervical irradiation and 12.3% had FDHTC.

Conclusion

In most patients a conclusive diagnosis was achieved with FNAB. The high prevalence of malignancy was similar to that described in the literature. FDHTC was the only factor found associated with an increased risk of malignancy.

Trends in papillary microcarcinoma prevalence in North of Portugal

Teresa Alves Pereira, Ana Amado, Patrícia Gouveia, Rosa Castro, António Moreira da Costa, André Couto de Carvalho, Cláudia Freitas & Fátima Borges

1Endocrinology Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal; 2Nuclear Medicine Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal; 3Surgery Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal.

Introduction and Objectives

The incidence of thyroid cancer has increased worldwide. This increase has been attributed to more diagnosed papillary thyroid microcarcinomas. The purpose of this study was to analyse the growing trend of first appointments in our Thyroid Cancer Unit, namely patients with papillary microcarcinomas.

Methods

We performed a retrospective study based on the patients diagnosed with thyroid cancer between 1960 and 2016. We divided these patients into groups, based on the year of first surgical treatment: 1960 to 1996, 1997 to 2001, 2002 to 2006, 2007 to 2011 and 2012 to 2016. We calculated the relative frequency of papillary microcarcinomas comparing to the total cancer diagnostics in each group.

Results

The total count of patients with registered thyroid cancer dimensions was 1146. The mean age was 48.2 ± 15.3 years old. 81.9% were female. We have found that papillary microcarcinoma frequency increased steeply from 11.2% [35/313, 95% confidence interval (CI) 8.2–15.2%] in 1960–1996 to 30.9% (42/136, 95% CI 23.7–39.1%) in 1997–2001. Since then we observed a stabilised rate of 30.8% in 2002–2006.

Conclusions

The prevalence of papillary microcarcinomas has increased until the end of the last century. After 2002 our data showed a somewhat stabilised rate of 1/3 of all diagnosed thyroid cancers.

Differentiated thyroid cancer – comparison between patients with and without remission

Ana Amado, Patrícia Gouveia, Teresa Alves Pereira, Rosa Castro, António Moreira da Costa, André Carvalho, Cláudia Freitas & Fátima Borges

1Endocrinology Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal; 2Nuclear Medicine Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal; 3Surgery Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal.

Introduction

Differentiated thyroid cancer (DTC) is one of the most frequent forms of malignancy. Because of its favourable outcome and low mortality rates, identifying prognostic factors has been a challenge. Several risk stratification systems have been developed. Most of them include demographic and tumour specific features, as well as extrathyroidal extension. Our objective was to identify specific features, as well as extrathyroidal extension. Our objective was to identify prognoptic factors has been a challenge. Several risk stratification systems have been developed. Most of them include demographic and tumour specific features, as well as extrathyroidal extension.

Methods

Data from patients followed for DTC between 1956 and 2016 was retrieved. Patients with less than 2 years of follow up, those submitted to subtotal thyroidectomy or with positive anti-thyroglobulin antibodies were excluded. They were divided in two groups, according to the presence or absence of remission criteria (undetectable TSH-suppressed thyroglobulin levels and no evidence of structural disease). Groups were compared for age at diagnosis, nodule dimensions, multitenchity, capsule presence and extrathyroidal involvement as well as the presence of node or distant metastasis.

Results

A total of 814 patients was included, 82.9% of which were female. The median age at diagnosis was 47 years old (min. 11; max. 89). Five hundred patients had criteria for remission (Group 1) and 314 didn’t (Group 2 [36 with cancer related death, 55 with persistent or recurrent disease and 223 with undeterminate response]). Median follow up was 10 years (min. 3; max. 50) in Group I and 9 years (min. 3; max. 57) in Group 2. Patients in group 1 were significantly younger (median 44.5 vs 49.5; P < 0.001) had more multitenchity (45.7% vs 37.7%; P = 0.041) and less local (22.7 vs 30.6%; P = 0.016) and distant metastasis (0.4% vs 5.7%; P < 0.001). No differences were found in nodule dimensions, capsule presence or extrathyroidal involvement.

Conclusion

Among patients with differentiated thyroid cancer, the older ones, with unicentric tumours, local or distant metastasis at presentation seem to have worst outcome.

Radioiodine (RAI) refractory differentiated thyroid cancer (DTC): outcome and prognostic factors for DISEASE progression

Katerina Salliki, George Simeakis, Elli Anagnostou, Michalis Apostolakis, Evangelia Zapanti, Eleni Anastasiou & Maria Alevizaki

Endocrine Unit, Department Medical Therapeutics, Alexandra Hospital, Athens University School of Medicine, Athens, Greece.

Introduction

Patients diagnosed with DTC have excellent prognosis. A small percentage of patients with disease persistence do not respond to treatment with RAI (RAI-refractory DTC) and have low median survival (3.5 years). We investigated the prognostic factors and the disease course in patients with RAI-refractory DTC.

Methods

Of all DTC patients (n = 1160) followed-up in our department in recent years, 800 received RAI treatment and were classified in 2 groups: RAI-refractory DTC...
The incidence of RAI-refractory DTC was higher in patients ≥45 years and particularly in those ≥65 yrs (3% vs 7.4% vs 17.4%, P = 0.001). Men had RAI-refractory DTC more frequently than women (P = 0.02). RAI-refractory DTC patients presented higher incidence of capsular, lymph node and extra-thyroid invasion (P < 0.001), larger size (P < 0.001), worse histological type (high-risk papillary: 34.9% vs 12% and features of poor differentiation: 14% vs 6% respectively, P < 0.001). They presented more frequently distant metastases at follow-up (73.3% vs 1.5%, P < 0.001). 12 RAI-refractory patients had local persistence. 5/12 had no distant metastasis; all underwent multiple surgeries and 3 with RAI plus anti-resorptive drugs showed less efficacy in preventing second SRE compared to patients treated with anti-resorptive drugs alone. Patients treated with RAI plus anti-resorptive drugs showed less efficacy in preventing second SRE (HR 0.01) and decreased mortality (HR 0.12) as compared to patients treated with RAI alone (P = 0.008 and P = 0.015 respectively).

Conclusions

Patients with RAI-refractory DTC present disease progression at high percentage (72.7%). In these patients, tumor size is the most important unfavorable factor predicting disease progression and occurrence of distant metastases. These data may be useful in designing treatment strategy.

Maria Nuova A.O. Reggio Emilia, Reggio Emilia, Italy; 13Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy; 14Department of Medicine and Surgery, University of Salerno, Salerno, Italy; 15Institute of Biostatute and Bioimaging of the National Research Council of Italy – CNR, Naples, Naples, Italy; 16Nuclear Medicine, Catholic University of Rome, Rome, Italy; 17Endocrinology, San Raffaele Vita-Salute University, Milan, Italy.

Although differentiated thyroid cancer (DTC) has the third highest propensity to spread to the bone after breast and prostate cancer, there is a paucity of data concerning the treatment of bone metastasis (BM) in this setting. The MOSCATI (Metastasi OSeSe da Carcinoma Tiroideo) was a multicenter, retrospective study investigating the real-life outcome and management of BM in 143 patients (80 F; 63 M; median age 60 years) with DTC involving 10 specialized centers in Italy. One or more skeletal related events (SREs) were diagnosed in 58% of patients in significant association with more aggressive tumor histotype (OR 5.39), higher number of BM (OR 1.36), localization of BM to thoracic spine (OR 2.7), cervical spine (OR 4.7) or skull (OR 2.28), and lack of radio-iodine (RAI) uptake (OR 6.03). RAI treatment was performed in 93% of patients. Bone active drugs were used in 32 patients with SRE (22.4%; zoledronate in 31 and denosumab in one). Bone active drugs were used more frequently in patients with more aggressive histotype of DTC (P < 0.001), with RAI-refractory BM (P < 0.001) who did not receive RAI therapy (P < 0.001) and/or in those with multiple BM (P = 0.006), malignant hypercalcemia (P = 0.001), pathological fractures (P = 0.02) and in those undergoing radiotherapy (P < 0.001). After treatment, 13.5% of patients developed new SREs and 39 patients (27.3%) died. RAI treatment significantly prevented the second SRE (HR 0.01) and decreased mortality (HR 0.12) as compared to patients treated with anti-resorptive drugs alone. Patients treated with RAI plus anti-resorptive drugs showed less efficacy in preventing second SRE and decreasing mortality as compared to treatment with RAI alone. In conclusion, in the real life, the use of bone active drugs is currently limited to zoledronate in patients with pre-existing SREs. In this specific clinical setting, RAI therapy, but not zoledronate, prevented progression of SREs and mortality. Future studies are needed to clarify the effectiveness of anti-resorptive drugs in primary prevention of SREs and possible advantages of denosumab versus zoledronate in the treatment of BM from DTC.

Germline mutations in RET-790 and RET-791 codons (exon 13) among subjects with sporadic medullary thyroid cancer

Darko Katalinic1, Miljenko Solter2 & Nora Nikolac2

1Department of Internal Medicine, Faculty of Medicine, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia; 2UHC Sisters of Charity, Faculty of Medicine, University of Zagreb, Zagreb, Croatia.

Background

Medullary thyroid carcinoma (MTC) is a rare calcitonin producing neuroendocrine tumour that originates from parafollicular C-cells of the thyroid gland. RET proto-oncogene germline mutations are crucial for the onset and the progression of MTC, and the occurrence of single nucleotide polymorphisms could predispose the clinical course of disease. The objective of this study was to evaluate possible differences in clinical presentation among patients with/without RET codon 790 and codon 791 mutations (exon 13) (group A) compared with 63 patients with “wild-type” genotype (group B). The study was conducted according to the Declaration of Helsinki, the protocol was reviewed and approved by the institutional independent ethics committee. All patients were provided with written informed consent.

Results

Mean age for the group A was 56.2 ± 11.4 years (range, 44.8–67.6) vrs. 49.4 ± 9.7 (range 39.7–59.1) for the group B. Lymph node metastases were found in all patients (group A, n = 46 vs. group B, n = 31; P < 0.001), and distant metastases in 11 patients (group A, n = 7 vs. group B, n = 4; P > 0.001). Postoperatively, 62% of patients in group A vs. 78% of patients in group B were biochemically cured (P < 0.001). In the group A, pT-category was: T1, n = 21; T2, n = 16; and T2, n = 9. In the group B, pT-category was: T1, n = 22; T2, n = 7; and T3, n = 2 (P < 0.001).

Conclusions

Patients with RET codon 790/791 (exon13) mutations have a more aggressive clinical course and lower biochemical cure rate in comparison with patients with “wild-type” genotype. This information should be considered by genetic counseling or by operative therapy and could have clinical importance when specific targeted therapy is needed.

GP233

Comparison of clinicopathological features in patients with familial and sporadic papillary thyroid cancer

Fatma Dilek Della1, Didem Ozdenen1,2, Cevdet Aydin1,2, Berna Ogemen1, Aydan Kilicaslan1,2, Mehmet Kilic1,2, Rehan Ersoy1,2 & Bekir Cakir1,2

1Ataturk Training and Research Hospital, Ankara, Turkey; 2Yildirim Beyazit University, Ankara, Turkey.

Introduction

Although, familial medullary thyroid cancer is a known condition, familial papillary thyroid cancer (PTC) is a rare and less well described clinical entity. While some studies suggest more aggressive features in familial PTC, some do not support these findings. We aimed to compare ultrasonographical, cytopathological and histopathological results of patients with familial and sporadic PTC.

Methods

Data of 194 patients diagnosed with PTC histopathologically between 2007–2016 were retrospectively reviewed. PTC in ≥2 members of the family was defined as familial PTC. Thyroid functions, ultrasonography features, cytological and histopathological findings were compared in familial and sporadic PTC.
Results
There were 35 tumor foci in 20 familial and 253 foci in 174 sporadic PTC patients. Gender, thyroid functions, thyroid autoantibody positivity, mean nodule number, thyroidectomy indications and surgical approach were similar in both groups. Preoperative ultrasonography features were available in 20 familial and 112 sporadic nodules. There was not any difference in mean nodule diameter, echogeneity, texture, microcalcification, macrocalcification, presence of hypo-echoic halo, taller than wide shape, margin irregularity and vascularization pattern. Cytological results were distributed similarly in two groups (P = 0.433). In histopathological examination, mean tumor number was 1.79 ± 0.98 in familial and 1.46 ± 0.77 in sporadic patients (P = 0.09). Mean tumor diameters were 6.26 ± 2.4.10 mm and 9.87 ± 11.62 mm in familial and sporadic tumors, respect-ively (P = 0.074). Multicentricity, microcarcinoma rate, variants of PTC, vascular invasion and extracapsular extension were similar (P = 0.155, P = 0.239, P = 0.094, P = 0.617 and P = 0.743, respectively). Capsular invasion was significantly increased in sporadic group (19.8% vs 5.9%, P = 0.049).

Conclusion
Whether familial PTC is more aggressive than the sporadic form of the disease is controversial. Clinical, ultrasonographical, cytological and most of the histopathological features of familial and sporadic PTC were identical in our study. Early detection of cases other than index patients might cause diagnosis at an earlier stage of the disease in familial form.

A rare case of medullary thyroid cancer, mesothelioma and meningioma, due to APC and RASAL1 mutations

Charalampos Lyssikatos1, Martha M Quezado2, Fabio R Fauz3, Anna Angelousi1,4, Nargis Nasiri-Ansari5, Constantine A Stratakis1 & Eva Kassi6,7

1Section on Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), National Institutes of Health (NIH), Bethesda, MD, USA; 2Laboratory of Pathology, National Cancer Institute, Bethesda, MD, USA; 3Section on Endocrinology & Genetics, NICHD, National Institute of Health, Bethesda, MD, USA; 4Department of Pathophysiology, Unit of Endocrinology, Kapodistrian University of Athens, Athens, Greece; 5Laboratory of Biochemistry, National and Kapodistrian University of Athens, Athens, Greece; 6Endocrine Unit of Clinical and Translational Research, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece.

Introduction
Patients with “mixed” phenotypes are common among patients with multiple endocrine and non-endocrine neoplasias. Their diagnoses do not fit a given pattern making genetic counseling difficult and testing impossible to guide. Most of these patients end up getting genome-wide studies for the identification of any predisposing genetic defect. We present a rare case of a 57 year old female who presented clinically with medullary thyroid cancer (MTC), mesothelioma and meningioma. As part of our diagnostic work-up for this category of patients, we performed a SNP microarray (comparative genomic hybridization; CGH) and whole exome sequencing (WES). CGH did not reveal any abnormalities; WES revealed two variants of unknown significance (VUS) in two separate genes, namely APC and RASAL1.

Case presentation
The patient, a 57 year old female patient, was diagnosed with AML at 41y old, peritoneal mesothelioma at 43y old, meningioma at 53y old and medullary thyroid cancer with lymph node metastasis at 53y old. She also suffers from autoimmune atrophic gastritis, alopecia universalis and relapsing perichondritis of the ear.

Results
WES was performed by DNA extracted from blood and revealed two specific VUS, in the APC gene: p.R1103W, c.3307 A>G and in the RASAL1 gene: p.R538H, c.1613 G>A. The APC gene (OMIM #17500) is a tumor suppressor gene involved in Wnt / β catenin signaling pathway; mutations have been reported in Familial Adenomatous Polyposis (FAP), brain tumors and Turcot syndrome. Mutations in the RASAL1 gene (OMIM#604118) have been found in thyroid cancer (both papillary and medullary) and Cowden syndrome. The above two variants found in this patient have not been reported previously as pathogenic. The mutations in the APC and RASAL1 genes are probably involved in the tumorigenesis. In addition, the mesothelioma and meningioma are likely related to mutations in the APC gene. This unique clinical presentation has not been reported before and is being proven by additional immunostaining and molecular studies.

Conclusion
Patients with unique phenotypes may present with a list of clinical manif e stations that do not fit any given diagnosis. These patients deserve genome-wide testing
that is often rewarding but also complex. In our patient with MTC, mesothelioma and meningioma two new gene defects were identified that are probable responsible for the phenotype.

Thyrotoxic Periodic Paralysis due to Graves’ disease: a mandatory differential diagnosis in Asian patients presenting with paralysis and hypokalemia

David Barbosa1, Carolina Faría1, Ana Sofia Osório1, Emęe Nobre1, Ana Paula Vilas1 & Maria João Bugalho1
1 Endocrinology and Nutrition Department, Parc Taulí Hospital Universitari, Institut d’Investigació i Innovació Parc Taulí. Universitat Autònoma de Barcelona, Sabadell, Barcelona, Spain.

Introduction Thyrotoxic periodic paralysis (TPP) is a potentially life-threatening complication of hyperthyroidism that is underdiagnosed due to its non-specific clinical presentation. It is relatively common in Asian men with Graves’ disease. TPP attacks are frequently associated with hypokalemia.

Case presentation
We describe a 26-year-old Asian male with an unremarkable past medical history who was admitted following sudden onset of flaccid paralysis of the lower extremities. Signs and symptoms such as weight loss, diaphoresis, palpitations and mild diffuse goitre were present. The electrocardiogram showed a sinus tachycardia and the laboratory evaluation revealed markedly low potassium and phosphorous levels (K+ 1.5 mmol/L; PO43− 1.8 mmol/L). The patient was managed with intravenous potassium chloride with markedly improvement of the neurological deficits, despite a rebound hyperkalemia shortly after replacement. A thyroid profile was taken due to the suspicion of TPP in the context of Graves’ disease, and the diagnosis was made (TSH 0.01 µU/mL; free T4 5.21 ng/dl; free T3 15.64 pg/ml; TRAb 37.64 UI/l). The patient then started on oral propranolol and tiamazol, with complete remission of the symptoms and sustained normalization of serum potassium.

Conclusion
TPP is an alarming and potentially lethal complication of hyperthyroidism characterized by muscle paralysis and hypokalemia due to a massive shift of potassium into cells. This condition mainly affects male patients of Asian descent. With increasing population mobility and admixture, TPP as the presenting feature of hyperthyroidism is now more common in Western countries. Early diagnosis not only aids in definitive management with nonselective beta-blockers and correction of hyperthyroidism, but also prevents the risk of rebound hyperkalemia due to excessive potassium replacement. We report this case to emphasize the importance of recognizing TPP to avoid missing a treatable and curable condition.

GP238
A fatal case of fetal goiter: autoimmunity is the key

Irene Berges-Raso1, Lara Albert1, Assumpta Caixa`s1, Ismael Capel1, Cesar Martí n Martí n ez3 & Mercedes Rigla1
1 Endocrinology and Nutrition Department, Parc Taulí Hospital Universitari, Institut d’Investigació i Innovació Parc Taulí. Universitat Autònoma de Barcelona, Sabadell, Barcelona, Spain. 2 Obstetrics and Gynecology Department, Parc Taulí Hospital Universitari, Institut d’Investigació i Innovació Parc Taulí. Universitat Autònoma de Barcelona, Sabadell, Barcelona, Spain. 3 SDI-IDIAT, Parc Taulí Hospital Universitari, Institut d’Investigació i Innovació Parc Taulí. Universitat Autònoma de Barcelona, Sabadell, Barcelona, Spain.

Introduction
Fetal goiter is an infrequent and potentially life-threatening condition derived from either fetal hypothyroidism or hyperthyroidism. TSH-receptor stimulating antibodies (TSH-R-ABs) can cross the placenta and induce fetal hyperthyroidism and goiter. We describe a rare case of TSH-R-ABs-induced hyperthyroidism in a woman with autoimmune hypothyroidism (AH) without previous hyperthyroidism.

Case report
A 28 years old pregnant woman under treatment with Levothyroxine (LT4) for 6 years because of AH was referred during pregnancy. She had history of 2 miscarriages: fetal death at 28th gestational week (GW) two years before and fetal loss in 2015 because of coroanoimmitis. Blood tests at 12th GW showed untreated AH (TSH 31.4 µU/mL, FT4L 0.97 ng/dL) and Levothyroxine dose was increased. At 24th GW, blood tests showed a mild hyperthyroidism (TSH 0.05 µU/mL, FT4 1.53 ng/dL) and LT4 dose was reduced. Fetal ultrasound (US) at 25th GW showed a male fetus with bilateral cerebral ventriculomegaly without other alterations. TORCH serologies were negative, amniocentesis revealed a normal karyotype and fetal MRI showed bilateral cerebral ventriculomegaly and fetal goiter. To study the fetal thyroid function a blood sample by cordocentesis was obtained and a maternal blood test to examine TSH-R-ABs levels was performed. Meanwhile, fetal US at 26th GW showed tachycardia, mild pericardial effusion, hydrothorax, cardiomegaly, hepatomegaly and splenomegaly. Fetal blood sample showed fetal hyperthyroidism (TSH <0.008, FT4 4.03, FT3 9.92) while maternal TSH-R-ABs were elevated (< 40 mU/L). Unfortunately, fetal death occurred before knowing the results and antithyroid drugs could not be started. As far as we know, this is the second reported case of TSH-R-ABs-induced fetal thyrotoxicosis in an AH woman.

Conclusion
TSH-R-ABs plasma determination should be mandatory in pregnant women with any previous autoimmune thyroid disease and fetal goiter or thyrotoxicosis. Antithyroid drugs should be started as soon as fetal hyperthyroidism is suspected.

Renal cell carcinoma metastasis to thyroid tumor: a case report

Carolina Faría, David Barbosa, Ana Sofia Osório, Ema Nobre & Maria João Bugalho
Hospital de Santa Maria, Lisboa, Portugal.

Introduction
Subacute thyroiditis (SAT) association with papillary thyroid carcinoma (PTC) has barely reported in the literature. Metastatic neoplasms to the thyroid are rare in clinical practice. Renal cell carcinoma (RCC) are the most frequent site of origin of thyroid metastases (12 to 34%). Tumor-to-tumor metastases, in which a thyroid neoplasm is the recipient of a metastasis, are exceedingly rare. Tuberos sclerosis (TS) is associated with several renal manifestations (80–85% of the patients) including angiomyolipomas (AMLs) (80%), renal cysts (50%) and RCC (2–4%).

Case report
A 19-year-old male, with personal history of TS, presented in the emergency department complaining of edema, jitteriness and pain in cervical region. SAT diagnosis was established based on complaints, physical examination and laboratory results. After the resolution of SAT, thyroid ultrasonography (US) revealed 2 suspicious nodules. The major nodule was submitted to fine needle aspiration cytology and the report was suspected of malignancy. Total thyroidectomy was performed. Postsurrgical pathology evaluation showed a bilateral PTC/follicular variant (pT3N0). Within the PTC were a few nests of a histologically distinct neoplasm. Immunoperoxidase stains of these cells were positive for CK8/18 and CK7 and were negative for thyroglobulin, calcitonin, vimentin, CK20, CD10 and racemase thus suggesting metastases of RCC. The body CT showed bilateral renal lesions likely to be angiolipomas without distinctive criteria. Suspicous lesions in the liver, lungs and bones were also reported without uptake in a 18F-FDG PET-CT.

Conclusion
This case illustrates an extremely rare occurrence of tumor-to-tumor metastasis where the recipient was a PTC and the donor likely to be an occult RCC.

GP240
Giant goiter with intrathyroid arteriovenous fistula as a cause of severe pulmonary hypertension

Elena Márquez Mesa, Estefanía González Melo, Cristina Lorenzo González, Pilar Olivera Márquez, Ricardo Darías Garzón, Maria Teresa Herrera Arranz, Bruno Francisco García Bray, Yolanda Zambrano Huerta & Enrique Palacio Abizanda
Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain.

Introduction
Hyperthyroidism has been described as a rare cause of pulmonary hypertension (PH) as well as systemic arteriovenous fistulas. However, we describe a case of pulmonary hypertension secondary to an intrathyroid arteriovenous fistula, not previously described in the literature.

Endocrine Abstracts (2017) Vol 49
Case report

A 56 year old woman followed in our consultations with multinodular goiter and a long standing hyperthyroidism, secondary to Graves Basedow disease with difficult management. She required methimazole and low doses of levothyroxine simultaneously to achieve hormonal control, needing multiple admissions for heart failure (HF). In her last admission to Cardiology, she had right HF stage III-IV of NYHA, and physical examination revealed grade III goiter with murmurs auscultation and thrill palpation. The blood tests revealed that she was euthyroid. The echocardiogram showed dilatation of both ventricles, ejection fraction 57%, moderate-severe biventricular dilatation, moderate mitral and tricuspid insufficiency, PAPs 73 mmHg. Cervical thoracic CT evident large multinodular goiter with intrathoracic extension and tracheal compression, multiple hypervascular nodules and cervico-vascular venous congestion. Right cardiac catheterization showed moderate precapillary PH with high saturations in the venous territory explored and cardiac output 8.1 l/min. These findings were consistent with the diagnosis of PH secondary to intrathyroid arteriovenous fistula. Definitive treatment was made by performing total thyroidectomy. The pathologic study of the piece was reported as multinodular thyroid goiter (12 x 13 x 5 centimeters and 140 grams) with signs of diffuse hyperplasia and arteriovenous fistula. Two months after surgery the patient had improved her functional class and the PAPs had decreased to 30 mmHg.

Conclusions

This is the first case described in which pulmonary hypertension is secondary to an arteriovenous fistula in a giant goiter. Surgery was a successful treatment, and one year after, the patient has a disease free survival.

Thyroid-related adverse events in patients treated with Nivolumab

I Peiró1, L San Martín2, A Simó-Servat1, J Otero2, JC Ruffinelli1, E Nadal1, P Iglesias3, JJ Diez4 & C Villabona2

1Clinical Nutrition Unit, Institut Catalá d’Oncologia (ICO), Hospital de Llobregat, Spain; 2Department of Endocrinology, Hospital Universitari de Bellvitge, Hospital de Llobregat, Spain; 3Department of Oncology, ICO, Hospital de Llobregat, Spain; 4Department of Endocrinology, Hospital Ramón y Cajal, Madrid, Spain.

Introduction

Nivolumab is an antibody that binds to and blocks the activation of programmed-death-receptor 1 (PD-1), promoting the activation of T-cells against tumor cells. Thyroid dysfunction (TD) is one of the most common immuno-related adverse events, with incidence up to 10% in patients treated with PD-1/PD-L1 blockade.

Objective

To report our experience of Nivolumab-TD in patients with advanced cancer.

Methods

All patients diagnosed of nivolumab-induced TD during 2016 were included. Data from thyroid function tests, autoimmunity and imaging study before and during nivolumab therapy were recorded.

Results

Twelve cancer patients (5 lung, 4 melanoma, 3 Hodgkin lymphoma) were evaluated. 75% women, mean age: 56.7 years (19-77). Ten patients were treated with nivolumab 3 mg/kg (with or without chemotherapy) every 15 days, 2 patients received combined immunotherapy (nivolumab 1 mg/kg plus ipilimumab 3 mg/kg). Three patients had previously well-controlled thyroid disease (1 overt primary hypothyroidism, 2 subclinical hypothyroidism). Baseline serum TSH and free thyroxine were evaluated in eleven patients, being normal in ten whereas one showed minimal subclinical hypothyroidism. During follow-up, 7 patients (58.3%) developed hyperthyroidism (4 overt and 3 subclinical). Six of them after cycle(C) 2, and 1 after C3. Thyroid antibodies were positive in 3 patients. One overt hyperthyroidism was treated with high dose steroids (prednisone 0.8 mg/kg per day) and nivolumab was temporarily withdrawn. Four of seven hyperthyroid patients became hypothyroid later, needing levothyroxine. Primary hypothyroidism occurred in 5 patients (41.7%) (3 overt and 2 subclinical), between C4-C7. Autoimmunity was positive in 3 hypothyroid patients. No patient discontinued nivolumab due to hypothyroidism.

Conclusions

In our series, hyperthyroidism is more frequent and appears earlier than hypothyroidism. A pattern consistent with a transient thyrotoxicosis followed by hypothyroidism is seen in one-third of patients. Monitoring thyroid function at baseline and before each therapeutic cycle is warranted to detect and treat TD promptly.

DOI: 10.1530/endoabs.49.GP241

GP242

False negative fine needle aspiration thyroid cytology: an institutional experience

Anabela Martins, Evelina Mendonça, António Garrão, Hugo Marques, Maria Cid, Francisco Rosário, Ricardo Veiga & Ana Catarino Hospital da Luz, Lisbon, Portugal.

Introduction

Fine needle aspiration cytology (FNA) is the most accurate diagnostic method for thyroid malignant nodule diagnosis. According to the literature, the percentage of false negative results (FN-FNA) is less than 1.5%, in tertiary health care centers. In this study we describe the cases reported in this Hospital, between 2014 and 2016, of benign cytology, histologically characterized as malignant. All pathologic specimens were reviewed.

Results

From a total of 299 benign FNA cases submitted to surgery, 6 cases with malignant histopathology were detected (2.0%). FN-FNA was identified in 5 males and 2 females, with ages ranging from 42 to 72 years old. The nodules size varied between 41 to 95 mm. The ultrasound malignancy risk was between 5 and 20% (ATA 2015 Risk Stratification System).

The benign FNA were described as hyperplastic nodule in 3 cases, cystic hyperplastic nodule in 1 case, cystic colloid nodule in 1 case and colloid nodule in the remaining.

In all the cases the histological diagnosis was of follicular variant of papillary carcinoma, with macrofollicular areas, either predominant or focially, and with a heterogeneous distribution of the distinctive nuclear features of papillary carcinoma.

Four patients were recommended for radioiodine therapy. One of these patients was diagnosed with pulmonary and bone metastases.

Four patients were available for follow-up (mean time = 1.5 years; 9-24 months). There is no imaging evidence of disease in any of the patients.

Conclusions

In our institution, the percentage of FN-FNA was 2.0%, in accordance with that described in the literature.

The ultrasound risk assessment did not significantly change the risk assessed by FNA.

In all the cases the histological diagnosis was follicular variant of papillary carcinoma. The presence of macrofollicular areas, cystic areas and a heterogeneous expression of the typical nuclear features of papillary carcinoma may explain the occurrence of FN-FNA.

DOI: 10.1530/endoabs.49.GP242

GP243

Risk factors associated with malignancy in thyroid nodules classified as Bethesda category IV (follicular neoplasm/suspicious for follicular neoplasm)

Bekir Kuru & Mehmet Kefeli

Ondokuz Mayis University School of Medicine, Samsun, Turkey.

Background

Thyroid nodules diagnosed as Bethesda category IV (follicular neoplasm/suspicious for follicular neoplasm [FN/SFN]) are recommended for surgery. However, only 25% of these nodules turn to be malignant on histopathology. Therefore, selection of nodules for surgery diagnosed as Bethesda category IV is important.

We aimed at to define the predictive factors for malignancy and predictive risk indices for selection of surgery.

Method

The records of all patients with nodules that underwent fine needle aspiration biopsy (FNA) and classified by Bethesda reporting system as FN/SFN between 2011 and 2017 at our institution were reviewed. Univariate and multivariate analysis were performed to select independent factors associated with thyroid cancer. Using independent risk factors for malignancy predictive indices were created.

Results

Among 6,217 nodules which underwent FNA, 163 (2.6%) were diagnosed as FN/SFN. Of the 163 patients classified as FN/SFN, 126 underwent surgery with an associated malignancy rate of 36% (45/126). Age under 45, solid structure, microcalcification, hypoechogenicity and increased vascularity were found to be significant and independent risk factors associated for malignancy. The risk
FFPE PTC samples were analysed for BRAFV600E mutation and 66 of them differently expressed with 1.4-fold (In Rc-PTC and NRc-PTC groups miRNA-21, -146b and -222 were significantly were over-expressed 13.8-fold and 3.7-fold, respectively (elevated with 55.6-fold over-expression in PTC. The expression levels of all three miRNAs were significantly increased in PTC.

**Results**

Lithuanian University of Health Sciences, Kaunas, Lithuania.

**Objective**

Expressions of miRNAs and BRAFV600E mutation detection in papillary thyroid carcinoma

Vaida Simonavičienė1, Aiste Kondrotiene2, Dauna Pamedytė1, Valdas Sarauskas3, Dalia Dauksiene4, Albertas Dauskas4, Aurelija Zvirbliene1 & Birute Zilaitiene1

1Institute of Biotechnology, Vilnius University, Vilnius, Lithuania; 2Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania; 3Department of Pathological Anatomy, Lithuanian University of Health Sciences, Kaunas, Lithuania; 4Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; 5Institute of Digestive Research, Medical Academy, Faculty of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction

Papillary thyroid carcinoma (PTC) is the most common type of thyroid malignancy. For the majority of patients with PTC, the prognosis is very good; however, up to 20% of patients suffer disease recurrence. Currently, the risk stratification for PTC recurrence is based on clinicopathological features which have limited prognostic value. Identification of molecular biomarkers of PTC recurrence such as protooncogene BRAF and miRNAs may help to improve risk-stratified patient management.

Objective

The aim of this study was to detect BRAFV600E mutation and identify miRNA biomarkers for PTC recurrence.

Methods

We selected 3 miRNA (miRNA-146b, -222 and -21) and measured the expression levels of these miRNAs in patients with recurrent PTC (Re-PTC) and without recurrence (NRc-PTC). 106 NR-PTC and 60 Re-PTC FFPE samples were analysed for selected miRNAs. 114 FFPE PTC samples (31 Re-PTC and 83 NR-PTC) were analysed for BRAFV600E mutation.

Results

The expression levels of all three miRNAs were significantly increased in PTC when compared to healthy thyroid tissue. miRNA-146b expression was extremely elevated with 55.6-fold over-expression in PTC (P<0.001). miRNA-222 and -21 were over-expressed 13.8-fold and 3.7-fold, respectively (P=0.001) and P=0.16. In Re-PTC and NR-PTC groups miRNA-21, -146b and -222 were significantly differently expressed with 1.4-fold (P=0.006), 1.8-fold (P=0.007) and 2.1-fold (P<0.001) higher expression in NRc-PTC compared with Re-PTC tissues. 114 FFPE PTC samples were analysed for BRAFV600E mutation and 66 of them (57.9%) were shown to be positive. Subsequently, DNA samples from Re-PTC and NR-PTC groups were analysed for BRAFV600E mutation and this mutation was found in 54.8% (17/31) of Re-PTC samples and 59.0% (49/83) of NR-PTC samples. There was no significant difference between these groups (P=0.686).

Conclusion

These results suggest that miRNA-21, miRNA-222, miRNA-146b might be potential biomarkers for PTC recurrence. BRAF mutation is not associated with PTC recurrence.

A statistical, in silico model predicts polygenic thyroid cancer risk

Livio Casarini1,2, Marco Marino1,2, Federico Nuzzo1,3, Manuela Simon1,3 & Giulia Brigante1,3

1Unit of Endocrinology, Department Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; 2Center for the Genomic Research, University of Modena and Reggio Emilia, Modena, Italy; 3Azienda Ospedaliero-Universitaria di Modena, Modena, Italy.

Introduction

The detection of a unique genetic marker is not possible for multifactorial diseases, such as thyroid cancer (TC), where the pathological phenotype is given by the contribution of multiple genes, environmental factors and lifestyle. We found a mathematical model for inferring the risk of thyroid cancer, an example of multifactorial disease.

Methods

Genetic data represented by 184 SNPs associated to thyroid tumors were used for Bayesian clustering of 2504 individuals from the 1000 Genomes database, by STRUCTURE software. Numerical values representing the inferred genetic structure of each individual is provided in the output file of the software and were matched with environmental and lifestyle parameters associated to thyroid functions, i.e. iodine exposure and obesity, by principal component analysis (PCA). Data analysis was performed using labels such as geographic origin of individuals, population, sex and thyroid cancer incidence.

Results

We found that seven thyroid tumor-related genetic clusters are differently represented among human populations. The matching of genotype, iodine and obesity data resulted in individuals’ gradient distribution by thyroid cancer incidence, revealing that all these components are required to infer the disease risk. Genetic background and, to a lesser extent, environmental factors and lifestyle, are not related per se to a specific range value of cancer risk. An exception is provided by individuals from Tuscany, Italy, which deviates from the overall distribution, preserving high cancer risk independently from obesity or iodine. This could result from a peculiar genetic setting or from the exposure to environmental factors not considered in the analysis.

Discussion

We demonstrated that TC risk may be detected a priori by applying polygenic model to specific population or individuals. This study provides a novel mathematical approach to infer the polygenic disease risk, as a promising diagnostic tool for personalized medicine.

Confirmatory tests for diagnosis of primary aldosteronism among Chinese hypertensives

Minchun Jiang1, Dujuan Ma2, Hailun Lin3, Ying Lin1, Yajuan Deng3, Juying Tang1, Shaoliang Zhang4 & Ying Guo5
1Department of Endocrinology and Metabolism, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; 2Department of Endocrinology and Metabolism, Guangzhou Panyu Central Hospital, Guangzhou, China; 3Shenzhen Hospital of Southern Medical University, Shenzhen, China.

Objective

Primary aldosteronism (PA) has emerged as the most frequent form of secondary hypertension. For the diagnosis of PA, confirmatory testing is indispensable and different tests are recommended by guidelines, including captopril challenge test (CCT) and saline infusion test (SIT). However, there are sparse studies evaluating and comparing CCT and SIT in Chinese population. Hence, we investigated the diagnostic efficiency of CCT and SIT for PA in Chinese hypertensives in our study.

Methods

In total, 183 patients with essential hypertension and 105 patients with PA were recruited in the study, and their clinical data were analyzed by constructing the receiver operating characteristics (ROC) curve to compare the accuracy of CCT and SIT.

Results

(1) A total of 277 patients underwent CCT. The AUC of post-CCT aldosterone, aldosterone suppression rate and post-CCT aldosterone/renin ratio (ARR) were 0.877 (95% CI 0.833 to 0.921, P<0.001), 0.683 (95% CI 0.617 to 0.748, P<0.001) and 0.929 (95% CI 0.896 to 0.963, P<0.001), and accuracy of ARR post-CCT is highest (P<0.001). For post-CCT ARR, at the optimal cut-off value of 30 ng·dl⁻¹·ng·ml⁻¹·h⁻¹, the sensitivity and specificity were 67.6% and 96.2% respectively. (2) The SIT was performed in 116 patients. The AUC of post-SIT aldosterone and post-SIT ARR were 0.829 (95% CI 0.731 to 0.928, P<0.001) and 0.923 (95% CI 0.860 to 0.954, P<0.001), and post-SIT ARR has higher accuracy (P<0.05). The best cut-off value of post-SIT ARR for identifying PA was 60 ng·dl⁻¹·ng·ml⁻¹·h⁻¹, with sensitivity and specificity of 81.8% and 95.2% respectively. (3) 110 patients underwent both CCT and SIT. In the consistency check of CCT and SIT, kappa value was 0.714, P<0.001. The AUC of post-CCT ARR, post-SIT ARR, serial test of post-CCT ARR and post-SIT ARR were 0.937 (95% CI 0.885 to 0.990, P<0.001), 0.921 (95% CI 0.858 to 0.984, P<0.001) and 0.939 (95% CI 0.881 to 0.981, P<0.001), there is no statistical difference among the three indices.

Conclusions

With a good consistency, CCT and SIT are both efficient confirmatory tests for PA, and applying ARR post-CCT or ARR post-SIT make it feasible to diagnose PA more accurately. However, combining two tests fails to further improve the accuracy for diagnosis of PA.

The correlation of salivary cortisol values with serum cortisol values

Bertina Dyrmish1, Taulant Oldiasha1, Ema Lumij1, Entela Paca1, Emvrina Kolici4, Dorina Ylli2 & Thanas Fureraj2
1Hygeia Hospital Tirana, Tirana, Albania; 2UHC Mother Teresa, Tirana, Albania; 3Regional Hospital Korca, Korca, Albania; 4Neo Style Clinic, Tirana, Albania.

Aim

The aim of the study was to evaluate the correlation between salivary and serum cortisol values to the healthy people and patients with Cushing’s syndrome.

Methods

33 cases; 21 healthy people aged 22 to 53 years old; 12 patients with Cushing’s syndrome values were included to our study. All the participants of control group were healthy without known disease. Two samples of salivary and serum cortisol was taken to all the participants of the study in the morning and after the midnight. All the subject respect the rolls of salivary collected samples.

Results

The mean age of the healthy subjects was 31±4.8 years old. Basal cortisol level was significantly correlated with serum salivary cortisol in the morning and at the midnight, P<0.05 in the morning and P=0.052 at the midnight. Pearson coefficients were 0.45 in the morning and 0.42 at the midnight (2300 h). The sensitivity of salivary cortisol values in diagnoses of Cushing’s syndrome was 100% for cut off values 2.18 mg/dl and for cut off values 3.14 mg/dl the sensitivity was 100% and specificity 83%. ACU 0.97.

Conclusions

In our study we found a correlation between salivary and serum cortisol values in both samples, at the morning and at the midnight to all participants; in healthy people, patients with Cushing’s disease.

Keywords: salivary cortisol; serum cortisol; correlation

Adrenocortical virilizing tumor in an adult woman in remission after surgical therapy performed more than 12 years ago

Terriblo Larumbe, Crespo Soto, Citores Pascual, Benito Fernandez, Calero Aguilar, Anacabe Goyogana, Urbon Lopez De Linares, Ventosa Viña, Cuellar Olmedo & Palacio Mures
Hospital Universitario Rio Hortega, Valladolid, Spain.

Introduction

Adrenocortical carcinomas (ACCs) are rare, frequently aggressive tumors. Pure virilizing carcinomas are infrequent, constituting 5 to 10% in most series.

Clinical case

A 36-year-old female consults for 5 years evolution of amenorrhoea associated with hirsutism attributed to polycystic ovary syndrome (PCOS) and treated with oral contraceptives during the previous 2 years. There was no other data on virilization, changes in body weight, hypertension or gastrointestinal symptoms. In the biochemical exam the following were observed: total testosterone 405 ng/dl (15–110), free testosterone 26.9 pmol/l (0.19–8.9), DHEA-sulphate 1000 µg/dl (35–430), FSH 2.9 ml/l and LH 11.4 ml/l. Basal and urinary cortisol, prolactin, beta-estradiol, 17-OH-progesterone, thyroid, hepatic and renal function, ions, were normal. The response to LHRH and ACTH and ovarian ultrasound were compatible with PCOS and ruled out late onset congenital adrenal hyperplasia. The diagnostic tests showed a solid adrenal mass in the left 10×13×14 cm, with prominent vascular structures inside it, which were embolized prior to surgical excision performed by bilateral subcostal laparotomy. The histological diagnosis of the tumor which weighed 1.152 kg and measured 20×12.5×8.5 cm, proved to be an adrenocortical tumor of low degree malignancy, without invasion of the capsule or adjacent tissues. Menstuation, hormonal tests and ovarian ultrasound became normal after surgery. The patient did not receive any therapy and the follow-up has not shown recurrence.

Discussion

Overall, survival is poor for ACC. Five-year survival is approximately 45–60% for early stage disease, and 10–25% for advanced stage disease. For patients with stage I to III disease, complete surgical resection as initial therapy is the only potentially curative treatment and open surgery remains the standard approach. Despite the large tumor size, the patient had a good prognosis based on the absence of invasion of the surrounding tissues, the histological grade of differentiation and the complete tumor resection. The interest of her case is due not only to the prolonged survival with an optimal quality of life, but also is a representative example of PCOS secondary to hyperandrogenism that disappears from the functional and morphological point of view after the suppression of its cause.

Investigation of atrophic adrenal glands in Cushing’s syndrome model rats induced by the administration of dexamethasone

Toshiro Seki1, Atsushi Yasuda1, Natsumi Kitsujima1, Masami Seki2, Masayuki Oki1, Atsushi Takagi1 & Masafumi Fukagawa1
1Tokai University School of Medicine, Isehara-shi, Kanagawa, Japan; 2Seiret Numazu Hospital, Numazu-shi, Shizuoka, Japan.

Cushing’s syndrome is a disease caused by excessive glucocorticoids from adrenocortical tumors. In most cases, impaired adrenocortical function is likely caused by atrophy of the normal adrenal tissue as a result of chronic suppression by the low ACTH levels in the hypercortisolism state. Secondary adrenal insufficiency can cause surgical resection of cortisol-secreting tumors. Therefore, we thought that it was necessary to prepare Cushing’s syndrome model rats for establishment of a new treatment method to promote improvement of the function of the remaining adrenal glands after adrenalectomy. Cushing’s syndrome model rats have already been published and they describe changes in blood pressure and body weight. Regarding atrophy of tissue, it is considered that the atrophy of cells and the appearance of apoptosis are observed in such tissues. However, the weight and histological changes of the adrenal glands are not

Endocrine Abstracts (2017) Vol 49
described. In this study, we investigate ACTH, the ratio of adrenal cortex to medulla and number of apoptotic cells as evaluation of atrophic adrenal glands in dexamethasone-treated rats (n=5) compared to control rats (n=5). In the group treated with dexamethasone, an increase in blood pressure (135 ± 24 mmHg) and suppression of plasma ACTH (20 ± 12 pg/ml) and the low serum corticosterone levels (7.5 ± 1.1 ng/ml) were observed as compared with the control group. In addition, adrenal gland weight decreased (13.6 ± 1.2 mg), and the low ratio of adrenal cortex to medulla and an increase of apoptotic cells were observed. Compared with control rats, dexamethasone-treated rats showed a significant decrease in hormonal secretory ability both endocrinologically and histologically. Our group is currently conducting experiments to investigate the levels of mRNAs for c-fos in adrenal glands as assessment of the recovery of adrenal atrophy.

**Long-term assessment of AddiQol and patient diaries may identify Addison patients at high risk for adrenal crises**

Maike Koch1, Klaus Badenhoop1, Eva Herrmann & Gesine Meyer1

1Department of Internal Medicine 1, Endocrinology, Goethe-University Hospital, Frankfurt, Germany. *Institute for Biostatistics, Goethe-University Hospital, Frankfurt, Germany.

**Introduction**

Several studies have shown a reduced quality of life (QoL) in patients with Addison’s disease (AD). However, by now there are no data investigating the changes of QoL over a long-term course. Adrenal crises (AC) are frequent and potentially life-threatening complications in patients with AD. Since no reliable laboratory indicator can predict impending crises it is difficult to detect patients at increased risk. The purpose of this study was to test whether the repeated use of questionnaires for self-assessment over longer periods can detect possible prodromal periods of an AC.

**Methods**

137 patients with AD were included. They were asked to complete the disease specific-quality of life questionnaires AddiQol once monthly over a period of ten months. In addition they also completed a short questionnaire about adverse events during the last month. AD was defined if at least two of the following symptoms were reported: a) hypotension, b) nausea or vomiting, c) severe fatigue, d) documented hyponatremia, hyperkalemia, or hypoglycemia, and subsequent parental glucocorticoid administration was carried out.

**Results**

110 patients completed the study by fulfilling at least 9 of the 10 required sets of questionnaires and not exceeding a time-lag over more than three months. Seven patients suffered an AC, resulting in 7.6 crises/100 patient years. AddiQol scores in patients with adrenal crises showed a trend (P=0.058) to a wider fluctuation over the ten months. 19 Patients reported about severe adverse events not fulfilling the named criteria of AC. In these patients we found a significantly lower median (P=0.017) of the AddiQol scores compared to patients not suffering a pre-crisis.

**Conclusions**

These are the first data showing the course of QoL during a period of ten months in patients with AD. Prevalence of AC lay by 7.6 per 100 patient years, in accordance with previous data. Our data show, that relevant medical adverse events in patients with AD are associated with a lower QoL. Furthermore, such events affect intra-individual AddiQol-scores over time with a trend to a stronger fluctuation. Long-term assessment of AddiQol and assessment of adverse events, e.g. via patient diaries, may be applied as an additional clinical tool to identify patients at risk for critical events.

**Impact of Cortrosyn treatment on weight and adrenal structure in the wistar rat**

Samarra Akkader-Oudahmane, Zohra Hamouli-Said & Fatma Hadj-Bekkouche

University of Algiers, Algiers, Algeria.

The corticotropic hormone (ACTH) mainly secreted by the anterior lobe of the pituitary gland which, following a physiological or psychological stress situation, stimulates the adrenal gland and induces the release of glucocorticoids. Many studies have shown their effects on several physiological functions such as immunity, inflammation as well as the cardiovascular system whose action is controlled by ACTH. For this purpose, the study carried out in the wistar rat revealed the effects of a treatment with Cortrosyn (ACTH of synthesis) on the weight and the adrenal structure in the wistar rat. The work was carried out on a lot of rat wistar divided into two lots: one batch of control rat (T) and one batch of treated rats (S) receiving a daily intramuscular injection of Cortrosyn at the rate of 0.01 ml/100 g of weight. Body for 20 days. After sacrifice of the animals, the adrenals are taken, weighed and immediately immersed in the fixing liquid in order to carry out the histological techniques. The results show that the intramuscular injection of Cortrosyn resulted in a very significant increase in absolute and relative adrenal weights in treated rats as compared to controls as well as an increase in the number of cells (hyperplasia), a different cell distribution and The appearance of optically empty space. These results to be investigated and could explain why the activation of the adrenal cortex during 20 days by the Cortrosyn would be in favor of an important structural and functional modification of the adrenal gland whose indirect trophic effect of this hormone could be regulated by several factors.

**Molecular variability determines subtle adrenal biosynthetic defect in non-classical congenital adrenal hyperplasia due to 21-hydroxylase deficiency**

Livia Mermeljo1, Fernanda Coeli-Lacchini1, Wendy Turatti1, Marcia Elamid2, RenataParente2, Carlos Martinelli2, Sonir Antonini2, Margaret Castro2 & Ayrton Moreira1

1Department of Internal Medicine Ribeirao Preto Medical School, University of Sao Paulo, Brazil, Ribeirao Preto/SP, Brazil; 2Department of Pediatrics Ribeirao Preto Medical School, University of Sao Paulo, Brazil, Ribeirao Preto/SP, Brazil.

There is a clinical spectrum of non-classical congenital adrenal hyperplasia due to 21-hydroxylase deficiency (NC-CAH). In addition, CYP21A2 gene mutations analysis present in homozygosis or as compound heterozygosis. Objectives To evaluate the relationship between the genotype and biochemical profiles and also compare with clinical severity in NC-CAH.

Patients and methods Clinical, hormonal and molecular data of 57 patients (47 female,10 male; 47 children,10 adults) with NC-CAH were retrospectively analyzed.

Results The majority of children (76%) presented with premature pubarche at the diagnosis and 12% showed clitoromegaly. Among adult patients, hirsutism (90%) and menstrual abnormalities (66%) were observed at diagnosis. The basal and ACTH-stimulated 17OHP mean levels were 1115 ± 919 (97-4125) and 4245 ± 2059 (1115–10648) ng/dl. The most frequent mutation was p.V281L (68% of alleles) being 42% in homozygosis and 39% of the patients were compound heterozygotes for one classic and one non-classical mutation (C/N/C). The severe mutations were p.I172N, IVS2-13AC>G, Δ8, CL6, p.Q318X, p.R356W and LGC. Basal and ACTH-stimulated 17OHP values were higher in patients carrying the C/N/C genotype group compared to NC/NC genotype (1549 ± 250 vs 806 ± 162; P=0.01 and 4740 ± 577 vs 3355 ± 345 ng/dl; P=0.04, respectively). Moreover, ROC curve analyses showed that the basal and ACTH-stimulated 17OHP levels of 610 and 3913 ng/dl were the best cutoffs to identify NC-CAH patients carrying compound heterozygosis with severe mutations. We observed a higher DHEAS (182 ± 150 vs 85 ± 69 μg/dl; P=0.03) and a bone age advancement trend (P=0.05) in C/N/C genotype group compared to NC/NC. There were no differences in age, height, weight, androstenedione and testosterone levels at diagnosis.

Conclusion Although no phenotype difference was observed between NC/NC and C/N/C genotypes, the present study showed graded severities of adrenal biosynthetic defect reflecting the molecular variability in NC-CAH.

Corticoids-therapy related complications in patients with primary adrenal insufficiency
Juan Carlos Romero Rodríguez, María Calatayud Gutiérrez, Laura Mola Reyes, Carlos Silva Vaca, Sonsoles Guadalix Iglesias & Guillermo Martínez-Díaz-Guerra
Hospital Universitario 12 de Octubre, Madrid, Madrid, Spain.

Introduction
Patients with primary adrenal insufficiency (PAI) require lifelong corticoids replacement and they are at risk of therapy-related osteoporosis and cardiovascular complications.

Objectives
Determine the prevalence of cardiovascular risk factors, osteoporosis, and other complications related with corticoids treatment.

Material and methods
Retrospective, descriptive study in patients with PAI follow up in our service during the last 30 years. Information was collected from clinical histories.

Results
Identified 30 patients with PAI. Clinical characteristics: 21 were women, mean age at diagnosis of 36.72 ± 5.3 years and mean time since diagnosis 263.8 ± 57.5 months. Etiology: 15 (50%) autoimmune disease; 7 (23.3%) post-surgery; 5 (16.6%) congenital adrenal hyperplasia; 2 (6.7%) tuberculosis and 1 (3.3%) metabolic disease.

Stereoid replacement: 26 (86.7%) used hydrocortisone (HC), 3 (10%) dexamethasone, 1 (3.3%) prednisone. 25 patients were on treatment with fludrocortisone. Mean glucocorticoid dose (HC or equivalent): 20.58 ± 1.5 mg/day, mean fludrocortisone dose 0.066 ± 0.008 mg/day.

Possible therapy-related complications: 23 (76.7%) patients developed at least 1 complication during follow-up: osteoporosis 11 (36.7%), dysplasia 10 (33.3%), prediabetes 8 (26.6%), hypertension 7 (23.3%), type 2 diabetes 6 (20%), 1 (3.3%) cardiodegenerative event. 88% patients with osteoporosis, 78.6% with diabetes or prediabetes, 85.7% hypertension and 70% with dyslipidemia used HC to treat adrenal insufficiency.

Complications
- Osteoporosis and cardiovascular complications are frequent in patients with PAI. Patients on treatment with higher corticoid dose are at risk of development and therapy-related complications. Adjustment in corticoid to minimal necessary dose could prevent these complications.

Discussion
The presence and type of hyperlipemia prior to therapy is likely to affect the adverse effects of mitotane on lipids and in this patient, TG levels have varied according to mitotane does and levels despite lipid-lowering therapy. On the other hand, dyslipidemia may induce an overestimation of plasma mitotane measurements, so it is necessary to closely monitor the lipid profile in all patients treated with this drug.

DOI: 10.1530/endoabs.49.EP8

EP9
Severe hypertriglyceridemia in relation to toxic levels of mitotane in a patient with stage IV adrenocortical carcinoma (ACC)
Terroba Larumbe, Crespo Soto, Anaacabe Goyogana, Urban López De Linares, Amon Sesmero, Ventosa Viña, Cuellar Olmedo, Marcos García, Otero Roussel & Almendros Muñoz
H. U. Rio Hortega, Valladolid, Spain.

Introduction
The use of mitotane as ACC therapy is associated with multiple adverse effects including hypercholesterolemia due to increased levels of LDL cholesterol. There are no reported cases of severe hypertriglyceridemia (HTG).

Clinical case
A 59-year-old male with a personal history of dysplasia phenotype IV and pulmonary emphysema, former smoker and drinker was diagnosed with non-functional left-sided ACC. Left adrenalectomy and right adrenalectomy and atypical segmentectomy of the upper right lung lobe due to the presence of metastases was performed. One month later, low-dose (2 g/day) mitotane therapy was initiated in combination with hydrocortisone and oral fludrocortisone replacement therapy. In the first post-mitotane control, triglycerides (TG) level which previously was 325 mg/dl increased to 953 mg/dl, coinciding with serum mitotane of 13.8 mg/dl. Other factors that could increase it were overruled. Fenofibrate 145 mg/day was prescribed but in the following control TG were 880 mg/dl with serum mitotane of 14.3 mg/l. The dose of mitotane was then reduced to 1 g/day, its level dropped to 10.5 mg/l and TG were 939 mg/dl. Consequently ezetimibe 10 mg/day was added to the therapy and the mitotane dose was increased to 1.5 g/day and subsequently to 2 g/day because the level was very low and a 4.5 cm unresectable metastatic adenoma that received radiotherapy appeared in the midureter. Coinciding with a mitotane level of 33.8 mg/l, the patient presented severe asthenia attributable to mitotane toxicity and TG of 1,528 mg/dl, without data of pancreatitis, which required a drastic decrease in the dose of drug. In the last review, the mitotane level was 6.7 mg/l. TG were 344 mg/dl, the symptoms disappeared and the mitotane dose was again raised while those of fenofibrate, ezetimibe, hydrocortisone and fludrocortisone remained the same.

Discussion
The usual clinical features of chronic AD are non-specific and include fatigue, nausea, vomiting and hyperpigmentation. We describe the case of a 58-year-old African black male with AD presenting with recurring severe hyperglycaemia. He had a body mass index of 14.9, blood pressure 98/57 mmHg and regular pulse of 64 bpm, with no other remarks on systemic examination. Biochemical analysis revealed Hb 11 g/dl, mild hypoponatemia (134 meq/l), normokalemia (4.1 meq/l), hyponadulinemia (32.4 g/l), and normal renal and hepatic function tests. Morning serum cortisol level was 2.3 µg/dl and ACTH 52.2 µg/ml, with normal levels of other pituitary hormones. ACTH stimulation test was performed and confirmed adrenal insufficiency. Computerised tomography scan of the abdomen showed normal shape and sized adrenal glands. HIV screening was negative and there were no clinical or radiological signs of active tuberculosis. He started treatment with hydrocortisone and fludrocortisone, and his symptoms readily improved. This case illustrates an unusual presentation of Addison’s disease and points out the need for a high index of suspicion so that morbidity and mortality can be decreased by a prompt diagnosis.

DOI: 10.1530/endoaab.49.EP10

Endocrine Abstracts (2017) Vol 49
infusion test confirmed the diagnosis of hyperaldosteronism. Abdominal MRI revealed a two-centimetre adenoma of the left adrenal gland. The patient underwent surgery to remove the adenoma. After surgery, hypokalemia and hypertension resolved.

Conclusions
Although primary aldosteronism (PA) is not included among the reported causes of PRES, it is important to consider its existence in PRES patients, particularly in those with hypokalemia. The occurrence of PRES in patients with PA might be independent of hypertension since the direct action of aldosterone on the mineralocorticoid receptor may cause endothelial dysfunction.

**Evaluation of cardiovascular risk in patients with adrenal incidentaloma**

Gökşür Yorulmaz1, Ayşen Akalın1 & Bürçü Yagız2
1Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; 2Uludag University School of Medicine, Bursa, Turkey.

Introduction
Recent studies indicate that patients diagnosed with adrenal incidentaloma may present with cardiovascular disease. The aim of this study was to investigate markers of subclinical cardiovascular disease in patients with adrenal incidentaloma and healthy control group.

Methods
This study included 50 patients with non-functional adrenal adenoma and 30 healthy controls. BMI and waist circumference of the patients were measured. The lipid parameters, glucose, insulin, C-peptide, erythrocyte sedimentation rate, fibrinogen, homocysteine, hsCRP levels of the patients and control group. HOMA levels of the patients were calculated.

Results
Patients with non-functional adrenal adenomas were compared with obese and non-obese control groups. Carotid intima media thickness and erythrocyte sedimentation rate levels of the patients with adrenal incidentaloma were significantly higher than the healthy controls. There was not statistically significant difference between lipid parameters, glucose, insulin, C-peptide, fibrinogen, homocysteine, hsCRP levels of the patients and control group.

Conclusion
In patients with nonfunctional adrenal adenomas the carotid intima media thickness, which is a cardiovascular risk indicator, was found to be thicker than the normal population. At the same time, erythrocyte sedimentation rate, another indicator of cardiovascular risk, was also higher in the adrenal incidentaloma group. These findings suggest that patients with adrenal adenomas have a higher risk for subclinical cardiovascular disease and close follow-up may be necessary.

**Hair cortisol in patients with primary aldosteronism**

Aaron Hodes1, Maya Lodish1, Amit Tirosh1, Jerrod Meyer3, Elena Belyavskaia2, Charalampos Lyssakatos2, Kendra Rosenberg4, Andrew Demidowich1, Jeremy Swan1, Nichole Jonas1, Constatine Stratakis1 & Mihail Zilbermann1,2
1Section on Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland, USA; 2Johns Hopkins University School of Medicine, Division of Endocrinology, Diabetes, and Metabolism, Baltimore, Maryland, USA; 3Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; 4Albert Einstein College of Medicine, Department of Radiology, Jacobi Medical Center, Bronx, New York, USA; 1Department of Psychological and Brain Sciences, University of Massachusetts, Amherst, Massachusetts, USA.

Context
Primary aldosteronism (PA) is a common cause of secondary hypertension, and some PA adrenal tumors co-secrete glucocorticoids, causing subclinical or overt Cushing syndrome (CS). We recently reported correlations between hair cortisol concentration (HCC) and serum and urinary levels of cortisol in patients with CS.

Objective
To determine correlations of segmental hair cortisol and biochemical markers of a referred cohort of patients for the evaluation of PA and to compare to patients with normal cortisol secretion. This pilot study was conducted at the National Institutes of Health Clinical Center.

Methods
Hair samples were collected from 12 study subjects (four with PA, two with PA and cortisol co-secretion, and six controls), with mean age 40.1 ± 21.4 years, mean BMI 28.1 ± 5.3 kg/m². Diurnal serum cortisol and ACTH measurements, 24-h-urinary free cortisol corrected by body surface area (UFC/BSA) and 17-hydroxysteroids, corrected for creatinine (17OHS/Cr) were measured. Patients underwent step-wise diagnosis, with measurement of serum aldosterone and plasma renin activity followed by saline suppression and/or oral salt loading tests. Patients without PA or CS were excluded as controls, if midnight serum cortisol > 1.8 μg/dL. Segmental hair samples from each patient were processed and analysed for cortisol according to the methods described by Meyer et al. (2014).

Results
Age, blood pressure, urinary and midnight cortisol levels were higher (P<0.05) in the PA group compared to the controls. Average hair cortisol values in the groups with PA and controls were 30.0 ± 31.0 μg cortisol/mg hair (median: 16.3 μg/mg; interquartile range: 12.6–37.4 μg/mg) and 22.9 ± 27.6 μg cortisol/mg hair (median: 11.3 μg/mg; interquartile range: 7.9–26.6 μg/mg), respectively (P<0.05). No correlation between hair cortisol and serum and urinary markers of hypercortisolemia was seen in the six patients with PA.

Discussion
We found that no statistically significant difference in hair cortisol between groups and no significant correlation of hair cortisol with urinary or serum cortisol evaluations. We speculate that the lack of correlation may be due to insufficient power. More research is needed on the use of hair cortisol in patients with PA.

**Salivary steroid levels during diagnostic tests for adrenal insufficiency**

Michiela Daiki1, Kateřina Šimůnková1, Jana Vítková1, Lucie Koláčová1, Hana Jandiková1, Hana Pospíšilová1, Monika Šrámková1, Kamilůškos1 & Luboslav Stárlka1
1Institute of Endocrinology, Praha, Czech Republic; 2Third Department of Medicine, General University Hospital and First Faculty of Medicine, Charles University, Praha, Czech Republic.

Diagnostic tests of the hypothalamic–pituitary–adrenal axis (HPA axis), measuring of free cortisol and use of other adrenal steroids are the subject of debate. We investigated 15 healthy men with mean/median age 27.4(26 ± 4.8) years, and mean/median BMI 25.38/24.82 (± 3.2) kg/m². All subjects underwent four dynamic tests of the HPA axis, specifically 1, 10, and 250 μg synacthen tests and an insulin tolerance test (ITT). Salivary cortisol, cortisone, pregnenolone, and DHEA were analysed using liquid chromatography-tandem mass spectrometry. During the ITT maximum salivary cortisol levels of over 12.5 nmol/l were found at 60 min. Maximum cortisol levels in all of the Synacthen tests were higher than stimulation in the ITT. Cortisone reacted similarly as cortisol, i.e. we did not find any change in the ratio of cortisol to cortisone. Pregnenolone and DHEA were higher during the ITT, and their peaks preceded the cortisol peak. There was no increase of pregnenolone or DHEA in any of the Synacthen tests. Our results indicate that a 10 μg Synacthen dose is a safe and cost-effective choice. This study was supported by the project MZCR for conceptual development of research organization 00023761 Institute of Endocrinology and grant 17-28092A. DOI: 10.1530/endoabs.49.EP14

**Assessment of quality of life of patients with Cushing’s syndrome depending on the disease course**

Gulchekhra Narimova, Zamira Yusupova, Ravshan Fayzullaev & Iskandar Arifjanov
Republican Specialized Scientific and Practical Medical Center of Endocrinology Uzbekistan, Tashkent, Uzbekistan.

Aim of the study
To evaluate effectiveness of pituitary transphenoidal surgery (TSS) in patients with ACTH-dependent Cushing’s syndrome (ACTH-DCS) in Republic of Uzbekistan (RUZ).

Materials and methods
Patients who included in CS register monitored in 2015. All data from 2000 to 2015 analyzed including outpatient, inpatient examines, tests and treatment. To present, 158 patients with ACTH-DCS registered and monitored. Of these 158 patients, 41 males (26%) and 117 females (74%). Mean age of patient varied from 12 to 38 years old. Mean age was 26.38±3.4 and 27.58±3.4 years old for males
and females respectively. Duration of the condition varied from 4 months to 25 years. 73 patients who had TSS were evaluated in 1, 3, 6 and 12 months period of time and the every 3 months for the follow-up period. TSS was performed initially in 73 patients and in ten patients it was carried out after medical treatment.

Results
Of 158 patients, 86 patients (54%) had surgery including 73 cases who underwent TSS. Pituitary surgery performed as a monotherapy in 32 patients (44%) and in 41 cases (56%) patients received combination therapy. Of 73 patients who underwent TSS, in 60 cases (82%) patients had cured, while repeat surgery performed in ten cases (13.7%). After repeat surgery all ten patients (13.7%) had remission, however, four of them relapsed in 15 months in average. After TSS remission was achieved in 82% of patients who included 62 patients with microadenomas (84.9%) and 12 cases with macroadenomas (16.6%). After 3 years of follow-up five patients (6.8%) who had total hypophysiotomy procedure developed no relapse, whereas of 62 patients (84.9%) with selective adenomectomy and of six patients (6.8%) who had hemihypophysiotomy recurrent disease observed in 5 (81.1%) and in (16.7%) cases respectively while remission has not developed in 6 (9.7%) and 1 (1.6%) respectively (P = 0.03).

Conclusion
Of 73 patients with CS who had pituitary surgery, remission observed in 60 patients (82%), whereas six patients (8.2%) relapsed and in seven cases (9.6%) remission has not developed. TSS remains as first treatment choice in CS and contributes to a steady remission in 82% according to our results.

Paraneoplastic Cushing’s syndrome and nephrotic syndrome in a patient with bronchial carcinoid

Daniel Grigorie1,2, Andra Caragheorghopol2, Carmen Iordachescu3, Dan Hoptopan1, Ionela Pascaru1, Livia Hara4, Julian Brezean1, Nicolae Galle1, Florina Vasilescu1, Eugen Mandache4 & Alina Sucalie1,2

1Carol Davila University of Medicine, Bucharest, Romania; 2National Institute of Endocrinology, Bucharest, Romania; 3University of Medicine, Targu Mures, Romania; 4Matei Bals Hospital, Bucharest, Romania; 5Carol Davila Nephrology Hospital, Bucharest, Romania.

**Introduction**

We report a case of Cushing’s syndrome association with nephrotic syndrome in a patient with occult ectopic ACTH (EAS) secretion by a bronchial carcinoid and resolution of both disorders after bilateral adrenalectomy.

**Case report**

A 42-year-old man was admitted to our department with the suspicion of EAS. He was in a very good health until several months ago when he developed suddenly nephrotic syndrome, severe hypertension, severe hypokalemia, hyperglycemia and rapidly progressive the full blown picture of severe hypercortisolemia: severe mental changes, muscle weakness, bruising, pigmented moon facies, no striae, distal muscular atrophy and weight loss. A renal biopsy showed podocyte foot process effacement and no inflammation/sclerosis; renal function was normal.

Serum cortisol was frankly elevated and variable (21–97 μg/dl), because of the

Frequency of diabetes and prediabetes in patients with adrenal incidentaloma without hormonal activity

Elzbieta Bandurska-Stankiewicz, Katarzyna Myszka-Podgorska, Joanna Rutkowska & Wojciech Matuszewski

Endocrinology, Diabetology and Internal Diseases Clinic, University of Warmia and Mazury in Olsztyn, Olsztyn, Poland.

**Aim of the study**

Estimation of the frequency of diabetes and prediabetes in patients with adrenal incidentaloma (AI) without hormonal activity.

**Material and methods**

The study comprised patients with AI without hormonal activity, verified by CT. The hormonal function of adrenal glands was determined according to the circadian rhythm of cortisol and/or dexametasone suppression test, ACTH, aldosterone, plasma renin activity, DHEAS, androstenedione, 17hydroxyprogesterone, metanephrines in urine.

Physical examination included: the BMI, the waist circumference (norm < 80 cm women, < 94 cm men), blood pressure. The biochemical assays: fasting glycemia, OGTT (excluded patients with diabetes), fasting insulin and lipids level (total, HDL and LDL cholesterol, triglycerides).

**Results**

125 patients were examined, aged 61.3 ± 8.8 years, 72 (57.6%) women. Size of tumors were 27.6 mm ± 15 mm. Carbohydrates disorders were observed in 62 (49.6%) persons aged 62.9 ± 7.5 years, including 32 (25.6%) women. Abdominal obesity was diagnosed in 87 (69.6%), 56 (44.8%) women and 31 (24.8%) men. Diabetes was recognised in 16 (13%) patients, IFG in 24 (19.2%), IGT in 34 (27.6%). The concentration of fasting insulin was 8.9 ± 5.5 μU/ml, higher in men then in women (9.16 ± 6.5 vs 8.71 ± 4.70; P = 0.01). The concentration of total cholesterol was 218 ± 49.7 mg/dl, HDL-cholesterol 59 ± 21.1 mg/dl, LDL-cholesterol 134 ± 44.1 mg/dl, triglycerides 116 ± 60 mg/dl; 83 (66.6%) of the patients had been diagnosed positive for dyslipidemia or were administered hypolipemic medications. Additionally arterial hypertension was diagnosed in 99 (79.2%) patients, with the arterial systolic BP 131 ± 15 mmHg, diastolic BP 80 ± 9 mmHg.

**Conclusions**

1) Diabetes was observed more often in patients with AI without hormonal activity then in the entire Polish population. Patients with AI without hormonal activity are a risk group of prediabetes and diabetes.

To big to work! Lymphoma presenting with primary adrenal insufficiency

Joel Capraro, Hanna Giessen & Beat Müller

Division of Endocrinology, Diabetes and Metabolism, Kantonsspital Aarau, Aarau, Switzerland.

**Background**

Primary adrenal lymphoma (PAL) is a rare cause of primary adrenal insufficiency (PAI). Most often patients present with unspecific symptoms. Bilateral adrenal enlargement with signs and symptoms of PAI are clues, percutaneous biopsy after having excluded pheochromocytoma in a situation of high suspicion is diagnostic. Most of PAL are highly malignant B-cell lymphomas with a bad prognosis.

**Case**

A 71-year-old patient was sent for endocrine workup because of a 2-month history of intermittent dyspnea, thoracic discomfort, weight loss and abdominal pain. An ambulant CT scan to exclude pulmonary embolism showed bilateral adrenal enlargement (right 77 × 31.55 mm, left 63.38 × 41 mm, native 25-29HE), which were new compared to a CT scan done one year earlier. On clinical examination, the patient was orthostatic and in an impaired general condition. He had hyperpigmented hand lines. Laboratory evaluation showed a slight hyponatremia (131 mmol/l), potassium in the upper normal range (4.2 mmol/l), pathologic ACTH-stimulation test (peak cortisol level: 153 nmol/l) and elevated ACTH levels (231 ng/l, normal range <46 ng/l). Antibodies for 21-hydroxylase were negative, as well as free metanephrines in plasma, aldosterone-renin ratio was decreased (aldosterone 122 pmol/l, renin 39 mU/l), 17-hydroxyprogesterone was normal (3.3 nmol/l, normal range 1.9–6.5 nmol/l). Quantiferon test was negative, and the CT scan did not raise suspicion for tuberculosis. We diagnosed PAI and started substitution with hydrocortisone (initial dose 50 mg/dl) and...
In this nationwide study we found the PT to have fairly high sensitivity but low specificity. The PT was 0.65 (22/34) for bilateral disease, 0.81 (22/27) for unilateral disease, and 0.45 (26/59) for unilateral disease. The PT was inconclusive. Average increase of s-aldosterone during PT in the bilateral group (BG) was 217 pmol/L, whereas in the unilateral group (UG) it was 27 pmol/L. The unilateral group (UG) consisted of 14 patients with APA and 70 were patients with metastatic lung, breast, or stomach tumors. Reasons for bilateral adrenal enlargement are adrenal hyperplasia (any cause), lymphoma to the adrenals, and unknown causes. The disease is most common in autopsy studies up to 25%. Other reasons for bilateral adrenal enlargement are adrenal hyperplasia (any cause), metastasis of lung, breast, and stomach (50% of metastases), bilateral pheochromocytoma, adrenal hemorrhage, and adrenal involvement with granulomatous diseases, histiocytosis, and primary pigmented nodular adrenal dysplasia (PPNAD). Symptoms of PA are specific (asthenia, weight loss, vague abdominal pain, fever). Diagnosis is made by percutaneous biopsy. In nearly 10% of cases PA are bilateral, causing primary adrenal insufficiency. Average age of affected patients is around 70 years. Most of PA are diffuse large B-cell lymphomas with BCL6 gene rearrangement and poor prognosis, as in our case. Therapy consists of R-CHOP.

Conclusion

Patients with bilateral adrenal enlargement and PA need immediate replacement of glucocorticoid (including instructions about dosing in stressful situations) and mineralocorticoid hormones. While PA is rare, it has a poor prognosis, thus rapid induction of treatment is necessary. DOI: 10.1530/endoabs.49.EP18

Collin is a cAMP effector in mediating actin cytoskeleton reorganization and steroidogenesis in mouse and human adrenocortical tumor cells

Rosa Catalano1,2, Erika Peverelli1,2, Elena Giardino1,2, Donatella Treppedelli1,2, Valentina Morelli1,2, Iacopo Chiiodini1,2, Lorenzo Marcon1,2, Cristina L Ronchi1, Jérôme Bertherat4, Felix Beuschlein1, Maura Arosio1,2, Anna Spada4,5 & Giovanna Mantovani1
1Endocrine Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico; 2Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; 3Department of Internal Medicine I, Division of Endocrinology and Diabetes, University Hospital, University of Wuerzburg, Wuerzburg, Germany; 4Institut Cochin, Inserm U1016, CNRS UMR8104, Descartes University, Department of Endocrinology, Reference Center for Rare Adrenal Diseases, Hôpital Cochin, Paris, France; 5Medizinische Klinik und Poliklinik IV, Endocrine Research Unit, Klinikum der Universität München, LMU, Munich, Germany.

The cAMP signaling pathway plays a major role in the pathogenesis of cortisol-producing adrenocortical adenomas (CPA). In adenocortical cells cAMP induces dramatic changes in cell morphology accompanied by actin cytoskeleton rearrangements that precede steroidogenesis, the causal relationship between these events being still undefined. In this study we investigated cAMP effects on cytoskeleton rearrangements and steroidogenic response in mouse (Y1) and human adrenocortical tumor cells, focusing on the role of the actin-severing protein collin, whose inactivation is regulated by phosphorylation on Ser3. Moreover, we tested possible alterations in collin phosphorylation status and expression in human CPA vs endocrine inactive adrenocortical adenomas (EIA). We demonstrated that forskolin induced cell rounding and reduced phosphorylation (P)-collin/total collin ratio in Y1 (−52±16%, P<0.001) and primary human CPA cells (−53±18%, P<0.05). Collin silencing in Y1 cells reduced both forskolin-induced morphological changes (75% rounding of control cells vs 63±7% in control cells, P<0.05) and progestrone production (1.3-fold increase in silenced cells vs 1.8-fold in control cells, P<0.05), whereas transfection of wild type or S3A (active) collin, but not S3D (inactive) collin, potentiated forskolin effects on cell rounding (80±6% and 85±14% rounded cells, respectively, vs 69±6% in control cells) and increased about threefold progestrone synthesis with respect to control cells (P<0.05). Furthermore, collin dephosphorylation by Y27632, a selective inhibitor of ROCK, the kinase that phosphorylates collin, potentiated forskolin-induced cell rounding (about 90% rounded cells) and steroidogenesis (about twofold increase vs forskolin alone). Finally, western blot analysis showed a reduced P-collin/total collin ratio and an increased total collin expression in CPA vs EIA (P-collin/total collin ratio 0.76 and 2.44 respectively, P<0.05, total collin/GAPDH 1.20 and 0.54, respectively, P<0.01).

Overall, these data identified collin as a mediator of cAMP effects on both morphological changes and steroidogenesis in mouse and human adrenocortical tumor cells. DOI: 10.1530/endoabs.49.EP20

Endocrine Abstracts (2017) Vol 49
infusion test (SIT) performed by a 4-hour intravenous infusion of isotonic saline, 500 ml/h. Thereafter, patients underwent a CT-scan and adrenal venous sampling (AVS) for distinguishing unilateral (UD) from bilateral disease (BD). Adrenalectomy was offered if UD was diagnosed.

**Results**

Thirty-six patients were diagnosed with PA during the period; 19 males and 17 females. All had s-aldosterone > 300 pmol/L on morning screening and 12 had an elevated 24-h urinary aldosterone (n=23). Median (range) s-aldosterone after SIT was 311 pmol/L (202-1715). By the end of 2016, 10 had a confirmed UD (32%), 21 BD (68%) and 5 were awaiting AVS. Six out of 10 UD underwent adrenalectomy by the end of 2016 and all had a cortical adenoma on histopathological examination. CT-scan showed unilateral adrenal nodule in 15 patients, 8 of whom had UD by AVS on that same side (positive predictive value 0.53).

**Conclusions**

This study indicates that PA is an important cause of HT in Iceland with equal gender distribution. Bilateral hyperplasia proved to be a more frequent cause than cortical adenoma which is consistent with prior Icelandic results from 2007–2011. Interestingly, no-one was diagnosed with unilateral hyperplasia during the study period.

Cardiovascular risk factors do not play a role in the risk factor profile of adrenal crisis

Marcus Quinkler¹, Robert D. Murray², Pinggao Zhang³, Pierre Zelissen⁴ & Bertil Ekman⁵

¹Endocrinology in Charlottenburg, Berlin, Germany; ²St James’s University Hospital, Leeds, UK; ³Shire, Lexington, MA, USA; ⁴University Medical Center Utrecht, Utrecht, The Netherlands; ⁵Linköping University, Linköping, Sweden.

**Introduction**

Adrenal crises (ACs) are life-threatening events in patients with primary (PAI) or secondary (SAI) adrenal insufficiency, occurring ~4–10 times per 100 patient-years. Major causes of ACs are infections, especially gastroenteritis and tonsillitis/laryngitis. Risk factors for ACs remain ill defined, but could include concomitant endocrine diseases (diabetes mellitus, premature ovarian failure) in PAI diabetes insipidus in SAI, and concomitant non-endocrine diseases (obesity, asthma, cancer, and cardiac and neurological diseases) in both groups.

**Design**

We analysed data from the European Adrenal Insufficiency Registry (EU-AIR; NCT01661387) with centres across Germany, the Netherlands, Sweden and the UK. Clinical and biochemical data at enrolment were compared for patients with frequent (n≥2) and infrequent ACs (n < 2) in each AI subset; 1969 patients were included (727 PAI, 1172 SAI) in the current analysis. Patients with congenital adrenal hyperplasia or tertiary AI were excluded.

**Results**

To November 2016, 27 patients with frequent ACs were identified (19 PAI, 8 SAI). The number of adverse events/patient was significantly higher in the frequent than the infrequent AC group in both subsets (PAI, 15.3±14.0 vs 3.9±6.5; SAI, 19.6±18.5 vs 2.2±4.3, respectively; P=0.0024). Patients with frequent ACs were more likely to be female (PAI, 78.9% vs 65.1%; SAI, 75.0% vs 47.9%), and less likely to have hypertension (PAI, 5.3% vs 21.0%; SAI, 25.0% vs 34.4%), with a lower BMI (PAI, 24.2±4.7 vs 26.2±4.9 kg/m²; SAI, 26.0±5.7 vs 28.7±5.1 kg/m²). There were no differences in daily glucocorticoid dose, frequency of diabetes mellitus, HBa1C levels, lipid profiles or use of statins. Interestingly, disease duration was shorter in patients with frequent compared with infrequent ACs in PAI (12.8±13.2 vs 18.9±14.5 years), whereas the opposite was true in SAI (15.6±12.3 vs 13.8±11.2 years).

**Conclusions**

Data suggest that known cardiovascular risk factors appear not to feature in the AC risk profile.

Bilateral adrenal incidentaloma: a diagnostic and therapeutic challenge

Ines Bilic-Curcic1,2, Tatjana Bacun1,2, Marija Tripolski3 & Biljana Zulj4

1Faculty of Medicine, University J.J. Strassmayer, Osijek, Croatia; 2Clinical Hospital Center, Osijek, Croatia.

Incidentally discovered adrenal masses (incidentalomas) present challenges both in diagnosis and management. The bilateral adrenal mass carries a risk of hormone hypersecretion, but it could also present a metastasis from another primary carcinoma or be a part of genetic syndrome.

We report a 68 year old patient with bilateral adrenal incidentalomas (revealed accidentally on US, confirmed by abdominal CT in 2015.) left 29 mm, right 33 mm in diameter, radiological characteristics indicating adenoma. Initial diagnostic work up showed subclinical Cushing syndrome with osteoporosis and arterial hypertension as part of clinical presentation. One year later, abdominal CT showed significant enlargement of both adrenal masses (left 50 mm, right 45 mm), still adenomas according to CT characteristics, but post contrast imaging could not be performed due to chronic renal impairment. Her laboratory results were still consistent with subclinical Cushing syndrome, now presenting with osteoporosis, hypertension and glucose impairment with no signs of other excessive hormone secretion but now her chest x-Ray revealed a lesion in her left lung 27 mm in diameter of unknown etiology (although she mentioned lung tuberculosis in her youth). As she did not have any signs of metastatic disease and her tumor markers were normal we decided to perform left adrenalectomy to provide definite diagnosis. Histological finding confirmed adrenal adenoma and hormone reevaluation showed possible excessive cortisol secretion with osteoporosis, but now glucose was normal, and anti-hypertensive agents were discontinued due to normal blood pressure. There was no change in the size of the lung lesion on her chest X ray (6 months after) and no signs of metastatic lesions. Thoracic CT and bronchoscopy are planned. While the initial diagnostic approach is similar to the unilateral incidentaloma, additional testing should be considered in the case of the bilateral adrenal mass and as oppose to unilateral incidentalomas surgery remains the mainstay of treatment in most cases.

**EP24**

Are we missing patients with primary aldosteronism (PA) if we require both elevated aldosterone: renin ratio (ARR) and elevated aldosterone levels?

Troy Puar, Joan Khoo & Meifen Zhang

Changi General Hospital, Singapore, Singapore.

**Introduction**

Although the Endocrine Society guidelines recommend using aldosterone: renin ratio (ARR) to screen patients for primary aldosteronism (PA), whether to include a cut-off for aldosterone levels remains controversial. In Singapore, most centres require both an ARR >550 (ng/dl)/(ng/ml per h) and aldosterone ≥15 ng/ml. However, it has been shown that patients with PA may have aldosterone levels <15 ng/dl, and also respond well to mineralocorticoid antagonists. We examined the prevalence of Asian patients with high ARR, and influence of including patients with unsuppressed aldosterone levels >5 ng/ml.

**Methods**

We determined the prevalence of patients with high ARR >550 (aldosterone, ng/dl; plasma renin activity, ng/ml per hr) in a multi-ethnic Asian population with hypertension being screened for PA in a single tertiary centre, and stratified them by aldosterone levels.

**Results**

A total of 786 patients were screened for PA from 2015–2016, with 219 of 786 (27.8%) patients having a high ARR. Amongst these 219 patients with a high ARR, 68 of 219 (31.1%) had an aldosterone levels ≥15 ng/dl, 51 (23.3%) had aldosterone levels 10-14.9 ng/dl, 60 (27.4%) had an aldosterone levels 5–9.9 ng/dl, and 40 (18.3%) had aldosterone levels <5 ng/dl. When both ARR >550 and aldosterone ≥15 ng/dl are required, only 68 of 786 (8.6%) patients will proceed for confirmatory tests as per current practice. However, if all patients with ARR >550 and unsuppressed aldosterone levels >5 ng/ml are included, then 179 of 786 (22.8%) of patients should be considered for the diagnosis of PA.

**Conclusion**

Current practice of requiring a high aldosterone level in addition to a high ARR may underdiagnose patients with PA. However, potential benefit of working-up all patients with a high ARR has to be weighed against increased cost. A possible alternative would be a trial of mineralocorticoid therapy in these patients.

Severe hypoglycaemic ketosis in a patient with adrenal crisis
Azmir Mohammed, Giridhar Tarigopula, Paul Peter, Praveen Partha & Shafiee Kamaruddin
Darlington Memorial Hospital, Darlington, UK.

We present a case of a 26 years old female who was rushed to hospital with 4 days history of abdominal pain, vomiting and dizziness. She also had one episode of diarrhoea. Further history revealed that she had lost 32 kilograms of weight over the last 18 months through diet and exercise. There were no signs suggestive of an eating disorder.

On examination she was peripherally cold, tachycardic (117/min), hypotensive (86/50 mmHg) and sweaty. Her Glasgow Coma Scale was 15. Her chest was clear and she had mild epigastric tenderness. She was fluid resuscitated with 0.9% sodium chloride. Blood test results; pH 7.01, pCO2 (3.2), pO2 (14.6), blood glucose (2.1 mmol/l), HCO3 (12), Na (126), K (5.6), ketones (7.6 mmol/l), urea 15.1 mmol/l and creatinine (79) and CRP (76). 10% Dextrose infusion was started. An adrenal crisis was suspected and she was commenced on IV hydrocortisone. A possible trigger was thought to be gastroenteritis. Her serum cortisol was 11 mg/dl, no ACTH was detected. She remained hypotensive despite aggressive fluids and was subsequently transferred to ITU. Over the next 24 hours her blood pressure was maintained on inotropes however her acidity was refractory to treatment (pH<7.2 after 8 hours). She was started on sodium bicarbonate 1.26% but the effect was not sustained and her pH continued to drop. Her ketones also remained high (5−6 mmol/l) despite a normal glucose (4−7 mmol/l). She was subsequently commenced on 5% Dextrose infusion to halt ketogenesis. Her HbA1c was 35 mmol/mol. Following 5% Dextrose infusions, her acidosis started to improve and normalisation of ketones. Learning points:
1. Adrenal crisis should be treated promptly
2. Euxycaemic or hypoglycaemic ketosis can complicate prolonged starvation, vomiting and eating disorders, so detailed and collateral history is important
3. Although very rare, type 1 diabetes can be masked by adrenal insufficiency and present with euglycaemic ketoacidosis. It should be considered in similar scenarios.

Assessment of the hypothalamic pituitary adrenal axis in patients receiving adjuvant mitotane treatment after radical resection of adrenocortical carcinoma
Giuseppe Reimondo1, Soraya Puglisi2, Barbara Zaggia1, Vittoria Basile1, Laura Sabat1, Paolo Masi1, Silvia De Feudis1, Maria Chiara Zatelli3, Salvatore Cannavo4 & Massimo Terzolo4
1Internal Medicine 1, Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy; 2Endocrinology Unit, Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; 3Pharmacology, Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy; 4Section of Endocrinology and Internal Medicine, Department of Medical Sciences, University of Ferrara, Ferrara, Italy.

Mitotane, used in the treatment of adrenocortical cancer (ACC), is able to inhibit multiple enzymatic steps of adrenocortical steroid biosynthesis, potentially causing adrenal insufficiency (AI). Recent studies in vitro have also documented a direct inhibitory effect of mitotane at the pituitary level.

The aim of the study was to assess the hypothalamic pituitary adrenal (HPA) axis in patients receiving mitotane as adjuvant treatment after radical resection of ACC getting insights on how mitotane affects the HPA axis and looking for markers to assessing AI.

We prospectively enrolled 16 patients on adjuvant treatment with mitotane after radical surgical removal of ACC, who were on stable mitotane dose and cortisol replacement therapy for at least 6 months and were disease free at the evaluation time. Patients underwent standard hormone evaluation and stimulation test with h-CRH. A group of 10 patients with Addison’s disease served as controls for the h-CRH test.

At the time of the study, six patients had mitotane levels within the therapeutic range, one had levels >20 mg/ml, while nine had levels <14 mg/ml. The median dose of cortisone acetate was 62.5 mg daily. Basal serum cortisol was reduced in 14 patients, being undetectable in 7 of them, and in the normal range in only two patients (12.5%); one of them had low mitotane concentrations. Only a non-significant trend between mitotane dose and either serum or saliva cortisol was evident. We demonstrated a close correlation between CBG levels and plasma mitotane levels (P=0.003) and between serum cortisol levels and salivary cortisol levels (P=0.005), while ACTH levels were inversely correlated with the daily dose of cortone acetate (P=0.006). ACTH levels were significantly higher in the Addison group than in ACC patients, both in baseline conditions (P=0.036) than following CRH (P=0.041).

In conclusion, measurement of salivary cortisol did not add useful information for assessing AI in mitotane-treated ACC patients. Assessment of some aid, since levels that are not frankly elevated may herald over-replacement. The observation of lower ACTH levels in ACC patients than in patients with Addison, both in basal conditions and after CRH stimulation, suggests that mitotane may play an inhibitory effect on ACTH secretion at the pituitary level. However, an effect of high-dose cortisol replacement should not be ruled out.

Extra-gastrointestinal stromal tumor in the retroperitoneum which had difficulty in differential diagnosis with adrenal cancer
Naotetsu Kanamoto, Makiko Nagatsuji, Keiko Yamagami, Shinya Tokunaga & Masayuki Hoso
Osaka City General Hospital, Osaka, Japan.

Extra-gastrointestinal stromal tumors (EGISTs) in the retroperitoneum are extremely rare. A 44-year-old man was referred from a private clinic suspicious of an adrenal tumor that was incidentally detected by abdominal ultrasound. Computed tomography (CT) scan showed a retroperitoneal mass of 12 cm harboring a feeding artery from the left adrenal gland contiguous with the left adrenal gland, which enhanced heterogeneously on postcontrast imaging. By magnetic resonance imaging, the tumor demonstrated heterogeneous low intensity in T1 weighted images and an extremely heterogeneous lesion composed of high and low signal intensity in T2 weighted images. PET CT imaging with fluorine-18-fluorodeoxyglucose ([18F-FDG] demonstrated 18F-FDG accumulation in the tumor in the early and late phase. Iodine-123-metiodobenzylguanidine and iodine-131-adenosil scintigram did not detect any accumulation in the tumor. The results of all conducted serum and urinary examinations of adrenocortical hormone and catecholamine were within the normal range. Adrenocortatony was performed. Histopathological diagnosis of the tumor was GIST. Immunohistochemical findings revealed that the neoplastic cells were positive for c-kit and CD34 and negative for S100 protein, alpha-SMA, and desmin. Mitotic activity (2−3/50 high power field) and the labeling index for MIB-1 (about 3.2%) were low. The GIST was diagnosed as a high-risk tumor because its diameter was over 5 cm. We started imatinib 400 mg/day according to the Japan GIST guideline 1 month after operation.

Perceptions of medical practitioners’ management of Addison’s disease across Africa: an on-line survey
Ian Louis Ross1, Thabiso RP Mofokeng2, Faizleh Mohamed2 & Saleem Beshyah
1University of Cape Town, Cape Town, South Africa; 2University of the Free State, Bloemfontein, South Africa; 3Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates.

Addison’s disease diagnostic and management challenges in Africa are not well documented. We aimed to identify the specific needs of patients with established Addison’s disease, across Africa. Methods

An online survey of a large pool of medical practitioners was undertaken. The questionnaire covered patient demographics, aetiology, therapy and limitations of diagnosis and treatment.

Results
Of the 36,203 recipients; 661 responded; 246 completed the questionnaire. 151 were actively treating Addison’s disease. The total number of patients identified with Addison’s disease in this study was 1134 (530 males; 604 females). The highest number were reported from South Africa (748; 66%). Majority of patients were in the age groups of 16-60 years with a slight excess of females (334 vs 403). Associations were reported with hypothyroidism in 13.5%, type 1 diabetes in 11.6%, pernicious anemia in 6.5%, premature ovarian insufficiency in 4.6% and Graves’ disease in 3.0%. Presentation in crisis was reported in 12.1% of cases, otherwise classical symptoms were seen fairly consistently. Over 60% of patients received hydrocortisone only and the remainder received combination of hydrocortisone and fludrocortisone. Fixed doses of steroid replacement were used by 35.3% of physicians, whereas 57.9% of respondents adjust doses on basis of body weight. Appropriate diagnostic investigations, proved to be the greatest

Improved metabolic outcomes for patients with subclinical Cushing’s syndrome treated with surgery: Ten year experience in a tertiary centre
Lih Ming Loh, Du Soon Swee, Wei Lin Tay & Peng Chih Kek
Department of Endocrinology, Singapore General Hospital, Singapore, Singapore.

Introduction
Subclinical Cushing’s syndrome (SCS) occurs in up to 12% of patients with incidentally found adrenal masses. Optimal management remains controversial. We report our experience of nine patients with SCS managed at our institution from 2007 to 2016.

Methods
All patients were referred for adrenal incidentalomas (AI) and had no discriminatory clinical features of Cushing’s syndrome. SCS was defined using cortisol levels > 138 nmol/l after overnight 1-mg dexamethasone suppression test and one additional abnormal biochemical test. ACTH was suppressed in all. Urinary free cortisol measurements were normal in the majority.

Patients and results
The median age of our patients was 53 years (range 36–63) and all but one were female. Mean size of the adenoma was 2.65 ± 0.52 cm. Majority of our patients had metabolic comorbidities of overweight, hypertension, glucose intolerance or diabetes and dyslipidemia. One patient initially followed up as a non-functioning AI developed SCS over 8 years of surveillance as her adenoma grew. Another patient had bilateral adrenal adenomas. All our patients underwent surgical resection. The patient with bilateral nodules underwent bilateral subtotal adrenalectomy. All but one required a period of postoperative corticosteroid support. Following withdrawal of steroids, there was observable median weight loss of 3.85 kg (0.5–10.7) compared to presurgical weight. Four patients had an improvement of their BMI category from overweight to normal. All six patients with hypertension had sustained improvement in their blood pressure: two became normotensive and the remainder had reduction of doses of antihypertensive agents. However there was no change to glycemic and lipid status.

Conclusions
In our small series of patients with SCS, surgical intervention resulted in improved metabolic outcomes. We therefore suggest that if patients are surgically fit, surgery should be considered for SCS.

Severe hyperaldosteronism after unilateral adrenalectomy for primary hyperaldosteronism
João Ananias Gonçalves1, Rui Barros1, Betânia Ferreira1 & Cláudia Amaral1,2
1Hospital da Luz Arrábida, Vila Nova de Gaia, Portugal; 2Centro Hospitalar do Porto - Hospital de Santo António, Porto, Portugal.

Introduction
Primary hyperaldosteronism is a known cause of arterial hypertension, classically with hypokalaemia. About 30–40% of the cases are caused by unilateral aldosterone-producing adenoma, and the recommended treatment is adrenalectomy. Hypoaldosteronism is an uncommon complication of unilateral adrenalectomy, but it can be life-threatening. We present a case of severe hypoaldosteronism after unilateral adrenalectomy for the treatment of primary hyperaldosteronism.

Case presentation
A 66 years old male with long term hypertension on triple drug therapy, chronic kidney disease and persistent hypokalaemia was diagnosed with primary hyperaldosteronism. He had increased aldosterone – 3426 pg/ml (normal 34.7–275 pg/ml) and low renin – 4 u/l (normal 4.4–46.1 u/l). An elevated plasma aldosterone to renin ratio was compatible with diagnosis. A CT scan revealed a right adrenal nodule suggestive of adenoma (21 × 19 mm). He was submitted to laparoscopic unilateral adrenalectomy. Pathology confirmed an adrenal adenoma.

At discharge, all anti-hypertensive drugs were suspended. 3 weeks after surgery he complained of asthenia, anorexia and diarrhea. Blood tests showed severe hyperkalaemia (7.8 mmol/l), metabolic acidosis and acute renal failure (creatinine 4.2 mg/dl). The serum aldosterone was low (<3 mg/dl) and renin (4.7 pg/ml) normal. We assume the diagnosis of hyporeninemic hypoaldosteronism and he was treated with fludrocortisone (0.1 mg id), sodium bicarbonate and fluids, with improvement in serum creatinine and normalization of potassium levels. 3 months after discharge he remained asymptomatic but fludrocortisone dependent, with stable potassium and creatinine levels and mild hypotension.

Conclusion
Despite uncommon, hypoaldosteronism after unilateral adrenalectomy is known to occur. Usually mild and transitory, it can also be severe, persistent and life-threatening. Long term hypertension and impaired renal function, both present in our patient, are associated with persistent disease. A close and regular follow-up is essential for earlier detection, especially in high risk patients.

The role of CYP11B2 polymorphism in the pathogenesis of hypertension in patients with adrenal incidentaloma
LuKasz Zakowski1-2, Natalia Wawrusewicz-Kuryłonek1, Janusz Mysliwiec2 & Marta Górka1
1Department of the Endocrinology, Diabetology and Internal Medicine, Medical University of Białystok, Poland; 2Department of Nuclear Medicine, Medical University of Białystok, Poland.

Background
Significant prevalence of hypertension in the world’s population and its consequences tend to an intensive search for pathogenesis and etiology of this disease. Epidemic of hypertension is accompanied by an epidemic of adrenal incidentaloma and grows in direct proportion to patients age. Polymorphism of aldosterone synthase (CYP11B2) in -344th region of promoter seems to have much in common with hypertension and adrenal incidentaloma.

Aim
The aim of this study was to assess what role may play CYP11B2 polymorphism in the phenotype of hypertension with associated adrenal incidentaloma. In this study, the analysis of alleles and genotypes focused on incidence of adrenal tumour and impact on the number of antihypertensive medications required to proper control.

Subjects and methods
Study was performed on 106 hypertensive patients with diagnosed adrenal incidentaloma (HAI), on 44 hypertensive patients without adrenal incidentaloma (HWA1) and on 63 healthy individuals forming control group. Groups matched to each other in terms of age, gender. Related patients and those who suffered from disease that may falsely affect the results were excluded. Severity of hypertension was determined by number of antihypertensive medications used to control. The significance of differences between the groups was evaluated through chi-square and Student’s t-test.

Results
TT genotype and T allele occurred significantly less frequently in HAI in comparison with Control Group (respectively: P = 0.049; P = 0.04). Patients with TT genotype needed more medication to control hypertension in comparison with CC genotype (3,080 vs 2,361, P = 0.039). Lack of significant differences between HWA1 to the rest groups.

Conclusions
• The presence of C allele in the region of -344 aldosterone synthase promoter predisposes to adrenal tumour, the TT genotype reduced that risk.
• Hypertension in patients with CC genotype is less severe, regardless of its phenotype.

Primary aldosteronism: more common than once thought: Two clinical cases
Nadine Monteiro, Eduarda Comenda, Joana Costa, Helena Vitorino, Sofia Santos, Filipa Moleiro, Cláudia Jesus, Ana Afonso & Helena Cantante
Lusíadas, Lisboa, Portugal.

Primary aldosteronism: more common than once thought: Two clinical cases
Introduction
Estimated prevalence of hypertension (HT) in Portugal is 42%. It is a major risk factor for coronary heart disease and cerebrovascular disease, the leading mortality cause in Portugal. Primary aldosteronism (PA) was once recognized as rare cause of secondary hypertension and hypokalemia a condition present in all cases. Nowadays, prevalence of this condition is about 10% in HT patients, being the commonest form of secondary HT. Secondary forms of HT should be excluded in young patients, severe increase in blood pressure, sudden onset or worsening of HT, poor blood pressure response to drugs and organ damage disproportionate to the duration of hypertension.

Case 1
A 69 years old female with a past medical history of HT for the last 20 years, presented with poor blood pressure control on bisoprolol 10 mg id perindopril 10 mg id and nifedipine 30 mg ER id at outpatient department. She had normal electrolytes. Screening tests for PA revealed high plasmatic aldosterone and suppressed renin plasmatic activity with a ratio > 25 mg/ml per h. Diagnosis was confirmed after saline infusion test. CT adrenal scan suggested left adrenal diffuse hyperplasia.

Case 2
A 48 years old female presented at the emergency room complaining of severe headache and four limbs’ muscle weakness. There was a past medical history of eclampsia and hypertension diagnosed at the age of 30, and eutrophic multinodal goiter. Labs revealed hypokalemia and she was started on oral KCl 600 mg bid. After electrolytes correction, she was screened for PA. High plasmatic aldosterone and low renin plasmatic concentration with a ratio > 3.8 was detected. Diagnosis was confirmed after saline infusion test. Conclusion
PA is an important cause of secondary hypertension, with a higher cardiovascular event rate than essential hypertension. It is frequently underdiagnosed and a potentially curable form of hypertension.

Baldr Thorstad
Eystein Sverre Huseby, Kristian Levås, Terje Hjalmars Larsen
1Haukeland University Hospital, Bergen, Norway; 2University of Bergen, Bergen, Norway.

Background
Primary aldosteronism (PA) patients have increased left ventricular mass (LVM) and increased cardiovascular morbidity compared with those with essential hypertension. Echocardiographic studies have demonstrated that adrenalectomy or spironolactone decreases LVM. The aim of the study was to use MRI to assess both LVM and cardiac function before and during stress testing, at baseline or spironolactone decreases LVM. The aim of the present study was to use MRI to assess both LVM and cardiac function before and during stress testing, at baseline or spironolactone, compared with healthy subjects (HS).

Material and methods
Fifteen recently diagnosed PA patients and 24 age- and sex-matched HS performed a baseline cardiac MRI with a 3.0 Tesla scanner. Imaging was performed at rest and during stress-testing with adenosine 140 μg/kg per min. Short-axis images were used for quantifications of LVM and left ventricular volumes. A follow-up MRI was performed in 20 of the HS and 14 of the PA patients, at least one year after starting specific treatment.

Results
Nine patients (60%) had unilateral PA, the remaining bilateral (n = 5, 33%) or not representative (n = 1, 7%) adrenal vein sampling. The PA and HS did not differ in age or sex. PA patients had higher baseline blood pressure (BP) than the HS (median BP 138/90 vs 118/75, P < 0.001). At follow-up, 8/14 PA were adrenalectomized (median 18 months). The remaining 6/14 were on spironolactone (median 21 months). LVM at baseline differed significantly between the PA and HS groups (median 145 vs 97 g; P < 0.001). At follow-up, the PA group had a significant reduction in LVM (median -18 g, P < 0.001), but no difference in cardiac output (CO) response to stress compared with baseline (follow-up PA median stress CO/rest CO 1.4 vs baseline 1.5, P = ns).

Conclusion
Cardiac MRI showed rapid reduction in LVM in PA after treatment with adrenalectomy or spironolactone. CO response to stress remained unchanged after treatment. Our results underline the importance of early diagnosis and treatment of PA.

EP34
The treatment with dual release hydrocortisone in patients with adrenal insufficiency: correlation between change of the evening cortisol exposure time profile and change in metabolic profile, depression status and quality of life
Chiara Simeoli, Rosario Ferrigno, Claudia Pivonello, Renata Simonana Urieomnia, Mariarosaria Negri, Gilda Di Gennaro, Davide Iacuaniello, Maria Cristina De Martino, Annamaria Colao & Rosario Pivonello
Dipartimento Di Medicina Clinica E Chirurgia, Sezione Di Endocrinologia, Università Federico Ii Di Napoli, Naples, Italy.

Conventional glucocorticoids (CGCs) are unable to mimic physiological cortisol rhythm in adrenal insufficiency (AI), resulting in increased metabolic morbidity and impaired quality of life (QoL). Non-physiological cortisol pattern and elevated evening cortisol levels may be responsible for the increased risk of metabolic disorders observed in AI patients under CGCs. Once daily dual-release hydrocortisone (DR-HC), which better reproduces physiological daily cortisol profile, significantly improves metabolic parameters and QoL in primary AI (PAI) and secondary AI (SAI) patients. The aim of the current study was to evaluate cortisol profile and its impact on metabolism, depression status and QoL in PAI and SAI patients switched from CGCs, including cortisone acetate and immediate-release hydrocortisone, to DR-HC. Fourteen AI patients underwent daily cortisol sampling, at 3 h intervals, at baseline (CGCs treatment) and 12 months after switching to DR-HC. Mean cortisol (24 h, 7-7am) AUC was 15.61% lower with DR-HC than with CGCs. In particular, mean (7am-1pm) and (1-7am) were 15.61% and 2.1% higher whereas mean (1-7pm), (7pm-1am) and (7pm-7am) AUC were 18.8% (P = 0.057), 58.39% (P < 0.001) and 41.87% (P = 0.004) lower with DR-HC than with CGCs, respectively. After 12 months of treatment, DR-HC induced a significant improvement in waist circumference (P = 0.002), depression status (P = 0.05) and QoL (P = 0.05). Moreover, the change (Δ) in cortisol 7pm-1am and 7pm-7am AUC appeared significantly correlated with the change (Δ) in insulin 1200 (Δ) after load (P < 0.005), depression score (P < 0.05) and QoL score (P < 0.05). The change (Δ) in cortisol 7pm-1am AUC appeared significantly correlated with the change (Δ) in fasting insulin (P = 0.045) and HOMA index (P = 0.045). In conclusion, the switch from CGCs to DR-HC in AI patients induces a significant improvement of waist circumference, depression status and QoL, and a significant decrease of late afternoon, evening and night GC overexposure; this reduction is significantly correlated with the improvement in metabolic profile, depression status and QoL.

EP35
Treatment of adrenal insufficiency with hydrocortisone dual-release formulation: glycometabolic profile and health-related quality of life
Laura Maria Mongioli, Rosita Angela Condorelli, Laura Cimino, Sandro La Vignera & Aldo Eugenio Calogero
Unit of Andrology and Endocrinology, Department of Clinical and Experimental Medicine, University of Catania, Catania, Sicily, Italy.

Introduction
Treatment of adrenal insufficiency (AI) in the last years has been object of important changes due to the development of a dual-release preparation of hydrocortisone (Plenadren®). Hydrocortisone dual-release therapy contemplates a once-daily tablet that allows more closely mimicking the physiological circadian rhythm of cortisol, thus avoiding overexposure.

Objective
The aim of the study was to value effects of Plenadren administration on the 24 h urinary free cortisol (UFC), the glycometabolic profile and health-related quality of life of patients with AI.

Methods and materials
We enrolled seven adults with secondary AI caused by panhypopituitarism (55.9±13.6 years) and seven adults with primary AI (36±6.2 years). We evaluated BMI, UFC levels, the glycometabolic profile and health-related quality of life (estimated by AddiQol questionnaire) before and 3, 6, 9 and 12 months after Plenadren administration. One patient dropped out the study for personal reasons.

Results
All patients, except one, reported a significant improvement of the quality of life after 3 months of treatment, whereas after 1 year everyone reported individual wellness. After 12 months of treatment, all parameters evaluated improved, though not in statistically significantly manner. The parameters for which there was evidence of a greater improvement were total cholesterol, low-density cholesterol and glycosylated hemoglobin levels.
Conclusions
The once-daily oral hydrocortisone dual-release therapy is a valid option for the treatment of patients with AI. It allows a good glycometabolic balance in the absence of side effects and improving compliance.

Transformation from Addison’s disease to adrenocortical carcinoma presented as Cushings’ syndrome with androgenisation
Antonela Sabati Rajic, Kristina Groti Resman, Tomaž Kocjan & Marija Pfeifer
Department of Endocrinology, University Medical Centre Ljubljana, Ljubljana, Slovenia.

We present a female patient 56 years old, who was treated at the endocrinology department from the year 2006. The diagnosis of Addison’s disease was established and she was properly treated. At the same time primary hypothyroidism was diagnosed, also started treating it properly. She was regularly controlled more often at the first time, than yearly at outpatient clinic. In September 2015 she was in menopause. A few months before she noticed oedematous legs and arms and diffuse bruising. Hypertension was also noticed for the first time and needed therapy. Her voice was different (became deep), she noticed hair loss and hirsutism, as well. She thought it was all in correlation with menopause. At the control examination she had hypokalemia, hypernatremia, hypertension, osteopenia with clear clinical aspect of Cushings. The abdominal ultrasound, CT scan and FDG-PET scan showed huge (13.8 cm in diameter) heterogeneous tumour mass in the right adrenal gland. The tumour infiltrates inferior vena cava and liver. Pelvic bone metastases were diagnosed also. CT angiography showed tumour thrombus and pulmonary embolism. Tumour biopsy showed adrenocortical carcinoma. The hormonal tests showed co-secretion of cortisol and androgens (Cushing’s syndrome and androgenisation). Tumour was inoperable so tumour embolisation was performed with idea of debulking. The patient was treated with mitotane in combination with systemic chemotherapy (EDP regimen: etoposide, doxorubicin), antiandrogen therapy per os and metaprazon. Because of the important hepatotoxicity mitotane was discontinued soon. She needed also hydrocortisone supplementation transitory, for the short time. The patient died due to the disease progression after one year.

Visinin-Like Protein-1 in the regulation of aldosterone biosynthesis
Celso Gomez-Sanchez1, Manselvan Kuppusamy1, Jeanne Ishimwe1, Tracy Williams2, Paolo Mulatero2 & Elise Gomez-Sanchez1
1University of Mississippi Med Center, Jackson, MS, USA; 2University of Turin, Turin, Italy.

Visinin-Like Protein-1 (Vsnl1) is a member of the EF-hand calcium sensor protein family that is expressed in the zona glomerulosa of the rat and human adrenal and upregulated in aldosterone-producing adenomas. We studied the expression pattern of Vsnl1 and co-localization with the CYP11B2 enzyme and the zona glomerulosa (ZG) marker Dlk1 (ZOG) using immunofluorescence and confocal microscopy techniques in normal areas and in the adrenals of rats on a normal and high sodium diet. We also studied the role Vsnl1 in aldosterone biosynthesis and calcium in the HAC15 cell. In the rat adrenal, Vsnl1 was expressed only in cells of the ZG and in cells expressing Dlk1, including undifferentiated cells between the ZG and zona fasciculata. Nearly all of the ZG cells from adrenals of rats on a low sodium diet expressed both Vsnl1 and CYP11B2. However in adrenals of rats on a normal and high sodium diet the staining for Vsnl1 was in many more ZG cells than those expressing CYP11B2. Vsnl1 and Dlk1 immunoreactivity was found not only cells that are steroidogenically active and producing aldosterone, but also in ZG and undifferentiated cells in the rat adrenal subcapsular area. Human adrenal cortical carcinoma cell line HAC15 was transduced with a lentivirus carrying Vsnl1. Three days after transduction cells were incubated with vehicle, angiotensin II (A-II) 10 nM, Forskolin 10 μM and potassium 16 mM and compared with control cells transduced with an empty lentivirus. Aldosterone and cortisol were measured after 24 h. The basal secretion of aldosterone was not increased, but that of cortisol was. Aldosterone and cortisol secretion were greater after A-II, forskolin and potassium stimulation in cells overexpressing Vsnl1. Proliferation of the HAC15 cells measured by the XTT and crystal violet methods and intracellular calcium, as measured by the Fluo-4 AM dye, were also increased after transduction with Vsnl1. Transduction of HAC15 cells with shRNA for Vsnl1 that reduced Vsnl1 expression decreased their basal and A-II stimulated aldosterone synthesis. The Vsnl1 has a myristoylation consensus sequence at the N-terminal domain. Site directed mutagenesis of Vsnl1 at the 2 position (G2A) lentiviruses transduced in HAC15 cells resulted in a significant decrease in the aldosterone response to A-II. In summary, the Vsnl1 is a zona glomerulosa protein that participates in calcium mobilization and increases the various secretagogue-induced aldosterone synthesis.

EP38
Metabolic syndrome is common among patients with adrenal incidentalomas, but not associated with functional adrenal status
Charalampos Tsentidis, Andreas Bampulis, Vasiliki Ntovà, Georgia Betsi & Georgia Kassi
Department of Endocrinology, Metabolism and Diabetes, Nikaia General Hospital ‘Ag. Panteleimon’, Athens, Greece.

Background
Adrenal incidentalomas (AI) have an increasing prevalence during last decades, probably due to the extended use of new imaging techniques and longer life expectancy. Adrenal hormonal hypersecretion, even subclinical, is probably related to cardiovascular disease (CVD).

Methods
We evaluated 100 patients with adrenal masses, incidentally discovered in imaging techniques performed for non adrenal disorders (67 Female, 33 Male, mean 58.1 ± 12.9 years, median 60.5y), according to NIH criteria of 2002 and ESE 2016. IDF 2006 criteria were used for metabolic syndrome (MS) definition.

Results
Mean incidentaloma size was 35.5 ± 20 mm. 20% were bilateral, while 41% were located to the right and 39% to the left adrenal. The majority (70%) was found to be non functional and 30% to be functional. Autonomous cortisol secretion (ACS) was found in 15%, pheochromocytoma (Ph) in 7% and hyperaldosteronism (HA) in 8% of all cases. Non functioning lesions were defined as non functioning adenomas (62%), non malignant cysts (2%), myelolipomas (2%), metastases (1%) and bilateral teratoma (1%). MS prevalence was higher in study group compared with general population (65% vs 23%, P<0.001). There was no difference in MS prevalence between patients with functional and non functional tumors (63.3% vs 64.7%, P=0.53), while no difference was found between functional tumors (ACS60% vs Ph57% vs HA75%, P<0.78). Hypertension had the greatest proportion in cases with hyperaldosteronism, while no difference in central obesity, hyperlipidemia and abnormal glucose metabolism was found between functional tumors.

Conclusions
The prevalence of metabolic syndrome was found to be high in patients with AI. A common pathophysiologic pathway (probably hyperinsulinaemia) must be the underlying mechanism between AI and MS, associated with an increased risk for CVD.

DOI: 10.1530/endoabs.49.EP38

The clinical course of patients with adrenal incidentaloma: Başkent University experience
Nazli Gulsoy Kirnap1, Ozlem Turhan Iyidir1, Yusuf Bozkus1, Lala Ramazanova1, Ashi Nar1, Aloug Kut2 & Neslihan Tutuncu1
1Department of Endocrinology, Baskent University Hospital, Ankara, Turkey; 2Department of Family Medicine, Baskent University Hospital, Ankara, Turkey.

The prevalence of incidentally discovered adrenal masses increased in last three decades. The major clinical concern is the risk of malignancy and hormone overproduction but most of them are non-functional and benign. Current practices in the management of adrenal incidentalomas reevaluated the follow-up suggestions considering low probability of the transformation of a benign and non-functional adrenal mass to a malignant or functional one. Therefore, in the present study we analysed the clinical course of patients with adrenal incidentaloma. We evaluated 203 consecutive patients (139 females, 64 males:mean age 55.8±0.8 years) who were referred to the Department of Endocrinology, Başkent University Hospital, between January 2007 and 2017. Among the 203 patients examined 171 had unilateral, 32 had bilateral adrenal masses. Mean size of tumors was 22.7±10.8 mm. In 157 (%77.3) patients their adrenal mass was benign and non-functional, 21 (%10.3) had autonomous cortisol...
secretion, 9 (54.4%) had Cushing syndrome, 5 (25.0%) had pheochromocytoma, 9 (54.4%) had primary hyperaldosteronism and, 2 (11%) had adenocortical carcinoma. Twenty-one patients went adrenalectomy. Median follow up time was 3 (1–10) years. During the follow up the change in the size of adrenal mass was non significant (P = 0.12) and there were no changes either in metanephrines and normetanephrines or in the activity of renin–aldosterone axis. There was a significant correlation between adrenum size and cortisol levels after dexamethasone suppression test in patients with autonomous cortisol secretion. As a result our study suggests that the risk of an adrenal adenoma initially diagnosed as benign or non-functional becoming malignant or hormonally active is low.

Introduction

Evaluation of glucocorticoid production generally requires a dynamic test. Cut-off levels for baseline cortisol concentrations predicting the outcome of a Synacthen test have been proposed for different cortisol assays. With introduction of the new Roche Elecsys Cortisol II assay, cortisol concentrations are expected to decrease by 20%. We have investigated cut-off levels for baseline P-cortisol concentrations measured with the Roche Elecsys Cortisol II assay that could predict the response to a Synacthen test in patients at risk of glucocorticoid-induced adrenal insufficiency.

Methods

In a cross-sectional study, 110 prednisolone treated rheumatologic patients had a 250 μg Synacthen test performed, fasting, in the morning, starting between 0800 and 1030 h, 36–48 h after the last prednisolone dose. P-cortisol was measured before and 30 min after Synacthen injection. The locally validated assay specific cut-off for normal adrenal function was 30 min P-cortisol ≥420 nmol/l.

Results

Forty-six patients (42%) had an insufficient response to the Synacthen test. Baseline and 30 min P-cortisol correlated positively (P < 0.001, r = 0.86). Receiver-operator curve analysis showed an area under the curve of 0.94 (95% CI: 0.90–0.98). All patients with baseline P-cortisol <139 nmol/l also failed the Synacthen test (positive predictive value = 100%). All patients with baseline P-cortisol >310 nmol/l had a normal response to the Synacthen test (negative predictive value = 100%). Applying these cut-off values baseline P-cortisol measurements predicted the response to the Synacthen test in 58/110 (53%) of cases; P-cortisol >310 nmol/l (33%); P-cortisol <139 nmol/l (20%).

Conclusion

We have presented assay specific baseline P-cortisol concentrations that could predict the response to a Synacthen test in half of patients at risk of glucocorticoid-induced adrenal insufficiency and potentially reduce the number of needed Synacthen tests in the worldwide many glucocorticoid treated patients. Baseline morning cortisol measurements might become a valid diagnostic screening tool in the future.

**LH and adrenal tumor size correlate with insulin resistance in menopausal patients with adenalin incidentalomas and (possible) autonomous cortisol secretion**

Ljiljana Marina 1,2, Milomir Ivovic 1,2, Milina Tanic-Gajic 1,2, Zorana Arizanovic 1, Dragana Rakovic 1, Jelena Milin-Lazovic 1,2, Aleksandra Kendereski 1,2, Dragana Micic 1,2, Srdjan Pandurevic 1,2 & Svetlana Vujovic 1,2

1Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia; 2Faculty of Medicine, University of Belgrade, Belgrade, Serbia; 3Institute of Medical Statistics and Informatics, Belgrade, Serbia.

High prevalence of insulin resistance (IR) has been shown in patients with adrenal incidentalomas (AI) and it has been demonstrated that an increase in IR is related to the adrenal tumor size (ATS). Also, responsive adrenal pathologies are well documented in patients with chronically elevated LH. The aim was to investigate the association between LH and IR and ATS in AI patients. The case-control study was conducted in Clinic for endocrinology, diabetes and metabolic diseases, Belgrade, Serbia. The total studied group consisted of 105 menopausal women: 75 AI patients (mean age 60.13 ± 7.28 years, mean BMI 27.60 ± 4.66 kg/m², mean menopause duration 10.86 ± 7.79 years, mean LH 31.82 ± 14.17 IU/l and mean ATS 31.25 ± 10.72 mm) and 30 age, BMI, menopause duration and LH matched healthy control (HC) women. Based on level of cortisol after 1 mg-dexamethasone suppression test AI patients were divided in two groups: <50 nmol/L, 27 with nonfunctional AI (NAI) and >50 nmol/l, 48 with (possible) autonomous cortisol secretion ((P)ACS). To estimate IR we used homeostasis model assessment (HOMA-IR). There was no significant difference between AI subgroups in terms of age, BMI, menopause duration, LH and HOMA-IR. HC subjects had significantly lower HOMA-IR when compared to NAI (P = 0.017). There was a significant positive correlation between LH and HOMA-IR in AI group (r = 0.230, P = 0.047) and in (P)ACS subgroup (r = 0.353; P = 0.013, but not in patients with NAI (r = −0.007, P = 0.623). The correlation of ATS and HOMA-IR was significant in AI group (r = 0.341; P = 0.003) and both NAI (P = 0.018, r = 0.445) and (P)ACS (P = 0.012, r = 0.362). After adjusting for age and BMI both LH and ATS were significant predictors of HOMA-IR.

**Silent pheochromocytoma – a rare case of adrenal incidentaloma**

Ana Filipa Martins 1, Sónia do Vale 1,2 & João Martin Martins 1,2

1Hospital de Santa Maria-CHLN, Lisboa, Portugal; 2Faculdade de Medicina de Lisboa, Lisboa, Portugal.

Introduction

Pheochromocytomas are rare tumors arising from adrenomedullary chromaffin cells. Pheochromocytomas are a serious clinical condition and undiagnosed cases are associated with increased unexpected cardiovascular mortality.

Case report

A female Caucasian patient aged 52-year-old was referred to the endocrine department of a public central hospital because of an incidental right adrenal mass first found 3 years before during the work out of non specific tiredness. Annual CT scan documented significant growth (34, 40 and 62 mm) of a hypodense lesion (less than 10 Housefield units). Presently the patient denied gastrointestinal or abdominal complaints and did not present clinical evidence for hypercortisolism, hyperaldosteronism, hyperandrogenism or for excessive catecholamine production. Past medical history revealed chronic gastritis treated with omeprazole daily. She reported three uneventful pregnancies 25, 20 and 19 years ago. Physical examination was unremarkable, with normal blood pressure and no orthostatic hypotension. Analytic evaluation excluded hypercortisolism and hyperaldosteronism. Urinary metanephrine and normetanephrine were high (12 and 16 times higher than the upper limit of the reference range) and dopamine 1.5 times over the upper limit. Serum calcium and calcitonin were in the reference range. 123I-MIBG scintigraphy presented increased right adrenal uptake. Uneventful laparoscopic right adrenalectomy was performed after preoperative treatment with doxazosin 8 mg, 2 l normal saline ev and propranolol 30 mg daily. Histologic evaluation confirmed a 55 mm pheochromocitoma, with no signs of malignancy. No genetic study was conducted.

Discussion and conclusion

About 7% of adrenal incidentalomas are pheochromocytomas. Although rare, clinically silent pheochromocytomas are recognized. Possible mechanisms may include 1) vasodilator peptides co-secreted by pheochromocytomas such as dopamine; 2) desensitization of target organs due to high catecholamine long-term exposure, 3) low circulatory volume in these patients and 4) malignancy with undifferentiation and minimal catecholamine production. This case highlights the need to exclude catecholamine producing tumors in all adrenal incidentalomas, even if they are asymptomatic.

*A case of recurrent Cushing’s disease due to total bilateral adrenalectomy*

Ivan Viecić1, Ivan Kruijć2, Miroslav Cacic2, Bozidar Perić2, Maja Filipovic-Grcic1, Gorana Mirosević1, Vatroslav Čerina3, Leo Pazarini & Milan Vrklijan

1University of Zagreb School of Medicine, Zagreb, Croatia; 2Department of Endocrinology, Diabetes and Metabolic Diseases ‘Mladen Sekso’; 3University Hospital Center ‘Sestre Milosrdnice’, Zagreb, Croatia.

Bilateral adrenalectomy usually results in lifelong primary adrenal insufficiency. Evidence exists that up to 34% of patients with Cushing’s disease (CD) have some degree of endogenous cortisol secretion after bilateral adrenalectomy due to ACTH driven hyperplasia of residual cortical tissue. We present a case of a patient with atypical corticotropinoma/carcinoma and recurrence of CD after bilateral adrenalectomy.

A 59-year-old man presented with Cushing’s disease (CD) in 2010. An MRI revealed intrasellar mass 8×8 mm suggestive of a microadenoma. After the surgery pathohistological evaluation was suggestive of atypical corticotropinoma (Ki-67 proliferation index 7%, positive nuclear staining for p53). CD recurred eight months after the surgery. Total hypophysectomy led to complete remission, followed by recurrence 5 months later. We performed radiosurgical treatment of the remnant tumor mass, along with bilateral two-stage adrenalectomy. Pathohistological evaluation confirmed complete removal of the left adrenal gland, and was inconclusive about the right one. Postoperatively, patient required replacement therapy. Two years after the adrenalectomy patient was diagnosed with Nelson’s syndrome due to enlargement of the pituitary mass. Fractionated radiotherapy was performed, after which ACTH slightly decreased, but UFC levels continued to increase, while taking hydrocortisone replacement.

Replacement therapy was stopped, but urinary free cortisol increased to 1400 nmol/24 h 3 years after the bilateral adrenalectomy, accompanied by the recurrence of signs and symptoms of CD. Computed tomography showed 4-cm large mass in the left adrenal bed suggestive of an adrenal tissue, along with the multiple liver lesions and without the signs of another primary tumor. Patient died five years after the initial diagnosis and his family refused an autopsy. This is the first case of a recurrent CD after bilateral adrenalectomy. This report highlights the importance of long-term monitoring of the patient and individual dosing of replacement therapy.

*Late-night salivary cortisol: cut-off definition and diagnostic value in Cushing’s syndrome*

Adriana Lages1, Joao Frade1, Isabel Paiva1, Patrícia Oliveira1, Diana Oliveira1, Diana Martins1, Mara Ventura1, Nelson Cunha1, Alexandre Rebelo-Marques2, Susana Antunes2, Fátima Leitão3 & Francisco Carrilho3

1Coimbra Hospital and University Center, Coimbra, Portugal; 2Faculty of Medicine University of Coimbra, Coimbra, Portugal.

Background

The diagnosis of Cushing’s syndrome (CS) remains a challenge in clinical endocrinology. Several screening tests have been proposed to establish hypercortisolism. Late-night salivary cortisol (LNSC) is used as screening tool, however, individualized cut-off levels for each population must be defined.

Methods

Three group of subjects were studied: healthy volunteers, suspected CS and proven CS. All patients collected saliva at 23.00 h using a Salivette. Salivary Cortisol was measured using an automated electrochemiluminescence assay – Eclisys 2010-Roche. The functional sensitivity of the assays is 0.018 μg/dl. Diagnostic cut-off level was defined by Receiver operating characteristic (ROC) curve and Youden’s J index.

Results

We studied 127 subjects: 57 healthy volunteers, 39 patients with suspected CS and 31 with proven CS (ACTH-dependent: 22 pituitary, two ectopic; ACTH-independent: two adrenal adenoma, five adrenal carcinoma).

The 2.5th–97.5th percentile of the LNSC concentrations in normal subjects was 0.054–0.1827 μg/dl, respectively. The mean ± s.d. LNSC concentration in patients with proven CS (0.6798 ± 0.52 μg/dl) was significantly higher than those in normal subjects (0.0642 ± 0.03 μg/dl; P < 0.0001) and suspected CS group (0.0803 ± 0.49 μg/dl; P < 0.0001). ROC curve analysis showed an AUC of 0.9881 (P < 0.0001) and a cut-off point of 0.1 μg/dl provides a sensitivity (S) of 96.77% (95%CI 83.3–99.92%) and specificity (E) of 91.23% (95%CI 80.7–97.09%).

Conclusions

Our results give to LNSC an excellent accuracy and reaffirm that can be used as a highly reliable noninvasive screening tool for outpatient assessment. In our population, the LNSC reference cut-off was 0.1 μg/dl with S 96.77% and E 91.23% for CS diagnosis. Given its convenience and diagnostic accuracy, LNSC may profitably be added to traditional screening tests such as LNSCe and UFC.

*Adrenal involvement in MEN1 families*

Mara Ventura, Miguel Melo, Leonor Gomes, Joana Saraiva, Luisa Barros, Dirce Rodrigues, Diana Oliveira, Diana Martins, Adriana Lages, Nelson Cunha & Francisco Carrilho

University and Hospital Center of Coimbra, Coimbra, Portugal.

Introduction

MEN1 is a rare autosomal dominant syndrome typically characterized by neoplastic lesions of parathyroid glands, anterior pituitary gland and endocrine pancreas. Several other tumours are associated with this syndrome, including adrenal lesions, but their prevalence and clinical characteristics (endocrine secretion and aggressiveness) are largely unknown.

Objective

To determine the prevalence, clinical characteristics and the possible genotype/phenotype association of adrenal lesions in MEN1 patients, as well as their global impact on patients’ outcome.

Material and methods

We retrospectively studied 16 patients belonging to six families of individuals with MEN1. Adrenal involvement was evaluated clinically, biochemically and imagiologically based on clinical records.

Results

Adrenal lesions were identified in 9 of 16 (56.3%) patients. This group comprises seven women and two men with a mean age of 55.6 years. The mean age at diagnosis of MEN1 was 46.3 years (18–68) and adrenal involvement was detected between 0 and 16 years after the syndrome was diagnosed. Among the 16 patients evaluated, a total of nine adrenal nodules were founded, with a median of two nodules per patient. Only three patients had unilateral involvement. The mean adrenal lesion diameter at diagnosis was 17.5 mm (6–30 mm). Hormonal hypersecretion – autonomous cortisol secretion – was founded in one patient. None of the patients was submitted to adrenalctomy. Adrenal lesions were evenly distributed between the different germline mutations.

Conclusion

Adrenal tumours are a common feature of MEN1 that can affect more than half of the patients. Most of the tumours are bilateral non-functional lesions, but hormonal secretion may occur and should be promptly identified in order to reduce the morbidity/mortality of the syndrome. Adrenal evaluation should be considered in patients with MEN1.

Differential effects of aldosterone excess on potassium homeostasis and blood pressure in Asian subjects
Du Soon Swee, Peng Chin Kek & Lih Ming Loh
Department of Endocrinology, Singapore General Hospital, Singapore, Singapore.

Introduction
Hypokalemia is considered as a late manifestation of primary aldosteronism (PA), long preceded by hypertension. However, there have been reports of normotensive PA patients presenting with hypokalemia. This study aims to examine the relationship of hypokalemia and blood pressure in patients with hyperaldosteronism.

Methods
A retrospective review of patients who underwent saline infusion test (SIT) from 2014 to 2016 was conducted. All patients had screening plasma aldosterone concentration (PAC): plasma renin activity (PRA) ratio of > 20. Postinfusion PAC level (< 5 ng/dl (139 pmol/l) indicated normal aldosterone suppression, PAC > 10 ng/dl (277 pmol/l) confirmed PA, whereas PAC 5–10 ng/dl (139–277 pmol/l) was regarded as indeterminate. Hypokalemia was defined as serum potassium < 3.5 mmol/l.

Results
Over a 3-year period, 52 patients referred for hypokalemia had non-suppressible postinfusion PAC (> 5 ng/dl). They comprised of 36 men and 16 women, with a mean age of 58.4 ± 9.1 and 57.3 ± 13.2 years respectively. In the PA group consisting of 26 men and 11 women, the mean serum potassium were 2.9 ± 0.3 mmol/l and 2.7 ± 0.5 mmol/l respectively. Eighteen (69.2%) men and 10 (90.9%) women were on ≤ 2 antihypertensive agents, including two women (age 48 and 51) with severe hypokalemia (< 2.5 mmol/l) who were normotensive and rendered normokalemic after adrenalectomy and spironolactone treatment separately.

In the indeterminate group comprising of ten men and five women, the mean serum potassium were 3.1 ± 0.2 mmol/l and 3.0 ± 0.2 mmol/l respectively. Five (50%) men and 4 (80%) women were on ≤ 2 antihypertensive agents. In all patients with moderate to severe hypokalemia (≤ 2.9 mmol/l), 7/11 (63.6%) men and 8/9 (88.9%) women were on ≤ 2 antihypertensive agents.

Conclusion
In our cohort of Asian patients, majority with hypokalemia secondary to autonomous aldosterone production required only 0–2 antihypertensive agents, even in those with more severe degree of hypokalemia. This suggests possible differential effects of aldosterone excess on potassium homeostasis and blood pressure.

EP47
Effect of adrenal mass lateralization on diagnostic tests in patients with Cushing
Ozlem Ustay Tarcin, Emre Pehlevan, Ezen Imre, Melin Uygun, Oguzhan Deyneli & Dilek Gogas Yavuz
Marmara University Pendik Hospital, Endocrinology and Metabolism, Istanbul, Turkey.

The frequency of adrenal masses is increasing in parallel with the progress of the technology. Most of these masses, which are detected by chance, are not functional, and only a part of them are exposed to an excess of hormone. The most common dysfunction in masses with hormonal activity is hypercortisolism. However, the diagnosis of Cushing’s disease is based on more than one test. In this study, we intended to compare the values of screening tests to determine whether the presence of a unilateral mass or bilateral mass would help in the diagnosis.

Materials and methods
Adrenal masses were detected in our clinic and 143 patients who were followed up were evaluated. 112 of these patients have unilateral adrenal mass, 31 have bilateral adrenal masses. Twenty (17.8%) of 112 unilateral adrenal masses and 15 (51.6%) of the patients with bilateral adrenal masses were diagnosed as Cushing. The 1 mg overnight dexamethasone suppression test (DST), 2 days 2 mg dexamethasone suppression test (Liddle test), and 24-h urine cortisol levels used for diagnosis in these patients were compared. Averages of tests were taken multiple times.

Conclusion
The mean age of the patients with bilateral and unilateral adrenal masses was around 60. When the mean values of 1 mg DST, Liddle test and 24 h urine were compared, no statistically significant difference was found between the two groups.

EP48
Late night salivary cortisol measurement may help in excluding Cushing’s syndrome in patients with chronic kidney disease
Urszula Ambrozia1, Agnieszka Kondracka1, Jadwiga Rojek-Trocka2, Pawel Gajkowski1, Agnieszka Staszyck1, Malwina Stepan1 & Tomasz Bednarzuk
1Department of Internal Medicine and Endocrinology, Medical University of Warsaw, Warsaw, Poland; 2Department of Nephrology, Medical University of Warsaw, Warsaw, Poland.

Objective
The diagnosis of Cushing’s syndrome may be challenging, especially in cases of patients with chronic kidney disease (CKD).

Aim
The assessment of late night salivary cortisol concentration, serum and salivary concentration in overnight dexamethasone suppression test in patients with CKD stage III–V and a control group.

Patients and methods
37 patients mean age 66 ± 12 (M = 13) with CKD stage III–V according to K/DOQI and 28 controls mean age 45 ± 15 years (M = 6) were enrolled to the study. Patients were recruited in the nephrology clinic during their routine control visits. Serum and salivary cortisol were measured by Roche ECLIA cortisol test (Cobas E411). Two samples of late night salivary cortisol (LNSC) from each subject were obtained from home. 1 mg dexamethasone suppression test (DST) was done in patients and controls with serum and saliva measurement at 0800 h. Serum creatinine assessment was done no longer than 1 week prior to cortisol measurement. GFR was obtained from the Cockcroft – Gault calculator.

Results
The mean GFR in patients was 33.89 ml/min (73–230) while in controls 125 ml/min (27–230) (P < 0.0001). The mean serum DST cortisol in patients was 2.62 μg/dl (0.46–7.42). In 19 (51.4%) patients serum DST cortisol was > 1.8 μg/dl (mean, min–max 0.70, 0.36–1.48). The mean DST salivary cortisol in patients was 0.88 μg/dl (0.11–0.88) while in controls 0.18 μg/dl (0.02–0.69) μg/dl. Although there was a significant difference between controls’ and patients’ salivary cortisol concentration in DST (P = 0.01), all but one patient’s salivary measurement were within control ranges. The mean LNSC cortisol was 0.26 μg/dl (0.10–0.65) while in controls 0.29 μg/dl (0.04–0.80), P = 0.4. All patients’ LNSC measurements were within control ranges. In the patients’ group the negative correlation between GFR and DST serum cortisol was detected, r = −0.6, P = 0.001 (the higher cortisol the lower GFR).

Conclusion
LNSC may be helpful in excluding Cushing’s syndrome in patients with CKD.

DOI: 10.1530/endoabs.49.EP49
Background
The Synacthen test is used to diagnose for adrenal insufficiency (AI) and non-classical congenital adrenal hyperplasia (CAH). The cut-off levels for s-cortisol and s-17-hydroxyprogesterone are derived from immunoassays that were not well standardized and are no longer in use. Introduction of liquid chromatography tandem mass spectrometry (LCMSMS) could resolve the lack of standardization of steroid hormone assays and enable increased diagnostic accuracy.

**Aim**

Define cut-off values for s-cortisol and s-17OH-progesterone by LCMSMS after intravenous administration of 250 μg tetracosactide acetate (Synachten).

**Methods**

The Synacthen test was performed in healthy individuals (n = 60) and patients referred for evaluation of adrenocortical function (n = 42). Steroids were assayed by LCMSMS. Cut-off level for s-cortisol was defined as the 2.5% percentile in healthy subjects not using oral estrogens (n = 55), and for 17-OH-progesterone as the 97.5% percentile in the healthy women.

**Results**

Cortisol cut-off levels were 415 and 493 nmol/l at 30 and 60 min, respectively. All controls had higher cortisol at 60 compared to 30 min. Applying the current cut-off of 550 nmol/l, 27 healthy controls would have had a false negative test at 30 min, and six at 60 min. For s-17-OH-progesterone the cut-off levels were 10.5 and 11.1 nmol/l at 30 and 60 min, respectively. Forty-two patients performed the test for suspected AI or non-classic CAH. Applying the new cut-offs, seven who had AI according to old criteria, now scored normal.

**Conclusions**

Cut-off levels for s-cortisol after Synacthen test are lower than the commonly recommended discriminating levels when cortisol is analyzed by LCMSMS. When applied, a significant proportion of patients can be re-categorized from adrenal insufficiency to healthy. We recommend using the 60 min value as standard, as cortisol increased from 30 to 60 min in all controls.

**DOI:** 10.1530/endoabs.49.EP49
Introduction

A 54-year-old woman with central obesity (BMI 34.3 kg/m²), diabetes and hypertension had a left adrenal mass of 15 mm and characteristics suggestive of adenoma (Hounsfield unit of <10). On CT revaluation, five years later, there was evidence of mass growth (28 mm) and the characteristics were suspicious of malignant lesion (Hounsfield unit of 38 and absolute contrast washout of 35%). She was then referred to our department for evaluation. Urinary catecholamines and metanephrines were normal, ACTH level was 4.2 pg/ml and the cortisol suppression test was consistent with ACTH-independent hypersecretion or incidental findings on imaging evaluation. Although most incidentalomas are non-functioning adenomas, it is important to appropriately evaluate such masses to exclude hormonal excess or malignancy. Case description

An 81-year-old male was admitted to our hospital for fever with 15 days of evolution. The patient also presented chills and loss of 3 kg in the last 4 weeks. Regarding past medical history, the patient had type 2 diabetes, hypertension, coronary artery disease, heart failure, cerebrovascular disease (stroke 8 years before), vertebral fractures (3 years before), deep vein thrombosis (3 months before), renal lithiasis and a right adrenal mass (3 cm in the abdominal tomography 16 months before; no functional study available). An elevated C-reactive protein (142 mg/l) was observed, with negative blood and urinary cultures and no other signs of infection. The abdominal ultrasound showed a right adrenal mass of 13 cm. On magnetic resonance, the mass was heterogeneous with invasion of inferior vena cava. The patient had no stigmata of Cushing’s syndrome. Plasma catecholamines, urine catecholamines and metanephrines, and renin and aldosterone levels were normal. The midnight salivary cortisol was normal and the plasma cortisol level after 1 mg overnight dexamethasone suppression test was 3.7 μg/dl. Given the risk for a surgical approach, the fast growth of the tumor and the imaging characteristics suggestive of adrenal carcinoma, a decision to preclude biopsy was made. The patient started mitotane and two months later the mass has 15 cm and the patient is still on follow-up in outpatient setting.

Conclusions

The authors present a case of adrenal carcinoma in a patient with previous adrenal mass not completely studied at presentation. Adrenal incidentalomas are frequent. This case highlights the importance of prompt evaluation of adrenal incidentalomas to early recognize rapidly growing adrenal carcinomas.

Adrenal cushing’s syndrome surprisingly unveiling breast cancer

João Sérgio Neves1,2, Ana Isabel Oliveira1,2, Pedro Souto1,3, Sofia Castro Oliveira1,3, Helena Baldaia1, Daniel Melo1, Celestino Neves1,3, Paula Freitas1,5 & Davide Carvalho1,5

1Department of Endocrinology, Diabetes and Metabolism, São João Hospital Center, Porto, Portugal; 2Department of Cirurgia e Fisiologia, Unidade de Investigação Cardiovascular, Faculdade de Medicina, Universidade do Porto, Porto, Portugal; 3Faculty of Medicine University of Porto, Porto, Portugal; 4Department of Pathology, São João Hospital Center, Porto, Portugal; 5Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal.

Introduction

Cushing’s syndrome is an endocrinopathy characterized by glucocorticoids excess. Adrenalec-tomy is the recommend treatment for unilateral adrenal Cushing’s syndrome and is usually associated with resolution of the disease.

Clinical Case

A 54-year-old woman with central obesity (BMI 34.3 kg/m²), diabetes and hypertension had a left adrenal mass of 15 mm and characteristics suggestive of adenoma (Hounsfield unit of <10). On CT reevaluation, five years later, there was evidence of mass growth (28 mm) and the characteristics were suspicious of malignant lesion (Hounsfield unit of 38 and absolute contrast washout of 35%). She was then referred to our department for evaluation. Urinary catecholamines and metanephrines were normal, ACTH level was 4.2 μg/ml and the cortisol following 1 mg overnight dexamethasone suppression test was 11.0 μg/dl. The 24 h urinary-free cortisol, late-night salivary cortisol and two-day low-dose dexamethasone suppression test were consistent with ACTH-independent Cushing’s syndrome. A left adrenalec-tomy was performed. At pathological evaluation, there was a neoplasm of solid pattern, with vascular invasion and a immunohistochemical pattern suggestive of a breast carcinoma metastasis. Mammography revealed a 15 mm nodule with speculated contours that on breast biopsy revealed a NST (no special type) breast carcinoma. The patient was submitted to neoadjuvant chemotherapy and surgical tumorcetomy. Five months after surgery she was admitted in Endocrine department for adrenalisufficiency. Ten months after the adrenalec-tomy, the patient presents an adrenal insufficiency (compensated with replacement therapy) and maintains follow-up on endocrinology and multidisciplinary breast cancer appointments.

Conclusion

The authors present a case of Cushing’s syndrome of adrenal origin, with a concomitant metastasis of a breast carcinoma. The find of a metastasis in an adrenal mass, is consistent with a tumor-to-tumor metastasis, a rare finding in concomitant metastasis of a breast carcinoma. The find of a metastasis in an adrenal mass, is consistent with a tumor-to-tumor metastasis, a rare finding in breast cancer.

The relative risk of developing Addison’s disease among patients with type 1 diabetes mellitus: a nationwide, matched, observational cohort study

Dimitrios Chantzichristos1,2, Anders Persson3, Björn Eliasson1,2, Merwete Mififaraj1, Stefan Franzen1, Ann-Marie Svensson1 & Gudmundur Johannsson1,2

1Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, at Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; 2Department of Endocrinology-Diabetes-Metabolism, Sahlgrenska University Hospital, Gothenburg, Sweden; 3Department of Medicine, National Diabetes Register, Centre of Registers, University of Gothenburg, Gothenburg, Sweden.

Background

Both prevalence and incidence of type 1 diabetes (T1DM) is increasing. T1DM is associated with other autoimmune diseases, such as Addison’s disease (AD). This combination is rare, with estimated prevalence in Norway 20 per million. Having both DM & AD is associated with marked excess mortality.

Objective

To study prevalence and incidence of AD among patients with and without T1DM.

Method

Nationwide, observational study cross-referencing the Swedish National Diabetes Register with Inpatient Register in patients with T1DM & AD and matched controls from the general population (matched 1:5 for age, sex and country). Demographics at baseline, group proportions and time to AD diagnosis using a Cox proportional hazards model were assessed.

Results

Prevalence: Between 1987–2012, 105 subjects were diagnosed with AD among 30,685 patients with T1DM, while 32 among 153,918 controls. The odds ratio for AD in T1DM patients vs controls was therefore 16.5 (95% CI 11.1–24.5).

DOI: 10.1530/endoabs.49.EP55

Reference
The prevalence of AD in patients with and without T1DM was 3400 and 200 per million, respectively. Incidence: Between 1998-2013, 67 subjects were diagnosed with AD at a mean age of 36.7 years (SD 13.1) among 36,705 patients with T1DM, while 33 were diagnosed with AD at a mean age of 43.1 (SD 15.1) among 184,304 controls. The estimated relative risk increase to develop AD in T1DM patients was therefore 10.7 (95% CI 7.0-16.2). The incidence of AD for a patient with and without T1DM was 195 and 18 per million patient-years, respectively.

Conclusion
This nationwide study shows that prevalence of AD is higher than previously reported and that the incidence of AD for a patient with T1DM is 195 per million patient-years. T1DM patients have a more than 10-fold higher risk of developing AD than matched controls and their AD develops at a younger age.

The frequency of incidental liver and renal masses in patients with adrenal incidentalomas
Narin Nasiroglu Inga, Yasemin Tutuncu, Mustafa Unal, Mazhar Mısırlı Tuna, Bercem Aycicek, Serhat Isik, Dilek Berker & Serdar Güler Department of Endocrinology and Metabolism, Ankara Numune Education and Research Hospital, Ankara, Turkey.

Purpose
Adrenal incidentalomas (AIs) are adrenal masses, which are found on imaging studies not performed related to an adrenal problem. Hepatic incidental and renal incidental masses are usually seen in abdominal imaging methods. We aim to investigate the frequency and the kind of hepatic and renal incidental masses in patients with AIs.

Methods
Retrospective evaluation of 381 (245 female and 136 male) AI patients and 285 (168 female and 117 male) controls were done. Adrenal masses were divided into two groups according to Hounsfield Units (HU) ≤ 10 and > 10, also classified as right, left and bilateral sided. The comparisons were made between hepatic and renal and both hepatic and renal incidental masses in AIs patients.

Results
Hepatic incidental mass and both hepatic and renal mass frequency were found higher in AIs group than controls. In AIs patients who had left sided unilateral adrenal mass HU >10, the frequency of both hepatic and renal incidental mass was found more than left sided unilateral adrenalinHU ≤ 10 group (P=0.003). Also in patients who had bilateral sided adrenal mass HU >10 the frequency of both hepatic and renal incidental mass was found more than bilateral sided unilateral adrenal HU ≤ 10 group (P=0.049).

Conclusions
Increased incidence of both hepatic and renal incidental masses were detected in AIs patients which adrenal mass HU greater than 10. We consider that the physicians should carefully evaluate these cases. Large studies are needed to define the incidence and follow-up of AIs patients with hepatic and renal incidentalomas.

Primary adrenal insufficiency: a Portuguese multicentre study by the adrenal tumour study group
Lia Ferreira1, João Silva2, Ana Martins3, Carlos Belo4, Diana Oliveira4, Helder Simões5, Isabel Paiva6, Joana Guimarães7, Marta Ferreira8, Rita Silva9, Susana Garro10, Tiago Silva11, Vera Fernandes12 & Maria Lopes Pereira12
1Centro Hospitalar do Porto, Porto, Portugal; 2Hospital das Forças Armadas, Lisboa, Portugal; 3Centro Hospitalar Lisboa Norte, Lisboa, Portugal; 4Centro Hospitalar Lisboa Ocidental, Lisboa, Portugal; 5Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; 6Instituto Português de Oncologia Lisboa, Lisboa, Portugal; 7Hospital do Bairro da Vouga, Aveiro, Portugal; 8Centro Hospitalar Leiria, Leiria, Portugal; 9Centro Hospitalar São João, Porto, Portugal; 10Hospital Tâmega e Sousa, Penalafiel, Portugal; 11Hospital Garcia da Orta, Lisboa, Portugal; 12Hospital de Braga, Braga, Portugal.

Introduction
Primary adrenal insufficiency (PAI) is a rare but severe and potentially life-threatening condition. There are no studies characterizing Portuguese patients with PAI.

Aims
To characterize the clinical presentation, diagnostic workup, treatment and follow-up of patients with confirmed PAI.

Methods
A multicentre retrospective study of PAI patients followed in 12 Portuguese hospitals.

Results
We investigated 278 patients with PAI (55.8% were females) with mean age of diagnosis of 33.6±19.3 years, 7.3 years after the beginning of the symptom presentation. The most frequently reported symptoms and signs were asthenia (60.1%), hyperpigmentation (55.0%), weight loss (43.2%), hypotension (42.8%) and hypoglycaemia (8.6%). Hypoamotrenia was documented in 36.3% of cases and hyperkalaemia in 25.9%, 29.1% of patients were diagnosed in adrenal crisis. In 122 patients the diagnosis was established using morning cortisol < 5 µg/dl and plasma ACTH 2-fold the upper limit of the reference range and in 39 cases by the corticotron stimulation test. The main causes were autoimmune adrenalitis (140 cases), idiopathic (48 cases), congenital adrenal hyperplasia (27 cases) and tuberculosis (17 cases). Concerning associated autoimmune diseases, the most common were autoimmune thyroiditidis (81 patients) and type 1 diabetes mellitus (29 patients). Seventy-nine percent were treated with hydrocortisone (mean dose 26.3±8.3 mg/day) in three (57.5%), two (37.4%), one (3.7%) or four (0.5%) daily doses; the remainder with prednisolone (10.1%), dexamethasone (6.2%) and methylprednisolone (0.7%); 66.2% were medicated with fludrocortisone (median dose of 100 µg/day). Since diagnosis 33.5% have been hospitalized due to disease decompensation. At the last consultation, 17.2% of the patients had complains (7.6% asthma and 6.5% depression) and 9.7% presented changes in the ionogram.

Conclusion
This is the first multicentre Portuguese study about PAI. As described in international studies a significant number of PAI patients continue to have symptoms of over or under-substitution despite optimal steroid replacement.

Adrenal incidentaloma: a challenging dilemma!
Câmille Bouner, Usman Shah, Anna Hawkins, Anthony Pittathankal, Imran Syed, Edel Casey & Khash Nikookam
King George Hospital, London, UK.

The prevalence of adrenal incidentaloma on abdominal Computed Tomography (CT) is around 4.4%. This prevalence is increased in obese, diabetic, hypertensive patients, and could be as high as 10% in older patients. Unilateral adrenal masses larger than 4 cm should be considered for surgical removal to avoid missing adrenal carcinoma, particularly in younger patients.

This is the case of a 67 year old gentleman with Type 2 diabetes mellitus, known to have hypertension, hypercholesterolaemia, ischaemic heart disease with six coronary stents, and iron deficiency anaemia. He was on polypharmacy including aspirin, clopidogrel, bisoprolol, amlopidine, oral hypoglycaemic agents, insulin and iron supplementation. He presented with increased urinary frequency and pain in the right flank. Urinalysis and examination of all systems were unremarkable. An ultrasound of kidney, ureter, and bladder (KUB) was performed showed a well-defined solid echogenic mass superior to the right kidney measuring 76×85 mm with no vascularity. CT of the adrenals and abdomen revealed a 7 cm right adrenal mass, most likely myelolipoma, multiple bilateral small renal cysts, and an extensively calcified atherosclerotic abdominal aorta. Plasma cortisol and renin, aldosterone ratio were normal. The patient was therefore counseled not to operate at this stage.

Conclusions
Is it best to leave it alone, bearing in mind his multiple co morbidities or to operate in view of right flank pain, the size of tumour, and the risk of bleeding in this type of tumour?

Assay of steroids with Liquid chromatography tandem mass spectrometry is superior to immunoassays in monitoring patients with 21-hydroxylase deficiency

Ingrid Nermoen1, Sandra Rinne Dahl1, Ingeborg Brøndstad1,3, Eystein S Husebye2,3, Per E Thorøy3 & Kristian Lavås2,3
1Oslo University HospitalHrmnatory Laboratory, Oslo, Norway; 2Akershus University Hospital, Lørenskog, Norway; 3University of Bergen, Bergen, Norway.

Objective
Immunooxays of steroids are still used in the diagnosis and biochemical monitoring of patients with congenital adrenal hyperplasia due to 21-hydroxylase deficiency (21 OHD). However, high levels of steroid intermediates can promote cross-reactivity between steroids giving rise to falsely elevated levels.

Design
Fifty-nine patients with classic 21OHD (38 women) were studied. Blood samples were collected in the morning after overnight medication fasting. Immunoassay and liquid chromatography tandem mass spectrometry (LC-MS/MS) quantification of the following steroids were performed: 17OH-progesterone (17OH), 21-deoxy cortisol (21DF), an 11-hydroxylated derivative of 17OHP, 11-deoxycortisol, testosterone and androstenedione.

Results
Concentrations of testosterone, androstenedione and 17OHP were lower when measured with LC-MS/MS compared with immunoassays, with exception of testosterone levels in men. Testosterone results differed by 30.0% in females and only a small difference in men (+1.1%). The difference was even larger for androstenedione (31.3%) and 17OHP (57.6%).

Conclusions
LC-MS/MS is superior to immunoassays in monitoring patients with 21-OHD on corticosteroid replacement therapy as they are more specific and can be multiplexed. Immunoassays seems to overestimate high levels of 17OHP and androstenedione considerably.

Treatment of patients with primary and secondary adrenal insufficiency with hydrocortisone modified-release (Plenadren®)

Tania Pilli, Raffaella Forleo, Sandro Cardinale, Valeria Cenci & Furio Pacini
Section of Endocrinology, Department of Clinical&Surfical Sciences and Neurosciences, University of Siena, Siena, Italy.

Introduction
Adrenal insufficiency is a life-threatening disease. Conventional treatment requires multiple daily doses of immediate-release hydrocortisone or cortisone acetate causing non-physiological peaks and nadir of cortisol and it has been also associated with premature mortality, high frequency of infections, reduced quality of life, altered metabolic profile and reduced bone mineral density. A modified-release hydrocortisone (Plenadren®, Shire) by combining a rapid with an extended-release of the hormone can mimic the normal circadian rhythm of cortisol and may be administered as a single daily dose. Plenadren has been also associated with a reduction of body weight and blood pressure and improvement of the glyco-metabolic parameters.

Purpose
The study objectives are: (1) to compare the area under the curve (AUC) of cortisol under conventional therapy and Plenadren and (2) to evaluate clinical (body weight, body composition, blood pressure), glyco-metabolic (HbA1c) and bone (T score, BMD, serum bone alkaline phosphatase (BAP) and cross laps) parameters at 3, 6 and 12 months of treatment with Plenadren.

Materials and Methods
Thirteen patients (7 M/6 F; age 53±17 (or ± s.d.)) with primary adrenal insufficiency in seven subjects and secondary in six cases were prospectively enrolled in the study.

Results
Daily cortisol profiles were more physiological on Plenadren and body exposure to cortisol, calculated as area under the curve, was not statistically significant between conventional therapy and Plenadren. Currently, the median follow-up is 9 months (range 3–24 months). In one obese and diabetic patient body weight decreased as well as fat mass while lean mass increased and HbA1c improved. In one patient with osteoporosis T score improved and accordingly cross laps decreased and BAP increased. All study parameters did not show significantly changes in the remaining patients.

Conclusions
Treatment with Plenadren provides a more physiological cortisol profile and in some patients shows a beneficial effect on glucose metabolism and bone and body composition without increasing adrenal crisis and/or infections.

Autoimmune Addison disease – data from long-term follow-up of patients from a tertiary hospital’s Endocrinology Department

Diana Oliveira, Isabel Paiva, Adriana Lages, Diana Martins, Mara Ventura, Nelson Cunha, Sandra Paiva & Francisco Carrilho
Endocrinology, Diabetes and Metabolism Department, Coimbra Hospital and University Center, Coimbra, Portugal.

Introduction
Autoimmune Addison disease requires lifelong glucocorticoid and mineralocorticoid replacement. Optimal therapy is not standardized and must balance adequate hormone substitution with prevention of treatment-related complications.

Objective
Assessment of patients followed at our department: epidemiology, associated conditions, treatment, cumulative hydrocortisone dose and comorbidities.

Methods
Review of clinical records of patients currently followed at our department, diagnosed from 1975 until 2015. Statistical analysis using SPSS v. 23.0.

Results
A total of 27 records were evaluated, 17 were women, 10 men. Mean age at diagnosis was 32±9.7 years, mean follow-up 19.7±13.8 years. Disease duration was 20 or more years in 55.6%. Mean current age 51±13 years. The most frequently associated immune system disorder was autoimmune thyroiditis (42.3%). Regarding glucocorticoid replacement, 92.6% were treated with hydrocortisone (HC), 2 patients with prednisolone. Mean daily dose of HC 31.2±10.0 mg (range 5.0–47.5 mg). Mineralocorticoid replacement with fludrocortisone, mostly 0.1 mg/d. Osteoporosis/osteopenia was found in 33.3% (n=9), hypertension (HT) in 25.9% (n=7), diabetes in 14.8% (n=4), treatment for depression or anxiety in 40.7% (n=11) and dyslipidemia in 51.9% (n=14).

Mean cumulative HC dose was higher in patients with osteoporosis/osteopenia and in those with HT, dyslipidemia and diabetes, although not reaching statistical significance. Tendency remained when adjusted for age.

Discussion and conclusion
Our sample shows a long follow-up time, associated with lifelong need of Endocrinology assessment. A significant number of patients developed comorbidities possibly related to long-term glucocorticoid therapy (osteoporosis, HT, dyslipidemia and diabetes). All of these were related to higher cumulative HC dose. Absence of statistical significance was likely due to sample size. To reduce the risk of complications, replacement therapy in autoimmune Addison disease should be individually adjusted and overtreatment avoided.

Effect of GH treatment on coagulation and fibrinolysis parameters in prepubertal children with growth hormone deficiency

Feneli Karachalios1, Maria Kafetzis2, Maria Drakopoulou2, Elips Vlachopapadoupolou2, Sofia Leka-Emiris2, Aspasia Fotinou2 & Stefanos Michalakos2
1Pediatric Endocrinology Unit, 3rd Department of Pediatrics, University General Hospital Attikon, Athens, Greece; 2Biochemistry–Hormonology Department, P & A Kyrkou Children’s Hospital, Athens, Greece.

Introduction
A significant number of patients developed GH deficiency (GHD) and may be treated with growth hormone (GH). GH can improve coagulation and fibrinolysis parameters. The objectives were: (1) to compare the AUC of coagulation and fibrinolysis parameters in healthy children (HC), GHD before GH treatment (GH1) and after GH treatment (GH2); and (2) to evaluate changes in these parameters between GH1 and GH2.

Materials and Methods
Thirty-one patients (18 M/13 F; age 10.0±3.1 years) with GHD were included in the study. GH treatment was initiated at a dose of 0.03 mg/kg/day and increased according to the clinical response. The mean duration of GH treatment was 33±22.4 months. Changes in the AUC of coagulation and fibrinolysis parameters were calculated using the trapezoidal method.

Results
Compared with HC, children with GHD before GH treatment (GH1) showed a significant decrease in Fibrinogen and D-dimer and an increase in Prothrombin time and Antithrombin III. After GH treatment (GH2), these changes were reversed. The changes in the AUC of coagulation and fibrinolysis parameters were statistically significant between GH1 and GH2.

Discussion
The results of this study indicate that GH treatment can improve coagulation and fibrinolysis parameters in children with GHD. These findings support the use of GH treatment for children with GHD.
Background
Increased fibrinogen levels have been reported in prepubertal children and adolescents with growth hormone deficiency (GHD), which were reduced after rhGH treatment. rhGH treatment has also been shown to exert a beneficial effect on the amount of aPAI-1 in children with GHD.

Aim
Of the study was to evaluate whether prepubertal GH deficient (GHD) children showed any impairment in coagulation- and fibrinolysis-related parameters and the effect of GH therapy on these parameters.

Patients and methods
Fifteen prepubertal children (10 girls and five boys) of a mean (s.d.) age of 9.8 (0.4) years with GH deficiency were included in this hospital based prospective study. Serum levels of PT, APTT, fibrinogen, VII, VIII, AT, PC, D-dimers, Plg, and PAI-1 were measured before and after 6–12 months of GH treatment.

Results
At baseline all studied parameters were within normal ranges. A significant increase in PT values was noted after a mean (s.d.) interval of 9.3 (0.4) months of treatment: 12.46 (0.2) s vs 12.10 (0.15) s, P = 0.045. A significant decrease in PAI-1 levels (3.04 (0.1) U/ml vs 2.28 (0.3) U/ml, P = 0.018) was noted at the same time.

No significant changes in the rest of parameters were found during the study period.

Conclusion
GH replacement therapy for 6–12 months led to a significant increase in PT values, while fibrinogen levels did not change. Moreover, GH treatment reduced PAI-1 levels in GHD children, suggesting a beneficial effect of GH treatment on possible risk of future atherothrombosis. Further evaluation of the clinical significance of these changes is needed.

Treatment with modified-release hydrocortisone for 6 months: A clinical audit in 15 patients with adrenal insufficiency
Charlotte Steffensen1, Marianne Andersen1, Ulla Feldt-Rasmussen1, Caroline Kistorp1 & Jens Otto L Jørgensen1
1Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; 2Department of Endocrinology and Internal Medicine, Odense, Denmark; 3Department of Endocrinology and Metabolism, Rigshospitalet, Copenhagen, Denmark; 4Department of Endocrinology and Internal Medicine, Herlev, Denmark.

Background
Patients with adrenal insufficiency (AI) exhibit increased morbidity, mortality and impaired quality of life (QoL). and conventional hydrocortisone replacement does not mimic the endogenous circadian pattern and may compromise adherence. A modified – release hydrocortisone formulation (Plenadren) for once-daily use is licensed in order to meet these needs.

Objective
To audit the effects of treatment change from HC to Plenadren in an out-patient, daily-life clinical setting.

Patients and methods
Fifteen consecutive patients with AI and problems with adherence and/or QoL, were shifted from HC to Plenadren treatment. The effect of treatment was assessed by clinical biochemistry, DEXA scanning and QoL, (AddQol) before and after 6 months.

Results
Fifteen patients (10F:5M) were included in the audit of whom 8 had primary AI with a mean age of 49.5 years. The mean daily HC dose was 21.4 mg and the mean daily plenadren dose was 20 mg. No significant changes were recorded in fasting lipid levels, morning salivary cortisol, serum electrolytes, HbA1c, or CRP before and after plenadren treatment. Likewise, body composition and BMD were unchanged. The AddQol questionnaire showed a trend towards improved sleep, less muscle pain and better concentration at 6 months. Fourteen of the 15 patients continued on Plenadren after 6 months.

Conclusion
Plenadren treatment for 6 months in patients with AI was well received but did not translate into detectable changes in clinical biochemistry or body composition. Longer treatment duration and a larger patient group are needed to evaluate the long term benefit of plenadren.

Cushing’s Syndrome During Pregnancy mimicking preeclampsia – case report
Danijela Radojkovic1,2, Milan Radojkovic1,3, Milica Pesić1,2, Slbobadan Antić1,2, Sonja Kostić1, Sanja Curković1, Vojislav Cirić2 & Ivan Ilic5,6
1Medical Faculty, University of Nis, Nis, Serbia; 2Clinic of Endocrinology, Diabetes and Metabolic Disorders, Clinical Center Nis, Nis, Serbia; 3Surgery Clinic, Clinical Center Nis, Nis, Serbia; 4Pathology Institute, Clinical Center Nis, Nis, Serbia.

Introduction
Physiological changes of pregnancy could be similar with classical presentation and biological confirmation of Cushing’s Syndrome (CS). To diagnose CS in pregnancy is very difficult especially in previously healthy women. Since the hypercortisolemia in the pregnancy increase maternal and foetal morbidity it is a concern for endocrinologists, gynaecologists, and paediatricians.

Patient case report
Herein, we present young woman (23 years old) admitted to the Genecology Clinic, with uncontrolled hypertension and gestational diabetes. The pregnancy was terminated with an emergency caesarean section at 28 weeks of gestation due to severe preeclampsia. Five months after delivery hypertension, weight gain, poor glycaemic control, irregular menstrual cycles and cushingoid features persisted. She was admitted to the Endocrinology Clinic for further evaluation. Computed tomography revealed right adrenal adenoma, size 32×41 mm. Endocrine evaluation verified increased cortisol and decreased ACTH. There was no plasma cortisol suppression after low- and high-dose dexamethasone suppression tests. Vanillylmandelic acid in 24 h diuresis, plasma catecholamine and chromogranin serum level, were normal. Potassium was decreased, but other electrolytes (sodium, calcium, phosphorous, magnesium) were in normal range. After adequately preoperative preparation, right adrenalectomy was performed. The procedure and postoperative course were uneventful. The histopathological examination confirmed a benign adrenocortical adenoma.

Conclusion
Even though CS in pregnancy is very rare, it is worthwhile to be considered when pregnant women develop hypertension and gestational diabetes. Delayed diagnosis and treatment could lead to maternal-foetal complications.

Potentially aggressive adrenal oncocytoma during pregnancy: about one case
Mouna Mezoued1,2, Maissa Smaili1 & Djamil Meskina1,2
1Laboratoire Endocrinologie et Metabolisme, Algiers, Algeria; 2EPH Bolghine, Algiers, Algeria.

Oncocytoma cells adrenal adenoma or adrenal oncocytoma is an extremely rare tumor, mainly composed by oncocytomes. The diagnosis is exclusively confirmed on histological findings. There are about 50 cases published in the scientific reviews, of which only one case described a pregnant woman.

We report an observation about a 31 years old patient, with no personal antecedent, explored in our unit for an adrenal mass, measuring 71×58×46 mm discovered during an abdominal CT scan done for low back pain. Patient did not present obvious signs of adrenal hypersecretion at clinical exam, we noticed some sympathetic signs associated to an amonorrhoea, and a pregnancy of 8 weeks of amenorrhea was then diagnosed. At CT scan the adrenal mass did match with the characteristics of an adenomatous one, having a spontaneous density of 40 HU, and an absolute washout up to 33%.

Methoxylated drift and hormonal exploration were normal. Regarding to the size of this mass and its radiological characteristics with a strong suspicion of malignancy, Surgical management was decided, and patient was treated at 12 weeks of amenorrhea with simple post-operative issues. Histological findings concluded to an adrenal adenoma with oncocytary cells presenting malignant potential (according to BISCEGLIA criteria).

Pregnancy was leaded to its term, with birth of a healthy new-born. The patient treated at 12 weeks of amenorrhea with simple post-operative issues. Histological findings concluded to an adrenal adenoma with oncocytary cells presenting malignant potential (according to BISCEGLIA criteria).

Patient case report
Herein, we present young woman (23 years old) admitted to the Genecology Clinic, with uncontrolled hypertension and gestational diabetes. The pregnancy was terminated with an emergency caesarean section at 28 weeks of gestation due to severe preeclampsia. Five months after delivery hypertension, weight gain, poor glycaemic control, irregular menstrual cycles and cushingoid features persisted. **Primary hyperparathyroidism associated with Cushing syndrome and primary hyperaldosteronism**

Fatma Mnif, Hamza Ellekhi, Mouna Elleuch, Fatem Hadjacakern, Dorra Ghorbel, Nabilah Reik, Mouna Ammar, Mouna Mnif & Mohamed Abd

Hedi-Chaker University Hospital, Sfax, Sfax, Tunisia.

**Introduction**

The simultaneous occurrence in the same patient of more than one endocrinological condition is rare and was described in the multiple endocrine neoplasia (MEN). Here, we report a patient with an unusual combination of primary-hyperparathyroidism, papillary thyroid microcarcinoma, primary-hyperaldosteronism and ACTH-independent Cushing’s syndrome.

**Case description**

A 54-year-old women with a primary-hyperparathyroidism was admitted to our hospital to undergo a parathyroidectomy for a single adenoma and total thyroidectomy for suspicious nodules in which one of it was confirmed histopathologically to be a 3 mm papillary thyroid microcarcinoma. An exploration of a resistant hypertension associated with hypokalaemia was done and the co-secretion excess of aldosterone (aldosterone-renin ratio > 23 ng/ng twice) and cortisol (negative overnight and low-dose Dexamethasone suppression with low ACTH level) was confirmed with an abdominal CT-scan showing a 19 mm left adrenal adenoma. The patient has also multiple lipomas.

**Conclusion**

The multiple endocrine hypersecretion exists and the MEN1 should be considered since there is a considerable number of atypical MEN1 syndrome thus the DNA exploration of a resistant hypertension associated with hypokalaemia was done and the co-secretion excess of aldosterone (aldosterone-renin ratio > 23 ng/ng twice) and cortisol (negative overnight and low-dose Dexamethasone suppression with low ACTH level) was confirmed with an abdominal CT-scan showing a 19 mm left adrenal adenoma. The patient has also multiple lipomas.

**Comparison of biochemical and hormonal parameters in patients with primary adrenal insufficiency of autoimmune and non-autoimmune cause**

Anna Angeloussi, Aggeliki Karapanagioti, Giorgos Nikolopoulos, Panagiotis Moschotouris, Marina Tsol, Vasiliki Mamouedi, Michalis Kokkinos, Nikolaos Asonitis, Fotini Petychaki, Gregory Kaltzas & Eva Kassi

Kapodistrian University of Athens, Athens, Greece.

**Introduction**

Primary adrenal insufficiency (PAI) can be of autoimmune origin (AI), non-autoimmune origin (bilateral adenectomy, acute hemorrhage, infection) (NAI) or pharmaceutical (mitotane) origin. Studies have shown that these patients develop long-term morbidities and increased mortality due to excessive glucocorticoid tissue exposure. Data about differences concerning hydrocortisone (HC) needs, cortisol hormonal levels and metabolic parameters in these patients are scarce.

**Methods**

This retrospective analysis included patients with PAI with follow-up more than 5 years (mean follow-up: 9 ± 6.9 years). Patients had two different day curves of cortisol (F) measurements and 24 h urinary cortisol levels (UFC) and were on oral HC replacement treatment (total mg/day).

**Results**

We included 12 patients with Addison disease (AD), 8 patients under therapeutic mitotane levels (>13 mg/dl) and six patients with PAI of other causes (NAI). BMI increases in all groups in the follow up and it is positively correlated with daily HC substitution (P=0.0017, r=0.5). Mitotane group had statistical significant higher BMI at diagnosis compared to the two other groups (P=0.015). This difference among groups in the BMI disappears in the follow-up thus probably due to ‘Cushing effect’. NAI group had higher HC substitution compared to AD group (P=0.01) and higher HbA1c and cholesterol levels during follow up compared to AD group (P=0.021) and mitotane group (P=0.05). As expected HC substitution as well as UFC levels were significant higher in the mitotane group compared to the two other groups (P=0.0014, P=0.05 respectively). Median F levels were positively correlated with HC substitution (P=0.0027) (mitotane group was excluded).

**Conclusion**

Patients with NAI had statistically higher HC substitution as well as HbA1c and cholesterol levels in the follow up compared to AD group. Despite the small sample of patients the over-substitution of these patients should be reconsidered regarding the consequences.

**The role of dehydroepiandrosterone sulphate (DHEAS) in the evaluation of autonomous cortisol secretion in adrenal incidentalomas**

Fotini Adamidou, Thomas Georgiou, Gesthunmi Mintziori, Efrosini Tsirou, Panagiota Anagnostis, Athanasias Panagiotou & Marina Kita

Ippokrateion General Hospital of Thessaloniki, Thessaloniki, Greece.

**Introduction**

Subclinical hypercortisolism (SH) has been reported in 5–20% of patients with adrenal incidentalomas (AIs), with various cardiometabolic consequences. We intended to investigate the contribution of DHEAS to standard testing, as another indicator of autonomous cortisol secretion in AIs.

**Materials and methods**

Ninety consecutive patients (n=90) with AIs were included in a prospective cohort study. SH was diagnosed if ≥2 criteria were fulfilled: an overnight dexamethasone suppression test (DST) ≥1.8 μg/dl, a 24 h urine free cortisol (UFC) above the upper limit of normal, midnight/morning serum cortisol ≥0.5 and plasma ACTH <10 pg/ml. Age- and sex-specific DHEAS ratios were calculated and a ratio of 1.25 was considered the cut off. Data are expressed as median (interquartile range).

**Results**

Ten cases of SH were found among the 90 patients (11%), harboring 112 AIs. DHEAS ratio in patients with SH was 1.55 (2.5) and 1.85 (2.67) in non-functional AIs. A DHEAS ratio ≥1.25 was not predictive of SH.

**Conclusion**

DHEAS failed to prove a useful screening tool for SH in patients with AIs in this study. Further study is needed to evaluate its potential as an adjunct to DST.

**Adrenocortical carcinoma in pregnancy**

Goknur Yorulmaz1, Nur Kebapci1, Funda Canaz2, Betul Aydin Buyruk1, Sevol Alaguney1, Bartu Badak1 & Mahmut Kebapci4

1Division of Endocrinology, Eskişehir Osmangazi University School of Medicine, Eskişehir, Turkey; 2Department of Pathology, Eskişehir Osmangazi University School of Medicine, Eskişehir, Turkey; 3Department of General Surgery, Eskişehir Osmangazi University School of Medicine, Eskişehir, Turkey; 4Department of Radiology, Eskişehir Osmangazi University School of Medicine, Eskişehir, Turkey.

**Introduction**

Adrenocortical carcinoma (ACC) is a very rare tumor. The mean age at onset is between 40 and 50 years. Patients with nonfunctioning ACC report symptoms of abdominal discomfort or back pain due to the large tumor size. Surgery for ACC should be performed by an expert surgeon.

**Case**

A 28-year-old patient with 25 weeks of pregnancy admitted at our clinic with right side pain. 10×11 cm solid mass on right adrenal gland was detected by ultrasonography. The lactate dehydrogenase level of the patient was 10 times higher than normal ranges. The urinary metabolits were within normal limits. Because of the increase in the size of the mass, the patient underwent operation urgently. The histopathological report indicates an adrenocortical carcinoma and tumor weighting 376 g and measuring 11 cm × 7 cm. The patient gave birth on the 32nd gestational week. The patient was evaluated after delivery and liver, pulmonary and brain metastases were detected. One week after delivery patient was died in intensive care unit.

**Conclusion**

Several clinical data shown that the secretion and or proliferation of adrenocortical tumors may have be affected by the hormonal context of pregnancy. Most of patients present with excess steroid hormone or abdominal mass effects. In our patient, a mass was detected in the ultrasonography performed with the cause of side pain. In pregnancy treatment procedure was not still standardized in ACC, but ACC was an aggressive malignant tumor, so our patient
was operated urgently. Because of her pregnancy chemotherapy was planned after birth. But one week after delivery patient was died.

EP70
Abnormal aldosterone/renin ratio is common in patients of African compared to European origin, is associated with hypokalaemia, and left ventricular hypertrophy, but is rarely associated with abnormal adrenal imaging characteristics

KS Ahmed, D Bogdanet, S Heshe, G Boran, LA Behan, M Sherlock & J Gibney
Departments of Endocrinology, Cardiology and Chemical Pathology, The Adelaide and Meath Hospital, Incorporating the National Children’s Hospital, Tallaght, Dublin 24, Dublin, Ireland.

Adrenal mineralocorticoid biochemistry differs between people of African and European ancestry. The aldosterone/renin ratio (ARR) is the initial screening test for primary hyperaldosteronism (PHA), but little data exists regarding ethnic variations in this.

Following clinical observation of a high prevalence of abnormal ARR in patients of African origin, we retrospectively reviewed all ARR measurements in a single center over 10 years. Rates of hypokalaemia and intraventricular septal thickness (IVS, by echocardiography) were studied as end-points of PHA, and adrenal imaging was reviewed. Data were analysed using Student’s t-test, χ-square test and Mann–Whitney–Wilcoxon test as appropriate.

ARR was available in 1,473 patients, and abnormal in 374 (25.4%). Abnormal ARR occurred in 305/1473 (20.7%) of European and 69/124 (55.6%) of African patients (P < 0.001). Among those with abnormal ARR, hypokalaemia (< 3.5 mmol/L) was documented on at least one occasion in 171/305 (56.1%) European and 43/69 (62.3%) African patients. Median (range) IVS was 1.57(0.78–2.80) cm in African-origin and 1.2 (0.69–2.18) cm in European-origin patients (P < 0.002).

In summary, ARR was abnormal in 55.6% of African-origin patients screened at first presentation and cardiac hypertrophy was more marked in African-origin patients. These findings have implications for the use of current screening guidelines for ARR in African-origin patients and also for the mechanistic role of aldosterone in hypertensive complications in African-origin patients.

Neutrophil-lymphocyte and platelet-lymphocyte ratios as biomarkers in distinguishing adrenocortical adenomas and carcinomas

Mirsala Solak1, Ivana Kraljevic1, Marko Kastelan1, Luka Kakarigi1, Tina Dusek1, Tanja Skoric Polovina1, Annemarie Balasko1, Nikola Knezevic2 & Darko Kastelan1
1Department of Endocrinology, University Hospital Center Zagreb, Zagreb, Croatia; 2Department of Urology, University Hospital Center Zagreb, Zagreb, Croatia.

The role of systemic inflammation in promoting tumor progression has been a topic of increasing interest. Neutrophil-lymphocyte ratio (NLR) > 5 and platelet-lymphocyte ratio (PLR) > 190 used as indicators of inflammation have been reported to have prognostic value in numerous solid tumors. The aim of this retrospective study was to investigate NLR and PLR as biomarkers in distinguishing between adrenocortical adenomas and adrenocortical carcinomas (ACC).

Nineteen patients with ACC (mean age 45 years, range 24–75; eight male, 11 female) and 22 patients with adrenal adenomas (mean age 47 years, range 28–71; six male, 16 female) were enrolled in the study. In the ACC group, only one patient presented with functional tumor (excess estradiol), whereas all the others were discovered incidentally. Eleven out of 19 patients with ACC were operated laparoscopically, while the open approach was used in eight of them. In the adenoma group, the first presentation of the disease was hyperandrogenemia in one patient, and in the rest of the group, adenoma was discovered incidentally. Open surgical approach was used in one patient with adenoma and the others were operated laparoscopically.

The mean size of adenoma was 5.8 cm while the mean ACC size was 9 cm (P < 0.05). In the ACC group, NLR > 5 was found in 26.3% (5/19) patients which was higher compared to 9% (2/22) of the patients with NLR > 5 in the adenoma group. PLR > 190 was found in 36.8% (7/19) of ACC patients compared to 18.2% (4/22) in the adenoma group. Mean NLRs in the ACC and in the adenoma group were 3.6 and 3.1, respectively (P = 0.886) and mean PLRs were 219.1 and 143.3, respectively (P = 0.026). Our results indicate that in addition to tumor size, PLR might potentially serve as biomarker of malignant tumor behavior.

Adrenal involvement of Non-Hodgkin’s lymphoma: a case report

Ozen Oz Gul, Soner Cander, Erdunc Erturk & Canan Esery
Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Introduction
The involvement of certain organs such as the adrenal gland is rare in non-Hodgkin’s lymphoma (NHL). Although lymphomas can involve virtually all extranodal organs, different organs show different frequency of involvement. Adrenal gland involvement is usually bilateral. We report that a rare case of unilateral adrenal involvement of diffuse large B-cell lymphoma presenting with abdominal pain.

Case
A 64-year-old man presented with abdominal pain, weakness, weight loss. Abdominal computed tomography (CT) revealed 59×53 mm right adrenal mass, 40×25 mm paraaortic lymphadenopathy, multiple solid mass lesions in the spleen and malignant infiltrating mass lesions in the perirenal vascular structures. Surgical lymph node biopsy demonstrated a diffuse large B cell lymphoma. The pathology specimens showed neoplastic infiltration of pleomorphic lymphoid cells with scanty cytoplasm, irregular nuclear contour, large nuclei, with one to three peripherally positioned nucleoli. He was treated with rituximab, cyclophosphamide, doxorubicin and vincristine (R-CHOP). The patient tolerated treatment well without significant side effects. After the six courses chemotherapy, the patient’s systemic symptoms were improved.

Conclusion
Extranodal organ involvement is more common in non-Hodgkin’s lymphoma than in Hodgkin’s lymphoma. Systemic chemotherapy has been regarded as the best therapeutic approach for NHL involving rare extranodal sites. Adrenal involvement of systemic lymphoma should be considered when evaluated the adrenal masses.

Challenges in differential diagnosis of adrenal incidentaloma or clinical case of multiple myeloma

Natalia Volkova1, Maria Porkheyeva1, Ilya Davidenko1, Kit Oleg2 & Dimitriadi Sergey3
1Rostov State Medical University, Rostov On Don, Russia; 2Rostov Research Institute of Oncology, Rostov On Don, Russia.

Adrenal incidentaloma (AI) in patients with cancer poses diagnostic challenge for doctors. We present clinical case of generalised metastatic bone diseases and adrenal mass.

Male 59 years old asked the second opinion about suspected adrenal cancer. There were excluded adrenal cancer metastasis affect liver and lung first, which were absent in this case, lack of rapid growth of adrenal mass, the suspected diagnosis of adrenal cancer was hardly probable. The suggestion for adrenal
biopsy was refused because of hematologic disturbances and potential hemorrhage. Also there was made an offer to perform the bone lesion biopsy, which is easier and safer to perform. The results were consistent with multiple myeloma. Patient was seen by hematologist, the appropriate treatment assigned. The interesting fact was that the hematologic, bony and urinary signs, which are typical for myeloma, were absent. Unfortunately, patient died after second course of chemotherapy.

This case illustrates as diagnostic as administrative issues. First, the urologist did not follow the diagnostic protocol for adrenal incidentalomas, which would have been fatal. Secondly, the management of AI in cancer or suspected cancer patients should be absolutely multidisciplinary. Thirdly, atypical signs of the disease requires doctors to be more educated in adjacent specialties.

Iatrogenic Cushing syndrome and suprarenal secondary insufficiency due to interaction between fluticasone and ritonavir

Suarez Gutierrez Lorena1, Veiguela Blanco Brenda2, Dieguez Felechosa Lorena2, Manjon Miguel Laura1, Riestra Gonzalez Maria1, Antuña García Nuria1, Diaz Fernandez Maria Jesus2 & Casal Alvarez Florentino1

1Hospital Universitario Central De Asturias, Oviedo, Spain; 2Hospital De Cabañas, Gijon, Spain.

Introduction

The interaction between corticosteroids and protease inhibitors (Pis) is a clearly described drug interaction.

Case report

A 44-year-old woman diagnosed with HIV category B3 diagnosed in 1989; severe lipodystrophy. In addition , HCV genotype IA. Bronchial asthma since 2000. Treatment with fluticasone 1 inh/24 h, salbutamol on demand, darunavir 800 mg/day and ritonavir 100 mg/day. He had known lipodystrophy since 2001 and the abdominal perimeter was monitored, aiming to increase it. Likewise, it presented progressive proximal weakness in lower limbs, with increased hair, hair fragility and alopecia reason why it is referred to Endocrinology. Moderate hirsutism, muscular atrophy and in the analytical study: normal FSH and LH are.

Discussion

Fluticasone is a synthetic steroid that is cleared by the cytochrome P450 CYP3A4 enzyme, which is inhibited or potentiated by a multitude of drugs, including ritonavir. As it is not metabolized, an increase in circulating levels leads to a decrease in the secretion of ACTH and therefore a suppression of the adrenal gland with insufficiency of the same and cushing syndrome.

The options are the substitution of Fluticasone by a non-substrate of CYP3A4 such as beclomethasone and the substitution of ritonavir for another antiretroviral.

Most cases resolve in about 9–12 months.

Body composition in women with Cushing’s syndrome of different etiology

Dusan Ilic, Djuro Macut, Ivana Bozic Antic, Bojana Popovic, Tamara Bogavac, Tatjana Isailovic, Valentina Elezovic, Sanja Ognjanovic & Svetozar Damjanovic

Clinic of Endocrinology, Diabetes and Metabolic Diseases, Belgrade, Serbia.

Introduction

Cortisol has important roles in the regulation of body composition and hypercortisolism have major impact on body fat distribution. The aim of this study was to analyze differences in adipose tissue distribution in women with Cushing’s disease and Cushing’s syndrome due to adrenal adenoma.

Method

We evaluated 12 women with Cushing’s syndrome, six with ACTH secreting pituitary adenomas (Group A) and six with adrenal adenomas (Group B). In all subjects BMI was calculated and body composition assessed by dual energy X-ray absorptiometry. Basal values of serum cortisol, ACTH and DHEA-S were determined at admission to the hospital.

Results

Mean age was comparable between Group A and Group B (44.5+/−14.7 years vs. 52.7+/−5.6 years, P=0.23) while BMI was significantly higher in Group B (32.7+/−5.5 kg/m² vs. 25.6+/−4.3 kg/m², P=0.034). Group B had significantly higher percent of total body fat (45.4+/−4.3% vs. 34.5+/−8.4%, P=0.021) but borderline difference in trunk fat percentage (Group B 44.3+/−6.8% vs. Group A 32.6+/−10.7%, P=0.055). Main difference in adipose tissue percentage was found on arms and legs, which was higher in Group B (arms 53.6+/−8.8% vs. 38.5+/−11.9%, P=0.077; legs 47.6+/−4.4%, vs. 39.0+/−5.9%, P=0.022).

There was no significant difference in lean body mass or bone mineral density between these two groups. As expected, ACTH was significantly higher in group A (74.3+/−16.4 ng/l vs. 14.7+/−7.6 ng/l, P=0.040), but with no significant differences in morning cortisol concentrations (Group A 664.2+/−210.4 nmol/l vs. Group B 432.8+/−146 nmol/l, P=0.060), midnight cortisol concentrations (Group A 461.3+/−236.2 nmol/l vs. Group B 330.3+/−206.3 nmol/l, P=0.410) or DHEA-S concentrations (4.9+/−5.4 nmol/l vs. 2.8+/−3.8 nmol/l, P=0.564) between groups.

Conclusion

Our group of women with Cushing’s syndrome due to adrenal adenoma had higher BMI and increased total fat adiposity. It was not determined yet if the origin of hypercortisolism, or derangements in other related hormones or metabolic pathways, could possibly influence body composition in those patients.

Clinical course of patients with adrenal incidentaloma: retrospective analysis of a single center

Ana Carolina Ruiz Serrano1, Ana Megia Colet1,2, Silvia Náf Cortes1,2, Joan Vendrell Ortega1,2, Inmaculada Simon Muela1,2, Esther Solano Fraile1 & Theodora Michalopoulou Alevras1

1Endocrinology and Nutrition Service University Hospital of Tarragona Joan XXIII, Tarragona, Spain; 2CIBERDEM, Tarragona, Spain.

In the adrenal incidentaloma (AI) it is fundamental to determine functionality and benignity. The aim of this study was to evaluate the clinical, radiological and hormonal evolution of AI and compare the frequency of autonomous cortisol secretion (ACS) between American and European Guidelines.

Methods

Retrospective evaluation of patients with AI referred to our service in the last 5 years.

Results

140 patients were included, 50.9% were men. At diagnostic, the media of age was 44.7 years and 80% had an adenoma-like appearance (49.3% left). Hormonal evaluation was performed in all patients.

Conclusions

The AI’s are predominantly small, benign, nonfunctioning; stable in time, tumor size and hormonal production. The use of the diagnostic criteria for ASC according to European guidelines shows an increase in the frequency of PACS/ACS, therefore, ACTH determination should be considered in the diagnosis.

DOI: 10.1530/endoabs.49.EP76
Adrenocortical carcinoma (ACC) is a rare malignancy, accounting for 0.02% of all annual cancer. The majority of these tumors are benign, non-functioning adenomas that are incidentally discovered on abdominal image studies. Others are functional adenomas secreting cortisol, aldosterone, or less commonly androgens or estrogens. Pure androgen-secreting adrenal tumors are very rare.

Case report
A 34-year-old female patient presented with pain in the left upper abdomen. A multiphasic CT scan abdomen was done, which revealed large adrenal mass measuring $18 \times 14 \times 14$ mm in dimension with central hemorragie. Patient gave history of amenorrhea since 6 months associated with increased hair growth of chest, lower abdomen, and face. Moreover the patient declare recent weight loss (11 kg in 2 months) with asthma, anorexia, and melanoderma.

On examination, heart rate was 84/min, blood pressure 120/70 mm of Hg. Hirsutism was evaluated based on Ferriman-Gallway score (result = 13). Biochemical screening showed a total testosterone $= 8$ ng/ml (0.06–0.82), DHEA-sulfate $= 3.27$ mg/ml (0.4–2.17 mg/ml), 17-hydroxyprogesterone $> 20$ ng/ml (0.1–0.8 ng/ml), LH $= 0.83$ mU/l and FSH $= 0.1$ mU/l. The diagnosis of Addison’s disease was confirmed by basal serum ACTH $= 125.82$ ng/l and serum cortisol=135 $\mu$g/l after ACTH test; serum aldosterone and 24-h urinary VMA were normal. A diagnosis of androgen-secreting adrenocortical cancer with adrenal insufficiency was made.

Patient underwent exploratory laparotomy with excision of large adrenal tumor without any complication. The histopathological examination described a mass $21 \times 18 \times 12$ mm with microscopic features of tumor cells sharing mild nuclear atypia and rare mitotic figures: histological and immunohistochemical aspect of adrenocortical carcinoma (Weiss score $= 3$, Ki67 = 10).

On follow-up after 6 months, patient was comfortable, and no longer had hirsutism or amenorrhea. Total testosterone was 0.03 ng/ml (0.06–0.82), DHEA-sulfate was 0.174 $\mu$g/ml (0.4–2.17 $\mu$g/dl) and CT scan abdomen was normal.

In everyday PHA diagnostics practice there is still lack of “game changer” bringing the final conclusion for diagnostic and profilactic strategies for the whole hypertensive population.

DOI: 10.1530/endoabs.49.EP77
After adjustment for BMI, waist, and presence of BAIs, SH were associated with adrenal mass size (odds ratio OR=1.101, 95% CI 1.041–1.166, P=0.001) and age (OR=1.086, 95% CI 1.021–1.155, P=0.009). LS-BMD and total-BMD were lower in BAIs than in UAI patients (0.94±0.13 vs 0.86±0.17, P=0.015, and 1.08±0.18 vs 1.02±0.14, P=0.029). There were no differences in FN-BMD. Patients with BAIs had an increased frequency of osteoporosis (46.4% vs 23.5%, respectively, P=0.036). The presence of osteoporosis was associated with SH (OR=5.775, 95% CI 1.423–23.426, P=0.014) and lower BMI (OR=1.226, 95% CI 1.071–1.405, P=0.003), after adjusting for age, menopause and vitamin-D.

This study suggests significantly higher prevalence of SH in patients with BAIs than in patients with UAI.s Tumor mass could be of importance for the amount of autonomous cortisol production. The prevalence of osteoporosis was higher in patients with BAIs due to SH.

EP81

Long term follow up of patients with adrenal incidentaloma and ‘autonomous cortisol secretion’
Ivana Kraljevic1, Mirsala Solak1, Tina Dusak1,2, Tanja Skoric Polovina1, Annemarie Balasko & Darko Kasteljan1,2
1University Hospital Center Zagreb, Zagreb, Croatia; 2Zagreb University School of Medicine, Zagreb, Croatia.

The aim of this study was to compare the long-term co-morbidities and biochemical data between patients with adrenal incidentaloma and ‘autonomous cortisol secretion’ who were treated surgically and conservatively.

Methods
The research of the database of the patients with adrenal incidentaloma diagnosed between 2007 and 2014 was performed. Among them, 43 patients with ‘autonomous cortisol secretion’ were identified and invited for a follow-up visit. Diagnostic criteria for ‘autonomous cortisol secretion’ were: cortisol >83 nmol/l after 1 mg dexamethasone suppression test plus one additional criteria (suppressed ACTH secretion or elevated urinary free cortisol). At follow-up visit the anthropometric as well as biochemical data were collected (blood glucose, lipid panel test, HOMA index, cortisol after 1 mg dexamethasone, urinary free cortisol, and ACTH). All patients were evaluated for hypertension, dyslipidemia, osteoporosis and diabetes mellitus/impaired glucose tolerance.

Results
Of the 43 invited patients, 26 patients performed follow up visit (4 males). Among them, 17 patients were treated surgically and 9 were treated conservatively. Median follow-up was 6 years (range 2–16), median age at follow-up was 62 years (range 41–76). There was no difference in BMI at baseline and at follow up in both groups. In the group of surgically treated patients, during follow-up period one patient was diagnosed with arterial hypertension, 4 with hyperlipidemia, and one with diabetes mellitus. Nevertheless, nine out of 12 patients with hypertension in the surgical group reported improvement/disappearance of arterial hypertension at the follow-up visit. Among conservatively treated patients, six out of nine patients had no difference in co-morbidities, one was newly diagnosed with osteoporosis, one with arterial hypertension and one with renal insufficiency. Conclusion: Patient who underwent surgery for ‘autonomous cortisol secretion’ experienced improvement in the regulation of hypertension after medium follow-up of 6 years. No other significant differences were found in the prevalence of co-morbidities between conservatively versus surgically treated patients.

Adrenocortical carcinoma - casuistic analysis
Catia Ribeiro, Joao Lobo, Ana Mesquita, Pedro C Martins, Mariana Peyroteo, Maria Joao Matos, Pedro Antunes, Cristina Sanches, Augusto Moreira & Joaquim Abreu de Sousa
IPO, Porto, Portugal.

Introduction
Adrenocortical carcinomas are rare neoplasms with an incidence of 0.7 to 1.5 million/year. Diagnosis often requires a multidisciplinary approach. When the disease is confined to the adrenal gland, absolute criteria defining malignancy, do not exist, however a score of Weiss > or = a 3 is considered diagnosis. The prognosis is usually reserved and conventional chemotherapy is not curative.

Material and Methods
Retrospective analysis of the clinical and demographic characteristics, review of the anatomicopathological and therapeutic criteria of patients with adrenocortical carcinoma treated at our Institution between 1999 and 2015.

Results
Twenty-two patients with a mean age of 56 years were evaluated, 50% of cases were male. The majority of patients (63.6%) were symptomatic and pain was the most frequent symptom (57.1%). All patients underwent surgical treatment. Multiorgan resection was performed in 5 cases (22.6%). The surgery was R0 in 72.7%. After histological examination, 72.7% presented Weiss score > 2. Adjuvant therapy was performed in 5 patients (22.6%). Considering the revision of the Weiss score, TNM staging and margins status, 50% of the patients would have indication for adjuvant treatments. In this series, the relapse rate (local or distance) was 38.1% (8 cases) and the overall survival at 5 years was 62%; which compares favorably with that described in the literature.

Conclusions
The rarity of this pathology makes diagnosis and therapeutic orientation difficult. A rigorous and standardized histological evaluation is imperative to ensure the most appropriate adjuvant treatment. The referral of this patients to centers of expertise is essential, with the hope that new target therapies will lead to better results.

A near miss on blaming the heart: a rare case of Adrenocortical carcinoma with thrombus extension into right atrium and Cushing syndrome
Hadeil Morsi1, Mohamed Eisa1, Lynsey Goodwin2, Peter Flegg2 & Myint Aye2
1North West Health Education England, Manchester, UK; 2Blackpool Victoria Hospital Foundation Trust, Blackpool, UK; 3Wellstar Atlanta Medical Center, Atlanta, GA, USA.

A 39 year old female patient presented with one week history of Shortness of breathing. Over the last four months she noted bilateral leg swelling, which failed to improve on diuretic. Examination revealed no further evidence of fluid overload or heart failure. An element of right heart strain rather than failure was raised on cardiologists review. Subsequently, an echo showed a friable mass extending form inferior vena cava to right atrium into proximal left ventricle. The nature of which was revealed to be a tumor thrombus extending from the upper pole of right kidney with resultant pulmonary emboli. To this end, an impression of invasive renal carcinoma was made. Until endocrinology review for erratic hyperglycaemia, when the patient reported irritability, 6 weeks amenorrhea, change in weight distribution and facial hirsutism in addition to abdominal strain on examination. Hence, the diagnosis shifted to Adrenocortical carcinoma with Cushing. Tertiary center was consulted. In the meantime, Mitotane was started gradually, alongside Hydrocortison. It was a difficult time for the patient who preferred palliative support at home. Unfortunately, few days after discharge she was readmitted with hypoglycaemia, metabolic acidosis and liver impairment. She was treated as Addison crises, though cortisol levels came normal later. Liver involvement was not confirmed to be Mitotane related toxicity or ischemic injury with progression of malignancy.

Unfortunately, she did not survive his well-known aggressive tumor. ACC are rare tumors and presentation with such vascular invasion is an additional rarity. As clinician on medical take, there is tendency to overcall heart failure. Having high index of suspicion for patients with Cushing syndrome is central, although not all tumors are functional. The definitive management of ACC is surgical which is not always feasible, particularly with such vascular extension. Wider scale clinical studies pave the management of ACC and optimize Mitotane therapy.

Congenital Adrenal Hyperplasia due to 11β-Hydroxylase Deficiency: clinical and molecular studies of two novel families with variable phenotypes
Alessandra Pfiztlicker, Luciana Valadares, Selma Sousa, Sarah Cardoso, Olivia Morais, Renata Santarem & Adriana Lofrano-Pinto
University of Brasilia, Molecular Pharmacology Lab, Brasilia DF, Brazil.

11β-hydroxylase deficiency is the second most frequent cause of congenital adrenal hyperplasia (CAH), corresponding to approximately 5% of cases, and caused by inactivating mutations in the CYP11B1 gene. We aimed to describe four new cases from two different families with a clinical diagnosis of 11β-hydroxylase deficiency. Family 1: Two siblings born from consanguineous parents. A 31-year-old (yo) woman presented at 5 yo with genital ambiguity (Prader II), high blood pressure (HBP) and precocious pubarche (PP). She lost follow and returned after 3 full term normal pregnancies while using prednisone. 4 years after last gestation, she remained normotensive without any treatment. Her 24 yo brother presented at age 7 yo with PP, hypokalemia and HBP, when glucocorticoids and anti-hypertensives were started. He had low treatment adherence and evolved with persistent hypertension and left ventricular hypertrophy. Family 2: A 2.9 yo boy presented with PP and high BP, managed with hydrocortisone and anti-hypertensives. His sister presented at 21 days of life with genital ambiguity and salt wasting, managed with hydrocortisone and oral sodium. A detailed steroid profile was performed in all subjects, which confirmed the diagnosis. The CYP11B1 coding region of the patients’ and their parents’ was automatically sequenced. In the two siblings from Family 1, a homozygous splice site point mutation, IVS4: −1G>A, was identified in exon 4 (g.3132G>A). In Family 2, both siblings harbored a nonsense mutation in exon 6 (c.1066C>T), which generates a truncated protein (p.Q356X). The mutations presented herein were associated with a highly variable phenotype, from a mildly virilizing phenotype to a high degree of virilization with hypertension and with salt wasting, which is unexpected. Further studies of variants in other genes associated with hypertension, in compensatory pathways of steroid synthesis and metabolism, or the verification of chimeric CYP11B1 genes are needed to clarify the phenotypic heterogeneity.

‘Record-breaking hyponatraemia’ with Addison’s disease
Irfan Khan & Elizabeth Cheyne
Southmead Hospital, Bristol, UK.

Addisons disease is a rare but potentially life threatening endocrine disorder. It is well known for disguising as a variety of presentations before diagnosis. Here we present a case report of Addison’s disease presenting with very severe hyponatraemia. A 35 year old lady was admitted with lethargy, low mood, weight loss and feeling generally unwell for the last 3 months. Six weeks prior to her admission, her GP arranged some routine investigations including U&E which were normal with a Na of 137. He later prescribed her Mirtazapine for her low mood and anxiety which she took for 4 days. This made her feel more unwell and triggered the hospital admission. She looked tanned but there was no buccal or palmar pitting. She was anxious and depressed. Her 24 yo brother presented at age 7 yo with PP, hypokalemia and HBP, when glucocorticoids and anti-hypertensives were started. He had low treatment adherence and evolved with persistent hypertension and left ventricular hypertrophy. Her 24 yo brother presented at age 7 yo with PP, hypokalemia and HBP, when glucocorticoids and anti-hypertensives were started. He had low treatment adherence and evolved with persistent hypertension and left ventricular hypertrophy. On physical examination, he had a body weight of 53 kg, a body mass index of 20, a blood pressure of 114/70 mm Hg and a heart rate of 80 b/min. On auscultation, a Grade 2/6 systolic ejection murmur was heard at the left lower sternal edge. His abdomen was soft and non-tender. The peripheral pulses were normal. A detailed steroid profile was performed in all subjects, which confirmed the diagnosis. The CYP11B1 coding region of the patients’ and their parents’ was automatically sequenced. In the two siblings from Family 1, a homozygous splice site point mutation, IVS4: −1G>A, was identified in exon 4 (g.3132G>A). In Family 2, both siblings harbored a nonsense mutation in exon 6 (c.1066C>T), which generates a truncated protein (p.Q356X). The mutations presented herein were associated with a highly variable phenotype, from a mildly virilizing phenotype to a high degree of virilization with hypertension and with salt wasting, which is unexpected. Further studies of variants in other genes associated with hypertension, in compensatory pathways of steroid synthesis and metabolism, or the verification of chimeric CYP11B1 genes are needed to clarify the phenotypic heterogeneity.

24 hour ambulatory blood pressure levels according to adrenal adenoma size
Alp Atasoy1, Evrim Cakir2, Suleyman Ahabb1, Derya Kayas1, Esra Ataoglu1 & Mustafa Yenigun1
1Internal Medicine Department, Haseki Training and Research Hospital, Istanbul, Turkey; 2Endocrinology and Metabolic Diseases Department, Haseki Training and Research Hospital, Istanbul, Turkey.

Aim
The etiology and underlying pathology of non-functional adrenal adenoma has not been clearly defined, yet. Blood pressure levels according to adrenal adenoma size has not been evaluated, yet. Therefore, we evaluated 24 hour ambulatory blood pressure levels in patients with non functional adrenal adenoma.

Materials & Methods
We studied thirty newly diagnosed adrenal adenoma patients in a tertiary health-care center. They grouped in two categories according to adenoma size. Cut-off size was taken 23 mm. 24 hour ambulatory blood pressure were evaluated in all participants. Delta blood pressure was found by calculating the difference between maximum and minimum blood pressure values.

Results
There were 17 patients with lower adenomas size, which was smaller than 23 mm, the remaining 13 patient’s adenomas size was equal or higher than 23 mm. Patients with higher adenomas size had statistically higher systolic delta levels compared to lower size group (70.84 ± 34.9 to 51.29 ± 18.9, P=0.004). Additionally; the maximum systolic (165.6 ± 28.7 to 152.0 ± 23.1) and maximum diastolic blood pressure (115.1 ± 37.8 to 100.2 ± 14.9) were higher and also minimum systolic (94.76 ± 11.05 to 100.70 ± 18.60) and minimum diastolic blood pressure (60.69 ± 9.01 to 62.41 ± 12.62) were lower in this group. However; the differences did not reach statistically significance.

Conclusion
Delta systolic blood pressure has been found to be higher in adenomas size group. Further studies are necessary to better clarify the association between blood pressure and non functional adrenal adenoma.

Endocrine Abstracts (2017) Vol 49
Conclusion
Phaeochromocytoma and Graves' disease are known by their similar clinical features making their differential diagnosis difficult. In our case, adrenal incidentaloma evaluation had revealed the phaeochromocytoma. Otherwise, a meticulous physical examination and detailed laboratory investigations are needed in order to make a precise diagnosis.

Phaeochromocytoma in neurofibromatosis type 1
Agustina Pia Marengò1, Paula García-Sanchez1, Fernando Guerrero1, Inmaculada Peiró1, Óliver Santacruz1, Andrea Ortiz1, Juan José Diez1, Pedro Iglesias1 & Carles Villabona1
1Hospital Universitari Bellvitge, L'Hospitalet de Llobregat, Barcelona, Spain; 2Institut Catala` D'Oncologia, L'Hospitalat de Llobregat, Barcelona, Spain; 3Hospital Ramón y Cajal, Madrid, Spain.

Background
Individuals with neurofibromatosis type-1 (NF1) carry an increased risk of phaeochromocytoma (PHEO). Detection strategy is unknown but most experts recommend screening if hypertension develops.

Objective
Report the characteristics of PHEO in patients with NF1 (NF1 group) and compare them with non-NF1-associated PHEO (non-NF1 group).

Methods

Results
Of 78 patients undergoing PHEO resection, 5 (6.4%) had NF1. NF1 patients were younger than those with non-NF1 (mean age 41.8 vs 52.5 yr, P = 0.068). Males comprised 60% versus 40% of the NF1 group and non-NF1 group, respectively. PHEO was incidentally diagnosed in 3 of 5 (60%) from NF1 group and only in 20 of 73 (39.7%) from non-NF1 group (P = 0.395). Remaining NF1 cases were diagnosed by screening (hypertension, n = 1) and compatible adrenergic clinic (n = 1). Hypertension was present in 2 (40%) NF1 patients and in 33 (45%) non-NF1 patients. Urinary and/or plasma catecholamines were elevated in all NF1 patients and in 55 (88%) of non-NF1 group. There was no significantly difference (P = 0.207) in tumor size between both groups of patients (median 4.6 cm vs 5.6 cm in NF1 and non-NF1 patients, respectively).

Conclusion
In our series, age at diagnosis and gender were similar in NF1 and non-NF1 PHEO patients. NF1-associated PHEO is diagnosed incidentally in more than half of the patients. Although all NF1-PHEO tumors were functioning, only two of five patients had hypertension. It is necessary to keep in mind the possibility of developing PHEO in NF1 patients even in those non-hypertensive patients. On the contrary, in all patients with PHEO is advisable to search clinical criteria used to diagnose NF1, and thus confirming an often-delayed diagnosis.

Should all patients with neurofibromatosis type 1 undergo biochemical screening for Phaeochromocytoma?
Ahmed Al-Shareef1, Sueh Asfarih1, Ramesh Vanka & Satyajit Nag
Department of Diabetes and Endocrinology, The James Cook University Hospital, Middlesbrough, UK.

Phaeochromocytomas (PHEO) are catecholamine secreting tumours which can occur sporadically or as part of other hereditary/familial syndromes including Neurofibromatosis 1 (NF-1). Unlike the case with other genetic syndromes, the current neurofibromatosis guidelines do not recommend a routine hormonal screening strategy for PHEO in the absence of hypertension or other symptoms. In this paper we describe 2 asymptomatic and normotensive patients with NF-1 where secretory PHEO were incidentally diagnosed. The first patient is 61-year old female with a history of NF-1 who received a diagnosis of takotsubo cardiomyopathy and was found to have an incidental adrenal mass of 2.4 cm where subsequent investigations confirmed a diagnosis of secretory PHEO. The second patient is a 44-year-old female with also a background of NF-1 who was found to have a 7.8 × 7.0 × 5.8 cm adrenal adenoma where further work up confirmed PHEO. Both patients underwent adrenalectomy and the histology confirmed the diagnosis and their catecholamines level normalised eventually.

Undiagnosed PHEO will put patients at unnecessary risk from having an adrenergic crisis and even death. These cases highlight the importance of considering routine biochemical screening for a catecholamine secreting tumour in all patients with NF-1 to prevent the development of catastrophic events in the future.

Phaeochromocytoma in pregnancy
Belgin Efe1,2,3, Goknur Yorulmaz1,2, Sevil Alagunez1,2, Funda Canaz1,3 & Bartu Badak1,4
1Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; 2Division of Endocrinology, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; 3Pathology Department, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; 4Department of General Surgery, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey.

Introduction
Phaeochromocytoma is a tumor originating from the chromaffin cells. These tumors secrete catecholamines which act on target organs and cause hypertensive crises. They are rare during pregnancy, and a differential diagnosis must be carried out mainly with pregnancy-induced hypertension.

Case
A 27-year-old patient in week 17 of pregnancy admitted to our clinic with hypertension and 45 × 55 mm heterogenous nodular lesion in left surrental. The hospitalized patient had tachycardia and hypertensive episodes despite the treatment. Urinary catecholamine and metanephrines were measured. The patient was diagnosed as undiagnosed pheochromocytoma. Magnetic resonance imaging identified a adrenal adenoma. After subsequent pharmacological treatment with alpha and beta blockers, a left adrenalecctomy was performed laparoscopically. The histopathological report indicates phaeochromocytoma (Phaeochromocytoma of the Adrenal gland Scaled Score: 6) and tumor weighing 70 g and measuring 6.5 × 5.5 × 5.5 cm. After the surgery urinary catecholamine and metanephrine collections was normal. Postoperatively the patient with 24 weeks gestation had no antihypertensive need.

Conclusion
Phaeochromocytoma in pregnancy can cause the death of both the fetus and the mother. This issue should be remembered in hypertensive pregnancies. The approach to the biochemical diagnosis is the same as for the nonpregnant patient. MRI (without gadolinium enhancement) is the preferred imaging modality, and 123I-MIBG is contraindicated. Adrenal phaeochromocytomas should be removed promptly if diagnosed during the first or second trimester of pregnancy. In our case, its recognized with new onset hypertension and adrenal tumor was removed in the 2nd trimester.

The role of p27 in phaeochromocytoma development
Andrea Kügler1, Enzo Lalli2, Juan Hiegared Almaraz2, Steffen Sass2 & Natalia Pellegata1
1Helmholtzzentrum München, Institute of Diabetes and Cancer, Munich, Germany; 2University Nice, Institute of Molecular and Cellular Pharmacology, Valbonne, France; 3Helmholtzzentrum München, Institute of Computational Biology, Munich, Germany.

Defective p27 function predisposes mice and rats to phaeochromocytomas (PCC), and reduction of p27 repression is a feature of human PCCs. These findings suggest that p27 plays a role in PCC tumorigenesis. Recently, it was reported that p27 indirectly regulates gene transcription by associating with transcription factors (TF) and inhibiting gene transcription at specific promoters. We hypothesized that defective p27 promotes tumor formation in adrenomedulary cells because of aberrant gene expression. To address this hypothesis, we used normal adrenomedulary tissue from wild-type rats or human individuals and performed chromatin immunoprecipitation-sequencing (ChIP-Seq). DNA sequences bound by p27-containing protein complexes were immunoprecipitated from rat and human tissue extracts using an anti-p27 antibody coupled with magnetic beads. DNA sequences were identified by quantitative next generation sequencing (NGS).

Endocrine Abstracts (2017) Vol 49
We successfully pulled down DNA sequences with the anti-p27 antibody, indicating that p27, together with unknown transcription factors or co-factors, binds the chromatin in adrenomedullary cells. DNA sequences bound by the p27-containing complexes were mapped on the rat/human genome and analyzed using both Genomatix and MEME suite software to identify the most enriched TFs and TF binding sites (Tcf19, Tcf4, Znf423, Runx1, Ascl2, Lhx4). The binding between p27 and these selected TFs is being verified by immunoprecipitation. The association of p27-containing complexes to specific promoters of these identified genes is currently being validated. The p27-dependent regulation of the expression of selected target genes will be verified by modulating p27 levels in PCC cell lines. The significance of the p27-dependent gene expression will also be obtained by analyzing the expression of these target genes in normal adrenal medulla and PCC of MENX-affected rats (with loss of functional p27). In conclusion, the observation that p27 may regulate gene transcription will give insight into the pathomechanisms associated with reduced p27 function specifically in adrenomedullary cells.

Role of microenvironment on metabolic control of murine pheochromocytoma SDHB silenced cells
Vanessa D’Antongiovanni1, Susan Richter1,4, Serena Martinelli2, Letizia Canu2, Tonino Ercolino1, Graeme Eisenhofer3,4, Karel Pacak5, Elena Rapizzi2 & Massimo Mannelli1
1Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; 2Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; 3Institute of Clinical Chemistry & Laboratory Medicine, Dresden, Germany; 4Department of Medicine III, Technische Universität Dresden, Dresden, Germany; 5Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, USA.

Pheochromocytomas (PHEOs) and paragangliomas (PGLs) are rare neuroendocrine tumors. About 30–40% of Pheo/PGLs are due to a germ-line mutation in one of the 13 main susceptibility genes which include the genes encoding the four subunits of the succinate dehydrogenase (SDH - mitochondrial complex II). In PHEO/PGL due to SDHB mutations up to 80% of affected patients develop metastatic disease and no successful cure is at present available. Tumor microenvironment plays a pivotal role in modifying the metabolism and the functional characteristics of tumor cells, becoming a potential therapeutic target. To obtain an experimental model resembling the in vivo conditions of the SDHB-mutated PHEO, we evaluated the effects of SDHB silencing and microenvironment on metabolism in the mouse tumor tissue-derived cell line (MTT), cultured alone or in association with mouse primary fibroblasts (here representing the tumor microenvironment). SDHB silenced cells showed a significant increase of both glucose and lactate uptake, and an increase of intracellular lactate compared on monocarboxilase transporter 4 (MCT4), responsible for the transport of lactate both glucose and lactate uptake, and an increase of intracellular lactate compared with the control. This increase was even more evident when SDHB silenced cells was co-cultured with mouse primary fibroblasts. The expression levels of monocarboxilase transporter 4 (MCT4), responsible for the transport of lactate from the intracellular to the extracellular space, was found upregulated in fibroblasts in co-culture with tumor cells. Consequently, in co-cultures, primary fibroblasts showed an increase of extracellular lactate. Surprisingly, SDHB silenced cells in co-culture showed a reduction of ATP levels compared to SDHB cultured alone and control cells in co-cultures. Our data demonstrate that SDHB silencing strongly affects tumor metabolism, and these changes are more evident in co-cultures. The comprehension of the mechanisms driving these changes in tumor metabolism may suggest new therapeutic targets.

Pheochromocytoma: a clinical and pathological study
Eliana Macarron1, Agustina Pia Mariango1, Andrea Ortiz2, Inna Pérez3, Héctor Pian4, Juan José Diez5, Paula García-Sancho6, Carles Villabona6 & Pedro Iglesias1
1Department of Endocrinology, Hospital Universitario Ramón y Cajal, Madrid, Spain; 2Department of Pathology, Hospital Universitario Ramón y Cajal, Madrid, Spain; 3Department of Endocrinology, Hospital de Bellvitge, L’ Hospitalet de Llobregat, Barcelona, Spain.

Objective To assess clinical features, diagnosis, treatment and outcome in patients with pheochromocytoma surgically treated in the past 3 decades in two tertiary referral hospitals. Methods A retrospective study on clinical and pathological characteristics, treatment, and outcome in patients with pheochromocytoma followed up in specialized neuroendocrinology units who underwent surgery in the period 1981–2016 was performed. Results 81 patients (45 women (56%); age 51 ± 15 year (range, 13–76)) were studied. The tumor was sporadic in 68 patients (84%) and familial in 13 patients, more frequently in the context of a MEN type 2 (n = 6) the pheochromocytoma were bilateral. Most of the patients (66%) were symptomatic. The main complaints were the classic triad (27%), and hypertensive crisis (27%). 40% of the pheochromocytoma were incidentally discovered on imaging investigations. 47% of patients were hypertensive at diagnosis. 24-h urinary catecholamines excretion was determined in 80% of patients, being elevated in 75% of cases. Fractionated urinary metanephrines were only determined in 23% of patients, and were elevated in 84%. Abdominal CT was the most used imaging technique (87%, n = 68), followed by 123I-MIBG scintigraphy (54%, n = 42) which detected 88% of those tumors (n = 37). MRI was performed in 50% of the patients, 87% of those tumors were hyperintense in T2. 39% (n = 65) patients had a preoperative alpha-adrenergic blockade. 17 patients (22%) had a complication during surgery, being hypertensive crisis the most common complication (12.5%, n = 10). Median tumor diameter was 5.9 ± 2.8 cm (range, 1.5–13). 15% of pheochromocytomas had vascular invasion, 15% had capsular invasion and 23% presented necrosis. Only 6% presented ganglionar or distant metastasis. 68 patients were followed in our two centers, 55 patients (81%) were cured, 4 of them (6%) had persistent disease and 9 (13%) had recurrence after surgery. Conclusion Pheochromocytoma in our series is generally a large, symptomatic and sporadic tumor. Incidentally discovered pheochromocytoma is common. Abdominal CT is the preferred imaging technique for localization. Surgical complications are common. Despite the high rate of vascular invasion in the histopathological study, ganglionar and distant metastasis are rare. The presence of cases with persistent and recurrent disease after surgery requires a long term follow-up, these tumors.

DOI: 10.1530/endoabs.49.EP94
Introduction
Biochemical testing for Paraganglioma/Phaeochromocytoma (PGL/PHEO) is recommended in patients with classical symptoms, in those harbouring an adrenal incidentaloma and in patients who have a hereditary risk for developing a PGL/PHEO. Measurements of plasma free metanephrines and/or urinary fractionated metanephrines provide a highly sensitive test for diagnosis but false-positive results remain a problem.

Aim
Comparative analysis of plasma and urinary metanephrines results in a group of individuals suspected of having PGL/PHEO.

Subjects and methods
Retrospective analysis of tests performed at a tertiary hospital during the year 2015 (January 1st-December 31th) and correlation with imaging studies and clinical data.

Results
686 measurements of urinary and/or plasma metanephrines, ordered by physicians of different medical specialties, were performed. From the analysis of these results, we identified 124 patients with both measurements: they were 77 women and 47 men with a mean age of 47.3 years (range 6-82). The main reason for testing was therapy-resistant or paroxysmal hypertension (n=68; 54.8%) followed by the presence of an adrenal incidentaloma (n=13,10.4%). Abnormal high values were observed in 56 patients; in 44 (45.2%) only abnormal urine values, in 6 (4.8%) both urine and plasma abnormal values and in 6 (4.8%) only abnormal plasma values. 3/6 patients who presented elevation of urinary and plasma metanephrines had histologically proven disease (2 PHEO, 1 abdominal PGL). Among the patients with normal plasma metanephrines and high urinary metanephrines only one (2.3%) had a bilateral paraganglioma in the context of a MEN2A syndrome. None of the 6 patients with normal urinary metanephrines and increased plasma metanephrines had disease.

Conclusion
In the present series, all patients with a histologic diagnosis of PGL/PHEO had elevated urinary metanephrines regardless, in one case, normal plasma metanephrines. On the other hand, the frequency of increased urinary metanephrines without a positive imaging was very frequent.

EP96
Paraganglioma and Fallot Tetralogy: case report
Ana Filipa Martins1, João Martin Martins1,2 & Sónia do Vale1,2
1Hospital de Santa Maria – CHLN, Lisboa, Portugal; 2Faculdade de Medicina de Lisboa, Lisboa, Portugal.

Introduction
Catecholamine secreting tumors are rare neoplasias. About 15% are para-gangliomas. If untreated, they are almost invariably lethal. Surgery is the only curative therapy.

Case report
A female caucasian patient aged 32 was evaluated in the endocrine department. She had a dramatic medical history: Fallot’s Tetralogy was diagnosed soon after birth due to severe cyanosis, an audible murmur, and poor and irregular pulses. The heart was palpably enlarged and prominent a and v waves were palpable in the jugular veins. There was a loud second heart sound with a grade 3 diastolic murmur at the apex. She had a recent weight loss with a BMI of 16 kg/m2. Examination revealed depressed cardiac indices: tachycardia, bounding pulses, hypotension, angina, and paroxysmal nocturnal dyspnoea. She had a recent history of hospitalization for acute pulmonary oedema due to atrioventricular heart failure. In the endocrine department she presented with a paradoxal increase in clonidine test. The CT scan revealed a solid hypervascular right paramedian retroperitoneal tumor with 49 mm of diameter at its greatest dimension, and a solid hypervascular hyperechoic intracardiac mass with 72 mm in its greater dimension. A magnetic resonance tomography did not detect a possible adrenal tumor.

Results
The medical records of patients admitted for pathologically confirmed paragangliomas against the 2016 guidelines were reviewed. We identified 40 patients with 43 resected pheochromocytomas. The mean age was 47 years with an equal distribution between genders. Twelve cases (30%) had a recent history of hospitalization for acute pulmonary oedema due to atrioventricular heart failure. The mean tumor size was 7 cm (range of 1.5–17.2 cm). Most of the lesions were functional (95%) and preoperative alpha-blockade has been instituted in 93% of the patients. Among them, 85% had a high surgical risk due to the severe comorbidities. A positive outcome was strongly dependent on the multidisciplinary collaboration of different departments.

Objective
To retrospectively evaluate the results of the phaeochromocytoma surgery in our institution assessing the surgical complications, perioperative hemodynamic instability and oncologic outcomes.

Methods
The medical records of patients admitted for pathologically confirmed phaeochromocytoma between 2000 and 2015 were reviewed. Patients with paragangliomas were excluded.

Results
We identified 40 patients with 43 resected phaeochromocytomas. The mean age was 47 years with an equal distribution between genders. Twelve cases (30%) had a syndrome known to have an increased incidence of phaeochromocytoma. The mean tumor size was 7 cm (range of 1.5–17.2 cm). Most of the lesions were functional (95%) and preoperative alpha-blockade has been instituted in 93% of the patients, with 48% having a beta blocker simultaneously. Fourteen cases (30%) underwent a minimal invasive approach. The mean operative time was 150 min and the median of intraoperative blood loss was 150 ml. More than a half of the patients (54%) had a hypertensive crisis at some point during surgery, almost always associated with manipulation of the lesion. Ten patients (25%) required vasopressor support after adrenal gland removal. Two patients (4.6%) had CTCAE 3/4 complications. There were no cases of mortality and the median length of stay was seven days. Two (5%) cases were defined as malignant: one secondary to metastatic disease to distant organs (recurrence at 30 months of follow-up in the form of multiple lung metastasis) and other to lymph nodes who is alive and disease-free. Three patients were diagnosed with contralateral phaeochromocytoma during the follow-up, admitted as a new primary lesion, in context of a known genetic syndrome.

Conclusion
We report a challenging situation, life-threatening without surgical treatment, but with a high surgical risk due to the severe comorbidities. A positive outcome was strongly dependent on the multidisciplinary collaboration of different departments.
Conclusion
The results of our retrospective study show that adrenalectomy is a safe, effective and a low morbidity procedure. However, the organization of surgical, anesthetic and medical teams experienced in this type of pathology is fundamental for peripерioperative management.

EP99
Role of urinary fractionated metanephrines and catecholamines in the diagnosis of pheochromocytoma/paraganglioma
Ma Luísa Martinez-Triguero, Ma Isabel del Olmo, Rosa Cámara del Olmo, Amparo Alba, Francis Fernández, Juan Francisco Merino & Begona Laiz
Servicio de Análisis Clínicos, Servicio de Endocrinología, Hospital Universitario y Politécnico La Fe, Valencia, Spain.

Introduction
Paragangliomas/pheochromocytomas present frequently with vague symptomatology which makes its diagnosis difficult and challenging. Quantification of fractionated metanephrines and fractionated catecholamines in 24 h urine sample are used for diagnosis. There are situations that can produce false positive results such as stress, drugs or smoking that must be taken into account.

Patients and methods
Retrospective study on the request data for the diagnosis of pheochromocytoma/paraganglioma to the laboratory with the determinations of fractionated catecholamines and metanephrines during 10 months. Determinations were analysed by HPLC with electrochemical detector (Teknochroma®).

Results
During this period 260 determinations (of 218 patients) were analysed. 10 of these patients were diagnosed of pheochromocytoma, nine of extraadrenal paraganglioma and 199 patients did not present either of the pathologies. Patients with paraganglioma were excluded (Table 1).

Table 1: Sensitivity and specificity of fractionated catecholamines and metanephrines.

<table>
<thead>
<tr>
<th></th>

</tr>
<tr>
<td>Metanephrines</td>
<td>0.9</td>
<td>0.71–1.09</td>
<td>0.88–0.92</td>
<td></td>
</tr>
</tbody>
</table>

Of the patients who did not present pheochromocytoma (199), 35 had elevated catecholamines and/or fractionated metanephrines (18% false positive), 17 were due to antihypertensive or antidepressive drugs, 11 had other adenalin pathologies and seven others.

Conclusions
1. Urinary fractionated metanephrines have a higher specificity than catecholamines. Both of them present the same sensitivity in our patients.
2. The rate of false positive results surpasses those of true positive, especially those produced by drugs, as published in literature.

Lung adenocarcinoma in a 34-year-old female SDHB asymptomatic mutation carrier – case report
Maria João Matos, Claudia Costa, Ana Paula Santos, Manuel Teixeira, Carlos Franco, João Bento, Isabel Azevedo, Susana Dias, Inês Lucena Samparo, Ana Luísa Cunha & Isabel Torres
Portuguese Oncology Institute of Porto, Porto, Portugal.

Introduction
Patients with germline mutations in one of the succinate dehydrogenase (SDH) genes are at substantially increased risk of developing paragangliomas (PGL) and pheochromocytomas (PCC). Mutations in SDHB are the most commonly found gene mutations in PC/PGL and are associated with younger ages at presentation, higher rates of metastases and poorer prognosis. Although familial PGL syndromes were initially thought to predispose only for PCC and PGL, other tumor types such as gastrointestinal stromal tumors (GISTs), renal cell carcinomas (RCCs), and pituitary adenomas (PAs) have expanded the SDHx-associated tumor spectrum.

Case Report
A 34-year-old female patient, with a history of mild asthma, non-smoker, was referred to the Endocrinology Department as an asymptomatic carrier of a pathogenic heterozygous germline SDHB mutation (c.1-?_72 +del). Her paternal-uncle died from metastatic bladder paraganglioma by the age of 39. She had also family history of breast cancer (paternal-aunt) and prostate cancer (paternal-grandparent). Twenty-four-hour urinary excretion of fractionated catecholamines and metanephrines were in the normal range. Screening computed tomography (CT) scan showed a 3 cm mass in the lower lobe of the right lung. CT guided transthoracic lung biopsy revealed adenocarcinoma of probable primary lung origin. Staging positron emission tomography with 2-deoxy-2-[fluorine-18]fluoro-D-glucose (18F-FDG PET/CT) showed, besides malignant right lung involvement, moderate left paratracheal FDG uptake. She underwent inferior right lobectomy with mediastinal lymph node resection and histologic examine confirmed lung adencarcinoma pT2a N0 M0 R0, stage I B.

The patient is under surveillance.

Discussion
Questions still remain unresolved concerning non PCC/PGL tumors in patients with germline pathogenic SDH mutations with regard to their pathogenesis, clinicopathological phenotype, and possible causal relation to the aforementioned mutations.

Pheochromosomata in childhood
Olcay Evilyaoglu, Oya Ercan, Aydilek Cakar, Duhan Hopurcuoglu & Betül Çınar
Istanbul University cerrahpasa Medical School Pediatric Endocrinology Department, Istanbul, Turkey.

Introduction
Pheochromosomata is a rare neuroendocrine tumor derived from chromaffin cells of adrenal medulla. The most characteristic clinical symptoms are headache, perspiration, palpitation, and paroxysmal hypertension. Childhood pheochromosomata is generally genetic while it is mostly sporadic in adults. Here we report three pheochromosomata cases in whom two had von Hippel Lindau syndrome (VHLs).

Case 1
10 years old girl with admitted with fever. Her physical examination revealed hyperthermia and hypertension. Urine VMA level was increased and ultrasound examination showed left adrenal mass, diagnosis of pheochromosomata was confirmed after resection. In the second year of her follow-up GA-68 Octreotide scintigraphy determined accumulations in right adrenal and pancreas, pathological diagnosis were feochromosomata and neuroendocrine carcinorespectively after resection. Two disorders together suggested VHLs and heterozygous p.L129P mutation in VHL gene was detected.

Case 2
11-years-old boy admitted with perspiration and palpitation in whom hypertension was determined. Urine VMA level was increased, and bilateral adrenal mass was determined in ultrasonography. Diagnosis of pheochromosomata was confirmed after resection. In his 5 years of follow-up he admitted with headache. Cranial MRI showed frontal, adrenal ultrasound showed right adrenal masses, after resection hemangioblastoma and pheochromosomata were diagnosed respectively. Association of two disorders suggested VHLs and heterozygous p.R161Q mutation in VHL gene was determined.

Case 3
9-years-old boy admitted with perspiration and palpitation in whom hypertension was determined. His family history was significant with pheochromosomata in his father and grandmother. His urine VMA levels were high and adrenal ultrasound revealed bilateral adrenal masses. Diagnosis of pheochromosomata was confirmed after resection of both masses. No mutation in VHL gene was detected.
Conclusion

Although rare pheochromocytoma should be thought in children with hypertension. In children pheochromocytoma is mostly genetic in which VHLs is most frequent. Genetic tests should be performed in all children after diagnosis.

A case of silent pheochromocytoma presenting with clinical and radiological findings suggesting metastatic adrenal lesion

Soner Cander, Ozan Oz Gul, Pınar Sisman & Canan Ersoy

1Uludag University Medical School, Bursa, Turkey; 2Kars State Hospital, Kars, Turkey.

Case

A 75-year-old male patient was treated for lung adenocarcinoma 12 years ago. During the routine imaging studies of the patient who was followed without treatment after curing, a suspicious, non-adenomatous lesion in the right adrenal gland, 16 × 9 mm in size was detected by thoracic computed tomography. Serum aldosterone/renin ratio and urine catecholamine tests were normal with no complaints of suspicion for pheochromocytoma. F18FDG PET-CT showed an increase in metabolic activity (SUVmax:4.8) in the right hilar region. The cytological examination was benign with bronchoscopy. Laparoscopic right adrenalectomy was performed because no other lesions were detected. Histopathologic examination revealed non-invasive pheochromocytoma showing positive staining with synaptophysin and chromogranin.

Discussion

Pheochromocytoma is very rare in adrenal incidentalomas, however, can be asymptomatic at rates up to 10%, as they can manifest with attack symptoms or less with persistent hypertension. It is suggested that catecholamine synthesis is defective in these tumors. In some reports it is specified that, this phenomenon may be seen in some mutations in the succinate dehydrogenase gene. In some reports, however, about 10–20% of silent pheochromocytomas were reported to be due to laboratory error. On the other hand, non-adenomatous lesions in the adrenal glands in a patient known as primary malignancy are generally considered as metastases. In our case, the patient was referred to a similar presentation and it was initially thought that the lesion may be a metastatic lesion. However, the fact that the primary malignancy has been in control for more than 10 years has been questioned about metastasis. One of the methods that can be applied in such a case is biopsy but pheochromocytoma should be firstly excluded. In this case report, we have demonstrated that; in non-adenomatous adrenal lesions, the absence of clinical signs and normal catecholamine levels do not exclude pheochromocytoma.

The storm before the calm: a phaeochromocytoma

Yasmin Nkookam, Caonione Bonner, Edward Bettany, Anthony Pittathunkali, Ranjan Gunasekara, Edel Casey & Khash Nkookam

King George Hospital, London, UK.

We report a case of a male patient aged 45 years who presented with a history of intermittent back discomfort over a year, but more persistent over the previous 2–3 months. His general practitioner (GP) referred him for an ultrasound of the spine for a possible encapsulated lipoma but the findings were unremarkable. He was then referred to a consultant gastroenterologist for further assessment. He had normal endoscopic examinations, however the MRI had shown a right adrenal lesion which led to a referral to the endocrine team.

On further history he reported episodes of perspiration and bursts of aggression, for the past few years. Investigations revealed a normal cortisol response following overnight dexamethasone suppression and a normal renin aldosterone ratio.

He had elevated 24-h urinary normetanephrines 6360 nmol/24 h and metanephrines 2530 nmol/24 h (normal <2129 and <1622 respectively), in keeping with pheochromocytoma. Subsequent meta-iobenzylguanidine (MIBG) scan showed prominent activity in the region of the right adrenal gland. The patient was initially commenced on an alpha blocker doxazosin, and the dose was incremented to the maximum of 16 mg BD. He was subsequently commenced on beta blocker bisoprolol, and his blood pressure dropped from average of 150/100 mmHg (no history of hypertension) to around 110/70 mmHg. This patient had a right adrenalectomy, made an uneventful recovery and was discharged with no medication. His BP remained at around 130/85 mmHg at his post-operative consultations. Pheochromocytoma presents with various forms of signs and symptoms. In our case, the history of episodes of intermittent perspiration, back pain and severe aggression were uncommon symptoms emphasising the importance of comprehensive history taking. Since surgery the patient has no longer experienced any of the above, and he describes himself to be calmer than ever.

DOI: 10.1530/endoabs.49.EP103

Introduction/case report

Diabetes mellitus is an important clinical manifestation of catecholamine excess in patients with pheochromocytoma, and glucose control is usually better after tumour removal. Both impaired insulin secretion and increased insulin resistance have been implicated as underlying causes. We describe the case of a 38-year-old male patient diagnosed with left adrenal pheochromocytoma and personal history of diabetes mellitus diagnosed at age 36, under treatment with metformin, saxagliptin and glarglize, with a preoperative HbA1c of 7.2%. BMI of the patient was 23 kg/m². After successful pheochromocytoma removal, the anti-diabetic medication was immediately stopped with remission of diabetes mellitus (HbA1c 3-months-postoperative 5.7%).

Methods

We performed oral glucose (75 g) tolerance tests and measured venous plasma glucose and serum insulin levels at the time of diagnosis and three months after successful surgery, to derive the insulinogenic index (IGI) as proposed by Wareham, and whole body insulin sensitivity index (ISI) as proposed by Matsuda and DeFronzo.

Results

Plasma glucose and serum insulin levels are shown in the table 1.

</tbody>
</table>

Improved glucose levels were associated with increased insulin levels and an increase in IGI, from a preoperative value of 5.7–33.6 pM/mM, while the ISI remained unchanged.

Conclusion/discussion

Remission of diabetes mellitus in our patient was associated with marked improvement of insulin secretion and oral glucose tolerance after removal of pheochromocytoma. Adrenergic alpha2A receptors on pancreatic beta cells play an important role in mediating inhibitory effects of catecholamines on insulin release, according to recent genetic association and pharmacological intervention studies. In our case, impaired insulin secretion could be corrected by surgery.

Ephedrine/caffeine toxicity masquerading as phaeochromocytoma in a vorgexic male with paroxysmal hypertension and headache
Manuel Nivelor-Rivadeneira, Agnieszka Kuzior, Sara Quintana-Arroyo, Carmen Acosta-Caleró, Claudia Armas-León, Ana Delta Santana-Suárez, Alba Lucía Tocino-Hernández & Francisco Javier Martín-Martín
1 Endocrinology Department, Hospital Universitario de Gran Canaria Dr Negrín, Las Palmas de Gran Canaria, Spain; 2 Outpatient Hypertension Clinic, Hospital Universitario de Gran Canaria Dr Negrín, Las Palmas de Gran Canaria, Spain; 3 Primary Care Center, Arucas, Las Palmas de Gran Canaria, Spain.

Clinical case
A 19-year-old male came to the Emergency Department complaining about a holocranial nonpusultable headache growing in intensity for the last 3 h, unresponsive to common analgesics. He had been suffering anxiety sleep deprivation, nervousness, tremor and heart palpitations for the last week. Family history was irrelevant, and the patient had no history of hypertension, dyslipidaemia, diabetes or smoking or medication use; he reported moderate alcohol, coffee and energy drink consumption but no cocaine nor amphetamines. He was on a high-protein diet with casein-based supplements, maintained a very high level of physical exercise and lately had been consuming a ‘fat-burner’ obtained from a local gym, but ignored its composition. The patient was fully conscious and did not have chest pain, fever or dyspnoea. His BP was 219/126 mmHg and HR 129 bpm, with sinus tachycardia in the EKG. He was treated with diazepam and diltiazem, discharged with BP 154/87 and HR 98 and referred to our Endocrine Clinic for phaeochromocytoma screening. He brought the ‘fat-burner’ pills containing ephedrine 50, ASA 100 and caffeine 150 mg; he had been taking 1–2 daily during the week before the hypertensive episode. He was asymptomatic, with athletic constitution, weight 87 kg, height 173 cm, BMI 29 kg/m², waist 88 cm, and impendimetry 19% fat mass, BP 119/76, HR 75. Physical exam was otherwise unremarkable. Lab tests included metanephrines, aldosterone, PRA, TSH and microalbuminuria; chest X-ray and 24 h ABPM were normal.

Diagnosis
Paroxysmal hypertensive episode caused by ephedrine/caffeine toxicity, with no target-organ damage. Vorgexia. Phaeochromocytoma/parangangioma were ruled out.

Commentary
Ephedrine is a sympathomimetic amine with no legitimate medical indications at present, but widely used as doping or to trim subcutaneous fat. Its use has been linked with major cardiovascular and renal events, including ictus and sudden death, and must be discouraged.

Discussion
This case illustrates the possibility of false negative results in hormonal evaluation of adrenal masses. These misleading results can happen, for example, by an inadequate urine sampling. If we had not repeated the measurement of metanephrines, the diagnosis of phaeochromocytoma had not been done at this time.

Unexplained resistant hypertension in a young male with recurrent transient ischemic attacks, resembling endocrine hypertension
Ana Delta Santana Suárez, Manuel Nivelor-Rivadeneira, Agnieszka Kuzior, Sara Quintana Arroyo, Carmen Acosta Calero, Claudia Armas León, Esperanza Perdomo Herrera & Francisco Javier Martín Martín
1 Endocrinology Department, University Hospital Dr Negrín, Las Palmas, Spain; 2 Primary Care Center of Escaleritas, Las Palmas, Spain; 3 Outpatient Hypertension Clinic, University Hospital Dr Negrín, Las Palmas, Spain.

A 27-year-old male without relevant familial or personal history had three TIA in the last year, lasting for about 20 min with partial right palsy and aphasia. By the time he was cared for in the Emergency Department, he had already recovered; his lab tests, chest X-ray and EKG were normal but his BP was high (170–190 mmHg, PAD 105–120 mmHg). He had no chest pain, headache or neurovegetative symptoms. On discharge the patient was treated with manidapine and ASA and referred to the Neurology Clinic and to our Hypertension Clinic for phaeochromocytoma/parangangioma screening and diagnostic workup.

Stress cardiomyopathy in pheochromocytoma
Cristina Alexandra Gheorghiu, Simona Jercaiu & Corin Badiu
National Institute of Endocrinology ‘C.I. Parhon’, Bucharest, Romania.

Introduction
Rare cases of pheochromocytoma are associated with stress induced Takotsubo cardiomyopathy explained by high catecholamine exposure causing microvascular spasm and direct myocardial impact.

Case report
A 49-year-old female with a history of poorly controlled hypertension, with paroxysmal elevations in blood pressure and rare supraventricular extrasystoles, lipothymic events, was firstly assessed in the cardiologic department. She presented with resistant hypertension, associated with acute pulmonary oedema and cardiogenic shock. Echocardiography revealed new mid LV segment motion abnormality with apical ballooning. ECG – acute ST-segment elevation in the anterior leads and a rise of cardiac biomarkers. The coronary angiography excluded any coronary artery lesion. Thoraco-abdominal CT imaging revealed an 80/85/88 mm left adrenal mass, suggestive for pheochromocytoma. Laboratory evaluation for 24-h urine and plasma catecholamine metabolites disclosed intermediary-low elevated values (plasmatic MN = 10/11 pg/ml; plasmatic NMN = 59/41 pg/ml; urinary MN = 114/881 µg/24 h; urinary NMN = 632/1121 µg/24 h), despite high cardiac impact of the spells. She was submitted to 12 days of alpha adrenergic blockade followed by beta blockers, during which control of blood pressure and spells was achieved. Improvement of systolic function (EKG and echocardiography) could be noticed. Laparoscopic adrenalectomy was safely performed without hemodynamic events during surgery or immediately afterwards. Metanephrines and normetanephrines levels normalised with good residual adrenal function. Long term systolic function as well as high blood pressure returned to normal.

Conclusions
Takotsubo cardiomyopathy is associated with reversible LV-ballooning. In this observation, we report a case of stress cardiomyopathy caused by

palpitations, diaphoresis or tremors. 121HBMIBIG scintigraphy revealed focus of hyperactivity located on projection of the right adrenal gland suggesting the presence of pheochromocytoma. We sent this patient to multidisciplinary expert team. Plasma-free metanephrines were measured with elevated results: 125 pg/ml (<65) and he will undergo unilateral adrenalectomy soon.

This case demonstrates that stress induced Takotsubo cardiomyopathy patient with resistant hypertension due to pheochromocytoma, a rare presentation.

Prolonged zona glomerulosa insufficiency with hyperkalemia in primary hyperaldosteronism after adrenalectomy
Feysu Yener Ozturk, Esra Cil Sen, Rumeysa Selvinaz Erol, Emre Sedar Saygili, Seda Erem Basmaz, Sezin Dogan Cakir, Adnan Batman & Yuksel Altuntas
Sissi Hamidiye Etfal Training and Research Hospital, Istanbul, Turkey.

Introduction
Hyperkalemia due to zona glomerulosa (ZG) insufficiency is generally transient and mild for patients with aldosterone-producing adenoma (APA) after adrenalectomy. We report here a case with prolonged ZG insufficiency requiring long-term mineralocorticoid replacement (MR) therapy.

Case report
A 45-years-old female with hypertension and hypokalemia admitted to outpatient clinic with incidentally detected right adrenal adenoma (3 cm) showing signal loss on opposed-phase images of MRI. Laboratory tests revealed high plasma aldosterone concentration (PAC) (72 ng/dl, N. 7-30 ng/dl), supressed plasma direct renin concentrations (DRC) (5.25 ng/ml, N. 5.41-34.53 ng/l) and high PAC/DRC ratio (13.71). PAC after saline infusion test was 30.7 ng/dl. After confirmation with adrenal venous sampling (AVS), right adrenalectomy was performed laparoscopically. Serum urea, creatinine, sodium, PAC (19.6 ng/dl) and DRC (13.6 ng/l) were in normal limits on postoperative 20th day; but serum potassium was markedly increased (5.9 mmol/l). The causes of pseudohyperkalemia and hyperkalemia were excluded. Because of low suppression index in the contralateral adrenal during AVS, hypoadosteronism was thought to be the etiology as PAC did not increase while serum potassium level was higher than 5 mmol/l. Patient was followed-up with high-sodium, low-potassium diet on postoperative 20th day. After then, serum potassium concentration remained at the upper limit of normal range (5.5 mmol/l) with normal renal function tests, PAC (10.8 ng/dl) and DRC (8.1 ng/l) without replacement.

Conclusion
Suppression of contralateral ZG function by supressed plasma renin level in APA can lead to ZG insufficiency and hypoadosteronism after adrenalectomy. Hyposaldosteronism cause impairment of renal potassium clearance and hyperkalemia. MR therapy may be essential in case of prolonged hyperkalemia.

Mature ganglioneuroma of the adrenal gland
Betül Aydin Buyruk, Medine Nur Kebapçı, Goknur Yorulmaz, Evrim Yılmaz & Enver İhtiyar
1Department of Endocrinology, Eskisehir Osmangazi University Medical Faculty, Eskisehir, Turkey; 2Department of Pathology, Eskisehir Osmangazi University Medical Faculty, Eskisehir, Turkey; 3Department of General Surgery, Eskisehir Osmangazi University Medical Faculty, Eskisehir, Turkey.

Introduction
Ganglioneuroma is an extremely rarely seen tumour in the adrenal gland, which originates from neural crest cells. Clinically, they generally have a silent course and in laboratory tests, the hormone levels expressed from the adrenal gland are within the normal range.

Case
A 46-year old male patient, for whom a mass in the adrenal gland was diagnosed incidentally on abdominal ultrasonography and MRI. The physical examination, laboratory tests and hormonal tests were within normal limits. As the appearance on dynamic adrenal CT was compatible with an adenomatous lesion, a biopsy was applied to the left adrenal gland. In the histopathological examination, findings were determined of neuroblastic tumour and ganglioneuroma, so adrenalectomy was applied and adrenal ganglioneuroma (mature type) was reported in the pathology examination.

Conclusion
Ganglioneuroma is rarely seen in adults and diagnosis is difficult as it is asymptomatic. As the masses are asymptomatic, they are not usually determined before reaching large dimensions. With increased availability of high-resolution tomography and MRI, an increase has been seen in the frequency of these types of masses. In recent years, ganglioneuroma have been separated into two sub-types as mature or maturing ganglioneuroma. In mature ganglioneuroma, the tumour is completely formed of a ganglioneuromatous component. Diagnosis is made histopathologically and it should be kept in mind as a rare tumour in adrenal masses.

Primary adrenal insufficiency and pregnancy – a case report
Slavica Savic1, Mirjana Stojkovic2 & 3, Biljana Nedeljkovic-Beleslin1,2, Tanja Njivic1, Milos Stojanovic1,2, Marija Miletic1, Jasmina Curić1,2, Svetlana Spremovic-Radjenovic3,5 & Milos Zarkovic1,2
1Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia; 2School of Medicine, University of Belgrade, Belgrade, Serbia; 3Clinic for Gynecology and Obstetrics, Clinical Centre of Serbia, Belgrade, Serbia.

Primary adrenal insufficiency (PAI) is uncommon in pregnancy. Women with PAI have reduced fertility and parity. If unrecognized or untreated during pregnancy PAI increases risk for maternal and foetal morbidity and mortality. Majority of women diagnosed before conception and appropriately treated, have uneventful pregnancies, with increased risk of cesarean section (CS) and preterm delivery.

We report a 38-year-old woman with PAI during first spontaneous pregnancy. The patient was diagnosed with Addison’s disease at the age of 17, and hyperthyroidism 14 years later. Her family history revealed hyperthyroidism in mother. She had regular menstrual pattern and no pregnancy during 5 years of marriage. Gynecological investigation was unremarkable, but she had adhisonian crisis during hysterosalpingography 6 months before conception. At that time she was taking 30 mg hydrocortisone, 0.1 mg fludrocortisone and 50 mcg levothyroxine/day. At 8 weeks of pregnancy she started to complain of fatigue, dizziness and palpitations. Physical examination was unremarkable, BP 100/70 mmHg, with no orthostasis or discolouration of skin/mucous membranes. Oral progesterone was started because of spotty vaginal bleeding and in 2 weeks she developed mild hyponatraemia. We recommended to split hydrocortisone in four doses, and increased fludrocortisone to 0.125 mg. During second trimester she was stable, plasma electrolytes and thyroid function test were normal, with no foetal or placental abnormalities on ultrasonography. In the middle of the third trimester hydrocortisone and fludrocortisone doses were further adjusted to 35 mg and 0.15 mcg respectively. She underwent CS at the 39th gestational week and a healthy baby girl weighing 3250 g was delivered. During the 15-month follow-up period mother and baby were in good condition.

We presented a case of women with autoimmune polyglandular syndrome (APS 2) and successful pregnancy outcome. Women with PAI should be monitored by a multidisciplinary team throughout pregnancy to ensure maternal and foetal health.

Paraganglioma (PG) and cyanotic congenital heart disease (CCHD): the role of tituslar hypoxia
Amelia Oleaga, Fernando Goni, Miguel Paja, Estibaliz Ugarte, Cristina Moreno, Natalia Iglesias, Eider Etxeberria, Laura Calles, Maddalen Dublang & Alba Zabalegui
Basurto University Hospital, Bilbao, Vizcaya, Spain.

Introduction
CCHD comprises a number of different congenital heart defects associated with elevated pulmonary artery pressure and pulmonary vascular resistance, resulting in a reversed or bidirectional shunt (Eisenmenger syndrome). These entities develop systemic hypoxia. Pheochromocytoma and paraganglioma (PHEO/PG)
are neuroendocrine tumours. Several inheritance genetic alterations have been reported in PHEO/PG syndromes. A pathogenic association between these entities is proposed.

Case report
A 41-year-old female diagnosed of a CCHD in the new-born period, on stable medical treatment, as surgery was rejected. She presented with symptoms suggesting exacerbation of heart failure. Catecholamine hypersecretion was suspected: 24-hour urine metanephrine: 215 µg/24 h (NV < 341) and normetanephrine (NM): 2491 µg/24 h (NV < 444). Abdominal CT showed a retroperitoneal lesion consistent with a PG. Functional imaging with Iodine-123MBI showed a pathological uptake area at the same localization. No other pathological images were observed. Genetic testing was performed and no mutations in SDHD, SDHC, SDHB, VHL, SDHAF2, MAX and TMEM127 genes were found. She underwent surgery after alpha blockade. Pathological examination confirmed the diagnosis of a PG. NM became normal after surgery and patient symptoms improved.

Discussion
Several hypothemic phenomenon have been related to be implicated in the pathogenesis of PHEO/PG, as it is known that some of the genetic alterations (SDHx, VHL, HIF2) lead to enhanced production of hypoxia inducible factors, which induce an increase in angiogenic factors leading to the development of tumours. The patient had an evolved heart disease with significant cyanosis. Chronic exposure to hypoxia in patients with CCHD could increase the risk for developing PHEO/PG. In addition, the noradrenergic biochemical phenotype found agrees with that observed in some of the PHEO/PG syndromes. In patients with CCHD the diagnosis of PHEO/PG can be difficult to suspect because symptoms may be confusing, nevertheless catecholamine excess may be present. Therefore we consider that the existence of a PHEO/PG should be ruled out in patients with CCHD and aggravation of the previous heart function.

Large adrenal adenoma presenting as a clinically inapparent Cushing syndrome, a trap diagnosis
Denisa Petrescu1, Cristina Alina Silaghi2, Doina Crisan3, Daniel Tudor Cosma1, Ionela Lungu1, Carmen Emanuela Georgescu1, Romeo Ioan Chira4 & Horatiiu Silaghi4
1County of Emergency Hospital, Cluj-Napoca, Romania; 2Department of Endocrinology, ‘Iuliu Hatieganu’ University of Medicine and Pharmacy, Cluj-Napoca, Romania; 3Discipline of Pathology, Department of Morphological Sciences, ‘Iuliu Hatieganu’ University of Medicine and Pharmacy, Cluj-Napoca, Romania;
4Diabetes, Nutrition and Metabolic Diseases Clinical Center, Cluj-Napoca, Romania; 51st Internal Medicine Department, ‘Iuliu Hatieganu’ University of Medicine and Pharmacy, Cluj-Napoca, Romania; 65th Department of Surgery, ‘Iuliu Hatieganu’ University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Adrenal incidentaloma (prevalence between 0.4 and 7%) have become a very common clinical problem, the major concern being the risk of malignancy and hormone overproduction.
A 57-year-old woman was admitted for asthma and uncontrolled hypertension. The only relevant clinical signs were abdominal obesity (BMI = 31.1 kg/m2) and hypertension. Abdominal ultrasonography showed a voluminous left adrenal solid mass of 10.9 cm, with well-defined sharp borders, hyperechoic with necrotic areas and hypochogenic foci of scars and calcifications. The differential diagnosis of an atypical adenoma and pheochromocytoma or adrenocarcinoma was difficult.
Laboratory assays revealed hypercortisolism, indicated by the loss of the circadian rhythm of cortisol secretion cortisol value at 8 a.m was treated at 7.8 µg/dl and at midnight of 11.2 µg/dl, elevated free 24 h urinary cortisol of 731.4 µg/24 h (normal range: 50-190 µg/24 h), no suppression at overnight dexamethasone suppression test (cortisol of 5.46 µg/dl), low ACTH level of < 1 pg/ml and decreased cortisol level <50% at the high dose dexamethasone test. Plasma metanephrines, normetanephrines, renine and aldosterone were normal. Abdominal CT scan indicated a tumoral left adrenal mass of 10/8.5/8.5 cm, well defined, inhomogeneous, with microcalcifications, <10 HU, induced caudal displacement of the left kidney, no lymphadenopathy or other visceral involvement. She underwent left laparoscopic adrenalectomy. The histopathological evaluation indicated Ki67<1% and chromogranin, synaptophysin, calretin, protein S100, inhibit were isolated low positive; PanCK, EMA were negative; CD31 showed the capillary network, without emboli; vimentin was positive; suggesting an atypical adenoma and excluding an adrenocarcinoma, a kidney and liver tumor, but also a pheochromocytoma. Two weeks after surgery, a large ischemic vascular attack occurred, with poor prognosis. We should keep in mind that voluminous cortisol-producing adrenal adenomas could have clinically inapparent features, but with hidden vascular damages and increased cardiovascular risk.

EP115
NK/T lymphoma adrenal presenting as adrenal insufficiency and cranial nerves neuropathies-a case report
Shalini Sree Dharan, Norazizah Aziz, Shueh Lin Lim & Pavithrah Jaspanshan
Penang General Hospital, Penang, Malaysia.

Adrenal Lymphoma is extremely rare with fewer than 200 cases reported. The most common subtype is the diffuse large B cell lymphoma. Malignant lymphoma arising in the endocrine glands represents only 3% of extranodal malignant lymphomas and is usually confined to the thyroid gland. NK/T-cell lymphoma presents primarily in the nasopharynx and sinuses. Although involvement of the adrenal glands can be seen in disseminated disease, primary presentation with adrenal masses and adrenal insufficiency is extremely rare. We report a case of 34 years old gentleman presenting with prolonged fever, constitutional symptoms and symptoms and signs of adrenal insufficiency. He was treated as adrenal crisis in the district hospital with hypotension, hypotension, and hyperkalemia. He appeared cachexic, with no hyperpigmentation or palpable lymph nodes. His lactate dehydrogenase enzymes (LDH) was elevated. Cortisol taken during this stressful period was deemed too low. This was confirmed by an inadequate response to the Synacthen test. CT Adrenal was performed and reported as bilateral enlarged adrenal, likely hyperplasia. He developed multiple cranial nerves neuropathies that progressively worsened. CT Brain was normal. Lumbar puncture revealed high opening pressure and CSF biochemistry revealed no cells and negative for tuberculosis. With the possibility of disseminated tuberculosis, empirical anti-tuberculosis medications were started but failed to abate his

Endocrine Abstracts (2017) Vol 49
symptoms. Laparoscopic left adrenal excision biopsy was performed and histology features are in keeping with high grade NK/T cell lymphoma. His condition deteriorated fast and he succumbed to his illness. This case illustrates the need to include Primary Adrenal Lymphoma in the differential diagnosis of adrenal masses especially when adrenal contour is preserved on imaging, hypoadrenalism and high LDH.

Primary hyperparathyroidism and primary hyperaldosteronism – cause or coincidence in arterial hypertension – case report
Trjana Icin1,2, Ivana Bajkin1,2, Dusan Tomic1, Jovanka Novakovic-Paro1,2, Bojan Vukovic1,2, Jovana Prodanovic1 & Milica Medic-Stojanaksa1,2
1Clinic of Endocrinology, Diabetes and Metabolic Disorders, Clinical Center of Vojvodina, Novi Sad, Serbia; 2Department of Internal Medicine, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia.

Introduction
30% of the adult population has high blood pressure. About 6% of the hypertension may be caused by primary aldosteronism and very rare by primary hyperparathyroidism. The combination of these two causes is very rare.

Case report
Our patient is women (age 50) with a 21 year long history of uncontrolled hypertension. Treatment of hypertension consist of a beta-blocker, calcium channel blockers, angiotensin converting enzyme inhibitor, loop diuretics and thiazide diuretics. Laboratory tests confirmed the presence of hypercalcemia (ionized calcium 1.42 mmol/l), and hypokalemia (3.4 mmol/l). After correction of medical therapy results shows elevated levels of parathyroid hormone (221.7 pg/ml) and aldosterone/renin ratio (A/R 30), normal value of metanephrines and normetanefrine, normal ACTH and cortisol levels and diurnal rithm (221.7 pg/ml) of secretion. CT of the abdomen showed adroma like enlargement of left adrenal gland of 2 cm. Scintigraphy and ultrasound confirmed the presence of hyperplasia/adrena of the lower left parathyroid gland. Bone mineral density indicates osteoporosis and ultrasound of abdomen described nephrolithiasis in the left kidney. Due to hypercalcemia, first we have decided to operate the parathyroid glands. Surgery leads to normalization of calcium. The pressure is regulated without both the diuretics at a reduced dose of a calcium channel blockers. After recovering from surgery, in a hospital setting we discontinued therapy and dynamic testing was conducted (volume loading test and postural stimulation test) that indicate adrenal hyperplasia as a cause of primary hyperaldosteronism. Patient started with spironolactone therapy that even in small doses leads to normaliziation of potassium and reduce the need for other antihypertensive agents.

Conclusion
More endocrine disorders can simultaneously affect arterial hypertension. Treatment of hyperparathyroidism may lead to better control of hypertension. Despite the existence of left adrenal enlargement that looks like an adenoma, adrenal hyperplasia is a possible cause of primary hyperaldosteronism.

Endocrine masses displayed as incidentalomas in patients with unilateral nephrectomy
Adina Ghemigian1, Eugenia Petrova2, Nicoleta Dumitruc2, Andra Buruiana2, Mara Carsote1 & Ana Valică1
1C.Davila UMF & 1Parhon National Institute of Endocrinology, Bucharest, Romania; 2Parhon National Institute of Endocrinology, Bucharest, Romania; 1Hatieganu UMF & Clinical County Hospital, Cluj-Napoca, Romania.

Introduction
Menopausal adrenal tumours may be elements of a complex panel of co-morbidities. Some of these are represented by the presence of a second pathology requiring surgery at the kidney level.

Aim
We aim to introduce a series of two cases involving menopausal women who were referred for specific endocrine assays after they had a unilateral nephrectomy (UN).

Method
This is a cases series observational study. The patients gave their consent. They were followed in different medical and surgical centres from Romania.

Results
A 61-year woman was admitted for a right adrenal and a thyroid incidentaloma after left UN for renal cancer with clear cells, Fuhrman Nuclear Grade of 2 (pT3N0M0). Post-operative endocrine panel of investigations were consistent for non-secretor low risk lesion. A fine needle aspiration biopsy at thyroid excluded a second malignancy. A 56-year old female had left UN 14 years ago for a benign condition. One year after surgery a right adrenal tumour of 1.2 cm was discovered at CT (computer tomography) scan. After 13 years, the subject became hypertensive and experienced hot flushes in association with secondary amenorhea so an endocrine evaluation was considered. Non-secretor adrenal profile and high Follicle Stimulant Hormone consistent for physiological menopause was associated with stationary CT aspects for right adrenal tumor but also a left adrenal tumor of 1.3 cm was identified. Nevertheless, abdominal CT scan performed 1 year later showed similar aspects. Further serial imaging was recommended.

Discussion
Adrenal incidentaloma discovered in menopausal patients with UN requires a complex differential diagnosis including the fact that they need to be differentiated from metastases arising from kidney cancer. Also, serial imaging assessments after kidney removal may lead to the discovery of different solid masses as thyroid incidentaloma or nodules.

Case with metastatic lung cancer who developed adrenal insufficiency
Buket Yilmaz Bulbul1, Ece Celik2, Mehmet Celik1, Semra Ayturk1, Funda Ustun1 & Sibel Guildeken1
1Department of Endocrinology and Metabolism, Medical Faculty, Trakya University, Edirne, Turkey; 2Department of Chest Diseases, Edirne Sultan 1. Murat State Hospital, Edirne, Turkey; 3Department of Nuclear Medicine, Medical Faculty, Trakya University, Edirne, Turkey.

Adrenal metastasis is common (35%) among the patients with lung cancer, while less than 3% of the patients develop bilateral adrenal metastasis. Adrenal metastases are generally small and clinically asymptomatic. Adrenal insufficiency is rare despite the presence of adrenal metastasis. Lam et al. reported this ratio as 0.7%. We aimed to present a case with lung cancer and bilateral adrenal metastasis who developed adrenal insufficiency.

A 63-year old male patient was presented with cough. Chest X-ray revealed a mass lesion in the upper zone of left lung. PET/CT examination was performed and demonstrated increased FDG uptake in upper lobe mass lesion of left lung, mediastinal lymph nodes, bilateral surrenal glands (9 mm at the right and 5.5 cm at the left), liver and bones. Following bronchoscopy, the patient was diagnosed with non-small cell lung cancer. Pathologic examination of surrenal biopsy material revealed surrenal metastasis. The patient had no signs of adrenal insufficiency and electrolyte imbalance at the time of diagnosis. He was scheduled for cisplatin + gemcitabine chemotherapy. Although lung and adrenal gland lesions were stable within 6 months after treatment, the patient developed hypoglycemia, hypovolemia, hypotension and hyperkalemia. Laboratory examination revealed ACTH: 1250 pg/ml (normal: 0-46), and cortisol 4.43 g/dl (normal: 135-145), K: 4 mEq/L (normal: 3.5-5.5) and A/R 0.7%. The patient was given prednisolone and fludrocortisone treatment with the diagnosis of adrenal insufficiency. Symptoms of the patient were subsided after treatment. Post-treatment laboratory examination revealed Na: 138 mEq/l (normal:135-145), K- 4 mEq/L (normal:3.5-5.5) and ACTH 37 pg/ml. It should be considered that patients with lung cancer and adrenal metastasis may later develop adrenal insufficiency despite the absence of adrenal insufficiency at the time of diagnosis. Although fatigue, nausea, hypotension and hypoponametra may also be seen in the patients with cancer, these may also be the signs of adrenal insufficiency.

Adrenal haemorrhage: from Urology to Endocrinology
Catarina Silvestre, Ana Gomes, Raquel Carvalho & Maria João Bugalho Santa Maria Hospital, Lisboa, Portugal.

Background
Bilateral adrenal haemorrhage (Waterhouse-Friderichsen syndrome) is a rare consequence of sepsis (usually a result of meningococcal infection), with an
Hemangioma a rare adrenal tumors: report of two cases

Ariby Yamina, Bensaleh Meriem, Brakni Lila, labassen Malek & Ould Kabila Samia
Central Hospital of the Army, Algiers, Algeria.

Introduction
Dramatically with increased use of computed tomography (CT) and magnetic resonance imaging (MRI), more and more uncommon adrenal masses have been detected at abdominal examinations. Adrenal cavernous hemangiomas (ACH) are rare vascular tumor. The first case report was published in 1995 by Johnson and Jeppesen. Approximately less than 70 cases were reported in the literature to date.

Case report
We describe two cases of ACH in a 66 years old woman and a 36 years old men.

Discussion
ACH is an uncommon benign vascular tumor. These rare tumors usually localized in the liver and the skin. Adrenal site is extremely rare occurring only in 0.01% of cases and accounts for 63 reported cases in the literature. ACH are often discovered as incidentalomas either by imaging studies or histologic examination.

The indications for resection of this neoplasm particularly in tumours more than 3 cm in diameter are to relieve the mass-effect-type symptoms, to exclude malignancy, and to treat complications such as haemorrhage, necrosis and thrombosis.

A rare case of adrenal lymphangioma

Yusuf Durmus1, Mehmet Celik2, Bukeet Yilmaz Bulbul2, Senra Aytkur2, Nuray Can2, Ebru Tastekin & Sibel Guldiken2
1Department of Internal Medicine, Medical Faculty, Trakya University, Edirne, Turkey; 2Department of Endocrinology and Metabolism, Medical Faculty, Trakya University, Edirne, Turkey; 3Department of Pathology, Medical Faculty, Trakya University, Edirne, Turkey.

Adrenal lymphangioma is a rare benign tumors of the adrenal gland. Because of the increased use of imaging methods in recent times, the diagnosis is usually made incidentally. It is usually due to malformation between the lymphatic and the venous system. Those with small indiameters are generally asymptomatic and can be evacuated by needlea spriration. However, surgery is recommended for cysts over 6 cm in diameter due to risk of infection, bleeding, compression of neighboring organs, and perforation. A 45-year-old male patient was admitted due to left abdominal pain and swelling for 2 months. There was no chronic disease or drug use in history. Blood pressure: 130/80 mm hg, pulse rate was 94/min. Ultrasonography revealed a grade II hepatosplenomegaly in the liver and a 70 mm multilocular cystic lesion in the left suprarenal region. A mass lesion with multicole cysstic components was observed in the abdominal MRI was T1 hypointense, T2 hyperintense in the left adrenal gland and 75 mm in diameter. There were no blood pressure attacks, flushing and palpitations. In laboratory tests: sodium 138 mmol/l (n:135–145), potassium 4.3 mmol/l (n:3.5–5.5), ACTH 27.4 pg/ml (n:0–46), cortisol 15.83 ug/dl (n:5–29), 1 mg dexemethasone supression test 0.83 ug/dl (<1.8) was detected. Plasma aldosteron-to-renin ratio was <10, metanephrine and normetanephrine were normal in 24 hour urine.

Laparoscopic left surenalactomy was performed for the hormone inactive mass. Pathologic examination revealed D2.40 positive, CD34 positive, MelanA on cystwall as local positive lymphangioma. The patient was asymptomatic for 8 months. We aimed to present the rare case of adrenal lymphangioma in our case.

The difficulty in predicting aggressive tumour behaviour of phaeochromocytomas

Edouard Mills, Ali Naqvi, Roberto Dina, Fausto Palazzo & Florian Wernig

Imperial Centre for Endocrinology, Imperial College Healthcare NHS Trust, London, UK.

Phaeochromocytoma and paragangliomas (PH/PG) are rare neuroendocrine tumours. Prediction of aggressive tumour behaviour remains a major challenge. The Phaeochromocytoma of the Adrenal gland Scaled Score (PASS) is used to separate benign from malignant lesions with a score > 4 showing potential for biologically aggressive behaviour. Pre-operatively, MIBG together with CT/MRI remain the diagnostic radiological gold standard.

We report a 68-year-old female who was found to have a locally arising coli
cenic adenocarcinoma on biopsies. Staging also identified a 10.7 cm right adrenal lesion and work-up revealed markedly raised urinary metanephrines and positive MIBG imaging. The MDT decision was to first remove the colonic cancer with appropriate alpha blockade. It was felt that a combined laparoscopic approach would not be appropriate given the adrenal lesion size, which might require an open procedure. Histology confirmed a stage III Duke’s C tumour and adjuvant chemotherapy commenced. Although adrenal surgery had been planned once she completed chemotherapy, she did not tolerate chemotherapy and it had to be discontinued. An open adrenalectomy was undertaken. Histology was consistent with a phaeochromocytoma with a PASS score of eight. 2 months after adrenal surgery, she reported intermittent tingling and numbness in the left arm with thoracic back pain. An MRI confirmed a soft tissue mass at T4 extending into the spinal cord. Urinary metanephrines confirmed persistently elevated normetanephrines and positive MIBG imaging. Histology confirmed a metastatic phaeochromocytoma. She is currently awaiting chemotherapy. We therefore propose that Ga68-DOTATATE PET-CT imaging may have identified a metastatic lesion(s) not seen on MIBG scanning. We therefore propose that Ga68-DOTATATE PET-CT may be a useful tool in the initial staging and follow-up of patients with phaeochromocytoma.

An unusual cause of unilateral adrenal haemorrhage

Jayamalee Jayaweera¹, Emily Symington² & John Clark¹

¹West Suffolk Hospital, Suffolk, UK; ²Addenbrookes Hospital-Cambridge University Hospitals, Cambridge, UK.

A 24 year old man was admitted by the Surgeons with left sided abdominal pain. He was febrile and tachycardic and found to have raised inflammatory markers. Abdominal CT scan revealed a 6 cm left adrenal lesion. The serum aldosterone level was normal. The left adrenal CT image (Figure 1) showed a 3.5 cm dense left adrenal mass with focal hypoattenuation. The adrenal mass was 38 Hounsfield units (HU). In arterial and venous phase tumor density was 70 and 44 HU, respectively. Dynamic analysis showed washout and tumoral blood flow of less than 5mm in diameter were described. PET F-18 FDG scan identified an hypodense centrum area suggestive of necrosis into the left adrenal. A tomography guided biopsy only detected necrotic cells. Finally a left adrenalectomy was performed and histopathological study revealed a diffuse large B-Cell non-Hodgkin’s lymphoma. The patient was started on chemotherapy with a successful response.

Conclusion

Biopsy could be necessary in the differential diagnosis of necrotic adrenal masses even when lymph nodes are present.

Incidentaloma as a first manifestation of lymphoma

Pamela R. Chávez Díaz, Cristina Alvarez Escola, Miriam Zapatero Larrauri, José Tomás Castell Gómez, Alfredo Aguilar Bazán & Lucrecia Herranz de la Morena

Hospital U. La Paz, Madrid, Spain.

Introduction

Incidentally discovered adrenal masses (incidentalomas) are common and in some cases differential diagnosis could be a challenge.

Case report

A 55-years old woman presented with an incidental left adrenal mass of 36mm discovered on an abdominal ultrasound. As sole background she underwent resective surgery of an ovarian serous cyst. She denied symptoms like flushing, headache, diaphoresis or palpitations. Physical examination was irrelevant. BP: 130/76 mmHg, CF:78 bpm.

Biopsies were taken from the adrenal nodule. Histological examination revealed adrenocortical cancer. Ki-67 expression was 8%. Immunohistochemistry for most markers was negative. Unfortunately, due to the presence of necrotic areas, no stains for ALK1, PR, CD34, CD117, Ki-67 could be interpreted.

Case control

We have screened the medical records of 22 cases of incidentaloma of the adrenal gland, found over a period of 8 years (2007-2014). The previously mentioned case of adrenocortical cancer was excluded. Six out of these 22 cases were found to be lymphomatous, all of which were represented in the posterior group (12 cases).

Conclusion

The difficulty in predicting aggressive tumour behaviour of phaeochromocytomas remains a major challenge.

Phaeochromocytoma and paragangliomas (PH/PG) are rare neuroendocrine tumours. Prediction of aggressive tumour behaviour remains a major challenge. The Phaeochromocytoma of the Adrenal gland Scaled Score (PASS) is used to separate benign from malignant lesions with a score > 4 showing potential for biologically aggressive behaviour. DOI: 10.1530/endoabs.49.EP123

A 24 year old man was admitted by the Surgeons with left sided abdominal pain. He was febrile and tachycardic and found to have raised inflammatory markers. Abdominal CT scan revealed a 6 cm left adrenal haemorrhage with no evidence of an underlying lesion. Initial endocrine investigations were unremarkable for Cushings, COn’s and adrenal insufficiency. Normetanephrine levels were high but settled subsequently. He had a coagulopathy and evidence of reactivation of EB virus. He had a past history of Multiple sclerosis treated eighteen months previously with Alemtuzumab.

He remained febrile and developed acute kidney injury. His symptoms and signs fitted the criteria for haemophagocytic lymphohistiocytosis (HLH), confirmed on bone marrow biopsy. His coagulopathy was due to antibodies to factor VIII (acquired haemophilia) and he developed autoimmune thyroiditis requiring Thyroxine replacement. His HLH was successfully treated with steroids and Rituximab. We think Alemtuzumab treatment had induced the autoimmune disorders (his coagulopathy and thyroid disease), as well as reactivating EB virus. The combination of coagulopathy and EB viral infection may have caused his adrenal haemorrhage. Endocrinologists should be aware of the wide spectrum of autoimmune disorders that can be precipitated by monoclonal antibody treatment.

DOI: 10.1530/endoabs.49.EP124

A 55-years old woman presented with an incidental left adrenal mass of 36mm discovered on an abdominal ultrasound. As sole background she underwent resective surgery of an ovarian serous cyst. She denied symptoms like flushing, headache, diaphoresis or palpitations. Physical examination was irrelevant. BP: 130/76 mmHg, CF:78 bpm.

Fractionated metanephrines and catecholamines in a 24-hour urine specimen, sodium and potassium levels, 24-hour urinary free cortisol, adrenocorticotropic hormone, aldosterone/plasma renin plasma ratio and dehydroepiandrosterone sulfate were normal.

Abdominal computed tomography showed an heterogeneous left adrenal gland and multiple nodes in locations such as subdiaphragmatic region, celiac trunk, gastrohepatic ligament, splenic hilum and retroperitoneal area, most of them with the presence of central necrosis.

Additionally axillary and paratracheal nodes were found, and also lungs nodules less than 5mm in diameter were described. PET F-18 FDG scan identified an hypodense centrum area suggestive of necrosis into the left adrenal. A tomography guided biopsy only detected necrotic cells. Finally a left adrenalectomy was performed and histopathological study revealed a diffuse large B-Cell non-Hodgkin’s lymphoma. The patient was started on chemotherapy with a successful response.

Conclusion

Biopsy could be necessary in the differential diagnosis of necrotic adrenal masses even when lymph nodes are present.

The case of adrenal incidentaloma due to unrecognized nonclassic congenital adrenal hyperplasia
Milina Tancic-Gagic, Miomira Ivovic, Ljiljana Marina, Zorana Arizanovic, Zorana Stojanovic, Aleksandra Kendereski & Svetlana Vujovic
Faculty of Medicine, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, University of Belgrade, Belgrade, Serbia.

Introduction
A rare cause of adrenal incidentaloma is congenital adrenal hyperplasia (CAH). Nonclassic CAH is one of the most frequent autosomal recessive disorders. Most cases of nonclassic CAH are never diagnosed due to very mild symptoms. Case report
A 62-year-old woman admitted at our Department for right adrenal incidentaloma sized 39 x 34 x 38 mm confirmed by MRI. She was asymptomatic. Her past medical history included stable hypertension, euthyroid Hashimoto thyroiditis, uterine leiomyoma, varicos vein surgery and pulmonary embolism. Menarche occurred at the age of 18, and the monthly menstrual cycle continued until the menopause at the age of 51. She had a miscarriage and three failed in vitro fertilisation attempts. Upon physical examination clitoromegaly was present. Endocrine assessment for excess of cortisol, catecholeamine and aldosterone concluded that the adrenal mass was hormonally non-functioning. ACTH level was normal, 17-hydroxyprogesterone, total testosterone, androstenedione and progesterone were elevated: 26 nmol/l, 3.4 nmol/l, 8.5 ng/ml, 16.2 nmol/l, respectively. A 0.25-mg intravenous ACTH-stimulation level of cortisol (341/347/402) and 17-hydroxypregesterone (29/51) showed partial cortisol insufficiency and nonclassic CAH. After informed consent molecular genetic study for CAH was conducted. Our patient was found to be a heterozygote with two mutations in the CYP21A2 gene: p.P30L and I2G, that verified the diagnosis of nonclassic CAH. In order to prevent adrenal insufficiency Hydrocortisone was advised in a case of surgical procedures or illness. During the 2 year follow ups there were no changes in either clinical and biochemical presentations or in repeated abdominal MRI examinations.
Conclusion
Undiagnosed nonclassic CAH is the cause of miscarriage, infertility and adrenal incidentaloma in our patient. 17-hydroxypregesterone would be determined in all patients with infertility or adrenal incidentaloma.

EP128
DOC secreting adrenal adenoma, a rare cause of hypertension
Miguel Paja, Maddalen Dublang, Alba Zabalegui, Cristina Arrizabalaga, Amalia Expósito & Javier Espiga
Hospital Universitario de Basurto, Bilbao, Vizcaya, Spain.

Secondary endocrine hypertension affects around 10% of all hypertensive population, most frequently primary aldosteronism (PA). Less frequent forms of adrenal hypertension include pharmocochromocytomas and other causes of mineralocorticoid excess than PA; featuring suppressed renin without excess of aldosterone. Featuring. We present a 29-year-old woman with difficult to control hypertension diagnosed two years before and poor response to ACEI and ARB treatment. She was referred for study and treatment. She had a normal appearance, without Cushing’s stigmata, overweight nor clinical suspect of pheochromocytoma. She had not noticed hirsuitism and maintained regular menstrual cycles. Biochemical study was normal except for slightly lower potassium (3.48 mmol/l). Hormonal study showed suppressed renin activity (<0.2 ng/ml per h), with normal to low aldosterone (7.3 ng/dl), normal urinary metanephrines and normal plasma ACTH (34.5 pg/ml). Abdominal CT revealed a well-defined heterogenous and much vascularized right adrenal mass of 6 cm in diameter. Deoxycorticosterone (DOC) measured in previous stored sample was 237.9 ng/dl (normal < 15 ng/dl) with normal deoxycorticosterone (4.5 mg/ml; NV < 7.2), testosterone, DHEAS and plumatic and urinary cortisol. Open right adrenalectomy was performed due to the size and suspicion of malignancy. On light microscopic examination, the tumour was an adenoma of 6.5 cm not encapsulated, composed of cells with clear and eosinophilic cytoplasm and large nuclei without mitosis nor necrosis. Weiss’s criteria classified it as adrenocortical adenoma. Postoperatively, DOC level fell to 7.1 ng/dl and blood pressure and potassium normalized.

Conclusion
DOC-producing adrenal neoplasm are exceptionally reported, and they are usually malignant tumours. They should be suspected in the presence of adrenal tumours with supressed renin but inappropriate low aldosterone, not suggesting PA. Early diagnosis can be very important because malignancy is the rule in this peculiar pathology.

EP129
Aldosterone-producing adrenocortical carcinoma and alteration of secretion pattern on recurrence: a case report
Joana Lima Ferreira, Ana Paula Marques, Carlos Sottomayor & Vitor Valente
Hospital Pedro Hispano, ULS Matosinhos, Portugal.

Introduction
Adrenocortical carcinoma (ACC) is a rare neoplasm with a variable but overall poor prognosis. The presentation is heterogeneous usually with mass effect and less often with evidence of hormonal secretion. About half of cases the tumors are hormonally active most commonly with cortisol secretion followed by sexual hormones production, being rare the aldosterone secretion.
Case report
A 41-year-old male presented with hypertensive crisis and marked hypokalemia. A primary hyperaldosteronism was diagnosed and Computer Tomography (CT) showed a 9 cm suspicious adrenal mass. The patient started on spironolactone and underwent an open adrenalectomy. A total resection was done (R0) and it was a 10 cm adrenal carcinoma, Weiss score 5, Ki67 30% and stage II ENSAT. There was clinical and biochemical normalisation and at 9 months CT didn’t show any recurrence. Due to high risk carcinoma therapy with mitotane was proposed, however the patient refused and left follow-up. 30 months after surgery, he was admitted to the Emergency Department for adrenal carcinoma relapse and disseminated metastatic disease with simultaneous secretion of aldosterone and cortisol. He started on chemotherapy with EDP-M (etoposide, doxorubicin, cisplatin and mitotane). Despite initial favorable course, the patient got worse with disease progression, culminating in death 44 months after the diagnosis.

Discussion
The management of ACC is challenging. Surgery is crucial for treatment and mitotane is important as an adjuvant therapy, as a chemotherapy agent and also to control the hormonal secretion. We report a case of an aldosterone-producing ACC, an extremely rare cause of primary hyperaldosteronism. Even rarer was the change on secretion profile throughout disease evolution with multiple steroid production. The hormonal profile should be carefully investigated in an ACC and the possibility of multiple combined hormonal secretion or the shift of the profile secretion should be considered.

Congenital adrenal hyperplasia: hazards of non-compliance with treatment!
Muzhar Dalvi & Faisal Dalvi
1Al Noor Hospital, Abu Dhabi, United Arab Emirates; 2Aster Medical Centre, Dubai, United Arab Emirates.

A 30-year-old male presented to emergency with history of palpitations for 6 months. At birth he was diagnosed with salt-losing congenital adrenal hyperplasia (female pseudohermaphrodite) and commenced on steroid therapy. He also underwent corrective surgery. He needed both fludrocortisone and hydrocortisone. At age 17, he visited urology because of bilateral testicular enlargement. On examination he had normal secondary sexual features, but his testicles felt hard and four times the normal size. His serum testosterone level was 50.4 nmol/l (10–38 nmol/l), 17-OH-progesterone 142 nmol/l (<13 nmol/l) and ACTH (corticotrophin) of 139 ng/l (0–50 ng/l), clearly indicating non-compliance with treatment. He had bilateral orchidectomy. Upon pathologic review, these lesions were most consistent with testicular tumors of the adenogenital syndrome. Patient continued to default at clinic appointments. At age 26, he presented to the surgeon with increasing abdominal girth and abdominal pain. CT of the abdomen demonstrated very low-density adrenal masses (18 x 11 cm on the left side and 8 x 4.5 cm on the right side). Blood work up showed high 17-OH-progesterone indicating inadequate suppression with glucocorticoids partly due to non-compliance. As these adenomas was new onset and there was a possibility of adrenocortical cancer the patient underwent laparoscopic bilateral adrenalectomy. The final histology to be consistent with adrenal myelolipomas. Hydrocortisone dose
was doubled and fludrocortisone 100 mcg/day was started. Now at age 30, he presented with history of palpitations and dizziness. He had sinus tachycardia. In ECG (HR 120/min). Blood work up: Na 130 mmol/l (135–145 mmol/l), K+ 5.33 mmol/l (3.5–5.1 mmol/l). Plasma renin 100 µIU/ml (<40 µIU/ml). This indicated under replacement. He was clearly tachycardic because of volume depletion. His compliance was enforced. Within 6 weeks his heart rate normalised with normalisation of renin levels. Persons with CAH are at increased risk of developing adrenal myelolipomas, testicular adrenal rest tumours particularly if their CAH is poorly controlled.

In the 24-h holter study, blood pressure values (using alpha-methyldopa) were found to be 134/92 mmHg (sleep), 24-hour urinary levels of catecholamine and metabolites were significantly higher than normal ranges; noradrenaline was 787.99 µg/24 h, dopamine 3635.43 µg/24 h, normetanephrine 1605.31 µg/24 h. MR imaging revealed a heterogeneous lesion (49 × 37 mm) in the left adrenal gland. Because of the early stage of pregnancy growth retardation, medical abortion was applied at the 27th gestational-week. Pheochromocytoma is a very rare cause of hypertension in pregnancy however, early detection are crucial because of the increased risk of maternal-fetal mortality. Therefore, in cases of high blood pressure which can not be explained by gestational hypertension, it is necessary to carefully evaluate other secondary causes such as pheochromocytoma. The most suitable period for the operation is the second-trimester. Surgical approach was used and no complication related to the operation occurred in our case. However, it was thought that the outcome of fetal loss due to developmental delay was related to the adverse effects of circulatory factors due to long-term illness in the patient. The fact that the patient could not be examined in the pre-pregnancy period and probably the prolongation of the duration of the illness resulted in a negative result. Especially in women of childbearing age, the importance of hypertension in terms of maternal and fetal outcomes is emphasized by this case report.

Adrenal insufficiency due to both hemorrhage and thrombosis related with primary antiphospholipid syndrome

Buket Bicero, Pinar Sisman, Soner Cander, Ozen Oz Gul & Canan Ersoy

1Uludag University Medical School, Department of Internal Medicine, Bursa, Turkey; 2Harakani State Hospital, Endocrinology and Metabolism Clinic, Kars, Turkey; 3Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Background

Antiphospholipid syndrome (APS) is characterized by venous or arterial thrombosis and/or an adverse pregnancy outcome in the presence of persistent laboratory evidence of antiphospholipid antibodies. Loss of adrenal function due to bilateral adrenal vein thrombosis, resulting in hemorrhagic infarction, may occur in association with APS.

Case presentation

We present the case of a 45-year-old woman with APS diagnosis since she was 37, with history of multiple thrombotic events (deep vein thrombosis, sigmoid sinus thrombosis, spontaneous abortion, adrenal hematoma and pulmonary embolism). She was hospitalized for adrenal hematoma under anticoagulant therapy with warfarin. The basal adrenal function tests revealed morning serum cortisol 0.7 µg/dl (reference range 3.7–19.4) and ACTH 345 pg/ml (5–46). Abdominal CT showed nodular lesion with 55 HU density (29 × 27 mm) suggestive of adrenal hematoma in the left adrenal gland; right gland is thickened. Adrenal insufficiency was associated with both hematoma in the left adrenal gland and thrombosis in the right gland. The patient was discharged under corticosteroid treatment and low molecular weight heparin (LMWH). After being discharged, warfarin was started again and she was admitted in the emergency department with dyspnea and pleuritic chest pain. Initial analytical study revealed INR (2.26), hypoxemia (PO2/64 mmHg) and hypocapnia (32 mmHg). She was restarted on therapy with LMWH. Further study showed deep vein thrombosis in right lower extremity. The patient was discharged after venacava filter replacement.

Discussion

The recurrence rate of thrombotic events among patients with APS is highly variable among studies, with an annual recurrent thrombosis risk ranging from 5 to 12%. However adrenal involvement has been reported in 13% of cases of catastrophic APS. In patients with antiphospholipid antibody syndrome, adrenal insufficiency is often seen with bilateral adrenal thrombosis, although rarely in some patients an adrenal gland hemorrhage may occur with other adrenal gland hematomas.

**Recurrent pheochromocytoma – Iatrogenic**

Samantha Anandappa, Jeya Navaratnam, David Fish, Brendon Conry, Sithara Perera & Jesse Kumar

Maidstone and Tunbridge Wells NHS Trust, Kent, UK.

Pheochromocytoma is a common endocrinological diagnosis with an incidence of 1–2 per 10 000 people. Prompt evaluation and treatment leads to an excellent prognosis. Recurrence has been documented rarely (with literature reporting possibility of up to 8 years delay) and causes are generally attributed to inherited mutations, seeding during surgery or malignancy. Malignancy rates have been variable from 10% depending on site and mutations. In addition, the definition of malignant pheochromocytoma-paraganglioma is not always clear as there is no combination of clinical, histopathologic, or biochemical features to reliably predict biologic behaviour. In general; pathologic evaluations provide little prognostic insight to predict risk of recurrences or metastases reliably. We present a case that demonstrates relapse as a result of possible seeding from original laparoscopic adrenalectomy as one of the factors. Thus, pre-operative features that potentially make the tumour a high risk for recurrence should be identified and aid in creating an individualised management plan. Aspects that have been recognised to be directly related to outcome such as the size of the tumour, underlying conditions such as MEN 2A/B and neurofibromatosis, the site of the tumour and anatomical ease of surgical intervention. This case highlights the importance of the recognition of such factors & multi-disciplinary team input, to prevent recurrences which have a significant effect on long-term cure and prognosis.

**An association of adrenal ganglioneuroma, Addison’s disease and Mediterranean fever: a case report**

Nabil Kh, Houcem Mrabet, Mouna Elleuch, Mouna Ammar, Faten Haj Kacem & Mohammed Abid

Department of Endocrinology, Hedi Cheker University Hospital, Sfax, Tunisia.

Introduction

Ganglioneuroma is a rare benign tumour arising from neural crest sympathogonia. It is usually asymptomatic and non functional. An association between ganglioneuroma and genetic or autoimmune diseases such as Addison’s disease or Mediterranean fever has never been described.

Case description

We report the case of a 24-year-old woman presenting with paroxysmal abdominal pain with loss of weight and no fever. Physical examination along with biological and hormonal explorations were normal. CT scan showed a solid tumour of the right adrenal gland, measuring 50×31 mm, with no sign of malignancy and a moderate ascites, so the patient underwent adrenalectomy. Anatomopathological examination of the adrenal gland confirmed the presence of a ganglioneuroma, and the patient presented an adrenal insufficiency 4 days after the surgery. Addison’s disease was confirmed with positive anti-adrenal antibodies, with anti-21-hydroxylase at 2866.9 U/ml and she received corticosteroid replacement therapy. The patient continued to have recurrent abdominal pain, fever and ascites. A Mediterranean fever was suspected, and she was put on colchicine 1 mg per day, with improvement of paroxysmal abdominal pain. Genetic confirmation is underway.

Conclusion

We report for the first time an association between ganglioneuroma, Addison’s disease and Mediterranean fever whose clinical features can be confused. A possible underlying genetic mechanism can be suspected rather than just a random association.

**Adrenal carcinoma after ovariectomy. Report of a case**

Eleni Xanthakou, Panagiotis Spyroupolos, Panagiotis Athanassiou & Iliergena Kostoglou-Athanassiou

Endocrine Abstracts (2017) Vol 49

Adrenocortical tumorigenesis has been observed in mice. It is speculated to be gonadotropin dependent. In particular LH receptors appear to be found within such adrenal tumors in high density and elevated LH levels may be related to adrenal tumorigenesis. The aim was to describe the case of a patient who after ovariectomy developed a large malignant adrenal tumor. A 50 years female, aged 42 presented with uterine leiomyomas. She was treated by surgical excision of the uterus along with ovariectomy. Subsequently, she refused to be treated with estrogens, developing however severe postmenopausal symptoms: At the age of 50 she presented with musculoskeletal symptoms affecting the spine, both knees and the left shoulder. A CT scan of the abdomen was performed showing a large mass originating from the left adrenal gland. An MRI was performed and the patient was treated by left adrenalectomy. The adrenal tumor was malignant, measuring 6×6×5 cm, androgen receptor positive and progesterone receptor positive in some areas. The patient recovered. On follow up 6 months later she was free of any malignant disease. She developed Hashimoto’s thyroiditis, antithyroglobulin antibodies being 425 IU/ml (normal values <115 IU/ml) and antimicrosomal antibodies being 213 IU/ml (normal values <34 IU/ml), while TSH was 3.9 IU/L (0.3–4.2 IU/L). In conclusion, the case of a patient is presented who developed a large adrenal tumor following ovariectomy. Adrenal tumorigenesis has been observed in mice following ovariectomy. It is believed to be related to LH stimulation by elevated LH levels, LH receptors having been observed within the adrenal tumors. In mice tumorigenesis may be prevented by the administration of agents lowering gonadotropin levels (Rahman et al, Reprod Biol 2001). It may be that in such cases of premature ovarian failure following surgical ovariectomy, thought should be given to possible treatment aiming at low gonadotropin levels.

**ACTH-independent Cushing syndrome with concomitant parathyroid carcinoma**

Georgiana Alexandra Smarandoi, Raluca Trifanescu, Anda Carageaheorgheopol, Andra Dumitrascul, Sorina Schipor & Catalina Poiana

1. C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; 2. Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Introduction

The incidence of parathyroid carcinoma in primary hyperparathyroidism is less than 1% and the association with ACTH-independent Cushing syndrome is very rare.

Case report

A 40-year-old female was admitted for weight gain and reddish-purple striae. One month earlier she had a ½ parathyroidectomy for primary hyperparathyroidism with histopathological examination showing a parathyroid carcinoma and two parathyroid adenomas. She also had a history of deep vein thrombosis. She had no family history of endocrinopathies. The physical exam revealed a positive Chvostek sign, facio-troncular obesity, reddish-purple striae and grade I hypertension. Biochemical assessment revealed hypocalcaemia (5.75 mg/dl) and diabetes mellitus. Hormonal assessment revealed hypoparathyroidism (PTH = 12.45 pg/ml), no catecholamine excess, normal prolactin level. High levels of urine free cortisol (415.91 μg/dl) and positive long low dose DST (2mg/day×2 days) (12.29 μg/dl) confirmed the clinical suspicion of Cushing syndrome. ACTH levels were suppressed. Chromogranin A levels were normal. We performed a pituitary MRI and a CT of the neck, thorax and abdomen that showed bilateral adrenal macronodular hyperplasia with no other suspicious masses including pituitary adenomas. DXA evaluation showed osteoporosis for which she later received bisphosphonate therapy. A bilateral adrenalectomy was performed and subsequent mineralocorticoid and glucocorticoid replacement therapy was initiated. Genetic test for MEN1 syndrome is pending. The hyperparathyroidism relapsed 18 months after the parathyroidectomy. Calcium levels remained in the high normal range during monitoring with normal renal function and the last scintigraphy and CT scan showed an adenoma of the remaining parathyroid with no sign of local recurrence of the parathyroid carcinoma. Periodic follow-up also revealed a pituitary microadenoma with minimally raised prolactin and a thymic lesion that were stationary over the last 7 years of monitoring.

DOI: 10.1530/endoabs.49.EP137
In patients with primary hyperparathyroidism special attention should be given to signs of other endocrinopathies as hyperparathyroidism could be the first manifestation of a MEN syndrome.

Incidental adrenal cyst: a case report

Aribi Yamina, Bensaleh Meriem, Brakni Lila, Khaldi Hassiba, Sellal Zoubir 
& Ould Kablia Samia

Central Hospital of the Army, Algiers, Algeria.

Introduction

Cystic adrenal lesions (CAL) are a rare diseases representing 5.4–6.0% of all pathological changes affecting adrenal glands. In about one-third of the cases, lesions are detected incidentally; in the remaining two-thirds cysts lesions are symptomatic, which is typically related to their large size or rapid growth. Although CAL are usually benign, since malignancy is reported in up to 7% of all CAL. Management algorithms for CAL vary and are controversial because of the overall rarity of such lesions.

Case report

We describe a case of a 29-year-old man who presented with abdominal pain. The computed tomography of the upper abdomen revealing the presence of a 4-cm simple cyst originating from the left adrenal. All serological and hormonal secretion tests were negative. So the final diagnosis was a simple left adrenal cyst; 8 months later, abdominal ultrasound follow-up revealed adequate cyst shrinkage down to 2.8 x 6.9 cm. The patient remains symptom free to date.

Discussion

Surgical excision of adrenal cysts is indicated by the presence of symptoms, suspicion of malignancy, or the detection of a functioning adrenal cyst. Cysts may coexist with primary and metastatic adrenal tumours. Malignancy of the cyst is found in 7% of all affected patients. Adrenocortical and adrenomedullar hyperfunction is accompanied by adrenal cysts in 15% of cases. What is more, adrenal cysts accompany approximately 7% of primary and metastatic cancerous processes, and in 0.5% of cases they are of parasitic origin and their clinical management remains controversial. However, surgical intervention is not recommended for asymptomatic patients with incidental cysts, for the fact that the pathological data of our series revealed no malignant cases. Patients after surgical resection should be followed up closely especially in functional cysts and when histopathology showed cystic tumor.

Gynecomastia in men: A rare case of adrenal feminizing tumors

Vitória Duarte, David Verissimo, Dolores Passos, Filipa Serra, João Silva, Luís Lopes, J.J. Castro & Mafalda Marcelino

Hospital das Forças Armadas, Lisboa, Portugal.

Estrogen-producing adrenal gland tumors (EPAGT) are extremely rare, accounting for only 1–2% of all adrenal tumors. They are most commonly observed in men or in children, and are unusual in women. They are almost always malignant even if they seem benign at presentation, and most of them have a poor prognosis. We present a case of a 71-year-old man with painful bilateral gynecomastia, without galactorrhea, over 4 months. Markedly elevated plasma estradiol levels were found (161.7 ng/l; normal 15.5–63.3) with low LH and FSH values. All other parameters were within normal range (b-HCG, PRL, TSH, FT4, total testosterone, SHBG, cortisol, ACTH, DHEA SO4, delta-4-androstenedione, 17OHPREG, fractionated metanephrines, cromogranine-A). Echographic images and mammography showed bilateral mammary gland hypertrophy excluding any nodules. CT abdominal scan indicated a large retroperitoneal mass measuring 14 x 8 cm with posterior and inferior deviation of the left kidney, with heterogeneous contrast uptake. It appeared to be a retroperitoneal tumor independent of any other retroperitoneal organ. To clarify its etiology, a biopsy was performed. The histology suggested an adrenal cortex tumor. It displayed cell proliferation with abnormal nuclei. Immunohistochemistry was positive for melan A, HMB-45, INHA and focal AE1/AE3. The Ki-67 was around 15%. While it was impossible to distinguish between adenoma and carcinoma, the images were suggestive of malignancy. Although there were no signs of metastasis in toraco-abdomino-pelvic-CT, a PET-scan is arranged to exclude some other lesions. Gynecomastia in adult males is usually related with drugs and systemic or endocrine diseases. However, it is less often related with rare conditions, such as the testicular tumor of Leydig cells and the rarest adrenal feminizing tumor. Surgery is the main option for EPAGT, nevertheless the prognosis is very poor.

Introduction

Adrenocortical carcinoma (ACC) is a rare and aggressive endocrine malignancy with a poor prognosis. Hormone-secretting ACC appear with manifestations of virilization, feminization or Cushing syndrome.

Case Report

A 63-year-old woman with no pathological history of referral was referred to Endocrinology evaluation with an history of deepening of the voice since 1-year ago, as well as hair loss and facial and abdominal hirsutism with 6-month evolution. The analytical study revealed the following results: total testosterone 6.03 (Normal Range (NR) 0.06–0.82) ng/ml, delta-4 androstenedione >10.00 (NR 0.30–2.99) ng/ml, DHEA-S 545.8 (NR 18.9–205) µg/dl, 17-OH-Progesterone 6.32 ng/ml, SHBG 71.4 (NR 14.1–68.9) nmol/l, FSH 7.96 ng/ml, LH 5.96 ng/ml Estradiol 123.8 pg/ml; normal urinary catecholamines and metanephrines; normal renin and aldosterone values; ACTH 2.1 ng/l (NR <63.3), urinary free cortical 353.6 (NR 36–137) µg/day, late-night salivary cortisol 0.499 (NR <0.32) µg/dl and plasma cortisol after 1-mg overnight dexamethasone suppression test 13.3 µg/dl (NR <1.8). She performed an abdominal MRI with documentation of a massive solid tumor lesion with heterogeneous contrast uptake, well delimited and measuring about 13.4 cm in diameter, which was admitted to be dependent on the left adrenal gland. Were identified several hepatic and lung nodularities suggestive of secondary lesions. In a multidisciplinary evaluation, it was decided to perform left adrenalectomy by laparotomy. No ascites or signs of peritoneal carcinomatosis were present. The anatopathological examination revealed an ACC ENSAT stage IV, pT2NxMx, with a modified Weiss score of five and a classic Weiss score of seven. The patient is now proposed for adjuvant chemotherapy with mitotane.

Conclusions

We report a case of an ACC combining hyperandrogenism with Cushin’s syndrome. Hormonal hypersecretion, particularly hypercortisolism, is associated with a worst outcome. Complete tumor removal remains the only potentially curative treatment.

The ovarian origin of hyperandrogenism in the postmenopausal woman with the adrenal adenoma – a case report

Marta Kialka1, Tomasz Milewicz2, Katarzyna Doroszewska1, Sandra Mrozinska2 & Robert Jach3

1Department of Gynecological Endocrinology, Jagiellonian University, Medical College, Cracow, Poland; 2Department of Gynecological Endocrinology, Jagiellonian University, Medical College, Cracow, Poland.
symptoms of defeminization and masculinization. Hormonally active adrenal and ovarian tumors and non-tumor causes must be considered in the differential diagnosis. The authors describe the case of a 77-year-old patient who had hirsutism and reduction of the timbre of the voice. At the beginning she was suspected to have adrenal hyperandrogenism because of the tumor in the adrenal gland. Then adrenalecctomy was conducted but it did not lead to alleviate symptoms. A MRI of the pelvis revealed a change of appendages projection and the patient underwent the total hysterectomy. The normalization of testosterone levels as well as reduction of the symptoms was observed after the operation. Finally, the ovary etiology of hyperandrogenism was confirmed. This case report is an example of difficulties in recognition the etiology of hyperandrogenism.

Secondary autonomic neuropathy in patient with polyglandular autoimmune syndrome type III and type 1 gastric neuroendocrine tumor: a case report

Jekaterina Nagaiceva1, Natalija Fokina2, Karina Levin1, Janis Mednieks1,2
1Latvian University, Riga, Latvia; 2Paul Stradins Clinical University Hospital, Riga, Latvia.

The polyglandular autoimmune syndromes (PAS) are rare disorders characterized as multiple autoimmune-mediated organ failure. PAS III includes chronic autoimmune thyroiditis with type 1 diabetes mellitus or pernicious anemia and/or vitiligo or alopeica and many other organ-specific autoimmune diseases, but never involves adrenal cortex. Several patients with PAS III and associated type 1 gastric neuroendocrine tumor (NET) have already been reported. We report probably the first case of PAS III, type 1 gastric NET and concomitant secondary autonomic failure as the main clinical manifestation. A 65-years-old woman with severe postural and postprandial orthostatic hypotension admitted to the hospital. The orthostasis has been debilitating and gradually has worsened in the past year. She has lost about 25 kg due to postprandial sickness and consequent dietary restrictions. The patient has a history of mild type 2 diabetes mellitus. She has been treated with metformin and her HbA1c has been < 6% during the last 8 years. Diabetes has resolved due to weight loss and the patient has had a good glycomic control without any treatment for the past year. The patient has a history of primary hypothyroidism due to chronic autoimmune thyroiditis. Besides that she has suffered from hair loss with global alopecia over the last decades of life. Initial B12 vitamin deficiency without anemia has been detected. Upper endoscopy was performed, showing multiple gastric polyps. Histological examination revealed chronic atrophic gastritis, hyperplasia of endocrine cells and non-functional NET, Ki-67 = 1%. Numerous gastric polyps have been removed during endoscopy. The patient has been treated with intramuscular B12 vitamin injections with a gradual positive effect on the autonomic dysfunction. Annual endoscopic follow-up and lanreotide injections are recommended to prevent progression and dissemination of the gastric NET.

Insulinoma- from diagnosis to full recovery. Case study

Marcin Lewicki1,2, Magdalena Urbanczuk1,2, Agnieszka Zvolak1,2, Marta Dzidzinska1,2, Monika Lenart-Lipinska1,2 & Jerzy S. Tarach1
1Chair and Department of Epidemiology and Clinical Research Methodology of Medical University of Lublin, Lublin, Poland; 2Department and Clinic of Endocrinology of Medical University of Lublin, Lublin, Poland.

Introduction
Insulinoma is a rare form of a functional neuroendocrine tumor with an estimated incidence at 1–2 new cases per million persons per year. This infrequent endocrinopathy, frequently escaping standard disease course, constitutes a diagnostic challenge for every endocrinologist. Successful surgical resection of the lesion is the only available method that ensures patient’s full recovery.

Case study
53 years old patient with complaints about recurring episodes of hypoglycaemia, without accompanying adrenergic symptoms though, was admitted to Department and Clinic of Endocrinology, Medical University of Lublin. During diagnostic procedures: low glucose levels (ranging from 1.94–3.56 mmol/l) with corresponding inadequately high insulin levels were observed in a prolonged glucose tolerance test, where glucose and insulin concentrations measurements had been carried out every hour. Afterwards supervised 72-h fast was introduced, only to be terminated after just 24 h, due to symptomatic hypoglycaemia (2.28 mmol/l). Insulin levels at the end of fasting remained disproportionately elevated (10.7 mU/l). Based on follow up diagnostic tests we were able to exclude other potential causes of hypoglycemia in the form of adrenal insufficiency and hypothroidism. Abdomen CT scan didn’t reveal any lesions in pancreas whereas abdomen MRI unveiled presence of the tumor, 2 cm in diameter, located in the tail of pancreas. On the 1st of September 2016 patient underwent surgical resection of the pancreas mass. Histologic evaluation confirmed the diagnosis of insulinoma (pNET: G2 insulinoma). Octreoscan and abdomen MRI didn’t indicate a diffuse process. Currently all of the symptoms subsided, the patient doesn’t require any additional treatment.

Conclusions
Insulinomas are neuroendocrine tumors of rare occurrence. The readily available imaging methods rarely allow for a location confirmed diagnosis because of borderline small size of lesions. Persistent hypoglycaemia being the most characteristic symptom facilitates the diagnosis and introduction of proper treatment.

Endocrine Abstracts (2017) Vol 49
Insulinoma masquerading as neurologic disease
Catarina Machado, Patrícia Tavares, Sara Monteiro, Gustavo Rocha & Maria João Oliveira
Centro Hospitalar de Vila Nova de Gaia/Espinho, EPE, Vila Nova de Gaia, Portugal.

Introduction
Insulinomas are the most frequent cause of hypoglycemia and the most common functional endocrine pancreatic tumors. Whipple triad is often present and should alert to the diagnosis.

Case report
A 36-year-old male was admitted in the emergency room with loss of consciousness, diaphoresis and blurred vision, and hypoglycemia (50 mg/dl). The patient recalled recurrent symptoms of diaphoresis, tremors and palpitations, sometimes with loss of consciousness and incontinence of urinary sphincters, for the past 4 months, having been diagnosed with epilepsy and medicated with anticonvulsive drugs. This symptoms were associated with weight gain, occurred before meals and were relieved with eating carbon hydrates. He had no family history of endocrine disease. Prolonged supervised fasting test was applied and led to symptomatic hypoglycemia with hyperinsulinemia (blood glucose 40 mg/dl, plasma insulin 68.7 μU/ml and C-peptide 7.07 ng/ml). Other hormonal studies were normal, rejecting the diagnosis of multiple endocrine neoplasia. He maintained severe hypoglycemia despite glucose fluid administration and nutritional adequate plan, and medical treatment was necessary with octreotide 300 mg/day and diazoxide 900 mg/day. Abdominal magnetic resonance demonstrated a well-defined enhanced lesion in the tail of the pancreas measuring 14 mm. Nodule enucleation was performed by laparoscopy and pathological examination revealed an encapsulated pancreatic mass measuring 17×14×15 mm. Mitotic index was <2 per 10 CGA and proliferation index ki-67 was estimated <2%. Immunohistochemically, tumor cells showed a positive staining for insulin, synaptophysin and chromogranine. Shortly after surgical treatment, glucose level increased to normal range. The patient was discharged without any hypoglycemic symptoms after 7 days.

Conclusion
The diagnosis of insulinoma may be challenging due to its rarity and variable presentation. Other diseases, such as neurologic, may be considered first, but it’s important to contemplate the diagnosis since chronic and severe hypoglycemia can be fatal and the surgery is usually curative.

DOI: 10.1530/endoabs.49.EP145

Endocrine Tumours and Neoplasia

Glucose metabolism abnormalities and insulin resistance are frequent in well differentiated digestive NETs
Ana P Santos1,2, Ana C Santos3, Clara Castro1,2, Luís Raposo2, Isabel Torres1, Rui Henriques4,5, Mariana P Monteiro1 & M Helena Cardoso1,6
1IPO Porto, Porto, Portugal; 2ISPUP/EPI Unit - UP, Porto, Portugal; 3UMIB/ICBAS - UP, Porto, Portugal; 4CHP, Porto, Portugal; 5FMUP - UP, Porto, Portugal; 6IPO Porto, Research Unit, Porto, Portugal; 7EPOP, Porto, Portugal.

Introduction
Incidence of Digestive NETs (DNETs) has increased in the last 40 years. Visceral obesity, metabolic syndrome (MetS) and insulin resistance (IR) have been associated with several types of cancer.

Aim
To evaluate possible associations of obesity, hyperinsulinemia and IR with well-differentiated (WD) DNETs through a case control study.

Materials and methods
Ninety-six patients with gastrointestinal (75.0%) and pNET (22.9%) WD DNETs were recruited from Endocrine Tumours Clinic of IPO Porto and cross-matched with a control group (n = 96) from PROMETS, a nationwide epidemiological study designed to evaluate the MetS prevalence in the general population, pair-matched by age, gender and place of birth. Hyperinsulinemia and IR were defined according to Matsuda’s classification. WD DNETs were classified according to primary tumour localisation, hormonal secretion, TNM stage and WHO grading. Results MetS was present in 45.8% of WD DNETs. According to grading, 66.7% were G1 and 27.1% were G2 tumours. The disease was localized in 31.3%, locoregional in 16.7% and disseminated in 43.8%. Both patients and controls had high mean body weight (26.9 vs 27.2 kg/m², P = 0.645). No significant differences were found between the two groups for waist circumference, Fasting Plasma Insulin (FPI) and HOMA-IR (P = 0.236; P = 0.372 and P = 0.274, respectively). Median Fasting Plasma Glucose (FPG) and Impaired Fasting Glucose (IFG) frequency were higher in WD DNETs (P < 0.001 and P = 0.013, respectively). FPG ≥ 100 mg/dl and HOMA-IR ≥ 5 were associated with a higher risk for WD DNETs (OR 4.3 (95%CI 2.3–8.2, P < 0.001); OR 4.1 (95%CI 1.2–13.5, P = 0.014), respectively). When anthropometric and metabolic parameters are compared, there was no difference between somatostatin analogues users and non-users.

Conclusion
Association of glucose metabolism abnormalities and IR with WD DNETs confirmation can open new perspectives for prevention and treatment, through modifying lifestyle and insulin sensitizers use.

Clinical and hormonal characteristics of adrenal incidentalomas
Rym Belaid, Ibtisssem Oueslati, Wafa Mimita, Karima Khiairi, Nadia Mchirgui & Nejib Ben Abdallah
Department of Endocrinology, Charles Nicolle Hospital, Tunis, Tunisia.

Introduction
Widespread use of abdominal imaging has led to the identification of an increasing number of adrenal incidentalomas (AI) in the last decades. Causes of these adrenal masses are multiple.

Aim
The aim of this study was to investigate the clinical and hormonal characteristics of AI.

Materials and methods
The study was a retrospective monocentric analysis of 44 patients with AI who underwent radiographic and endocrine evaluations.

Results
The mean age was 59.25 ± 10.3 years and the sex ratio (F/M) was 1.3. Arterial hypertension was diagnosed in 27 patients (61.4%), obesity or overweight in 84%, diabetes in 18 patients (40.9%), dyslipidemia in 7 patients (15.9%). Five patients had an extra-adrenal tumor (11.4%). First diagnostic procedure was computed tomography (CT) in 63.6%, abdominal ultrasonography in 31.8% and magnetic resonance imaging in 4.5%. Regarding the location of the masses: 36.4% were in epigastralgia in 13.6%, thorax pathology in 6.8%, rheumatologic causes in 6.8%. The mean age was 59.25 ± 10.3 years and the sex ratio (F/M) was 1.3. Arterial hypertension was diagnosed in 27 patients (61.4%), obesity or overweight in 84%, diabetes in 18 patients (40.9%), dyslipidemia in 7 patients (15.9%). **Pituitary insufficiency, the beginning of a diagnostic journey**

Amalia Ioana Arhire1, Lumnita Cima1,2, Simona Petrescu1,2, Miron Adrian1,2, Florin Andrei1 & Carmen Gabriela Barbu1,2

1Elias Hospital, Bucharest, Romania; 2Carol Davila’ University of Medicine and Pharmacy, Bucharest, Romania.

Introduction

We report a case of a pituitary insufficiency apparently resistant to treatment. Case report

A 74 year old patient was admitted through the ER in our department for a recently discovered pituitary macroadenoma. His general condition was poor in spite of the initiation of corticotherapy. Evaluation: Smoker, with no significant medical history, the BP: 100/60 mmHg, no orthostatic hypotension, disoriented, confused, with moderately altered general state and no visual deficit. Biologically: normal ionogram, TSH: 0.076 mIU/l, FT3: 0.767 ng/dl, total T4 <40 ng/dl, prolactin: 21.5 ng/l, IGF1: 84.8 ng/l (low). He had leukocytosis, high neutrophils, but normal markers of inflammation. No causes of infection were found, but the clinical condition worsened in the next 2 days despite an i.v. treatment with Hydrocortisone and oral Levothryoxine. Additional imaging studies showed an adenoma of 3.4/2.8/3.3 cm, with a mass effect on the optic chiasm, multiple secondary lesions in the upper and infratentorial regions at the cerebral MRI. During the neck ultrasound we found a multinodular goiter with a large nodule of 1.53/1.33 cm with multiple large pathological latero-cervical adenopathies. The thoraco-abdomino-pelvic CT found a large pulmonary mass of 45/49 mm in the left lung, some osteolytic lesions in the right ribs and body of L5, a large cephalic pancreatic lesion of 35/24 mm and bilateral adrenal metastatic lesions. The ¹¹¹Indium-oxine scan showed multiple skeletal metastatic lesions. The lab values at the admission were: hemoglobin: 89 g/l (80–100), hematocrit 27% (37–47), leucocytes 21.4 10⁹/l (4–10), neutrophils 20.8 10⁹/l (2–7), lymphocytes 1.1 10⁹/l (1.5–4.5), eosinophils 0.5 10⁹/l (0–1), monocytes 0.7 10⁹/l (0.2–1), thrombocytes 100 10⁹/l (150–400). The biochemistry tests showed: creatinine: 1.83 mg/dl (0.6–1.2), urea: 49.5 mg/dl (7–25), bilirubin: 0.9 mg/dl (0.2–1.2), sodium: 134.2 mEq/l (135–145), potassium: 5.0 mEq/l (3.5–5.5), calcium: 9.7 mg/dl (8.5–10.1), magnesium: 1.7 mg/dl (1.6–2.6), phosphates: 4.5 mg/dl (2.5–4.4), total protein: 6.8 g/dl (6.5–8.2), albumine: 3.6 g/dl (3.5–5.5), globulines: 3.2 g/dl (2.3–3.7), alkaline phosphatase: 181 U/l (40–160), alanine transaminase: 94 U/l (0–65), aspartate transaminase: 178 U/l (0–46), lactic dehydrogenase: 943 U/l (200–400), cholesterol: 215 mg/dl (140–240), triglycerides: 101 mg/dl (40–175). The endocrine tests showed: T3: 2.2 ng/dl (2.6–4.2), T4: 7.9 ng/dl (7.0–13.0), TSH: 0.076 mIU/l, GH: 13 ng/l (1–10), prolactin: 21.5 ng/l, IGF1: 84.8 ng/l (low). Urinary tests showed: proteinuria: a trace, urinary ketones: negative, glucosuria: negative.

Conclusion

The pituitary insufficiency in normally a benign condition which responds to treatment and has a favourable outcome; if this is not the case we must search for additional causes of poor responders. DOI: 10.1530/endoabs.49.EP148

**Thyroid carcinoma in multiple endocrine neoplasia type 1**

Khelif Nour El Houla1,2, Loudjidi Lotfi3, Meghelli Sidi Med1,2 & Berber Necir1,2

1Abou Bekr Belkaid University, Tlemcen, Algeria; 2University Hospital of Tlemcen, Tlemcen, Algeria.

Introduction

Multiple endocrine neoplasia type 1 (MEN1) is a cancer syndrome characterized by the development of neuroendocrine tumors of the pituitary gland, parathyroid and pancreas, and other neoplasms such as adenocortical tumors and carcinoma. Observation

We report the case of a 70-year-old woman with acromegaly that diagnosed 15 years ago, in relation with pituitary macroadenoma (30×25 mm) invading the left cavernous sinus and in contact with the third ventricle without endocrine or ophthalmological repercussions. The impact of acromegaly is diabetes mellitus treated with insulin complicated by retinopathy. The visceral assessment revealed a hypertension with cardiomegaly and a multinodular goiter diagnosed 2 years after the discovery of the acromegaly. Refusing pituitary surgery and radiotherapy, the patient remains uncontrolled with maximal dose of somatostatin analogues and dopaminergic agonists, the Gh level is 125.11 in OG vs 18.7 in RG P<0.005. The patient had a CgA assessment at diagnosis. Median CgA value was 179 μg/l (72–304). At the end of follow up, 88% in OG of patients had no change in tumor size, the rest had tumor growth <20%; In OG no PNETs-I resection were needed, and none of the patients metastatized or died because of PNETs-I in this group. Conclusions

Non functioning PNETs-I is increasing in incidence in our center. After almost 36 months of follow up, no patients had significant growth, developed metastases and neither of them died from PNETs-I. In OG, active surveillance is safe in selected PNETs-I patients. We need prospective multicentric studies to confirm our results. DOI: 10.1530/endoabs.49.EP149

**Small pancreatic neuroendocrine incidentalomas: an observational prospective study**

C Villalona1, J Busquets2, L San Martin1, A Planas1, N Peladez3, J Fabregat1, A Teule1 & I Peiro6

1Department of Endocrinology, Hospital Universitari de Bellvitge (HUB), l’Hospitalet de Llobregat, Spain; 2Department of Surgery, HUB, l’Hospitalet de Llobregat, Spain; 3Department of Oncology, Institut Català d’Oncologia (ICO), l’Hospitalet de Llobregat, Spain; 4Clinical Nutrition Unit, ICO, l’Hospitalet de Llobregat, Spain.

Background

Diagnosis of small pancreatic neuroendocrine incidentalomas (PNETs-I) is increasing during last years and often their management remains unclear. Objective

To describe our experience with patients with PNETs-I in our institution. Methods

Since March 2000, patients with non-functioning PNETs-I ≤30 mm were evaluated in our center, prospectively. A descriptive analysis of all patients and a comparative study between observational group (OG) vs resection group (RG) was made. Results

Forty-six patients were evaluated: 36 in OG and 10 in RG. Median follow up (months) was 35.9 in OG and 76.6 in RG. Most of patients (69.9%) were diagnosed in the last 6 years. Mean age (years): 69.5 in OG and 57 in RG (P<0.003). Gender: 56.5% women. Mean tumor size (mm) was 12.5 (11 in OG vs 18.7 in RG P<0.005). PNETs-I were multiple in 17.4% cases. At diagnosis, all PNETs-I’s size were ≤20 mm in OG, without metastases. In RG, 8 patients (80%) had surgery complications, mostly mild to moderate without deaths. Diagnosis was made by imaging procedures in 91.6% of OG. In our series, 82% had a CgA assessment at diagnosis. Median CgA value was 179 μg/l (72–304). At the end of follow up, 88% in OG of patients had no change in tumor size, the rest had tumor growth <20%. In OG no PNETs-I resection were needed, and none of the patients metastatized or died because of PNETs-I in this group. Conclusions

Non functioning PNETs-I is increasing in incidence in our center. After almost 36 months of follow up, no patients had significant growth, developed metastases and neither of them died from PNETs-I. In OG, active surveillance is safe in selected PNETs-I patients. We need prospective multicentric studies to confirm our results. DOI: 10.1530/endoabs.49.EP150

**Potential inhibitory effect of progesterone on breast cancer metastasis via the regulation on protein expression of apoptosis- and EMT-related genes**

Gyu-Sik Kim, So-Ye Jeon & Kyung-Chul Choi

Laboratory of Biochemistry and Immunology, Veterinary Medical Center and College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Breast cancers that are estrogen receptor (ER)/progesterone receptor (PR)-positive are more likely to respond to hormone-related treatments than tumors that are ER/PR-negative. The present study investigated the effect of progesterone (P4) on 17β-estradiol (E2)-induced cell proliferation, apoptosis, EMT, and migratory and invasive features of MCF-7 clonal variant (CV) breast cancer cells that are ER/PR-positive. Preferentially, E2 was verified to induce breast cancer progression by stimulating cell proliferation, EMT, and migration of MCF-7 CV breast cancer cells. On the other hand, P4 reduced E2-induced MCF-7 CV cell proliferation by down-regulating the protein expression of cyclin D1 and E1 and induced apoptosis of MCF-7 CV cells by up-regulating Bax and p53 and by
down-regulating Bcl-2. Also, P4 appeared to inhibit E2-induced EMT process by increasing mRNA and protein expression of E-cadherin, a crucial epithelial marker, as well as by reducing the expression of mesenchymal markers such as N-cadherin and vimentin and EMT-associated transcription factors such as snail andslug. Eventually, E2-induced migration and invasion ability of MCF-7 CV cells and the protein expression of proteolytic enzymes such as MMP-9 and cathepsin B were reduced by P4 treatment. Co-treatment of RU486, a PR inhibitor, restored the inhibited cellular migration and invasion and the reduced expression of proteases by P4 to the control levels, suggesting the involvement of PR in P4-induced inhibition on migration and invasion of MCF-7 CV cells. Taken together, P4 treatment may be suggested as an effective tool for suppression of human breast cancer progression and metastasis. (This work was supported by a grant from the Next-Generation BioGreen 21 Program (no. PJ011355-2015), Rural Development Administration, Republic of Korea.)

**Incidental paraganglioma, diagnosis and follow-up – case report**

Alice Violante1, Roberto Lemme1, Sarah Galva˜o1 & Erika Naliato2

1Department of Endocrinology, University of Medicine and Pharmacy “Victor Babes”, Timisoara, Romania; 2Department of Morphopathology, University of Medicine and Pharmacy “Victor Babes”, Timisoara, Romania.

Paragangliomas and Pheochromocytomas are tumors originated from chromaffin cells (Pheochromocytoma (PHEO): adrenal glands; Paragangliomas (PGL): paravertebral thoracic, abdominal, and/or pelvic sympathetic ganglia, and glossopharyngeal and vagal neck and skull base parasympathetic ganglia). Catecholamine hypersecretion predominates in PHEO, while PGL are oligosymptomatic with compression-related symptoms. The authors report the case of a 33-year-old male with an incidental retroperitoneal PGL, detected during an investigation for urinary lithiasis (abdominal pain that shifted to lumbar region). No recurrence or clinical evidence of disease after a 5-year period.

Keywords: Progesterone; breast cancer cells; epithelial-mesenchymal transition; metastasis; migration.

**Primary hepatic neuroendocrine tumor with multiple liver metastases treated with somatostatin analogues: case report**

Ioana Golu1, Melania Baluș1, Daniela Amzar1, Mariocara Cornelaniu2 & Mihaela Vlad2

1Department of Endocrinology, University of Medicine and Pharmacy “Victor Babes”, Timisoara, Romania; 2Department of Morphopathology, University of Medicine and Pharmacy “Victor Babes”, Timisoara, Romania.

Introduction

Somatostatin analogues (SSA) have been used as first line treatment to control the symptoms in hormonally active neuroendocrine tumors (NET), for over three decades. Primary hepatic neuroendocrine tumors (PHNETs) are rare neoplasms. Despite increased incidence of PHNETs over time, these tumors remain a rarity. According to the previously reported cases, primary neuroendocrine carcinoma of the liver is usually multicentric, often mimicking liver metastases. The demonstration of the hepatic origin of a neuroendocrine carcinoma is often arduous.

Case presentation

A 59-year-old woman underwent ultrasound examination 3 years ago, that revealed two liver nodular tumors (the largest having approximately 4 cm), with a complex structure. Abdominal IRM images confirmed multiple liver nodular tumors with intense vascularization, suggesting liver metastases. The patient was asymptomatic. In order to determine the primary site of the tumor, the patient underwent multiple imagistic investigations and endoscopies. Among the blood tests (5-hydroxy indole acetic acid, carcionemobryonic antigen, chromogranin A, serotonin), only chromogranin A presented significantly high values. Further, a liver aspiration biopsy was performed. The histopathological examination result completed with the immunohistochemistry techniques suggested a well differentiated neuroendocrine carcinoma of an intermediary stage, with a proliferation marker ki67 of 4%, most likely a metastasis. For a full diagnosis, Octreoscan (11In-pantreotide scintigraphy) was performed. The whole body scintigraphy at 10 minutes completed with the SPEC/CT at 4 hours established a primary liver site with secondary spleen metastases, along with liver and renal adenopathies. Treatment with somatostatin analogues (SANDOSTATIN LAR 30 mg/month), was commenced, with favourable outcome. After 18 months of treatment, serum chromogranin values are still normal, while the volume of the tumors decreased significantly (by repeated MRI).

Conclusion

Despite that the liver represents the common site for metastases from other gastrointestinal neuroendocrine carcinomas or other tumors, primary hepatic neuroendocrine tumors are rare, but can occur. The diagnosis of primary neuroendocrine tumors of the liver is difficult, as radiological appearances on ultrasound, CT scan and MRI can mimic other pathologies.

Keywords: Neuroendocrine tumors; liver metastases.

**Development of an everolimus-resistant BON1 cell line with altered cell cycle and c-Met activity**

Elke Tatjana Aristizabal Prada, Julian Maurer, Gerald Spottl, Christoph Aurenhammer & Svenja Nöllting

Klinikum der Universität München, Munich, Germany.

Introduction

Pancreatic neuroendocrine tumors (panNETs) are often inoperable at diagnosis. The mTORC1 inhibitor everolimus is approved for the treatment of advanced NETs. Unfortunately, the development of resistance against everolimus limits its clinical efficacy.

Aim

Our aim was to establish an everolimus-resistant panNET cell line to find common mechanisms of resistance.

Methods

Pancreatic neuroendocrine tumor cells (BON1) were treated for 24 weeks with 10 nM everolimus (Novartis). Medium supplemented with 10 nM everolimus was changed every 3 days. Two independent everolimus resistant BON1 cell lines were established (RR1 and RR2). Resistance was defined with an at least 2-fold higher IC50 compared to the parental/control cell line.

Results

After 24 weeks of permanent exposure to everolimus both cell lines (RR1 and RR2) showed morphologic changes when compared to the control cell line. The control cell line showed sensitivity to everolimus with cellular survival declining to 54.70% (IC50 = 34 nM) at 144 h treatment, whereas RR1 and RR2 showed resistance with cellular survival rates of 96.70% (IC50 = 5200 nM) and 92.30% (IC50 = 2500 nM), respectively. Western blot analysis showed different adaptive changes of the protein expression level in RR1 and RR2, but two prominent mutual features: The cell cycle component CDK1 (cdk2), which orchestrates the G1-S and G2-M progression was remarkably downregulated and the tyrosine kinase c-Met responsible for tumor cell motility, invasion and metastasis formation was upregulated. Consequently, flow cytometric analysis showed a significant cell cycle shift to G1 phase in RR1 and RR2 cells as well as a higher migration potential than control cells after everolimus treatment.

Synaptophysin.

for aromatic-L-aminoacid decarboxylase (AADC), Chromogranin A and slides were reassessed. Non-NET tissues were immunohistochemically stained was inconsistent with the diagnosis of a NET, both the scan and the pathology from medical charts. We compared the original 18F-FDOPA PET scan report NET between January 2004 and December 2014. Clinical data were retrieved under a 18F-FDOPA-PET scan for the clinical suspicion or follow-up of a NET. A single-center study was conducted among patients, aged 18 years or older, who underwent a 18F-FDOPA-PET scan for the clinical suspicion or follow-up of a NET between January 2004 and December 2014. Clinical data were retrieved from medical charts. We compared the original 18F-FDOPA PET scan report with the pathology report of the 18F-FDOPA PET-positive lesion. In case this was inconsistent with the diagnosis of a NET, both the scan and the pathology slides were reassessed. Non-NET tissues were immunohistochemically stained for aromatic-L-aminoadic decarboxylase (AADAC), Chromogranin A and Synaptophysin.

Background/Aim

Neuroendocrine tumors (NETs) are rare tumors arising from neuroendocrine cells throughout the body. Positron Emission Tomography (PET) scanning with 6-[18F]fluor-L-3,4-dihydroxphenylalanine (18F-FDOPA) has been shown to be a valuable technique for the imaging of NETs. While the sensitivity has been assessed numerous studies systematically describing false positive results, other than physiological variants, are lacking. Our aim was to systematically examine, in a large series of 18F-FDOPA PET scans, false-positive results and determine which other tumor types have the potential of 18F-FDOPA uptake.

Patients and methods

A single-center study was conducted among patients, aged 18 years or older, who underwent a 18F-FDOPA-PET scan for the clinical suspicion or follow-up of a NET between January 2004 and December 2014. Clinical data were retrieved from medical charts. We compared the original 18F-FDOPA PET scan report with the pathology report of the 18F-FDOPA PET-positive lesion. In case this was inconsistent with the diagnosis of a NET, both the scan and the pathology slides were reassessed. Non-NET tissues were immunohistochemically stained for aromatic-L-aminoadic decarboxylase (AADAC), Chromogranin A and Synaptophysin.

Results

1070 18F-FDOPA PET scans from 705 patients were evaluated. Focal or multiple 18F-FDOPA avid lesions were described in 709 18F-FDOPA PET scans (66%). Histology of these 18F-FDOPA PET positive lesions was present for 508 (72%) scans. In eight cases the original pathology report and revision was not compatible with a NET but showed a squamous cell carcinoma of the cervix and larynx, a multiple myeloma (in two cases), a hepatocellular carcinoma, a schwannoma, an adenocortical carcinoma and a skeletal myxoid chondrosarcoma, with positive immunohistochemical staining for AADC in four out of the seven stained tumor tissues.

Conclusions

Pathological uptake of 18F-FDOPA does not always indicate the presence of a NET. The possibility of 18F-FDOPA uptake by tumor types other than NETs should be considered.

Medullary thyroid carcinoma and pheochromocytoma in multiple endocrine neoplasia type 2A – a reversed order diagnosis

Ana Coelho Gomes, Catarina Silvestre, Jose Matçalo, Maria Raquel Carvalho & Maria João Bugalho

Endocrinology, Diabetes and Metabolism Department, Santa Maria Hospital, Lisbon, Portugal.

Introduction

RET germline mutation in codon 634 of exon 11 is one of the most frequent mutations of classical multiple endocrine neoplasia type 2A (MEN2A). Virtually all patients with classical MEN2A develop medullary thyroid carcinoma (MTC), which is often the first manifestation of the disease and usually occurs early in life. Pheochromocytomas (PHEOs) tend to be diagnosed several years later or simultaneously with the MTC.

Case report

The patient, a 45 year-old man, was referred to the Endocrinology outpatient department following a bilateral adrenalectomy, performed 2 months before, which is often the first manifestation of the disease and usually occurs early in life. Pheochromocytomas (PHEOs) tend to be diagnosed several years later or simultaneously with the MTC.

The patient, a 45 year-old man, was referred to the Endocrinology outpatient department following a bilateral adrenalectomy, performed 2 months before, (Pheochromocytoma of the Adrenal gland Scaled Score: left = 0, right = 4) and the finding of a thyroid micro nodule in a neck ultrasonography. There was no familiar history of MEN2 neither of its components. The physical examination did not disclose particular signs namely skin alterations in the interscapular region. Laboratory tests revealed elevated calcitonin (63.47 pg/ml, n <2). CEA, calcium, phosphorus, parathyroid hormone and plasmatic metanephrines were within the normal range. Thyroid, ultrasound guided, fine needle aspiration cytology of a 7 mm nodule in the left lobe was negative. Genetic testing of the RET proto-oncogene identified the heterozygous pathogenic variant c.1901G>A (p.Cys634Tyr) in the exon 11. The patient was submitted to total thyroidectomy with bilateral central neck dissection. The histology revealed multifocal and bilateral MTC (biggest diameter - 10 mm).

Discussion

Although less common the PHEO can be the first manifestation of MEN2A. Moreover, MTC is not always the most aggressive component of the syndrome.

DOI: 10.1530/endoabs.49.EP157
Multiple endocrine neoplasia 2A (MEN2A), an autosomal dominant genetic syndrome caused by germline mutation in RET proto-oncogene, associates medullary thyroid carcinoma (MTC), pheochromocytoma (PHEDO) and primary hyperparathyroidism (HPT). Thyroid hemiagenesis (TH), the absence of one lobe, is a rare congenital abnormality (300 cases are reported in literature). Most cases of TH are diagnosed when patients present a lesion in the functioning lobe. TH was observed among members of the same family and genetic causes have been evoked. The present case is a 35-year-old female patient with family history of MEN2A (the pedigree was studied). Genetic testing of the patient’s cousin and nephew indicated heterozygosity for the same mutation at codon 634. Plasma metanephrines, normetanephrines, parathormone (PTH) and calcitonin (CT) levels were increased. Serum ionized calcium was normal. Abdominal computed tomography provided the bilateral heterogeneous adrenal masses measuring 30×21 mm on the right and 20×16 mm on the left with an intense enhancement after contrast infusion. Neck ultrasound examination described 2 hypo-echoic, heterogeneous thyroid micro-nodules in the right thyroid lobe, with micro-calculations inside, which measure 78×58, respectively 45×47 mm. In the left side, hemiagenesis of the thyroid lobe was observed. No parathyroid adenoma or lymphadenopathy were found. The patient had underwent a bilateral laparoscopic adrenalectomy for PHEDO followed by total right thyroidectomy. Microscopic examinations established the diagnosis of multicentric PHEDO and synchronousity of C-cell hyperplasia with medullary thyroid microcarcinoma. Although the identified RET mutation has high risk, suggesting a possible aggressive evolution, in this case the CMT development was gentle, with a good prognosis (lesion < 1 cm diameter, without distant metastases, preoperative basal calcitonin < 150 pg/ml). In conclusion our patient is a rare case of association of an anatomic thyroid abnormality and MTC in the context of a complex genetic disease.

A case of silent pancreatic neuroendocrine tumour of carcinoid variety masquerading as an insulinoma

Tarik Elhadd1, Noor Saleiman1, Mohamed Bashir1, Emad Naem1, Khalid Mohamed2, Ahmed Elaffandi3 & Abdul Badie Abou Samra3

1Qatar Metabolic Institute, Hamad Medical Corporation, Doha, Qatar; 2Section of Hepato-biliary Surgery, Hamad Medical Corporation, Doha, Qatar.

Objective
To highlight an unusual cause of hyperinsulinaemic hypoglycaemia

Methods: Case Report

Results or Case Presentation
A previously healthy and fit 52 year old gentleman of Asian descent presented with recurrent severe neuroglycopenic hyperinsulinaemic hypoglycaemic symptoms, suggestive of insulinoma. On several occasions he was confirmed to have severe hypoglycaemia with venous blood glucose values ranging between 1.5 and 2.7 mmol/l with inappropriate high level of insulin and C-peptide of 32 mc/unit per ml (N. 2–23) & 4.5 ng/ml (N. 0.78–5.19) respectively. Other hormonal assessment including pituitary hormones, chromogranin A, urinary 5-HIAA, and cortisol were all normal. CT imaging picked up a 4×4 cm well circumscribed lesion in the tail of the pancreas, with no lesion elsewhere. Endoscopic ultrasonography confirmed the mass to be avascular and within the pancreas. He underwent laparoscopic distal pancreatectomy uneventfully in February 2016. Histology of the tumour showed a well differentiated neuroendocrine tumour of a carcinoid variety, grade 2, with positive staining for chromogranin A, and Synaptophysin CK. Following surgery, the patient had no further hypoglycaemia and remained symptom free up to 9 month of follow up. Postoperative PET scan and CT scanning of chest, abdomen and pelvis showed no recurrence of the tumour, and no lesion elsewhere.

Discussion
Non-islet cell tumours induced hypoglycaemia is generally caused by big IGF-II molecules secretion. Rarely carcinoid tumours were reported to secrete insulin but this is usually in the context of carcinoid syndrome and has been reported to arise from tumours in the lungs, appendix and the liver. For a silent pancreatic carcinoid tumour to cause hyperinsulinaemic hypoglycaemia is rather unusual. Plausible mechanisms include processing and secretion of insulin from tumour cells. Additionally secretion of insulin from adjacent islet cells may have been caused by paracrine effects. The exact mechanism in our case, however, only remains speculative.

Conclusion
Tumours of the pancreas causing hypoglycaemia may not necessarily be insulinoma. Silent neuroendocrine tumour of the carcinoid (Argantafinoma) variety may be the culprit.

Follow-up of adrenal incidentalomas after the initial approach

Ángel Rebolledo-Román, Paloma Moreno-Moreno, Inmaculada Prior-Sánchez, Aura-Dulcinea Herrera-Martínez, Ana Barrera-Martín & María-Ángeles Gálvez-Moreno

Endocrinology Service, Hospital Universitario Reina Sofía, Córdoba, Spain.

Objective
To describe the follow-up of adrenal incidentalomas (AI) classified as non-functioning and no suspicious for malignancy in the first approach.

Methods and materials
Observational retrospective study of a cohort of patients who consulted in the Endocrinology service between 2005 and 2015 because of an AI. Statistical analysis performed with SPSS 19th version.

Results
Two hundred and one patients with IA were firstly evaluated. Thirty two of them (15.92%) underwent surgery after the initial evaluation. One hundred and twenty four patients out of the 169 who didn’t undergo surgery (73.37%) were followed: 97 unilateral AI and 27 bilateral AI. Age: 58.48±11.84 years. Size: 26.36±14.14 mm. 57.3% Women. Repeated measurement of plasma metanephrines in 26 patients (20.97%): 21 unilateral AI (21.58%) and five bilateral AI (18.52%). No catecholamine production in any AI. Median follow-up: 4.12±3.34 years. Ninety eight patients (79.03%) underwent a 1 mg dexamethasone suppression test to screen the cortisol autonomous production: 76 unilateral AI (78.35%) and 22 bilateral AI (82.47%) and 23 with bilateral AI (85.19%). Median follow-up: 2.77±2.70 years. In four patients (5%) with unilateral AI there was a significant growth (28.85±15.63 mm), so they underwent surgery to remove them. None of them were malignant.

Conclusions
There wasn’t any patient with new catecholamine production in the follow-up. In 10.20% of patients we discovered a subclinical Cushing. Our findings agree with previously published studies. There was a significant AI growth in 5% of the patients so they were operated upon. Pathological diagnosis didn’t show malignancy in any case, which is consistent with the available scientific evidence.

Ectopic ACTH-syndrome – 31 consecutive patients from the Helsinki University Hospital
Sanna Toivanen1, Helena Leijon2, Timo Sane1 & Camilla Schalin-Jäntti1
1Endocrinology, Abdominal Center, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; 2Department of Pathology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.

Background
Ectopic ACTH syndrome (EAS) is rare and published series are scarce.

Aim
To increase the understanding of EAS we describe 31 consecutive cases in years 1997–2016.

Results
Of the 31 patients, 65% (20/31) were women and 35% (11/31) men. Median follow-up was 23 months (0–217). Median age at diagnosis was 62 years (21–78), with peak incidences in age groups 30–39 and 60–69 years. Most patients presented with hypokalemia (87%), muscle weakness (77%), ankle edema (74%), hypertension (71%), psychiatric manifestations (58%), changes in body fat distribution (58%), and bruises (51%). Median (range) cortisol, ACTH and 24 h urinary free cortisol were 1467 nmol/l (121–4380), 155 ng/l (16–4700), 8221 nmol/l (568–60038), and median (range) cortisol after 1 mg DST 1103 nmol/l (74–3390), respectively. Thirty (42%) underwent CRH-testing, which was accurate (< 50% increase in ACTH and < 20% in cortisol) in 9/13 (69%) patients. Underlying tumours: pancreatic NET (n = 6), pulmonary NET (n = 6), pulmonary small cell carcinoma (n = 6), unknown primary (n = 4); no tumour detected n = 2, disseminated disease n = 2), medullary thyroid carcinoma (n = 3), thymic NET (n = 2), and, ileum NET, prostate carcinoma, poorly differentiated pulmonary NEC, poorly differentiated pulmonary LCC (n = 1 for each). Median overall survival was 23 month (0–217). At the end of follow-up, 12/31 (39%) patients were alive. Four patients initially cured recurred at 2, 6, 10 and 12, respectively. Surgery of the primary tumour was possible in 10/31 (32%) patients, nine (90%) of whom were alive at the end of follow-up. Bilateral adrenalectomy was performed in 10/31 (32%) patients, three (30%) of whom were alive at the end of follow-up. Outcome was best in thymic and pulmonary NETs.

Conclusion
EAS affects women in 65% of cases. Incidence peaks in age groups 30–39 and 60–69 years. Recurrences are possible > 10 years later. Overall survival is poor.

Ectopic Cushing’s syndrome caused by a pulmonary adrenocorticotropic hormone secreting tumour: a case report
Renata Pauliukienė1, Edita Prakapienė1, Rasa Koreviene1,2, Raimonda Klimaitė1,2, Lina Barsienė1 & Valdas Sarauskas3
1Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Endocrinology Department, Kaunas, Lithuania; 2Lithuanian University of Health Sciences, Kaunas, Lithuania; 3Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Pathological Anatomy Department, Kaunas, Lithuania.

Introduction
Ectopic adrenocorticotropic hormone (ACTH) production by the pulmonary neuroendocrine tumour (p-NET) is rare, and is considered an aggressive variant of carcinoid tumours with poor prognosis.

Case presentation
59-year-old male with fast progressing generalized fatigue, abdominal discomfort, and diarrhea was hospitalized in gastroenterology unit of Hospital of Lithuanian University of Health Sciences, Kauno klinikos (HLUHS KK). Digestive tract diseases were ruled out. Persistent hypokalaemia (up to 2.2 mmol/l) was observed and endocrine pathology changes were considered. Examinations revealed markedly elevated plasma ACTH (44.4 pmol/l) and cortisol (> 1665 nmol/l) levels, diabetes, osteoporosis. No suppression of serum cortisol level with high-dose dexamethasone test was found, confirming ACTH dependent Cushing syndrome. The treatment with Metipranop was started. Pituitary and abdominal magnetic resonance imaging (MRI), abdominal computer tomography (CT) scans were normal. Thoracic CT scan showed nodules in the S2, S3, S6 of the left lung. No cytologic changes were found in repetitive bronchial leachates through endoscopic bronchoscopy. There were two episodes of pneumonia (Pseudononas aeruginosa) and two episodes of sepsis (Staphylococcus aureus and Enterococcus faecium). Suspected fungal infection, intended antifungal treatment. Single nodule in S3 of the left lung with no changes in size was found in repeated chest CT. 99mTc-tectrotyd SPECT-CT showed left lung S3 neuroendocrine tumour. The radical surgery (bilobectomy superior sinistri) was performed. Histological result was well-differentiated pulmonary ACTH (44.4 pmol/l) and cortisol (> 1665 nmol/l) levels, diabetes, osteoporosis. No suppression of serum cortisol level with high-dose dexamethasone test was found, confirming ACTH dependent Cushing syndrome. The treatment with Metipranop was started. Pituitary and abdominal magnetic resonance imaging (MRI), abdominal computer tomography (CT) scans were normal. Thoracic CT scan showed nodules in the S2, S3, S6 of the left lung. No cytologic changes were found in repetitive bronchial leachates through endoscopic bronchoscopy. There were two episodes of pneumonia (Pseudononas aeruginosa) and two episodes of sepsis (Staphylococcus aureus and Enterococcus faecium). Suspected fungal infection, intended antifungal treatment. Single nodule in S3 of the left lung with no changes in size was found in repeated chest CT. 99mTc-tectrotyd SPECT-CT showed left lung S3 neuroendocrine tumour. The radical surgery (bilobectomy superior sinistri) was performed. Histological result was well-differentiated pulmonary NET (pT1a N0 R0 G1). No radiochemotherapy was suggested. On the follow up visit after three months normal glycaemia, potassium and cortisol were found.

Conclusion
We present ectopic ACTH secreting neuroendocrine lung carcinoma with likely good prognosis. No clearly defined guidelines of follow up exist.

Could alcohol ablation become the standard of care for benign insulinomas?
Isabel Mazarro1, David Subías1, Félix Junquera2, Carme Vilardell3, Ignasi Saigí1, Albert Canó1, Laia Casamitjana1, Olga Giménez-Palop1, Lara Albert1, Isaac Capel1, Assumpta Caixas1 & Mercedes Rigla1
1Endocrinology and Nutrition Department, Parc Taulí Hospital Universitari, Institut d’Investigación i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell, Spain; 2Department of Gastroenterology, Parc Taulí Hospital Universitari, Institut d’Investigación i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell, Spain; 3Endocrinology and Nutrition Department, Althaia Fundation, Manresa, Spain; 4Internal Medicine Department, Consorci Hospitalari de Vic, Vic, Spain.

Introduction
Surgical resection is currently considered the standard treatment for symptomatic insulinomas; however, its morbidity is high (>10%) and it is restricted to suitable candidates. In recent years, alternative minimally invasive therapies, such as endoscopic ultrasound (EUS)-guided ethanol ablation (EA), have emerged as new therapeutic options, especially for small lesions or poor surgical candidates. We report two cases of insulinoma ablated with EA.

Cases report
We report two cases of recurrent hypoglycaemia due to benign insulinoma: a 75-year-old man, with a 9 mm hypoenchic lesion in the neck of the pancreas, unfit for surgery because of comorbidities (case 1); and a 71-year-old man with a 19×14 mm hypoenchic lesion in the pancreas head, who refused surgery treatment (case 2). EUS fine needle aspiration (EUS-FNA) confirmed neuroendocrine tumor with a Ki67 <5% in both of them. They were admitted to our department for EA. Insulinomas were punctured under EUS guidance with a 22 G needle. A total volume of 0.8 ml (case 1) and 13 ml (case 2) ethanol 98% was injected. After each injection a whistal halo was observed inside the lesion, and no extravasation of alcohol was detected. There were no perioperative or postoperative complications. In case 1, hypoglycaemia was not reported along the two years follow-up period. Case 2 presented occasional mild hypoglycaemia 1 year after treatment, so we considered repeating EA, but the patient refused it.

Conclusion
EUS-guided ethanol ablation of a single small insulinoma is an effective, minimally invasive, and safe therapeutic modality. Currently, it is considered when surgery cannot be an option. However, this new technique should be applied to a wider range of potential candidates. A multicentric study seems necessary to establish the indications of EA in insulinomas.

Clinical characteristics and survival of patients with paraganglioma: a single center experience
Valentina Elezovíc, Dijuro Macut, Sanja Ognjanovic, Tatjana Isailovic, Bojana Popovic, Ivana Bozic-Antic, Tamara Bogavac, Dusan Ilic, Jovana Bankovic & Svetozar Damjanovic
Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia.

Paragangliomas (PGLs) and pheochromocytomas (PCCs) are rare neuroendocrine tumors that derived from pluripotent neural crest stem cells. PCCs are derived from the adrenal medulla, while PGLs are histologically identical tumors derived from ganglia outside the adrenal gland. Even though the majority of tumors are benign, they are associated with high morbidity rates caused by excessive catecholamine secretion. We retrospectively analyzed 71 patients (36 female and 35 males) with PGLs between January 2002 and December 2016. Twenty three patients were lost to follow up. Kaplan-Meier curve was used as the univariate version of survival analysis. The median age at diagnosis was 47.0 years (11–75) and the mean tumor size was 53 mm (20–170 mm). PGLs in our group were mostly distributed in abdomen (60%), head and neck (26.2%), rarely in spine (9.2%) and chest (4.6%). Hereditary form of disease was present in 22.5% of patients. The most common mutation was in SDHD gene (10/16), hereafter in VHL gene (3/16); two patients had mutation in SDHC gene and one in SDHD. Multiple PGLs were identified in six patients. Hormonally secreting tumors were present in 28%; 16/30 patients had positive finding on 1-23 MBIG scintigraphy. Surgical resection was performed in 79% of patients, tumor embolization in 11%. At 22 patients the median proliferation index Ki67 was 1.8% (0.1–18%) and median PASS score 3(1–6). Metastatic disease was present in 18.8% of patient at the time of diagnosis and five patients had acquired metastasis. These patients were treated with PRRT (6/14), chemotherapy (3/14) and sutent (3/14). Median overall survival (OS) was 284 months (95% CI 251–318) with 10-year OS 88%. Mean disease free survival was estimated 20 months (95% CI 8–31). We presented clinical characteristics, genetic profile, treatment options and survival of our patients with PGLs, our experience as single tertiary center.

Introduction
The metabolic stressor, hypoglycaemia, elicits integrated counterregulatory responses, including activation of the hypothalamic–pituitary–adrenal axis. However, it is suggested that recurring insulin-induced hypoglycaemia can impair this counter-regulation. Here we report three cases of patients with insulinoma and corticotroph deficiency.

Case reports
The first case, 38-year-old man was referred because of recurrent episodes of hypoglycaemia. Hormonal investigations were in favour of dissociated anterior pituitary failure, with growth hormone and corticotroph deficiency. The hypothalamic-pituitary MRI was normal. The fasting test argued in favour of a hyperinsulinemic hypoglycaemia. The abdominal scan and the endoscopic ultrasound showed a mass within the tail of the pancreas. Distal pancreatectomy was performed. Histology disclosed an insulinoma. On follow up, no hypoglycemic episodes recurred and cortisol and GH response to induced hypoglycaemia was normal. The second case, 68 years old man referred for investigation of hypoglycemic episodes. He was diagnosed with corticotroph deficiency and hypergonadotropic hypogonadism with negative investigations. The hypothalamic-pituitary MRI was normal. After treatment with glucocorticoids, hypoglycemic episodes were significantly improved. After 6 years, he presented severe hypoglycemia and investigations revealed a 1.5 cm tumor in the head of the pancreas with hepatic and pulmonary metastases. The third case, 38 years old woman with a history of primary hypothyroidism for 6 years, presented with symptomatic hypoglycaemia and a history of weight gain. Laboratory investigations argued in favour of a hyperinsulinemic hypoglycaemia and the abdominal scan showed a mass within the tail of the pancreas. Furthermore, she was diagnosed with corticotroph deficiency. The hypothalamic-pituitary MRI was normal.

Conclusions
Our clinical cases show that hyperinsulinemia and hypoglycaemia in patients with insulinoma can give rise to functional corticotroph deficiency. The pathophysiological mechanism of this defective counter-regulation remains to be clarified; some studies suggest it could be related to hyperinsulinemia-induced decreased in CRF gene (3/16).

Hyperinsulinemic hypoglycemia in a 71-year-old patient with a suspected case of β-cells hyperplasia of pancreatic body and tail: case report

Jelena Malinovic Pancić,1,2, Bojana Carlež-3, & Bojana Popović1
1University Clinical Center of Republic of Srpska, Banja Luka, Bosnia and Herzegovina; 2Medical Faculty Banja Luka, Banja Luka, Bosnia and Herzegovina; 3Clinical Center of Serbia, Belgrade, Serbia.

B-pancreatic cells are programmed to react to plasma glucose level with insulin secretion. Insulin secretion is precisely regulated and in the physiological conditions fasting glucose levels are maintained in the range 3.5–5.5 mmol/l. In hyperinsulinemic hypoglycemia, a disorder of the regulation of insulin secretion, insulin secretion continues at low concentrations of plasma glucose. In adults hyperinsulinemic hypoglycemia is the cause of 0.5 to 5.0% of hypoglycaemias and are result of either β-cells tumor (insulina), or β-cell hyperplasia. Rapid diagnosis and treatment is essential in the prevention of acute and chronic complications of hypoglycaemia, especially in central nervous system.

We are presenting the 71-year-old patient who had been previously diagnostic evaluated at the primary health care level due to frequent episodes of unconsciousness and weakness periodically in period of 3 years prior to admission. After established refractory hypoglycaemia patient was sent to our department where endogenous hyperinsulinism after 72-hour test of hunger was found. After endoscopic ultrasound showed probable β-cells hyperplasia of the body and tail of the pancreas, 1-131 octreotide scintigraphy of somatostatin receptors was negative. Calcium artery stimulation of the pancreas with insulin b found. After endoscopic ultrasound showed probable β-cells hyperplasia of the body and tail of the pancreas. Rapid diagnosis and treatment is essential in the prevention of acute and chronic complications of hypoglycaemia, especially in central nervous system.

Clinical Case

A 39-year-old woman was referred to our Hypertension Clinic for workup after three episodes of TIA with SBP > 180 mmHg in the last 6 months. Diagnosed and treated of hypertension and hypokalemia since she was 15 years old, no secondary cause had been searched. She was treated with Telmisartan/Amlodipine/Hydrochlorothiazide 80/10/25 mg plus Carvediol 12.5 mg BID and potassium supplements. She had no history of diabetes or dyslipidemia and did not smoke. Height was 168 cm, weight 63 kg, IMC 22.3 kg/m2, office BP 142/88 mmHg, HR 72 bpm. The physical exam was otherwise normal. Treatment was changed to Diltiazem/Doxazosin for 3 weeks. Lab: normal including TSH and metanephrines, except venous pH 7.51, Cr 1.23 mg/dl, CKD-EP1 eGFR 57 ml/min/1.73 m2, albuminuria 139 mg/g Cr, aldosterone 792 ng/ml, PRA 58 ng/ml per h, normal ratio (13.7).

AngioCT excluded renal artery sclerosis, but showed a 12 mm subcapsular mass in the right kidney. The adrenals were normal.

Renal venous sampling for renin: Peripheral 628 U/l (normal < 42), Left renal vein 645 right renal vein 3120 U/l; right/left ratio 4.8. Laparoscopic nodulectomy was performed; a encapsulated 14 mm adenoma with clean margins was obtained. It tested positive for renin.

Diagnosis Secondary aldosteronism due to reninoma, resistant hypertension and target-organ damage (retinopathy, brain microinfections and TIAx, stage IIA CKD with microalbuminuria, LVH). Two months after surgery the patient is normotensive with mandipine 10mg/day: aldosterone, ARP, K+; venous pH and albuminuria are normal.

Commentary Reninoma is rare but probably infradiagnosed, and a long diagnostic delay is not unusual. Even with well-controlled BP, it may cause severe organ damage due to hyperaldosteronism. Thus, it should be included in the workup of secondary hypertension.

Endocrine Abstracts (2017) Vol 49

Management and outcome
The patient was hospitalized due to suspected insulinoma and supervised 72-hour fast test was performed. Plasma glucose was 3.5 mmol/l, plasma insulin - 49.3 pmol/l (43–210 pmol/l) and C-peptide - 780 pmol/l (260–1730 pmol/l) at the baseline. The test was ended after 16 hours with plasma glucose of 1.7 mmol/l, plasma insulin - 29.7 pmol/l, C-peptide - 521 pmol/l. These results confirmed the diagnosis of insulinoma. Abdominal computed tomography scan with contrast demonstrated a well-defined hypervascular lesion involving the head of pancreas measuring 10×15 mm in diameter, typical of neuroendocrine tumor. The patient underwent laparoscopic extirpation of the pancreatic mass. Histopathological evaluation revealed a pancreatic well-differentiated (G1) neuroendocrine tumor – benign insulinoma. The patient gradually discontinued all psychotropic medications following the operation. Currently he is feeling well, without any seizures and normal plasma glucose for about 1.5 years.

Conclusion
We recommend to check plasma glucose for all patients with seizures of unknown origin, although they are not typical to hypoglycemia.

A nomogram consisted of routine biochemical tests may increase the diagnostic accuracy of chromogranin A in detecting patients with neuroendocrine tumors
Ivan Vurnek1, Ivan Kruljac2, Miroslav Caćić2, Božidar Perić2, Maja Filipović-Grubić2, Gorana Mirošević2, Davor Kust* & Milan Vrkljan1,2
1School of Medicine, University of Zagreb, Zagreb, Croatia; 2University Hospital Center ‘Sestre Milosrdnice’, Zagreb, Croatia.

Introduction
Falsely elevated serum chromogranin A (CgA) is associated with the use of proton pump inhibitors, the presence of renal impairment and systemic inflammation. We aimed to investigate which laboratory parameters are independently associated with increased CgA and to develop a nomogram, in order to improve the diagnostic accuracy of CgA in detecting patients with neuroendocrine tumors (NET).

Methods
Our retrospective study included 155 subjects (controls) and 55 treatment naïve patients with NET, with available data on CgA, other laboratory tests, medical history and anthropometric parameters. Nomogram was developed in a form of scoring system, based on z-score obtained from receiver operating curve analysis for each parameter that was independently associated with CgA.

Results
CgA was positively associated with erythrocyte sedimentation rate, red cell distribution width, serum creatinin, glucose, urine leukocyte casts and the use of proton pump inhibitors. The combination of all these parameters was associated with increased CgA and to develop a nomogram, in order to improve the diagnostic accuracy of CgA in detecting patients with neuroendocrine tumors (NET).

Conclusion
The nomogram could allow the clinicians to assess the probability of increased CgA levels in each patient and consequently to avoid unnecessary serious diagnostic procedures.

Introduction
The Neuroendocrine Tumors Study Group of the Portuguese Endocrine Society (SPEDM) performed the first observational study between November 2012 and July 2014 to assess the profile of Gastroenteropancreatic Neuroendocrine Tumours (GEP-NET) patients (pts) followed at the main Portuguese hospitals. Several demographic and clinical data were collected

Objective
Characterize the clinicopathological features and treatment of patients with NET originating in the jejunum and ileum.

Material and methods
Included 71 pts with ≥18 years and a confirmed diagnosis of jejunum /ileum NET based on histopathology/cytology findings.

Results
Mean age was 57.2 (32–83) years, 61% (n = 43) males. Most tumors 89% (n = 63) were located at the ileum; two were multifocal. K67 was available in 86% of pts, 64% G1. At diagnosis 91% (51/56) had lymph node metastases and 70% (43/61) distant metastases. The most common symptom, available in 59 pts, was abdominal pain in 49% (29/59). Serum Chromogranin A (Crg A) was available in 65% (46/71) and was 2× or more upper limit of normal in 61% (29/48). Urinary 5HIAA checked in 61% (43/71) was elevated in 56% (24/43), 86% of these with distant metastases. CT scan was the preferred radiologic procedure in 87% of pts. Nuclear medicine imaging, either octreotide scan or 111In-DOTA-NOC Pet Scan was used in 75% (53/71) of pts. Tumor size known in 58 pts was 24 (11–70) mm. Primary tumor surgery was performed in 90 and 32% did surgery of hepatic metastases. 62% of the pts received somatostatin analogues (SA), two were treated with SA and interferon and two with systemic chemotherapy. 11 cases were submitted to hepatic transarterial embolization. Peptide Receptor Radionuclide Therapy with 177Lu was done in 9%.

Endocrine Abstracts (2017) Vol 49
Conclusions
This paper reveals important information regarding clinical practice. Most of our pts presented with well differentiated tumors but in an advanced stage. Regarding therapy there was an extensive use of surgery and systemic treatment mainly with SA.

Follow-up in neuroendocrine tumors: is chromogranin A the confounder?
Diana Martins1, Carla Baptista1, Ana Velez2, Fernando Macário2 & Francisco Carrilho1
1Endocrinology, Diabetes and Metabolism Department of Coimbra Hospital and University Centre, Coimbra, Portugal; 2General Surgery Department of Coimbra Hospital and Universitary Centre, Coimbra, Portugal;

Introduction
Chromogranin A continues to be one of the most valuable markers for neuroendocrine tumors (NETs), however, it has several limitations, including its reduced specificity.

Methods
The authors present the case of a patient diagnosed with a midgut NET, during follow-up.

Results
Male patient, 61 years old, with chronic renal disease (CRD), underwent right hemicolectomy owing to ileo-cecal valve lesion; histological result consistent with NET. Pre-operative staging: without metastatic disease on thoracic-abdominal CT; octreoscan with elevated expression of somatostatin receptors on ileo-cecal valve topography; CgA 32 nmol/l (<6.0),NSE 14 ng/ml (<15.0). Anatomopathological examination of surgical specimen: well-differentiated G1 NET; mesenteric infiltration and metastatization in 1 of 20 lymph nodes (T3N1Mx; AJCC-III: R0). After 3 years of stable disease, the patient presented CgA of 1173.8 ng/ml (<85), with impaired CRD (Cr 4.42 mg/dl), on dyalisis. 3 months later: CgA 1619.0 pg/ml and Calcitonin 26 pg/ml (!1173.8 ng/ml (<110), 395.43 ± 488.18 pg/ml (300–960), 12 ± 11.36 ng/ml (2–20) and 58.02 ± 75.08 ng/ml (20–350), respectively. Intestinal metaplasia appeared in 48 patients (81.35%) with GNEN1; 41 (85.5%) had large IM, 1 (2%) had small IM and 6 (12.5%) had both small and large IM. In univariate regression analysis, only mean follow-up from the parameters studied (age at diagnosis, gender, biochemical markers) predicted the presence of intestinal metaplasia (OR: 0.579; 95%CI 0.961-0.997, P = 0.021).

Conclusion
Our study showed a high prevalence of large IM in GNEN1. Mean follow up predicted IM presence. Further clinical studies are required to determine which parameters predict the presence of IM in patients with GNEN1.
DOI: 10.1530/endoabs.49.EP176

Methods
Fifty-nine (45 females) patients with GNEN1 were retrospectively studied. All patients included in the study had positive paretial-cell antibodies. All patients underwent a gastroscopy with multiple biopsies. Chromogranin A, gastrin, vitamin B12, folate and ferritin levels were also assessed.

Results
The mean age and follow up were 54.14 ± 13.62 years and 67.66 ± 48.9 months, respectively. At diagnosis, chromogranin A, gastrin, vitamin B12, folate and ferritin levels were: 277.54 ± 173.54 ng/ml (<98), 896.18 ± 818.98 pg/ml (<110), 395.43 ± 488.18 pg/ml (300–960), 12 ± 11.36 ng/ml (2–20) and 58.02 ± 75.08 ng/ml (20–350), respectively. Intestinal metaplasia appeared in 48 patients (81.35%) with GNEN1; 41 (85.5%) had large IM, 1 (2%) had small IM and 6 (12.5%) had both small and large IM. In univariate regression analysis, only mean follow-up from the parameters studied (age at diagnosis, gender, biochemical markers) predicted the presence of intestinal metaplasia (OR: 0.579; 95%CI 0.961-0.997, P = 0.021).

Pancreatic neuroendocrine tumors (PNETs) in patients with MEN1 syndrome
Tatjana Isailovic1, Djuro Macut1, Sanja Ogjanovic1, Milan Petakov1, Valentina Elezovic1, Ivana Milicic1, Bojana Popovic1, Ivana Bozic Antic1, Tamara Bogavac1, Dusan Ilic1 & Svetozar Damjanovic1
1Clinic for Endocrinology, Department for Endocrine Tumors and Heritable Cancer Syndromes, Belgrade, Serbia; 2Clinic for Endocrinology, Genetic Laboratory, Belgrade, Serbia.

PNETs represent the leading cause of mortality in MEN1 patients. Yet, their characteristics, behaviour, and therefore management, are still uncertain. The aim of this study was to describe the main clinical characteristics of NETs in MEN1, and to compare them with sporadic NETs.

We investigated 164 patients with PNETs retrospectively, treated in one centre from 2004–2016. We identified 15 (9.1%) patients with MEN1. All patients had germline mutations in MEN1 gene, except one who had sporadic MEN1. There was no gender difference among the groups. No difference in age at onset between the groups was noted (48±16.1 in MEN1 vs 53.8±13.5 years in sporadic, P > 0.05). According to WHO classification, well-differentiated tumors were the most frequent in MEN1, in contrast to sporadic PNETs where well-differentiated carcinomas prevailed (P < 0.01). Functioning PNETs were more frequent in MEN1 group (60 vs 30%; P < 0.05). Among functioning tumors, insulinoma and gastrinoma were the most frequent in both groups (P > 0.05). MEN1 patients had multiple tumors more frequently (33.3 vs 5%, P < 0.05). Metastatic disease as initial presentation had 17% in MEN1, and 26% of sporadic patients (P > 0.05). Surgery was performed in 70% of MEN1 and 92% of sporadic patients. Tumor size did not correlate with the presence of metastases at surgery in any of the groups. Median OS was 149 months (95%CI 71–226) with no difference between the groups (X² = 2.409, P > 0.05). Mean time to tumor progression (TPP) was estimated to 41 months (95%CI 10–75). However, no difference was found regarding the MEN1 status (X² = 0.22, P > 0.05). TTP negatively correlated to Ki-67, local invasiveness and stage of the disease in all patients, but not to size or functionality. These data suggest that MEN1 PNETs share similar clinical behaviour as sporadic PNETs. Therefore, close tumor surveillance and early surgery are advocated, irrespective of the tumor size or functionality.

Dysregulation of the components of the splicing machinery in neuroendocrine tumors and its association with malignancy and aggressiveness
Sergio Pedraza-Arévalo1, Emilia Alors-Pérez1, Aura D. Herrera-Martínez2, Mercedes del Río-Moreno3, Rafael Sánchez-Sánchez3, Rosa Ortega-Salas1, Raquel Serrano-Blanch4, María A. Gálvez-Moreno2, Manuel D. Gañete1, Raúl M. Luque1 & Justo P. Castaño1
1Endocrine Abstracts (2017) Vol 49

Background
Intestinal metaplasia (IM) of the gastric mucosa is a relatively frequent precancerous lesion. The aim of the study was to assess the prevalence and the kind of IM and also to find parameters that could predict the presence of IM in gastric neuroendocrine neoplasms type 1 (GNEN1).
1Department of Cell Biology, Physiology and Immunology, Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Reina Sofia University Hospital (HURS), University of Cordoba (UCO), CIBER Physi, Cordoba, Spain; 2Service of Endocrinology and Nutrition, HURS/IMIBIC, Cordoba, Spain; 3Service of Anatomical Pathology, HURS/IMIBIC, Cordoba, Spain; 4Service of Medical Oncology, HURS/IMIBIC, Cordoba, Spain.

Dysregulation of the splicing machinery is emerging as a novel cancer hallmark due to its association with multiple dysfunctions in tumor cells. An inappropriate function of the components of this machinery (splicesome) could be primarily linked with the generation of tumor-associated aberrant splicing variants. In line with this, we have previously reported that overexpression of aberrantly spliced variants of somatostatin receptor 5 (sst5TMD4) and ghrelin (In1-ghrelin) is directly associated to malignancy features in gastroenteropancreatic neuroendocrine tumors (GEP-NETs). Therefore, in this study we aimed to characterize, for the first time, the pattern of expression of a selected set of components of the splicing machinery in GEP-NETs samples, compared to adjacent non-tumoral control tissues, and to determine its relationship with the aggressiveness of these tumors. Accordingly, we designed a PCR-based array to determine the expression levels of components of the major (n=13) and minor spliceosome (n=4) and associated splicing factors (n=28) using a microfluidic technology in 20 pancreatic NET samples (47% G1, 47% G2 and 6% G3) and control tissues. The results showed that the expression of several splicers and splicesome components was altered in tumor tissues compared to non-tumoral adjacent tissues. Remarkably, important splicing factors (e.g. CELF4, NOVA1, SNW1, and RAVER1) and components of splicesome (e.g. PRP8) were clearly overexpressed in NET samples, wherein they were correlated with some malignancy features. Furthermore, in vitro assays using NET cellular models (i.e. BON-I/QGP-I-cells) demonstrated that CELF4 and NOVA1 overexpression induced an increase on cell-proliferation, while their silencing (using specific siRNAs) caused a marked decrease on cell-proliferation, suggesting a role in the aggressiveness of these tumors and their putative suitability as therapeutic targets in pancreatic NETs. Hence, our results demonstrate an alteration of splicing machinery in pancreatic NETs and unveil its putative relevance in NETs development/progression, where it could provide novel diagnostic biomarkers and therapeutic tools for this pathology.

Introduction
Malignant paraganglioma/pheochromocytoma (MPP) are very rare neuroendocrine tumors with heterogeneous prognostic and no gold-standard treatment. Several potential influencing factors on patient survival have been recently identified. These factors could help predict patient prognosis.

Objectives
Analysis of the long-term survival of our GEP-NETs cohort according to the presence of metastatic disease, tumor grade, age, sex, tumor functionality and tumor origin.

Materials and methods
Retrospective study of patients with GEP-NETs in Hospital Universitario La Princesa (Madrid, Spain) from 1995 to the present. Survival analysis and factors involved were assessed by Kaplan-Meier method and Cox regression analysis using STATA v12.0.

Results
One hundred and four patients were evaluated (55 women, age 61 ± 16 years). Median survival is reduced in patients with G3, metastasis, and primary tumors (GEP-NETs) is their wide heterogeneity and variable outcome. Several potential influencing factors on patient survival have been recently identified. These factors could help predict patients’ prognosis.

Conclusions
Several factors influence the heterogeneity and clinical outcome of patients with NETs. Median survival is reduced in patients with G3, metastasis, and primary tumors of unknown origin. Knowing these factors guides the therapeutic approach of this rare disease.

Introduction
One of the main difficulties in the study of gastroenteropancreatic neuroendocrine tumors (GEP-NETs) is their wide heterogeneity and variable outcome. Several potential influencing factors on patient survival have been recently identified. These factors could help predict patients’ prognosis.

Objectives
Analysis of the long-term survival of our GEP-NETs cohort according to the presence of metastatic disease, tumor grade, age, sex, tumor functionality and tumor origin.

Materials and methods
Retrospective review of clinical records of patients diagnosed with insulinoma at a central hospital
Joanna Prokop, Ana Cláudia Martins, Carolina Neves, Teresa Sabino, Paula Bogoal, José Silva Nunes, Fernando Fonseca & Ana Agapito
Department of Endocrinology, Centro Hospitalar Lisboa Central, Lisbon, Portugal.

Insulinoma, a rare neuroendocrine tumor (NET), is benign in more than 90% of cases. We present a review of patients diagnosed with insulinoma at our Department.

Methods
Retrospective review of clinical records of patients diagnosed with insulinoma between 2011 and 2016.

Results
Six female patients were diagnosed with insulinoma (age at presentation 30-66, follow-up: 0.25–32.5 years). Episodes of sweating, palpitations, tremor, confusion, visual disturbances and weight gain were present in five patients from 2 months to 5 years before diagnosis. There was no familial history or
Clinical findings of hereditary tumor syndromes. The 72-h fast confirmed endogenous hyperinsulinism in 4–12 h of fast. Abdominal CT: pancreatic lesion in four patients (14–25 mm). Endoscopic ultrasound done in four patients revealed pancreatic nodule; three performed cytology biopsy compatible with pancreatic neuroendocrine tumor (pNET). Five patients underwent surgery: two tumor enucleation, three central and distal pancreatectomy with left hepatectomy and splenectomy in 1 of these. Histopathology: well differentiated pNET G1 (two patients) and G2 (three patients). Two patients had lymph node involvement and one of them liver metastases. Among five surgically treated patients: four did not have recurrence of hypoglycemia and the one with liver metastases was treated with octreotide and deceased 2 years after diagnosis. The sixth patient had undergone central and distal pancreatectomy with splenectomy 5 years earlier due to pNET without diagnosis of insulinoma at that time and presented us with large hepatic metastases and hypoglycemia. Octreotide and peptide receptor radio-nucleide therapy (DOTA-TATE) were started due to hepatic hyperfibration in PET-68Ga-DOTANOC.

Discussion
In this group there was a high prevalence of malignancy, which is unusual. Time elapsed from onset of symptoms to diagnosis was highly variable. The natural history of malignant insulinoma is difficult to predict, however uncontrolled hypoglycemia, liver tumor burden exceeding 30% of liver volume, morphologic progression and Ki67 > 10–20% are factors of poor prognosis.

Effects of ketoconazole on ACTH-producing and non ACTH-producing neuroendocrine tumor cells
Aurora D Herrera-Martinez1,2, Richard Feeleders1, Justo Castaño1,4, Fadime Dogan1, Peter van Koetsveld1 & Leo Hofland1
1Department of Internal Medicine, Division of Endocrinology Erasmus University Medical Center, Rotterdam, The Netherlands; 2Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), Cordoba, Spain; 3Endocrinology and Nutrition Service, Reina Sofia University Hospital, Cordoba, Spain; 4Department of Cell Biology, Physiology, and Immunology, University of Cordoba, Cordoba, Spain.

Prolonged spontaneous remission of hypercortisolemia in ectopic ACTH syndrome after long-term treatment with steroidogenesis inhibitors has been described. Direct drug effect on the adrenal glands, effects on tumor ACTH secretion and/or POMC gene expression have been suggested. Medical treatment could be used for symptoms, but also for disease control.

Materials and methods
In human BON-1 and DMS-79 cells, we have evaluated the effects of ketoconazole on cell growth, apoptosis, cell cycle, LDH production, POMC/chromogranin-A mRNA expression and ACTH/serotonin secretion.

Results
In the BON-1 cells, ketoconazole significantly suppressed cell growth in a dose and time-dependent manner. Maximal inhibitory effects by 10 μM ketoconazole were 41 and 95% after 3 and 7 days (P < 0.0001); the ratio LDH/DNA after 3 days was increased. The IC50 value of growth inhibition was 7.8 μM after 7 days of treatment. Ketoconazole also induced a significant G1-phase arrest accompanied by a decrease in S-phase and G2-phase, as well as a significant increase in early and late apoptosis (P < 0.01), confirmed using an ELISA method. Ketoconazole (up to 10 μM) did not significantly affect the chromogranin-A expression or serotonin secretion (corrected for cell number). DMS-79 cells are less sensitive to ketoconazole, with maximally inhibitory effects by 50 μM ketoconazole of 44 and 94% after 3 and 7 days of treatment (P < 0.0001). The IC50 value of the growth inhibitory effect was 15 μM after 7 days of treatment. The highest ketoconazole concentration (50 μM) tested induced a significant G1-phase arrest (P < 0.001), increased number of dead cells (P < 0.001) without significant effect on early/late apoptosis, increased total apoptosis (ELISA; P < 0.001), as well as the LDH/DNA (P < 0.001). Ketoconazole up to 10 μM suppressed ACTH secretion (P < 0.01). POMC expression did not show significant changes.

Conclusions
These results suggest a potential direct effect of ketoconazole on cell proliferation, apoptosis and cell cycle in ACTH- and non-ACTH producing NET cells. Additional studies are required to confirm and extend these results.

Treatment with (177Lu)-DOTATATE in patients with advanced metastatic somatostatin receptor-positive tumors
Antonio Ballesteros Martín-Portugues, María Isabel Del Olmo García, Pilar Bello Arqués, Angel Segura Huerta, Rosa Cámara Gómez & Juan Francisco Merino Torres
Hospital La Fe, Valencia, Comunidad Valenciana, Spain.

Introduction
The NETTER 1 trial resulted in markedly longer progression-free survival (PFS), with preliminary evidence of an overall survival benefit. We report the results of PFS and safety of (177Lu)-DOTATATE in patients treated in our hospital between 2014 and 2016.

Methods
Transversal and descriptive study of seven patients with advanced, progressive, somatostatin receptor-positive tumors who had received previous treatments. All of them were treated in progressive disease with (177Lu)-DOTATATE. Results are expressed in average (s.d.) or percentage (%). SPSS version 2.2 was used for statistical analysis.

Results
71.4% (5) were women, with an average age of 46.4 (16.2). Histological classification was: 4 (57%) well-differentiated differentiated neuroendocrine tumors (three pancreatic, one ileal), 2 (28.6%) paranganglias and 1 (14.3%) follicular thyroid carcinoma. At the time of administration of (177Lu)-DOTATATE, all tumors were in metastatic stage. The localization of the metastasis was: bone 85.7% (6), liver 57.1% (4), lymph nodes 42.8% (3) and lungs 14.3% (1). All patients had received previous treatments: two underwent surgery exclusively, five of them several systemic therapies: one with somatostatin analogues (SA) and surgery, two only SA, one surgery, SA, temsirolimus and sunitinib, and one patient with diagnosis of metastatic follicular thyroid carcinoma, received: surgery, radioiodine, sorafenib, sunitinib, everolimus, adryamine, and SA. 177Lu-DOTATATE was infused every eight weeks in four doses, except in two patients who have received only three. At the data-cutoff date PFS was of 20.29 (7.13) months. Two patients had adverse events related to the treatment: one hematologic events (mild-moderate thrombocytopenia and anemia), and one self-limited nausea and vomiting. Death occurred in one patient after 15 months of stable disease.

Conclusions
In real world practice treatment with (177Lu)-DOTATATE not only shows benefit in advanced intestinal NETs but also in other patients with metastatic disease, previous treatments, and positive somatostatin-receptor expression it seems to have favorable results attending to PFS and safety.

Gastroenteropancreatic neuroendocrine tumors (GEP-NETs) followed in the endocrinology and nutrition service’s monographic outpatient clinics of neuroendocrine tumors in hospital clinico san carlos (HSCC). Description of its characteristics and evolution
Ines Jimenez-Varas1, Angela Amengual1, Rona Penso1, Anna Ortola2, Ane Azkaita1, Lorea Herraez1, Paz de Miguel1 & Jose Angel Diaz1
1Hospital Clinico San Carlos, Madrid, Spain; 2Hospital Clinico Universitario, Valladolid, Spain.

Introduction
The multidisciplinary approach of the patients with GEP-NETs is very important, having a fundamental role the participation of the endocrinologist.

Methods
Description of cases of GEP-NETs followed in the Service of Endocrinology of the SCCH from 1990 to 2016.

Results
95 patients were included, 53.7% were males, age 61.2 years (IR: 50.5–73.5). The diagnosis was incidental in 53.8%, 27.6% presented clinical secretion, from them the most frequent was carcinoid (13.8%). The median primary tumor size was 3 cm (IR: 2–4). The most frequent localization was pancreas (43.2%) followed by small intestine (20%). The initial stage was 49.5% I and 39.6% IV (72% hepatic metastases). Clinic as a cause of diagnosis was significantly associated with staging (Cramer’s V (V) 0.72, P ≤ 0.05). Chromogranin A (CgA) was high in 30% and 5-Hydroxyindolacetic in 18.7% (only 73.7 and 58.4%, respectively) were
studies. 9.4% of the patients had history of familiar syndrome. Degree of differentiation (DD) 1 and 2 (63 and 30.3%) predominated. The follow-up was 6.63 years (IR: 4.6-9.3). During that period, 30.2% of the cases were lost, with mortality rate of 17.9% of the remaining group, due to progression in 83.3% of the patients. The most frequently used treatment was surgery (39.1%). From stage IV patients 20.8% received only somatostatin analogues and 45% received more than one treatment (surgery, chemotherapy, antiangiogenic drugs, somatostatin analogues or everolimus) There was significant association between mortality and stage (V 0.42, P 0.004), CEA (V 0.38, P 0.012), presence of symptoms at diagnosis (V 0.32, P 0.017) and DD (V 0.41, P 0.02).

Conclusion

Patients followed in the endocrinology outpatient clinic are more frequently stages I and DD and DD that have been incidentally diagnosed. More than 50% of the cases were treated only with surgery or somatostatin analogues. One third of the patients had secretion.

Descriptive and survival study of 142 cases of gastroenteropancreatic neuroendocrine tumor (GEP-NETs) diagnosed at the Hospital Clínico San Carlos (HCSC)

Rona Penso1, Inés Jiménez-Varas1, Angela Amengual1, Lorea Herraz1, Ane Azkutia1, Anna Ortolà1, Paz de Miguel1 & José Angel Díaz1

1Hospital Clínico San Carlos, Madrid, Spain; 2Hospital Clínico Universitario, Valladolid, Spain.

Introduction

Neuroendocrine tumors (NETs) constitute a very heterogeneous group of rare neoplasms, although their incidence has increased in recent years. We describe its evolution and survival.

Methods

Retrospective study. All patients with histopathological diagnosis of GEP-NETs performed at the HCSC between 2000 and 2016 were selected, data from the medical history were included. Statistical analysis were done with SPSS.

Results

One hundred and forty-two patients, 54.9% male, mean age 60.2 years (S.D. 19.7). The median follow-up time was 3.3 years (IR: 0.78-6.33). The most frequent locations were pancreatic (28.2%) and rectal (16.2%). The tumor stage was: I 47.2%, II 4.9%, III 13.4%, IV 34.5%. The initial stage (IS) presented positive correlation with the degree of differentiation (DD) (Cramer’s V 0.46, P <0.05) and with levels of Chromogranin A (Cramer’s V 0.37, P <0.05). 12% had progression and 64% died during follow-up (72% due to tumor). Overall survival at 5 years was 69 and 53% at 10 years. There were significant differences in survival according to location, with gallbladder and colon being the lowest (0 and 38% at 5 years, respectively). DD, IS and sex were also associated with survival (at 10 years: G1 95% vs G3 14.3% P <0.01, stage I 91% vs IV 28% P <0.01, median males 7.5 years vs 16.9 in females P 0.018). These differences were maintained after multivariate analysis in the case of DD and IS.

In stage IV survival was modified according to surgical treatment (operated median 5.9 years vs non-operated 0.64 years, P <0.01).

Conclusion

In our sample the overall mortality was high, despite having a low rate of progression. DD and IS were determinants of survival. In advanced stages surgical treatment improves survival significantly.

Nonfunctional adrenal incidentaloma affects central blood pressures and arterial stiffness parameters

Tolga Akkan1, Mustafa Alay1, Yaşemin Aydogan Unsal1, Murat Dagdeviren2 & Esin Beyan1

1Internal Medicine, Keceri Education and Research Hospital, Ankara, Turkey; 2Endocrinology and Metabolism, Keceri Education and Research Hospital, Ankara, Turkey.

Introduction

In recent years, it is thought that cardiovascular risk is increased in patients with nonfunctional adrenal insidentaloma (NFAI). There are not enough studies in the literature that evaluating this condition in patients with NFAI who don’t have traditional cardiovascular risk factors. The aim of our study is to determine peripheral and central blood pressures and arterial stiffness in patients with NFAI who don’t have traditional risk factors and autonomous cortisol release with pulse wave analysis (PWA) measurement.

Material and methods

In our cross-sectional study, we evaluated 70 participants (35 patients with NFAI and 35 healthy volunteers) without traditional cardiovascular risk factors. All participants were similar in terms of gender, age and body mass index. Measurements of peripheral and central blood pressures and PWA were made with Mobil-O-Graph PW/A/ABPM device (I.E.M. GmbH, Stolberg, Germany). Radiological and biochemical data were obtained retrospectively in the NFAI group.

Results

In the NFAI group, systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial pressure (MAP), central SBP, central DBP, peripheral vascular resistance, augmentation pressure (AP), augmentation index that corrected based on pulse rate of 75 bpm (Aix75) and pulse wave velocity (PWV) were significantly higher than control group. We also found that PWA measurements are affected by age and the time from diagnosis to PWA measurement. There was no significant correlations between biochemical parameters and central blood pressures and arterial stiffness parameters in NFAI group.

Conclusion

In patients without traditional cardiovascular risk factors who have NFAI that known as cardiometabolically innocent, both peripheral and central blood pressures and arterial stiffness parameters are affected negatively. These patients are at risk for cardiovascular diseases.

Landscape of sporadic adrenal tumours from surgical unit – histopathological audit of 101 cases from a single centre in Poland

Anna Jojkowska1, Maçiej Sroczyński1, Monika Sępek1, Krzysztof Tępkowski1 & Grzegorz Mazur1

1Department and Clinic of Internal and Occupational Diseases, Hypertension and Clinical Oncology, Wroclaw Medical University, Wroclaw, Poland; 2Department of Minimally Invasive Surgery and Proctology, Wroclaw Medical University, Wroclaw, Poland; 3Department of Urologic Oncology, Lower Silesian Oncology Centre, Wroclaw, Poland.

Laparoscopic surgery of adrenal tumours is widely used because of its high effectiveness, patients safety and relatively low cost. Current indications to adrenalectomy of oncological and endocrinological origin are highly accepted. However there is still lack of perfect clinical tool identifying malignant lesions. In everyday practice clinicians rely on low specific features, especially considering larger nomenclature tumours to surgery.

To show the landscape of sporadic adrenal tumours we analysed retrospectively histopathological findings from 101 consecutive adrenalectomies performed in our centre in 71 women and 30 men of average age 57.7 years (s.d. 13.5), between 2009 and 2016 years.

There were 53 (52.47%) adrenomas found; 7 (6.93%) of them secreting: 4 (3.96%)-cortisol, 3 (2.97%)-aldosterone. Pheochromocytoma occurrence was notably often-14 cases (13.86%). Adrenal cancer was found in two cases (1.98%), metastatic lesions from lung, kidney and urinary bladder in three cases (2.97%); and 10(9.99%) malignant peripheral nerve sheath tumor (MPNST) derived from ganglioneuroma of adrenal gland was found. Thirteen cases (12.87%) of adrenal hyperplasia were found. In 16 cases (15.84%) the histopathological findings were classified as “various” in detail consisting of: 3 myelolipomas, 1 angiomylipoma, 2 cysts, 6 pseudocysts or secondary posthaemorrhagic/inflammatory lesions, 1 normal adrenal tissue, 1 fatty tissue, 1 mesenteric cyst and 1 teratoma. In two cases benign adrenal lesions coincided with unilateral kidney cancer. Seventeen patients (16.83%) had previous oncological anamnesis positive, while patients with adrenal cancer had negative previous oncological anamnesis.

We observe that adrenalectomy of oncological indications is prevalent: adrenal lesions with positive previous cancer history; lesions suspected of

An elevated chromogranin A: is it always a tumor progression?-case report

Anamaria Bursuc1, Alina Daniela Belceanu1, Ioana Armasu1, Mirela Tîrnovyan1, Adina Manolache1, Felicia Crumpe2, Delia Ciobanu1, Letitia Leustean1 & Carmen Vulpoi1
1Department of Endocrinology, 2Gr. T. Popa University of Medicine and Pharmacy, Iasi, Romania; 3Department of Radiology, 4Gr. T. Popa University of Medicine and Pharmacy, Iasi, Romania; 5Department of Pathology, 6Gr. T. Popa University of Medicine and Pharmacy, Iasi, Romania.

Introduction
Pancreatic neuroendocrine tumors (PNET) are rare, with an incidence of 1/100,000/year. Chromogranin A (CgA) is the most valuable marker in the diagnosis and monitoring of PNET. One of the disadvantages is its low specificity and the existence of a number of processes leading to an increase in its concentration, which often results in confusion and diagnostic difficulties.

Case report
We present a 44-years-old female patient with a history of PNET-pT3NxMx-G3 surgically excised in 2007, chemotreated with 6 cycles of Gemcitabine and Capcitabine. In 2009, a left thoracotomy for lung metastasis was performed, followed by 10 cycles of chemotherapy and in 2015 the patient was diagnosed with a recurrence of PNET which required atypical pancreatectomy. Immunohistochemistry revealed intense positive markers: NSE, chromogranin, synaptophysin CD56 and ki67.3%. The subsequent evaluations showed normal biological (CgA, serotonin, 5HIAA) and morphological (thoraco-abdominal CT) parameters until 2016, when CgA level was 7-fold higher that the upper normal value (545 ng/ml vs 76 ng/ml) but with normal thorax and abdominal-pelvic CT. As the patient took moderate doses (40 mg/day) of Omeprazole 6 months for gastroesophageal reflux disease, iatrogenic elevation of CgA was suspected. After cessation of proton pump inhibitors (PPIs) therapy for 1 week, serum CgA level rapidly decreased to 66 μg/l (N<100 μg/l).

Conclusions
In this case, the elevated CgA raised the suspicion of a new recurrence which required further investigations. PPIs may cause serious differential diagnostic problems with elevation of serum CgA especially in suspected neuroendocrine tumors. An interesting phenomenon highlighted by this case is the report of rapid normalization of CgA after withdrawal of PPI. Giving particular attention to the use of PPIs as a possible cause for elevated CgA levels might help to prevent the need for further diagnostic procedures.

A challenging case of metastatic paraganglioma and metastatic melanoma and prolactinoma

EP190

Rehmat Karim1, Kamrudeen Mohammed1, Najeeb Zaheer Shah1 & Muhammad Fahad Arshad2
1Hull Royal Infirmary, Kingston Upon Hull, East Yorkshire, UK; 2Doncaster Royal Infirmary, Doncaster, South Yorkshire, UK.

Background
Paragangliomas are extremely rare endocrine tumours and can cause diagnostic difficulty, especially with a coexistent metastatic malignancy. This case describes a 78-year-old man with diagnosed metastatic melanoma underwent a PET scan for staging of the malignancy. It showed a left upper quadrant mass with multiple skeletal deposits and a lesion in the pituitary all with intense focal uptake. The mass was unusual for a metastatic lesion from melanoma although other lesions, including pituitary could be explained by metastatic melanoma. A biopsy of the abdominal mass showed histological features of a paraganglioma: 24-h urinary catecholamines showed raised noradrenaline 1474 nmol/24 h (70–550 nmol/24 h), dopamine 6277 nmol/24 h (400–3000 nmol/24 h) and a normal adrenaline <21 nmol/24 h (0–190 nmol/24 h) confirming a functional paraganglioma. The diagnosis of the skeletal lesions was unclear, and a 123-MIBG scan showed increased activity at the skeletal lesions but no avidity at pituitary confirming skeletal metastases from the paraganglioma with no definite explanation for the pituitary lesion. An MRI pituitary showed diffuse enlargement of pituitary gland with focal expansion indicating chronicity and suggestive of prolactinoma rather than metastasis as his prolactin was 9400 mU/l and rest of his pituitary function was normal. He had no symptoms of diabetes insipidus. Resection of the paraganglioma was performed after preoperative alpha and beta blockade. His post-operative catecholamines normalised and post operative PET scan has shown stable appearance of skeletal lesions. He was started on Cabergoline for his prolactinoma and referred for chemotherapy for the metastatic skeletal lesions.

Conclusion
Metastatic paragangliomas in patients with a separate existing metastatic malignancy provides a diagnostic and management challenge. With a structured approach to investigation and management the clinical picture can be clarified, which then facilitates appropriate intervention.

An unknown giant neuroendocrine tumor

EP189

Nabila Rekik, Dorra Ghribel, Fatma Mnif, Mahdi Kalthoum, Houcem Mrabet, Nadia Charfi, Hamza Ellichki, Mouna Mnif & Mohamed Abid
The Department of Endocrinology and Diabetology of Hedi Chaker Hospital in Sfax, Sfax, Tunisia.

Introduction
Neuroendocrine tumors may develop in almost any organ. These types of tumors may present with giant and asymptomatic mass. We describe a case of a large non-functional neuroendocrine tumor reported in the department of endocrinology and diabetology of Hedi Chaker hospital in Sfax-Tunisia in 2016.

Presentation of case
A 28 years old male presented with asthenia, gastric heaviness and epigastric pain. Further computerized tomography, a large mass (20 cm) near the stomach in the coelomesenteric region has been demonstrated. Magnetic Resonance Imaging has showed the presence of a voluminous encapsulated mass with abundant vascularization and central necroses, measuring 18.5 cm×14.5 cm compressing the vascular structures. The dosage of methoxylated plasma derivatives was negative. The dosage of NSE was returned positive at 30.5 ng/l. The biopsy of the mass showed a histological and immunohistochemical aspect of a neuroendocrine tumor. The therapeutic decision was to start with exploratory laparotomy and tumor excision if possible. Because of the vascularized character and significant bleeding during the intervention, a surgical abstention was decided. The patient had two chemoembolization sessions with good tumor response. It is being evaluated for possible re-intervention.

Conclusion
The incidence of neuroendocrine tumors has been increasing during the last decade, underscoring the need to improve our understanding of their biology and behavior especially.

Biology and differential diagnosis of calcitonin secreting neuroendocrine tumors
Bojana Popovic, Djuro Macut, Valentina Elezovic Kovacevic, Tatjana Isalovic, Ivana Brozie Antic, Tamara Bogarac, Dusan Ilic, Sanja Ognjanovic, Gordana Kodic, Milan Petakov & Svetozar Djuric.
Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia.

Introduction
Calcitonin secreting neuroendocrine tumors (NET) are rare and not well recognized. Due to many similarities, it is sometimes difficult to differentiate them from medullary thyroid carcinoma (MTC), which can hamper choice of proper therapy. We investigated our group of patients with this type of NET in terms of diagnosis and biology.

Patients and Methods
We analyzed 38 patients with calcitonin secreting NET (5% of all our patients with NET). In addition to standard work up, calcium-stimulation test for calcitonin was performed in 15 of them, and results compared to 34 patients with MTC, and 21 control subjects with elevated calcitonin level and thyroid pathology other than MTC. Statistical analysis was done with SPSS software.

Results
Primary localization of NET was lung (16), pancreas (12), unknown primary (8) and intestine (2), with majority (54.1%) being grade G3, and high majority being metastatic (94.7%). Majority (55.6%) had goiter and 26.3% concomitant TPOAb, while 28.9% co-secreted another hormone (ADH, insulin, serotonin, PTHP).

Patients with NET had significantly higher basal calcitonin levels compared to controls (P<0.01), but with no significant difference compared to patients with MTC (P=0.427). Unlike this, patients with NET achieved significantly lower calcitonin levels after calcium stimulation compared to patients with MTC (P=0.01), but no different compared to controls (P=0.102). There was no significant correlation between basal calcitonin level and presence of TPOAb (P=0.816) or goiter (P=0.670) in these patients. Their median overall survival was 24.0 months (95% CI 10.9–37.1).

Conclusion
Patients with calcitonin secreting NET can secrete very high calcitonin levels, but can be differentiated from patients with MTC by absence of significant response to stimulation with calcium. Survival of these patients is poor, but influence of calcitonin on survival is yet to be determined.

EP192
Cancerous neuroendocrine vs endocrine tumours: broad commonalities and differences
Nicola Jervis & Catherine Bouvier
NET Patient Foundation, Leamington Spa, UK.

Endocrine cancers are defined, by European Taskforce on Endocrine Cancer, as malignant tumours arising from endocrine organs including thyroid, adrenal, parathyroid, pituitary, as well as neuroendocrine tumours in general. Cancerous neuroendocrine tumours arise from neuroendocrine cells which can be found within the endocrine system: in the pituitary, pineal, parathyroid and (medulla of the) adrenal gland, or more scantily within the thyroid, pancreas, ovaries and testicles, or more diffusely throughout the body, being present in respiratory, urinary and digestive tracts, as well as breast, skin, prostate and gynaecological structures.

Neuroendocrine and most endocrine cancers are considered both rare and complex. Commonalities exist in terms of gross classification, that is, designation by site, cell type and whether they are associated with excess hormone/peptide secretion – differences are revealed as this broad definition narrows. For example: within the adrenal gland:

Endocrine – adrenocortical carcinoma (ACC) arises within the cortex, and may be associated with excess secretion of steroid hormones. TNM staging. Neuroendocrine – pheochromocytoma arises within the medulla, and may be associated with the overproduction of catecholamines. No standardised staging and malignancy designation may be withheld in the absence of metastatic disease, though presentation, family history and proliferation rate will influence treatment planning and follow-up. Both may be associated with inherited disorders such as multiple endocrine neoplasia, therefore careful history taking and consideration of genetic counselling (Table & diagram of sites, cell type and associated hormone).

EP193
Short-term contralateral recurrence of a Litynski-Conn adenoma
Agneszka Kuzior1, Manuel Nivelov-Rivadeniera1, Ana Delia Santana-Suárez2, Claudia Armas-Leon1, Carmen Acosta-Calero1, Sara Quintana-Arroyo3, Marta Martin-Perez1 & Francisco Javier Martínez-Martín1
1Division of Endocrinology and Nutrition, Doctor Negrín University Hospital of Las Palmas of Gran Canaria, Las Palmas of Gran Canaria, Spain; 2Primary Care Center of Guía, Doctor Negrín University Hospital of Las Palmas of Gran Canaria, Las Palmas of Gran Canaria, Spain.

Clinical Case
A hypertensive 60-year-old woman with nephroangiosclerotic stage IV chronic renal failure (eGFR 23.44 ml/min/1.73 m²) was referred to our hypertension clinic after the CT finding of a 26-mm left adrenal mass with adenoma density during hypertension workup, with normal right adrenal. Physical exam was unremarkable except for BP 167/98 mmHg. Plasma aldosterone was 353 ng/ml, PRA 1.3 ng/ml/h, ratio 90.2. K⁺ 3.1 mEq/l, and metanephrines were normal. Primary aldosteronism was confirmed by standard captopril test. Adrenal vein sampling showed full left lateralization of aldosterone secretion. The patient underwent laparoscopic adrenectomy, and a 21-g left adenoma -including a 4-cm adenoma with clean margins- was removed. One month after surgery, K⁺, aldosterone and ARP were normal, and BP was controlled with manidipine 20 mg.

One year later, BP and plasma K⁺ were still controlled but the patient showed again a pattern of primary aldosteronism with aldosterone 747 ng/ml, PRA 0.9 ng/ml/h, ratio 83.0. A new CT showed absent left adrenal, and a 17×11 mm mass in the right adrenal, with adenoma density. Low-dose (12.5 mg) spironolactone was added to the treatment, but surgery was deferred.

Diagnosis
Primary aldosteronism caused by aldosterone-producing adenoma (Litynski-Conn syndrome), with contralateral recurrence after one year. Secondary hypertension with nephroangiosclerotic stage IV chronic renal failure.

Commentary
Contralateral recurrence of an aldosterone-producing adenoma in a previously normal adrenal after a complete surgical removal is exceedingly rare, particularly after such a short follow-up. The differential diagnosis would include familial type II aldosteronism (as types I and III usually cause severe hypertension in the pediatric age and associate normal or bilaterally hyperplastic adrenals but not adenomas, while type II may associate adenomas in adult patients) but as there is no known genetic marker for this condition, confirmation is not possible at this point.

EP194
Acinic cell adenocarcinoma of the parotid gland associated with paraneoplastic Cushing’s syndrome – a rare clinical case
Soﬁa Castro Oliveira1,2, João Sérgio Neves1,2, Pedro Southeiro1,2, Sandra Belo1,2, Ana Isabel Oliveira1,2, Celestino Neves1,2, Paula Freitas1,2 & Davide Carvalho1,3
1Department of Endocrinology, Diabetes and Metabolism of São João Hospital Center, Porto, Portugal; 2Faculty of Medicine, University of Porto, Porto, Portugal; 3Instituto de Investigação e Inovação em Saúde, Universidade de Porto, Portugal.

Introduction
Primary acinic cell carcinoma (ACC) is an uncommon salivary gland (SG) tumor, making up 1–3% of all SG neoplasms, more frequent in women, at 40–60 year old. The cause is still unknown and the only well-established risk factor is
ionizing radiation. ACC metastasize in 10–15% of the cases, 35% tends to recur and the rate of disease-associated death is about 16%. Surgical resection is the mainstay treatment, but radiation therapy may be used in some cases and, more rarely, chemotherapy in advanced ACC.

Case Report
We describe a case of a 46-year-old man referred by paresthesias, general malaise and hypokalemia of 2.5 mEq/l. The patient had a history of pericentimetric nodule in the left submandibular gland diagnosed 1 year before, hypertension and dyslipidemia diagnosed 4 months before and also new-onset diabetes mellitus (DM) diagnosed in the previous month. Ambulatory analysis showed endogenous hypercortisolism, and he was admitted to the endocrinology department for further investigation. Hormonal study revealed: ACTH 206.8 (<63.3) ng/l; cortisol 30.1(6.2–19.4) µg/dl; cortisolibria, 24-hour salivary cortisol and low-dose dexamethasone suppression test confirmed Cushing’s syndrome(CS); high-dose dexamethasone suppression test was compatible with ectopic CS. Initial imaging study found several hepatic nodular lesions, suggestive of secondary lesions by neoplastic process. Investigation was continued, with imaging and cytological documentation of probable primary parotid malignancy with hepatic metastasis. Octreoscan revealed increased uptake in the parotid gland and mild expression in hepatic metastasis. No uptake was observed in PET-Gallium. The patient underwent right parotidectomy, with the histological diagnosis of ACC, pT3NxR1, with no neuroendocrine differentiation, Ki67 70%. Imaging reevaluation revealed disease progression, with pulmonary and bone metastasis, and the patient started chemotherapy. Meanwhile, hypercortisolism was controlled with metyrapone (3 g/day), ketoconazole (400 mg/day) and lanreotide (120 mg/month).

Conclusion
The authors present a very rare case of ACC, with paraneoplastic CS and multiple metastases, with good response to treatment. Octreoscan revealed increased uptake in the parotid gland and mild expression in hepatic metastasis. No uptake was observed in PET-Gallium. The patient underwent right parotidectomy, with the histological diagnosis of ACC, pT3NxR1, with no neuroendocrine differentiation, Ki67 70%. Imaging reevaluation revealed disease progression, with pulmonary and bone metastasis, and the patient started chemotherapy. Meanwhile, hypercortisolism was controlled with metyrapone (3 g/day), ketoconazole (400 mg/day) and lanreotide (120 mg/month).

Malignant pheochromocytoma – a challenging diagnosis with nonconsensual management
Sofia Castro Oliveira1,2, João Sáérgio Neves1,2, Pedro Soutelho1,2, Eva Lau1,2, Ana Isabel Oliveira1,2, Celestino Neves1,2, Paula Freitas1,2 & Davide Carvalhao1,2
1Department of Endocrinology, Diabetes and Metabolism of São João Hospital Center, Porto, Portugal; 2Faculty of Medicine, University of Porto, Porto, Portugal; 3Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, Portugal.

Introduction
Pheochromocytomas and extra-adrenal paragangliomas are rare neuroendocrine tumours, with a peak incidence between the 3rd-5th decades of life and about 10% are malignant. Although they have the same radiographic and histologic characteristics of their benign counterpart, malignant pheochromocytomas are diagnosed by the presence of local invasion or metastatic tumor in the non-chromaffin tissues, and offer a poorer prognosis. Treatment is typically extirpative surgery, although MIBG-radiotherapy and chemotherapy have been offered in nonsurgical cases.

Case Report
An 83-year-old man with history of diabetes mellitus and hypertension presented abdominal pain, anorexia and weight loss. An abdominal CT revealed a large, hypovascular and heterogeneous neovascular formative lesion of left adrenal gland, 48 × 58 mm, and adjacent metastatic adenomegaly with 18 mm. He was then referred to our Endocrinology Department. Imaging study was repeated and a newly identified left renal mass, on the posterior face, exophytic, with 40 × 13 × 38 mm, suspected for metastasis. Biochemical diagnosis of pheochromocytoma was established by a marked increase of urinary catecholamines and fractionated metanephrines: normoephinephrine 1222 (97) µg/24 h, ephinephrine 106 (<27) µg/24 h and dopamine 1166 (<500) µg/24 h; normetanephrines 3711 (>390) µg/24 h and metanephrines 1226 (<320) µg/24 h; vanillylmandelic acid (VMA) was 29.3 (1.4–6.5) mg/24 h. 123I-MIBG scintigraphy was performed and evidenced left adrenal gland lesion compatible with pheochromocytoma, without uptake on left renal mass. The patient started alpha-adrenergic blockade with phenoxybenzamine (10–10 mg/day) and 6 weeks later underwent exploratory laparotomy surgery, with left adrenalectomy and nephrectomy. Histological examination confirmed malignant pheochromocytoma diagnosis and the patient maintains close surveillance.

Pancratic neuroendocrine tumours (pNETs) are rare neoplasms arising from the endocrine pancreas. The fist line treatment is surgery that is often not curative in the presence of metastatic disease. Therefore, there is an increasing need for medical therapy. Sunitinib is a multi-target receptor tyrosine-kinase (RTK) inhibitor, described as having as main target VEGF receptor, with antitumor and antangiogenic effects, approved for pNETs medical treatment. This study is aimed at evaluating Sunitinib effects in the human pNET cell line, BON1, in order to identify tissue-specific molecular targets that might predict the efficacy of the treatment. We tested BON1 cell viability and proliferation by means of Proliferation Assay and Luminescent Cell Viability Assay after treatment with Sunitinib (0.25–7.5 µM) and found an IC50 = 5 µM. Western blot analysis confirmed that BON1 cells express VEGF, IGFI and EGF receptors, therefore, we tested the effects of VEGF 50 ng/ml, IGFI 100 nM and EGF 15 nM alone or each in combination with Sunitinib 5 µM. We found that BON1 cell viability is not affected by VEGF and EGF, while it is significantly enhanced by IGFI (+20%; P < 0.05), that was capable of blocking the antiproliferative action of Sunitinib, suggesting that the main target of this drug is IGFI receptor. Therefore, we tested Linsitinib, a specific IGFI receptor inhibitor, and found that it significantly reduces BON1 cell viability (~25%; P = 0.05) and blocks the proliferative effects of IGFI. These data indicate that IGFI1 receptor represents the main molecular target of Sunitinib in BON1 cells and that it may play a crucial role in pNET cell proliferation control, suggesting that Linsitinib might be an effective medical treatment.

Study of different in vitro systems for the evaluation of Sunitinib effects in pancreatic neuroendocrine tumour cells
Giulia Bresciani1, Teresa Gagliano1, Leo J Hofland2, Erica Gentilin1, Simonetta Falletta2, Eleonora Riva1 & Maria Chiara Zattei1,3
1Section of Endocrinology, Department of Medical Sciences, University of Ferrara, 44121 Ferrara, Italy; 2Department of Internal Medicine, Erasmus Medical Center, Rotterdam, The Netherlands; 3Laboratorio in Rete del Tecnofpolo Tecnologie delle Terapie Avanzate (LTTA), University of Ferrara, 44121 Ferrara, Italy.

Finding new preclinical models to study the effects of anticancer drugs is one of the aims of biomedical research. Indeed, testing different in vitro systems can lead to a better understanding of the molecular pathways regulating tumor development and growth, and help to find new therapeutic approaches. This is crucial especially in the settings of pancreatic neuroendocrine tumours (pNET), where one of the main drugs approved for medical treatment is Sunitinib, a multi-targeted receptor kinase inhibitor. Clarifying the effects of this drug may be important to develop more effective medical treatment, therefore we tested Sunitinib on the human pNET cell line, BON1, grown in two different in vitro systems, monolayer and spheroid, in order to understand the different effects of the drug in 2D and 3D settings.

Endocrine Abstracts (2017) Vol 49
BON1 cells were grown in monolayer and treated with Sunitinib at increasing concentrations (0.25–5 μM). Cell Proliferation Assay and Luminescence Cell Viability Assay were employed to test Sunitinib antiproliferative effects. We found that Sunitinib 5 μM significantly reduced BON1 cell viability by 30% (P < 0.01 vs control) after 3 days. Similarly, Sunitinib 5 μM significantly reduced BON1 cell proliferation by 50% (P < 0.05 vs control) after 3 days and by 90% (P < 0.05 vs control) after 7 days.

Then, BON1 cells were grown in spheroids with Sunitinib at increasing concentrations (0.25–5 μM). Spheroids size was analyzed with ImageJ software after 3 and 7 days. We found that Sunitinib does not affect spheroid size, but induces spheroid disgregation after 7 days of treatment at 5 μM. These results indicate that measuring spheroid diameter in a 3D system is not the optimal system to assess the antiproliferative effects of Sunitinib on BON1 cells. On the other hand, the differences observed between the employed models could reflect the variations in drug response depending on cell aggregation state.

Von Hippel–Lindau syndrome: in vivo portrait with 68Ga-DOTANOC PET-CT

Ana Paula Moreira1,2, Gracinda Costa1,3 & Joa˜o Pedroso de Lima1,2

1Centro Hospitalar e Universitário de Coimbra (Nuclear Medicine Department), Coimbra, Portugal; 2Instituto de Ciências Nucleares Aplicadas à Saúde – Universidade de Coimbra (ICNAS-UC), Coimbra, Portugal; 3Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal.

Introduction

Von Hippel–Lindau syndrome (VHL) is an autosomal dominantly inherited neoplastic disorder with marked phenotypic variability, characterized by a broad spectrum of clinical manifestations in central nervous system (CNS) and viscera. Specific gene mutation can be demonstrated; however imaging plays an important role in diagnosis. 68Ga-labelled somatostatin analog (68Ga-DOTANOC) PET-CT is routinely employed for somatostatin receptor (SSTR) imaging, mainly for neuroendocrine tumors evaluation, but could be an optimal whole body imaging method for screening and follow-up VHL patients.

Purpose

To present 68Ga-DOTANOC-PET-CT findings in three VHL female patients (58, 55 and 65 years old), demonstrating both CNS and visceral tumors.

Material and Methods

68Ga-DOTANOC-PET/CT scan was acquired 45 min after intravenous administration of 100–200MBq 68Ga-DOTANOC in three patients with VHL referred for pancreatic neuroendocrine tumor (PNET) evaluation. Abnormal findings were correlated with histopathology or other imaging modalities (CT, MR, ophthalmoscopy).

Results

68Ga-DOTANOC-PET/CT showed, in all patients, other lesions than PNET, which proved to be related to VHL. Retinal and spinal cord hemangioblastomas were detected in two patients. Endolymphatic sac tumor was demonstrated in one. Lung hemangioblastoma was suspected in one. Liver and lymph node metastasis were present in one patient. Two patients had a pheochromocytoma previously removed by surgery.

Discussion

In VHL diagnosis a multidisciplinary approach is mandatory. Although genetic testing is available, imaging plays a key role in the identification of abnormalities, their follow-up and in the screening of asymptomatic gene carriers. Several analytic and imaging modalities are needed for diagnosis and follow-up. Screening is essential because the lesions in VHL disease are treatable. Early detection enables more conservative therapy and may enhance the patient’s length and quality of life. In these three VHL patients, 68Ga-DOTANOC-PET-CT has demonstrated to be a promising whole-body screening high-resolution imaging method for evaluation of the entire picture of this disease.

Gastroenteropancreatic neuroendocrine tumors (GEP-NETs): clinicopathological characteristics and disease outcome of 110 patients treated at single referral medical center

Shlomit Koren1, Karen Or1, Miri Steinschneider2, Esther Kummer1, Nirit Yarom1,2, Haim Shirin1,3, Ron Lavv1, Gratiana Gratiniana1 & Carlos Benbassat4

1Department of Endocrinology, Asaf Harofe Medical Center, Zeriffin, Israel; 2Department of Oncology, Asaf Harofe Medical Center, Zeriffin, Israel; 3Department of Gastroenterology, Asaf Harofe Medical Center, Zeriffin, Israel; 4Department of Surgery, Asaf Harofe Medical Center, Zeriffin, Israel; 5Department of Pathology, Asaf Harofe Medical Center, Zeriffin, Israel; 6Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel.

Introduction

GEP-NETs incidence increased markedly over the past decades probably due to increased imaging. GEP-NETs are generally indolent but often have unpredictable biological behavior and aggressive clinical course.

Aims

To collect information regarding demographics, presentation, pathology characteristics, treatment and outcome of GEP-NETs.

Methods

Following approval of our institutional ethical board, pathology and clinical records of all GEP-NETs patients diagnosed and treated at our institution during 2005–2015 were reviewed.

Results

We identified 110 patients with GEP-NETs distributed by site as pancreatic 32 (F = 45.1%, age 61.2 ± 6.8), gastrin 19 (F = 50%, age 66.2 ± 11), duodenum 9 (F = 33.3%, age 66.3 ± 12), small bowel 13 (F = 25%, age 60 ± 12), appendix 34 (F = 55.8%, age 36 ± 19) and colorectal 3. The PNETs presented with abdominal pain (45.1%) incidentally (25.8%) or syndromic (21.8%); including two insulinomas, one gastrinoma and four MEN1 patients. Mean size was 31 ± 23 mm and grading was G1 39.2, G2 42.8, G3 17.8%. Distant metastases (DM) were seen in five patients (M1 = 3). Surgery was performed in 61.3%, additional treatment given to 32.2% (re-op, somatostatin analogue, TKI, chemotherapy). The GNETs presented mostly during work-up for anemia or GI bleeding (70.6%). Mean size was 15 mm and the majority (82.3%) were GCT1 and there were no DM. The dNETs presented with anemia (43%), abdominal pain (43%) or incidentally. None was syndromic. Mean size was 11.2 mm, 50% were G1, and 2 had DM at presentation. Surgery was performed in 33.3% patients. The sNETs presented with bowel obstruction (27%), abdominal pain (36%) or incidentally. None was syndromic. Only 15% were G1, 6 had DM (M1 = 5), and 77% had surgery. Excluding aNETs, the overall mortality at last visit was 23.7% (7.9% disease related) at mean follow-up of 34.5 months.

Conclusion

GEP-NETs are associated with significant morbidity and mortality. The primary site of the tumor has clinical implication for disease management.

Insulinoma: diagnostic features and treatment management

Liana Khacimova1, Tatiana Karonova2, Uliana Tsoy1, Liubov Ianevskaia1 & Elena Grineva1,2

1Federal Almazov North-West Medical Research Centre, Saint-Petersburg, Russia; 2Pavlov First Saint Petersburg State Medical University, Saint-Petersburg, Russia.

Background

Insulinoma is the most common functional pancreatic neuroendocrine tumor originating from β-cells, with unregulated insulin production and rarely associated with MEN-1 syndrome. Diagnosis and treatment of insulinoma are a challenge in the practice of endocrinologist.

Aims

To determine on the basis of retrospective analysis the optimal approaches to the management of patients with organic hyperinsulinism.

Materials and methods

Medical records of 72 patients admitted with suspected organic hyperinsulinism had been screened and medical histories of patients with a confirmed diagnosis of organic hyperinsulinism were included into the analysis. Anamnesis, results of objective, laboratory and instrumental examinations, methods and results of the treatment were analyzed.

Results

The diagnosis of insulinoma was confirmed in thirty two cases. Hypoglycemia was achieved within the first 48 h after the start of the 72-h fasting test in 100% of cases. Study results showed that in 50% of cases the size of the pancreatic neoplasm was more than 1.4 cm. Inverse correlation between tumor size and plasma glucose concentration at the time of hypoglycemia was found (r = −0.45,
EP201
Non-islet cell tumor hypoglycemia (NICTH) is a rare paraneoplastic syndrome and is the second most common cause of tumor-related hypoglycemia following insulinoma. Its prevalence is not known and is likely that many cases would go undiagnosed. In here, we describe a patient with PNET who presented with severe hypoglycemia. A 37-year-old male with known metastatic Pancreatic neuroendocrine tumors (PNET) presented with weight loss, sweating, and tremor, episodic altered sensorium. He had documented blood glucose values below 35 mg/dl during those episodes. He received two cycles of lutetium therapy and was referred to our institute. At blood glucose of 33 mg/dl, he had undetectable plasma insulin (<0.19 mU/L), low C-peptide 0.159 ng/ml (normal: 0.8–4), cortisol: 5.6 µg/dl (normal: 5–29), GH: <0.05 ng/ml and low IGF1 <2.5 mg/ml (normal: 109–284 mg/ml). ACTH: 60 pg/ml (normal: 0–46), Na: 136 mmol/l (normal: 132–146), K: 4.2 mmol/l (normal: 3.5–5.5), TSH 1.274 µIU/ml (normal: 0.35–4.54), FT₄: 1.47 ng/dl (normal: 0.7–1.48), FT₃: 2.6 pg/ml (normal: 1.71–3.81), prolactin: 8.28 ng/ml (normal: 2.1–17.7), Na: 136 mmol/l (normal: 132–146), K: 4.2 mmol/l (normal: 3.5–5.5), TSH 1.274 µIU/ml (normal: 0.35–4.54), FT₄: 1.47 ng/dl (normal: 0.7–1.48), FT₃: 2.6 pg/ml (normal: 1.71–3.81), prolactin: 8.28 ng/ml (normal: 2.1–17.7), LH: 5.08 IU/l (1.5–9.3), FSH: 10.22 IU/l (1.4–18.1), testosteron: 405.78 ng/dl (normal: 121–270). Magnetic resonance imaging of pituitary gland was normal. We were started prednisolone 30 mg/day with which his symptoms abated. After prednisolone treatment, there was no recurrence of hypoglycemia on follow-up. In NICTH patients, the serum levels of insulin, C-peptide, and IGF1 are usually decreased or undetectable; however, the circulating level of total IGF2 as determined by conventional immunometric or receptor assays may be increased, decreased, or normal. In the absence of IGFB2 assays, low serum insulin in combination with low IGF1 levels at the time of hypoglycemia is a strong biochemical evidence of NICTH. High-dose glucocorticoid therapy has immediate beneficial effect on symptomatic hypoglycemia.

Late manifestation of a mixed adeno-neuroendocrine carcinoma of the cecum
Paraskevi Kazakou, Xakousti Tzamali, Alexis Travlos, Evangelia Vogiatzi, Georgia Ntali, Vasiliki Sarantopoulou & Antonis Polymenis
Department of Endocrinology, Alexandra General Hospital, Athens, Greece.

Introduction
Mixed adeno-neuroendocrine carcinoma (MANEC) is a rare tumor of the gastrointestinal tract that consists of a dual adeno-neuroendocrine carcinomatous and neuroendocrine differentiation. The clinical behavior seems to be influenced by the neuroendocrine component. We report a patient with mixed adeno-neuroendocrine carcinoma of the cecum who presented 18 years after her initial diagnosis and treatment.

Case report
A 59-year-old woman presented with a 3-month history of episodic hypotension, tachycardia and face and upper trunk flushes. She had a history of cecum tumor resection 18 years ago. It was a poorly differentiated mixed adeno-neuroendocrine carcinoma of the cecum. The tumor extended in the pericolic adipose tissue with perineural and lymphonodular invasion. It was TNM stage IIIB (TNM10). Postoperatively, she received interferon and 5-fluoracil chemotherapy for 6 months. The patient was asymptomatic for 18 years until symptoms of carcinoid syndrome (CS) appeared. Serum chromogranin A and 24-h urine 5-hydroxy-indole-acetic-acid (5-HIAA) were abnormally high. An abdominal magnetic resonance imaging revealed multiple metastatic liver lesions confirmed by biopsy. 111In-labelled octreotide scan detected the lesions in the liver and others in the left shoulder and the right sternum-clavicle joint. Bone lesions were also demonstrated by Tc-99m DTP scan. Octreotide LAR 30 mg per month was initiated and resulted in amelioration of symptoms. Chromogranin A and 5-HIAA decreased but remained above normal range. The symptoms of CS reappeared after 2 years and the patient received 9 cycles of targeted radiotherapy (177Lu-Dotate), which finally resulted in clinical and imaging improvement.

Conclusions
We report a rare case of a patient with a mixed adeno-neuroendocrine carcinoma of the cecum who presented with metastatic disease and carcinoid syndrome 18 years postoperatively. Due to the rarity of these tumours and the unknown natural history, lifelong follow up is required.

Quality of life in patients with neuroendocrine tumors treated with 177Lu-[DOTA,Tyr³]-octreotate: a Single Tertiary Care Portuguese Center Experience
Adriana Lages, Helder Moreira, Gracinda Costa, Patrícia Oliveira, Diana Oliveira, Diana Martins, Mara Ventura, Nelson Cunha & Francisco Carrilho
Coimbra Hospital and University Center, Coimbra, Portugal.

Introduction and purpose
177Lu-[DOTA,Tyr³]octreotate (177Lu-DOTA-TATE) is a radiopharmaceutical frequently used in peptide receptor radionuclide therapy (PRRT), which is a promising treatment modality in patients with metastasized neuroendocrine tumors (NETs). We propose to evaluate the quality of life (QoL) in patients with somatostatin receptor positive inoperable or metastatic NETs throughout the three cycle’s (with three months intervals) protocol used in our hospital.

Patients and methods
We included 24 patients, 16 men and 8 women (age: mean = 67 years; range: 29–81). The majority (13/24 cases; 54.2%) were gastroenteropancreatic NETs. Patients were treated with a mean cumulative 177Lu-DOTA-TATE activity of 614 mCi (range: 303–1177 mCi). Patients were invited to self-report QoL during PRRT cycles. We analyzed the overall QoL and specific domains of QoL according to the Organization for the Research and Treatment of Cancer Quality of Life Questionnaire C30 (EORTC QLQ-C30) scoring manual.

Results
From 24 patients, 15 completed at least 2 copies of the EORTC QLQ-C30 at different time-points (during the 1st or 2nd cycle and during the 3rd). Twelve patients had progressive disease, eleven had stable disease and one had notable lesions regression during PRRT. Regardless the treatment outcome, Global Health Status/QoL (GHS/QoL) and all the functional scales (except social status) improved significantly in all group (P<0.05). On GHS/QoL, we found an improvement on scores superior to 10 points before vs after therapy (Δ+10.56; P=0.003). Besides GHS and functional scales, we observed also a favorable impact on disease-related symptoms as fatigue (P=0.0003), insomnia (P =0.0003), appetite loss (P=0.0003), constipation (P =0.003) and diarrhea (P =0.014).

Conclusions
A better health-related QoL in cancer patients with incurable disease is an important outcome of cancer therapy, especially when survival is prolonged. Therapy with 177Lu-DOTA-TATE significantly improved QoL regarding to several functions and had favorable impact on global health status even on those with progressive disease.

**Triple tumors in a patient with insulinoma**

Urska Ksela & Mitja Krajnc

UKC Maribor, Maribor, Slovenia.

**Introduction**

Hypoglycemia is a rare clinical problem in patients not being treated for diabetes mellitus and requires further evaluation and management if Whipple’s triad is present. Insulinoma commonly presents with fasting hypoglycemia. Insulinoma is rarely associated with type 1 multiple endocrine neoplasia, when tumors are usually multiple and more frequently malignant. The diagnosis of insulinoma is established by demonstrating inappropriately high serum insulin concentrations during a spontaneous or induced episode of hypoglycemia, e.g. 72-h fast.

**Patient**

45-year old female was referred to our department for evaluation of spontaneous fasting hypoglycemia. She had multiple episodes of temporary probably neurohypoglycemic symptoms (confusion, unusual behaviour) and gained a lot of weight in 2016 (+20 kg). Before the beginning of 72-h fast her serum glucose was 1.8 mmol/l, insulin concentration 20.6 μU/ml, C-peptide 1.2 mmol/l. Testing was stopped after 6 h due to very low glucose levels (1.5 mmol/l) but without any obvious symptoms of hypoglycemia, insulin was high. After glucagon 1 mg i.v. glucose increased for 1.5 mmol/l. Her serum calcium, iPTH, prolactin and IGF-1 were normal. CT showed 1.8 cm lesion in the pancreatic neck and also unusual lesion in proximal jejunum that appeared to be a neuroendocrine tumor. There was also typical teratoma in left ovary (maximal size 6.6 cm), also seen on US. The patient underwent operation – partial pancreatectomy, proximal jejunal resection with anastomosis and left ovariectomy. Based on pathohistology results benign insulinoma was confirmed, in jejunum there was typical teratoma and in left ovary there was mature teratoma of left ovary. We have not performed genetic testing for MEN1 since we thought it was unlikely. After operation, the patient was asymptomatic and normoglycemic.

**Conclusions**

We found three different tumors, including insulinoma, in a single patient. This combination has not yet been described to coincide and is not due to multiple endocrine neoplasia.

**An analysis of R356W and Q318X mutations and 8 bp deletion in 21-hydroxylase gene CYP21A2 in causing pseudo-precocious puberty in patients with congenital adrenal hyperplasia in Pakistani children**

Nadraj Parveen1, Samar Minallah1, Muhammad Ismail2, Qaiser Mansoor2, Gulbin Shahid3, Faheem Tahir4, Afzaal Ahmed Naseem1, Mazhar Qayyum1 & Syed Shakeel Raza Rizvi1

1Department of Zoology, Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Rawalpindi, Punjab, Pakistan; 2Institute of Biomedical and Genetic Engineering (IBGE), Islamabad, Pakistan; 3Department of Animal Sciences, Quaid-e-Azam University, Islamabad, Pakistan; 4The Children’s Hospital, Pakistan Institute of Medical Sciences (PIMS), Islamabad, Pakistan; 5Reproductive Physiology, Public Health Laboratories Division, National Institute of Health, Islamabad, Pakistan.

The first signs of puberty are visible around the age of 8 years in girls and 9 years in boys. If signs of puberty appear before the designated ages in girls and boys, puberty is viewed as precocious. In peripheral precocious puberty, androgens concentrations increase due to testicular tumors or congenital adrenal hyperplasia (CAH). Two mutations, R356W and Q318X, and one 8 bp deletion in CYP21A2 gene, causing CAH type of precocious puberty were examined. Blood samples were obtained from 42 CAH patients (30 boys and 12 girls) exhibiting higher 17-OH progesterone concentrations and 42 normal healthy controls. DNA was extracted, primers of exons of CYP21A2 splice sites were designed and PCR-RFLP method was employed. The PCR-RFLP method was employed. The PCR was digested by enzyme Fnu4HI for R356W mutation gave bands of AA (~106, 110, 229 and 37 bp). The frequency of this genotype was 100% in both groups indicating absence of R356W mutation in both groups. For Q318X, the restriction enzyme, PstI gave bands of 5 different genotypes, GG (161 and 329 bp segments) in 18 patients, GC (490, 329 and 161 bp segments) in 21 patients and CC (segment of 490 bp) in 3 patients (2 boys and 1 girl). For 8 bp deletion, PCR amplification with allele specific primers yielded a segment of ~710 bp. 8 bp deletion was not found in any patient but 3 control subjects were heterozygous for it. The frequency of homozygous wild type (NN) was 1 in patients and 0.85 in controls; the frequency of homozygous mutants (DD) was 0 in both groups, whereas the frequency of heterozygous (DN) was 0 in patients and 0.15 in controls. The frequency of allele D was 0 in patients and 0.075 in controls. The frequency of allele N was 1 and 0.925 in patients and controls respectively.

**Congenital adrenal hyperplasia: impact of therapy on growth and sexual maturation – a 5-year retrospective study of a Tertiary Pediatric Endocrinology Center**

Camelia Procopiuc, Madalina Vintila, Iuliana Gherlan, Amel Cirila, Andreea Breher, Andra Caragheorgheopol, Suzana Vladou Oana Popa & Cristina Dumitrescu

CI Parhon National Institute of Endocrinology, Bucharest, Romania.

**Objective**

To evaluate the comparative effects of different glucocorticoid treatments on growth and sexual maturation in patients with congenital adrenal hyperplasia.

**Patients and methods**

We conducted a retrospective observational cohort study in 78 patients (60 girls, 18 boys) diagnosed with congenital adrenal hyperplasia (CAH), followed-up for a period of 5 years. The majority had 21-hydroxylase deficiency (75 patients), 2 had 11β-hydroxylase deficiency and 1 patient had 3-β-hydroxysteroid dehydrogenase deficiency. Patients received either Prednisone (PDN), Hydrocortisone (HC) or Hydrocortisone plus Dexamethasone (DEX). Data on growth, bone maturation, puberty onset, predicted adult height, and parental height were collected. Height gain was calculated as the difference between parentally determined target height and final or predicted height at the last evaluation.

**Results**

Height gain with therapy was 0.42 ±0.24 cm over the initial estimated height deficit. Height gain correlated with the clinical form of CAH, with better outcome in non-classical vs classical forms (P<0.01). There were no significantly differences between groups in regard to type of therapy (P=0.164). There was no difference in change of body mass index regarding the type of treatment (P=0.99). Girls over 12 years of age treated with HC had higher rates of spontaneous menarche versus PND treated girls (P=0.006). Twelve children developed precocious puberty, which correlated with older age at treatment initiation (P=0.048).

**Conclusions**

The type of therapy did not influenced height gain. HC facilitated spontaneous menarche onset in normal age range. Late diagnosis and therapy led to higher rates of precocious puberty in children with CAH.

**The risk of hypotension, evaluated by ambulatory blood pressure monitoring, during fasting and outside fasting in patients with adrenal insufficiency**

Melika Chihakou1, Wafa Graira2, Meriem Yazidli3, Oms Rejeb3, Fatma Chaker1, Bisetssem Oueslati1, Jihane Bettayeb1 & Hedia Slimane1

1Department of Endocrinology, Faculty of Medicine of Tunis, La Rabta Hospital, University of Tunis El Manar, Tunis, Tunisia; 2Department of Medical Epidemiology, Faculty of Medicine of Tunis, Pasteur Institute of Tunis, University of Tunis El Manar, Tunis, Tunisia.

The risk of hypotension during Ramadan fasting in patients with adrenal insufficiency is unknown. The aim of our study was to evaluate objectively this risk.

**Methods**

It is a prospective case-crossover study on 28 patients with known and treated AI. Patients had no hypotension and were regular fasters. All patients underwent a clinical examination and a 24-hours blood pressure monitoring during Ramadan fasting then outside fasting.

**Endocrine Abstracts (2017) Vol 49**
Results
There were 23 women. The mean age was 37 ± 14 years. It was a central adrenal insufficiency in 26 patients. The mean duration of the disease was 9 ± 8 years. The mean daily dose of hydrocortisone was 19 ± 3 mg. Systolic hypotension (<90 mmHg) did not occur during fasting and occurred in two cases outside fasting. Diastolic hypotension (<60 mmHg) occurred in 12 cases during fasting and in 13 cases outside fasting without a significant difference. All cases of hypotension were asymptomatic. The levels of systolic and diastolic blood pressure during the 24 h and during the fasting period (from pre dawn to sunset) did not significantly differ between the fasting day and the non-fasting day.

Conclusion
Blood pressure levels during fasting were comparable to those outside fasting and there was not an increased risk of hypotension during fasting.

Steroid metabolome changes in the 1 mg dexamethasone suppression test
Václav Hana jr1, Mikuláš Kosák1, Václav Hana1 & Martin Hili1,2
13rd Department of Internal Medicine, 1st Faculty of Medicine, Charles University and General Teaching Hospital, Prague, Czech Republic; 2Institute of Endocrinology, Prague, Czech Republic.

Introduction
Dexamethasone induced negative feedback on CRH, ACTH and cortisol secretion is one of the key principles in the diagnostic workup of hypercortisolism. Cortisol secretion has been studied extensively, but changes of other steroids remained apart. Our aim was to establish steroid profile changes in 1 mg dexamethasone test.

Methods
The steroid profile consisting of 103 steroids and their metabolites from the serum of 9 male and 8 healthy female controls was measured before and in the morning at 0800 hours after 1 mg dexamethasone administered at 1100 hours. Samples were analyzed using GCMS/MS for the measurement of most of the steroids. Only a few were measured by RIA.

Results
Dexamethasone administration suppressed the most the levels of corticosterone (29×), cortisol (20×), 11-OH-androstenedione (12×), 11β-Hydroxy-androsterone (13×), 11β-Hydroxy-etiocholanolone (13×), 11β-Hydroxy-epiandrosterone (6×), 17-Hydroxyprogrenolone (5×). Other steroids like DHEA (3×), Androstenedione (2×), Pregnenolone (2×) were suppressed at much lower rate than their 11β-hydroxylated metabolites. As expected, none of the measured steroids increased after dexamethasone.

Conclusions
Inhibition of ACTH secretion leads to a strong suppression of the whole adrenal steroidogenesis including androgen production. The most prominent changes were observed in corticosterone, cortisol, and interestingly 11-OH-androstenedione and their 5β-reduced metabolites, which all decrease more than 10 times in comparison with the basal levels.

This clearly demonstrates the key role of 11β-hydroxylase being the most influenced enzyme by the adrenocortical axis suppression.

Thyroid Cancer

EP209
Clinical relevance of RET proto-oncogene variants L769L and S836S (exon 11, 13, 14, and 15) in patients with sporadic medullary thyroid carcinoma
Darko Katalinic1, Miljenko Solter2 & Nora Nikolac2
1Department of Internal Medicine, Faculty of Medicine, J.J. Strossmayer University of Osijek, Osijek, Croatia; 2Faculty of Medicine, UHC Sisters of Charity, University of Zagreb, Zagreb, Croatia.

Background
Medullary thyroid cancer (MTC) makes up to 5–10% of all cases of thyroid malignancies. The clinical course of MTC varies from an extremely indolent tumour to an aggressive variant that is associated with a high mortality rate. RET proto-oncogene germline mutations are crucial for the onset and the progression of MTC. The aim of this study was to evaluate the L769L (subgroup L) and S836S (subgroup S) allele frequencies in patients with sporadic MTC (group A, n=89) compared to healthy subjects (group B, n=83) and to determine if these polymorphisms have influence the clinical presentation and the course of MTC.

Methods
A non-isotopic polymerase chain reaction based single strand confirmation polymorphism analysis and heteroduplex gel electrophoresis method was used to screen tumour DNA extracted from 89 formaldehyde fixed and paraffin embedded MTC specimens. We also analysed relevant clinical data in the group of patients with MTC. The study was conducted according to the Declaration of Helsinki, the protocol was reviewed and approved by the institutional independent ethics committee. All patients were provided with written informed consent.

Results
Mean age was 51.6±9.2 years for the patients with MTC (range, 42.4–60.8) vs 45.4±7.1 (range 38.3–52.5) for the group of healthy subjects. The allele frequencies showed a similar level of the L769L and S836S variants in both subgroups of examinees (group L, n=42 vs subgroup S, n=47; P>0.001), and distant metastases in nine patients (subgroup L, n=4 vs subgroup S, n=5; P>0.001). Postoperatively, 52% of patients in subgroup L vs 55% of patients in subgroup S were biochemically cure (P>0.001).

In the subgroup L, pT-category was: T0, n=23; T1, n=14; and T2, n=5. In the subgroup S, pT-category was: T0, n=21; T1, n=16; and T2, n=10.

Conclusion
We did not find any statistically significant difference in representation of the L769L and S836S gene variants. The RET L769L, and S836S (exon 11, 13, 14, and 15) gene variants are not contributing factor in the development of sporadic MTC and are not promoting factor for development of metastatic MTC.

Bisphosphonate related osteonecrosis of the jaw: risk factors: a case report
Pablo Young, Natalia Elias, Noelia Rella, Marcela Moran & Marina Curria
British Hospital, Buenos Aires, Argentina.

Introduction
Bisphosphonates (BP) have been employed for many years and have demonstrated an excellent safety profile. Nevertheless, severe osteonecrosis of the jaw (ONJ) have been described in patients with bone metastases that were treated with BP for many years.

Case
A 72 year old female with breast cancer and bone metastases treated with zoledronic acid. She underwent lumpectomy of the right breast and axillary lymph node dissection followed by radiotherapy. She presented severe pain and suppuration. The right side of the jaw was removed.

Conclusion
The aim of this presentation is to emphasize the importance of taking into account the risk factors of ONJ in patients with malignancy who receive BP seems to range between 1 and 10%. The risk factors of ONJ are related to BP, local, systemic and demographic factors. The use of less traumatic techniques available and adequate antibiotic treatment is mandatory in the presence of risk factors of ONJ. BP treatment should be interrupted after surgery until the wound is fully healed.

Salmon calcitonin affects thyroid endocrine cells and trabecular bone in a rat model of male osteoporosis
Branko Filipovic1, Branka Sošić-Jurjevic1, Jasmina Živanović1, Milica Manojlović-Stojanovski1, Tatjana Nestorović1, Svetlana Trifunović1, Ivana Jarić1, Gordana Ušćebka2 & Verica Milošević1
1Institute for Biological Research “Simina Stanković”, University of Belgrade, Belgrade, Serbia; 2Faculty of Agriculture, University of Novi Sad, Novi Sad, Serbia.

Calcitonin (CT) is a hypocalcemic hormone produced by thyroid C-cells that acts as an bone antiresorptive agent. The other endocrine cell population in thyroid, called follicular cells produce hormones (TH) which also affect bone turnover. In this study, we evaluated the effects of salmon CT administration on structure and function of both CT and TH producing thyroid cells as well as trabecular bone microarchitecture in orchidectomized (Orx) middle-aged rats. Fifteen-month-old male Wistar rats were either Orx or sham-operated (SO). One group of Orx animals were injected subcutaneously with synthetic salmon CT (Orx + CT; 100 IU/kg b.w.) every second day for 6 weeks. The rats from SO and second Orx group received the same volume of vehicle alone by the same schedule. The peroxidase–antiperoxidase method was applied for localization of CT in C-cells. CT-immunopositive thyroid C-cells, thyroid follicular epithelium, interstitium and colloid were evaluated morphometrically. An ImageJ public domain image processing program was used to measure bone histomorphometric parameters of the proximal tibial specimens. Blood serum samples were analyzed for CT, osteocalcin (OC) and thyroxine (T4), and urine samples for calcium (Ca2+) and phosphorus (P) concentrations. We found a significant decrease in the Vc and Vv of thyroid C-cells after CT treatment compared to both SO and Orx. The Vv of the colloid was higher, while Vc of the follicular epithelium was lower after CT treatment compared to Orx. Analysis of trabecular microarchitecture showed that salmon CT administration significantly increases cancellous bone area (B.Ar), trabecular thickness (Tb.Th), and trabecular number (Tb.N) whereas trabecular separation (Tb.Sp) was significantly decreased. CT treatment markedly elevated serum CT, but serum OC, T4 and urinary Ca2+ concentrations were lower than in the Orx group. These findings indicate that administration of salmon CT inhibits calcitonin-producing thyroid C-cells and changes the structure of the thyroid gland indicating hypoactivity.

Primary hyperparathyroidism: hormonal profile and risk of complications
Alina-Andreea Gatu1, Cristian Velicescu1,2, Cristina Preda1,2, Voichita Mogos1,2, Carmen Vulpoi1,2, Simona Mogos1,2, Valentin Zaharia2, Adrian Aancute3 & Dumitru Bransteanu1,2
1Gr. T Popa University of Medicine and Pharmacy, Iasi, Romania; 2St. Spiridon Emergency Hospital, Iasi, Romania.

Background
Vitamin D deficiency is frequently associated with primary hyperparathyroidism, but the impact of this association on disease evolution and complications is ill defined. Aims: to assess the role of vitamin D status on the metabolic profile and spectrum of complications at patients with primary hyperparathyroidism.

Materials and methods
Transversal study involving 42 patients with primary hyperparathyroidism submitted to parathyroidectomy. We evaluated serum calcium, phosphate, serum PTH and 25OHD3, bone mineral density by DXA (Hologic) and anamnestic spectrum of complications at patients with primary hyperparathyroidism.

Results
Twenty-nine of the 42 patients had 25OHD3 in the range of deficiency (lower than 30 ng/ml) and 20 had severe 25OHD3 deficiency (lower than 10 ng/ml). Serum calcium and phosphate were similar irrespective of the presence or absence of complications. No differences were found between mean PTH and 25OHD3 levels of patients with or without osteoporosis. Patients with kidney lithiasis had, however, higher PTH (390+/- 90 pg/ml vs 209+/- 64 pg/ml, P<0.001) and lower 25OHD3 levels (12.8+/- 6 ng/ml vs 19.2+/- 7.8 ng/ml, P<0.05) than patients without kidney lithiasis.

Conclusions
D hypovitaminosis accompanies frequently primary hyperparathyroidism. Patients with higher risk of kidney lithiasis seem to have higher PTH and lower 25OHD3 levels.

Efficacy and safety of bisphosphonate discontinuation in postmenopausal osteoporosis: a systematic review
Panagiotis Anagnostis1, Stavroula Paschou1, Gethshimi Mintziori1, Irene Lambrinoudaki1 & Dimitrios Goulis1

1Department of Medicine, Moore Hospital, Athens, Greece.

Background
Bisphosphonates (BP) are drugs that are used to treat osteoporosis. They reduce the risk of fractures by inhibiting bone resorption induced by osteoclasts. BP treatment is usually lifelong. However, patients may request discontinuation of BP therapy after improvement of bone mass. Objective: to assess the efficacy and safety of discontinuation of BP therapy in postmenopausal osteoporosis.

Methods
We systematically searched Medline database using terms related to BP discontinuation in postmenopausal osteoporosis. We identified 294 papers. Of these, 23 were selected for full-text analysis. Four studies met the following eligibility criteria: randomized controlled trials or prospective cohort studies, with a minimum follow up of 1 year, in postmenopausal women with osteoporosis, treatment with BP for at least 1 year, and discontinuation of BP therapy after improvement of bone mass.

Results
Three studies evaluated the effect of discontinuing BP on bone mass. Two studies used alendronate, one of which showed a significant decrease in bone mass at 1 year. The third study used risedronate and found that bone mass was maintained at 1 year. Two studies evaluated the effect of discontinuing BP on vertebral fractures. Both studies showed no significant difference in vertebral fracture incidence between the discontinuation and continuation groups. No differences were found in non-vertebral fracture incidence.

Conclusions
Discontinuation of BP therapy in postmenopausal osteoporosis is associated with a decrease in bone mass and an increase in vertebral fracture incidence. Further research is needed to determine the optimal strategy for discontinuing BP therapy in postmenopausal osteoporosis.

EP215 Osteopetrosis vs Osteogenesis Imperfecta—is that so hard to distinguish?

Case report
Theodor-Eugen Oprea, Mirela Bonea, Suzana Florea & Carmen Barbu Elias University Emergency Hospital, Endocrinology Clinic, Bucharest, Romania.

Osteopetrosis and O.I. are both bone metabolic disorders with opposite features in terms of the metabolic turnover; while osteopetrosis has a low turnover and increased BMD due to the failure of osteoclasts to resorb bone, O.I. is well known as a high turnover disease with low BMD caused by mutations in the COL1A1 and COL1A2 genes that encode type 1 procollagen; yet, both condition, in spite of different mechanism, end up with increased fracture prevalence. We report the case of a 46 year old women who presented for clinical and biological evaluation with a prior diagnosis of osteopetrosis. The anamnesis revealed that the diagnosis of osteopetrosis was set when the patient was 2 year old based on radiological features and multiple nontraumatic fractures suffered in childhood; last fracture she recalls was at 20 year old. And also she claims a familial history of osteogenesis imperfecta (maternal grandfather). The classical clinical examination revealed: Height-125 cm; Weight-50 kg; BMI-32 kg/sm; blue sclerae, left leg orthisis, with unequal inferior limbs accompanied by difuze joint pain. Lab tests highlighted mild hypercholesterolemia, 25OHvitD insufficiency, low beta-crosslaps level, normal PTH, normal TSH and FT4. Near normal BMD. Dorsal and lumbar spine X-ray: rarefaction of trabecular bone structure, suggesting a medium grade of deminerlization.

Our O.I. final diagnosis proved to be quite difficult, taking into account the prior one of osteopetrosis, the history of pubertal fractures, familial history of O.I., growth impairment, lack of decreased BMD and increased bone turnover, mild VitD insufficiency. However, the importance of establishing the diagnosis, in our case, consists in choosing the optimal treatment; bisphosphonates are used in O.I. but not indicated in osteopetrosis. Our approach was to treat her with activ vit.D products since her actual fracture risk was not considered increased.

EP216 Osteonecrosis of the jaw and bilateral atypical femoral fracture both occurring during treatment of osteoporosis

Edelisa Payumo, Thelma Crisostomo & Ivan Cudal Makati Medical Center, Makati, The Philippines.

Background Osteonecrosis of the jaw (ONJ) and atypical femoral fracture (AFF) are rare potential adverse effects of bisphosphonates and RANK-L inhibitor, occurring in 1 and 2 per 100,000 person-years, respectively. The pathogenic mechanisms of both conditions are known to be independent of each other. Here, we report both conditions sequentially occurring in the same patient.

Clinical case
An 81 year-old, obese, diabetic, female was admitted due to hypertensive urgency and persistent jaw pain after tooth extraction. The patient has postmenopausal osteoporosis for fourteen years and was on intermittent unsupervised treatment with alendronate, denosumab and ibandronate. She had suffered sequential fracture of both femurs during the eighth and eleventh year of treatment. Both fractures were transverse, non-committed, at the proximal femoral shaft, which occurred after a minor trauma, and were managed with open reduction and internal fixation.

Upon presentation, the patient was noted with tenderness intraorally of tooth number 35 periapical region, no pus, no mandibular swelling. There was peripheral leukocytosis, elevated erythrocyte sedimentation rate, C-reactive protein. Panoramic with perivalpe view radiograph showed presence of bony sclerosis which represent a sequestrum compatible to chronic osteomyelitis in the molar area of the left hemi-mandible. Antibiotic infusion and excision and debridement of left posterior mandible were done. Necrotic bone with histopathologic finding of acute and chronic osteomyelitis with bacterial colonies was removed consistent with a diagnosis of osteonecrosis of the jaw. The patient was discharged on the fourth post-operative day and was placed on drug holiday.

Conclusion
ONJ and AFF can occur both in the same patient during prolonged treatment with bisphosphonates and RANK-L inhibitor and may suggest a common pathogenic mechanism. This case further emphasized that to avoid these grave consequences, bisphosphonates should be given in a limited period—five years, as recommended by experts.

DOI: 10.1530/endoabs.49.EP216
Methods
A 61-year old female patient with family history of OI (son and sister) was treated in our clinic. She had history of multiple repeated fractures since 18 years old, short stature (138 cm), discolouration of the sclera, dental abnormalities, poor muscle tone in arms and legs, triangular face and skeletal deformities such as osteoporosis, spinal canal stenosis and kyphoscoliosis. Bone densitometry found severe osteoporosis. Treatment included zoledronic acid IV, vitamin D and calcium carbonate per os.

Results
After treatment with zoledronic acid the patient reported reduced bone pain and had stable bone mass (0.547 g/cm² before treatment and 0.535 g/cm² (femoral neck) after treatment) and increased T-score (femoral neck) (−3.3 SD before treatment and −2.08 SD after treatment, 3 years later).

Conclusion
Osteoogenesis imperfecta is a heterogeneous disease and may have an indolent course. The diagnosis may be brought forward late in adulthood. The management includes replacement of a calcium and vitamin D deficit and bisphosphonates. Bisphosphonates remain effective and can increase bone mass, reduce bone pain and fractures.

DOI: 10.1530/endoabs.49.EP217

EP218
Special features of body composition and bone mineral metabolism in children with primary nephrotic syndrome
Natalia Volkova1 & Angelika Soltisava1
12-City Children’s Hospital, Minsk, Belarus; 2Belarusian State Medical University, Minsk, Belarus.

Objective
To learn characteristics of biochemical markers of bone metabolism, parameters of bone mineral density (BMD) and fat component of body composition for early diagnosis of bone disorders in children with primary nephrotic syndrome (NS).

Material and methods
We compared data of laboratory investigations (phosphorus (P), total calcium (Ca), parathyroid hormone (PTH), and alkaline phosphatase (ALP)), protocols of dual-energy X-ray absorptiometry of the axial skeleton and total body of 27 children with NS (group 1 – G1, age 9.71 ± 4.23 yrs) and 13 children of control group (G2, age 10.84 ± 3.84 yrs, P = 0.48). Group 1 was divided in subgroups G1a (relapse of NS, n = 12) and G1b (remission of NS, n = 15). Results were processed using SPSS17.

Results
G1 showed significantly lower age-matched z-score of BMD of lumbal spine (L1-4) (−0.71 ± 0.096) compared with G2 (0.08 ± 1.13, P = 0.036). One child of G1 had low bone density of lumbal spine with z-score −2.9. Total BMD was similar in the groups (0.88 ± 0.12 g/cm² in G1 vs 0.91 ± 0.19 g/cm² in G2, P = 0.39). Fat component of body composition was increased in G1 (38.33 ± 11.30%) compared with G2 (27.52 ± 6.59%, P < 0.0001). Android/gynoid fat ratio was higher in G1 (0.70 ± 0.20, P = 0.013). Children of G1a showed lower level of Ca than control (2.24 ± 0.18 mmol/l vs 2.37 ± 0.07 mmol/l, P = 0.009). Concentration of Ca in G1b was similar to G2 (2.37 ± 0.07 +/− 0.13 vs 2.44 ± 0.15 mmol/l, P = 0.71). We didn’t reveal significant difference in of PTH, P and ALP levels in the groups (P > 0.05).

Conclusions
Most children with NS showed normal BMD of lumbal spine, though it was lower than in healthy controls. Patients with NS had low bone density of lumbal spine with z-score 2.37. Children of G1a showed lower level of Ca than control (2.24 +/− 0.18 mmol/l vs 2.37 ± 0.07 mmol/l, P = 0.009). A negative and significant correlation was found between the serum levels of 25OHD3 and those of PTH. This correlation persisted after adjusting for age and BMI. Our study did not find any significant relationship between PTH levels and BMD scores with (P = 0.609).

Conclusion
According to data from the literature and despite normal BMD in patients with type 2 diabetes, it should be borne in mind that BMD alone is insufficient to assess bone status, management of other factors such as Diet rich in vitamin D and sufficient calcium intake is required.

1Federal State Institution “The National Research Center for Endocrinology”, Moscow, Russia; 2Federal Research and Clinical Center FMBA, Moscow, Russia; 3N.N. Burdenko Neurosurgery Institute, Moscow, Russia.

Molecular basis of the bone disorders in patients with acromegaly are largely unknown.

Objective
To investigate gene expression profiles that regulate bone metabolism in bone tissue samples from patients with acromegaly.

Materials and Methods
Patients with clinically evident and biochemically proven active acromegaly and patients with hormonally inactive pituitary adenoma matched by age, sex and BMI were invited to participate. Bone samples were taken during transsphenoidal tissue samples from patients with acromegaly.

Molecular basis of the bone disorders in patients with acromegaly are largely unknown.

Objective
To investigate gene expression profiles that regulate bone metabolism in bone tissue samples from patients with acromegaly.

Materials and Methods
Patients with clinically evident and biochemically proven active acromegaly and patients with hormonally inactive pituitary adenoma matched by age, sex and BMI were invited to participate. Bone samples were taken during transsphenoidal tissue samples from patients with acromegaly.

Results
We enrolled 21 subjects (12 patients with acromegaly and 9 with hormonally inactive pituitary adenomas); 13 females and 8 males, the mean age was 38 years (confident interval (CI) 95% 33−43) mean BMI – 28 (CI95% 25−31) kg/m². There

EP219
Bone densitometry of type 2 diabetics (about 290 patients)
Samir Ait Abderrahmane, Zahra Kemali, Sihem Hatri, Elmahdi Haffaf, Nacer Sobhi, Lilà Brakni & Brahim Oudjit
HCA, Kouba, Algeria.

Introduction
The improvement of the survival of diabetics is accompanied by the emergence of bone fragility which can directly affect, at various levels, the various components of the bone tissue leading to quantitative and qualitative abnormalities. The effects of type 2 diabetes on bone are complex because they are associated with the sometimes associated disorders of nutrition, weight and age. Densitometric studies in this context are quite contradictory. We proposed to study the bone status of type 2 diabetics.

Patients and methods
We carried out a cross-sectional study of 290 type 2 diabetics. These patients benefited from a measurement of bone mineral density (BMD) associated with PTH, vitamin D and calcemia.

The results
The average age of our population was 62.5 years. 38% of our patients were treated with insulin with a predominantly mixed regimen (basal insulin combined with oral treatments), with an average HBA1C of 7.05% for an average duration of diabetes of 8 years. Mean calcium in the general population was 2.33 mmol/l, with 2.36 mmol/l in males and 2.27 mmol/l in females, with no significant relationship between the two sexes (P = 0.1370).

5 patients had secondary hyperparathyroidism (> 65 pg/ml), the mean PTH in the study population was 46.82 ng/ml, higher in women than in men. 75.6% of patients had normal BMD, 23.3% had osteopenia, 24.3% were women, and 21% were men. The mean concentration of vitamin D is 13.93 ng/ml, with a maximum of 35 ng/ml and a minimum of 3 ng/ml. The mean concentration in males was 15, 14 ng/ml, significantly higher than that of females in the order of 11.91 ng/ml (P < 0.1 = P = 0.0018). A negative and significant correlation was found between the serum levels of 25OHD3 and those of PTH. This correlation persisted after adjusting for age and BMI. Our study did not find any significant relationship between PTH levels and BMD scores with (P = 0.609).

Conclusion
According to data from the literature and despite normal BMD in patients with type 2 diabetes, it should be borne in mind that BMD alone is insufficient to assess bone status, management of other factors such as Diet rich in vitamin D and sufficient calcium intake is required.

DOI: 10.1530/endoabs.49.EP220
were no significant differences in the groups. Mean IGF-1 in subjects with acromegaly—785 (CI95% 527–1042) ng/ml. The expression of SOST 5.7 (CI95% 1.01–10.44, P = 0.022), DKK1 7.97 (CI95% 4.4–11.54, P < 0.001), BGLAP 1.51 (CI95% 0.82–2.19, P < 0.001) was increased in subjects with acromegaly compared to inactive pituitary adenoma. miRNA 199a-5p 0.37 (CI95% 0.06–0.68, P = 0.023) was suppressed.

Conclusion
In spite of increased expression of Wnt signaling antagonist, bone formation is not suppressed in subjects with acromegaly. The suppression of miRNA might explain the predominant differentiation to the cartilage tissue.

Osteoporosis and fractures in the real world setting

Eleni Pantazi¹, Alexis Travlos², Evagelia Vogiatzi² & Ilgenia Kostoglou-Athanassiou²

¹Department of Endocrinology, Alexandria Hospital, Athens, Greece;
²Department of Endocrinology, Red Cross Hospital, Athens, Greece.

Osteoporosis is a bone disease predisposing to bone fragility. Nowadays, the population is screened for osteoporosis and measures are taken for fracture prevention. Additionally, people are urged to have a diet rich in calcium, are given calcium supplements and are being treated for vitamin D deficiency. Moreover, osteoporosis treatment is administered. Therefore, the relationship between osteoporosis and fractures in the real world setting is very interesting.

The aim was to study the prevalence of fragility fractures in a cohort of patients being followed up and treated for osteoporosis in a center of excellence for the management of osteoporosis in Athens. A cohort of 91 patients, 82 female and 9 male, aged 69.71 ± 1.09 years, who were followed up and treated as needed for osteoporosis in a center of excellence was studied. Bone mineral density was measured in the spine and the hip. The number of fractures having occurred in the cohort studied was recorded.

Bone mineral density in the spine as assessed by T score was −1.9 ± 0.11 (mean ± SEM) and in the left hip −2.6 ± 0.11. In the cohort of patients studied 19 patients (20.88%), 15 female and 4 male, suffered a fracture. The fractures recorded were 8 vertebral, 7 distal radius, 2 tarsal joint, 2 fib fractures and 1 fracture of the calcaneus. Within the cohort studied 2 patients had suffered two fractures, a distal radius and a vertebral and a rib and a vertebral fracture, respectively. It appears that in the modern real world setting despite the measures taken for osteoporosis prevention and management in a cohort of patients being followed up within a center of excellence in Athens, fractures tend to occur especially in the female population. However, interestingly, within the cohort studied many patients with osteoporosis remained free of fracture at the point of time of the study.

Is osteoporosis a curable disease?

Ilgenia Kostoglou-Athanassiou¹, Eleni Pantazi² & Panagiota Athanassiou²

¹Department of Endocrinology, Red Cross Hospital, Athens, Greece;
²Department of Endocrinology, Alexandria Hospital, Athens, Greece;
³Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece.

Osteoporosis may be a disease of unknown etiology, or a degenerative disorder in the context of aging. Nowadays, the availability of multiple forms of effective drug treatment for osteoporosis have raised the hypothesis that osteoporosis may be not only a treatable but moreover a curable disease.

The aim was to describe the case of a patient with osteoporosis who after treatment with alendronate for 6 years had osteopenia and remains in the state of osteopenia for a long period after drug cessation.

A patient, female, aged 65 years, postmenopausal, presented with osteoporosis, T score in the spine being −3.2. Alendronate 70 mg once weekly was administered along with calcium and vitamin D. The patient also had hypothyroidism on treatment with L-thyroxine, TSH levels being within the normal range.

Bone mineral density measurement was performed yearly while the patient was on treatment with alendronate, calcium and vitamin D. Six years later bone mineral density measurement in both the spine and the hip revealed osteopenia, T score being −1.3 and −1.1 in the spine and the hip, respectively. Alendronate was discontinued, while calcium and vitamin D were administered to the patient.

The patient is being followed for her osteopenia yearly, T score in the hip being −1.1 five years after treatment cessation.

In the case presented alendronate appears to have had a long lasting beneficial effect on the bone in a patient with osteoporosis. The state of osteopenia appears to be stable in the presented patient. This case of persistent improvement of osteoporosis after long lasting treatment with alendronate raises the question of whether osteoporosis may be a curable disease, not being merely a manifestation of aging. This case raises the hopeful hypothesis that osteoporosis with the emergence of novel effective forms of therapy may be cured.

Fractures at post-partum and lactation: common presentation of different clinical entities

Zoe Efstatiadou, Albana Sykja, Athanasios Panagioutis & Marina Kita

“Hippokration” General Hospital of Thessaloniki, Thessaloniki, Greece.

Introduction
Osteoporosis of pregnancy and postpartum is a rare clinical entity, which usually presents with back pain, due to spine fractures. We aimed to describe four different cases presenting with back pain and fractures post-partum, in who, with diverse underlying pathophysiology, recovery time and treatments used.

Case 1
A 32-year-old patient presented with intense back pain and difficulty in standing and walking, 2 weeks after delivery. She had hypercalcaemia, hyperphosphatemia and multiple vertebral fractures. Breast examination and mammography were inconclusive due to lactation. The diagnosis of metastatic breast cancer was made after a bone lesion biopsy. The patient received zolendronic acid and was referred to an oncologist.

Case 2
A 35 year-old patient, several weeks after a singleton pregnancy, presented with acute back pain. Imaging studies revealed an L2 fracture and laboratory assessment showed increased bone turnover markers and vitamin D deficiency. She received zolendronic acid and was started on vitamin D3 substitution. Her clinical course was uneventful.

Case 3
A 41 year-old lady was diagnosed with T12 and L3 vertebral fractures, while still breast-feeding. No secondary causes of osteoporosis were found. She received an 18-month course of teriparatide and Vitamin D3 supplementation. Six months after teriparatide discontinuation she presented with urinary tract lithiasis complicated by upper urinary tract infection.

Case 4
A 32-year-old patient presented with lumbar spine bone mineral density Z-score of −2.8, but no fractures, after her first pregnancy. She was treated with intranasal calcitonin and VitD3 supplementation. An improved BMD (Z-score = −2.1) was measured after 2 years. Her second pregnancy was uneventful.

Conclusions
Post-partum osteoporosis is a rare cause of bone pain during the puerperium. Fractures should be diagnosed early in order to avoid permanent incapacity. It is mandatory to look for and exclude secondary causes of osteoporosis including breast cancer and vitamin D deficiency.

A multidisciplinary clinic for bone metabolism diseases: descriptive analysis of our experience in quiron salud malaga hospital
Araceli Muñoz-Garañ1, Maria Carmen Ordoñez-Cañizares2, Ana Nieto-González2, Pablo Manzano Fernández-Amigo3 & Jose Manuel García-Almeida
1 Endocrinology and Nutrition Department. Quiron Salud Hospital, Málaga, Spain; 2 Rheumatology Department. Quiron Salud Hospital, Málaga, Spain.

Introduction
A multidisciplinary clinic has been developed to optimize the diagnosis and treatment of bone metabolism diseases. Initiated in March 2013, it is carried out simultaneously, once a week by an Endocrinologist and a Rheumatologist.

Objective
To describe the experience of this unit in the last 12 months.

Material and methods
Cross-sectional observational study. 235 patients were attended from December 2015 to December 2016. In the first visit, we carried out a medical record using a checklist form and impedanceometry. We requested a blood test with bone remodeling markers (CTX-I and PINP), vitamin D, PTH, sex hormones and 24-hour urine with calcitriol and phosphaturia, densitometry and dorsum-lumbar spine x-rays. In the following visit the results were evaluated and the team formed by both specialists agreed the protocol of action. Subsequently we studied treatment tolerance and analytical, radiographic and densitometric changes.

Results
97% were women with a mean age of 60±9.7 years. Weight 66.3±12.7 kg, height 158.2±5.8 cm, BMI 26.6±2.4 kg/m². Impedanceometry showed mean lean mass was 43.0±5.9 kg and mean fat mass 23.3±10.1 kg. 36.2% and 20% of the patients had a personal and family history of fracture, respectively. 15.2% patients had taken previous corticoid treatment; 9.5% had more than 2 falls in the last year. 5.7% were active smokers. 87.4% had menopause; early menopause in 13.4% and surgical menopause in 10.7%. 60% practiced more than 3 days of physical activity per week. 78.8% sunbathed more than 10 minutes a day and 36.2% took adequate dairy milk consumption. Among the treatments, the most used was bisphosphonates. The aggregate management by two specialists agreed the protocol of action. Subsequently we studied treatment tolerance and analytical, radiographic and densitometric changes.

Conclusions
A high percentage of patients received treatment before coming to the clinic. The most used was bisphosphonates. The aggregate management by two specialists in the multidisciplinary clinic is beneficial and improves the quality of care in our patients.

Spontaneous recovery of BMD after surgical cure of Cushing’s syndrome due to an adrenocortical adenoma: a 9-years follow-up
F. Baleanu, L. Iconaru, R. Karmali & J.J. Body
Centre Hospitalier Universitaire Brugmann, Université Libre de Bruxelles, Brussels, Belgium.

A 33-year-old Belgian woman was referred in June 2006 to our Metabolic Bone Diseases Clinic for recent vertebral fractures. X-Rays showed a 3-level severe compression fractures with collapse of the superior endplates of D11, D12 and L1. DXA showed significantly decreased lumbar spine (LS) and femoral neck (FN) Z-scores, at –3.1 and –2.5, respectively.

She was complaining of severe back pain, muscle weakness, cognitive dysfunction, anxiety and irritability. Physical examination revealed moon-shaped face, ecchymosis, purple stretch marks on the breasts, arms, abdomen and thighs. Morning cortisol was normal but ACTH level was suppressed. Urinary free cortisol was elevated. A late-night salivary cortisol also elevated. Standard 2-day 2-mg dexmethasone suppression test showed no cortisol suppression. A loss of diurnal variation in ACTH and cortisol levels was also demonstrated. Cushing’s syndrome was confirmed. Abdominal MRI showed a 3 cm left adrenal mass.

Osteoporosis was considered secondary to this endogenous hypercortisolism. Bone turnover markers (BTMs) and 24h urinary calcium excretion were elevated. Successful laparoscopic left adrenalectomy was performed in October 2006.

Spontaneous BMD increase (LS Z-score –2.4) was observed already 2 months after surgery. Except for calcium and vitamin D supplementation, no bisphosphonate therapy was prescribed, given this impressive increase of BMD and because she was still premenopausal. X-Rays did not show any new vertebral fracture. BMD continued to increase, 24 months after surgery, densitometry showed 40% absolute increase in LS BMD and 16% in FN BMD, vs baseline. She reached normal BMD values at all sites 3 years following surgery. After a 9-years follow-up (DXA and BTMs, yearly), complete spontaneous BMD recovery was confirmed (LS T-score +1.2 and FN T-score +0.3) with normal and stable BTMs.

Our case suggests no need for any antiresorptive therapy in severe osteoporosis due to cortisol-secreting adrenal adenoma after successful surgery, at least in premenopausal women.

Cinacalcet for control of primary hyperparathyroidism: a single centre experience
Tiago Nunes da Silva, Ana Gonçalves Ferreira, Maria Carlos Cordeiro, Ana Catarina Martins & Jorge Portugal
Endocrinology Department Hospital Garcia de Orta, Almada, Portugal.

Although primary hyperparathyroidism (PHPT) is usually cured by surgery, some individuals are unable to undergo parathyroidectomy and are refractory to standard calcium lowering medical therapy. In such cases, targeted therapy with cinacalcet may be useful.

The aim of this study was to access the short-term efficacy of cinacalcet in lowering calcium (Ca⁰²⁺) levels in patients with PHPT unable to undergo parathyroidectomy and refractory to standard medical therapy.

Methods
Patients with PHPT refractory to standard medical treatment were treated with cinacalcet. Statistical analysis was carried out using the Wilcoxon test.

Results
Five patients (all female) with a median age of 76 years were included. The known duration of the PHPT was 60 months. The median follow-up of cinacalcet treatment was 12 months. Hypercalcemia related comorbidities were mental changes in 4, osteoporosis in 3 and kidney stones in 2 patients. Before medical treatment, baseline median (quartile 1 (Q1), Q3) serum PTH was 252 (159, 614) pg/ml (reference range 15–65) and serum Ca²⁺ was 11.7 (11.6, 12.6) mg/dl (reference range 10.5–11.8). After standard medical treatment, baseline median (quartile 1 (Q1), Q3) serum PTH was 222 (149, 304) pg/ml and serum Ca²⁺ was 11.9 (11.2, 12.6) mg/dl (P>0.05). After the last stable dose of cinacalcet, median (quartile 1 (Q1), Q3) serum PTH was 190 (139, 361) pg/ml and serum Ca²⁺ was 10.1 (9.7, 12) mg/dl (P=0.005). Serum Ca²⁺ normalized in 60% of patients. The median decrease of Ca²⁺ was 15.1% (P=0.005) and of PTH was 14.4% (P=0.074). Only one patient developed side effects (muscle spasms) without the need to stop cinacalcet.

Conclusions
These results demonstrate the efficacy and safety of cinacalcet in controlling hypercalcemia refractory to standard medical therapy.

Association between bone mineral density and muscle strength in patients with Turner syndrome, after consideration of selected hormonal and metabolic parameters
Elzbieta Sowinska-Przepiera, Monika Koziolek, Lilianna Osowicz-Korolew, Jakub Poblocki, Martyna Patulon-Novak & Anhelli Syrenicz
Pomeranian Medical University, Szczecin, Poland.

Turner syndrome (TS), resulting from complete or partial loss of X chromosome, occurs in 1 per 2000-2500 liveborn female neonates. Most patients with TS, especially those untreated with growth hormone, present with osteoporosis or osteopenia, and are at increased risk of bone fractures. Available evidence suggests that depletion of bone mass may be associated with inadequate level of physical activity, and consequently, with too low muscle mass and strength. The aim of the study was to analyse an association between muscle strength and bone mineral density in patients with TS, after consideration of selected hormonal and metabolic factors. The study included 52 subjects (age 28–45 years), among them 32 women with TS (45.X karyotype; Group A) and 20 controls (Group K). The list of analysed variables included body height, body weight, BMI, bone mineral density (BMD L1-L4 and BMD Total), total body fat (BF) and visceral adipose tissue (VAT) volumes determined by means of DXA, hand grip strength measured with a manual dynamometer, and laboratory parameters: TSH, FT4, FSH, oestriadiol, testosterone, DHEA-SO4, ACTH, cortisol, PTH, vitamin D3 concentrations, lipopigment, levels of glucose and insulin during OGTT. Patients from Group A presented with significantly lower left (P = 0.001) and right handgrip strength (P < 0.000), lower BMD (P < 0.000), lower concentrations of testosterone (P < 0.000) and DHEA-SO4 (P = 0.006), larger VAT volumes (P < 0.005), higher BMI (P = 0.05), higher levels of insulin (P = 0.026) and FSH (P = 0.000). The study groups did not differ in terms of their TSH, FT4, ACTH and cortisol concentrations, and the only significant difference in lipopigment pertained to triglyceride level, higher in Group A (P = 0.032). Right handgrip strength in Group A correlated significantly with BMD L1-L4 (r = 0.1318, P = 0.0486), VAT volume (r = 0.1478, P = 0.0360) and BMD Total (r = 0.1921, P = 0.0154). These findings suggest that handgrip strength may constitute a predictor of osteoporosis in patients with TS.

Effect of chronic atrophic gastritis on bone mineral density of Korean women

CB Lee1, YC Jeon1 & KY Lee2
1Hanyang University Guri Hospital, Guri, Republic of Korea; 2Incheon Gil Hospital, Incheon, Republic of Korea.

Hydrochloric acid has been demonstrated to be important for the absorption of calcium and the bone loss is often seen in human after total gastrectomy. The aim of our study was to document the change of calcium and bone metabolism in the patients with decreased capacity of gastric acid secretion like chronic atrophic gastritis.

The study sample consisted of chronic atrophic gastritis group and control group. Chronic atrophic gastritis group was 20 post-menopausal females (age: 60.3 ± 5.1 yr) who was confirmed by gastroscopic biopsy, demonstrating atrophic change of gastric mucosal secretory tissue. Control group had 21 healthy females (age: 58.7 ± 6.5 yr) with normal gastroscopic biopsy results. Gastric pH, serum levels of calcium, phosphorus, total alkaline phosphatase, intact PTH, and bone mineral density (Delphi, Hologic, USA) were monitored in all the patients in both group before medication. There were no significant differences of gastric pH (3.9 ± 0.6 vs 3.3 ± 1.0, P > 0.05), calcium (8.9 ± 0.9 vs 8.8 ± 1.4 mg/dl, P > 0.05), phosphorous (3.2 ± 1.5 vs 3.5 ± 0.9 mg/ml, P > 0.05), total alkaline phosphatase (72.5 ± 24.5 vs 60.3 ± 22.4 U/l, P > 0.05) and intact PTH (29.3 ± 5.1 vs 27.2 ± 3.8 pg/ml, P > 0.05) between chronic atrophic gastritis group and control group. Bone mineral density showed decreased average value in atrophic gastritis group comparing control group (0.78 ± 0.27 vs 0.85 ± 0.31 g/cm², P = 0.09).

In conclusion, chronic atrophic gastritis which have lower capacity of gastric acid secretion may cause decrease of bone mineral density. And this mechanism may be one of the pathogenesis of senile osteoporosis.

May serotonin metabolism polymorphisms 5HTTVNTR and 5HT2A have a clinical impact in osteoporosis development?

Raquel Simões1,2, Joana Freitas1,2, Ana Paula Barbosa1,2, Rui Mascarenhas3,4 & Manuel Bicho1,2
1Institute for Scientific Research Bento Rocha Cabral, Lisbon, Portugal; 2ISAMB, Genetics Laboratory, Lisbon Medical School, Lisbon, Portugal; 3Clinic of Endocrinology, Diabetes and Metabolism, Lda., Lisbon, Portugal; 4Department of Endocrinology, Diabetes and Metabolism, Santa Maria Hospital, Lisbon, Portugal.

Objectives

To study the association of serotonin transporter gene (SLC6A4) polymorphism 5HTTVNTR and serotonin receptor 2A polymorphism 5HT2A_T102C with bone mineral density and metabolic parameters of bone remodelling.

Materials and methods

BMD (g/cm²) was measured by DEXA in 105 post-menopausal women: 35 with normal BMD (age = 58.30 ± 1.33 years; BMI = 28.18 [19.13-39.87] kg/m²) and 70 with osteoporosis (age = 68.30 ± 1.09 years; BMI = 28.90 [20.78-43.86] kg/m²). Metabolic bone remodelling parameters were analysed: LDL, HDL, total cholesterol, HOMAins, insulin, glycaemia, alkaline phosphatase, osteocalcin and parathormone. It was determined the platelet and plasma serotonin concentrations by ELISA. 5HTTVNTR was evaluated by PCR and the 5HT2A_T102C by PCR-RFLP. Statistical analysis by SPSS 21.0.

Results

In osteoporosis, we found increased osteocalcin (P = 0.030) and plasma 5HT concentration (P = 0.012) and decreased insulin (P = 0.023) and total cholesterol (P = 0.027). In women with normal BMD, we found an association between genotype 10/10 of 5HTTVNTR and decreased osteocalcin (P = 0.035), and between genotype CC of 5HT2A and decreased HDL (P = 0.029). Within this group, we also found inverse correlations between HDL and alkaline phosphatase (P = 0.030) and HOMAins (P = 0.018). In women with osteoporosis, we found direct correlations between glycaemia and osteocalcin (P = 0.017) and HDL (P = 0.049).

Conclusion

In normal BMD, 5HTTVNTR and 5HT2A_T102C polymorphisms appear to modulate directly or indirectly some metabolic parameters associated with bone remodelling. These polymorphisms seem to have no effect in women with osteoporosis suggesting that they may play a relevant role in the susceptibility to osteoporosis development by modulating metabolic bone remodelling parameters.

Beta-2 adrenergic receptor (ADRB2) gene polymorphism Arg16Gly as risk factor for osteoporosis
Raquel Simões1-2, Joana Freitas1-2, Ana Paula Barbosa3-4, Mario Mascarenhas3-4 & Manuel Bicho5
1Institute for Scientific Research Bento Rocha Cabral, Lisbon, Portugal; 2ISAMB, Genetics Laboratory, Lisbon Medical School, Lisbon, Portugal; 3Clinic of Endocrinology, Diabetes and Metabolism, Lda., Lisbon, Portugal; 4Department of Endocrinology, Diabetes and Metabolism, Santa Maria Hospital, Lisbon, Portugal.

Objectives
To study the association of Beta-2 adrenergic receptor (ADRB2) gene polymorphism Arg16Gly with bone mineral density and metabolic parameters of bone remodelling.

Materials and methods
BMD (g/cm²) was measured by DEXA in 105 post-menopausal women: 35 with normal BMD (age = 58.30 ± 1.33 years; BMI = 25.18 [19.13-39.87] kg/m²) and 70 with osteoporosis (age = 66.30 ± 1.09 years; BMI = 28.90 [20.78-43.86] kg/m²). Metabolic bone remodelling parameters were analysed: LDL, HDL, total cholesterol, HOMAAR, insulin, glycaemia, alkaline phosphatase, osteocalcin and parathormone. Arg16Gly polymorphism was evaluated by PCR-RFLP.

Results
We found association between Arg16Gly polymorphism and osteoporosis with an increase of homozygous Gly/Gly in women with osteoporosis (P = 0.009). They showed a higher risk for the development of osteoporosis (OR = 6.517; CI95% [1.663-25.539]). In osteoporosis, we found increased osteocalcin (P = 0.030) and decreased insulin (P = 0.023) and total cholesterol (P = 0.027). In women with normal BMD, we found an association between genotype carriers of allele Arg (Arg/Arg + Arg/Gly) and decreased total cholesterol (P = 0.018). We also found an association between carriers of allele Gly (Arg/Gly + Gly/Gly) and decreased levels of glycaemia (P = 0.010). Within women with normal BMD, we also found inverse correlations between HDL and alkaline phosphatase (P = 0.030) and HOMAAR (P = 0.018). In women with osteoporosis, we found direct correlations between glycaemia and osteocalcin (P = 0.017) and HDL (P = 0.049).

Conclusion
Arg6Gly polymorphism of ADRB2 gene is associated with a higher risk for the development of osteoporosis. This polymorphism also appears to modulate directly or indirectly some metabolic parameters associated with bone remodelling.

Bone histomorphometry and bone marrow adipocytes in premenopausal women with type 2 diabetes
Vicente Andrade1, Victoria Borba1, Domingos Chula1, Felippe Barreto2, Cesar Boguszewski3 & Carolina Moreira4
1Institute for Scientific Research Bento Rocha Cabral, Lisbon, Portugal; 2ISAMB, Genetics Laboratory, Lisbon Medical School, Lisbon, Portugal; 3Clinic of Endocrinology, Diabetes and Metabolism, Lda., Lisbon, Portugal; 4Department of Endocrinology, Diabetes and Metabolism, Santa Maria Hospital, Lisbon, Portugal.

Few studies have evaluated bone histomorphometry in type 2 diabetic patients (DM2) and none has established if the disease control plays a role on bone morphology and bone marrow adipocytes. The aim of this study is to present preliminary data on bone microstructure, bone formation rate and bone marrow adipocytes in premenopausal women with DM2 with different levels of glucose control. Bone biopsy, followed by tetracycline labelling, was obtained for analysis of static and dynamic parameters of bone histomorphometry and volume of bone marrow adipocytes. To date, 12 bone biopsies and 6 histomorphometry analysis were performed in a group of women with mean age of 40.92 ± 6.0 yrs, mean duration of DM2 of 6.8 ± 2.6 years and median glycosylated haemoglobin of 8.1% (range 6.5-12.3). Initial results have shown a normal bone volume, reduced bone formation and an increase in adipocytes content in comparison to normal premenopausal women values at the literature. Our preliminary results suggest that bone morphology and bone marrow adipocytes content is altered in premenopausal women with DM2.

Differences in bone strength and metabolic parameters according to the presence of hyperadiponectinemia and obesity in Korean adults: The KoGES- ARIRANG study
Jung Soo Lim1, Eunhee Choi1, Ji Hyo Hu1, Mi Young Lee1, Jang Yeol Shin1, Choon Hee Chung1, Sang Bae Koh1 & Song Yong Ahn1
1Department of Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Gangwon, Republic of Korea; 2Smith Center for Outcomes Research in Cardiology, Beth Israel Deaconess Medical Center, Boston, MA, USA; 3Department of Preventive Medicine, Yonsei University Wonju College of Medicine, Wonju, Gangwon, Republic of Korea.

Adiponectin has been thought to exert important influences in energy homeostasis and insulin signalling pathway. Some obese individuals showed paradoxical hyperadiponectinemia-mia (HA), however, the effect of HA on bone metabolism has not been fully clarified.

This study aimed to evaluate bone strength and metabolic parameters according to the presence of HA and obesity in Korean adults. A total of 9,172 adults (59.4% women) aged 40–70 years assessed in the Korean Genomic Rural Cohort Study from 2005 to 2008 were examined. HA was defined as the levels of higher than or equal to the upper tertile among metabolically healthy subjects with a body mass index (BMI) less than 23 kg/m².

Moreover, obesity was defined as a BMI of more than or equal to 25 kg/m². The serum con-centrations of adiponectin were measured by radioimmunoassay. In addition, bone status was assessed using the calcaneal quantitative ultrasonound method. Obese subjects and those who have HA accounted for 40.3% and 15.7%, respectively; about twenty percent of the non-obese and 9.5% of the obese had HA. Although most of metabolic parameters such as fasting glucose and lipid profiles were significantly better in the HA group compared with the non-HA group, bone stiffness index (BSI) in the former was lower in the latter. In both the non-obese and obese groups, individuals with HA had lower waist circumference and BMI. Moreover, obese subjects without HA showed the highest BSI levels among the group-s, which was especially prominent in women. Our results suggest that bone strength in obese individuals may be more negatively affected by high adiponectin levels. Further studies are necessary to confirm the effects of adiponectin on bone health in subjects with obesity.

Do the surgical outcomes change if the surgeon accompanies the endocrinologist during the preoperative ultrasonography examination? Ibrahim Kilic1, Setifa Burcarak Polat2, Seygul Faki2, Mehmet Tokac1, Reyhan Ersoy2, Mehmet Kilic1 & Bekir Cakir2
1Department of Surgery, Ataturk Education and Research Hospital Education and Research Hospital School of Medicine, Ankara, Turkey; 2Department of Endocrinology and Metabolism, Yildirim Beyazit University, School of Medicine, Ankara, Turkey; 3Department of Surgery, Yildirim Beyazit University, School of Medicine, Ankara, Turkey.

Introduction
Parathyroid surgical therapy differs because the glands are small and of variable number and location. Although localization studies have improved greatly, we may not reliably determine the number and location of all diseased glands preoperatively. Ultrasonography (US) is the most widely used imaging method. In this study, we aimed to demonstrate how the surgical outcomes change when the surgeon accompanies the endocrinologist during preoperative ultrasonography examination.

Methods
This prospective study included 50 patients with primary hyperparathyroidism (PHPT) who underwent a minimally invasive parathyroid adenectomy under local anaesthesia at our institution from January 2014 to December 2015. The patients were divided in two groups. In group A, all patients underwent neck US performed by an experienced endocrinologist and the surgeon on the day of operation and the location of the lesion was specified by the surgeon. Group B patients were operated according to the previous US performed by the endocrinologist only.

Results
There were 25 patients in Group A and 25 patients in Group B. The two groups were similar in regard to demographic features, biochemical and hormonal parameters. Postoperative parathyroid hormone (PTH), calcium and phosphorus levels didn’t differ between the groups. In group A operation duration was significantly shorter compared to Group B (25.7 min vs 45 min, P = 0.000).
Teriparatide discontinuation in a patient with post surgical hypoparathyroidism: a clinical challenge

Alessandro Brancatella, Matteo Apicella, Emilio Fiore, Giovanni Cecconari, Edda Vignali, Claudio Marocci, Paolo Vitti & Eleonora Molinaro

Department of Endocrinology and Metabolism, University of Pisa, Pisa, Italy.

Context
Teriparatide may represent a possible treatment for hypoparathyroidism when oral supplementation with calcium and calcitriol fail to maintain adequate serum calcium level (SCL). The switch from teriparatide to oral calcium and calcitriol could be challenging and there is no consensus for clinical management.

Case presentation
A 50-year-old man was admitted at our Department for teriparatide discontinuation. Three years before admission, the patient underwent total thyroidectomy for a multinodular goiter. Three months after thyroidectomy, the patient was admitted to the intensive care unit for the onset of symptomatic hypocalcemia. Laboratory exams were consistent with hypocalcemia related to post-surgical hypoparathyroidism. The patient was discharged with calcium carbonate and calcitriol therapy but in the following months the patient was re-admitted several times to the E.R. for the recurrence of symptomatic hypocalcemia. Therefore in addition to the oral therapy, teriparatide was introduced. After two years of treatment, teriparatide has been discontinued in accordance to the national drug administration (AIFA) authorizing regulations. At the admission, the physical examination was normal. Laboratory exams were notable for low SCL and an elevated serum TSH level despite high dose of Levothyroxine supplementation (250 mcg/d). After teriparatide discontinuation SCL progressively decreased (6.5 mg/dl) with the onset symptoms of hypocalcemia, despite high doses of calcium carbonate and calcitriol. Further investigations revealed an atrophic autoimmune gastritis, confirmed at gastroscopy. It was decided to switch from calcium carbonate to calcium citrate and to modify patient’s diet. SCL slowly increased up to 8.6 mg/dl so that the patient could be discharged. In six months, no symptomatic hypocalcemia occurred and the SCL were stable with oral therapy.

Conclusions
Teriparatide discontinuation in patients treated for hypoparathyroidism is challenging and clinically does not differ from “hungry bone syndrome” after parathyroidectomy. Furthermore calcium citrate could be an alternative to calcium carbonate in patients with achlorhydria.

DOI: 10.1530/endoabs.49.EP238

Teriparatide discontinuation in patients with achlorhydria: a clinical challenge

Alessio Briscella, Matteo Apicella, Emilio Fiore, Giovanni Cecconari, Edda Vignali, Claudio Marocci, Paolo Vitti & Eleonora Molinaro

Teriparatide discontinuation in patients treated for hypoparathyroidism is challenging and clinically does not differ from “hungry bone syndrome” after parathyroidectomy. Furthermore calcium citrate could be an alternative to calcium carbonate in patients with achlorhydria.

Endocrine disorders in treatment-naïve male patients with HIV infection

Nikolaos Kalogeris1, Markolla Nzei1, Maria Chini2, Athina Lionti2, Vissaria Sakka4, Nikolaos Mangafas2, Styliani Kaoustou1, Marios Lazanas2 & Andromachi Vryonidou3

1Department of Endocrinology, Diabetes and Metabolism, Red Cross General Hospital, Athens, Greece; 2Infectious Diseases Unit, Red Cross General Hospital, Athens, Greece.

Objective
To investigate endocrine disorders concerning bone metabolism, thyroid and gonadal axis in treatment–naïve HIV-infected male patients.

Subjects and methods
We studied 70 male, treatment-naïve patients (stage A = 60, stage B = 10) from the Infectious Diseases Unit of our Hospital. Anthropometric indices were measured and BMI was calculated for each participant. Blood samples were obtained after an overnight fasting for the evaluation of thyroid hormones, 25(OH)D3, gonadotropins, total testosterone, sex hormone binding globulin (SHBG) levels. Free Androgen Index (FAI) and bioavailable testosterone (BAT) were calculated. Bone mineral density (BMD) in the lumbar spine and adipose tissue percentage (FMR) was measured with DEXA. SPSS 16.0 was used for statistical data processing.

Results
Mean TBS (Trabecular Bone Score) values of the group was 1.26 ± 0.275, P = 0.005 and mostly C-telopeptide (r = −0.314, P = 0.001). Actually TBS values and both T and Z scores correlated negatively and significantly with serum calcium levels. TBS was in the partially degraded range but did not differ by vitamin D status, even when compared with severely deficient patients (33 pts, mean TBS 1.25). PTH correlated negatively with 25(OH)D and TBS correlated strongly (r = 0.536) with aBMD.

Conclusion
We observed a good and negative correlation between TBS and serum C-telopeptide which favor the notion that TBS might reflect degraded microarchitecture.

Normocalcemic primary hyperparathyroidism (NPH)

Cristina Cortina Pop-Radoi1

1University of Medicine and Pharmacy, Targu Mures, Transilvania, Romania; 2Mures Clinic County Hospital, Targu Mures, Transilvania, Romania.

Normocalcemic primary hyperparathyroidism (NPH) is characterized by normal total and ionized serum calcium concentrations and consistently elevated PTH levels. These patients have no obvious causes for secondary elevations of PTH, such as renal disease, vitamin D deficiency or malnutrition. The group consisted
of 22 postmenopausal women, six premenopausal women, and two men, aged 55 ± 2 years (range 31–77) investigated between 2011 and 2016.

Results
All subjects had normal renal function and 25-hydroxyvitamin D levels >20 ng/ml (80% had levels >30 ng/ml); none used thiazide diuretics or lithium or demonstrated significant hypercalcemia. The reasons for referral included elevated PTH discovered during the evaluation of low bone mass (n = 22), recent fragility fracture (n = 2), nephrolithiasis (n = 6). At the time of diagnosis, 70% had osteoporosis by BMD (measured at the lumbar spine, hip or distal one-third of the non-dominant radius), 6.6% had documented fragility fractures, and 20% had nephrolithiasis. PTH was elevated, while albumin-corrected serum calcium, serum phosphorus, alkaline phosphatase activity, and urinary calcium, were all in the mid-normal range. Nine patients with positive localization studies (cervical ultrasonography, technetium 99 m sestamibi scanning) underwent successful parathyroidectomy.

Material and methods
The lumbar spine BMD (g/cm²), and TBS (obtained from DXA scans) were evaluated in a group of normal men more than 40 years old. Fasting blood was collected for osteocalcin, 25(OH)D and iPTH measurements. This group was divided in normal, insufficiency and deficiency vitamin D groups (ES Guidelines) and also in normal BMD, low BMD and osteoporosis groups. Total body fat and lean masses were also assessed by DXA. Adequate statistical tests were used (statistical significance P < 0.05).

Results
The mean (± s.d.) BMD and TBS of the vitamin D groups are shown in Table 1. Men of the deficiency vitamin D group were the heaviest and had the lowest TBS. Significant relations were detected between the blood 25(OH)D vs. TBS, vs. weight and vs. total fat mass but not vs. BMD.

Conclusions
Blood 25(OH)D levels may play an important role on the bone microarchitecture (by TBS) in vitamin D deficient men, as they have worse bone quality. These data suggest that further studies are needed on larger cohort of men and it might be worth to investigate also elderly men with osteomalacia.

Impact of vitamin D on the bone quality assessed by trabecular bone score in men
Mário Rui Maçarenhas1,2, Ana Paula Barbosa1,2, Nuno Duarte2, Ana Westling2, Ana Raquel Coelho Gomes3, Carolina Farinha, Raquel Paixão1, David Barbosa1, Catarina Silvestre1, José Poupino2, Ana Sofia Osoirio3, Francisco Sampaio2, Jacinto Monteiro2, Didier Hans4, Manuel Bicho1 & Maria João Bugalho1,3
1Endocrinology and Metabolic Diseases, Faculty Medicine of Lisbon, Lisbon, Portugal; 2Fractuary Osteoporosis, Outpatient Clinic – Endocrinology, Diabetes and Metabolism Department, Santa University Maria Hospital-Chln, Epe, Lisbon, Portugal; 3Endocrinology, Diabetes and Metabolism Department, Santa University Maria Hospital-Chln, Epe, Lisbon, Portugal; 4Bone Center, Lausanne University Hospital, Lausanne, Switzerland.

Trabecular bone score (TBS) is a recent noninvasive analytical method, based upon DXA images, related to bone microarchitecture or bone quality; together, TBS and DXA may evidence bone strength. Falls and osteoporotic fractures increase with ageing, while both BMD and vitamin D levels slowly decline. Data about the influence of vitamin D on the TBS are scarce.

Aim
To evaluate the influence of the blood vitamin D levels on the TBS in normal men.

Material and methods

- 14.4 yrs; 190 patients are on continuous dialysis due to end-stage chronic kidney disease. Of these patients, 122 were with normal PTH and 29.7% – with SHPT (by TBS) in vitamin D deficient men, as they have worse bone quality. These data suggest that further studies are needed on larger cohort of men and it might be worth to investigate also elderly men with osteomalacia.

EP244
Neutrophil lymphocyte ratio in 6 month teriparatide therapy of osteoporosis
Bengur Taskiran1, Goknur Yorulmaz2, Guven Baris Cansu1 & Ayse Akalin2
1Yunus Emre State Hospital, Eskisehir, Turkey; 2Osmanagazi University, Eskisehir, Turkey.

Aim
Low BMD and atherosclerosis may share similar underlying biological mechanisms including higher serum phosphate and inflammation. Neutrophil-lymphocyte ratio (NLR) as a simple marker of inflammation. There are scarce data indicating improved atherosclerosis and cardiovascular events with biphosphonate and teriparatide therapy. We aimed to evaluate NLR before and after 6 months of teriparatide therapy in patients with severe established osteoporosis.

Methods and materials
Electronic data of 53 (49 female, four male) patients with severe osteoporosis and history of fracture of femur neck and/or lumbar spine were evaluated. None of them were previously diagnosed with rheumatoid arthritis, DM, and secondary osteoporosis. Sixteen had with HT and/or other cardiovascular disease.

Results
Mean age was 74 ± 9 years, baseline 25 OH vitamin D level 25.6 ± 17.6 ng/ml, baseline NLR 2.22 ± 0.89, 25 OH vitamin D level at 6th month 27.8 ± 13.4 mg/ml, NLR at 6th month 2.10 ± 0.96. Mean baseline and 6th month measurements of NLR, 25 OH vitamin D, parathormone, ALP, ESR, and phosphorus were similar in patients with and without cardiovascular disease. NLR did not change significantly after 6 months of teriparatide therapy.

Conclusion
NLR does not change in short term teriparatide therapy and association between osteoporosis and cardiovascular disease cannot be settled in advanced age.

Management with Cinacalcet of non-surgical primary hyperparathyroidism in the elderly.
Juan Martí1, Jose Luis Salsamendi1, Jon Martí-Ayerd2 & LLuis Jordana1
1Hospital Zumarraga, Zumarraga, Spain; 2Complejo Hospitalario Navarra, Pamplona, Spain.

Primary hyperparathyroidism (PHPT) is a common condition. The prevalence since the introduction of multichannel analysers is approximately 1:1000, with the older female being the typical patient. PHPT is predominantly a sporadic disorder. Surgery remains the only curative approach to most primary hyperparathyroidism (PHPT), medical treatment with cinacalcet has been proven to be an alternative for patients with hyperparathyroidism.

Objective
Analyze treatment with cinacalcet, in older patient with primary hyperparathyroidism not tributary of surgery.

Material and patients
Between 2011 and 2015, 13 patients with PHPT who were not suitable for surgery were identified. Data collected: age, gender, comorbidities, levels of calcium and PTH and follow-up.

Results
We present 13 patients 8 women and 5 man with a mean of age 80.5 ± 6.59 year-old (range 71–92). Comorbidities, diabetes mellitus 50%, frailty 58%, heart disease 40%, depression 33%, cognitive impairment 17%. Calcium levels previous treatment was 11.85 ± 0.28 mg/dl and PTH 123 ± 3.42 pg/ml. T cinacalcet 30 mg. daily was initiated, in 12 patients and 60 mgr. in one. Patients were followed for 1–4 years (2.75 ± 2.21) calcium were adequately controlled (0.98 ± 0.278 mg/dl), but PTH 112±42 pg/ml remains high, renal function was unchanged in all patients. Two patients died during the follow-up, not related with hyperparathyroidism. Adverse events were observed in 1 patient (vomiting) that disappeared to diminishing doses.

Discussion
Geriatricians will readily recognize the clinical conundrum of an incidental finding of PHPT in the older that was unexpected. Retrospective questioning may identify some pertinent symptoms, but none strong enough on their own to have made the diagnosis obvious prior to testing serum calcium. This group of patients is hard to define and hence there is little published guidance on how to manage the increasingly common clinical scenario of the frail, relatively asymptomatic, older patient with PHPT.

Conclusions
Cinacalcet, the first available calcimimetic, increases the sensitivity of the calcium-sensing receptor (CaR) to circulating serum calcium, thereby safely reducing serum calcium and PTH concentrations in patients with mild-to-moderate PHPT, intractable disease, and also parathyroid carcinoma. Cinacalcet in a reasonable and safe alternative to treatment of PHPT not tributary of surgery.
11 weeks were respectively injected of dexamethasone (Dex). ER antagonist (IC187,780) and PR, GR antagonist (RU486) were injected 30 min prior to steroid hormones. We compared the changes in the CaBP-9k expression of each group using polymerase chain reaction.

Results
In the estrogen and progesterone treated immature mice lung, the CaBP-9k gene expression had no significant change in mRNA and protein level but significantly increased in Dex treated mice lung. It is suggested that glucocorticoids may play a role in regulation of CaBP-9k expression in lung.

Conclusion
Our results has significance to the regulation of CaBP-9k by Dex. By studying the effects on lung surfactant through the control of CaBP-9k, it may be presented as a basis data of pulmonary surfactant associated disease or research.

Vitamin D intoxication caused hypercalcemia: Case report
Kader Ugur1, Hakun Arta2, Mehmet Balin3, Esra Aykan3, Selcuk Demircan3, Bedrettin Orhan3 & Nevzat Gozel3
1Firat University Department of Endocrinology, Elazig, Turkey; 2Firat University Department of Radiology, Elazig, Turkey; 3Firat University Department of Internal Medicine, Elazig, Turkey.

Introduction
Vitamin D is a fat soluble prohormone and can be produced in the body with adequate sunlight exposure or taken up by consumed foods or supplements. Recently vitamin D deficiency has been seen in pandemic. A rare disease, vitamin D intoxication is usually iatrogenic. High levels of 25(OH) vitamin D increases the intestinal calcium absorption and causes severe and refractory hypercalcemia.

In this case report we presented a patient with pancreatitis and hypercalcemia secondary to vitamin D intoxication. Case
79-years-old female patient presented to emergency department with generalized pain, lack of appetite, dry mouth, nausea, vomiting and abdominal pain. Serum calcium level was 13.8 mg/dl. In her medical history she used 12 ampules of vitamin D-3 in the last month. In her physical examination there was abdominal tenderness. Laboratory findings were as follows; 25-OH vitamin D-3: 455 ng/ml (20–150), WBC: 19 570 10e3/µl, Creatinine: 2 mg/dl (0.6–1.2), Ca: 13.8 mg/dl (8.5–10.8), phosphorus: 2.9 mg/dl (2.6–4.5), albumin: 3.7 mg/dl (3.5–5.5), amylase: 132 U/l (28–100), Lipase: 115 U/l (7–60).

Parathormone: 28 pg/ml (19.8–74.9). Abdominal CT scan showed interstitial oedematous pancreatitis. In the follow up, patient was hydrated with isotonic saline infusion. To lower the calcium levels, intravenous furosemide infusion was used. Calculated QTc level when serum calcium is 9.1 mg/dl, was 443 msec. According to literature we could see osborn wave in the ECG but we did not.

Discussion
Vitamin D toxicity develops when serum levels of 25 OH vitamin D-3 levels reach 150 ng/ml or above and daily intake should exceed 10.000 IU. In the treatment, cessation of vitamin D intake and controlling of hypercalcemia is mandatory. Limiting daily calcium intake, hydration, loop diuretics, corticosteroids, calcitonin and bisphosphonates can also be used. Dialysis can be performed to those who are refractory to these treatment modalities.

Conclusion
Uncontrolled and over the counter use of vitamin supplements is a common issue worldwide. Patients who need vitamin D supplements should be followed with laboratory and clinically.

Gitelman syndrome and primary hyperparathyroidism – a rare association
Teresa Rego, Fernando Fonseca & Ana Agapito
Endocrinology Department, Centro Hospitalar de Lisboa Central, Lisbon, Portugal.

Gitelman’s Syndrome (GS) is a rare autosomal recessive salt-losing tubulopathy of young adults, characterized by secondary hyperaldosteronism, hypokalemia, hypomagnesemia, hypocalciuria and metabolic alkalosis. It is caused by mutations in SLC12A3 gene. Hypercalcemia due to hypocalciuria in these patients is extremely rare and requires further evaluation. A 25-year-old normotensive female was referred to Endocrinology clinic for evaluation of persistent hypokalemia. She presented history of malaise, fatigue, myalgias, cramps and paresthesia. She denied diarrhea, recent treatment with diuretics or laxatives. Her physical exam was normal. Laboratory workout revealed: aldosterone 47.1 ng/ml (r.v. 4–31), active renin 374.7 mU/ml (r.v. 4.4–46.1), K+ 2.7 mEq/l (r.v. 3.5–5.1), 24 h urinary K+ 84.7 mEq/24 h (r.v. 25–125), Mg2+ 0.71 mg/dl (r.v. 1.6–2.0), 24 h urinary Mg2+ 143.1 mg/24 h (r.v. 73–122), Ca2+ 12 mg/dl (r.v. 8.4–10.2) and 24 h urinary Ca2+ 133 mg/24 h (r.v. 100–300). GS was diagnosed and she was treated with spironolactone, oral K+ and Mg2+ supplementation. Further investigation confirmed hypercalcemia due to primary hyperparathyroidism (parathyroid hormone (PTH) 107.3 pg/ml (r.v. 14.8–83.1)) caused by a large single parathyroid adenoma. Following parathyroidectomy calcium profile normalized. The sequencing of SLC12A3 gene detected the variant c.602–16G>A and the mutation c.2221G>A (p.Gly741Arg), both in heterozygosity. In this context genetic study of the progenitors was required. The father presents the variant c.602–16G>A and the mother the mutation c.2221G>A (p.Gly741Arg), in SLC12A3 gene. The association of hypokalemia, hypomagnesemia and hypercalcemia is uncommon but potentially lethal. Current knowledge favors that hypomagnesemia in GS’s patients protects them from hypercalcemia. In this context of multiple electrolyte imbalances, correction of hypomagnesemia is a challenge and should be done carefully. Like in our patient hypercalcemia’s etiology should be promptly diagnosed and reversed.

DOI: 10.1530/endoabs.49.EP251

EP252
The volume of parathyroid adenoma is related to presurgical PTH and 25OH-D3, but not calcium levels at patients with primary hyperparathyroidism
Cristian Velicescu1, Cristina Gat1, Alexandru Grigorovici1, Radu Danila1, Valentin Munteanu1, Voichita Mogos2, Carmen Vulpoi1, Cristina Preda1, Simona Mogos1 & Dumitru D Brunsteanu1
1University of Medicine and Pharmacy ‘Gr.T.Popa’, Iasi, Romania; 2University of Medicine and Pharmacy ‘Juliu Hatieganu’, Cluj, Romania.

Aims
We wanted to evaluate the correlations between the volume of the surgically removed parathyroid adenoma and the presurgical metabolic profile of patients diagnosed with primary hyperparathyroidism.

Materials and methods
Prospective multicentric study, enrolling 52 patients with primary hyperparathyroidism from two medical units, proposed for surgery. Serum calcium and PTH were evaluated in all patients before surgery, and 25OH-D3 was measured only in the 33 patients recruited from one of the two surgery departments. Parathyroid volume was measured immediately after excision, using the formula of a rotating ellipsoid. Data were statistically evaluated by using Pearson correlation analysis. Correlations were considered significant at P values lower than 0.05.

Results
We observed a significant correlation between the volume of parathyroid adenomas and presurgical PTH (P<0.001) but not presurgical calcium levels at patients from the two medical units and in the whole group. Twenty-nine out of the 33 patients diagnosed with primary hyperparathyroidism recruited from the first medical unit had 25OH-D3 levels in the range of vitamin D deficiency or insufficiency. 25OH-D3 was not significantly correlated with PTH or calcium levels, but a significant negative correlation was found between the volume of the parathyroid adenoma and serum 25OH-D3 levels (P<0.05).

DOI: 10.1530/endoabs.49.EP252
Conclusion
The volume of parathyroid adenoma seems to be related to presurgical PTH and 25OH-D3, but not calcium level. D hypovitaminosis is frequently found at patients with primary hyperparathyroidism and may contribute to particular disease profiles. Higher PTH and lower 25OH-D3 levels, as well as larger adenomas may be accompanied by increased disease severity, or by a different spectrum of disease complications.

DOI: 10.1530/endoabs.49.EP252

Pseudohypoparathyroidism type Ib: a case of chronic severe hypocalcaemia and seizures diagnosed in adulthood
Ana Claudia, Martins, Paula Bogoalho & Ana Agapito
Department of Endocrinology, Centro Hospitalar Lisboa Central, Lisbon, Portugal.

Pseudohypoparathyroidism (PHP) is a rare group of genetic disorders characterised by end-organ resistance to parathyroid hormone (PTH). We describe the case of a 34-year-old Caucasian female with severe hypocalcaemia presenting with a first generalised seizure. Her medical history was significant for bilateral cataract. She had three healthy children, and no family history of note. On examination, she had positive Chvostek’s sign. Biochemical analysis showed serum calcium 4.5 mg/dl (n.r. 8.4–10.2 mg/dl), phosphorus 5.8 mg/dl (n.r. 2.3–4.7 mg/dl), PTH 94.7 pg/ml (n.r. 14.76–73.1 pg/ml) and vitamin D 19.6 ng/ml (n.r. 30–100 ng/ml), with normal serum albumin and normal alkaline phosphatase. Electrocardiogram demonstrated prolonged corrected QT interval. Brain imaging revealed basal ganglia and cerebellar calcifications, and electroencephalogram did not show paroxysmal activity. We excluded a number of causes of secondary hyperparathyroidism based on her medical history and investigations, and concluded that PTH resistance would be the most likely diagnosis. Since she lacked the typical clinical features of Albright hereditary osteodystrophy and did not present with other hormones’ resistance, a genetic test was requested and identified abnormal methylation of the 20q13.32 region, confirming the diagnosis of PHP type Ib. The patient is currently medicated with calcium carbonate and calcitriol, maintaining a satisfactory calcium-phosphate product. Electroencephalography did not show paroxysmal activity. While nonskeletal benefits of vitamin D remain a matter of debate, its importance in bone health is known for decades. Secondary hyperparathyroidism is considered to play a significant role in the pathogenesis of age-related bone loss. In the present study we investigate the association between serum PTH, 25-hydroxyvitamin (25(OH)D) and other clinically related variables in a cross sectional sample of patients followed in an Endocrine consultation during the year 2016. Patients with diseases or medications known to affect calcium metabolism were excluded. 509 participants, 365 female and 145 male, were selected for analysis. Mean age ± s.d. was 52.1 ± 16 yrs (2–86); 47% were diabetics; 31% suffered of thyroid disorders and 7% were obese. The mean ± s.d. serum level of 25(OH)D was 20.4 ± 10.2 ng/ml; 17.8 ± 8.7 ng/ml in measurements during winter months and 23.4 ± 10.04 during summer. In 61 patients (12% of the sample) with more than one determination, there was a 51.9% increase in 25(OH)D from a mean level of 16.81 ± 9.3 ng/ml during winter to 24.94 ± 11.2 ng/ml during summer months (P < 0.002). Patients treated with statins presented significantly lower levels of 25(OH)D than non-treated patients, 15.9 ± 6.7 ng/ml and 26 ± 10.1 ng/ml, respectively (P < 0.01). This difference remained statistically significant after adjusting for age, sex and disease. We found an inverse relationship between 25(OH)D and PTH. The best fitted line was obtained as a logarithmic expression of 25(OH)D (r = 0.65; P < 0.001). There was no further significant decrease in PTH for serum levels of 25(OH)D of more than 25 ng/ml. In conclusion, more than half of our patients were Vit D deficient (<20 ng/ml) particularly elderly people treated with statins, but serum levels of 25(OH)D above 25 ng/ml are needed in order to prevent secondary hyperparathyroidism. This value can be considered as the lower limit of Vitamin D sufficiency in the sample studied.

A practice review of the use of cinacalcet in primary hyperparathyroidism
Kahat Tauni1,2, Nida Ali1 & Ritwik Banerjee2
Cambridge University Hospitals, Cambridge, UK; 2Luton and Dunstable University Hospital, Luton, UK.

Background
The treatment of choice for primary hyperparathyroidism (PHPT) is surgical parathyroidectomy. Cinacalcet is the first calcimimetic approved by European Medicines Agency (EMA) in 2008 for use in patients with PHPT who are not fit for surgery or refuse surgery. British National Formulary (BNF) recommends it for hypercalcemia in PHPT where parathyroidectomy is inappropriate. The main aim of treatment with cinacalcet is to keep calcium levels at safe levels.

Objectives
To evaluate the efficacy and safety of cinacalcet in patients with PHPT who were unfit for surgery, refused surgery or remain hypercalcemic post-parathyroidectomy and not amenable to further intervention (complex PHPT).

Methods
We assessed the demographic and clinical characteristics and biochemistry in 12 patients seen in endocrinology and biochemistry clinics with complex PHPT at the commencement of cinacalcet and after approximately 1, 3, 6 and 12 months. We also checked doses, tolerability and side effects of cinacalcet.

Results
Most patients (66.67%) needed small maintenance dose of cinacalcet once a day. Mean baseline adjusted calcium level was 3.36 mmol/l (13.44 mg/dl). There was a significant reduction in adjusted calcium levels at approximately 1 month (10.08%), 3 months (11.93%), 6 months (13.57%) and 12 months (20.17%). Calcium normalised in most patients (83.33%), and one patient developed hypocalcaemia necessitating cinacalcet dose reduction. All patients adhered to the treatment with two people experiencing self-limiting nausea and vomiting.

Conclusion
Our patient cohort indicates that cinacalcet is an effective and safe alternative to surgery in patients with complex PHPT. Cost-effectiveness analyses are needed to allow more widespread use in such patients. Further studies with long-term follow-up are required to assess efficacy in preventing osteoporosis and renal complications related to PHPT.

Spontaneous remission of parathyroid adenoma due to parathyroid apoplexy: a case report
Cem Onur Kirac, Suleyman Baldane, Suleyman Ipekci & Levent Kebapcian
Division of Endocrinology and Metabolism, Selcuk University Faculty of Medicine, Konya, Turkey.

Introduction
Primary hyperparathyroidism (PHPT) is a disease that is characterized by elevated calcium and parathyroid hormone levels. The most common cause of PHPT is the parathyroid adenoma and the first line treatment option is surgical removal of the adenoma. Rarely, the haemorrhage in the lesion may cause the spontaneous remission of the disease.

Case report
A 54-year-old woman patient with fatigue was referred to our department due to calcium level of 11.4 mg/dl (normal range: 8.4–10.2) and PTH level of 76.1 pg/ml (normal range: 15–65). Neck ultrasound examination revealed a 10 × 5 mm mass lesion in the posterior-inferior region of the left lobe of the thyroid. Sestamibi scan showed activity in the same region with neck ultrasound. Surgical resection of the parathyroid adenoma was planned but the patient refused surgical excision because of personal reasons. One year after the diagnosis of PHPT, her calcium concentration returned into the normal range (9.4 mg/dl), at the same time neck ultrasound showed a 5 mm mass which was attached inferiorly to the left lobe of the thyroid. The mass was diagnosed as hemorrhagic parathyroid adenoma because the mass was imaged as a high intensity area by T₁-weighted MRI. At that time the sestamibi scan was negative. Six months after the haemorrhage of the lesion, it was seen that the calcium level rose to 11.1 mg/dl and the PTH level was 89 pg/ml so the PHPT has been reoccurned.

Conclusion
Parathyroid apoplexy can lead to spontaneous remission of the PHPT but the remission is usually temporary and finally recurrence of the disease could be seen.

Normocalcemic versus Hypercalcemic Primary Hyperparathyroidism: a comparative study
Natalya Moktsynshya, Svetlana Mirmaya, Anna Eremkina, Julia Krupinova & Elena Kovaleva
Endocrinology Research Centre, Moscow, Russia.

Introduction
Normocalcemic primary hyperparathyroidism (NPHPT) is defined as a condition in which persistently normal serum calcium levels are observed in the presence of high levels of parathyroid hormone (PTH). NPHPT is a new entity which possibly represents a clinically symptomatic disease and which has generated a considerable scientific interest.

Aim
To compare the clinical and laboratory data between the normocalcemic and hypercalcemic forms of PHPT.

Materials and methods
A comparative study of 357 patients with PHPT whom were separated into normocalcemic (n = 56) and hypercalcemic (n = 301) subgroups on the basis of their fasting serum total calcium value. Bone mineral density (BMD) and T-scores were evaluated by densitometry of the lumbar spine, femoral neck and total of the radius. Nephrolithiasis and bone fractures were documented by a review of the medical records.

Results
Patients with NPHPT had, on average, a lower serum PTH concentration 150 pg/ml ± 115 (N = 15–65, Me 114) and a lower serum calcium level 2.44 mmol/l ± 0.08 (N 2.15–2.55) vs hypercalcemic PHPT – 408 pg/ml ± 651 (Me 186) and 2.89 mmol/l ± 0.3 respectively. There was no significant difference in urine calcium excretion. The frequency of nephrolithiasis was 27% in normocalcemic patients and 16% in the hypercalcemic ones (P < 0.05). There were no statistical differences in relation to BMD of the lumbar spine and femoral neck, but BMD significantly differed in the total radius area. BMD in the total radius was 0.423 g/cm² (Me 0.415), mean T-score was ~2.2 s.d. of the normocalcemic patients, 51.8% had osteoporosis in at least one of the three sites evaluated. In addition, normocalcemic patients differed from hypercalcemic patients by lower values of markers of bone turnover osteocalcin and b-C-teleopeptide, P < 0.05. 20.4% of normocalcemic patients had a previous history of fractures compared to 20.3% of hypercalcemic patients (P > 0.05).

Conclusion
NPHPT is as present one of the most common reasons for consultation in bone metabolism departments, especially in postmenopausal women. Identifying these patients is important because of the consequences of untreated hyperparathyroidism, which include nephrolithiasis, osteoporosis and atraumatic fractures.

Parathyroid carcinoma: experience of a Portuguese centre
Carlos Tavares Bello¹, Sara Donato², Susana Prazeres², Helder Simoes² & Valeriano Leite²
¹Hospital de Egas Moniz, Lisboa, Portugal; ²Instituto Portugueses de Oncologia Lisboa Francisco Gentil, Lisboa, Portugal.

Introduction
Parathyroid Carcinomas are rare malignant neoplasms, accounting for less than 1% of primary hyperparathyroidism cases. Apart from certain genetic mutations, no additional risk factors are known. Diagnosis is challenging in the absence of metastatic disease since no consensual histological criteria have so far been developed. These neoplasms typically present with severe hypercalcaemia and markedly elevated serum PTH levels. Treatment is surgical and despite frequent metastatic disease at diagnosis, clinical course is usually indolent. The authors report the experience of a tertiary reference centre in Portugal regarding parathyroid carcinomas.

Methods
Observational, retrospective study. Patients with diagnosed parathyroid carcinoma from 1999 until 2016 were included. Clinical data was obtained from patient’s clinical, laboratory and imaging files. Descriptive statistical methods were used and results are presented as mean and standard deviation.

Results
The sample is composed of ten patients (five females) with a median age of 53 ± 16.9 years at the time of diagnosis. Clinical presentation was heterogeneous. All patients had hyperparathyroidism (mean 1229 ± 642 pg/ml), nine hypercalcaemia (13.4 ± 2.2 mmol/l) and four hypophosphataemia (2.1 ± 0.6 mmol/l). Histological findings: intratumorall septa (90%), vascular, capsular, perineural invasion (70%, 80%, 10% respectively), extraglandular extension (50%). Mitotic index was evaluated in four patients. CDC73 mutations were present in four patients. Metastases were present in one patient. All patients underwent en bloc resection and three received external beam radiotherapy due to recurrent loco-regional disease. After a mean follow up of 9 years, 90% are in remission and no mortality has been documented.

Conclusion
The authors describe a series of ten parathyroid carcinoma patients. Despite the clinical and biochemical severity at the time of diagnosis, most patients achieved sustained remission. Genetic mutations were identified in a significant proportion of patients, having important clinical implications. This series is noteworthy for the good outcome of such an aggressive neoplasm.

Vitamin D prescribing bias in liver transplant referrals
KJ Gan¹, Niamh O’Sullivan², Bernadette Hanley¹, Paul Armstrong¹, Mark Kilbaine³, Diarmuid Houlihan² & Rachel Crowley¹
¹Department of Endocrinology, St Vincents University Hospital, Dublin, Ireland; ²Department of Hepatology, St Vincents University Hospital, Dublin, Ireland.

Vitamin D (VD) deficiency (25 OHD < 50 nmol/l) is common is chronic liver disease at 64%–92% regardless of aetiology. The only guidelines for routine VD supplementation are for cholestatic (C) liver disease; a population considered being at high risk of low bone mineral density (BMD). BMD decreases further following orthotopic liver transplant (OLT). To assess VD intake in an at risk population, retrospective analysis of intake was performed in OLT patients with C liver disease; this was excellent at 81%. Prospective analysis comparing C with non-cholestatic (NC) patients at time of dietetics referral at OLT assessment was then undertaken (n = 94, 27% C and 73% NC). Median 25OHD in C patients was 86.7 nmol/l compared to 24.7 nmol/l in NC (P < 0.001). 36% of C patients compared to 76% of NC had 25OHD measurement of < 50 nmol/l (P < 0.0001). 48% of C patients compared to 16% of NC were receiving VD supplementation

Endocrine Abstracts (2017) Vol 49
before OLT assessment. We have observed a prescription bias at referral to transplant hepatology; VD is prescribed more frequently to C than NC patients with end-stage liver disease, although both populations are at risk of reduced BMD.

How to differentiate primary hyperparathyroidism with D hypovitaminosis from secondary hyperparathyroidism due to D hypovitaminosis?
Aline-Andreea Gatu1, Cristian Velicescu1,2, Cristina Preda1,2, Carmen Vulpoi1,2, Simona Mogos1,2, Vouchta Mogos1,2, Valentin Zaharia1, Adrian Auncute1 & Dumitru Braianesteau1
1Gr. T Popa University of Medicine and Pharmacy, Iasi, Romania; 2St. Spiridon Emergency Hospital, Iasi, Romania.

Conclusions
From group P when compared with patients from the group S (whereas serum phosphate and radius BMD were significantly lower in the patients group P. Initial PTH and serum and urinary calcium were significantly higher, correlated with serum calcium in both groups, but with serum phosphate only in AHO. This disorder caused by methylation defects of GNAS1, is characterized by Albright Hereditary Osteodystrophy (AHO). AHO include short stature, round face, brachydactyly, shortened metatarsals, subcutaneous ossifications and osteoporosis, spontaneous fragility fractures, medular fibrosis with normocytic normochromic anemia. The complication in the moment of diagnostic were: bone lesion, pubis and ischium fracture, two osteolithic lesions on the right acetabulum.

Introduction
Pseudohypoparathyroidism as an etiological cause for epilepsy: a case report
Naile Gokkaya1, Arzu Bilen1 & Habib Bilen1
1Division of Endocrinology and Metabolism, Department of Internal Medicine, Faculty of Medicine, University of Ataturk, Erzurum, Turkey; 2Department of Internal Medicine, Erzurum Training and Research Hospital, Erzurum, Turkey.

Pseudohypoparathyroidism is an uncommon cause of hypocalcemia. Blood electrolytes must be called to mind in case of epilepsy or neurological evidence. Early diagnosis and treatment of PPHP prevent complications.

Aim
How to differentiate primary hyperparathyroidism with D hypovitaminosis from secondary hyperparathyroidism due to D hypovitaminosis?

Materials and methods
Prospective study involving 71 patients admitted in our department for 1 year with the initial diagnosis of primary hyperparathyroidism. Serum and urinary calcium and phosphate, PTH and 25OHD3 were evaluated at admission. Patients with vitamin D levels under 30 ng/ml were repleted with 2000 IU/day of 25OHD3 for 1 month and 1000 IU/day for other 5 months. Values between groups were compared using student’s t test. Correlations were evaluated by using Pearson correlation analysis.

Results
Forty-eight of the 71 patients had vitamin D deficiency (< 20 ng/ml) and 15 had vitamin D insufficiency (between 20 and 30 ng/ml), only eight having 25OHD3 of over 30 ng/ml. Both 25OHD3 and PTH levels normalized after 6 months of repletion with vitamin D in only 24 of the 63 patients with initial low 25OHD3 levels and they were therefore diagnosed with secondary hyperparathyroidism (group S), whereas in the other 39 patients PTH levels remained elevated despite normalization of 25OHD3 levels, setting the diagnosis of primary hyperparathyroidism associated with D hypovitaminosis (group P). Initial PTH was correlated with serum calcium in both groups, but with serum phosphate only in AHO. This disorder caused by methylation defects of GNAS1, is characterized by Albright Hereditary Osteodystrophy (AHO). AHO include short stature, round face, brachydactyly, shortened metatarsals, subcutaneous ossifications and reduced intelligence. PHP type 1b has laboratory findings but do not has phenotype of AHO. This disorder caused by methylation defects of GNAS1 regulatory region. We present a patient who was detected PHP while following for epilepsy.

Case report
A 17 years old male patient referred to endocrinology clinic with paresthesias of the hands. He had under treatment due to epilepsy for 3 years. He had normal mental activity and phenotypic features. His family history had no specialty. His laboratory examination revealed hypocalemia and hyperphosphatemia with a calcium level 7.4 mg/dl (reference range, 8.5–10.5 mg/dl), phosphorus 6.8 mg/dl (reference range, 2.5–4.5 mg/dl), albumin 4.4 g/dl (reference range, 3.5–5.2 g/dl), magnesium 2.06 mg/dl (reference range, 1.8–2.6 mg/dl), 25 hydroxvitamin D (25 OHD) 64.3 ng/ml (reference range, 30–70 ng/ml) and PTH 115 pg/ml (reference range, 15–65 pg/ml). His rest of the laboratory findings and ophthalmic examination were normal. Brain computed tomography scan showed basal ganglia calcifications. Calcitriol and calcium supplements were started to patient whose biochemical findings support PHP diagnosis. Genetic testing of the patient did not show GNAS coding region mutation and we planned methylation study in terms of methylation abnormality in GNAS regulatory region.

Conclusion
PHP is an uncommon cause of hypocalcemia. Blood electrolytes must be called to mind in case of epilepsy or neurological evidence. Early diagnosis and treatment of PHP prevent complications.

EP262
Long standing primary hyperparathyroidism consequences after parathyroid surgery: fast recovery not only for bone mass
Cristina Stefan1,2, Amalia Afriu1, Luminita Cima1,2 & Carmen Barbu1,3
1Endocrinology Department, Elias Hospital, Bucharest, Romania; 2Ghioulouse Medical Center, Bucharest, Romania; 3Carol Davila University, Bucharest, Romania.

Background
Primary hyperparathyroidism is usually a long evolving disease before the diagnosis, thus patients who are not diagnosed by routine screening tests may have a lot of complications affecting the bone, kidney, bone marrow.

Aim
Pointing out the possibility of fast recovery not only for bone mass.

Material
We present a case of primary hyperparathyroidism, a female patient 66 years old, sent to emergency room, dehydrated, asthenic, with important hip pain, low back pain. Her Ca=14.3 mg/dl, PTH>4000 pg/dl, Hb=8.5 g/dl, CT: osteolitic lesion, pubis and ischium fracture, two osteolitic lesions on the right acetabulum and the S1 vertebra, bone biopsy: perytrabecullar fibrosis, aspects of bone remodeling and normal medullar cellularity. DXA T score: total hip -3, L1-L4 -1.8, forearm -4.4. The complication in the moment of diagnostic were: osteoporosis, spontaneous fragility fractures, medular fibrosis with normocytic normochromic anemia.

Results
Surgery was successful with the normalization of blood calcium and PTH. Questions were raised regarding the high level of PTH/neoplasia was taken into account) and also the impact of medular fibrosis the on the prognosis of the patient. After one year BMD was in age range, DXA T score: total hip -1.2, L1-L4 -0.2, forearm -2, anemia have remitted Hb=12.5 g/dl, and maintained during 2 years follow up.

Conclusion
In spite of high level of PTH and dangerous medular fibrosis, our case show surgical recovery of bone mass but also of medular complications.

Associations of nitric oxide with vitamin D and other serological factors in healthy adolescents
Nasser Al-Daghri1, Sobhy Yakout1, Naji Aljohani2, Yousef Al-Saleh1, Omar Al-Attas1 & Majed Alokail1
1King Saud University, Riyadh, Saudi Arabia; 2King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.

Nitric Oxide (NO) has been considered a very important molecule in the biological system because of its interaction with other molecules for mediating various bio-pathways. Its interaction with vitamin D in particular studied well in animal models, cell lines and patients with various diseases. However, the
relationship between NO and vitamin D has never been studied in healthy adolescents. We aimed to determine the association of NO with vitamin D and other serological factors in healthy Saudi adolescents. We recruited 740 individuals (245 boys and 495 girls) from Riyadh, Saudi Arabia. Socioeconomic status, food habits, BMI and data regarding major medical complications were recorded. Blood samples were performed for estimation of vitamin D, traces of NO and other possible serological parameters. Data revealed that NO has inverse correlation with vitamin D but showed significant and positive association with serum triglycerides and systolic blood pressure. Here, it is suggested that some unknown limiting factors may restrict the relationship of NO and vitamin D in healthy individuals. Therefore, the factors which limit the NO association with vitamin D and other molecules should be investigated in vitro and in vivo.

Primary hyperparathyroidism in pregnancy
Belgin Efe1, Goknur Yorulmaz1, Sevil Alaguney4 & Bartu Badak2
1Division of Endocrinology, School of Medicine, Eskişehir Osmangazi University, Eskişehir, Turkey; 2Department of General Surgery, School of Medicine, Eskişehir Osmangazi University, Eskişehir, Turkey.

Introduction
Primary hyperparathyroidism is the most common cause of hypercalcemia in the general population. Hypercalcemia during pregnancy can result in significant maternal and fetal morbidity and mortality.

Case
A 30-year-old pregnant female primigravida in the 31st weeks of gestation with complaint of obstinate constipation was admitted to our emergency department. In laboratory tests, hypercalcemia was detected. She was a Syrian refugee and was unable to communicate in English and Turkish. The parathyroid hormone (PTH) and albumin-corrected serum calcium levels were high. The results were 203 (12–65) mg/ml and 15.1 (8.5–10.5) mg/dl respectively. Urinary calcium excretion rate was 440 mg/per day. Tubular phosphorus reabsorption rate was 73%, and the chlor/phosphorus ratio was 54.7. In the light of all these data, primary hyperparathyroidism was diagnosed. Ultrasound imaging revealed a parathyroid adenoma (6×6×9 mm) at the inferior of the left thyroid lobe. In our case we started 3000 cc saline infusion and furosemid treatment but her calcium levels didn’t decrease. We started to hemodialysis but still calcium levels didn’t decrease to safe range. Intravenous calcitonin was added to our case we started 3000 cc salin infusion and furosemid treatment but her calcium levels didn’t decrease. We started to hemodialysis but still calcium levels didn’t decrease to safe range. Intravenous calcitonin was added to

Discussion
The main treatment modality of hyperparathyroidism is surgery but if hyperparathyroidism is diagnosed in third trimester surgical approaches have high risk. Because of the high risk, we trained our patient with medical treatment at the hospital until safe birth time. In the postpartum interval to avoid a high risk, we trained our patient with medical treatment. The factors contributing to this phenomenon have not been fully elucidated yet. In this study, we retrospectively analysed the data of patients whose serum Ca levels returned to normal after parathyroid surgery in our center.

Patients and methods
Computer records of 35 patients who had undergone parathyroid surgery and achieved normal serum Ca levels were retrospectively analysed. Despite serum Ca values within the normal ranges, patients were divided into two groups according to their PTH values 6 months after surgery (elevated PTH (ePTH) group (PTH ≥65 pg/ml) and low PTH (iPTH) group (PTH <65 pg/ml)). Fifteen patients were classified as having ePTH and 20 as iPTH. The frequency of ePTH was determined as 42%. The mean pre and postoperative PTH levels in ePTH and iPTH groups were 265 ±119, 94 ±32 and 206 ±136, 39 ±17 pg/ml, respectively. The mean pre and postoperative 25(OH) vitamin D3 levels in ePTH and iPTH groups were 12 ±7, 22 ±11 and 22 ±14, 32 ±12 ng/ml, respectively.

Results
Although ePTH group had higher preoperative PTH values as well as lower pre and postoperative 25 (OH) vitamin D3 levels, there was no statistically significant difference between the groups. For the remaining parameters, two groups had similar results.

Discussion
Several hypotheses have been proposed to explain the etiopathogenesis of persistently elevated PTH values despite normal Ca levels following parathyroid surgery. Suggested causes of this phenomenon include 25 (OH) vitamin D3 deficiency, secondary hyperparathyroidism resulting from insufficient renal function, stimulation of PTH secretion induced by relative hypocalcemia postoperatively, and increased bone turnover. However, this condition may also indicate possible recurrence due to multifocal/nodular hyperplasia rather than a single parathyroid adenoma.

DOI: 10.1530/endoabs.49.EP265

Acute pancreatitis as the first presentation of primary hyperparathyroidism
Alexandra Vieira, Marta Ferreira, Daniela Guelho, Teresa Pereira, Luís Filipe Silva, Estela Ferreira & Ana Inácio
Leiria Hospital Center, Leiria, Portugal.

Introduction
Serum parathormone (PTH) levels may remain elevated in some patients after parathyroidectomy despite achievement of normal serum Ca levels. The factors contributing to this phenomenon have not been fully elucidated yet. In this study, we retrospectively analysed the data of patients whose serum Ca levels returned to normal after parathyroid surgery in our center.

Patients and methods
Computer records of 35 patients who had undergone parathyroid surgery and achieved normal serum Ca levels were retrospectively analysed. Despite serum

Discussion
It should be considered that primary hyperparathyroidism may have bone lesions that mimic bone metastasis. Especially in cases where the thyroid nodule is visible but there is no evidence of parathyroid adenoma in parathyroid scintigraphy intrathroidal parathyroid adenomas should be considered in the differential diagnosis of cystic neck lesions.

DOI: 10.1530/endoabs.49.EP266

Endocrine Abstracts (2017) Vol 49
Background

Hypercalcemia due to primary hyperparathyroidism is a rare cause of acute pancreatitis, with a reported prevalence of 1.5–8%.

Clinical case

A 25-year-old male patient was referred to the Endocrinology outpatient clinic for hypercalcemia diagnosed in the context of acute pancreatitis. He had medical and surgical pathological antecedents of: clavicle fracture after car accident, cholecystectomy and appendectomy, gastroesophageal reflux disease. Current medications included proton pump inhibitor daily. Laboratory analysis reported serum calcium of 3.46 mmo/l (2.20–2.65), phosphorus of 0.70 mmo/l (0.81–1.45) and intact parathyroid hormone of 569 pg/ml (12–88). Biochemical screening for type 1 and type 2 multiple endocrine neoplasia was performed and was negative. The neck ultrasonography showed a nodular heterogeneity with hyperchogenic contours with cystic areas, and posteriorly and inferiorly to the left lobe an hypoechogenic nodular formation, with 2.4 cm of greater axis, which may correspond to the parathyroid gland with increased dimensions. Bone densitometry showed osteopenia. Sestamibi parathyroid scintigraphy revealed a focus of significant radiopharmaceutical retention on the projection of the lower left lobe pole, alteration compatible with parathyroid adenoma. A lower left parathyroidectomy and left lobectomy of thyroid was performed without complications. The histopathological result confirmed the diagnosis of parathyroid adenoma. At the last visit, he had normal PTH and calcemia values.

During the follow-up he had recurrent acute pancreatitis episodes.

Conclusions

The authors present this case because of its rarity: hyperparathyroidism in a young patient whose presentation was of acute pancreatitis without the classic clinic manifestations of hypercalcemia.

EP268

Gender difference in clinical presentation of primary hyperparathyroidism

Laura Gianotti, Elena Castellano, Francesco Tassone, Claudia Baffoni, Flora Cesario, Giaquobalo Magro, Micela Pellegrino & Giorgio Borretta
Division of Endocrinology, Diabetology & Metabolism, S.Croce & Carle Hospital, Cuneo, Italy.

Objective

Primary hyperparathyroidism (PHPT) is one of the most common endocrine disorders, with a female to male ratio of 3:1. Currently most patients with PHPT are asymptomatic. However, data about the gender impact on the clinical presentation of PHPT are lacking.

Methods

We evaluated the difference in symptoms and biochemical parameters between men and women with PHPT in a single center series of 417 patients.

Results

Male PHPT patients resulted significantly younger (P=0.046) and more frequently symptomatic than women (62.3% vs 47%, P=0.016). Furthermore, renal stone incidence was higher in male than in female patients (50.5% vs 33%, P=0.003) while no difference was found in the incidence of osteitis fibrosa cystica (21.5% vs 20.7%). Instead, osteoporosis, established as T score Z ≤ −2.5, was significantly predominant in women (56.5% vs 39.3%, P=0.015) than in men. However, no differences were found in classical biochemical disease parameters (i.e. PTH, serum calcium, phosphorus, 24 h urine for calcium) nor in creatinine and vitamin D levels. Finally, the proportion of patients with surgical indications (symptomatic patients and asymptomatic patients meeting surgical criteria recommended by current guidelines) was similar in male and in female PHPT patients (84.6% vs 84.9%).

Discussion

Gender leads to a different clinical presentation in PHPT patients, male patients being usually younger and more frequently affected by a symptomatic form of the disease. In addition, renal stones are significantly more frequent in men, while in women osteoporosis is prevalent. On the other hand, PHPT biochemical presentation seems not to be influenced by gender. Furthermore, surgical indication is reached equally in male and female PHPT patients.

Conclusions

In male patients PHPT is less frequent but more commonly symptomatic than in female patients. PHPT clinical presentation is influenced by gender, although there are no sex-related differences in its biochemical profile.

Prevalence of hypocalcemia in adults in Minsk, Belarus

Elena Brutskaya-Stempkovskaya1,2, Alla Shepelkevich1 & Georg Kostin1,3
1Belarusian State Medical University, Minsk, Belarus; 2Minsk City Polyclinic N31, Minsk, Belarus; 3Minsk Consulting and Diagnostic Centre, Minsk, Belarus.

The prevalence of hypocalcemia among patients non-operated the thyroid and parathyroid glands has increased significantly with the introduction the screening of calcemia. The main reasons for hypocalcemia are hypoproteinemia and hypoparathyroidism.

Objective

To study the prevalence of hypocalcemia in the adult in Minsk.

Materials and methods

We studied 1207 people, average age 53.9±17.25 (892 women, 315 men) from 18 to 96 years. Examination: total calcium, total protein. Hypocalcemia was detected in total calcium level <2.2 mmo/l.

Results

Hypocalcemia was recorded in 40 people (3.3/100 adults), the mean age was 42.9±17.63 years (32 women, men – 8). In the age group up to 30 years hypocalcemia was revealed in 12 cases (8.3%, in women – 10.3%); in the group 30–44 years – five cases (1.3%, in men – 4.7%, in women – 0.3%), 45–59 years – three cases (1.1%, in men – 2.5%, in women – 0.5%); 60–74 years – ten cases (2.5%, in men – 2.6%, in women – 2.4%); >75 years – one case (0.7%, in men – 3.2%). The prevalence of hypocalcemia in the group up to 45 years – 6.6 per 100 adults. The prevalence of hypocalcemia in the group 45 years over – 1.7/100 adults. The results of the study indicate a significant occurrence of hypocalcemia in the age group up to 45 years (χ²=20.34, p=0.00001).

Conclusion

The prevalence of hypocalcemia in the adult population of Minsk-city was 3.3/100 adults (33:1000). The prevalence of hypocalcemia in the age group up to 45 years was 6.6/100 adults, in the age group 45 years over was 1.7 per 100 adults. The results of the study indicate a significant occurrence of hypocalcemia in the age group up to 45 years.

Assessment of changing in the therapeutic attitude in patients with primary hyperparathyroidism in conservative management after the realization of radial densitometry

Jose Alvaro Romero Porcel, Guillermo Martinez De Pinillos Gordillo, Fernando Garcia Perez, Eyvee Arturo Cuellar Lloclla, Jose Ignacio Fernandez Peña, Carmen Carretero Marin, Juan Manuel Garcia De Quiros, Ignacio Fernandez Lopez, Mariana Tome Fernandez-Ladreda & Maria Victoria Cozar Leon
Hospital De Valme, Sevilla, Spain.

Introduction and objectives

In the 4th Workshop on Primary Hyperparathyroidism, it is recommended to perform BMD by DXA of third radius as well as lumbar spine and hip DXA in the initial assessment and follow up of patients with primary hyperparathyroidism. This test is not available in many centers, which means that only T Score values of the lumbar spine and hip are used to certify the absence of osteoporosis in asymptomatic patients with conservative management is performed. Our objective is to evaluate if the recent addition of radius DXA has modified the management of this patients.

Materials and methods

Retrospective study including patients in follow-up by primary asymptomatic hyperparathyroidism in conservative management according to the Fourth Workshop criteria when radial densitometry for the first time in its evolution. Changes after the DXA results were evaluated.

Results

20 patients (65.4 years ±11.14, 90% women) with a follow-up of 3.95 years ±1.97 were included. Blood calcium levels 11.05±0.45 mg/dl, mean PTH of 105.46 pg/ml ±60.9. None presented lumbar and/or femoral T-Score values lower than –2.5 DS (lumbar T –0.15 DS ±2.17, femoral –0.77 DS ±0.98). The radial T Score was –2.67 DS ±2.45. The radial densitometry changed the clinical attitude in 70% of the patients, from the recommended conservative management to surgical treatment in those with a T-Score lower than –2.5 DS in the distal radius and T-Score higher than –2.5 DS in the lumbar and/or femoral.

Conclusions

Our study reinforces the importance of performing distal radius densitometry in patients in which conservative management is giving to be performed, as is
Primary hyperparathyroidism is the most common cause of hypercalcemia. 87% of the cases present with single adenoma, 9% of them have hyperplasia, while multiple adenomas and parathyroid malignancy are detected in 3% and 1% of the cases, respectively. Although it is rare, parathyroid adenomas may be ectopic. The most common locations for ectopic parathyroid adenomas are thymus, tracheoesophageal cleft, carotis sheath, intrathyroidal and parasaecal area. In this study, we aimed to present an intrathyroidal parathyroid adenoma as a rare case.

A 46-year old female patient who received hemodialysis for chronic renal failure secondary to chronic glomerulonephritis for 7 years and then underwent cadaveric renal transplantation in 2010 was presented for routine follow-up visit. Laboratory examination revealed urea:19 mg/dl (n:15–43), creatinin:11.5 mg/dl (n:8.6–10.2 mg/dl), phosphorus:2.7 mg/dl (n:2.4–5.1 mg/dl), albumin:4.2 g/l (n:3.2–4.8 g/l), iPTH:340 pg/ml (n:15–68), creatinin clearance in 24-h urine: 82 ml/min, calcium in 24-h urine: 410 mg/day. Neck ultrasonography was performed, which demonstrated 12×9 mm sized well-circumscribed nodular lesion with heterogeneous echo at inferior part of lower pole of left thyroid gland (thyroid nodule? Parathyroid adenoma?). Femoral neck and L1–L4 vertebra were osteopenic on bone densitometry. Parathyroid scintigraphic examination detected no scintigraphic adenoma). Femoral neck and L1–L4 vertebra were osteopenic on bone densitometry. 

Conclusions

Compliance with guidelines recommendations was suboptimal in certain areas, not entirely explained by the adoption of a palliative approach with focus on symptom control in cases. Training opportunities will be devised locally to improve practice. Bisphosphonate use in the Emergency department should be controlled for the appropriate circumstances. Vigilance is recommended assigning causality in active malignancy, given that 11.1% of pre-existing malignancy cases were found to have concurrent PTH driven hypercalcemia, despite only 38.9% of them being investigated with a PTH level.

Higher circulating parathyroid hormone concentration facilitates preoperative diagnostic imagings for localization in primary hyperparathyroidism

Kentar0 Okamoto1, Yoshishiku Itoh1, Akiyuki Kawashima1, AyA Amano1, Kyoko Okazaki1, Hirofumi Murabe1, Yoshibhu Yokota1, Risa Yoshimoto2, Akiko Sahara2, Junko Tomokuni2 & Keita Hamamatsu3

1Kurashiki Central Hospital, Department of Endocrinology and Rheumatology, Okayama, Japan; 2Kurashiki Central Hospital, Department of Laboratory Medicine, Okayama, Japan; 3Graduate School of Medicine and Faculty of Medicine Kyoto University, Department of Diabetes, Endocrinology and Nutrition, Kyoto, Japan.

Introduction

For minimally invasive surgery of primary hyperparathyroidism (PHPT), the identification of the accurate localization is required. As preoperative diagnostic imagings, we perform ultrasound, technetium 99m-sestamibi scintigraphy and either or both of megnetic resonance imaging or computed tomography in all cases. The aim of the present study is to evaluate the clinical biochemical factors that facilitate preoperative diagnostic imagings for localization.

Methods

We retrospectively searched the medical records of patients with PHPT who were admitted in our hospital from 2014 to 2016. Fifty-five patients were identified. Four patients with parathyroid carcinoma, multiple endocrine neoplasia type 1, familial hypocalciuric hypercalcemia, and detectable parathyroid hormone-related protein were excluded. Fifty-one patients were included in the study. We defined 36 patients as the ‘localized’ group, including 30 patients who underwent curative operation and 6 non-operative patients whose suspicious adenoma was consistently identified by two or more of diagnostic imagings. And other 15 patients were defined as the ‘non-localized’ group. We computed biochemical data including intact parathyroid hormone (iPTH), serum calcium, urine calcium, and tartrate-resistant acid phosphatase 5b.

Results

iPTH was statistically higher in the ‘localized’ group (146 [103–195] vs. 98 [82–136] pg/ml; p = 0.010). Multivariate logistic regression analysis demonstrated that the usefulness of preoperative diagnostic imaging was ensured only in higher iPTH (p = 0.014). When we set the cut-off value of iPTH to 150 pg/ml, sensitivity was 48.6% and specificity was 87.5% (AUC: 0.73 [95% CI 0.59–0.87]). When we used whole parathyroid hormone (wPTH) in place of iPTH, we obtained similar results: the cut-off value 85 pg/ml with sensitivity 51.7% and with specificity 87.5% (AUC: 0.84 [95% CI 0.72–0.96]).

Conclusion

Both iPTH and wPTH as circulating parathyroid hormone concentration are useful to predict whether preoperative diagnostic imagings can identify the accurate localization of the parathyroid adenoma.

EP274
Calcifediol is more effective than cholecalciferol in the treatment of severe vitamin D deficiency in a patient submitted to malabsorbitive bariatric surgery: a case report
Alessandro Brancatella, Daniele Cappellani, Edda Vignali, Domenico Canale & Claudio Marconcini
Department of Endocrinology and Metabolism, University of Pisa, Pisa, Italy.

Context
Vitamin D deficiency following malabsorptive bariatric surgery can lead to osteomalacia. We report a patient with severe vitamin D deficiency following malabsorptive bariatric surgery successfully treated with calcifediol but not cholecalciferol.

Case description
A 40-year-old woman, submitted to biliopancreatic diversion 20 years before and chronically treated with 50,000 IU cholecalciferol weekly, was admitted to our Endocrine Unit because of severe low-back pain, muscle weakness, generalized muscular hypotrophy, associated with hypocalcemia and elevated PTH levels. Initial evaluation revealed low albumin-corrected serum calcium (7.4 mg/dl), high serum PTH (240 pg/ml), bone-specific alkaline phosphatase (125 μg/dl) and 1,25-dihydroxyvitamin D (112 pg/ml) concentrations, and undetectable serum 25-hydroxyvitamin D (<7 ng/ml). Bone mineral density (BMD) was markedly low. Normocalcemia was initially restored with i.v. albumin and calcium gluconate. Treatment with calcitriol (0.5 μg three times daily) and oral calcium carbonate (1000 mg daily) was simultaneously started and cholecalciferol was replaced with calcifediol (125 μg (5000 UI) daily). During follow-up the calcifediol dose was progressively tapered to 25 μg (1000 UI) daily and the calcitriol dose progressively reduced and finally withdrawn. Serum biochemistry normalized, BMD significantly increased and the patient’s clinical conditions progressively improved, with a substantial recovery of autonomy.

Conclusions
Our data suggest that calcifediol might be more efficacious than cholecalciferol for prevention and treatment of vitamin D deficiency in patients treated by malabsorptive bariatric surgery.

The changing face of primary hyperparathyroidism
Ilfigenia Kostoglou-Athanasiou1, Alexios Travlos1, Evaggelia Vogiatzi2 & Eleni Pantazi2
1Department of Endocrinology, Red Cross Hospital, Athens, Greece; 2Department of Endocrinology, Alexandra Hospital, Athens, Greece.

Primary hyperparathyroidism is a disease which nowadays is being diagnosed with increasing frequency. The diagnosis of primary hyperparathyroidism is based on routine calcium measurement, which if detected abnormally elevated leads to the screening of the patient for primary hyperparathyroidism. Therefore, primary hyperparathyroidism is frequently detected early in the course of the disease. Consequently, severe musculoskeletal manifestations may be lacking in the modern world setting in patients with primary hyperparathyroidism. The aim was to describe musculoskeletal manifestations in patients with primary hyperparathyroidism being followed up in a center of excellence in Athens. A cohort of 38 patients, 33 female and five male, with primary hyperparathyroidism aged 62.31 ± 1.87 years, being followed up within a center of excellence in Athens was studied. Musculoskeletal manifestations were recorded in the cohort of the patients studied.

Within the cohort of 38 patients with primary hyperparathyroidism being followed up within a center of excellence in Athens, 12 patients (31.58%) had osteoporosis, 2 (5.26%) had osteopenia, 7 (18.42%) had diffuse bone pain, 2 (5.26%) had diffuse myalgia and 1 (2.63%) had suffered a wrist fracture. Within the cohort studied 18 (47.37%) patients did not have any musculoskeletal manifestations.

It appears that primary hyperparathyroidism does not have severe musculoskeletal manifestations, such as osteitis fibrosa cystica, in the real world setting in patients followed up for the disease within a center of excellence in Athens. However, patients with primary hyperparathyroidism appear to have diffuse bone pain as well as osteoporosis, which may be complicated by a fracture in some of the cases. Early detection and diagnosis of the disease seems to have altered the face of primary hyperparathyroidism in the real modern world setting.

Single center experience of intact parathyroid hormone determination in washout samples of suspicious parathyroid adenomas
Mustafa Sahin1, Asena Gokcay Campolat1, Elif Eliboglugi1, Caglar Keskin1, Sule Canlar1, Ozgur Demir1, Sevim Gulru1, Murat Faik Erdoglu1, Rifat Emral1 & Denet Corapcioglu1
1Ankara University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; 2Ankara University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey.

Introduction
Minimally invasive surgery is an alternative surgical approach for primary hyperparathyroidism with less surgical trauma and anesthesia complications. Neck ultrasonography and scintigraphy are still the first step tools for localising parathyroid lesions. Intact parathyroid hormone (PTH) determination in washout samples is really very useful when parathyroid lesions can not be easily distinguished from thyroid lesions or sometimes lymph nodes.

Method
In our clinic, we performed ultrasonography guided parathyroid fine needle aspiration procedure for 119 patients diagnosed with primary hyperparathyroidism between January 2005 and January 2016. Intact parathyroid hormone determination was performed in washout samples. 80 of the study group also had a parathyroid scintigraphy. All of the patients underwent parathyroid surgery.

Results
In 106 of the study group had positive parathyroid hormone washout (phw) results according to blood PII levels. Significant difference was achieved in localisation of the lesion (p<0.006), serum calcium levels (p<0.01) and PIIH levels (p<0.001) between washout negative and positive group. No difference was observed in gender, age, presence of stone, levels of serum phosphorus, creatinin, alkaline phosphatase, parathyroid hormone, vitamin D and 24 h urinary calcium levels. 28 patients in the scintigraphy group had negative scan whereas 47 of them had both scintigraphy and PIIH positive. 24 of the patients had positive PIIH results but negative scintiscans.

Conclusion
The present study represents that ultrasonography combined with PIIH evaluation seems to be more diagnostic according to parathyroid scintigraphy.

**Primary hyperparathyroidism due to atypical adenoma: clinical, biochemical and histological features of an Italian cohort**

Federica Saponaro1, Marina Di Giulio1, Elena Pardi1, Simona Borsari1, Gabriele Materazzi1, Claudio Marcocci1 & Filomena Cetani1

1Endocrinology Unit 2, University of Pisa, Pisa, Italy; 2Endocrine Surgery, University of Pisa, Pisa, Italy.

Primary hyperparathyroidism (PHPT) is mostly due to a benign parathyroid tumor (99%). Some have parathyroid ‘atypical adenomas’, rare tumors with histological features of parathyroid cancer (PC) (fibrous trabeculae, thick fibrous bands, mitotic figures in parenchymal cells), without local invasion or metastasis. We evaluated 20 patients with histological diagnosis of atypical adenoma. Patients were 13 women and seven males (mean age: 55 ± 13 yrs). Nineteen patients had a sporadic PHPT and one a Familial Isolated PHPT (FIHP). At least one of the following symptoms was present in 8 (40%) patients: nephro lithiasis (n = 8), clinical fragility fractures (n = 1), neuropsychiatric symptoms (n = 6). In the remitting patients (n = 12) PHPT was asymptomatic. Osteoporosis was detected in 8 (40%). Preoperative imaging was positive in 16 (80%) patients. The association with other tumors was recorded: papillary thyroid carcinoma (n = 4), adrenal bilateral hyperplasia (n = 1), breast cancer (n = 1), Morton’s neuroma (n = 1).

Biochemical tests at baseline were: albumin adjusted serum calcium 12.4 ± 7 ng/ml, PTH 204 (160–277) pg/ml and 25OHGD 13.4 ± 7 ng/ml. All patients underwent PTx. The histological diagnosis was of atypical adenoma (mean diameter 24 ± 10.6 mm) with the following features: fibrous trabeculae in two, thick fibrous bands in 13, capsular invasion infiltration in seven and mitotic figures in two. All but one patients were cured after PTx and remained normocalcemic (mean follow-up 5 years). One patient, with apparently sporadic PHPT, had persistent hypercalcemia and he is in follow-up. This study suggests that PHPT due to atypical adenoma is generally asymptomatic at diagnosis, it has a moderate-severe biochemical profile resembling that of PC, it is a sporadic disease and shows a benign prognosis in the majority of cases. We found an association with other tumors, that will be evaluated in further studies.

**Medullary vertebral compression in primary hyperparathyroidism**

Fedala Saïda, Meskine Djamilia, Kedad Lamia, Fafa Nadira & Touba Zakia

Laboratory of Endocrinology and Metabolism (LEM 1), Algiers, Algeria.

We report the case of an ectopic parathyroid adenoma, revealed by a medullary vertebral compression by a brown spinal tumor in a 44-year-old woman. Physical examination revealed a lower limb weakness, paresthesia and radicular lower extremity pain. Magnetic resonance imaging (MRI) showed osteolytic vertebral lesions suggesting metastatic localizations. A thoracic CT scan identified a mediastinal mass measuring 6.2 cm in the major axis. Biological evaluation revealed a hypercalcemia (135 mg/l) with very high PTH (1896 pg/ml), parathyroid scintigraphy confirmed the mediastinal ectopic parathyroid. The patient underwent surgical resection of the mediastinal mass that proved to be a parathyroid adenoma. She showed a remarkable improvement in her clinical condition observed 6 months after parathyroidectomy. Medullary vertebral compression by a brown spinal tumor in primary hyperparathyroidism is rare, surgery of parathyroid adenoma improved clinical condition without resection of the brown tumor. However surgical decompression may be necessary in some cases.

**Management of primary hyperparathyroidism: Experience of a large UK teaching hospital**

Rebecca Sagar, Amy Longhurst & Afroze Abbas

Leeds Centre for Diabetes and Endocrinology, Leeds Teaching Hospitals, Leeds, UK.

Background

Primary hyperparathyroidism (PHPT) is a common cause of hypercalcaemia seen in outpatient endocrinology clinic. Diagnosis is based on biochemistry and exclusion of other conditions, such as familial hypocalciuric hypercalcaemia. Symptomatic patients should usually be referred for parathyroidectomy. For asymptomatic patients there are clear guidelines for surgical referral, based on the Fourth International Workshop (2014) recommendations. This study evaluates current practice for diagnosing and managing primary hyperparathyroidism compared to international guidelines, at a large UK teaching hospital.

Methods

We evaluated all new cases of PHPT seen in outpatient endocrinology clinics between January 2014 and July 2016. Data were collected using a standardised proforma. Data fields included demographics, biochemistry and imaging. Follow-up data on surgical referrals, histology and outcomes were also collected.

Results

Of the 121 patients, at diagnosis, 50.4% were symptomatic. Complete investigation data were available for 117. 59.8% had all relevant investigations performed as recommended per guidelines. Urinary calcium was conducted in 67.5% of patients, of those, 44.3% had inappropriate vitamin D levels at the time of collection. At diagnosis, 30.0% patients had renal complications and 36.3% had osteoporosis. 84% of the 121 met criteria for surgery, although 58.8% were actually referred. The most common reasons for non-referral were patient choice (33.3%) and fitness for surgery (45.5%). On imaging, 74% had a single adenoma, 11.7% had no obvious adenoma, 75% had positive correlation between imaging and surgical findings. 3 months post-operatively, 91% of patients had normal calcium and 68% had normal PTH.

Conclusions

This study shows that the majority of patients with PHPT are diagnosed and investigated as per guidelines. Almost all patients had a normal calcium 3 months post operatively, suggesting surgery was curative. However, urinary calcium estimation was performed without the correction of vitamin D levels in a significant percentage of patients, thereby affecting accuracy of interpretation.

**Fahr Syndrome and idiopathic primary hipoparathyroidism – clinical case**

Ana Filipa Martins1, João Martin Martins1,2 & Sónia do Vale1

1Hospital de Santa Maria – CHLN, Lisboa, Portugal; 2Faculdade de Medicina de Lisboa, Lisboa, Portugal.

Introduction

Fahr syndrome (FS) is a neuropsychiatric condition due to progressive basal ganglia calcification. Although pathophysiology is not completely understood, it may be secondary to infectious, metabolic and genetic diseases.

Case report

A 65-year-old male Caucasian was referred to the outpatient endocrine department because of hypercalcaemia. No perioral paresthesia or tingling of the fingers and toes were noticed. He complained of longstanding hand tremor and since one year ago apathy and gait instability were evident. Past medical history revealed High Blood Pressure under treatment. He also referred previous use of anti-convulsivant medication since he was 15 because of diagnosed epilepsy. Drugs were suspended at 20th with no further seizures. No previous cervical surgery or irradiation were done. Her death mother was also diagnosed of epilepsy. Besides slow and rigid movement, physical examination was otherwise normal, with negative Chvostek and Trousseau. Deafness, visual field defects or dysmorphisms were absent. Analytic evaluation confirmed albumin-corrected hypercalcemia, hyperphosphatemia, normal serum magnesium, hypoparathyroidism with sufficient 25OH-vitamin D levels. Slight ferropenia and chronic renal disease grade 2 were diagnosed. Besides Hashimoto thyroiditis, no other endocrinopathy was evident. Echocardiogram evidenced left auricular dilatation and reduced global systolic function. Cystic renal disease and slight cystic calcifications were documented on kidneys ultrasound and cervical ultrasound evidenced multinodular goiter. Bone densitometry of femur and lumbar spine was normal. Cranioencephalic TC identified bilateral simetric parangiomatous calcifications, both supra and infratentorial, with extensive involvement of basal ganglia. 112- SestaMIBI scintigraphy did not fixate in cervical imaging. Anti-NALP5 antibody was negative, as well as CASR activating mutation.

Discussion and conclusion

Parathyroid hormone and calcium abnormalities are the most common metabolic disorders associated to FS. We describe a patient diagnosed of idiopathic hypoparathyroidism. Basal ganglia calcifications support a long-standing
hypoalactemia, and chronic ion disturbance may have contributed to the absence of usual muscular complaints.

Clinical presentations of four patients with familial isolated hyperparathyroidism and hyperparathyroidism-jaw tumor syndrome

Taner Bayraktaroglu1, Utku Sentosun1, Dilek Karakaya Arpaci1, Ali Ugur Emre2, Mertol Gokce3, Serkan Uysal1, Rabibi Uulu Erdemir1, Burak Bahadin1 & Guldeniz Cakmak1 1Bulent Ecevit University, Faculty of Medicine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Zonguldak, Turkey; 2Bulent Ecevit University, Faculty of Medicine, Department of General Surgery, Zonguldak, Turkey; 3Bulent Ecevit University, Faculty of Medicine, Department of Chest Surgery, Zonguldak, Turkey; 4Bulent Ecevit University, Faculty of Medicine, Department of Nuclear Medicine, Zonguldak, Turkey; 5Bulent Ecevit University, Faculty of Medicine, Department of Medical Pathology, Zonguldak, Turkey.

Introduction

Primary hyperparathyroidism is commonly treated with targeted parathyroidectomy guided by preoperative imaging and intraoperative parathormone monitoring. Despite advanced imaging techniques, failure of parathyroid localization still occurs. Hyperparathyroidism-jaw tumor syndrome and familial isolated hyperparathyroidism are a rare autosomal dominant tumor syndrome characterized by hyperparathyroidism. In this report, we present four patients with familial isolated hyperparathyroidism and hyperparathyroidism-jaw tumor syndrome.

Case 1

A 26-year-old man with left maxillary tumoral lesion is referred. He had the elevated serum calcium and parathormone levels, osteoporosis, rena anomalia, nephrolithiasis. According to the diagnosis of hyperparathyroidism jaw-tumor syndrome, imaging modalities included neck sonography, scintigraphy, computed tomography indicated a ectopic parathyroid adenoma, then it was removed by videoscopic assisted medastinoscopy with temporarily hypoparathyroidism.

Case 2

A 43-year-old man who is a relative of Case 1 is presented with persistent myalgia-arthralgia and nausea due to hypercalcemia caused by increased parathormone levels. Sonographic and scintigraphical evaluations of the neck showed that multiple irregular nodules of thyroid and suspected parathyroid adenomas. Fine needle aspiration cytology of the nodules and pathological lymphadenopathy revealed a suspect of the low differentiated thyroid carcinoma with lymphatic invasion. In wash-out sampling from suspected parathyroid adenoma, parathormone levels were increased. Total thyroidectomy with central and lateral neck dissection in addition adenomectomy with hungry bone syndrome.

Case 3

A 600-year-old man who is in relations with Case 1 and Case 2 is complained with nausea-vomiting and lower back pain with osteoprototic fractures of left femur and left humerus. His serum levels of calcium and parathormone are highly increased. Imaging modalities showed a suspected lesion in the inferior region of the left thyroid localization. After minimal invasive intervention and selective parathyroid sampling, the second operation included exploration and thyroidectomy with 3.5 parathyroidectomy and implantation to sternocleidomastoid.

Case 4

The patient was a 51-year-old man (who is a brother of Case 3) presenting without any symptoms. He had hypercalcemia (12.2 mg/dl) and hyperparathyroidism (247 pg/ml). Parathyroid lesion detected with sonography and scintigraphical evaluations, and it is referred to minimal invasive parathyroid adenomectomy.

Conclusion

Primary hyperparathyroidism is a common clinical problem for which the only definitive management is surgery. Diagnosis of the familial primary hyperparathyroidism caused by CDC73 (formerly known as HRPT2) is based on the biochemical findings of primary hyperparathyroidism, identification of ossifying fibromatous(s) of the maxilla and/or mandible on imaging studies, family history, and detection of a heterozygous germine CDC73/ pathogenic variant on molecular genetic testing. The spectrum of CDC73-related disorders includes hyperparathyroidism-jaw tumor syndrome, familial isolated hyperparathyroidism and parathyroid carcinoma. In familial primary hyperparathyroidism, reoperative parathyroidectomy are challenging entities that require special consideration and expertise.

When is it worthwhile to perform parathyroid SPECT/CT scintigraphy in primary hyperparathyroidism?

Malgorzata Trofimuk-Muldner1,2, Anna Skalnik1,2, Lukasz Kulczynski1,2, Aleksandra Zapendorska-Dudek1, Aneta Dudek2, Monika Buziak-Bereza1,2, Anna Sowa-Staszczak1,2 & Alicja Hubalewska-Dydejczyk1,2 1Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; 2Endocrinology Department, University Hospital in Krakow, Krakow, Poland.

Introduction

Observed increasing frequencies of asymptomatic or oligosymptomatic PHP cases may increase the rate of false negative imaging results.

Aim

To determine the level of PTH and calcium at which an enlarged parathyroid gland can be detected by parathyroid SPECT/CT.

Material and methods

A retrospective analysis of 117 patients diagnosed with PHP (100 females and 17 males, aged 16–88 years) was performed. In each patient parathyroid SPECT/CT after administration of 500 MBq of 99mTc-MIBI was conducted (Siemens Symbia T16). Serum calcium and parathormone (PTH) were measured in each patient. serum phosphate was estimated in 109 subjects. Statistical analysis was performed with Statistica 12 Software.

Results

Median serum calcium level was 2.77 mmol/l (LQ and UQ – 2.66 and 2.87 mmol/l, respectively); median serum PTH level was 122.8 pg/ml (97.2 and 191.9 pg/ml); median plasma phosphate was 0.84 mmol/l (0.74 and 0.98 mmol/l). In 70 (59.8%) patients an enlarged parathyroid gland was detected with SPECT/CT. There was a statistically significant difference in PTH levels (median 138.15 and 114.80 pg/ml, respectively; Z 0.02) and serum calcium levels (median 2.74 and 2.67 mmol/l, P < 0.01) between patients with positive and negative parathyroid SPECT/CT. Serum phosphate levels did not differ significantly (P = 0.19). Receiver–operator curves (ROCs) were drawn to establish PTH and serum calcium cut-off levels for positive parathyroid SPECT/CT imaging. Sensitivity and specificity of parathyroid scintigraphy were 38 and 86.9%, respectively, for PTH cut-off level of 191.9 pg/ml, and 52 and 79%, respectively, for serum calcium cut-off level of 2.74 mmol/l.

Conclusions

Limiting parathyroid SPECT/CT to patients with significantly increased PTH and/or serum calcium levels, particularly if surgical treatment is not considered, may decrease false negative imaging rates and allow to avoid unnecessary radiation exposure. More precise determination of PTH and calcium cut-off levels requires analysis of larger patients group data.

Parathormone (PTH) as a marker of vitamin D (VitD) deficiency

Malgorzata Trofimuk-Muldner1,2, Anna Skalnik1,2, Malgorzata Kiec-Klimczak1,2 & Alicja Hubalewska-Dydejczyk1,2 1Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; 2Department of Endocrinology, University Hospital in Krakow, Krakow, Poland.

Introduction

VitD deficiency, the pandemics of which we currently observe, may result in secondary hyperparathyroidism even if not accompanied by hypocalcaemia.

Aim

To assess VitD levels as a cause of secondary hyperparathyroidism.

Material and methods

257 healthy volunteers with normal kidney function (GFR < 60 ml/min) (28.4% males), median age 57 years were included. In each participant, serum calcium,
phosphates, creatinine, PTH and total VitD levels, as well as urinary calcium in urine morning sample, were measured. Daily calcium intake was estimated with a dietary questionnaire. Statistical analysis was performed with Statistica 12 Software.

Results
Median VitD level in the investigated group was 21.22 ng/ml; PTH = 41.17 pg/ml, serum calcium = 2.39 mmol/l, serum phosphates = 1.12 mmol/l, serum creatinine = 0.12 mmol/l, and urinary calcium = 2.69 mmol/l. Median daily calcium intake was 689 mg. There was statistically significant negative correlation between VitD and PTH levels ($r = -0.19$, $P = 0.0018$), independent of serum creatinine. This relationship was particularly significant for measurements performed during autumn/winter ($r = -0.34$, $P < 0.0001$), while losing its significance in study subjects subgroup investigated during spring/summer ($r = -0.06$, $P = 0.5153$). Kruskal-Wallis ANOVA analysis showed a statistically significant difference in PTH levels in relation to VitD deficiency severity (predefined ranges: < 10; 10–19.9; 20–29.9 and ≥ 30 ng/ml) ($P = 0.0078$). A significantly higher PTH level was observed in subjects with severe VitD deficiency (< 10 ng/ml) when compared to subgroups with VitD levels of 20–29.9 ng/ml ($P = 0.0147$) and ≥ 30 ng/ml ($P = 0.0401$). A significant negative correlation was found also between serum PTH and serum calcium ($r = -0.13$, $P = 0.0447$).

Conclusions
Lack of significant negative correlation between serum PTH and VitD, seen during spring and summer confirms that appropriate sunlight exposure is sufficient to correct VitD deficiency. Significant increase in PTH levels is seen mostly in subjects with particularly low VitD levels, which may be an argument for redefining the recommended normal range of VitD.

Diseases associated with hypercalcemia
Elena Brutskaya-Sternpokovskaya1 2, Alla Shepelkevich1, Georg Kostin3 4, Eduard Chterkov2 5 and Janna Matsushava2
1Belarusian State Medical University, Minsk, Belarus; 2Minsk City Polyclinic N31, Minsk, Belarus; 3Minsk Consulting and Diagnostic Centre, Minsk, Belarus.

Introduction
According to modern studies, hypercalcemia is associated with an increased risk of urolithiasis, cholelithiasis, gastritis and peptic ulcer.

Objective
To study the prevalence of urolithiasis, cholelithiasis, gastritis and peptic ulcer in patients with hypercalcemia in Minsk-city.

Materials and methods
we studied 1207 people, average age 53.9 ± 17.25 (802 women, 315 men) from 18 to 96 years. Examination: total calcium, total protein, creatinine, ultrasonography, fibrogastroduodenoscopy, an analysis of morbidity.

Results
Hypercalcemia has been found in 31 people, mean age was 58.39 ± 11.6 years. Urolithiasis was detected in 141 cases (in patients with hypercalcemia – in nine cases) cholelithiasis was detected in 107 cases (in patients with hypercalcemia – in ten cases) gastritis was detected in 397 cases (in patients with hypercalcemia – in 21 cases) peptic ulcer was detected in 102 cases (in patients with hypercalcemia – in nine cases).

Significant differences was detected in the prevalence of urolithiasis ($\chi^2 = 8.54$, $P = 0.0035$), cholelithiasis ($\chi^2 = 19.33$, $P = 0.00001$) gastritis ($\chi^2 = 16.41$, $P = 0.00001$) peptic ulcer ($\chi^2 = 15.001$, $P = 0.0001$) in patients with hypercalcemia compared all studied patients.

Conclusion
The results of the study show an increasing risk of urolithiasis, cholelithiasis, gastritis and peptic ulcer in patients with hypercalcemia. The results may indicate an important role of hypercalcemia in the pathogenesis of these diseases.

PTH levels in vitamin D deficiency
Merve Catak1, Derya Koseoglu2, Ozden Ozdemir Basel1 and Dilek Berker1
1Numune Education and Research Hospital, Ankara, Turkey; 2Hitit University Hospital, Corum, Turkey.

Introduction
High level of Parathormone (PTH) impair bone health by increasing the risk of fracture. The aim is to determine the threshold value of PTH elevation to accompany deficiency or failure of Vit D. This may be an important parameter in assessing bone metabolism in clinical practice.

Material and method
931 patients who were referred to the endocrinology clinic were retrospectively studied and 880 patients diagnosed with Vit D deficiency included to the study. Patients were divided into three groups according to their vitamin D levels: < 10 ng/dl, 10–19.9 ng/dl, 20–29.9 ng/dl. The mean Ca, P, PTH, Vit D, ALP levels were calculated.

RESULTS
880 patients included in the study, 710 were female and 170 were male. The mean PTH levels were 68.99, 56.10, 50.92 pg/ml when Vit D levels were < 10 ng/dl, 10–20 ng/dl, 20–30 ng/dl and respectively and a statistically significant difference was found between PTH levels ($P < 0.0001$).

When ROC analysis was performed, while Vit D level < 5 ng/dl; PTH level was > 71.25 pg/ml (sensitivity 45%, specificity 78%), while the Vit D level was < 10 ng/dl; PTH level was > 66.75 pg/ml (sensitivity 50%, specificity 77.4%), while Vit D level < 20 ng/dl; PTH level was > 61.1 pg/ml (sensitivity 40.3%, specificity 80.9%).

Conclusion
As the Vit D level decreases, the calcium level decreases statistically significantly while the parathormone level increases. Patients with Vit D deficiency have elevated PTH levels but PTH levels are still in the normal reference range. Prospective studies are needed to evaluate the effect of increased but still in a normal range PTH levels on bone with measurement of bone mineral density.

The results of parathormone assay in parathyroid aspirates in preoperative localization of parathyroid adenomas for focused parathyroidectomy in patients with negative or suspicious sestamibi scans

Ayseen Ozderya, Sule Temizkan, Kenan Cetin, Sule Ozugur, Aylin Ege Gul & Kadriye Aydin
Kartal Dr Lutfi Kirdar Training and Research Hospital, Istanbul, Turkey.

Objective
In primary hyperparathyroidism (PHPT), increasing the number of patients treated by focused parathyroidectomy should be the main objective of pre-surgical imaging modalities. Suspicious or negative imaging results do not always mean multiglandular disease, most of the patients may single adenoma and therefore these patients may still benefit from focused parathyroidectomy.

Methods
Retrospectively, we analyzed the data of 65 patients with PHPT with suspicious or negative sestamibi scans who admitted at a tertiary reference center between January 2013 and December 2016. We excluded patients who had history of chronic renal failure, renal transplant and multiple endocrine neoplasia. All patients underwent an endocrinologist operated ultrasonographic examination and parathyroid fine needle aspiration wash-out procedure.

Results
Of the 65 patients, 23 patients had nodular guair disease. Fifty-four patients had positive parathormone (PTh) wash-out results. A total of 43 patients underwent surgery. Of the 43 patients, four patients had redo-surgery. Of the operated patients, 40 had positive parathormone wash-out results and had successful focused surgery. All of the patients with redo-surgery had positive parathormone wash-out results and successfully re-operated. Three patients with negative PTH wash-out results, two of them had successful bilateral neck exploration, but a patient’s operation was not successful although bilateral neck exploration.

Conclusion
Endocrinologist operated US and PTH wash-out increases the number and success of focused surgery. Especially, patients with redo-surgery may benefit from this procedure.

Weight has a weak influence on calcium-phosphorus metabolism in HIV-patients with vitamin d deficiency

Carolina García-Figueiras Mateos & Manuel Cayón-Blanco
Hospital Jerez de la Frontera, Jerez de la Frontera (Cádiz), Spain.

Introduction
In contrast to general population, clinical consequences related to low levels of 25-hydroxyvitamin D in HIV-infected patients with overweight are not established. The aim of our study was to investigate the influence of weight on clinical parameters and on calcium-phosphorus homeostasis in HIV-patients with vitamin D deficiency.

Methods/design
Prospective study of HIV outpatients treated in our hospital. Vitamin D deficiency (D-DEF) was defined as serum 25-hydroxyvitamin D below 20 ng/ml. Patients were classified as “overweight/obesity” if body mass index (BMI) ≥ 25 Kg/m². Their clinical, metabolic and immunological data were compared to HIV-individuals classified as “normal weight” (BMI: 18.5–24.9 Kg/m²). Results
One hundred and six HIV-infected individuals (86.8% male, mean age: 46.4 ± 6.5 years) were included. 51.9% were classified as “overweight/obese”. Levels of vitamin D were lower in “overweight/obese”, but no significant difference was observed between both groups (14.8 ± 4 vs 15.3 ± 1.8 μg/ml; P = 0.772). In overweight HIV-patients, although into the normal range, the serum phosphorus levels were higher as compared as those without D-DEF (3.3 ± 0.8 vs 2.9 ± 0.5 mg/dl; P = 0.04). Levels of i-PTH were also higher in overweight D-DEF patients (66.1 ± 35.1 vs 48.9 ± 19.8 pg/ml; P = 0.04). No others differences were observed between these groups. Analyzing individuals with D-DEF only, there was no difference in calcium, phosphorus or i-PTH levels between patients with or without overweight.

Conclusions
In HIV-infected patients with low levels of 25-hydroxyvitamin D, BMI ≥ 25 Kg/m² determines subtle changes on calcium-phosphorus homeostasis which clinical significance remains to be determined. Further follow-up studies to establish potential clinical implications of these findings are needed.

Chronic hypoparathyroidism disease profile from 492 patients in the PARADIGHM™ natural history global registry

Bart L. Clarke1, Steven Ing2, Aliya Khan3, Michael Mannstadt4, Michael McDermott5, Rebecca Piccolo6, Michael H. Shanik7, Tamara J Vokes8 & John Germak9
1Mayo Clinic, Rochester, MN, USA; 2Ohio State University Wexner Medical Center, Columbus, OH, USA; 3McMaster University, Ontario, Canada; 4Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA; 5University of Colorado Hospital, Aurora, CO, USA; 6Shire Human Genetic Therapies, Inc., Lexington, MA, USA; 7Endocrine Associates of Long Island, PC, Smithtown, NY, USA; 8University of Chicago Medicine, Chicago, IL, USA; 9Shire International GmbH, Zug, Switzerland.

PARADIGHM™ is a global registry (NCT01922440) of patients diagnosed with hypoparathyroidism (HPT) ≥ 6 months regardless of aetiology and management. Routine medical care data were entered using electronic case report forms; the 36-item Short Form Health Survey was completed by patients. Baseline-recorded data are reported for 492 patients enrolled as of 1 December 2016 from 41 centres. At baseline, 78% were women, mean (s.d.) age was 49 (17) years, and mean (s.d.) BMI was 29.8 (8.6) kg/m². Medical histories included mood disorder (29%), arthritis (16%), kidney stones (11%), fractures (8%), chronic renal disease (6%), and hypercalcemia (3%). 93% of patients had baseline symptom data (for the
Vitamin D deficiency is highly prevalent among Saudi women. The aim of this study was to determine the prevalence of cardiometabolic risk factors in apparently healthy Saudi women with vitamin D deficiency. A Retrospective chart review was conducted in the “Center of Excellence for Osteoporosis Research” (CEOR), King Abdulaziz University, Jeddah, Saudi Arabia. Only healthy women 20–40 years old, with no history of previous illnesses and not on any medications were included. Data on anthropometric measurements as well as blood pressure (BP) were obtained. Body mass index (BMI) was calculated. Any medications were included. Data on anthropometric measurements as well as demographic characteristics were collected. Laboratory mean (S.D.) values were PTH 1.5 (1.5) pmol/l, albumin-corrected total serum calcium 2.1 (0.3) mmol/l, phosphate 1.4 (0.3) mmol/l, magnesium 0.8 (0.1) mmol/l, and 24-hour urinary calcium 7.2 (4.6) mmol/day. Among 330 patients who had imaging, calcifications were reported in 40 patients (12%): kidney (n = 12), brain (n = 9), cardiovascular (n = 7), and other sites (n = 12). In the previous 12 months, 47% of patients had 2–3 doctor visits and 49% had ≥1 emergency room visit owing to HPT. Mean (S.D., range) SF-36v2 summary scores for physical and mental components were 45.6 (10.7; 11.2–64.2) and 48.4 (11.0; 11.9–70.5). These real-world data for 492 patients enrolled in the PARADIGHM registry provide valuable insight into disease variability, symptom burden, and HPT treatment approach.

Prevalence of cardiometabolic risk factors among Saudi Women with vitamin D deficiency

Hanan Al Kadi & Eman Alissa1

1Physiology Department, Center of Excellence for Osteoporosis Research, King Abdulaziz University, Jeddah, Saudi Arabia; 2Biochemistry Department, King Abdulaziz University, Jeddah, Saudi Arabia.

Vitamin D deficiency is highly prevalent among Saudi women. The most common reason for this is deficiency of 25-hydroxyvitamin D3 (25(OH)D3) and parathyroid hormone (PTH) were also analyzed. Key laboratory mean (S.D.) values were PTH 1.5 (1.5) pmol/l, albumin-corrected total serum calcium 2.1 (0.3) mmol/l, phosphate 1.4 (0.3) mmol/l, magnesium 0.8 (0.1) mmol/l, and 24-hour urinary calcium 7.2 (4.6) mmol/day. Among 330 patients who had imaging, calcifications were reported in 40 patients (12%): kidney (n = 12), brain (n = 9), cardiovascular (n = 7), and other sites (n = 12). In the previous 12 months, 47% of patients had 2–3 doctor visits and 49% had ≥1 emergency room visit owing to HPT. Mean (S.D., range) SF-36v2 summary scores for physical and mental components were 45.6 (10.7; 11.2–64.2) and 48.4 (11.0; 11.9–70.5). These real-world data for 492 patients enrolled in the PARADIGHM registry provide valuable insight into disease variability, symptom burden, and HPT treatment approach.

18F-choline PET/CT in patients with primary hyperparathyroidism and negative sestamibi SPECT/CT – report of two cases

Michal Krcma

Department of Internal Medicine I, Faculty of Medicine in Pilsen, Charles University, Pilsen, Czech Republic.

Primary hyperparathyroidism is a common disorder which is curable by surgery. Exact localisation of parathyroid adenoma is essential for minimal invasive approach. The gold standard is sestamibi SPECT/CT nowadays - but fails in approximately 10% cases. In last 3 years some case report with 18F-choline PET/CT were published. We describe two cases with SPECT/CT invisible parathyroid adenoma.

First case was 36y/o woman, with osteopenia diagnosed after pregnancy (was attributed to LMWH treatment in pregnancy) and no relevant health problems. Mild hypercalcemia (2.7 mmol/l) was found in 2014 in context with vitamin D deficiency and patient was referred to our department. Primary hyperparathyroidism was clearly stated (serum calcium 2.9 mmol/l; PTH 139 ng/l; 25-OH-D vitamin 69 mmol/l), bone turnover was also slightly elevated. According to age, osteopenia and planned pregnancy we decided for surgery, but ultrasonography and sestamibi SPECT/CT was without any parathyroid adenoma. Patient did not agreed with surgical revision of all four glands and we choosed conservative approach. In 2015, hypercalcuria was appeared, therefore next SPECT/CT and ultrasonography was performed, with still negative results. In 2016 we used PET/MRI with 18F-choline for the first time in our hospital – upper left parathyroid adenoma was found (9×6 mm, SUV max 5.8). Patient was referred to surgery and histologic examination reveals parathyroid adenoma and patient went normocalcemic, normocalicuric and with normal PTH level, with continuing D vitamin treatment due to osteopenia. No hungry bone syndrome was presented.

Second case was 59 y/o man, with primary hyperparathyroidism treated for 3 years by cinacalcet, with twice negative sestamibi SPECT/CT, repeatedly negative ultrasonography. During the treatment was slightly hypercalcemic (2.6 mmol/l), normocalicuric, with non-progressing osteopenia. PET/MRI revealed 8mm left bottom parathyroid adenoma and patient was referred for surgical resection, planned for March 2017.

Despite our limited experiences, 18F-choline PET seems to be a promising diagnostic option. Using MRI instead of CT has some advantages – radiation load, no risk of iodine contrast allergy and slightly better resolution in neck region.

Severe hypocalcemia induced by Denosumab in a patient with Osteoporosis after malabsorptive bariatric surgery

Ana Jiménez Portilla, Guillermo Serra Soler, Juan Ramón Urgeles Planella, María Soledad Gogorza Pérez, Mercedes Noval Font, Honorato García Fernández, Iñaki Argüelles Jiménez & Vicente Pereg Macazaga

Universitary Hospital Son Espases, Palma de Mallorca, Spain.

Introduction

Denosumab is a monoclonal antibody indicated in the treatment of postmenopausal osteoporosis. Hypocalcemia is a rare adverse effect.

Case report

We present the case of a 58-year-old woman with a clinical history of bariatric surgery in 2001 and osteoporosis with multiple vertebral and hip fractures. Under treatment with Zinc sulphate, Vitamin A, 25-OH-vitamin D, calcium and iron. She came to the A&E for general malaise, generalized weakness, paraesthesia, dysarthria and weight loss of some weeks of evolution. She was admitted due to a severe hypocalcemia: calcium 5 mg/dl (8.4–10.2), ionized calcium 2.5 mg/dl (4.64–5.28), phosphate 1.2 mg/dl (2.3–4.7), magnesiam 2.35 mg/dl (1.6–2.6), albumin 38.8 g/l (35–50), PTH 284 pg/ml (15–65), 25-OH-vitamin D 22 ng/ml (30–100), alkaline phosphate 360 U/l (40–150) and normal kidney function. The ECG showed a prolonged QT. The signs for hypocalcemia were negative. The patient had received treatment with subcutaneous Denosumab 60 mg 22 days before, with prior calcium values of 8.4 mg/dl, phosphorous 3.1 mg/dl, 25-OH-vitamin D 25 ng/ml, PTH 76 pg/ml and Ca-urine 27 mg/24 h. Treatment started was treated with intravenous calcium for 8 weeks, together with oral calcium, phosphorous and 25-OH-vitamin D. The patient improved symptomatically, with a normalization of the QT and analysis with ioncic calcium 4.6 mg/dl, phosphate 3.5 mg/dl, magnesiam 2.8 mg/ml, PTH 139 pg/ml, Ca-urine 2.3 mg/dl and 25-OH-vitamin D 39 ng/ml. The treatment to discharge was oral calcium 2.5 g/day and 25-OH-vitamin D 16,000 UI daily.

Conclusions

Hypocalcemia after Denosumab is a rare adverse effect but it can be serious. The patients who have undergone malabsorptive bariatric surgery have a greater risk. It is important to monitor the 25-OH-vitamin D and calcium in patients who start treatment with Denosumab and at 15 days in patients who are at the greatest risk, as is the case of this patient.

Performance characteristics of a new Waters MassTrak™ Vitamin D assay
Norina Breen, Leanne Davey, Declan Roche, Philip Lambert, Danielle Cullen & Padhraic Rossiter
Water Technologies Ireland Ltd, Wexford, Ireland.

The Waters MassTrak Vitamin D Kit is designed for the quantitative determination of serum or plasma 25-hydroxyvitamin D3 (25(OH)D3) and 25-hydroxyvitamin D2 (25(OH)D2), which in combination provide the total 25-hydroxyvitamin D concentration as an aid in the assessment of vitamin D sufficiency.

The MassTrak Vitamin D Kit is validated for use with the Waters® ACQUITY UPLC® I-Class®/Xevo® TQD IVD System and the sample preparation has been validated using the Tecan® Freedom 100/4 Evo® Offline Automated Liquid Handling system. Screening for vitamin D deficiency is recommended by the Endocrine Society Clinical Guidelines- Evaluation, Treatment and Prevention of Vitamin D Deficiency by the Task Force for all individuals at risk for deficiency.

Vitamin D status (Total 25OHD, which is the sum of 25OH2D and 25OH3D) has been a challenge to measure accurately because the antibodies used in many immunoassays do not have 100% co-sensitivity for both 25OH2D and 25OH3D.

Precision, sensitivity, linearity, potential interferences and carryover were all assessed during the development of the MassTrak™ Vitamin D kit and found to meet the performance criteria specified for the kit.

To further assess the accuracy and performance of the MassTrak™ Vitamin D kit assay, Waters enrolled in the CDC Vitamin D Standardisation Certification Program (VDSCP) for 25(OH)D in serum, which assesses bias and precision of assays relative to reference measurement procedures.

The MassTrak™ Vitamin D kit calibrator materials are traceable to NIST SRM2972 via a documented unbroken chain of calibrations. The accuracy of this traceability to NIST SRM2972 has been verified through participation of the Vitamin D Standardisation Certification Program (VDSCP).

Vitamin D intoxication complicated with parathormon treatment in elderly: a case report
S Nur Boysan, Burcu Altunrende, Levent Dalar, M Eren Acik, I Polat Canpolat, C Selcan Akdeniz & M Sait Gonen
Istanbul Bilim University, Istanbul, Turkey.

Parathormon treatment for osteoporosis is rarely complicated with hypercalcaemia. Vitamin D treatment with high doses frequently can cause asymptomatic intoxication. We present a case with a life-threatening hypercalcaemia complicated both parathormon and high-dose vitamin D.

A 85-year-old woman hospitalized for sudden-onset confusion. In history she had coronary artery bypass operation and a serebrovascular accedant. She was treated with teriparatide 20 μg subcutaneously and cholecalciferol 0.25 μg per oral for one year. She had a pulmonary infection one month before admission. Since vitamin D is popular in media for public health, her daughter gave three doses of 300 000 IU vitamin D for infection. She has hallucinations and hypoxia. Her laboratory was: Ca 15.6 mg/dl, P 3.3 mg/dl, PTH 6.88 pg/ml, 25(OH) vitamin D > 70 ng/ml, 1.25(OH)2 vitamin D 86.4 ng/ml. She had also increased serum creatinine level. She was followed in intensive care unit for 2 days. For hypercalcaemia she had hydration, forced diuresis, calcitonin and glucocorticoid therapy. Thorax CT showed bilaterally linear atelectatic areas at basal zones. She continued to have nebulisation and oxygen after transmission from intensive care unit. Ejection fraction was 40% on echocardiography. She was discharged after 1 week when serum calcium was 10.2 mg/dl and PTH was 16.37 pg/ml. Vitamin D replacement, in elderly, could be life-threatening in megadoses. In this case, parathormon treatment with vitamin D replacement complicated presentation.

Tc-99m sestamibi uptake by brown tumours in a patient with primary hyperparathyroidism
Daniela Dias, Daniel Macedo, Rita Santos & Valeriano Leite
Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal.

Tc-99m sestamibi (MIBI) imaging is able to localize parathyroid adenomas/carcinomas in patients with primary hyperparathyroidism. Brown tumours are one of the skeletal manifestations of long standing hyperparathyroidism and its incidence has been reported to be 3%. Radiological features of these tumours may mimic bone metastasis. There are only a few reports showing brown tumours uptake in the whole-body Tc-sestamibi scan.

We report a 72-year-old female with a previous history of right nephrectomy for renal lithiasis at age 49 and a left clavicle mass fracture. A neck and thoracic computed tomography (CT) scan revealed multiple lytic lesions of the skeleton (including in the left clavicle) and a pathological mandibular fracture, suggesting metastatic lesions.

18F-FDG PET scan showed multiple skeletal hypermetabolic lesions and a hypermetabolic nodule close to left lower pole of the thyroid gland. The biopsy of the lesion in the left clavicle revealed histiocytic proliferation with multinucleated osteoclast-type giant cells compatible with a brown tumor. Laboratory data showed an elevated serum calcium of 12.8 mg/dl (8.4–10.2), alkaline phosphatase of 264 U/L (9–36), and parathyroid hormone of 756 pg/ml (1–65).

In this patient with a long standing hyperparathyroidism the intense uptake of brown tumours in both 18F-FDG PET scan and MIBI can mimic a parathyroid carcinoma with bone metastases.

Thyroid suppression in patients with primary hyperparathyroidism may improve pre-surgical scintigraphy localisation
Mariana Tomsé1, Guillermo Martínez de Pinillos2, Evyde Arturo Cuéllar2, Juan Manuel García de Quirós2, Fernando García2 & Ignacio Fernández2
1Punta de Europa Hospital, Algeciras, Spain; 2Valme Hospital, Seville, Spain.

Introduction
The cause of primary hyperparathyroidism (PHPT) is a single adenoma in 85% of cases. Scintigraphy with technetium-sestamibi (MIBI) is the test of choice for localising adenomas in patients with PHPT, allowing minimally invasive surgery in most patients. Some articles recommend thyroid function suppression to improve scintigraphy results.

Methods
A prospective study was conducted in which 8 patients were included with diagnosis of PHPT and negative scintigraphy for adenoma localisation. These patients did not have a contraindication for thyroid hormone intake. We started treatment with a dose of 1 mcg/Kg per day with dose titulation until achievement of TSH <0.3 μU/mL. Once the objective was reached, MIBI was repeated with the same technique and interpreted by the same specialist in Nuclear Medicine.

Results
75% of patients were women, mean age 51.9 ± 20.55 years. De los ocho pacientes incluidos en el estudio, 6 eran mujeres (75%), con una edad media de 51.9 ± 20.55 años. Mean preoperative calcium level was 11.49 ± 0.61 mg/dl. Mean preoperative PTH level was 146.26 ± 79.58 ng/ml. Mean TSH level before repeating scintigraphy was 0.17 ± 0.08 μU/ml. Thyroxine suppression scan was positive in four of the eight patients (50%). Only two of these four patients underwent surgery for the moment. Minimally invasive surgery was performed in these cases, confirming the existence of a parathyroid adenoma where the MIBI suggested. The level of calcium in these patients normalized after surgery.

Conclusions
In our study suppression of thyroid function by thyroxine administration improved MIBI sensitivity for parathyroid adenoma localization in our patients with previous negative studies, however, a larger number of patients would be required to confirm these results.

Serum vitamin D in overweight patients with normal and impaired GFR

Stelios Tiga, Athanasios Kito, Evagelia Dounou, Ragas Kalaitzidou, Anna Challa and Costas Stamatopoulos

1Department of Endocrinology, University of Ioannina, Ioannina, Greece; 2Department of Nephrology, University of Ioannina, Ioannina, Greece; 3Pediatric Research Laboratory, Child Health Department, Ioannina, Greece.

Introduction

Obesity is a strong risk factor for incident chronic kidney disease (CKD). Furthermore, high body mass index (BMI) is consistently associated with low serum vitamin D in the general population. The aims of the present study were to i) compare vitamin D metabolite levels in overweight/obese versus normal weight individuals with normal to severely impaired renal function and ii) to assess the impact of 25(OH)D on the development of secondary hyperparathyroidism (SHPT).

Methods

Serum 25(OH)D, 1,25(OH)2D, PTH, calcium and phosphate were measured in 104 CKD outpatients with BMI > 25 kg/m2. Participants were categorized according to the eGFR (ml/min/1.73 m2): G1: ≥ 60 (n = 53), G2: 30–59 (n = 35) and G3: 15–29 (n = 16). Fifty normal-weight subjects with comparable eGFR levels composed the control group (G1-nw – G3-nw).

Results

25(OH)D was lower in overweight/obese G1 patients compared to G1-nw (21.7 ± 6.5 vs 26.5 ± 7.0 ng/ml, P = 0.02) and in G2 versus G2-nw (19.0 ± 6.0 vs 25.0 ± 5.2 ng/ml, P = 0.005), whereas the level did not differ among G3 groups (15.8 ± 4.7 ng/ml vs 20.3 ± 4.5 ng/ml, P = 0.49 in G3 vs G3-nw respectively). Mean 1,25(OH)2D and PTH levels were similar in obese/overweight versus normal-weight individuals in each eGFR category. Multivariate regression analysis in the entire cohort revealed that factors independently associated with low 25(OH)D levels were BMI > 25 kg/m2, eGFR < 30 ml/min/1.73 m2 and female gender whereas low 1,25(OH)2D levels were associated with eGFR < 30 ml/min/1.73 m2, older age and increased serum phosphate. Even though serum 25(OH)D levels were suboptimal (< 30 ng/ml) in both overweight and controls and in all eGFR groups, significant SHPT was only observed in the groups with eGFR < 30 ml/min/1.73 m2.

Conclusions

Lower serum 25(OH)D but similar 1,25(OH)2D and PTH levels were observed in overweight/obese compared to normal weight individuals and preserved or moderately impaired renal function. Even though vitamin D insufficiency was a common feature across all eGFR categories, SHPT was only observed in those with severely impaired renal function.

Ectopic production of calcitriol by non-hodgkin lymphoma as a cause of hypercalcemia: case report

Elvira Alarcón, Mariana Tomé, Carmen Bautista & Daniel González

Punta de Europa Hospital, Algeciras, Spain.

Introduction

Hypercalcemia of malignancy usually appears in patients with osteolytic metastasis and in those patients with humoral hypercalcemia due to secretion of PTHrP by the tumor. Hypercalcemia due to calcitriol production by the tumor is uncommon (< 1% of cases of hypercalcemia of malignancy). It is the cause of virtually all cases of hypercalcemia in patients with Hodgkin’s lymphoma and approximately one third of cases in non-Hodgkin’s lymphoma. It has also been described in some cases of ovarian dysgerminoma.

Methods

We describe the case of a patient with MALT Non-Hodgkin lymphoma admitted to our hospital with severe hypercalcemia.

Results

Our patient was admitted to the hospital with calcium levels above 15 mg/dl. After hydration, loop diuretics and zoledronic acid he reached calcium level of 10.5–11 mg/dl but after withdrawal of i.v hydration he presented recurrence of hypercalcemia up to the initial values. Analytics showed very low levels of PTH and 25-OH-Vitamin D (5.76 pg/ml, 3 ng/ml respectively). Imaging tests (body CT) did not show osteolytic lesions suggestive of metastases. Given the suspicion of humoral hypercalcemia we initiated treatment with Cinacalcet 60 mg daily and steroids (Prednisone 1 mg/kg per day) without a satisfactory response in reducing calcium levels. Analytical result showed undetectable levels of PTH-related protein (< 1.1 pmol/l) and very high calcitriol levels (148 pg/ml, N: 16–56 pg/ml). Our suspicion of calcitriol tumoral production associated with lymphoma is therefore confirmed. In view of the poor response to medical treatment and the need for intense hydration to maintain acceptable calcium levels a splenectomy with cytoreductive objective (19 cm splenomegaly) was performed. After this, calcium levels reached the normal level (9.5–10.2 mg/dl) and remained stable.

Conclusion

Although tumor production of calcitriol is an uncommon cause of hypercalcemia, it is usually related to lymphomas. We must think in this disorder in patients with lymphoma and hypercalcemia.

The importance of ultrasound in the preoperative evaluation of patients with primary hyperparathyroidism: a case report

José Marçalo, Alexandra Araújo, Ana Wessling, Maria Raquel Carvalho & Maria João Bugalho

Hospital de Santa Maria, Lisbon, Portugal.

Introduction

Primary hyperparathyroidism is the most common cause of hypercalcemia in the outpatient setting, and a single parathyroid adenoma is usually the culprit. Clinical presentation is commonly dictated by hypercalcemia. Symptoms can range from mild non-specific malaise and gastrointestinal disturbances, through bone disease, kidney stones, cardiovascular and neuromuscular dysfunction to, ultimately, coma and death. However, the vast majority of patients are asymptomatic.

Case report

A 46-year-old female with a half-year endocrinology monitoring for type 2 diabetes and obesity, resorted to our hospital after 3 weeks’ evolution of persistent nausea and vomiting. Laboratory workup showed increased PTH levels (596 pg/ml), severe hypercalcemia (17.4 mg/dl), mild hyperphosphatemia (2.4 mg/dl), acute kidney injury (creatinine clearance 34 ml/min) and hyperuricemia (14.8 mg/dl). A 25-hydroxyvitamin D deficiency was also present (6.3 ng/ml). The first neck ultrasound did not show abnormalities; 99mTc-sestaMIBI scan was negative. Repetition of neck ultrasound revealed a left-postero-inferior nodule likely to correspond to an enlarged parathyroid. The clinical evaluation supported this hypothesis. Pamidronate, antiemetics and volume expansion with isotonic saline reverted the clinico-laboratory condition and served as a bridge to parathyroidectomy. Surgery went uneventful and a 3 cm inferior-left parathyroid was sent to ananatomopathological examination. The final diagnosis was parathyroid adenoma. In subsequent postoperative follow-up the patient was asymptomatic and had normal serum calcium levels (9.3 mg/dl) and slightly upper-limit PTH (77.3 pg/ml).

Conclusion

Despite the considerable size of the resected parathyroid, initial ultrasound failed to locate it. Seeking for a topographical diagnosis, a second ultrasound was performed by a different operator in our hospital. This case highlights the importance of carefully selecting experienced centers to address parathyroid preoperative studies. Furthermore, despite the adenoma size, its inferior location, and the associated severe hypercalcemia, the 99mTc-sestaMIBI scan was negative, reminding of potential false-negative results of this method.

EP303  
Primary hyperparathyroidism: elective parathyroidectomy versus conservative management; results of a retrospective cohort study  
Melanie Nana, Holly Morgan, Natasha Shrirkishnapalasuryi & Atul Kalhan  
Royal Glamorgan Hospital, South Glamorgan, UK.  

Background  
The optimum management strategy for primary hyperparathyroidism remains debatable especially in patients with mild or asymptomatic disease. We aimed to compare the baseline characteristics and long-term outcomes of patients with primary hyperparathyroidism who were either managed conservatively or underwent elective parathyroidectomy.  

Methodology  
We carried out a retrospective cohort analysis of patients with primary hyperparathyroidism under follow-up at the Royal Glamorgan Hospital, Wales from 1995 to 2016. The baseline characteristics were recorded from case records while the clinical portal was used to collate biochemical and radiological data. The patients were categorised into two main groups based on management approach (conservative treatment vs elective parathyroidectomy group).  

Results  
Out of a total of 336 patients with confirmed primary hyperparathyroidism, 72 (21.4%) underwent elective parathyroidectomy. Mean duration of follow up was shorter for the surgically treated patients as compared to the ones treated conservatively (3.7 vs 5.2 years). There was no significant difference between mean calcium levels at diagnosis although the mean parathyroid hormone (PTH) level at diagnosis was significantly higher in the surgical group (15.0 vs 11.4, P = 0.038). Despite age adjustment using binary logistic regression, prevalence of hypertension and ischaemic heart disease was significantly lower in patients undergoing elective parathyroidectomy as compared to the group managed conservatively.  

Conclusion  
There was a significant difference in prevalence of hypertension and ischaemic heart disease in patients managed conservatively as compared to the group who underwent elective parathyroidectomy despite adjustment for age. The duration of follow up for this group was relatively shorter which can potentially offset costs associated with surgery. The higher PTH levels at baseline for the elective parathyroidectomy group may also signify a correlation of PTH levels with increased risk of complications. Prospective large randomised controlled trials need to be designed to assess cardiovascular outcomes comparing surgical versus conservative management approach.

EP304  
Calcium metabolism and autoimmune thyroiditis  
Armine Khroyan1,2, Edvard Toromanyan1,2, Maria Badalyan1,2 & Mariam Khachatryan1,2  
1Department of Endocrinology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; 2Department of Endocrinology, Emergency County Hospital, Timisoara, Romania.

Objectives  
The objective of our investigation is to find out the role of D3 vitamin deficiency – and calcium in patients with autoimmune thyroiditis and calcified nodules. Methods  
The research has been carried out at “Muratsan” University Hospital and “Armenia” Medical Center, in 2013–2016. 80 patients (ages ≥4-0, of which 68 women and 12 men) with autoimmune thyroiditis and calcified nodules have taken part in the clinical research. They have been tested on TSH, FT4, anti-TPO, vitamin D3, Ca2+, PTH, as well as undergone a thyroid ultrasound, elastography. Results  
TSH – 58%, 42% N  
FT4 – 60%, 40% N  
Anti-TPO – 100%  
Vitamin D3 – 84%, 16% N  
Ca2+ – 94%, 6% N  
PTH – 89%, 11% N  

Thyroid ultrasound – Calcificates proved to be present in 76% of nodules, which have been formed on the background of autoimmune thyroiditis. Thyroid elastography after 6 month taking vitamin D3 13% 3b elastography is go to 3a. The increased level of PTH hormone and lower vitamin D3 should be taken into consideration, since this can result from secondary hyperparathyroidism and cause formation of calcificates.  

Conclusions  
Vitamin D3 shout be tested in the first place during the treatment of any kind of calcified nodular goiter, since calcificates can be caused not only by oncologic processes, but also secondary hyperparathyroidism.

EP305  
Pseudohypoparathyroidism (PHP) and GNAS gene mutations – clinical spectrum from PHP type 1a to pseudopseudohypoparathyroidism  
Ana Saavedra1,2, Elisabete Rodrigues1,2, Filipe Cunha1,2, Miguel Leão1 & Davide Carvalho1,2  
1Department of Endocrinology, Diabetes and Metabolism of Centro Hospitalar de São João, Porto, Portugal; 2Faculty of Medicine, University of Porto, Porto, Portugal.  

Introduction  
Pseudohypoparathyroidism (PHP) refers to a heterogeneous group of disorders that have in common end-organ unresponsiveness to parathyroid hormone (PTH). The most frequent form, PHP type 1a, results from different genetic/epigenetic changes in the GNAS gene.  

Case 1  
Woman, 25 years-old, sent to Endocrinology from Genetics consultation after her daughter had been diagnosed with PHP type 1a (heterozygous pathogenic variant at exon 13 of GNAS gene c.1174G>A (p.e392K)). Our patient and her father present some clinical manifestations as observed in the child, suggestive of Albright Hereditary Osteodystrophy (AHO), and both present the same mutation as encountered in index case. We tested phosphocalcic metabolism of our patient and she presented normal serum calcium/phosphorus levels as well PTH levels. Other pituitary hormones were evaluated, with normal results except elevated TSH (18.72 mU/l) in context of primary autoimmune hypothyroidism. Patient started treatment with levothyroxine.  

Case 2  
Male, 31 years-old (case 1 brother). He was sent to Endocrinology in December 2015 for lymphocytic thyroiditis evaluation. During the physical examination, it was recognized a phenotype suggestive of AHO, as was found in his relatives (round facies, brachydactyly and subcutaneous calcifications). Patient’s lab tests showed normal serum calcium/phosphorus levels and high PTH in the context of vitamin D deficiency. Other pituitary hormones levels were in normal range. Patient performed genetic test - results ongoing.  

Conclusion  
Different pathological entities may result from mutations in the GNAS gene. PHP type 1a is characterized by the presence of AHO and PTH resistance. However, AHO manifestations may occur in patients without PTH resistance (pseudopseudohypoparathyroidism), as in the two cases presented. This occurs when the mutation is paternally transmitted. These cases somehow demonstrate de complexity of GNAS gene mutations, which merited recently a new classification. It is also highlighted that although pseudopseudohypoparathyroidism needs no treatment, genetic counselling should also be recommended.

EP306  
Hyperparathyroidism and cardiovascular risk  
Daniela Amzar1, Melanial Balas2, Ioana Golui3, Mihaela Vlad1, Ramona Sandu1 & Maria Cornianu1  
1Department of Endocrinology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; 2Department of Endocrinology, Emergency County Hospital, Timisoara, Romania; 3Department of Pathology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania.

Background  
Primary and secondary hyperparathyroidism (HP) are associated with increased risk for cardiovascular complications and high mortality. Risk factors correlated with hypertension in HP are hyperlipidemia, glucose intolerance, insulin resistance, vitamin D deficiency, etc. The aim of the study was to assess the incidence of cardiovascular complications in HP.  

Material and methods  

Endocrine Abstracts (2017) Vol 49
The study included 45 patients (15 men, 30 women), with a mean age of 45 years (range 21–65 years). Thirty-two patients were diagnosed with primary HP and 13 with secondary HP due to chronic kidney disease (stages 3 and 4). The patients were evaluated by biochemical, hormonal parameters, imagistic tests, and cardiac sonography.

Results
Vitamin D deficiency was documented in all patients with secondary HP and in 24 patients with primary HP (75%). Other metabolic disturbances and risk factors for cardiovascular diseases were as follows: diabetes mellitus (24.4%), smoking (28.8%), obesity (22.2%), and dyslipidemia (46.6%). The incidence of mitral and/or aortic valvular stenosis (caused by calcifications) was similar in the two groups, affecting 31.1% of the patients. Hypertension prevailed in the group of secondary HP (12 cases), as compared to primary HP (10 cases, \( P=0.0002 \), Fisher’s exact test). Peripheral atherosclerotic manifestations were noted in 11 cases (24.4%). Seven patients (15.5%) experienced an acute coronary event and three patients underwent PTCA procedures with stent implantation. Ten patients showed ventricular hypertrophy (22.2%); the incidence was similar in the two groups (eight patients with primary HP, respectively two with secondary HP).

Conclusion
Our study shows that hyperparathyroidism is associated with higher incidence of severe cardiovascular complications, occurring at younger ages as compared to general populations.

Risk factors associated with osteoporosis in beta-thalassemia major patients
Elena Mirela Iancu, Alice Ioana Albu & Irina Nicolaescu
Elias University Clinical Hospital, Bucharest, Romania.

Beta-thalassaemia major (BTM) is a rare disease that encompasses a vast range of endocrinological complications, despite of the improvement of treatment protocols. The aim of this study was to identify the clinical and hematological parameters associated with osteoporosis, a frequent complication found in beta-thalassaemia patients.

Patients with BTM were evaluated in the Endocrinology Department of Elias Hospital between February 2004 and March 2016. Only patients who provided written informed consent were included in the study. A complete physical and hormonal evaluation was performed on all patients, and data regarding treatment of hematological disease were collected. The bone density was evaluated using dual energy X-ray absorptiometry (DXA).

Forty-nine patients were included in the study (median age 28.37 years; range 12–47). We found that 35 patients (71.4%) had osteoporosis documented using DXA, 16 of them (45.7%) had fracture injuries caused by decreased BMD.

Patients with osteoporosis were older (median age 31.51 vs 20.5 years, \( P=0.05 \)) and started the iron chelation therapy at an older age compared with subjects without this condition (105.72 months vs 63.58 months, \( P<0.05 \)). Although the levels of serum ferritin were higher in patients with osteoporosis (1062 vs 77 mg/ml), the difference did not reach statistical significance.

Hypogonadism was significantly more frequently found in patients with osteoporosis (30 pts, 85.7% vs 5 pts, 14.3%) in comparison to patients without osteoporosis (\( P=0.014 \)). The risk of developing osteoporosis was six times greater in hypogonadal study subjects.

Our data show that osteoporosis is a highly prevalent complication among Romanian β-thalassaemia patients, its presence being associated with older age, delayed initiation of iron chelation therapy and the presence of hypogonadism.

Giants walk amongst us
Raj Tanday1, Bonnie Grant1, Akin Ojo2, Edel Casey1 & Khash Nikookam1
1Department of Endocrinology, King George Hospital, London, UK; 2Department of Surgery, King George Hospital, London, UK.

We present the case of a 51-year-old gentleman who had a giant parathyroid adenoma. He has a past medical history of deep vein thrombosis and hypertension. He is taking amlopidine 10 mg od. He is a non-smoker and drinks alcohol in moderation. He was admitted with right leg swelling found to be a new thrombosis. Incidental finding of extreme hypercalcaemia found on bloods with raised PTH (ConCa 4.23 mmol/l, PTH 83.1 pmol/l). Patient was completely asymptomatic. CT imaging of chest, abdomen and pelvis demonstrated extensive above knee thrombosis, renal calculi and a large thyroid nodule. However, an ultrasound and Sestamibi confirmed spectacularly this was an enlarged parathyroid. He was anticoagulated with heparin and then oral anticoagulant. He was given aggressive i.v. fluids and bisphosphonates with limited effect so cinacalcet was initiated. We were still unable to control calcium levels and so in patient parathyroidectomy was performed. At operation the gland appeared grossly enlarged and vascular. However, there was no tethering to adjacent tissues and easily removed weighing 43 g. Our patient made a good recovery with normalisation of calcium. Histology showed features in keeping with parathyroid adenoma rather than carcinoma. On review in clinic two months later he remains normocalcemic. A DEXA has shown osteoporosis which we expect to improve in time.

Our case is interesting as there are features of this case in keeping with parathyroid malignancy rather than adenoma and we shall discuss this.

Hungry bone syndrome after treatment of severe primary hyperparathyroidism
El Mghari Ghizlane & El Ansari Nawal
Chu Med6, Marrakech, Morocco.

Introduction
Persistent hypocalcaemia after surgery for severe hyperparathyroidism is not uncommon and may be secondary to transient or permanent hypoparathyroidism but may also be due to bone pathology.

Observation
Patient of 44 years old was hospitalized for fractures of the pelvis, and shaft of left femur, spontaneous without trauma turned out. Laboratory tests shows severe hypercalcaemia to 156 mg/l, serum phosphorus at 22 mg/l, elevation of PTH to 1150 pg/ml and proper renal function with a serum creatinine to 8 mg/ml. PAL is increased to 709 U/I.

A spot of mediastinal fixation compatible with ectopic parathyroid adenoma was seen on the MIBI scintigraphy with several brown tumors. Ectopic mediastinal parathyroidectomy was made after medical preoperative treatment with bisphosphonates, vitamin D and active metabolite of vitamin D.

In postoperative period a severe hypocalcaemia reaching 65 mg/l at the fifth day was observed, the PTH was (9.9 pg/ml) and PAL are increased to 560 U/I with a lowered serum phosphorus.

The difficulty of standardization of serum calcium despite supplementation of calcium element and 1alpha and vitamin D, high PAL and the presence of diffuse bone lesions guide to The diagnosis of HBS.

Conclusion
HBS is a heightened greened bones for calcium. It occurs in situations of demineralization and intense bone remodeling.

Clinical review of nine cases of pseudohypoparathyroidism
David Barbosa1, Brigida Robalo2, Carla Pereira2 & Lurdes Sampayo2
1CHLN – Hospital de Santa Maria, Endocrinology, Diabetes and Metabolism Department, Lisbon, Portugal; 2CHLN – Hospital de Santa Maria, Pediatric Endocrinology Unit, Lisbon, Portugal.

Objective
To analyze the clinicopathological features of pseudohypoparathyroidism (PHP), that would help clinicians to consider this rare condition in children.

Methods
A retrospective review of nine patients with PHP (including seven males and three females) admitted to our hospital between 1990 and 2014 was conducted. Clinical and biochemical parameters along with epidemiological data were extracted and analyzed.

Severe hypercalcemia revealing an atypical parathyroid adenoma
El Ansari Nawaï & Bouchra Radi
Department of Endocrinology, Diabetology Metabolic Diseases and Nutrition Laboratory PCIM, FMPM, Cadi Ayyad University, UHC Mohamed VI, Marrakech, Morocco.

Introduction
Primary hyperparathyroidism is a common cause for hypercalcemia, however severe hypercalcemia remain a rare complication. The atypical parathyroid adenoma is an uncommon cause to severe hypercalcemia. We report a case of a 40-year-old male with very high serum calcium due to a possible atypical parathyroid adenoma diagnosed after a spontaneous fracture.

Case report
A 40-year-old male was admitted to the traumatology department for the management of spontaneous fracture of the humerus. The clinical history revealed clinical symptoms of hypercalcemia (abdominal pain, neurologic irritation, asthenia, etc.). The initial blood work up found a severe hypercalcemia (203 mg/l) and high PTH levels, although it is not clear whether this normalization was beneficial. Genetic testing was performed in six children.

Conclusion
PHP is a rare and heterogeneous genetic disease with a high rate of misdiagnosis and no specific treatment. It should be considered in children presenting with a round face, obesity, brachydactyly, learning/behavior disabilities, subcutaneous calcifications and subclinical hypothyroidism. Laboratory evaluation of blood calcium, phosphorus, PTH and thyroid hormones should be ordered as soon as possible, as well as neuroimaging and a genetic profile for further confirmation.

DOI: 10.1530/endoabs.49.EP311

EP312
Hypercalcemia and cardiovascular disease
Elena Brutskaya-Stempkowskaya1,2
1Belarusian State Medical University, Minsk, Belarus; 2Minsk City Polyclinic N31, Minsk, Belarus.

Introduction
According to modern studies, patients with hypercalcemia have an increased cardiovascular risk.

Objective
To study the prevalence of cardiovascular disease in patients with hypercalcemia.

Materials and methods
We studied 1207 people, average age 53.9 ± 17.25 (892 women, 315 men) from 18 to 96 years. Examination: total calcium, total protein, creatinine, cholesterol and triglycerides, HbA1C, ambulatory blood pressure monitoring, ECG, an analysis of morbidity (hypertension, coronary heart disease, cardiovascular events).

Results
Hypercalcemia has been found in 31 people, mean age was 58.39 ± 11.6 years. Arterial hypertension was detected in 677 cases (in patients with hypercalcemia – in 23 patients), coronary heart disease was detected in 599 cases (in patients with hypercalcemia – 21), acute myocardial infarction – in 52 cases (in patients with hypercalcemia – 1), acute cerebrovascular accident – in 39 cases (in patients with hypercalcemia – 1).

Significant differences in the prevalence of arterial hypertension (χ²= 4.03, P=0.0447); in the prevalence of coronary heart disease (χ² = 3.87, P=0.046) in patients with hypercalcemia were detected. In the same time the differences in the prevalence of acute myocardial infarction (χ²=0.09, P=0.8) and acute cerebrovascular accident (χ²=0, P=1) in patients with hypercalcemia were not revealed.

Conclusion
The results of the study show an increasing risk of arterial hypertension and coronary heart disease in patients with hypercalcemia. In the same time the risk of acute cardiovascular events is not increased. The results may suggest the influence of hypercalcemia on the development of cardiovascular disease.

Vitamin D levels in obese adults and cardiovascular risk
Andreia Domingues1, Bruno Oliveira2,3 & Flora Correia2,4

Introduction
The prevalence of vitamin D deficiency is high, and yet still little recognized and treated. Cardiovascular diseases are the leading causes of morbidity and mortality worldwide and the emergence of evidence with the link suggesting an association between vitamin D deficiency and cardiovascular risk (CVR), it is pertinent to better understand this association.

Objective
This study aimed to relate the levels of 25 (OH) D in obese patients with the cardiovascular risk.

Methodology
Cross-sectional observational study with a sample of 31 individuals between 40 and 64 years, of both sexes diagnosed with obesity. They evaluated sociodemographic data, solar exposure and use of sunscreen, skin color phenotype of skin color, sources of vitamin D, physical activity, anthropometric data, clinical and biochemical and CVR.

Results
The average value of 25(OH) D was 15.6 ng/ml, 71.0 and 22.6% had deficiency and insufficiency, respectively. We observed lower levels of 25(OH) D in smokers, those with less solar exposure time, with a higher waist-to-height ratio and in those with lower levels of DBP. We did not find a statistically significant association between vitamin D deficiency and cardiovascular risk (CVR), it is pertinent to better understand this association.

Conclusions
We found a high prevalence of vitamin D deficiency in our sample of patients with obesity and a significant association with the waist-to-height ratio. Despite the evidence that suggests that vitamin D deficiency is associated with an increased CVR, we found this association but without statistical significance. The measurement of total 25(OH) D routinely in people with central obesity can help identify those who are at most CVR.

Keywords: vitamin D cardiovascular risk; obesity; SCORE; metabolic syndrome.

Partial giantism: case report

Munira Karimova & Zamira Khalimova

Center for the Scientific and Clinical Study of Endocrinology, Department of Neuroendocrinology, Mirzo Ulugbek str. 56, 100125, Tashkent, Uzbekistan.

The aim
To study case of partial gigantism.

Methods
To evaluate the patient’s condition we conducted hormonal and biochemical investigations, as well as total blood and clinical urine analysis; Doppler sonography and multislice computed tomography were performed.

Results
STH – 25.8 mU/l (normal range: 5–50 mU/l); LH – 15.6 mU/l (normal range: 0.8–9.5 mU/l); FSH – 14.5 mU/l (normal range: 0.6–7.0 mU/l); T3 – 2.1 µg/dl (normal range: 1.1–2.7 µg/dl); T4 – 5.3 µg/dl (normal range: 4.5–12.0 µg/dl); TSH – 0.3 µIU/ml (normal range: 0.5–3.5 µIU/ml); ACTH – 31.4 pg/ml (normal range: 1.5–44.0 pg/ml); cortisol – 26.5 µg/dl (normal range: 5.0–20.0 µg/dl); aldactone – 6.5 µg/dl (normal range: 2.0–10.0 µg/dl); 17-OHCS – 7.5 µg/dl (normal range: 2.0–15.0 µg/dl); 17-KS – 1.2 µg/dl (normal range: 1.0–2.0 µg/dl); cholesterol – 182 mg/dl (normal range: 130–200 mg/dl); triglycerides – 84 mg/dl (normal range: 50–150 mg/dl); glucose – 90 mg/dl (normal range: 70–110 mg/dl); albumin – 3.6 g/dl (normal range: 3.5–5.0 g/dl); total protein – 7.6 g/dl (normal range: 6.0–8.0 g/dl); creatinine – 0.9 mg/dl (normal range: 0.6–1.3 mg/dl); urea – 26 mg/dl (normal range: 10–30 mg/dl); WBC – 8400 cells/mm³ (normal range: 3500–10000 cells/mm³); red blood cells (RBC) – 4.0 million/mm³ (normal range: 4.0–5.5 million/mm³); Hb – 13.0 g/dl (normal range: 12.0–16.0 g/dl); platelets (PLT) – 155.000/mm³ (normal range: 140.000–400.000/mm³); ESR – 85 mm/h (normal range: 20–100 mm/h); CRP – 0.80 mg/ml (normal range: <0.5 mg/ml); alkaline phosphatase (ALP) – 84 U/L (normal range: 30–120 U/L); parathormone (PTH) – 179 pg/ml (normal range: 14–72 pg/ml); 25(OH)Dvit – 9.1 μg/L (normal range: 20–70 μg/L); 1.25(OH)Dvit – 18 pg/ml (normal range: 20–60 pg/ml); calcium – 9.5 mg/dl (normal range: 8.8–10.6 mg/dl); phosphorus – 4.5 mg/dl (normal range: 2.5–4.5 mg/dl); uric acid – 5.2 mg/dl (normal range: 2.5–4.5 mg/dl);

Conclusions
Due to similar symptoms with limited experience for their managing, it is necessary to:
– choose the wait and see approach. The excessive growth making a patient’s movements hard progresses, correcting surgical procedures and appropriate footwear are necessary,
– let the closure of growth zones be accomplished for correcting surgical reconstruction to be performed; the body part disproportionally enlarged should be surgically removed after that, generate a databank to generalize the results, and to develop drug and radiotherapy regimens.

Clinical Case Reports – Thyroid/Others

**EP315**

An unique case of celiac disease with hypeocoagulation and secondary hyperparathyroidism in elderly patient – a case report

Gocha Barbakadze, Lali Tsigishvili, Lavan Ramishvili, Nani Tsikarishvili & Koba Burnadze

Enmedic Clinic, Tbilisi, Georgia.

Introduction
Celiac disease (CD) an autoimmune disorder of the small intestine, was considered as a disease of childhood. The symptoms can be obvious. That is the main reason why CD is underdiagnosed in elderly patients.

Aims & Methods
The purpose of our study was to demonstrate a clinical case of CD which was diagnosed in a 41-year-old female patient. The patient attended our clinic with complains of weakness, tenderness, abdominal distension, weight loss. Laboratory tests find severe iron deficiency anemia (Hb -9 g/dl, Ery- 3.1 million/mm³) and to develop drug and radiotherapy regimens.

Results
His lab results are as follows: Ca:13 (8.8–10.6), P:2.2 mg/dl (2.5–4.5), ALP:84U/L (30–120), parathormone: 179 pg/ml (14–72), 25(OH)Dvit:8.2 ug/l (10–80). Urine Ca: 1159 mg/24 h(100–300), urine P:134 mmol/24 h(13–42).

CD was suspected. Serologic test for anti-gliadin antibodies was positive. Another examination of the biopsy after the first endoscopy revealed extensive collagen depositions in the lamina propria of the small bowel, giving the diagnosis of CD. Also antibodies against Transglutaminase were positive. After gluten-free diet the above mentioned symptoms disappeared and patient’s anemia and blood clot markers as well as parathormone and Ca level were well controlled.

Conclusion
The presence of other immune-related diseases in our case suggests that immunological mechanism plays a crucial role in CD. We recommend active specific screening in older patients belonging to at risk-group like other autoimmune disorders. Disappeared and patient’s anemia and blood clot markers as well as parathormone level were well controlled.

Optic neuritis as presenting complaint in primary hypoparathyroidism

Muhammad Fahad Arshad1, Steven Kang2, Nauman Arif Jadoon2 & Rehmat Karim2

1Doncaster Royal Infirmary, Doncaster, South Yorkshire, UK; 2Hull Royal Infirmary, Hull, UK.

Background
Papilledema and raised intracranial pressure has been reported frequently in patients with hypoparathyroidism but very rarely optic neuritis (1).

Clinical case
We report a case of 63-year-old male who presented to ophthalmology with right-sided visual loss and a relative afferent papillary defect. He was diagnosed with optic neuritis and underwent MRI brain which showed bilateral white matter changes with the possibility of demyelination. He was initially diagnosed with relapsing-remitting multiple sclerosis by the neurologist but was later found to have severe hypocalcaemia (adjusted calcium 1.32 mmol/l (2.20–2.60)) and idiopathic primary hypoparathyroidism (PTH<0.3 µg/ml (1.6–7.2)). Cerebrospinal fluid examination was entirely normal with negative oligoclonal bands. The initial MRI changes were thought to be secondary to severe hypocalcaemia as per neuroradiology MDT and subsequently, the diagnosis of multiple sclerosis was reversed. Although the underlying mechanism is not very clear, we believe there is an association between optic neuritis and primary hypoparathyroidism, especially in the absence of any other underlying cause for optic neuritis.

Conclusion
Although rare, but primary hypoparathyroidism can present as optic neuritis. Therefore, serum calcium should be checked in patients with no clear cause of optic neuritis.

The parathyroid carcinoma in a young adult male

Sevile Nur Firat1, Anara Karaca2, Nujen Colak Bozkurt1 & Hatice Unverdi3

1Ankara Teaching and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey; 2Ankara Teaching and Research Hospital, Pathology, Ankara, Turkey.

Introduction
Parathyroid carcinoma is a rare malignancy of the parathyroid glands. Parathyroid carcinoma may be suspected, but it usually cannot be confirmed prior to operation.

Case
A 35-year-old male was consulted to Endocrinology department with persistant kidney stones. He was operated five times in 10 years for recurrent kidney stones. The parathyroid carcinoma in a young adult male was diagnosed in a 41-year-old female patient. The patient attended our clinic with complains of weakness, tenderness, abdominal distension, weight loss. Laboratory tests find severe iron deficiency anemia (Hb -9 g/dl, Ery- 3.1 × 10^12), serum iron 4 mmol/l and severe hypeocoagulopathy (prothrombine index-48%, INR-2.98, but mild thrombocytoppenia 130×100). She had suffered with these symptoms for 2 years.

Results
Number of investigations was performed. We also checked parathormone which revealed secondary hyperparathyroidism (parathormone 187 pg/ml, Ca 1.01 mmol/l). The hemolytic anemia was excluded (haptoglobin was in normal range). Stool examination revealed no pathogens.

Conclusions
Due to few similar cases and limited experience for their managing, it is necessary to:
– choose the wait and see approach. The excessive growth making a patient’s movements hard progresses, correcting surgical procedures and appropriate footwear are necessary,
– let the closure of growth zones be accomplished for correcting surgical reconstruction to be performed; the body part disproportionally enlarged should be surgically removed after that, generate a databank to generalize the results, and to develop drug and radiotherapy regimens.

DOI: 10.1530/endoabs.49.EP314

Endocrine Abstracts (2017) Vol 49
Neck USG revealed 17 × 11 × 12 mm PTH adenoma with cystic components, but with no pathological cervical lymphadenopathies. Radionuclide scan confirmed increased parathyroid gland activity on the right inferior of the thyroid gland.

The patient underwent right inferior parathyroidectomy. Postoperative PTH < 6, Ca: 8.17, which confirmed successful removal of the pathological parathyroid gland. The histological findings reported marked pleomorphism in the cells, divided by the typical fibrotic septae and Ki-67: 4–5%. All those findings were consistent with parathyroid carcinoma.

After 4 months his last lab results were as follows; PTH: 57.8 pg/ml; Ca: 8.8 mg/dl; P: 4.6 mg/dl; urine Ca: 124 mg/24 h.

Conclusion
There is a challenge in the diagnosis of parathyroid carcinoma, because it is commonly diagnosed with histological evaluation. Although, parathyroid carcinoma is a rare disease, it should be kept in mind even in young adults.

Clinical case of atypical parathyroid adenoma with severe hypercalcemia and multiple fragility fractures
Anna Eremkina, Natalia Mokrysheva, Julia Krupinova, Svetlana Mironaya & Iya Voronkova
Endocrinology Research Centre, Moscow, Russia.

Introduction
Atypical parathyroid adenoma (APA) is rarely encountered cause of primary hyperparathyroidism (PHPT). No definite criteria are considered to distinguish preoperatively APA from parathyroid typical adenoma or carcinoma. The aim
To describe the clinical course of a patient with an atypical parathyroid adenoma with severe hypercalcemia and multiple fragility fractures.

Case presentation
A 61-year-old woman was evaluated for multiple fractures, skeletal deformities, pain in the large joints and bones, tachycardia, oppressive chest pain. She had severe hypercalcemia (calcium level 14.7 mg/dl), hypophosphatemia (serum phosphate 2.1 mg/dl) with an elevated intact parathyroid hormone level of 1871 pg/ml. Ultrasoundography revealed a large structure (4.7 cm) of the right parathyroid gland. 99mTc-sestamibi SPECT/CT showed the lesion 43 × 34 × 40 mm behind the middle and lower third of the left thyroid lobe. Renal function was impaired, GFR 46 ml/min/1.73 m<sup>2</sup>. Whole-body Tc-99m bone scan demonstrated multiple skeletal changes accepted as parathyroid osteodystrophy. As a result of the determination of severe hypercalcemia, heart rhythm disturbances (permanent form of atrial fibrillation), a high risk of hypertensive crisis, intravenous hydration was started with no significant effect. Patient received denosumab 60 mg s.c. She underwent a surgical resection of parathyroid adenoma and intra-operative PTH levels fell to 0.9 pg/ml. In the postoperative period serum calcium was decreased to 8.9 mg/dl. On pathological examination, the tumor consisted mainly of chief cells. Capsule invasion, peripherical vascular and perineural invasion of the adjacent tissue, high mitotic activity or large bands of fibrosis were not observed. Ki67 immunostaining was generally positive in about 3% of the studied metaphases. Tumor vessel invasion was detected in the central node part. These changes corroborated the diagnosis of atypical parathyroid adenoma.

Conclusion
APA are rare and have been a challenge for diagnosis. They have some features of carcinoma but lack the indisputable evidence of malignant disease like invasion or metastases. They have unpredictable clinical course, long-term follow up is prudent to assess for local recurrence and metastatic disorder to distinguish between benign and malignant parathyroid disease.

EP319
Congenital fibrous dysplasia and Klinefelter syndrome: coincidence or not?
Maria Alexandra Grama<sup>1</sup> & Constantin Dumitrache<sup>1,2</sup>
<sup>1</sup>Institute of Endocrinology IC Parhon, Bucuresti, Romania; <sup>2</sup>University of Medicine and Farmacology Carol Davila, Bucuresti, Romania.

Congenital fibrous dysplasia is a rare disease with a broad spectrum of manifestations, including various endocrinopathies: precocious puberty, hyperthyroidism, excess growth hormone, hypophosphatemia mediated by FGF23. We present the case of a 33 year old male, who presented in our endocrinology service with infertility and bone pain. He was diagnosed at the age of years old with congenital fibrous dysplasia and suffered multiple surgeries for bone decompression. Blood tests showed vitamin D insufficiency (16.01 ng/ml), very high levels of alkaline phosphatase (919 U/L), normal levels of calcium, phosphorus and parathormone. Bone mineral density was low at the femoral neck: BMD 1.385 g/cm<sup>2</sup>, Tscore = −2.4, Zscore = −2.3.

His semen analysis showed a normal aspect, volume and viscosity, but with a low A mobility of spermatozoa and a low percentage of normal form spermatozoa. His testosterone was within the normal range (3.44 ng/ml), with a TSH of 4.10 microU/ml. We further performed a karyotype analysis, which showed the presence of an extra X chromosome in 10% of the studied metaphases, with the diagnosis of mosaic Klinefelter: 47XXY/10%/46 XY (90%). This is the first description of a case with congenital fibrous dysplasia which associates mosaic karyotype 46XY/47XXY. Although the link between the two conditions is not known, further investigations are necessary to establish a possible correlation between them. It remains to establish if karyotype analysis should be a routine investigation for those diagnosed with fibrous dysplasia.

Parathyroid nodular hyperplasia: when imaging exams fail
Ana Sofia Oso´rio<sup>1</sup>, Jose´ Rocha<sup>2</sup>, Carolina Faria<sup>1</sup>, David Barbosa<sup>1</sup>, Ema Nobre<sup>1</sup> & Maria Joa˜o Bugalho<sup>1</sup>
<sup>1</sup>Serviço de Endocrinologia, Diabetes e Metabolismo; Hospital de Santa Maria; Centro Hospitalar de Lisboa Norte, Lisboa, Portugal; <sup>2</sup>Serviço de Cirurgia I; Centro Hospitalar de Lisboa Norte, Lisboa, Portugal.

Introduction
Parathyroid hyperplasia is the second cause of primary hyperparathyroidism (PH), representing 15–20% of all cases. The scintigraphy with Tc-99m-Sestamibi is a preoperative exam used to identify parathyroid adenomas or hyperplasia. It has a sensibility of 50–90%, which increases with larger parathyroid size. The neck ultrasonography (US) has also an important role detecting parathyroid enlarged glands with 70% sensibility. We report a case of parathyroid hyperplasia where the imaging exams fail to detect a 40 mm parathyroid.

Case report
75-year-old woman with osteoporosis, spontaneous bone fracture and osteoarticular pain. Laboratory evaluation showed a parathormone (PTH) of 145 pg/ml (range 14–72), a serum calcium of 12.0 mg/dl (range 8.6–10.2) and a phosphorous of 2.2 mg/dl (range 2.5–4.5). A neck US was performed revealing a 17 mm hypoechogenic vascularised nodule consistent with the inferior left parathyroid. The histological findings reported marked pleomorphism in the cells, divided by the typical fibrotic septae and Ki-67: 4–5%. All those findings were consistent with parathyroid carcinoma.

Conclusion
Coincidental results of an anatomic exam (US) and a functional one (Tc-99m-Sestamibi), suggesting the involvement of a single gland, do not exclude pluriglandular HP. Vitamin D and Calcium were started considering the bone disease; discontinuation and tapering of therapy will be managed according to calcium and PTH levels.

As clear as mud: an atypical case of primary hyperparathyroidism

Jessica Lai1,2, Navin Niles1,3 & Namson Lau1
1Liverpool Hospital, NSW, Australia; 2South Western Sydney Clinical School, University of New South Wales, NSW, Australia; 3Macquarie University Hospital, NSW, Australia; 1LIVE DIAB CRU, Ingham Institute of Applied Medical Research, NSW, Australia.

Objective
A young woman presented with marked hyperparathyroidism with post-operative course complicated by hungry bone syndrome and diagnostic and management challenges of ongoing hypercalcemia with hyperparathyroidism.

Method
ML, a 32-year-old Fijian Indian female, was referred with severe hypercalcemia, following one-year history of migratory debilitating bone pain. Initial labs showed corrected calcium (CaC) 3.17 (2.10–2.60 mmol/l), parathyroid hormone (PTH) 305.4 [2.0–6.0 pmol/l] and 25-hydroxyvitamin D (25-VitD) of 22 [40–80 nmol/l]. Acute management included admission for intravenous fluids and bisphosphonates, which normalised CaC. A parathyroid SESTAMBIICI/T-SPECT demonstrated a 3×9×33 mm soft tissue mass in anterior superior mediastium with focal uptake at T3. Further CT neck demonstrated 10×5×5 mm mass between left common carotid and subclavian arteries.

Results
ML’s surgical resection of the mediastinal mass was immediately complicated by generalised bony pain, pleural effusions and despite aggressive replacement of calcium, marked hypercalcemia (Day 1 CaC 1.99); consistent with an exaggerated ‘hungry bone syndrome’. ML has been followed closely for on-going optimisation of calcium and vitamin D; three-month labs showed elevated PTH (30.7 pmol/l), despite normalisation of 25-VitD (79 nmol/l) and improved CaC (2.04 mmol/l). Her pre-operative DEXA scan showed T-scores: lumbar spine -5.15SD and bilateral femoral necks -5.65SD. An MRI cervical spine demonstrated widespread lytic lesions including, a lesion in the C2 spinous process and posterior pedicles, considered consistent with pathological fracture. Histopathology reported a 70×65×51 mm; 41 gm mass with no invasive features. Paraffinum was positive, whilst PGP9.5 was negative; other patterns of staining were normal, making HRPT2/CDC73 mutation unlikely.

Conclusion
This case highlights: 1) the diagnostic challenge of marked hyperparathyroidism with a clinical picture suggestive of malignancy, but histological evidence not supporting invasion; 2) the management issues of moderating post-operative severe hypercalcemia and ‘hungry bone’ phenomenon; and 3) the on-going diagnostic and management of post-operative hyperparathyroidism with hypercalcemia. In summary, atypical primary hyperparathyroidism presents unique diagnostic and management challenges.

Familial hypocalciuric hypercalcemia with a new heterozygous missense mutation of CaSR gene and cinacalcet treatment

Sinem Kiyici1, Burcin Uygun1 & Orhan Gorukmez2
1Liverpool Hospital, NSW, Australia; 2South Western Sydney Clinical School, University of New South Wales, NSW, Australia.

Introduction
Familial hypocalciuric hypercalcemia (FHH), a common autosomal-dominant disorder, is caused by gain-of-function mutations in the CaSR gene coding for the calcium-sensing receptor. This leads to inappropriately elevated parathyroid hormone (PTH) levels, causing hypercalcemia and hypocalciuria. We report a young woman with a new heterozygous missense mutation in the CaSR gene, suggesting the diagnosis of FHH. This mutation has never been reported in literature or in the Human Gene Mutation Database. In the follow up of the patient 30 mg/day cinacalcet treatment was started and increased up to 60 mg/day due to the persistent asymptomatic hypercalcemia. Plasma calcium levels were normalized and PTH levels decreased slightly after the treatment.

Conclusions
FHH is a rare disorder, but it is clinically important because it can be confused with asymptomatic primary hyperparathyroidism. FHH is usually asymptomatic but rarely symptoms of fatigue, weakness, and excessive thirst and concentration problems are experienced. Cinacalcet is potentially a useful treatment of patients with intractable hypercalcemia caused by mutations in the CaSR gene.

DOI: 10.1530/endoabs.49.EP322

Parathyroid carcinoma can be misdiagnosis with medullary thyroid cancer: how is that possible?

Natalia Mokryshева, Julia Krupinova, Ekaterina Pigarova, Nadezhda Platonova, Iya Voronkova & Kiriil lanschakov
Endocrinology Research Centre, Moscow, Russia.

Background
Hypercalcemia may stimulate thyroid’s C-cells to produce the calcitonin, that could lead to misdiagnosis of medullary thyroid cancer.

Clinical case
A 47-year-old woman suffered from fracture of the left knee. She could not walk and used a wheelchair. CT scan in a public hospital detected multiple bone lytic changes in the ribs and vertebrae (mts?), tumor in the liver (mts?) and node in the thyroid gland 2.6×1.9 cm. Thyroid biopsy showed follicular neoplasia (cancer?). At the same time, blood analysis showed high level of serum calcitonin 190 pg/ml (0-5.5). Thus, her state was determined as the medullary thyroid cancer (MTC) with mts in bone and liver and she was sent to our center for surgery of MTC.

Medical examination uncovered primary hyperparathyroidism (PH): total calcium – 3.78 mmol/l (2.10–2.55), PTH – 1513 pg/ml (15–65) in combination with 3.72, 3.92, 2.4 cm tumor behind the thyroid gland showed by the US exam. Osteitis fibrosa cystica was suspected after radionuclide bone imaging. Renal functions were impaired, GFR 10 ml/min/1.73 m2. The symptoms and findings of the disease the parathyroid cancer (PC) was suspected, so “en bloc” removal of the tumor was performed. The diagnosis was confirmed by histological examination. PTH, total serum calcium levels as well as calcitonin were decreased down to the reference level after the surgery. The liver biopsy shows no tumor cells. PET/CT did not observe the abnormal accumulation of 18FDG in the liver and in bones. The patient’s condition has significantly improved 4 month after the surgery – she can walk without a wheelchair.

Conclusions
High level of calcitonin caused by hypercalcemia in combination with nodules in the thyroid gland can lead to incorrect diagnosis. It is important to exclude hypercalcemia in case of high levels of calcitonin.

Clinical case of pachydermoperiostosis

Munira Karimova & Zamira Khalimova
Center for the Scientific and Clinical Study of Endocrinology, Department of Neuroendocrinology, Republic of Uzbekistan, 100125, Tashkent, Mirzo Ulugbek str. 56.

The aim
To study the case of Pachydermoperiostosis.

Material and methods
We report a case of a 24-year-old male complaining of marked changes in appearance due to the disfiguring thickening and wrinkling of skin, excessive greasiness and perspiration, marked horizontal creases on the forehead, with deep furrows between them, increase in the thickness of eye lids, “senile expression” of the face, thickening of distal parts of extremities, fingers and toes. The patient is unsocial, aloof and focused on his emotions. To evaluate the patient’s condition we conducted hormonal and biochemical investigations, as well as total blood and clinical urine analysis; MRI of pituitary and ultrasonography of inner organs were performed.

Results
GH – 2.2 (normal range: 0–20 mU/l); IGF–1 114.6 (normal range: 219–644 mg/l); prolactin – 5.3 (normal range: 1–18 ng/ml); TSH – 0.87 (normal range: 0.5–5.0 mIU/l); T4 – 14.8 (normal range: 8–19 ng/dl); T3 – 0.70 (normal range: 0.80–1.80 ng/dl). Neuroendocrinological exam included TSH, FT4FT3, fasting glucose, urine acetone (negative), urine cortisol (negative). MRI pituitary was normal. CT scan of parathyroid showed a 4.25×3.25×3.25 cm mass on the right side of the neck with compression of feeding vessels. Parathyroid hormone and calcium were increased up to 181.7 pg/ml and 12.3 mg/dl. We performed Tg and Calcitonin. Tg was increased up to 35.1 ng/ml (normal range: 0–1.6 ng/ml). Calcitonin was increased up to 391.1 pg/ml (normal range: 0–10 pg/ml). Calcitonin was increased up to 391.1 pg/ml (normal range: 0–10 pg/ml). The patient was operated on. The diagnosis was confirmed by histological examination.
0.17–4.05 μIU/l), free T4 – 15.5 (normal range: 11.5–23 pmol/l). The patient was diagnosed with pituitary microadenoma, mastoiditis, ethmoiditis, and sinusitis; US revealed chronic cholecystitis, pancreatitis, and reactive hepatitis. Total blood and local chemical urine analysis demonstrated no deviations. The patient presented pachydermia of scalp with moderately painful, rough skin folds in the parietal-occipital region, resembling cerebral gyri, thickening and enlargement of eyelids due to hypertrophy of the cartilage tissue, dystrophic changes of the conjunctiva, atrophy of the tarsal glands with formation of cysts and granulomas in them. The patient is unsocial, aloof and focused on his emotions.

Conclusions
Although the prognosis for patients with pachydermoperiostosis is unfavorable, and there are no specific prevention techniques, they can maintain the ability to work for a long time and live to old age if the appropriate treatment is applied (the latter can be achieved by a thorough medical and genetic counseling of families of patients. Some cases, severe articular syndrome may cause permanent disability.

EP326
Equivocal preoperative imaging including 18F-fluorocholine PET-CT in primary hyperparathyroidism and nodular thyroid disease – case report
Katerina Zajickova
Institute of Endocrinology, Prague, Czech Republic.

66-year-old woman came first for an evaluation of nodular thyroid disease. Primary hyperparathyroidism (PHPT) was incidentally diagnosed during the entrance lab test with total calcium 2.62 mmol/l and PTH 93 ng/l. Serum creatinine was normal and 25 OH vitamin D was 97 nmol/l. Dual-energy X-ray absorptiometry was carried out and revealed osteoporosis at lumbar spine. Moreover, there were two low-trauma fractures in a recent patient history. Biochemical or ultrasonography, these two patients have moderate-high PTH values. The patient is unsocial, aloof and focused on his emotions.

Parathyroid adenomas (85% of cases of primary hyperparathyroidism) are usually and false positive preoperative imaging might influence the extent of preoperative evaluation and the choice of surgical approach in PHPT.

EP327
Vascular dementia in a 57-year old woman with adenoma of parathyroid gland
Maria Anna Kopeckova
Cantonal Hospital, Zenica, Bosnia and Herzegovina.

Dementia describes a set of symptoms such as memory loss, difficulties with thinking, problem solving or language. Vascular dementia is a second most common type of dementia, rare under 65 year old. I report a case of 57-year-old woman with diagnosed dementia vascularis in Neurology department. Beside neurological diagnostic methods (brain scan-CT, MRI, Color Doppler of carotids, she had hypercalcemia (2.96–3.04 mmol/l; normal range 2.0–2.60) as high calciuresis/24-hour (concentration 6.98 mmol/l). Her parathyroid hormone is elevated (hyperparathyroidism) due to adenoma of right inferior parathyroid gland (PTH is 95 μg/ml). Because of progression on patient’s physiological and clinical state, immobility, difficulty to communicate and feeding with nasogastric tube, an operation of adenoma of parathyroid gland was not an option. She ended with stones in her left urether and postsurgery complications.

Keywords: dementia vascular; adenoma of parathyroid gland; hypercalcemia; hyperparathyroidism; parathyroid hormone.

A rare case of giant parathyroid adenoma: diagnostic and therapeutic aspects
Cristina Alina Silaghi1, Horatiu Silaghi2, Gheorghe Cobza3, Svetlana Enciu-ca, Romina Alina Rădu1, Daniel Tudor Cosma5, Ana Ciurea1, Carmen Emannuela Georgescu1
1Department of Endocrinology, “Iuliu Hatieganu” University of Medicine and Pharmacy Cluj-Napoca, Cluj Napoca, Romania; 25th Department of Surgery, “Iuliu Hatieganu” University of Medicine and Pharmacy Cluj-Napoca, Cluj Napoca, Romania; 3Clinic of Nuclear Medicine, County Emergency Hospital, Cluj-Napoca, Cluj Napoca, Romania; 4Department of Pathology, “Niculae Staniciu” Heart Institute, Cluj Napoca, Romania; 5Clinic of Endocrinology, County Emergency Hospital, Cluj-Napoca, Cluj Napoca, Romania; 6Diabet, Nutrition and Metabolic Diseases Clinical Center Cluj-Napoca, Cluj Napoca, Romania; 7Department of Radiology “Iuliu Hatieganu” University of Medicine and Pharmacy, Cluj-Napoca, Cluj Napoca, Romania.

Parathyroid adenomas (85% of cases of primary hyperparathyroidism) are usually small in size (weigh 70 mg – 1 g). Giant parathyroid adenomas (GPTA) weighing more than 3.5 g are very rare, more common in males, in the 6th decade of life, generally affect one parathyroid gland, are oxyphilic and ectopic in 50% of cases. We report the case of a 53-year-old woman presented for asthenia, fatigue, tingling in the arms and legs without other symptoms of hypercalcemia. Laboratory analysis showed: ionized calcium 6.5 mg/dl (normal: 4.2–5.4 mg/dl), total calcium 13.9 mg/dl (normal: 8.8 to 10.0 mg/dl), hypophosphoremia 2.0 mg/dl (normal: 2.3 to 4.7 mg/dl) and 809 pg/ml intact-parathyroid hormone (normal: 11.0 to 67.0 pg/ml). Calcinonin, thyroxin and thyroid-stimulating hormone levels were normal. Cervical ultrasonography revealed a solid hypoechogenic nodule located posterior-inferior of the right thyroid lobe with retrosternal extension. An ectopic GPTA localised in para-aortic region of superior mediastinum stretching down to the bifurcation of the trachea was
detected using technetium-99m sestamibi scintigraphy and single photon emission computed tomography/computed tomography (SPECT/CT). GPTA measuring 8.5 × 4.4 5.4 cm was removed via cervical approach. Histopathology revealed an atypical GPTA with main cells, oncocyte cells, follicular areas, Ki67 < 5% (rarely, in very small areas Ki67 was up to 10%); chromogranin and cytokeratin AE1/3 were positive; carcinoembryonic antigen, thyroid transcription factor 1, and thyroglobulin were negative. The peculiarities of this case: GPTA but poor symptomatology of hypercalcemia and moderately elevated serum calcium levels; ablation of GPTA by cervical incision although mediastinal expansion; mild hungry bone syndrome postoperatively (not correlated with GPTA volume). In conclusion, GPTA is a very rare condition but their size is not an argument in favour of malignancy. Cervical incision should be considered before sternotomy and thoracic/mediastinal approach.

Autosomal dominant hypocalcemia in a Portuguese family: novel mutation in the calcium-sensing receptor gene

Vânia Gomes, Florbela Ferreira, Catarina Silvestre, Raquel Castro & Maria João Bugalho
Santa Maria Hospital, Lisbon, Portugal.

Introduction

Autosomal dominant hypocalcemia (ADH) is a rare condition, caused by activating mutations in the calcium-sensing receptor (CASR) gene. Affected individuals have hypocalcemia with inappropriately low parathyroid hormone (PTH) levels.

Case report

A 50-year-old woman, asymptomatic, was referred to our Endocrinology department for investigation of hypocalcemia detected in routine blood analysis (serum corrected calcium was 7.4 mg/dl – normal: 8.6–10.2). There was also hyperphosphatemia (5.4 mg/dl – normal: 2.4–5.1) and abnormally low PTH (9.9 pg/ml – normal: 14–72).

Her past medical history was irrelevant except for depression in the past. She denied taking any prescription. There was no history of neck surgery/radiation or known family history of hypocalcemia. Thyroid function, morning serum cortisol and 24-h urinary cortisol, fasting glucose, 25-hydroxyvitamin D, renal function, serum magnesium, sodium and potassium were normal. Auto-antibodies against thyroid, parathyroid and adrenal gland were negative. Brain computed tomography identified basal ganglia calcifications. A few first-degree relatives (74-year-old mother, sisters aged 44 and 49, and 30-year-old son) were also screened for hypocalcemia. The mother and the younger sister, both asymptomatic, had hypocalcemia and inappropriately low PTH. The mother also presented basal ganglia calcifications. The son and the older sister had normal calcium levels. Genetic analysis identified a novel heterozygous CASR variant: c.2269G>A (p.Glu757Lys) in the proband, her mother and younger sister whereas it was not identified in the son and older sister. Affected individuals started calcium replacement aiming to a low-normal calcium level (8–8.5 mg/dl).

Conclusion

The co-segregation of the novel CASR variant with the hypocalcemic phenotype in this family favor its pathogenic role. Clinical investigation and diagnosis of this condition can be challenging, but treatment and long-term monitoring are essential to prevent complications, such as neurological.

A case of intrathyroidal parathyroid adenoma presented with severe 25(OH)D3 deficiency, bone pain and high PTH

Ömercan Topaloglu¹, Bahri Evren¹, Iбраhим Sahin¹ & Bulent Unal²
1Inonu University Medical Faculty, Department of Endocrinology, Malatya, Turkey; 2Inonu University Medical Faculty, Department of General Surgery, Malatya, Turkey.

The most frequent pathology of primary hyperparathyroidism presented with the findings of hypercalcemia is parathyroid adenoma. Some patients having the signs of primary hyperparathyroidism may have intrathyroidal parathyroid adenoma and it may be overlooked. We present a case of intrathyroidal parathyroid adenoma presented with bone pain. 47-year-old female patient referred to our clinics with bone pain and she had no pruritus, dry mouth, dyspepsia, abdominal pain, nausea, vomiting, polyuria or polydipsia. She did not have any history of hypertension, nephrolithiasis, renal failure or bone fracture; and she was taking risendronate for one week for osteoporosis. On physical examination, vital signs and systemic findings were normal. Blood count revealed mild anemia (hemoglobin: 10 g/dl, MCV: 80 fl); and in biochemical analyses, creatinine was 0.65 mg/dl, Ca: 12 mg/dl, P: 2.2 mg/dl, Mg: 2.07 mg/dl, albumin: 3.1 g/dl, ALP: 738 U/l. Hormonal parameters showed biochemical primary hyperparathyroidism (PTH: 1938 pg/ml, 25(OH)D3: <3 ng/ml). BMD showed severe osteoporosis in lumbar vertebra (T score = –4.0). There were osteopenia in bone X-rays and “Brown tumor” in fifth metacarpal bone of right hand. No nephrolithiasis or nephrocalcinosis was found in abdominal sonography. Neck sonography revealed a large (37 × 24 mm), vascular, heterogeneous nodule having both cystic and solid areas in right lobe of the thyroid gland. 99mTc-sestamibi scintigraphy showed MIBI uptake in the nodule, making us to define the nodule as intrathyroidal parathyroid adenoma. Then, the patient underwent to surgery, and right hemithyroidectomy was done; and postoperative pathological examination confirmed the parathyroid adenoma. Postoperative calcium and PTH levels were 7.3 mg/dl and 24.3 pg/ml. When clinical and biochemical findings point to primary hyperparathyroidism, we should keep in mind that intrathyroidal nodules may be parathyroid adenoma.

The rare cause of primary hyperparathyroidism: Parathyroid Carcinoma

Nagihan Bestepe¹, Didem Ozcemir², Setika Burcak Polat³, Berna Evranos¹, Reyhan Erozy¹ & Bekir Cakir¹
¹Ankara Ataturk Training and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; ²Ankara Yildirim Beyazit University Medicine Faculty Department of Endocrinology and Metabolism, Ankara, Turkey.

Introduction

Parathyroid carcinoma (PC) is a rare endocrine malignancy which accounts for 0.005% of all cancers and less than 1% of primary hyperparathyroidism cases. This uncommon tumor usually occurs during the fifth decade of life, with equal frequency in both sexes, and has an indolent but progressive course. It’s frequently symptomatic and patients may have high values of serum calcium and parathyroid hormone (PTH) with a palpable cervical mass. PC generally occurs as a sporadic disease, and less frequently in the setting of genetic syndromes such as hereditary multiple endocrine neoplasia. In this study we present five different PC cases followed in our clinic.

Cases

There were 2 female and 3 male patients with PC. The mean age of the patients was 50.4 ± 13.7 (38–65). They had presented with weakness, headache, nausea and vomiting, and widespread bone pain. One of the patients had bone fracture and one other patient had nephrocalcinosis. The mean serum calcium, phosphorus and PTH levels were 15.3 ± 2.7 mg/dl (ranging between 11.6 and 18.9 mg/dl), 2.4 ± 0.8 mg/dl and 869.4 ± 991.9 pg/ml (ranging between 87 pg/ml and 2590 pg/ml), respectively. Histopathologically, mean tumor size was 29.2 ± 11.1 (15–44) mm. Plasma calcium, phosphorus and PTH levels were in the normal range and 36 months after surgery in 2 patients. Local recurrence was observed in 2 patients and reoperation was performed. One other patient with lung and bone metastasis had still high serum Ca and PTH levels despite recurrent surgeries for six times.

Conclusion

PC is usually that of a slow-growing neoplasm and indicates progressive end-organ damage from disturbed calcium homeostasis. While some patients present with mild increases in serum calcium and PTH levels, some might have very severe hypercalcemia and hyperparathyroidism. Similarly, prognosis varies from cure to life threatening unresectable and metastatic disease depending on the presentation and surgical success.

A parathyroid adenoma presented with diffuse bone lesions and anemia

Irem Kok, Fatma Dogan, Soner Cander, Ozen Oz Gul, Erdinc Erturk & Canan Erozy
Uludag University Medical School, Bursa, Turkey.

Endocrine Abstracts (2017) Vol 49

19th European Congress of Endocrinology 2017
Primary Hyperparathyroidism is a common endocrine disorder characterized with high parathyroid hormone (PTH) and calcium (Ca) levels. Although most of the patients are asymptomatic, some patients may be presented with renal, gastrointestinal, musculoskeletal, neurologic or cardiovascular signs associated with hypercalcemia or elevated parathyroid hormone related findings such as bone disease, nephrolithiasis, hypophosphatemia increased production of calcitriol, hypomagnesemia, hyperuricemia and anemia. Brown tumor is one of the manifestations of Primary Hyperparathyroidism and is more commonly found in trabecular bone pattern of the mandible, bones of the upper and lower extremities and ribs.

Case A 54 year-old female with a history of recurrent nephrolithiasis was referred with fragile bones fractures. Biochemical assay revealed an increased value of serum PTH 1570 pg/ml and calcium 13.5 mg/dl. The serum phosphorus level was 3.4 mg/dl, ALP:14 IU/L, 25OH vitamin D: < 8 ng/ml. Direct radiographies revealed multiple lesions of the upper and lower extremities, iliac bones, femoral heads, sacrum, sternum, ribs and vertebrae. A complete blood count (CBC) of the patient revealed a low hemoglobin and hematocrit levels (Hg:6.93 g/dl, Htc:20.00%). There was no evidence of neutropenia or leucopenia. After consulting to Hematology department, it was reported that anemia was associated with diffuse bone lesions and it was not possible to make bone marrow biopsy due to diffuse bone lesions. Follow up of anemia for recovery after parathyroidectomy was also suggested. Ultrasound of neck revealed mass of 3 cm associated with parathyroid adenoma. After erythrocytuses transfusions, the patient was planned for surgery.

Multiple bone lesions are common in Primary Hyperparathyroidism and Brown tumour may also be a part of this clinical condition. These lesions are usually localized and have a tendency for recovery of the primary disease. It should be in mind that diffuse bone marrow lesions may be seen resulting progenitor cells failure in bone marrow and cytopenia.

Histopathological examination revealed parathyroid carcinoma with invasion to vertebra. MR imaging also showed lesions compatible with metastasis. There were no other risk factors for osteoporosis. There was nothing of significance to find on examination.

Investigations & Results

DxA scan - Spine L1-L4 T-score ~3.6, Left hip T-score ~2.4, CTX 0.24 mcg/L (normal), P1NP 34 mcg/L (normal). Spine X-rays: T11 grade 1 fracture & T4 grade 2 fracture. No other secondary cause of low bone mass identified (normal levels of testosterone, parathyroid hormone, vitamin D, calcium, phosphate and coeliac antibodies).

Discussion

This is a case of a young man with seemingly unexplained fragility fractures and low bone mass. The clue to the aetiology for low bone mass was the gentleman’s hereditary eye condition. The eye problems are caused by a condition known as Familial Exudative Vitreoretinopathy (FEVR); a rare genetic disorder affecting retinal angiogenesis that can cause progressive visual loss. FEVR may be mediated by mutation in LRPS5 coding for the LRPS5 transmembrane receptor. LRPS5 plays a key role, alongside Frizzled protein, in the Wnt signalling pathway, which has effects on cellular proliferation, adhesion and migration. Importantly, Wnt signalling is also known to regulate bone mass. Therefore, it is the defect in this pathway that is the common denominator for this gentleman’s blindness and bone problems. We speculate that upcoming new drugs that target Wnt signalling in osteoporosis, such as Romosozumab (a Sclerostin inhibitor), may be particularly beneficial in patients with low bone mass associated with FEVR.

Broken bones and blindness- a rare cause of osteoporosis

Rebecca Sagar & Afroze Abbas
Leeds Centre for Diabetes and Endocrinology, Leeds Teaching Hospitals, Leeds, UK.

Case History

A 37 year-old gentlemen was referred to metabolic bone clinic due to recurrent recent fragility fractures. He had several fractures throughout childhood, and these had continued to occur into his adult life. He was blind in his left eye since birth. He felt that this had contributed to his fractures, due to falls. There had been no other previous major health problems. His brother had a similar eye condition. There were no other risk factors for osteoporosis. There was nothing of significance to find on examination.

Investigations & Results

DxA scan - Spine L1-L4 T-score ~3.6, Left hip T-score ~2.4, CTX 0.24 mcg/L (normal), P1NP 34 mcg/L (normal). Spine X-rays: T11 grade 1 fracture & T4 grade 2 fracture. No other secondary cause of low bone mass identified (normal levels of testosterone, parathyroid hormone, vitamin D, calcium, phosphate and coeliac antibodies).

Discussion

This is a case of a young man with seemingly unexplained fragility fractures and low bone mass. The clue to the aetiology for low bone mass was the gentleman’s hereditary eye condition. The eye problems are caused by a condition known as Familial Exudative Vitreoretinopathy (FEVR); a rare genetic disorder affecting retinal angiogenesis that can cause progressive visual loss. FEVR may be mediated by mutation in LRPS5 coding for the LRPS5 transmembrane receptor. LRPS5 plays a key role, alongside Frizzled protein, in the Wnt signalling pathway, which has effects on cellular proliferation, adhesion and migration. Common bone lesions may be a sign of parathyroid carcinoma in the primary hyperparathyroidism

Soner Candır1, Ozgen Öz Gul2, Pinar Sisman2 & Canan Ersoy1
1Uludag University Medical School, Bursa, Turkey; 2Kars State Hospital, Kars, Turkey.

A 60-year-old male patient who presented with left hip and knee pain was found to be compatible with primary hyperparathyroidism (PTH:2233 pg/ml, calcium: 15.7 mg/dl, phosphorus: 2.9 mg/dl creatinin:1.99 mg/dl, 25-OH D:9.7 g/ml, ALP:532 mU/ml). Bone grafts of the patient showed multiple lytic lesions in the pelvis, cranium and long bones. Neck ultrasonography showed hypoechoic solid nodule with cystic areas, 2×2 cm with size in the left thyroid gland inferior region and delayed wash-out was detected by the parathyroid scintigraphy. Bone scintigraphy was suspicious in terms of metastasis. Left hemi thyroidectomy and left inferior parathyroidectomy was performed. In thorax lytic lesions compatible with multiple metastases in bone structures were observed. Thoracal and lumbar vertebral MR imaging also showed lesions compatible with metastases. Histopathological examination revealed parathyroid carcinoma with invasion to the thyroid gland.

Primer hyperthyroidism has been increasing in recent years as a laboratory diagnosis the contribution of asymptomatic cases has increased. Frequent routine examinations have also led to the early recognition of the disease, and osteitis fibrosa cystica and bone lesions such as brown tumor, which are among the complications of primary hyperparathyroidism, are increasingly rare. Primer Hyperparathyroidism is often associated with solitary parathyroid adenoma, hyperplasia or multiple adenomas, mostly seen with the genetic syndromes. Parathyroid carcinoma is very rare and is recognized only by the presence of metastases or histopathologically significant invasion findings, such as those present in our case. Clinically, incompatibility in tumor size and serum PTH levels, extremely high PTH levels may be a sign of parathyroid carcinoma. Apart from this, common bony lesions which are rarely seen in primary hyperparathyroidism due to early diagnosis and noisy clinical picture can be considered as malignancy findings as it in our patient. Therefore, in patients with widespread pain and common bony lesions, the patient should be carefully examined for parathyroid carcinoma and an appropriate approach should be sought.

An usual cause of post operative hypocalcaemia

Fatma Mmif, Wajdi Safi, Nabila Rekkik, Houcem Mrabet, Hamza Elfeikh, Nadia Charfi, Mouna Mmif & Mohammed Abd Department of Endocrinology, Hedi Chaker University hospital, Sfax, Tunisia.

Introduction

The otorhinolaryngologist can be confronted to multiple surprises after a thyroid surgery

Case Description

We report the case of a 48 year-old woman admitted with post operative hypocalcaemia (after thyroidectomy?). The patient has a history of hypothyroidism since 5 years. She then presented a cervical swelling. The ultrasound confirmed the presence of a suspicious thyroid nodule measuring 4 cm. A thyroidectomy was then conducted. Post operative, the patient presented with symptoms of hypocalcaemia, confirmed by low level of blood calcium at 1.59 mmol/L. The anatomopathological examination showed no sign of thyroid tissue, along with the presence of five adenomatous parathyroid nodules. Post operative scintigraphy showed a conserved thyroid tissue, with absence of parathyroid glands. Hungry Bone Syndrome was confirmed led to the prolonged and severe hypocalcaemia, associated to the adenomatous aspect of the parathyroid measuring more than 6 cm. Because of the family history of pituitary prolactinoma, primary hyperparathyroidism and multinodular goitre and the personal history of uterine fibroma and hypothyroidism, Multiple Endocrine Neoplasia 1 (MEN1) was suspected. Genetic confirmation is underway.

Conclusion

This is the case of an asymptomatic hyperparathyroidism discovered by a severe post-thyroidectomy hypocalcaemia. This hyperparathyroidism is due to multiple parathyroid adenomas misdiagnosed as thyroid nodules, and probably falls within a multiple endocrine neoplasia type 1.

Brown tumor in a normocalcemic patient
Pinar Sisman1, Ozen Oz Güli1, Soner Cander2, Erdinc Erturk2 & Canan Ersoy1
1Harakani State Hospital, Endocrinology and Metabolism Clinic, Kars, Turkey; 2Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Background
Brown tumor of bone is a non-neoplastic lesion resulting from abnormal bone metabolism in hyperparathyroidism. Brown tumor, as the only and initial symptom of normocalcemic primary hyperparathyroidism is extremely rare.

Case presentation
A 69-year-old female patient was admitted to the hospital with a mass in the right thigh. A mass lesion of the right distal femur with bone and soft tissue infiltration was observed in the lower extremity magnetic resonance imaging (MRI). The size of the mass was measured as approximately 10×3.7×4.6 cm. Apart from this lesion, nodular lesions were detected in various dimensions on the right femur, left femur and left patella. Brown tumor was detected in pathologic evaluation of the mass of the right distal femur. The patient was examined for hyperparathyroidism. Serum parathormone (PTH) level was 2698 pg/mL (reference range 15–68), calcium level was 8.8 mg/dL (8.4–10.2), phosphorus level was 2 mg/dL (2.4–4.4) and 25-OH D level was 10 ng/mL. Vitamin D treatment was given to the patient. 24-hour urine calcium could not be assessed because of the patient’s low compliance. The total ionized T score was –4.7 and the femur neck T score was –5.5 in the bone mineral density. Localization studies were performed and neck ultrasonography and parathyroid scintigraphy revealed a parathyroid adenoma in the inferior right lobe. Patient underwent parathyroidectomy and in histopathological evaluation solitary parathyroid adenoma was observed. The follow-up of the patient whose postoperative PTH decreased to 161 pg/mL is being continued.

Discussion
Cytologically, it is difficult to separate the brown tumor from any other giant cell lesions. To prevent unnecessary surgical procedures, PTH assay is necessary in any patient with expansive lytic lesion of the bone, even if serum calcium level is normal.

Symptomatic bisphosphonate-induced hypocalcaemia after severe idiopathic hypercalcaemia
Joana Lima Ferreira, Teresa Tavares, Rui Moço & Pedro Melo Hospital Pedro Hispano, ULS Matosinhos, Portugal.

Introduction
Bisphosphonates, generally considered as safe drugs, are potent inhibitors of bone calcium outflow used to treat osteoporosis and hypercalcemia associated with malignancy. Bisphosphonate-induced hypocalcaemia is an increasingly reported complication, but it has not yet been a subject of comprehensive research.

Case report
A 65-year-old woman had a history of Crohn’s disease and ankylosing spondylitis medicated with prednisolone and etanercept. Due to vitamin D deficiency she had been taking calcium and vitamin D supplementation. At a consultation she presented with difficulty in concentration and balance, and blurred vision. Analysis revealed severe hypercalcemia (ionized Ca²⁺ 2.18 mmol/l), elevated serum creatinine and normal parathyroid hormone (PTH). She was treated with intravenous fluids and a single intravenous dose of zoledronate, resulting in calcium normalization and clinical remission. Five days later she returned for delirium, tetany, perioral paraesthesia and carpopedal spasm. Chvostek’s sign was positive. Hypocalcaemia (ionized Ca²⁺ 0.97 mmol/l), vitamin D deficiency, elevated PTH, hypomagnesaemia, hypophosphataemia and hypokalaemia were detected. She required intravenous calcium and long-term oral calcium and vitamin D supplementation with gradual but sustained improvement. Denstometry revealed femur and lumbar spine osteoporosis. Study was negative for malignancy. Brown tumor was detected in pathologic evaluation of a lesion, nodular lesions were detected in various dimensions on the right femur, left femur and left patella. Brown tumor was detected in pathologic evaluation of the mass of the right distal femur. The patient was examined for hyperparathyroidism. Serum parathormone (PTH) level was 2698 pg/mL (reference range 15–68), calcium level was 8.8 mg/dL (8.4–10.2), phosphorus level was 2 mg/dL (2.4–4.4) and 25-OH D level was 10 ng/mL. Vitamin D treatment was given to the patient. 24-hour urine calcium could not be assessed because of the patient’s low compliance. The total ionized T score was –4.7 and the femur neck T score was –5.5 in the bone mineral density. Localization studies were performed and neck ultrasonography and parathyroid scintigraphy revealed a parathyroid adenoma in the inferior right lobe. Patient underwent parathyroidectomy and in histopathological evaluation solitary parathyroid adenoma was observed. The follow-up of the patient whose postoperative PTH decreased to 161 pg/mL is being continued.

Discussion
Cytologically, it is difficult to separate the brown tumor from any other giant cell lesions. To prevent unnecessary surgical procedures, PTH assay is necessary in any patient with expansive lytic lesion of the bone, even if serum calcium level is normal.

Transient hyperglycemia during the course of primary hypoparathyroidism: Case study
Magdalena Urbanczuk1,2, Marcin Lewicki1,2, Agnieszka Zwołak1,3, Marcin Urbanczuk1, Joanna Swińska1,2, Monika Lenart-Lipinska1,2 & Jerzy S Tarach1
1Chair and Department of Clinical Pathomorphology of Medical University of Lublin, Lublin, Poland; 2Department of Internal Medicine and Internal Medicine in Nursing, Medical University of Lublin, Lublin, Poland; 3Chair and Department of Family Medicine of Medical University of Lublin, Lublin, Poland; 4Department of Laboratory Diagnostics of Medical University of Lublin, Lublin, Poland.

Introduction
Calcium ions (Ca²⁺) play an essential role in process of correct β-cell insulin secretion. Hypocalcaemia impairs insulin secretion leading to glucose metabolism disorders and insulin resistance.

Case study
62-year old female patient with 18 years history of type 2 diabetes, treated with insulin, suspected of hypoparathyroidism, was admitted to the Department and Clinic of Endocrinology, Medical University of Lublin because of hypocalcaemia. She was experiencing latent tetany signs like muscle tremors, paresthesia and an unpleasant tingling sensation in her hands, additionally persistent dry cough. Clinical observation and laboratory findings with classic constellation of symptoms (hypocalcaemia, hyperphosphatemia, undetectable concentrations of parathyroid hormone (PTH), latent tetany signs, history of nephrolithiasis and of subcuticular nuclei calcifications) have confirmed the diagnosis of late onset primary hypoparathyroidism. Significant clinical improvement following introduction of calcium and active form of vitamin D supplementation were achieved. Based on normal blood glucose levels with relatively low daily insulin requirement an attempt at discontinuing insulin therapy was made. In spite of hypoglycemic therapy cessation, patient’s glucose levels remained in the normal range. For the purpose of diagnosis verification oral glucose tolerance test (OGTT) was performed, and did not reveal any glucose metabolism disorders. These observations led us to conclude that recognized hyperglycemia was secondary to prolonged hypocalcaemia.

Conclusions
The optimal concentrations of organism’s cytosolic Ca²⁺ are required for appropriate β-cell insulin release. Hypocalcaemia is regarded as a factor implicated in pathogenesis of glucose metabolism disorders thus normalizing serum calcium levels allows for restoration of adequate insulin secretion.

Hyperparathyroidism jaw tumour syndrome (HPT-JT)
KS Ahmed, M Sherlock, L Stassen, C Timon & ML Healy
1Department of Endocrinology, St. James Hospital; 2Department of Endocrinology, Adelaide and Meath Hospital; 3Department of Maxillofacial Surgery, St. James Hospital; 4St. James Hospital. Department, Dublin, Ireland.

Hyperparathyroidism jaw tumour syndrome (HPT-JT) is an autosomal dominant disease with variable penetrance. Onset is typically in late adolescence or early adulthood. Primary hyperparathyroidism is typically caused by a single
Endocrine Abstracts (2017) Vol 49

Parathyroid adenoma but parathyroid carcinoma occurs in 10–15%. Ossifying fibroma of the mandible or maxilla occurs in 30–40%, and may be locally aggressive. 15% of patients have renal manifestations which include polycystic kidney disease, Wilms tumour and renal cell carcinoma. In women there is an increased risk of uterine tumours. The gene causing HPT-JT, HRPT2, is located on chromosome 1q31.2a, coding for parafibromin (tumour suppressor gene) found in 50–75%.

We recently identified a patient with HPT-JT which led to detection of a kindred with the CDC73 pathogenic variant. A 54-year-old male presented to the maxillofacial services for surgical removal of a jaw tumour. Histology confirmed an ossifying fibroma of the maxilla. During his admission he was noted to have hypercalcaemia (Ca. 12.3 mmol/l; PTH 110 pmol/l). On review of previous history, he described poor dentition since the age of 20, and he reported that his sister had died at the age of 35 from metastatic parathyroid carcinoma. Diagnosis of primary hyperparathyroidism was established and he underwent parathyroid surgery with normalisation of Ca++ and PTH. Histology was consistent with parathyroid adenoma. His genetic analysis detected a mutation in the CDC73 gene (Exon 7 c.664 C to T leading to protein PArg222Ter). Family members were screened, which confirmed CDC73 mutation in one daughter and one son, and 1 son was mutation negative.

Fahr syndrome revealing a pseudoendoparathyroidism

Fatma Chaker, Ons Rjeb & Hedia Slimane

Introduction

Fahr syndrome is a rare entity characterized by the presence of bilateral intracranial calcifications with predilection for the basal ganglia and dentate nuclei. It is commonly associated with endocrine disorders, particularly parathyroid and Vitamin D disturbances. Herein we report a case of pseudoendoparathyroidism revealed by Fahr syndrome.

Observation

A 29-old-year male was referred to our department for symptomatic hypocalcaemia. He showed a decrease in his school performances with memory problems. He reported that his sister had died at the age of 35 from metastatic parathyroid carcinoma. Diagnosis of primary hyperparathyroidism was established and he underwent parathyroid surgery with normalisation of Ca++ and PTH. Histology was consistent with parathyroid adenoma. His genetic analysis detected a mutation in the CDC73 gene (Exon 7 c.664 C to T leading to protein PArg222Ter). Family members were screened, which confirmed CDC73 mutation in one daughter and one son, and 1 son was mutation negative.

Conclusion

In the absence of chronic renal failure, the coexisting of hypocalcaemia, hyperphosphatemia, elevated PTH and normal vitamin D level is consistent with the diagnosis of pseudoendoparathyroidism.

DOI: 10.1530/endoabs.49.EP340

Parathyroid cyst: the forgotten diagnosis of a neck mass

Esperanza Miranda, Mariana Tomé, Carmen Bautista & Daniel Gonzalez

Punta De Europa Hospital, Algeciras, Spain.

Introduction

The differential diagnosis of cystic cervical masses includes thyroid cyst, thymic cyst, thyroglossal duct cyst, branchial cleft cyst, bronchogenic cyst, lymphangiofibroma and parathyroid cyst (PC). PC is one of the less common causes of the cervical masses.

Methods

We report the case of a 37-year-old man admitted to the hospital with a neck mass of 48 mm.

Results

Our patient presented with neck pain and an hypechogetic nodule on ultrasound (US) on the left side of the neck adjacent to the lower pole of the left thyroid lobe. An US-guided fine-needle aspiration was performed and follicular cells where described. Measurement of TSH, T4 and AShPO had a normal result. Given the suspicion of thyroid nodule, >4 cm surgical treatment was decided. While waiting for surgery the US was performed and we observed markedly reduction on the size of the nodule (28 mm) and the radiologist suggested the possibility of a parathyroid adenoma. Our patient referred prior episodes of nephrolitisis a few years ago and that he had been told to had high serum calcium levels but did not undergo further studies. We measured PTHi levels and Calcium (100.5 pg/ml; 10 mg/dl) showing a normocalcemic hyperparathyroidism. Left thyroid lobectomy was performed showing a normal left thyroid lobe, a parathyroid cyst and ectopic thymus.

After nodule resection PTHi levels went back to normal and calcium levels remain less than 10 mg/dl.

Conclusion

PCs are rare lesions and often considered as thyroid cysts. Diagnosis is best made by monitoring serum calcium levels and sending cyst fluid for PTH analysis. Therefore, PCs must be included and be remembered within the differential diagnosis of all neck masses.

DOI: 10.1530/endoabs.49.EP341

“Pseudo or not”: differential diagnosis of hyperparathyroidism with severe electrolyte imbalance in transgender patient: a challenging case report

Ieva Ruzi1,2 & Linda Kundzina2

1Riga Eastern Clinical University Hospital, Riga, Latvia; 2Riga Stradins University, Riga, Latvia.

Introduction

Differential diagnosis between secondary hyperparathyroidism (SHPTH) and possible pseudohypoparathyroidism can be challenging in case of insufficient diagnostic tools and co-existing medical conditions. We report a diagnostic road to final diagnosis.

Case report

A 48-years old white male-to-female transgender patient was admitted to our clinic for evaluation due to mental deterioration, general fatigue, slowly progressing bilateral upper arm and epigastric area cramps over last 2 years, pain in the lumbar area and right hip region leading to reduced mobility. No remarkable history, except crural DVT during estrogen therapy, received from 2004–2015 without any specialist’s supervision, not any therapy used in last year. Possible previous delusion episodes since head trauma during teenage years were reported by patient’s brother. The patient was severely obese. Biochemical tests revealed low calcium (1.74 mM [2.2–2.55]) and potassium (3.12 mM [3.3–3.5]), normal phosphate, creatinine and glucose level. Preliminary suspected Cushing’s and Fahr’s syndromes were excluded after seeing suppressed cortisol axis and elevated PTH (624.2 pg/ml [12–68]). No substantial changes in other tests. No electrolyte loss with 24 h urine was seen. Thyroid and gonadical axis were unchanged. Head CT scan revealed no basal ganglia calcinosis. No data of paratadenoma. In spite of high normal phosphate level and not characteristic phenotype, our first suspected diagnosis was pseudohypoparathyroidism. Additional tests showed low 25(OH) vitamin-D (< 7 ng/ml [30–50]) and elevated alkaline phosphatase (320 U/l [44–147]). Pelvic MRI showed left femoral periosteal cyst formation and right hip joint synovitis.

Though we were restricted in many diagnostic tools due to multiple factors, no further data strongly supported evidence of pseudohypoparathyroidism. Based on these findings we suggest the final diagnosis of secondary hyperparathyroidism with severe osteomalacia. Treatment was continued with calcitriol, cholecalciferol, oral calcium. Some improvement of symptoms was seen over the hospitalization course.

Conclusion

We would like to stress the importance of multi-focused investigation for bone-metabolic problems.

Adolescent onset distal renal tubular acidosis presenting with significant growth retardation without rickets
Sagarjyoti Roy, Sandipan Banik, Indira Maisnam, Aniruddha Ray & Apurba Kumar Mukherjee
R G Kar Medical College and Hospital, West Bengal, India.

Introduction
Distal renal tubular acidosis (RTA) can have varied presentation. Onset in infancy is usually severe. However, adolescent onset has variable presentation ranging from hypokalemia to nephrocalcinosis, and rarely with rickets or growth retardation. We describe a girl with distal RTA presenting with hypokalemia and growth retardation.

Case
12 year old girl presented with recurrent episodes of weakness of all four limbs and failure to gain height and weight for last 4 years. There was no sensory or autonomic involvement. She had normal birth history and developmental milestones, no dysmorphism or bony abnormality, no sensorineural deafness and a negative family history. Nutritional status was average. Height and weight were below Indian Academy of Paediatrics 3rd percentile.

Investigations
K⁺ = 2.9 mmol/l; Urine K = 30 mmol/24 hr (increased). pH = 7.324, HCO3⁻ = 12.4 meq/l, PCO2 = 23.9 mm-Hg; anion gap = 10 mmol/l Urine pH = 7.0. UAG: Positive (28 meq/l), urine calcium-creatinine ratio = 0.6/3N <0.2) ANA & ENA: negative. Genetic testing not done due to non-availability CBC, LFT, serum 25-OH Vitamin D & iPTH, Ca²⁺, P, Ca × P, alkaline phosphatase, FT4/TSH, IGF-1 were all normal. X-ray of wrist: no evidence of rickets. USG Abdomen: Medullary Nephrocalcinosis in both kidneys.

Diagnosis
Growth retardation with hypokalemic periodic paralysis in a case of distal RTA of adolescent onset based on normal anion gap acidosis with high urinary pH with positive urine anion gap gap.

Treatment
She was managed successfully with intravenous potassium and is on oral sodium bicarbonate 500 mg twice daily. Her response is good.

Conclusion
The take home points are that every child presenting with hypokalemia should be evaluated for RTA. The presentation of distal RTA can be subtle to severe. Even in the absence of bony involvement like rickets children can suffer from significant growth retardation. Growth failure should be actively searched for even in asymptomatic patients.

Differential roles of carboxylated and uncarboxylated Osteocalcin in stage I breast cancer as a diagnostic biomarker
Anara Karaca¹, Nese Ersöz Gulcelik¹, Filiz Bakar², Giray Akgül³, Zeynep Sahiner¹ & Mehmet Ali Gulcelik³
¹Ankara Teaching and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey; ²Ankara University, School of Pharmacy, Biochemistry, Ankara, Turkey; ³Ankara Oncology Teaching and Research Hospital, General Surgery, Ankara, Turkey.

Objective
The finding of new biomarkers is needed to have an early diagnosis of breast cancer. In this study we evaluated serum levels of carboxylated osteocalcin (OC) and uncarboxylated osteocalcin (uOC), CRP as a diagnostic biomarker for breast cancer.

Design and methods
Blood samples of 39 women with newly diagnosed breast cancer with stage I were obtained before surgery and 39 age and BMI matched health women were selected as controls.

Results
The mean age was 52±7 years (P = 0.8). Circulating logOC was significantly lower in breast cancer patients compared to controls (2.1±1.23 mg/ml vs. 3± 1.23 mg/ml, P <0.05), while logCRP levels were significantly higher in breast cancer patients than controls (0.8 vs. −0.6, P <0.05). Serum levels of log uOC were not different between groups (6.39 ±0.4 mmol/l vs. 6.39 ±0.9 mmol/l, P = NS). OC had a positive correlation with uOC (r = 0.3, P = 0.03). In contrast, CRP was not correlated with OC and uOC (P = 0.2, P = 0.3, respectively).

Conclusion
We conclude that circulating OC has a potential use as a sensitive diagnostic biomarker for early detection of breast cancer.

Gross CDC73 deletions in young patients with primary hyperparathyroidism in Russia
Elizaveta Mamedova, Natalya Mokrysheva, Evgeny Vasilyev, Iya Voronkova, Elizaveta Orlova, Maria Kareva, Zhanna Belaya, Liudmila Rozhinskaya & Anatoly Tulipakov
Endocrinology Research Center, Moscow, Russia.

Introduction
Hyperparathyroidism-jaw tumour syndrome (HPT-JT) is a rare disorder, which is frequently characterized by the development of parathyroid carcinomas and atypical parathyroid adenomas and, thus, severe course of primary hyperparathyroidism (PHPT).

Case reports
Two patients (1 male and 1 female, 18 y.o. and 13 y.o. at the time of diagnosis of PHPT, respectively) among a cohort of young patients (<40 y.o.) with PHPT, underwent next-generation sequencing (NGS) (Ion Torrent™ PGM™, Thermo Fisher Scientific-Life Technologies, USA) using a custom-designed Ion AmpliSeq™ panel. NGS did not reveal any pathogenic variants in genes associated with familial PHPT in these two patients, but the analysis of the sequence data by the ExomeDepth program [Plagnol V et al, 2012] allowed us to assume the existence of large deletions in CDC73 gene. To confirm this observation MLPA (MRC-Holland, the Netherlands) of CDC73 on ABI 3500XL Genetic Analyzer (Applied Biosystems, USA) was performed. In a male with severe PHPT (serum total calcium 4.49 mmol/l [2.15–2.55], ionized calcium 2.03 mmol/l [1.03–1.29], PTH 1833 pg/ml [15–65], osteitis fibrosa cystica) and histological diagnosis of atypical parathyroid adenoma, a gross deletion including the entire CDC73 gene and four additional genes (TROVE2, GLRX2, R3GALT2 and LIN20103) was detected. In a female with severe PHPT (serum total calcium 3.57 mmol/l, ionized calcium 1.58 mmol/l, PTH 1550 pg/ml, osteitis fibrosa cystica) and histological diagnosis of parathyroid carcinoma, the deletion of 1–10 exons of CDC73 gene was detected. The patients’ mother also had PHPT due to parathyroid adenoma.

Conclusion
These two cases illustrate that NGS data could be successfully applied for indirect assessment of large gene deletions which could be further confirmed by MLPA. Search for CDC73 mutations is necessary among patients with parathyroid carcinomas and atypical parathyroid adenomas, which could occur at any age.

Endocrine Abstracts (2017) Vol 49
secretion: 15 GH-secreting, 3 ACTH-secreting, 1 PRL-secreting, 1 non-functioning PA. Median age at the time of inclusion was 61 years [Q25-Q75: min-max:57–66.5;54–79], median age at the time of PHPT diagnosis was 57 years [Q25-Q75: min-max:54–62;51–72], median age at the time of PA diagnosis was 47 years [Q25-Q75: min-max:40.5–57.5;21–61]. Five patients had mild PHPT, 15 – manifest PHPT (though it was difficult to assess the role of PHPT in osteoporosis development due to concomitant menopause and Cushing disease in some cases). Imaging techniques revealed: in 15 patients – solitary parathyroid tumour, in 2 patients – two parathyroid tumours, in 3 patients parathyroid dysplasia were not visualized. In the majority (n=16) of patients PA was the first manifestation, only in 4 patients PHPT was diagnosed before PA. In all patients no MEN1 mutations were identified by Sanger sequencing, confirming diagnosis of MEN-1 phenotype. Next-generation sequencing of a custom-designed Ion AmpliSeq panel of genes associated with familial PHPT (MEN1, CASR, CDC73, CDKN1A, CDKN1B, CDKN1C, CDKN2A, CDKN2C, CDKN2D) using semiconductor sequencer PGM® Ion Torrent (Thermo Fisher Scientific, USA) was performed. ANNOVAR was used for variant annotation.

Results
No pathogenic or likely pathogenic variants in the abovementioned genes were identified.

Conclusion
Mutations in the genes associated with familial PHPT are unlikely to have any role in the development of MEN-1 phenocopies with combination of PHPT and PA.

DOI: 10.1530/endoabs.49.EP346

Recurrent ectopic parathyroid carcinoma
Julia Krupinova, Natalia Mokrysheva, Anna Eremkina, Ekaterina Pigarova & Svetlana Mirnaya
Endocrinology Research Centre, Moscow, Russia.

Background
In most cases of parathyroid carcinoma (PC) only recurrence could be a credible feature of malignancy.

Clinical case
At the age of 19 years a woman was diagnosed with urolithiasis. At the age of 22 years she had a surgical resection of the neck nodule at the right site in the projection of carotid triangle. After the histological study, ectopic parathyroid tumor was misdiagnosis with paraganglioma (material is available for review). At the age of 37 years the patient noted deteriorating state of health: severe weakness, nausea, vomiting (10 times per day), rapid loss of body weight (10 kg in 6 months). She noted the appearance of nodule in the neck to the right in the projection carotid triangle again. A month later she was diagnosed with a primary hyperparathyroidism: total calcium – 3.0 mmol/l (2.19–2.55), PTH-786 pg/ml (15-65). CT-scan showed two tumors sized up to 3.3*1.7 cm; 3.2*1.3 cm between right m. sternocleidomastoideus and the common carotid artery. The next day the hypercalcemic crisis developed (total calcium – 5.33 mmol/l) and therefore, ectopic parathyroid tumors were urgently resected in our center. PC was diagnosed after a histological examination. At the age of 47 years the local recurrence was diagnosed: total calcium – 3.51 mmol/l, PTH-450 pg/ml. PET/CT showed a focus with the pathologocal accumulation of 18FDG in singles upper jugular lymph node on the right at the level of C3-4, 16,7*19,7 cm. After another surgery, the tumor went through the immunocytochemical analysis which showed a diffuse intensive expression of PTH, Ki-67- 15%

Conclusions
The diagnosis of PC is challenging due to the lack of credible diagnostic criteria.

Treatment of choice in PC is an en bloc resection of the mass with total ipsilateral thyroid lobectomy and central compartment lymphadenectomy and timely detection and resection of mts.

Parathyroid cancer – clinical presentation, prognostic factors and long-term evolution
Beata Jurecka-Lubieniecka1, Barbara Michalik1, Grzegorz Bulã, Jacek Gawrychowski2, Dariusz Kajdaniuk, Bogdan Marek1, Andrzej Takendorf3 & Barbara Jarzab4
1Department of Nuclear Medicine and Endocrine Oncology, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland; 2Department of General and Endocrinial Surgery, Bytom, Silesian Medical University, Katowice, Poland; 3Department of Pathophysiology and Endocrinology, Silesian Medical University, Katowice, Poland; 4Department of Epidemiology and Silesia Cancer Registry, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland.

Background
Parathyroid carcinoma (PC) is a rare endocrine malignancy affecting 0.5–5% of all patients with primary hyperparathyroidism. Due to the rarity of PC there is still lack of prognostic implications of the disease and clear consensus regarding management. Our purpose was to evaluate prognostic factors and treatment outcomes of patients treated at the Department of Nuclear Medicine and Endocrine Oncology.

Methods
The target group covered 44 patients with parathyroid carcinoma treated in years 1995-2016 at the department of Nuclear Medicine and Endocrine Oncology.

Results
All the patients were treated surgically, 17 of them repeatedly, however, only in 19 patients the en bloc resection was performed, 25 patients underwent only parathyroidectomy. During an average 10-year-observation among all the patients operated non-radically the recurrence of the disease appeared. Deaths occurred only in this group, despite radio- and chemotheraphy. An interesting clinical observation are benefits resulting from cinacalcet treatment: taking the medicine only in this group, despite radio- and chemotherapy. An interesting clinical observation are benefits resulting from cinacalcet treatment: taking the medicine
distant metastases and organ complications, mainly renal failure were statistically crucial in patients survival. Occurrence of distant metastases increases the risk of early death seven times (HR = 6.82, P = 0.02) whereas in renal failure the risk increases nine times (HR = 8.92, P = 0.008).

Conclusions
In patients with parathyroid carcinoma, definition of prognostic factors and the role of the radiation, chemotherapy and cinacalcet treatment still has to be elucidated. In our analysis distant metastases and renal failure were critical factors regarding increased risk of death.

Bone mineral density in obese children
Hanna Mikhno1, Anzhalika Solntsava1, Olga Zagrebaeva2 & Natalia Vasilieva2
1Belarusian State Medical University, Minsk, Belarus; 2Republican Center of Medical Rehabilitation and Balneotherapy, Minsk, Belarus

Aim
To evaluate bone mineral density (BMD) and its relationship with calcium (Ca) and phosphorus (P) metabolism in children with obesity.

Methods
We examined 105 children in the University Hospital (Minsk) from 2011 to 2015 yrs. Their anthropometric parameters (height, weight, BMI) were determined. Body composition with evaluating of mineral component were made by dual energy X-ray absorptiometry with the calculation of feet, hands, spine, ribs, hips. BMD (g/cm²), T-test. The levels of Ca and P, alkaline phosphatase (AIP) were determined. All children were divided into two groups: group one – children with obesity (n = 75, boys/B/girls/G = 47/28, age 15.34 ± 2.12 yrs, BMI 32.7 ± 5.3 kg/m²; group 2 – normal-weight control (n = 30, B/G = 19/11, 15.08 ± 2.47 yrs (P = 0.3)), 19.4 ± 2.4 kg/m² (P = 0.0001)).

Results
Legs BMD were increased in boys with obesity (0.94 ± 0.11 g/cm² vs 1.13 ± 0.17 g/cm² (P = 0.03)) compared to control group without significant differences in G (1.29 ± 0.12 g/cm² vs 1.23 ± 0.02 g/cm² (P = 0.5)). Ribs BMD were higher in group 1 children compared to group 2 (B 0.72 ± 0.08 g/cm² vs 0.59 ± 0.06 g/cm² (P = 0.02)); G 0.71 ± 0.05 g/cm² vs 0.65 ± 0.06 g/cm² (P = 0.05)). There were no significant differences in hand BMD (G 0.87 ± 0.10 g/cm² vs 0.85 ± 0.13 g/cm² (P = 0.836); B 0.93 ± 0.14 g/cm² vs 0.85 ± 0.15 g/cm² (P = 0.360)); total (G 1.18 ± 0.09 g/cm² vs 1.11 ± 0.13 g/cm² (P = 0.29); B 1.17 ± 0.13 g/cm² vs 1.06 ± 0.14 g/cm² (P = 0.21)) in obese children compared to control. A significant increase in Ca levels were in obese B compared to control (2.48 ± 0.07 vs 2.41 ± 0.001 mmol/l (P = 0.001)) with no differences in G (2.43 ± 0.09 vs 2.41 ± 1.2 mmol/l (P = 0.86)). There were no differences in P (G 1.23 ± 0.22 vs 0.95 ± 0.64 mmol/l (P = 0.78); B 1.32 ± 0.27 vs 1.30 ± 0.18 mmol/l (P = 0.85)), and AIP (G: 108.06 ± 26.66 vs 85.13 ± 65.64 IU/l (P = 0.46); B: 217.93 ± 57.24 vs 157.72 ± 26.41 IU/l (P = 0.68) in two groups.

Conclusions
A significant increase in ribs and legs BMD, Ca levels were found in children with obesity compared to normal weight control.

Progressive osseous heteroplasia in a child with pseudohypoparathyroidism type 1
Madalina Vintila, Iuliana Ghertan, Cristina Dumitrascu, Anda Dumitrascu & Camelia Procopie
1Endocrinology Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal; 2Internal Medicine Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal.

Introduction
Progressive osseous heteroplasia (POH) is a rare genetic condition of progressive heterotopic ossification (HO), from skin and subcutaneous tissues into deep skeletal muscles. Most cases are caused by heterozygous inactivating mutations of GNAS gene. Related disorders are Albright hereditary osteodystrophy (AHO), pseudohypoparathyroidism (PHP), and primary osteoma cutis. Distinction from other GNAS-based conditions is made by the extension of HO from superficial to deep tissues in POH.

Case report
We present the case of a 10-year-old girl who came to medical attention at 3-months of age for umbhar and scapular subcutaneous ossifications. The biopsy confirmed osseous metaplasia of the connective tissue. The ossification process progressed in size, depth and area, up to painful swelling and mechanical compression in the shoulder. She underwent surgical resection of the scapular lesion at 3-years of age but the ossification recurred 2 years later. There were no congenital hallux valgus or other skeletal deformities. She had clinical features of AHO: round facies, flat nasal bridge, short neck, brachydactyly, obesity. Lab tests revealed mild elevated TSH (4.98 µU/ml) at 5-years of age and later, at 8-years of age, elevated parathyroid hormone (395.9 pg/ml) with hypocalsemia (Ca = 8.1 mg/dl) and hyperphosphatemia (P = 7.18 mg/dl). She was diagnosed as having PHP most probably type IA/c based on the typical clinical findings of AHO phenotype and biochemical profile. She received treatment with calcitroil and levohydroxy. Follow-up examinations revealed moderate progression of the heterotropic ossifications and favourable clinical course with spontaneous puberty and no other hormone resistance identified yet at age of 12.

Conclusions
Overlapping features of POH and PHP type 1 can be present, as part of the spectrum of the heterogeneous GNAS related disorders. Awareness and distinction of these conditions are important for appropriate management.

Genetic variations in the HSD11B1 gene in patients treated with glucocorticoids show associations with bone mineral density

19th European Congress of Endocrinology 2017
Endocrine Abstracts (2017) Vol 49
Physiological glucocorticoids play an essential role in bone formation but can cause osteoporosis if present in excess. The key enzyme converting inactive cortisone into the active cortisol and vice versa is 11-beta-hydroxy-steroid-dehydrogenase (11\(^\beta\)-HSD1). We have reported that genetic variations in the \(\text{HSD11B1}\) gene correlate with increased cortisol levels in dexamethasone suppression and with changes in bone mineral density (BMD) suggesting individual differences in 11\(^\beta\)-HSD1 activity caused by polymorphisms. In this study we investigated the effect of \(\text{HSD11B1}\) SNPs on BMD in patients on glucocorticoid therapy.

**Methods**

In 246 patients treated with different glucocorticoids the \(\text{HSD11B1}\) SNPs rs11811440, rs1000283 und rs932335 were determined. Patients received glucocorticoids due to rheumatoid arthritis or asthma (64%), or other rheumatic, gastrointestinal or pulmonary disorders. An equivalent glucocorticoid dose was calculated for the different glucocorticoids used. BMD of the spine or femoral neck, and the number of fractures and falls were correlated to the \(\text{HSD11B1}\) SNPs.

**Results**

BMD, the number of fractures and falls did not show an association with daily or cumulative equivalent dose or type of glucocorticoid. Since the three genetically linked SNPs in intron 5 of the 11\(^\beta\)-HSD1 gene – rs11811440, rs1000283, and rs932335 \(\text{HSD11B1}\) highly correlated, only rs11811440 was further analyzed. In patients treated with the glucocorticoids prednisolone or methylprednisolone the presence of the A-allele was associated with lower BMD levels.

**Discussion**

Our results suggest that in patients treated with glucocorticoids the function of 11\(^\beta\)-HSD1 is dependent on \(\text{HSD11B1}\) polymorphisms. Hence, inactivation of prednisolone or methylprednisolone by 11\(^\beta\)-HSD1 would be the crucial step for BMD levels in glucocorticoid-treated individuals.

Metabolic syndrome in digestive neoplasms
Sahloul University Hospital, Sousse, Tunisia.

Introduction
The metabolic syndrome (MS) is a real public health problem on a global scale. People with MS are at increased risk not only for cardiovascular diseases but also for neoplasia. The aim of our study is to determine the prevalence of MS in patients with digestive neoplasia and to study the impact of MS on the epidemiological, clinical profile and prognosis of digestive neoplasms.

Material and methods
This is a retrospective study including patients with digestive neoplasia who were hospitalized in our department between January 2015 and June 2016. For all patients, BMI, waistline, systolic and diastolic blood pressure, HDL cholesterol, triglycerides, and blood glucose levels were determined. A MS was defined according to the criteria of the International Diabetes Federation IDF 2005.

Results
78 patients were included (40 men and 38 women), with an average age of 61.7 years (between 28 and 89 years). The digestive neoplasias found were: colorectal cancer (CRC) (n=21.27%), hepatocellular carcinoma (CHC) on cirrhosis liver (n=18.23%), gastric cancer (n=13.16%). Cholangiocarcinoma (n=10.12%), pancreatic cancer (n=9.11%), esophageal cancer (n=3.8%), small bowel lymphoma and a Cancer of the gall bladder in two cases each (n=2.6%). The mean tumor size at diagnosis was 6.2 cm (1.5–18 cm). The tumor was metastatic in 26 cases (33.3%). MS was present in 29 cases (37.2%). The analytical study found that MS was more frequently found in female patients (50% versus 25%, P = 0.022), older patients (68.2 years versus 58 years, P = 0.001) and having a CRC (57% versus 29%, P = 0.027). However, the presence of a MS did not influence the average survival of patients (10.3 months versus 8 months, P = 0.138).

Conclusion
In our study, more than one-third of patients had MS. It was associated with an older age, the female sex and the CRC. However, diagnosis and management of MS remains difficult in these patients because of the malnutrition and weight loss caused by the disease.

Dyslipidemia-associated skin lesions as a short key for etiology unraveling and management of life-threatening acute pancreatitis in young male
Zorán Gluvić1, Bojan Mitrović1, Vladimir Šamardžić1, Jelena Tica Jevtić1, Marina Vujović2, Vesna Popović-Radionović2, Aleksandar Stanojević2 & Esma R. Iseović2
1Division of Internal Medicine, Department of Endocrinology, Zemun Clinical Hospital, School of Medicine, University of Belgrade, Zemun, Serbia; 2Division of Internal medicine, Department of Gastroenterology, Zemun Clinical Hospital, School of Medicine, University of Belgrade, Zemun, Serbia; 3Laboratory for Molecular Endocrinology and Radio-biology, Institute for Nuclear Sciences ‘Vinča’, University of Belgrade, Belgrade, Serbia.

Background
After the gall bladder stones and alcohol abuse, dyslipidemia is among the most frequent causes of acute pancreatitis, especially in youngsters. Some clinical signs can be useful to alleviate either a medical condition diagnosis confirmation or unraveling of its etiology.

Aim
We present a case 30 years old male, presented with nausea, vomiting and diffuse abdominal pain. Three months before hospital admission, patient was unsuccessfully treated for painful, redish skin lesions 5mm in diameter, dispersed on abdominal wall, arms and legs, interpreted as ‘viral papillomata’. Out of mentioned skin lesions-eruptive xanthomata, hypotension, light abdominal tenderness and moderate distention, other physical examination was normal.

Results
Laboratory findings revealed lipemic serum, elevated inflammatory, pancreas and liver necrosis markers, hyperglycemia, hyponatremia and hypocalcaemia. Performed imaging procedures (ultrasound and computed tomography) showed enlarged pancreatic body and tail, and left pleural effusion. Lipemic serum and eruptive xanthomata taken together with other case findings pointed to life-threatening acute pancreatitis caused by mixed dyslipidemia, obviously serious (lipids could not be measured initially). In association with aggressive pancreatitis management, nil-by-mouth treatment with plasmapheresis successfully lowered lipids and enabled their measurement (triglycerides 19.9 mmol/l and cholesterol 10.8 mmol/l). After plasmapheresis, diet and lifestyle, triglycerides and cholesterol levels were 4.04 and 3.99 mmol/l, respectively. Patient was referred to lipid clinic, gastroenterologist and surgeon (formed pancreatic cyst).

Conclusions
Adequately interpreted eruptive xanthomata can act as a shortkey for faster confirmation of acute pancreatitis. Treatment of serious acute pancreatitis and dyslipidemia is done at the same time. Plasmapheresis, as well lifelong diet and pharmacotherapy later, are the mainstay for management of dyslipidaemia that caused pancreatitis (presumably mixed one).

DOI: 10.1530/endoabs.49.EP356

EP357

Metformin and changes in blood pressure and heart rate in lean patients with polycystic ovary syndrome (PCOS)- preliminary study
Marta Kialka1, Tomasz Milewicz1, Marek Klocek2 & Rita Tomczyk1
1Department of Gynecological Endocrinology, Jagiellonian University, Medical College, Cracow, Poland; 2Department of Cardiology and Hypertension, Jagiellonian University, Medical College, Cracow, Poland.

Introduction
The aim of our study was to assess the value of blood pressure and heart rate using the 24-h blood pressure monitoring (ABPM) before and after treatment with metformin to patients with polycystic ovary syndrome (PCOS) and normal lean. Material and methods
20 patients received metformin 1500 mg/day in three divided doses. ABPM was performed to each patient with PCOS twice: before and after 6 months of treatment with metformin.

Results
In patients with PCOS and normal lean after treatment with metformin we observed: statistically significant lower systolic blood pressure (120.2 ± 22.33 mmHg vs 113.22 ± 21.43 mm Hg, P = 0.0248); lower systolic blood pressure of daily measurements (127.1 ± 32.13 mmHg vs 116.1 ± 22.08 mmHg, P = 0.0062); reduction in average arterial pressure MAP daily measurements (95.52 ± 27.76 mmHg vs 88.36 ± 16.41 mmHg, P = 0.048); oscillometric pressure reduction (96.27 ± 27.93 mmHg vs 87.82 ± 21.61, P = 0.0004 mmHg); oscillometric pressure reduction of daily measurements (102.1 ± 27.93 mmHg vs 91.85 ± 21.61 mmHg, P = 0.0032); oscillometric pressure reduction in the measurement of the night (88.81 ± 24.83 mmHg vs 82.22 ± 20.54 mmHg, P = 0.0089). In women after treatment with metformin has also been observed higher average heart rate (65.82 ± 21.61/min vs. 70.71 ± 24.85/min; P < 0.01).

Conclusions
Treatment with metformin in patients with PCOS and normal lean leads to lower blood pressure and increases the frequency of heart rate.

DOI: 10.1530/endoabs.49.EP357
In patients with type 2 diabetes mellitus (T2DM), cardiovascular lesions are 3-4 times more often than in non-diabetics. Screening for T2DM in 1564 people from all Ukraine revealed that 12% had HbA1c at 6.1–6.4% and 16% had HbA1c above 6.5%. Those with HbA1c above 6.5% were examined for BMI, glycemia, total cholesterol, HDL-C, non-HDL-C. Dyslipidemia was defined as total cholesterol over 5.20 mmol/l, HDL-C – less than 1.02 mmol/l for males and less than 1.29 mmol/l for females. Total cholesterol averaged 6.41±0.03 mmol/l in screened men and 6.23±0.01 in women. HDL-C was respectively 1.89±0.08 and 1.85±0.07 mmol/l. Whereas non-HDL-C was 4.60±0.02 and 3.38±0.05 mmol/l respectively. As for total cholesterol, objects were divided into the following groups (in mmol/l): 5.2; 5.3–5.6 and over 5.6. Males with these indicators were distributed: 38%, 37%, 5%, females – 28%, 64% and 8% respectively. According to correlation of total cholesterol to fasting glucose, men with glycemia under 6.1 mmol/l had cholesterol 5.70±0.01 mmol/l, those with glycemia 6.2–7.8 mmol/l had cholesterol 5.90±0.05 mmol/l and those with glycemia over 7.8 mmol/l had cholesterol 5.99±0.04 mmol/l. While in women, cholesterol levels were (mmol/l): 4.86±0.03, 6.09±0.03, and 7.50±0.03 in relation to the above mentioned levels of glycemia. In accordance with division of BMI into normal weight, overweight and obesity, cholesterol levels in males were (mmol/l): 5.81±0.06, 6.12±0.04 and 6.10±0.05 respectively, while in females 5.48±0.04, 5.56±0.02 and 5.77±0.01. Consequently, dyslipidemias were found in 70% of our group with T2DM of both sexes. They are induced by increase in serum estradiol. Serum estradiol was determined by ECLIA. Male IC females were characterized by: higher (P<0.05) serum TCH, lower (P<0.05) hepatic TCH and its biosynthetic precursors, lower (P<0.05) hepatic 7α-hydroxysterol but elevated (P<0.05) 27- and 24-hydroxysterol in comparison to YA IC. Both GEN and DAI decreased (P<0.05) hepatic 27-hydroxysterol, with no effect on any other parameter of cholesterol metabolism. We obtained age-related reduction of serum estradiol, which was reversed by both soybean phytoestrogens. In conclusion, age-related dyslipidemia was associated with reduced 7α-hydroxysterol, main intermediate of neutral pathway, and higher 27—hydroxysterol, main intermediate of alternative acidic pathway of Chol degradation to bile acid. Both GEN and DAI lowered hepatic 27-hydroxysterol, which might be associated with elevated serum estradiol concentrations. Further research is needed to examine this possibility.

**Soybean phytoestrogens reduce 27-hydroxysterol concentration in the liver of middle-aged female rats**

Branka Sošić-Jurjević1, Snežana Janjović1, Dieter Lütjohann1, Ivana Jurić1, Marko Miler1, Branko Filipović1, Vladimir Ajdžanović1 & Verica Milošević1

1 Institute for Biological Research ‘Simina Stanković’, University of Belgrade, Belgrade, Serbia; 2 Institute for Science Application in Agriculture, University of Belgrade, Belgrade, Serbia; 3 Institute für Klinische Chemie und Klinische Pharmakologie Universitätssklinikum Bonn, Bonn, Germany.

Hypercholesterolemia is associated with atherosclerotic disease, a leading cause of mortality worldwide. Advances in both dietary and pharmacological interventions contribute to prevention and treatment of modifiable risk factors. Purified soybean phytoestrogens, isoflavones genistein (GEN) and daidzein (DAI), were reported to exert moderate cholesterol-lowering effect. In this research first we studied age-related modifications in hepatic cholesterol metabolism and serum estradiol concentration of acyclic middle-aged (MA) female rats. Then we tested if purified isoflavones may prevent or reverse these changes. Serum and hepatic total cholesterol (TCH), bile acid and cholesterol precursors were determined by comparing data obtained for MA with young adult (YA) intact (IC) females. Effects of subcutaneously administered GEN or DAI (35 mg/kg per day during four weeks) to MA rats were evaluated vs vehicle (sterile olive oil) – treated MA females. After decapitation, perfused rat livers and serum were used to determine total cholesterol (TCH), its oxidative metabolites (7α-, 27- and 24-hydroxysterol) and precursors (lanosterol, desmosterol, dihydro-lanosterol and lathosterol), using gas chromatography/mass spectrometry. Serum estradiol was determined by ECLIA. MA IC females were

**Awareness and prevalence of metabolic syndrome among high-risk individuals attending internal medicine clinics across Jordan**

Rania Efraish1, Rana Abu Farha2 & Eman Alefshat1

1 Medical Supply Department, Directorate of Royal Medical Services, Amman, Jordan; 2 Department of Clinical Pharmacy and Therapeutics, Faculty of Pharmacy, Applied Science Private University, Amman, Jordan; 3 Department of Biopharmaceutics and Clinical Pharmacy, Faculty of Pharmacy, The University of Jordan, Amman, Jordan.

**Purpose**

To examine the prevalence and awareness of metabolic syndrome (MetS) in high-risk individuals attending 30 internal medicine clinics in Amman, Jordan, and also to evaluate the various factors associated with increased risk of MetS among them.

**Methods**

This retrospective cross-sectional study was carried out across Amman, Jordan from October to December 2014. During the study period, 900 high-risk individuals (with hypertension, diabetes, central obesity and/or dyslipidemia) were recruited from thirty internal medicine clinics in Amman, Jordan. Data collection forms were filled based on patient interview and medical case file.

**Results**

The prevalence of MetS among high-risk individuals was around 40% (361/900), with around 79% (284/361) of MetS patients unaware of their condition. Older age, lower income and family history of premature cardiovascular diseases were associated with a higher prevalence of MetS.

**Conclusion**

Although MetS was found to be highly prevalent among high-risk individuals in this study, the awareness of the condition in this group is very poor. These findings support the need for educational programs that involve both health care providers and patients. These programs should especially target those at risk of MetS, in order to improve awareness of the concept of MetS.

**Nine months of practice in California - self-referrals in endocrinology**

Jelena Maleškovic

UCLA, Los Angeles, California, USA.

**Objective**

A great number of patients are self-referred to endocrinologist. Most of these patients had some research of their symptoms and have a specific diagnosis that they want to investigate.

**Method**

A retrospective chart review of 628 new consults conducted in one outpatient endocrine office at University of California, Los Angeles was conducted.
Results
Of the 628 new patients 326 were referred by another physician and were excluded from further review. Of 302 self-referred patients 248 patients had a preexisting endocrine diagnosis and were excluded. The remaining 54 patients were being endocrinologist for the first time and these patients were included in further study. Most common complaints were: weight gain (78% of patients), fatigue (72%), cold intolerance (46%), heat intolerance (31%), constipation (24%). Other common complaints observed were hair loss, low libido, erectile dysfunction, anxiety, palpitations, weight loss, hirsutism, acne, muscle weakness, stretch marks, buffalo hump and polydipsia. When asked if they had a specific hormone abnormality in mind most of the patients reported that their main concern was hypothyroidism (69%), high cortisol level (13%), low testosterone (10%), low cortisol (5%), hyperthyroidism (5%), diabetes insipidus (4%), diabetes mellitus (2%). After conducting endocrine studies based on presenting symptoms none of the 54 patients were found to have confirmation of suspected diagnosis. Four patients were found to have elevated TPO antibodies but thyroid functions tests were normal. Six patients were found to have diabetes mellitus that was previously not diagnosed or suspected. Two patients were found to have elevated cholesterol.

Discussion
Common problems lead to online research that offers a number of endocrine conditions as a possible underlying problem. With access to subspecialist care oftentimes unnecessary work-up is done.

Conclusion
A longer period of investigation would add valuable data in determining the impact of self-referrals on subspecialty practices as well as health care in United States in general.

Identifying underdiagnosed or undertreated patients with familial hypercholesterolemia from the central laboratory registries
Cem Haymana1, Hamza Berlik2, Yalcin Gunes2, Orhan Enes Tuncer2, Cihat Aytekin2, Zafer Tapikara2, Huseyin Guzel2, Ozlem Ozturk3, Cem Barcin4, Taner Ozgurtas3, Omer Azal1 & Alper Sonmez1
1Department of Endocrinology and Metabolism, Gulhane Training and Research Hospital, Ankara, Turkey; 2Gulhane School of Medicine, Health Sciences University, Ankara, Turkey; 3Department of Biochemistry, Gulhane Training and Research Hospital, Ankara, Turkey; 4Department of Cardiology, Gulhane Training and Research Hospital, Ankara, Turkey.

Objective
Familial hypercholesterolemia (FH) is a life-threatening genetic disease associated with elevated low density lipoprotein cholesterol (LDL-C) and premature coronary heart disease that is globally underdiagnosed and undertreated. This study aimed to search for the demographical characteristics, awareness and treatment adherence of underdiagnosed or undertreated FH patients from the records of the central biochemistry laboratory.

Methods
Patients with a central laboratory measurement of LDL-C >250 mg/dl were identified. Patients with older than 18 years without secondary causes of dyslipidemia were called by medical students and interviewed about demographic characteristics, awareness of dyslipidemia and treatment adherence.

Results
A total of 147 patients (mean age 51.7 ± 16.6 years, 59.2% female) were interviewed. The mean LDL-C levels were 292.8 ± 49.9 mg/dl. According to the Dutch Lipid Clinic Network Criteria, the patients with definite, probable and possible FH were 18.4%, 66.0% and 15.6%, respectively. Although the majority of the patients (93.9%) were aware of their high LDL-C levels, only about half of them (n=75, 51.0%) were under treatment. Of all the patients who were interviewed, 21% (n=31) had never taken, and 28% (n=41) had stopped taking lipid-lowering drug.

Conclusion
The results of this pilot study show that, undiagnosed or undertreated FH patients can practically be detected from the high LDL-C registries of the Hospital Laboratories. Nationwide implementation of this method may help us reach and manage these high-risk patients.

The effect of admission hyperglycemia on clinical outcome of ischaemic stroke patients
Vina Yanti Susanti1, Iswandi Darwis2 & Fidha Rahmayani3
1Internal Medicine Department, Universitas Gadjah Mada/Sardjito General Hospital, Yogyakarta, Indonesia; 2Resident on Internal Medicine Department, Universitas Gadjah Mada/Sardjito General Hospital, Yogyakarta, Indonesia; 3Resident on Neurology Department, Universitas Gadjah Mada/Sardjito General Hospital, Yogyakarta, Indonesia.

Background and objective
Hyperglycemia exacerbates multiple deleterious derangements and this process would influence the clinical outcome in diabetic patient. The objective of this study is to know the effect of admission hyperglycemia on clinical outcome of ischaemic stroke patients admitted in Sardjito General Hospital.

Method
Observational cohort study over 5 months’ period from August 1-2016 to December 31-2016 was done. All patients 18 years old and above, admitted as stroke ischaemic patients in Sardjito General Hospital Yogyakarta were screened. In order to qualify, patient were subjected to initial random blood sugar determination upon admission and monitored to 48–72 h. Capillary blood glucose was monitored using blood glucose monitor device by Bayer. Hyperglycemia status is blood glucose above 200 mg/dl. Clinical outcome was evaluated and recorded using The National Institutes of Health Stroke Scale (NIHSS) on day 1 and discharge. Participants who are below 18 years old, previously stroke, or those with acute co-morbid disease like acute myocardial infarction, pneumonia, or critical infection, ketoacidosis diabeticum, hyperglycemia hyperosmolar state were all excluded. All patients managed according to guidelines for stroke and hyperglycemia.

Result
Sixty four eligible subjects admitted at Sardjito General Hospital, 12 (19.35%) were hyperglycemia and 50 (80.65%) normoglycemia. The mean value of blood glucose at admission were 153.45 ± 69.09 mg/dl. Patients who have worsening clinical outcome at discharge are 18 (29.03%) based on NIHSS. Six patients (44.4%) who had hyperglycemia had worsening clinical outcome and four patients (9.09%) did not have worsening clinical outcome (P-value 0.003; OR 8; min 2 001–max 31 988).

Conclusions
Hyperglycemia at admission have correlate with worsening of clinical outcome ischaemic stroke patients.

Keywords
Hyperglycemia; Ischaemic stroke patients; The National Institutes of Health Stroke Scale.

Deleting genomic region of Hsd17b1 in mice results into a hypomorphic Naglu allele, and consequently to a phenotype mimicking a lysosomal storage disease
Heli Jokela1, Janne Hakkarainen1, Pirjo Pakarinen1,2, Suvi Ruohonen1, Fuping Zhang1 & Matti Poutanen1,2
1University of Turku, Turku, Finland; 2Turku Center for Disease Modeling, Turku, Finland.

Abstract
Hydroxysteroid 17-beta dehydrogenase 1 (HSD17B1) is an enzyme catalyzing the reduction of estrone (E1) to estradiol (E2), as well as androstenedione (Adione) to testosterone (T). To elucidate the physiological function of HSD17B1, we generated knockout mice with disrupted Hsd17b1 gene using targeted ES cells (clone 10231) obtained from KOMP repository (www.komp.org). In these ES cells the whole coding region of Hsd17b1 was replaced with LacZ/Neo cassette, expressing the reporter gene. As previously shown by us, the homozygous Hsd17b1-LacZ/Neo females were found to be subfertile and have a defect in pseudopregnancy maintenance, likely caused by the imbalance in ovarian steroid synthesis. In addition, the Hsd17b1-LacZ/Neo males present with a metabolic phenotype, including reduced adipose mass, increased lean mass and lipid accumulation in the liver. During the characterization of the metabolic phenotype, it became evident that the expression of N-acetyl-alpha-glucosaminidase (Naglu) gene, located 8399-739 bp upstream of the Hsd17b1 transcription start site, was severely reduced (13-40-fold) in all tissues analyzed in Hsd17b1-LacZ/Neo mice. Furthermore, similar results were observed from Hsd17b1-LacZ/Neo mice after removing the Neo cassette or by crossing the Hsd17b1-LacZ/Neo mice with transgenic mice constitutively expressing human HSD17B1. Deficiency of the Naglu gene causes the accumulation of glycosaminoglycans (GAGs) in several tissues, and accordingly, GAG accumulation was observed in all the above mentioned mouse models lacking the genomic region coding for Hsd17b1. Furthermore, biochemically and morphologically similar metabolic phenotype, mimicking lysosomal storage disease, was observed both in Naglu knockout mice (with the presence of active HSD17B1), and all the mouse models lacking 2.3 kb long genomic region of Hsd17b1 gene. Thus, the data indicate the presence of a strong Naglu enhancer inside the Hsd17b1 gene, and the metabolic phenotype in mice lacking the Hsd17b1 genomic region is caused by the off target effect.

Salivary lactate levels during anaerobic threshold (AT) training
Hugo Ogando Beraa1, Laura Tobu Estevez1, Juan Fandiño Gómez1, Yolanda Diz Chaves1, Jose Luis Garcia Soidán1, Lucas Gonzalez Matías1 & Federico Mallo Ferrer1
1Labendo, Cbinbo, Vigo University, Campus Lagoas-Marcosende s/n 36310 Vigo, Spain; 2Faculty of Educational Sciences and Sports, University of Vigo, Campus a Xunqueira, s/n 36005 Pontevedra, Spain.

Anaerobic threshold (AT) is defined as the point of maximum intensity at which lactate is being produced but does not accumulate in blood during exercise. Training at this intensity is common in athletes. Lactate is currently regarded as indicator of effort intensity. It is usually quantified by reflectometry of capillary blood. This procedure although not very invasive, may be annoying during repeated measurements. Saliva is proposed as an alternative sample. The objective of the present study is to quantify the variation of salivary lactate levels during AT training, in order to prove its usability in this field. 10 male subjects (32 ± 2.96 years) performed a treadmill test recording intensity (watts/min), VO2 and heart rate (HR) to determine AT. After two days resting they performed 6 running series of 1km at AT rhythm with 2 minutes of resting between series. Saliva samples by Salivette system (SARSTEDT, Germany) and HR were taken at pretest, the end of each series, and 3, 6 & 9 min of resting after. Eating, smoking, drinking (except water) or teeth brushing was forbidden in 2 h previous to test. Salivary lactate concentrations increased significantly from 1st to 3rd series (P = 0.002). Afterwards, a plateau of salivary lactate concentration was observed in all subjects up to the end of the series (4th-6th). After a small reduction, an additional increase in salivary lactate was also consistently observed after 6 min of rest. HR hardly changed during the exercise series. Since we can conclude that: The salivary lactate was increased according to the accumulated workload despite exercise was performed at constant intensity (AT). That was confirmed because the heart rate (HR) hardly changed at this constant rate. Since, saliva lactate levels in an AT training are independent of heart rate and mostly of effort intensity.

The effect of tocilizumab – an interleukin-6 receptor antagonist – on lipid levels in rheumatoid arthritis
Ilgenia Kostoglou-Athanassiou1, Lambros Athanassiou2, Akaterini Tzanavari1, Charoula Katsavouni1, Markos Kostopoulos2, Dimitrios Pantelidis2 & Panagiotis Athanassou1
1Department of Endocrinology, Red Cross Hospital, Athens, Greece; 2Department of Rheumatology, St Paul’s Hospital, Thessaloniki, Greece.

Tocilizumab is an interleukin-6 receptor antagonist used in the treatment of rheumatoid arthritis (RA). It is known to induce remission and inhibit radiographic progression in RA. Tocilizumab may be administered either intravenously or subcutaneously. Its effect on lipid levels and the cardiovascular risk has not been fully investigated. The aim was to study the effect of tocilizumab i.v. on disease activity, lipid levels and cardiovascular risk in RA patients. Tocilizumab was administered i.v. once monthly in 25 patients with RA for a period of 1 year. Inflammation indices, ESR and CRP and lipid levels were measured before and 1 year after tocilizumab administration. The DAS28 disease activity index was also calculated.

Inflammation indices ESR and CRP decreased from 34.3 ± 4.04 mm/h and 2.02 ± 0.34 mg/dl before to 8.3 ± 1.62 mm/h and 0.27 ± 0.07 mg/dl, respectively (P < 0.001) after tocilizumab administration. The DAS28 disease activity index decreased from 5.02 ± 0.26 to 2.42 ± 0.26 after tocilizumab (P < 0.001). Total cholesterol and HDL cholesterol increased from 207.4 ± 8.53 mg/dl and 57.68 ± 2.65 mg/dl before to 231.08 ± 12.30 mg/dl and 72.51 ± 4.76 mg/dl, respectively (P < 0.001) after tocilizumab administration. LDL cholesterol and triglyceride levels increasing from 126.8 ± 7.45 mg/dl and 108.48 ± 7.83 mg/dl before to 136.17 ± 9.39 mg/dl and 130.58 ± 15.82 mg/dl, respectively (P < 0.001) after tocilizumab. No acute cardiovascular events were recorded during the study. Tocilizumab administered i.v. in patients with RA was shown to decrease inflammation indices and disease activity. Lipid levels increased significantly. However, total cholesterol increased in parallel with HDL cholesterol. Cardiovascular events were not observed during the study period. It appears that tocilizumab may be accompanied by lipid level alterations, cardiovascular risk not increasing as the adverse effects of total cholesterol may be countered by HDL cholesterol.

Homocysteine-significant marker of metabolic syndrome and atherosclerosis risk
Branko Srećkovic1, Vesna Dimitrijevic-Srećkovic2,3, Ivan Soldatovic3,2, Hristina Janeski1, Nenad Janeski1, Jasna Gacic1, Mirjana Sumarac-Dumanovic2,3 & Igor Mrdovic1
1Clinical Center Bezanija Kosa, Belgrade, Serbia; 2Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; 3Institute for Medical Statistics and Informatics, Belgrade, Serbia; 4University Children’s Hospital, Belgrade, Serbia; 5Clinical Hospital Center Zemun, Belgrade, Serbia; 6Clinic for Cardiovascular Diseases, Clinical Center of Serbia, Belgrade, Serbia; 7Faculty of Medicine, Belgrade University, Belgrade, Serbia.

Background
Obesity is followed by insulin resistance (IR) and low grade inflammation. In patients with metabolic syndrome (MS) and clinically evident vascular complications homocysteine values are higher. Hyperhomocysteinemia correlates with hyperinsulinemia and IR, resulting in oxidative stress, which causes endothelial lesions and dysfunction, promoting atherosclerosis and hypertension. Objectives
To examine homocysteine levels in patients with and without MS, and find correlation between factors of MS and homocysteine values.

Methods
The study included 76 obese individuals (age over 30, BMI ≥ 25 kg/m²) classified into two groups: I- with MS (35 patients); II- without MS (41 patients). OGTT was used to evaluate the extent of glucose regulation disorder. IDF classification was

DOI: 10.1530/endoabs.49.EP367
applied for diagnosing MS. SI MS risk score by Soldatovic I et al 2016 was used. IR was determined by HOMA IR. Serum CRP was measured by immunometric assay. Microalbuminuria was determined immuno-nephelometrically. Homocysteine was determined by immunassay FIAA-Abbot.

Results
Patients with MS had increased WC: (I-110.6 ± 15.4, II-115.4 ± 15.4 cm), BMI: (I-35.3 ± 6.6, II-30.4 ± 7.4 kg/m²), blood pressure (I-136.4 ± 15.9 / 90.5 ± 9.5, II-118.4 ± 12.2/78.1 ± 9.7 mmHg), glycaemia (I-5.4 ± 1.6, II-4.8 ± 0.8 mmol/l), HOMA IR (I-8.8 ± 9.4, II-5.3 ± 8.8 mmol/l/μl per ml), triglycerides (I-2.17 ± 1.95, II-1.45 ± 0.7 mmol/l), CRP (I-7.7 ± 0.0, II-3.7 ± 3.8 mg/l), microalbuminuria (I-8.74 ± 8.1, II-56.4 ± 56.9 mg/24h), homocysteine (I-13.0 ± 3.2, II-11.8 ± 3.7 μmol/l) and decreased HDL (I-1.07 ± 0.2, II-1.35 ± 0.35 mmol/l). Statistical significance between groups was found for WC, BMI, systolic and diastolic pressure, triglycerides, HDL-cholesterol (P < 0.001) and CRP. Apo B, HOMA IR (P < 0.005). Correlations: Homocysteine with systolic and diastolic pressure, Apo B and hyperlipoproteinemia (P < 0.05). SI MS risk score with homocysteine (P < 0.001), r = 0.263.

Conclusion
Abdominal obesity, hypertension, hypertriglyceridemia, inflammation factors, IR, homocystein and microalbuminuria as markers of endothelial dysfunction were more present in patients with MS. Correlation of homocystein values with SI MS risk score indicates that it is significant co-founding factor of MS. Correlation of homocystein with hypertension and hyperlipoproteinemia indicates importance of homocystein as significant marker for atherosclerosis.

Graft vs host disease and insulin resistance after bone marrow transplantation
Panagiotis Athanassiou1 & Ifigenia Kostoglou-Athanassiou2
1Department of Rheumatology, St Paul’s Hospital, Thessaloniki, Greece; 2Department of Endocrinology, Red Cross Hospital, Athens, Greece.

Graft vs host disease is a disorder in which the graft, i.e. bone marrow, attacks the host after bone marrow transplantation. It has various manifestations, one being skin and muscle involvement with cutaneous sclerosis and diffuse muscle pain. The aim was to describe the case of a patient with graft vs host disease complicated by insulin resistance and metabolic syndrome, after bone marrow transplantation for the treatment of acute lymphoblastic leukemia. A patient, male, aged 2.5 years old, developed acute lymphoblastic leukemia. He was treated and the disease went into remission. At the age of 7 years, the patient had a recurrence. He was found to be compatible with his elder brother and bone marrow transplantation was performed. During the following months the patient developed a skin eruption, diffuse cutaneous sclerotic lesions, muscle edema and pain. He was treated with thalidomide and cyclosporine and clinical manifestations of graft vs host disease improved. Diffuse skin and muscle involvement improved. The patient developed hypertriglyceridemia and insulin resistance. Metformin and fenofibrate were administered. The patient developed also hypothyroidism. Thyroxine was administered. At the age of 29 the patient developed proioriasis like lesions in the maxilla and the external genital organs. In conclusion, the case of a patient is described with graft vs host disease after bone marrow transplantation for the management of acute lymphoblastic leukemia. Graft vs host disease may have various clinical manifestations. In the case described skin and muscle involvement, along with insulin resistance and metabolic syndrome were the predominant manifestations.

Coronary artery calcium score in prediabetes – preliminary results
Milica Marjanovic Petkovic1, Ivana Sasic1, Miljanka Vukanovic1,2 & Teodora Beljic Zivkovic1,2
1Zvezdara University Medical Center, Belgrade, Serbia; 2Belgrade University School of Medicine, Belgrade, Serbia;

Introduction
Coronary artery calcium (CAC) is examined through multislice CT. Calculations indicate late-stage subclinical coronary atherosclerosis. An association exists between CAC with coronary vascular disease (CVD), Agatston score being an independent predictor of CVD. Including CAC may improve CV risk prediction in addition to conventional risk factors. The AIM of our study was to assess CAC in subjects with prediabetes (preDM) at the beginning of the long term follow-up for occurrence of cardiovascular disease.

Methods
After diagnosing preDM with oral glucose tolerance test and HbA1c, ECG was performed and subjects were evaluated for CVD risk. Score charts were used to calculate the CVD risk. Thereafter, all subjects were appointed for multislice CT to obtain the CAC.

Results
70 subjects with preDM were screened for CVD. CAC score of 0 was present in 32 subjects. Minimal calcifications with a CAC score of 1–10 AU were present in 12 subjects with pre DM. Moderate calcification of 11–100 AU were present in 15 subjects. Nine subjects had significant calcifications with 101–400 AU. Two subjects had a CAC score of 100 AU which meant significant calcifications. Score risk below 2% was present in only 19 subjects, while a score risk of 15% and more was present in 23 subjects. No significant correlation was found between Score charts and CAC. However, a trend of finding more calcifications in those with a 10% and above Score risk was noted.

Conclusion
An approach to risk assessment that combines the traditional risk factor-based paradigm with a more personalized atherosclerosis-imaging model may be appropriate for high risk individuals, such as subjects with pre diabetes.

Cardiometabolic risk and female sexuality: focus on clitoral vascular resistance
Elisa Maseroi1, Egidia Fanni1, Irene Scavello1, Francesca Pampaloni1, Cesare Battaglia2, Massimiliano Fambrini1, Edoardo Mannucci1, Emmanuele A Jannini1, Mario Magli1,4 & Linda Vignozzi1,4
1University of Florence, Florence, Italy; 2University of Bologna, Bologna, Italy; 3Tor Vergata University of Rome, Rome, Italy; 4Istituto Nazionale Biostrutturare e Biosistemi, Rome, Italy.

The relation between sexual and cardiovascular health in women is not well defined. Clitoral colour Doppler ultrasound (CDU) with assessment of the pulsatility index (PI), reflecting resistance to blood flow, has been proposed as an objective measurement of sexual functioning. We aimed to investigate the associations between clitoral PI and cardiometabolic risk factors. Seventy-one adult heterosexual women attending our clinic for sexual dysfunction were consecutively recruited. Clitoral PI was positively correlated with BMI (P < 0.0001), waist circumference (WC; P < 0.0001), glycaemia (P = 0.029), insulin (P = 0.002), homeostatic model assessment index (P = 0.005), triglycerides (P = 0.011), total cholesterol (P = 0.016), and LDL-cholesterol (P = 0.016). All relations, with the exception of glycaemia, retained statistical significance after adjusting for age, smoking habit, and years since menopause (P < 0.0001 for BMI, WC and triglycerides; P < 0.05 for all other associations). Analysis of covariance, after adjusting for confounders, showed that women with obesity or metabolic syndrome (MetS) showed significantly higher PI values (obyey = P = 0.001; MetS: P = 0.019). In particular, a stepwise increase of PI was found as a function of increasing MetS components (P = 0.007). Clitoral PI was negatively associated with Female Sexual Function Index arousal (P = 0.014) and satisfaction (P = 0.026) scores and positively associated with Middlesex Hospital Questionnaire somatized anxiety symptoms, even after adjusting for confounders (P = 0.011). A positive association also was observed between PI and the Body Uneasiness Test (BUT) positive symptom distress index (P = 0.039) and BUT for dislike of the womb, genitals, and breast (P < 0.0001; P < 0.0001, respectively). After introducing WC as another covariate, the associations between clitoral PI and the BUT positive symptom distress index and BUT dislike of the womb, genitals, and breast retained statistical significance (P = 0.038 for positive symptom distress index; P = 0.0001 for dislike of womb, genitals, and breast). Clitoral vascular resistance is positively associated with MetS (in particular insulin resistance), decreased sexual arousal, body image concerns, and increased somatized anxiety symptoms. Further studies are needed to establish whether treatment of metabolic abnormalities might improve clitoral CDU indices and sexual outcomes.

Metformin and changes in serum lipid profile in lean patients with polycystic ovary syndrome (PCOS)

Marta Kiałka1, Tomasz Milewicz2, Anna Wajda1, Patrycja Czekanska1, Barbara Zdziezak1 & Sandra Mrozinska2
1Department of Gynecological Endocrinology, Jagiellonian University Medical College, Cracow, Poland; 2Department of Metabolic Diseases, Cracow, Poland.

Introduction

The aim of our study was to assess the values of total cholesterol, HDL-C, LDL-C and triglycerides before and after treatment with metformin in patients with polycystic ovary syndrome (PCOS) and normal lean.

Material and methods

32 patients received metformin 1500 mg/day in three divided doses. Lipids measurements were performed to each patient with PCOS twice: before and after 6 months of treatment with metformin.

Results

In patients with PCOS and normal lean after treatment with metformin we observed: statistically significant lower LDL-C levels (4.16 ± 0.79 mmol/l vs 3.4 ± 0.86 mmol/l, P < 0.05) and triglycerides levels (1.8 ± 0.53 mmol/l vs 1.12 ± 0.64 mmol/l, P < 0.05). We observed an increase in HDL values and a decrease in total cholesterol values, but these changes were not statistically significant (1.5 ± 0.71 mmol/l vs 1.71 ± 0.69 mmol/l, P = 0.09; 5.87 ± 0.92 mmol/l vs 5.69 ± 0.97 mmol/l, P = 0.11).

Conclusion

Our study showed that treatment of 1500 mg metformin for about 6 months among PCOS women result in improvement in serum lipids. We observed a significant decrease in LDL-C and triglycerides values after metformin treatment.

The role of leptin signalling in the development of cardiovascular diseases in obesity

Stephanie Simonds & Michael Cowley
Monash University, Melbourne, Victoria, Australia.

Cardiovascular diseases are the greatest cause of death globally. Obesity significantly increases the risk for the development of cardiovascular diseases. However research does not under stand the physiological and molecular connections of these diseases. We have identified that the hormone leptin in obesity plays a key role in elevating blood pressure in obesity. However recent findings in humans treated with lepin in the disease state of lipodystrophy, did not result in the elevation of blood pressure. In the research present here we suggest that one reason as to why lepin fails to increase blood pressure in lipodystrophy patients is that plasma leptin concentration in not increasing high enough. For the development of cardiovascular complications in obesity plasma leptin concentration needs to increase significantly to concentrations similar to that of obese animals (ten times the concentration measured in lean animals). In rodents we dose dependent demonstrate the differing effects of concentrations of leptin on changes in body weight, food intake, brown adipose tissue temperature, blood pressure and heart rate. We can demonstrated in obese hypertensive mice that changes to the signaling components of specific neurons within the Dorsomedial Hypothalamic leptin receptor expressing neurons in the brain can substantially change leptin's influence on cardiovascular control. Hence we can control in rodents the development of hypertension in obesity, via manipulating the responsiveness of leptin receptor responsive neurons. We are mapping the connections of this specific subset of neurons and are gaining a true understanding on how the adipose derived hormone leptin plays a key role in the development of cardiovascular diseases.

Prevalence of major cardiovascular risk factors among people living with HIV in a low risk country for cardiovascular disease

Carolina García-Figuera Mateos & Manuel Cayón-Blanco
Hospital Jerez de la Frontera, Jerez de la Frontera (Cadiz), Spain.

Introduction

It is well known that the prevalence of major cardiovascular risk factors has increased in HIV-infected people since improvement of antiretroviral therapy. Currently, Spain is defined as a ‘low risk country’ for cardiovascular diseases (CVD) by 2016 European Guidelines on cardiovascular disease prevention. The objective of this study is to assess the prevalence and characteristics of CVD risk factors and risk for CVD in a cohort of HIV-infected adults living in the South of Spain according to current guidelines.

Methods/design

Cross-sectional study. Measurements included anthropometry, blood pressure, fasting lipids and glucose assessment. Demographic, clinical, immunological, and antiretroviral therapy data were obtained from electronic medical records. 10-year risk of heart disease or stroke was calculated using the SCORE- European low risk chart.

Results

218 patients were evaluated. Hypertriglyceridemia was the most prevalent disturbance (44.3%) found, followed by low HDLc levels (41.7%). 8.7% of the cohort had hypertension and 6.9% had type 2 diabetes. 68.5% were current smokers. High risk (10-year risk of fatal CVD > 10%) was found in 13.3% of the cohort. People at higher risk were mostly men (100% vs 81%; P = 0.005), had higher BMI (25 ± 2 vs 23 ± 2.7 kg/m²; P = 0.04) and had a lower CD4 count (405.5 ± 156.2/mm³ vs 551.5 ± 211.7/mm³; P = 0.035) and were more likely to receive protease inhibitors (48% vs 30%; P = 0.04).

Conclusions

According to our results, the prevalence of major risk factors for CVD is high in HIV-infected patients of our area, especially among those with worse immunity and higher BMI. Physicians should screen their patients for metabolic and cardiovascular risk at the regular visits to reduce CVD risk among people with HIV. Changes in antiretroviral therapy to more metabolic neutral antiretroviral drugs may also be considered.

Influence factors on lipid profile among patients with rheumatoid arthritis

Manuel Cayón-Blanco1, Carolina García-Figuera Mateos1, Raúl Menor-Almagro2 & Mario H Cardiel Rico3
1Hospital Jerez de la Frontera, Jerez de la Frontera (Cadiz), Spain; 2Universitary Hospital Virgen del Rocio, Seville, Spain; 3Hospital Dr. Miguel Silva, Morelia, Mexico.

Introduction

Patients with rheumatoid arthritis (RA) face an increased risk of developing premature cardiovascular disease and limited ability to modify risk factors such exercise or dietetic habits. Influence of exercise, dietetic habits or treatment on lipid profile has been little studied in patients with RA. Here we aim to determine differences in lipid profile between two cohorts of patients with RA with different habits and patterns of treatment.

Methods/design

Cross-sectional study. Lipid profiles of 50 RA out-patients from South Spain were compared with 50 age and sex matched controls from Central Mexico. Traditional risk factors were analyzed such as overweight or obesity, smoking status and hypertension. Glucose and lipid profiles as well as dietetic habits and physical activity were recorded.

Results

RA patients from Spain were more likely to practice physical activity (66.7% vs 33.3%; P = 0.001), had lower BMI (24.9 ± 4.6 kg/m² vs 26.7 ± 3.6 kg/m²; P = 0.004). No significant differences in smoking status, prevalence of diabetes (steroid induced diabetes or type 2 diabetes), alcohol consumption or mean dose of steroid treatment were found. Regarding to lipid profile, Mexican patients had lower levels of LDLc (86.3 ± 31.5 vs 128.7 ± 24.9 mg/dl; P < 0.001) In contrast, the European population had lower levels of triglycerides (124.9 ± 14.6 vs 145.3 ± 3.6 mg/dl; P < 0.001) and higher HDLc (60.5 ± 12.8 vs 52.1 ± 21.4; P < 0.005).

Conclusions

In patients with RA, exercise can modulate lipid profile favourably irrespective of corticoid dose or steroid induced diabetes. More accurate studies focusing on specific nutrients would be useful to confirm our results.

Oxidative stress and metabolic profiles assessment after melatonin and irbesartan co-administration in a novel pharmaceutical formulation

Cristina Manuela Dragoi, Alina Crenguta Nicolae, Daniela Elena Popa, Ion-Bogdan Dumitrescu, Andreea Letitia Arsene, Corina Grigore & Cristina Elena Dinu-Pirvu

University of Medicine and Pharmacy ‘Carol Davila’, Faculty of Pharmacy, Bucharest, Romania.

The concurrence of glucose intolerance, hypertension, dyslipidemia and obesity has been termed metabolic syndrome. Each component of the metabolic syndrome is an independent risk factor for cardiovascular disease and diabetes type 2, the combination of these risk factors elevating the rates and severity of cardiac pathology.

The therapeutic use of irbesartan, a selective blocker of the AT1 receptors, administered in arterial hypertension, coronary heart disease and diabetic nephropathy, is extremely important due to the presence of these receptors both centrally and in the periphery.

Melatonin is an endogenous indoleamine hormone synthesized by the pineal gland. Melatonin release into the circulation is augmented in darkness and decreased during exposure to light, and facilitates the synchronization of the body’s physiologic systems to circadian patterns. Melatonin shows properties of a powerful antioxidant, at sufficiently high concentrations as a direct radical scavenger, but, at lower, near-physiological levels, as a regulator of redox-relevant enzymes, suppressor of prooxidant excitatory and inflammatory processes and as a mitochondrial modulator. Increased oxidative stress has emerged as playing a central role in metabolic syndrome and its component pathologies and may be a unifying factor in the progression of this disease. In the present study, we evaluated in a hamster experimental model, the influence of irbesartan and melatonin, co-administered in a novel pharmaceutical multiparticulate formulation, on metabolic markers and oxidative profile. Our results depicted blood glucose, serum cholesterol and triglycerides lowering effects, being maximum for the new formulation irbesartan and melatonin, revealing a potentiating effect of the two drugs. On the oxidative status, the new formulation presented a tremendous decreasing effect, due to the simultaneous release in the bloodstream the two medicines, depicting a synergic unique effect, reasoning the use of the two molecules in a single pharmaceutical formulation.

The dual FXR/TGR5 agonist INT-767 counteracts nonalcoholic steatohepatitis and visceral adipose tissue dysfunction in a rabbit model of high fat diet-induced metabolic syndrome

Paolo Cornegli2, Ilaria Cellai2, Sandra Filippi1, Annamaria Morelli3, Erica Sarchielli3, Luciano Adorini4, Mario Magni2,3 & Linda Vignozzi2,3

1Interdepartmental Laboratory of Functional and Cellular Pharmacology of Reproduction, Department of Neuroscience, Psychology, Drug Research and Child Care, University of Florence, Florence, Italy; 2Sexual Medicine and Andrology Unit, Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; 3L.N.B.B., Rome, Italy; 4Intercept Pharmaceuticals, New York, USA; 5Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy.

The nuclear Farnesoid X receptor (FXR) and the G protein-coupled bile acid receptor 1 (TGR5) are bile acids receptors that play a key role in energy metabolism. In an animal model of non-genomic metabolic syndrome (MetS), obtained with a high fat diet (HFD), treatment with the dual FXR/TGR5 agonist INT-767 reduced visceral adipose tissue (VAT) accumulation, insulin resistance, hypercholesterolemia and nonalcoholic steatohepatitis (NASH). In liver, INT-767 reduced the high macrophage M1 (pro-inflammatory)/M2 (anti-inflammatory) ratio observed in MetS. Furthermore, INT-767 increased the expression of: IL10 and FOXP3, markers of M2 macrophage and Treg cell, respectively; PPARz, marker of hepatic fatty acid metabolism; VAMP4 and Syntaxin5, markers of lipid droplet formation; IRS1 and STAMP2, markers of insulin signaling while decreased lipogenesis markers. Moreover histomorphological sign of NASH were significantly improved by INT-767.

MetS induced insulin resistance, which shows VAT derangements like adipocytes hypertrophy and reduced GLUT4 translocation to membrane. Treatment with INT-767 counteract these VAT alterations and induced the expression of brown adipocytes markers. The analysis of adipocytes (rPADs) obtained with a high fat diet revealed that INT-767 increased insulin sensitivity and mitochondrial ultrastructure and dynamic whereas reduced superoxide production. In rPADs, when compared to HFD, INT-767 increased the expression of CIDEA and TME3 (brown fat markers); TFAM and NRF1 (mitochondriogenesis markers); SDHB (membrane respirative chain marker) and MFN2 and FIS1, (mitochondria fusion/fission markers).

To conclude, INT-767 significantly improve MetS and VAT alterations induced by HFD, restoring insulin sensitivity and inducing the differentiation of rPADs to a metabolically healthy phenotype.

Prevalence of metabolic syndrome and its relation to physical activity and nutrition in Azerbaijan

Afruz Mammadova1,2, Selen Yilmaz Isikhan3, Aylin Acikgoz4 & Okan Bulent Yildiz2,5

1Department of Internal Medicine, Hacettepe University School of Medicine, Ankara, Turkey; 2Azerbaijan Medical University Therapeutic Training Clinic, Baku, Azerbaijan; 3Department of Biostatistics, Hacettepe University School of Medicine, Ankara, Turkey; 4Department of Nutrition and Dietetics, Faculty of Health Sciences, Hacettepe University, Ankara, Turkey; 5Division of Endocrinology and Metabolism, Hacettepe University School of Medicine, Ankara, Turkey.

Aim

Metabolic syndrome is a major public health challenge associated with an increased risk for cardiovascular disease and type 2 diabetes. The prevalence of metabolic syndrome in Azerbaijan is unknown. The purpose of this study was to examine the prevalence of metabolic syndrome and its relation to physical activity and nutrition in a representative sample of adult population in Azerbaijan.

Methods

The study population consisted of 288 adults, 20 years of age and over, from Guba, Azerbaijan recruited between January and April of 2016 by random sampling in line with the gender and age distribution. Revised NCEP/ATP III criteria were used to define metabolic syndrome and prevalence estimates of each individual component were determined. Physical activity and food consumption were assessed with validated questionnaires and their relations with components of metabolic syndrome were evaluated.

Results

The participants were 159 women and 129 men (mean ± s.d. age of 43.1 ± 15.2 y (range 20–83 y)). Overall prevalence of metabolic syndrome was 28.4%. Abdominal obesity was the most common individual component (49% and 85.4% in whole population and in those with metabolic syndrome respectively). Interestingly, it was also the only component that was more common in women than men (P < 0.005 for both whole population and patients with metabolic syndrome) whereas the other components did not show a gender difference. The odds ratio for having metabolic syndrome was 0.56 (95% CI, 0.34–0.95) in moderate-high physical activity group compared to low physical activity group suggesting a reduced risk of metabolic syndrome with increased physical activity. Total calorie intake, protein, fat and carbohydrate consumption did not show a significant difference in participants with and without metabolic syndrome.
Conclusions
Metabolic syndrome in Azerbaijan is common and associated with low physical activity. Preventive measures should be taken to address this public health problem and related risk factors in the country.

Isolated low HDL-Cholesterol in patients with type 2 diabetes about 168 cases
El Ansari Nawal, Habra Bahia & El Mghari Ghizlane
Endocrinology, Diabetes and Metabolic Diseases Mohammed the 6th University Hospital, Faculty of Medicine, Cadi Ayyad University, Marrakesh, Morocco.

Introduction
Lipid abnormalities in diabetics both quantitative and qualitative contribute to the increased cardiovascular risk.

Aim
The aim of this study is to determine the prevalence of isolated hyoHDLémie in type 2 diabetics and assess cardiovascular risk in two populations of type 2 diabetes with and without Low HDL-Cholesterol isolated.

Patients and methods
Prospective study started in diabetic patients seen in diabetologic consultation at the University Hospital of Marrakech.

Preliminary results
One hundred and sixty eight patients were identified, 72% female. The average age of patients was 55 years, average duration of diabetes was 7 years, hyoHDLémie was found in 40.4% of cases (68 patients), the prevalence of isolated hyoHDLémie is estimated at 26.19% (44 cases), with overall cardiovascular risk estimated at more than 20% in the group of patients with isolated Low HDL-Cholesterol.

Discussion
Lipid disturbances are widely studied in diabetic patients, but few studies have examined the Low HDL-Cholesterol isolated. In diabetic patients, current treatment guidelines target low-density lipoprotein cholesterol (LDL-C) with statins. In patients with elevated TGs, non-HDL-C is considered a secondary treatment guidelines target low-density lipoprotein cholesterol (LDL-C) with statins. In patients with elevated TGs, non-HDL-C is considered a secondary target of therapy. Despite the use of statin therapy in diabetes, a significant number of fatal and nonfatal coronary heart events still occur, indicating the need to target other modifiable risk factors for coronary heart disease, including Low HDL-Cholesterol. This study shows a high prevalence of isolated diabetes correlated with cardiovascular risk also important that the interests of the target of therapy.

Isolated low HDL-Cholesterol isolated. In diabetic patients, current treatment guidelines target low-density lipoprotein cholesterol (LDL-C) with statins. In patients with elevated TGs, non-HDL-C is considered a secondary target of therapy. Despite the use of statin therapy in diabetes, a significant number of fatal and nonfatal coronary heart events still occur, indicating the need to target other modifiable risk factors for coronary heart disease, including Low HDL-Cholesterol. Can hypoglycemic episodes in type 1 diabetes trigger cardiac arrhythmias?
Kelly Regina Lainetti, João Pimenta, Márcio Faleiros Vendramini & José Luiz B. Cassiolato
Hospital do Servidor Público Estadual, São Paulo/SP, Brazil.

Type 1 diabetes mellitus (DM1) accounts for 5 to 10% of DM cases, and can occur both in childhood and adults. Studies show an association between severe hypoglycemia and increased vulnerability to cardiac arrhythmias due to conduction disorders, interval ST-segment changes, and even sudden death. The aim of this study is to evaluate the occurrence of cardiac arrhythmias during episodes of hypoglycemia. A prospective study with DM1 patients under insulin therapy for at least 5 years, aged 18–60 years, of both sexes. Before study initiation, all patients underwent a two-dimensional echocardiogram and laboratory tests, and those who did not present structural heart disease or any hormonal alterations that could cause arrhythmias, were included. The study was approved by the Research Ethics Committee of the Institution and after signed the

Informed Consent Forms, the intermittent interstitial glucose reading device (IPro2 - Medtronic/USA) was implanted and simultaneous electrocardiographic recording was performed by the Holter system (Cardios Systems/Brazil). The patients were monitored for hypoglycemia (defined as interstitial glucose value <70 mg/dl according to the International Diabetes Federation without any induction for this occurrence and arrhythmia detection for 24 hours. Twenty-two patients were studied. From these eight patients (36.3%) did not have hypoglycemia: two patients (25%) had no arrhythmia, while six patients (75%) had arrhythmias interpreted as non-significant. Hypoglycemic events were detected in the other 14 patients (63.7%), corresponding in this scenario from 4% (55 minutes) to 68% (16 hours) of total monitoring time. In this group, seven patients (50%) presented no arrhythmia, while the other seven patients (50%) had some non-significant arrhythmia that is common in non-diabetic subjects, being more prevalent as ventricular and supraventricular extrasystoles, isolated/paired with low frequency and sinus tachycardia. In the evaluated group, we find no relation between episodes of hypoglycemia and clinically relevant cardiac arrhythmia.

EP381
Family hypercholesterolemia: about 4 cases
Aicha Bouzid & Djamil Minees
Dr, Algiers, Algeria.

Familial hypercholesterolemia (HF) is a rare hereditary dyslipidemia characterized by a major elevation of LDLc, cutaneo-teninous xanthomas and atheromatous manifestations. This anomaly exposes a high vascular risk, more than 50% for men and 30% for women, occurring early.

Observations
We report four cases of HF from the same family, three girls and one boy and whose parents are affected by hypercholesterolemia. The average age of patients is 11 years. Only the eldest siblings present tendon xanthomas. The mean total cholesterol is 3.45 g/l, the average LDLc is 2.80 g/l, the mean HDLc level is 0.37 g/l, the average triglyceride level is 1.30 g/l. The search for vascular and cardiac repercussions was negative outside aortic narrowing in the elder. For lack of means the genetic diagnosis could not be made.

Discussion
Xanthomas were the main manifestation in this family. The presence of these clinical signs led to the prescription of a biological check-up in search of a lipid perturbation and of early vascular pathologies. Familial hypercholesterolemia results from a lack of binding and internalization of LDL through the LDL receptor. Identification of the mutation should be systematically performed. Genetic diagnosis provides diagnostic certainty and facilitates family screening.

Description of an educational intervention lifestyle program in reducing cardiovascular risk factors
Eduardo Oliveira
Universidade Estadual do Pará, Belém, Pará, Brazil.

Goals
The purpose of this article is to describe an educational program of lifestyle intervention rather successful, taught for 25 groups of customers of a private hospital in Amazon, for a total of 2,215 individuals between 2008 and 2014, 1,448 being female and male 767 and briefly assess its results in relation to some of the main risk factors.

Methods
The PVS - Programa Vida Saudável, promotes evaluations and individual group counselling, consisting of two phases, the first being, with eight meetings of the group with the multidisciplinary team in 12 weeks, followed by the second phase, with monthly meetings during 52 weeks for a total of 15 months. Clinical evaluations occur with individual counselling and laboratory dosages at the beginning and end of each phase, as well as an assessment of reaction to the end of each of the sessions. The goals of the intervention were presented progressively and easy to perform encouraging the adoption of habits and health principles, widely established.

Endocrine Abstracts (2017) Vol 49
Results
We analyse those who obtained 75% or more of the meetings frequency (n=1723) in 15 months and as controls, those who did the assessments and exams, however, did not participate in the educational program (n=132). Preliminary results showed a significant evolution in the percentage of each risk factor in patients with blood glucose reduction, improvement in cholesterol, with reduction in LDL-c reduction in triglycerides, reduction in blood pressure and weight reduction.

Conclusion
Based on studies of the data, this program of health education (PVS) presented a good adhesion of the customers and proved to be effective to reduce the risk levels in its active participants.

Role of lactate dehydrogenase-A (LDH-A) in atherosclerosis
Keun Guy Park, Yeon Kyung Choi, Kwi Hyun Bae & Jung Beom Seo
Kyungpook National University Hospital, Dae Gu City, Republic of Korea.

Pathological proliferation and migration of vascular smooth muscle cells (VSMCs) has been implicated in the pathogenesis of accelerated atherosclerosis in patients with diabetes mellitus. Increased aerobic glycolysis is a key feature of cellular phenotypes including cancer and immune cells. However, it remains largely unknown about the role of aerobic glycolysis in atherogenic phenotype of VSMCs. Here, we investigated the role of lactate dehydrogenase-A (LDH-A), which is a key enzyme for glycolysis, on proliferation and migration of VSMCs. Activation of VSMCs with platelet-derived growth factor (PDGF) or fetal bovine serum (FBS) resulted in cellular proliferation and migration and increased glycolytic activity accompanied by the increased expressions of glucose transporter 1 (GLUT1), hexokinase (HK) 2 and LDH-A in primary rat VSMCs. Through wound healing assay, actin stress fiber staining and transwell migration assay, we observed that both pharmacological inhibition (oxamate) and siRNA-mediated knockdown of LDH-A (siLDH-A) effectively inhibited cellular migration. Oxamate reduced PDGF stimulated glucose uptake, lactate production, ATP production and NAD+ nicotinamide adenine dinucleotide (NADH) ratio. Nicotinamide mononucleotide (NMM), nucleotide precursor of NAD+, partially but significantly recovered oxamate treatment or siLDH-A induced inhibition of VSMC proliferation and migration, suggesting NAD+ involvement in LDH-A mediated VSMC proliferation and migration. Taken together, this study shows that enhanced aerobic glycolysis in PDGF- and FBS-stimulated VSMCs plays an important role in their proliferation and migration and suggests that LDH-A can be a potential therapeutic target for the prevention of vessel lumen constriction in the course of atherosclerosis or restenosis.

Prediction of type 1 diabetes in autoimmune polyglandular syndrome type 2
Ahuza Karaca, Nese Ersöz Gulcelik, Tulay Omma, Isilay Taskaldiran, Sevde Nur Firat & Nujen Bozkurt
Ankara Teaching and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey.

Introduction
Autoimmune Polyendocrine Syndrome (APS) is a very rare endocrinopathy, characterized by the coexistence of at least two glandular autoimmune mediated diseases. In this case a patient presented with hyperpigmentation of the whole body, significant weight loss for last 6 months. Case A 49-year-old male were referred to our department with loss of appetite, fatigue, nausea, weight loss and with marked buccal pigmentation. Blood pressure was 80/50 mmHg. Biochemistry revealed fasting glucose:95 mg/dl, Na:127 mmo/l, K:5.35 mmo/l, Hb:16.6. CT abdomen showed normal adrenal gland morphology with no local masses or infectious pathology. Pituitary MRI demonstrated enlarged heterogeneous gland with 9 mm height, probably due to high ACTH levels. All findings were consistent with Addison disease, which was confirmed with morning cortisole of 2.44 mg/dl (normal range 6-22), ACTH: 1250 pg/ml (0-46).

Once Addison’s disease had been confirmed, other autoimmune diseases regarding APS were undertaken. Subclinical hypothyroidism with autoimmune thyroiditis; TSH:8 (0.4-5.3), FT4: 0.9 ng/dl (0.6-1.25), anti-TPO:1016 IU/ml (0-9) was detected. Despite his normoglycemia; C-peptit:1.69 ng/ml, fasting insulin:22.3 uIU/ml, A1c:5.6%, he had high anti-GAD and anti-sellet cell antibodies, widely used as a diagnostic and predictive tool for type 1 diabetes mellitus, indicating that he may develop type 1 diabetes mellitus in future. After a week of steroid replacement his physical discomforts were alleviated with improved electrolytes.

Discussion and Conclusion
Herein, we reported an uncommon case, who had complete two-glandular deficiency with third component; predicted type 1 diabetes. This patient is being monitored closely on glycaemic state. Therefore, once an autoimmune disease is identified, the early screening for antibodies against associated disease such as anti-TPO, GADA, ICA, and antibodies to 21-hydroxylase is crucial, which facilitate the diagnosis of further disorder at an early stage.

Insulin autoimmune syndrome (Hirata Disease) triggered by a tyrosine kinase inhibitor drug in a Latin American patient
Susana Mallea Gil, Carolina Ballarino, Daniel Lotero Polesel, Maria Teresa Kleine, Emilio Batagelj & Nicolas Picon
Hospital Militar Central, Buenos Aires, Argentina.

Hirata syndrome is a rare cause of spontaneous hypoglycaemia, more prevalent in Japanese population, very infrequent in Caucasian patients. It has been described that it can be triggered by medication with sulfhydryl compounds or z-lipoic acid. A 73-year-old male patient was sent to the Endocrinology Division in December 2015 because he had been presenting with episodes of sweating, palpitations and feeling hungry for 6 months; these symptoms improved when he ate carbohydrates. In the last 15 days before his visit, the episodes worsened, every 3 hours. The patient had a history of a synchronous bilateral clear cell renal carcinoma, the right kidney was removed in 2007, and the left renal carcinoma was not surgically removed because he presented worsening of a large thoracoabdominal aortic aneurysm and the patient refused to be operated due to the high risk involved in this surgery. He was treated with sunitinib, but this drug was switched to sorafenib because of adverse effects in 2008. In 2013, he presented cancer progression and he began treatment with pazopanib but there was no response and the oncologist decided to switch to axitinib 10 mg/day in 2014. A year later the patient began with endocrine symptoms. Pancreatic CT and MRI were normal. Lab tests: glycaemia 41 mg%, insulin >1000 uIU/ml (N: 0-12) C-peptide: 5.4 ng/ml (N: < 2.6). Insulin antibodies were performed: >50 U/ml (N: < 10) which confirmed the diagnosis of Hirata disease. Axitinib was stopped immediately and fractional eating was indicated. The hypoglycaemic episodes became progressively less frequent and some days there were no episodes. HLA analysis revealed the HLA-DRB1*04:15 allele. As the patient improved, insulin antibodies were repeated but they remained elevated. The patient had renal cancer progression and died a year after.

Conclusions
Episodes of hypoglycaemia with very high levels of insulin in a non-diabetic patient suggest a probable autoimmune origin. This is the first report of Hirata disease triggered by Axitinib, a drug not previously involved in this syndrome. Another novel finding is that HLA phenotype results in HLA-DRB1*04:15 allele, which has not been described before neither in Asian nor in European patients and this may be due to the fact that this patient is Latin American.

**Fulminant diabetic ketoacidosis complicating nivolumab immunotherapy**

Ploutarchos Tzoulis1, Justin Stebbing2, Elly Baker2, Daniel Heaton1 & Richard Corbett1

1Whittington Hospital, London, UK; 2Imperial College/Imperial Healthcare NHS Trust, London, UK.

A 56-year-old woman, recently commenced on immunotherapy as second-line treatment for advanced non-small cell lung cancer, presented at the hospital critically unwell with severe diabetic ketoacidosis (DKA) (glucose 47 mmol/l, blood ketones 7.5 mmol/l, pH 6.95, bicarbonate 6.6 mmol/l). One week prior to presentation, she was clinically well with random glucose of 6.1 mmol/l. Following admission to Intensive Care Unit, she responded well to standard treatment for DKA and discharged on basal bolus insulin regime. Her anti-GAD antibodies were 12 kU/l (0-5 kU/l), while islet cell antibodies and serum C-peptide were undetectable. Nivolumab has been recommenced without the development of other immune-mediated phenomena to date. Besides metastatic lung adenocarcinoma diagnosed 3 years ago, she had no personal/family history of diabetes mellitus (DM), while venous glucose had been normal at numerous measurements. She was initially treated with Pemetrexed and Cisplatin followed by Pemetrexed as maintenance chemotherapy which was discontinued due to side-effects two months prior to her emergency presentation. At that stage, Nivolumab every 2 weeks was initiated. She has maintained good radiological and clinical response to treatment.

Nivolumab is an anti-PD-1 monoclonal antibody and as a checkpoint inhibitor acts as an immunomodulatory antibody that augments the anticancer immune response through downregulation of T-cell inhibition. Immunotherapy has a beneficial effect in an increasing number of tumour sites, but is associated with immune-mediated endocrinopathies. Development of new-onset type 1 DM after receiving anti-PD-1 antibodies, especially as single agent, is extremely rare. This patient developed fulminant type 1 DM leading to severe DKA and remains insulin dependent. Both endocrinologists and oncologists need to recognise this potentially life-threatening complication and to monitor patients for hyperglycemia prior to and periodically during immunotherapy. Further studies examining the pathophysiology and natural history of immunotherapy-associated diabetes are warranted in order to guide optimal patient monitoring and management.

**Dyslipidemia and antiretroviral therapy: a case report**

El Meghari Ghizlane, Elbahi Meryam, Rafii Sana & El Ansari Nawal

Faculty of Medecine and Pharmacy, Marrakech, Morocco.

Introduction

The use of highly active antiretroviral therapy in 1996 helped greatly reduce the morbidity and mortality in patients infected by HIV. Very quickly, secondary metabolic complications to this same treatment have been described. Dyslipidemia occupy a large part of these complications and give the patients an atherogenic profile favouring the occurrence of acute coronary events. We report a case that illustrates the lipid abnormalities associated with anti retroviral treatment.

Case report

The subject was 54 years old woman, diabetic for 8 years, without history of hypertension or smoking. BMI was 29 Kg/m², diagnosed as HIV infected for 1 year, treated by antiretroviral therapy. Her initial lipid profile reveals a moderate hypertriglyceridemia of 2.5 g/l, total cholesterol was 1.7 g/l and HDL cholesterol was 0.3 g/l. High plasma viral loads persisted after 6 months of antiretroviral therapy, thus the patient was considered to have a treatment failure. The control of her lipid profile, after 2 months of a second-line combination therapy, reveals an aggravation of her previous dyslipidemia with a severe hypertriglyceridemia of 6.36 g/l, an hypercholesterolemia of 2.72 g/l and HDL cholesterol was 0.4 g/l.

Discussion

While the retroviral infection itself, especially at the AIDS stage, is responsible for an increase in triglycerides and a decrease in total cholesterol, antiretroviral therapy exacerbates abnormal lipid metabolism. This is mainly dyslipidemia with predominant hypertriglyceridemia, associated with an increase in total cholesterol and LDL-cholesterol; HDL-cholesterol is either lowered or slightly modified, these abnormalities are partly due to increased hepatic synthesis of large VLDL and decreased purification of remnants rich in triglycerides. The Knowledge of lipid abnormalities induced by antiretroviral treatment is critical for better patient management between infectiologist, biologist and endocrinologist.

**Diabetic patient with suppurative thyroiditis caused by Salmonella enterica complicated with acute kidney injury**

Alessandra Hermi1, Ewelina Szczepanek-Paluska3, Bogusz Falkowski1, Hanna Komarowska2, Anna Wejman-Mateła2, Michał Drews1 & Marek Ruchala1

1Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; 2Department of General, Endocrine and Gastrointestinal Oncological Surgery, Poznan University of Medical Sciences, Poznan, Poland.

Incidence of acute thyroiditis is about 0.1% of thyroid gland conditions requiring surgical treatment. Main pathogen causing acute thyroiditis is Staphylococcus aureus while Salmonella enterica is extremely rare. Here we report a 61-year-old obese woman with sore throat and fever. She had chronic atrial fibrillation, hypertension, and well-controlled type 2 diabetes mellitus (HbA1C 5.5%) for 3 years (on metformin and glitaziders). Her medical history was negative for thyroid and renal disorders. Ultrasound examination (US) of the neck demonstrated mixed solid/cystic lesion. Moreover, empirical therapy with cldamicyn was introduced (1.2 g/day) and the patient was referred to the endocrinology department. On admission she was weakened and dehydrated. Physical examination revealed restricted, swollen, tender and painful lesion in the lower part of the neck. Laboratory tests indicated inflammation, acute kidney injury and hyperthermia. Fine-needle aspiration biopsy (FNAB) of the lesion was performed. Cytological diagnosis was consistent with acute thyroiditis, while microbiologically Salmonella enterica was identified as pathogenic factor. Blood and stool cultures were negative for Salmonella. Neck CT revealed thyroid lesion 6.8 cm in size. Patient received adequate therapy for acute kidney injury (mostly probably clindamycin-induced). I. v. treatment with ceftazidime according to antibiogram and thiamazole was administered. The patient was qualified for incision and percutaneous drainage. She was discharged after 11 days of hospitalization presenting significant clinical improvement. A year later on US six mixed solid/cystic lesions of size below 1 cm were visualized, benign on FNAB. She remains clinically and biochemically euthyroid. Typical infections with Salmonella concern gastrointestinal tract, while conditions associated with atypical infections are: HIV infection, transplant recipients, diabetes mellitus, thyroid gland disorders (e.g. multinodular goiter, after FNAB), anatomical abnormalities (piriform sinus fistula), corticosteroid therapy, advanced age, neoplastic disease and contact with breeding animals. The only risk factor for acute thyroiditis in our patient was diabetes mellitus, although it was well-controlled.

**Improved xanthomas after leptin replacement short therapy in congenital lipodystrophy patient**

Antonio F Oliveira-Filho1, Irla A Dantas3, Renata N Velloso1, Sofia N P de Oliveira2, Diego F F Candido2 & Adriana Nunes1

1Paráiba Health State Department, Campina Grande, Brazil; 2Federal University Campina Grande, Campina Grande, Brazil; 3Federal University Rio Grande Norte, Natal, Brazil; 4Faculty of Health Sciences, João Pessoa, Brazil.

Berardinelli-Seip syndrome is an autosomal recessive disorder characterized by generalized lipodystrophy, extreme insulin resistance with dyslipidaemia in childhood and development of diabetes and hepatic steatosis in adolescence. The metabolic derangements can be severe and lead to substantial comorbidities, including acute pancreatitis, hepatic cirrhosis, and premature cardiovascular disease. Other manifestations can include polycystic ovarian syndrome, acanthosis nigricans, and eruptive xanthomas. Lipodystrophy syndromes have caught interest because adipose tissue has been found to secrete a variety of cytokines/hormones such as leptin, adiponectin, resistin, and many others. Here we describe a dramatic response to treatment with leptin. A 15-year-old girl was given the diagnosis of Berardinelli-Seip congenital lipodystrophy syndrome (BSCL). She presented generalized lipodystrophy, muscle hypertrophy, xanthomas in elbows legs and soles, umbilical hernia, hirsutism, hyperphagia, acanthosis nigricans and hepatomegaly. Her BMI was 20.67 kg/m², body fat was 5.72%, and BMR was 1 440.3 Kcal. Computer tomography revealed hepatic steatosis, one cyst on the right kidney, and absence of subcutaneous and adipose tissues. Patient had difficult to manage metabolic parameters, requiring 3000U of insulin and combined therapy. She started a leptin-replacement therapy (1 ml/day). After ten days, her xanthomas became vanished, cholesterol levels decreased from 550 to

19th European Congress of Endocrinology 2017 Vol 49

Endocrine Abstracts (2017) Vol 49
196 mg/dL, and triglycerides 5.000 to 840 mg/dL. She observed progressive reduced fasting blood glucose and insulin dose simultaneously with improvement in clinical signs, symptoms and quality of life. In a ten days course, leptin replacement showed to be able to manage metabolic state of the patient and xanthomas.

1Endocrinology and Nutrition, Hospital Doctor Negrín, Las Palmas de Gran Canaria, Spain; 2Internal Medicine, Hospital Doctor Negrín, Las Palmas de Gran Canaria, Spain.

A 49-year-old male was referred to our Hypertension Clinic with uncontrolled hypertension, treatment Valsartan/Amlodipine/Hydrochlorothiazide 80/10/25 mg + Doxazosine 4 mg. Mean home BP was 156/103 mmHg. Personal history: dyslipidaemia, central obesity and type 2 diabetes, with mild diabetic retinopathy, persistent microalbuminuria and preserved renal function. Treatment: Metformin/Sitagliptin 1000/50 mg; Pravastatin/Fenofibrate 40/160 mg. Height 172 cm, weight 112 kg, BMI 37.8 kg/m², waist 126 cm, clinic BP 165/109, HR 77, unremarkable physical exam except abdominal adiposity. Glycemia 132 mg/dL, HbA1c 7.2%, Cr 0.92 mg/dL, GFR (CKD-EPI) 97 mL/min per 1.73 m². Cholesterol 166 mg/dL, HDL 38, LDL 96, Triglycerides 161 mg/dL, Albuminuria 126 mg/g Cr; TSH, Metanephrines, Aldosterone, PRA and ratio were normal. Heart US: normal function, mild LVH (PW and IVW 14 and 13 mm). 24 h. ABPM: Awake BP 157/96, Sleeping 146/89, non-dipper.

With CPAP, weight loss and Duslaglutide, BP and glycemic control were achieved and target-organ damage was reversed.

Morgagni-Stewart-Morel Syndrome in a 61-years patient: case report
Mihaela Stanciu
Lucian Blaga University of Sibiu, Sibiu, Romania.

Introduction
Morgagni-Stewart-Morel syndrome is a disorder defined by the presence of internal frontal hyperostosis, variably associated with metabolic disorders, endocrine and neuropsychiatric disorders. Hyperostosis frontalis interna (HFI) is a morphological change of the frontal bone like a single or multiple bilateral nodules on the inner lamina, characteristically sparing the diploë and the midline calvaria.

Case presentation
We present a 61-years old woman with hypertension and diabetes mellitus (with oral antidiabetic therapy), obesity, osteoporosis; also the patient was operated in 2012 for a multidisciplinary goiter (total thyroidectomy), treated with i-thyroxin 100 µg per day. She was referred to our department for severe frontal headache which she had suffered for several years, with gradually worsened, failing to respond to nonsteroidal anti-inflammatory drugs in last six months and a history of psychotic disorders. MRI demonstrated the internal hyperostosis frontalis with compression of the cerebral cortex and a small image in the pituitary gland, which is now under observation.

Conclusions
The clinical features of this syndrome was according to those described in the literature. Metabolic and endocrine disorders should not be interpreted as isolated pathogenetic but as possible pathogenetic factors. We underline the essential role of MRI in detecting the disease correlated with intense headache. The neurological symptoms and psychiatric symptoms were correlated with the severity of internal frontal hyperostosis and cortical atrophy.

Continuous glucose monitoring in glycoen storage disease type Ia – a major improvement for patients
Diana Martins1, Diana Oliveira1, Carla Baptista1, Sandra Paiva1, Nuno Vicente1, Luís Cardoso1, Adriana Lagos1, Mara Ventura1, Nelson Cunha1, Sónia Moreira2, Hugo Clemente2, Helder Esperto3 & Francisco Carrilho1
1Department of Endocrinology, Diabetes and Metabolism of Coimbra Hospital and University Centre, Coimbra, Portugal; 2Department of Internal Medicine of Coimbra Hospital and University Centre, Coimbra, Portugal.

Introduction
Glycogen storage disease (GSD) type Ia (von Gierke’s disease) is an inherited metabolic disorder of glycogen metabolism, caused by defects in the glucose-6-phosphatase complex, with associated risk of severe hypoglycemia within 3–4 h after a meal.

The aim of the present study was to evaluate the efficacy of continuous glucose monitoring (CGM) system in determining the magnitude of hypoglycemia in patients with GSD type Ia.

Methods
We retrospectively analyzed data from three patients with GSD type Ia, who underwent CGM with iProTM CGM device (Medtronic, Northridge, CA), over a 7.0 days period, under real life conditions.

Results
A total of 5.520 glucose data points were analysed. Concerning to low glycemic excursions (<70 mg/dL), we identified 15 episodes (three of them below 55 mg/dL and reaching 40 mg/dL in one case). Most of the episodes of hypoglycemia were asymptomatic and occurred 3 or more hours after meals or during the nocturnal period. The individual CGM analysis revealed a mean area under the curve of blood glucose below 70 mg/dL (AUC<70) respectively of 0.1, 0.5 and 0.8. One patient presented with important glycemic variability: MAGE 3.11 (reference range 0.0–2.8).

Conclusions
The analysis of continuous glucose monitoring data revealed significant periods of asymptomatic hypoglycemia and provided better perception into glycemic variations therefore, it may serve as a safe and useful tool for the long-term management of patients with GSD type Ia. We suggest that CGM can be used as an instrument to detect hypoglycemia, especially in the nocturnal period, helping patients with GSD to modify their nutritional regimens if necessary.

Diabetes mellitus; one train may hide another
Sara Vandewalle1,2, Nike Van Doninck1 & Peter Coremans1
1AZ Nikolaas, Sint-Niklaas, Belgium; 2Ghent University Hospital, Ghent, Belgium.

A 26-year-old Chinese male with autism spectrum disorder and mental retardation, was referred to start insulin therapy for uncontrolled diabetes mellitus (DM) (HbA1c 9%; C-peptide: 1.75 ng/mL; anti-GAD AB: negative) treated with oral antidiabetic drugs since 2012.

Clinical examination revealed a tall man with overweight and truncal obesity in light of his ethnicity. We withheld facial dysmorphism with hypertelorism, scarce facial hair, and clindamycy. He had a true gynaecomastia and acanthosis nigricans. Tanner genital stage was IV, however testicular volume was <4 ml.

DOI: 10.1530/endoabs.49.EP393
A 45-year-old female presented with recurrent episodes of neuroglycopenic symptoms 6 years after Roux-en-Y gastric bypass surgery. Her symptoms occurred during both the fasting and postprandial state. She had a history of Rheumatoid Arthritis. Her symptoms did not respond to a complex carbohydrate diet or Acrabose use. Whipple’s triad was demonstrated during a 72 h fast; symptomatic hypoglycemia (1.8 mmol/l) occurred which resolved with glucose administration. Simultaneous C-peptide, IGF1, IGFB2 and insulin samples were requested during the hypoglycaemic episode.

The Insulin level was 10 pmol/l, IGF1 level was 11.6 nmol/l, the IGFB2 level was 36.3 mmol/l, IGFB2/I ratio was 3.1 (≤10), C-peptide level was <94 pmol/l, GH was 7.5 μg/l and Sulphonhylurea screen was negative. Ketones was ‘Zero’ confirming an insulin independent mechanism for hypoglycaemia. Hydroxochloroquine for Rheumatoid Arthritis was discontinued which led to complete resolution of her symptoms. This is the first case of severe hypoglycaemia in a patient who did not have diabetes, who underwent bariatric surgery and developed hypoglycaemia due to hydroxochloroquine therapy with complete resolution of symptoms on discontinuing hydroxochloroquine.

This case demonstrates the need for a structured approach to the evaluation of hypoglycaemia. Roux-en-Y gastric bypass surgery is associated with subsequent development of hypoglycaemia which can respond to a complex carbohydrate diet or acarbose therapy. The lack of response however should prompt a thorough evaluation. The demonstration of an insulin independent mechanism for hypoglycaemia eliminated post gastric bypass hypoglycaemia as a cause and prompted a review of the medication list. Hydroxochloroquine is associated with the development of hypoglycaemia and cessation resulted in complete resolution of symptoms which were occurring at a frequency of 3–4 times per week resulting in termination of employment and driving.

Acquired generalized lipodystrophy associated with latent autoimmune diabetes mellitus in adults: a new metabolic phenotype

Federica Ferrari1, Marianna Maranghi2, Giovanni Cecconari1, Silvia Magno3, Caterina Pelosin1, Margherita Maffei1, Paolo Vitti1, Marcello Arca2 & Feruccio Santini1

1Obesity and Lipodystrophy Center at the Endocrinology Unit, University of Padua, Padua, Italy; 2Department of Internal Medicine, Medical Specialties, University La Sapienza, Rome, Italy.

The Insulin Autoimmune Syndrome (IAS) also called Hirata’s disease consists of hypoglycaemia, high insulin concentration and presence of anti-insulin antibodies. IAS is the third leading cause of spontaneous hypoglycaemia among Japanese population. The syndrome is exceptionally rare among Caucasians, with <50 cases described in literature.

In this report we showcase a 67-year-old female patient. She presented with paroxysmal sweating, daily fatigue and weakness with no triggering factors for these symptoms. Her blood glucose levels during those episodes were below 50 mg/dl measured by using a standard home glucometer device. Prolonged 72 h fast test showed extremely high insulin-glucose ratio with moderate elevation of C-peptide levels. CT scans did not reveal any significant masses in the abdomen. The subsequent laboratory analysis showed high levels of anti-insulin antibodies with low insulin recovery by using polyeylene glycol precipitation method. After treatment with low glycemic index diet and prednisone the average glycemia has increased with the remission of the symptoms. There have been no incidents of hypoglycaemia since the establishment of the treatment.

Our report indicates that at IAS should be considered in the differential diagnosis of spontaneous hypoglycaemia in Caucasians. The treatment might lead to the remission of the symptoms.

Hypoglycaemia due to hydroxochloroquine in a patient who underwent Roux-en-Y gastric bypass surgery

Kamrudeen Mohammed & Altayeb Abdalalaz

Hull Royal Infirmary, Hull, East riding of Yorkshire, UK.

This is the first case of severe hypoglycaemia in a patient who did not have diabetes, who underwent bariatric surgery and developed hypoglycaemia due to hydroxochloroquine therapy with complete resolution of symptoms on discontinuing hydroxochloroquine.

This case demonstrates the need for a structured approach to the evaluation of hypoglycaemia. Roux-en-Y gastric bypass surgery is associated with subsequent development of hypoglycaemia which can respond to a complex carbohydrate diet or acarbose therapy. The lack of response however should prompt a thorough evaluation. The demonstration of an insulin independent mechanism for hypoglycaemia eliminated post gastric bypass hypoglycaemia as a cause and prompted a review of the medication list. Hydroxochloroquine is associated with the development of hypoglycaemia and cessation resulted in complete resolution of symptoms which were occurring at a frequency of 3–4 times per week resulting in termination of employment and driving.

Humalog Mix50® massive overdose for suicidal purpose: a case report
Daniel-Tudor Cosma1, Cristina Alina Silaghi2, Horatiu Silaghi3, Mihaela Mocan3, Ioan Andrei Veresiu4
1Center for Diabetes, Nutrition and Metabolic Diseases Cluj-Napoca, Cluj County, Romania; 2Endocrinology Clinic, Cluj-Napoca, Cluj County, Romania; 35th Department of Surgery, ‘Iuliu Hatieganu’ University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania; 45th Department of Surgery, ‘Iuliu Hatieganu’ University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania.

Intentional insulin overdose in diabetic patients is a rare critical situation. The severity is due to numerous neurological complications, electrolyte disturbances, liver and lung damage or death. A 76-years old female, with significant cardiac pathologies, diagnosed with type 2 diabetes and treated with Humalog Mix50® 0-0-24 U/day, is admitted to our center via ER (emergency room) after an episode of severe hypoglycemia after administration of 1500U Humalog Mix50. She arrived in the ER one hour after the overdose with a glycemic value of 111 mg/dl after 50 ml of glucose 33% and 500 ml 10% glucose. At admission: altered general status, bradylalia, bradypsychia, generalized edema, marked fatigability, BP 140/90 mmHg, pulse 96 b/min, holosystolic murmur in the mitral area. Lab findings revealed: BG =401 mg/dl, glycosuria (1 g/dl), proteinuria (300 mg/dl), low serum iron, mild normochromic and normocytic anemia, high INR and NT proBNP levels, hypocalcaemia, low HDL, cholestrol, slightly elevated CRP, cholesterol syndrome and Alc =14.01% was consistent with a sever glycemic imbalance in the last 3 months. Intravenous insulin infusion and few boluses were needed to correct the hyperglycemic values followed by initiation of a basal regimen with glargine insulin and metformin. On 3rd day since admission, edematous swelling and cyanosis of the right arm with collateral circulation at the shoulder girdle was observed. The echo-Doppler showed a massive thrombosis from brachial to the brachiocephalic and internal jugular vein and the CT pulmonary angiogram thrombi at the level of segmental arteries bilaterally. Treatment with LMWHs was initiated and the patient was transferred to the Cardiology department with a favorable outcome. The screening for thrombophilia emphasized hyperhomocysteinemia and a slightly elevated S protein activity.

Our case illustrates an extensive UEDVT and pulmonary embolism in a newly diagnosed type 2 diabetic patient. The modifications in the thrombophilia screening together with the hypercoagulable state induced by hyperglycemia might have lead to the development of this extensive UEDVT.

DOI: 10.1530/endoabs.49.EP398

Extensive venous thrombosis of the upper extremity in a newly diagnosed type 2 diabetic female
Daniel-Tudor Cosma1, Cristina Alina Silaghi2,3, Vlad Florin Bonțea2, Calin Homorodean4, Horatiu Silaghi5, Ioan Andrei Veresiu4
1Center for Diabetes, Nutrition and Metabolic Diseases Cluj-Napoca, Cluj County, Romania; 2Endocrinology Clinic, Cluj-Napoca, Cluj County, Romania; 31st Internal Medicine Department, Cluj-Napoca, Cluj County, Romania; 45th Department of Surgery, ‘Iuliu Hatieganu’ University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania; 5Department of General Surgery ‘Iuliu Hatieganu’ University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania.

Upper extremity deep vein thrombosis (UEDVT) is not infrequent and accounts for approximately 14% of deep vein thrombosis. The risk of pulmonary embolism is lower than in lower extremity DVT and prompt diagnosis is essential to select those patients who deserve anticoagulant treatment. Previous studies indicated that type 2 diabetes (DM) patients carried greater risk of DVT development or recurrence than the general population. A 49-years old female, with no previous medical history, was admitted to our center via Emergency Room (ER) for optimizing glycemic control. At admission: altered general status, bradylalia, bradypsychia, general edema, marked fatigability, BP =140/90 mmHg, pulse =96 b/min, holosystolic murmur in the mitral area. Lab findings revealed: BG =401 mg/dl, glycosuria (1 g/dl), proteinuria (300 mg/dl), low serum iron, mild normochromic and normocytic anemia, high INR and NT proBNP levels, hypocalcaemia, low HDL, cholesterol, slightly elevated CRP, cholesterol syndrome and Alc =14.01% was consistent with a sever glycemic imbalance in the last 3 months. Intravenous insulin infusion and few boluses were needed to correct the hyperglycemic values followed by initiation of a basal regimen with glargine insulin and metformin. On 3rd day since admission, edematous swelling and cyanosis of the right arm with collateral circulation at the shoulder girdle was observed. The echo-Doppler showed a massive thrombosis from brachial to the brachiocephalic and internal jugular vein.

Our case illustrates an extensive UEDVT and pulmonary embolism in a newly diagnosed type 2 diabetic patient. The modifications in the thrombophilia screening together with the hypercoagulable state induced by hyperglycemia might have led to the development of this extensive UEDVT.

Early association of three autoimmune disorders in a young male with polyglandular autoimmune syndrome type III
Daniel-Tudor Cosma1, Cristina Alina Silaghi2,3, Mihaela Mocan3, Horatiu Silaghi1, Ioan Andrei Veresiu1
1Center for Diabetes, Nutrition and Metabolic Diseases Cluj-Napoca, Cluj County, Romania; 2Endocrinology Clinic, Cluj-Napoca, Cluj County, Romania; 31st Internal Medicine Department, Cluj-Napoca, Cluj County, Romania; 45th Department of Surgery, ‘Iuliu Hatieganu’ University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania; 5Department of General Surgery ‘Iuliu Hatieganu’ University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania.

Polyglandular autoimmune syndromes (PAS) are a heterogeneous group of rare diseases characterized by autoimmune activity against more than one endocrine organ, although non-endocrine organs can be affected. In PAS III, autoimmune thyroiditis occurs with another organ-specific autoimmune disease, but the syndrome cannot be classified as PAS I or II. A 29-years old man was referred to our center for diagnostic conformation with the following complaints: xerostomia, polyuria, polydipsia, nocturnal enuresis, 10 kg weight loss in the last 2 months, blurred vision and marked fatigability. One week before admission the lab exams revealed: blood glucose (BG) of 276 mg/dl, severe dyslipidemia, glycosuria, ketonuria and a basal bolus regimen with insulin glargine and lispro was started. Labs findings displayed: BG =276 mg/dl, moderate hypertriglyceridemia, glycosuria, low sodium and chloride and the Alc =17.73% was consistent with a sever glycemic imbalance in the last 3 months. The specific antithyroid type 1 diabetes (GAD, ICA, IA2, anti-insulin) were negative and the C peptide was low. The screening for other autoimmune diseases was positive for thyroiditis (high TPO antibodies) and celiac diseases (high IgA anti-transglutaminase antibodies) and were confirmed by thyroid
ultrasound, gastroscopy (paving stone duodenum) and histopathological examination. In order to improve the glycemic control, the insulin doses were adjusted according to the glycemic values and carbs ingestion. Nutritional education was conducted emphasizing the importance of gluten-free diet and correct estimation of the carbs intake. The lipid profile normalized after normoglycemia was achieved. Despite the lack of specific antibodies, the patient profile, lab exams and association with other autoimmune diseases support the diagnosis of type 1 diabetes. The zinc transporter-8 (ZnT8) antibodies are not yet available in our country. The evolution in these cases may be unpredictable and requires the concomitant treatment of all the conditions involved in order to achieve the therapeutic success.

Background

Dietary protein could have an important role, because of its positive effects on surgery, and is simultaneously beneficial for avoiding long-term complications.

Methods

Participants who previously had undergone primary gastric bypass surgery were studied during an oral Mixed Meal Tolerance Test (MMTT). Satiety and hunger were assessed every 30 min by means of a visual analogue scale. Blood samples were collected at baseline, every 10 min during the first half hour and every 30 min till 210 min after the start. The plasma samples were assessed for 24 amino acids including derivatives and four gastrointestinal hormones.

Results

30 female and 12 male subjects aged 48 ± 11 years, 31–76 months after surgery with total weight loss of 30 ± 9% completed the MMTT. After ingestion increases in satiety, the hormones PYY, active GLP1, inactive GLP1 and most amino acids were observed, while hunger, ghrelin and citrulline declined. Satiety scores above the median were associated with increased plasma levels of PYY, active and inactive GLP1. Hunger scores below the median (indicating less hunger) were associated with increased levels of PYY and a reduced attenuation in ghrelin. Higher concentrations of several plasma levels of amino acids especially histidine, serine, arginine, glutamine and glycine were observed in subjects experiencing more satiety, higher levels of PYY, active or inactive GLP1. Additional analyses are underway.

Conclusions

Our exploratory analysis shows positive associations between various plasma amino acids in groups with differences in satiety and gastrointestinal hormones. This provides new insights to optimize the outcomes of bariatric surgery.

Nutritional status in ambulatory patients by Medicine Laboratory

Francisco Javier Merida De La Torre & Nieves Bel Peña

Health Management Area Serrania, Medicine Laboratory, Ronda, Malaga, Spain.

Nutritional status has an important effect on the progression of any disease, not only in hospitalized patients, even more in ambulatory patient of primary care. Although there are many systems of evaluating nutritional status, they are costly and subject to variability amongst individuals. The Medicine Laboratory can correctly perform a nutritional evaluation in a quick and efficient manner.

Objectives

Analyze the nutritional status by CONUT nutritional evaluation method performed by the Medicine Laboratory in ambulatory patients of primary care our Health Management Area in 2016.

Materials and methods

The CONUT method for nutritional evaluation was used. This method is based on determining undernutrition according to levels of total lymphocyte count total cholesterol and serum albumin. During the study, the results of routine blood tests were used, not additional blood tests were performed. The focus was a sample size of all patient admitted in primary care centers, n = 1454 patients. Statistics data: acceptance error 3.5%, C.I. 99%. The frequency of nutritional risk was calculated analysed alongside data on patients’ sex, age.

Results

1454 patients were studied, 68.5% were not undernourished, 27.4% were mild undernourished and 4.1% were moderate or severe undernourished. The mean age of patients was 57.9 years, 60.9% were women and 39.1% were men. 6.7% of men were moderate or severely undernourished, only 2.3% of women studied were moderate or severely undernourished. The statistics differences by gender were significatives.

Conclusion

The nutritional evaluation performed by the Medicine Laboratory is an effective tool to evaluate nutritional status and take corrective measures. Although there are many experiences in CONUT nutritional evaluation in hospitalized patients, we think that this method is useful in primary care too.

Satiety, hunger and gastrointestinal hormones after a test meal in patients after gastric bypass surgery: an association with amino acids

EP402

Merel van den Broek1, Loek de Heide1, Nic Veeger2,3, Marloes Emous5 & André van Beek4

1Department of Internal Medicine, Medical Center Leeuwarden, Leeuwarden, The Netherlands; 2Department of Epidemiology, University of Groningen, University Medical Center Groningen, Groningen, The Netherlands; 3Department of Epidemiology, Medical Center Leeuwarden, Leeuwarden, The Netherlands; 4Department of Endocrinology, University of Groningen, Groningen, The Netherlands; 5Department of Surgery, Medical Center Leeuwarden, Leeuwarden, The Netherlands.

Background

Nutrition is essential in achieving maximal treatment success after bariatric surgery, and is simultaneously beneficial for avoiding long-term complications. Dietary protein could have an important role, because of its positive effects on preservation of muscle mass and induction of satiety in non-bariatric subjects. Therefore, we investigated the effects of dietary protein, assessed by amino acid composition, on satiety, hunger and gastrointestinal hormones after gastric bypass surgery.

Objective

To characterize, and compare, fatty acids profile in children with Type 1 diabetes and healthy children.

Methods

Several studies have shown a link between pro-inflammatory activity and the presence or relative deficit of some fatty acids. A low amount of omega 3 fatty acids, appears to promote an inflammatory profile. The omega 6 fatty acids have also the same effect. It is well known that a chronic low-grade inflammation is associated to several diseases, namely, diabetes. The follow-up of children and young people with Type 1 diabetes involves the periodic evaluation of their lipidic profile, however it is not done regularly the evaluation of the profile on the concentration of different types of fatty acids.

Objective

Characterize, and compare, fatty acids profile in children with Type 1 diabetes and healthy children.

The authors observed that the ratio of omega 6/omega 3 fatty acids was higher in the control population. Omega 6 levels were higher in the diabetic children compared to the control group. Several other differences in free fatty acid composition were observed.

Conclusion

Our findings showed higher levels of alpha-linolenic acid, EPA and DHA, as well as mono and polyunsaturated fatty acids in diabetic children. This fact is attributed to pharmaceutical therapy and nutritional management of these children. These findings reinforce the importance of a precocious nutritional attention and intervention in the diabetic child treatment.

Satiagluptin use may reduce oral cancer risk in patients with type 2 diabetes

EP404

Chin-Hsiao Tseng

National Taiwan University Hospital, Taipei, Taiwan.

Endocrine Abstracts (2017) Vol 49
Background
Whether sitagliptin may affect oral cancer risk has not been investigated.

Methods
The reimbursement database of the National Health Insurance in Taiwan was used. Diabetic patients newly treated with sitagliptin (n=50033) or other antidiabetic drugs (n=277038) within 1999–2008 were followed for oral cancer until December 31, 2011. The treatment effect was estimated by Cox regression adjusted for propensity score (PS) or using PS weighting by inverse probability of treatment weighting approach.

Results
The overall hazard ratios suggested a 20% lower risk without statistical significance. In tertile analyses, the PS-adjusted hazard ratios for the first (<6.53 months), second (6.53–14.00 months) and third (>14 months) tertile of cumulative duration were 1.382 (0.899, 2.125), 0.908 (0.566, 1.456) and 0.464 (0.272, 0.789), respectively; and were 1.324 (0.864, 2.030), 0.871 (0.545, 1.394) and 0.447 (0.263, 0.760), respectively, for PS-weighted.

Conclusions
Sitagliptin may reduce oral cancer risk when the cumulative duration is >14 months.

Does a first-degree family history of diabetes impact placental vascular circulation and placental inflammatory response?
Jacob Bar
WMC and Tel Aviv University, Tel Aviv, Israel.

Background
Experimental and clinical studies have demonstrated that heritability of diabetes is associated with marked hyperinsulinemia, impaired endothelial function, and inflammatory up-regulation. However, no studies have examined whether a family history of diabetes effects placental maternal and fetal vascular circulation, or placental inflammatory response. The present study was designed to investigate the impact of first-degree family history of diabetes (FHD) on placental vascular circulation and inflammatory lesions.

Methods
402 pregnant women were divided into two groups according to presence of first-degree FHD: Group 1 included 255 subjects without FHD, Group 2 included 145 subjects with FHD. Placental histology was performed for vascular circulation and inflammation lesions of maternal and fetal origin.

Results
Maternal vascular supply (MVS) abnormalities of the placental bed was significantly higher in subjects with FHD, compared to group 2 (33% vs 52%, P<0.005). Fetal vascular supply (FVS) abnormalities as well as maternal and fetal inflammatory lesions (MIR and FIR) did not differed significantly between groups. In the logistic regression analysis, FHD is an independent and significant predictor predictor of maternal vascular supply abnormalities (P=0.001) and more than doubles risk of this outcome (OR 2.084, 95% CI 1.337-3.247, P=0.001). Gestational diabetes incidence was significantly higher in subjects with FHD.

Conclusion
We demonstrated that first-degree family history of diabetes is associated with an increased rate of maternal vascular malperfusion abnormalities.

Episodes of poorly controlled diabetes in 1486 patients admitted in Orthopedic Surgery and Traumatology
Maria Molina Vega1, Pilar Losada Mora1, Alfonso M Garrido Castro2, Jose M Garcia Almeida1, Juan L Carrillo Linares2, Miguel Damos Fuentes1, Carmen Rodriguez Garcia1 & Cristina Diaz Perdigones1
1Endocrinology, Hospital Virgen de la Victoria, Malaga, Spain; 2Internal Medicine, Hospital Virgen de la Victoria, Malaga, Spain.

Introduction
Episodes of poorly controlled diabetes (DM) are one of the most frequent medical complications during hospitalization in the elderly population.

Objectives
To analyze the prevalence of episodes of diabetic decompensation in patients admitted to Orthopedic Surgery and Traumatology (OST) area.

Material and methods
Descriptive analysis of patients admitted to OST Service who presented abnormally high or decreased blood glucose levels according to the criterion of the Orthopedic Surgeon who performed the consultation.

Results
From June 2008 to December 2014, 1486 consultations were sent to Internal Medicine, Cardiology or Endocrinology, regarding patients admitted to the OST area who had suffered some type of medical decompensation during admission. Of these patients, 437 (29.4%) had a documented history of DM. The reason for consultation was poorly controlled DM in 124 patients (8.3%), with 111 patients (89.5%) presenting hyperglycemia and 13 (10.5%) presenting hypoglycemia. However, since the consultations were made by the Orthopedic Surgeon who requested it, after the initial evaluation of all these patients, the diagnosis of poorly controlled DM was only considered in 108 patients (7.4% of the total decompensated patients), since the rest, despite presenting glycaemia above 125 on fasting, were considered controlled taking into account their particular clinical situation. This implies an actual decompensation of 24.7% of patients with known DM.

Conclusions
DM is a cause of medical decompensation in 8.3% of patients admitted to OST. One in four known diabetics had abnormal blood glucose levels.

Together with previous studies in which we concluded that approximately one in six known hypertensive patients is decompensated during admission to surgical areas, we suggest that an early evaluation of blood glucose and blood pressure performed by Cardiology, Endocrinology or Internal Medicine could be beneficial in terms of morbidity.

Episodes of poorly controlled diabetes in 173 patients admitted in Vascular Surgery
Maria Molina Vega1, Pilar Losada Mora1, Alfonso M Garrido Castro2, Jose M Garcia Almeida1, Juan L Carrillo Linares2, Miguel Damos Fuentes1, Carmen Rodriguez Garcia1 & Cristina Diaz Perdigones1
1Endocrinology, Hospital Virgen de la Victoria, Malaga, Spain; 2Internal Medicine, Hospital Virgen de la Victoria, Malaga, Spain; 3Cardiology, Hospital Virgen de la Victoria, Malaga, Spain.

Introduction
Episodes of poorly controlled diabetes (DM) are one of the most frequent medical complications during hospitalization in the elderly population.

Objectives
To analyze the prevalence of episodes of diabetic decompensation in patients admitted to the area of Vascular Surgery and Angiology (VS).

Material and methods
Descriptive analysis of patients admitted to the VS Service who presented abnormally high or decreased blood glucose levels according to the criteria of the Vascular Surgeon who performed the consultation.

Results
From February 2011 to December 2014, 173 consultations were sent to Internal Medicine, Endocrinology or Cardiology regarding patients admitted to the VS area who had suffered some type of medical decompensation during admission. Of these patients, 94 (49.1%) had a documented history of DM. The reason for the consultation was ‘poorly controlled DM’ in 8 patients (4.6%) of whom had hyperglycemia 4 (50%) and hypoglycemia, 4 (50%) as well as ‘control of vascular risk factors’ in 18 (10.4%). However, after analysis of all patients, only 22 (12.7%) were diagnosed as decompensated DM in the discharge report. This implies a real decompensation of 23.4% of patients with known DM.

Conclusions
DM is a single cause of medical decompensation in 4.6% of patients admitted to VS. However, associated with decompensation of other vascular risk factors, one out of four known diabetics had abnormal blood glucose levels.

Together with the previous studies in which we conclude that approximately one in six known hypertensive patients is decompensated during admission to surgical areas, we suggest that an early evaluation of blood glucose and blood pressure performed by Cardiology, Endocrinology or Internal Medicine could be beneficial in terms of morbidity and hospital stay, since previous studies associate the diabetic uncontrol in patients admitted to Vascular Surgery to an average stay 9 days superior compared to non-diabetics.

Postprandial triglyceride responses and insulin resistance among night shift health care workers
Kiranmala Keithellakpam, Aslam Mohn, Brijsish Mishra, Rajat Jambh & Madhu Sri Venkata
Diabetes, Endocrinology and Metabolism Centre, Department of Medicine, University College of Medical Sciences, New Delhi, Delhi, India.

Background
A higher cardiometabolic risk has been reported in night shift workers. Postprandial hypertriglyceridemia (PPTG) is recognized as an independent cardiovascular risk marker. Few studies have shown that acute disruption of circadian rhythm is followed by significantly altered insulin secretion and lipid tolerance.

Aim and objectives
In this study we compared the postprandial triglyceride (PPTG) responses to standard oral fat meal between health care night shift workers and non-night shift workers to ascertain if it contributes to cardiometabolic risk in them.

Methods
20 health care night shift workers (>4 night duties/month for last one year), aged 20–40 years with normal glucose tolerance (NGT) following a 75 g glucose OGT and 20 age and sex matched non-night shift workers who had not done night duty in the last one year or ever were recruited. Anthropometric, OGT, HbA1c (%), insulin, HOMA-IR, HOMA-% (%), fasting lipids parameters and inflammatory markers (IL-6 & Hs CRP) were measured. PPTG responses were obtained after a standard fat meal given at 8 am, and sampling done every two hours for next 8 hours, that is at 0, 2, 4, 6 and 8 h and compared between the two groups.

Results
Night shift and non-night shift workers were matched for age (29.70 ± 2.23 years) and sex (M/F 12.8 ± 12.8). The duration of night shift exposure was relatively short (4.2 ± 3.3 years) among cases. There was no significant difference between the two study groups with respect to anthropometric, glycemic, fasting lipids parameters or inflammatory markers. However, 2 h postprandial glucose in health care night shift workers was comparatively higher than non-shift workers (103.8 ± 18.53 mg/dl vs 91.5 ± 19.96) though it just fell short of statistical significance (P=0.50). PPTG measures – PPTG area under the curve (TG AUC) and TG peak values were comparable in both the groups. PPTG response showed significant positive correlation with fasting insulin and HOMA-IR indicating insulin resistance, and HOMA-% (%) indicating insulin secretion in night shift health care workers but not in others. There was no significant correlation of PPTG parameters with any other clinical, biochemical and inflammatory measures.

Conclusions
Postprandial triglyceride burden is significantly associated with insulin resistance in night shift workers even with a relatively short duration of night shift,

Improving safety in diabetes management and reducing insulin errors in hospital – practically achievable or a utopian fantasy?
Wyn Burbridge, Lynne Bracytton, Amar Puttanna, Mahender Yadagiri, Dee Isley, Sagnik Mukhopadhyay, Karthik Munichoodappa & Parijat De Sandwell & West Birmingham NHS Trust, Birmingham, UK.

42 insulin related incidents were reported within our Trust in 2014. Subsequent Root Cause Analysis revealed numerous insulin errors, hyperglycaemia mismanagement and highlighted significant deficits in diabetes knowledge amongst nursing staff. To address the above issues, new safety interventions were introduced and five key outcomes are:

1. A new stand-alone insulin prescription chart introduced May’15 has seen insulin incidents decrease from 60 (Apr’14 – May’15) to 37 (June’15 – Apr’16).
2. A new abbreviated DKA protocol and DKA App launched Aug’15 has shown significant clinical benefits and crucially, helped earlier discharge by 3.2 days (audit of 40 patients; 13 between May – July’15 and 27 between Aug’15 – Mar’16).
3. A mandatory new “6 steps to insulin safety online module” introduced for all junior doctors & nurses (Dec’15) – 91 staff have already completed the module.
4. Daily Hypoglycaemia email alerts and Precision (Abbott) web database introduced to specifically target & educate problem wards. A number of changes have been already made as a result.
5. Ulysses SAFEGUARD IT now reports all insulin incidents monthly which are discussed as part of Quality Improvement. A monthly junior doctor insulin/ prescription error alert (Aug’15) now mandates all error discussions with Educational Supervisors helping them to reflect/learn from mistakes (11 insulin incidents in Jan/Feb’16 vs 19 in Nov/Dec’15).

Thus, over a relatively short period of 1 year, we have shown that our simple, yet helpful, safety innovations can be very effectively applied to reduce diabetes errors, improve staff knowledge & satisfaction. Our approach can be easily replicated by any NHS Trust to improve overall safety in insulin and diabetes management.

Heterozygote c.313DelC (p.H105TfsX11) mutation of Glucokinase gene in patient with Waardenburg syndrome type 1
Huseyin Ant Korkmaz
Division of of Pediatric Endocrinology, Balikesir Ataturk State Hospital, Balikesir, Turkey.

Background
Waardenburg syndrome is known as an inherited disorder associated with sensorineural deafness and pigmentation abnormalities affecting the skin, hair, and eye. There are rare case reports of Waardenburg syndrome with diabetes mellitus in the literature.

Case
A 9-years-old boy from consanguineous family was admitted to pediatric endocrine department because of fasting and postprandial hyperglycemia. In the medical history, it was learned that his aunt and uncle had brilliant blue irises, fasting and postprandial hyperglycemia. On physical examination: Height: 131.5 cm (10–25p), Weight: 28.9 kg (25–50p), Weight SDS: -0.29, Body mass index: 16.72, Body mass index SDS: 0.16. On physical examination, the patient with a brilliant blue iris had dystopia canthorum, skin hypopigmentation, synophrys, broad nasal root, hypoplasia alae nasi and mild sensorineural hearing loss. When our patient was evaluated for Waardenburg syndrome clinical criteria, Waardenburg syndrome was diagnosed with Waardenburg Consortium. Blood glucose was 148 mg/dl (75–100), insulin was 19.1 IU/ml (2–18) and serum C-peptide level was 3.72 nmol/l (1.1–4.4). Hba1c value was 6.2%, anti insulin antibody was 0.01 U/ml (0–0.5U), anti-GAD was < 1 U/ml (< 1 U/ml) and islet cell antibody was negative. When our patient was evaluated for maturity onset diabetes of the young, MODY type 2 was diagnosed with heterozygote c.313DelC (p.H105TfsX11) mutation in glucokinase gene. Regaplinide was started for controlling blood glucose levels and blood glucose regulation was achieved.

Conclusion
We reported the case of a patient with Waardenburg syndrome accompanied by glucokinase gene mutation, To the best of our knowledge, we believed the first reported Waardenburg syndrome patient with these concomitant disorder.

Keywords: Waardenburg syndrome type 1; glucokinase gene; MODY; hyperglycemia.

GLIS3 rs7020673 and rs10758593 polymorphisms interact in the susceptibility for type 1 diabetes mellitus
Daisy Crispim1,2, Guilherme Duarte1,2, Tais Assmann1,2, Cristine Dieter1,2, Bianca de Souza1,2 & Luis Canani1,2
1Division of of Pediatric Endocrinology, Balikesir Ataturk State Hospital, Balikesir, Turkey.
2Post-graduation Program in Medical Sciences: Endocrinology, Faculdade de Medicina, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil.

The transcription factor Gli-similar 3 (GLIS3) plays a key role in the development and maintenance of pancreatic beta-cells as well as in the regulation of insulin gene expression in adults. Accordingly, genome-wide association studies identified GLIS3 as a susceptibility locus for type 1 diabetes mellitus (T1DM) and glucose metabolism traits. Therefore, the aim of this study was to investigate the association of the rs7020673 (G/C) and rs10758593 (G/A) single nucleotide polymorphisms (SNPs) in the GLIS3 gene with T1DM in a Brazilian population.

5. Ulysses SAFEGUARD IT now reports all insulin incidents monthly which are discussed as part of Quality Improvement. A monthly junior doctor insulin/ prescription error alert (Aug’15) now mandates all error discussions with Educational Supervisors helping them to reflect/learn from mistakes (11 insulin incidents in Jan/Feb’16 vs 19 in Nov/Dec’15). Thus, over a relatively short period of 1 year, we have shown that our simple, yet helpful, safety innovations can be very effectively applied to reduce diabetes errors, improve staff knowledge & satisfaction. Our approach can be easily replicated by any NHS Trust to improve overall safety in insulin and diabetes management.

GLIS3 rs7020673 and rs10758593 polymorphisms interact in the susceptibility for type 1 diabetes mellitus
Daisy Crispim1,2, Guilherme Duarte1,2, Tais Assmann1,2, Cristine Dieter1,2, Bianca de Souza1,2 & Luis Canani1,2
1Division of of Pediatric Endocrinology, Balikesir Ataturk State Hospital, Balikesir, Turkey.
2Post-graduation Program in Medical Sciences: Endocrinology, Faculdade de Medicina, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil.

Background and Aims
The transcription factor Gli-similar 3 (GLIS3) plays a key role in the development and maintenance of pancreatic beta-cells as well as in the regulation of insulin gene expression in adults. Accordingly, genome-wide association studies identified GLIS3 as a susceptibility locus for type 1 diabetes mellitus (T1DM) and glucose metabolism traits. Therefore, the aim of this study was to investigate the association of the rs7020673 (G/C) and rs10758593 (G/A) single nucleotide polymorphisms (SNPs) in the GLIS3 gene with T1DM in a Brazilian population.
Methods
Frequencies of the rs7020673 and rs10758593 SNPs were analyzed in 503 T1DM patients (cases) and in 442 non-diabetic subjects (controls). Genotyping was performed using Real-Time PCR and TaqMan MGB probes (Thermo Scientific). Haplotypes constructed from the combination of these SNPs were inferred using a Bayesian statistical method.

Results
GLI3 rs7020673C allele frequency was 47.3% in T1DM patients and 45.1% in the non-diabetic group (P = 0.365), while the rs10758593A allele was present in 43.3% of cases and 41.1% of controls (P = 0.341). Genotype distributions of these SNPs were in agreement with those predicted by Hardy-Weinberg Equilibrium in controls (all P ≥ 0.05), and did not differ significantly between groups (P = 0.468 and P = 0.279, respectively). In addition, frequencies of rs7020673 and rs10758593 SNPs did not differ between groups under dominant, recessive or additive inheritance models (all P ≥ 0.05). However, frequency of three or more minor alleles of the analyzed SNPs in haplotypes was higher in T1DM patients compared to non-diabetic subjects (6.2 vs 1.6%; P = 0.001). Presence of ≥ 3 minor alleles remained independently associated with risk for T1DM after adjustment for T1DM high-risk HLA DR/DQ haplotypes, age and ethnicity (OR 8.9 ± 2.1 vs 8.2 ± 2.0; P = 0.038). In conclusion, our results indicate that the rs7020673 and rs10758593 SNPs interact in the predisposition for T1DM.

EP413
Association of wolfram syndrome with chronic renal failure in a boy
Huseyin Anil Korkmaz
Balikesir Ataturk State Hospital, Balikesir, Turkey.

Wolfram syndrome, rare neurodegenerative disorder, is known to be DIDMOAD (diabetes insipidus, diabetes mellitus, optic atrophy and deafness). There are rare case reports of Wolfram syndrome with chronic renal failure in the literature. A 19-year-old male patient was admitted to our pediatric emergency department because of headache, chest pain and diurnal and nocturnal enuresis. He had been diagnosed with diabetes mellitus at 13 years of age (Plasma glucose was 386 mg/dl, urinary ketone negative, normal blood gases, serum C-peptide level 0.1 pmol/ml (0.15–1.10) and HbA1c value of as 9.6%) and had received four doses of regular insulin (0.9 U/kg per day) treatment. Anti-insulin antibody was 3 U (0–8 U), anti-GAD 0.4 U/ml (< 1 U/ml), and islet cell antibody negative at the diagnosis. In addition, fundus oculi examination had demonstrated bilateral optic atrophy and no sign of diabetic retinopathy at 13 years of age. He was the sixth child of apparently healthy consanguineous parents, born at full-term by normal vaginal delivery. Family history disclosed that his uncle, aunt and sister had diabetes mellitus. Physical examination: weight: 31 kg (< 3 percentile), height: 136.5 cm (< 3 percentile), blood pressure: 160/80 mmHg and pulse rate 96/dk. He had bilateral blindness. High renal function tests (BUN:78 mg/dl, creatinine: 4.7 mg/dl), serum electrolytes (Na: 133.7 mmol/l, K: 4.2 mmol/l, Cl: 103.7 mmol/l, serum calcium: 8.4 mg/dl), serum phosphorus: 8 mg/dl) and high parathyroid hormone (PTH: 321.63 pg/ml range. 15 to 65) suggested chronic renal failure. Urinary ultrasound imaging disclosed small kidney size. Glomerular filtration rate was calculated as 13 ml/min/1.73 m². Audiometric examination for Wolfram syndrome revealed bilateral sensorineural hearing loss. A known homozygous mutation (Y508fsX541, c.1523_1524delAT) in exon 8 of WFS1 was found in the proband.

We reported a case with Wolfram syndrome accompanied by chronic renal failure. Early diagnosis and appropriate management for Wolfram syndrome would prevent development of complications.

Could we prevent insulin induced lipohypertrophy in diabetic patients?
Natalya Volkova, Ilya Davidenko, Maria Porkhuyeyan, Alexander Zibarev
Alexey Harlamov
Rostov State Medical University, Rostov-on-Don, Russia.

Introduction
Lipohypertrophy (LH) is a chronic complication of diabetes mellitus that caused by frequent subcutaneous injections of insulin. Nowadays, on the basis of results of ultrasonography of subcutaneous fat prevalence of LH in diabetic patients is still high.

Design
The aim has been to develop prevention of insulin induced LH in diabetic patients. This study was done on 140 diabetic patients who had been under the treatment with insulin a mean 8 years. On first stage all patients were divided into two groups. First – 117 patients with LH, second – 23 diabetics without LH.

Further, all known LH risk factors were statistically processed using Spearman’s, Gamma rank correlation coefficients. Results were statistically significant when P<0.05. On second stage 65 patients from first group were divided into two subgroups: First – 50 patients with LH and corrected risk factors, second (control) – 15 diabetics with LH and uncorrected risk factors. Ultrasoundography of subcutaneous fat were used in assessing new LH in these subgroups after 3 and 6 month.

Results
As a result, 10 factors from 23 were remained after statistic analysis on first stage. Statistically insignificant parameters were eliminated (P>0.05). On next stage, in first subgroup only two patients (4%) had new LH, while in second – 9 diabetics (60%) had new pathologic areas of subcutaneous fat after 3 month. And in first subgroup only 6 patients (12%) had new pathologic areas of subcutaneous fat, while in second – 12 diabetics (80%) had new LH after 6 month.

Conclusions
Nowadays, primary prevention of LH is necessary for diabetic patients under the treatment with insulin. There were stated that only 10 risk factors strongly influence on LH progress. Correction of these risk factors doesn’t lead to development of new subcutaneous fat pathological changes and could be used to prevent LH in diabetic patients in clinical daily practice.

Relation between serum leptin concentration and insulin resistance syndrome in patients with type 2 diabetes mellitus
Tamer Shebl, Nour El Dein Abd El Azeem & Hosny Abd El Kareem
Alazhar University, Assuit, Egypt.

Type 2 diabetes mellitus is known for its morbidity and mortality all over the globe. It has been demonstrated in recent studies that abnormal levels of adipocytokines may contribute to insulin resistance and type 2 diabetes.

Objectives
The aim of the present study was to assess the relation between serum leptin levels and insulin resistance syndrome in type 2 diabetic patients.

Methods
Eighty persons were enrolled in this study and were divided into two groups. Twenty healthy persons as a control group and 60 patients with type 2 diabetes mellitus as a disease group. The disease group were further divided into those who have evidence of metabolic syndrome (30 patients), and those who do not (30 patients). Parameters like age, sex, anthropometric measurements and biochemical indicators such as fasting and post prandial blood sugar, HbA1c, lipid profile, leptin and fasting insulin were determined.

Results
Higher Leptin and insulin levels were observed in patients with metabolic syndrome (P<0.001).

Conclusion
High serum leptin is a good indicator and could provide a minimally-invasive marker for early detection of the insulin resistance syndrome.

Keywords
leptin concentration; insulin resistance syndrome; type 2 diabetes mellitus.

Epidemiological and clinical study of diabetes in immigrants from Bangladesh in Athens versus Greek patients
Georgios Papadakis1, Thomas Zambelis2, Kostas Konstantopoulou3 & Stylianos Chatzipanagiotou4
1STEPS Stoffwechselzentrum, Biel/Bienne, Switzerland; 2Department of Neurology, Aegionin Hospital, Athens, Greece; 3Department of Hematology, Laikon University Hospital, Athens, Greece; 4Department of Medical Biopathology, Aegionin Hospital, Athens, Greece.

Objectives
Diabetes risk for Asians is related to a greater tendency to adiposity, which increases insulin resistance. Various studies have highlighted the fact that people from South Asia have a younger age of onset of diabetes, greater upper-body adiposity and lower body mass index (BMI) and higher risk compared to those from other nations. Greece has experienced a large wave of immigration from Asian countries, especially Bangladesh. The purpose of this study was to explore the ethnic differences and special needs that must be taken into account when treating patients with different cultural background.

Methods
A total of 166 randomly selected immigrants with diabetes from Bangladesh were compared with 123 randomly selected Greek Caucasian patients with diabetes.

Results
Patients from Bangladesh had a mean duration of living in Greece of 10.34±6.2 years. The Bangladeshi group was younger compared with the Greek group (44.05±8.1 vs 48.75±9.2 years old, P=0.009) and had an earlier age at onset of diabetes (39.3±7.3 vs 41.7±10.1 years old, P=0.025). The reported duration of diabetes was lower in the Bangladeshi group (4.86±4.5 vs 7.34±6.21 years, P=0.05). The Bangladeshi group had a significantly lower BMI (24.19±3.3 vs 29.04±8.7 kg/m², P=0.01), and waist circumference (92.2±8.9 vs 103.1±15.7 cm, P<0.001). Bangladesh group had a slightly worse, but not statistical significant, glycemic control as compared with the Greek group (AIC=7.74±1.6 vs 7.55±1.7, P=0.3). A significant number of Bangadeshis stated that they rarely checked their self-monitoring blood glucose as compared with the Greek group (1.26±2.6 vs 8.87±9.9 times per week, P<0.01). There were also no significant differences between the two groups for most laboratory findings, although Bangladeshi had higher mean levels of glucose (190.3±72 vs 160.8±81 mg/dl, P=0.4), cholesterol (199.8±44.4 vs 178.86±44.9 mg/dl, P=0.9), LDL (129.3±33.2 vs 110.62±33.9 mg/dl, P=0.8) and triglycerides (231.4±215 vs 181.95±166 mg/dl, P=0.07). In the Bangladeshi group, the mean HDL level was significantly lower as compared with the Greek group (33.99±9.4 vs 44.05±10.43 mg/dl, P=0.037).

Conclusions
Bangladesh immigrants are less likely to engage self-care behaviors and have worse glycemic control and less access to medication, laboratory test and healthcare units.

DOI: 10.1530/endoabs.49.EP417

Vitamin D levels in newly diagnosed type I diabetes mellitus and relationship with organ specific autoimmune disorders
Belgin Efe1, Gonca Akdere2 & Gökmen Yorulmaz1
1ESOGÜ Faculty of Medicine Department of Endocrinology, Eskisehir, Turkey; 2ESOGÜ Faculty of Medicine Department of Internal Medicine, Eskisehir, Turkey.

Based on the effects of Vitamin D on immune system it has been suggested that vitamin D may play a role in the pathogenesis of type I diabetes mellitus (T1D) and other organ specific autoimmune disorders. In our study, we aimed to show the effect of Vitamin D deficiency in the development of newly diagnosed T1D and other autoimmune disease that may associated with T1D such as autoimmune thyroid disease (ATD), celiac disease, Addison’s disease, vitiligo and atrophic gastritis. In addition to 50 newly diagnosed T1D patients and 60 healthy controls, we evaluated the data of the formerly diagnosed 50 T1D patients. The frequency of vitamin D deficiency in newly diagnosed T1D patients was found 88%. 30% of these patients were anti parietal cell antibody (APA) positive which is marker for pernicious anemia, 24% of had ATD, 10% of was positive for anti-tissue transglutaminase IgA which is marker for celiac disease and 2% of had vitiligo. Levels of 25(OH)D were statistically significant lower in newly diagnosed T1D patients with positive APA than patients with negative APA. Frequency of
vitamin D deficiency was 66.7% in healthy controls and 84% in formerly diagnosed T1D patients. When we considered all T1D patients, we found the frequency of ATD was 25%, frequency of positive APA was 28%, frequency of positive anti-tissue transglutaminase IgA was 10% and frequency of villusitis was 2%. We found that ATD and prediabetes of celiac disease were much frequent in T1D patients than healthy controls. Vitamin D levels were found lower; in patients with T1D than healthy controls; when we evaluate all subjects we found that patients with ATD had lower vitamin D levels than patients without ATD and also patients with ATD and positive APA had lower vitamin D levels than patients without ATD and negative APA.

**Conclusion**
We think our study was determined as evaluating the change of FKN levels that will occur with oral glucose tolerance test (OGTT). The aim of this study was to determine positive effect cannot be achieved in all patients. New medications in DPNP have to be studied.

**Is secreted frizzled-related protein 4 (SFRP-4) a possible biomarker for β cell dysfunction?**

Suleyman Baldane¹, Suleyman Ipekci¹, Sedat Abusoglu², Ali Unlu² & Levent Kebapcilar²

¹Division of Endocrinology and Metabolism, Selcuk University Faculty of Medicine, Konya, Turkey; ²Department of Biochemistry, Selcuk University Faculty of Medicine, Konya, Turkey.

**Introduction**
SFRP-4 is a recently described inflammatory cytokine influencing insulin secretion from human β cells as an extracellular modulator of Wingless (Wnt) pathway. The aim of this study is to compare serum SFRP-4 levels in patients with normal glucose tolerance (NGT), impaired glucose tolerance (IGT) and type 2 diabetes (T2DM), and to investigate its relation with other parameters.

**Methods**
The study included 152 patients who applied to the endocrinology outpatient clinic of our hospital. Eighty-two patients who had history of T2DM constituted the T2DM group. Patients who underwent OGTT within the last three months were categorized in either IGT (n = 34) or NGT (n = 36) groups according to their test results. All patients provided blood samples between 08 am and 09 am following overnight fasting. Fasting insulin, fasting glucose, HbA1c and SFRP-4 levels were measured.

**Results**
T2DM group had significantly higher serum SFRP-4 levels compared to BGT and NGT groups (0.282 ng/ml vs 0.183 ng/ml, P = 0.001; and 0.282 ng/ml vs 0.170 ng/ml, P = 0.004, respectively). In comparison of BGT and NGT groups, although serum SFRP-4 levels were higher in BGT group, the difference was not statistically significant (0.183 ng/ml vs 0.170 ng/ml, P = 0.630). SFRP-4 level showed significant positive correlation with fasting glucose (r = 0.274, P = 0.001) and HbA1c (r = 0.291, P = 0.002) levels.

**Conclusion**
Progressive β cell dysfunction is observed during the normal course of T2DM, and inflammatory cytokines are held responsible. Recent studies have demonstrated the association between increased SFRP-4 expression on β cells and reduced insulin release. Additionally, studies have found an association between serum SFRP-4 levels and high fasting glucose level and impaired insulin sensitivity in non-diabetic individuals. We found increased serum levels of SFRP-4 in patients with T2DM in our study, and SFRP-4 level was positively correlated with fasting glucose and HbA1c levels in the whole study group. We think our results support the idea that increased plasma SFRP-4 levels may be a good indicator of β cell dysfunction and insulin resistance.

Epidemiological features of type 1 diabetes in children and adolescents in the Republic of Armenia
Yelena M Aghajanova, Gayane M Baybardyan, Lusine V Navasardyan, Renata L Markosyan & Lusine G Kalantaryan
Yerevan State Medical University, Yerevan, Armenia.

Background
Diabetes is the most prevalent chronic metabolic disorder in children and adolescents, and incidence rates for both type-1 and type-2 diabetes are increasing worldwide. In recent years, the number of patients with type 1 diabetes is increasing mainly due to children under 5-years-old.

Objective
To study the epidemiological indicators of T1DM among children of the Republic of Armenia (RA) from 2007 to 2016. Methods: Retrospective analysis of the Republican Children’s Endocrinology Center database using conventional statistical methods.

Results
During the period 2007–2010 in Armenia there was a relatively stable incidence of diabetes in children 0–18 years: 7.1 in 2007, 6.45 in 2008, 6.3 in 2009 and 6.8 in 2010 (per 100 000 child population), while during 2010–2016 period incidence is seen (6.7 in 2011, 9.4 in 2012, 8.7 in 2013, 9.99 in 2014, 10.69 in 2015). The study of age-specific morbidity in children with T1DM in RA showed that the maximum incidence in different years was at the age of 5–9 or 10–14 years. According to the Republic Children’s Endocrinology Center data rejuvenation of type 1 diabetes can be traced. Mean age of patients in 2007 was 11 years. In 2014 mean age was 8.9 and 9.8 in 2016. The incidence rate in children of younger age group (0–4 years) increased from 2.24 in 2007 to 5.05 in 2010, 7.14 in 2014 and 5.8 in 2016 (per 100 000 child population).

Conclusions
In RA an increased incidence of type 1 diabetes among children and adolescents is seen. The highest incidence occurs in the age groups 5–9 and 10–14 years. Further studies are needed to look into the cause of these changes.

High incidence of glucose metabolism disorders in patients undergoing coronary angiography without history of diabetes
Stavroula A Paschou1, Sotirios Koka2, Grigorios Avdikos2, Efstathios Lazaris2 & Andromachi Vryonidou1
1Department of Endocrinology and Diabetes, Hellenic Red Cross Hospital, Athens, Greece; 2nd Department of Cardiology, Hellenic Red Cross Hospital, Athens, Greece.

Introduction
The aim of this study was to investigate the incidence of glycemic disorders in patients undergoing coronary angiography with no prediagnosed type 2 diabetes (T2D), as well as the association of the glycemic status with the extent of the coronary artery disease (CAD).

Patients and methods
We studied 170 consecutive patients (134M/36W), 63.9±13.1 (23–95) years old, with not known T2D, who underwent coronary angiography. HbA1c was measured and patients were classified into 3 groups accordingly: i) normal HbA1c<5.7%, ii) prediabetes HbA1c 5.7–6.4%, and iii) T2D HbA1c ≥6.5%. The presence of other risk factors for CAD was recorded, while the extent of CAD was examined. Vessel disease (VD) was defined when stenosis was >70%.

Results
From the total of 170 patients, 19.4% (33/170) presented normal HbA1c, 17.6% (30/170) prediabetes and 63% (107/170) were diagnosed with T2D. Patients with normal HbA1c were 60.5±16.7 years old, with BMI 29.1±5.2, 18.2% (6/33) were women, 48.5% (16/33) had hypertension, 36.4% (12/33) dyslipidemia, while 21.2% (7/33) had history of CAD. Of these, 33.3% (11/33) one VD, 21.2% (7/33) two VD, 6% (2/33) three VD and 6% (2/33) left main along with another one VD.

Conclusion
Prediabetes and T2D were detected in the majority of patients undergoing coronary angiography without previously known glycemic disorders. Therefore, HbA1c should be determined in all patients hospitalized for possible CAD, regardless of the history for diabetes.

The relation between type II diabetes and chronic depression in primary care practice in Jordan
Abdallah Alzoubi, Renad Abu Naser, Ady Khasawneh & Aws Khasawneh
Jordan University of Science and Technology, Ibdid, Jordan.

Diabetes is a major health problem that affects 8.5% of adults worldwide, and 13.2% of adults in Jordan. Studies suggest a bidirectional relationship between diabetes and chronic depression. Diabetic patients are twice as likely to suffer from depression that is symptomatically worse when compared to nondiabetic individuals. Depressed diabetics suffer from poor glycemic control and increased risk of diabetes complications. Because little is known about the bidirectional relationship between diabetes and chronic depression in Jordan, we screened for depressive disorders among diabetic patients using the Patient Health Questionnaire-9 (PHQ-9) and screened for diabetes among depressed individuals by measuring their HbA1c, in a cross-sectional study design. A total of 146 diabetic patients (74 males, 72 females) participated in the study, with a mean age of 56±8.5 years. Almost 60% of participants were uncontrolled for diabetes (HbA1c ≥7%) with a mean HbA1c of 8.9%±1.7 and a mean PHQ-9 score of 6.2±5.5. The remaining 40.4% were controlled for diabetes (HbA1c <7%) with a mean HbA1c of 6.1±0.6 and a mean PHQ-9 score of 6.7±4.5. The prevalence of chronic depression (PHQ-9 score ≥10) among diabetic patients was 27.4%. No correlation was found between PHQ-9 scores and HbA1c levels (Spearman’s r = −0.03, P = 0.75). Additionally, 20 depressed patients were recruited from the psychiatry clinic with a mean age of 41.7±8.3 years, and were then screened for diabetes by measuring HbA1c levels. None of these was found to be diabetic, with a mean HbA1c of 5.4%±0.4. In conclusion, our results thus far deny a correlation between depression and diabetes. However, our future plan of examining the effect of treating depression on glycemic control and diabetes complications, and the effect of improving glycemic control on the severity of depression, might improve our understanding of this relationship.

1Ain Shams University Division of Endocrinology and Diabetes, Cairo, Egypt; 2Ain Shams University Division of Gynecology and Obstetrics, Cairo, Egypt.

Background
Gestational diabetes mellitus is any degree of glucose intolerance with first diagnosis during pregnancy; it affects 3–10% of pregnancies. The presence of diabetes-related autoantibodies has been shown to be able to predict the development of type 1 diabetes before hyperglycemia arises.

Aim of work
To recognize the prevalence of islet cell antibodies among a sample of Egyptian females with gestational diabetes and its possible relation of development of Type 1 diabetes within 1 year.

Design and methodology
Our cross sectional study was conducted on 150 Egyptian pregnant females with gestational diabetes aged 19-39 years diagnosed by 75-g 2-h oral glucose tolerance test. All females were subjected to full history, thorough clinical examination and laboratory measurement of anti-islet cell antibodies, those
females with positive antibodies were followed up 6 months and 1 year after delivery for their fasting insulin, fasting blood glucose and 2 h postprandial levels.

Results
The prevalence of pregnant females with gestational diabetes having positive anti islet cell antibodies was (44%), the prevalence of females diagnosed to have diabetes mellitus was (37.8%) 6 months and (51.52%) 1 year postpartum.

Conclusion
Gestational diabetes can be of type 1 diabetes due to islet cell antibodies and not only type 2 diabetes due to increased insulin resistance

Keywords
Pregnancy; Gestational diabetes; anti-islet cell antibodies; Type 1 diabetes; Type 2 diabetes; Insulin resistance

A retrospective analysis of the impact of new diagnostic criteria for gestational diabetes mellitus on the endocrinology service at a tertiary hospital
Thaw Dar Htet1, Alice Lam2, Iouri Banakh2, Rumes Sriamareswaran1, Samuel Wu1, Jasmina Felsing1, Kati Matteisson2 & Elisabeth Nye1
1Department of Medicine, Peninsula Health, Melbourne, Australia; 2Department of Endocrinology, Peninsula Health, Melbourne, Australia.

Background
The prevalence of gestational diabetes mellitus (GDM) may increase with the implementation of revised diagnostic criteria (as recommended by the International Association of the Diabetes and Pregnancy Study Groups) aimed at identifying pregnancies at increased risk of adverse perinatal outcomes. There are clear implications for health-care services in terms of resources and the associated cost-benefit relationship. Our study analysed the impact on clinic visits, the initiation of insulin treatment and fetal and maternal outcomes.

Methods
A retrospective cohort study was conducted. The medical records of patients with GDM referred to Diabetes in Pregnancy Clinic were reviewed, comparing two 12-months periods: March 2012 to February 2013 (period 1) and March 2015 to February 2016 (period 2), before and after implementation of the new criteria. Maternal and fetal outcomes were analysed for six months of each period.

Results
165 GDM patients attended the clinic in period 1 vs 323 patients in period 2. Insulin treatment increased significantly in period 2, from 34.2 to 53.1% (P=0.002). The number of Endocrinologist consultations (government billed) increased from 3.6 to 4.2 (P=0.006) and with a Diabetic Educator from 1.6 to 1.8 (P=0.006). The rate of caesarean sections (CS) in patients with GDM increased from 31.1% in period 1–47.0% in period 2 (P=0.038). The number of neonates grouped as “Small for Gestational Age” (SGA) increased in insulin-treated patients in period 2 vs period 1 (17 vs 0. P < 0.001) but the number of “Large for Gestational Age” neonates was similar (6 vs 5. P = 1).

Conclusion
The new GDM diagnostic criteria have impacted on existing health-care resources with a corresponding increase in costs with minimal evidence of clinical benefits. Hospital systems will need to plan for the increased demands on pregnancy-related diabetes services.

Insulin autoimmune syndrome—a case report
Elif Sevil Alaguney, Belgin Efe, Gokmar Yorulmaz, Berat Acu & Insaft Durmus
Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey.

Introduction
Hypoglycemia is a medical emergency that can have many different causes in etiology. Autoimmune hypoglycemia in patients with very high insulin levels should also be considered in the differential diagnosis.

Case
A 50-year-old man was admitted to our clinic for investigation and treatment of hypoglycemic episodes. He did not have any evidence for the use of oral antidiabetic medications, insulin, herbal substances. However, in our history, we learned that hepregabalin and alfapatic acid were given to the patient considering neuropathic pain and proton pump inhibitors for dyspeptic complaints. Physical exam revealed a healthy-appearing middle-aged male with BMI of 21.4. Initial tests showed low venous blood glucose (44 mg/dl), high insulin levels >1000 μIU/mL, C-peptide 15.6 mg/mL. To rule out pancreatic or extrapancreatic insulinoma; abdominal ultrasound, abdominal computer tomography scan, abdominal MRI and Ga-68 DOTATATE PET/CT was performed. The results did not show an evidence of insulinoma. Intra-arterial calcium stimulation test was also performed to rule out insulinoma but the results were inconclusive. Anti-insulin antibody test was performed for the differential diagnosis and it was positive. The symptoms associated with low glucose levels and high serum insulin levels along with positive anti-insulin antibody lead us to the diagnosis of insulin autoimmune syndrome. According to the current literature suggesting the relationship between insulin autoimmune syndrome and alpha lipoic acid and proton pump inhibitors we discontinued that drugs and started alpha glucosidase treatment and nutritional management. During the follow up the patient did not report a hypoglycemic episode.

Discussion
Insulin autoimmune hypoglycemia is a rare cause of endogenous hyperinsulimic hypoglycemia. It is a condition that should be kept in mind in patients who have very high levels of insulin and who can not detect a specific focus through imaging modalities.

Incidence estimate of type 1 Diabetes in Youth in Dhaka
Ana Balsa1, Bedowra Zabeen2, Graham Oggle3, Samin Tayyeb2 & Kishwar Azad3
1Servicio de Endocrinologia Centro Hospitalar Baixo Vouga, Aveiro, Portugal; 2Department of Changing Diabetes in Children, Bangladesh Institute of Research and Rehabilitation in Diabetes, Endocrine and Metabolic Disorders, Dhaka, Bangladesh; 3International Diabetes Federation Life for a Child Program, Sydney, Australia; 4Bangladesh Institute of Research and Rehabilitation in Diabetes, Dhaka, Bangladesh.

Introduction
Analysis of epidemiologic patterns in diabetes helps with understanding of etiology, natural history and current and future needs. Bangladesh is a low-middle-income, densely populated country where there is limited information regarding incidence of childhood diabetes.

Aim
To assess the type of diabetes in children and young adults in Dhaka, Bangladesh, from July 2011 until June 2016, and estimate minimum incidence of type 1 diabetes (T1D).

Methods
Retrospective study using clinical records from Diabetic Association of Bangladesh (BADAS) clinics in Dhaka and affiliated satellite centers in other districts. Subjects under 25 years (y) diagnosed in the study period were identified. Diabetes type was classified according to clinical evaluation. Demographic information was obtained from the 2011 population census and extrapolated using the estimated growth rate. Incidence was calculated for the area surrounding the main clinics (Dhaka District) to minimize any ascertainment bias.

Results
Were identified 2347 subjects. Type of diabetes was more fully characterized for those <18 years (1634 cases), and showed 1437 (87.9%) T1D, 151 (9.2%) type 2, 23 fibrocalscular pancreatic diabetes (1.4%), 5 (0.3%) neonatal, 18 (1.1%) other types. For T1D incidence estimation a total of 526 subjects were ascertainment. The mean Dhaka district incidence rate for subjects <25 y was 1.24/100,000 per y (males 0.92, females 1.71) and 0.96/100,000 for <15y (males 0.63, females 1.55).

Discussion
The support to BADAS by the Changing Diabetes in Children and IDF Life for a Child programs have centralized care and permitted tracking of diabetes cases in young people in Bangladesh. T1D is commonest, but other forms occur which could benefit from different management: further typology studies are warranted. T1D had a female preponderance. Peak T1D onset is at 10–14 y, as in developed nations.

Is thiol/disulfide homeostasis related to parity and gravidity in gestational diabetes?

Faruk Yildiz1, Cemile Bicer2, Mahmut Senyurt1, Murat Alisik3 & Ayse Carlioglu1

1Regional Training and Research Hospital, Erzurum, Turkey; 2Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey; 3Ataturk Training and Research Hospital, Ankara, Turkey.

Purpose

The purpose of this study was to evaluate the relation gestational diabetes mellitus (GDM) and the thiol/disulfide balance, used as a marker of oxidative stress, by measuring that exchange using a novel technique.

Material/Methods

Thirty one subjects diagnosed with GDM and 30 healthy pregnant women were included in the study. Thiol/disulfide homeostasis concentrations were measured by a newly developed method in this study. After native thiol, total thiol and disulfide levels were determined; measures such as disulfide/native thiol, disulfide/total thiol, and native thiol/total thiol were calculated.

Results

Fasting blood glucose (FBG) levels (P<0.001), 50-g glucose load values (OGTT 50) (P<0.001), parity (0.002) and gravidity (P=0.005) were significantly higher and native thiol (P<0.001) and total thiol levels (P<0.001) were significantly lower in patients with GDM compared to control subjects. We found negative correlations between native and total thiols and FBG and OGTT 50. Parity and gravidity had a significantly negative correlation between the disulfide, the disulfide/native thiol ratio, the disulfide/total thiol ratio, had a positive correlation between the native thiol/total thiol ratio. Low native thiol and total thiol levels in patients with GDM were found to be independent of age, gestational weeks and bmi in multivariate regression analyse.

Conclusion

It can be concluded that oxidative stress is increased in patients with GDM, can play a pathophysiologisc role in the development of GDM and this increase is not associated age, gestational weeks and bmi. However, studies with larger sample sizes are needed in this area.

Endocrine factors associated with postprandial hypoglycaemia in patients with cystic fibrosis: a pilot study

Yasir Elamin1, Rachel Crowley1,2, ED Mc kite1, Patrick Twomey1,2, Siobhan Hatton1, Julie Martin-Grace1 & S Kearins1

1St. Vincent’s University Hospital, Dublin, Ireland; 2University College Dublin School of Medicine, Dublin, Ireland.

Postprandial hypoglycaemia in patients with cystic fibrosis (PWCF) is frequently reported but poorly understood. The aim of this pilot study was to investigate the aetiology of postprandial hypoglycaemia in PWCF. Serum cortisol, insulin and C-Peptide were measured at the 2 hour timepoint of the annual glucose tolerance test (AGT; 9–3 CF related diabetes, 4 impaired fasting glucose and 2 impaired glucose tolerance). There was a difference in insulin level at 2 hours between groups (P=0.007; Wilcoxon); subanalysis showed a difference between AGT (mean 48.9 mu/l) and PPH groups (16.6 mu/l)(P=0.003) and between AGT and NGT groups (28.4 mu/l)(P=0.015). Of the PPH cases none had symptomatic hypoglycaemia. Three PPH cases noted before 500 mmol/l underwent short synacthen test (SST); 2 had a cortisol post-SST > 550 mmol/l. One patient showed suboptimal response with a cortisol level at 416 mmol/l and is undergoing further investigation. There were no differences between groups in body mass index (median 22.1 kg/m²) or lung function. PPH occurred in 19% of the cohort and was associated with detectable insulin at the 2 hour OGTT timepoint, suggesting the possibility of dysregulated insulin release. AGT patients had higher insulin levels than NGT cases, suggesting relative rather than absolute insulin deficiency in this cohort of PWCF.

Vascular dementia and type 2 diabetes: incidence and outcomes in elderly patients in a ten year study

Nuria Muñoz-Rivas1, Francisco Javier del Cañizo-Gómez1,2, Manuel Méndez-Bailón1, Ana López-de Andéñes2, José María de Miguel-Yunes3, Valentín Hernández-Barrera3, Javier de Miguel-Díez3 & Rodrigo Jiménez-García4

1Hospital Universitario Infanta Leonor, Madrid, Spain; 2Hospital Clínico San Carlos, Madrid, Spain; 3Hospital Universitario Gregorio Marañón, Madrid, Spain; 4Universidad Rey Juan Carlos, Madrid, Spain.

Background

To describe trends in the incidence and outcomes for vascular dementia in elderly patients with and without type 2 diabetes (T2DM) in Spain between 2004 and 2013.

Methods

We used National Hospital Discharge Data to select all patients aged 70 years or over discharged from hospital with a vascular dementia primary diagnosis. Discharges were grouped by diabetes status (T2DM or non-diabetic). Incidence was calculated overall and stratified by diabetes status and age groups. We analyzed diagnostic and therapeutic procedures, patient comorbidities, infectious complications, length of hospital stay and in-hospital mortality (IHM).

Results

We identified a total of 170,607 admissions for vascular dementia (34.3% with T2DM). The adjusted incidence was higher among people with T2DM over the study period. We found a higher incidence in men than women in all years studied. T2DM was positively associated with vascular dementia hospitalization (IRR 2.14, 95% CI). Mean age at admission was higher than 80 years for all groups and more than 70% has a Charlson Comorbidity Index (CCI) ≥2. Pneumonia was significantly associated with a higher mortality (OR: 2.59; 95% CI 2.52–2.67). We found that percutaneous endoscopic gastrostomy (PEG) was associated to lower IHM (OR: 0.37, 95% CI 0.31–0.43) while parenteral nutrition had the opposite effect (OR: 1.29, 95% CI 1.18–1.41). Diabetes was not associated to a higher IHM (OR: 0.99, 95% CI 0.93–1.06). For the entire sample, time trend analyses showed a significant decrease in mortality in patients admitted for vascular dementia (OR: 0.98, 95% CI 0.97–0.99).

Conclusions

Incidence rates were higher in T2DM patients. Men have higher significant incidence rates than women. Pneumonia and parenteral nutrition were associated with mortality while PEG was associated to survival. The presence of diabetes is not associated with a higher IHM during admission with vascular dementia.

Study of the glycemic control in the hospitalized patient

Lucía Vera Pacheco1, Lorena Rentero Redondo1, Carlés Iniesta Navalón1, Amparo Meoro Áviles1, María Teresa Gallego García1, Cristina Del Peso Gilsana1, María Amparo Egea Valera1, Noelia Victoria García-Talavera Espin1 & M. Bienvenida Gómez Sánchez1

1University Hospital Reina Sofía, Murcia, Spain; 2University Hospital Rafael Méndez, Lorca, Murcia, Spain.

Objective

To evaluate the degree of compliance of the glycemic objectives in non-critically hospitalized patient and determine the factors associated to the lack of compliance of the aforesaid objectives.

Material and method

Retrospective observational study in hospitalized patients during 2014. Adult patient age 18 or older, who had at least two points of care de glucose measurements (capillary blood glucose) during their hospitalization, were included. By the revising of the computerise-clinic-history, sociodemographic, clinic and administrative datum were obtained. The results of the glycaemia were obtained from electronic devices.

Results

2610 patients were included, 54.6% were men. The average age was 71.9 ± 14.2 years old (73.7% older than 65 years old). The 73.5% of the patients were hospitalized in medical service. The main diagnoses when they were hospitalized were related with breathing system (20.1%), circulatory system (18.8%) and the central nervous system (11.1%) diseases. The main chronic diseases were diabetes (60.9%), Chronic kidney disease (18.9%), chronic obstructive
The importance of islet antigen-2 and glutamic acid decarboxylase antibodies in proper diagnosis of diabetes mellitus at the age ≥30 and <70 years
Aiste Kondrotiene¹, Evalda Danyte²,³, Rimantas Zalinekevicius³ & Rasa Verkauskiene²³
¹Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania; ²Department of Endocrinology, Kaunas clinics, Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania; ³Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Objective
Misclassification of type 1 (T1DM) and type 2 diabetes mellitus (T2DM) is quite common and crucial to choice of appropriate therapy. The aim of the study was to evaluate the correspondence of islet antigen-2 (IaIA2) and glutamic acid decarboxylase (Anti GAD65) antibodies with clinical diagnosis.

Methods
The Anti IaIA2 and Anti GAD65 were measured in 583 patients (337 males and 246 females) diagnosed with T1DM or T2DM with no typical manifestation at the age ≥30 and <70 years. The data for analysis was collected from medical files.

Results
245 (42.02%) cases had primary diagnosis of T1DM, and 338 (57.98%) – T2DM. One or both positive antibodies were found in 271 patients (group I), and all negative in 312 (group II). The mean age at onset of diabetes mellitus was 42.55 ± 9.29 yrs in group I vs. 41.83 ± 8.53 yrs in group II; P = 0.33. One or both antibodies were found in 141 patients with primary diagnosis of T1DM (odds ratio (OR) 1.84 (95% CI 1.69–2.01, sensitivity 57.55%), 77 males (OR 0.92 (95% CI 0.83–1.04, sensitivity 49.01%) and 27 females (OR 6.16 (95% CI 5.34–7.11, sensitivity 71.28%). 208 patients with T2DM had negative antibodies (OR 2.56 (95% CI 2.38–2.77, sensitivity 61.54%), 63 males (OR 3.81 (95% CI 3.45–4.22, sensitivity 66.13%), and 67 females (OR 1.61 (95% CI 1.44–1.81, sensitivity 71.28%).

Conclusion
The presence of antibodies corresponded to primary diagnosis in 49.01% to 71.28% at the age ≥30 and <70 years.

The increase in unsaturated fatty acids is related to an anti-inflammatory profile in the hypothalamus of non-diabetic IRS2-deficient mice
Vicente Barrios¹, María Vinaixa¹, Laura M. Frago¹, Sandra Canelles¹, Angela M. Valverde¹, Jesús Argente¹ & Oscar Yanes²
¹Department of Endocrinology, Hospital Infantil Universitario Niño Jesús, Instituto de Investigación La Princesa and CIBERObn, Instituto de Salud Carlos III, Madrid, Spain; ²Centre for Omic Sciences, Universitat Rovira i Virgili and CIBERdem, Instituto de Salud Carlos III, Tarragona, Spain.

Background
IRS2-deficient (IRS2⁻/⁻) mice are considered a good model to analyze the development of diabetes as some of them present an increase in glyceria comparable to that observed in diabetes onset in humans, whereas a high proportion of these mice do not develop diabetes. Energy homeostasis regulation by the hypothalamus can be disturbed by an inflammatory environment, which predisposes an individual to the onset of diabetes. Saturated fatty acids induce hypothalamic dysfunction, whereas unsaturated fatty acids mediate several anti-inflammatory actions.

Objectives
Our aim was to determine the pattern of fatty acids in the hypothalamus of non-diabetic IRS2⁻/⁻ (ND) and diabetic IRS2⁻/⁻ (D) mice and its possible association with hypothalamic inflammation.

Methods
We studied 18 male mice including controls, ND and D mice. We analyzed enzymes involved in the generation of NADPH, fatty acid synthesis and regulation of energy homeostasis by western blotting and pro- and anti-inflammatory chemokines/cytokines by multiplexed bead immunoassay. Metabolomic studies were performed by proton nuclear magnetic resonance (H-NMR) after extraction of hypothalamic metabolites in organic solvents.

Epidemiological indicators and prevalence of risk factors of diabetes type 2 among the inhabitants of Almaty city and Almaty region of Kazakhstan
Laura Danyarova, Akmaral Tashmanova & Zhamdeder Shyman
Scientific-Research Institute of Cardiology and Internal Diseases, Almaty, Kazakhstan.

Relevance
The main risk factors for developing diabetes type 2, such as obesity, overeating and a sedentary lifestyle are common to a variety of chronic non-infectious diseases.

Purpose of the study
Investigate the source of epidemiological indicators, risk factors for type 2 diabetes based on cross-sectional study of the population of Almaty city and Almaty region of Kazakhstan.

Methodology
The material for the research were population at the age of 18–69 years living in Almaty city and Almaty region. The study was conducted in three stages: interviews with respondents, physical measurements and laboratory tests.

Results of the study
Analysis of the survey results on a national basis has revealed a significant prevalence of diabetes among Russians (15.35%) compared with the Kazakhks (4.9% r < 0.01), with other Asian ethnic groups (10.7%, r < 0.05). But compare the results of Russians with other European nationality (8.3%) and Ukrainians (7.1%) have not showed significant differences (P > 0.05). The age has been proved as a significant risk factor in the development of type 2 diabetes, and the ratio is 1: 9 (OR = 9.266), ie in the age group over 45 years the risk of developing type 2 diabetes increases by 9 times. Genetic inclination of diabetes refers to a group of diseases.

Conclusion
The survey revealed that people with diabetes and without diabetes showed significant differences in body mass index (BMI), blood pressure, both systolic (SBP) and diastolic (DBP). The values of all parameters in patients with diabetes were significantly higher than in those without diabetes (P <0.05). The survey revealed that people with diabetes compared with those without diabetes suffer the hypertension 2 times harder, ischemic heart disease - more than 3 times, myocardial infarction occurs 6 times, stroke – 4 times more often.

EP437
Association of FGF21 soluble levels with metabolic profile in Gestational Diabetes patients
Cristian A. Saezdo-Toral, Maria L. Lazo-de-la-Vega-Monroy, Martha E. Fajardo-Araujo, Manuel A. Espinosa-Nava, Francisco J. Anaya-Torres, Lorena R. Ibarra-Reynoso & Yeniley Ruiz-Noa
1Universidad de Guanajuato, León, Guanajuato, Mexico; 2Clínica Médica Campestre, León, Guanajuato, Mexico.

Introduction
Gestational Diabetes Mellitus (GDM) has been associated with complications both in the neonate and in the mother; including increased risk of Type 2 Diabetes Mellitus (DM2), obesity, and cardiovascular disease. Fibroblast growth factor 21 (FGF21) is a key regulator of glucose and lipid metabolism. Recently, the relationship between FGF21 and metabolic component diseases such as diabetes mellitus and obesity has been demonstrated. In addition, FGF21 mRNA and protein levels, as well as soluble levels of this molecule, have been reported to be increased in patients with GDM compared to normoglycemic pregnant women.

Objective
To associate FGF21 serum levels with metabolic profile of patients with GDM.

Material and methods
Twenty patients with GDM and fifteen clinically healthy pregnant women were included; serum FGF21 levels were determined by ELISA, and glucose, triglycerides, total cholesterol, HDL, LDL and VLDL values were measured.

Results
Our results shown that serum levels of FGF21 are significantly higher in the group of patients with GDM compared to the control group (31.73 ± 8.9 vs 116.46 ± 31.41 pg/mL, P = 0.013). The values of triglycerides, cholesterol and VLDL showed a similar behavior between groups; while HDL levels were higher in the control group. Serum FGF21 levels positively correlated with triglyceride values (r = 0.344, P < 0.05) and postprandial glucose (r = 0.556, P < 0.05). There was no correlation between total cholesterol, HDL, LDL and VLDL levels and FGF21 levels in our study group.

Conclusion
The FGF21 molecule may play an important role in the GDM pathophysiology, since it alters the metabolic profile, both glycemic and lipid, of these patients.

EP438
Site-specific cancer risk in people with type 2 diabetes: Nationwide population-based cohort study in Korea
Du-Hyung Cho, Ju-Young Jang, Suk Kyeong Kim, Dong-Lim Kim & Kee-Ho Song
1Konkuk University School of Medicine, Seoul, Republic of Korea; 2School of Medicine, Eulji University, Daejeon, Republic of Korea.

Background
Many studies indicated an increased cancer incidence and cancer mortality in subjects with diabetes mellitus. But most of studies have been surveyed in western countries and have problems in applying the results to Korean. We aimed to evaluate the site specific cancer risk of diabetic patients in Korea over 30 years, and investigate causal relationship and temporal relationship by analyzing the organ-specific cancer risk in diabetics according to duration.

Methods
Using a database provided by NHIS, we conducted a retrospective, population-based cohort study for adults over 30 years from January 1, 2005 to December 31, 2013. We calculated the hazard ratio (HR) for each cancer by using Cox regression. And we compared HR for each cancer according the duration of diabetes divided in to 6month, 6months to 3years and more than 3years to verify the possibility of detection bias or reverse causation.

Results
The incidence of total cancer per 1,000 Subjects with diabetes was higher than with non-diabetes group. Hazard ratio(HR) for cancer of pancreas, liver, kidney, bladder, colorectum, thyroid, lung, stomach and leukemia were significantly higher in diabetes group than those of non-diabetes group. HR for laryngeal cancer in male was higher in diabetes group. The total cancer risk was higher in < 6 months of diabetes duration (HR 2.03; 95% confidence interval [95% CI], 1.99–2.07), whereas the hazard ratio decreased with increasing duration of diabetes, raging from 1.19 (95% CI, 1.18–1.21) between 6 months and 3 years to 1.12 (95% CI, 1.11 to 1.13) at over 3 years, but remained significantly higher than the non-diabetic group. HR for pancreas, liver, colorectum, prostate and endometrium were higher in diabetes group for entire duration of diabetes. When excluding diabetes duration less than 6months, HR for stomach, colorectum, liver, pancreas, kidney, bladder, thyroid, prostate, endometrium and cervix showed similar pattern including diabetes duration less than 6 months. Conclusion
Cancer incidence risk increases in T2DM patients, and the phenomenon is more prominent in short durations, i.e. shortly after diagnosis of diabetes. As the duration increases, incidence risk of cancer varies depending on the site of cancer.
Endocrine Abstracts (2017) Vol 49

and patient’s gender. Thus, in diabetes patients, cancer screening should be individualized regarding duration of diabetes, sex, and the site of cancer.

Erosio interdigitalis blastomycetica- discrete and early sign for diabetes mellitus
Anca E. Chrisie & Doina Azoica
University of Medicine and Pharmacy, ‘Grigore T Popa’, Iasi, Romania.

Erosio interdigitalis blastomycetica is a special form candidiasis commonly seen in the third web space of digits, but can spread to all web spaces. Diagnosis is clinically suspected in the presence of maceration and ulceration, erythema, sometimes associated with pain. The main predisposing condition is chronic maceration (for example in launderers), irritant chronic agents and prolonged moisture affect skin barrier with subsequent colonization of Candida spp. Direct mycological examination and fungal culture certify the diagnosis and exclude similar clinical disorders, mostly irritant contact dermatitis and psoriasis. Erosio interdigitalis blastomycetica is frequently diagnosed in daily practice especially in diabetes patients. We present cases series of erosio interdigitalis blastomycetica as initial sign of undiscovered diabetes mellitus. Suspection of diabetes should be made in any case of erosio interdigitalis blastomycetica. Screening for diabetes is mandatory in case of erosio interdigitalis blastomycetica.

Postpartum T2 DM follow-up after gestational diabetes mellitus
Seda Sancak1, Ali Özdemir2, Kerem Yiğit Abacar2, Ahyan Celik1, Nalan Okuroğlu1, Yaşar Serbaş1 & Hasan Aydın1
1Fatih Sultan Mehmet Training and Educational Hospital, Division of Endocrinology and Metabolism, Istanbul, Turkey; 2Fatih Sultan Mehmet Training and Educational Hospital, Department of Internal Medicine, Istanbul, Turkey; 3Fatih Sultan Mehmet Training and Educational Hospital, Division of Obstetrics and Gynecology, Istanbul, Turkey; 4Yeditepe University Hospital, Division of Endocrinology and Metabolism, Istanbul, Turkey.

Purpose
GDM is defined as any degree of carbohydrate intolerance that is first diagnosed during pregnancy. Patients diagnosed with GDM are expected to have complications such as Type 2 DM, obesity, hypertension in the long term. Prevalence of GDM diagnosis during pregnancy changes between 2 and 10%. Our purpose is to revaluate the OGTT of the patients diagnosed with GDM, with regard to their postpartum Type II DM progress.

Materials and methods
450 pregnant women who were not diagnosed with diabetes in the beginning of their pregnancy were included to the study, who had consulted to our clinic between 2012 and 2014. Seventy-two of those quit the study willingly, 20 of those quit during follow-up, 12 of those quit due to spontaneous abortion in the first trimester. 346 remaining patients were included to the study. After 75 g OGTT, GDM screening was made to those patients between 24th and 28th weeks of their pregnancy. With 75 g OGTT, 61 patients were diagnosed with GDM. They were reevaluated with regard to their postpartum Type II DM progress. But 36 of these 61 patients were made 75 g OGTT. Two of those became pregnant again, two of those moved out of the city, 21 of those could not be reached; thus, they could not be reevaluated. Among the patients diagnosed with GDM, 29 of them were followed without diet, four of them with basal and short-acting insulin, two of them only with basal insulin, one of them only with short-acting insulin. Three of those who were followed with diet and one of those who were followed with basal and short-acting insulin were followed with metformin during postpartum period. None of the patients used insulin during postpartum period.

Results
Patients called postpartum in the mean month period 20.82 ± 5.66. Mean age average of the patients was 32 ± 5. Postpartum BMI was 29.10 ± 5.47 kg/m². HbA1c average of the patients was 5.77 ± 0.39%. Four patients who were using metformin during postpartum period were accepted as type 2 DM and were not given OGTT. According to 75 g OGTT; with their basal average being (101.83 ± 10.77 mg/dl) and 2nd hour glucose average being (124.66 ± 39.53 mg/dl), 11 (34.3%) patients were not diagnosed with diabetes. Thirteen (36.11%) patients were diagnosed with impaired fasting glucose, three (8.33%) with impaired glucose tolerance, three (8.33%) with impaired fasting glucose and impaired glucose tolerance, six (16.67%) with type 2 DM.

Discussion
Our study included pregnant women who had not been diagnosed with DM in the beginning of their pregnancy who later on were diagnosed with GDM during pregnancy. We followed them during their postpartum period. With these results, it is found necessary to follow and evaluate the postpartum period of the patients diagnosed with GDM during pregnancy with regard to Type II DM progress.

Diabetic nephropathy in type 1 diabetes mellitus
Ines Barka, Nesrine Chikhirou, Amel Maaroufi, Maha Kacem, Molka Chaieb & Koussay Ach
Department Endocrinology, Farhat Hached University Hospital, Sousse, Tunisia.

Nephropathy is a serious complication of Type 1 diabetes mellitus (T1DM) with a grave prognosis after the onset of proteinuria. End stage of renal disease remains the major cause of excess morbidity and premature mortality in patients with T1DM. The aims of the present study were to investigate the prevalence of diabetic nephropathy and to evaluate risk factors for its development among patients developing T1 DM. Seventy six patients with T1DM history over 20 years were included in our study. We analysed the occurrence and risk factors of diabetic nephropathy. Microalbuminuria and macroalbuminuria were defined as urinary albumin excretion 31–299 mg and 300 mg, respectively, per 24 h in at least two of three consecutive samples, kidney failure was defined as a glomerular filtration rate (GFR) <30 ml/min/1.73 m. The following risk factors were considered: sexe, diabetic control (HbA1c) and duration, hypertension, smoking. A total of 76 patients were enrolled: 43 men and 33 women, the mean age and the mean diabetes duration was 39.9 years ± 9.5 (24–61 years) and 28.18 ± 5.9 years respectively. During follow-up, persistent microalbuminuria developed in four patients (5.3%), macroalbuminuria developed in seven patients (9.2%) and kidney failure in 12 patients (15.8%). The risk of diabetic nephropathy was significantly higher in men than in women (P = 0.012). Our study suggests that several potentially modifiable risk factors predict the development of nephropathy in type 1 diabetic patients.

Diabetes and smoking: epidemiological study in two ethnic groups
Georgios Papadakis1, Thomas Zambelis2, Kostas Konstantopoulos1 & Stylianos Chatzipanagiotou3
1STEPS Stoffwechselzentrum, Biel/Bienne, Switzerland; 2Department of Neurology, Aeginition Hospital, Athens, Greece; 3Department of Haematology, Laikon University Hospital, Athens, Greece.

Objectives
Smoking tobacco is a risk factor for several diseases and has been increasing in many developing countries. Smoking cessation counseling should be a routine component of diabetes care. The aim of the present study was to examine the association between smoking status in two different groups of patients with diabetes: Immigrants from Bangladesh who live in Greece and Greek-born subjects.

Methods
A total of 166 immigrants with diabetes (122 with Type 2 and 44 with Type 1 diabetes mellitus) from Bangladesh were compared with 123 Greek Caucasian patients (82 with Type 2 and 41 with type 1 diabetes mellitus). Patients from
Bangladesh had a mean ±s.d. duration of 10.34 ± 6.2 years of living in Greece. A questionnaire was formulated and pilot-tested for the comprehensibility of questions by both ethnic groups. Interviews were conducted, a physical examination followed and blood samples for plasma glucose and HbA1c were collected. Demographic characteristics and diabetes-related information was collected.

Results
A total of 40 (24.1%) patients from Bangladesh and 58 (47.2%) patients from Greece were smokers, 18 (10.8%) patients from Bangladesh and 37 (30.1%) patients from Greece reported that they were ex-smokers at the time of examination and interview, whereas 108 (65.1%) patients from Bangladesh and 28 (22.8%) patients from Greece never smoked (P < 0.001). Patients from Bangladesh reported less tobacco use than Greek patients (5.61 ± 11.91 vs 24.77 ± 24.20 pack-years, P = 0.001).

Conclusions
Most immigrants reported less tobacco use than native Greeks. Higher education is associated with less smoking prevalence in both ethnic groups. Patients living alone were more likely to smoke than those who live with families. Employed persons had a lower smoking prevalence than unemployed persons in both ethnic groups. Smoking is associated with higher glucose and HbA1c values in both ethnic groups. From the literature tobacco smoking is related to insulin resistance, systemic inflammation, decreased β-cell function and pancreatic inflammation. Understanding some culturally relevant predictors of tobacco use among different ethnic population might assist health care providers in designing successful smoking control programs especially for patients with diabetes.

EP443
Prevalence of hyperglycemia in patients hospitalized in the health area of cuenca (Spain)
José Pérez-Rodríguez, Lidia Guerra-Navarro, Mubarak Alramadan, Paula García-Notario, David Martín-Iglesias, Santiago Aranda-Regules & Dulce Calderón-Vicente
Virgen de la Luz Hospital, Cuenca, Spain.

Introduction and objectives
Hyperglycemia is a common problem in hospitalized patients, that increases infections, mortality, costs and the hospital stay. The objective of this study is to know the prevalence of hyperglycemia in our hospital.

Methods
We designed a cross-sectional observational study. We included patients admitted in the hospital every 3 days in 2 months. We excluded patients younger than 15 years, stays less than 3 days and those of the pediatric, gynecological, emergency and intensive care services. We collected the data from these patients the third day of admission and at discharge. We defined hyperglycemia as two or more capillary glucose values greater than 140 mg/dl.

Results
A total of 328 patients (173 females and 155 males) were included, with a median age of 73 years. The 75% were in medical services and 25% in surgical services. The main reason for admission was infection (26%), followed by organ failure (12%). 33% (109) patients had hyperglycemia. Of these patients, 71.6% (78) were of age of 73 years. The 75% were in medical services and 25% in surgical services.

Conclusion
In this sample we found a high prevalence of LST in men with diabetes, similar to data described in other studies. Age and BMI were correlated with testosterone levels such as in men without diabetes, and no association was observed with A1C levels. Only FT < 15 pg/ml had a significantly higher A1C. 8.40 ± 1.71% vs 7.54 ± 1.38% (P = 0.029). BMI ≥ 25 kg/m² was associated an increased risk of LST (odds ratio (OR): 6.50; 95% confidence interval (CI) 1.33–31.83), such as antipatelet medication (OR: 5.83; CI: 1.40–24.23).

EP445
Vitamin D and testosterone in diabetes mellitus: cross-sectional study results
Nelson Cunha1, Leonor Gomes1,2, Diana Martins1,2, Diana Oliveira1,2, Adriana Lages1, Maria Ventura1, Lúcia Fadiga1, Diana Catarino1 & Francisco Carrilho1
1Endocrinology, Diabetes and Metabolism Department, University Hospital of Coimbra, Coimbra, Portugal; 2Faculty of Medicine of University of Coimbra, Coimbra, Portugal.

Background
In the recent years, Vitamin D role has grown in cardiovascular and inflammatory diseases, and some relations were made with low serum testosterone (LST) levels. It is equally known that in patients with diabetes, the prevalence of LST is higher.

Objective
To determine the prevalence of low levels of vitamin D and its relation with LST in men with diabetes.

Material and methods
A cross-sectional study of 65 men with type 1 and type 2 diabetes was conducted, with age ranging from 25 to 73 years. Clinical data was obtained from clinical records, like disease duration, diabetes mellitus type, insulin dose, retinopathy, hypertension and medication. Biochemical parameters evaluated were: total testosterone (TT), free testosterone (FT), gonadotropins, prolactin, glycated haemoglobin (A1C), urinary albumin/creatinine relation. LST was considered TT < 3.0 ng/ml.

Results
Mean age was 51.9 ± 19.9 years, 60% had type 2 and 40% type 1 diabetes and the mean disease duration was 15.6 ± 10.2 years. 76.9% had body mass index (BMI) ≥ 25 kg/m². Twenty-seven patients (41.5%) had LST, 6 (23.1%) in type 1 group and 21 (53.8%) in type 2. In patients under 40 years-old 5 (26.3%) had LST. In multiple linear regression model TT was associated with BMI (β = –0.355, P = 0.005) and age (β = –0.255; P = 0.044) and no associations were found with FT. However, patients with FT < 15 pg/ml had a significantly higher A1C, 8.40 ± 1.71% vs 7.54 ± 1.38% (P = 0.029). BMI ≥ 25 kg/m² was associated an increased risk of LST (odds ratio (OR): 6.50; 95% confidence interval (CI) 1.33–31.83), such as antipatelet medication (OR: 5.83; CI: 1.40–24.23).

Conclusion
In this sample we found a high prevalence of LST in men with diabetes, similar to data described in other studies. Age and BMI were correlated with testosterone levels such as in men without diabetes, and no association was observed with A1C levels. Only FT < 15 pg/ml had a significantly higher A1C. To clarify this relation, more data is needed.

The relationship between serum uric acid and insulin resistance and sensitivity parameters in Turkish type 2 diabetes mellitus patients
Betül Ekiz-Bilir1, Bülent Bilir1, Neslihan Soysal-Atile1 & Gülşah Elbüken1
1Tekirdag State Hospital, Endocrinology and Metabolic Diseases Division, Tekirdag, Turkey; 2Department of Internal Medicine, Medical Faculty, Internal Medicine Department, Endocrinology and Metabolic Diseases Division, Tekirdag, Turkey.

Summary
Hyperuricemia is associated with glucose metabolism disorders clinically. In this study, we evaluated the relationship between serum uric acid concentrations and some insulin resistance/sensitivity parameters in Turkish type 2 diabetes mellitus patients.

Methods
The anthropometric and laboratory data of 87 type 2 diabetes patients of both sexes (35 male, 52 female) were evaluated retrospectively. HOMA-IR (homoeostatic model of insulin resistance) and QUICKI (quantitative insulin sensitivity check index) measurements were made by the formulae of \[\text{log glu (mg/dl)} \times \text{insulin (\mu/ml)} /405\] and \[1/\text{log ins (\mu ml)} + \log glu (mg/dl)\], respectively.

Results
The mean age of the patients were 54.4 ± 11.2 (minimum 20, maximum 77) years. The serum uric acid levels ranged from 1.7 to 9.6 with a mean of 4.82 ± 1.39. HOMA-IR values ranged from 0.51 to 25.99 with a median of 3.27 ± 2.57. QUICKI values ranged from 0.25 to 0.43 with a median of 0.32 ± 0.04. There was a positive and significant correlation between serum uric acid and insulin levels \( (r = 0.301; P = 0.005) \). There was a negative and significant correlation between serum uric acid and A1c and glucose levels \( (r = -0.372; P = 0.000) \). The correlation of uric acid to age, diabetes duration and body mass index did not reach statistical significance. Although the correlation of uric acid to HOMA-IR and QUICKI values did not reach statistical significance \( (r = 0.128; P = 0.236) \) and \( r = -0.128; P = 0.236 \), HOMA-IR values increased but QUICKI values decreased with increasing uric acid levels.

Conclusion
Although the correlations did not reach statistical significance, serum uric acid levels are positively correlated to insulin resistance parameter (HOMA-IR) and negatively correlated to insulin sensitivity parameter (QUICKI) as expected. The small sample size of our cohort might be responsible for this statistical insignificance. The negative correlation of serum uric acid to glucose and A1c might be related to increased renal excretion of uric acid together with glucose due to osmotic diuresis. These results must be confirmed with larger studies.

Relationship with T helper 1 cytokines and type 2 diabetes
Havva Gönca Tamer1, Örge Telci Çakılı1, İlkyar Kartal1, Kagan Gungör4 & Hasan Hüseyin Mutlu1
1Division of Endocrinology and Metabolism, Department of Internal Medicine, Medeniyet University, Göztepe Training and Research Hospital, Istanbul, Turkey; 2Division of Endocrinology and Metabolism, Department of Internal Medicine, Medeniyet University, Göztepe Training and Research Hospital, Istanbul, Turkey; 3Department of Family Medicine, Medeniyet University, Göztepe Training and Research Hospital, Istanbul, Turkey.

Objectives
T helper1 (Th1) cells were determined to have important roles in the development of type 2 diabetes (T2D). We aimed to investigate relationship between Th1 cytokines (IFN-γ, IL-2 and TNF-α) and T2D.

Material and methods
The study included 32 newly diagnosed type 2 diabetic patients (T2DPs) who had not begun to take antidiabetics except from insulin and 30 healthy subjects (CG) who did not have glucose intolerance (fasting or after glucose load). Serum IFN-γ, IL-2 and TNF-α levels were measured using ELISA method. Serum levels of those cytokines in T2DPs were compared with those in controls.

Results
TNF-α levels of T2DPs were higher \( (P < 0.05) \) than those in controls. There were no differences between the IFN-γ and IL-2 levels of T2DPs and controls \( (P > 0.05) \).

Conclusion
TNF-α levels increase in T2D. Decreased insulin action in T2D may be due to the increased TNF-α levels, since TNF-α has been suggested to down regulate the tyrosine kinase activity of the insulin receptor.

DOI: 10.1530/endoabs.49.EP444

Adipocytokines, incretins, insulin resistance and body composition coherence in women with previously diagnosed gestational diabetes mellitus
Migle Francanate-Daugeliene & Dzilda Veškelioniene
Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Adipose tissue is a major source of adipocytokines. It plays an important role for the development of insulin resistance (IR). Data implicate that incretins enhance insulin sensitivity. One aspect of the pathophysiology of gestational diabetes (GDM) is IR. The relationship between adipocytokines, incretins and GDM might be closely associated.

 Aim
To evaluate the coherence of adipocytokines (adiponectin and leptin), incretins (GIP, GLP-1), insulin resistance and BMI in women with previously diagnosed GDM.

Methods
We examined 126 women with previously (16–43 years ago) diagnosed GDM. BMI, incretins, adipocytokines were evaluated. IR was calculated with HOMA-IR index. Data expressed as mean ± s.o. for parametric data or median (min-max) for non-parametric data. ANOVA was used to compare data between groups of three or more variables. Non-parametric data correlation analysis was performed using the Spearman’s correlation coefficient. The results were considered statistically significant at \( P < 0.05 \).

Results
Women’s average age was 53.52 ± 8.34 years (39–77 years). The coherence between adipocytokines, incretins and BMI was observed: increased BMI determined decreased adiponectin \( (r = -0.361, P < 0.01) \), and increased leptin \( (r = 0.838, P < 0.01) \) either incretins concentrations (GIP \( r = 0.270, P = 0.01 \) and GLP-1 \( r = 0.167, P = 0.21 \)). HOMA-IR was higher in obese women \( (r = 0.641, P < 0.01) \). Data analysed in different BMI categories (normal weight/overweight/obese): adiponectin \((26.8(12.2–27.6)/21.4(10.8–54.4)/17.9(5.2–41.6), P < 0.01) \), leptin \((5.9(0.2–16.1)/12.5(3.8–12.1)/24.7(11.1–74.9), P < 0.01) \), GIP \((0.8(0.2–2.9)/0.97(0.2–5.2)/1.29(0.2–18.2), P = 0.145 \), GLP-1 \((0.06(0.04–21.7)/0.06(0.04–18.2), P = 0.517) \), HOMA-IR \((2.2(0.5–4.7)/2.5(0.4–6.4)/4.6(1.2–27.2), P < 0.01) \). No significance between adiponectin and GIP, GLP-1 was defined \( (r = 0.152, P = 0.156/r = 0.02, P = 0.824) \). Women with lower adiponectin had higher HOMA-IR \( (r = -0.22, P = 0.03) \). The correlation between leptin and GIP, GLP-1, HOMA-IR \( (r = 0.3, P = 0.05/r = 0.231, P = 0.03/r = 0.697, P < 0.01) \) was observed. The positive correlation between GIP, GLP-1 and HOMA-IR \( (r = 0.388, P = 0.01/r = 0.352, P = 0.001) \) was found.

Conclusion
Adipocytokines and incretins are closely linked to the amount of fat tissue in the body: increased BMI correlates with decreased adiponectin and increased leptin/incretins levels in women with previously diagnosed GDM. HOMA-IR is closely associated with leptin and incretins.

EP449
The coherence of carbohydrate metabolism and metabolic parameters (adipocytokines, incretins, insulin resistance) in women with previously diagnosed gestational diabetes mellitus
Migle Francuatz-Daugelieze & Dzida Velickiene
Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
There is growing evidence that gestational diabetes mellitus (GDM) significantly increases the risk of adverse consequences, the most significant of which is a predisposition to the development of metabolic syndrome and diabetes mellitus (DM). The reasons why some women develop DM, while the others not, are still studied. The relationship between various metabolic parameters and GDM might be closely associated.

Aim
To evaluate the coherence of carbohydrate metabolism and metabolic parameters (adipocytokines, incretins, insulin resistance) in women with previously diagnosed GDM.

Methods
We examined 126 women with previously (16–43 years ago) diagnosed GDM. BMI was evaluated. Fasting plasma glucose (FPG) was examined for women with DM. OGTT was performed for carbohydrate metabolism testing for the rest. Women assigned to different groups: NG – normal glucose, IFG-IGT – impaired fasting glucose/impaired glucose tolerance and DM group. Incretins, adipocytokines were evaluated. IR was calculated with HOMA-IR index. Data expressed as mean ± SD for parametric data or median (min-max) for non-parametric data. ANOVA was used to compare data between groups of three or more variables. Non-parametric data correlation analysis was performed using the Spearman’s correlation coefficient. The results were considered statistically significant at P < 0.05.

Results
Women’s average age was 53.52±8.34 years (39–77 years). Age differed in separate carbohydrate metabolism groups (P=0.001). Carbohydrate metabolism was set for 58%: IFG-IGT for 16.7%, DM for 41.3% patients. The correlation between adipocytokines, incretins and FPG was evaluated: higher FPG was seen in women with lower adiponectin (r=−0.186, P=0.037), higher leptin levels (r=0.340 P<0.01) as well as incretins concentrations (GIP r=0.368, P<0.01 and GLP-1 r=0.05, P=0.004) and HOMA-IR (r=0.656, P<0.01). Data analysed in different carbohydrate metabolism groups (NG/IFG-IGT/DM): BMI (26.7 (18.8–52.2)/27.9 (20.1–52.9)/34.8 (20.5–52.9), P=0.001), adiponectin (21.6 (10.3–76.8)/18.7 (9.9–54.4)/17.7 (5.2–52.9), P=0.07), leptin (14.7 (2.2–74.9)/10.9 (2.2–48.6)/9.6 (1.6–66.3), P=0.327), GIP (0.8 (0.2–12.1)/0.8 (0.2–5.2)/0.07 (0.05–21.7), P=0.416), GLP-1 (0.06 (0.04–16.6)/0.07 (0.04–5.4)/0.07 (0.05–21.7), P=0.044), HOMA-IR (2.3 (0.5–4.7)/2.4 (1.4–7.2)/4.5 (0.5–27.2), P<0.01).

Conclusion
Age, BMI, adipocytokines, incretins and IR are closely linked to the carbohydrate metabolism: IFG-IGT and DM was more frequently seen in elder overweight/obese women, having lower adiponectin, higher GLP-1 concentration and higher HOMA-IR.

Instable diabetes revealing pheochromocytoma
Samir Ait Abderrahmane, Imad Boumarka, Mounia Chenegreha, Lilia Brakni, Samia Ouldkaabia & Braham Oudjit
HCA, Kouba, Algeria.

Introduction
Pheochromocytomas are secreting tumors, producing catecholamines (dopamine, noradrenaline and adrenaline), responsible for arterial hypertension; Pheochromocytoma in the diabetic may be responsible for a glycemic imbalance and this considerably alters the management.

Clinical case
A 70-year-old patient is hospitalized for unexplained unstable diabetes mellitus (Several episodes of severe hypo-hyperglycaemia per week with a 7.5% Hba1c. It is diabetes mellitus evolving for 20 years, marked by instability of glycemic figures For 3 years, during his hospitalization for management of severe hypertension was discovered associated with headache and slimming. Infectious and inflammatory balance without anomaly, no lipodystrophy, in search of endocrinopathy responsible for this hypertension and unstable diabetes Biological assays: chromogranin at 10 times normal and Metanephrine at 3.3 times normal, abdomino-pelvic ultrasound finds a supra-renal mass supplemented by pelvic CT recovering an oval tissue formation measuring 46.8×36.5 mm Enhancing intensity after injection of contrast medium, evoke a pheochromocytoma confirmed by a MIBG scintigraphy which finds a focus of intense hyperfixation of the tracer radio corresponding to a right adrenal neuroectodermal tumor of 52×36 mm. In search of other pathologies coming within the framework of a multiple endocrine neoplasia the assessment of extension is without anomaly. Patient is programmed in surgery for a management.

Conclusion
In patients with pheochromocytoma 35% are diabetic, the diagnosis of pheochromocytoma in the diabetic may be responsible for a glycemic imbalance and this considerably alters the management.

Unacylated ghrelin does not seem to influence glucose homeostasis in obese women
José Silva-Nunes,1,2 Miguel Brito3, Carina Silva2, Ana Oliveira3 & Luisa Veiga3
1Endocrinology Department – Curry Cabral Hospital, CHLC, Lisbon, Portugal; 2Research Group in Genetics and Metabolism – Lisbon School of Health Technology, Lisbon, Portugal.

Background and Aim
Unacylated ghrelin (UAG) is the major form of circulating ghrelin. Initially considered as a non-functional peptide, soon after UAG has been associated to a negative action on energy balance, suppression of hepatic glucose production and decrease in circulating levels of insulin. The aim of this study was to analyze the association between the serum levels of UAG and glucose metabolism parameters in obese women, independently from the eventual interference of adiposity.

Material and Methods
One hundred lean and 254 obese Caucasian women were studied. Each woman was characterized for total body weight, body mass index (BMI), waist and hip circumferences, glucose at fasting and 2 hours after an oral glucose tolerance test (OGTT), fasting insulin, glycated hemoglobin (HbA1c), and UAG. Insulin resistance was assessed by the homeostasis model assessment (HOMA-IR).

Obese women were classified in three glycemic status subgroups (normoglycemia, prediabetes and diabetes) according to HbA1c and glucose values.

Results
When compared with the lean group, significantly lower UAG levels were observed in obese women when compared with the lean group (350.2±251.9 vs 219.2±147.7 pg/ml; P<0.001). However, no significant difference was observed through obesity classes I to III. UAG levels were not significantly different among glycemic status subgroups and did not show any direct association with glucose, insulin, HOMA-IR, or HbA1c values.

Conclusions
Although the level of the unacylated form of ghrelin shows an association with anthropometrics it seems not to be involved in glucose homeostasis.

Influence of a part of Korean red ginseng on blood glucose control and complication markers of type 2 diabetic NSY rats
Jung Hye Kim, Sang Hwa Lee, Jung Hye You, Yusik Kim, Jung Suk Park, Ji Sun Nam & Chul Woo Ahn
Gangnam Severance Hospital, Seoul, Republic of Korea.

Objective
Ginsenoside or saponin, is considered as the major bioactive component mediating the therapeutic properties of Korean red ginseng (KRG). However, the exact physiological mechanism underlying anti-diabetic effects is still not fully Clarified. More than 30 different saponins together account for only about 3–4% of KRG, thereby, it is assumed that non-saponin fraction of KRG also carry potential anti-diabetic effects; however, there is no study reporting the differentiated effects of saponin and non-saponin fractions of KRG on glycemic indications and hyperglycemia-associated complication markers.

Endocrine Abstracts (2017) Vol 49
Methods
12-week-old male Nagoya-Shibata-Yusuda (NSY) mice were allocated into 4 groups: control group given standard rodent diet (SRD) or treatment groups given either Korean red ginseng extract (KRG), saponin fraction from KRG extract (Spn) or non-saponin fraction from KRG extract (NSpn) admixed in SRD. The targeted administration doses of KRG, Spn and NSpn were all 200 mg/kg/day; all mice were fed assigned regiments for 24 weeks. Parameters for glycemic control, blood lipid profile, inflammation, oxidative stress, and anti-oxidant enzymatic activities were measured.

Results
KRG had positive effects on glycemic control by attenuating the increase in FBG at 24-week and by increasing glucose clearance and insulin response during i.p. GTT as compared to control. KRG also attenuated increases in TNF-α, oxidized LDL (oxLDL), advanced glycation end-products, and accumulation of malondialdehyde in skeletal muscle. Spn had a positive effect on insulin response while NSpn attenuated oxLDL, as compared to control.

Conclusion
This study showed that anti-diabetic properties of KRG are not mainly mediated by saponin, but the therapeutic potentials of KRG may be due to the orchestral effects of both saponin and non-saponin.

The prevalence of diabetic neuropathy, painful diabetic neuropathy and the at risk diabetic foot in Qatar
Tarik Elhadd1, Georgios Ponirakis2, Khaled Ashawesh1, Khaled Dukhan1, Adel Badie Abou Samra1 & Rayaz Malik1,2
1Qatar Metabolic Institute, Hamad Medical Corporation, Doha, Qatar; 2Weil Cornell Medical College, Doha, Qatar.

Objective
To define the prevalence of Diabetic Peripheral Neuropathy (DPN), painful diabetic neuropathy (PDN) and the at risk diabetic foot in 2 out of the 3 National Diabetics Centres in Qatar.

Methods
712 people with Type-1 & Type-2 diabetes recruited from Alwakra Hospital and Hamad General Hospital underwent assessment for DPN & PDN using the Neurothesiometer and the DN4 questionnaire, respectively.

Results
The average age, duration of diabetes, systolic BP, BMI, HbA1c were: 52.2 ± 0.49, 10.8 ± 0.32 years, 132.6 ± 1.26 mmHg, 32.2 ± 0.52 kg/m² and 8.3 ± 0.11%, respectively. The prevalence of DPN and PDN were 31% and 36%, respectively. However, 4 in 5 adults with DPN and 9 in 10 adults with PDN were undiagnosed. One in ten adults with diabetes were at high risk for diabetic foot ulceration (VPT > 25) and had not been diagnosed. Patients with DPN were significantly older (57.1 ± 0.73 v 49.8 ± 0.62, P < 0.0001), had a longer duration of diabetes (14.34 ± 0.57 v 9.1 ± 0.36, P < 0.0001), higher systolic blood pressure (139.8 ± 2.25 v 129.2 ± 1.46, P = 0.001) and higher creatinine (118.6 ± 16.76 v 70.9 ± 2.54, P = 0.007), but no difference in HbA1c (8.6 ± 0.21 v 8.2 ± 0.13), vitamin D (23.7 ± 1.7 v 23.3 ± 0.9) or B12 (344.7 ± 39.17 v 323 ± 21.3).

Conclusion
The overall prevalence of DPN, PDN and those at risk of foot ulceration in Qatar are comparable to that reported in Europe and the US. However, an alarmingly low proportion of patients are diagnosed and treated for DPN and PDN. There is a need for a systematic screening for DPN and PDN in Qatar. Age, duration of diabetes, blood pressure and high creatinine are risk factors for DPN.

Changes in gene expression MADCAM1, S1PR1, CXCR4 and CCR7 in offspring of rats with streptozotocin-induced diabetes and after metformin administrations
Denis Putulin, Alex Kamshysh & Vita Kamshysh
ZSMU, Zaporozhie, Ukraine.

Introduction
mTOR is not only a central regulator of lipid metabolism, controlling the processes of adipogenesis and lipolysis, but also a regulator of immunometabolism of immune cells infiltrating the adipose tissue. In its turn, the level of progression of diabetes is largely limited by Treg subpopulation, the complexity and heterogeneity of which is confirmed by the detection of numerous tissue-specific Tregs, including the so-called VAT Tregs (visceral adipose tissue CD4+ Foxp3+ regulatory T cells). Therefore, the purpose of the work was to find out the level of expression of mRNA genes of mTOR, Foxp3, IL1β and IL17A in parapancreatic adipose tissue of rats with streptozotocin-induced diabetes after introduction of metformin.

Methods
We use RT-PCR method for investigating of mRNA expression levels of genes MADCAM-1, CXCR4, CCR7 and S1PR1 in MLN of the offspring of rats with experimental gestational diabetes. To determine the level of target genes was performed RT-PCR in real-time by thermocyclor CFX96™ Real-Time PCR Detection Systems. The relative level of gene expression were studied with rat reference genes GAPDH by the method ΔΔCt. Statistical analysis were conducted using available software «Bio-Rad CFX Manager 3.1» (Bio-Rad, USA).

Results
Expression analysis of homing receptors in MLN revealed an expected significant increasing of CCR7 and MADCAM-1 mRNA in offspring of animals with EGD, indicating the activation of the immune cells in the GALT, which is accompanied by intensification of lymphocytes homing and confirms the involvement of these receptors in the pathogenesis of diabetes. We were unable to detect changes in the mRNA levels of another regulator – CXCR4 in MLN of the offspring of rats with EGD. Increased expression level of S1PR1 mRNA of MLN lymphocytes in the offspring of animals with diabetes confirms its important role in the progression of diabetes.

Conclusions
Signals of chemokine receptors affect the activation of different Th cells subsets and we may assume their pivotal role in the development of autoimmune diseases, particularly diabetes mellitus. The revealed changes evidence of abuse of formation of peripheral immunological tolerance and can trigger the development of AID in the offspring of mothers with EHD.

Study of expression of genes mTOR, Foxp3, IL1β and IL17A in parapancreatic adipose tissue of rats with streptozotocin-induced diabetes and after metformin administrations
Denis Putulin, Alex Kamshysh & Vita Kamshysh
ZSMU, Zaporozhie, Ukraine.

Introduction
mTOR is not only a central regulator of lipid metabolism, controlling the processes of adipogenesis and lipolysis, but also a regulator of immunometabolism of immune cells infiltrating the adipose tissue. In its turn, the level of progression of diabetes is largely limited by Treg subpopulation, the complexity and heterogeneity of which is confirmed by the detection of numerous tissue-specific Tregs, including the so-called VAT Tregs (visceral adipose tissue CD4+ Foxp3+ regulatory T cells). Therefore, the purpose of the work was to find out the level of expression of mRNA genes of mTOR, Foxp3, IL1β and IL17A in parapancreatic adipose tissue of rats with streptozotocin-induced diabetes after introduction of metformin.

Methods
We use RT-PCR method for investigating of mRNA expression levels of genes mTOR, Foxp3, IL1β and IL17A. To determine the level of target genes was performed RT-PCR in real-time by thermocyclor CFX96™ Real-Time PCR Detection Systems. The relative level of gene expression were studied with rat reference genes GAPDH by the method ΔΔCt. Statistical analysis were conducted using available software «Bio-Rad CFX Manager 3.1» (Bio-Rad, USA).

Results
The development of diabetes causes the transcriptional activation of the gene of the protein kinase mTOR, does not affect the expression of mRNA of proinflammatory cytokines IL1β and IL17A. At the same the introduction of metformin in diabetic rats inhibits the expression of mRNA of mTOR and increases the level of transcriptional activity of the gene Foxp3 in parapancreatic adipose tissue.

Response to stroke in diabetic versus non-diabetic patients. Should Diabetes education systematically include advise on stroke symptoms and the correct response to them?

Paloma González-Lázaro1, Julia Silva-Fernández1, Rafael García-Ruiz2, Rosa García-Ruiz2, Francisco Javier Gómez-Alfonso3, Florentino Del Val-Zaballos1, Belvis Torres-Arroyo1 & Carolina González-Pereira4

Introduction
We systematically analysed stroke-specific education in diabetes and explored the correct response to stroke symptoms. Our results suggest that diabetes education systematically include advise on stroke symptoms and the correct response to them.
Introduction
Stroke is the second cause of death in the world and the first cause of disability. It is also the second cause of Diabetes-related death. The success of reperfusion therapies is time-dependent, with most delays being patient-related. We investigated the response to stroke in diabetic patients (DM), as their risk of stroke is increased by 1.86 times.

Material and Methods
Consecutive patients with acute stroke or transient ischemic attack were prospectively included. Sociodemographic and clinical data, time from stroke onset to decision to seek medical attention (Decision delay (DD)) and to hospital arrival (Prehospital Delay (PD)) and first medical contact (FMC) were obtained. Decision to call the 112 Emergency Services (112-ES) within the first 15 min was considered the correct decision.

Results
382 patients were included. 138 (36.1%) were diabetic. DD was < 15 min in 41 (29.7%) DM vs 57 (23.4%) non-diabetic patients (non-DM) (P = 0.17), FMC was 112-ES in 20 (14.5%) DM vs 50 (20.5%) non-DM (P = 0.14), and a correct decision was made in 13 (9.4%) DM vs 32 (13.1%) non-DM (P = 0.28). PD was < 60 min in 14 DM vs 29 non-DM. No significant differences were found after adjustment for potential confounders.

Conclusions
Response to stroke symptoms in DM was different to non-DM, while carrying a greater load of vascular risk factors and a higher risk of stroke. Even more, although not significant, the use of the 112-ES was quite lower in DM. We propose to systematically incorporate information on stroke risk, symptoms, consequences and how to respond to stroke into DM education.

Conclusion
This study showed no association between the rs1746661 and rs3480 polymorphisms and GDM; however, the rs1746661T mutated allele seems to be associated with increased SBP in pregnant women independently of GDM.

DOI: 10.1530/endoabs.49.EP457
discharge. No other abnormalities were detected. Abdominal US was normal. During hospitalization, the patient progressively achieved adequate glucose and he was discharged with a basal-bolus insulin regimen, pending on the results of pancreatic autoimmunity, and the performance of a magnetic cholangiorenos- nance. During follow-up the patient showed no evidence of islet-cell antibodies nor glutamic acid decarboxylase antibodies (Anti GAD65 0.46 IU/mL, Anti IA2 2.13 U/mL, anti insulin 0.51 U/mL), a C-peptide of 237 ng/ml and the magnetic cholangiorenosonance that revealed aplasia of the dorsal pancreas. The diagnosis of MODY 5 diabetes was made after a genetic study for detecting HNF-1beta gene mutations confirmed a missense mutation (M_000458.2:c.884G>A - p.Arg295His+) in the DNA-binding homeodomain. The insulin was progressively withdrawn and metformin was introduced.

Conclusion

MODY 5 encompasses a wide clinical spectrum. Analysis for mutations of HNF-1B is warranted in young patients with an AD pattern family history of diabetes particularly when pancreatic atrophy, kidney or genital abnormalities are present.

New-onset diabetes after transplantation (NODAT): an evaluation of risk factors in renal transplantation

Raquel Almeida, Andreia Campos, La Salete Martins & Jorge Dores

Centro Hospitalar do Porto, Porto, Portugal.

**Background**

The identification of patients with high risk of diabetes mellitus (DM) after renal transplantation in the pre-transplantation period is crucial for the prevention of the complications and reduction of the risk of cardiovascular morbidity and mortality. With this study we intended to identify the risk factors for NODAT in renal transplantation.

**Methods**

All patients submitted to renal transplantation at Centro Hospitalar do Porto between 01/01/2009 and 12/31/2013 were retrospectively evaluated. Patients with history of DM, transplantation of more than one organ, younger than 18 years at transplantation, and patients with less than 6 months of follow-up were excluded. DM was defined according to WHO criteria. To identify risk factors for DM, two groups were formed: people with diabetes (DM +) and without diabetes (DM −).

**Results**

Of the 556 patients undergoing renal transplantation, 247 patients were excluded and 309 patients were eligible for the analysis. A total of 68 patients (22%) with DM criteria were identified, with a mean time to onset of the disease of 8.59 ± 15.3 months posttransplant. Patients were followed for an average of 4.2 ± 1.5 years (DM +) and 4.2 ± 1.8 years (DM −). DM + patients were significantly older at the time of transplantation (54.1 ± 11.5 vs 45.7 ± 13 years, P<0.001), had higher frequency of family history of DM (30.9% (P<0.001), higher obesity rate (17.6% vs 6.4%, P<0.001) and higher deceased-donor rate (86.8% vs 75.5%, P=0.048). There was no statistically significant difference between groups in recipient sex distribution, donor age and sex, renal disease etiology, immunosuppressive therapy used or HCV/CMV infection occurrence.

**Discussion and conclusion**

The only modifiable pre-transplant risk factor found is obesity, whereby a healthy lifestyle and weight loss should be encouraged within the specific limitations of patients with end-stage renal disease. Since cardiovascular diseases are the main cause of morbidity and mortality in these patients, a tight control of all vascular risk factors is required.

Malnutrition and sarcopenia in diabetic institutionalized older people: are there differences with non diabetic people?

Beatriz Lardies-Álvarez, 1 Alejandro Sanz-París, 2 Guayente Verdes-Sanz 3 & Leticia Pérez-Fernández2

1Royo Villanueva Hospital, Zaragoza, Spain; 2Miguel Servet Hospital, Zaragoza, Spain; 3Obispo Polanco Hospital, Tijuana, Mexico.

**Backgrounds and aims**

The aims of the study were, on the one hand, to analyze the prevalence of type 2 diabetes mellitus in a population of institutionalized older people and, on the other hand, to evaluate if the anthropometric parameters and the prevalence of malnutrition and sarcopenia were different in diabetic patients compared with the group of non-diabetics.

**Methods and material**

A total of 312 institutionalized elderly people volunteers with a mean age of >65 years were selected, being 207 women and 105 men. They had preserved functional capacity and absence of cognitive impairment. Anthropometric variables were measured, test of physical performance were carried out and muscle mass was determined by biocelluclast impedance analysis (BIA). For the diagnosis of sarcopenia, the criteria recommended by the European Working Group on Sarcopenia in Older People (EWGSOP) were used, which consist of using the presence of both low muscle mass and low muscle function (strength or performance), and the method to evaluate if the patients had malnutrition was the Mini Nutritional Assessment test.

**Results**

The prevalence of type 2 diabetes mellitus in this population was 21.15%, being 57.6% of them women and 42.4% men (P=0.089). There were statistically significant differences in the variables age, weight, BMI, arm circumference, tricipital skinfold and abdominal circumference, between diabetic and non diabetic people, being all this variables higher in the diabetic group. According to the results of the MNA test, the prevalence of malnutrition in the diabetic group was of 52.2%, while in non diabetic people was 44% (P<0.05), and with regards to the prevalence of sarcopenia, there were statistically significant differences between the non diabetic group, in which the prevalence of sarcopenia was 27.3%, and diabetic people, with a higher prevalence (36.58%).

**Conclusion**

The prevalence of type 2 diabetes was 21.15%, which was higher in women than in men, without statistically significant differences. Moreover, there were significant differences in the anthropometric parameters evaluated and the prevalence of malnutrition and sarcopenia was higher in the diabetic group.

Incidence of diabetic ketosis and ketoacidosis in Caucasian adults with type 2 diabetes mellitus: a population-based study
Petra Cačić1, Ivan Krtuljac1, Miroslav Cačić2, Božidar Perić1,2, Maja Filipović-Grčić1, Gorana Mršević1 & Milan Vrkljan1,2
1University of Zagreb School of Medicine, Zagreb, Croatia; 2University of Zagreb School of Medicine, Zagreb, Croatia; 3University Hospital Center ‘Sestre Milosrdnice’, Zagreb, Croatia.

Aims
Diabetic ketosis (DK) and diabetic ketoacidosis (DKA) are known complications of type 1 diabetes mellitus (T1DM). However, DK and DKA have been described in T2DM. Referred to as ketosis-prone T2DM, this subtype of T2DM has been described in Hispanics and Afro-Americans of sub-Saharan Africa, but the incidence and pathogenesis remains unknown. We aimed to analyze characteristics of patients with diabetic ketosis (DK) and diabetic ketoacidosis (DKA) in Caucasian adults with T2DM.

Methods
Studied population included 261 749 adults. DK criteria included plasma glucose >13.9 mmol/l, and ketonuria >2; while in DKA bicarbonate <18 mmol/l or pH <7.30 was also required. Hyperglycemic crises without these criteria were defined as non-ketotic hyperglycemia (NKH).

Results
During 5-year period, we observed 630 episodes of DK and 215 episodes of DKA. Only 8.6% of DKA episodes and 34.4% of DKA were attributed to T1DM. Patients with T1DM were younger, leaner, majority had newly diagnosed disease, and hyperglycemia was the main cause of admission. Standardized incidence ratio for DK was 48.1 (95% CI 44.5–52.1) and 17.0 (95% CI 14.9–19.4) for DKA. Incidence for both DK and DKA was increasing with age. Patients with T2DM had a risk of 0.8% for developing DKA and 2.9% for DK over 5-year period.

Conclusions
Our study showed that DK and DKA are not uncommon in Caucasian adults and the majority of episodes were contributed to T2DM. Further studies are needed to assess the impact of these clinical entities.

HOMA-IR and HOMA-islet indices in the evaluation of different carbohydrate metabolism disorders during glucocorticoid therapy
Guzel Nurrulina, Farida Valeeva & Kamilya Khasanova
Kazan Medical State University, Kazan, Russia.

Introduction
Diabetogenic effect limits the use of glucocorticoids (GC). To evaluate the role of modified HOMA-IR and HOMA-islet indices in different carbohydrate metabolism disorders (CMD) during oral (OGCT) and PULSE (GCPT) glucocorticoid therapy (GCT).

Patients and methods
A study including 165 patients with systemic lupus erythematosus (n = 53), systemic vasculitis (n = 45) and chronic glomerulonephritis (n = 67) was performed. 98 patients received GCPT (course dose – 1800–3000 mg) and 67 – oral GCT (OGCT). All patients underwent standard clinical and laboratory evaluation, oral glucose tolerance test (OGTT), evaluation of C-peptide, HOMA-IR and HOMA-islet indices.

Results
CMDs developed less often in patients receiving GCPT compared to long-term OGCT (p = 0.035). In patients receiving OGCT the most prevalent CMDs were IGT and DM – in 21 (31.1%) and 19 (28.4%) patients respectively, which was significantly higher compared to patients in GCPT group (P = 0.038 and P = 0.049). In both groups of patients with DM and IGT baseline C-peptide and HOMA-IR before the treatment and OGTT was higher than in patients without CMD or with IFG, which indicates the presence of insulin resistance in this patient group. In DM patients a decrease of HOMA-islet index was observed in the first group from 13.96 before OGTT to 11.8 after glucose load and in the second group from 147 at baseline to 78.4 after the test.

Conclusions
GCT leads to IGT and DM in patients with increased insulin resistance both during GCPT and long-term OGCT. Long-term OGCT is associated with more CMDs compared to GCPT.

Carbohydrate metabolism disorders associated with different glucocorticoid therapy schemes
Guzel Nurrulina, Farida Valeeva & Kamilya Khasanova
Kazan Medical State University, Kazan, Russia.

Introduction
Glucocorticoid therapy (GCT) is one of the risk factors of carbohydrate metabolism disorders (CMD) in patients with systemic inflammatory diseases. CMD development is a concern not only with long-term therapy, but also during intensive short-term glucocorticoid (GC) administration, which can lead to different CMDs, including impaired glucose tolerance (IGT) and diabetes mellitus (DM).

Aim
To evaluate the prevalence of CMD after long-term and intensive GCT in patients with systemic lupus erythematosus (SLE), systemic vasculitis (SV) and chronic glomerulonephritis (CGN).

Patients and methods
The study included 165 patients, among them with SLE – 53, SV – 35 and CGN – 67 patients. Ninety-eight patients received GC pulse-therapy (GCPT) (one series of three sessions), and 67 – oral GCT (OGCT). All patients underwent standard clinical and laboratory evaluation, oral glucose tolerance test (OGTT), evaluation of C-peptide, HOMA-IR and HOMA-islet indices.

Results
CMDs developed less often in patients receiving GCPT compared to long-term OGCT (p = 0.035). In patients receiving OGCT the most prevalent CMDs were IGT and DM – in 21 (31.1%) and 19 (28.4%) patients respectively, which was significantly higher compared to patients in GCPT group (P = 0.038 and P = 0.049). In both groups of patients with DM and IGT baseline C-peptide and HOMA-IR before the treatment and OGTT was higher than in patients without CMD or with IFG, which indicates the presence of insulin resistance in this patient group. In DM patients a decrease of HOMA-islet index was observed in the first group from 13.96 before OGTT to 11.8 after glucose load and in the second group from 147 at baseline to 78.4 after the test.

Conclusion
The evaluation of modified HOMA-IR and HOMA-islet indices before the start of intensive GC treatment and during OGCT may improve early detection of risk groups for serious CMDs – IGT and DM.

Parvovirus B19 infection may have a role in the etiopathogenesis of type 1 DM
Hasan Ruseyn Gunuscu1, Kveser Onbas1 & Nilgun Kasifoglu2
1Dumlupinar University, Kutahya, Turkey; 2Eskisehir Osmangazi University, Eskisehir, Turkey.

Parvovirus (Erythrovirus) B19 (EVB19) infection may trigger autoimmune diseases like SLE, RA, and vasculitis. Parvovirus B19 belongs to the parvoviridae family and to the erythrovirus genus. The etiopathogenesis of autoimmune diabetes mellitus could not be explained yet. The aim of our study was to investigate whether EVB19 may have a role in the etiopathogenesis of type 1 DM. Therefore have we examined whether EVB19 is more frequent among type 1 diabetics. 32 patients with type 1 diabetes and 30 control patients were included in the study. 25 of the 32 type 1 diabetic patients had parvovirus B19 IgG positive sera. The seroprevalence of IgG parvovirus B19 among controls were in 16 of 30 persons. This was statistically significant (p level was 0.039). 25-OH vitamin D levels were lower among Parvovirus B19 IgG seropositive patients than higher patients. This may be related to the fact that the immune status is impaired in vitamin D insufficiency. In conclusion, parvovirus B19 infection may play a role in triggering type 1 diabetes and low vitamin D levels may increase susceptibility to parvovirus B19 infection.

Hyperinter study: evaluation of glycemic values in acute inpatients from medical and surgical units. population without diabetes
Helena Santos Gonçalves, Anusca Lopes Paixao, Cristina Lameira, Ana Rafael, Marta Gomes, Rita Silva, Rita Queiros, Natalia Lopes, Ana Filipa Rebelo & Paula Vaz Marques
Vila Real Hospital, Centro Hospitalar Trás os Montes e Alto Douro, Vila Real, Portugal.

Introduction
Although inpatients hyperglycemia is a current uneasiness among the medical community, its prevalence in Portugal in unknown. We aim to identify ‘Stress hyperglycemia’ and ‘New onset diabetes’ cases in inpatients in a district hospital.

Methods
We evaluated inpatients from Internal Medicine (IM), General Surgery (GS), Orthopedics and Traumatology (OT) and Stoke Unit (SU) departments, admitted from the emergency department, during August 2017. Excluded patients who were diabetic (phase 1). Non diabetic integrated a 3 phase study: phase 2 – Capillary glycemia evaluation 2 h after first meal; if >140 mg/dl patient did another evaluation (fasting, 2 h after meal) (phase 3); if patient still hyperglycemic, the evaluated Hba1c and hemoglobin (phase 4).

Results
Evaluated 317 patients (121 diabetic, 196 non diabetics). Non diabetic group: 89 female, 107 male, average 68.75 ± 18.55 years, 75 patient from IM, 75 from GS, 33 from OT and 13 from SU. 134 patients finished in phase 2, 47 in phase 3 and 15 in phase 4. From patients that finished in phase 4, Hba1c average was 6.12 ± 1.3% (four: A1c ≥6.5% and three: 5.7 < A1c < 6.5%). In the previous group, only one patient had a hemoglobin <12 g/dl and three were under corticosteroids. There was no statistical significance between glycemia values and the section of internment or days of hospital admission.

Conclusion
In the non diabetic group we calculated a 23.98% of ‘Stress Hyperglycemia’, 7.66% of the patients were at higher risk of developing diabetes, because they had at least two hyperglycemic values and 2.04% were positive for Diabetes Mellitus (Hba1c ≥6.5%). The study identified a relevant percentage of people with a higher risk of developing diabetes, but a small percentage of people with diabetes; this may be explained by the inefficiency of the national screening programmes.

Evaluation of oral glucose tolerance test as a screening test detecting glucose metabolism impairment in patients chronically treated with glucocorticoids without previous history of diabetes
Karolina Nowak1, Katarzyna Romanowska-Prochnicka2,3, Katarzyna Bornkowska1, Wojciech Zgliczynski1 & Lucyna Papierska1
1Department of Endocrinology, Centre of Postgraduate Medical Education, Warsaw, Poland; 2Department of General and Experimental Pathology, 2nd Faculty of Medicine, Medical University of Warsaw, Warsaw, Poland; 3Department of Systemic Connective Tissue Diseases, Eleonora Reicher National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland.

Introduction
One of the most common side effects of glucocorticoid treatment is glucose intolerance and diabetogenesis. Although glucocorticoids cause mainly postnatal hyperglycaemia the International Diabetes Federation, American Diabetes Association and The European League Against Rheumatism recommend to screen patients chronically treated with glucocorticoids by regularly determining fasting plasma glucose. Such an approach can lead to false negative results. Since pre-diabetes and diabetes lead to life-threatening conditions such as chronic renal failure and myocardial infarction it is important to correctly diagnose these conditions.

Objectives
The aim of the study was to evaluate if oral glucose tolerance test (OGTT) is a better screening tool than plasma fasting glucose levels in diagnostics of diabetes in patients chronically treated with glucocorticoids without previously diagnosed pre-diabetes or diabetes. The second objective was to determine the risk factors of developing steroid-induced glucose metabolism impairment.

Material and methods
In 50 patients on GCS treatment diagnosed with connective tissue diseases OGTT was performed. All participants underwent clinical and biochemical evaluation (age, sex, time of treatment, current and cumulative dose and type of steroid, family history of diabetes, BMI, WHR, Hba1c, HOMA-IR).

Results
13 patients (28%) had impaired glucose tolerance (three of them had coincided impaired fasting glucose). One patient (2%) diagnosed with diabetes had normal levels of plasma fasting glucose. 36 patients had normal glucose metabolism. Apart from age the statistical analysis showed no significant difference between groups in the rest of analyzed parameters thus the prediction of risk factors was impossible.

Conclusions
Only by performing OGTT 22% of patients could be correctly diagnosed with pre-diabetes and diabetes. The oral glucose tolerance test is the only standardized tool that is able to effectively detect the steroid-induced impairment in glucose metabolism. It should be performed in every patients chronically treated with GCS even without other risk factors of diabetes.

Impact of exercise training on insulin sensitivity estimated by HOMA model in elite athletes: association with body composition
Marina Djelic1, Sanja Mazic1, Mirjana Sumarac Dumanovic1, Rada Jeremic2, Aninka Vujovic1, Tijana Durnic1, Snezana Cvetkovic1 & Dragan Micic2
1Institute of Physiology, School of Medicine, University of Belgrade, Belgrade, Serbia; 2Clinic for Endocrinology, Diabetes and Metabolic Diseases, School of Medicine, University of Belgrade, Belgrade, Serbia; 3Institute of Forensic Medicine, University of Belgrade, Belgrade, Serbia; 4Clinics for Pulmology, Clinical Center of Serbia, Belgrade, Serbia.

It has been shown that low values of insulin sensitivity have been related to metabolic diseases. Exercise prescription is crucial to prevent low insulin sensitivity in general population, and athletes are good physiological model. If this assumption is correct, examine insulin sensitivity in elite athletes should reflect the positive effect of exercise on insulin sensitivity. The aim of this study was to investigate the effects of regular exercise on insulin sensitivity estimated by HOMA model in elite athletes, as well as the possible relationship the insulin sensitivity with body composition. Sixteen low fat athletes (LFAG, BF<12%), 15 high fat athletes (HFAG, BF≥12%) and 15 sedentary subjects participated in study. The subjects underwent to an assessment of body composition. All subjects were exposed to one bout exercise test on treadmill in order to examine acute changes of insulin response. Blood samples were obtained at rest, immediately after the exercise test and 30 minutes after recovery. Separated serum were used for insulin ELISA analysis and glucose levels. Insulin resistance index (HOMA-IR) was calculated. At rest, LFAG had significantly lower insulin compared to control group (P<0.05). Also, there were no statistically differences in basal level of glycaemia and HOMA index between groups. In all three study groups insulin levels were higher immediately after an acute bout of exercise compared to baseline values (P<0.05), and remained equal (LFAG, P<0.05 compared to baseline) or even higher (P<0.05, HFAG, P<0.05, controls) in recovery. There is no significant correlation between the parameters of body composition and HOMA-IR in all groups. In conclusion, our findings show that insulin respond to acute exercise dose not altered insulin sensitivity estimated by HOMA model in elite athletes.

Abstract withdrawn.

Debut diabetes characteristics
María Rosa Alhambra Expósito, Inmaculada Prior Sánchez, Paloma Moreno Moreno & María Ángeles Gálvez Moreno
Hospital Universitario Reina Sofía, Córdoba, Spain.

The diabetes type 1 (DM1) is a chronic autoimmune disease, it tends to appear in childhood, its incidence continues to rise and the complications arising from improper care poses serious health problems for those who suffer. LADA diabetes is autoimmune diabetes which appear in adults.

Objective
To describe the characteristics of the new diabetes debut in our environment.

Material and methods
We included all patients who attended the Diabetes Day Hospital of our hospital for unknown type 1 or MODY diabetes from October 2015 to September 2016. Results
A total of 43 patients were enrolled. With an average age of 36±13 years, 48.8% were men. The 34.9% were LADA type diabetics and the rest DM1. At diagnosis they had a mean BMI of 23±4 kg/m², with an abdominal perimeter of 86±12 cm, mean arterial tension 116±70/70±12 mmHg. An average glucose concentration of 238±106 mg/dl and an HbA1c of 11±3%. Initial cholesterol of 173±40 mg/dl, HDL 46±16 mg/dL, LDL 103±34 mg/dl was noted. The level of peptide C at the diagnosis was 0.3±0.2 ng/dl (N up to 0.5 ng/dl). In DM1, 72% of patients had positive anti-GAD antibodies and 78% had anti-IgA antibodies. In the patients with diabetes type LADA 61% had positives only the Anti Ia2, 24% antiGAD, the rest had positives both. Of the patients, 8% associated autoimmune thyroid disease. Without other autoimmune comorbidities.
Conclusions
The incidence of type 1 diabetes and MODY type diabetes is increasing in recent years. In our setting, 78% of patients with DM-1 have positive antibodies. There were few comorbidities al diagnosis.

Effect of vitamin D supplementation on Glucose Tolerance, HOMA indices and on the risk of GDM in pregnant women with vitamin D deficiency - a prospective interventional study
Ramesh Jayanthi1 & Naga Satya Vani Mudiganti2
1Sai’s Institute of Endocrinology, Hyderabad and Visakhapatnam, India; 2Osmania Medical College, Hyderabad, India.

Background
Vitamin D deficiency and GDM are highly prevalent with long term implications. Prospective studies to analyse the effect of vitamin D supplementation on glucose tolerance in pregnant women are limited.

Objectives
Objectives of the study are: 1) To determine the relation between vitamin D deficiency and HOMA indices and glucose tolerance in the first trimester among pregnant women. 2) To study the effect of vitamin D supplementation on HOMA indices and on the occurrence of GDM in pregnant women with vitamin D deficiency.

Methods
50 pregnant women in first trimester were enrolled. FPG, 2 hrPG, FPI, Plasma 25(OH)D were done and HOMA IR and HOMA B were calculated at baseline and at 28 weeks of gestation. Vitamin D deficient women were prescribed 2000 IU of vitamin D per day as per ACOG recommendations.

Results
There was no correlation between 25(OH) vitamin D and FPI, FPG, 2hrPG, HOMA IR and HOMA B in both vitamin D deficiency and sufficiency groups in the first trimester. At 28 weeks of gestation, in the vitamin D deficiency group, significant rise in FPG, 2hrPG, FPI and HOMA IR occurred despite correction of vitamin D deficiency with supplementation. The risk of GDM was similar in both the groups.

Conclusion
There is no correlation between 25(OH)D and HOMA IR, HOMA B, FPG or 2hrPG in the first trimester of pregnancy. Vitamin D supplementation, in pregnant women with vitamin D deficiency, has no role in decreasing the risk of GDM at 28 weeks follow up.

Lack of postpartum reclassification test in gestational diabetes – factors conditioning loss of follow-up
Rita Bettencourt-Silva1,2, Pedro Soutére1,2, Daniela Magalhães1,2, Sandra Belo1,2, Ana Oliveira1,2, Davide Carvalho1,2, Joana Queiroz1,2, & Diabetes and Pregnancy Study Group Portuguese Society of Diabetology3
1Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar São João, E.P.E., Porto, Portugal; 2Faculty of Medicine, University of Porto, Porto, Portugal; 3Diabetes and Pregnancy Study Group, Portuguese Society of Diabetology, Porto, Portugal; 4Outpatient Clinic of Obstetrics and Endocrinology, Centro Hospitalar São João, E.P.E., Porto, Portugal.

Introduction
Gestational diabetes mellitus (GDM) is a risk factor for maternal-fetal complications and development of diabetes or intermediate hyperglycemia after pregnancy. The follow-up should be done by a multidisciplinary team. After delivery, all women diagnosed with GDM should undergo an oral glucose tolerance test (OGTT) for reclassification.

Aim
To evaluate the non-adherence factors to reclassification OGTT after GDM.

Methods
A cohort of 5271 Portuguese women from the National Registry of GDM was studied. Demographic, anthropometric and analytical data and maternal-fetal outcomes were evaluated. The diagnosis of GDM was made according to WHO criteria.

Results
In our sample, 1666 (31.5%) women with DGM did not undergo reclassification OGTT. Of those who underwent OGTT, 92.2% had a normal test, 0.9% diabetes and 6.9% intermediate hyperglycemia. The chance of follow-up loss was 46.5% significantly lower when there was fetal (OR = 1.318–1.962, P < 0.001) and 40.9% higher in those with ≥ 3 pregnancies (OR = 1.409, 95% CI = 1.243–1.599, P < 0.001). Women treated with insulin during pregnancy had increased adherence to the reclassification test (OR = 1.377, 95% CI = 1.222–1.552, P < 0.001), but those with worse glycemic control with HbA1c ≥ 5.7% in 3rd trimester had 60% more chance of follow-up loss (OR = 1.608, 95% CI = 1.318–1.962, P < 0.001). The adherence to postpartum reclassification was also significantly lower when there was fetal death (OR = 5.085, 95% CI = 2.402–10.763, P < 0.001) or neonatal (OR = 4.661, 95% CI = 1.365–16.055, P = 0.013) death. Age, number of pregnancies, HbA1c in the 3rd trimester and insulin treatment remained statistically significant in the multivariate analysis.

Conclusion
Younger women, with a higher number of pregnancies, worse glycemic control and fetal/neonatal mortality associated with pregnancy appear to be more likely to lose the follow-up. Given the risk of diabetes after pregnancy, we should emphasize the need for OGTT reclassification in the puerperium and define strategies to promote their accomplishment.

Endocrine Abstracts (2017) Vol 49
Gonarthrosis is a severe problem of movement system. It is a restrictive health problem for modern human. And also; it is the other restrictive problem which coexistence of diabetes mellitus (DM) and gonarthrosis. Perhaps; an other parameter that is deserved to research for this coexistence is metabolic syndrome. Today, relationship between this clinical conditions are clear enough. And also two lobotomy parameters as Leptin and Nesfatin-1 are an other headstone for obesity and metabolic syndrome. Many studies established relationships between obesity and Leptin, Nesfatin-1 separately. Leptin is a hormone that is made by adipocytes and affects NeuroPeptid-Y levels. Its gene Ob is located in Chromosome-17. Leptin regulates food intake and gain weight. Nesfatin-1 is a hormone that is released by hypothalamus. It regulates hungry and fat storage. We aimed to evaluate the levels of these two hormones in diabetic patients that have gonarthrosis. 101 patients were measured clinically and laboratory by X-rays, levels of insulin, Leptin and Nesfatin-1 on 2014-2016. 46 patients have Type 1 DM and 55 patients have Type 2 DM. All patients have gonarthrosis clinically and radiologically. 31 of all patients have overweight (25–29.9), 43 patients have obese (30–34.9), 20 patients have severely obese (35–39.9) and seven patients have morbidly obese (40 and up) according to BMI. In the Leptin results; there are high levels of 81 patients with insulin resistance. And these patients have increasing BMI. In the Nesfatin-1 results; there were significant lower in diabetic patients except in 11 patients. And also there were correlation between Nesfatin-1 lowerity and overweighty. It seem like Leptin levels is related with BMI directly. High insulin levels may increase Leptin levels. But; Nesfatin-1 is lower almost all patients with insulin resistance. Leptin and Nesfatin-1 has severe regulation on body energy storage. And they deserve more studies about diabetic population with gonarthrosis.

Bone mineral density in male patients with type 2 diabetes mellitus, with and without hypogonadism
Agathi Vasileiou1, Joanna Karathanassi1, Parthena Navrozidou2, Marianna Vlychou2, Georgios Koukoulis1 & Alexandra Bargiota1
1Department of Endocrinology and Metabolic Diseases, University of Thessaly, Larissa, Greece; 2Department of Radiology, Faculty of Medicine, University of Thessaly, Larissa, Greece.

Introduction
Type 2 diabetes mellitus (T2DM) affects bone metabolism, but its relation with bone mineral density (BMD) remains controversial. It is also known that T2DM is associated with hypogonadism in males. Male hypogonadism can also affect BMD. Thus the aim of this study was to evaluate BMD in male patients with T2DM with and without hypogonadism.

Methods/design
Hypogonadism was defined as serum free Testosterone (T) value <5 ng/dl or 5–9 ng/dl +1 major sign suggestive of androgen deficiency and eugonadism was defined as T value >9 ng/dl. We studied 119 patients with T2DM and hypogonadism (Group H) (age: 61.2 ± 8.2 years) and 45 patients with T2DM without hypogonadism (Group NH) (age: 58.4 ± 10.3 years) matched for age, duration of diabetes, BMI and HbA1c. In both groups, we measured, lumbar spine (LS) BMD and total T-score measured by Dual-energy X-ray absorptiometry (DEXA).

Results
Mean BMI (kg/m²) was similar in both groups (H: 30.9 ± 5.0 vs. NH: 29.6 ± 5.9, P = 0.17). Mean duration of diabetes was 9.4 ± 8.5 years in Group H and 8.6 ± 7.8 years in Group NH (P = 0.54) and mean HbA1c was 7.8 ± 1.9% in Group H and in Group NH 7.61 ± 1.5% (P = 0.47). BMD at LS (g/cm²) and total T-score measured by DEXA were lower in Group H compared to Group NH (0.53 ± 0.08 vs 0.81 ± 0.07, P = 0.041) (-0.12 ± 1.0 vs 0.78 ± 0.72, P < 0.001).

Conclusion
Male patients with T2DM and hypogonadism are found to have lower BMD compared to T2DM males without hypogonadism. Thus, in male patients with T2DM, hypogonadism is a risk factor for low BMD.

Pregnancy outcome in relation to a disorder of glucose tolerance during pregnancy
Violeta Mladenovic1,2, Jelena Nesic1,2, Marija Andjelkovic1,2, Zoran Glavic1,4,6, Aleksandar Djukic1,2 & Djuro Macut1,6
1Center for Endocrinology, Diabetology and Metabolic Diseases, Clinical Center «Kragujevac», «Kragujevac», Serbia; 2Faculty of Medical Sciences, University of «Kragujevac», «Kragujevac», Serbia; 3Department of Laboratory Diagnostics, Clinical Center «Kragujevac», «Kragujevac», Serbia; 4Division of Internal Medicine, Department of Endocrinology, Zemun Clinical Hospital, Belgrade, Serbia; 5Clinic for Endocrinology, Clinical Center Belgrade, Belgrade, Serbia; 6School of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction
Pregnancy as a state of insulin resistance can predict diabetes development in some women, and is associated with increased risk for adverse outcome of neonate and for mother.

Aim
The aim of this study is to analyse pregnancy outcome in relation to a disorder of glucose tolerance during pregnancy.

Material and methods
The study included 77 healthy pregnant women in third trimester registered in Center for endocrinology CC Kragujevac that were tested, according to conducted 3 h OGTT with 100g glucose (ADA criteria). As parameters of adverse outcomes we included: premature labor (before 37 gw., Low Appgar score (<9), neonatal malformations, respiratory complications, hypoglycemia, birth body weight >4 000 g or <2 500 g, hyperbilirubinemia

Results
The mean age of patients was 30.8 ± 4.7 years. The frequency of risk factors for diabetes were: obesity (3.9%), hypertension (5.2%), previous gestational diabetes.
mellitus (23.5%), smoking (23.4%), positive family history for diabetes (27.3%). From 77 patients, 18 was with GDM (23.3%). It has been shown that the number of risk factors significantly affect the outcome of pregnancy ($P<0.005$, $\chi^2$ test), and that the degree of disorder of glucose tolerance during pregnancy affect the outcome of pregnancy ($r=0.164$, $\chi^2$ test). It has been shown that patients with normal glucose tolerance usually have a favorable outcome of pregnancy, and a growing number of pregnancies with an adverse outcome.

**Conclusion**

This study demonstrates that glucose intolerance during pregnancy predicts unfavorable adverse outcome

**Keywords:** glicoregulation, pregnancy outcome

DOI: 10.1530/endoabs.49.EP484

**Table 1**

<table>
<thead>
<tr>
<th>State</th>
<th>Hyperglycaemia phase</th>
<th>Hypoglycaemia phase</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Glucose Mean peak at 1 h (mg/dl)</td>
<td>Ins/c-pep ratio (uU/ng)</td>
</tr>
<tr>
<td>Active disease</td>
<td>199 (range 187–210)</td>
<td>7.0</td>
</tr>
<tr>
<td>Recovery disease</td>
<td>166</td>
<td>11.2</td>
</tr>
</tbody>
</table>

**Active disease state**

The insulin/c-peptide ratio increased significantly from hyperglycaemia to hypoglycaemia ($P=0.023$) even after adjusting for the glucose levels (glycaemia to insulin/c-peptide ratio) ($P=0.027$).

**Recovery disease state**

Patient showed a decrease in hyperglycaemia peak with a corresponding increase in the insulin/c-peptide ratio and a decreased insulin/c-peptide ratio during hypoglycaemia phase.

**Discussion**

During active disease, a lower insulin/c-peptide ratio during hyperglycaemia and the paradoxical increase during hypoglycaemia seem to support the role of insulin antibodies in the disease. During the recovery state, there is a reversal of these ratios supporting an increase in bioavailable insulin with lower antibody titers.

DOI: 10.1530/endoabs.49.EP486

**Insulin autoimmune syndrome: the relationship between insulin, c-peptide and glucose in active and recovering disease states**

**EP486**

**Objective**

To assess the effect of gestational diabetes (GD) on labour outcomes in pregnancies with gestational diabetes (GD) regarding different delivery tactics.

**Design and methods**

The retro- and prospective study evaluating labour outcomes included 443 age matched patients with GD who had given birth during 2014 (1st group – $n=251$) and 2015 (2nd group – $n=192$) according to the two clinical protocols, respectively. Expectant management in 2014 was supposed to use until 39–40 weeks of gestation in the absence of any earlier delivery indications, in 2015 – until 40–41 weeks similarly. Statistical analysis was performed with SPSS 21.0 (SPSS Inc.) program. Statistical methods used: Student criteria for quantitative analysis, $\chi^2$ criteria for qualitative analysis; $P<0.05$.

**Results**

Labour induction rate was lower in the second group: 13.5% (26 of 192), than in the first: 17.1% (43 of 251), thus the rate of spontaneous labour raised (74.9% (188 of 251) and 78.2% (150 of 192)). The rate of pre-arranged and urgent caesarian section, macrosomia, diabetic embryopathy did not significantly differ between groups, the same as dysthyroidism and fetal distress after induction of labour: 7% (3 of 43) and 9.3% (4 of 43) – in the first, 7.7% (2 of 26) and 11.5% (3 of 26) – in the second group, respectively. However, uterine inertia rate after induction was twofold lower in the second group comparing to the first one: 7% (3 of 43) and 15.4% (4 of 26), respectively.

**Conclusion**

Expectant management until 40–41 weeks in patients with GD in the absence of earlier delivery indications has led to the labour complications rate fall and spontaneous labour rate rise. Probably, single standard tactic for labour at 38–40 weeks in all patients with GD is not one of choice. Such management is preferable for high risk antenatal fetal death pregnancies: fetal distress, macrosomia, diabetic fetopathy or severe maternal conditions, first of all, preeclampsia.

**Lipoprotein particle size in women with type 1 diabetes mellitus and its relationship to carotid intima-media thickness**

**EP487**

Anjuli Gunness1, Mohamed Ahjmed1, Agnieszka Puzderska1, Niamh Phelan1, Kevin Moore1, Gerard Boran1, Lucy-Ann Behan1, Mark Sherlock1 & James Gibney1

1Department of Endocrinology, Adelaide and Meath Hospital, Tallaght, Dublin 24, Ireland; 2Department of Clinical Chemistry, Adelaide and Meath Hospital, Tallaght, Dublin 24, Ireland.

Although cardiovascular disease (CVD) is greatly increased in type 1 diabetes mellitus (T1DM), patients typically have apparently healthy lipid profiles. Simple measurement of plasma lipids however does not provide information regarding lipoprotein particle size which in the nondiabetic population is independently predictive of CVD. Plasma lipids and lipoprotein subclasses (using polyacrylamide gel/tube electrophoresis) were studied in reproductive age women with T1DM and compared to a matched control group. Outcomes were correlated with carotid intima-media thickness (CIMT), a validated marker of atherosclerosis. Compared to nondiabetic women, T1DM women were younger (29 vs 34 years) and of lower BMI (24.7 vs 31.3 kg/m2), with all data reported as median. Total (TC) and LDL-cholesterol (LDL-C) did not differ between groups. Triglyceride (TG) levels were lower (0.76 vs 0.91 mmol/L, $P=0.0331$) and HDL-cholesterol (HDL-C) greater (1.65 vs 1.49 mmol/L, $P=0.00331$) in T1DM. T1DM women had a greater proportion (46% vs 5%, $P<0.0001$) of small LDL-C particles,
lower mean LDL particle size (269 vs 272 Å, P < 0.0001) and a greater percentage of small-dense-LDL particles (%SDLDL: 3 vs 0%, P < 0.0001), CIMT correlated positively in T1DM with %SDLDL (r = 0.2983, P = 0.0098) and negatively with LDL size (r = -0.3118, P = 0.0068), but did not correlate with TC, HDL-C, LDL-C or TG. Despite apparently healthy lipid profiles, women with T1DM have a greater proportion than nondiabetic women of atherogenic small LDL particles. The likelihood that this is clinically relevant is strengthened by the observed correlation of CIMT with particle size and lack of correlation with standard lipid profile. Further studies are needed to explore the mechanisms underlying these abnormalities.

The upper limb infection in diabetic patients (about 32 cases)
El Ansari Nawal, Habra Bahia & El Mghari Ghizlane
Service of Endocrinology Diabetology and Metabolic Diseases CHU Mohammed VI, Faculty of Medicine and Pharmacy, Marrakech, Morocco.

Introduction
The diabetic patient is vulnerable to infection compared to the general population. This is due to the deleterious effect of hyperglycemia on the basis of chemotaxis, phagocytosis and bactericide neutrophils → What weakens the defenses of the diabetic person to infections. Infections of the upper limb in diabetics are not uncommon, and are often characterized by severity and often unfavorable developments. The objective of this work: determine the prevalence, clinical and therapeutic characteristics of the infection of the upper limb in diabetics.

Matériaux et méthodes
Study including 32 patients seen in the emergency. The parameters: epidemiological characteristics: age, sex, weight, size, marital status, housing environment, origin, nature of the work, the pets, Characteristics of the diabetes: type, age of the beginning, evolution, treatment, glycemic balance, the follow-up.

Characteristics of the lesions: type, Seat, the mechanisms, bacteriological sample.
Deadline between the consultation and the appearance of the lesions. Management emergency: medical treatement, surgical care.

Discussion
At our patients, the hurts were grave and spread, this can give some explanation by the delay of the consultation been understandable by the educational lack and by the particularly vulnerable fragile ground to the infections seen the diabetes. The diabetes was discovered on the occasion of the lesions of the upper limb in 18% of the cases, during the evolution, in spite of the institution of a local treatment and an antibiotic treatment, a locol extension regional and sometimes general of the infection drove to make an amputation in 25% of the cases for saving of the patient.

The peculiarities of structural and functional state of the myocardium and blood vessels in patients with type 2 diabetes mellitus and arterial hypertension depending on the dynamics of adipokines
Olena Al-Trawneh, Oleksandr Bilovol & Lesya Bobronnikova
Kharkiv National Medical University, Kharkiv, Ukraine.

Purpose
To study the features the structural and functional state of the myocardium and blood vessels in patients with diabetes mellitus and arterial hypertension depending on omentin level.

Methods
A total of 65 patients (32 men and 33 women, mean age 51.6±5.2 years); 31- with type 2 diabetes and hypertension (group 1), 34 – with isolated arterial hypertension (group 2). Control group 20 healthy volunteers. We evaluated data of transthoracic echocardiography and ultrasound thickness of the intima-media complex of the common carotid artery (IMC CCA). Omentin level in blood serum were determined by ELISA kit.

Results
Left ventricular hypertrophy (LVH) was diagnosed in 67.5% of patients in group 1 and 34.2% of patients in group 2 (P<0.05). IMC CCA patients of group 1 was significantly higher than in the comparison group (P<0.001). Omentin level in group 1 was reduced in comparison with the 2 – nd group and the control (262.24±10.46; ng/ml versus 296.43±12.72; ng/ml and 379.46±6.22 ng/ml, respectively, P<0.001). There was a negative correlation relationship between the content omentin plasma and left ventricular hypertrophy (r = -0.54; P<0.05) and IMC CCA (r = -0.46; P<0.05).

Conclusions
It was found that patients with type 2 diabetes and hypertension observed the progression of LVH and remodelling of the vascular wall, which are related to an imbalance omentin serum. Thus omentin reduction level can be considered as a biomarker of cardiovascular complications in these patients.

Casuistic from Endocrinology Medical Consultation at Clinica Girassol 2015
Domingos LIRA, Anselmo Castela, Gertrudes Béu & Francisca Silva
Clinica Girassol, Luanda, Angola.

Introduction
There are few studies either hospital bases or population based in Africa and in Angola we also have the same situation regarding endocrinology data. With this paper, the Angolan Society of Endocrinology Diabetes and Metabolism (SAEDM), wants to contribute to the systematic and continued study of endocrine pathology in Angola.

Objective
Study of the casuistic of endocrine pathology in ambulatory setting regarding the year 2015.

Methods
Compilation of data obtained from medical notes files from the ambulatory appointments available in digital and physical support. Files with incomplete data or without prove or clinical-laboratory correlation have been discarded. We designed the distribution of patients according to the pathology, or group of pathologies at the respective frequencies as per sex and age group. Diabetes Mellitus and Obesity have been considered as specific pathologies. Thyroid diseases have been included in the same entity considered as Thyroid Pathologies and the others in a group classified as Other Endocrine Pathologies. Diabetes Mellitus and Obesity (including overweight) were profiled according to the WHO criteria; Disturbances of Thyroid have been established obeying to the ultrasonography criteria or to functional anomalies.

Results
We worked with a pool of 1630 processes (files) related to patients that had endocrine pathology. Ninety one (5.58%) were incomplete. Therefore were excluded because had not confirmation data of endocrine disease. The validated files (1539 files) could be distributed as follows: 1159 (75.3%) corresponding to Diabetes Mellitus, 156 (10.1%) corresponding to Pathologies of Thyroid, 85 (5.5%) corresponding to Obesity and 139 (9.0%) classified as Other Pathologies. Distribution per sex: 794 (51.6%) were women and 745 (48.4%) men. The distribution of pathologies per sex: Diabetes Mellitus: 533 (45.9%) women and 626 (54.1%) men; for Obesity: 56 (65.9%) women and 29 (34.1%) men and for Pathology of Thyroid we found 132 (84.6%) women and 24 (15.4%) men.

**Depression and quality of life in patients with type 2 diabetes mellitus**
Andreae Maric, Dunja Molnár, Tea Premosa, Sonja Novak, Jurica Vidovic & Maja Mikolaj Kiric
County Hospital Cakovec, Cakovec, Croatia.

**Introduction**
Depression is the leading cause of disability worldwide, and is a major contributor to the overall global burden of disease. People with DM have 2.4–4.3 times greater risk of depression than people without DM as well as patients (pts) treated with insulin. Women experience depression more often than men. Symptoms of depression can make it more difficult to successfully manage diabetes and prevent diabetes-related complications.

**Materials and methods**
A total of 138 subjects (74 males, 64 females; aged 18–80 years) with T2DM participated in cross-sectional study. Two questionnaires: BDI (Beck depression inventory) and SF-36 (Short-Form-36 Health Survey) were used. Using BDI the severity of depression was detected; SF-36 was used for measuring self-reported physical and mental health status.

**Results**
The prevalence of depression was higher in females with diabetes (45.3%) compared to males (35.1%). Women with depression (29/64 of pts) were aged 39–76 yrs, BMI 22.3–44.6 kg/m², HbA1c > 7% was observed in 17/29 of depressive women, duration of DM2 was 2–192 months. Men with depression (26/74 of pts); age 35–79, BMI 23.2–43.2 kg/m², HbA1c > 7% in 13/26 of depressive men, duration of DM2 was 6–360 months. According to BDI questionnaire scores, mild depression was reported in 17 male and 15 female pts, moderate depression was found in 6 males and 9 females and severe depression in 3 male and 5 female pts. Mean scores of SF-36 questionnaire were compared between diabetics with and without depression, and correlated to BDI scores. Depressive pts had statistically lower scores than non depressive (both sexes) in Physical functioning, Emotional role functioning, Mental health, Bodily pain (just males) and General health perceptions.

**Conclusion**
T2DM is associated with an increased risk of depression. In order to prevent negative consequences of non recognized and untreated depression, evaluation of psychological status in patients with T2DM is recommended.

**Diabetes Mellitus type 1: characterization of patients at the endocrinology ambulatory follow up during the year 2015**
Anselmo Castela, Gertrudes Béu, Francisca Silva & Domingos Lira
Clinica Girassol, Luanda, Angola.

**Introduction**
Diabetes Mellitus is a chronic disease that has serious effects on the morbidity-mortality. Diabetes type 1 is less prevalent, representing 5–10% of the total cases. Data collected in Africa are scarce, and prevalence and incidence at sub-Saharan Africa are about 3-12/100,000 and 1.1–2.1/100,000 people, respectively. The Angolan reality is not known.

**Objective**
To show the casuistic of diabetes type 1 obtained from the ambulatory consultation of Endocrinology for the year 2015.

**Methods**
We performed a retrospective study of the available clinical files in digital and physical support. The diagnosis of type 1 diabetes was according to the diagnostic criteria defined by the WHO. Parameters that have been studied: sex, age, A1c, clinical onset, duration of the disease.

**Results**
In the year 2015, 1630 patients have been observed at the Endocrinology Ambulatory Service. Only 1539 process were considered for analysis. Among these patients, 1159 (75.3%) were diabetic, being 19 of them (1.63%) type 1 diabetes. The distribution by sex was: 9 (47.4%) men and 10 (52.6%) women. The age spread from 4 to 40 years with a mean of 23 years. Diabetic ketoacidosis (63.11%) was the clinic presentation found at the time of the diagnosis. The time of evolution of the disease varied from 6 months to 15 years of age with an average of 4.6 years. The average glycosylated hemoglobin (HbA1c) was 8.86%.

**Conclusion**
The epidemiology of diabetes is not known, and we cannot advance conclusions from the data collected by our team. Most of the patients observed in endocrinology (75.3%) had the diagnostic of Diabetes Mellitus. The fact that type 1 diabetes is more prevalent among women is in accordance to the international data. It is important to highlight that significant number (63%) of the patients have been diagnosed in the status of diabetes ketoacidosis.

**Endocrine Abstracts (2017) Vol 49**
A Poisson distribution was assumed when calculating 95% confidence intervals for prevalence and incidence rates.

Results
After age standardization, the prevalence of T2DM in Korean adults aged more than 30 years, was 6.3%–7.5% and the annual incidence rates of T2DM ranged from 9.0–11.0/1,000 person-year during the six year. The incidence rates of T2DM in men and women aged more than 30 years significantly decreased from 2013 to 2015 (P<0.001). On the other hand, the incidence in women aged more than 65 years significantly increased from 2013 to 2015 (P<0.001). The incidence rates of CAD and CVD with T2DM patients were 21.4 and 13.6/1,000 person-year.

Conclusion
This study estimated the incidences and prevalence of T2DM in most of Korean population which is the great concern for public health. We also confirmed the relatively higher risk of as the complications with the T2DM patients compared to the general population in Korea.

**EP495**

Prevalence of obesity and diabetes among in a developing country (Albania)

Dorina Yili1, Tomi Thomo3, Violeta Hoxha1, Marjeta Kerma1, Gerond Husi1, Thanas Fureraj1 & Agron Yilli1

1 "Mother Teresa" University Hospital Center, University of Medicine Tirana, Faculty of Medicine, Tirana, Albania; 2 Ministry of Health, Tirana, Albania.

It is well known nowadays the positive effect that early detection of prediabetes has in preventing and postponing the diabetes onset. The aim of our study is to explore the diabetes prevalence in Albania and to identify and stratify the population at risk for developing diabetes.

Material and methods
A large scale multicentre screening was performed in Albania as part of a National Campaign. 15744 patients were consecutively recruited. The following data were obtained: age, weight, height, BMI, waist circumference, glycaemia, total cholesterol, LDL, Triglycerides, HDL. The subject were subdivided according gender and age group.

Results
In 15744 subjects, 62% females, 38% males, 49% was aged between 40–49 years old, 46% between 50–59 years old and 20% between 60–65 years old. 6.3% were already diagnosed with diabetes mellitus (5.5% female and 7.4% male of the explored population). 15% of the patients who declared not having diabetes had a fasting glycaemia > 100 mg/dl. Of these 15%, 24% had a glycaemic value above 126 mg/dl and 75.6% have glicemic value between 100–126 mg/dl (impaired fasting glucose (IFG) or pre-diabetes). In the population with IFG 39.8% have a WC > 80 cm and 74% of males a WC > 92 cm.

Conclusions
Albania is a developing country who went through important socio-economical changes in the last decade. We find a high diabetes mellitus prevalence which could be higher because of the not yet diagnosed diabetes. An important role have the pre-diabetes population where a high prevalence of overweight and obesity is observed. Campaign to rise diabetes and pre-diabetes awareness and encourage lifestyle modification are very important to prevent and postpone the diabetes onset in the prediabetes population.

The relationship between Serum Vaspin and atherogenic risk factors in T2DM

Magda Shokry Mohamed, Manal Mohamed Abushady, Mona Mohamed Abdelsalam, Maram Mohamed Mahir, Lila Mahmoud Hendawy & Rana Hashem Ibrahim

Ain Shams University, Cairo, Egypt.

Introduction
Increased visceral adiposity is usually associated with a clustering of atherogenic risk factors, such as insulin resistance, hypertension, dyslipidemia, alterations in coagulation and inflammatory cytokine profiles. Visceral adipose tissue derived serpin (Vaspin) is an adipokine with insulin sensitizing effect which is markedly elevated in high body mass index (BMI) people.

Aim
To evaluate serum Vaspin level in relation to atherogenic risk factors such as insulin resistance, dyslipidemia, hypertension, inflammation in obese subjects with T2DM and obese subjects without T2DM.

Method
80 subjects participated, with BMI ranging from 27-39 selected from outpatient clinic of Endocrinology of Ain Shams University Hospital. They were divided into 2 groups 40 obese subjects with T2DM (group I) and 40 obese subjects without T2DM (group II). History, clinical examination, FBS, 2-PP, HBA1C, Total cholesterol, Triglycerides, HDL and LDL, HOMA-IR, Serum Vaspin level (by ELISA) and CRP were done.

Results
Serum Vaspin was higher in group II than group I (P≤0.01). HOMA-IR was higher in group I than group II (esp. females) with P≤0.01. Regarding hs-CRP there was no significant difference. In Group I serum vaspin had a negative correlation with age (P=0.010), diabetes duration (P=0.015), a positive correlation with Waist/hip ratio (P=0.047), and LDL (P=0.034). There were no correlation with BMI, systolic blood pressure, diastolic blood pressure, HbA1c, fasting blood glucose, 2 HPP, total cholesterol, triglycerides, HDL, hs-CRP and HOMA-IR (P>0.05). In group II, serum vaspin had no correlation with any of the variants (P-value>0.05). Vaspin level was found to be independently correlated with male gender and younger age with (P=0.031).

Conclusion
Obese subjects with T2DM have more atherogenic risk profile and lower Vaspin level than obese subjects without T2DM. It was inversely correlated with age and diabetes duration and positively correlated with Waist/hip ratio, LDL. Male gender and age are strong independent predictors of serum vaspin level. Vaspin may be an important adipokine that may play an important protective role against metabolic disturbance and cardiovascular risk in obese subjects with T2DM.

Maturity onset diabetes of the young - clinical characteristics of a portuguese cohort

Ana Amado, Raquel Almeida, André Carvalho, Cláudia Amaral, Cláudia Freitas, Conceição Bacelar, Joana Vilaverde, Maria Helena Cardoso, Sofia Teixeira & Fátima Borges

Endocrinology Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal.

Introduction
Maturity onset diabetes of the young (MODY) accounts for 1-2% of all forms of diabetes mellitus (DM). As classic criteria that lead to its suspicion have low sensitivity, patients are often misdiagnosed with type 1 or type 2 DM. Correct classification of this type of diabetes becomes essential for proper management of the disease. Our objective was to describe clinical features of patients with MODY diagnosed at our institution.

Methods
We collected clinical data from patients with clinical characteristics and genetic confirmation of MODY.

Results
We included 30 patients (15 females). All patients but one had diagnosis of DM (one female had gestational diabetes, but currently has no criteria for diabetes). Mean age at diagnosis of MODY was 27.5+/−10.8 and 46.3+/−13.2 years, respectively. Genetic testing was positive for mutation in the Glucokinase (GCK) gene in 3 patients, the ATP-binding cassette transporter sub-family C member 8 (ABCC8) gene in 1 patient and the hepatocyte nuclear factor-1 homeobox A (HNF1A) gene in 26 patients. Currently, 9 patients are exclusively treated with oral antidiabetic agents and 3 patients have no pharmacological treatment. Last mean HbA1c was 7.5+/−1.3%. Peripherial neuropathy was diagnosed in 11 patients (36.7%), autonomic neuropathy in 5 patients (16.7%), diabetic retinopathy in 16 patients (53.3%), diabetic kidney disease in 11 patients (36.7%), ischemic cardiac disease in 2 patients (6.7%), vascular cerebral disease in 3 patients (10%) and peripheral arterial disease in 4 patients (13.3%).

Conclusions
There is a relevant delay in MODY diagnosis and clinicians should be alert for this type of diabetes. The most frequent mutation identified in our population was in the HNF1A gene. This study confirms the clinical heterogeneity of MODY patients.
Diabetes Complications

EP498

Prevalence of diabetic neuropathy and nephropathy in different ethnic minorities

Rajah Khan

University of Manchester, Manchester, UK.

Introduction

The focus on diabetic complications has increased over the years yet it is only recently that research has identified a link between ethnicity and the development of diabetic complications.

Aims

To establish the relationship between ethnic group and the prevalence of either diabetic neuropathy or nephropathy.

Method

A retrospective note review was undertaken for all diabetic patients who had a status of ‘current’ in the database. This returned 6608 patients, however, only 1838 patients met the inclusion criteria. The notes were reviewed, analysed and compared with the current literature on ethnicity and diabetic microvascular complications.

Results

Of the 1838 patients: 56.9% were Caucasian, 13.9% Afro-Caribbean, 23.0% South Asian and 6.3% Other. Afro-Caribbean’s had a higher mean systolic blood pressure (139.03 mmHg) compared to other ethnicities with Caucasians having the lowest mean at 132.91 mmHg. Afro-Caribbean’s were found to have poorer glycaemic control (69.5 mmol/mol) compared to the remaining ethnic groups. Nephropathy was found to be most common in Afro-Caribbean’s (14.3%) followed by South Asians (13.1%). Caucasians and Other groups had lower rates at 7.8% and 8.6%, respectively. Neuropathy was most common in Caucasians (24.4%) and least in Afro-Caribbean’s (14.7%); the other two ethnic groups, South Asians and Other, had similar levels at 17.4% and 16.4% respectively.

Conclusion

The link between ethnicity and complications was found to be statistically significant (P<0.001). Future research and epidemiological studies must focus on why these differences occur and if they are independent of socio-demographic, anthropometric and clinical characteristics.

Correlation of homocysteine with macro and microvascular complication in patients with diabetes mellitus type 2

Marija Krstevska1 & Ksenija Bogoeva Kostovska2

1Department of Medical and Experimental Biochemistry, School of Medicine, University Ss. Cyril and Methodius, Skopje, Center, Macedonia,
2Doctor’s Practices Prof. Dr Bogoev, Skopje, Center, Macedonia.

In recent years, plasma homocysteine (Hcy) level, has been reported to be associated with the vascular complications of diabetes mellitus type 2 (DM2). In patients with DM2, elevated Hcy levels were associated with insulin resistance and nephropathy. The aim of this study was to investigate the association of hyperhomocysteinemia with micro and macrovascular complications, increased levels of Hba1c and lipid parameters in patients with DM2 in a Macedonian population. 80 DM2 patients were enrolled for the study and were classified into two groups: 30 patients with no associated complications, control, and 50 patients with complications. Homocysteine levels and the other conventional parameters (Hba1c, lipid profile, and microalbuminuria) for identifying complications of DM2 were measured. The Hcy levels were significantly higher in DM2 patients (16.05 ± 6.12 vs 10.44 ± 3.33 mmol/l) compared with control. Significantly elevated homocysteine levels were found in DM2 patients with CAD (P<0.001), neuropathy (P<0.000), retinopathy (P<0.05), high blood pressure (P<0.02) and microalbuminuria (P<0.000) as compared to control subjects. There was a positive correlation between elevated Hba1c (r=0.475) levels and serum LDL-cholesterol (r=0.871) with Hcy concentration in DM2 patients with complications. The results of this study have shown that homocysteine levels were significantly higher in DM2 patients with developed micro-/macro-vascular complications and highly positive correlated with Hba1c and serum LDL-cholesterol, also. Results have shown that hyperhomocysteinemia is risk factor in etiology of vascular complications in DM2 patients.

Overweight and obesity in pregnant with diabetes mellitus type 1

Paloma Moreno-Moreno, Ángel Rebollo-Román, Rafael Palomares-Ortega, Concepción Muñoz-Jimenez, María Rosa Alhambra-Expósito & María Ángeles Gálvez-Moreno

Management Unit of Clinical Endocrinology and Nutrition, University Hospital Reina Sofia, Córdoba, Andalucia, Spain.

Objectives

Pregnant women who are overweight or obese have an increased risk of complications during pregnancy, as do pregnant women with type 1 diabetes mellitus (DM1). The objective of this study is to describe the prevalence of overweight/obesity in pregnant women with DM1, and associated complications.

Patients and methods

Retrospective descriptive study of pregnant women with DM1 (2004–2014). Variables analyzed: age, initial body mass index (BMI), Hba1c, abortions, type of delivery and fetal malformations. Statistical analysis: comparing proportions with the chi-squared and comparing means with Student’s test.

Results

156 pregnancies in women with DM1. Age 31.41 ± 4.51 years. At the beginning of pregnancy, 50.4% were normal weight, 36.2% were overweight (12.4% grade 1 and 23.8% grade 2) and obesity was 10.5% (7.6% grade 1, 1.9% grade 2, 1% grade 3). 3% women had BMI <18.5 kg/m2. Normal weight vs overweight/obesity: unplanned pregnancies 70.4 vs 66.7% (P=0.85); Hba1c (%) previous gestation 7.4 ± 1.4 vs 7.4 ± 1.2 (P=0.98), first trimester 7.4 ± 1.7 vs 7.1 ± 1.3 (P=0.88), second trimester 6.3 ± 0.8 vs 6.5 ± 0.8 (P=0.31), third trimester 6.5 ± 0.8 vs 6.5 ± 0.8 (P=0.88); newborn weight 3516.1 ± 755.22 vs 3617.07 ± 693.10 g (P=0.82); newborn size 50.9 ± 2.4 vs 50.8 ± 2.5 cm (P=0.76). Maternal and neonatal complications (%) normal weight vs overweight/obesity: maternal hypoglycemia 3.7 vs 6.7 (P=0.3); gestational hypertension 5.7 vs 12.2 (P=0.3); abortions 3.8 vs 9.5 (P=0.33); induced childbirth 58 vs 61 (P=0.92); caesarean section 38 vs 55 (P=0.12); macrosomia 29.4 vs 24 (P=0.71); congenital malformations 8 vs 7.1 (P=0.78); newborn hypoglycemia 6 vs 5 (P=0.93).

Conclusions

In our series, the prevalence of overweight/obesity in pregnant women with DM1 is high, occurring in almost half of pregnancies. There were no differences in glycemic control during gestation or in the occurrence of maternal or neonatal complications associated with overweight/obesity.

EP501

Does empowerment from an ‘ABC approach’ and ‘Telemedicine’ improve outcomes in a nurse-led diabetes kidney clinic?

Susan Irwin & Parijat De

Sandwell & West Birmingham Hospital NHS Trust, Birmingham, UK.

Aims

Implementation of a protocol-driven, nurse-led clinic to see influence on cardiovascular risk and renal disease progression using a simple ‘ABC’ approach – target Hba1c <7%, BP <125/75 mm Hg and Cholesterol <4 mmol.

Method

Weekly Diabetes Specialist Nurse (DSN) clinic with emphasis on ABC approach and guided FLORENCE Telehealth free texting technology for medication reminders and self-monitoring of BP (machines provided).

Results

May 2008 – Apr 2009 (12 months) – Cohort A 41 patients. May 2010 – June 2014 (24 months) – Cohort B 133 patients. Mean age 64 years, 78–90% patients Asians/Afro Caribbean. Excellent patient satisfaction scores, significant reductions in Hba1c in Cohort A and B by 0.7% (7.62 vs 8.32%) and 1.5% (9.1 vs 7.6%) respectively, SBP (12–16 mmHg) and DBP (3–6 mmHg) and Cholesterol in all cohorts were achieved. Urine ACR decreased significantly in both cohorts (by mean 17–39 mg/mmol). Number of BP medications (3) increased in all cohorts. 95 and 85% patients respectively in both cohorts were prescribed ACE, ARB or both.

Conclusions

Outcomes suggest that our nurse-led clinic is highly effective in DN patients. The ‘ABC approach’ and simple information sharing strategy (Telehealth

Endocrine Abstracts (2017) Vol 49
Endocrine Abstracts (2017) Vol 49

FLORENCE) were effectively used to inform strategic decision making/intensification of therapy through patient empowerment, up-skilling of knowledge and improved medication compliance – 3 key processes in any chronic disease management.

Causes of diabetic ketoacidosis: type 1 diabetes versus type 2 diabetes
Marwa Omri, Rayene Ben Mohamed, Imen Rezgani, Sanaa Mníldhi, Aroua Temessek & Faika Ben Mami
National Institute of Nutrition, Tunis, Tunisia.

Aim
The aim of our study was to compare the clinical profile of type 1 and type 2 diabetic patients who are hospitalized in our service for diabetic ketoacidosis.

Methodology
This was a descriptive study involving 121 diabetic patients hospitalized for diabetic ketoacidosis in the C department of diabetology of the national institute of nutrition of Tunis.

Results
Of the 121 subjects studied, 57.85% are type 2 diabetic patients and 42.15% are type 1. Type 2 diabetic patients are older, have a higher glycated hemoglobin level and a higher BMI compared to the type 1 diabetic patients. For both type of diabetes, the principal causes of ketoacidosis are infectious diseases represented mainly by urinary tract infection. For type 2 diabetic patients cessation of treatment, inauguration of diabetes, insulinopenia and lipodystrophy are observed respectively in 22.7, 12.3, 11.9 and 10.1% of patients presenting ketoacidosis. For type 1 diabetic patients cessation of treatment, inauguration diabetes, pregnancy and lipodystrophy are observed respectively in 18.4, 14.6, 8.9 and 7.1% of patients hospitalized for ketoacidosis.

Conclusion
The main causes of diabetic ketoacidosis are infectious diseases and cessation of treatment, in type 2 diabetic patients as well as in type 1 diabetic patients. So that, education remains the best way to prepare diabetic patients to face situations of stress and to have a good therapeutic compliance.

Abstract withdrawn.

EP504
Is proteinuria always associated with diabetes mellitus?! Do we always make right diagnosis?!
Natia Katamadze & Anna Shumanadze
V.Iverieli Endocrinology, Metabology, Dietology Center ‘ENMEDIC’, Tbilisi, Georgia.

Introduction
Proteinuria is a condition in which urine contains an abnormal amount of protein. Proteinuria is a sign of chronic kidney disease (CKD), which can result from diabetes, high blood pressure and other diseases that cause inflammation in the kidneys. If CKD progresses, it can lead to end-stage renal disease, when the kidneys fail completely.

Case presentation
Sixty-three years old female patient attended our clinic as her glycaemia was poor controlled. She is diagnosed with diabetes mellitus (DM) type 2 during 9 years. Laboratory studies were performed: HbA1c- 9.4%, elevated plasma creatinine 176.32 (N53, 0–97.2) and proteinuria in urine with dipstick 1.01 g/l was observed.

Additional investigations were performed: kidney ultrasound, which revealed shrunken kidneys, Urea- 64.21 (N 15.0–45.0), Phosphorus-1.98 (N 0.48–2.19), Parathyroid hormone-273.76 (N 9.0–79.5), Vitamin D- 7 (N 30.0–100.0); Potassium-5.59 (N3, 5–5), pH-7.26 (N 7.32–7.72) Hemoglobin-10.2 (N 12–16). The patient had no diabetic specific complications. When DM was diagnosed the patient had already got dipstick proteinuria 0.3 g/l and it was considered as the result of diabetes. Therefore no further investigations were performed to find out the cause of proteinuria. We have not performed renal biopsy to diagnose the real cause of proteinuria, we just started to treat CKD.

Conclusion
Often proteinuria is revealed when DM is diagnosed, that’s why, no further investigations are performed to precise the real cause of it. Yes, hyperglycemia can cause various damages of kidney, but not in all cases. So, we always have to remember that in diabetic patients the cause of proteinuria may be due to other reasons. We always have to pay attention to other diabetic specific complications and always ask about detail clinical history, for correct diagnosis, better management and prevention of progression of renal disease.

EP505
A Review of the literature: What are the impacts of hypoglycaemia in insulin-dependent diabetic adults?
Charles O’Donovan1 & Olivia O’Donovan2
1University of Leeds, Leeds, UK; 2Bradford Teaching Hospitals, Bradford, UK.

Background
The prevalence of diabetes has reached epidemic proportions and according to the World Health Organisation (WHO) more than 220 million people worldwide have diabetes. The main complication in insulin-dependent diabetes mellitus (IDDM) patients is hypoglycaemia, with approximately 90% of all IDDM patients having experienced a hypoglycaemic episode. Hypoglycaemia has a substantial clinical impact in terms of mortality, morbidity and quality of life.

Methods
A systematic search of MEDLINE and EMBASE was performed for all relevant published articles. Reference lists of all included studies were also searched. Studies were included assessing fear of hypoglycaemia, recognition of symptoms, health-seeking behaviour and impact on overall wellbeing. One reviewer screened abstracts of all identified citations, selected potentially eligible studies and assessed their full-text versions using the STROBE (Strengthening the reporting of observational studies in epidemiology) checklist for cohort, case-control and cross-sectional studies (combined.) Findings from the studies were then narratively synthesized.

Results
Eight studies were included in this review. After hypoglycaemia, IDDM patients have significantly (o < 0.01) raised fears of future hypoglycaemia, more fatigue, reduced alertness and a negative impact on health-related quality of life (HRQL.)

Conclusion
Hypoglycaemia has a wide range of negative emotional, social and behavioural consequences on IDDM patients. These impacts, hence are a major barrier to IDDM patients achieving optimal glycaemic control. There remains a need for a large multi-country study that incorporates mixed-methods data collection, including a qualitative aspect to provide more in-depth views of the effects of hypoglycaemia.

A protective effect of lobeglitazone on renal fibrosis in unilateral ureteral obstruction mice model
Hye-Soon Kim1, Kwi Hyun Bae 1, Gwon Soo Jung 1, Hye Jin Ham1, Bo Yoon Park1, Yeon Kyung Choi 1, hyun Ae Seo 2, Jung Beom Seo 1 & Keun Gyu Park1
1Kyungpook National University Hospital, Dae Gu City, Republic of Korea; 2Fatima Hospital, Dae Gu City, Republic of Korea.

Renal tubulointerstitial fibrosis is a common feature of the final stage of nearly all cause types of chronic kidney disease. Although classic peroxisome
proliferator-activated receptor-gamma (PPAR \( \gamma \)) agonists have a protective effect on diabetic nephropathy, much less is known about their direct effects in renal fibrosis. This study aimed to investigate possible beneficial effects of lobeglitazone, a novel PPAR \( \gamma \) agonist, on renal fibrosis in mice with unilateral ureteral obstruction (UUO). Through hematoxylin/eosin and Sirius red staining, we observed that lobeglitazone effectively attenuates UUO-induced renal atrophy and fibrosis. Immunohistochemical analysis in conjunction with quantitative RT-PCR and western blot analysis revealed that lobeglitazone treatment inhibited UUO-induced upregulation of renal Smad-3 phosphorylation, alpha-smooth muscle actin, plasminogen activator inhibitor-1, and type 1 collagen. In vitro experiments with rat mesangial cells and NRK-49F renal fibroblast cells suggested that the effects of lobeglitazone on UUO-induced renal fibrosis are mediated by inhibition of the TGF-\( \beta \)/Smad signaling pathway. In conclusion, the present study demonstrates that lobeglitazone has a protective effect on UUO-induced renal fibrosis, suggesting that its clinical applications could extend to the treatment of non-diabetic origin renal disease.

Using the plastic closure techniques of wound defecting treatment of patients with diabetic foot syndrome

Maksym Prystupiuk, Juliia Onofriichuk, Liudmyla Naumova, Lev Prystupiuk & Marianna Naumova
Bogomolets National Medical University, Kyiv, Ukraine.

Purpose
To improve methods of plastic closure of wound defects in patients with diabetic foot syndrome using skin flaps on vascular pedicle of the perforating vessels.

Methods
The study involved patients with diabetes type 2 complicated with diabetic foot syndrome neuroischemic form. The study included 31 patients, 15 people in the study group and 16 people - the control group. Area wounds ranged from 3.8 to 21 cm\(^2\). Cleansing the wounds was performed by ultrasonic cavitation. On the wound bandage with sorption-based antimicrobial composition of nanosized silica. Thus, the wound was purified for 2–3 days. On the third day, the wound was applied vacuum-assisted closure with a standard negative pressure of 101.3 kPa over 3 days. Gauze bandage was applied over the wound for 10 days. For 3 days G was applied with sorption-based antimicrobial composition of nanosized silica. Thus, the wound was purified for 2–3 days. On the third day, the wound was applied vacuum-assisted closure with a standard negative pressure of 101.3 kPa over 3 days. Gauze bandage was applied over the wound for 10 days. Gauze bandage was then taken off, and a plastic flap was applied. The plastic flap was left for 5 ± 10 years.

Results
In the study group noted engraftment graft in 14 patients. Time of full engraftment and the healing of the wound defect in patients of the main group was 14 ± 3 days in the control group healing ulcers - 51 ± 10 days.

Conclusions
Improved techniques in the treatment of wound autodermoplastic defects in patients with diabetic foot syndrome, which is preparation wounds using an ultrasonic cavitation, vacuum bandage hardware. Using a split skin flap can effectively cover the bandage wounds, supporting the ability to save limbs and improve the quality of life.

Prayer marks in immigrants from Bangladesh with diabetes mellitus who live in Greece

Georgios Papadakis\(^{1,2}\), Thomas Zambelis\(^{3}\), Kostas Konstantopoulos\(^{4}\) & Stylianos Chatzipanagiotou\(^{1}\)
\(^{1}\)StEPS Stoffwechselzentrum, Biel/Bienne, Switzerland; \(^{2}\)Department of Neurology, Aeginition Hospital, Athens, Greece; \(^{3}\)Department of Haematology, Laikon University Hospital, Athens, Greece; \(^{4}\)Department of Medical Biopathology, Aeginition Hospital, Athens, Greece.

Introduction
Prayer marks (PMs) have been reported in the literature among Muslim prayers. PMs are found most often on the forehead, knees, ankles and dorsa of the feet. The most common changes consist of thickening, lichenification and hyperpigmentation of the skin, the causative factors being repeated pressure and friction during prayer.

Objectives
Immigrant populations are disproportionately affected by diabetes and its complications. Moreover, diabetic foot ulcer is a major complication of diabetes mellitus, and probably the major component of the diabetic foot. PMs are foot lesions that can ulcerate. In our study we focused on the frequency of PMs among Bangladesh immigrants who live in Athens, Greece and have diabetes.

Methods
A total of 166 immigrants from Bangladesh (150 men and 16 women) with diabetes mellitus and 65 (58 males and eight females) normal subjects from Bangladesh were recruited. Characteristic pictures of PMs are taken and provided.

Results
The mean duration of living in Greece was 10.34 ± 6.2 years. The mean age was 44.05 ± 8.1 years old and the reported duration of diabetes 4.86 ± 4.5 years. The mean A1C was 7.74 ± 1.6% and the mean Glucose values 190.3 ± 72 mg/dL. A total of 28 patients with diabetes (16.9%) (one patient with type 1 DM, and 27 patients with type 2 DM) and one subject in control group (1.5%) had PMs and all of them where males. Diabetic patients with PMs and diabetic patients without PMs had similar and not statistical significant BMI (23.67 ± 2.89 vs 24.30 ± 3.42 kg/m\(^2\), \(P=0.187\)), age (44.04 ± 7.3 vs 44.06 ± 8.35 years, \(P=0.488\)), disease duration (3.86 ± 3.0 vs 5.07 ± 4.74, \(P=0.080\)), and A1C values (7.4 ± 1.3 vs 7.8 ± 1.6%, \(P=0.408\)). None of the PMs had infection, ulceration or bleeding at the time of examination. The marks were not itchy or painful and they were observed on the dorsal aspect of the left foot.

Conclusions
PMs can often provide clinicians with helpful information for the patient’s cultural background. PMs could ulcerate and our study emphasizes the need for clinical awareness of PMs, especially for patients with diabetes. Moreover, people
come from different ethnic groups and ethnicity can have important effects on health and on the management and treatment of diabetes.

Therapy of hormonal disorders in women with acne
Liudmyla Naumova, Lev Prystupiuk, Maksym Prystupiuk, Marianna Naumova & Iuliia Onofriichuk
Bogomolets National Medical University, Kyiv, Ukraine.

Introduction and objectives
About 9% of world population suffer from acne, which occupies the 8th place among all human diseases, and the 3rd place among dermatological disorders. Acne is diagnosed in 54% of 18 year aged women. Acne manifests mostly in 12–14 year age and regresses after 20 year age, even though more and more women have recently addressed their doctors for acne problem developing after 20 year age. Location of this dermatosis in open areas of skin leads to depression and social disqualification, which underlines the actuality of this problem. It is well known that a leading role in the development of adult acne is played by hyperandrogenism, which is often caused by polycystic ovarian syndrome (PCOS). Well known also is that combined oral contraceptives are used for the treatment of female acne caused by hyperandrogenism syndrome. However, not all patients benefit from this kind of treatment. Therefore, the aim of our study was to better investigate endocrine system status and establish disorders stimulating the appearance and development of acne in adult women and then prescribe the proper therapy.

Material and methods
Our study involved 126 women with acne, of 18–37 year age. It included the performance of Sonography of thyroid gland and pelvic organs as well as the determination of levels of the following hormones: Prolactin, TSH, FSH, LH, 17-Hydroxyprogesterone, DHEAS, Free testosterone, Oestradiol, Progesterone, Anti-Mullerian hormone.

Results
The investigation confirmed high androgenic hormones level in 86.5% of women with acne, although clinical manifestations of hyperandrogenism syndrome were found only in 45% of these women. i) PCOS was found in 20.2% of women with acne. ii) Hyperprolactinemia – in 34.9%. iii) Atypical (late) form of congenital adrenal dysfunction – in 44.9%. So, it was established that, other than PCOS, Hyperprolactinemia and Atypical (late) form of congenital adrenal dysfunction are also main causes of hyperandrogenism in women, which can lead to acne. Depending on the endocrine pathology of patients, appropriate treatment was prescribed: i) Oral contraceptives for PCOS. ii) Dopamine agonists for Hyperprolactinemia. iii) Synthetic glucocorticoids for Atypical (late) form of congenital adrenal dysfunction. Also, regardless of the type of hormonal disorders, all women received proper topical therapy in accordance with the severity of acne.

Conclusions
As a result, we got to the following conclusions: i) On the background of the proposed differentiated combined therapy within 6 months, positive effects were achieved in 85% of women with significant reduction of the eruption and without its recurrent appearance. ii) The condition of skin and acne eruptions was clearly dependent on hormone levels in the blood. iii) In order to achieve efficient treatment of female acne, combined therapy should be based on the correction of hormonal disorders.

N-Terminal pro-B-type natriuretic peptide level in type 2 diabetic patients
Volha Vasylkova1,2, Tatiana Mokhort2, Elena Naumenko3 & Margarita Zmailik3
1Gomel State Medical University, Gomel, Belarus; 2Belarusian State Medical University, Minsk, Belarus; 3The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus.

Objective
A diabetic state is causally related to heart failure (HF) which is a leading cause of mortality. Early detection of high-risk individuals is imperative for primary prevention. The aim of this study was to investigate the role of N-terminal pro-B-type Natriuretic Peptide (NT-proBNP) in patients with diabetes type 2 (DT2).

Methods
We investigated 86 patients both sexes with DT2 aged 65.54 ± 11.37 years (from 50 to 65 years) without clinical cardiovascular disease at baseline. Plasma levels of NT-proBNP and other biochemical data were measured. Control group included 34 healthy subjects the same age.

Results
NT-proBNP level increased with age in both the diabetic and control group but patients with DT2 had higher NT-proBNP levels (P<0.05). NT-proBNP was significantly correlated with HbA1c (r=0.53, P<0.001), serum creatinine (r=0.62, P<0.001), serum cystatin C (r=0.48, P<0.001), and age (r=0.31, P<0.001). Multivariate linear regression analysis of the significant variables showed that age (P=0.011), male gender (P=0.012), triglyceride (P<0.001), systolic blood pressure (P<0.001), and cystatin C (P<0.001) were the independent predictors of fasting serum log-NT-proBNP levels in diabetic patients.

Conclusions
We showed the role of risk factors to heart failure in patients with DT2. In these patients, the presence of dyslipidemia, hypertension, and renal impairments were predictors of fasting serum log-NT-proBNP levels. Thus adjustments for the age, sex and renal function are necessary for determining cardiac risk based on NT-proBNP level.

Metabolic risk factors in adolescent girls with type 1 diabetes
Marta Isabel Pinheiro1, Juliana Oliveira1, Rita Santos Silva2,3, Cintia Castro Correia2 & Manuel Fontoura2,3
1Department of Pediatrics, Hospital Pedia´trico Integrado, Centro Hospitalar de Sãö João, Porto, Portugal; 2Pediatric Endocrinology and Diabetology Unit, Hospital Pedia´trico Integrado, Centro Hospitalar de Sãö João, Porto, Portugal; 3Faculdade de Medicina da Universidade do Porto, Porto, Portugal.

Background
Adolescent girls with type 1 diabetes (T1DM) have a higher incidence of metabolic risk factors like hypertension, dyslipidemia, non-alcoholic hepatic steatosis (NASH), abdominal adiposity and polycystic ovarian syndrome (PCOS) when compared with their non-diabetic peers. Moreover, metabolic risk factors seem to appear even in T1DM girls without overweight or obesity. We aimed to determine the prevalence of several metabolic risk factors in adolescent T1DM females, according to their nutritional status.

Methods
Girls older than 14 with T1DM for a period longer than 2 years were included. They were divided into two groups according to their body mass index (BMI above or below the 85th percentile). The two groups were compared in what regards the presence of abdominal adiposity, hypertension, lipid profile abnormalities, NASH and PCOS.

Results
44 adolescents were included: 25 with normal weight and 16 (39%) with obesity or overweight. No difference was found between age (17 ± 1.8 for girls with normal weight vs 17 ± 1.7 for obese and overweight girls; P=0.49) or mean A1c among groups (8.5 ± 1.4 vs 8.5 ± 1.1; P=0.98). Girls with normal weight had a longer duration of T1DM (9 ± 4 vs 7 ± 4; P=0.03). In what regards overweight or obese girls, 23% had abdominal adiposity, 14% hypertension, 21% lipid profile abnormalities, 23% NASH, 23% PCOS and 20% metabolic syndrome. Among normal weight diabetic girls, 6% had abdominal adiposity, 19% hypertension, 5% lipid profile abnormalities, 6% NASH and 6% PCOS. No statistical significant differences were found between the two groups.

Discussion
The prevalence of metabolic risk factors, including NASH and PCOS, was similar of that reported in the published data concerning diabetic young women, although there are few studies in the pediatric population. Even though metabolic syndrome and its components were more prevalent among overweight and obese T1DM girls, they were also present among normal weight diabetic individuals.

DOI: 10.1530/endoabs.49.EP512
Background and aims

Depression is a common co-morbidity among people with diabetes that reduces quality of life and is associated with morbidity, mortality, and health care costs. We aimed to assess the prevalence of depression among patients with type 2 diabetes in two Arabic nations, Egypt and Yemen and to examine its relationship with socio-demographic data and diabetes complications.

Methods

We conducted a cross-sectional analysis on 200 subjects with type 2 diabetes, divided into two groups: 100 Egyptian and 100 Yemeni subjects. All selected subjects were subjected to full medical history and clinical examination. Laboratory tests included fasting plasma glucose and HbA1C. MADRS scale was used for diagnosis of depression.

Results

Both groups were age and sex matched. The prevalence of depression was 39% in Egyptian and 34% of Yemeni patients, with no statistical significance. In Egyptian diabetics, depression was significantly associated with female gender, duration of diabetes, poor glycemic control, higher number of children, low and very low socioeconomic levels, high mean number of cigarette smoking, lower mean number of years of education and presence of diabetes complications. However, in Yemeni diabetics, depression was significantly associated with female gender, birth order, poor glycemic control, low and very low socioeconomic levels, lower mean number of years of education, diuretic usage for medical co-morbidities. The most important predictors of depression were female sex, higher number of children, divorce, low and very low socioeconomic levels and lower mean number of years of education.

Conclusion

High prevalence of depression among Egyptian and Yemeni type 2 diabetic patients. Depression associated with poor glycemic control.

Uncontrolled hyperglycemia accelerates endothelial damage and vascular inflammation caused by proinflammatory cytokines including tumor necrosis factor α (TNF-α), which leads to arteriosclerotic cardiovascular diseases. Glycogen synthase kinase 3β (GSK3β) is reported to mediate TNFα-stimulated nuclear factor-κB (NF-κB) activation and expression of vascular adhesion molecules. Although a few clinical trials have suggested that telmisartan, an angiotensin II type 1 receptor blocker (ARB), decreases cardiovascular complications in diabetic patients, the underlying molecular mechanisms for the beneficial effects have not been fully elucidated. Here, we investigated a molecular mechanism mediating the telmisartan’s beneficial effects on vascular inflammation in hyperglycemia-treated endothelial cells. Telmisartan dose-dependently attenuated the hyperglycemia-activated vascular cell adhesion molecule-1 (VCAM-1) expression and TF-α monocytes adhesion, which accompanied an increased GSK3βSer9 phosphorylation and a decreased NF-κB p65Ser56 phosphorylation. Among ARBs, including losartan and fimasartan, only telmisartan induced GSK3βSer9 phosphorylation and showed the inhibitory effects on expression of VCAM-1 and phosphorylation of NF-κB p65Ser56. The telmisartan’s beneficial effects were not changed by pretreatment with GW9662, a specific and irreversible peroxisome proliferator-activated receptor γ (PPARγ) antagonist, although GW9662 clearly inhibited rosiglitazone-induced CD36 expression. Ecotopic expression of GSK3β-S9A, a constitutively active mutant of GSK3β, significantly restored the telmisartan-attenuated VCAM-1 expression, NF-κB p65Ser56 phosphorylation, and TF-α monocytes adhesion. Finally, both increased NF-κB p65-Ser56 phosphorylation and decreased GSK3β-Ser9 phosphorylation in the aortas from high-fat fed mice were reversed by treating with telmisartan. Taken together, our findings demonstrate that telmisartan ameliorates hyperglycemia-exacerbated vascular inflammation at least in part by increasing GSK3β-Ser9 phosphorylation, which mediates a decreased VCAM-1 expression in a PPARγ-independent manner. Telmisartan may be useful for the treatment of DM-associated vascular inflammation and cardiovascular diseases.

DOI: 10.1530/endoabs.49.EP514

Uncontrolled hyperglycemia accelerates endothelial damage and vascular inflammation caused by proinflammatory cytokines including tumor necrosis factor α (TNF-α), which leads to arteriosclerotic cardiovascular diseases. Glycogen synthase kinase 3β (GSK3β) is reported to mediate TNFα-stimulated nuclear factor-κB (NF-κB) activation and expression of vascular adhesion molecules. 1.73 m² and worsening nephropathy was defined as eGFR <45 ml/min per 1.73 m².

Results
Among the 208 elderly patients with T2DM, 95 patients (45.7%) had CKD at baseline. Obesity, longer diabetes duration, and usage of ACEI or ARB were independent factors related to the presence of CKD. Mean follow-up duration was 54.9 months. On multivariate Cox analysis, elderly patients with diabetes duration ≥ 10 years had a 2.82-fold increased risk for worsening nephropathy compared with those with diabetes duration < 5 years (95% CI 1.29–6.30; P = 0.010). Compared with HbA1c < 8.0%, HbA1c ≥ 9.0% had a 2.82-fold increased risk for worsening nephropathy (95% CI 1.40–5.69; P = 0.004). Elderly patients with obesity showed worse renal prognosis than those without obesity (HR 1.89; 95% CI 1.01–3.35; P = 0.045).

Conclusions
Since CKD was commonly accompanied in elderly patients with T2DM, it is important to monitor and manage renal function in those patients, especially who had diabetes duration ≥ 10 years or HbA1c ≥ 9.0% or obesity.

Association of metabolic risk factors with hyperfiltration and urine albumin creation ratio in represent Korean population (Korea National Health and Nutrition Examination Survey 2011–2014) without chronic kidney disease
Eun-Gyong Hong, Sangmo Hong & Yun Mi Choi
Hallym University Dongtan Sacred Heart Hospital, Hwaseong-si Gyeonggi-do, Republic of Korea.

The development of glomerular hyperfiltration precede the diagnosis of diabetes, but most study had undertaken with diabetes or obesity patients. In this study, we determine the association between glomerular hyperfiltration and other metabolic risk factors which associated diabetes in represent Korean population without chronic kidney disease. We analyzed 19 244 subjects with a estimated glomerular filtration rate(eGFR) above 60 ml/min per 1.73 m² and urine albumin creation ratio (ACR) below 30 mg/g from the 5th (V-2.3, 2011–20012) and 6th (VI-1.2, 2013–2014) Korea National Health and Nutrition Examination Survey (KNHANES). The estimated glomerular filtration rate was calculated on the basis of the CKD-EPI equation. Hyperfiltration was defined as eGFR above the age- and sex-specific 95th percentile for healthy subjects. According to glucose tolerance, the prevalence of hyperfiltration were increased 4.7% in normal, 4.9% in prediabetes, and 5.4% in diabetes (P for trend <0.001). After adjusting age, sex, body weight, hyperfiltration associated with higher body mass index (P<0.001), waist circumference (P<0.001), systolic blood pressure (P=0.003), Hba1c (P=0.039), fasting plasma glucose (P=0.005), triglyceride (P=0.001), energy intake (P=0.001), protein intake (P=0.034), and sodium intake (P=0.002). Hyperfiltration was independently associated with ACR (B = 0.053, P<0.001) in multiple regression analysis with above mentioned factors. Higher waist circumference (P<0.001), systolic blood pressure (P<0.001), HbA1c (P=0.039), fasting plasma glucose (P=0.001), and triglyceride (P=0.001) were also independently associated with ACR. In Korean general population, both hyperfiltration and ACR were associated with similar metabolic risk factor and each were independently associated. Longitudinal studies are needed to explore the risk for hyperfiltration and microalbuminuria.

Clinical correlates of TNF alpha levels in anemic patients with early diabetic nephropathy
Ivan Pchelin & Alexander Shishkin
Saint Petersburk State University, Saint Petersburg, Russia.

Anemia occurs early and predicts high risk of cardiovascular events and death in patients with diabetic nephropathy (DN). It results from various factors including erythropoietin (EPO) deficiency and inflammation. The aim of this study was to evaluate clinical correlates of TNF alpha levels in anemic patients with early diabetic nephropathy. We investigated 95 anemic patients with type 2 diabetes mellitus and chronic kidney disease (stages 1–3). Glomerular filtration rate was calculated by Cockcroft-Gault formula. Anemia was defined according to World Health Organization criteria (2008). In addition to routine clinical tests we measured serum levels of EPO and TNF alpha using immunoassay. Correlations were assessed by Spearman’s correlation coefficient (rs). We found EPO deficiency in 46.3% and decreased serum ferritin levels in 11.6% patients. Serum level of TNF alpha correlated negatively with hemoglobin level (rs = -0.311, P = 0.003). It had no significant interrelations with age, serum creatinine, ferritin, cholesterol, glomerular filtration rate and urinary albumin excretion. In patients without EPO deficiency TNF alpha level correlated with mean cell hemoglobin content (rs = -0.700, P = 0.003), serum EPO (rs = 0.375, P = 0.017) and urea concentrations (rs = 0.433, P = 0.011). In EPO-deficient patients it correlated with serum urea (rs = 0.393, P = 0.032) but not with mean cell hemoglobin content (P = 0.950) and EPO level (P = 0.247). The results of the study suggest that anemia in patients with early DN is multifactorial. EPO-deficient and EPO-sufficient anemic patients with DN are characterized by different clinical correlates of serum TNF alpha level. Further larger studies are needed to elucidate clinical implications of these findings.

Non-alcoholic steatohepatitis and diabetes mellitus: a case report
Sara Castelo Branco1, Miguel Vasques2, Lurdes G. Matos3, Edite Filipe4 & Adelmo Milheiro5
1Santa Marta Hospital, Lisbon, Portugal; 2Curry Cabral Hospital, Lisbon, Portugal.

Non-alcoholic steatohepatitis (NASH) is a clinical entity characterized by the infiltration of fat into the liver associated with hepatic inflammation. The etiology is unknown, however its most frequently observed in patients with type 2 diabetes mellitus (DM 2), obesity or insulin resistance. DM 2 is an independent risk factor for the progression of NASH. Usually there are no symptoms, so it is not possible to estimate its prevalence. The treatment focuses on the control of associated diseases such as DM 2 and obesity. A 65-year-old woman without alcohol or toxicophilic abuse, without obesity (BMI of 22.7) and with clinical history of immune thrombocytopenic purpura, DM 2 (controlled under diet), hypertension and cystic lesion of the pancreas (5 years before biopsy compatible with mucinous lesion). Due to the increasing of the pancreatic lesion, with dilatation of the wursing canal, the patient was submitted to body-caudal pancreatic resection. During the intraoperative period, the liver presented with a cirrhotic pattern, and liver biopsy was performed. Histology showed steatohepatitis, with fibrosis grade 5/6 and focal balloonization of hepatocytes. Additional study: ANA 1/160, remaining autoimmunity (AMA, SMA, LKM and antibodies anti-liver antigens) and viral serologies (HIIV, hepatitis B and C) negative. After the surgery, insulin therapy was initiated with good metabolic control. The patient did not present micro or macrovascular complications. The present case describes a diabetic patient with an incidental diagnosed cirrhotic liver caused by NASH. The association of NASH and DM2 is present in more than 75% of the diabetics and in this case other related conditions (as obesity, hyperlipidemia, insulin resistance, and drugs) were excluded. The early intervention in DM 2 is crucial, in order to reduce related pathologies and their progression especially in this case with silent steatohepatitis and cirrhotic liver.

The prevalence of common risk factors for depression development in diabetes mellitus of the type 1
Yana Nuvmenova1, Eelena Mahlina1 & Tatyana Mohor1,2
1The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus; 2Gomel State Medical University, Gomel, Belarus; 3Belarusian State Medical University, Minsk, Belarus.

Objective
To evaluate the frequency of common risk factors for depression development in patients with the diabetes mellitus of the type 1 (DM1).

Materials and methods
163 patients with DM1 at the age of 18–65 years old, period of DM is 11.18 (4.28; 22.33) years. The evaluation of the anxiety and depression level was carried out with the use of the Hospital anxiety and depression scale (HADS); a questionnaire was carried out with the use of specially developed form to reveal common risk factors for depression development. A study group was divided into two subgroups depending on the level of depression in accordance with the HADS: group 1 included patients with DM1 and depression (n = 46) and group 2 included patients with DM1 without depression (n = 117).

Results and conclusion
i) There are more patients that live alone (23.9% in comparison with 9.4% consequentially, p = 0.04) and person with disability status (69.6% in comparison with 47.9% consequentially, p = 0.03), among patients with DM1 and depression, than among patients with DM1 without depression. ii) The disability status is associated with the risk for depression development in DM1 (OR = 2.41; P = 0.01; 95% CI 1.16–4.19).

Comorbidities and morbimortality of patients with hospital hyperglycemia in the health area of Cuenca (Spain)
José Pérez-Rodríguez, Dulce Calderón-Vicente, Santiago Aranda-Regules, Lidia Guerra-Navarro, Paula García-Notario, Mubarak Alramadan & David Martín-Iglesias
Virgen de la Luz Hospital, Cuenca, Spain.

Introduction and objectives
Hyperglycemia (HG) is a common problem in hospitalized patients that increases infections, mortality, costs and the hospital stay. The objective of this study is to know the association of the HG with cardiovascular risk factors (CVRF), stress factors, hospital stay and mortality.

Methods
We designed a cross-sectional observational study. We included patients admitted in the hospital every three days in two months. We excluded patients younger than 15 years, stays less than three days and those of the pediatric, gynecological, emergency and intensive care services. We collected the data from these patients the third day of admission and at discharge. We defined HG as two or more capillary glucose values greater than 140 mg/dl. We consider stress factors as infection/sepsis, surgery and corticosteroids treatment.

Results
A total of 328 patients were included 109 of patients had HG. Regarding CVRF, the hyperglycemic patients had hypertension in 67%, dyslipidemia in 45.9% and
both disorders in 38.5%; compared to 42.9%, 24.7% and 17.8%, respectively in non-hyperglycemic patients. The HG group had two stress factors in 33.7% vs 8.4% in non-HG group; and three stress factors in 10.6% vs 3.6% respectively. Hypoglycemic patients were treated with corticosteroids in 36.7% vs 15.6% in non-hyperglycemic patients. The mean hospital stay was 9.17 days in HG group compared with 7.53 days in non-HG group ($P < 0.05$). Longer stays were observed in HG group. Finally, the rate of mortality in hyperglycemic patients was of 3.7%, vs 0.5% of the non-hyperglycemic patients ($P < 0.004$).

Conclusions

Patients with hospital HG are more likely to have other CVRF associated. Stress factors such as surgery, corticosteroids treatment and infection/sepsis increase the risk of HG. Finally HG is associated with a longer hospital stay and higher mortality.

**Diabetes and mental health disorders: not a good combination**

Rahat Tauni\(^1,2\), Nida Ali\(^2\), Ravina Tanna\(^2\), Debbie Charles-Obi\(^2\), Jyotsna Bhudia\(^2\) & Ritwik Banerjee\(^2\)

\(^1\)Cambridge University Hospitals, Cambridge, UK; \(^2\)Luton and Dunstable University Hospital, Luton, UK.

A 49 year old lady presented to the hospital unconscious with severe hypoglycaemia. She had type 1 diabetes for 24 years and coeliac disease. She was hypo-unaware and had multiple admissions with DKA and hypoglycaemia over the years. She did not engage in the self-management of diabetes, therefore, insulin was being injected by the carers in the community and by nurses in the hospital. Her erratic and unpredictable glycaemic control was attributed to non-compliance. She admitted to eating gluten diet, and recent upper GI endoscopy showed mark villous atrophy. Her meal size and pattern were variable at home. During admission, she was found to be self-injecting her own insulin without a clinical indication. She was assessed by a psychiatrist and was diagnosed to have a personality disorder. She was deemed to have full mental capacity and insight into her condition and the harm that can occur with her behaviour. She was seen by a psychologist and admitted to self-injecting insulin without a clinical indication. It transpired that this was due to an ongoing court battle with her children, and the secondary gain was to get the attention of her children. Diabetes can contribute to the pathogenesis of psychiatric disorders, and some psychiatric disorders are significant risk factors for the development of diabetes. Up to 45% of mental disorders and severe psychological distress goes undetected in people being treated for diabetes. Psychiatric disorders co-existing with diabetes include delirium, mood disorders, substance abuse, anxiety, eating disorders and psychosis. There could also be some overlap between physical features of diabetes especially hypoglycaemia and symptoms of psychiatric disorders. Physicians and endocrinologists should actively seek these issues especially in people with 'brittle' diabetes as early recognition and treatment of psychiatric and behavioural problems may lead to satisfactory diabetes control and avoid hospital admissions.

**Management of diabetic peripheral neuropathy (DPN) using low frequency pulsed electro magnetic field (LF-PEMF)**

Satish Chander Wasoori\(^1\), Deepak G. Pande\(^2\), Chetan Bhardwaj\(^1\) & Manoj Naik\(^1\)

\(^1\)Park Hospital, Gurgaon, Haryana, India; \(^2\)G D Diabetes Center, Delhi, India.

Objective

To evaluate the effectiveness of low frequency pulsed electromagnetic field (LF-PEMF) in the management of diabetic peripheral neuropathy (DPN) symptoms.

Methods

A comparative observational study of 60 patients, male and female (1:1) aged 60–85 years. Enrolment criteria – known diabetics, HbA1c 7–9 and DPN of 1–5 years. Patients were randomized into 2 treatment groups G1 and G2. The study period was 4 weeks (w) with results assessed at baseline and bi-weekly follow-ups using diabetic neuropathy symptom (DNS) score. G1: 30 patients with an established DPN were treated with PEMF therapy – frequency of 10 Hz, thru two emitters of 20 mTelsa and 6 mTelsa, keeping non-thermal intensity towards the body. A total of 15 sitting of 20 (10+10) min – one per day. G2: 30 patients with an established DPN were continued on oral symptomatic treatment options like – amitriptyline, duloxetine, gabapentin, pregabalin and tramadol. Patients in both the groups were on Vitamin B 12 + Alpha Lipoic Acid which were continued. Results

In G1 application of LF-PEMF therapy significantly facilitated the regression of the main clinical symptoms of DPN. Patient scores were more differentiated on DNS score. Complete relief in the symptoms of DPN was achieved in four patients at 2 w which sustained at four patients at 4 w. DNS score of 1 was achieved in ten patients. DNS score of 2 was achieved in 18 patients at 2 w which was sustained at 4 w. Overall 32 patients had a relief of main clinical symptoms on the DNS score. In G2 there was a mild regression of the main clinical symptoms of DPN. Complete relief in the symptoms of DPN on DNS score was achieved in 0 patients at 2 w and in one patient at 4 w. DNS score of 1 was achieved in two patients at 2 w which increased to three patients at 4 w. DNS score of 2 was achieved in seven patients at 2 w which was increased to 11 patients at 4 w. Overall 14 patients had a relief of main clinical symptoms on the DNS score.

Conclusion

The present study provides convincing data regarding the effectiveness of LF-PEMF therapy, on patients with DPN symptoms. The usage of oral symptomatic drugs is limited due to the high frequency of adverse events, lack of evidence of long term efficacy and concern about dependence. Considering the benefits and safety, in comparison to oral symptomatic drugs, LF-PEMF can be used as an adjacent in the management of diabetic neuropathy cases. A bigger study is warranted to determine whether DPN can be modulated with LF-PEMF and how it can influence nerve regeneration. Limitations of this study include small sample size, short duration of treatment and non-availability of follow-up data.

Keywords: LF-PEMF – low frequency pulsed electromagnetic field, DPN – diabetic polyneuropathy, DNS – diabetic neuropathy symptom, w – weeks.

**Correlation of NGAL and thyroid function in patients with type 1 diabetes**

Alena Sazonava\(^1,2\), Tatiana Mokhort\(^1\), Volha Shyshko\(^1\), Alena Mokhort\(^1\) & Natalia Karlovich\(^1,2\)

\(^1\)Belarusian State Medical University, Minsk, Belarus; \(^2\)City Endocrinological Dispensary, Minsk, Belarus.

Neutrophil gelatinase-associated lipocalin (NGAL) was shown to be highly useful in assessing kidney injury in patients with diabetic nephropathy. Taking into account recent data that dysthyroidism may have reversible effects on GFR the purpose of the study was to investigate potential relationship between serum NGAL levels, thyroid status and ultrasound thyroid characteristics in patients with type 1 diabetes (T1D) with CKD.

**Materials and methods**

We recruited 118 patients (43m; 75f; age 40.78±12.41 years; BMI 25.50±4.956 kg/m²; duration of T1D 22.86±9.737 years) with CKD. Hypertension was observed in 76 (64.4%) patients; 56 (47.46%) took ACE inhibitors. Lipid profile changes were found in 87 (73.73%) patients, and only 30 (25.42%) of them received statins. GFR was estimated by CKD-EPI formula. All patients were divided into two groups: group 1 comprised 95 patients with GFR >45 ml/min, group 2 – 23 patients with GFR <45 ml/min. Biochemical parameters, NGAL, thyroid hormones levels were measured. USG of thyroid gland was performed. Nonparametric statistical methods were used. A $P$-value <0.05 was considered significant.

Results

Groups were matched by age, gender, HbA1c, TSH, FT4, ATPO levels, thyroid gland volume (VolThG). Comparative analysis of patients in the subgroups according to GFR revealed reliable differences in FT3 ($P = 0.028$) and NGAL levels ($P = 0.0003$). Low-FT3 was occurred significantly more often in group 2 –
Impaired awareness of hypoglycemia in adults with type 1 diabetes is not associated with peripheral neuropathy

Diamantos Tsitlakidis, Milena Djordjevic, Nicole Müller, Ulrich Müller & Christof Kloos
University of Jena, Jena, Germany.

Objective
The impaired awareness of hypoglycemia (IAH) affects people with type 1 diabetes and is a risk factor for severe hypoglycemia. This study aims to evaluate the association between the impaired awareness of Hypoglycemia by diabetes type 1 and the peripheral neuropathy (PNP).

Methods
276 adults with type 1 diabetes, 135 men and 141 women, were studied from May 2015 to January 2016 to the outpatient department of University Hospital of Jena. A cross sectional study was performed, using the Gold Score for assessing hypoglycemia awareness and the peripheral neuropathy was evaluated with the Neuropathy Symptons Score (NSS) and the Neuropathy disability Score (NDS) from Young and Boulton.

Results
The median age of the group was 51 ± 16 years with 23 ± 13 years diabetes duration. The BMI score was 27 ± 5 kg/m² and the DDCT adjusted HbA1c was 7.27% ± 1.1. 85 patients had PNP and 80 had IAH. 27.6% of patients without PNP and 38.8% of patients with PNP had IAH (P = 0.067). The HbA1c did not show any difference between the adults with and without IAH (7.1 vs 7.5%; P = 0.121). The duration of diabetes was longer for the adults with IAH (31.34 vs 26.95 years; P = 0.001). In the regression analysis, a significant association of the IAH to the diabetes duration (Exp(B) = 1.031; P = 0.007), but not to PNP (Exp(B) = 1.387; P = 0.284) or HbA1c (Exp(B) = 0.801; P = 0.115), is shown.

Conclusions
This study revealed in adults with diabetes type 1 association between the diabetes duration and the IAH but not with the presence of PNP.

A rare presentation of diabetic ketoacidosis: Rhino-orbito-cerebral mucormycosis

Aim and objective
Mucormycosis is a rare life-threatening fungal infection. Immunocompromised patients are often affected. We report a rare diabetic patient with pancreatic adenocarcinoma who was presented diabetic ketoacidosis and rhino-orbito-cerebral mucormycosis.

Case presentation
A 66 years old man with pancreatic adenocarcinoma and type 2 diabetes mellitus was presented diabetic ketoacidosis and severe infection of the facial sinuses, orbita, and soft palate in the right half of the face. It was learned that the infection developed after tooth extraction. Diabetic ketoacidosis improved after fluid and electrolyte replacement and insulin treatment. Non-septate hyphae structures were shown in biopsy sample from affected tissues. Brain MRI showed that this infection was extended to the brain. Amphotericin B therapy was started immediately due to delay rapid progression and recommended surgical debridement. Surgical debridement is the main therapy for mucormycosis but patient and his relatives did not accept surgical treatment. Amphotericin B therapy was continued but he dead within the following 2 months.

Conclusion
In diabetic patients with impaired immunity, procedures such as tooth extraction can cause rare serious infections like mucormycosis.

Renal function preservation with Manidipine vs Amlodipine in type 2 diabetic hypertensive patients with persistent microalbuminuria

Sara Quintana-Arroyo1, Carmen Acosta-Caler1, Claudia Arnáu-León1, Ana Delia Santana-Suárez1, Agnieszka Kuzior1, Margarita Sáez-Sáptes2, Manuel Niveló-Rivadeniera3 & Francisco Javier Martínez-Martin3
1Servicio de Endocrinología y Nutrición, Hospital Dr. Negrín de Gran Canaria, Las Palmas de Gran Canaria, Spain; 2CAP Rambla Terrassa, HUMT, Barcelona, Spain

Objectives
The AMANDHA randomized study (PROBE design) showed that the addition of Manidipine 10 mg for 2 years in 91 hypertensive type 2 diabetic patients with persistent microalbuminuria, uncontrolled with a renin-angiotensin system inhibitor (given full-dose for at least the 6 previous months) was more effective in reducing albuminuria in spite of similar blood pressure control. Patients with significant renal impairment (PiCr > 1.4 mg/dl in women and > 1.5 in men) had been excluded. However, no data were published on the progression of renal dysfunction, with only PiCr values reported, which were not significantly different. We undertook to establish if there were differences in glomerular filtration rate (GFR) progression.

Methods
Post-hoc analysis of AMANDHA. GFR was estimated by the MDRD-4 equation for each individual measurement. Point-to-point GFR were compared by unpaired t-test and progression was compared by the Kruskal-Wallis test. (non-parametric ANOVA). Values are given as mean (± standard error).

Results
Baseline GFR were 67.3 (± 5.2) and 70.2 (± 5.0) ml/min/1.73 m² with Manidipine and Amlodipine, respectively; at 6 months they were 68.6 (± 5.6) and 69.5 (± 5.3), and at 2 years 66.9 (± 4.7) and 65.5 (± 5.0). During follow-up, patients treated with Manidipine lost 0.4 (± 3.9) ml/min/1.73 m² of FGR vs 4.7 (± 5.2) with Amlodipine. Point-to-point GFR were not significantly different between the groups, but GFR loss after 2 years was lower with Manidipine (P = 0.032).

Conclusions
The previously published data of AMANDHA showed a markedly greater albuminuria reduction (about 40% more) with Manidipine vs Amlodipine, which was attributed to efferential arteriolar dilatation. The present post-hoc analysis also shows a better preservation of renal function with Manidipine. These results strengthens the case for combined treatment with Manidipine and a renin-angiotensin system blocker in hypertensive type 2 diabetic patients with persistent microalbuminuria.

A rare presentation of diabetic ketoacidosis: Rhino-orbito-cerebral mucormycosis

Significance of hemorheological approach for screening diabetic nephropathy in the type II diabetes mellitus
Sangbae Lee, Kuhui Park, Jung Hye Kim, Ji Hong You, Yusik Kim, Ji sun Nam, Jong Suk Park & Chul Woo Ahn
Gangnam Severance Hospital, Seoul, Republic of Korea.

Objective
Hemorheologic alterations or changes in blood viscosity have been suggested to play a role in the pathogenesis of diabetic microvascular complications. We measured various hemorheologic parameters in type 2 diabetes patients and assessed their possible role as a diagnostic tool for diabetic nephropathy.

Methods
Four hundred-seventy patients with type 2 diabetes were included in this study. Hemorheologic parameters, including erythrocyte deformability, elongation index (EI), critical shear stress (CSS), and aggregation index (AI) were measured using microfluidic hemorheometer. Various metabolic parameters were assessed from fasting blood samples and urinary albumin to creatinine ratio was used to assess diabetic nephropathy.

Results
There were significant differences in Elongation index at 3 Pascal (EI at 3Pa), Fibrinogen/EI, and shear stress among patients in different stages of chronic kidney disease (all \( P < 0.05 \)). EI at 3 Pa, Fibrinogen/EI, and shear stress significantly differed among the groups. Fibrinogen/EI differed between normal or CKD 1 and CKD 2 patients. In multiple regression analysis, Fibrinogen/EI at 3Pa was an independent predictor of albumin to creatinine ratio independent of age, ESR, hematocrit, HbA1c, and body mass index (BMI). Also, critical time, critical stress, fibrinogen/EI at 3Pa, CSS/EI at 3Pa, fibrinogen/CSS at 3Pa were significantly different among patients at different stages of diabetic nephropathy (all \( P < 0.05 \)). Among the variables, Fibrinogen/EI at 3Pa showed area under the ROC curve of 0.721, suggesting 860 mg/dl% as a cut off point for diabetic nephropathy with the sensitivity of 74% and specificity of 62%.

Conclusion
Fibrinogen/EI is a sensitive parameter measured via point-of-care testing for screening diabetic nephropathy in patients with type 2 diabetes.

The effect of different antihypertensive treatment protocols on glycemic control and lipid profile in type 2 diabetic patients with microalbuminuria and stage 1 hypertension
Muge Erek1, Alparslan Erisoy1 & Canan Erisoy2
1Department of Nephrology, Uludag University Medical Faculty, Bursa, Turkey; 2Department of Endocrinology and Metabolism, Uludag University Medical Faculty, Bursa, Turkey.

In hypertensive diabetic patients, renal angiotensin system blockers are first preferred due to their antihypertensive and antiproteinuric activities. Carvedilol, a third generation beta blocker, may provide additional benefits in diabetic patients. We aimed to compare the short-term efficacy of losartan treatment alone and in combination with cilazapril or carvedilol on blood pressure, glycemic control and lipid profile in microalbuminuric type 2 diabetic patients.

Methods
The study conducted in 30 consecutive patients with type 2 diabetes mellitus and stage 1 hypertension. After 2 weeks follow-up period (Period 1), all patients received losartan 50 mg/day as a single dose for 6 weeks (Period 2). Then, patients were randomized into 3 groups at the end of 6th week. Losartan dose was increased to 100 mg/day in the first group (Group 1, n:10). Carvedilol (25 mg/day) in the second group (Group 2, n:10) and cilazapril (5 mg/day) in the third group (Group 3, n:10) was added to losartan 50 mg/day treatment for another 6 weeks (Period 3).

Results
In all three groups, effective blood pressure control was provided during losartan 50 mg administration and post-randomization treatment period. Body mass index in Group 1 significantly decreased during the losartan dose-increasing period. When the losartan dose was increased in Group 1, fasting glucose values were significantly decreased, but not in other groups. There was no significant difference in measurements of post-prandial glucose, and serum fasting insulin, fructose, lipid and apolipoprotein levels between the three groups. A1c values in the losartan group significantly decreased from baseline 8.2% to 7.8% at 6th week and 7.5% at 12th week. The reductions in A1c values of losartan plus carvedilol and losartan plus cilazapril groups were not significant (\( P > 0.05 \)).

Conclusion
As a result, the use of high-dose losartan in hypertensive microalbuminuric type 2 diabetic patients provided short-term more effective glycemic control when compared to carvedilol or cilazapril treatments with low-dose losartan. Significant decreases in the high dose losartan group in terms of body mass index, fasting blood glucose and A1c levels, it could explained by diet compliance and better weight control when compared with other groups.

Impact of skin bundle implementation on hospital acquired pressure foot ulcers and length of stay in inpatients with diabetes
Khaled Ashawesh¹, Asma Elyouni², Masoud Alam³, Lynda Bloomer⁴ & Abdal Waied Sal³
¹Dudley Group of Hospitals Foundation Trust, Dudley, UK; ²University of Leicester, Leicester, UK.

Objective
To assess the impact of launching SKIN (Surface, Keep moving, Incontinence, Nutrition) bundle on development of pressure foot ulcers among in-patients with diabetes.

Methods
SKIN Bundle was launched at Dudley Group of Hospitals Foundation Trust in mid-February 2011. Data on pressure foot ulcers were collected among patients with and without diabetes admitted during February 2010–February 2011 and then from February 2011–March 2012, from pressure ulcer database.

Results
Between 14/02/2010 and 13/02/2011, number of admissions to adults’ wards was 64,000. Of these, 5,452 had diabetes. Out of the latter, 72 patients were identified to have foot ulcers, of them 23 patients developed the foot ulcers during their hospital stay, giving rise a 0.42% rate of development of hospital acquired foot ulcers among in-patients with diabetes. During the thirteen and a half month period following SKIN bundle launch (14/02/2011 – 31/03/2012), there were 13 patients who developed hospital acquired foot ulcers out of 6,232 in-patients with diabetes admitted during the same period, giving rise to a lower rate (0.21%) of development of foot ulcers in the hospital among patients with diabetes. The development of hospital acquired foot ulcers among patients with diabetes, therefore, dropped significantly by 51% P value of 0.04 (<P<0.05) after the launching SKIN bundle. The average length of hospital stay (LOS) among patients who had foot ulcers was significantly shorter by an average of 3.55 days, P value of 0.044 (P<0.05), after this SKIN bundle implementation.

Conclusion
SKIN bundle resulted in more than 50% reduction in pressure foot ulcers, with significant decrease in LOS among those who developed ulcers. SKIN Bundle can therefore be considered as a tool to reduce inpatient pressure Ulcers.

Continuous glucose monitoring system in patients with gestational diabetes mellitus: a prospective study
Rosa Marquez-Pardo, Isabel Torres-Barea, Mgloria Baena-Nieto, Concepcion Cruzado-Begines, Manuel Cayon-Blanco, Rosario Lopez-Velasco & Lourdes Garcia-Garcia-Doncel
Jerez Hospital, Jerez de La Frontera, Cádiz, Spain.

Introduction
Gestational diabetes mellitus (GDM) is associated with an increase of maternal-fetal complications. Continuous glucose monitoring system (CGMS) detects postprandial hyperglycemia and hypoglycemia during 24 h.

Methods
Women with GDM in gestational weeks 26–32 were allocated a CGMS (Ipro™2) after diagnosis in an observational prospective study. It was analysed:
- CGMS: Mean glucose and standard deviation, area under the curve (AUC) with glucose >140 and <70. Percentage of glucose above or below the limit of normality before and after breakfast, lunch, dinner and night. (Target ranges: before meals 70–95, after meal 70-140 and night 70–120 (expressed: mg/dl)).
- Maternal and neonatal outcomes.

Results
n = 32. Maternal age 33 years (>35 years = 43.8%), family history of diabetes 47%, personal history of diabetes 34.4%, prepregnancy BMI 25.9 kg/m² (>30 kg/m² = 21.8%), weight gain 7.7 kg, HbA1c 4.9%, insulin treatment 28%. CGMS: Glucose before breakfast 90±7.5, after breakfast 120±2.0, before lunch 86±9.9, after lunch 112±19.6, before dinner 93±12.3 and after dinner 119±17.8. AUC >140 = 0.81 and <70 = 0.59. Percentage of glucose above or below targets: before breakfast >95 = 33.6% and <70 = 5.4%, after breakfast >140 = 24.6% and <70 = 0.6%, before lunch >95 = 20.8% and <70 = 11.9%, after lunch >140 = 14.5% and <70 = 2.2%, before dinner >95 = 37.6% and <70 = 6.3%, after dinner >140 = 8.6% and <70 = 8.9%. Maternal and neonatal outcomes: Caesarean 28%, gestational age at delivery 39 week, macrosomia 12.5%, large for gestational age 25%, small for gestational age 6.3%, neonatal hypoglycaemia 21.9%, need for supplemental oxygen in the neonatal 6.3%.

Conclusions
SMCG showed prepandial hyperglycemia, mainly before breakfast and dinner. Few hypoglycemias were detected but before lunch and night. Maternal and neonatal outcomes were similar to other studies.

DOI: 10.1530/endoabs.49.EP535

The analysis of interrelation of filtration ability of kidneys and indicators of the androgenic state in patients with diabetes mellitus type 1
Elena Vaschenko¹ & Tatjana Mokhort²
¹The republican Research Centre for Radiation Medicine and Human Ecology, Gomel, Belarus; ²Belarusian State Medical University, Minsk, Belarus.

Objective
To analyze correlation between the duration of diabetes mellitus (DM), renal function and androgenic state indicators in patients with DM type 1.

Material and methods
191 males with DM 1 type in the age of 18–55 years. The control group included 25 almost healthy males in the age 21–41 years. The compensation of DM was estimated by the level of glycosylated hemoglobin. Also, the indicators of lipid profile, glomerular filtration rate MDRD, total testosterone, luteinizing hormone/follicle-stimulating hormone (LH/FSH), prolactin, sex hormone-binding globulin.

Results
It was defined that diabetes duration significantly it is above at patients with GFR <60 ml/min/1.73 m². In the group with GFR <60 ml/min/1.73 m² in the absence of compensation (Hb A1c >7.5%) more than LH, FSH, LH/FSH high levels and significantly lower levels of the general and free testosterone were noted significantly. At patients with GFR MDRD >60 ml/min/1.73 m² significant distinctions on the level of testosterone and gonadotrophins at various compensation of SD haven’t been revealed.

Conclusion
The revealed changes are important risk factors for development and progression of vascular complications and require appropriate arrangements.

DOI: 10.1530/endoabs.49.EP536

PDE5i preserves renal function in models of Diabetic Nephropathy: from bench to bedside
Riccardo Pofi¹, Daniela Fiore¹, Tiziana Feola², Elisa Giannetta², Giulia Le Grazie³, Carla Di Dato¹, Daniele Gianfriilli¹, Biagio Barbano², Mary A. Venneri¹, Andrea Lenzi¹ & Andrea M. Isidori³
¹Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; ²Department of Clinical Medicine, Sapienza University of Rome, Rome, Italy.

Objective
One third of diabetic patients suffer from Diabetic Nephropathy (DN) that leads to end-stage renal disease (ESRD). The molecular pathways involved remain underexplored. We showed that chronic phosphodiesterase-5 inhibition (PDE5i) improve vascular inflammation [1] and tissue remodelling, reducing proteinuria [2] in murine diabetes. Our aim was to investigate the effect of PDE5i on animal and human models of DN.

Materials and methods
16 mice were randomly assigned to four groups: control (CTRL), sildenafil (SILD), streptozocin (STZ), STZ + SILD. Renal Doppler ultrasound (RDU) was performed at baseline and after 6 weeks. Renal resistive index (Bx) GFR (ml/min), mean Blood Pressure-MBP (mmHg) were recorded. FITC-dextran (2 mg/kg) was used to assess permeability and integrity of renal endothelium. 30 type 2 diabetic (T2DM) patients were randomly assigned to placebo (PLC) or tadalafil (TAD) 20 mg/die. RDU was performed at baseline and after 5 months.

Results
All STZ-treated animal developed diabetes. Compared to the STZ, STZ + SILD preserved renal function. Specifically, SILD treatment prevented: (a) the ESRD-related hypertension (MBP, mean change from baseline: STZ 28.7±3.76, STZ + SILD – 9.46±4.84, P = 0.002); (b) the fall in GFR (STZ – 15.24±3.67, STZ + SILD 17.79±3.67; P = 0.005); (c) the rise in RII (STZ 0.10±0.03, STZ + SILD – 0.07±0.03; P = 0.026); (d) the reduction in FITC-perfuse vessels

Relationship between microvascular complications of Diabetes Mellitus and trace element levels
Zelilha Temurer Afsar, Yasemin Tütüncü, Berçem Ayçiçek, Engin Sennaroglu, Dilek Berker & Serdar Guler
Ankara Numune Training and Education Hospital, Ankara, Turkey.

Objective
To determine whether relationship between trace element levels and microvascular complications of type 2 Diabetes Mellitus (T2DM).

Methods
One hundred eighty patients with type 2 DM (mean age: 56 ± 6.2 years) and 40 control subjects (mean age: 40.0 ± 8.8 years) were included in the study. Group 1 (n = 40 patients) was composed of patients with no microvascular complications and it divided into two subgroup, first subgroup (n = 20) included patients with glycemic regulation, the second subgroup (n = 20) with not glycemic regulation. Group 2 included 38 patients with diabetic retinopathy, 19 patients had proliferative retinopathy, 19 patients had nonproliferative retinopathy. Group 3 included 40 patients with both diabetic retinopathy and nephropathy (20 patients had microalbuminur, 20 patients had macroalbuminur). Patients with type 2 DM who had liver disease, renal disease, malabsorbtive disease and who had been taken any diuretic drugs were excluded. Trace elements including Crom (Cr) (µg/l), Copper (Cu) (µg/l), Zinc (Zn) (µg/l) were measured by Inductively Coupled Plasma-Mass spectrophotometry (ICP-MS). And, Iron (Fe) (µg/dl) was measured by ELISA.

Results
Difference of age was only found between control subject and all patients with DM (P < 0.001). Mean age were found not difference between in Group 1,2,3 (P < 0.22, P < 0.24, P < 0.26). Magnesium, Fe, Zn, Cr levels were lower in all patients with microvascular complications (P < 0.01, for both). Also, Cr levels were found lesser in patients with only diabetic nephropathy than in only with diabetic retinopathy (P < 0.01).

Conclusions
The study indicated that an association between low Crm levels and existence of microvascular complications of DM when trace element levels were measured by ICP-MS.

Somnological parameters for patients with type 1 diabetes and nocturnal hypoglycemia
Ina Darashkevich1, Tatiana Mokhort2, Lola Nikanava1, Ludmila Smirnova1 & Serhej Tishkovsky3
1Grodno State Medical University, Grodno, Belarus, 2Belarus State Medical University, Minsk, Belarus.

Objective
To determine the effects of hypoglycemia while sleeping on somnological parameters for patients with type 1 DM.

Materials and methods
The study included 57 person with type 1 DM (Group 1 – patients with blood glucose levels (BGL) during sleep < 3.9 mmol/l; Group 2 – Patients with BGL – from 3.9 to 10.0 mmol/l. The examination included: daily monitoring of blood glucose by ‘CGMSGold’ (‘MedtronikMINIMED’ (USA)), polysomnography «SOMNOlab2 (PSG) Polysomnography (R & K)», the definition of HbA1c.

Discussion and conclusions
For patients of Group 2 marked shortening of TST – 5.30 [4.51; 6.20] hours vs 6.24 [5.40; 7.10] hours (P = 0.0219). Night hypoglycemia extend REM-sleep [39.50 [26.00; 48.00] %] vs [29.70 [23.00; 45.80] %] in the comparison group (P = 0.0479), N1 sleep stage [14.11 [10.60; 23.00] %] vs [8.80 [7.40; 14.30] %] (P = 0.0110), as well as reduce the N4 stage of sleep (1.45 [0.00; 2.89] %) vs 3.00 [1.00; 8.40] %). The share of hypoglycemia ‘before sleep’ extends N1 (r = 0.5442); an increase
in the length of N1 leads to a reduction in the duration of the deep stages of slow-wave sleep N3 (r = −0.6835), N4 (r = −0.5673); an increase in the duration of REM reduces N3 (r = −0.5887).

Conclusion
Hypoglycemia during sleep lengthens REM-sleep, REM sleep so reduces REM reduces N3 (r = 0.5887).

Objective
To establish the differences in terms of sleep for patients with type 1 diabetes, depending on the level of blood glucose levels (BGL) during the night.

Materials and methods
The study included 43 participants with type 1 diabetes (Group A – patients with BGL during sleep from 3.9 to 7.4 mmol/l, Group B – 7.5–10.0 mmol/l). Patients had daily monitoring of BGL using ‘CGMSGold’ by ‘MedtronicMINIMED’ (USA), polysomnography ‘SOMNOlab2 (PSG) Polysomnography (R & K)’, the definition of HbA1c.

Results
See Table.

Conclusion
BGL 4.5 mmol/l during sleep increases the duration of sleep by increasing the N2, N4 and extending reduce REM sleep.

EP542
Emotional state association with microvascular complications, disease duration and glycaemic control in type 1 diabetic patients
Edita Prakapiene1, Karolis Zukas1, Lina Radziveiciene2,3 & Rasa Verkauskienė1,2,3
1Lithuanian University of Health Sciences (LUHS), Faculty of Medicine, Kaunas, Lithuania; 2Department of Endocrinology, Lithuanian University of Health Sciences (LUHS), Kaunas, Lithuania; 3Lithuanian University of Health Sciences (LUHS), Institute of Endocrinology, Kaunas, Lithuania.

The aim
Of the study was to determine the relationship between depression and anxiety symptoms and chronic diabetes complications, disease duration, glycaemic control in type 1 diabetic patients.

Methods
18–54 year old 215 patients with T1DM were enrolled in the study. Participants filled questionnaires about DM, disease duration, complications and Beck’s depression (DB) and anxiety (BA) inventory. All patients were evaluated for microvascular complications. Laboratory tests: HbA1c, creatinine, albumin in 24 h urine sample were performed.

Results
124 females (57.67%) and 91 males (42.33%) participated in the study. Cohort consisted of 66 participants with DN (mean age 32.44 ± 6.5 years) and 149 without DN (mean age 31.53 ± 9.99). The group without DN consisted of 53 patients without any complications (mean age 29.49 ± 2.95) and 96 patients with DP and/or DR (mean age 31.07 ± 9.11). The emotional state of females was worse than males (BD: female 9.78 ± 9.07; male 7.51 ± 7.11; P < 0.05; BN: female 13.86 ± 9.99; male 8.86 ± 7.79; P < 0.01). There was no statistically significant difference between DB among patients with or without complications (P < 0.05). There was a statistically significant difference (P = 0.04) between BA scores among patients without any complications (N = 53, female 31/male 22) (BA 9.42 ± 8.1) and those with DN (N = 66, female 36/male 30) (BA 12.05 ± 8.84). The emotional state of patients with longer disease duration (> 30 years) (BD 13.59 ± 11.49; BN 15.61 ± 9.79) was worse than patients with shorter one (< 10 years) (BD 8.14 ± 6.55; BN 10.86 ± 9.67) (P < 0.05). There was no found statistically significant different between the emotional state and glycaemic control in T1DM patients.

Conclusions
The emotional state of females with type 1 diabetes mellitus is worse than males’. Patients with chronic diabetes complications have more anxiety symptoms than those without any complications. Emotional state is worse in diabetics whose disease duration is longer.

Endocrine Abstracts (2017) Vol 49

EP543
The trigger off severe vomiting and hypertension during pregnancy in type 1 diabetic patient: case report
Egle Kreivaitienė1, Ruta Kriksciuniene1,2 & Evalda Danyte1,2
1Department of Endocrinology, Hospital of Lithuanian University of Health Sciences (LUHS), Kaunas, Lithuania; 2Lithuanian University of Health Sciences (LUHS), Institute of Endocrinology, Kaunas, Lithuania.

Diabetic mothers have an increased risk for pregnancy (early pregnancy loss, polyhydramnios, pre-eclampsia, premature labor) and progression of diabetic complications. We present a case of the progression of diabetic-related complications including autonomic neuropathy (AN) which caused severe vomiting during pregnancy. A 27-year-old type 1 diabetic woman with pregnancy of 8 weeks gestational age (GW) was admitted to our hospital for glycaemia and diabetic-related complications control. She has had diabetes for 13 years. The control of diabetes was poor (HbA1c 9.13%). She was already diagnosed with multiple diabetes-related complications (nonproliferative diabetic retinopathy and maculopathy, polyneuropathy, nephropathy). An insulin-pump therapy was started to achieve a better glycaemia control during pregnancy. The minor progression of albuminuria was noticed during first hospitalization. Around 11 GW she was hospitalized for the second time because of the sudden blood pressure (BP) elevation (160/110 mmHg), nausea, vomiting, headache, glycaemia variability. The progression of diabetic nephropathy was observed, antihypertensive (AH) drugs for the treatment of secondary hypertension were started. Despite the better glycaemia control which was achieved (HbA1c 6.1%) in few months, the patient was hospitalized for the other nine times during the pregnancy. The main complains were severe nausea, vomiting, BP elevation and ketonemia. The progression of all diabetes-related complications was observed. The maximum doses of AH drugs were required for management of BP. Albuminuria progressed to nephrotic level, hyperalbuminemia and hypoproteinemia occurred. Diabetic retinopathy developed to proliferative. Severe vomiting led to electrolytes dis-balance. Nausea and vomiting was considered to be caused by the progression of AN, when other possible causes were excluded. At 36 GW during planned C-section a healthy girl was born (Apgar 8/8). Poor control of diabetes may lead to the severe
Gestational diabetes mellitus (GDM) is associated with an increased risk of pregnancy-induced hypertension (PIH). Ambulatory blood pressure monitoring (ABPM) has been used to screen for PIH and preeclampsia. To date, there are no data regarding ABPM in women with GDM. Currently, little is known in GDM about the role of inflammatory biomarkers in PIH development and their impact on perinatal morbidity and the risk of future complications. With this study we aim to identify, in women with GDM, at an early stage inflammatory markers and BP profiles (detected by ABPM) that could define a population at higher risk of developing PIH and preeclampsia. We prospectively studied 113 normotensive women with GDM consecutively recruited at 28–32 weeks of pregnancy. ABPM was carried out for one 24-h period on each patient, using the SPACELABS 90207 ABP monitor. Serum biomarkers (PAI-1, IL-6, IL-8, leptin, IL1-β, TNF-α, adiponectin, resistin, NGF, HGF and MCP1) were determined in 61 patients by MILLIPLEX kit. Clinical and metabolic data, obstetric and perinatal outcomes were analysed. The mean age was 34.4 ± 4.2 years and BMI was 27.5 ± 5.3 kg/m². Fifty-six percent of the patients had non-dipper pattern. In this group, BMI was significantly higher (P < 0.05) and the levels of night-time systolic (105.3 vs 98.8 mmHg) and diastolic BP (63.1 vs 57.2 mmHg), and furthermore, higher levels of PAI-1 (296.99 ± 161.3 vs 162.07 ± 117.52 pg/ml) and resistin (175.69 ± 92.17 vs 101.74 ± 64.34 pg/ml) were observed. Seventy-eight women delivered to date, 3% had preeclampsia and 7% PIH. Higher levels of adiponectin (125 992.7 ± 94 472.4 vs 39 850 ± 31 136 pg/ml) were observed in patients who not develop PIH. We concluded that a higher rate of non-dippers pattern and night-time systolic/diastolic BP were observed. The non-dipper group had higher BMI and levels of PAI-1 and resistin, which could be a useful predictor of PIH. Adiponectin was significantly lower in patients with PIH and then could point at a protective mechanism in PIH. Further studies will be needed to determine the relationships between BP alterations and inflammatory markers, and obstetrics and perinatal outcomes.

Patient first admitted as diabetic ketoacidosis and diagnosed as MODY 3
Ahmet Kaya, Mustafa Kulaksizoglu & Ilker Cordan
Necmettin Erbakan University, Meram Medical Faculty, Division of Endocrinology and Metabolism, Konya, Turkey.

A male patient aged 63 years old was admitted to the emergency department with the complaints of polydipsia, polyuria and dizziness. He had hyperventilation which was on a calcium channel blocker and his hypertension was in control. His plasma glucose was measured as 564 mg/dl and hospitalized due to his new onset diabetes. His family history showed that, his mother, uncle, aunt and all six brothers were diagnosed as diabetes mellitus. His uncle, aunt and aunts children were using oral antidiabetics. His system query showed that he had poliakuria and nocturia for the last 3 months. His physical examination was normal except diminished skin turgor tonus. His laboratory was normal except blood glucose of 564 mg/dl, HbA1c 8.2%, urea 50 mg/dl, creatinin od 1.34 mg/dl, urine ketone bodies were ++ + +, urine glucose 500 mg/dl. He was treated with i.v. saline, and insulin. On the follow up basal-bolus regimen was initiated. He had hypoglycemias due to four units bolus insulin and 14 units basal insulin glargine so bolus insulin was stopped and vildagliptine-metformin and insulin glargine was added. He had hypoglycemias as well and insulin glargine was stopped and glizaclide MR 60 mg was started and discharged. After 2 weeks his HbA1c was 6.9%, fasting plasma glucose was 122 mg/dl so vildagliptine-metformin was stopped and glizazide was tapered to 30 mg/day. After 3 months his fasting blood glucose was 98 mg/dl and HAlc was 5.1%. His peripheral blood analysis was consistent with HNF1A gene and diagnosed as MODY 3. Transcription factor defects are the most common reasons of the MODY. Insulin secretion is decreased up to 85% but is sensitive to sulfonylureas. Low dose sulfonylureas generally control glyemica very well. But diabetic ketoacidosis is a very rare complication for MODY 3.

Osteoprotegerin as a cardiovascular risk marker in diabetic patients
Anna Dabrowska1, Beata Wojtyja-S-Duma2, Dariusz Duma3, Anna Torun-Jurkowski3, Anna Mieszковska3, Beata Matyjaszek-Matuszek1 & Jerzy Tarack1
1Department of Endocrinology, Medical University of Lublin, Lublin, Poland; 2Department of Biochemical Diagnostics, Chair of Laboratory Diagnostics, Medical University of Lublin, Lublin, Poland; 3Department of Laboratory Diagnostics, Medical University of Lublin, Lublin, Poland; 4Department of Mathematics and Medical Biostatistics, Medical University of Lublin, Lublin, Poland.

Introduction
It’s known that type 2 diabetes is an independent risk factor for cardiovascular disease. Osteoprotegerin (OPG), a glycoprotein secreted mainly by osteoblasts, is also produced by heart muscle and vessels. Its role in the pathogenesis of atherosclerosis and future cardiovascular events is still discussed.

Material and methods
The study was conducted in 113 patients (48 F, 65 M) with type 2 diabetes mellitus (DM2) and coronary heart disease (CHD), aged mean 68.22 ± 9.56. The studied group was divided into subgroups: 61 subjects with acute coronary syndrome (ACS) and 52 subjects with stable angina (SA). Among patients with ACS two groups were separated: with myocardial infarction (MI) and with unstable angina (UA). The control group was composed of 46 well-balanced patients (33 F, 13 M) without DM2 and CHD. Determinations of serum OPG levels with the use of MicroVue OPG-EIA (an assay sensitivity of 0.4 pmol/l) were performed. Statistica 10.0 StatSoft was used for data analysis. OPG concentrations were shown as medians.

Results
Patients with DM2 and ACS as well as patients with DM2 and SA had significantly higher OPG levels than patients in control group (6.5 pmol/l and 5.64 pmol/l vs 3.48 pmol/l) (H = 62.58%; P = 0.000) (P < 0.001). The tendency of higher OPG concentrations in subjects with ACS compared to patients with SA was observed (P > 0.05). Higher OPG levels were noted in patients with MI (7.36 pmol/l) than in those with UA (4.72 pmol/l) (P < 0.05). Patients with complications in the course of ACS such as: cardiac arrhythmias, pulmonary oedema, cardiac tamponade had statistically significantly higher OPG concentrations (8.40 pmol/l) compared to subjects with uncomplicated course of ACS (5.86 pmol/l) (P < 0.05). Higher OPG levels were also found in patients with transmural MI – with Q-wave MI (8.37 pmol/l) than in patients with subendocardial MI – with non-Q wave MI (6.44 pmol/l) (P < 0.05).

Conclusions
OPG may be a marker of cardiovascular disease and ischemia’s severity in diabetic patients.

Diabetic ketoacidosis in an intensive care unit – review
Joana Oliveira, Rodolfo Gomes, Bárbara Picado, Fernando Gonçalves & José Araújo
Hospital Beatriz Ângelo, Lisboa, Portugal.

Diabetic ketoacidosis (DK) is one of the most serious complications of diabetes mellitus (DM). We performed a case review of DK patients admitted to the intensive care unit (ICU) of our Hospital between 1 June 2012 and 30 June 2016. A demographic analysis was made, time of DM evolution, the therapy and the factors that led to its decompensation. Thus, a total of 42 DK patients were admitted to the ICU in the referred period, mean age was 45 years, a clear predominance of female patients (67%) and Caucasian patients (76.7%). The majority of the patients were type 1 diabetics (57%), 40% were diabetic type 2 and 3% had a diagnosis of diabetes secondary to corticosteroids. The mean duration of the disease was 12 years, and diabetes was previously unknown in 12% of the patients, where appears as an inaugural diagnosis. The mean HbA1c value of these patients was 12.6%. Regarding the treatment, 64% of the patients were exclusively treated with insulin, 21% only with oral antidiabetics and 12% did not do any type of therapy, considering that the disease was not known. Half of the patients presented nausea and vomiting, and prostration was the second most frequent presentation (33%). Infection was the most common decompensation factor (50%), followed by therapeutic failure (40%). Add that, 21% of patients required ventilatory support, 19% needed vasopressor support and only 2.3% of the patients were dialyzed. This review shows that despite all the teachings and warnings about the disease and its severity, many patients maintain a poor understanding of it, and it continues to be necessary to develop strategies to improve adherence to therapy and to achieve a better metabolic control.

Prognostic factors and all-cause mortality in patients with type 2 diabetes presenting with diabetic ketoacidosis: a population based, case-control study
Petra Cačić1, Miroslav Cačić2, Ivan Krulj2, Božidar Perić2, Maja Filipović-Gričić2, Gorana Mirošević1 & Milan Vrkljan1,2
1University of Zagreb School of medicine, Zagreb, Croatia; 2Department of Endocrinology, Diabetes and Metabolic Diseases ‘’Mladen Sekso’’, University Hospital Center ‘’Sestre Milosrdnice’’, Zagreb, Croatia.

Introduction
Little is known about diabetic ketoacidosis (DKA) in type 2 diabetes mellitus (T2DM). Moreover, the clinical impact of diabetic ketosis (DK) in T2DM is elusive. The aim of this study was to analyze characteristics and mortality of patients with DKA and DK and to identify possible prognostic factors.

Methods
This was a population-based, cross-sectional study that included all patients with T2DM presenting to emergency department with DKA, over the 5-year period. We analyzed all first admissions of 137 patients with DKA and 137 age- and gender-matched patients with non-ketotic hyperglycemia (NKH) and DK.

Results
During a median follow-up of 35.0 months, 55 (39.9%) patients in the NKH group, 32 (23.2%) patients in the DK group and 61 (44.2%) patients in the DKA group died. Patients with DKA had significantly higher mortality rates when compared with DK (HR 2.55, 95% CI 1.65–3.92, P < 0.001) and NKH (HR 1.27, 95% CI 1.05–1.53, P = 0.012). In patients with DKA, age, serum urea and sodium, the use of calcium channel antagonists, ASA and insulin therapy correlated positively with mortality, while weight loss and increased body temperature prior to the DKA episode, smoking and alcohol consumption were associated with decreased mortality. A nomogram derived from these variables associated with a sensitivity of 69.7%, specificity of 90.0% (AUC = 0.866).

Conclusion
DK and DKA represent two distinct subgroups of patients with T2DM. A nomogram derived from independent prognostic factors may have important clinical role in selecting high risk patients with DKA.

DOI: 10.1530/endoabs.49.EP549

Can the most frequent DRB1* gene’s alleles be associated with cardiovascular autonomic neuropathy among patients with type 1 diabetes mellitus? A case – control pilot study
Dovile Razanskaite-Virbickiene1, Vilma Vezbaviciene1, Erika Skrodeniene2 & Rimantas Zalinkevicius3
1University of Zagreb School of medicine, Zagreb, Croatia; 2Department of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; 3Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Background and aim
HLA alleles are associated with type 1 diabetes (T1D) and a spectrum of risk can be from increased to neutral or to protective. We aimed to evaluate the association

DOI: 10.1530/endoabs.49.EP550
of cardiovascular autonomic neuropathy (CAN) with DRB1* gene’s alleles among T1D.

Methods
The case – control pilot study included 70 patients with T1D at the age 18-54 years. 36 patients with CAN were assigned to the case group and 34 patients without CAN – to the control group. The groups were homogeneous according to the duration of diabetes, mean age at diabetes presentation and gender. The diagnosis of CAN was confirmed when 2 or more pathological standartized cardiovascular tests were present. HLA alleles identification was determined for all participants by using the polymerase chain reaction with sequence specific primers.

Results
70 patients with T1D were included in the study: 26 males and 44 females. Patients mean age was 30.48 ± 11.22 years, mean duration of diabetes -17.52 ± 6.96 years, mean HbA1c 9.26 ± 1.74%. The frequency distribution of DRB1 gene’s alleles among case group showed, that the most frequent alleles were: *04 allele - 18 (25.00%), *03 – 12 (16.66%), *01 – 11 (15.27%), *07 – 8 (11.11%), *08 – 6 (8.33%), and among control group - *04 allele – 22 (32.35%), *01 – 14 (20.58%), *03 – 8 (11.76%), *13 – 6 (8.82%). We confirmed the 3.20 (p < 0.018) increased relative risk for CAN in T1D with DRB1 gene’s *08 allele, also *11 (OR 1.67), *07 (OR 1.66) and *03 (OR 1.63) alleles were associated with increased risk. The highest probability was to find heterozygotes of *08/*X (OR 3.20), *03/*04 (OR 3.20), *07/*X (OR 2.07), *03/*X (OR 1.79) genotypes among T1D with diagnosed CAN.

Conclusion
DRB1 gene’s *08 allele and *08/*X, *03/*04, *07/*X, *03/*X genotypes are associated with increased risk for CAN among patient with T1D.

Conclusion
Our results provide evidence that diabetic CVD is associated with methylation changes in metabolic pathway alterations in blood leukocyte DNA. These differences in methylation are worthy of further validation using larger cases of diabetic patients with and without cardiovascular disease.

EP552
Prevalence of eye complications and its correlation with kidney function: clinical practice data of diabetes patients
Kalpana Dash, Sunil Kumar Ch, Aftab Ahmed, Sambit Das, Balaji Jagannathan, Surekha Tippisetty, Vamsi Krishna Kolukula & Krishna G. Seshadri
Apollo Sugar Clinics, Hyderabad, India.

Background
Type 2 Diabetes Mellitus (T2D) patients are at very high risk to have eye complications. Purpose of the study was to determine the prevalence of diabetes eye complications (DEC) and its correlation with glomerular filtration rate (GFR) in diabetes population attending community clinics across India.

Methods
A total of 1547 T2D patients (935 males and 612 females) EMR records were retrospectively analyzed. For DEC correlation with GFR, patients were grouped into GFR ≤ 60 and GFR > 60 mg/ml/1.73m2. Statistical analysis was done using SPSS version 20, with significance P ≤ 0.05.

Results
In 1547 T2D patients, 204(13.1%) had DEC, mean (SD) age 56.7(10.0) years; 122(59.8%) males and 82(40.2%) females. Of these, GFR calculated for 443 patients had mean GFR of 91.2 mg/ml/1.73 m2; 388(87.5%) and 55(12.5%) patients had GFR > 60 and ≤ 60, respectively. DEC was observed in 79(17.8%) patients, mean (SD) age 55.5(13.8) years; among them 49(62%) males and 30(38%) females. GFR was significantly lower in patients with DEC compared to patients without DEC (79.4 vs. 93.8 mg/ml/1.73m2; P=0.000). Prevalence of DEC in patients with GFR ≤ 60 was higher compared to patients with GFR > 60(38% vs. 15%; P=0.000). However, there was no specific gender preponderance.

Conclusion
Our study is one of the few studies from India that reports the prevalence of DEC from a community based clinics based on fundus photographs and correlating with GFR, thus diabetes kidney disease (DKD). The correlation of DEC with low GFR can suggest presence of DKD in a community, thus, reiterating the significance of EC screening in community diabetes practices. Implementing these findings into clinical decision pathways may improve the quality of health care delivery.

Atherosclerotic cardiovascular risk assessment score in diabetes patients: a retrospective analysis of clinical data
Sanjiv Shah, Jayaprakash Jana, Balaji Jagannmohan, Raja Selvarajan, SG Mozam, Vamsi Krishna Kolukula, Surekha Tippisetty & Shashank R Joshi
Apollo Sugar Clinics, Hyderabad, India.

Background
The study aimed to minimize the risk causing factors and evaluate new atherosclerotic cardiovascular disease (ASCVD) risk score using Million Hearts® Longitudinal ASCVD risk assessment tool among type 2 diabetes mellitus (T2DM) patients.

Methods
A non-interventional retrospective analysis of electronic medical records of Apollo Sugar Clinics, India. A total of 365 patient’s data was collected, and were categorized into normotensive (<120/80-90, mmHg), prehypertensive (130-139/80-89, mmHg), and hypertensive (>140/90, mmHg) based on their blood pressure (BP). ASCVD risk score of each patient was calculated using Million Hearts® Longitudinal ASCVD Risk Assessment Tool, as per ACC/AHA 2016 guidelines. Statistical analysis was done by using SPSS version 20, with significance set at 2 tailed $P \leq 0.05$.

Results
Total 365 patients were analysed, their mean (SD) age was 52.6 (11.9) years, 63.6% were males and 36.4% were females. Of these patients 45.8%, 24.4%, and 29.9% were normotensive, prehypertensive, and hypertensive, respectively. The indicators of ASCVD risk, age, BMI, and total cholesterol (each $P < 0.05$) were significantly different among three groups. Of the 365 patients only 161 patients who met the ASCVD risk assessment criteria the score was calculated. The 10-year baseline risk score was 16.8% and expected risk would reduce to 12.5% if statin therapy is initiated. A significant difference in risk score was observed among three groups at baseline (14.4%; 15.6%; 19.4%, $P = 0.05$), and expected 10-year risk (10.3%; 11.6%; 14.4%, $P = 0.07$) if statin therapy initiated.

Conclusion
Treatment of cholesterol level by moderate or high intensity statins should be an essential component of multifactorial intervention for primary prevention of CV disease in diabetes patients.

The association between pancreatic steatosis and diabetic retinopathy in patients with non-obese type 2 diabetes mellitus
Jee Sun Jeong1, Mee Kyung Kim1, Kyung do Han2, Ki-Hyun Baek1, Ki-Ho Song3, Dong Jin Chung4 & Hyuk-Sang Kwon1
1Department of Internal Medicine of The Catholic University of Korea, Seoul, Republic of Korea; 2Department of Medical Statistics of The Catholic University of Korea, Seoul, Republic of Korea; 3Department of Radiology of The Catholic University of Korea, Seoul, Republic of Korea.

Background
In the previous study, it was demonstrated that pancreatic steatosis was significantly associated with subclinical atherosclerosis in patients with non-obese T2DM. As the result, it was suggested that pancreatic steatosis might be related to macrovascular complication of T2DM. However, the association of pancreatic steatosis on microvascular complication of T2DM has been unknown. Objective
This study aimed to investigate the relation between pancreatic steatosis and diabetic retinopathy in T2DM subjects.

Method
Attenuations of pancreas and spleen of 168 patients with T2DM were measured by using non-enhance computed tomography (CT) imaging. Then the difference of attenuation between pancreas and spleen (P-S) and attenuation ratio of pancreatic-to-spleen (P/S) values were calculated for evaluation of pancreatic steatosis. Obesity was defined when subjects had BMI $> 25$ kg/m$^2$ according to the Asian-specific BMI cut-offs. The presence of diabetic retinopathy was assessed by an expert ophthalmologist using dilated fundoscopy.

Results
The attenuation values of P-S and P/S were significantly related to diabetic retinopathy in patients with non-obese T2DM. In the non-obese group, compared with those without, P-S odds ratio (OR) of patients with pancreatic steatosis was 0.192 (95% CI 0.051, 0.727) and P/S OR was 0.12 (95% CI 0.028, 0.515) for diabetic retinopathy, after adjusting for age, gender, and BMI. However, there was no association between pancreatic steatosis and diabetic retinopathy observed in the obese group.

Conclusion
In this study, pancreatic steatosis was strongly associated with diabetic retinopathy in non-obese subjects with T2DM. This result suggests that pancreatic steatosis might affect the prevalence of microvascular complication in patients with T2DM. However, we still need more studies to define the relationship between pancreatic steatosis and microvascular complication of diabetes mellitus in details.

Dyslipidaemia and diabetes: a real world clinical evidence in Indian scenario
Shantharam Duvvuru, Sambit Das, Mozam SG, N Rajendiran, S Venkataraman, NK Narayan, AV Bhanu Keerthi, Vamsi Krishna Kolukula & Shashank Joshi
Apollo Sugar Clinics, Hyderabad, India.

Background
Dyslipidaemia, a major risk factor for cardiovascular disease (CVD) is considerably increasing in patients with diabetes. The purpose of the study was to evaluate the lipid profiles of diabetes patients attending Apollo Sugar Clinics across India.

Methods
The current study was a retrospective analysis of electronic medical records of 1487 type 2 diabetes (T2DM) patients who registered at (Dec 2014 to Oct 2016) Apollo Sugar Clinics, across India. Patients with diabetes were diagnosed as per the ADA guidelines, and the data was collected from the patients after signing informed consent. Statistical analysis was done by using SPSS version 20, and a 2-tailed $P \leq 0.05$ was set to be significant. Results
In total (N = 1487) T2DM patients, males and females were 64.9% and 35.1%, respectively and had mean (SD) age 53.0 (10.6) years. Of these patients analysed, 54.8% had high low density lipoprotein (LDL; $> 100$ mg/dl), 86.1% had low high density lipoprotein (HDL; $< 50$ mg/dl), 40.7% had hypercholesterolemia ($> 180$ mg/dl) and 76.3% had hypertriglyceridaemia ($> 200$ mg/dl). In low HDL group of 86.1%, 54.3% had high LDL and 79% had high TG. Further, mean concentrations of LDL (111.1 vs 105.6; $P = 0.01$), HDL (43.3 vs 38.9; $P < 0.001$), and TC (177.9 vs 169.2; $P < 0.001$) were significantly higher in females compared to males ($P < 0.01$). However, of these patients 45.2% and 59.3% are at LDL and TC targets, respectively.

Conclusions
The prevalence of dyslipidaemia was observed to be high in diabetes patients than reported in normal population. The pattern of dyslipidaemia is different in India which is termed as ‘atherogenic dyslipidaemia’ wherever, in addition to low HDL, there were elevated levels of both TG and LDL. This increases morbidity of non-communicable disease and needs multifactorial intervention for primary prevention of CVD in diabetes.

Markers of nonalcoholic fatty liver disease in patients with diabetes
Irma Savasteeva1, Maria Rusalenko1, Yulia Yarets1, Veronika Selkina1, Yana Navmenova1, Marina Kaplieva2, Alena Makhлина3, Tamara Yeudachkova1, Elena Vaschenko1 & Tamara Moskvicheva1
1Republican Scientific and Practical Center for Radiation Medicine and Human Ecology, Gomel, Belarus; 2Gomel State Medical University, Gomel, Belarus.

Given the significant correlation between the indices of lipid metabolism, liver dimensions, glycated hemoglobin and indicators cytokysis of hepatocytes identified a number of predictors that have had a significant influence on the formation of NAFLD. At a BMI above 26.5 kg/m$^2$, the relative risk (RR) for BMI was 20.02 and was statistically significant ($8.25$; $Z = 10.19$, $P = 0.001$). With increasing levels of triglycerides above 1.00 mmol/l relative risk for NAFLD also was statistically significant ($RR = 28.30; Z = 14.87$, $P = 0.001$).

DO: 10.1530/endoabs.49.EP556

Endocrine Abstracts (2017) Vol 49

19th European Congress of Endocrinology 2017
1.43 mmol/l relative risk for NAFLD was 34.69 and was statistically significant (12.68–94.91). In the course of the factor analysis, we analyzed the contribution of isolated predictors in the development of NAFLD patients with diabetes. So with type 2 diabetes have made the contribution to such predictors as a BMI (65.4%), and increase level of triglycerides (16.85%), while type 1 diabetes - BMI (65.4%) and the level of VLDL (81.0%). In type 2 diabetes the leading influence obesity and atherogenic focus lipogenesis. Patients with type 1 diabetes on the development of obesity affects both NAFLD and associated levels of atherogenic lipids, and the degree of compensation of carbohydrate metabolism and associated level of glycation of proteins.

Meal composition affects risk markers for kidney disease differently in type 2 diabetes and healthy subjects
Camilla Olofsson1, Agneta Hilding2, Nicola Orsini2, Inga-Lena Andersson1, Ole Torfvit1, Kerstin Brismar1, 2 & Neda Rajamand Ekberg3
1 Karolinska Institutet, Stockholm, Sweden; 2 Karolinska University Hospital, Stockholm, Sweden; 3 Lund University Hospital, Lund, Sweden.

Background/aims
Oxidative stress and inflammation play a role in development of diabetic kidney disease. Postprandial hyperglycemia and hyperlipidemia are speculated to be associated with increased oxidative stress and inflammation. The aim was to examine the effect of meal composition on post-prandial risk markers for kidney disease among those with type 2 diabetes (T2D) and healthy subjects (HS).

Materials/methods
On four occasions 21 patients with T2D and 21 HS ingested an isocaloric lunch (600 kcal) with different compositions of carbohydrate (CH) (54%), CH & fibers (15 g), fat (50%) and protein (40%). Blood samples were taken and urine samples collected before and up to four hours after the meal. B-glucose, insulin, triglycerides, CRP, IL-6, IL-18, and urine IgG2, IgG4 and ACR were analyzed.

Statistical method: repeated measure ANOVA and area under the curve.

Results
T2D had a mean age (±SD) of 63 (4) years while HS had a mean age of 52 (16), *P = 0.004, and T2D had higher BMI (29 vs 24 kg/m², *P < 0.001). There were postprandial differences between the meals for glucose, insulin and triglycerides for both groups, all *P < 0.05. High CH meals resulted in higher peaks of glucose and insulin, while high fat meal gave higher peaks of triglycerides. Both groups had an overall increase in IL-6 for all meals. IL-18 decreased after CH meal only in HS, *P = 0.003. Urine IgG2 and IgG4 responses were different between the groups after CH-meal (P = 0.032). CRP, urine ACR, urine IgG2 & IgG4 was not affected by meal composition within the groups.

Conclusion
CH meal showed higher glucose and fat rich meal higher triglyceride levels suggesting risk for oxidative stress in T2D. However, CRP, IL-6, IL-18, urine albumin excretion, IgG2 & IgG4 were not significantly modulated by meal composition in this population.

EP558
Audit of a nurse-led and pharmacist assisted diabetes renal out-patient clinic – does it help improve medicines management and clinical outcomes?
Susan Irwin, Gurpreet Kaur, Caroline Lacy & Parjat De Sandwell & West Birmingham NHS Trust, Birmingham, UK.

Aim
To audit clinical outcomes and adherence to prescription recommendations in a diabetes renal clinic.

Method
Baseline data was compared to the final clinic visit within a 12 month period, using information from clinic letters and electronic records of patients attending our hospital diabetes renal clinic in 2016 (1st January – 31st December). Patients with at least 1 follow-up within a 12 month period were included.

Results
82 patients were seen in total. 64 patients had full medicines management review whilst the pharmacist individually reviewed 34 patients. Complete data for this audit was available in 48/82 patients. 30/48 (62%) were males. Ethnicity distribution was: Asian 17, Afro-Caribbean 16, Caucasian 12, others 3. A mean reduction in HbA1c from 75 to 70 mmol/mol (P = 0.01) was achieved. Systolic blood pressure reduced from 136.8 to 137.2 mmHg (NS). No significant change in diastolic blood pressure was seen either (71.5 to 71.0). Significant urinary albumin:creatinine ratio (ACR) improvement was observed: 49 down to 40 mg/mmol (P < 0.01). 28/64 (43%) patients were not on an antplatelet agent. 60/64 (94%) were on a lipid-lowering agent. 47/63 (75%) patients received an ACE inhibitor, ARB or both. 9/48 (19%) patients were either referred to renal physicians or discussed in the renal-diabetes MDT. 11/48 (23%) patients used Telmedicine and patient held records to improve self – management skills (FLO Telemedicine-8, Patient Knows Best PKB-3).

Conclusion
These results suggest that the nurse-led clinic is effective in reducing HbA1c and urine ACR levels in this high CV risk patients and should help improve cardiovascular and renal outcomes in future. Pharmacist presence helps improve medication knowledge and adherence - most patients received lipid-lowering agents and majority were on ACE/ARBs, whilst aspirin prescription remained low. We hope to further improve results as the clinic progresses to its full potential in future.

DOI: 10.1530/endoabs.49.EP559

Inhibin B levels and bone health in male adult patients with Type 1 Diabetes Mellitus
Eleftheria Barmpa1, Spiros Karamagiolis2, Stelios Tigas3, Panthema Navrozidou1, Marianna Vlychou2, Inoanis Fozoulidis4, Georgios N. Kousoulis5 & Alexandra Bargiota5
1 Department of Endocrinology and Metabolic Diseases, University of Thessaly, Larissa, Greece; 2 General Hospital of Larissa, Larissa, Greece; 3 Department of Endocrinology, University of Ioannina, Ioannina, Greece; 4 Department of Radiology, University of Thessaly, Larissa, Greece.

Introduction
Existing data suggest that Type 1 Diabetes Mellitus (T1DM) can affect both hypothalamic-pituitary-testis axis and bone health. The mechanisms by which sex steroids influence bone remodeling remain incompletely understood. Data linking gonadal function and bone turnover in male patients with T1DM are lacking. The purpose of this study was to examine any possible association between sex steroids levels and parameters of bone assessment in male adult patients with T1DM.

Methods/design
We studied 53 male patients with T1DM (Group-D) and 42 healthy controls (Group-C) matched for age, sex and BMI. In both groups HbA1c, Inhibin B (InhB), total testosterone (TT), SHBG, L/H, FSH, β-crosslaps, type 1 procollagen total N-terminal propeptide (TP1NP) and BMD at lumbar spine (LS), femoral neck (FN) and total hip (TH) by dual energy X-ray absorptiometry (DEXA) were measured.

Results
Mean age (years) (D: 34.9 ± 10.6 vs C: 34.1 ± 9.9, P = 0.41) and BMI (kg/m²) (D: 23.7 ± 8.1 vs C: 24.5 ± 7.7, P = 0.38) were similar in both groups. In Group-D, mean duration of DM was 14.4 ± 8.5 years and mean HbA1c was 7.8 ± 1.3%. Higher levels of FSH (P = 0.043) and SHBG (P = 0.041), and a trend towards lower InhB (P = 0.049) and TT (P = 0.051) concentrations, were observed in Group-D compared to controls. LH was similar in both groups (P = 0.069). Total BMD (bMDD, g/cm²) and z-scores were lower in Group-D at all three sites (LS: P = 0.031 and P = 0.036, FN: P = 0.042 and P = 0.039, TH: P = 0.046 and P = 0.044). No significant difference in β-crosslaps (P = 0.080) and TP1NP (P = 0.086) was found between the two groups. Regression analysis showed: a negative association between InhB and HbA1c (P = 0.038), InhB and bMDD at LS (P = 0.041) and a positive association between InhB and β-crosslaps (P = 0.044) and InhB and TP1NP (P = 0.047).

Conclusion
These data suggest that InhB might contribute to bone turnover changes observed in T1DM. Further studies are needed.

Cardiovascular disease and risk factors in patients with type 1 diabetes mellitus
Irina Tenu1, Cornelia Bala2, Silvia Ianuc3, Gabriela Roman4 & Ioan Veresia
1Department of Endocrinology, Cluj County Clinic Emergency Hospital, Cluj-Napoca, Romania; 2Department of Diabetes, Nutrition and Metabolic Disease, Cluj County Clinic Emergency Hospital, Cluj-Napoca, Romania.

Objective
The occurrence of cardiovascular disease (CVD) in patients suffering from type 2 diabetes is a widely discussed issue, less so in those with type 1 (T1DM). The purpose of this study was to evaluate the frequency of these complications as well as certain risk factors that they are associated with.

Material and methods
We conducted a retrospective observational study by analyzing data from the observation charts of 106 patients evaluated in our clinic between January 2015 and December 2016. All patients had a history of T1DM of more than 20 years. We assessed the occurrence of hypertension (HT), stroke, acute coronary syndrome (ACS) and peripheral artery disease (PAD), as well as certain risk factors. One patient was excluded due to insufficient information.

Results
We included 105 patients (46% women), with a mean age of 51.46 ± 12.58 years, mean disease duration of 30.16 ± 8.49 years and the mean age at diagnosis of 21.31 ± 11.82 years. The frequency of chronic diabetes complications was: 87% retinopathy, 89% nephropathy, 42% nephropathy and 12% amputations, and for CVD: 60% HT, 10% ACS, PAD 19% and 5% stroke. There was a statistically significant higher risk in patients diagnosed with CVD in regard to the mean age, mean duration of disease and mean age at diagnosis of T1DM. There was a statistically significant correlation for the presence of peripheral neuropathy and retinopathy in patients with HT (P = 0.0205 and 0.0001 respectively).

Patients suffering from PAD had a worse glycemic control (Hba1C 9.4 vs 8.8% P = 0.033) and lower HDL-cholesterol levels (54.04 vs 63.30 mg/dl, P = 0.040) than those without. Patients who had suffered a stroke had higher cholesterol and LDL-cholesterol levels (158.8 vs 189.04 mg/dl, P = 0.00196 and 81.8 vs 106.33 mg/dl, P = 0.029 respectively).

Conclusion
More attention should be awarded in the screening for CVD in patients with a long history of T1DM.

Platelet aggregation and physiological anticoagulants in acute insulin-induced hypoglycemia in patients with type 1 diabetes (DM1)
Karina Sarkisova1,2, Ivona Renata Jarek-Martynowa1, Marina Shestakova1 & Ekaterina Koksharova1
1I.M. Sechenov First Moscow State Medical University, Moscow, Russia; 2Endocrinology Research Centre, Moscow, Russia.

Background and aims
Hypoglycemia can be a risk factor for adverse cardiovascular and cerebrovascular events. However, changes in platelets and coagulation hemostasis during hypoglycemia have not been extensively studied. The aim of this study was to assess the impact of insulin-induced hypoglycemia on the platelet activity, endothelial dysfunction and the physiological anticoagulant level in patients with DM1.

Research design and methods
We studied seven patients with DM1 (four male and three female, age 26.5 ± 8.6 years, mean duration of disease and mean age at diagnosis of T1DM. There was a statistically significant correlation for the presence of peripheral neuropathy and retinopathy in patients with HT (P = 0.0205 and 0.0001 respectively). Patients suffering from PAD had a worse glycemic control (Hba1C 9.4 vs 8.8%, P = 0.033) and lower HDL-cholesterol levels (54.04 vs 63.30 mg/dl, P = 0.040) than those without. Patients who had suffered a stroke had higher cholesterol and LDL-cholesterol levels (158.8 vs 189.04 mg/dl, P = 0.00196 and 81.8 vs 106.33 mg/dl, P = 0.029 respectively).

Conclusion
More attention should be awarded in the screening for CVD in patients with a long history of T1DM.

Biomarkers status and their relation with the presence of type 2 diabetes with and without angiopathy
Ana Valente1,2, Manuel Bicho1,4, Rui Duarte3, João Raposo2 & Helena Soares Costa1,6

Introduction
A useful tool for disease clinical characterization and treatment of type 2 diabetes is the knowledge on the status of several biomarkers. The aim of this study was to evaluate the levels of cardiovascular, oxidative stress and nutritional biomarkers and their relationship with the presence of type 2 diabetes and angiopathy.

Methods
A population-based case-control study in 150 Portuguese type 2 diabetic patients was performed. Group I – 75 diabetics with angiopathy, group II – 75 diabetics without angiopathy and group III – non-diabetic controls. Plasma levels of homocysteine, cysteine, malondialdehyde (MDA), vitamins B6, C, A and E and carotenoids were measured by HPLC methods. Vitamin B12 and folate serum levels were achieved by an electrochemiluminescence method.

Results
The hyperhomocysteinemia prevalence was 20% (group I), 8.7% (group II) and 0.71% (group III). Group I showed the higher prevalence of hyperhomocysteinemia (17%). The MDA serum levels were above the reference value for all groups. The percentage of subjects with ascorbic acid low plasma levels were statistically different in diabetic (I: 55%; II: 47%) compared to non-diabetic subjects (III: 22%). The prevalence of hypovitaminosis B6 deficiency was at least 30% for all groups. In group I, the probability to have hyperhomocysteinemia was around three times higher (P = 0.04) in comparison with group II and 35 times (P = 0.0006) with group III. The combined effect of type 2 diabetes and angiopathy is associated with high MDA (OR: 5.33; P = 0.002) serum levels compared to group III. Type 2 diabetes predisposes to hypovitaminosis C (OR: 3.10; P = 0.0002).

Conclusion
The prevalence of hypovitaminosis C and B6 were relevant. The presence of type 2 diabetes increases the risk of hyperhomocysteinemia, oxidative stress and hypovitaminosis C. The isolated effect of angiopathy increases the probability to have hyperhomocysteinemia.

Severe hypoglycaemias in patients with unnoticed hypoglycaemias: a two-year follow up
Evyee Arturo Cuellar Llocla, Guillermo Martínez de Pinillos Gordillo, Carmen Carretero Marín, Fernando García Pérez, José Álvaro Romero Porcel, Ignacio Fernández Peña, Juan Manuel García de Quiro Muñoz, Ignacio Fernández López, Mariana Tomé Fernández-Ladreda & María Victoria Cózar León
Hospital de Valme, Sevilla, Spain.

Endocrine Abstracts (2017) Vol 49

19th European Congress of Endocrinology 2017
Introduction and objectives

Having frequent hypoglycaemias can enable the appearance of severe and unnoticed hypoglycaemias, as well as favouring vascular damage in these patients. Our objective is to evaluate de incidende of severe hypoglycaemias (SH) in patients with Diabetes Mellitus type 1 and the reduction of perceived hypoglycaemias.

Material and methods

A prospective study was conducted. Patients attending to their Endocrinology appointments between September 2013 and January 2014 were surveyed to evaluate their capacity to perceive hypoglycaemias (Clark’s test). Patients with a test result compatible with a diminished capacity to sense hypoglycaemia were tracked 2 years later. The data was analysed using a Chi-squared test (IC 95%) with SPSS 21.0.

Results

104 patients were surveyed, out of which 41 had a diminished capacity to perceive hypoglycaemia (mean age 36.6±11.6 years, 61% women, HbA1c, 26% ≥ 1.04% and 58.5% had > 20 years diabetes evolution). After 2 years, 43.9% referred having had severe hypoglycaemias, out of those 55.6% had had more than 3 episodes and 33.3% had had a loss of consciousness. 19.5% had an insulin pump (21.4% in patients with severe hypoglycaemia). We found a statistically significance between Clark’s test results and severe hypoglycaemias (P<0.002).

Conclusions

A pathological Clark’s test may be able to identify patients at risk for severe hypoglycaemia, which makes it a useful tool to detect this group of patients. If a high incidence of severe hypoglycaemia is observed, measured should be taken to educate this patients to be able to recognize and interpret the symptoms of low blood glucose as well as developing therapeutic strategies to avoid them, all of which would improve their quality of life.

DOE: 10.1530/endoabs.49.EP564
Osteoarthritis is a great public health problem indiscriminately; ie gonarthrosis, coxarthrosis or degenerative spine diseases. Osteoarthritis is focuse sixth decades in elderly people, especially in women. Many studies assigned the efficiency of Diabetes Mellitus in the etiology of Osteoarthritis. Correlations between bone-destructive characteristics and carbohydrate metabolism errors is now quite accused in this clinical views. A comparing between Diabetes Mellitus Type 1 and 2 is aimed in this study which one cause in much more osteoarthritis. 167 (69 gonarthrosis, 57 coxarthrosis and 41 degenerative spine diseases) patients is joined to this trials for 4 years. All patients were evaluated by endocrinologists and orthopaedists. According to results; there were more counts of Type 2 patients in all groups (51 Type 2 and 18 Type 1 in gonarthrosis; 46 Type 2 and 11 Type 1 in coxarthrosis, 32 Type 2 and 9 Type 1 in degenerative spine diseases). Statistical difference is significant ($P < 0.05$). Many recently clinical and laboratory studies assigned a correlations between Diabetes Mellitus and all rheumatoid diseases. Carbohydrate metabolism is a headstone of all metabolic systems. All defects and errors in carbohydrate metabolism can affect other metabolic systems and bone-soft tissue systems by the metabolits, especially sorbitol. And also predisposition of Type 2 to Metabolic Syndrome can mark pathophysiology of Osteoarthritis as difference proportions of these types.

**Conclusion**

Diabetic patients admitted within a 5 months period were evaluated with the MNSI and the SWME after exclusion of other causes of polyneuropathy. A score $> 2$ in the clinical examination of MNSI and $\leq 7$ positive answers in a total of 10 in SWME were considered positive.

**Results**

Twenty-three patients were included (75.6 ± 13.7 years; 56.5% male; 9.9 ± 6.1 years of disease duration). Only 2 (8.7%) had previously been diagnosed with DSPN. The SWME was in positive in only one of these patients while the MNSI was positive in both. In the remaining undiagnosed 21 patients, 12 patients (57.1%) were positive for the MNSI, while 14 (66.7%) were positive for the SWME. Both MNSI and SWME were positive in 10 out of 23 patients (43.5%) and 19 out of 23 (82.6%) had at least one screening test positive.

**Conclusion**

In this study, more than half of the diabetic patients without a previous diagnosis were screened positive for either the MNSI or SWME test. Data indicates that using both MNSI and SWME increases the detection of DSPN. This study confirms that DSPN is a prevalent complication of diabetes and that hospitalization is an excellent opportunity to screen for DSPN.

**Materials and methods**

12 T1DM patients with normo- ($AER < 20$ mg/l, $n = 7$) and microalbuminuria ($AER > 199$ mg/l, $n = 5$) with liraglutide 1.2 mg as add on to insulin for 6 months and 12 patients with normo- ($AER < 20$ mg/l, $n = 8$) and microalbuminuria ($AER > 199$ mg/l, $n = 4$) on standard insulin therapy. Biomarkers of kidney damage (collagen i.v, nephrin, podocin, cystatin C, kidney injury molecule-1 (KIM-1), neutrophil gelatinase-associated lipocalin (NGAL), uromodulin, osteopontin) were measured by enzyme-linked immunosorbent assay ELISA in the morning urine and fasting plasma; overnight AER by immunoturbidimetry assay; glomerular filtration rate (GFR) by CKD-EPI formula were measured before and after 6-month treatment. Concomitant RAAS blockade-drugs given in stable doses. Differences were examined for statistical significance ($P < 0.05$) using Wilcoxon Signed-Rank Test.

**Results**

Initially the groups were similar by average age, HbA1c, plasma glucose, BP, lipids, uric acid, C-reactive protein, creatinine, eGFR. HbA1c before and after 6 month treatment. There were no significant differences in BP, albuminuria, creatinine, eGFR. HbA1c in 6 month. BMI decreased from 29 (22;38) to 26.8 (21;34.7) $kg/m^2$, $P = 0.01$ in GLP1 group. Urinary levels of podocin, KIM-1 and collagen did not changed before and after therapy. In GLP1 group observed significant reduction in the urinary levels of NGAL/creatinine $1.480(81.2)$ vs $0.650(34.0)$ $ng/mmol$, $P = 0.015$; KIM-1/creatinine $151(35.3)$ vs $47(21.1)$ $ng/mmol$, $P = 0.02$; cystatin C $881(464;1579)$ vs $136(91;205)$, $ng/mmol$, $P = 0.011$; nephrin $0.10(0.05;0.15)$ vs $0.004(0.01;0.1)$, uromodulcreati- nine rised from $175(82.278)$ to $438 (235;754)$; and plasma levels of cystatin and osteopontin after treatment: $1264 (877;1472)$ vs $722 (672;848) ng/ml, $P = 0.007$; $126.8 (45;161)$ vs $65 (45;74)$, $P = 0.02$, respectively compared to the stable levels of markers in the standard insulin treatment group.

**Conclusion**

The present data suggest that GLP-1R adding to standard insulin therapy might be effective for the weight reduction and as potential nephroprotective strategy for attenuating the chronic kidney injury in T1DM.

**Background**

Distal symmetric polyneuropathy (DSPN) is one of the most prevalent chronic complications of diabetes and the most common cause in the pathway to diabetic foot ulceration. Screening for DSPN enables early intervention and prevention of complications. The Semmes-Weinstein Monofilament Examination (SWME) is currently the method of choice to screen DSPN, but ideally two neurologic tests should be used. The Michigan Neuropathy Screening Instrument (MNSI), which evaluates vibratory sensation and ankle reflex, has been proposed as a useful screening test of DSPN. The objective of this study was to determine the prevalence of DSPN in diabetic patients in general medicine wards.

**Methods**

Diabetic patients admitted within a 5 months period were evaluated with the MNSI and the SWME after exclusion of other causes of polyneuropathy. A score $> 2$ in the clinical examination of MNSI and $\leq 7$ positive answers in a total of 10 in SWME were considered positive.

**Results**

Twenty-three patients were included (75.6 ± 13.7 years; 56.5% male; 9.9 ± 6.1 years of disease duration). Only 2 (8.7%) had previously been diagnosed with DSPN. The SWME was positive in only one of these patients while the MNSI was positive in both. In the remaining undiagnosed 21 patients, 12 patients (57.1%) were positive for the MNSI, while 14 (66.7%) were positive for the SWME. Both MNSI and SWME were positive in 10 out of 23 patients (43.5%) and 19 out of 23 (82.6%) had at least one screening test positive.

**Conclusion**

In this study, more than half of the diabetic patients without a previous diagnosis were screened positive for either the MNSI or SWME test. Data indicates that using both MNSI and SWME increases the detection of DSPN. This study confirms that DSPN is a prevalent complication of diabetes and that hospitalization is an excellent opportunity to screen for DSPN.

Risk factors of diabetic foot complications
Radhouane Gharbi, Melika Chihouou, Ous Rejeb, Meriem Yazidi, Ibtssem Oueslati, Fatma Chaker & Hedia Slimane
University of Tunis El Manar, Faculty of Medicine of Tunis, La Rabta Hospital, Department of Endocrinology, Tunis, Tunisia.

Introduction
Diabetic foot disease is a major health problem. The identification of its risk factors should guide preventive measures. The aim of this study was to determine the factors associated with diabetic foot complications.

Patients and methods
It is a retrospective study including 47 patients admitted at the department of Endocrinology in La Rabta hospital for diabetic foot complications during the years 2015 and 2016. Clinical and para-clinical data were collected.

Results
The mean age was 51 years (27 to 78). There were 39 men (83%). It was a type 2 diabetes in 85% of patients. The mean duration of the disease was 13 years (0 to 30 years). Patients were illiterate or had a primary school level in 73%. Hypertension was present in 23% of the patients, smoking in 61% and dyslipidemia in 29%. Diabetes was complicated with peripheral neuropathy in 81% of the patients, retinopathy in 54% and nephropathy in 53%. Coronary artery disease was present in 15%, stroke in 6% and peripheral artery disease in 46%.

Conclusions
Diabetes foot problems occur more often in men with a long duration of diabetes, peripheral neuropathy and peripheral artery disease.

Diabetes mellitus as an important comorbidity in patient with sepsis
Entela Puca1, Edmond Puca2, Agron Ylli2 & Pellumb Pipero2
1 American Hospital 2, Tirana, Albania; 2UHC Mother Teresa, Tirana, Albania.

Sepsis represents the host’s systemic inflammatory response to a severe infection. It is a common condition in hospital settings and is associated with high rates of morbidity and mortality. Since 1982 the knowledge about sepsis epidemiology has clearly improved. There are differences in epidemiologic data about sepsis identification in different countries. The aim of our study is to make a panoramic view of sepsis at the service of Infectious Diseases, University Hospital Center, ‘Mother Teresa’, Tirane, Albania during January 2009 to December 2013 and to highlight its accompanying diseases.

Material and methods
In our study we included patient over > 14 years old, since we are a service for adult patients only. Our study was a retrospective one. A septic patient was defined based on the 2001 sepsis conference definition. Study period was from January 2009 to December 2013.

Results
During our study time from 2009–2013 we had 707 patients with sepsis. The mean age was 50.3879 years old and SDEV resulted 19.59 years old. The most affected age resulted 54/ 85% 9/ 15% 2244/ 84% 397/ 16%

Conclusions
In nowadays sepsis definition is modified. However its concept remains the same. The sepsis cases are increasing. The age and other comorbidities are risk factors that play an important role in the increasing of morbidity and mortality. Diabetes mellitus resulted as a major comorbidity in patient with sepsis.

The prevalence of chronic kidney disease and albuminuria in patients with Type 1 and Type 2 diabetes attending a single centre
MS Majeed, G Boran, LA Behan, M Sherlock & J Gibney
Departments of Endocrinology1, and Chemical Pathology 2, The Adelaide and Meath Hospital, Incorporating the National Children’s Hospital, Tallaght, Dublin 24, Dublin, Ireland.

Chronic kidney disease (CKD) is an important complication of diabetes and determinant of mortality. Albuminuria represents early diabetic nephropathy, and also indicates generalised vascular dysfunction. Understanding the epidemiology of CKD and albuminuria helps inform health planning and identify opportunities to prevent or delay progression of diabetic kidney disease. The last available serum creatinine and urine albumin/creatinine ratio (UACR) in patients with Type 1 (T1DM) or Type 2 (T2DM) diabetes recorded on the DIAMOND database were used for analysis. Patients were divided into tertiles of age. CKD was defined as eGFR < 90 ml/min; microalbuminuria as UACR > 2.5 mg/mmol (male), > 3.5 mg/mmol (female); macroalbuminuria as UACR > 20 mg/mmol. NA-normal albumin excretion; MA-microalbuminuria; A-macroalbuminuria; ND-not done CKD was common and increased with age. Microalbuminuria also increased with age and was similar in patients with and without CKD. Macroalbuminuria was uncommon. In summary, CKD is common in hospital-based diabetic patients. The low prevalence of macroalbuminuria indicates that this mostly does not reflect classical diabetic nephropathy.

Endocrine Abstracts (2017) Vol 49
Achromobacter exacerbations and higher prevalence of infections by MRSA and xylosoxidans. CFRD patients show more frequent severe pulmonary endocrine control as well as the need to a multidisciplinary approach for the This reinforces the importance of adequate nutritional and clearance and improved insulin sensitivity. Anuric dialysis patients do not have improved glycaemic control due to reduced kidney gluconeogenesis, less insulin treatments of DKA, however anuric dialysis patients are at risk of fluid overload. Diabetes mellitus is the commonest cause of chronic kidney disease leading to end-stage renal failure (ESRF). Fluid replacement is one of the cornerstone relationship with pulmonary complications. Material and methods We conducted a retrospective study with 71 patients of our CF unit (age 30+/− 9 years, 50.5% women, BMI 22.2+/−3.8 kg/m² and CF evolution 22+/−9 years). Patients were classified, according to the glycemic response to oral glucose overload, in 3 categories: normal glucose tolerance (NGT, 31%), pre-diabetes (preDM, 29.6%) and diabetes (CFRD, 39.4%). The analysis included the variables: age, sex, BMI, lung function, chronic bronchial infection, pulmonary exacerbations and its degree of severity. 32.4% of the patients received some hypoglycaemic treatment (78.6% of them were CFDR); 32% were under bolo-basal insulin, 28% basal insulin, 16% oral drugs and 24% other treatments. Statistical analysis was performed with STATAv12.0.

Results Lower BMI was observed when comparing patients with CFRD (20.6+/−0.6 kg/m²) and preDM (23.72+/−0.7 kg/m²) (P = 0.005); and a tendency was noticed between CFRD and NTG (22.84+/−0.6 kg/m²) (P = 0.1). CFRD patients showed greater frequency of severe pulmonary exacerbations than preDM (P = 0.016). Higher colonization prevalence by Staphylococcus aureus metilcin-resistant (MRSA) (NTG 4.54%, preDM 9.5%, CFRD 17.86%) and Achromobacter xylosoxidans (NTG 4.54%, 19.05% preDM, DRFQ 21.43%) was observed. This trend was not noticed for Staphylococcus multisensible aureus, Pseudomonas aeruginosa, and Haemophilus influenzae.

Conclusions HF is frequent among our CF patients. Lower BMI is associated with higher frequency of severe pulmonary exacerbations and higher prevalence of infections by MRSA and Achromobacter xylosoxidans. This reinforces the importance of adequate nutritional and endocrine control as well as the need to a multidisciplinary approach for the treatment of CF patients.

We report the case of a 34-year-old woman with type 1 diabetes mellitus (T1DM) with diabetic nephropathy and gastroparesis, and a reasonable glycaemic control (haemoglobin A1c 6.9%) on insulin-pump regimen. Gastric emptying scan revealed 100% contrast retention 2 hours after its ingestion, confirming severe gastroparesis. Repeated vomiting, refractory to oral anti-emetics, led to her hospitalization 8 times in one year in a total of 109 days. She also underwent a medical pregnancy interruption due to hyperemesis gravidarum. Due to difficult management of vomits the patient underwent a gastric peroral endoscopic pyloromyotomy (G-POEM). After the procedure she had pronounced symptomatic improvement and reduced need of hospitalization (only 10 days in the 6 months of follow-up). The post-procedure scan showed a near-normal gastric emptying (52% contrast retention at 2 hours).

2nd case - A 23-year-old woman with T1DM with diabetic gastroparesis with no other end-organ damage. She presented a poor glycaemic control with a haemoglobin A1c of 10.3%. Gastric scan revealed severe retention with a half-emptying time of 862.6 minutes (normal time of 80-120). She was severely disabled by vomit episodes that required frequent and prolonged hospitalization periods. She also underwent G-POEM with fair symptomatic improvement and reduced need of hospitalization during her follow-up despite post-procedure gastric scanning still showed a delayed gastric emptying (93% retention at 2 hours).

Conclusions Diabetic gastroparesis presents a challenging treatment since medical therapy has disappointing results in some patients. In those cases, endoscopic procedures can lead to symptomatic relief and enhanced quality of life obviating the need of more aggressive alternatives like gastroectomy.
Background
Diabetes mellitus is a lifelong chronic disease with higher risk of mortality and morbidity.

Objective
To study the risk factors of death in hospitalized diabetic patients.

Methods
Data obtained from the database of the National Health Fund (NHF), a public organization financing medical procedures in Poland regarded 958305 hospitalizations of adult (≥ 18 years old) patients with diabetes in 2014 year. Logistic regression models were performed to identify independent predictors of in-hospital mortality.

Results
With assumption of only one mild hypoglycemia during the first year of SU versus SGLT2 inhibitor initiation as add-on to metformin for the elderly Ontarian population with type 2 diabetes, the total cost from the patients’ perspective would lead to an annual cost-savings of CDN $2,066,224 due to less cost for mild hypoglycemia episodes treatment. Sensitivity analysis resulted in a minimum annual cost-savings of CDN $691,048 and a maximum annual cost-savings of CDN $8,402,373 for SGLT-2 inhibitor versus SU initiation after metformin due to mild hypoglycemia reduction for the Canadian population with type 2 diabetes.

Conclusions
This study illustrates that reduction in mild hypoglycemia episodes (which mostly are not reported in real-world clinical settings) due to SGLT2I utilization instead of SU in elderly Ontarians with type 2 diabetes can lead to a significant cost-savings from patients’ perspective.

Gestational diabetes mellitus: 4 years study case at a tertiary level maternity hospital
Francisco Evora, Marta Pinto & Céu Almeida
Bissaya Barreto Maternity – CHUC, Coimbra, Portugal.

Introduction
Gestational diabetes mellitus (GDM) is a carbohydrate intolerance with onset or recognition during pregnancy. Timely screening and proper management of this condition is essential to maximize pregnancy and neonatal outcomes.

Methods
Retrospective analysis of all cases of GDM, and the respective new-borns, followed in our obstetrics unit between 2012 and 2015. Clinical and workup parameters were evaluated.

Results
From a total of 644 cases of GDM, median age was 33, median BMI was 27 (overweight/pre-obese) and the most common academic qualifications was a licentiate degree (13 years of school). In terms of risk factors, 51% had a family history of DM and a personal history of: GDM (11%), macrosomia (4%), hydramnios (3%), fetal malformations (5%) and fetal death (0.3%). With respect to pregnancy and maternal complications we verified that 7% had hypertension diagnosis during pregnancy, 4% had one or more urinary tract infection and 11% had preterm birth. The labour was induced in 36% of the times, and we had a 37% cesarean rate, 20% of dystocic deliveries and an eutocic delivery in 43%. Neonatal outcomes consisted of a morbidity rate of 22% and 0.5% mortality rate (3 cases). Pharmacological management was necessary in 38% (35% insulin vs 3% metformin).

Conclusions
There is no denying that GDM is increasing worldwide. From an obstetric perspective this is probably related with the increased maternal weight (obesity epidemic) and the delayed age for the first pregnancy (social motives), which are represented at our casistic. Not long ago, GDM management was a dichotomy that consisted of lifestyle changes (diet and physical exercise) or insulin therapy. Nowadays, for selective cases we can also add to our therapeutic arsenal metformin, which was contraindicated in the past. At our maternity the metformin therapy was implemented in 17 cases on 2014 and 2015, translating this new tendency.

Do adding B vitamins and folate to metformin has beneficial effect on renal function and lipids in type 2 diabetic patients
Marina Sharogorodsky & Elena Omelchenko
Wolfson Medical Center and Tel Aviv university, Holon, Israel.

Introduction
Metformin is effective in reducing cardiovascular mortality, however may decrease vitamin B12 and folate levels, and increase levels of homocysteine. Hyperhomocysteinemia is associated with adverse impact on lipid parameters and renal function. The present study was designed to determine the effect of homocysteine lowering therapy by using group B vitamins and folate supplementation on lipid metabolism especially HDL cholesterol as well as kidney function assessed by serum creatinine, urine microalbumin (MA), albumin creatinin ratio (MaCR) and GFR in diabetic patients treated with high doses of metformin.

Methods
In a randomized, placebo-controlled study, 60 diabetic patients treated with a high dose of metformin were randomly assigned to receive daily oral supplementation with folate (1000 mcg), vitamins B12 (400 mcg) and B6 (10 mg) (Group 2) or placebo (Group 1). Metabolic parameters were measured at baseline and after 4 months follow-up.

Results
The two groups were similar at baseline in terms of metabolic parameters. After 4-months, HDL cholesterol was significantly greater in patients who received vitamin supplementation than patients in the placebo group (P<0.0001). Post-treatment vitamin B12 and folic acid levels were greater in group 1 vs group 2 (P=0.007 and P<0.0001, respectively). Hcy level decreased significantly in the treatment group from 10.0±4.4 to 7.6±2.5 mol/L, P=0.002 and did not change in the placebo group (P=0.964). In GLM model, group was significant independent predictor of endpoint HDL cholesterol (P=0.018), while post-treatment LDL cholesterol did not differ by group after controlling for the other

DOI: 10.1530/endobubs.49.EP580

Endocrine Abstracts (2017) Vol 49
variables in the model ($P = 0.158$). Posttreatment GFR was significantly greater in patients who received vitamin supplementation than patients in the placebo group ($P < 0.003$). Plasma creatinine, urine protein and urine microalbumin did not differ significantly by treatment group at baseline at the end of the study. Nevertheless, within the vitamin -treated group, MaCR deceased from baseline ($P < 0.036$) and did not change in the placebo group.

Conclusion
Adding B vitamins and folate supplementations to metformin was associated with beneficial effects on HDL cholesterol and renal function in diabetic patients.

The role of sodium-glucose co-transporter 2 inhibitors as add-on therapy in type 2 diabetes
Maria Hayon Ponce1, David Blánquez Martínez2, Maria Jose Jiménez Jiménez2, Rossana Sofia Manzanares Cordova1, María del Carmen Serrano Laguna1, Miguel Quesada Charranco1 & Martín López de la Torre Casares1
1UGG Endocrinología y Nutrición, Complejo Hospitalario Universitario de Granada, Granada, Spain; 2Farmacia Hospitalaria, Complejo Hospitalario Universitario de Granada, Granada, Spain.

Objective
SGLT2 inhibitors, have been shown to improve glycaemic control, stabilize insulin dosing and mitigate insulin-associated weight gain in patients whose type 2 diabetes mellitus (T2DM) was inadequately controlled. The objective is to evaluate the real-world efficacy and safety of adding iSGLT-2 therapy in inadequately controlled patients with oral antidiabetic drugs and with or without insulin therapy.

Materials and methods
This observational study assessed the efficacy and safety of SGLT-2 inhibitors used as add-on therapy in a group of 45 T2DM patients from a community endocrinology practice from January 2015 to April 2016. Primary endpoint was HbA1c mean change from baseline at 15 months. Secondary endpoints included change in body weight, other glycaemic parameters, and percentage of patients reporting adverse effects of therapy.

Results
A total of 45 patients met all the study criteria. 60% with oral antidiabetic drugs, 11.1% with oral antidiabetic drugs and basal insulin regimens, 11.1% with basal-bolus insulin therapy. Baseline patient characteristics were as follows: average age, 60.2 ± 9.7 years; mean duration of T2DM, 11.3 ± 8.3 years; 80% males; baseline body mass index (BMI), 32.76 ± 4.96 kg/m²; mean baseline HbA1c, 9.17 ± 2.02%; systolic BP 143.67 ± 15.46 mmHg and diastolic BP 80.44 ± 10.16 mmHg. Mean duration of SGLT2 inhibitors 7.42 ± 4.22 months. HbA1c and weight were significantly reduced by 1.36 ± 1.79% and 4.22 kg/m²; mean baseline HbA1c, 9.17 ± 2.02%; systolic BP 143.67 ± 15.46 mmHg and diastolic BP 80.44 ± 10.16 mmHg. Mean duration of SGLT2 inhibitors 7.42 ± 4.22 months. HbA1c and weight were significantly reduced by 1.36 ± 1.79%, $P < 0.000$ and 4.22 kg/m², $P < 0.000$, respectively; systolic BP (129.1 ± 10.57 mmHg, $P < 0.000$), diastolic BP (63.9 ± 7.34 mmHg, $P < 0.000$) and triglycerides (45.58 ± 115.65 mg/dl, $P < 0.011$). Genital- and urinary tract infections were reported by 6.7% patients. Any diabetic ketoacidosis case was reported.

Conclusion
SGLT-2 Inhibitors added to other oral antidiabetic drugs or insulin in patients with uncontrolled T2DM significantly improved glycaemic control, reduced weight, blood pressure and triglycerides, and was generally well tolerated. In conclusion, SGLT-2 inhibitors appear to be an important addition to the therapeutic options for the management of type 2 diabetes, particularly when used as add-on therapy.

Hypoglycemia, weight changes and health related quality of life (HRQoL) instruments for diabetes care
Carolyn Askadious1 & Pendar Farahani2
1St. George’s University of London, London, UK; 2McMaster University, Hamilton, Ontario, Canada.

Background
Diabetes is a chronic disease with significant negative impact on quality of life. Hypoglycemia and weight gain are two important variables that can impact HRQoL negatively in patients with diabetes under treatment with medication. Observve
The objective of this study was to evaluate HRQoL tools and questionnaires and to explore if the HRQoL instruments address issues related to hypoglycemia and weight gain, which impact HRQoL along other domains.

Methods
A systematic review was conducted utilizing databases on PubMed, Google and Google Scholar to find HRQoL tools that have been utilized in diabetes care. The tools in English language were selected. The construct of the HRQoL tools were analysed by the domains.

Results
In general, three types of HRQoL tools and questionnaires have been utilized in diabetes care (total N = 84): diabetes specific (N = 27), domain specific (N = 33) and general HRQoL (N = 24). 9.5% (N = 8) and 2.5% (N = 2) of tools had domains for hypoglycemia or weight changes, respectively. None of the tools had both domains, simultaneously. 88% (N = 74) of tools had no domain for hypoglycemia or weight changes.

Conclusion
This study illustrated that few HRQoL instruments incorporated domains related to hypoglycemia, weight gain and hypoglycemia and weight gain on quality of life of patient with diabetes on pharmacotherapy. Addressing such an issue is very timely, in light of recent utilization of newer classes of medications in diabetes care such as SGLT2 and GLP1A which have safer glycemnic profile and cause weight loss.

Use of an innovative Technology Enabled Care service (TECS) ‘Florence’ to empower patients and enhance adherence to BP treatments in diabetes
Susan Irwin & Parijat De
Sandwell & West Birmingham NHS Trust, Birmingham, UK.

Background
Social deprivation is high within our large ethnic and diabetes prevalent population. Compliance is a major stumbling block in the achievement of Blood Pressure (BP) targets. Given the above, we took the opportunity to enrol with West Midlands Academic Health Science Network (WMAHSN) Florence (Flo) Exemplar project mobile phone texting service. Flo sends advice and collects patient information which clinicians can access through any device connected to the internet.

Aims
Our aims were to improve adherence to BP treatment via engaging and motivating patients and determine the clinical and cost effectiveness of this simple Telemedicine model.

Method and results
Of the 100 patients enrolled for BP management (April 2015–2016) from diabetes renal clinics:
- 46/100 (46%) patients were discharged with good BP control following medication adjustment.
- Total outpatient attendances prevented: 107
- 45 (for those we continue to follow up)
- 62 (for those discharged)

This has saved £11 663 (national average £109 per OP attendance) simply from the 107 patients have used the WMAHSN Hypertension CKD/diabetes protocol for the full 12 weeks (364 texts/patient, cost per patient £29.12 for the service).

Conclusion
Flo’s use continues to grow and 5 new teams are ready to join in our Trust. Thus, this clinically and cost effective model of care delivery (with high patient
The decreased adiponectin level after the treatment with glibenclamide is associated with deterioration of left ventricular function

Merita Emini1, Edmond Haliti2, Nikica Car3, Luljeta Begoli4, Artan Ahmeti5 & Gani Bujakarti1
1Clinic of Endocrinology, University Clinical Center of Kosovo, Prishtina, Kosovo; 2Clinic of Cardiology, University Clinical Center of Kosovo, Prishtina, Kosovo; 3University Clinic of Diabetes, Endocrinology and Metabolism ‘Vuk Vrhovac’, University Hospital ‘Merkur’, Zagreb, Croatia; 4Institut of Biochemistry, University Clinical Center of Kosovo, Prishtina, Kosovo.

Background and aim
Hyperglycemia is an important pathogenetic factor, which causes abnormalities at the cardiac myocyte level, leading to structural and functional abnormalities and diabetic cardiomyopathy (DCM). It has been proposed that DCM could also occur as a consequence of other metabolic alterations. Adiponectin concentration is negatively associated with obesity, insulin resistance (IR), oxidative stress and endothelial dysfunction. It can be considered as a predictive biomarker of IR and cardiovascular risk. Treatment of diabetic patients with conventional sulfonylurea such as glibenclamide has been reported to be associated with adverse cardiovascular effects and a higher incidence of cardiovascular death. The aim of this study was to assess the effect of glibenclamide on adiponectine level and its impact on left ventricular function in type 2 diabetic patients.

Methods
This single-blind, prospective, randomized controlled study consists of 32 weeks screening period and a 24-weeks treatment period with glibenclamide. From the 167 patients screened, most of whom were treated for hypertension or with metformin, 40 type 2 diabetic patients, were divided in two groups (glibenpiride vs glibenclamide) with a body mass index (BMI) >25 treated with glibenclamide for more than 3 months before screening were included in the study. Anthropometric, biochemical and echocardiographic measurements were performed before and at the end of treatment.

Results
In the glibenclamide group significant differences were observed in Hba1C which was decreased from 8.8% ±1.4 to 8.3% ±1.1% (P<0.001), and in the other hand adiponectin was significantly decreased (from 34.3 ±22.6 to 20.3 ±11.3 ng/ml, P=0.011). From echocardiographic measurements early diastolic (e’) and systolic (s’) myocardial wall velocity of the septum (from 6.7 ±1.4 cm/s to 5.6 ±1.5 cm/s, P=0.04, and from 7.0 ±1.2 cm/s to 6.1 ±1.2 cm/s, P=0.03, respectively); as well as right e’ and s’ (from 11.7 ±2.7 cm/s to 7.9 ±3.8 cm/s, P=0.01, and from 12.5 ±4.3 cm/s to 8.4 ±3.2 cm/s, P=0.01, respectively) were decreased from baseline to the 24 weeks treatment. While dCT time was significantly increased in the group of Glibenclamide, which can explain worsening of diastolic dysfunction in diabetic patients treated with this drug.

Conclusions
The decreased adiponectine level after the treatment with glibenclamide is strongly associated with deterioration LV diastolic and systolic function, in type 2 diabetic patients. This finding highlights the need of further investigations of the impact of metabolic disorders on cardiac function in diabetic patients, beyond hyperglycemia.

Effects of inositol on glucose homeostasis: systematic review and meta-analysis of randomized controlled trials

Inka Miñambres1, Gemma Cuixart1, Ana Gonzalves2 & Rosa Corcoy1
1Hospital de la Santa Creu i Sant Pau, Barcelona, Spain; 2Centre Hospitalar Do Algarve, Algarve, Portugal.

Aim
To analyze the effects of inositol administration on parameters related to glucose homeostasis.

Material and methods
Systematic review and meta-analysis of articles published in Medline or Web of Science Until February 1, 2016. We included studies that met the following criteria: i) Randomized controlled clinical trials of inositol/inositol isomer supplementation against placebo in parallel design, ii) performed in humans, iii) with information about glycemic control parameters and iv) published as full article. The following parameters were considered: Fasting plasma glucose (FPG), blood glucose at 2 h after an oral glucose tolerance test (OGTT), impaired oral glucose tolerance, need for insulin treatment, body mass index (BMI), insulinemia, HOMA-IR and HbA1c. For the meta-analysis, Revman 5.1 software with a random effects model was used.

Results
The search retrieved 476 publications, of which 22 articles were finally included, with a total of 1533 individuals. Treatment time ranged from 28 days to 12 months. Significant differences were observed in all parameters evaluated except in BMI, HbA1c and % of patients who needed treatment with insulin. Treatment with inositol decreased FPG (mean difference −0.44 mmol/l (−0.65, −0.23)), glycermia at 2 h of OGTT (mean difference −0.69 mmol/l (−1.14, −0.23)), % of patients with impaired glucose tolerance (relative risk 0.28 (0.12, 0.66)), insulinemia (mean difference −38.49 pmol/l (−52.63, −24.36)) and HOMA-IR (mean difference −1.96 mU/l×mMol/l (−2.62, 1.30)). No relevant side effects were observed in patients treated with inositol.

Conclusions
Inositol treatment improves glucose tolerance and insulin resistance by a mechanism independent of body mass index.

A rare pediatric presentation of type 1 diabetes mellitus with duchenne muscular dystrophy - what to expect in the future?

Pascu-Gabara Elena-Iuliana1, Arhite Amalia Ioana1, Ioacara Sorin1,2 & Fica Simona1,2
1Elias University Emergency Hospital, Bucharest, Romania; 2Carol Davila university of medicine and pharmacy, Bucharest, Romania.

Introduction
Duchenne muscular dystrophy (DMD) is a genetic condition caused by mutations in the X-linked dystrophin-gene leading to muscle degeneration and early death in males. Since DMD is characterized by aggressive inflammation it is recommended the use of pharmacological treatment with corticosteroids (CS). Type-1 diabetes mellitus (T1DM) is one of the most common chronic diseases in childhood and is caused by insulin deficiency resulting from the autoimmune destruction of insulin producing beta-cells of the pancreas.

Case presentation
We present the case of a 3-years-old male patient who was admitted in our clinic for episodes of symptomatic hypoglycemia alternating with hyperglycemia. He was diagnosed with T1DM and DMD 1-year prior his admission and had been on Humulín-N and Humulín-R combination and Delflazarcot 12mg/daily treatment ever since.His medical history includes upper respiratory tract infection remitted after bronchodilator and expectorant medication in the last month.Clinical examination revealed short stature and overweight patient.height=90.9 cm (−2.71 SDS), (5-th percentile); weight=14 kg (25-th percentile); BMI=17.28 kg/m², (88-th percentile); pubertal stage-1 according to Tanner; hypotonic muscular system, hypokinetic, normal thyroid palpation, language deficiency. Lab tests revealed glycemic control with HbA1c =7.8% (in target for age), hepatic cytolysis (AST=244 IU/l), ALT =583 IU/l), euthyroidism (TSH=3.95 IU/l). Funduscopic examination and thyroid ultrasound were normal. During admission the patient is switched from multiple-dose-injection therapy (MDI) to cutaneous-insulin-infusion therapy (CSI) with aspart, well tolerated; basal rates, the correction factor and carbohydrates-ratio are set, followed by glycemic profile evolving favorably. Considering the risks of untreated DMD and the metabolic pathology association, the patient continues treatment with Delflazarcot 12 mg/daily under multidisciplinary surveillance. Parents received nutritional counseling.

Conclusion
Possible endocrine complications of DMD with chronic CS treatment consequences regarding growth failure, pubertal disorder due to hypoglycemia,
Significant effect of a group education program on glycemic control and incidence of hypoglycemia in patients with diabetes mellitus type 1: A case-controlled study

Zadalla Mouslehi1, Maria Somali2, Sarantis Livadas3, Christos Daramilas3, Christos Savopoulo3 & Apostolos I. Hatzitolios3
1 1st Medical Propedeutic Department of Internal Medicine, AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloniki, Greece; 2Endocrinology, Metabolism and Diabetes Unit, Evromedica General Clinic, Thessaloniki, Greece; 3Endocrine Unit, 3rd Pediatric Department, Aristotele University, Hippokration Hospital, Thessaloniki, Greece; 4Department of Endocrinology, Metabolism and Diabetes, Aretaioio Hospital, School of Medicine, National and Kapodistrian University Athens, Athens, Greece; 5Endocrine Unit, Metropolitan Hospital, Athens, Greece.

Introduction
DM1 constitutes a real challenge in everyday practice for both physicians and patients. Due to the complexity of the disease and its unpredictable nature, structured education and training programs are nowadays implemented that ensure active patient involvement and self-care behaviors to achieve adequate glycemic control, prevent diabetic complications and improve the quality of life of patients. These programs provide patients with the necessary knowledge and skills to self-monitor and self-manage the disease and its associated metabolic conditions.

Aims
To evaluate the effect of a structured 12-month education program that motivated patients to follow a healthy Mediterranean diet and exercise regularly as well as to adjust carbohydrate intake and insulin dose according to their needs.

Methods
The education group (EG) was comprised of 62 patients (45 males) with type 1 diabetes mellitus with a mean age of 36±4.2 years and BMI of 24.2±3.1 kg/m². An age- and BMI-matched control group (CG, n=25, mean age 41±6.4 years, BMI: 25.7±4.2 kg/m²) was composed of patients referred but not enrolled in the project.

Results
At the end of this program, HbA1C levels were significantly decreased (8.5±2.1% vs. 7.08±0.79%, P<0.0001) as was also the incidence of hypoglycemic episodes (P<0.05). Regarding daily glucose fluctuations, significant improvement (P<0.05) was observed, as reflected in low, high and daily median glucose values. On the other hand, the above parameters remained stable in the CG.

Conclusions
These results strongly support the need for long-lasting structured education group courses in adult diabetic patients keen to change their habits in order to achieve self-management of the disease.

Efficacy of body weight reduction on SGLT-2 inhibitor in people with type 2 diabetes mellitus

Chong Hwa Kim1, Hyun A Cho1, Su Jin Jung1, Ki Young Lee2 & Sung Rae Kim3
1Sejong General Hospital, Bucheon, Kyunggido, Republic of Korea; 2Gachon University Gil Hospital, Incheon, Republic of Korea; 3The Catholic University of Korea Bucheon St. Mary’s Hospital, Bucheon, Kyunggido, Republic of Korea.

Objective
Dapagliflozin, sodium-glucose cotransporter-2 (SGLT-2) inhibitor, reduces hyperglycemia and body weight by inhibiting renal glucose reabsorption. However, only a few studies have shown the efficacy of dapagliflozin in type 2 diabetic patients. We evaluated the efficacy and safety of body weight reduction of dapagliflozin in real practice with type 2 diabetes in Korea.

Methods
This is a retrospective, observational study, data from 61 patients with 12 months of dapagliflozin (10 mg once-daily) therapy were analyzed, visited medical center from January 2015 to July 2016. We had divided into three treatment groups: first group taking combination of dapagliflozin and metformin (Group 1); second group taking triple combination of dapagliflozin and metformin with sulfonylurea or dipeptidyl-peptidase IV (DPP-4) inhibitors (Group 2); third group taking quadruple combination of dapagliflozin, metformin and sulfonylurea with DPP-4 inhibitors (Group 3).

Results
After 12 months, mean change from baseline body weight was −3.4±2.6 kg (P<0.001) for total, −3.4±3.1 kg (P<0.001) for group 1, −2.7±2.0 kg (P=0.008) for group 2, −4.0±2.3 kg (P<0.001) for group 3. In total, mean change from baseline SBP and DBP were −6.0±14 mmHg (P=0.003) and −3.4±7.7 mmHg (P=0.002) respectively. Patients who achieved body weight reduction of ≥5% after 12 months were classified in the responder group and <5% non-responder group. There were baseline fasting C-peptide level was higher in responder group than non-responder group (3.25±1.07 ng/ml vs. 2.62±1.02 ng/ml, P=0.023). In total, reductions in Hba1c and PP2 glucose levels were −0.61±0.82% (P<0.001) and −35.4±62 mg/dl (P<0.001) respectively. There were no serious adverse event including hypoglycemia in dapagliflozin group.

Conclusions
In patients with type 2 diabetes, SGLT-2 inhibitor improved glycemic control and reduced body weight reduction with safety of dapagliflozin.

DOI: 10.1530/endoabs.49.EP590
Modification of lifestyle and influence on leptin and insulin resistance to prevent type 2 diabetes mellitus

Shishiko Elena & Mokhort Elena
Belarusian State Medical University, Minsk, Belarus.

The aim of the present study was to determine the change of fasting serum leptin and insulin levels and insulin resistance in patients with risk factors of diabetes mellitus of type 2 (DM 2) including impaired glucose tolerance/impaired fasting glucose (IGT/IFG), obese and first-degree relatives of patients with diabetes after lifestyle modification.

Material and methods
The study included 100 patients (32 men, 68 female) 25–65 years old at risk factors of DM 2. All patients received recommendations on a balanced diet and physical activity. The average fasting plasma glucose (FG), 2-h plasma glucose concentrations (2-h PG) following a 75-g oral glucose tolerance test, HbA1c, index HOMA-IR. Fasting serum leptin and insulin levels were detected by sensitive ELISA.

Results
During 18 months our study 56 patients carried out this recommendations (research group) and 44 patients did not (control group). Patients of the research group demonstrated mean reduction of body mass index (−2.6 ± 0.4 kg/m²) and waist-to-hip ratio (−0.2 ± 0.01) (P < 0.01) and persons of the control group had significant increase of these parameters (P < 0.05). Among subjects with IGT/IFG at baseline, glucose levels normalized in 56.0% of patients from the research group and 4.5% in control group (P < 0.05). Fasting serum insulin and HOMA-IR in research group decreased from 11.1 ± 4.3 to 9.6 ± 4.5 μU/ml and from 3.6 ± 1.1 to 2.7 ± 1.4 accordingly (P < 0.05). In control group the specified parameters had increased significantly (P < 0.01). The main novel finding was that serum leptin median in research group was decreased from 34.7 to 26.4 ng/ml (P < 0.01) and increased in control group from 37.9 to 44.7 ng/ml (+17.9%, P < 0.01). The risk reduction of DM 2 development among patients of the research group was 48.0% compared to the control group.

Conclusion
Thereby, lifestyle modification can prevent the development of type 2 diabetes in subjects with risk factors by reduction leptin and insulin resistance.

EP592
Australian women with diabetes survey of contraceptive use and beliefs about safety of contraceptive options
Santhi Chalasani1, Pinar Kozan1,2, Rickie Myerska2, Kirsten Black1,3, Kris Park2 & Emily Hibbert1,2
1University of Sydney - Sydney Medical School Nepean and Central, Sydney, Australia; 2Nepean Hospital, Kingswood, Australia; 3Royal Prince Alfred Hospital, Sydney, Australia; 4Garvan Institute of Medical Research, Sydney, Australia; 5University of New South Wales- St Vincent’s Clinical School, Sydney, Australia.

Introduction
Women with diabetes mellitus (DM) are at increased risk of adverse maternal and foetal outcomes. Preconception planning is required to minimize risks, including good understanding of contraceptive options.

Objectives
To determine in Australian women with DM beliefs regarding safety of various contraceptive methods in DM, information sources regarding contraception, recent and previous contraceptive use, knowledge of pregnancy risks, access to preconception planning and pregnancy history.

Methods
We conducted a cross-sectional 22 item structured questionnaire-based study of Australian women with DM (Type 1 or 2) aged 16–49 years attending Nepean Hospital, a tertiary referral centre. Women were recruited via mail, at scheduled appointments or hospital admission.

Results
Of 107 of approximately 215 (49.7%) women completed the questionnaire. 83% were aware of risks related to DM in pregnancy. However, the majority of women (74%) had not received preconception counselling. The main source of information regarding contraception was the general practitioner (70%). Most women (78%) believed combined oral contraceptive pills (COCs) were safe in DM. 63% of women were uncertain of the safety of intra-uterine devices (IUDs) in DM and 44% were uncertain of contraceptive implant (CI) safety. The main forms of contraception ever used were condoms (87%) and COCPs (74%), with 34% using long-acting reversible contraception (LARC) of IUDs and CIs. 29% of sexually active women were not using any contraception or planning pregnancy. Amongst 110 pregnancies in 47 women there were 78 (71%) live births, 4 (4%) stillbirths, 16 (15%) miscarriages, 2 (2%) ectopic pregnancies and 10 (9%) terminations.

Conclusion
Despite knowledge of pregnancy risks, preconception counselling is lacking and pregnancy outcomes poor. There was uncertainty regarding safety of LARC, the most reliable contraceptive methods and over a quarter of women used no contraception. Better education of women with DM regarding contraception and preconception planning is needed.

EP593
Management and control of hospital hyperglycemia in the health area of cuenca (Spain)
José Pérez-Rodríguez, Paula García-Notario, David Martín-Iglesias, Lidia Guerra-Navarro, Mubarak Alramadan, Santiago Aranda-Regules & Dulce Calderón-Vicente
Virgen de la Luz Hospital, Cuenca, Spain.

Introduction and objectives
Hyperglycemia is a common problem in hospitalized patients that increases infections, mortality, costs and the hospital stay. The objective of this study is to know the management and control of hyperglycemia in our hospital.

Methods
We designed a cross-sectional observational study. We included patients admitted in the hospital every three days in two months. We excluded patients younger than 15 years, stays less than three days and those of the pediatric, gynecological, emergency and intensive care services. We collected the data from these patients the third day of admission and at discharge. We defined hyperglycemia as two or more capillary glucose values greater than 140 mg/dl.

Results
A total of 328 patients were included. 109 patients had hyperglycemia and 85 were known diabetics. Diabetic patients had the next previous treatments: only oral antidiabetic agents (55.3%), insulin (38.8%), and without treatment (5.9%). During admission 48.5% were treated with insulin sliding scales, 19.2% with insulin bolus-basal regimen, 12.1% with basal insulin, 7.1% with premixed insulin, 2% with only antidiabetic agents and 11.1% without treatment. The glycemic control during admission was considered good in 25% (mean glycemia <140 mg/dl), regular in 45% (140–200 mg/dl) and bad in 29% (>200 mg/dl). Hypoglycemia was diagnosed in 12.5% (2.1% severe). Only 23% patients had a recent HbA1c, with a mean HbA1c of 7.37 ± 1.4%. When the patients discharge from hospital, the antidiabetic treatment for home was not adequately adjusted in 47.4%.

Conclusions
A high percentage of diabetic patients are still treated with insulin sliding scales during hospitalization. Few patients have a good glycemic control. Most of patients hadn’t a recent HbA1c. Finally, treatment is not adequately adjusted at discharge in almost half of patients. That’s why, we believe it’s necessary to create a multidisciplinary protocol to improve the management of the hospital hyperglycemia.

Impact of the insulin pump therapy on quality of life children and adolescents with diabetes mellitus type 1

Natalia Nikolaeva
Saratov Medical University, Saratov, Russia.

Objectives
To investigate the changes parameters of quality of life (QoL) in children and adolescents with diabetes mellitus type 1 (T1DM), using different regimes insulin therapy.

Research design and methods
Thirty patients with diabetes mellitus type 1, aged 5–18 years (mean 13.3±3.04 yr), with disease duration from 1 to 10 years (mean 5.4±3.4 yr) took part in paired study. QoL was assessed with the PedsQL (Generic Core Scales and Diabetes Module, Russian version) at two time points: 1st – during multiple daily insulin injection (MDI); 2nd – after initiation continuous subcutaneous insulin infusion (CSII). Data were analyzed in subgroups aged 5–7 yr, 8–12 yr, 13–18 yr.

Results
Nevertheless, analysis demonstrated positive dynamic of QoL in patients after initiation CSII. Treatment barriers decreased due to reduction of a number of injections (75.3 vs. 90.0, P<0.05) in preschool-age children. Patients at the age of 8–12 evaluated higher physical function (74.2 vs. 94.0, P<0.05) after initiation CSII. In adolescent’s group social activity indicates improved (85.0 vs. 95.0, P<0.05). Further, they were less worried about long-term complications (70.0 vs. 85.0, P<0.05).

Conclusions
Using of insulin pump therapy in children with T1DM allows to improve of quality of life. Preschoolers get used to the necessary of insulin therapy and schoolchildren and adolescents have opportunity to increase the level of their physical and social activity.

Efficacy of insulin detemir treatment in type 2 diabetes mellitus is associated with a allele of the catechol o-methyltransferase polymorphism

Tomislav Bozek¹, Antonela Blazekovic², Matea Nikolac Perkovic¹, Kristina Gotovac³, Lea Smircic-Duvnjak¹, Nela Pivac³ & Fran Borovecki³
1Vuk Vrhovac University Clinic, Merkur University Hospital, Zagreb, Croatia; 2Department for Functional Genomics, Center for Translational and Clinical Research, University of Zagreb School of Medicine, Zagreb, Croatia; 3Division of Molecular Medicine, Rudjer Boskovic Institute, Zagreb, Croatia.

Introduction
Growing evidence suggests that nutrients and hormonal signals converge and directly act on brain centers, leading to changes in energy metabolism and stable body weight over time. Catechol O-methyltransferase (COMT) is one of the major enzymes involved in catecholamine and estrogen degradation. There is a well-established association between the COMT Val108/158Met polymorphism and abdominal obesity, blood pressure increase and T2DM. Basal insulin detemir besides a low pharmacodynamic coefficient of variability, exhibits anorexigenic features, probably through a complex interplay of its effects on the CNS and on the finely tuned efferent and afferent signals between muscle, brain, liver, renal and adipose tissues.

Aims
To investigate the association of COMT Val108/158Met polymorphisms with effectiveness of insulin detemir in achieving glucose control and body weight control.

Methods
Observational study included 185 T2DM patients inadequately controlled with premix insulin analogues, which were replaced with three doses of insulin aspart at mealtime and insulin detemir at bedtime that were followed for 52 weeks. After DNA isolation from blood samples, genotyping of COMT Val108/158Met polymorphism (rs4680) was performed.

Results
The mean age of participants was 67.1±8.01 years, with a mean duration of diabetes 16.1±5.9 years. HbA1c and fasting plasma glucose were significantly decreased after 52 weeks (8.58% vs 7.78%, 11.7 mmol/l vs 8.7 mmol/l, respectively, P<0.001). At the end of the follow up period, 28.1% of patients achieved HbA1c <7.0%. Insulin detemir had a significant weight sparing effect in overweight patients. The most prominent finding was that A carriers (the combined AG and AA genotype) of the COMT Val108/158Met achieved significantly better HbA1c values compared to patients carrying GG genotype.

Conclusions
Our results showed that the presence of one or two A allele of the COMT Val108/158Met was associated with improved glycemic response, and with a better response to insulin detemir therapy in T2DM patients.

A dramatic improvement in metabolic parameters and cutaneous manifestations of insulin-resistance in a type 2 diabetic patient with Congenital Generalized Lipodystrophy (Berardinelli-Seip Syndrome) treated with pioglitazone

Carolina Chaves, Catarina Moniz, Bernardo Dias Pereira, Isabel Sousa, João Anselmo & Rui César
Hospital do Divino Espírito Santo, Ponta Delgada, Portugal.

Background
Berardinelli-Seip Congenital Lipodystrophy (BSCL) is a autosomal recessive disorder with only up to 500 reported cases. It is characterized by generalized absence of fat since birth and severe metabolic derangements such as insulin resistance, hyperglycemia and dyslipidemia. Diabetes mellitus generally develops during the second or third decade of life. This is a rare clinical condition, with worldwide prevalence of 1 in 10 million people and incidence of 1:500.000 newborns/year in Portugal.

Patient and methods
11-year-old caucasian boy was referred to the Pediatric Endocrinology consultation because of fasting hyperglycemia detected during routine blood tests. There was no history of polyuria, thirst or weight loss. He was medicated with antihypertensive medication since 6-years-old. Physical examination revealed a thin patient with acromegaloal features and severe acanthosis nigricans involving the posterior cervical region, axillary and periumbilical areas. Subcutaneous tissue atrophy was notoriously evident in the face, trunk and limbs. Secondary sexual characteristics were compatible with stage V of TANNER scale. Blood tests revealed hyperglycemia with hyperinsulinemia, dyslipidemia, low leptin, HOMA-IR index indicating insulin resistance, alterations in hepatic function suggesting fatty liver and all autoantibodies searched were negatives. Thyroid function, IGF-1 and Growth Hormone (GH) were within the normal range for age and sex. Abdominal ultrasounds revealed a hepatosplenomegaly.

Results
The presumptive diagnosis of BSCL was admitted and the patient was started on metformin 1000 mg twice daily. Pioglitazone, 30 mg/day in two divided doses was added three months later. After 18 months of treatment, glucose and triglycerides levels were near normal, hepatic enzymes, liver echographic features and cutaneous manifestation of insulin-resistance were improved. Leptin remained undetectable.

Conclusion
Early introduction of pioglitazone in diabetic patients with BSCL may dramatically improve insulin resistance without relevant side effects.

Comparison of neonatal outcome in women with gestational diabetes on different pharmacological agents delivered at term

Tarik Elhadd¹, Sindu Jacob², Vincent Booma²,³, Khaled Ashawesh¹, Khaled Dukhan¹, Stephen Beer¹ & Hiba Satti²
1Qatar Metabolic Institute, Hamad Medical Corporation, Doha, Qatar; 2Department of Obstetrics, Alwakra Hospital, Hamad Medical Corporation, Doha, Qatar; 3Sidra Hospital and Research Centre, Doha, Qatar.

Objective
Though many studies have looked at the neonatal outcomes in patients with gestational diabetes on different medications, there is no consensus on the preferred drug for initiation of therapy. We aim to compare the neonatal outcome in a cohort of patients attending our service, to determine if one modality is superior to the other.

Endocrine Abstracts (2017) Vol 49
Methods
This is a prospective observational study from 1-07-2015 to 31-04-2016. The data of all gestational diabetic patients referred to the Joint Diabetic Clinic, in a local secondary Hospital, who required pharmacological intervention were entered into an excel spreadsheet. This included their antenatal, intrapartum and postnatal details. P values calculated with Student’s t-test. Statistical significance if P < 0.05.

Results
The total number of patients studied was 107. There were 58 patients (54%) who were treated with Metformin only, their BMI at booking was 30 kg/m², average HbA1c 5.69%. The average birth weight of the neonates of this group was 3287.78 g and there were 9 (15.15%) Neonatal ICU admissions. 17 patients were commenced on insulin, their HbA1c was 5.78% and their booking BMI was 32. The average birth weight in this subgroup was 3409.24 g with 2 (11.76%) NICU admissions. 32 (29.90%) of our patients required Metformin and insulin. Their average weight at booking was 35, and their HbA1c was 5.8%. In this subgroup, the average birth weight was 3494.56 g with 5 (15.62%) requiring NICU admission. The least birth weight was observed in the subgroup with Metformin alone (54% of our patients), P <0.4. The subgroups with insulin showed a higher neonatal birth weight. The least NICU admissions were in the insulin only group.

Discussion
The least birth weight was observed in the subgroup with Metformin alone (54% of our patients), with the subgroups with insulin showed a higher neonatal birth weight. However, the least NICU admissions were seen in the insulin only group.

Conclusion
Whether the increase in birth weight seen in patients on insulin, is indicative of uncontrolled blood sugars or due to the direct effect of insulin as shown in some studies, requires further evaluation. Further analysis of the ongoing cohort is needed before we can recommend any one mode of treatment as the preferred choice in our setting.

The hypolipidemic and hepatoprotective efficacies of a fixed-dose combination of essential phospholipids with methionine (EPL + M) during atorvastatin (A) therapy in hyperlipidemic patients with cardiovascular diseases (CVD) and type 2 diabetes mellitus (DM) (OLYMP trial)
M G Bubnova, D M Aronov, Marina Bubnova & David Aronov
State Research Center of Preventive Medicine, Ministry of Health of the Russian Federation, Moscow, Russia.

Objective
Objective to study the hypolipidemic efficacy, hepatoprotective activity, and tolerance of the fixed-dose combination of essential phospholipids with methionine (EPL + M) - Eslidine in the combination therapy with A in patients (pts) with cardiovascular diseases (CVD) and type 2 DM who suffer from hyperlipidemia (HL) in order to optimize their treatment in daily clinical practice. Subjects and methods
The trial enrolled 60 pts (mean age 58.1 ±4.5 years) with type 2 DM. All the pts had essential hypertension, 84.8% were obese; 80% had increased echogenicity in the liver and its enlargement, as evidenced by ultrasound study. The patients received standard therapy appropriate for this disease, other than agents affecting blood cholesterol (Ch) levels. After adherence to a hypolipidemic diet for 2 weeks, the pts were randomized to two groups: i) 30 pts received A in a dose of 20 mg/day; 2) 30 pts had the drug in the same dose in combination with Eslidine (EPL + M). The therapy duration was 12 weeks. The impact of therapy on lipid, lipoproteins, hepatic enzymes.

Results
After 12 weeks, the group of pts receiving A showed a significant reduction in the levels of total Ch by 42.4%, LDL-Ch by 44.9%, and TG by 45.4%; in the A + Eslidine group, these indicators decreased by 37.8, 47.9, and 26.4%, respectively. By the end of a course of therapy, the number of pts with LDL-Ch goals was 26.9 and 36.4% in Groups 1 and 2, respectively. In the pts with significant hypercholesterolemia (LDL-Ch ≥4.2 mmol/l), the LDL-Ch decline was 46.9 and 54.6% in those on A and A + Eslidine, respectively (P <0.05); in the pts with elevated TG levels (1.7 mmol/l or higher), the fall was 36.2 and 47.2%, respectively (P <0.05). A caused a 47% increase in ALT activity (P <0.05), without exceeding the upper normal range. In the pts on therapy A + Eslidine, the activity of ALT was, on the contrary, unchanged, there was a significant decrease in total bilirubin concentrations, glutamyl transpeptidase activity, and bile acid levels.

Conclusion
A 20 mg/day and its combination with Eslidine showed a good hypolipidemic efficacy and tolerability in hyperlipidemic pts with CVD and type 2 DM. Addition of Eslidine to statintherapy resulted in a more reduction in LDL-Ch and TG levels and noticeably improved hepatic functional activity.

Pancreas transplantation: experience in a central hospital
Ana Cláudia Martins1, Miguel Vasques1, Paula Bogoalho2, Inês Aires2, Aníbal Ferreira2, Francisco Renédo2, Jorge Paulino3, Fernando Nolasco3, Américo Martins4 & Ana Agapito4
1Department of Endocrinology, Centro Hospitalar Lisboa Central, Lisbon, Portugal; 2Department of Nephrology, Centro Hospitalar Lisboa Central, Lisbon, Portugal; 3Department of Surgery, Centro Hospitalar Lisboa Central, Lisbon, Portugal.

Introduction
Pancreas transplantation is an established treatment for selected patients with type 1 diabetes mellitus (T1DM) and severe chronic kidney disease (CKD), reducing mortality and morbidity.

Methods
We retrospectively reviewed the cases of pancreas transplantation performed at our centre from 1-January-2011 to 30-June-2016.

Results
In this period, 53 transplants were performed: 48 simultaneous pancreas-kidney transplants and 5 pancreas after kidney. Age at time of transplantation was 38 ±7 years; 34 were male (64.2%). Patients had T1DM for an average of 26.8 ±18.5 years (age at diagnosis: 12±5 years). All patients had severe CKD, 78.4% on hemodialysis and 15.7% on peritoneal dialysis. Major postoperative complications occurred in 23 cases (43.4%): 8 infectious, 8 haemorrhagic, 7 thrombotic. Pancreas graft survival was 86.7% at 1 year (39/45) and 83.3% after 2 years (30/36). Kidney graft survival was 92.7% at 1 year (38/41) and 90.6% after 2 years (29/32). Graft failure ensued in 6 pancreatic grafts and 3 transplanted kidneys. There were 12 acute organ rejections (22.6%). Three patients died (5.9%): 2 from infection, one from haemorrhagic shock. Patients had, on average, 2 hospital readmissions, mainly due to infection. Among those with preserved pancreatic grafts, 93.2% are insulin-free. Over the last 2 years, compared to the first 2 years, there were more transplants performed (23 vs 13), fewer postoperative complications (30.4% vs 61.5%) and higher 1-year pancreas graft survival rate (93.8% vs 69.2%). Young age at diagnosis of T1DM was negatively related to pancreas and kidney graft survival (P <0.05). Duration of dialysis and coronary disease were negatively related to renal graft survival (P <0.05).

Conclusions
Patient and graft survival rates were similar to those described in literature. Better outcomes observed in recent years reflect the experience acquired. Young age of onset of T1DM, duration of dialysis and coronary disease may represent poor prognostic factors concerning graft function.

Correlates of health-related quality of life in Bulgarian patients with type 2 diabetes mellitus
Georgi Levterov1, Boryana Letverová2 & Maria Orbetzova2,3
1UMHAT Kaspela Ltd, Plovdiv, Bulgaria; 2Medical University – Plovdiv, Plovdiv, Bulgaria; 3UMHAT St Georgi, Plovdiv, Bulgaria.

Background
Diabetes mellitus (DM) is one of the greatest threats to global health and development of the 21st Century worldwide. In Bulgaria, it affects 9.6% of residents between ages 18-69 and has a profound impact on healthcare, economy and individuals. Diabetes and its complications are major causes of early death in our country - each year 4 125 women and 4 000 men die of diabetes-related complication. Diabetes not only reduces patient’s physical wellbeing but also compromises other aspects of Health-Related Quality of Life (HRQoL). The aim of this study was to investigate the impact of demographic factors and glycaemic control on quality of life in patients with type 2 diabetes.

Endocrine Abstracts (2017) Vol 49

Effects of sitagliptin monotherapy on insulin resistance and immune functions in type 2 diabetic patients
Serdar Almacigolu1, Ozan Oz Gul2, Soner Cander2 & Canan Erssoy2
1Department of Internal Medicine, Diyarbakir Gazi Yasargil Education and Research Hospital, Bursa, Turkey; 2Department of Endocrinology and Metabolism, Uludag University Medical School, Bursa, Turkey.

Background
Sitagliptin, unlike the some major antihyperglycemic drugs, is not associated with weight gain and has neutral effects on body weight. It is unclear whether sitagliptin treatment alters immune functions and insulin resistance in people with type 2 diabetes. The aim of the present study was to assess the effect of sitagliptin on insulin resistance and immune functions in patients with type 2 diabetes mellitus.

Methods
Twenty type 2 diabetic subjects were randomly assigned to receive sitagliptin (100 mg/day; n=10) or medical nutrition therapy (MNT) (n=10) for 12 weeks. Changes in anthropometric variables, glycemic control, insulin resistance, lipid parameters and immune functions were evaluated at baseline and following 12 weeks of treatment. T lymphocyte subgroups like as CD3, CD4, CD8 and TGF-β1, IL-12 were analyzed to evaluate immune function.

Results
Significant decreases in body weight and body mass index were observed over the entire study period in MNT group but not statistically significant while they were unchanged in the MNT group. There was a significant decrease c-peptide levels, showing a difference of -0.9 mg/dl after 6 months on canaglifozina. We have studied separately people older than 65 years old: 15 patients (10 men and 5 women) had to stop the drug (three because of genital pruritus, one canaglifozina 100 and 100% for cana 300 (Table 1).

Conclusion
In this study of patients with type 2 diabetes, treatment with sitagliptin was associated with a significant decrease in insulin resistance. The decrease in CD4 lymphocyte count was thought be possibly related to the upper airway tract infection-like side effect described in the literature.

Real practice experience: Degludec vs Glargina U300
Maria Rosa Alhambra Expo'soto, Inmaculada Prior Sanchez, Paloma Moreno Moreno & M Angeles Galvez Moreno
Hospital Universitario Reina Sofia, Cordoba, Spain.

Background
In last year, different analogues of very long duration basal insulin have appeared, which favors the flexibility in its use. Both ensure a decrease in the rate of hypoglycemia and improve glycemnic control in clinical trials. However, in real practice we have few data in real practice.

Objective
To compare the two ultralente insulin analogues in real practice. To analyze if they are cost effective.

Material and methods
Observational study including patients with type 2 diabetes, referred to Diabetes Day Hospital (DDH) to management diabetes in which we changed the basal insulin regimen to Tresiba® or Toujeo®. We revised them 3-6 months from change.

Results
123 patients were included (68.3% Toujeo® vs 41.7% Tresiba®). Mean age: 52.60 ± 19.67 years; 65-58.5%. Most patients (83.7%) were with glargina basal insulin regimen. After 3 to 6 months from change insulin blood glucose reduced significantly in both groups (to average of 233.04 ± 87.80 mg/dl down from 132.39 ± 66.03 mg/dl in Toujeo®; P < 0.001) and (to 233.44 ± 56.28 mg/dl low from 143.11 ± 66.90 mg/dl in Tresiba®; P < 0.001).

We also observed a significant reduction in HbA1c levels (average reduction in Toujeo® of 2.03 ± 2.28%, P < 0.001) and (average decrease of 1.19 ± 1.46%, in Tresiba®; P < 0.001). However, comparatively no differences in efficacy were found between groups (0.49 ± 0.32%; P = 0.185). At the end of follow-up, the number of units of Toujeo® increased an average of +5.08 ± 18.55 U1 (P = 0.014) while insulin requirements in Tresiba® decreased an average of −4.20 ± 7.36 U1 (P = 0.001). With regard to the cost, an average cost of 436.84 ± 252.57 € per person (Toujeo® group) vs 601.82 ± 419.61 € per person (Tresiba® group), (mean difference: 164.98 €, P = 0.027).

Conclusion
Both basal insulin analogues are effective in reducing basal glycemia and HbA1c. Although there is an increase in insulin requirements when switching to Toujeo®. Potential economic savings are realized by using Toujeo® instead of Tresiba®.

Glycemic control and weight evolution in DM2 patients with canaglifozina
Lidia Urbón López de Linares, Cristina Crespo Soto, Concepción Terroba, Sara Garrote, Marta Ventosa, Tomás Marín & Luis Cuellar
Hospital Río Hortega, Valladolid, Spain.

In the late years ISGLT2 have become an usual choice to treat diabetes. The inhibition of the sodium-glucose co transporters (SLGT2) inhibits also the glucose reabsorption in the proximal tubule and increases the glucose excreted in the urine. Therefore hyperglycemia decreases and so does weight. This is a very convenient side effect since type 2 DM is highly associated with overweight/obesity. We show the results of HbA1c and weight evolution after starting canaglifozina 100 (added to the previous treatment) in 60 patients. Six of them (four women) had to stop the drug (three because of genital pruritus, one deterioration of renal function and one non related metastatic cancer). We also show the results of canaglifozina 300 in 17 patients. Women represented the 33% and the medium age was 62 ± 7.8years. We show data after 6 and 12 months on canaglifozina100. We have studied separately people older than 65 years old: 15 patients with medium age of 71 ± 4 years, 10 of them women. This group showed no side effects and no treatment interruptions. In 30 people we studied uric acid levels, showing a difference of -0.9 mg/dl after 6 months on canaglifozina. Seventeen patients progress to canaglifozina 300, the medium age was 63.2 (± 5.6) years. After 6 months they got an additional weight loss of 1.8 kg (± 0.5) and decrease on HbA1c of −0.3% (± 0.1%). There were 18 patients on insulin therapy with an average of 32 (± 26) daily units one year later the average was 21 (± 30) daily units of insulin. 2 patients stopped insulin therapy. Three patients stopped sunitumibrauea previously to canaglifozina 100. Initially HbA1c increased 0.3% (± 0.1) and weight decreased 3.3 (± 1.7) kg, patients referred decrease or disappearance of hypoglycemia. After one year on canaglifozina HbA1c decreased 0.2 (± 0.1)% and weight decreased 4.8 (± 2.2) kg. The 96% were satisfied with the new treatment for cana 100 and 100% for cana 300 (Table 1).

Conclusions
Canaagliozina 100 added to the previous treatment for DM2 improved glycaemic control and produced weight loss. Canagliozina 300 improved even more this results. A decrease in uric acid levels was showed. The results were the same in the elderly group without increase of side effects. Patients on insulin decrease the dose with an improvement in the glycemic control. Stopping sulfonylurea produced a transient increase in glycaemia with less hypoglycemia. The main side effect was non complicated urinary infection.

EP604 Intralesional epidermal growth factor treatment on diabetic foot ulcers Aydin Cifci1, Birhan Oktas1, Senay Arikan Durmaz3, Askin Gungunes4
1 Department of Internal Medicine, School of Medicine, Kirikkale University, Kirikkale, Turkey; 2 Department of Orthopedics and Traumatology, School of Medicine, Kirikkale University, Kirikkale, Turkey; 3 Department of Endocrinology and Metabolism, School of Medicine, Kirikkale University, Kirikkale, Turkey; 4 Department of Internal Medicine, Yenimahalle Training and Research Hospital, Ankara, Turkey; 2 Department of Cardiology, School of Medicine, Kirikkale University, Kirikkale, Turkey.

Objective
Treatment of diabetic foot ulcer is complex and difficult. Blood glucose regulation, debridment and surgical revascularization are used in management of diabetic foot ulcer. Intralesional Epidermal Growth Factor (EGF) is a new treatment approach for diabetic foot ulcer. We report our experience with eight patients with diabetic foot ulcer who were treated by intralesional EGF.

Patients and methods
A total of eight patients whose diabetic foot ulcers did not fully recover with other treatments were included our study (Table 1).

A typical healing was observed all diabetic foot ulcers after the intralesional EGF treatment.

Conclusion
Our diabetic foot ulcers improved with intralesional EGF. Although our results are quite impressive, this treatment is very expensive and caused of some allergic reactions. Relation with malignancies is not known for long-term. In our opinion, intralesional EGF treatment should be used on wounds that did not heal with the other treatments.

EP605 Efficacy and safety of evogliptin monotherapy in patients with type 2 diabetes
Doo-Man Kim1, Sungwoo Park2, Mookyu Lee3 & Kunho Yoon3
1 Hallym University College of Medicine, Seoul, Republic of Korea; 2 Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; 3 Catholic University, Seoul, Republic of Korea.

Background and aims
To evaluate the efficacy and safety of the newly developed dipeptidyl peptidase-4 (DPP-4) inhibitor evogliptin in drug-naïve patients with inadequately controlled type 2 diabetes.

Materials and methods
In randomized, double-blind, placebo-controlled, parallel-group, multicenter, phase III study, 180 patients with type 2 diabetes were randomized to evogliptin 5 mg or placebo for 24 weeks. The primary efficacy outcome measure was mean changes from baseline to endpoint in hemoglobin A1c (HbA1c).

Results
The mean baseline HbA1c levels of the evogliptin group and the placebo group were 7.2 ± 0.56% and 7.2 ± 0.63%, respectively (P > 0.05). Although the baseline HbA1c was very lower when compared with other phase III clinical trials using DPP-4 inhibitors, evogliptin provided significant placebo-corrected reductions in HbA1c from baseline of -0.23% (P < 0.0001) at 24 weeks. Also, the response rate achieving HbA1c < 6.5% was significantly higher in the evogliptin group than placebo group (P = 0.008). Overall, incidences of adverse event and hypoglycemia were similar between the two groups.

Conclusion
In this 24-weeks study, once-daily evogliptin monotherapy significantly improved glycemic control and was well tolerated in patients with type 2 diabetes.

EP606 Rabson mendenhall syndrome-a dilemma to treat in a resource poor country
Shelia Tabassum & Qamar Masood
Aga Khan University, Karachi, Pakistan.

Background
Rabson Mendenhall Syndrome (RMS) is a rare genetic syndrome that is caused by the mutation in the insulin receptor gene. Such mutation consequently results in severe insulin resistance. Patients suffering from RMS develop constant hyperglycaemia from a progressive decline of endogenous insulin secretion.

Drug therapy for RMS includes metformin, pioglitazones, large doses of insulin alongwith recombinant human methionyl leptin or IGF-1. Here we describe a case of RMS who management poses a big dilemma due to unavailability of these treatment options in a low income country like Pakistan.

Case presentation
A young Pakistani girl of 16 years of age presented in our Endocrine clinic with uncontrolled blood glucose levels. She was diagnosed as case of type i diabetes mellitus (DM) at the age of 4 years due to the complaints of polyuria, polydipsia and weight loss. She was being treated with insulin since then. Initially she attained a good diabetic control but later on, her diabetes worsened. She was never admitted to a hospital as a case of Diabetic Ketoacidosis (DKA). At the time of her visit to our clinic, she was taking 70 units of Humulin-70/30 twice a day. Her fasting insulin level was 589 μU/ml, HbA1C was 16.8% with self-monitoring of blood glucose levels being always recorded as ‘High’ at home. Examination showed her body mass index of 17, short stature (less than 5th centile), severe acanthosis nigricans, coarse facial features, broad nose, thick lips, dental dysplasia, proophthalmism, hirsutism, small hands with thick fingertips and abdominal distension. As genetic testing for RMS is not available in Pakistan, so she was diagnosed as a case of RMS with severe insulin resistance on clinical grounds only. Her insulin dosage was increased gradually to 520 units/day & Metformin + Pioglitazone were added (as insulin sensitizers) to the regimen, but still her blood glucose levels were uncontrolled. At last, she was admitted to hospital for diabetic control. There she received Metformin + Pioglitazone + 20 unit/day of insulin (regular+NPH) along with continuous insulin infusion @ 30 units/h but still her blood glucose levels ranged between 400 and 600 mg/dl. As the 500 U/ml insulin is not available in a resource poor country like Pakistan along with the availability of latest treatment options like recombinant leptin or IGF-1, so it becomes a big dilemma for Endocrinologists about how to treat such patient with RMS. Currently the patient is having poorly controlled DM and has started developing multiple bullous, ulcerated lesions all over the body due to poor diabetic control.

DOI: 10.1530/endoabs.49.EP606

Endocrine Abstracts (2017) Vol 49
Conclusion
Several challenges are encountered by healthcare professionals while treating patients of RMS in resource poor countries of the world. Concentrated insulin (U-500) is not available everywhere to ease the pain of several daily insulin injections and to improve compliance. We hope that future will hold promising horizon for such patients and the global equal access to its available treatment options will result in their better quality of life.

EP607
Does tolerance develop toward GLP-1 receptor agonists’ glucose-lowering effect?
Tuuli Sedman1,2, Maarja Kraas1, Kertu Rünkorg1, Eero Vasar1 & Vallo Volke1,2
1Department of Physiology, Institute of Biomedicine and Translational Medicine, University of Tartu, Tartu, Estonia; 2Tartu University Hospital, Tartu, Estonia.

Background
Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have become a popular tool for the treatment of type 2 diabetes. Unlike many other antidiabetic drug classes, distinct GLP-1 RAs have different therapeutic profiles, mostly due to their different pharmacokinetic properties. Animal experiments and human data indicate that tolerance develops toward at least some of their effects, e.g., gastric motility. Whether tolerance develops toward the glucose-lowering effect of GLP-1 receptor agonists has never been formally tested. We have conducted a series of experiments in mice and a pilot clinical trial in healthy volunteers to address the hypothesis of tolerance development.

Methods
Male C57Bl/6J mice were used. Liraglutide (600 μg/kg once a day s.c.) or exenatide (10 μg/kg twice a day s.c.) were given for 11 days (subchronic group) or 18 days (chronic group). Treatment effects on nonfasting glucose level and during the glucose tolerance test (GTT) were evaluated. Ten healthy volunteers were treated with 0.6 mg liraglutide s.c. once daily for 21 days. The drug’s effect was quantified by serial graded insulin infusion tests, with glucose and c-peptide measured every 20 min and insulin secretion rate calculated.

Results (Mice)
The effect of liraglutide on nonfasting glucose was clearly weaker after chronic administration, compared to acute administration (P<0.01 Duncan’s post hoc test) while exenatide remained equally effective. During the GTT both liraglutide and exenatide, decreased AUC for glucose significantly more after acute test while exenatide remained equally effective. During the GTT both liraglutide and exenatide, decreased AUC for glucose significantly more after acute and chronic treatment (P<0.05) and chronic treatment (P<0.01) compared to acute effect. Humans: (will be revealed during the presentation).

Conclusions
Prolonged treatment with exenatide and liraglutide induced tolerance in mice.
DOI: 10.1530/endoabs.49.EP607

EP608
Comparative evaluation of the effects of bariatric surgery and exenatide treatment on the clinical and laboratory parameters in obese type 2 diabetic patients
Onur Elbasan1, Pinar Sisman1, Hande Peynirci1, Ozan Oz GÜ1, Soner Cander2, Erdinc Erturk4 & Canan Ersoy1
1Department of Internal Medicine, Uludag University Medical School, Bursa, Turkey; 2Endokrinoloji ve Metabolizm Kliniği, Harakani State Hospital, Kars, Turkey; 3Endokrinoloji ve Metabolizm Cliniği, Münif İslamoğlu State Hospital, Kayseri, Turkey; 4Department of Endokrinoloji ve Metabolizm, Uludag University Medical School, Bursa, Turkey.

Background
Obesity and diabetes are major causes of morbidity and mortality that are increasing all over the world. As obesity is a major risk factor for type 2 diabetic patients, weight loss has an important place in the treatment of type 2 diabetic patients. In our study, it’s aimed to evaluate the effects of exenatide and laparoscopic sleeve gastrectomy (LSG) in obese diabetic patients on the clinical and laboratory parameters.

Subjects and methods
Twenty-five patients who had undergone bariatric surgery and 25 patients who started exenatide treatment and followed up in our outpatient clinic were included in the study.

Results
At the end of the six month follow-up, weight loss was approximately 35.4 kg in the surgery group and 11.5 kg in the exenatide group. Although postprandial glisem (PPG) and HbA1c were significantly decreased in both groups, the decrease was significantly higher in LSG group compared to the exenatide group. Although there was no significant change in fasting blood glucose (FBG) in the exenatide group, there was a significant decrease in FBG in LSG group.

Discussion
LSG is a method that should be performed upon indication and much more radical compared to exenatide administration but appears to be a more efficient application that corrects diabetes and obesity related metabolic parameters compared to exenatide treatment in diabetic obese patients. Both treatment options must be evaluated for each patient regarding the advantages and disadvantages and appropriate treatment option for each patient should be decided according to patient’s characteristics.
DOI: 10.1530/endoabs.49.EP608

EP609
Increase in time in target when using a basal-bolus algorithm for insulin dosing with insulin glargine U300 during hospital stay
Julia K. Mader1, Klaus Donsa2, Felix Aberer1, Katharina Lichtenegger1, Christian Lanz1, Edin Smajic1, Bernhard Höll1, Peter Beck2, Thomas R. Pieber2,3 & Johannes Plank1
1Medical University of Graz, Graz, Austria; 2Joanneum Research GmbH, Graz, Austria; 3Decide Clinical Software GmbH, Graz, Austria.

Background and aims
Insulin therapy and the use of clinical decision support systems to achieve glycaemic control in hospitalized patients with hyperglycaemia are recommended by clinical guidelines. The aim of this evaluation was to assess time in target by continuous glucose monitoring (CGM) achieved by a basal-bolus insulin algorithm using insulin glargine U300 during hospital stay in patients with type 2 diabetes (T2D).

Material and methods
30 patients with T2D (12 female, age 67 ±11 years, HbA1c 79 ±2.6 mmol/mol, BMI 32 ±6 kg/m², diabetes duration 14 ±11 years) were treated with GlucoTab, a mobile system providing automated workflow support and suggestions for insulin dosing to health care professionals, during hospital stay. Insulins glargine U300 and glulisine were used for basal-bolus therapy. Additionally to blood glucose measurements, blinded CGM (iPro2, Medtronic) was performed throughout the study.

Results
Mean total daily insulin dose was 63.8 ± 39.8 U. A total of 49,846 CGM values were collected. Mean daily sensor glucose was 8.4 ±1.2 mmol/l. Percentage of CGM values in the ranges was as follows: 5.6–7.8 mmol/l (42.0%), 3.9–6.1 mmol/l (54.1%), and 2.8 mmol/l (0.15%). Percentage in the hypoglycaemia range were low: < 3.9 mmol/l (0.77%), < 3.3 mmol/l (0.35%) and < 2.8 mmol/l (0.15%), respectively. When comparing the first vs last full 24-h period, time in target 3.9–10 mmol/l (61.8% vs 85.2%) increased, whereas time in hyperglycaemia > 10 mmol/l (37.1% vs 14.2%) and hypoglycaemia < 3.9 mmol/l (1.2% vs 0.6%) decreased.

Conclusions
Basal-bolus insulin therapy using insulin glargine U300 safely establishes glycaemic control as assessed by CGM. Over time percentage of values in target increases without increasing the risk of hypoglycaemia.
DOI: 10.1530/endoabs.49.EP609

EP610
Intensity of dapagliflozin induced glycosuria correlates with previous glycemic control but not with body weight or duration of type 2 diabetes
Manuel Cayón-Blanco & Carolina García-Figueras Mateos
Hospital Jerez de la Frontera, Jerez de la Frontera (Cádiz), Spain.
Introduction
Inhibitors of sodium-dependent glucose co-transporter 2 (SGLT2i) reduce circulating glucose concentrations via a renal mechanism. Its metabolic effects have not been fully described and there is a discrepancy on some clinical results found in studies on SGLT2. Our aims were to detect if there are some predictor factors to identify what patients will have higher response to dapagliflozin, a SGLT2i, and second, to explore whether intensity of glycosuria is correlated to the intensity of metabolic and anthropometric changes.

Methods/design
23 participants with type 2 diabetes (T2D) (age: 53.1 ± 7.6 years; 56.5% males, T2D duration 12.1 ± 6 years) received dapagliflozin (10 mg/day) for 18 weeks in conditions of normal medical practice. Parameters related to glucose metabolism, renal function and anthropometric variables were measured at baseline and at week 18. Glycosuria was quantitatively measured at baseline and at the end of the follow-up.

Results
At week 18, glycosuria increased from 6.4 ± 2.2 to 68.9 ± 50.4 g/24 (P < 0.001). Significant reductions in body mass index (BMI), Hba1c, fasting plasma glucose (FPG) were observed (P < 0.01). Quantitative glucose urine levels at week 18 positively correlated with the following variables at baseline: FPG (r = 0.631; P = 0.001), Hba1c (r = 0.399; P = 0.03), glycosuria (r = 0.397; P = 0.034) and inversely correlated with albumin/creatinine ratio (r = −0.409; P = 0.037) but not with age, T2D duration, eGFR or BMI. Intensity of glycosuria correlated with diuresis increase (r = −0.602; P = 0.002) but didn’t with and Hba1c or BMI falls.

Conclusions
Glycosuric effect of dapagliflozin is correlated with glycemic control at baseline independently of time of T2D evolution as result of a higher expression of SGLT2 receptors in poorly controlled diabetic patients. The magnitude of glycosuria did not provide higher weight loss or higher falls in Hba1c.

DO: 10.1530/endoabs.49.EP610

EP611
How can dapagliflozin affect blood pressure response in a real-life cohort of people with type 2 diabetes and hypertension?
Manuel Cayón-Blanco & Carolina García-Figueras Mateos
Hospital Jerez de la Frontera, Jerez de la Frontera (Cádiz), Spain.

Introduction
In clinical trials, dapagliflozin has been shown to lower blood glucose, reduce weight and blood pressure in people with type 2 diabetes (T2D). However, there are limited published data on quantitative changes on blood pressure of this drug in routine clinical practice. Our aim was to examine the clinical efficacy of dapagliflozin in patients with T2D and hypertension in a real-life cohort.

Methods/design
Prospective study including patients with poorly controlled T2D and hypertension who were added dapagliflozin in conditions of routine medical practice. Metabolic profile, renal parameters and hemodynamic parameters were measured prior to dapagliflozin intensification and at week 24.

Results
16 patients were evaluated. At week 24, urine volume increased from 1761 ± 693.6 ml/day to 2570.83 ± 758.6 ml/day (P < 0.001) as well as natriuresis (from 211.6 ± 73.7 mEq/day at baseline to 252.8 ± 94.5 mEq/day; p = 0.009). No significant differences were observed in eGFR and albumin/creatinine ratio. Systolic blood pressure significantly decreased from baseline (148.9 ± 20.8 vs 141.5 ± 17.9; P = 0.02) as well as diastolic blood pressure (84.3 ± 11.9 vs 78.8 ± 8.9; P = 0.001). In five patients, variability of blood pressure was measured showing a significant reduction (15.2 ± 1.9 vs 10.4 ± 2.1; P = 0.02).

Conclusions
Our results show a higher decrease in blood pressure that observed in clinical trials. Dapagliflozin might potentially improve not only the average blood pressure, but also reduces its variability. We included a little number of patients. Further investigations are needed to verify our observation and determine its potential role on cardiovascular outcomes.

EP612
Trends in prescription of Sodium-glucose co-transporter-2 inhibitors (SGLT2i) over the last three years in a specialized setting
Carolina García-Figueras Mateos & Manuel Cayón-Blanco
Hospital Jerez de la Frontera, Jerez de la Frontera (Cádiz), Spain.

Introduction
Sodium-glucose co-transporter-2 inhibitors (SGLT2i) are a newly developed class of oral anti-diabetic drugs with a unique mechanism of action and its use is becoming more widespread. Given that dapagliflozin was the first drug of this class used in Spain, available since December 2013, 3 years after its inception, we aimed to investigate whether there have been differences in prescription patterns of SGLT2i (using dapagliflozin as reference) in a Sanitary district from Spain over time.

Methods/design
Using electronic medical records, data of patients with type 2 diabetes who were prescribed dapagliflozin 10 mg/day, were collected at two periods of time: i) between January to June 2013 (consecutive first prescriptions of dapagliflozin in our area) and ii) between June to December 2016 (last prescriptions).

Results in this study shows that the chosen IDS has a vital impact in psychopathological symptomatology and in the levels of QoL that patients reveal. This data allow us to conclude that the minor constraints that this IDS has due to its utilization does not contribute negatively to CSII perception, moreover when it is compared with multiple daily dosage.

DO: 10.1530/endoabs.49.EP613
**EP614**  
**New long-acting insulins in type 1 diabetes: implications for real clinical practice**  
Miguel Dámas-Fuentes, Cristina Díaz-Perdigones, Araceli Muñoz-Garach, María Molina-Vega, Carmen Hernández-García, Isabel Cornejo-Pareja, Isabel Mancha-Doblas & Francisco J Tijinaones-Maduelo  
Endocrinology and Nutrition Department, Virgen de la Victoria University Hospital, Málaga, Andalucía, Spain.

The emergence of a new generation of long-acting insulin analogues (insulin degludec -ID- and insulin glargine 300 U/ml -IG300-) has increased treatment options in type 1 diabetes (T1D), demonstrating in clinical trials better metabolic control with lower hypoglycemia rates.

**Objectives**

To assess characteristics of T1D patients who were given ID and IG300 in clinical practice and to evaluate their effect on metabolic control, weight, insulin dose and hypoglycemia, comparing results obtained.

**Methods**

Observational, retrospective study. We studied T1D patients whose habitual treatment had been modified. We analyzed anthropometric data (weight, BMI), biochemical parameters (fasting glycemia, HbA1c, lipid profile), insulin dose and number of hypoglycemic events per month (<5; 5–10; >10, initially and after 6 months).

**Results**

38 patients: 50% women, age 38 ± 12.7 years, BMI 25.8 ± 3.9 kg/m², T1D evolution time 14.9 ± 8.6 years and HbA1c 7.4 ± 0.8%. 57.9% initiated ID and 42.1% IG300. They presented: 7.9% hypertension, 13.2% retinopathy, 2.6% history of ischemic heart disease, 2.6% nephropathy and 0% neuropathy. Initially, there were no differences between the two groups, except for higher blood glucose in ID group (189.2 ± 12.1 vs 144.3 ± 22.4 mg/dl, P = 0.003). There was a significant decrease in insulin dose with ID (29.05 ± 9.23 vs 24.82 ± 20.8 IU, P = 0.010). There was a weight loss of 1.9 ± 4.4 kg in patients with IG300, but not statistically significant. We observed a significant decrease in the number of hypoglycemia events in general (75% with >10 decreased to <5, P = 0.009). When stratified by comparison groups, the significance is maintained with ID but not with IG300.

**Conclusions**

1) ID group significantly decreased basal insulin dose. 2) We observed weight loss, not statistically significant, in IG300 patients. 3) There was significant reduction of hypoglycemia rates with both basal insulin analogues. 4) Further studies are needed to distinguish which type of patient benefits more from each insulin analogue.

**Effect of oral nitrate administration on glucose metabolism and inflammation in obese type 2 diabetic rats**  
Asghar Ghasemi1 & Sevda Gheibi1,2  
1Endocrine Physiology Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; 2Neurophysiology Research Center and Department of Physiology, Faculty of Medicine, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

**Introduction**

Type 2 diabetes is associated with impaired nitric oxide (NO) bioavailability; nitrate administration might act as a potential therapeutic agent in diabetes through nitrate/nitrite/NO pathway. The aim of this study was to determine the effects of sodium nitrate on glucose tolerance, insulin sensitivity, inflammation, glucose-stimulated insulin secretion (GSIS), and insulin content in obese type 2 diabetic rats.

**Methods**

Male Wistar rats were divided into four groups: Control, control + nitrate, diabetes + nitrate. Diabetes was induced using high-fat diet and low-dose of streptozotocin. Sodium nitrate (100 mg/l) in drinking water was administered for 2 months. Serum levels of fasting glucose, insulin, and lipid profile were measured and the insulin resistance/sensitivity indices were calculated every 2-weeks. At the end of the study, tissue levels of glucose transporter 4 (GLUT4) protein and serum interleukin-1 beta (IL-1β) were measured as well as glucose and insulin tolerance test were done. GSIS from isolated pancreatic islets and islet insulin content were also determined.

**Results**

Compared to the control group, diabetic rats had glucose intolerance, dyslipidemia, and higher serum glucose and insulin. In diabetic rats, nitrate significantly improved glucose (area under the curve: 26603 vs. 31947, P < 0.001) and insulin (area under the curve: 6981 vs 8968, P < 0.001) tolerance, insulin resistance, insulin sensitivity, lipid profile, and decreased fasting glucose (8%) and insulin (11%), but had no effect on GSIS and islet insulin content. In diabetic rats, nitrate significantly increased tissue levels of GLUT4 by 17% and 22% in soleus muscle and epididymal adipose tissue, respectively. Nitrate also decreased elevated serum IL-1β in diabetic rats (4.7 ± 0.5 vs. 3.2 ± 0.6 pg/ml, P = 0.02).

**Conclusion**

Nitrate administration had favourable effects on glucose tolerance, insulin resistance, insulin sensitivity, inflammation, and dyslipidemia in type 2 diabetic rats.

Liraglutide restores the hyperglycemia-induced endothelial oxidative stress in vitro

Sofia Gougozoua, Alexandra Bargiota & Georgios N Koudouli
Department of Endocrinology and Metabolic Diseases, University Hospital of Thessaly, Larissa, Greece.

Introduction
Diabetes is characterised by increased oxidative stress and an insufficient antioxidant response, which are crucial for the initiation and progression of atherosclerosis. GLP-1 agonists, used for the treatment of diabetes, are considered to influence the endothelial antioxidant response.

Methods
In order to answer this question we studied the influence of liraglutide, a known long-acting GLP-1 agonist, on the antioxidant response markers (superoxide dismutase (SOD), catalase, glutathione (GSH) system, endothelial nitric oxide synthase (eNOS) and extracellular nitric oxide (NOx)) of Eahy926 macroendothelial cells pre-treated in hyperglycemic (25 mM) environment for 2 h.

Results
Hyperglycemia significantly increased the endothelial intracellular ROS content (P < 0.001) and decreased eNOS (P < 0.05), SOD (P < 0.05) and catalase (P < 0.001) activity, GSH recycling rate (P < 0.001) and Nox levels (P < 0.05). Liraglutide (40 nM) restored the increased intracellular ROS to levels comparable to normal glucose treated cells (control). The elimination of intracellular ROS was accomplished by the activation of SOD (P < 0.05) and catalase (P < 0.001) enzymatic antioxidant response and the increase (P < 0.001) of intracellular GSH recycling rate. Moreover, liraglutide restored also eNOS activity and NOx release (P < 0.05).

Conclusions
Our results indicate that liraglutide is involved in the redox balance of endothelial cells. Its ability to counterbalance the increased oxidative stress radicals induced by hyperglycemia seems to work as a protective mechanism restoring cell function and ameliorating the progression of atherosclerotic process.

Incretin-based therapies and pancreatic/biliary tract cancer

Diana Boj-Carceller1, Sara Cay-Melero1, Isabel Azcona-Monreal1, Leticia Pérez-Fernández1, PILAR CALMARZA-CALMARZA2 & ALEJANDRO SÁNCHEZ-PARTÍN3
1Endocrinology and Nutrition Unit, Hospital Miguel Servet, Zaragoza, Spain; 2Laboratory of Clinical Biochemistry, Hospital Miguel Servet, Zaragoza, Spain.

Objective
To study the relation between incretin-based therapies, DPP-4 inhibitors and GLP-1 receptor agonists, and tumor stage at the time of diagnosis of pancreatic and biliary tract cancer.

Methods
Retrospective study of type 2 diabetic patients with newly diagnosed of pancreatic or biliary tract cancer attended consecutively in a tertiary hospital between the years 2012 and 2015.

Results
A total of 37 patients were included. The prevalence of use for DPP-4 inhibitors in our cohort was 37.8% (sitagliptin, linagliptin and vildagliptin). No one patient was under treatment with GLP-1 receptor agonists. Subjects’ characteristics are shown in Table 1. Men developed cancer earlier than women (68.4 vs 75.5 years, P = 0.038). Smoking prevalence and time of diabetes evolution was higher for males. Subjects who were taking DPP-4 inhibitors exhibited stages more advanced at diagnosis (Table 2). However, this result did not reach statistically significant differences (70 vs 50%, P = 0.250). Metformin use was not associated with different tumor staging (P = 0.169).

Conclusions
This study supports DPP-4 safety from the point of view of tumorigenesis in humans. However, the small sample size due to the low incidence of this lethal disease makes us to be cautious in the conclusions. Further research is needed in order to ensure that incretin-based therapies are safe from the oncological point of view.

EP620
Palpable purpura in an uncontrolled diabetic patient: an uncommon possible side effect of linagliptin

Omercan Topaloglu, Bahri Evren, Mahmut Kara, Seyfullah Yucel & Ibrahim Sahin
Department of Endocrinology, Inonu University Medical Faculty, Malatya, Turkey.

Introduction
Incretin-based therapeutics have commonly been used in the last years for the management of patients with type 2 diabetes mellitus (DM). Linagliptin is a member of “dipeptidyl peptidase 4” (DPP-4) inhibitors and often preferred owing to some advantages over the others. We present a diabetic case developing skin findings after the initiation of linagliptin.

Case
66 year-old woman with a history of type 2 DM for 10 years was admitted to our clinics with the complaints of dry mouth, polydipsia and polyuria. She had also history of coronary heart disease confirmed by coronary angiography. She had been taking metformin, acetazolamide, and oral nitrate for 10 years. On physical examination; vital signs and examinations of cardiovascular, pulmonary and gastrointestinal systems were normal. She had no skin rash or lesions. Blood
glucose was 319 mg/dL, urine ketone negative, creatinine 0.78 mg/dL; and liver tests and arterial blood gas analysis were in normal limits. Firstly, we initiated intensive insulin regimen together with tight glucose monitoring, to improve uncontrolled hyperglycemia. We increased the dosage of rapid acting insulin gradually to achieve optimal glucose control. Metformin was continued and linagliptin was added to treatment. Lesions like palapable purpura arised on lower legs and upper arms of the patient on the second day of linagliptin therapy. No other drugs, chemicals or herbal preparations were given at this time. After cessation of linagliptin, palapable purpura lesions both on lower and upper extremities regressed gradually.

Conclusion
Due to impact of DPP-4 inhibitors on the other DPP enzymes to some degree, musculoskeletal and dermatological adverse reactions may occur during the treatment with these agents. To our knowledge, palapable purpura lesions were detected with linagliptin therapy in our patient for a first time in the literature.

Dulaglutide added on Empagliflozin improves blood pressure, body weight, glycemic control and albuminuria in obese diabetic patients
Carmen Acosta-Calero1, Claudia Armus-Leon1, Ana Delia Santana-Suarez2, Manuel Nivalo-Rivadeineira1, Agneszka Kuzior1, Sara Quintana-Arroyo1, Nery Salbón-Gonzalez1 & Francisco Javier Martinez-Martín1
1Endocrinology Department, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain; 2Outpatient Hypertension Clinic, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas de Gran Canaria, Spain.

Objective
GLP-1 receptor agonists and SGLT2 inhibitors improve glycemic control, body weight, blood pressure and albuminuria by different pathways. However, their combination is not endorsed by ADA/EASD guidelines, and available data are scarce. Our objective in this observational study was to elucidate the effect of added Dulaglutide in obese type 2 diabetic patients previously treated with Empagliflozin but insufficiently controlled.

Methods
Dulaglutide 1.5 mg/week was added to the treatment of 20 type 2 diabetic patients with BMI >30 kg/m2 previously treated with Empagliflozin 10 mg/day for at least 3 months but having HbA1c >7%. They were re-evaluated after 3–6 months without additional medication changes, except for insulin dosage adjustments and iDPP4 discontinuation. Besides clinical routine, 24 h. ABPM were performed before and after. Stats were performed by two-tailed paired t-test, *meaning P <0.05. Values are given as mean ±SD.

Results
Age was 49±11 and diabetes duration 8±3 years. 53% were women. Baseline BMI was 34.9±2.5 kg/m2; ABPM: Awake, BP 131±8/58±5 mmHg; HR 74±10 bpm; Sleep, 127±8/78±10 mmHg, 69±10 bpm. Fasting glycaemia was 167±46 mg/dL; HbA1c 8.0±0.6%, urate 6.9±1.4 mg/dL, Cr 0.91±0.17 mg/dL, GFR (CKD-EPI estimation) 87.1±16.8 ml/min/1.73 m2, Albuminuria 291±261 mg/g Cr; median 222, IQR 23-460. At follow-up there were no withdrawals due to side effects, one patient was lost to follow-up and 16% reported mild nausea and/or diarrhoea. Body weight change was −4.0±2.6 kg, HbA1c −1.37±0.83% kg/m2. ABPM: Awake SBP −4±4*, DBP −1.3±2.3 mmHg, HR 1±4 bpm; Sleep, SBP −6.5±5*, DBP −4.2±6 mmHg, HR +2±7 bpm. Fasting glycaemia change −41±23* mg/dL; HbA1c −1.1±0.6*%, urate −0.12±0.24* mg/dL; Cr −0.04±0.11 mg/dL, GFR +1.9±7.3 ml/min/1.73 m2, albuminuria −71±105* mg/g Cr (−29±31%).

Conclusions
Dulaglutide added on Empagliflozin in obese type 2 diabetic patients was well tolerated and effective for glycemic control, body weight, blood pressure (particularly nocturnal) and albuminuria.

Modern treatment approaches of patients with type 2 diabetes and non-alcoholic fatty liver disease
Kateryna Kondratkiv1, Nazarii Kobylaik2, Petro Bodnar1, Mykola Lysiyany2, Liudmyla Belska1 & Valentyna Kondratkiv2
1Bogomolets National Medical University, Kyiv, Ukraine; 2State Institution “Institute of Pediatrics, Obstetrics and Gynecology of NAMS of Ukraine”, Kyiv, Ukraine; 3State Institution “Institute of neurosurgery named after academician AP Romodanov of NAMS of Ukraine”, Kyiv, Ukraine.

Background
One of the most significant complications of type 2 diabetes (T2D) is non-alcoholic fatty liver disease (NAFLD). The search for new effective approaches to the treatment of patients with comorbid chronic condition such as type 2 diabetes and NAFLD is relevant.

Methods
We have observed 118 patients, including 64 patients with T2D and NAFLD, 26 patients with T2D and 28 patients with NAFLD. The control group consisted of 25 healthy individuals. Recommended treatment included individualized diet therapy with energy value of daily ration 1800–2300 kcal/day, a hepatoprotective salt of arginine and glutamic acid at 0.75 mg 3 times a day and alive multistrain probiotic at 10 mg twice a day. Clinical manifestations, echography semiotics, protein, lipid, enzyme and carbohydrate metabolism, the degree of IR, subpopulations of lymphocytes and interleukins, IgG antibodies to LPS, the range of average weight molecules, circulating immune complexes (CIC), dysbiotic disorders of the intestine in patients with T2D and NAFLD were studied.

Results
The application of the developed medical complex that included individualized diet, the salt of arginine and glutamic acid and a multiprobiotic contributed to the normalization of lipids, enzyme, carbohydrate metabolism, improvement of cellular and humoral links of the immune system, reducing levels of CIC 53.8%, reduction of endogenous intoxication (level MCM254 – 30.5%, MCM280 – 52.4% and the level of IgG antibodies to LPS in 1.6 times), improvement of intestinal microbiocenosis in 84.4% of patients with T2D with NAFLD and normalization of pathological clinical manifestations in 68.8% of patients.

Conclusions
This study revealed the effects of proposed treatment complex on the major lymphocyte subpopulations and cytokine status, reduction of endotoxemia, promotion of the positive dynamics of lipid and carbohydrate metabolism indicators and intestinal microbiocenosis of patients with T2D and NAFLD.

The role of diabetic educational programs in glycomic control in patients attending to our day hospital
Maríana Tome1, Guillermo Martínez de Pinillos2, Fernando García3, Ewyé Arturo Cuéllar4, Ignacio Fernández4 & Juan Manuel García de Quiros5
1Punta de Europa Hospital, Algeciras, Spain; 2Valme Hospital, Sevilla, Spain.

Objective
To assess improvement in glycomic control in those diabetic patients who have received structured education in diabetes in our Day Hospital.

Methods
A retrospective observational study was carried out in which 42 diabetic patients who had attended to educational courses in 1 year were included, determining the age of the patient, type of Diabetes, score obtained in the questionnaires at the beginning and end of the course, as well as HbA1c before, at 6 months and at 12 months after the courses.

Results
Of the 42 patients, 25 were diabetic type 1 and 17 diabetic type 2. Mean age 43.64±14.36 years (Type 1 diabetes mellitus (DM1): 36.8±12.17 years; Type 2 diabetes mellitus (DM2): 53.7±11.2 years). Mean HbA1c before the course was 9.14±2.2% (DM1: 8.99±1.74%, DM2: 9.36±2.38%). Mean HbA1c at 6 months of the course was 8.06±1.51% (DM1: 8.09±1.45%, DM2: 8.03±1.64%). A reduction of HbA1c of 1.08±1.87% (P <0.001) was obtained. In the DM1 group the mean reduction of HbA1c was 0.9±2.79% (P=0.014) whereas in the DM2 group it was 1.34±2% (P=0.008). Of the 42 diabetic patients in the sample, HbA1c values were determined at 12 months in 27 of them (17 DM1 and 10 DM2). HbA1c at baseline in this group was 9.17±2.29%; At 6 months 8.13±1.58% (P=0.007) and at a year 8.05±1.25% (P=0.007). In DM1 at the beginning 8.64±1.47%, at 6 months 7.93±1.48% and at 12 months 8.06±1.1%. In DM2 at baseline, 10.07±2.72%, at 6 months 8.48±1.75 (P=0.019), at 12 months 8.02±1.78% (P<0.009).

Conclusions
Attending courses in Diabetes Education significantly improved glycomic control in all our patients. The type 2 diabetic group showed the greatest improvement in glycomic control, obtaining even greater reduction of HbA1c at one year of the Education course. This is probably because it is the group that most benefits from lifestyle modification.

Real-time detection of hazardous changes in blood glucose at the first trimester of pregnancy in women with type 1 diabetes: a pilot study
Orit Barenholz-Goulitschki,1,2 & Michal Shauly-Alaronov1
1Shaare Zedek Medical Center, Jerusalem, Israel; 2Hebrew University, Jerusalem, Israel.

Introduction
Type 1 diabetes (TID) in pregnancy is known to be associated with increased risks of birth defects and miscarriages. Despite the technological improvement and availability of continuous glucose monitoring (CGM), women with TID who are adequately controlled according to CGM average and HbA1C still face these complications. Glucose variability was suggested as an explanatory factor of the difference between actual obstetric outcome and the expected outcome according to currently available monitoring tools.

Aim
To present an algorithm and to verify that it has a practical potential to notify early enough of increased risk of miscarriage or birth defect.

Methods
Change-point detection methods were applied on CGM data of eight pregnant women with TID during the entire first trimester of pregnancy.

Results
Seven pregnancies ended with good outcome and one pregnancy ended at a late miscarriage (patient H). The average first trimester HbA1C of the pregnancies with good outcome was 6.58 ± 1.2 (range 5.1–8.8), which is similar to the HbA1C of the pregnancy that ended with a late miscarriage (6.6). The daily averages of CGM data were not higher for patient H. Nevertheless, the statistical method (aimed at detection of an increase in the hourly SD of glucose levels) did detect an exceptional elevation of glucose variability of patient H, at 8 weeks of pregnancy, which was 7 weeks before the actual miscarriage. Namely, we could have predicted this poor outcome early enough to lessen glucose variability.

Conclusions
Analysis of eight first-trimester follow-ups (of more than 1600 hours = 20,000 measurements for each patient) showed the change-point detection method to fully discriminate between proper pregnancies and pregnancies with adverse outcome. This approach might serve as an additional tool to detect pregnancies at risk in real-time and to plan better glucose control in order to improve pregnancy outcome.

Sence of coherence and glycaemic control among a sample of newly diagnosed type II diabetics in rural Crete
Dimitrios Anyfantakis,1,2 Anastasios Anyfantakis4, Michaela Foukaki3 & Serafin Kastanakis2
1Primary Health Care Centre of Kissamos, Chania, Crete, Greece; 2Saint George General Hospital of Chania, Chania, Crete, Greece; 3Diabetes Unit, Heraklion, Crete, Greece; 4Endocrinology Department, Veneizeleio Hospital, Heraklion, Crete, Greece.

Aim
Currently there is much discussion on the protective effects of the sense of coherence (SOC) on health. Our aim was to examine possible associations between SOC and glycaemic control among 60 newly diagnosed adults with type 2 diabetes.

Methods and results
Thirty males and 30 females diagnosed 3 months before with type 2 diabetes mellitus were included in the study. SOC was measured with the Greek translated and validated version of Antonovsky’s 29 item sense of coherence scale. Biochemical tests and blood pressure measurements were also performed in all participants. SPSSv 20 was used for the statistical analysis. Blood pressure has been associated with low sense of coherence levels (P < 0.001). Remarkably albuminuria presence has been associated with poor SOC (P < 0.001) while good glycemic control presented a statistic significant positive association with SOC (P < 0.001).

Conclusion
Further future investigations are required in order to address the effect of SOC on diabetic patients.

Gestional diabetes mellitus with and without insulin therapy: a case study
Francisco Evora, Marta Pinto & Céu Almeida
Bissaya Barreto Maternity - CHUC, Coimbra, Portugal.

Introduction
Gestational Diabetes Mellitus (GDM) is a pregnancy complication that has experienced a worldwide growth. The use of insulin has to be considered as it may be beneficial for both the mother and the new-born.

Methods
Retrospective analysis of all cases of GDM, and the respective new-borns (NB), followed in our obstetrics unit between 2012 and 2015. Clinical and workup parameters were evaluated in 2 groups: GDM with no insulin therapy (GDMNIT) and GDM with insulin therapy (GDMIT). Data analysed using SPSSv23.0.

Results
We studied 644 GDM and 35% of them were treated with insulin. The BMI was significantly higher in GDMIT (P < 0.001). Induced labour occurred in 36% of GDMNIT and in 49% of GDMIT, with statistically significant difference (P = 0.027). The number of CS-sections was superior in GDMIT (41 vs 36%), but without significant difference. The need for hospitalization of the NB in the Neonatal Intensive Care Unit (NICU) was significantly higher in GDMIT. The NB weight (Fenton) was also significantly different between both groups (P = 0.019), with “large for gestacional age” being higher in GDMIT (7 vs 3%).

Postpartum positive screening for Diabetes Mellitus was 0% in GDMNIT and 2% in GDMIT.

Conclusions
One of the indications for induced labour is GDMIT because of the higher risk of fetal complications, which was verified in this study. As the literature states, GDMIT is associated with a difficult blood sugar control during pregnancy. This means that an unsuccessful maintenance of euglycemia may be associated to heavier NB and eventual peripartum complications. However, GDMNIT was associated with more hospitalizations in NICU, and the main causes were prematurity, hyperbilirubinemia and acute respiratory distress syndrome. The results of postpartum screening are in accordance with the literature.

Evaluation and descriptive analysis of our type 1 diabetes population and their insulin therapy
Cristina Díaz Perdigones, Araceli Muñoz Garach, María Molina Vega, Carmen Hernández García, Miguel Dámas Fuentes & Francisco J. Tinahones Madueño
Endocrinology, Malaga, Spain.

Objectives
To evaluate the different insulin regimens and types of insulin used in our population of type 1 diabetes (DM1) patients in the last revision in our clinic.

Method
A descriptive study was carried out in our population of 535 DM1 patients. They had their initial diagnosis between 1967 and 2014.

Results
In our population, 47.3% were women and 52.3% were men. The mean age of our patients was 33.8 years (S.D. ± 12.13 years) and the mean age of diagnosis was 16.67 (S.D. ± 12.13 years). 17.39% of our population was taking antipalpeter therapy, 17.4% had hypertension, and 36% dyslipidemia. There were 22.9% smokers and 10.3% who had given up. The glycated hemoglobin value was 7.8 (S.D. ± 1.28%) and the body mass index 27.18 (S.D. ± 4.69 kg/m²). 91% had previously received diabetic education assistance, and 32.1% completed the program. Total insulin dose was 40.52 units (S.D. ± 29.91 IU) with 0.68 (S.D. ± 0.33 U/kg). Insulin regimes used were: basal-bolus 91.3%, basal alone 1.5%, prandial plus mix 2.7% and mix combination 4.5%. In those using basal-bolus regimen, 42.67 (S.D. ± 25.8%) of total insulin dose (TID) was prandial insulin and basal insulin 54.05 (S.D. ± 17.2%).

- Basal insulin used were: lispro 41%, aspart 46.5%, glulisin 7.7% and regular 4.9%.
- Basal insulin used were: glargin 85.4%, detemir 13.5%. NPH 0.8%. Time of injection was breakfast 17.9%, lunch 15.8%, dinner 17.6%, before bedtime 34.2%; 14% breakfast and before bedtime. We observed a higher dose of insulin among patients with two daily doses of basal insulin: 35.9 (S.D. ± 20) vs 25.54 (S.D. ± 12.2) IU (P < 0.05).

Conclusions
Basal-bolus therapy is the most used regimen in our DM1 population. Those patients using two basal doses per day needed higher TID. The majority of our patients had educational support but less than a half complete the educational program. It is important to aware our patients to finish these activities to better self control of their disease.

**Effects of dapagliflozin in treatment of gastroparesis considering the state of carbohydrate metabolism in patients with type 2 diabetes mellitus**

Iryna Kostińska, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine.

Diabetic gastroparesis (DG) is associated with high morbidity and is the most common precipitating factor to decompensation of carbohydrate metabolism. SGLT2 inhibitors are becoming a common and useful drug to treat type 2 diabetes. Principle treatment of gastroparesis considering the state of carbohydrate metabolism in patients with type 2 diabetes mellitus are very limited. The aim of this study was to compare the effects of dapagliflozin for management patients with DG. 16 patients with type 2 DM were randomly allocated into 2 groups: a first group (n=8 (3M/5F), mean age was 41.4±6.7 years old, DM during 12.2±4.5 years, body mass index (BMI) was 33.7±1.4 kg/m2) with gastroparesis, and a second (control) group (n=8 (4M/4F), mean age - 45.3±3.9 years old, DM - 13.2±6.2 years, BMI - 32.9±2.5 kg/m2) to take dapagliflozin (daily doses 10 mg) for 3 months. Gastric emptying rate (GER) measurement with the help of 13C-octanoic breath test (13C-OBT), prandial and postprandial glucose levels and glycated haemoglobin (HbA1C) were performed at entry and at end of treatment period as well. Low gastric motility has been diagnosed in all patients first group with help of 13C-OBT: T 1/2 = 98.84±4.22 min, in the second group that result is T 1/2 = 69.82±9.23 min. After the end of 3 months therapy in the first group significantly improved T 1/2 = 83.11±2.31 min (P<0.05). In the result after treatment we show that glycemic control to be significantly higher (prandial glycemic: 7.81±0.6 mmol/L, postprandial - 8.57±2.88 mmol/L, P=0.05) in the patients of the first group than subjects of the second group (prandial glycemic: 8.44±1.34 mmol/L, postprandial - 9.28±0.13 mmol/L, P>0.05). After treatment level of HbA1C significantly decrease in both groups (P<0.05).Dapagliflozin is an useful drug for treating type 2 diabetes with and without of gastroparesis. Patients with DKI get normalization of gastric emptying rate. It appears that this effect may be due to non-specific mechanisms.

**Self-monitoring of blood glucose: how are glycemic readers used in practice?**

Meriem Haddad, Samir Aouiche & Aissa Boudiba

Department of Diabetes Research CHU Mustapha Bacha, Algiers, Algeria.

**Introduction**

In recent years, the technique of ASG has gained much in simplicity, speed and acceptability, using readers more and more reliable. Despite this, some patients do not acquire the skills needed to achieve it. The aim of this study is to evaluate the technical gestures of use of blood glucose readers in current practice.

**Material and method**

This is a prospective descriptive study including 369 diabetics for over a year, followed in diabetic consultation in Algiers. A questionnaire was drawn up using the following items: frequency of capillary blood glucose checks, blood glucose readers (choice, number of years of use, rhythm of change), modalities of capillary sampling., The possible impact on daily life.

**Results**

Of the 369 diabetics we found 17% type 1 and 83% type 2, sex ratio at 1, the average age is 52.6±15.5 years, with a duration of diabetes of 10.3±8 years. More than half are treated with insulin. Their average HbA1c is 8.25±1.8%. Patients have more than two readers in 33.9% of cases, the latter are changed with an average rhythm of 4.2±2.9 years. 32.36% of patients do not systematically wash their hands before capillary blood glucose, and use of alcohol or other antiseptics is observed in 32.5% of patients, 59.2% use recommended sites for stitching, alternative stitch sites are never used, the regular change of the lancets is observed in 20/3 of the cases and the elimination of the lancets is done with the household waste In 86% of cases.

**Conclusion**

Learning from the GSM must be included in a therapeutic patient education program, as the Haute Autorité de santé has highlighted, practical workshops will help them to master the GSM and easy use of the blood glucose meters.

**Determinants of patient’s adherence and its relation to therapeutic success after hospital admission for decompensated diabetes**

Danieła Mugułháes1,2, Ana Saavedra1, Pedro Soutério1,2, Rita Bettencourt-Silva1,2, Maria Manuel Costa1,2, José Luís Casteleiro1,2, Paula Freitas1,2, Cláudia Nogueira1, Joana Querétro2 & Davide Carvalho1,2

1Department of Endocrinology, Diabetes and Metabolism of Centro Hospitalar de São João, Porto, Portugal; 2Faculty of Medicine, Porto, Portugal; 3Department of Endocrinology of Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal.

**Introduction**

Diabetes mellitus (DM) is a chronic disease that requires continuous medical care. Health care providers should adopt approaches that improve patient outcomes and adherence.

The study was carried out on 86 patients admitted at Endocrinology department in 2014–2015. Two types of assessment were available after discharge: consultation and blood analysis. Adequate adherence was defined by the compliance to ≥80% of the evaluations. We considered therapeutic success as A1c reduction ≥1.5% after discharge and persistence of success as no increase of A1c after success achievement.

**Results**

After discharge, 79 patients maintained ambulatory follow-up, 62 with adequate adherence. Noncompliant patients were younger (52[1QR 39–60] years) than compliant patients (60[1QR 51–67] years) (P=0.041). For each year of increase in patient’s age at admission we observed a 4% increase in adherence (OR=1.04, 95%CI 1.00–1.08, P=0.035). Hypertensive (HBP) patients showed 88.5% compliance (P<0.05). Patients with HBP, compared to those without HBP, showed an adherence of 9.61 (OR=9.60, 95%CI 2.85–32.61, P<0.001). Previous treatment with metformin, DPP4i and statins was associated with a 3.9-fold (OR=3.90, 95%CI 1.16–13, 46, P=0.028), 4.7-fold (OR=4.70, 95%CI 1.22–17.87, P=0.025) and 3.5-fold (OR=3.50, 95%CI 1.15–10.6, P=0.027) higher adherence, respectively. The degree of adherence to follow-up didn’t influence the therapeutic success at 6 (P=0.547) nor 12 months(M) (P=0.611). Of the compliant patients, 55.4% achieved therapeutic success at 6M, however only 26.9% of these maintained success at 12M. On the other hand, of compliant patients who did not achieve therapeutic success at 6M, only 20.8% achieved it at 12M.

**Conclusions**

Approximately 80% of our sample showed adequate adherence. Advanced age, HBP and previous therapy with metformin, DPP4i or statin were associated with greater adherence. Therapeutic success was not related to follow-up adherence.

**Study of metabolic and some hormonal aspects among pubertal type 1 diabetic girls**

Fatma Hamad & Mohsen Khalid

National Institute of Diabetes and Endocrinology, Cairo, Egypt.

**Background**

The onset of type 1 diabetes before menarche was a risk factor for the subsequent development of hyperandrogenic disorders. It has been also suggested that the use of exogenous insulin to treat type 1 diabetes mellitus in those patients may contribute to the development of PCOS. Abnormal lipid levels were also reported in children with type 1 diabetes mellitus during pubertal years.

**Aim of work**

This study was designed to investigate metabolic and some hormonal changes in relation to puberty among type 1 diabetic girls.

**Subjects and methods**

The study was carried out on 60 girls, 40 of them were type 1 diabetic patients (the diabetic group), subdivided into two groups (according to age and Tanner breast staging), and 20 of them were normal healthy girls (the control group), also subdivided into two groups (according to age and Tanner breast staging). All girls were subjected to full history taking, thorough clinical examination, estimation of fasting blood glucose and HbA1c (as an estimation for glycemic control), lipid profile, hormonal profile (FSH, LH and free testosterone) in addition to pelvic ultrasound.

**Results**

There is an increased frequency of dyslipidemia in the form of hypercholesterolemia and increased levels of LDL among type 1 diabetic girls, and pubertal type 1 diabetic girls show higher BMI and cholesterol levels compared to controls, and also show
higher levels of LDL compared to prepubertal type 1 diabetic children. Age at menarche is delayed in prepubertal type 1 diabetic girls having PCOS, while not delayed in those without PCOS but positively correlated to the longer duration of diabetes and with the level of HbA1c. Both the frequency of PCOS and the level of free testosterone are higher in prepubertal type 1 diabetic girls compared to their normal controls.

Bone-to-muscle endocrine axis modulating adaptation to exercise in athletes of mountain cycling in a Portuguese Marathon

Isanete Alves de Alonso1, Andrea Matos2, Angela Gil2,2, Carlos Cardoso1, Luis Bettencourt Sardinha1,2 & Manuel Bicho1,4
1Genetics Laboratory and Environmental Health Institute of Faculdade de Medicina da Universidade de Lisboa, Lisbon, Portugal; 2Instituto de Investigação Científica Bento de Rocha Cabral, Lisbon, Portugal; 3Laboratório de Análises Clínicas, Grupo Do Joaquim Chaves, Lisboa, Portugal; 4Exercice and Health Laboratory, CIPEKER, Facultad de Human Kinetics, Universidade de Lisboa, Lisboa, Portugal.

**Introduction**

Besides the benefits of low-to-high intensity physical activity (PA) on metabolism, it is currently emerging that excessive PA can be deleterious with serious implications not only in muscle but also, bone remodeling. Despite recent findings remains still unclear and controversial, we hypothesize that exercise of impact, like mountain cycling, beyond influencing the metabolic and skeletal profile, represents an important model of profoundly changes in bone metabolism.

**Methods**

55 participants (mean age 44.8 ± 7.1 years old) of mountain cycling race (TransPortugal) were evaluated at the beginning/basal (M0) and 9-days post-race (M9). Anthropometric/body composition parameters, haematological and liver function were evaluated by conventional methods. Serum Irisin and plasma osteocalcin and IL-6 measurements were evaluated with ELISA (R&D systems and Phoenix Pharmaceuticals-Irisin). Statistical analyses included departure from normality and adequate parametric or non-parametric test to compare the means and the medians. The results were significant for P < 0.05.

**Results**

In the metabolic point of view, we found that this strenuous exercise induced a significant decrease of fasting insulin, triglycerides, total-cholesterol, non-HDL cholesterol, LDL and an increase of glucose, creatinine, uric acid, HDL, HOMA-B (P < 0.05). These results reflected the important modifications in muscle, being the myokine/adipokine, irisin, significantly decreased post-race (P = 0.002).

In terms of bone remodelling, although not statistically significant, osteocalcin was decreased post-race (P = 0.154), yet the plasma IL-6, a cytokine involved in osteoclastic proliferation, was significantly increased post-race (P < 0.0001).

**Conclusions**

Our preliminary results, revealed a possible regulation of osteocalcin in glucose and insulin metabolism, being the slowdown in bone formation observed, a prompt metabolic response of bone to the increased energy demands of the muscle.

Dumping syndrome post total gastrectomy

Samir Ait Abderrahmune, Soumia Abdellkerim, Fadoua Boucelma, Lila Brakni & Brahim Oudjit

HCA, Koubia, Algeria.

**Introduction**

Dumping syndrome, also known as rapid gastric emptying, is a relatively rare disorder. It is conventionally due to the brutal flooding of the small bowel by a hyperosmolar food bolus and to the release of various digestive hormones whose real responsibility in the syndrome remains poorly known. It is usually a complication of the gastrectomy (10 to 40% of the cases). Hypoglycemia after surgery for digestive cancer is sometimes severe, but rare, and revealed by the monitoring of blood glucose, and then more frequent. The variability of the definitions in the studies supports a single definition, Whipple, with a blood glucose level below 0.55 g/l.

**Discussion**

We report the case of a patient, aged 32 years with a personal history of total gastrectomy for gastric adenocarcinoma, regularly followed surgery consultation, a family history of diabetes and hypertension. The onset of the disorders dates back to a postoperative month marked by the appearance of signs of adrenergic hypoglycemia without glycogenic signs in late postprandial periods i.e. 2–3 h after a meal. Capillary glucose levels were made with regard to clinical symptomatology. Have returned to < 0.50 g/l. Patient in average general condition with a normal BMI of 19 kg/m². Remainder of the review is without peculiarities. On the biological level, GAF: 0.79, GR 3.6, Hb 10.3, VGM 91, CCHM 31%, GB 5360, Correct renal count: MDRD at 107. Hepatic balance without abnormalities. Malabsorption balance: Normal calcium an 2.28 mmol/l, Phosphoeremia: 1.46 mmol/l, Iron serum: 9.65 mmol/l, ECG and Telthorax with no abnormalities. Glycemic variability is high in our patient, with hypoglycemia and abnormalities in the glycemic Holter (CGMS) or even recording. The symptoms disappeared following a dietary treatment with improvement of the quality of life of the patient, without any medicinal intervention.

**Conclusion**

It is necessary to educate the patients operated on for gastric surgery, after the resumption of the oral feeding, so that he learns how to manage his functional disorders, that he understands the interest of a supplementation, of fat soluble vitamins and Calcium and accepts the idea of regular clinical, biological and ideally osteodensitometric monitoring, unlimited in time.

A case report of insulinoma in a patient with chronic headache

Enulda Demaj & Marjeta Kerma

1Regional Hospital of Berat, Berat, Albania; 2University Hospital Center ‘Mother Theresa’, Tirana, Albania.

**Introduction**

Pancreatic endocrine tumors are rare lesions, with an incidence of 4 cases per 1 million pts-yr. Of these lesions,insulinomas are the most common. The nonspecific symptoms and small sizes of these tumors led to difficulties of diagnosis and localization.

**Case report**

A 60 year female pts, had history of episodic and repetitive symptoms of strong headaches for the last 5 years; which were relieved with eating or taking glucose water orally. She noticed increased appetite over the past few years. No medications at the time of evaluation. She was obese. Normal visual field exam. On admission serum glucose level 55 mg/dl, insulin, c-peptide in normal range. Prolonged supervised fasting test was applied and produced symptomatic hypoglycemia (33 mg/dl), with slightly elevated insulinemia 26 mU/l(4-23), normal levels of C-peptide, cortisolemia and chromogranina A; interrupted on the first day after Shours.Abdominal RMN with contrast demonstrated a well-defined hypervascular lesion involving head-body of pancreas measuring about 1.6 cm. Postoperatively the patient was discharged in good health with normal glucose level.

**Conclusion**

Insulinoma remains a diagnostic challenge to practitioners. This case illustrated the importance of carefully questioning and examining patient for subtle symptoms and signs of hypoglycemia. A chronic headache may hide an insulinoma.

Real-time continuous glucose monitoring during pregnancy in women with type 1 diabetes: glycemic control and key obstetric outcomes
Harold de Valk1, Judith van Niel2, Blanca Silvius3 & Nel Geelhoed-Duijvestijn1
1University Medical Center, Utrecht, The Netherlands; 2Medisch Centrum Haaglanden, den Haag, The Netherlands.

Introduction
Real time continuous glucose monitoring (RTCGM) has been shown to improve glycemic control. Limited data are available on the effects of RTCGM during pregnancy. The current study assesses glycemic control and obstetric outcomes in women with type 1 diabetes, comparing RTCGM with usual self measurement of blood glucose (SMBG).

Patients and methods
Patients were recruited from two hospitals. All patients were eligible. Glycemic control was assessed by preconception HbA1c and HbA1c during pregnancy. Obstetric outcomes reported are premature delivery (PD, <37 weeks), and macrosomia (Large for Gestational Age (LGA); birth weight ≥90th percentile; Very Large for Gestational Age (VLGA); birth weight ≥97.5th percentile).

Results
67 women were included; 53 (79%) used RTCGM PD occurred in 22% of the pregnancies, 19.6% with RTCGM, 31% on SMBG (P=0.5). LGA occurred in 58% of pregnancies, VLGA in 31%, LGA with RTCGM 61%, with SMBG 46% (P=0.4). VLGA with RTCGM 37.5%, SMG 50%, P=0.9). Mean HbA1c was significantly lower before pregnancy (52.1±6 vs 67.8±18.4 mmol/mol, P<0.001) and during the first trimester (6 weeks: 47.9±5.4 vs 58.9±18.1 mmol/mol, P=0.002) and 12 weeks (43.9±7.0 vs 53.8±12.8 mmol/mol, P=0.05), but not later in pregnancy.

Conclusion
RTCGM was associated with better early HbA1c. Premature delivery occurred less frequently with RTCGM, macrosomia more frequent. Future analysis with larger number of participants may help to establish whether these differences persist at this moment, better early control is not readily associated with less macrosomia.

Differential pattern of insulin signalling in adipose tissue and skeletal muscle in adult female sheep exposed prenatally to testosterone
Daniel Sandoval1, Mónica P Recabarren1, Albert Carrasco1, Teresa Sír-Petermann1 & Sergio E Recabarren1
1Laboratory of Animal Physiology and Endocrinology, Faculty of Veterinary Medicine, University of Concepcion, Chillan, Region BioBio, Chile; 2Laboratory of Endocrinology and Metabolism, Western School of Medicine, Universidad de Chile, Santiago, Chile.

Insulin resistance is defined as the incapacity of insulin to increase glucose uptake by peripheral tissues (skeletal muscle and adipose tissue principally). This phenomenon is present in different animal models for PCOS by prenatal exposure to androgens. In the PCOS condition, the metabolic pathway of insulin activity is defective in skeletal muscle and adipocyte whereas the activation of sterogenesis is maintained. The decreased insulin stimulated glucose uptake is due to impaired signaling and multiple downstream intracellular defects including impaired glucose transport and glucose metabolism. Previous results from our laboratory have demonstrated that female sheep born to testosterone treated mothers (testosterone-females), and born to untreated mothers (C-females). Our aim was to define if prenatal exposure to testosterone affects insulin signaling in adipose tissue and skeletal muscle. Adults females (38 weeks of age) were sacrificed and samples of skeletal muscle (Gastrocnemius superficialis) and adipose tissue (visceral) were collected. The qPCR assays were performed to analyze gene expression of IR, IRS-1, IRS-2, PI3K, Akt, PKC, GLUT4 and β-actin. Expression pattern of insulin signaling were similar between groups with the exception that in skeletal muscle, IRS-2 showed higher expression in testosterone-females (P≤0.05) than C-females while on the contrary, the GLUT4 RNAm was lower in testosterone-females compared to C-females (P≤0.05). In the visceral adipose tissue, AKT transcript expression was higher in testosterone-females (P≤0.05) than C-females. Results show that prenatal exposure to testosterone affects the insulin signaling, suggesting a change in the type of oxidative metabolism in the muscle tissue and increase in adipogenesis.

The evaluation of sexual function of women with type 1 diabetes mellitus
Edita Prakapiene2, Kornelija Bagdonaitė1, Lina Radzieviciene2 & Brute Zilaitiene3,4
1Faculty of Medicine, Lithuanian University of Health Sciences (LUHS), Kaunas, Lithuania; 2Department of Endocrinology, Lithuanian University of Health Sciences (LUHS), Kaunas, Lithuania; 3Institute of Endocrinology, Lithuanian University of Health Sciences (LUHS), Kaunas, Lithuania.

Aim
The aim of this study was to evaluate the influence of age, disease duration, glycemic control and diabetic nephropathy for the sexual function of women with type 1 diabetes mellitus (T1D).

Methods
Study subjects – 18–52 year old women with type 1 diabetes. Participants filled the Female Sexual Function Index (FSFI) and questionnaires about T1D, disease duration, glycemic control and complications. Laboratory tests including glycated hemoglobin (HbA1C), creatinine, testosterone, Sex hormone-binding globulin (SHBG), estradiol levels and albumin in 24h urine sample were performed. Postmenopausal women were excluded from the study. Female sexual dysfunction (FSD) was diagnosed based on FSFI total score lower than 26.55.

Results
113 women (mean age 34.8±8.34) with T1D were included to the study. Diabetic nephropathy (DN) was diagnosed to 43.4% (mean age 35.2±9.50), 56.6% had no DN (mean age 34.50±7.90). FSD was diagnosed to 42.6% (N=40) of participants. Neither age nor disease duration had influence to FSD. Worse glycemic control had a statistically significant impact to the prevalence of FSD (P=0.028). Negative correlations between participant age and FSFI subscales of desire and arousal were observed (P<0.001). Lubrication (P=0.015) and orgasm (P=0.027) subscales were negatively affected by age only in the group of DN. Statistically significant negative impact was found between glycemic control and lubrication in group without DN (P=0.009). There was no statistically significant difference between FSFI scores or sex hormones and disease duration or DN. Free androgen index had impact neither to the FSFI subscale scores nor to total score. Negative SHBG and high glycemic level correlation was observed only in DN group (P=0.031).

Conclusion
Female sexual function is often diagnosed in women with type 1 diabetes mellitus. Sexual function correlates with glycemic control and age. Worse glycemic control has negative impact to SHBG levels.

Growth hormone IGF axis - basic

Insulin is related to hepatic mitochondrial activity in humans
Peter Wolf, Sabina Smajis, Martin Gajdosiik, Lorenz Pfleger, Yvonne Winhofer, Christian-Heinz Anderwald, Siegfried Trautting, Anton Lugers, Martin Kessak & Michael Krebs
Medical University of Vienna, Vienna, Austria.

Background
Altered hepatic mitochondrial activity plays a key role in the development of non-alcoholic fatty liver disease (NAFLD). GH has been shown to stimulate mitochondrial function in skeletal muscle. Therefore we hypothesized that the time course of serum GH concentrations during an oral glucose tolerance test might be related to hepatic mitochondrial energy metabolism in vivo in humans.

Methods
15 volunteers (male/female: 7/8; 55±4 years; BMI 25±4 kg/m2) were investigated on two study days; i) oral glucose tolerance tests were performed to assess dynamics of glucose, insulin, C-peptide and GH concentrations and ii) hepatic lipid content was measured by 1H/31P magnetic resonance spectroscopy (MRS). Saturation transfer technique was applied to assess ATP synthesis rate (k).

Endocrine Abstracts (2017) Vol 49
Results
Basal GH concentrations and GH dynamics strongly correlated with hepatic mitochondrial activity (GH/insulin:Kcreat, r = 0.783; P < 0.0001; GH/UC:Kcreat, r = 0.676; P = 0.008). There was no association between HCL and GH, as well as between HCL and kinsulin. Six subjects fulfilled criteria for NAFPD (HCL ≥ 5.5%). They presented significantly higher glucose levels and insulin resistance. The strong relationship between GH and kinsulin did not differ between patients with and without NAFPD.

Discussion
Our data indicate that basal as well as postprandial (oGTT) GH concentrations are directly related to hepatic energy metabolism in insulin sensitive and insulin resistant humans.

DOI: 10.1530/endoabs.49.EP638

EP639
Modulation of the 22 kD/20 kD growth hormone (GH) ratio by exercise, fasting and glucose load in premenopausal women
Michael Haenelt, Katharina Schilbach, Christina Gar, Andreas Lechner, Rita Schwaiger & Martin Bidlingmaier
Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, München, Germany.

We previously have shown in a cohort of 236 non-fasted women that before and after a short high intensity exercise protocol (HIP) till exhaustion serum concentrations of 20 and 22 kD growth hormone (hGH) are highly correlated (P < 0.0001). Although the GH response to exercise exhibited huge inter-individual differences, the 20 kD/22 kD-GH-ratio remained unchanged (9.6% vs 11.1%, P = 0.313). A subgroup of the women was also studied under fasting conditions in a moderate intensity protocol, applying an exercise (70% VO2 peak) over a longer time (mean duration 45 min). In contrast to the HIP under non-fasted conditions, baseline and post exercise 20 kD/22 k D GH ratio were significantly higher in the fasted protocol (mean 15.33% vs. mean 10.85%, P = 0.0021). To further investigate the impact of fasting and glucose intake on the 20 kD/22 kD-GH-ratio, we analyzed GH isoform secretion before and after an oral glucose tolerance test (OGTT, 75 g glucose) in a subset of the cohort (n = 60; mean age 36 years (yr), range 20–44y; BMI: mean 23, 2 kg/m²). GH isoforms were measured using the IDS-iSYS GH CLIA specific for 22 kD GH and an in-house IFMA for 20kD GH (LoQ 0.025 ng/ml), respectively. 20 kD GH was > LoQ of the assay in all subjects at baseline and in 86% 60 minutes after glucose ingestion. At baseline, fasting 20 kD/22 kD ratio in the subset was 12.9%. Ratio was not changed 60 min after glucose intake (12.3%; P > 0.05). Due to the expected suppression of GH following glucose intake, after 120 min the 20 kD/22 kD-ratio could only be measured in 18.3% of the subjects, but no significant change in the abundance of 20 kD GH was observed (mean ratio 12.1%; P > 0.05). In conclusion, the 20 kD/22 kD-GH-ratio is lower in the non-fasted compared to the fasted state, both at baseline and following exercise. However, short-term oral glucose intake per se does not significantly influence the 20 kD/22 kD-GH ratio.

Inulin resistance and acromegaly: about 15 cases
El Ansari Nawal & Sara Askouli
Service of Endocrinology Diabetes and metabolic diseases, Cadi Ayad University, CHU Mohamed VI, Marrakech, Morocco.

Contexte
Acromegaly is a rare disease, usually caused by hypersecretion of growth hormone (GH) by a pituitary adenoma and very rarely by ectopic secretion of GHRH. It remains a serious disease reduces life expectancy because of its cardiovascular and metabolic impact.

Objective
The objective of this study is to report the glycemic profile in patients followed for acromegaly in the endocrinologic center of CHU Med VI of Marrakech.

Patient – Intervention
We performed a retrospective study over a period of 2 years. Fifteen cases were identified.

Intervention
In terms of methodology, we studied: a family history of diabetes, hypertension and dyslipidemia; Girth, body mass index (BMI), hypertension, diabetes mellitus or impaired glucose tolerance and dyslipidemia in these patients.

Main outcome measure
Glucose intolerance and diabetes with insulin resistance are commonly encountered complications acromegaly. Some studies have shown a direct correlation between the rate of GH and the degree of glucose intolerance. The hyperinsulinemia and insulin resistance may play an important role in the cardiovascular risk of these patients. The role of insulin resistance, but also of pancreatic β dysfunction has been invoked in the pathogenesis of carbohydrate metabolism disturbances secondary to chronic excess GH.

Result
The average age was 43 years (20–63) with a sex ratio (M/F) = 0.33. The duration of the disease at diagnosis was on average 7 years (3–14). Family history were 13.3% diabetes mellitus and heart disease. Pathological BMI was objectified in 52% of cases; 46.6% of these patients had pre-diabetes, 40% diabetic (a total of 84.6% of carbohydrate anomalies) and 46.7% had dyslipidemia. Moreover 26.6% of our patients where hypertensive.

Conclusion
Approximately 84.6% in our series of cases had carbohydrate abnormalities. Diagnostic and therapeutic delay can worsen or even cause the patient’s death. After surgical recovery, the evolution of diabetes and or glucose intolerance is usually favorable.

Comparison of GHRH + arginine vs glucagon test for the evaluation of growth hormone secretion status in a cohort of adults with Prader-Willi syndrome (PWS)
Laia Casamitjana, Giménez-Palop Olga, Corriño Raquel, Pareja Rocío, Hurtado Marta, Gabau Elisabet, Cobo Jesús, Berlanga Eugenio, Cano Albert, Albert Lara, Rigla Mercedes & Caixàs Assumpta
Parc Taulí Hospital Universitari, Institut d’Investigació i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell, Barcelona, Spain.

Background
Prader-Willi syndrome (PWS) is a rare genetic disorder evolving morbid obesity and growth hormone deficiency (GHD). Testing GHD-IGFI axis is required before treatment with rhGH in adults with PWS (1). The most common used tests in these patients are GHRH + arginine (GHRH+α) and insulin tolerance test. There are no prospective data for glucagon test (GT) in comparison to GHRH+α in adults with PWS. Mechanism by which GT causes GH release remains unclear, glucagon-induced GH release via noradrenaline secretion has been postulated.

Objectives
To compare two diagnostic tests to evaluate GH secretion status in a cohort of adults with PWS.

Methods
Twenty-one SPW (8M and 13F, aged 29(17–51), BMI 36.2 ± 10.2 kg/m²) participated in the study. After an 8–10 h fast, all patients underwent the two different provocative tests in separate days: GHRH (1 ng/kg/min intravenously, max 100 ng/kg/min) and insulin tolerance test. There
were 22 patients achieved GH peak at minute 45: 3.31 ng/ml (1.6–9.6), median (interquartile range) with GHRH+α, whereas GH response was blunted with GT. After the glucagon injection, an increment in plasma glucose levels was observed at 30 min with a peak at 60 min. One patient suffered an asymptomatic hypoglycemia during the test.

Conclusions
Glucagon seems to fail to stimulate GH in adults with PWS. Further studies are necessary to elucidate if the underlying autonomic dysfunction described in PWS could be involved.

**Dietary intake of linoleic, linolenic, oleic, and arachidonic acid PPAR-gamma gene expression in visceral and subcutaneous adipose tissue among healthy subjects**

Emad Yavuzbashi, Maryam Zarkeh, Golaleh Asghari, Azita Zadeh-Vakili, Behnaz Mahmooudi, Afsoon Daneshafroz, Mehdi Hedayati & Parvin Mirmiran

1Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; 2Student Research Committee, Biochemistry of Nutrition Research Center, School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran; 3Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran.

**Objective**

To investigate whether peroxisome proliferator-activated receptor gamma (PPAR-gamma) gene expression in visceral and subcutaneous adipose tissue was related to intake of several fatty acid intakes.

**Methods**

For the current study 97 subjects (41 non-obese, 18 obese, and 38 morbid obese) were selected. All of the subjects were free of diabetes and cancers and without using anti-lipid medication. Visceral and subcutaneous adipose tissues were obtained during an abdominal open surgery with minimal impact on dietary intake. The PPAR-gamma gene expression was assessed by Real-Time PCR. Usual dietary intake was measured using a validated semi-quantitative food frequency questionnaire. For calculation linoleic (18:2), linolenic (18:3), oleic (18:1), and arachidonic acid (20:4) intakes, the USDA Food Composition Table was used.

**Results**

The PPAR-gamma expression in visceral adipose tissue among non-obese subjects was correlated with oleic acid (r = -0.417, P = 0.007) and linoleic acid (r = -0.401, P = 0.009). There were significant correlations between subcutaneous adipose tissue PPAR-gamma expression and linoleic acid (r = -0.310, P = 0.049) among non-obese subjects. PPAR-gamma expression among obese subjects in visceral adipose tissue was correlated with oleic acid (r = -0.686, P = 0.002) and linoleic acid (r = -0.699, P = 0.031) and also in subcutaneous adipose tissue was correlated with oleic acid (r = -0.453, P = 0.048). Furthermore, among morbid-obese subjects PPAR-gamma expression in visceral adipose tissue was correlated with linoleic acid (r = -0.336, P = 0.039) and in subcutaneous adipose tissue was correlated with linoleic acid (r = -0.326, P = 0.046) and oleic acid (r = -0.352, P = 0.030). There were no significant association of dietary intakes of arachidonic acid with PPAR-gamma gene expression.

**Conclusions**

PPAR-gamma gene expression was negatively correlated with linoleic and oleic acids among non-obese and obese subjects.

**Association between meal intake behavior and body composition/psychological well-being in Japanese adults**

Toshifro Takao, Yoshiyuki Yamanaka, Sohachi Fujimoto & Tomoari Kamada

Kawasaki Medical School, Kurashiki, Japan.

The study aims to evaluate the association between body composition/psychological well-being and meal intake behavior such as eating fast, snacking after dinner, dinner within 2 h before sleep. This cross-sectional study includes n = 5066 participants aged 19-89 who had participated in an annual health checkup in 2015. BMI, Waist circumference (WC) and the World Health Organization (WHO)-5 Well-Being Index were assessed to determine. The meal intake behavior were assessed with a modified questionnaire based on focused on metabolic syndrome in Japan. In addition, the relation with BMI/ WC/psychological well-being and meal intake behavior by controlling age, smoking, alcohol drinking, exercise habit, medication and sleep condition were assessed by multiple regression analysis. Having a short lunch time, preferring salty taste, snacking after dinner and dinner within 2 h before sleep were positively associated with BMI, WC and WHO-5 score after adjusting for all confounders. Although eating vegetable and fruits were not independent of BMI, both are positively associated with WHO-5 score. The present data demonstrate that adjusting meal intake behavior could be helpful in preventing psychological distress as well as obesity.

A comparison of the metabolic parameters of obese and non-obese nafld patients with insulin resistance

Pinar Karakaya, Bahar Pehlivan, Meral Mert, Hamide Karagöz & Yıldız Okuturlar

1Department of Endocrinology, Bakırköy Sadi Konuk Training and Research Hospital, Bakırköy, Turkey; 2Department of Internal Medicine, Bakırköy Dr. Sadi Konuk Training and Research Hospital, Bakırköy, Turkey.

**Introduction-aim**

Non-alcoholic fatty liver disease (NAFLD) is a clinical condition of uncertain etiology, whose pathogenesis several mechanisms are involved and which is defined by fat vacuoles in more than 5% of hepatic histiocytes in the absence of serious alcohol consumption. It is frequently comorbid with obesity and insulin resistance. However, NAFLD is also seen in non-obese individuals. The purpose of this study was to compare insulin resistance and metabolic parameters in obese and non-obese NAFLD patients.

**Materials-method**

50 obese (BMI > 30) and 50 non-obese (BMI < 30) presenting to the Bakırköy Dr. Sadi Konuk Education and Research Hospital Endocrinology, Diabetes and Obesity Clinic with hepatic steatosis determined at ultrasonography (USG) and with no causes such as alcohol use, viral diseases or drug use to account for fat deposition and consenting to participate were included in the study. Patients’ demographic characteristics, biochemical tests and insulin levels were investigated. Insulin resistance was determined using homeostasis model assessment (HOMA-IR), a mathematical technique, with the formula fasting insulin (U/ml) x fasting glucose (mm/dl)/405. Insulin resistance was defined as HOMA-IR > 2.5.

**Results**

One hundred patients with NAFLD, 63.3% female, were enrolled in this study. Fifty were obese and 50 were non-obese. Mean age was 44.1 ± 11.1 years. Hepatomegaly accompanied steatosis in 55% of patients. Mean BMI was 37.3 ± 5.3 in the obese group and 28.2 ± 1.35 in the non-obese group. Mean blood sugar values were 99.3 ± 9.78 in the obese group and 103.40 ± 8.3 in the non-obese group, and the difference was not statistically significant (P=0.08). Insulin levels were 10.1 ± 3.3 in the obese subjects and 13.85 ± 12.3 in the non-obese subjects, while HOMA-IR values were 3.48 ± 3.38 in the obese subjects and 2.57 ± 9.1 in the non-obese subjects, and the difference was not statistically significant (P>0.05). Insulin resistance was determined in 60% of obese patients and 50% of non-obese patients (in 55% of the entire group). The difference was not significant (P>0.3). When the general characteristics and metabolic parameters of the groups with and without insulin resistance were compared (Table 1), significant differences were observed in terms of BMI, waist circumference, insulin level, HOMA-IR, GGT and indirect bilirubin levels, but none between the other parameters.

Conclusion
We compared metabolic parameters of obese and non-obese patients with NAFLD and insulin resistance. Insulin resistance was present in 55% of the total group. We observed significant differences between insulin levels, HOMA-IR, GGT and indirect bilirubin levels in subjects with insulin resistance. In conclusion, we think that fatty liver disease is by itself a risk factor for insulin resistance independent of obesity, and that GGT and indirect bilirubin levels in particular can show insulin resistance in patients with hepatic steatosis.

Associations between dietary food patterns and metabolic syndrome risk in Albanian adolescents
Alba Themeli & Edmond Pista
Medical Training Center Santa Maria, Lezhe, Albania.

Background
Adolescence is a period of rapid body growth and cognitive development, requiring balanced and sufficient nutrient intake. Since dietary habits are usually acquired in this period and could affect dietary practice in later life. It is crucial for adolescents to acquire healthy dietary behaviors for long-term health. However, the prevalence of diet-related metabolic syndrome risks such as obesity, glucose intolerance, elevated blood pressure, and dyslipidemia is increasing worldwide due to unbalanced nutrient intake among adolescents.

Objectives
The main objective of this study is to assess the association between habitual dietary patterns and the MetS risks after adjustments for biological and lifestyle variables in 112 adolescents aged 14–19 in Albania.

Methods
A validated food frequency questionnaire was used to assess dietary patterns, in which three dietary patterns were identified and labeled as ‘western-based’, ‘healthy based’ and ‘typical food’ patterns, whereas MetS risks was determined using multiple indicators such as waist circumference (WC), systolic and diastolic blood pressure (BP), and fasting glucose, triglycerides and HDL cholesterol levels. The outcome variables were statistically normalized and expressed as z-scores. A MetS risk score was computed as the means of these z scores.

Results
Multivariate analyses show that higher intake of western-based diet was significantly associated with the MetS risk scores ($P < 0.0001$) and WC ($P < 0.0001$) and BP compared to those at lower intakes of western-based diet, after adjusting for age, gender, ethnicity, pubertal growth status, total physical activity and sedentary screen-based levels. Similar pattern was found in typical-based diet, whereby adolescents who had higher intake of typical-based diet was significantly associated with higher levels of BP ($P < 0.0001$) and MetS risk score ($P = 0.0002$) compared to those at lower intake group. In contrast, high intake of ‘healthy’ diet pattern was significantly associated with lower WC ($P < 0.0001$), BP ($P = 0.022$) and MetS risk scores ($P < 0.0001$) than those at lower intake diet pattern.

Conclusion
These findings suggest that high intake of ‘healthy’ diet that is high in dairy foods, legumes, fruits and vegetables and low-intake of western-based diet and typical based diet were significantly associated with lower risks of abdominal obesity and MetS among adolescents. Hence, effective dietary intervention strategies should emphasize the promotion of healthy dietary practices among adolescents during these critical years of growth in order to prevent the risk of excessive weight gain and metabolic-related disorders.

Type 1 diabetes and metabolic syndrome
Ach Taieb, Hasti Yosra, Maaroufi Amel, Kacem Maha, Chaieb Molka & Ach Koussay
CHU Farhat Hached Sousse, Sousse, Tunisia.

Introduction
Contrary to type 2 diabetes, type 1 often occurs in young people, without obesity or cardiovascular or metabolic diseases. The association of type 1 diabetes with an authentic metabolic syndrome including obesity is very rare, though possible, with a mixed clinical picture. The goal of our study is to evaluate the association of type 1 diabetes with the metabolic syndrome.

Material and methods
This is a retrospective cross-sectional study based on the observation of patients admitted for diabetes with insulin deficiency. The positivity of anti-pancreas antibodies testified to the auto-immune characteristic; anti glutamic acid decarboxylase GAD and/or anti tyrosine phosphatase IA2. The goal of the study is to determine the patients’ clinical and biological aspects as well as their metabolic profile.

Results
Our series was conducted with 359 patients; 209 men and 150 women, aged between 10 and 69 years with an average of 28.75 years. Metabolic heredity was found in 26 patients (7.2%), Diabetes heredity in 216 patients (60.1%); 147 (40.9%) of whom with type 2 history and 69 (19.2%) with type 1 history. Vascular heredity was found in 27 patients (7.5%), 117 patients (32.6%) were smokers and alcohol consumption was found in 85 of them (23.7%). The clinical picture was ketotic in the majority of cases: 336 (93.6%), with inaugural ketosis in 313 cases (87.2%). Insulin deficiency varied between one week an 36 months, with an average of 3.75 months and a standard deviation of 6.8 months, exceeding 6 months achieving a slow form and a previous oral treatment in 24% of cases.

Regarding weight, the average BMI was 22 (extremes: 15 and 39), over 30 in 22 patients. Overweight was more significant in patients over 20 years old, with 6% in the younger population, 14% between the ages of 20 and 40, and 34% in the patients over 40 years of age. Regarding waist size in women, a size over 80 cm was more significant in patients over 40 (38%) against 4% in women younger than 20. Men’s waist size over 94 cm was more significant in patients over 40 (19%), against 4% in the ones younger than 20. An obesity previous to the discovery of Diabetes was found in 80 patients (22%). Hypertension was found in 14 patients (4%). Upon admission, average blood sugar levels were 16.40 mmol/l with an average glycosylated hemoglobin HbA1C of 12.32%. Average LDL levels were of 0.912 g/l with a minimum of 0.2 g/l and a maximum of 3.18 g/l.

Conclusion
Even though obesity is often associated with type 2 Diabetes, some type 1 Diabetics present with a metabolic syndrome that could mislead the diagnosis and delay the appropriate management. Obesity in type 1 Diabetes is more correlated with advanced age and metabolic heredity.

Intima media thickness of carotid arteries and cognitive function in Georgian nondiabetic obese and overweight hypertensive subjects
Ketevan Chagunava1 & German Lomtatidze2
1New Hospitals, Tbilisi, Georgia; 2Chaphidze Heart Centre, Tbilisi, Georgia.

Purpose
Obesity is a serious health problem that has reached very high proportions in our country; prevalence of obesity and overweight together is 56%. Obesity is strongly associated with risk factors for cardio and cerebrovascular disease, AH, type 2 diabetes and cognitive disorders. The aim of our study was to analyze the impact of AH and weight change on carotid artery intima-media thickness (IMT) and cognitive function in Georgian nondiabetic obese and overweight hypertensive individuals.

Materials and methods
We studied 131 patients with mild to moderate AH (89 males/42 females, mean age 53.4±3.1 years, BMI 29.8±3.4 kg/m², duration of AH 5.5±2.3 years). Examination included: color triplex carotid artery scanning; 24-h BP monitoring, mini-modal state examination test. 60 overweight patients (23< BMI< 29.9 kg/m²) were assigned to group 1 and 71 obese patients (BMI> 30 kg/m²) to group 2.

Results
The groups were comparable by the age, duration of AH, daily mean BP values. Mean values of IMT (gr1:1.04±0.04 mm;gr2: 1.09±0.05 mm) were certainly increased in obese patients compared with overweight ones ($P < 0.001$). Prevalence of carotid atherosclerosis was higher in gr2 (78% vs 65%). Occurrence of cognitive disorders was significantly higher in gr 2 (38vs26%)(P<0.05), BMI positively correlated with IMT ($r=0.25$, $P<0.02$).

Conclusion
Thus, in Georgian obese nondiabetic hypertensive subjects we detected more pronounced and frequent carotid artery affection and cognitive dysfunction.

CGI-58 gene expression profile in individuals with different body mass index
Daisy Crispim1,2, Jakeline Rheinheimer1,2, Milene Moehlecke1, Bianca de Souza1,2 & Cristiane Leito1,2
1Endocrine Division, Hospital de Clínicas de Porto Alegre, Porto Alegre, Rio Grande do Sul, Brazil; 2Post-Graduation Program in Medical Sciences: Endocrinology, Faculdade de Medicina, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil.

Background and aim
Although chronic low-grade inflammation is observed in obese subjects, the underlying mechanisms modulating this process are still unclear. The Compritive Gene Identification-58 (CGI-58) is a lipid droplet-associated protein that has an important role in mediating intracellular fat hydrolysis by acting as a coactivator of the adipose Triglyceride Lipase (ATGL). Recent evidence suggests that CGI-58 also has a role in chronic inflammation and insulin resistance (IR). Accordingly, macrophage specific Ctg-58 knockout aggravated high fat diet-induced inflammation and IR in mice through activation of the NLRP3 inflammasome. However, to date, only few studies have evaluated CGI-58 expression in obese patients, with inconclusive results. Therefore, the aim of this study was to evaluate CGI-58 expression in subcutaneous adipose tissue (SAT) from subjects with different BMI. Methods: SAT was obtained from 67 individuals who undergone bariatric surgery or elective abdominal surgery. Twenty-six patients were classified as having morbid-obesity (BMI ≥ 40 kg/m²), 27 as having moderate-obesity (BMI: 30.0 – 39.9 kg/m²), and 14 as non-obese subjects (BMI < 25 kg/m²). CGI-58 expression was quantified using RT-qPCR technique. Basal metabolic rate (BMR) was measured by indirect calorimetry and body composition variables by dual-energy X-ray absorptiometry. All subjects underwent complete physical and laboratory evaluations. Results: CGI-58 expression was decreased in morbid-obese and moderate-obese patients compared with the non-obese group (median 0.59 (minimum 0.18 – maximum 1.39) vs 0.83 (0.28 – 2.15) vs 1.70 (0.75 – 3.63); n-fold change; P < 0.001). CGI-58 expression was also negatively correlated with BMI (r = −0.432, P < 0.001), fat mass (r = −0.380, P = 0.003), free fat mass (r = −0.488, P < 0.001), and BMR (r = −0.373, P = 0.002). Regarding lipid profile, CGI-58 expression negatively correlated with triglycerides (r = −0.585, P < 0.001) and cholesterol levels (r = −0.305, P = 0.015) while positively correlated with HDL levels (r = 0.250, P = 0.046). Negative correlations were also found between CGI-58 expression and HbA1c (r = 0.421, P < 0.001), insulin levels (r = −0.332, P = 0.009) and IR (r = −0.317, P = 0.013). Conclusions: CGI-58 gene expression is decreased in obese patients compared to non-obese subjects and is inversely correlated with a worse metabolic profile.

Fractalkine as an inflammatory marker in obese subjects
Fatma Hamad, Mohsen Khalid, Asmaa Ibrahim & Ayat Gharem
National Institute of Diabetes and Endocrinology, Cairo, Egypt.

Background
Fractalkine (CX3CL1) is known to convey its signals through a single G-protein coupled receptor (CX3CR1). It is characterized as a structurally unique chemokine with both membrane-bound and soluble forms. Fractalkine expression has been detected in activated or stressed endothelial, smooth muscle, skeletal muscle, macrophages, neurons, hepatocytes and adipocytes. Inflammation up regulates Fractalkine particularly in adipose tissue of obese individuals.

Aim of Work
This study was designed to assess fractalkine level in obese subjects and its relation with some clinical and laboratory findings. It compares basal plasma fractalkine and hs-CRP in obese patients (with and without metabolic syndrome) and lean healthy controls.

EP650

The case of 36 years old obese male patient with high degree of proteinuria and a looming weight as the major strategy of treatment
Natiya Katamadze, Natalia Chochishvili & Anna Shamandaze
V.Iverieli Endocrinology, Metabolology, Dietology center ‘ENMEDIC’, Tbilisi, Georgia.

Introduction
Obesity-related glomerulopathy (ORG) is a secondary form of focal segmental glomerulosclerosis (FSGS) occurring in obese patients with a body mass index (BMI) higher than 30 kg/m². ORG is typically manifested by nephrotic-range proteinuria without full nephrotic syndrome, and progressive renal insufficiency.

Case presentation
Thirty-six years old male patient (BMI 39.2 kg/m²) visited endocrinologist with complaints of weight gain, hypertension, swollen lower extremities, dyspnea. Laboratory studies revealed: dyslipidemia, primary hypothyroidism and nodular goiter. Liver function- normal. Fasting glucose, postprandial glucose and A1C was normal-diabetes mellitus was excluded. In urine with dipstick proteinuria was found > 3 g/l. The patient was sent to nephrologist. The level of Creatinine-normal, Urea- normal, 24 hour protein urine test: 18872 mg/24 h (N < 150) and kidney biopsy was recommended. The patient was given low calorie diet (1600 kcal), L-Thyroxine 50 mkg., Simvastatin 20 mg. Because of Heart failure II (NYHA), arterial hypertension III (ESC) AR blockers and diuretics were advised. Despite of strict diet and high doses of diuretics he gained 6 kg in 7 days. Laboratory tests-slightly decreased albumin. Because of no effect of diuretics Albumin transfusion was performed. For 4 days he lost 9 kg. Only moderate edema of lower extremities rested, with AR blockers T/A was within normal range. After month proteinuria decreased till 2641 mg/24 h. He lost nearly 20 kg. He disappeared for 10 months, started to gain weight and whole clinical picture restored. Proteinuria was 4250 mg/24 h. Kidney biopsy was performed-secondary form of FSGS was diagnosed. Treatment strategy remain the same. We concluded that the main reason for proteinuria in this case was obesity.

Conclusion
ORG is in correlation with BMI. With the weight gain the level of proteinuria increases. In the early stage of kidney disease process can be reversible. Loosing weight is one of the most effective strategy of treatment.

Mobile and wireless technology to combat obesity. Using on-line program of good nutrition and weight diet: prevention and part of the treatment of diabetes mellitus
Vadim Krylov
First Moscow State Medical University, Moscow, Russia.

Introduction
It is too much easier and cheaper to combat obesity, than in the future to treat diabetes mellitus and its complications.
Methods
We used an online system for patient education based on the video lessons, full of humor, pictures, and cartoons to convey the necessary information on good nutrition, necessary to do exercises and the need for exposure to the sun to our patients.

Results
Watching the short movies, the patients formed the habits of good nutrition during the first month already, which includes a diet with restriction of fat, digestible carbohydrates and daily consumption of low-fat dairy products, slow carbohydrates, protein and fiber. There were also presented recommendations for compliance with the physical activity, as well as vitamin D consumption. A patient was in touch with a doctor-endocrinologist if he has any additional questions. We examined data from a survey of 500 patients registered in the online system and 100 patients control group who were given the same recommendations on the appointment. Surprisingly, persistent decrease in body weight by an average of 6.5 kg over 6 months was demonstrated in all patients of the main group, the consumption of milk and dairy products increased by 2.6 times, compared with patients in the control group. The exposure to the sun was observed 15 to 30 minutes daily, compared with the control group 5–10 minutes. Regular physical activity were the main group of 260 minutes per week, in control group 80 minutes per week.

Discussions
Mobile and wireless technology helps physicians to combat obesity and be a part of the treatment of Diabetes Mellitus and we need to improve the quality of information material, including using online technologies to improve the quality and duration of life of our patients.

Oligonol supplementation decreases abdominal obesity and the prevalence of metabolic syndrome in a sample of overweight and obese Saudi females without dietary restriction or lifestyle modification
Suhad Bahijri1,2, Ghada Ajabanour1,2, Zuheir Awan1,2, Anwar Borai2,3 & Altaf Abdulhakil2,4
1Department Clinical Biochemistry, Faculty of Medicine, King Abdulaziz University (KAU), Jeddah, Saudi Arabia; 2Saudi Diabetes Research Group - KAU, Jeddah, Saudi Arabia; 3Pathology Department, King Abdullah International Medical Research Center, King Saud bin Abdulaziz University for Health Sciences, King Abdulaziz Medical City, Jeddah, Saudi Arabia; 4Department Clinical Biochemistry, Faculty of Medicine, Umm Al-qura University, Makkah, Saudi Arabia.

Background
Obesity, and metabolic syndrome (MS) are highly prevalent in Saudi Arabia, increasing the risk for type 2 diabetes (T2DM), and cardiovascular disease (CVD). Oligonol produced from lychee fruit polyphenols (LFP) has been reported to increase the risk for type 2 diabetes (T2DM), and cardiovascular disease (CVD). Oligonol produced from lychee fruit polyphenols (LFP) has been reported to reduce visceral obesity, and ameliorate MS in Japanese subject.

Aim
To investigate the effect of oligonol supplementation on MS risk factors in overweight and obese Saudi females.

Subjects and methods
Sixty obese and overweight healthy Saudi females were recruited. Blood pressure (BP), height, weight, waist circumference (WC) were measured, and glucose, triglycerides, and HDL cholesterol were assayed in fasting serum samples. Dietary intake, and lifestyle habits were recorded by questionnaire. Subjects were divided into two groups with equal mean body mass index (BMI), in a double-blind /Case-Control study design. Group A (GA) was given placebo, and group B (GB) was given oligonol, and were followed for three months, with all measurements being repeated at the end.

Results
Some subjects were excluded for various reasons, leaving 25 in GA, and 22 in GB. Therefore, the two groups differed significantly in recalculated mean BMI at zero time (29.30 ± 3.97 for GA, and 31.63 ± 4.16 for GB, P = 0.046). No side effects or significant differences in diet or lifestyle were found at the end of the study. Mean triglycerides was significantly increased in GA (P = 0.008), and decreased in GB (P = 0.008). Mean WC increased in GA (P = 0.027), Percentage of subjects with high diastolic BP (DBP) in GB decreased significantly from 36% to 9% (P = 0.031), and percentage of subjects with metabolic syndrome decreased significantly from 27% to 5% (P = 0.039) by the end of the study.

Conclusion
Oligonol supplement succeeded in reversing MS in obese Saudi females by controlling abdominal obesity, and DBP, and decreasing hyperglycemia, therefore decreasing cardiovascular risk without dietary restriction or lifestyle modification.

Metabolic and bone effects of high fat diet on adult zebrafish
Marta Carnovali1, Livio Luzi2,3, Giuseppe Bantir4,5 & Massimo Mariotti1,5
1Gruppo Ospedaliero San Donato Foundation, Milan, Italy; 2IRCCS Policlinico San Donato, San Donato Milanese, Milan, Italy; 3University of Milan, Milan, Italy; 4Vita-Salute San Raffaele University, Milan, Italy; 5IRCCS Galeazzi Orthopedic Institute, Milan, Italy.

Obesity and type II diabetes have been linked to several health issues, including an increased risk of bone fractures. It is well known that an increase of visceral fat affects bone health causing fragility, mechanical strength reduction and increased propensity of fractures because of impaired bone matrix microstructure and aberrant bone cells function. Adult Danio rerio (zebrafish) represents a powerful model to study fat and bone metabolism. Then, the aim of this study was to evaluate bone and metabolic effects of high fat diet in adult zebrafish. Fish blood glucose levels have been monitored in time course experiments and glycaemia curve was found altered in fat fish compared to non-fat ones (Figure 1). The adult bone remodeling has been evaluated in fish using the scales as read-out system. The scales of high-fat diet fish showed bone resorption lacunae associated with an intense osteoclast activity. In addition, high-fat fish scales showed a significant decrease of alkaline phosphatase (ALP) activity and increase of tartrate-resistant acid phosphatase (TRAP) activity. These data suggests that an imbalance in fat metabolism leads to an alteration of glucose metabolism and an osteoprotective-like phenotype in adult zebrafish. The zebrafish model of obesity can contribute to elucidate in vivo the molecular mechanisms of metabolic changes derived from a high fat diet, which influence the bone tissues regulation and insulin signaling in human obese patients.

Growth hormone signaling and action in obese versus lean human subjects: evidence of increased hepatic GH sensitivity in obesity

Morten Högild Pedersen1; Ann Mosegaard Bak2, Steen Bøntlokke Pedersen1, Niels Jessen1, Niels Møller2 & Jens O.L. Jørgensen1
1Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; 2Department of Clinical Pharmacology, Aarhus University Hospital, Aarhus, Denmark.

Context
Obesity is accompanied by blunted GH secretion but relatively normal serum IGF-I levels, which suggests increased GH sensitivity. This, however, remains to be tested at the level of GH signaling in human subjects.

Objective
To compare the effects of an acute intravenous GH bolus in obese vs normal weight subjects on GH signaling pathways in adipose and muscle tissue, substrate metabolism and insulin sensitivity.

Subjects and methods
Nine obese (BMI 35.7 ± 0.9) and nine lean (BMI 21.5 ± 0.4) young men were studied twice in a randomized crossover design: (1) After an overnight fast (12 h) (‘Control’) and (2) After an overnight fast with an intravenous GH bolus (0.005 mg/kg) (‘GH bolus’). Each study day consisted of a 4-h basal period (t = 0 – t = 240 min) followed by a 2-h hyperinsulinemic, euglycemic clamp (HEC). GH was injected at t = 0 and biopsies from muscle and fat were drawn. Muscle and fat biopsies were taken at t = 60 min.

Results
Spontaneous serum GH levels were lower in obese subjects, whereas the PK of the GH bolus was comparable. The GH bolus was associated with a BMI-independent increase in STAT5b phosphorylation and CISH mRNA transcription in muscle and adipose tissue. The GH bolus, however, produced a larger relative increase in serum IGF-I levels in obese subjects (P < 0.01). GH acutely stimulated lipolysis (AFPA in serum, serum palmitate levels and fluxes) to the same extent in both groups. GH significantly reduced glucose uptake during the HEC in both groups (P = 0.23), but GH only antagonized insulin-induced suppression of endogenous glucose production (EGP) in the obese (P = 0.01).

Conclusions
(1) Acute GH exposure induces pSTAT5b and CISH mRNA and transcription in fat and muscle, and lipolysis to the same extent in obese and lean subjects. (2) A GH-induced relative increase in serum IGF-I levels and suppression of EGP was only recorded in the obese. (3) Our data thus suggest increased hepatic sensitivity to GH in obesity, which in turn may contribute to the blunted endogenous GH secretion.

Insulin signaling is involved in the regulation of UCP-1 expression in brown adipose tissue after chronic central leptin infusion

Vicente Barrios1, Laura M. Frago1, Sandra Canelles1, Emma Burgos-Ramos2, Julie A. Chowen1 & Jesús Argente1
1Department of Endocrinology, Hospital Infantil Universitario Niño Jesús, Instituto de Investigación La Princesa and CIBERobn, Instituto de Salud Carlos III, Madrid, Spain; 2Facultad de Ciencias Ambientales y Bioquímica, Universidad Castilla-La Mancha, Toledo, Spain.

Background
Brown adipose tissue (BAT) plays a pivotal role in the regulation of energy homeostasis and thermogenesis. This tissue responds to insulin, favoring the expression of uncoupling protein-1 (UCP-1), that in turn is inhibited by insulin-desensitizing cytokines. Leptin may abolish some of the effects of fasting on these parameters through its cross-talk with insulin-related signaling targets.

Objectives
We hypothesized that leptin infusion prevents UCP-1 depletion induced by food restriction through activation of insulin signaling in brown adipose tissue.

Methods
We studied 18 male Wistar rats divided into three groups: rats receiving saline icv (controls, C), those treated icv for 14 days with a daily dose of 12 µg of leptin (L) and a pair-fed group (PF) that received the same food amount consumed by L. We analyzed relative mRNA levels of UCP-1 and glucose transporter 4 (GLUT4) by real-time PCR and changes in the cytokine levels and activation of insulin-related signaling targets by multiplexed bead immunoassay.

Results
Relative UCP-1 mRNA levels were reduced in PF and unchanged in the L group. The mRNA levels of GLUT4 were increased in L rats, as well phosphorylation of insulin receptor substrate 1. Akt phosphorylation on threonine 308 was reduced in PF and increased in L. Among the studied cytokines, fractalkine and TNF-α were decreased in the L group, with no changes in PF rats.

Conclusion
Central leptin infusion could preserve UCP-1 expression in brown adipose tissue through activation of insulin-related signaling.

EP656

Can night eating syndrome increase basal metabolic rate?

Senay Topsakal, Guzun Fidan YaylaH & Sermin Melahat Fenkci
Endocrinology Department, Pamukkale University Medical Faculty Denizli, Turkey.

Introduction
Night eating syndrome (NES) is an eating disorder associated with obesity, characterized by a delayed pattern of food intake in which recurrent episodes of nocturnal eating and/or excessive food consumption occur after the evening meal. (1) Studies showed significant weight gain among patients with NES. However, the underlying reason is still controversial. The aim of this study is to investigate the body composition and energy metabolism in patients with NES.

Methods
Obese patients were divided into two groups according to the diagnostic criteria. Diagnostic criteria for NES include: (1) recurrent episodes of night eating, as manifested by eating after awakening from sleep or by excessive food consumption following the evening meal, (2) awareness of those eating episodes, and (3) significant distress or impairment caused by the disorder. Patients meeting these three criteria were considered NES(+), (2) 281 women and 46 men, (101 NES(+), 226 NES(−)) were included to study. Body mass index (BMI) and waist to hip ratio (WHR) were measured. Biochemical tests were performed. Total fat mass (FM), fat-free mass (FFM), Body water (BW), basal metabolic rate (BMR) were measured by Bioelectrical Impedance Analysis (BIA).

Results
BMI and WHR were similar in both groups. There were no significant differences in total cholesterol, triglyceride, LDL, HDL, ALT, GGT, fasting glucose, insulin levels, postprandial glucose and insulin levels. There were significant increase in BMR in patients with NES, and not significant differences in FM, FFM, BW.

Conclusion
BMR is the least amount of energy necessary for life. It accounts for 60–70% of total energy expenditure in sedentary man and hence forms the basis for human energy requirements. In this study, BMR was found high in patients with NES. Fat distribution was similar in both groups. There is no study that examines the effects of this syndrome on energy metabolism. There was a need for further work in this regard.

Association between cardiometabolic risk indicators and FGF 19 in healthy Saudi individuals of different BMI grades

Ghada Ajabnoor1,2, Yomna Hajjar2,3, Suhad Bahijri1,2 & Anwar Borai2,4
1Department of Clinical Biochemistry, Faculty of Medicine, King Abdulaziz University, Jeddah, Saudi Arabia; 2Saudi Diabetes Study Research Group, King Fahd Medical Research Center, King Abdulaziz University, Jeddah, Saudi Arabia; 3Postgraduate Student, Department of Clinical Biochemistry, Faculty of Medicine, King Abdulaziz University, Jeddah, Saudi Arabia; 4King Abdullah International Medical Research Center (KAIMRC), College of Medicine, King Saud Bin Abdulaziz University for Health Sciences (KSAU-HS), Jeddah, Saudi Arabia.

Background
Fibroblast growth factor 19 (FGF19) is an enterokine derived from the ileum, and synthesized in response to release of bile acids following food ingestion. It was proposed to be an important regulator of the postprandial adaptive metabolic response, by stimulating glycogen and protein synthesis in the liver, and down regulating glucose production after a meal. There is limited research investigating the association between FG-19 and metabolic dysregulation in overweight and obese Saudi subjects.
Aim
To study association of circulating FGF 19 in healthy individuals of different BMI grades, with some cardiometabolic risk indicators.

Subjects and methods
Healthy adults aged 19–36 years were recruited. Height, and weight were measured to calculate body mass index (BMI). Sixty males and 60 females were included in the study, divided equally between BMI categories (underweight, normal, overweight and obese). Waist, hip, and neck circumference (WC, HC, NC) were measured. Glucose, total cholesterol, triglycerides, high-density lipoprotein cholesterol (HDL-C), insulin, FGF19 and highly sensitive CRP (hs-CRP) were estimated in fasting serum samples, and low-density lipoprotein cholesterol (LDL-C), Atherogenic index of plasma (AIP), and homeostatic model assessment-insulin resistance (HOMA-IR) were calculated.

Results
No significant correlation (P = 0.457), or difference in means of FGF19 was noted between different BMI categories (P = 0.905). A negative significant correlation was found between FGF19 and WC, NC, and LDL-C; HDL-C ratio (r = −0.203, P = 0.027, r = −0.297, P = 0.002, r = −0.187, P = 0.041 respectively).

Conclusions
Serum FGF19 levels do not appear to be related to general obesity expressed as BMI. However, it was found to be associated negatively with indicators of abdominal, and upper torso obesity, reported to be associated with increased cardiometabolic risk, indicating the relationship of FGF19 with this risk. The strong correlation between FGF19 and serum LDL-C:HDL-C; a well established indicator of cardiometabolic risk; validate the link further.

EP658
The role of pioglitazone and vitamin E for the treatment of NASH with or without metabolic syndrome
Nino Khabeishvili, Gocha Barbakadze, Ketevan Mikadze & Koba Burnadze
Clinic “Emmedic”, Tbilisi, Georgia.

Introduction
Obesity is a global public health problem and is associated with metabolic syndrome and dyslipidemia as well as very often with non-alcoholic steatohepatitits (NASH).

Aim & methods
The aim of the present study was to evaluate the preventive and curable role of vitamin E and pioglitazone (thiazolidinedione-type) in NASH patients with or without metabolic syndrome. 51 patients with NASH were divided into two groups: 26 patients with insulin-resistance (IR) plus obesity and 24 patients without IR. 12 patients from 1-st group (another 14 patients from this group served as a control subgroup) and 12 patients from 2-nd group were treated at least during 3 months with vitamin E (500–1000 mg daily) plus pioglitazone 15–30 mg/d (another 13 patients – control subgroup) as well as put on the low-fat diet. Gender distribution of the patients was equal in each subgroup (26 male, 25 female). Mean age was 46.6±1.6 years. Mean BMI (body mass index) – 34.6±4.1 kg/m². HOMA-IR of patients from 1-st group was 2.7±0.8.

Results
The concentration of the serum aspartate aminotransferase (AST), alanine aminotransferase (ALT) levels (P<0.01) as well as cholesterol and triglycerides (P<0.05) were found to be higher in the both subgroups without pointed treatment. HDL level, however, was comparable in both groups (P>0.05). Results also indicated that this therapy reduced BMI (P<0.05) and HOMA-index (P<0.05) in both subgroups.

Conclusions
Insulin resistance appears to be the underlying pathophysiological defect leading to NASH. The data from this study demonstrate the possible mechanism by which pioglitazone and vitamin E mediate their beneficial clinical and metabolic effects in patients with NASH. To prevent this condition is to maintain a healthy diet and rigorous exercise regimen.

EP659
MicroRNAs, associated with coronary heart disease in patients with obesity and diabetes mellitus type 2
Teona Shvangiradze1, Irima Bondarenko1, Ekaterina Troshina1 & Marina Shestakova1,2
1Endocrinology Research Centre, Moscow, Russia; 2I.M. Sechenov’s First Moscow State Medical University, Moscow, Russia.

Introduction
Obesity and diabetes mellitus type 2 (T2DM) are considered as one of the major risk factor for coronary heart disease (CHD) development, but the mechanisms beyond this relationship still need to be clarified. miRNAs are supposed to be involved in regulatory mechanisms in this relationship.

Aim
To determine miRNAs expression in patients with obesity and T2DM.

Methods
MiRNAs were detected in peripheral blood of 43 patients, aged 48–65 years with obesity and T2DM. Patients were divided in two groups: 1st group – 21 patients with CHD, 2nd group – 22 patients with excluded CHD after Tredmil-Test. All patients from the 1st group underwent coronary angiography (CAG).

Results
Nine CHD-related miRNAs were selected as candidates for the investigation: miRNA-1, miRNA-21, miRNA-26a, miRNA-27a, miRNA-33a, miRNA-33b, miRNA-133a, miRNA-133b and miRNA-208. Expressions of these miRNAs were compared in studied groups. Expression of miRNA-21 (3.44 vs. 0.37; P = 0.0007) and miRNA-27a (0.86 vs. 0.31; P = 0.015) in patients with CHD were higher than that in 2nd group, while expression of miRNA-26a (1.06 vs. 2.14; P = 0.022) was lower in patients with CHD. Spearman correlation analyses showed that miRNA26a was positively associated with cholesterol level (r = 0.316, P = 0.042). MiRNA-21 and miRNA-27a were negatively correlated with HbA1c in both groups (r = −0.363, P = 0.042 and r = −0.420, P = 0.036, respectively). MiRNA-208 was positively correlated with hypertrophy of the interventricular septum (r = 0.61, P = 0.027) and number of significantly affected coronary vessels according to CAG (r = 0.65, P = 0.034), negatively - with left ventricular diastolic dimension (r = −0.52, P = 0.029).

Conclusions
1) Expression of miRNA-21 was increased by 9 times, miRNA-27a in 2.5 times in patients with CHD, while miRNA26a compared with patients with type 2 diabetes and obesity was lower in 2 times.
2) We revealed correlations of miRNA-208, 27a, 21 with pathological angiogenesis, and heart remodeling processes in patients with obesity and T2DM.
3) Increased expression of miRNA-208 can determine the severity of cardiovascular disease in patients with obesity and T2DM.

EP660
The surgical approach to obesity in numbers
Nuno Cordeiro Raposo, Andreia Sousa Ferreira, Sónia Pratas & Cristina Valadas
Hospital Beatriz Ángelo, Loures, Portugal.

The prevalence of obesity has greatly increased worldwide in the last decades, particularly in Europe and Portugal. It is associated with many health problems, including cardiovascular diseases, cancer and diabetes.

Methods
Revision of the clinical records of all 61 patients who underwent bariatric surgery between 2013 and 2015. Analysis of their metabolic profile prior to surgery and its evolution after the operation.

Results
61 patients were reviewed, namely 90.2% females and 9.8% males. The mean age was 43.6 years. All patients had class II or III obesity according to their BMI, with an average score of 46.4 kg/m². The associated cardiovascular risk factors include: hypertension (47.5%), total cholesterol >200 mg/dl (35.8%) and type 2 diabetes mellitus (16.6%). 60% had an apnea-hypopnea index greater than 5/h. Most patients underwent gastric sleeve surgery (93.4%) and only 6.6% received a bypass surgery. Six patients were treated with an endoscopic intragastric balloon prior to surgery. Weight was evaluated at 3 months’ intervals in the first 1.5 years, and then every 6 months. 13.6 months was the mean follow-up time after the procedure. The average weight loss prior to surgery was 9.6% of the initial body weight. After the operation, weight loss was more pronounced between the first and third months (7.4% of the initial body weight). The trend of weight loss remained until 9 months, stabilizing afterwards. The mean BMI reduction was 27.1% at the end of the follow-up time. Both HbA1c and triglycerides were reduced by 11% and 15%, respectively, after surgery. HDL increased by 16%.

Conclusions
The majority of patients eligible for bariatric surgery were young females with class II or III obesity. Many had other cardiovascular risk factors, particularly hypertension and dyslipidemia. Gastric sleeve was the preferred technical procedure and only a few patients received an endoscopic intragastric balloon to aid weight loss prior to surgery. Weight loss was more pronounced in the first 3 months after surgery, but that tendency was mitigated after only 9 months.

Decreased HDL cholesterol efflux capacity in morbidly obese individuals as a surrogate marker for increased cardiovascular risk
Idit Dotan1-2, Anouar Haflane3, Isauelle Ruel1, Rajesh Aggarwal1, Amin Andalib1, Jacques Genest1-2 & Mark Sherman1-2
1McGill University Health Center, Montreal, Quebec, Canada; 2Research Institute of the McGill University Health Center, Montreal, Quebec, Canada.

Background
Obesity has become a worldwide epidemic and carries excess cardiovascular morbidity and mortality. HDL efflux capacity (HEC), shown to be inversely correlated with cardiovascular risk (CVR), both in the acute and the chronic phases. Our aim was to understand if decreased HEC can serve as a surrogate marker for increased CVR in this population.

Methods
Forty patients: 10 obese diabetic (OD), 10 obese non-diabetic (OND), 10 with stable Coronary Artery Disease (sCAD) and 10 healthy controls were blindly selected from another cohort and their HECs were studied using radioactive cell-based assays.

Results
The mean age of the cohort was 50±12 years, 72.5% men. Mean BMI for the obese groups was 46.8±7.03 kg/m² for the sCAD group 27.2±3.3 kg/m² and for the controls 24.2±2.26 kg/m². Mean HEC (adjusted to ApoA1 mass) was 14.18±0.95% for the OD group, 14.73±3.18% for the OND group, 19.11±1.6% for the sCAD group and 16.01±1.6% for the controls. A linear regression analysis was significant between HEC and TG, while BMI was not significantly lower in obese or sCAD groups compared to controls.

Discussion
In the current study, we found that morbidly obese individuals have significantly lower HEC in comparison to controls. Given that HEC has an inverse correlation with CVR, these findings may explain, at least in part, the increased CVR in morbidly obese patients. It is unclear if bariatric surgery improves HEC, but it is reasonable to speculate it does, given the other metabolic effects the surgery exerts.

Conclusion
HDL function is compromised in morbidly obese individuals and contributes to progressive atherosclerosis and increased CVR in this population. If HEC does improve post-metabolic surgery, decreased HEC might serve as another indicator for bariatric surgery.

The association of anthropometric measurements and PPAR-γ gene expression among healthy adult subjects
Maryam Zarkesh1, Emad Yuzbashian2, Azita Zadeh-Vakili2, Kimia Tabaei3, Afsoun Daneshfazroo1, Golaleh Asghari2, Parvin Mirmiran1, Mehdi Hedayati4 & Alireza Khalaj4
1Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; 2Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; 3School of Advanced Sciences in Medicine, Tehran Medical Sciences Branch, Islamic Azad University, Tehran, Iran; 4Tehran Obesity Treatment Center, Department of Surgery, Shahed University, Tehran, Iran.

Introduction
Peroxisome proliferator activated receptor-γ (PPAR-γ) is a distinguished transcription factor abundantly expressed in the adipose tissues and plays a key role in the regulation of adipocyte differentiation and development of obesity. In the current study, we aimed to investigate the association of PPAR-γ mRNA expression in omental and subcutaneous adipose tissues with anthropometric indices and blood pressure (BP) among healthy adults.

Methods
97 subjects (41 non-obese, 18 obese, and 38 morbid obese) were eligible for the study. Omental and subcutaneous adipose tissues were obtained during open abdominal surgery. The PPAR-γ mRNA level was evaluated in omental and subcutaneous adipose tissues using Real-Time PCR assay. Height, weight, BMI, waist, hip, and neck circumferences, and BP were determined according to standard protocols.

Results
The mean of BMI was 24.8, 34.9, and 46.8 kg/m² in morbid obese, obese and non-obese subjects, respectively. PPAR-γ gene expression was not significantly different between omental and subcutaneous adipose tissues in each group. However, PPAR-γ mRNA expression was down-regulated in omental adipose tissues of non-obese and obese subjects compared to subcutaneous subjects and up-regulated compared to morbid obese ones (P<0.05). Among morbid obese subjects, diastolic and systolic blood pressures were positively correlated with omental PPAR-γ expression (r=0.409, P=0.020 and r=0.371, P=0.037, respectively); waist and neck circumferences were positively correlated with both adipose tissues (P<0.05). Among obese subjects, PPAR-γ expression in both tissues had significant positive correlation with waist circumference (P<0.05).

Conclusion
Our study suggested that several obesity-related indices have a positive correlation with PPAR-γ expression in omental and subcutaneous adipose tissues.

Results of computer-assisted intravital microscopy in overweight and obesity
Volha Shyshko1, Tatjana Mokhort1, Elena Konstantinova2 & Natalia Tsapaeva3
1Belarusian State Medical University, Minsk, Belarus; 2Institute of Heat and Mass Transver, National Academy of Science, Minsk, Belarus.

Rationale
Obesity, prediabetes and diabetes are strongly associated with microcirculation abnormalities. It is known that pathological changes in microvessels predispose to CHD, CKD and retinopathy. Also it is widely recognized that biochemical and immunological changes accompanied with obesity and overweight lead to MC damage.

Objective
The study was to assess changes in MC in patients with obesity and overweight. Materials and methods
Computer-assisted intravital microscopy (CAIM) was used to assess intra- (six scores) and extra- (three scores) and vascular (11 scores) changes of bulbar conjunctiva and vascular indexes were calculated. We included 91 patients with overweight (group 1), 103 patients with obesity (group 2) both with concomitant prediabetes and diabetes and 58 almost healthy person (group 3).

Results
Overweight and obesity are characterized by progressive changes in MC. A significant difference was observed in perivascular edema in patients with overweight (0.5 (0.0;1.0) compared to patients with obesity (1.5 (0.5;1.0) (P1–2=0.025, P2–3=0.012) compared to group 3. There were no any significant intravascular changes between groups. Vascular changes included equality in vessels size (1.0 (1.0;1.0) in groups 1 and 2 vs 1.0 (0.0;1.0) in group 3) P1–2=0.012, P2–3=0.010), meanedous tortuosity of venules (1.0 (0.0;1.0) in groups 1 and 2 vs 0.0 (0.0;1.0) in group 3) P1–2=0.002, P2–3=0.001) and meanedous tortuosity of capillaries (0.0 (0.0;0.1) in groups 1 and 2 vs 0.0 (0.0;0.1) in group 3) P1–2=0.001, P2–3=0.004. Calculating of partial vascular indexes and total vascular index optimizes results of CAIM. Vascular index was significant higher in patients with overweight (1.0 (0.0;1.10) compared to patients with obesity (1.0 (0.0;1.10) (P1–2=0.001, P2–3=0.001).

Conclusion
Overweight and obesity are associated with MC abnormalities and mostly expressed in extra and vascular changes. Use of partial and total vascular indexes optimizes evaluation of MC changes.

DOI: 10.1530/endoabs.49.EP663
PCOS is characterized by abdominal obesity along with conventional diagnostic features.

Objective
To assess body composition in women with PCOS and normal body weight.

Materials and methods
35 women (24 ± 1.1 years old) with confirmed diagnosis of PCOS according to Rotterdam criteria, 27 almost healthy women (25 ± 1.2 years old), both groups wore normal weight. Whole Body Dual-energy X-ray Absorptiometry (DEXA Total Body) scans were carried out using ‘Prodigy Lunar’ machine (USA).

Results
Registered differences included increase of total fat accumulation, fat accumulation in android compartments as well as android-gynoid fat ratio index. Basic anthropometric measurements and DEXA of patients with PCOS and control group. 29 (82.86%) patients in study group demonstrated significantly higher waist circumference (77.1 ± 11.2 cm) and higher percentage of adipose tissue in android area (37.9 ± 3.0%) correspondingly compared to control group ($R = 0.846176$ at $P < 0.05$).

Conclusion
Abdominal fat accumulation is attributable to patients with PCOS. Lack of significant differences between BMI and total fat accumulation is apparently explained by age, dietary habits, patient’s disease awareness as well as reasonable lifestyle modification and physical exercises modification.

**Decreased muscle strength is associated with vitamin D and albumin levels after bariatric surgery**

Dilek Gogas Yavuz & Melilha Melin Uygur
Marmara University School of Medicine Section of Endocrinology and Metabolism, Istanbul, Turkey.

Bariatric surgery patients are at risk of decreasing in muscle mass, vitamin and protein deficiency. The aim of this study is to assess muscle strength, serum protein and vitamin levels after bariatric surgery.

Methods
264 patients underwent bariatric surgery who completed 6 th month polyclinic visits were included in the study. Patients were followed appropriately supplemented protein and vitamins as suggested; all study parameters were assessed before and after 3rd. mo. and 6th mo. of bariatric surgery. Handgrip dynamometry was used to measure static muscle strength. Serum Albumin, 25OH vitamin D (25OHD), Vitamin B12, ferritin and creatinine levels were measured by immuno-chemiluminescence method.

Results
Postoperatively, all patients showed a significant decrease in the BMI in 3 mo and 6 mo compared to preoperative levels ($P<0.0001$). Biochemical measurements are shown in Table 1. Serum ferritin and, creatinine levels were in reference range and not change during the follow-up. In a multivariate regression model showed that 25OHD D and creatinine levels were independent risk factor for muscle strength ($r^2=0.0152$, $P<0.0001$). Serum albumin and handgrip measurements showed a positive correlation ($r=0.23$, $P<0.001$).

Introduction
Non-alcoholic fatty liver disease (NAFLD) is an emerging disease in Mexico, comprising a spectrum of histopathological findings ranging from simple steatosis to steatohepatitis and cirrhosis. The gold standard continues to be the liver biopsy, but several mathematical indices have been proposed, such as non-invasive techniques, however there are very few studies in our population.

Objective
This study aims to compare mathematical indices and histopathological findings for the detection of NAFLD in Mexican population.

Methods
A cross-sectional study was performed at the ‘Hospital General Leon’ between November 2016 and January 2017. Patients aged 18 years or above that underwent laparoscopic cholecystectomy were recruited. No history of alcohol consumption habit or hepatic diseases characterized the patients. The fatty liver index (FLI) and the lipid accumulation product (LAP) were calculated. Demographics, blood samples, and a liver biopsy were obtained. Results between FLI, LAP and livery biopsy were compared.

Results
A total of 59 patients were included (80.1% women and 19.9% men). The mean age was 39.6 ± 14.8 years. BMI 29.7 ± 10.11 kg/m². The FLI identified 31 patients with NAFLD of which 11 were corroborated with biopsy, whereas the LAP identified 26 patients of which 17 were corroborated with biopsy. From the patients with negative FLI index (n=26), a total of 11 (42%) were diagnosed with steatosis by histopathology. For LAP, 31 patients (54.3%) were negative, four of which (7.01%) presented positive for NAFLD by histopathological diagnosis.

Conclusion
According to our results, at least in our population these two mathematical indices are not useful for the diagnosis of NAFLD, so liver biopsy remains to be the gold standard for the detection of NAFLD. Future studies should be performed in order to continue looking for other non-invasive markers for NAFLD.

Obesity and infertility among Tunisian women of reproductive age: about 40 cases
Fatene Hadjikacem1, Mariem Rebai2, Dahla Saidane2, Dorra Ghorbel1, Mohamed Ahi1
1Department of Endocrinology and Diabetology of Hedi Chaker Hospital, Sfax, Tunisia; 2Faculté de Pharmacie, Monastir, Tunisia.

Obesity is on the increase worldwide and mainly in women of reproductive age. In turn, it is associated with various reproductive complications. To assess the detrimental effect of obesity on reproductive health and the means of its management, this retrospective cohort study of 40 obese and infertile women has been conducted in the department of endocrinology and diabetology of Hedi Chaker hospital in Sfax-Tunisia from 2009 to 2014. These patients have a mean age of 34 years and a mean BMI of 37.29 kg/m². They were to suffer from infertility for a mean period of 5.7 years. The polycystic ovary syndrome was the most common cause of infertility diagnosed in 52.5%. Classic morbidities of obesity were dominated by metabolic (52.5%) and cardiovascular (37.5%) complications. Ovulation disorders were identified in 77.5% of cases and serious complications during pregnancy were observed. These complications affect the obese mother as well as the child: abortions (52.5%), delivery by caesarean section (35%), gestational diabetes (20%), foetal malformation (12.5%), neonatal death (7.5%). Though the management of the combination of obesity and infertility was quite difficult, a weight loss of 5–8% has resolved 61.2% of menstrual irregularities and improves the chances of pregnancy in 20% of cases. Insulin resistance and hyperleptinemia are the main mechanisms linking obesity to infertility. Thus the establishment of a healthy lifestyle since a young age is the best therapeutic solution for obesity-induced infertility. Obese women have a higher prevalence of infertility, maternal morbidity, mortality and foetal anomalies. For these reasons it’s necessary to raise the public awareness on the detrimental effects of obesity on reproductive health.

Mindfulness-oriented weight management course in a tier 3/tier 4 obesity service
Peta Hanson, Louise Halder & Thomas Barber
University Hospital of Coventry and Warwickshire, Coventry, UK.

Overeating contributes to obesity epidemic and has many causes. Evidence shows that problematic eating behaviours can be modulated with mindfulness. In the UK the use of mindfulness in management of obesity has been studied only once before. We aimed to pilot a new weight management course that would improve patients’ skills and confidence in ability to lose weight, and reduce patient waiting time. The course covered mindful eating, compassion and self-esteem, managing relapses and weight loss orientated marketing. Four interactive sessions were delivered by dietitians and psychologists over 8 weeks, resulting in frequent contact with participants. Patients were invited to participate in this course following their first appointment, and received normal follow-up regardless of their participation. Ten patients were included in the final analysis. Anonymized feedback and eating style questionnaires were collected before and after the course. The average weight and age were 120 kg and 45 respectively, and eight were women. 90% of patients lost weight (0.4–5 kg). Average weight loss was 1.54 kg. Patients were seen more frequently in the initial phase of their treatment pathway, leading to improved experience. 30% of participants heard of mindful eating prior to our course, with 90% finding it a useful concept for weight management on completion. Patients became more confident, compassionate and felt more in control. Eating styles were assessed by a validated questionnaire. Paired t-test was applied to analyse results. Statistically significant improvement (P=0.001) was found in emotional eating (P=0.001), food fretting (P=0.022), unappetizing atmosphere (P=0.042) and overall eating style (P=0.017). This holistic course equipped patients with new skills to change eating behaviours, coping strategies and changed their mindset and will be incorporated into the standard service for all bariatric patients. However, the results of this project have global implications as management of obesity should incorporate holistic approach and utilize mindfulness in future.

Menopause is a major determinant of endocannabinoid 2-arachidonoylglycerol plasma level and of its relevance as biomarker of dyslipidemia and insulin resistance in lean women
Flaminia Fanelli, Marco Mezzullo, Margherita Baccini, Elena Casadio, Daniela Ibarra Gasparini, Valentina Vicennati, Renato Pasquali & Uberto Pagotto
Endocrinology Unit and Center for Applied Biomedical Research Department of Clinical and Surgical Science, University of Bologna, S.Orosia-Malpighi Hospital, Bologna, Italy.

Context

The endocannabinoid system (ECS) hypertycocity contributes to obesity development and maintenance. Excess circulating levels of ECS mediator 2-arachidonoylglycerol (2AG) were reported in obese humans, however, unstandardized experimental settings (i.e. analytical conditions, sample size, concurrent diseases/medications, statistics, gender, body mass index (BMI) and age), clouded its role in dysmetabolism and its usefulness as biomarker. The study aimed at describing 2AG associations with visceral obesity, dyslipidaemia, insulin resistance and hypetension in females according to BMI and menopausal status.

Methods

Adult, unmedicated, disease-free premenopausal (preMP, n=103) and meno-

pausal (MP, n=81) females were stratified in normal weight (NW, BMI 18.5–

24.9 kg/m²), overweight (OW, BMI: 25.0–29.9 kg/m²) and obese (BMI ≥ 30.0 kg/m²) classes. Plasma 2AG, anthropometric and metabolic parameters were assessed.

Results

Menopause (P<0.001) and BMI (P=0.001) independently increased 2AG levels. NW (P=0.001) and OW (P<0.001), but not OB, MP women, displayed higher 2AG than preMP counterparts. 2AG increased with BMI in preMP (P<0.001), but not in MP cohort. 2AG displayed BMI-independent relationships with triglycerides in both preMP (P=0.006) and MP (P=0.005) and with glucose in MP (P=0.036). When analyzed within preMP BMI classes, only in OB class 2AG significantly associated with total cholesterol (TC, P=0.040) and triglycerides (P=0.020). In MP cohort, 2AG associated with TC (P=0.006), glucose (P<0.001), HOMA-IR (P=0.035) and triglycerides (P=0.001) within NW, with triglycerides in OW (P=0.034) and with none of the parameters in OB class. Moreover, increasing BMI significantly reduced 2AG associations with TC (P=0.037) and glucose (P=0.002) in MP cohort, while 2AG associations with TC, glucose and HOMA-IR significantly distinguished NW MP from NW preMP women (P=0.036, P=0.005 and P=0.027, respectively). No 2AG associations were found with waist circumference and blood pressures.

Conclusions

Plasma 2AG is a valuable biomarker of clustering insulin resistance and dyslipidemia in lean menopausal women, and may play a causative role in menopause-related metabolic worsening.

Genetical predictors of neuroendocrine disturbances in children with severe obesity
Anzhalka Solntsava1, Olga Zagrebaeva1, Elena Aksyonova2, Tatsiana Shatarnova2 & Tatsiana Yemelyantsava3
1Belarusian State Medical University, Minsk, Belarus; 2Institute of Genetics and Cytology of NAS of Belarus, Minsk, Belarus; 3Republican Research and Practice Center for Mental Health, Minsk, Belarus.

Objectives

Neurogenetical predictors of psychological disturbances in children with severe obesity.

Methods

We examined 254 pubertal obese children: group1 (simple obesity) 187 children, 14.3±2.0 yrs, 30.4±2.8 kg/m²; group2 (severe obesity) 67 children, 14.7±2.1, 39.1±3.8. Control 80 children, 14.4±2.0 yrs, 19.7±1.7 kg/m². Dopamine levels were determined. Genotyping was performed on polymorphic genes COMT, MAOA, A1 Tag 1A allele of DRD2/ANKK1 polymorphism (rs1800497).

Results

A statistically significant difference between dopamine levels were in patients with simple (8.84±4.70) and severe obesity (48.8±9.30). GA genotype (P=0.05). We found the significant increasing of dopamine levels (82.5 (61.3; 116.3)) in boys with severe obesity and 3-3 MAOA genotype comparison.

EP671
Endocannabinoid 2-arachidonoylglycerol plasma level is a BMI-independent biomarker of cardiometabolic risk in adult males with higher prevalence of lean and aged conditions
Flaminia Fanelli, Marco Mezzullo, Margherita Baccini, Elena Casadio, Daniela Ibarra Gasparini, Valentina Vicennati, Renato Pasquali & Uberto Pagotto
Endocrinology Unit and Center for Applied Biomedical Research

Context
Ageing and obesity are similarly characterized by metabolic impairment in terms of visceral fat, dyslipidemia, insulin resistance and hypertension. Obesity is featured by endocannabinoid system (ECS) hyperactivation. Increased levels of endocannabinoid 2-arachidonoylglycerol (2AG) found in obesity were variously associated to dysmetabolic features, however, it is not clear whether such associations exist in normal weight conditions. Moreover, ageing contribute in modulating 2AG tone and involvement in worsening metabolic profiles was not addressed. The study aimed at defining 2AG relevance as BMI-independent biomarker of metabolic impairment in males and whether its relevance is modulated by ageing.

Methods
Unmedicated, disease-free male volunteers (n = 144) aged 18-84y were stratified in normal weight (NW, BMI:18.5–24.9 kg/m², n = 61), overweight (OW; BMI: 25.0–29.9 kg/m², n = 61) and obese (BMI ≥ 30.0 kg/m², n = 22) classes. Plasma 2AG, anthropometric and metabolic parameters were assessed.

Results
Age did not influence 2AG levels in the overall cohort nor within BMI classes. 2AG levels increased with BMI (P = 0.019), however, significance was lost after adjustment for each metabolic parameter. 2AG displayed age- and BMI-independent positive relationships with SBP (P = 0.020), insulin (P = 0.011), HOMA-IR (P = 0.006), total cholesterol (P = 0.001) and triglycerides (P < 0.001) and negative with HDL-cholesterol (P = 0.046). 2AG correlation with triglycerides was confirmed in each BMI class (NW and OW: P < 0.001; OB: P = 0.029). Positive 2AG correlation was found with SBP (P = 0.023) and DBP (P = 0.048) within OB, and with total cholesterol within OW (P < 0.001) class. Finally, within the NW class, 2AG negatively associated with HDL-cholesterol (P = 0.004) and positively with glucose (P = 0.015), insulin (P = 0.003) and HOMA-IR (P = 0.001); notably, the last two correlations were positively influenced by age (both P = 0.044). No associations were detected between 2AG and waist circumference.

Conclusions
Plasma 2AG is a valuable biomarker of clustering hypertension, insulin resistance and dyslipidemia in male gender. Results in lean males may suggest a causative role for 2AG in age-related insulin resistance.

Unfavourable blood pressure and lipid levels in obese individuals from the general population
Bruce Wolfenbuttel, Sandra Slagter, Robert van Waateringe, Jana van Vliet-Ostapchouk, André van Beek & Melanie van der Klauw
Univ Med Ctr Groningen, Groningen, The Netherlands.

Background
Early diagnosis and treatment of high blood pressure (BP) and high cholesterol is important to reduce cardiovascular mortality risk.

Methods
We assessed actual BP and LDL-cholesterol (LDL-C) levels in 88,029 participants (36,122 men, aged 18-80 yrs, without diabetes, from the Dutch Lifelines Cohort study. Participants were categorized according to degree of obesity (normal weight, overweight, obese) and age decade group. BP measurement was rigorously standardized. Mean systolic and diastolic BP were calculated depending on BP-treatment status for the three BMI classes, and for each age group. We repeated these evaluations for LDL-C levels.

Results
In total, 13.3% of men and 15.6% of women were obese. BP increased gradually in each age group, with mean levels of 124/68 mmHg in the youngest and 142/77 mmHg in the oldest male participants, and was significantly higher in obese vs. non-obese and overweight individuals in all age groups (P < 0.01). The largest difference (10-11 mmHg) between obese and non-obese was observed in males below 50 yrs. Despite the use of BP-lowering medication (5.1-6.2% in non-obese, 21% in obese), still 20-50% had elevated systolic BP ≥ 140 mmHg. Overall mean LDL-C was 3.5 ± 0.9 mmol/l in obese vs. 3.2 ± 0.9 mmol/l in non-obese men (P < 0.001), and 3.3 ± 0.9 vs 2.9 ± 0.8 mmol/l in women (P < 0.001). More untreated obese than non-obese participants had an LDL-C ≥ 5.5 mmol/l (men: 56% vs 37%, women: 41% vs 24%, both P < 0.001). Only 37% of obese men and 28% of obese women treated with statins reached an LDL-C target < 2.5 mmol/l. A small percentage of obese individuals treated with BP-lowering drugs also were using statins (33% in men, 16% in women).

Conclusions
Obese individuals have higher BP and LDL-C compared to non-obese, and especially obese men younger than 50 yrs have elevated BP levels. There is considerable undertreatment of elevated BP and elevated LDL-C in the general population.

DO: 10.1530/endoabs.49.EP672

EP673
Relation of insulin resistance to neurocognitive function and electroencephalography in obese children
Onur Akın, Ibrahim Eker, Mutfuay Arslan, Süleyman Tolga Yavuz, Sevil Akman, Mehmet Emre Taşçılar & Bülent Ünay
Güllhane Education and Research Hospital, Ankara, Turkey.

Background
Obese children have higher BP and LDL-C compared to non-obese, and especially obese men younger than 50 yrs have elevated BP levels. There is considerable undertreatment of elevated BP and elevated LDL-C in the general population.

Conclusions
Obese children have higher BP and LDL-C compared to non-obese, and especially obese men younger than 50 yrs have elevated BP levels. There is considerable undertreatment of elevated BP and elevated LDL-C in the general population.

Lipid profiles and vitamin D receptor polymorphisms in overweight/obese dialysis patients
Gokhan Bagci1, Can Huzmeli2, Binnrn Bagci3, Ferhan Candan4, Lale Akkaya5 & Mansur Kayatas2
1Cumhuriyet University, Medical Biochemistry, Sivas, Turkey; 2Cumhuriyet University, Medical Biochemistry, Sivas, Turkey; 3Cumhuriyet University, Nephrology, Sivas, Turkey; 4Cumhuriyet University, Nutrition and Dietetics, Sivas, Turkey.

Background
Vitamin D receptor (VDR) is present on adipocytes, and many studies were carried out to investigate the association between single nucleotide polymorphisms (SNPs) in VDR gene with obesity. However, little is known about the role of VDR gene polymorphism with obesity in dialysis patients. Therefore, we aimed to investigate lipid profile and VDR gene TaqI, ApaI and FokI SNPs in overweight/obese dialysis patients.

Methods
Seventy one normal weight and 68 overweight/obese patients were included in study. PCR-RFLP method was used for genotyping.

Results
For all three SNPs, no significant association was found between normal and overweight/obese patients (P>0.05). The level of LDL, total cholesterol and triglycerides was found significantly high, and HDL level was found significantly low in overweight/obese patients compared to normal weight patients (P<0.05).

In overweight/obese patients, patients carrying Apal CC genotype have higher triglyceride levels compared to AA and AC genotype (CC vs AA P=0.001; CC vs AC P<0.001) and CC = 627±653; AC = 193±85; AA = 233±156). No significant association was found between other SNPs and lipid profiles.

Conclusions
Our results suggest that Apal polymorphism are associated with high triglyceride levels in overweight/obese dialysis patients.

Bone mineral density and bone turnover markers after bariatric surgery
Meliha Melin Uyar1 & Dilek Gogas Yavuz
Marmara University School of Medicine, Endocrinology and Metabolism Disease Department, Istanbul, Turkey.

Although bariatric surgery has beneficial effects on obesity related complications, rapid weight loss might have negative effects on skeletal health. The objective of our study was to evaluate changes in bone mineral density (BMD) and bone biochemical markers in patients, before and 1 year after bariatric surgery.

Methods
One hundred and two morbidly obese subjects (mean 43±15 years, BMI 48.5±9.08 P<0.0001), serum CTX levels were significantly higher at 1 year (P<0.0001). Changes in calcium, PTH, 25 OH vitamin D, CTX and osteocalcin at baseline and first year of the surgery. Lumbar BMD was 1.284 versus 1.260 g/cm2 (P=0.32), femoral neck BMD was 1.034 versus 1.030 g/cm2 (P=0.85), before and after surgery, respectively. We didn’t find any correlation between BMI and BMD but there was a negative correlation between 25-OH D and PTH (r= −0.298 P=0.0003)

Effects of mediterranean diet in obese patients with metabolic syndrome and depression
Vesna Dimitrijevic-Sreckovic1,5, Hristina Janoski2, Branko Sreckovic3, Ivan Soldatovic4,3, Nevena Nesovic1 & Milica Vujovic3
1Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; 2University Children’s Hospital, Belgrade, Serbia; 3Clinical Center Bezanjicka Kosa, Belgrade, Serbia; 4Institute for Medical Statistics and Informatics, Belgrade, Serbia; 5Faculty of Medicine, Belgrade University, Belgrade, Serbia.

Introduction
Central obesity is the source of inflammatory factors, causing endothelial dysfunction. In central nervous system, inflammatory factors mediate neurotransmitter metabolism promoting excitotoxicity and increase oxidative stress, and a major clinical symptom is depression. Mediterranean diet (MD) resulted as a good prevention method for depression.

Aim
To examine the relationship of depression with abdominal obesity and metabolic syndrome (MS) criteria, blood pressure, lipids, glycaemia and inflammation factors. Analysing effects of MD on weight correction, abdominal obesity and consequence less score points in Hamilton scale for depression.

Methods
Study included 36 adolescents and youth (16–30 years) and 22 adults over 30 years, overweight and obese patients with MS, diagnosed with depression using Hamilton scale. MS was diagnosed using ATP III classification criteria. The following parameters were observed: BMI, waist circumference (WC), blood pressure, lipids, CRP and basal glycaemia and insulin. Seven day scheduled MD was used by patients.

Results
Correlation is found between Hamilton’s scale score and body weight, BMI, WC (P<0.01) and CRP (P<0.05) in adolescents and youth. Implementation of MD resulted in reduction of body weight and WC (P<0.05), Hamilton’s scale score (P<0.001), insulinemia, HOMA-IR and CRP (P<0.5). Hamilton’s scale and Hamilton’s scale score correlated with insulin (P<0.05) and glycaemia (P<0.05), basal insulin correlated with CRP (P<0.05). After MD values of Hamilton’s score, WC, insulin and CRP were lower (P>0.5).

Conclusions
Mediterranean diet resulted with reduced values of Hamilton’s scale score, waist circumference, insulinenia and CRP in patients with MS and depression. Positive correlation of Hamilton’s scale score with glycaemia and insulinenia suggest importance of insulin resistance and glucoregulation disorder on occurrence and stage of depression in obese patients with metabolic syndrome. CRP is useful marker for low grade inflammation in obese patients with MS, hence depression.

EP678
Visceral obesity in youth followed by decreased testosterone leading to erectile dysfunction and risk of early atherosclerosis
Vesna Dimitrijevic-Sreckovic1,5, Hristina Janoski2, Branko Sreckovic3, Ivan Soldatovic4,5, Milica Pajovic1 & Marko Stojanovic1
1Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; 2University Children’s Hospital, Belgrade, Serbia; 3Clinical Center Bezanjicka Kosa, Belgrade, Serbia; 4Institute for Medical Statistics and Informatics, Belgrade, Serbia; 5Faculty of Medicine, Belgrade University, Belgrade, Serbia.

Background
Abdominal obesity, which in fact is a metabolic syndrome (MS), is related to decreased testosterone, insulin resistance (IR), increased inflammatory factors,
non-alcoholic fat liver disease (NAFLD) and risk of early atherosclerosis. Elevated inflammatory markers (CRP) may interfere with insulin signal transduction at the neuronal level inducing hypogonadotropic hypogonadism.

Objective

To examine testosterone relationship with abdominol obesity, lipid status, blood pressure, IR and NAFLD in obese young males with pre-MS and MS.

Methods

The study included 52 obese male individuals with pre-MS or MS (age16–30) classified in two groups: I-with low testosterone <12.0 nmol/l; II-with testosterone ≥12.0 nmol/l. The following parameters were observed: waist circumference (WC), blood pressure, lipids, microalbuminuria, SGOT, SGPT and γ-GT were liver function parameters. ATP III classification was applied for diagnosing MS. Patients with less than three above criteria were considered pre-MS. IR was determined by HOMA IR. OGTT was used to evaluate glycoregulation disorder. Testosterone was determined by radioimunoassay.

Results

BMI: I-35.7 ± 35, II-33.0 ± 4.9 kg/m²; WC: I-117.3 ± 15.5, II-109.9 ± 14.2 cm; HDL: I-0.96 ± 0.18, II-1.04 ± 0.23 nmol/l; triglycerides: I-2.74 ± 1.6, II-1.8 ± 1.0 mmol/l; insulin 0’Ι-113.12, II-40.1 ± 61.2 IIU; insulin 30’Ι-199.8 ± 124.1124.1 ± 90 IIU; insulin 120’Ι-119.8 ± 114.4; BMI: 53.9 ± 70.8 IIU; HOMA IR: I-26.8 ± 31, II-9.1 ± 14 nmol/mU/ml; SGOT-I-50.5 ± 39.3, II-26.8 ± 7.8; SGPT-I-81.8 ± 48.2, II-40.2 ± 18.0 IIU; γ-GT-I-49.8 ± 19.3 IIU, II-39.7 ± 21.9 IIU; CRP-I: 5.2 ± 2.5, II: 5.25 ± 5.8 mg/l.

Correlations

Testosterone negative with body weight, BMI and WC (P < 0.05). Decreased testosterone (<12.0 nmol/l) was found in 13.5% obese young males (8.5 ± 2.6 mmol/l), with normal FSH, LH and estradiol. A statistically important difference between groups was found for 0, 30 and 120 minute insulin values (P < 0.05) and for liver function parameters SGOT and SGPT (P < 0.001).

Conclusion

Low testosterone is characterized by obesity, MS parameters, hyperinsulinism, IR and NAFLD. Negative correlation of testosterone with WC and statistical importance of insulinemia and liver function parameters differences confirm the important effect of visceral obesity and IR on the occurrence of erectile dysfunction, NAFLD and risk of early atherosclerosis in obese adolescents and youth.

**The prevalence of obesity and related factors: An urban survey study**

Ayla Gokmen Salıcı1, Pinar Sisman2, Özen Oz Gür3, Tugce Karayel4, Soner Cander1 & Canan Ersoy1

1Department of Internal Medicine, Usak State Hospital, Usak, Turkey; 2Department of Endocrinology, Kars State Hospital, Kars, Turkey; 3Department of Endocrinology and Metabolism, Uludag University Medical School, Bursa, Turkey; 4Department of Internal Medicine, Uludag University Medical School, Bursa, Turkey.

**Objectives**

Obesity is a chronic and progressive disease that limits physical activity, causes psychological problems, and finally leads to social isolation of the person. Detecting the factors affecting obesity and its prevalence in the population are important steps in dealing with the problem. In this study, we aimed to evaluate the obesity prevalence and the factors affecting this prevalence in randomly selected volunteers from the city of Bursa.

**Methods**

A questionnaire consisting of 40 questions evaluating the sociodemographic aspects, healthy nutrition and exercise habits and comorbidities of the subjects was performed face to face to 528 volunteers (414 females, 114 males) participating in our study. Height, weight, waist, hip, neck and wrist circumferences and random blood glucose levels were measured. BMI and waist to hip ratio were calculated for each participant.

**Results**

The mean age of the whole study population, female and male participants were 12.8, 40.2 ± 12.7 and 37.1 ± 12.9 years, respectively. According to BMI values 23.5% of the whole study population, 25.8% of females and 14.9% of males were obese. For the female subjects, the obesity prevalence was found to be increasing with age, being married, being housewife and having lunch at home and decreasing with higher education level and income. When we investigated the male subjects, the only factor related to and found to be increasing the obesity prevalence was having lunch at home.

**Conclusions**

Obesity is a worldwide problem. Its prevalence is increasing in our city and country. Education level of the subjects seems to be the most important factor in controlling body weight. It is possible to prevent most of the morbidities and mortality related to obesity by preventing weight gain. Every effort should be made to increase the level of education about healthy nutrition habits and importance of regular physical activity.

**Effect of Vitamin D supplementation on body composition in overweight men: A randomized controlled trial**

Christos Karayiakisth1,2, Anniailara Artander2, Stefan Sörnblad2, Peter Rask2 & Eva Rask2,3

1Department of Internal Medicine, Division of Endocrinology and Diabetes, Örebro University Hospital, Örebro, Sweden; 2Faculty of Medicine and Health, School of Health and Medical Sciences, Örebro University, Örebro, Sweden; 3Department of Clinical Physiology, Örebro University Hospital, Örebro, Sweden.

**Introduction**

The prevalence of vitamin D deficiency is higher in obese individuals but it is unclear whether vitamin D deficiency impacts body composition or if body composition impacts the vitamin D status. The research regarding vitamin D supplementation and weight loss in obese individuals is ambiguous. One hypothesis for the presumed fat reductive effect of vitamin D is that vitamin D inhibits adipocyte differentiation. Aim To investigate if treatment with vitamin D can reduce fat mass in obese men with vitamin D deficiency.

**Methods**

This study was designed as a randomized prospective, placebo controlled, double blind intervention. Thirty eight overweight men (BMI > 25 kg/m²) with vitamin D deficiency (25(OH)D < 55 nmol/l) were randomized to receive 2000 IU Cholecalciferol drops or the equivalent amount of placebo drops for 6 months. At baseline and after 6 months body composition and BMI was measured and blood samples were obtained; body composition was measured using bioelectrical impedance analysis (BIA).

**Results**

The mean change in body fat percentage for the vitamin D group and the placebo group was a 0.6%-units (baseline compared to follow up; P = 0.222) and a 0.1%-units (P = 0.857) increase, respectively. The mean change in BMI in the vitamin D group was a 0.2 kg/m² decrease (P = 0.272) and for the placebo group a mean decrease in BMI of 0.5 kg/m² (P = 0.049). There was no statistically significant difference between the placebo group and the intervention group regarding change in fat percentage or BMI (P = 0.544, P = 0.256, respectively). Moreover no statistically significant difference was observed between the groups regarding change in any of the metabolic laboratory values.

**Conclusion**

We conclude that treatment with 2000 IU vitamin D daily for 6 months does not impact BMI or fat percentage in overweight men with vitamin D deficiency.

Instituto Investigación Sanitaria La Fe-Universitat de Valencia, Valencia, Spain; 6Centro de Investigación Biomédica en Red en Bioingeniería, Biomateriales y Nanomedicina (CIBER-BBN), Madrid, Spain.
Background

PREDIRCAM2 is a web platform for obesity treatment and follow-up. It contains modules for: dietary prescription and registry with nutritional analysis based on individualized and mediterranean dietary goals, physical activity prescription and tracking with individualized targets, and anthropometric tracking. An ongoing multicenter randomized clinical trial evaluates the intervention’s effectiveness in obesity treatment and cardio-metabolic-risk prevention.

Methods

Inclusion criteria: 18–65 years-old, BMI 30–39 kg/m², no medication for type-2 Diabetes Mellitus (DM), dyslipidemia (DLP) or hypertension (HT). Randomization to intensified technological intervention (TI) supported by PREDIRCAM2 platform, or traditional non-technological face-to-face intensified treatment intervention (NTI).

Both groups receive one year follow-up through 12 appointments with health-care professionals, 4 of which are exclusively telematic in the TI group.

Basal characteristics

183 participants have been included, BMI 34.74 ± 2.74, age 44.27 ± 10.62, 84% female (31% postmenopausal, 65% history of gestational DM), 54% high education level, 54% married. Comorbidities: 2.2% type-2 DM, 5.5% HT, 11.5% DLP, 6.5% Depression, 2.7% diagnosed eating disorders. 56% received medication, most frequently antidepressants (24.5%) followed by vitamin D supplements (11.8%). 68% reported anxiety towards food, overeating in the form of: pecking 84.7%, binge-eating 35.5%, binge-and-vomiting 3.2%.

Preliminary results

119 participants have completed 3-month follow-up: 60 TI, 59 NTI. Both groups have lost weight significantly (P < 0.0001). 26.7% TI, and 25.4% NTI have achieved at least a 5% weight-loss (P=0.88). 81 participants have completed 6-month follow-up: 41 TI, 40 NTI. Both groups have lost weight significantly (P < 0.0001). 46.3% TI, and 32.5% NTI have achieved at least a 5% weight-loss (P=0.20). Both groups have achieved a reduction in HbA1c levels (P < 0.0001), TI −0.81 ± 1.9% and NTI −1.36 ± 2.2% (P=0.24).

Conclusion

Our study population is mostly composed of highly educated females who report a high frequency of anxiety towards food and eating. PREDIRCAM2 shows to be a promising tool for obesity treatment and cardio-metabolic-risk prevention.

Suboptimal prediction of advanced fibrotic liver disease by standard non-invasive scoring systems in obese patients undergoing bariatric surgery

Niall Dempster,1,2 Michael Watson,3 Rachel Franklin,1 Maciej Juszczak,2 Lisa Rickers,2 Caroline Fletcher,2 Bruno Sgromo,3 Richard Gilles,1 Jeremy Cobbold,4 Leanne Hodson,1 Jeremy Tomlinson1 & John Ryan4

1Oxford Centre for Diabetes, Endocrinology and Metabolism, Churchill Hospital, Oxford, UK; 2Department of Vascular Surgery, John Radcliffe Hospital, Oxford, UK; 3Department of Bariatric Surgery, Churchill Hospital, Oxford, UK; 4Department of Hepatology, Churchill Hospital, Oxford, UK.

Introduction

Non-Alcoholic Fatty Liver Disease (NAFLD), is present in over 90% of obese patients undergoing bariatric surgery. It is a spectrum of pathology ranging from steatosis through to inflammation (Non-Alcoholic Steatohepatitis, NASH) and fibrosis. Bariatric surgery is currently the most effective treatment for NAFLD, but post-operative hepatic decompensation can occur and therefore pre-operative stratification of liver disease severity is beneficial. Several non-invasive scoring systems have been developed to stage NAFLD, but validation in the bariatric surgical population has been limited.

Methods

135 consecutive patients who underwent bariatric surgery in a tertiary referral unit from November 2014 to December 2016 were identified and the following NAFLD risk scores calculated: AST/ALT, APRI, BARD, FIB4 and NAFLD Fibrosis Score (NFS). All patients had an intraoperative liver biopsy performed for accurate histological staging of disease. Logistic regression analysis was used to determine their efficacy in detecting NASH (NAFLD Activity Score ≥5), advanced fibrosis (Brunt F3/F4) and cirrhosis (F4) identified on liver biopsy using R software.

Results

BARD and AST/ALT were independent predictors of NASH on multivariate logistic regression analysis. However, only AST/ALT ratio was significant in the final model (AST/ALT P = 0.04, BARD P = 0.08). AUROC for the regression model which included AST/ALT and BARD was 0.75. BARD and APRI were significant factors (P=0.03, P=0.04) on stepwise regression for F3/4 cirrhosis and they were included in the final model, which had AUROC 0.73. Only Fib4 scoring was independently associated with cirrhosis (F4) on multivariate regression analysis (P=0.04) and AUROC for the final model incorporating this factor was 0.70. In contrast to observations in non-bariatric patients, the NFS was of limited value and not an independent factor in predicting NASH, advanced fibrosis or cirrhosis.

Conclusion

Currently used non-invasive serum-based scoring systems have only a modest predictive value for staging the severity of NAFLD in patients undergoing bariatric surgery. Intra-operative liver biopsy to detect and subsequently manage advanced liver disease therefore remains of value. There is a need to develop and validate non-invasive biomarkers of disease that offer better predictive value in the bariatric population.

Discussion with cases: Could we achieve the goal with non-surgical treatments in morbid obese patients?

Aydin Cifci1, Senay Arikan Durmaz2, Askin Gungunes2, Irfan Karahan2, Selim Yalcin1 & Kubra Ozdemir1

1Department of Internal Medicine, School of Medicine, Kirikkale University, Kirikkale, Turkey; 2Department of Endocrinology and Metabolism, School of Medicine, Kirikkale University, Kirikkale, Turkey; 3Department of Internal Medicine, Yenimahalle Training and Research Hospital, Ankara, Turkey; 4Department of Oncology, School of Medicine, Kirikkale University, Kirikkale, Turkey.

Objective

Diet, lifestyle changes, medical agents and surgical approaches are treatment options in obese patients. We reported two morbid obese patients who lost 25 and 21% of their previous weight respectively with only lifestyle changes and orlistat therapy.

Case 1

Forty nine year-old woman had type 2 diabetes mellitus for 20 years. She took premix insulin twice a day. Her height was 157 cm, her weight was 120 kg, body mass index was 48.6 kg/m². One month later, she lost 3 kg with diet and exercise and then orlistat was started. After seventh month of orlistat therapy, her weight reduced to 85 kg and body mass index was 34.4 kg/m².

Case 2

Fifty-four year-old man has type 2 diabetes mellitus and took metformin for 10 years. His height was 168 cm, his weight was 118 kg, BMI was 41.8 kg/m². One month later, he lost 2.5 kg with diet and exercise and then orlistat was started. After seventh month of orlistat therapy, his weight reduced to 93 kg and body mass index was 32.9 kg/m². Both patients lost their weight 35 and 25 kg respectively with lifestyle changes and orlistat therapy. First year of treatment, patients maintain their weight without any gain.

Conclusion

The number of patients undergoing obesity surgery has increased at the present time. Patients prefer surgery instead of lifestyle changes. Our results of patients with morbid obese emphasize importance of lifestyle changes and orlistat therapy.

Endocrine Abstracts (2017) Vol 49
Introduction and aim

Overt thyroid dysfunction is well recognized to affect weight, but the influence of minor perturbations of thyroid function remains unclear. There is ongoing debate regarding the influence of minor changes in thyroid hormones status within the normal range and BMI. The aim of this study was to investigate the association between thyroid function within normal ranges and obesity via BMI and body compositions analyzed by bioelectrical impedance.

Materials and methods

One hundred twenty persons with normal thyroid functions were included in our study. According to the BMI, the patients were divided into 5 groups. Group 1: normal weight (n=20), group 2: overweight (n=20), group 3: class I obesity (n=20), group 4: class II obesity (n=20), group 5: morbid obesity (n=20). Measurements of serum TSH, free T3, free T4 and lipid profile were recorded. Body compositions and BMI were evaluated by bioelectrical impedance (TANITA).

Results

In group 1, TSH was negatively correlated with BMI (r = -0.430, P < 0.006). On the contrary, TSH was positively correlated with percentage of body fat (BF%) (r = 0.391, P = 0.014). Free T3 was positively correlated with BF% (r = 0.333, P = 0.038). In group 2, free T3 was positively correlated with BF% and fat mass (r = 0.517, P = 0.010, r = 0.751, P < 0.001 respectively). In group 3, free T3 was positively correlated with BF%, fat mass, HOMA-IR and LDL (r = 0.521, P = 0.018; r = 0.543, P = 0.013; r = 0.512, P = 0.021; r = 0.469, P = 0.037 respectively). Similarly, TSH was positively correlated with BMI (r = 0.553, P = 0.011). In group 5, free T4 was negatively correlated with LDL (r = -0.485, P = 0.030).

Conclusion

We demonstrated that differences in thyroid function within the normal range may correlate with differences in BMI and body compositions in subjects within different BMI categories. Further large scale data from the population is required to confirm our findings.

Association of Transforming growth factor β and Fibroblast growth factor 21 with cardiovascular diseases in obese patients

Teona Shvangiradze1, Ekaterina Toshchina1, Irina Bondarenko1, Marina Shestakova1, Larisa Nikankina1

1Endocrinology Research Centre, Moscow, Russia; 2I.M. Sechenov’s First Moscow State Medical University, Moscow, Russia.

Introduction

Obesity and type 2 diabetes mellitus (T2DM) are associated with cardiovascular diseases (CVD). Fibrotic changes in obesity include several molecular processes, including activation of Transforming growth factor β (TGF-β). Recent data indicate the involvement of Fibroblast growth factor 21 (FGF-21) as an important metabolic regulator, and even biomarker of metabolic changes in obesity and T2DM.

Aim

To determine TGF-β and FGF-21 level in patients with obesity and T2DM.

Methods

TGF-β and FGF-21 were identified in peripheral blood of 66 patients, aged 48–65 years with obesity. They were divided into 3 groups. 1st – 21 patients with coronary heart disease (CHD) confirmed by coronary angiography (CAG) and T2DM, the 2nd – 22 patients with T2DM, in the 3rd – 23 patients without T2DM and CHD. CHD was excluded in the 2nd and 3rd groups by Tredmil test. Control (4th) group included 14 healthy person matched by age and sex.

Results

TGF-β was significantly different in the studied groups (P = 0.046). We found that TGF-β was significantly lower in patients with CHD (group 1) compared with the group of “metabolically healthy” obesity (P = 0.02). TGF-β negatively correlated with atherogenic fractions of cholesterol – LDL (r = -0.426, P = 0.043) and with the degree of internal carotid artery őstenosis (r = -0.426, P = 0.039) in patients with T2DM. In contrast, patients with verified CHD demonstrated a negative correlation with the duration of obesity (r = -0.395, P < 0.033), and the processes of heart muscle remodeling (thickness of the left ventricular posterior wall (r = -0.386, P = 0.029) and interventricular septum (r = -0.335, P = 0.031). FGF-21 and TGF-β in the 1st group showed a negative correlation with the number of significantly affected vessels according to CAG (r = -0.73, P = 0.041 and r = -0.52, P = 0.056, respectively). All patients with obesity had significantly increased level of FGF-21 compared with the control group (P = 0.03) and FGF-21 positively correlated with BMI (r = 0.47, P = 0.021).

Conclusions

1. FGF-21 and TGF-β reduction were associated with CHD in patients with obesity.
2. Increased TGF-β may play a protective role in atherosclerosis in patients with diabetes and obesity.

**EP686**

The dynamics of anthropometric data in fertile age women by various types of the treatment

Maryam Abdulkhafavova & Saidganikhoja Ismailov

Tashkent Paediatric Medical Institute, Tashkent, Uzbekistan.

The aim

To study efficiency of pathogenetic therapy and dynamics of anthropometric indexes for women with obesity of fertile age at different endocrinopathies and through 6 months after treatment.

Material and research methods

On the etiologic factor of patient with obesity were up-diffused on three groups: 1 g. are patients with obesity at the polycystic syndrome of ovaries (PCOS) – 30 patients, 2 g. are patients with hypothyroid obesity – 21 cases and 3 g. – patient with endocrine obesity (a primary hypothyroidism) – 20 patients. Age of patients in 1st group was 39 from 20 to 28, on 2nd and 3rd group – patients aged from 23 to 46 years. Patients were divided into three groups: 1. PCOS, 2. Thyroid obesity, 3. Endocrine obesity. According to the BMI patients were divided into 3 groups: 1. Normal weight (n = 20), overweight (n = 20), 3. Morbid obesity (n = 20). Measurements of anthropometric data were recorded. Anthropometric data were analyzed by bioelectrical impedance.

Results

In 1 and 2 groups of patients marked reliable decline of BMI 1 and 2 degrees after 6 months of treatment, while for patients 3 groups of reliable changes of BMI through 6 months of treatment were not attained at none of degree of BMI. Thus, for patients 1 and 2 groups with BMI 3 degrees through 6 months a tendency was attained to the decline of BMI. In addition, renewal of fecundity and pregnancy was attained for the patients of a 1 group – in 19.5% cases (at 10 patients).

Conclusions

Optimization of treatment of obesity for the women of reproductive age is based on drafting of the individual programs, the choice of that is determined by the values of anthropometric indexes, state of hormonal and metabolic status, features of food behavior and personality-emotional sphere, state of menstrual and reproductive function.

Effects of IL-1β on the hypothalamic-pituitary-gonadal axis in men with obesity and metabolic syndrome – A randomized, double-blind, placebo-controlled trial

Fahim Ebrahimizadeh1,2, Philipp Schuetz2,3, Beat Mueller2,3, Sandrine A Urwyler1,2, Marc Y Donath1,2 & Mirjam Christ-Crain1,2

1Department of Internal Medicine, Division of Endocrinology, Diabetes and Clinical Nutrition, University of Basel Hospital, Basel, Switzerland; 2Department of Clinical Research, University Hospital Basel, Basel, Switzerland; 3University Department of Medicine, Kantonsspital Aarau, Aarau, Switzerland.

Background

Low testosterone levels in men appear to be an independent cardiovascular risk factor closely associated with the metabolic syndrome. Reciprocally, the metabolic syndrome leads to a decrease in testosterone levels, suggesting a bidirectional relationship. It has been hypothesized that increased inflammation is causative for the development of obesity-associated hypogonadism. However,

Endocrine Abstracts (2017) Vol 49
clinical evidence supporting this hypothesis is lacking. The aim of the present study was to determine whether anti-inflammatory treatment may restore endogenous testosterone production in obesity-associated hypogonadism.

Methods

This is a randomized, placebo-controlled, double-blind, trial including 70 hypogonadal men with the metabolic syndrome. Patients were randomly assigned to either receive 100 mg of a recombinant human interleukin-1–receptor antagonist subcutaneously twice daily for 4 weeks or to receive placebo. The primary endpoint was the change in total testosterone levels between baseline and 4 weeks. Predefined secondary endpoints included a change by week 4 in insulin resistance, body composition, muscle strength, hypogonadal symptoms and hemodynamic parameters.

Results

From April 2016 to January 2017, 66 patients have been enrolled at two tertiary care centers in Switzerland. Median age was 51 years (IQR 41–65) and patients had a median BMI of 37 kg/m² (34–39 kg/m²). Patients had hypogonadotropic hypogonadism with median baseline serum testosterone levels of 8.8 nmol/l (231 ng/dl) (7.6–10.1), median LH levels of 3.7 IU/l (3–5.2 IU/l) and median C-reactive protein levels of 2.9 mg/l (1.4–4.0 mg/l) mirroring a low-grade inflammatory state. Final results will be available in March 2017 and will be presented first at the ECE 2017.

Significance

This study will show whether there exists causality between obesity-associated inflammation and hypogonadism.

**Metabolic profile reversal after bariatric surgery**

Daniela Gallo1, Silvia Ippolito1, Giovanni Veronesi2, Eugenia Dozio1, Francesco Frattini1, Eugenia Trotti1, Adriana Lai1, Lorenza Sassi1, Jessica Sabatino2, Elvira Masiello3, Paola Premoli1, Eleonora Bianconi3, Sara Rossetti1, Claudio Casini1, Maria Laura Tanda1, Gianlorenzo Dionigi2, Luigi Bartalena1 & Eliana Piantanida1

1Department of Medicine and Surgery, University of Insubria, Varese, Italy; 2Research Center for Endocrine Surgery, University of Insubria, Varese, Italy.

Bariatric surgery is the most-effective treatment for morbid obesity, superior to medical treatment. Metabolic syndrome (MS) is a condition characterized by multiple major risk factors for coronary heart disease, diabetes, fatty liver, and several cancers; the main, diagnostic, components of MS are low HDL-cholesterol (< 40 mg/dl in man, < 50 mg/dl in woman), raised triglycerides (> 150 mg/dl), blood pressure > 130/85 mmHg, fasting plasma glucose > 100 mg/dl and waist circumference > 94 cm in man and > 80 cm in woman. Indeed, in addition to weight loss, changes in metabolic profile after bariatric surgery could improve long-term outcomes.

Complete demographic, clinical and laboratory data from 38 people (35 women, mean age 41 ± 13 years) undergoing bariatric surgery and followed by a dedicated clinical team were analyzed. Descriptive statistics detailed clinical characteristics of the cohort of patients. Paired T-test compared baseline clinical parameters, lipid and glycemic profile index at three (T3) and six (T6) months after surgery. General Linear Model for Repeated Measure compared the five conditions defining MS over time. Weight, BMI, waist circumference and systolic blood pressure decreased significantly at T3 and T6, compared to baseline [all P < 0.05]. Triglycerides and LDL cholesterol decreased at T3 and T6, HDL notably raised at T6 [all P < 0.05]. Fasting plasma glucose and HbA1c decreased at T3 and T6; HOMA index improved over time [all P < 0.05]. Prevalence of MS according to IDF/FAHA/NHLB harmonized definition in our population was 50% at baseline, 10 times higher for age than average prevalence in literature; at 6 months such prevalence decreased to 16%. In conclusion, in our population of patients undergoing bariatric surgery and a dedicated follow-up program, we observed a trend towards a noticeable improvement of the metabolic profile in the mid-term.

**Hydroxysteroid (17beta) dehydrogenase 13 knockout mice present with inflammation associated liver steatosis**

Hanna Heikela1, Marion Adam1, Dorothea Portius1, Jenni Mäki-Jouppila1, Arfa Mehmood1,3, Prem Adhikari1, Irene Esposito1, Laura Elio1,3, Maria Laura Tanda1, Gianlorenzo Dionigi2, Lorenza Sassi1, Laura Elo1,3, Dorothea Portius2, Jenni Mäki-Jouppila1, Marina Lai1, Adriana Lai1, Lorenza Sassi1, Jessica Sabatino2, Elvira Masiello3, Paola Premoli1, Eleonora Bianconi3, Sara Rossetti1, Claudio Casini1, Maria Laura Tanda1, Gianlorenzo Dionigi2, Luigi Bartalena1 & Eliana Piantanida1

1Department of Physiology, Institute of Biomedicine and Turku Center for Endocrine Abstracts

We characterized the phenotype of knockout (KO) mice deficient in HSD17B13 (HSD17B13KO). The data revealed normal serum sex steroid concentrations and proper reproductive performance in both male and female HSD17B13KO mice, indicating a minor role for HSD17B13 in sex steroid metabolism and reproduction. In line with the strong expression in the liver, histological analysis showed the presence of liver steatosis in HSD17B13KO mice that was associated with inflammation. The phenotype was more pronounced in males than females. The severity of the phenotype progressed with aging, and accumulation of triglycerides was observed in the livers of the male mice from 3 months onwards. Furthermore, metabolic profiling showed a tendency for increased hepatic phospholipid content in the 9 month-old HSD17B13KO males with two acylcarnitines (C16:0 and C18:1) showing the most profound increase (~ 2-fold). Additionally, presence of microgranulomas (Kupffer cell aggregations) with increased portal inflammation and ductular proliferation was observed in liver specimens from HSD17B13KO mice. This was associated with increased expression of immune response genes in the HSD17B13KO male liver. In conclusion, the lack of HSD17B13 impacts hepatic lipid metabolism in mice, resulting in liver steatosis and inflammation. The data, thus, indicate that HSD17B13 is involved in fatty acid metabolism in the liver, while the enzyme does not play a major role in the regulation of reproductive functions.

**Visceral vs subcutaneous white adipose depots response to insulin treatments in rats**

Milica Markelic1, Aleksandra Jankovic2, Igor Golic1, Marija Aleksic1, Ana Stancic1, Vesna Otaševic1, Sava Masovic1, Marija Marin1, Bato Korac1 & Aleksandra Korač1

1University of Belgrade, Faculty of Biology, Belgrade, Serbia; 2University of Belgrade, Institute for Biological Research “Sinisa Stankovic”, Belgrade, Serbia.

Visceral and subcutaneous white adipose depots (sWAT) and visceral and subcutaneous WAT (vWAT) display different metabolic roles and it could be presumed that exert different response to various hormones. Numerous studies revealed leading role of insulin in both fat accumulation (lipogenesis) and adipocyte differentiation (adipogenesis) although it is not clear is there a difference in response among these two depots. The aim of this study was to reveal effects of insulin treatments on sWAT and vWAT morphology. Male Wistar rats were treated acutely (1 day) or chronically (3 days) with low (0.4 IU/kg bm) or high (4 IU/kg bm) dose of insulin. Saline-treated animals served as controls. The portions of retroperitoneal, epidymal and subcutaneous WAT (rWAT, eWAT, sWAT, respectively) were removed and prepared for microscopic and Western blot analyses. Tissue components (adipocytes, blood vessels and stroma) volume density and cell profile density per unit area were determined. To establish adipogenic origin of multilocular/paucilocular cells PCNA immunoexpression was examined, while protein expression and cell presence of phosphorylated form (phospho-IR) of insulin receptor (IR) was used to analyze insulin signaling. Our results demonstrate slightly higher number of adipocytes and adipogenic cells and increased capillarization in vWAT depots. A stronger response of vWAT to insulin treatment in comparison to sWAT is due to higher phospho-IR expression in endothelial and multilocular/paucilocular cells of analyzed vWAT depots. Namely, in hyperinsulinemia canonical insulin-signaling pathway favors adipogenesis and capillary remodeling in vWAT to a greater extent than in sWAT depot. Our results suggest that insulin-induced differences in remodeling of vWAT and sWAT depots may contribute to visceral obesity and development and progression of insulin resistance and diabetes type 2 among other visceral obesity-associated metabolic diseases.

DOI: 10.1530/endoabs.49.EP693
Abstract
Glomerular hyperfiltration has been suggested as a possible mechanism linking obesity and chronic kidney disease, independently of classic risk factors such as diabetes. In terms of determining the creatinine clearance has numerous drawbacks, in clinical use are predictors of glomerular filtration rate (GFR) which vary showing degrees of accuracy in obese patients. The aim of our study was to determine whether it is in our group of obese patients without type 2 diabetes, glomerular hyperfiltration associated with metabolic disorders. This cross-sectional study included 30 obese patients at the beginning of treatment in Center for Obesity. Excluded were patients with type 2 diabetes, moderate/severe hypertension and cardiovascular comorbidity. We analyzed metabolic parameters (fasting glucose and insulin, HOMA-IR, HbA1c, liver enzymes and renal function (GFR, proteinuria and albuminuria). According to the degree of GFR determined by: 1. the creatinine clearance (CCR); 2. The use of predictors GFR · MDRD and Cockcroft-Gault (CGG) equation, patients were divided into two groups: with hyperfiltration and with normal levels of glomerular filtration rate. According to the level of GFR, 44.4% (CCR), 25.9% (MDRD), 66.7% (CGG) had hyperfiltration, while 55.6% (CCR), 74.1% (MDRD) 33.3% (CGG) patients had normal filtration. Patients with hyperfiltration had significantly higher fasting glycemia (CCR: 4.9 ± 0.8 vs 4.7 ± 0.5, P = 0.038; MDRD: 5.1 ± 0.3 ± 0.9 vs 4.9, P = 0.039; CGG: 5.2 ± 0.9 vs 4.7 ± 0.5, P = 0.034) and HbA1c (CCR: 6.1 ± 0.4 vs 5.6 ± 0.6, P = 0.015; MDRD: 5.8 ± 0.9 vs 5.3 ± 0.3, P = 0.022; CGG: 6.1 ± 0.4 vs 5.3 ± 0.3, P = 0.038) compared to patients with normal filtration. The value of gamma-GT was significantly higher in the group of patients with hyperfiltration compared another group [CCR: 30 (18–80) vs 24 (15–58), Z = 2.3, P = 0.024; MDRD: 41 (19–80) vs 30 (15–57), Z = 2.0, P = 0.030]. In our group of patients has been shown that obese patients with glomerular hyperfiltration had significantly higher values of the parameters of glycemic control and gamma-GT compared to those with normal levels of glomerular hyperfiltration had significantly higher values of the parameters of glycemic control and gamma-GT compared to those with normal levels of glomerular filtration rate. According to the degree of GFR determined by: 1. the creatinine clearance (CCR); 2. The use of predictors GFR · MDRD and Cockcroft-Gault (CGG) equation, patients were divided into two groups: with hyperfiltration and with normal levels of glomerular filtration rate. According to the level of GFR, 44.4% (CCR), 25.9% (MDRD), 66.7% (CGG) had hyperfiltration, while 55.6% (CCR), 74.1% (MDRD) 33.3% (CGG) patients had normal filtration. Patients with hyperfiltration had significantly higher fasting glycemia (CCR: 4.9 ± 0.8 vs 4.7 ± 0.5, P = 0.038; MDRD: 5.1 ± 0.3 ± 0.9 vs 4.9, P = 0.039; CGG: 5.2 ± 0.9 vs 4.7 ± 0.5, P = 0.034) and HbA1c (CCR: 6.1 ± 0.4 vs 5.6 ± 0.6, P = 0.015; MDRD: 5.8 ± 0.9 vs 5.3 ± 0.3, P = 0.022; CGG: 6.1 ± 0.4 vs 5.3 ± 0.3, P = 0.038) compared to patients with normal filtration. The value of gamma-GT was significantly higher in the group of patients with hyperfiltration compared another group [CCR: 30 (18–80) vs 24 (15–58), P = 0.080; MDRD: 29.5 (19–80) vs 24.5 (15–58), P = 0.006; CGG: 41 (15–80) vs 18 (15–72), P = 0.003]. In our group of patients has been shown that obese patients with glomerular hyperfiltration had significantly higher values of the parameters of glycemic control and gamma-GT compared to those with normal levels of filtration, regardless of age and BMI, which could suggest important interrelationship among the initial development of chronic kidney disease with diabetes and nonalcoholic fatty liver disease in obesity.

Associations between the dysregulation of splicing machinery components and the development of hepatic steatosis in obese women

Mercedes del Río-Moreno1, Sergio Pedraza-Arévalo1, Sandra González-Rubio1, Gustavo Ferrín2, Manuel Rodríguez-Peralvarez2, Rhonda D Kineman3, Alejandro Buitéz-Costa1, Manuel de la Mata2, Justo P Castaño1, Raúl M Luque1 & Manuel D Gañéte1

1Maimonides Institute of Biomedical Research of Cordoba (IMBIC); Reina Sofia University Hospital (HUROS); Department of Cell Biology, Physiology and Immunology, University of Cordoba (UCO); CIBER Physi, Cordoba, Spain; 2Department of Hepatology and Liver Transplantation, HURS/I-MBIC; CIBER Enfermedades Hepáticas y Digestivas (CIBERehd), Cordoba, Spain; 3Research and Development Division, Jesse Brown Veterans Affairs Medical Center and Department of Medicine, Section of Endocrinology, Diabetes, and Metabolism, University of Illinois at Chicago, Chicago, Illinois, USA.

Hepatic steatosis is a common obesity-associated pathology characterized by the accumulation of fat within the liver, which can progress to liver fibrosis, cirrhosis and ultimately lead to hepatocellular carcinoma. Remarkably, obesity and cancer course with a profound dysregulation of the genetic expression patterns and, particularly, with the aberrant expression of splicing variants that could contribute to the aggressiveness and comorbidities of these pathologies. Since the appearance of alternative splicing variants could be related to a dysregulation of the cellular machinery responsible for this process (spliceosome core elements and splicing factors (SFs)), the objective of the present study was to determine the association between the expression pattern of the components of this machinery and hepatic steatosis of obese patients. To this end, we collected clinical and demographic data and liver biopsy samples from obese women (IMC > 30) with and without hepatic steatosis. RNA from liver samples was extracted and retrotranscribed to determine the expression levels of selected components of the major (n = 13) and minor spliceosome (n = 4), and associated SFs (n = 28) using a qPCR-based array. Results revealed that the liver of steatotic patients exhibit a profound dysregulation of certain spliceosome components and SFs compared to non-steatotic patients (e.g. RN16, SF3B1, etc.). Although these alterations were not associated with the hepatic steatosis level, the expression pattern of the components of this cellular machinery could define discrete groups of steatotic patients that presented similar alterations in certain spliceosome components and SFs. Interestingly, these groups of patients were also characterized by particular hepatic and clinical-metabolic alterations (e.g. ALT, hyperglycemia, hyperinsulinemia, etc.). Therefore, although further confirmatory studies are needed, these results could suggest that the development of hepatic steatosis and its associated comorbidities could be linked to the dysregulation of certain components of the splicing machinery, which may provide novel diagnostic/therapeutic tools for this pathology.

Irisin and cardiovascular risk

Yavor Assyov1,2, Antoneta Gateva1,2 & Zdravko Kamenov1,2

1Medical University, Sofia, Bulgaria; 2University Hospital Alexandrovska, Sofia, Bulgaria.

Aims

Irisin is a recently discovered myokine that has been implicated in the pathogenesis of type 2 diabetes (T2D) and metabolic syndrome (MS). Its involvement with cardiovascular disease (CVD), however, has not yet been elucidated. The aim of the current study was to shed light on the potential association with irisin and cardiovascular risk.

Methods

Eighty patients with obesity (BMI > 30 kg/m²) and mean age 50.4 ± 10.6 years were included in the study which was realized in a third level university endocrine department. Biochemical measurements consisted of fasting plasma glucose, serum immunoreactive insulin, serum uric acid, lipid profiles, liver enzymes. Measurements of weight, height, waist circumference and arterial blood pressure were performed. Cardiovascular risk was estimated by means of Framingham Risk Score calculation and a measurement of mean carotid intima media thickness (CIMT) as measured by an automated software via B-mode ultrasound. Ankle-brachial index (ABI) measurement was also performed. Circulating serum irisin was measured by a commercially available ELISA kit.

Results

Among parameters of interest, circulating irisin correlated positively with BMI (r = 0.246, P < 0.05) and negatively with age (r = −0.457, P < 0.001), total cholesterol (r = −0.246, P < 0.05), LDL-cholesterol (r = −0.234, P < 0.05), ABI (r = −0.272, P < 0.05), CIMT (r = 0.353, P < 0.001) and with Framingham Risk Score (r = −0.400, P < 0.01). Associations with CIMT, Framingham Risk Score and ABI persisted after adjustment for age and sex. In a ROC–curve analysis circulating serum irisin was of use (AUC = 0.665, 95% CI: 0.525–0.804, P = 0.037) for distinguishing subjects with CIMT ≥ 75th percentile, which was found in 32.5% of the study participants.

Conclusions

Circulating irisin levels were negatively associated with established CVD estimates. Irisinemia could be useful for distinguishing subjects with increased CIMT. Larger, prospective studies are required to establish the particular mechanisms for these observations.

Circulating adipomyokines, inflammatory marker, insulin resistance, and physical fitness among severely obese Korean children and adolescents

Kyung Hee Park1, Young-Gyun Seo1, Hye Ja Lee2, Han Byul Chang2, Sang Ik Park2, Yoon Myung Kim3 & Hyun Jung Lim4

1Hallym University Sacred Heart Hospital, Anyang-si, Republic of Korea; 2National Institute of Health, Cheongwon, Republic of Korea; 3Yonsei University, Seoul, Republic of Korea; 4Kyung Hee University, Seoul, Republic of Korea.

Background

Associations between obesity and adipomyokines, inflammatory marker, and level of physical fitness have not been well evaluated in severe obesity in children and adolescents. Despite a BMI below 25 kg/m², there were no significant differences in age, time after surgery, cancer stage, history of axillary lymph node dissection, chemotherapy, or radiotherapy between patients with and without obesity. The association between obesity status and biomarker levels and physical fitness among severely obese Korean children and adolescents. Participants were classified into 3 groups according to their BMI status based on sex and age-specific BMI percentiles: severely obese (SO, ≥ 120% of the 95th percentile), overweight or obese (OB, 85th < BMI < 120% of the 95th percentile), and non-obese (NW, < 85th). Levels of circulating adipomyokines, inflammatory marker, insulin resistance (HOMA-IR), and physical fitness were compared across the groups adjusted for sex and age. Cross-sectional associations between obesity status and biomarker levels and physical fitness were assessed.

Results

Participants in SO group tended to have higher levels of leptin (NW, 12.19 ± 1.05: OB, 25.64 ± 1.05: SO, 40.77 ± 1.09), hsCRP (NW, 0.37 ± 1.09: OB, 1.18 ± 1.09: SO, 1.82 ± 1.16), and HOMA-IR (NW, 1.78 ± 1.06: OB, 3.55 ± 1.06: SO, 6.28 ± 1.10). Compared to participants in NW or OB(all P < 0.001). Levels of physical fitness tended to be significantly decreased across the BMI groups (P for trend, arm curl test 0.03: wall sit test < 0.001). Circulating levels of irisin showed overall significance (P for trend 0.04), but did not show significant difference between groups. FGF-21 did not show significant difference across the BMI groups.

Conclusions

Severe obesity in children and adolescents compared with NW or OB is associated with higher levels of leptin, inflammatory marker and insulin resistance, circulating irisin was of use (AUC = 0.665, 95% CI: 0.525–0.804, P = 0.037) for distinguishing subjects with CIMT ≥ 75th percentile, which was found in 32.5% of the study participants.

DOI: 10.1530/endoabs.49.EP700
resistance and lower levels of physical fitness, which implies problems with further weight gain and cardio-metabolic health risks.

Genetic variants of the adiponectin gene and its association with adiponectin level in metabolic syndrome women
Abhishhek Gupta1,2, Sunita Tiwari1, Suraksha Agrawal3, Arun Kumar Singh4, Bhola Nath Paul1 & Katherine Cianflone5
1Department of Physiology, King George’s Medical University, Lucknow, Uttar Pradesh, India; 2Department of Molecular and Clinical Medicine, University of Gothenburg, Gothenburg, Sweden; 3Department of Medical Genetics, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, Uttar Pradesh, India; 4Immunobiology Division, Indian Institute of Toxicology Research, Lucknow, Uttar Pradesh, India; 5Department of Medicine, Institut Universitaire de Cardiologie et de Pneumologie de Québec, Quebec, Canada.

Background
Adiponectin is an adipocyte-derived adipokine, down-regulated in obesity linked disorders. Here, we investigated the genotypic variability of adiponectin (at position; +T454G and +G276T) and its association with circulating adiponectin and metabolic syndrome in North Indian adult women.

Methods
We compared metabolic syndrome (MetS; 269) women to without metabolic syndrome (wMetS; 272) women of North India. Genotype frequencies of the adiponectin gene were performed using PCR-RFLP method and circulating adiponectin estimated by sandwich ELISA method.

Results
Low level of adiponectin (P < 0.001) and high HOMA-IR were found (P < 0.001) in MetS women. Gene frequency of combined mutant genotype (TG + GG) at position + 454T/G of adiponectin was found to be significantly less (P = 0.017) while mutant G allele was significantly high (P = 0.008) in MetS women as compared to wild type. However, frequency of mutant T allele in MetS women was found to be significantly (P = 0.027) less as compared to wMetS at position + 276G/T of adiponectin gene. In the mutant genotype GG of +454T/G and TT of +276G/T of adiponectin were significantly associated with lower adiponectin level and higher HOMA-IR (all P < 0.001) in adult metabolic syndrome.

Conclusions
Results suggest that adiponectin gene variants might be associated with lower adiponectin level and metabolic syndrome.

Obesity, cardiomyopathy and anabolic hormones
Elena Gangitano, Daniela Costantini, Rosella Tozzi, Francesca De Giorgi, Eleonora Poggiogalle, Stefania Mariani, Elisa Petrangeli, Lorenzo Maria Donini, G. Barbaro, Lucio Gnassi & Carla Lubrano
1Department of Physiology, IBILI, Faculty of Medicine, University of Coimbra, Coimbra, Portugal; 2Neurology Department, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal; 3IBILI, Faculty of Medicine, University of Coimbra, Coimbra, Portugal; 4Laboratory of Biostatistics and Medical Informatics, IBILI, Faculty of Medicine, University of Coimbra, Coimbra, Portugal; 5Laboratory of Neurochemistry, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal; 6Faculty of Medicine, University of Coimbra, Coimbra, Portugal.

Obesity is associated with hemodynamic alterations that may lead to heart failure (HF), through the development of cardiac structural abnormalities and impairment of ventricular function. Obesity-related neurohormonal and metabolic disturbances may predispose to HF, even in the absence of comorbidities. Excess adipose tissue and in particular visceral adiposity contributes to the altered production of a number of anabolic hormones also involved in the regulation of the cardiac function. The aim of the present study was to evaluate cardiac morphology and function by echocardiography and the relationships between echocardiographic parameters, BMI and hormonal status in a population of obese patients. 1821 patients (mean age 46.94 ± 13.62 yrs, 1331 females and 490 males) were studied. 157 were normal weight (BMI 22.14 ± 1.83), 247 overweight (BMI 27.76 ± 1.45), and 1417 obese (BMI 39.39 ± 6.88). Anthropometric data, blood pressure, lipid and glycemic parameters and a complete hormonal status were recorded. Two-dimensional echocardiography and carotid intima/media thickness measurement were performed. Total testosterone in males and SHBG in both sexes were significantly and inversely correlated with epicardial fat thickness (EFT) (r = -0.33 and r = -0.44, P < 0.001). Circulating levels of DHEAS were positively related with E/A ratio (r = 0.26 P < 0.001) and inversely with left ventricular mass index (LVMi) (r = -0.20 P < 0.01) and carotid intima-media thickness (cIMT) (r = -0.24 P < 0.005). Urinary free cortisol was positively related with EFT (r = 0.22 P < 0.001). Circulating IGF1 levels were positively related to E/A ratio (r = 0.27 P < 0.001) and negatively correlated with EFT (r = 0.14 P < 0.001), LVMi (r = -0.16 P < 0.001), end diastolic left ventricular diameter (r = -0.16 P < 0.001), cIMT (r = -0.25 P < 0.001), and left atrial diameter (r = -0.14 P < 0.001). All the echocardiographic and hormonal parameters evaluated showed significant correlation with the degree of weight excess and the duration of obesity (P < 0.001). In conclusion, cardiac function and morphology associate with weight excess, duration of obesity and anabolic hormones deficiencies.

Are there any associations between vitamin D levels and insulin resistance in obese patients?
Omercan Topaloglu1, Bahri Evren1, Saim Yologlu2 & Ibrahim Sahin1
1Inonu University Medical Faculty, Department of Endocrinology, Malatya, Turkey; 2Inonu University Medical Faculty, Department of Biostatistics, Malatya, Turkey.

Introduction
Most of the human studies suggested an association between obesity and low 25(OH)D3 levels. It has been proposed that co-existence of vitamin D deficiency may have a role in the development of IR in obesity. We aimed to reveal whether any association was present between IR and 25(OH)D3.

Materials-methods
223 obese patients referred to our clinics were evaluated for the study. 24 patients with known diabetes mellitus were excluded. Finally, 199 patients were included and anthropometric (height, body weight, body mass index) and biochemical (fasting blood glucose, HbA1c) and hormonal (fasting insulin, C-peptide, 25(OH)D3) measurements were assessed. We evaluated IR by ‘homeostasis model assessment of IR’ (HOMA-IR). The patients having HOMA-IR value of equal to or greater than 2.5 were accepted as insulin resistant. The patients were grouped according to body mass index (BMI) (BMI, HOMA-IR, and 25(OH)D3).

Results
25(OH)D3 levels were significantly lower in the groups of BMI > 50 kg/m2 and BMI 40–50 kg/m2 in comparison to the group of BMI <40 kg/m2 (mean 25(OH)D3 D3 levels 12.0, 12.12, 17.02 ng/dl; respectively) (P = 0.042, P = 0.025; respectively). BMI levels were significantly lower in the group of 25(OH)D3 > 30 ng/ml in comparison to the group of 25(OH)D3 < 10 ng/ml (mean BMI 42.27 vs 45.59 kg/m2; respectively) (P = 0.05). Likewise, there was significant negative correlation between BMI and 25(OH)D3 (P = 0.045, r = –0.142). There was no difference between 25(OH)D3 levels in patients with IR (HOMA-IR 2.5) and not IR (HOMA-IR < 2.5) patients (P = 0.071). Similarly, there was no significant correlation between HOMA-IR values and 25(OH)D3 levels (P = 0.98).

Conclusion
Our study showed that 25(OH)D3 levels decreased in obesity; and 25(OH)D3 levels were not different in patients having IR or not. These findings suggest that decreased vitamin D levels in obesity may be result of increasing BMI rather than IR.

Elevated serum adiponectin in Alzheimer’s disease as neuroprotective strategy
Liliana Letra1,2; Tiago Rodrigues1; Paula Matafome1; Diana Duro2; Raquel Lemos2; Miguel Patrı́cio4; Miguel Castelo-Branco1; Ineˆs Baldeiras5; Raquel Seic¸a 1 & Isabel Santana2,6
1Physiology Laboratory, IBILI, Faculty of Medicine, University of Coimbra, Coimbra, Portugal; 2Neurology Department, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal; 3IBILI, Faculty of Medicine, University of Coimbra, Coimbra, Portugal; 4Laboratory of Biostatistics and Medical Informatics, IBILI, Faculty of Medicine, University of Coimbra, Coimbra, Portugal; 5Laboratory of Neurochemistry, Centro Hospitalar e Universitario de Coimbra, Coimbra, Portugal; 6Faculty of Medicine, University of Coimbra, Coimbra, Portugal.

Are there any associations between vitamin D levels and insulin resistance in obese patients?
Background
Several studies have highlighted the contribution of adipose tissue dysfunction to the development and progression of Alzheimer’s Disease (AD), which may depend on alterations in adipokine secretion. Leptin and adiponectin are the most abundant adipokines in circulation, with recognized systemic effects, but also able to cross the blood-brain barrier and influence cognitive-related structures, such as the hippocampus.

Objective
To determine if serum and CSF adiponectin and leptin/adiponectin ratio are correlated with AD biomarkers and can constitute predictors of progression.

Methods
A total of 53 AD and 71 MCI subjects (mild cognitive impairment amnestic type) were included and underwent a thorough clinical and neuropsychological evaluation (MMSE, MoCA, ADAS-Cog). Serum and CSF adiponectin and leptin, serum insulin and AD biomarkers (CSF Aβ42, t-tau, p-tau and hippocampal formation volumetry) were also performed. Sixty-seven MCI patients had clinical and neuropsychological follow-up in order to identify progression to AD.

Results
Serum adiponectin was 33% higher in AD when compared to MCI. In CSF, leptin and t-tau showed a negative correlation in AD patients (r = -0.597, P = 0.026) while adiponectin was positively correlated with Aβ42 (r = 0.590, P = 0.002), but only in women. A robust association between CSF adiponectin and hippocampal volume was observed in a subgroup of patients with CSF-based AD diagnosis. However, no correlation was found with total cognitive scores. Twenty-seven MCI progressed to AD upon a mean follow-up of 38.2 ± 18.83 months, whereas 40 maintained the diagnosis. Baseline serum and CSF adipokine levels were similar in both groups. Only serum adiponectin positively correlated with time of progression (r = 0.484, P = 0.049), though incapable of predicting progression to dementia.

Conclusions
Higher CSF adiponectin levels are associated with less Aβ42 deposition and higher hippocampal volume. Accordingly, higher adiponectinemia observed in AD could be looked as a strategy to maintain its central levels and, consequently, its beneficial effects.

Late dumping syndrome in pregnant women after ROUX-EN-Y gastric bypass (RYGB) surgery
Lucia Vera Pacheco1, María Teresa Gallego García2, Cristina Del Peso Gilsanz2, Lorenia Rentero Redondo2, Carles Iniesta Navalón2, Noelia Victoria García-Talaverá Espín2, Mª Bienvenida García-Talaverá Espín2, Manuel Romero Muñoz2 & Amparo Meoro Avilés2
1University Hospital Rafael Méndez, Lorca, Murcia, Spain; 2University Hospital Reina Sofía, Murcia, Spain.

Introduction
Dumping syndromes are common after bariatric surgery and can present diagnostic and therapeutic challenges in pregnancy.

Case report
A 23-year-old female who underwent a RYGB surgery because of morbid obesity in 2013. She had no medical history of diabetes nor any other comorbidity related to obesity. Two years later, her weight had reduced from 128 to 76 kg and also her body mass index (BMI) from 43.8 to 26 kg/m². She was treated with multivitamins, iron vitamin B12 and calcium. She remained clinically asymptomatic. In 2016, she got pregnant and on the 24th gestational week she checked herself post prandial capillary blood glucose (CBG) that confirmed hypoglycemia, with glucose levels from 55 mg/dl to 30 mg/dl, accompanied by clinical intense asthenia. Fasting plasma glucose was 71 mg/dl and insulin 5 mIU / ml (2.6-24.9). Dietary modification with frequent intakes every 3 hours, with low glycaemic index food and avoidance of physical activity immediately after oral intake were recommended. At the beginning, the episodes were reduced, but on the 35th gestational week hypoglycemia episodes had increased in severity and frequency, raising concerns of the risk of maternal neuroglycopenia and fetal hypoglycemia, that’s why it was decided to treated with Diabetes-specific Oral Nutritional Supplement (low in carbohydrates with no added sucrose, high in protein and contains soluble fiber) twice a day between the main meals.

Oral Nutritional Supplement
Folate: a new player in metabolic syndrome?
Silvia Paredes1,2, Marta Alves1, Maria Lopes Pereira1, José Maia da Costa1, Aline Fernandes1, Fernando Manso1, Olinda Marques1 & Laura Ribeiro1,2
1Hospital de Braga, Braga, Portugal; 2Faculty of Medicine, University of Porto, Porto, Portugal; 3IIS-Instituto de Investigación e Innovación en Salud, Universidade do Porto, Porto, Portugal.

Introduction
Bariatric surgery (BS) candidates display several nutritional deficiencies that can aggravate after surgery. Metabolic syndrome (MS) is a cluster of cardiovascular risk factors with several disturbed metabolic pathways. Therefore, individuals with MS submitted to BS are probably more prone to nutritional deficiencies.

Objective
To evaluate the prevalence of nutritional deficiencies and eventual differences between BS candidates with and without MS.

Materials and methods
Retrospectively, databases of 385 patients who underwent BS between 01/2011 and 07/2015 were analyzed. Nine subjects were excluded due to missing data on MS parameters. Subjects with ≥3 criteria according to the NCEP ATP III report were classified as having MS.

Results
A total of 181 individuals with MS (150 females, body mass index (BMI) 44.56 ± 6.4, mean age 45.14 ± 10.9) and 195 without MS (174 females, BMI 42.98 ± 5.9, mean age 39.44 ± 9.3) were included. No significant differences were found in iron metabolism (iron/ ferritin/hemoglobin), vitamin B12, vitamin D, albumin and homocysteine between males and females with and without MS. However, both males and females with MS had significantly higher levels of folate than individuals without MS. Males with MS exhibited significantly lower levels of magnesium comparing to males without MS. In females, folate was positively associated with glucose (r = 0.206; P < 0.001), glycated hemoglobin (A1c) (r = 0.294; P < 0.001), total cholesterol (r = 0.153; P = 0.006) and low-density lipoproteina cholesterol (r = 0.117; P = 0.037). In males, folate was positively associated with glucose (r = 0.402; P = 0.003), A1c (r = 0.362; P = 0.012) and triglycerides (r = 0.372; P = 0.007), whereas magnesium was negatively associated with glucose (r = -0.437; P = 0.001) and A1c (r = -0.298; P = 0.042).

Conclusion
There were no significant differences in nutritional deficiencies between individuals with and without MS. However, in our study individuals with MS presented significantly higher folate levels than individuals without MS. Interestingly enough, folate levels positively associated with lipid and glucose metabolism. The metabolic and clinical significance of our results warrants further investigation.

Evolution of body composition 3 years after sleeve gastrectomy
Silvia Paredes1,2, Marta Alves1, Maria Lopes Pereira1, José Maia da Costa1, Aline Fernandes1, Fernando Manso1, Olinda Marques1 & Laura Ribeiro1,2
1Hospital de Braga, Braga, Portugal; 2Faculty of Medicine, University of Porto, Porto, Portugal; 3IIS-Instituto de Investigación e Innovación en Salud, Universidade do Porto, Porto, Portugal.

Background
Sleeve gastrectomy (SG) has effective results on weight loss, which should result from fat mass loss and efforts should be made to preserve lean mass. Few studies have evaluated body composition (BC) changes after SG for periods > 2 years. Objective
To investigate the impact of SG on weight and BC, comparing by gender.

Materials and methods
Retrospectively, databases of patients who underwent SG between 2011 and 2013 were analyzed. Data was obtained before and 1, 2 and 3 years after SG. BC was measured by bioelectrical impedance.

Conclusions
Sleeve gastrectomy in pregnant women that have gone through a RYGB surgery need to be distinguished from common symptoms of a normal pregnancy. Its therapeutic use gets more difficult, because it was restricted to dietetic modifications and not having medicines that have indication by FDA during pregnancy.

DOI: 10.1530/endoabs.49.EP707

Endocrine Abstracts (2017) Vol 49
Results
Fifty-five females, mean age 42.11 ± 10 years, mean body mass index (BMI) 44.59 ± 4.9 Kg/m² and 11 males, mean age 39.55 ± 10.9 years, mean BMI 44.66 ± 5.4 Kg/m² were included. One year after SG, males had lost 36% of weight, 67% of fat mass and 18% of lean mass. In females, 1 year after SG, weight decreased 32%, fat mass 52% and lean mass 12%. Two and 3 years after surgery, males had lost 33% and 30% of weight, 59% and 53% of fat mass and 20% and 19% of lean mass, respectively. In females, 2 and 3 years after surgery weight decreased 33% and 30%, fat mass 52% and 48% and lean mass by 14% and 13%, respectively. Males presented the lowest weight and fat mass 1 year after surgery; females had the lowest weight and fat mass 2 years after SG.

Conclusion
Despite both genders show a weight loss of 30% 3 years after SG, males initially lose more weight that is regained after the first year. Males also present a greater loss of lean mass. Our results highlight the need to develop strategies to avoid weight regain, which seems to start 1 and 2 years after SG, respectively for males and females. Efforts should be also made in order to avoid lean mass loss.

Comparative study between laparoscopic gastric bypass and laparoscopic sleeve gastrectomy

Aurora Aragón-Alonso, Mercedes Ferrer Gómez, José Ramón Cuenca Sánchez, David Ruiz de Angulo Martín, María Dolores Frutos Bernal, María Angeles Campillo Espallardo, Pedro Seguro Luque & Antonio Hernández Martínez

Hospital Universitario Virgen de la Arrixaca, Murcia, Spain.

Introduction
Bariatric surgery is currently considered the most effective treatment for morbid obesity. Laparoscopic gastric bypass (LGB) and laparoscopic sleeve gastrectomy (LSG) are the most widely used bariatric procedures today.

Objectives
In this study we compared LGB and LSG in order to establish whether there is any superiority of one or the other in effectiveness and complications.

Methods
We included all the patients who underwent bariatric surgery in Hospital Universitario Virgen de la Arrixaca during one year (n=101) of which 62 received LGB and 39 LSG. Both groups were comparable in age, body mass index, rates of hypertenston (HT), type 2 DM (T2DM), hypercholesterolemia (Hchol), hypertriglyceridemia (HTG) and obstructive sleep apnea syndrome (OSA). A higher percentage of women was present in the LGB group. We retrospectively compared postoperative complications and excess weight loss (EWL) and comorbidity resolution (HT, T2DM, Hchol, HTG and OSA) at one year after surgery.

Results
LGB was superior to LSG in HT remission (75% vs 43.8%, P=0.046) and Hchol remission (96.3% vs 33.3%, P<0.001). We found no significant differences between LGB and LSG regarding EWL (77.7% ± 23.3% vs 76.9% ± 17.8%), T2DM remission (78.6% vs 75%), HTG resolution (86.7% vs 75%) and OSA remission (55.6% vs 16.7%). Also, both techniques were comparable regarding rate of postoperative complications (17.7% vs 10.3%).

Conclusions
At one year postsurgery, LGB was superior to LSG in HT and Hchol remission. However, both techniques are comparable in terms of safety, weight loss and resolution of other comorbidities (T2DM, HTG and OSA).

Prevalence of mono-ethyl-hexyl phthalate and mono-ethyl phthalate in Serbian population and their influence on leptin and thyroid function in obesity

Ivana Bašački1,2, Nataša Milošević3,1, Jovanka Novaković-Paro1,2, Tijana Ilic1,2, Jovana Prodanović1,2, Nika Cvirić4, Bojan Vuković1,2 & Milica Medic-Stojanović1,2

1Clinic of Endocrinology, Diabetes And Metabolic Disorders, Clinical Center of Vojvodina, Novi Sad, Vojvodina, Serbia; 2Faculty of Medicine, University of Novi Sad, Novi Sad, Vojvodina, Serbia; 3Department of Pharmacy, University of Novi Sad, Novi Sad, Vojvodina, Serbia; 4Center for Laboratory Medicine, Clinical Center of Vojvodina, Novi Sad, Vojvodina, Serbia.

Introduction
Phthalates are ubiquitous endocrine disruptors (EDs). EDs induce obesity. MEP and MEHP affect thyroid function.

Aim
Estimation of burden of MEP and MEHP in our population, evaluation of leptin in obese MEP and MEHP positive and negative subjects and evaluation of connection between leptin, MEP, MEHP and thyroid indicators in that subgroup.

Materials and methods: a cross-sectional study, with 201 subjects divided into MEP/MEHP positive and negative, subdivided in obese and lean. Anthropometric parameters done: body height, weight, waist and body mass index. Laboratory tests: morning urine sample for MEP/MEHP and venous sample for free thyroxine (FT₃), free tri-iodothyronine (FT₂), thyroid stimulating hormone (TSH) and leptin. Statistical analysis was done in SPSS. Results: Mean age of participants was 36.74 (±8.55) years, 86 (42.8%) males and 115 (57.2%) females. There were 64 (31.2%) MEP+, and 44 (22%) MEHP+ participants, and 5 (5.0%) positive for both. There were 93 (46.3%) participants in obese subgroup, MEHP+ 64 (68%), MEHP+ 29 (32%); MEP+ 58(62%), MEP+ 38%.

Independent t-test and Mann Whitney U test did not show statistical significance in leptin level neither in MEP+ and MEHP+ (t=−0.316, P<0.753; Z=−0.242, P<0.809), nor in MEHP+ and MEHP− obese participants (t=−1.049, P=0.30). Significant correlations were found for leptin with MEP+ subgroup was statistically significant (r=−0.347, P<0.01), No significant correlations could be found for leptin with T3 (r=−0.123, P<0.48) and TSH (r=0.078; P<0.655). In MEHP+ obese patients we did not find any significance (FT₃: r=0.189, P<0.25; FT₂: r=−0.023, P<0.897; TSH r=0.082, P<0.928).

Conclusion
Half of our population is exposed to MEHP and MEP. In obese subjects higher leptin correlates with lower FT₃.

Using diaserein on the patients with glucose intolerance

Kenan Cadirci1,2 & Kadri Yıldız2

1Erzurum Regional and Educational Hospital, Erzurum, Turkey; 2Erzurum Palandoken State Hospital, Erzurum, Turkey.

Diaserein is used in the specific and long-term treatment of degenerative joint diseases (as osteoarthritis). In vitro studies have showed that Diaserein and its active metabolite Rheinin inhibit production and activity of interleukin-113 (IL-113), some proinflammaratory cytokines. Interleukin-113 is a proinflammaratory cytokine that plays an important role to trigger production of more proinflammaratory factors as cytokines, cyclo-oxygenases, prostaglandines, nitric oxide, matrix metalloproteinases in chondrocyte degradation, snobal enflamation, remodelling of subchondral bone. Diaserein stimulates synthesis of chondral matrix components as proteoglicans, glicoseam inoglicans, hyalur onic asids. After all Diaserein exists. Diaserein stimulates synthesis of chondral matrix components as proteoglicans, glucoseaminoglycans, hyaluronic acids. After all Diaserein decreases the loss of chondral components continuously. We present 41 case series of patients that is used Diaserein on the treatment of osteoarthritis in various joints (gonarthrosis, coxarthrosis, degenerative lomber diseases). 41 patients have followed up clinically in 2014–2016. 17 patients in this serie have show intolerance to medicine by diarrhea, vomiting and some clinical complaints. At the research of these intolrated patients 16 patients have glucose intolerance as Diabetes Mellitus Type 1 and 2. At the researching of literature, Diaserein were not advised severe renal insufficiency, gastrointestinal disorder (Chrone, Ulserative Colit...), hepatic insufficiency and also glucose intolerance. Diaserein must be used carefully in the patients that have renal and hepatic insufficiency and failure. And also it must not be preferred on the patients which have glucose intolerance because of seem severe side effects.

EP712
Role of cognitive-behavioral therapy in the treatment of obesity
Snjezana Popovic-Pejic
Faculty of Medicine, University of Banja Luka, Republic of Srpska, Banja Luka/Republic of Srpska, Bosnia and Herzegovina.

Dietary therapy, programmed physical activity and cognitive-behavioral therapy are basic measures in the treatment of obesity. Cognitive-behavioral therapy applies methods which change eating habits of obese persons, aiming to remove barriers relating dietary therapy and programmed physical activity. The goal is to try efficiency of applying cognitive-behavioral therapy in the program for the reduction of body mass of obese persons, versus the application of dietary therapy and programmed physical activity alone. The study included 60 obese persons, who were divided into two groups with 30 patients in each group, 20 to 58 years of age with the body mass index ≥ 30 kg/m² and hyperlipidemia (LDL cholesterol ≥ 4.2 mmol/l). Patients from both groups were on hypocaloric diet, individually designed and had programmed physical activity every day. Patients in group II underwent group cognitive-behavioral therapy under the supervision of a psychiatrist once a week with the duration of 120 min. Both groups also went to see an endocrinologist 6 times, on which occasions their body weigh, blood pressure, parameters of lipid status serum and level of glucose in serum were measured. Results showed that in group II the medium value of body mass reduction after twelve weeks of treatment was 9.5 kg (8.9%) and in group I 14.4 kg (4.1%). In group II, LDL cholesterol decreased for 34.5% and in group I for 5.0%; HDL cholesterol increased for 2.7% while in group I it decreased 2.5%; total triglycerides decreased for 15.3% and in group I for 5.4%; values of glycaemia decreased for 14.8% while in group I they remained unchanged. Cognitive-Behavioral therapy affected the improvement of motivation and readiness of patients to stick to the dietary regime and programmed physical activity. In designing the program for the reduction of obesity it is necessary to include cognitive-behavioral therapy, which brings significantly better therapy outcomes.

Concern about body image, impulsiveness and personality traits in the morbidly obese before bariatric surgery and in patients who have undergone surgery
Isabel Mateo-Gavira1, Daniel Medina-Rivero1, José Pedro Novalbos-Ruiz2, Amelia Rodríguez-Martín2, María José Santi-Cano3, D Ogalla de Castro3 & Manuel Aguilar-Diosdado1
1Endocrinology, Puerta del Mar Hospital, Cádiz, Spain; 2Preventive Medicine and Public Health, University of Cadiz, Cádiz, Spain; 3Nursing and physiotherapy, University of Cadiz, Cádiz, Spain.

Objectives To analyse the levels of anxiety, depression, impulsiveness, bulimic behaviour, concern about body image and the quality of life of patients included in the care process following bariatric surgery, in our field.

Methods Observational study of the patients included in the care process for bariatric surgery at University Hospital Puerta del Mar. Two cohorts were identified according to their situation before or after surgery. Studies were made of variable anthropometrics, clinics, personality traits and quality of life. The instruments used were: Anxiety inventories (BAI) and Depression (Beck); Body Sharp Questionnaire (BQ21); BULIT-R test of bulimic behaviour, impulsiveness (BIS) and SF12 questionnaire on quality of life.

Results and conclusions A total of 198 patients were studied, women constituted 69.2% of the subjects; the average age was 45 without differences in the cohorts before/after 12 months; the BMI in patients before surgery was 48 (s.d. 7) and in patients post surgery, 34 (s.d. 6). The patients on waiting lists presented higher levels of concern regarding to their body image (BQ21: 65), bulimic behaviour (BULIT: 62) and depression (BECK: 15). The SF12 reflected good mental health but scored lower on points concerning physical health. The levels of impulsiveness were not high (BIS: 53), so no patient reached the cut off point (104). The cohort of post-surgery patients presented high levels of concern about body image (BQ21: 65) and anxiety (BAI: 34). Impulsiveness was moderate (BIS: 58). It was noted that the proportion of patients with extreme concern about their body image (BQ21 > 105) was higher in patients who had already undergone surgery (12.5 vs 6.4%). Attending to the depressive state of patients (BECK) prior to surgery required professional care for 35.9% for the morbidly obese, against 16.7% of post-surgery patients; severe depression was detected in 11.7% and 4.8% of patients respectively.

EP713
Dynapenic obesity and myosteatosis in women with and without the metabolic syndrome
Eleonora Paggiogalle, Lorenzo Donini, Lucio Gnassi, Stefania Mariani, Michele Di Martino, Barbara Cicciantelli, Cecilia Mancini, Marcello Arca, Andrea Lenzi & Carla Lubrano
Sapienza University, Rome, Italy.

Introduction
Insulin resistance is a well-known hallmark of the metabolic syndrome (MetS), and it detrimentally affects also protein metabolism, favoring to the decline of lean body mass. The aim of the present study was to explore muscle strength (as a functional consequence of sarcopenic obesity) and muscle quality (namely, myosteatosis) in women with and without the Metabolic Syndrome (MetS).

Methods
Our study included 35 patients followed for obesity. Bone mineral density was ordered in all patients.

Results
The mean age was 40 years, ranging between 21 and 69 years, 94.2% of our patients were female, mean body mass index was 43.9 kg/m² with an average waist circumference of 120 cm, over two thirds of the patients were morbidly obese, 31.4% had diabetes and 14.2% had hypertension, 18.1% of our female patients were postmenopausal. One female patient had osteopenia with a T score of −1.2 at the spine. The rest of our patients had normal bone mineral density with a mean T score at the spine and the femur of 0.65 and 1.39 respectively.

Conclusion
Obesity is associated with normal bone mineral density even in postmenopausal obese women, suggesting a protective effect of obesity against osteoporosis that was highlighted in several literature studies. That said, this beneficial effect should always be weighed against its adverse effects especially the metabolic and cardiovascular ones.

Lifestyle of morbidly obese patients awaiting bariatric surgery and in the cohort of patients who have undergone surgery  
Isabel Mateo-Gavira, Daniél Medina-Rivero², Amelia Rodríguez-Martín³, José Pedro Novalbo-Ruiz³, María José Santi-Canó², A Díaz-Yelamos¹ & Manuel Aguilar-Diosdado¹  
¹Endocrinology, Puerta del Mar Hospital, Cádiz, Spain; ²Preventive Medicine, University of Cádiz, Cádiz, Spain; ³Nursing and Physiotherapy, University of Cádiz, Cádiz, Spain.

Objectives
To determine the habits and lifestyle of the morbidly obese before and after bariatric surgery.

Material and methods
Transversal study of two groups of morbidly obese patients attending the Endocrinology Unit of Puerta del Mar, Cádiz: one group before and the other after bariatric surgery. Clinical and analytical data of the patients was collected: socio-demographic and lifestyle characteristics, BDI-R Questionnaire (Bulimia), BIS (impulsiveness), BQ1 (body image), BAI (anxiety), BECK (depression) and quality of life through questionnaire SF12.

Results
111 morbidly obese were studied before surgery (31.5% men, 68.5% women) and 87 morbidly obese post-surgery (29.9% men and 70.1% women). Before surgery mean weight was 153.4 (S.D. 24.4) and BMI 48.6 (S.D. 7.0), and post-surgery 54.9 (S.D. 19.8) and BMI 34.5 (S.D. 6.5). In both groups there was a predominance of primary and lower secondary education (25.8% of total); the greater proportion of subjects with a higher level of education was in the post-surgery group (3.6% vs 13%). Only 25% were actively in work before surgery, rising to 36.5% in the post-surgery group. Significant differences were observed between the two groups in relation to habits and lifestyle such as tobacco consumption (21.1 vs 7.1%), alcohol consumption (21.1 vs 17.4%), physical exercise (55 vs 82.6%), hours of physical exercise (4.75 hours/week vs 5.9) and increase in meals per day from 3 to 5. Family support is greater for the post-surgery group (90 vs 83.8%), excluding differences in professional support services (14%).

Conclusions
Significant differences were observed in patients’ habits and lifestyle before and after bariatric surgery; factors which could contribute to the care, prognosis and evolution of the patients. Social and family support is greater for post-surgery patients.

EP716  
Thyroid hormone treatment reduces inflammatory cytokines in mesenteric adipose tissue improving insulin sensitivity of obese rats  
Ana Carolina Panvellosi-Costa, Caroline Serrano-Nascimento, Leonice Poyares, Gabriela Souza Viana, Paula Bargi-Souza & Maria Tereza Nunes  
University of Sao Paulo, Sao Paulo, SP, Brazil.

Thyroid hormone plays an important role on carbohydrate and lipid metabolism. In a hypothyroidism the reduction of glucose transporter-4 expression and insulin sensitivity and in hyperthyroid states the key enzymes of gluconeogenesis and glycogenolysis are induced, and both conditions lead to glucose intolerance. It has been reported an increased prevalence of thyroid dysfunction in obese and diabetic patients. Recently we have demonstrated a hypothyroid state in alloxan-induced diabetic rats, in which the treatment with triiodothyronine (T3) improved glycemia control and insulin sensitivity. These alterations were accompanied by reduction of inflammatory cytokines in white adipose tissue and skeletal muscle. The present study aimed at evaluating the thyroid hormone function of cafeteria diet-induced obese rats and the effects of thyroid hormone treatment on their glycemia control, insulin sensitivity and subclinical inflammation.

Methods
Obesity was induced in male Wistar rats by cafeteria diet. A subset of the obese rats was treated with T3 (1.5 μg per 100 g body weight) for a 28-day period (DT). Thyroid function was evaluated by molecular (TG, NIS, TSHR and TPO expression in thyroid gland) and biochemical parameters (serum TSH, T4 and T3 concentrations). Cytokines concentration was measured in mesenteric white adipose tissue (MWAT) (MILiplex assay kit).

Results
Obese rats exhibited decreased insulin sensitivity, thyroid function and serum TSHR concentration, and increased MWAT inflammatory cytokines, NIS and TSHR expression in thyroid gland. Thyroid hormone treatment improved insulin sensitivity, glucose tolerance and reduced MWAT inflammatory cytokines content, which are known to induce insulin resistance.

Conclusions
The present data provide evidence that thyroid function is reduced in obese rats and reinforce the role of T3 treatment on improvement of insulin sensitivity by its negative modulation of inflammatory cytokine expression in metabolic disorders as obesity or diabetes mellitus.

Predictive factors of outcome in bariatric surgery  
Aurora Aragón-Alonso, Mercedes Ferrer Gómez, José Ramón Cuenca Sánchez, David Ruiz de Angulo Martín, María Dolores Frutos Bernal, María Ángeles Campillo Espallardo, Pedro Segura Luque & Antonio Hernández Martínez  
Hospital Universitario Virgen de la Arrixaca, Murcia, Spain.

Introduction
Bariatric surgery is currently considered the most effective treatment for morbid obesity, although rates of weight loss and comorbidities resolution differ among bariatric techniques and depending on preoperative factors.

Objectives
In this study we analyse possible factors that influence the outcome of bariatric surgery (weight loss and improvement in metabolic comorbidities) in order to identify those patients most likely to benefit from surgery.

Methods
We included all the patients who underwent bariatric surgery in Hospital Universitario Virgen de la Arrixaca during one year (n=101) of which 62 received LGB and 39 LSG. We retrospectively analysed which preoperative factors were related to percentage of excess body mass index (%EBMIL), type 2 diabetes remission (T2DM), and higher rates of hypertension (HT) and hypercholesterolemia (Hchol) persistence one year after surgery.

Results
%EBMIL one year after surgery was significantly higher (P=0.016) in patients with preoperative BMI ≤50 kg/m² vs BMI >50 kg/m² (79.4±21.3 vs 65.6±15.4). Age, sex and presurgery T2DM were not associated with %EBMIL one year after surgery. Absence of insulin treatment at baseline (89% vs 50%, P=0.03), less than five years after diagnosis of T2DM (100 vs 53.8% P=0.017) were associated with higher T2DM remission one year post surgery. Age, sex, presurgery BMI, HbA1c and smoking status were not associated with higher remission rates. HT persistence one year after surgery was significantly associated to age >50 (30.3% vs 8.2% P=0.005) and baseline T2DM (30.8% vs 10.3%, P=0.015). HChol persistence one year after surgery was significantly associated to age >50 (28.1% vs 8.5%, P=0.013) and baseline T2DM (28% vs 10.6%, P=0.04). Sex, baseline BMI nor smoking status were not associated with HT nor HChol persistence.

Conclusions
There is a heterogeneous pattern of presurgical factors that predict the outcomes of bariatric surgery.

Prevalence of obesity in Algeria  
Nadira Fafa¹,², Djamilia Merkine¹,², Saida Fedala¹,² & Lamia Kedad¹,²  
¹Laboratory of Endocrinology and Metabolism LEM1, Algiers, Algeria; ²Ibn Ziri Bologhine Hospital, Algiers, Algeria.

Introduction
The epidemiological transition has resulted in a major increase in the prevalence of obesity in our country. Obesity is closely associated with chronic diseases such as type 2 diabetes, hypertension and dyslipidemia. The aim of our study is assessing the prevalence of general obesity, central obesity (OA), associated risk factors (D2, HTA and dyslipidemia) and tries to provide information on determinants of obesity in Algerian adult.

Testosterone deficiency in obese males: is insulin resistance the one to blame?
Pedro Soutêiro1,2, Daniela Magalhães1,2, Jorge Pedro1,2, Sofia Castro Oliveira1,2, João Sérgio Neves2, Sandra Belo1,2, Maria Manuel Costa1,2, Rita Bettencourt-Silva1,2, Ana Varela1,2, Joana Queiroz2,2, Paula Freitas1,2, Davide Carvalho1,2 & Group AMTCO3
1Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar São João, Porto, Portugal; 2Faculty of Medicine of University of Porto, Porto, Portugal; 3Multidisciplinary Group for Surgical Management of Obesity, Centro Hospitalar São João, Porto, Portugal.

Introduction

Obesity is a growing worldwide public health issue and it is associated with multiple comorbidities, namely the so called Male Obesity-associated Secondary Hypogonadism (MOSH). However, the mechanisms that explain this association are not fully understood.

Methods

Cross-sectional study of 163 obese men that were evaluated for several clinical and analytic parameters. Testosterone deficiency was defined as: total testosterone <2.8 ng/ml and/or free testosterone calculated by the Vermeulen formula <50 pg/ml.

Results

The studied population had a mean age and BMI of 40.8 ± 10.5 years-old and 45.8 ± 6.7 kg/m², respectively. Testosterone deficiency prevalence was 47.2%. The majority (96.1%) of these men had hypogonadotrophic dysfunctions and 2.9% presented high gonadotrophins. When only calculated free testosterone levels were considered, the deficiency prevalence was 18.1%. Higher BMIs correlated with lower levels of SHBG (sex hormone binding globulin): r = −0.19; P < 0.05. BMI (r = −0.26; P < 0.001), age (r = −0.21; P < 0.05) and HOMA-IR (r = 0.39, P < 0.001) had a negative correlation with calculated free testosterone levels, while SHBG levels exhibited a positive correlation (r = 0.18; P < 0.05). There was no significant correlation between oestradiol levels and free/total testosterone or BMI. When the aforementioned significant variables were included in a linear regression model, HOMA-IR (β = −0.33; P < 0.001) and SHBG levels (β = 0.12; P < 0.01) could predict the free testosterone levels, while age (P = 0.07) and BMI (P = 0.23) lost their significance after the adjustment. In accordance, males with normal glucose tolerance had higher free testosterone levels than those with pre-diabetes or diabetes even after adjusting for age and BMI (β = 0.22; P < 0.01).

Conclusions

Testosterone deficiency is frequent in obese males, with most of them presenting hypogonadotrophic dysfunction. SHBG levels and mainly insulin resistance, and not obesity per se, seem to be the true mediators of this interplay. We found no correlation between oestradiol and testosterone levels suggesting that androgen aromatization in adipose tissue is not a key determinant as previously thought.

Anthropometric and metabolic effects of a milk-based intensive lifestyle intervention in severely obese adults
Julia Andrade Ioana, Faraz Ratey Mohammied, Conor Murphy, Katriona Kilkeely, Colin Brassil, Katie Cunningham, Robert McGrath, Helena Griffin, Paula O'Shea & Francis M Finucane
Galway University Hospital, Galway, Ireland.

Therapeutic options for patients with severe obesity are limited. Low energy meal replacement regimes can induce significant short-term weight loss and improvements in metabolic variables. We sought to estimate the effect size on adiposity and cardiovascular risk factors of a relatively inexpensive 24-week regime based on meal replacement with semi-skinned milk in severely obese adults. A retrospective cohort analysis showed that of 206 patients in our hospital-based bariatric medicine service who started, 112 (54%) completed the programme and underwent an initial milk-based weight loss phase, followed by weight stabilization and weight maintenance phases, each lasting 8 weeks. Patients were seen every two weeks by the bariatric physician, nurse and diettian. We compared outcomes in completers (who had similar baseline characteristics to non-completers) at time 0, 8, 16 and 24 weeks, with repeated measures ANOVA. 50.9% of completers were female, 40.2% had diabetes, mean age was 50.9 ± 10.3 years. BMI decreased from 52.7 ± 9.3 to 46.9 ± 8.7, 44.8 ± 8.6 and 43.8 ± 9.2 kg/m² at 0, 8, 16 and 24 weeks, respectively (P < 0.001 with repeated measures ANOVA), equivalent to 24.8 kg weight loss and a reduction in excess body weight from 110.6 ± 37.2 to 75.2 ± 36.9%, P < 0.001 over 24 weeks. In patients with diabetes, HbA1c decreased from 63.2 ± 2.0 to 63.2 ± 2.14 mmol/mol, P = 0.01. There were very significant reductions in all diabetes medications, except for metformin. These preliminary findings suggest that a 24-week milk-based meal replacement programme can have large effect sizes on important outcomes in severely obese. However, attrition was high. A more formal assessment of the efficacy of the intervention as well as its safety, feasibility and cost-effectiveness seems warranted.

Association of cortisol, DHEA-S and cortisol/DHEA-S ratio with insulin resistance in overweight and obese women
Adam Maciejewski1, Monika Litwinowicz2, Emilia Marcinkowska2, Mariann Gryzmalski1 & Katarzyna Lacka1
1Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; 2Department of Internal Medicine, Metabolic Diseases and Diabetics, Poznan University of Medical Sciences, Poznan, Poland.

HPA axis plays important controlling and modulating functions in organism and is also linked with insulin resistance and weight control. The number of evidences linking cortisol secretion with obesity and other metabolic complication increase, but still there is a lack of definitive results. Therefore the aim of our study was to compare adrenal function parameters between high and normal insulin resistant overweight and obese women. This retrospective analysis was performed on the group of 70 adult polish Caucasian overweight and obese women with the mean age of 40 years. Mean BMI for the whole group was 38 kg/m². Exclusion criteria were: pregnancy or breastfeeding, history of any pituitary or adrenal gland disorders, current or previous usage of any glucocorticoid-containing medications, other drugs known to affect cortisol level and patients with diagnosis of severe liver or kidney dysfunctions and acute or chronic inflammatory disorder at the time of measurements. Patients were divided into two groups according to HOMA-IR value (cut-off point of 3.8). Statistical analysis was performed using Statistica software. Differences between lower HOMA-IR and higher HOMA-IR groups were determined by student t test and Mann-Whitney U test when appropriate. To analyze correlations between measured values Spearman correlation coefficient was calculated. P value < 0.05 was considered statistically significant. Patients with higher HOMA-IR have higher morning cortisol concentration (504.36 vs 425.82 nmol/l) and lower DHEA-S concentration (170.18 vs 227.49 µg/dl), although these differences were not statistically significant. There was statistically significant difference between higher and lower HOMA-IR groups in evening cortisol concentration (248.28 and 186.02 nmol/l, respectively, P = 0.007) and cortisol/DHEA-S ratio (5.73 vs 2.73, P = 0.003). For the whole group studied there was statistically significant positive correlation between cortisol/DHEA-S ratio and HOMA-IR (r = 0.39, P < 0.001). There is a significant association between evening cortisol secretion and HOMA-IR and between cortisol/DHEA-S ratio and HOMA-IR.

**Obesity and fruit and vegetables consumptions in children**

Bruno Sousa1,2
1Universidade Lusofona de Humanidades e Tecnologias, Lisboa, Portugal; 2Research Center for Biosciences and Health Technologies, Lisboa, Portugal.

**Introduction**

Obesity is associated with the low consumption of fruit and vegetables.

**Objective**

Evaluate the obesity and the fruit and vegetables consumptions in children after an intervention of school food education program.

**Methodology**

It was implemented a food education program in three classes (n=55) of 1st cycle, on school year (2016/2017) and the evaluation of this action was done comparing fruit and vegetables consumptions and nutritional status of this children between beginning and the end of the program (after 12 weeks). Fruit and vegetables consumptions were assessed through the application of a food frequency questionnaire and the nutritional status was determined by BMI. Weight and height were assessed in all children and BMI was calculated. To determine the obesity was used CDC criteria. The educational intervention consisted in promoting fruit and vegetables consumptions at school environment, involving formative and recreational activities, as well as a greater supply of fruit and vegetables in school.

**Results**

This sample had between 6 and 8 years old and 54.5% were girls. Fruit consumption increased and considering the 3–5 pieces of fruit per day recommended by the Portuguese Food Wheel, the consumption in these students evolved from 16.3% to 41.8%. Vegetables consumption also increased. At beginning 54.5% ate two or more servings per day of vegetables, and at end 74.5%. In nutritional status, it was observed that obesity decreased from 20% to 16.4%.

**Conclusions**

This type of educational intervention in schools increased fruit and vegetables consumptions and reduce the prevalence of obesity in children.

**Neuromedin B receptor: role in adipogenesis and a possible target for obesity treatment**

Gabriela Paula1, Marianna Wilieman1, Luana Souza1, Karina Ribeiro2, Leandra Baptista2 & Carmen Cabanelas3
1Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; 2National Institute of Metrology, Quality and Technology, Duque de Caxias, Rio de Janeiro, Brazil.

Neuromedin B (NB) is a peptide highly expressed in adipose tissue (AT) but its influence after differentiation. Cells were fixed and stained with Dapi and Bodipy for cell and lipid measurements. After 21 days DMC group exhibited 2.7 times more cells number than GMC but DMA group presented similar cell number to GMC. DMC group reached 83% of well area as lipid while DMA did only 7% although it was corrected by cells area. When NBR antagonist was added for 6 days to DMC it decreased cells number by 40% and lipid accumulation diminished 10%. In conclusion NBR-KO AT cells have impaired induced-adipogenesis and NBR antagonist promoted less adipogenesis, reduced adipocytes number and decreased lipid accumulation.

Data demonstrate, for the first time, a role for NBR in adipocyte differentiation, suggesting it is a possible target for obesity treatment. Presently, we are analyzing hormones and factors involved in adipogenesis, lipogenesis and cell death to clarify mechanisms.

**Intracranial lesions in children and adolescents with morbid obesity; results of long-term follow-up**

Ayca Torel Ergur1, Sevinc Odabasi Günes1, Sinan Tan2 & Umit Ayse Tandircioğlu2
1Department of Pediatric Endocrinology, Kirikkale University Faculty of Medicine, Kirikkale, Turkey; 2Department of Radiology, Kirikkale University Faculty of Medicine, Kirikkale, Turkey.

**Introduction**

Childhood obesity has become an important health problem nowadays. Intracranial lesions (IC) can affect the hypothalamic - hypophyseal axis depending on the localization of the lesion and lead to hypothalamic hormone deficiencies, especially growth hormone. Although IC lesions are important in the etiology of obesity, there’s limited data in the literature about this subject. Aim of this study is to evaluate the incidence of IC lesions and their role in clinical symptoms and etiology in cases with morbid obesity (MO) in childhood.

**Materials and methods**

One hundred twenty cases admitted with the complaint of MO in 13 years (2002–2015) were included in this study. Anthropometric evaluation and detailed physical examinations were performed. Biochemical and hormonal parameters (glucose, lipid metabolism, adrenal steroids and diurnal cortisol) were evaluated. Contrast-enhanced dynamic magnetic resonance imaging (CDMRI) technique was used to assess the hypothalamo-hypophyseal field. Height of hypophyss was evaluated according to age and sex.

**Results**

In our study, 16.6% of the MO patients had an IC lesion. Most of the cases had adenoma of the hypophysis (55% of the cases with IC lesion.) Six of the patients with IC lesion had high prolactin levels. Prolactin levels were increased in the 6 patients but front hypophyseal hormone levels were in between normal range in the rest of the patients. None of the patients had decreased growth velocity.

**Conclusion**

In this long-term study, the important result is that; IC lesion frequency was significantly higher in children and adolescents with MO than those of the normal population. Moreover, these lesions show no other endocrinological or neurological symptom besides obesity. Furthermore; due to this study; we suggest that cranial imaging with CDMRI in these cases, even if the physical-neurological examination is normal, will contribute greatly to the early diagnosis and treatment of lesions without causing other symptoms.

DOI: 10.1530/endobbs.49.EP724
somatostatin analogues. Patient no 1 developed various cognitive deficits and epilepsy, however patient no 2 experienced an entirely normal neurodevelopment.

Conclusion
We report the case of two siblings with diazoxide-resistant CHI caused by the same compound ABC282 mutation (which was never before described, to the best of our knowledge). Their phenotype and therapeutic management had some differences and this could offer a potential explanation for the distinct neurological outcomes, despite the same genetic basis for the disease. Molecular diagnosis and better knowledge of the disease behaviour seemed to contribute to a better medical care in patient no 2, which ultimately resulted in a better outcome. This highlights the importance of early recognition and diagnosis of this disease.

EP726
Association between oxidative stress and bone turnover markers in the obese children
Paweł Matusik1, Magdalena Oliszanecka Glinianowicz2, Jerzy Chudek2 & Ewa Malecka-Tendera1
1Department of Pediatrics and Pediatric Endocrinology, Medical University of Silesia, Katowice, Poland; 2Department of Pathophysiology, Medical University of Silesia, Katowice, Poland.

Background
Recent data have been showed that free radicals are involved in either bone resorption and atherosclerosis development in adults. In paediatric population the important risk factor for the early atherosclerosis development is obesity, which can be also associated with the disturb bone turnover.

Objective and hypotheses
The aim of the study was to evaluate the interrelationship between oxidative stress and bone turnover markers in obese children vs lean controls and correlated them with the anthropometrical status and metabolic activity of adipose tissue. Method
Bone turnover markers (osteocalcin (OC), N-terminal telopeptide of type I collagen (NTx)), oxidative stress markers (TAC – total antioxidative capacity, glutathione peroxidase, oxLDL) and leptin were determined in 50 obese children and 79 healthy controls. Anthropometrical status by BMI calculation and body composition parameters as: fat mass (FM), fat-free mass (FFM), predicted muscle mass (PMM) and total body water (TBW) were evaluated using bioelectrical impedance analyzer (BIA) in all children.

Results
OC was significantly lower in obese children and correlated significantly (negatively \( P<0.01 \)) with BMI in the lean group. There was also significant positive correlation between OC and TAC in obese children. NTx correlated significantly with oxy-LDL (positively) in either, obese and lean group (\( P<0.05 \) and \( P<0.01 \) respectively). The lean group only, there were significant relations between NTx vs leptin and body composition parameters (\( r=0.245 \) vs leptin, \( r=0.245 \) vs FFM\% , \( r=0.252 \) vs PMM\%, and \( r=−0.245 \) vs FFM\% respectively).

Conclusion
Bone turnover seems to be disturbed in the obese children and pathophysiological factor with can be involved in that mechanism may be an increase oxidative stress level. Osteocalcin and NTx levels seem to be related to the anthropometrical status and adipose tissue activity (leptin level).

In vivo porcine and in vitro HepG2 models with 11β-HSD1 overproduction
Hee Young Kang, Jae Hwan Lee, Jin Yong An, Dinh Nam Tran & Eui-Bae Jeung
Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Introduction
11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) has been associated with several human metabolic disorders and is converted from inactive 11-keto form to glucocorticoid (GC or cortisol), GC overproduction or hypercortisolism is a major diagnostic factor of Cushing syndrome and Anorexia. GCs regulate carbohydrate, fat, and protein metabolism.

Materials and methods
Previously we established porcine fibroblasts overexpressing 11β-HSD1. Based on these, transgenic piglets overexpressing 11β-HSD1 were born through somatic cell nuclear transfer (SCNT) and re-cloning methods. Transgenic piglets were identified by PCR methods using specific primers for the targeting cassettes from the genomic DNA of piglets. HepG2 cell line overproducing 11β-HSD1 (11β-HSD1-HepG2) was established for in vitro model. In vivo porcine and in vitro hepatic models were analyzed by real-time PCR, immunohistochemistry and Western blotting methods.

Results
Six live piglets were born. Integration of target gene into the genomic DNA was confirmed from all of them. Excessive expression of 11β-HSD1 induced up-regulation of gluconeogenesis (G6PT, G6Pase, PEPCK and etc.) and lipogenesis related genes (FASN, ACC, and 3CD) in vivo and in vitro models. To compensate for energy loss by anabolism, it stimulates AMPK and SIRT signaling, which controls energy balance and mitochondrial biogenesis.

Conclusions
These results suggest that the overproduction of 11β-HSD1 induce activation of complementary energy gaining processes through mitochondrial respiration. Our in vivo and in vitro models will be useful for further study and potential application in metabolic diseases.

DOI: 10.1530/endoabs.49.EP727

Hepatic and adipose tissue insulin resistance as a consequence of intermittent hypoxia are exacerbated by glucocorticoid receptor antagonism in man
Jonathan Hazlehurst, Catriona Charlton, Diana Mantripp, Leanne Hodson & Jeremy Tomlinson
Oxford Centre for Diabetes, Endocrinology & Metabolism and NIHR Biomedical Research Centre, University of Oxford, Oxford, UK.

Introduction
Obstructive sleep apnea (OSA) affects up to 20% of a Western population and is associated with non-alcoholic fatty liver disease and type 2 diabetes (T2D). OSA is characterized by intermittent episodes of hypoxia (IH) that occur during sleep. It is not yet known if IH is directly linked to insulin resistance within key metabolic target tissues (adipose; liver and skeletal muscle) and what the potential underlying mechanism may be. It has been suggested that individuals with OSA have high circulating glucocorticoid levels which may be linked to the development of IR and T2D.

Methods
17 healthy male volunteers were recruited and underwent detailed metabolic phenotyping in a fasted state including a hyperinsulinaemic-euglycaemic clamp, incorporating the use of stable isotopes of glucose and palmitate to measure fatty acid partitioning. Initial assessments were made in normoxic conditions; volunteers were then randomised either to no treatment (n=9) or treatment with the glucocorticoid antagonist Mifepristone (600 mg once a day) (n=8). After 1 week of treatment, assessments were repeated under conditions of IH (12 desaturations/h to arterial saturations of 85-91%).

Results
Global insulin sensitivity as measured by M/I values was unchanged by IH or by IH + Mifepristone (control: 8.65 ± 4.1; IH: 9.13 ± 5.4; control (pre-drug): 8.9 ± 3.7; Mifepristone + IH: 10.13 ± 3.3). However, IH impaired the ability of insulin to suppress TAG, an effect that was worsened by Mifepristone (insulin mediated suppression of TAG: control: −449 ± 124; IH: −218 ± 131 (P = 0.0034); control (pre-drug): −339 ± 201; Mifepristone + IH: −76 ± 128; (P = 0.008). In addition, adipose tissue IR, as measured by a reduction in the ability of insulin to suppress circulating NEFA, was worsened by Mifepristone under conditions of IH (insulin mediated change in plasma NEFA control: −501 ± 164; IH: −411 ± 187 (P = ns); control (pre-drug): −549 ± 130; Mifepristone + IH: −367 ± 109; (P = 0.03)).

Conclusion
Acute IH causes insulin resistance in liver and adipose tissue. These effects are worsened rather than improved by antagonism of the glucocorticoid receptor, highlighting the importance of understanding tissue specific glucocorticoid
actions and suggesting activation of the HPA axis is not the link between OSA and metabolic risk

**Dexras1 regulates MSC-derived adipogenesis and osteogenesis**

Jo Woon Seok¹, Daem Kim¹, Hye min Lee¹, Bo kyung Yoon¹, Hyo Jung Kim¹ & Jee-woo Kim¹,²

¹Department of Biochemistry and Molecular Biology, Integrated Genomic Research Center for Metabolic Regulation, Institute of Genetic Science, Yonsei University College of Medicine, Seoul, Republic of Korea; ²Severance Biomedical Science Institute, Yonsei University College of Medicine, Seoul, Republic of Korea.

Mesenchymal stem cells (MSCs) are multipotent stromal cells that can differentiate into various types of cells including chondrocytes, osteoblasts and adipocytes. Since these types of cells are simultaneously derived from the same precursor cell, adipogenesis and osteoblastogenesis are thought to be counter-related. It is well-known that chronic treatment of steroid can induce Cushing’s syndrome which has phenotypes like visceral adiposity and osteoporosis. Cell fate of differentiation into either adipocytes or osteoblasts is one of the critical factors of these symptoms, but the molecular mechanism of cell fate decision of MSCs under the steroid treatment is unclear. Recently, we showed that Dexras1 mediates glucocorticoids and IGF-1 signaling followed by MAPK activation and results in increased adipogenesis while its abolishment decreases adipogenesis. Now we established that lack of Dexras1 exhibited increased osteogenesis in mesenchymal stem cells including both bone marrow derived stem cells (BMSCs) and mouse embryonic fibroblasts (MEFs). Corroborative to our previous data, decreased adipogenesis in MSCs was also observed in the absence of Dexras1.

Despite less dramatic change in differentiation, it is also shown that lessened mature osteoblasts in Dexras1-overexpressing preosteoblast cell line, MC3T3-E1, down regulating Smad signaling in the early period of differentiation. Furthermore, we found that Dexras1 is involved in increased central obesity associated with chronic treatment of steroids but rescued steroid-induced osteoporosis in mouse model treated with dexamethasone for 8 weeks followed by increased gene expression related to osteoblast in the murine bone. Above all these results, we suggest that Dexras1 is a key molecule which stimulates adiposity and down regulates osteogenesis via counter-regulating action.

**Gender specific metabolic phenotype in the 5β-reductase knockout mouse**

Laura Gathercole¹,², Petra Klusonova³, Nikolaos Nikolakou², Jonathan Hazlehurst³, Ahmad Moolla³, Niall Dempster⁴, Trevor Penning³, Roger Cox³, Alex Odermatt³ & Jeremy Tomlinson⁴

¹University of Oxford, Oxford, UK; ²Oxford Brooks University, Oxford, UK; ³University of Basel, Basel, Switzerland; ⁴Medical Research Council Harwell, Oxfordshire, UK; ⁵University of Pennsylvania, Philadelphia, USA.

Steroid hormones and bile acids are potent regulators of metabolism. The enzyme 5β-reductase (AKR1D1) has a crucial role in bile acid synthesis and also generates 5β-reduced dihydrosteroid metabolites, regulating intra-cellular steroid availability though the clearance of cortisol, testosterone, androstenedione, and progesterone. As AKR1D1 sits at the interface of bile acid synthesis and steroid metabolism, we have hypothesised that it plays a key role in metabolic homeostasis and have generated and characterised an entirely novel, global AKR1D1 knockout (KO) mouse. As expected AKR1D1 KO mice had altered hepatic steroid (in vitro cortisone clearance: 100% (WT), 70% (KO); in vitro 5α-cortisone/cortisol metabolite generation increased 3.9-fold (KO)) and bile acid metabolism (hepatic bile acid concentration males: 1164 ± 626 pmol/mg (WT), 122 ± 42 pmol/mg (KO) P < 0.05; females: 310 ± 67 pmol/mg (WT), 113 ± 23 pmol/mg (KO) P < 0.01). At 30 weeks male, but not female, AKR1D1KO animals were lighter than wildtype (WT) littermates (males: 35.6 ± 0.9 g (WT), 33.2 ± 0.6 g (KO) P < 0.05; females: 25.3 ± 0.6 g (WT), 24.9 ± 0.4 g (KO) P = ns) with lower total (9.7 ± 0.7 g (WT), 7.4 ± 0.5 g (KO) P < 0.05) and % (29 ± 1.4% (WT), 24 ± 1.5% (KO) P < 0.05) fat mass, as determined by DEXA. At termination, male AKR1D1 KO mice had smaller subcutaneous adipose depots (1.0 ± 0.1 g (WT), 0.7 ± 0.1 g (KO) P < 0.05) and, despite no difference in body weight or composition, female KO animals had smaller gonadal fat depots (0.5 ± 0.1 g (WT), 0.3 ± 0.03 g (KO) P < 0.05). Both male and female AKR1D1KO mice had enhanced insulin sensitivity (ipITT AUC males: 793 mMol min (WT), 647 mMol min (KO); ipITT AUC females: 663 mMol min (WT), 568 mMol min (KO)), without changes in glucose tolerance. AKR1D1 KO mice display a sexually dimorphic metabolic phenotype. Whereas both male and female AKR1D1 KO mice have increased insulin sensitivity, only male AKR1D1 KO mice have a lean phenotype. Although the underpinning mechanisms remain to be fully defined, AKR1D1 may represent a future novel therapeutic target for the treatment of metabolic disease.

Measuring of quality of life and health characteristics among 40–79 old population in South Hungary

Anita Zubrečki1, Ivan Devosa2, Marta Jako1, Attila Vass3, Klara Deak1, Sandor Kolozsar2, Melinda Vanya1, Imre Foldesi4 & Gyorgy Bartfai1

1Department of Obstetrics and Gynaecology, University of Szeged, Szeged, Hungary; 2Athene Pallasz University, Kecskemét, Hungary; 3Department of Ophthalmology, University of Szeged, Szeged, Hungary; 4Mediteam Zrt, Szeged, Hungary; 5Department of Obstetrics and Gynaecology, Kálmán Pandy Hospital Gyula, Gyula, Hungary; 6Department of Laboratory Medicine, University of Szeged, Szeged, Hungary.

Introduction
Life expectancy is increasing in most developed countries, in part due to improved socio-economic conditions and in part to advances in healthcare. It is widely acknowledged that the promotion of healthy ageing by delaying, minimizing or preventing disabilities or diseases is one of the most important public health objectives in this century.

Methods
243 Women and 181 men aged 40–79 years were recruited in Szeged (Hungary). Subjects were recruited from population registers and those who agreed to take part completed a detailed questionnaire including aspects of personal and medical history, lifestyle factors. Objective measures of body size, cognition, vision, skeletal health and neuromuscular function were obtained. Internal consistency of the questionnaire was also investigated (Cronbach’s alpha: 0.715).

Results
Mean age of participants was 59.17 ± 10.71 years. There were significant correlation between the quality of life and systolic blood pressure of the right & left hand (P = 0.007 and P = 0.013) and smoking use (P = 0.002). The cardiovascular risk was significantly higher in the 40–50 age groups compared to the older age groups (P = 0.002).

Conclusion
We provide new data among the health characteristics of older population in South Hungary. Such information is an important prerequisite to develop effective strategies to reduce age-related disabilities and optimise health and well-being into old-age.

Does standardising the dynamic endocrine testing process improve patient communication and safety?

Rahat Tauni & Ritwik Banerjee

1Cambridge University Hospitals, Cambridge, UK; 2Luton and Dunstable University Hospital, Luton, UK.

Background and objectives
Ineffective communication is one of the leading causes of medical errors and patient dissatisfaction. We implemented an initiative for dynamic endocrine tests to enhance communication with primary care colleagues and patients.

Methods
We introduced a comprehensive system of organising dynamic tests, structured documentation, weekly endocrine meeting to discuss the results and standardised escalation process for suspected abnormal results. We retrospectively analysed 50 tests prior to and 50 after the initiative was introduced (n = 100). Most were routine short synacthen tests (SST) with a small proportion of other tests including urgent/semi-urgent SST, dexamethasone suppression tests, TRH and GnRH stimulation tests, prolonged oral glucose tolerance test and prolonged supervised fast.

Results
The mean time from the date of test and the letter to general practitioner/patient of routine tests reduced from 22.07 days to 13.92 days for normal SSTs and 5.16 days to 4.83 days for abnormal SSTs, although the latter was not statistically significant. The other test numbers were too small to establish significance. There was no significant difference in time taken for organising the tests and no patient harm was reported in both groups. Anecdotal reports from trainees suggested that there were more training opportunities with the introduction of the new process.

Discussion
Our data suggests that streamlining the dynamic endocrine function test system reduces the delay in communicating normal routine dynamic endocrine test results and can increase the training opportunities for trainees. We aim to perform another analysis with a larger sample and analyse patient satisfaction data and consider confounding factors such as time taken from the dictation of letters to typing and postal delays, and observer effect from trainees. The endocrine meeting is not happening every week, and trainees are not attending it consistently due to other clinical commitments. We are actively looking to rectify these issues.

Endocrinology training programs in member countries of the International Society of Endocrinology (ISE): a pilot survey evaluation comparing regions and cultures

Maite P Basty & Juan C Galafre

Department of Endocrinology, University of Navarra, Pamplona, Spain.

Background
Endocrinology is a relatively young subspecialty of internal medicine. No consensus on international standards for training has been established, and hence the variability between training programs and endocrinologist qualifications may be great.

Methods
A standardized questionnaire was constructed to explore individual national standards for endocrinology training, evaluating the responding programs for physician entry criteria for each program, medical content, duration of the programs, procedural competency, and qualification and re-certification requirements. Representatives from member societies of the ISE were solicited to provide specific characteristics of their respective national training programs via a questionnaire on SurveyMonkey.

Results
Sixteen of 54 (30%) ISE member countries responded regarding training program characteristics. Spanish-speaking (SS) countries were more likely to have an entrance exam compared with non-SS countries (80 vs 27%, χ² = 3.88, P = 0.049). On average 62–85% of programs included all general endocrinology knowledge content with the exception of endocrine surgery (15%) and genetics (31%). Genetics was included more frequently in SS vs non-SS countries (60 vs 13%, χ² = 3.26, P = 0.071) and less frequently in European Union (EU) vs non-EU countries (17 vs 43%, χ² = 3.61, P = 0.057). Pediatric endocrinology was included more frequently in SS vs non-SS countries (100 vs 43%, χ² = 4.29, P = 0.038). Endocrinology research was included less frequently in EU vs non-EU countries (50 vs 86%, χ² = 3.26, P = 0.071). Thyroid procedures were taught only 33–38% of the time across programs while diabetes-related procedures and DEXA were required by 62–69% of the programs, and both were included more frequently in the SS vs non-SS countries (χ² = 8.70, P = 0.003, χ² = 5.08, P = 0.024, respectively). While 100% of countries required certification to practice endocrinology, only 38% had a certifying examination, with significantly lower administration in EU vs non-EU (17 vs 57%, χ² = 5.08, P = 0.024).

Conclusion
The questionnaire identifies differences in endocrinology training, which can be addressed by ISE member countries in the hope of an overall improvement in the quality of training and international harmonization of the discipline of endocrinology.

The basic characteristics of delivery of endocrinologic care in Slovakia from outpatients care perspective

Jan Bielik1 & Peter Glaz2

1Trencín University of Alexander Dubček, Trencín, Slovakia; 2Consultancy, Bratislava, Slovakia.

The prevalence of endocrinologic diseases in Slovak Republic in 2015 was about 390 000 patients e.g. the prevalence was about 7.1%. The objective of this study was to find out the basic relevant characteristics of delivery of endocrinologic care based on data from General Insurance Company with covering cca 63% of all inhabitants.

Methods
The combined analysis from the GIC was used. Results 246 195 patients, 212 977 women and 33 597 men, were examined in this study. The patients visited 150 endocrinologic outpatients departments (EOD). The number amounted from 1100 to 2800 patients per one department. The prevalence
of endocrinologic diseases differed from 6.1% to 9.3% compared 8 administrative regions. The ratio of EOD varied between 2.9% and 6.7% per 100,000 inhabitants. The migration of patients among regions varied from 3% to 10%. The thyroid diseases represented 88.4% of all patients, metabolic diseases – 8.3%, bone diseases – 6.5%, all other diseases – 5.4% (1 patient had one and more diseases). The prevalence of benign tumors in patients was cca 1.85% and malignant tumors about 1.7%. Some endocrinologic diseases were treated by more than 50 other specialists like internal specialists etc. In this thyroid diseases represented about 21.9%, bone diseases – 666%, metabolic diseases – 18.6% and all others diseases – 65.4%. From 2013 to 2015 y. was observed an increase of patients with thyroid diseases in 7.0%, bone diseases – 4.5%, other diseases 5.3%. Together 21 activities from daily practice were observed and evaluated. The most often were: first and followed examination, blood taking, evaluation of laboratory exams, ultrasonography, advice to the patients, densitometry, biopsy, etc.

Conclusions

The prevalence of endocrinologic diseases in Slovakia is high. There are some non explainable differences among administrative regions in access to endocrinologic outpatient services and high level of overlapping among endocrinology and other medical specialties.

Gestational diabetes risk in three Israeli population subgroups
Anat Jaffe1, Shmuel Giveon2, Carmit Rubin1, Ilia Nvokov3, Arnona Ziv3 & Ofra Kaller-Leibovici1
1Hillel Yaffe Medical Center, Hadera, Israel; 2Sackler School of Medicine, Tel Aviv, Israel; 3Gertner Institute for Epidemiology and Health Policy Research, Ramat Gan, Israel.

Objective

Israeli Ethiopian Jews (EJ) and Arabs have at reproduction age higher incidence of diabetes than other Israeli Jews. We aimed to compare gestational diabetes (GDM) risk among these population subgroups.

Methods

The study cohort included age-matched EJ, non-Ethiopian Jews (NEJ) and Arab women age 20–45 years. GDM diagnosis was based on the two step screening method of 50 and 100 g oral glucose load tests. Univariate comparisons and the association between population subgroups and the risk for GDM were tested in multiple logistic regression analysis, adjusted for age, parity and pre-gestational levels of the metabolic syndrome components.

Results

The study included 13 943 women (2938 EJ, 5156 NEJ and 5849 Arabs). During the years 2008–2011, birth rate was 0.358, 0.475 and 0.526 (P <0.001). Diabetes screening was performed in 84, 81, 85 and GDM prevalence was 4.3, 2.2 and 2% among Ethiopian, non-Ethiopian and Arab women respectively. The multivariate odds ratios (OR) for GDM were age 2.9–per 10 years (95% CI 2.1–4.1), BMI 1.12 (95% CI 1.1–1.2), triglycerides 1.05–per 10 mg/ml (95% CI 1.0–1.1), systolic blood pressure 1.05–per 10 mmHg (95% CI 1.02–1.11), parity 0.8 (95% CI 0.7–0.9) and Ethiopian ethnicity 2.55 (95% CI 1.6–4.1). Arab-ethnicity 1.4 (95% CI 0.95–2.15) and HDL-c 0.99 (95% CI 0.91–1.08) were not associated with risk for GDM.

Conclusions

Ethiopian ethnicity is an independent risk for GDM. The higher GDM prevalence in Arab women is mainly explained by higher obesity rates.

Improvement of specialised help to patient with diabetic foot syndrome in Uzbekistan
Nilufer Ilmajunova, Telman Kamalov, Hamidulla Shakirov, Oxana Platonova & Lyudmila Kokareva
Charity Public Association of the Persons with Disabilities and People with DM ‘UMID’, Tashkent, Uzbekistan.

Goal

Decrease a number of lower limb amputations in PDM in Uzbekistan by improvement of specialised help given to patients with DFS.

Materials and methods

Prior to 2010 there were only 2 ‘Diabetic foot’ rooms in Tashkent, Uzbekistan. In 2010–2012, CPA ‘UMID’ jointly with Uzbekistan Ministry of Health and Research Centre for Endocrinology implemented a project ‘Prevention of lower limb amputations in patients with diabetes mellitus in Uzbekistan’ granted by the World Diabetes Fund (WDF).

Results

Within the framework of the project for the first time in Uzbekistan, 288 ‘Diabetic foot’ rooms were set up under 14 endocrinological dispensaries and in 274 rural district clinics which were also equipped with a medical armchair for feet examination, a tuning fork, monofilament, percussion hammer, kit of dressing materials. To work in these rooms, 615 podiatrists were trained who render a qualified medical help to PDM and teach them rules of foot care. Annually over 28 800 PDM undertake feet examination and training in these rooms. A twofold decrease in a number of amputations and increased awareness of PDM in foot care proves improvement of specialised help to people with DFS. Within the framework of the project, 288 multidisciplinary teams (surgeon + endocrinologist + podiatrist) were trained throughout the country and now they render a specialised help to patients with DFS.

Conclusions

Implementation of the project ‘Prevention of lower limb amputations in patients with diabetes mellitus’ was planned for 3 years; results of the project were impressive enough for the Ministry to continue this project.

DOI: 10.1530/endoabs.49.EP736

Assessment of the prevalence of type 1 diabetes microvascular complications in young adults in the republic of Belarus with regard to the duration of the disease
Yuliya Dydyshka1, Alla Shepkeyevich2, Vladislav Yurkovets1, Elena Brutskaya-Stempkovskaya1,2 & Marina Mantachik1
1Belarusian State Medical University, Minsk, Belarus; 231th city polyclinic in Minsk, Minsk, Belarus.

Background and aims

According to current recommendations of the American Diabetes Association expedient screening of microvascular complications in all patients with type 1 diabetes (T1D) with a duration of 5 years of the disease. Therefore, the aim of the study was to assess the prevalence of microvascular complications in T1D patients aged 30–45 years with regard to the duration of the disease 5–10 years and over 10 years.

Materials and methods

We examined 360 patients with type 1 diabetes, 196 (54.4%) men and 164 (45.6%) women. The average age of the patients was 37.9 ± 4.5 (37.4–38.4) years, the age of onset of diabetes – 28.1 ± 6.2 (27.5–28.8) years, duration of the disease – 9.0 (7.0–12.0) years, BMI – 24.8 ± 3.95 (23.6–25.2) kg/m2, HbA1c – 8.37 ± 1.83 (8.18–8.56). In the study, carried out a detailed clinical examination of patients with medical records analysis.

Results

Diabetic peripheral neuropathy (DPN) was diagnosed in 133 (36.9%) patients; diabetic retinopathy (DR) – 78 (21.7%) patients, diabetic nephropathy (DN) – in 146 (40.6%) patients, albuminuria was detected in 137 (38.1%) persons. In general, microvascular complications of diabetes were set at 270 (75%) patients. With increasing duration of the disease for more than 10 years showed a significant increase in microvascular complications: DPN 30.6% vs 47.1% (χ2 = 9.91; P = 0.002); DN – 34.2 vs 50.7% (χ2 = 9.66; P = 0.002); albuminuria – 31.9 vs 47.8% (χ2 = 9.06; P = 0.003); DR – 40.1 vs 71.7% (χ2 = 34.2; P <0.005); any microvascular complications – 67.6 vs 86.9% (χ2 = 17.06; P <0.001). However, no significant differences in HbA1c – 3.12 ± 1.83 vs 8.45 ± 1.82% (P = 0.539).

Conclusions

Patients with type 1 diabetes with disease duration 5–15 years microvascular complications recorded in 75% of cases. The increase in the prevalence of microvascular complications associated with the duration of the disease, but not with the level of HbA1c.

Endocrine disrupting chemicals exacerbate type 1 diabetes mellitus model
Changhwan Ahn, Jin Yong An, Dinh Nam Tran, Seon Young Park & Eui-Bae Jeung
Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

It has been proposed that cellular Ca^{2+} signals activate hormone secretion. In pancreatic β cells, which produce insulin, Ca^{2+} signals have been known to contribute to insulin secretion. In previous study, demonstrated that endocrine disrupting chemicals (EDCs) such as bisphenol A (BPA) and Octylphenol (OP) could cause increase in insulin level and insulin transcription factors. But in regulations of plasma glucose level were not decreased as much as insulin increase. For identifying this phenomenon, we evaluate the HOMA-IR which is used for calculating insulin resistance, trace that EDCs has ability to increase insulin resistance. We hypothesized that EDCs disrupt calcium homeostasis and the altered intracellular calcium levels may induce insulin resistance. The expression of genes involved in transporting calcium ions to the endoplasmic reticulum (ER) was decrease while the expression of those affecting the removal of calcium from the ER was increased. Depletion of calcium from the ER leads to ER-stress and can induce insulin resistance. Taken together, these results imply that the disruption of calcium homeostasis by EDCs induces ER-stress and leads to the insulin resistance. Additionally, findings from this study suggest that imbalances in calcium homeostasis due to EDCs such as BPA and OP could promote insulin resistance and its harmfulness especially to the Type 1 diabetes mellitus patients.

Stimulating effect of 17β-estradiol and TCDD and on the protein expression of cytochrome P450 1A1 gene in cellular and xenografted models of breast cancer
Ryoo-Eun Go, Kyung-A Hwang & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, Veterinary Medical Center and College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Cytochrome P450 (CYP) 1A1 plays a major role in the metabolic activation of procarcinogens to carcinogens via aryl hydrocarbon receptor (AhR) pathway. Especially, 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is known as an agonist of AhR. In estrogen responsive cancers, 17β-estradiol (E2) may influence on AhR dependent expression of CYP1 family via the interaction between estrogen receptor (ER) and AhR. In the present study, the effect of E2/E2R on the expression of AhR and CYP1A1 genes was investigated for MCF-7 clonal variant (MCF-7 CV) breast cancer cells expressing ER. In reverse transcription (RT)-PCR and western blot analysis, mRNA level of AhR was not altered, but its protein level was increased by TCDD or E2. The transcriptional and translational levels of CYP1A1 appeared to be increased by TCDD or E2. The increased expression of AhR and CYP1A1 induced by E2 was restored to the control level by the co-treatment of ICI182,780, indicating that E2 induced the protein expression of AhR and CYP1A1 like TCDD via an ER dependent pathway. In an in vivo xenograft mouse model transplanted with MCF-7 CV cells, the protein levels of AhR and CYP1A1 of tumor masses were also increased by E2 or TCDD. Taken together, these results indicate that E2 may promote AhR dependent expression of CYP1A1 via ER dependent pathway in MCF-7 CV cells expressing ER in the absence of TCDD, an agonist of AhR. The relevance of E2 and ER in CYP1A1 activation of estrogen responsive cancers may be targeted for developing more effective cancer treatments. (This research was supported by a grant (14182MFDS977) from Ministry of Food and Drug Safety in 2016.)

24 hrs chronomics of BP/HR in terms of double amplitude, acrophase, hyperbaric index and its relation with circadian rhythm of 6-sulafoty melatonin in night shift nursing professionals: A Case-control study
B Anjum,1 Narsingh Verma,1 Sandeep Tiwari,1 Ranjana Singh2 & Abbas Mahdi2
1Department of Physiology, King George’s Medical University, Lucknow, UP, India; 2Department of Biochemistry, King George’s Medical University, Lucknow, UP, India; 1Department of Surgery (Gen), King George’s Medical University, Lucknow, UP, India.

The present study was aimed to investigate the 24 hours chronograms of BP/HR in terms of Double amplitude, Acrophase and Hyperbaric index and its relation with circadian rhythm of 6-sulafoty melatonin in night shift nurses and actual day workers. 56 night shift nurses, aged 20–40 years, performing day and night shift duties were recruited from the Trauma Center, KGMU, India, and 56 age sex matched actual day workers were also enrolled as controls. BP and HR were recorded by ABPM at every 30 min intervals in day time and each hour in night time synchronically with circadian rhythm of 6-sulafoty melatonin during shift duties. Highly significant difference was found in double amplitude (DA) of SBP between night (23.10±14.68) and day shift (34.27±16.44) (P<0.0005). In night shift, hyperbaric index (HBI) of mean SBP was found to be increased at 00-03 am (midnight) while during day shift, peak was found at 06-09 am. HBI of mean HR was found to be increased at 18-21 pm during night shift while in controls, peak was found at 09-12 & again 15-18 pm of SBP, DBP & HR. Alterations in Acrophase of BP/HR were very common among night shift workers and Ecphasia was found in few night shift workers. Alteration in morning and night melatonin level was also found during night shift as compare to their day shift and in actual control group. Reverse pattern of Acrophase and HBI of HR & HR along with 6-sulafoty melatonin during night shift represents desynchronisation. It indicates that the circadian rhythm was disrupted during night shift and recovery occurs during day shift.

The biological organisms are complex systems regulated by the homeostatic back-end network. In these days the growing environmental loads (from industry, household, etc.) contain chemical exposure e.g. halogenated hydrocarbons (monuron: MU (C9H11ClN2O), diuron: DU (C9H10Cl2N2O)), which can be endocrine disruptor compounds (EDCs). Synthesis, release of hormones and cell processes of endocrine cells, and the biochemical properties of hormones can be changed by these agents. The disturbance of endocrine regulation by the EDCs can induce different diseases for example in the reproductive-, neurological, and/or psychical, and/or immunological system. In this study the aim was to investigate the effects of uron herbicides (fenuron: PU (C9H12N2O); MU, DU) on the monamine activated ocytocin (OT) release from neurohypophysis (NH) cells. The primary monolayer NH cell cultures were prepared from the evidenced Wistar rats (d) for the experiments. The separated NH tissues were dissociated by enzymatic (trypsin, collagenase, DNA-se I; II) and mechanic methods. The 14 days old cultures were standardized for cell-viability and OT content. The NH cells were tested for functional OT hormone volume by acrophase stimulus (30 mM [K+]). The untreated cultures were the controls, and the treating system was the consequential: A: 1 hour 0.1 µg/ml EDCs: B: 10^{-7}M monamines (epinephrine, norepinephrine, dopamine, histamine, serotomine) alone; C: combined E and monamines agents with EDCs. The OT content was measured from supernatant media by RIA method. The results showed that the uron herbicides alone did not have significant effects on the OT release in the primary monolayer NH cell cultures. The EDCs caused the alteration of the monamine activated hormone release. The uron herbicides can play as strong environmental stress factors in the homeostatic system regulation. This work was supported by: TAMOP-4.2.2.D-15/1-KOVN-2015-0010, TAMOP-4.2.4.2-A/2-11-1-2012-0001.

The protective role of Zingiber officinale extract against methyl thiophanate induced toxicity in male rats
Rachid Mosbah1,2, Malikia Bahri1, Said Azzoug1, Zouhir Djerroua1 & Alberto Mantovanib
1Department of Biobio, University of Boumerdes, Boumerdes, Algeria; 2Laboratory of Eco-biology, ENS Koub, Algiers, Algeria; 3Hospital of Lamine Debagbine B.E.O, Algiers, Algeria; 4University of Skikda, Skikda, Algeria; 5Istituto Superiore di Sanità, Rome, Italy.

In this study, we attempted to assess the toxicity of Methyl Thiophanate (MT) on the biochemical and reproductive parameters in male Wistar rats as the possible protective role of Zinger officinale (Ginger, Ging) extract against MT-induced toxicity. Hence, forty adult Wistar rats were allocated into four groups of 10 rats for each; the first group served as control, groups 2, 3 and 4 were treated orally (5/week) for 8 weeks by MT (150 mg/kg bw), Ging (100 mg/kg bw) and MT plus Ging respectively. At the end of experiment, blood samples were collected under anesthesia for measuring the biochemical parameters and testosterone level, while, the reproductive organs were excised and used for semen quality analysis and histopathological examinations. Results indicated that MT exposure increases the level of blood glucose, cholesterol, triglycerides, urea, uric acid, AST, ALT and total protein, whereas, no clear impact on testosterone level was noted compared to the control. Semen analysis showed a decrease in spermatis number, sperm count, motility and viability. Moreover, a marked histopathological damage in testis and epididymis was detected which reflect a poor semen quality. Ginger extract co-treatment with MT alleviates and/or repairs all adverse toxic effects caused by MT on the reproductive, biochemical and histopathological parameters. This amazing preventive role may be related to its potential antioxidant properties. In conclusion, ginger extract supplementation plays crucial protective role against MT-induced toxicity in male rats.

Systematic screening for environmental and behavioral determinants identifies factors detrimental to skeletal health
Ling Oei1,2, Joy Wu1, Edwin Oei1, Fernando Rivadeneira1,2,3, Andre Unterlinder1,2, John Ioannidis4, Michael Snyder1 & Chirag Patel1
1Department of Genetics, Stanford University School of Medicine, Stanford, USA; 2Department of Internal Medicine, Erasmus MC, Rotterdam, The Netherlands; 3Division of Endocrinology, Stanford University School of Medicine, Stanford, CA, USA; 4Department of Radiology and Nuclear Medicine, Erasmus MC, Rotterdam, The Netherlands; 5Department of Epidemiology, Erasmus MC, Rotterdam, The Netherlands; 6Stanford University School of Medicine, Stanford Prevention Research Center, USA; 7Department of Biomedical Informatics, Harvard Medical School, Boston, MA, USA.

Background
An increasing amount of biomedical data is becoming available, and methods are needed to tackle these “big data.”

Methods
We performed a systematic evaluation of 138 environmental and behavioral factors in relation to bone mineral density (BMD) in the National Health and Nutrition Examination Survey (NHANES). Dual energy X-ray absorptiometry (DXA) scans were available for total body, head, pelvis and lumbar spine for 27,259 participants from NHANES surveys 1999–2000 (A), 2001–2002 (B), 2003–2004 (C) and 2005–2006 (D). A discovery environment-wide Association Study (EWAS) was performed on cohorts B and D, and replication was sought in cohorts A and C.

Results
Higher serum levels of α-tocopherol (per s.d. β = −0.25% for lumbar spine) and of γ-tocopherol (β = −0.54% for total body), forms of vitamin E, were associated with decreased BMD. In contrast, retinol serum levels were related to higher BMD (per s.d. β = +0.21% for total body). Serum lead levels had a negative relationship to BMD of the lumbar spine (per s.d. β = −0.43%) and head (per s.d. β = −0.87%). Higher levels of physical activity were associated with increased BMD of the total body, pelvis and head.

Conclusion
In conclusion, our study demonstrates consistently that several behavioral traits and fat-soluble vitamins may have detrimental effects on BMD, while reinforcing the benefit of physical activity for skeletal health.

The accuracy of lifestyle management information on websites for the management of PCOS

Thaw Dar Htet1, Samatha Cassar2, Milicent Burregraf1, Jacqueline Boyle1, Melanie Gibson-Helm1, Nigel Stepto1 2 & Lisa Moran1 2

1Monash Centre for Health Research Implementation, School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia; 2Clinical Exercise Science Program, Institute of Sport Exercise and Active Living, Victoria University, Melbourne, Australia.

**Background**

Lifestyle approaches (diet, physical activity and/or behavioural) play an integral part in Polycystic Ovary Syndrome (PCOS) management. The internet is widely used as a resource for health information. However, the accuracy of lifestyle information on PCOS websites is unknown. This study aimed to assess the accuracy of lifestyle recommendations on PCOS websites.

**Methods**

The internet search was conducted through three search engines across different web browsers and countries. Keywords “PCOS”, “Polycystic Ovary Syndrome” and “Polycystic Ovarian Syndrome” were used to identify websites using a previously defined internet search protocol. Websites providing lifestyle information in less than 10 sentences were excluded. The accuracy of the information was assessed through a checklist of 29 questions developed based on National and International guidelines for diet, physical activity and weight management for the general population and PCOS with higher scores indicating greater accuracy. Websites were scored by two independent reviewers.

**Results**

Fifteen websites were eligible from 72 websites in total (20%). The total accuracy score was 56±13 (potential range – 29 to 87) comprising 23±6 for diet (potential range – 11 to 33), 15±5 for physical activity (potential range – 9 to 27) and 14±3 for weight management (potential range – 8 to 24). A moderate proportion of websites provided general information on appropriate diet (40-80%) or weight management strategies (47–60%) but only 10–40% of the websites provided information on aspects such as core food, discretionary foods, exercise quantity/intensity, specific energy deficits or behavioural strategies.

**Conclusion**

A limited number of Internet sites for PCOS contain information on lifestyle management. Of these, the majority provided information on general diet, physical activity and weight recommendations but less information on a healthy lifestyle implementation. These findings suggest that PCOS-related websites need to be improved to provide more detailed and practical information for consumers to apply to their PCOS management.

Learning from adult growth hormone deficient patients’ advisory panel

Judith Hey-Hadavi1, Cécilia Camacho-Huber1 & Nicky Kelepouris1

1Pizer Inc. Endocrine Care, New York, NY, USA; 2Pizer Inc. US Endocrine Care, Collegeville, PA, USA.

**Introduction**

Adult Growth Hormone Deficient (AGHD) patients have often a difficult path from diagnosis to treatment. A patient advisory panel was conducted to better understand the AGHD patient journey and how this could be supported. This format was chosen to allow for direct patient to patient interactions and discussions and for physicians to learn.

**Findings**

A total of nine patient advisors (three childhood-onset; six adult-onset, age 33–67 years; 4M: 5W) were invited through different US endocrinology offices for a one day meeting. All had multiple pituitary hormone deficiencies (MPHD) and received daily GH. Six HCPs attended the meeting to learn from the interactions. An independent moderator facilitated the meeting and discussion. All patients reported that their journey was challenging regardless of age at diagnosis or MPHID. They felt that there is a lack of AGHD knowledge, and unawareness among physicians and patients. Symptoms were unrecognized for years prior to-diagnoses/treatment: and included: weight gain, arthralgia, social withdrawal/a-pathy and extreme fatigue (labelled ‘laziness’). The majority was misdiagnosed: mainly with depression and treated with antidepressants for variable period of time. The patients felt their ‘life caving in’. Some were too fatigued to go to the doctor. After diagnosis, it sometimes took months to get on GH replacement therapy due to insurance issues and finding a physician who would treat. Support was very limited without the opportunity to learn about AGHD or connect with other patients. The advisors proposed several ideas to improve their experience, i.e. education of HCPs, and patients, patient ambassador programs, patient panels etc.

**Conclusions**

Hearing live from patients is an innovative way of learning outside the traditional clinical setting. We identified a major need for more education, awareness, and resources for AGHD patients as well as physicians to improve their care.

Iodine supplementation in children and pregnant women from rural areas of Belarus in 2015–2016

Tatsiana Mokhort1, Sergey Petrenko2, Boris Leushev2, Olga Bartoshevich3, Natalya Koloniets1, Elena Mokhort1 & Ekaterina Fedoreenko1

1Belarusian State Medical University, Minsk, Belarus; 2International Sakharov Environmental Institute, Minsk, Belarus; 3Liakhovichy Central Regional Hospital, Brest Region, Belarus; 4Belarusian Medical Academy of Post-Graduate Education, Minsk, Belarus; 5Republican Research and Practical Centre ‘Hygiene’, Minsk, Belarus.

The efficiency of the Belarusian model for iodine deficiency elimination based on obligatory use of iodized salt in the industrial food production and bread baking has been often challenged in other countries. In support the facts are presented evidencing of insufficient iodine intake in groups of increased risk of iodine deficiency in children and pregnant women from the rural areas of Belarus. The goal of the recent study is to compare the dynamics of iodine supplementation for the period of 2015–2016 in groups of increased risk in Brest region. The iodine status of the body was determined by the iodine urine concentration. The study included 30 pregnant women examined in 2015 and 40 pregnant women examined in 2016 aged 23–32 years, and 51 children examined in 2015 and 44 children examined in 2016 aged 8–14 years. Statistical processing was performed by nonparametric statistics.In 2015 in the rural area ioduria median was 165.7 μg/l in children and 107.5 μg/l in pregnant women. Iodized salt was used by 86.2% of schoolchildren and only 66.7% of pregnant women. In 2016 ioduria median in children of the same region increased to 233.0 μg/l, and in pregnant women to 152.4 μg/l. Iodized salt in 2016 was used by 89.4% of schoolchildren and 78.8% of pregnant women. Thus, the Belarusian model of iodine deficiency elimination having been used since 2001 has demonstrated its long term efficiency even in the risk groups of iodine deficiency development.

**Comparison of 17-OH-Progesterone results by a radioimmunoassay and a chemiluminescent assay**  
Conceicao Godinho & Isaara Rodrigues  
Centro Hospitalar Lisboa Central, Lisboa, Portugal.

**Introduction**  
The major clinical importance of 17-OH-Progesterone is related to the diagnosis and therapeutic monitoring of Congenital Adrenal Hyperplasia (CAH). Radioactive assays are widely used in clinical laboratories for measuring 17-OH-Progesterone. The appearance of a non-isotopic, chemiluminescent automatic assay, may be an interesting alternative if the performance of the assay remains the same or higher.

**Objective**  
To compare the 17-OH-Progesterone results by a radioimmunoassay (RIA) and a chemiluminescent assay (CLIA) and to analyze the clinical impact taking into account the % concordance.

**Material and methods**  
We studied 74 patients, aged 6 months to 83 years old, observed at CHLC endocrinology appointments, in Lisbon. The serum samples were analyzed by ‘17α-Hydroxyprogesterone (17-OHP)-RIA-CT’; DIAsource (wt: 0.04–12.5 ng/ml) and ‘Maglumi 17-OH Progesterone (CLIA)’ Snibe (wt: 0.1–20 ng/ml). An excel tool was used for statistical treatment and the clinical concordance of patients was analyzed according to the reference values of both. For statistical comparison nine patients were excluded and to analyze the clinical impact we divided patients into groups according to age and gender.

**Results**  
Pearson correlation coefficient r=0.90 and the equation of linear regression was: y=0.46x+0.17. Group 1=24 both gender (6m-11y); Group 2: 12 male (12 y-47y); Group 3: 38 female (13y–83y). For the group 1 and 2: % agreement was 62.5 and 66; It was impossible to classify 25% of group 1 because CLIA has no reference values for age. Group 3 had insufficient clinical data.  

**Conclusion**  
There is a good correlation but in order to become an alternative to RIA it is fundamental to have reference values between 3 months and 3 years for a further reassessment since its main usefulness is the diagnosis and monitoring of CAH.

**The effect of parathyroidectomy on graft function in kidney transplant recipients with persistent hypercalcaemia**  
Aysegul Oruc1, Alparslan Erosoy1, Ozen Oz Gul2 & Canan Erosoy3  
1Department of Nephrology, Uludag University Medical Faculty, Bursa, Turkey; 2Endocrinology and Metabolism, Uludag University Medical Faculty, Bursa, Turkey; 3Department of Nephrology, Uludag University Medical Faculty, Bursa, Turkey.

Although serum calcium (Ca), phosphorus and parathyroid hormone (PTH) levels tend to normalize after successful kidney transplantation (KT), persistent hyperparathyroidism (PHPT) can have deleterious effects on graft function. We aimed to evaluate the effect of parathyroidectomy (PTx) on graft function in recipients after KT.

**Methods**  
This retrospective study conducted in 319 adult KT recipients. PHPT is defined as serum corrected Ca level >10.2 mg/dL (at least twice in a 6 month period) and PTH >150 pg/ml at 6th month of KT.

**Results**  
The mean follow up time was 49.4±1.4 months. Mean serum PTH levels before and at 6th month of KT and prevalence of hyperparathyroidism were 529±474 and 212±236 pg/ml, and 83.9% and 51.9%, respectively. Fifteen recipients with PHPT received cinacalcet for an average of 14.2±5.7 months. After cessation of cinacalcet therapy, serum Ca levels increased within 6 months. Mean serum Ca levels at 1st, 6th and 12th months of 12 recipients who underwent PTx before KT were 9.3±1.2, 9.6±0.8 and 9.2±1.2 mg/dL, respectively. The duration between PTx and KT in 16 recipients who underwent PTx after KT at the median value of 8.9 months (range: 5–41 months). Two of 16 had operation at 5th and 1st at 7th month of KT because of severe hypercalcaemia. Mean serum Ca levels of 16 recipients at 1st, 6th and 12th months of KT were 10.3±0.9, 10.8±0.9 and 10.6±0.9 mg/dL, respectively. There was no significant difference in graft function between post-transplant follow-ups in both groups.

**Conclusion**  
In recipients who underwent PTx before and after KT, PTx provided sustained decrease in serum Ca and PTH levels without affecting graft function.

**The effect of corticosteroids on development of femoral head osteonecrosis in patients after kidney transplantation**  
Enis Gursel1, Omer Faruk Bilgen1, Sadik Bilgen1, Basak Erdem Gursel2, Canan Erosoy3 & Alparslan Erosoy4  
1Department of Orthopedics, Uludag University Medical Faculty, Bursa, Turkey; 2Department of Radiology, Uludag University Medical Faculty, Bursa, Turkey; 3Endocrinology and Metabolism, Uludag University Medical Faculty, Bursa, Turkey; 4Department of Nephrology, Uludag University Medical Faculty, Bursa, Turkey.

Corticosteroid-induced osteonecrosis is seen in 3–4% of patients undergoing kidney transplantation (KT), especially at the head of the femur. The use of corticosteroids for any reason is responsible for approximately 41% of total hip arthroplasty performed due to osteonecrosis. In this study, we investigated factors affecting osteonecrosis development after KT.

**Methods**  
Among 205 recipients who underwent KT, 32 (15.6%) had symptomatic femoral head osteonecrosis (FHO group). Fifty patients who were similar in terms of age, sex, and posttransplant follow – up period constituted the non-FHO group.

**Results**  
The gender, age and pre-transplant BM1 of both groups were similar. In patients who developed FHO, the onset of symptom was median 6 months (range: 1–40). In patients who developed bilateral FHO, the mean duration of symptomatic changes in the other hip was 2.1 months (range: 0–6). The median value of the patients’ diagnosis time was 9 months (range: 1–40). The serum creatinine, calcium, phosphorus, ALP and PTH values at 1st, 6th and 12th after KT in both groups did not differ. There was no significant difference in hip and lumbar DEXA values between the groups in terms of osteonecrosis development. Three patients (9.4%) in the FHO group and seven patients (14%) in the non-FHO group had steroid treatment before KT. Cumulative steroid doses taken after KT the FHO and non-FHO groups were 6366 mg (range: 3230–13947) and 5664 mg (range: 3717–13887) at 12th month (P=0.068). A total of 17 hips total hip prosthesis were performed in 11 patients (six female, five male, mean age 45.2) who developed FHO.

**Conclusion**  
We did not find any association between post-transplantation FBO development, lumbar and femoral bone density measurements, and steroid doses.

**Resveratrol increases hepatic SHBG expression through human constitutive androstane receptor: a new Contribution to the French Paradox**  
Cristina Saéz-López1, Laura Brianso-Llort1, Javier Torres-Torrenteras2, Rafael Simo1, Geoffrey Hammond3 & David Selva1  
1Diabetes and Metabolism Research Unit, Vall Hebron Institut de Recerca (VHIR), Barcelona, Spain; 2Research Group on Neuromuscular and Mitochondrial Diseases, Vall Hebron Institut de Recerca (VHIR), Barcelona, Spain; 3Cellular & Physiological Sciences, University of British Columbia, Vancouver, British Columbia, Canada.

Sex hormone-binding globulin (SHBG) carries sex steroids in blood regulating their bioavailability. Red wine consumption increases plasma SHBG levels, and we have discovered that resveratrol, a polyphenol enriched in red wine, acts specifically through the human constitutive androstane receptor (CAR), a drug/xenobiotic detoxification gene regulator, to increase hepatic SHBG production. Chromatin immunoprecipitation and luciferase reporter gene assays show that human CAR binds to a typical direct repeat 1 nuclear hormone receptor-binding element in the human SHBG proximal promoter. Resveratrol also increased hepatic SHBG production in humanized SHBG/CAR transgenic mice.
mice. Moreover, SHBG expression correlated significantly with CAR mRNA levels in human liver biopsies. We conclude that the beneficial effects of red wine on the metabolic syndrome and its associated co-morbidities, including cardiovascular disease and type 2 diabetes, may be mediated in part by resveratrol acting via CAR to increase plasma SHBG levels.

Therapeutic potentials of small molecular weight allosteric agonist of relaxin receptor
Alexander Agoulnik1, Irina Agoulnik1, Xin Hug2, Elena Kaftanovskaya2, Zaohua Huang3, Courtney Myhr3, Jingbo Xiao3, Mariluz Soula1, Brian Ho1, Elena Barnea2, Noii Southall2, Marc Ferrer & Juan Marugan1
1Herbert Wertheim College of Medicine, Florida International University, Miami, Florida, USA; 2NIH Chemical Genomics Center, National Center in vitro

The anti-fibrotic, vasodilatory, and angiogenic therapeutic properties of relaxin peptide have been shown in several animal models of human diseases and in clinical trials. Using high-throughput screening of small molecule library, structure-activity relationship (SAR) studies, ligand-receptor interaction modeling, site-specific mutagenesis, and transgenic animal studies we discovered the first series of small molecule agonists of relaxin GPCR, RXFP1. The lead compound ML290 is a selective RXFP1 agonist with low cytotoxicity, preferred in vitro ADME and in vivo pharmacokinetic properties. ML290 displays efficacy similar to the natural hormone in several functional assays in vitro. ML290 activates human, macaque, pig, and rabbit RXFP1, but not rodent receptors. Computational modeling of small molecule binding with human RXFP1 and related receptors in combination with site-directed receptor mutagenesis studies indicated that the small molecules activated RXFP1 through an allosteric site and did not compete with relaxin binding to RXFP1. To test agonist activity in vivo we produced mice with knock-in of human RXFP1 into mouse gene. The analysis of transgenic mice showed that the human receptor fully complement the deletion of mouse gene. Intravenous injection of relaxin led to a rapid increase in heart rate in unconscious WT and humanized mice, but not in RXfp1 deficient animals. The ML290 injection increased heart rate in humanized but not in WT animals suggesting specific target engagement by small molecule agonist in vivo. Similar to relaxin IV injections of ML290 caused increased blood osmolality. Therapeutic potentials of the small molecular weight relaxin receptor agonist can be now tested in various preclinical cardiovascular and fibrotic models of human diseases.

PCSK9 inhibitors effects on lipid profile in familial hypercholesterolemia in a specific Lipid Unit: experience in first year commercialization
Inmaculada Gonzalez-Molero, Víyu Doulatram, Marta Domínguez, Francisco Sanchez Torralbo, Ignacio Ruiz García, Gabriel Oliveyra & Francisco Tinahones
Hospital Regional de Málaga, Málaga, Spain.

Objective
Analyse possible effects on physical examination, blood count, liver and kidney function, and steroidal hormones synthesis. Know the satisfaction of patients with the first injectable treatment for hypercholesterolemia approved in our country.

Material and methods
Data were collected from patients with heterozygous familial hypercholesterolemia treated with PCSK9 inhibitors. Clinical, physical and analytical data were collected at baseline, 1 month and 3 months. Satisfaction test (TO12IM-9) was performed 3 months after treatment.

Results
Data were obtained from 13 patients, 45.5% male. Mean age: 49.5 years (26-74). Mean pre and posttreatment levels were: TC: 243.8 ± 27.7 vs 148.5 ± 47.4 mg/dl (P 0.01), LDL-C: 159 ± 23.9 vs 69.9 ± 39.3 (P 0.01), non-HDL-C 185.3 ± 21.5 vs 91.8 ± 32.7 (P 0.01), 100% on therapeutic target, TG 130 ± 46.2 vs 109 ± 54.8 (P 0.3), Apo B 136 ± 19.9 vs 64.3 ± 11.0 (P 0.01), lipoprotein a (a) 135.1 ± 2.9 vs 112.5 ± 5.1 (P 0.04). Only 2 patients had mild side effect: one patient with pseudogripal syndrome that spontaneously disappeared in 2 days and another patient with injection site reaction.

Conclusion
PCSK9 inhibitors were well tolerated and significantly reduced levels of TC, LDL-C, ApoB, non-HDL C and lipoprotein a, with 100% of patients achieving therapeutic goals after 3 months of treatment.

Endocrine Abstracts (2017) Vol 49
Objectives
The AMANDHA randomized study (PROBE design) showed that the addition of Manidipine 20 mg vs Amlodipine 10 mg for 2 years in 91 hypertensive type 2 diabetic patients with persistent microalbuminuria, uncontrolled with a renin-angiotensin system inhibitor (given full-dose for at least the 6 previous months) was more effective in reducing albuminuria in spite of similar blood pressure control. Patients with significant renal impairment (PiCr > 1.4 mg/dl in women and > 1.5 in men) had been excluded. However, no data were published on the progression of renal dysfunction, with only PiCr values reported, which were not significantly different. We undertook to establish if there were differences in glomerular filtration rate (GFR) progression.

Methods
Post-hoc analysis of AMANDHA. GFR was estimated by the MDRD-4 equation for each individual measurement. Point-to-point GFR were compared by unpaired t-test and progression was compared by the Kruskal-Wallis test. (non-parametric ANOVA).

Results
Baseline GFR were 67.3 (±5.2) and 70.2 (±5.0) ml/min/1.73 m² with Manidipine and Amlodipine, respectively; at 6 months they were 68.6 (±5.6) and 69.5 (±5.3), and at two years 66.9 (±4.7) and 65.5 (±5.0). During follow-up, patients treated with Manidipine lost 0.4 (±3.9) ml/min per 1.73 m² of FGR vs 4.7 (±5.2) with Amlodipine. Point-to-point GFR were not significantly different between the groups, but GFR loss after two years was lower with Manidipine (P=0.032).

Conclusions
The previously published data of AMANDHA showed a markedly greater albuminuria reduction (about 40% more) with Manidipine vs Amlodipine, which was attributed to efferential arteriole dilatation. The present post-hoc analysis also shows a better preservation of renal function with Manidipine. These results strengthens the case for combined treatment with Manidipine and a renin-angiotensin system blocker in hypertensive type 2 diabetic patients with persistent microalbuminuria.

DOI: 10.1530/endoabs.49.EP757

EP758
Effects of calcineurin inhibitors on abdominal obesity in kidney transplant recipients
Emel Isiktas Sayilar1, Alparslan Ersoy1 & Canan Ersoy2
1Department of Nephrology, Uludag University Medical Faculty, Bursa, Turkey; 2Endocrinology and Metabolism, Uludag University Medical Faculty, Bursa, Turkey.

Calcineurin inhibitors (CNI: cyclosporine A: CsA and tacrolimus: Tac) cause post-transplant diabetes mellitus, hypercholesterolemia and hypertension. Post-transplant weight gain can be related to the type of CNIs. Distribution of obesity is one of the major predictors of cardiovascular diseases. Several indices assessed upper body obesity such as waist circumference (WC) and waist to hip ratio (WHR) are more accurate than whole body obesity (body mass index: BMI). This study aimed to compare the effects of CNI on obesity after kidney transplantation.

Methods
The 133 consecutive transplant patients were randomized into 2 groups: CsA (n=62) and Tac (n=71) for two years. In all patients, BMI, body fat percentage, WC, hip circumference (HC) and WHR were measured.

Results
The weight, BMI, body fat percentage, WC and HC were significantly increased up to month 24 in both groups. There was no significant difference in increases of BMI, WC, WHR and body fat percentage between both groups. The ratio of diabetics in CsA group was higher than Tac group (21% vs 14%, P<0.001). The ratios of de novo diabetics (4.8% vs 12.7%) and hypertensives (29% vs 26.8%) were similar in the CsA and Tac groups, respectively. Although the abdominal obesity ratios in the CsA and Tac groups increased, the ratios were comparable in the preoperative (17.7% vs 23.9%), after 12 (37.3% vs 39.3%) and 24 (40% vs 45.9%) months of transplant, respectively. There was no significant difference in glucose and lipid profile between CsA and Tac groups.

Conclusion
The type of calcineurin inhibitor used did not affect anthropometrical measurements throughout two years although both of them caused weight gain after transplant.

EP759
Anthropometric measurements, nutrition and exercise habits in kidney transplant recipients
Alparslan Ersoy1, Nizameddin Koca1, Tuba Gulul Koca2 & Canan Ersoy2
1Uludag University Medical Faculty, Department of Nephrology, Bursa, Turkey; 2Uludag University Medical Faculty, Endocrinology and Metabolism, Bursa, Turkey.

After a successful kidney transplant, the nutrition of patients is improved and they gain weight. Increased appetite due to medication, age of transplant, gender, race, pre-transplant obesity story and dialysis type increase the obesity frequency. We aimed to evaluate the effect of gender on nutrition and exercise habits on transplant recipients.

Methods
Stable patients were divided into two groups according to gender: 29 males and 33 females. Their nutrition and exercise habits of recipients were questioned by a survey. The 3-day dietary regimen of all patients was studied using the BEBBS™ programme.

Results
Characteristics of groups similar. BMI, blood pressure, hip circumference, suprailiac and suprascapular fold thicknesses of the groups were not different. The weight (90.3 vs 98.2 cm, P=0.01), mid-arm (27.2 vs 28.9 cm, P=0.05), triceps (16.1 vs 11.8 cm, P<0.01) and neck (36.6 vs 41.3 cm, P<0.001) circumferences in female recipients were lower than those of males. The body fat percentage of females (30.9 vs 23.8, P<0.01) were lower. HDL levels in males are significantly lower among lipid and apolipoprotein levels. The ratios of eating at home, using oils and exercising in both groups were similar. When recipients' daily diets were evaluated, intake of fat in males was higher than that of females (63.3±4.1 vs 70.1±3.1 g, P<0.05). There was no difference in total energy (1645±68 vs 1681±62 kcal), water (1590±79 vs 1665±76 ml), protein (70.4±2.4 vs 75.8±3.5 g), carbohydrate (197.7±2.9 vs 191.8±11.4 g), fiber (25.7±2.4 vs 24.1±1.7 g) and polyunsaturated fatty acid (12.8±1 vs 13.4±1) intakes between females and males, respectively. Also vitamin intake of both groups were comparable except carotene intake of females (5.3±0.4 vs 4±0.3, P<0.05).

Conclusion
We observed no difference in nutrition and exercise habits between male and female recipients. Although the percentage of body fat in males was lower, the amount of fat consume in their diets was higher. The waist and neck circumferences, which is important for the risk of cardiovascular disease, were higher in males.

EP760
Hyperglycemia as a factor changing the level of the patient's rehabilitation after ischemic stroke
Irina Dzherieva, Natalia Volkova, Natalia Maslova & Nikolay Krivonosov Rostov State medical University, Rostov on Don, Russia.

The aim of the study was to defined the level of rehabilitation after the stroke depending on the type of hyperglycemia.

Materials and methods
The retrospective analysis of 122 (54 female and 68 men) cases of ischemic stroke (IS) has been done. The diagnosis of IS was confirmed by computer tomography. According to the level of hyperglycemia at the debut of IS the patients were divided into three groups. Group 1 (60 patients) – with normoglycemia, group 2 (27 patients) – with stress hyperglycemia and group 3 (35 patients) with chronic hyperglycemia. At the beginning and the end of hospitalization the level of neurological deficit was determined according to NIHSS scale. The comparison of averages was carried out using the Kruskal-Wallis test (a posteriori pairwise comparisons were made using the method of Nienme), program R Foundation for Statistical Computing, Vienna, Austria (Version 3.2).

Results
The patients with normoglycemia and stress hyperglycemia have had the same level of rehabilitation (50% (CI: 45–75%) and 50% (CI: 32–73%) respectively). The statistical significant difference has been found between groups 1 and 3. In patients with chronic hyperglycemia the average relative level of rehabilitation was 33% (CI: 22–50%, P=0.023). The level of rehabilitation of patients 60 years old was 57% and between 60–75 years old and older this level was 50%.

Endocrine Abstracts (2017) Vol 49
Conclusion
The negative influence of chronic hyperglycemia has been revealed. The stress hyperglycemia does not influence on the level of rehabilitation. The age exerts on the regression of neurological deficit regardless of the hyperglycemia kinds.

An investigation into role of circulating concentrations of vitamin D and calcium in the development of hypertension and related cardiovascular diseases
Saba Nazir1, Nadia Afzal1, Maleeha Akram1, Zubaria Iqbal1, Abidah Raza2, Mazhar Qayyum1, Afzal Ahmed Naseem1, Syed Ali Raza Kazmi1, Faheem Tahir1, Kiran Afshan1, Sarwat Jahan2 & Syed Shaekezal Raza Riviz1
1Department of Zoology, Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Rawalpindi/Punjab, Pakistan; 2Department of Biophotonics, National Institute of Laser and Optopinics (NILOP), Nilore/Islamabad, Pakistan; 3Aga Khan Health Centre, Rawalpindi/Punjab, Pakistan; 4Reproductive Physiology, Public Health Laboratories Division, National Institute of Health (NIH), Islamabad, Pakistan; 5Department of Animal Sciences, Quaid-i-Azam University, Islamabad, Pakistan.

Vitamin D plays a key role in the control of cardiovascular diseases (CVDs), acting as a negative regulator of renin-angiotensin-aldosterone-system (RAAS), whereas calcium directly affects central blood pressure (BP) control center, nucleus tractus solitarus. We investigated associations between plasma concentrations of vitamin D and calcium and BP in 100 hypertensive CVD patients and 100 normotensive subjects of 21–60 years. Vitamin D concentrations were measured using ECLIA system, whereas calcium concentrations were determined using spectrophotometric system. Data were analyzed using Student’s t-test, ANOVA and Pearson correlation.

r: Out of 10 RAAS inhibitors (RAASi) treated patients, nine were vitamin D deficient and one was vitamin D insufficient. Of 29 non-RAASi treated patients, 28 were vitamin D deficient and one was vitamin D insufficient. Among 36 patients treated with combination of RAASi and non-RAASi, 35 were vitamin D deficient and one was vitamin D insufficient. Out of 23 untreated patients, 22 were vitamin D deficient and three were vitamin D insufficient. Ninety one control subjects were vitamin D deficient, eight were vitamin D deficient and one was vitamin D insufficient. In patients treated with RAASi, calcium concentrations were at lower limit of normal range in 7 and at upper limit in 3. In non-RAASi treated patients, calcium concentrations were at lower limit in 13 and at upper limit in 16. In both RAASi and non-RAASi treated patients, calcium concentrations were at lower limit in 27 and at upper limit in 9. In untreated patients, calcium concentrations were at lower limit in 15 and at upper limit in 10. In control subjects, calcium concentrations were at upper limit in 21, at lower limit in 77 and below lower limit in 2. There were weak correlations between vitamin D and calcium concentrations and mean BP and systolic and diastolic BP in all patients.

Multiple autoimmune syndrome; about six observations
Soumaya Mrabet1, Aya Hammami1, Elleuch Nour1, Jazin Hane2, Ben Slama Aida1, Braham Ahlem2, Ajmi Salem2, Mehdi Ksiaa2, Jmaa Ali2 & Ben Jazia Elhem1
1Farhat Hached University Hospital, Sousse, Tunisia; 2Sahloul University Hospital, Sousse, Tunisia.

Introduction
Autoimmune disorders are known to be more frequent in women and often associated each others, but it is rare to see multiple autoimmune diseases in a single patient. Multiple autoimmune syndrome (MAS) is defined as the combination of at least three autoimmune diseases in the same patient. The pathogenesis of MAS is not known. Genetic, infectious, immunologic and psychological factors have all been implicated in its development.

Observations
We report six new observations of MAS.

Results
Observation 1: A 24-year-old female patient followed for Hashimoto’s thyroiditis, Addison disease and celiac disease. The patient was explored for cytology. The diagnosis of autoimmune hepatitis was retained and the patient was treated with oral corticosteroid and azathioprine. Observation 2: A 61-year-old woman without special history who was diagnosed to have autoimmune hepatitis, celiac disease, autoimmune pancreatitis and sclerosing cholangitis. The patient was put on a gluten-free diet, corticosteroid therapy, azathioprine and ursooxyacetic acid. Observation 3: A 37-year-old man, with a history of vitiligo and Hashimoto’s thyroiditis, presented asthma and normocytic normochromic anemia. Biermer’s disease and celiac disease have been diagnosed. Observation 4: A 41-year-old woman with a history of Hashimoto thyroiditis presented a dry syndrome and asthma and liver cytology. The anti-nuclear, anti-SSA and anti-SSB antibodies were positive and labial biopsy showed a lymphocytic sialadenitis stage III of Chisholm confirming the association autoimmune hepatitis and syndrome of Gougerot Sjogren. Observation 5: A 29-year-old female patient with a history of Type 1 diabetes, Basedow and Addison diseases was diagnosed to have a celiac disease revealed by diarrhea and abdominal pain. Observation 6: A 31-year-old woman followed for Systemic erythematous lupus and Gougerot Sjogren syndrome presented a persistent anemia. Anti- transferrinaminase antibodies were positive and duodenal biopsies showed subtotal villous atrophy confirming celiac disease.

Conclusion
Patients with autoimmune diseases have a tendency to develop additional autoimmune disorders indicating the need for continued surveillance for the development of new autoimmune disease in predisposed patients.

Endocrine complications in a female patient with β-thalassemia major following bone marrow transplantation
Luminita Nicoleta Cima1, Ioana Maria Lambrescu1, Lavinia Stejereanu2, Anca Colita3 & Simona Fica1,2
1Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2Endocrine Department, Elias Hospital, Bucharest, Romania; 3Hematology Department, Fundeni Hospital, Bucharest, Romania.

We report the case of a 14-year-old female patient with β-thalassemia major (β-TM) that presented numerous endocrine complications following bone marrow transplantation (BMT). The patient was admitted in our department for endocrine evaluation 3 years after BMT. She was diagnosed with β-TM at 1 year of age and received chronic blood transfusions and oral chelating therapy until 2012 when BMT was performed. The patient developed acute skin and intestine graft-versus-host disease remitted with glucocorticoids and suffered severe convulsions as a result of cyclosporine administration with two subsequent vertebral fractures appearance (T5–T6). At first admission in our department she complained of irregular menses. The physical exam revealed H = 148.4 cm (~2.35 s.d.), BMI = 20.17 kg/m2. Tanner PSB5. The laboratory tests were normal, except for low normal estradiol (34.4 pg/ml) with elevated FSH (57.9 mIU/ml), low 25-OH-vitamin D and high titre of thyroid antibodies with normal thyroid hormones level. The thyroid ultrasonography showed a hypoechocine, heterogeneity thyroid with increased vascularity. DXA whole-body revealed low bone mineral density (Z score = -2.2 s.d.) and the vertebral MIRI showed reduced vertebral height at T6–T8 and L3–L5. She started treatment with Diphasthon and vitamin D. At 1 year follow-up, she presented normal menses, both FSH and estradiol normalized (FSH = 5.11 mIU/ml, E2 = 76.37 pg/ml) and no further fractures occurred.

Conclusion
Endocrinopathies are a common late effect of both β-TM and BMT, resulting in thyroid dysfunction, impaired growth, ovarian insufficiency and decreased bone mineral density. Because of the possible endocrine complications, lifelong endocrine follow-up is necessary in these patients.

EP764
Association of Basedow disease with pernicious anemia: a case report
Mihai Radu Diaconescu & Smaranda Diaconescu
‘Gr T Popa’ University of Medicine and Pharmacy, Iasi, Romania.

Introduction
Immunologic background often present different association of two or more autoimmune diseases. However the coexistence of Basedow disease (BD) – the prototype of these disorders – with pernicious anemia (PA), sometimes as a component of pancytopoenia, is rarely described. Between 50 patients operated on immunologic hyperthyroidism in a 20 years period only one case related this uncommon combination.

Endocrine Abstracts (2017) Vol 49
Case report
AB, a 46-year-old woman with a long standing BD treated from 1 year with antithyroid drugs (propylthiouracil) and β-blockers (propranolol) recorded a notable clinical improvement but with stationary or even increase size of her diffuse goiter. In addition she charged in the last three months palled skin, giddiness, tiredness, anorexia and coldness of the extremities. Laboratory workup showed TSH = 4.6 mIU/L, FT4 = 38 pmol/L, FT3 = 9 pmol/L, TRAB = 1.8 = 1.8 U/L. Current thyroid scan and US objectifies a diffuse 8×6×5 cm homogeneous, hypo-vascularised gland with uniform uptake. Though full blood count indicate pancytopenia with normochromic, normocytic anemia (Hb = 9 g/dL, MCV = 88 fL, MHCH = 34 g/l). Also total white count was 3400 μL, platelet count was 48 000 μL and reticulocyte count was 1%. Peripheral smear show oval macrocytes, hypersegmented granulocytes and anisopackilocytosis so a diagnosis of megaloblastic anemia secondary to Vitamin B12 deficiency was established. The standard treatment with intramuscular cyanocobalamin obtained substantial resolution of woman’s symptomatology. However maintained thyroidomegaly prompted our patient to undergo surgery. An adjusted near total thyroidectomy (Dunhill technique) was practiced followed by a smooth postoperative course. Histological examination of the operative piece (150 g) showed all stygma of thyrotoxicosis. Astonishingly endocrine equilibration was obtained together with positive hematological response occurring gradually within few months and maintaining further.

Discussions and conclusion
1-3% of patients with immunogenic hyperthyroidism (BD) have associated hematological disorders as single-cell lineage abnormalities like pernicious anemia and related troubles or pancytopenias. In all cases BD precedes the blood disease. Causes of these pathologic coincidences reside unlikely as pure coincidence but rather from reciprocal influence, immune-mediate effects, outcomes of antithyroid therapy or vitamin B12 deficiency. Appropriate surveillance of all cases of untreated or treated BD is mandatory, recommended for early detection of pernicious anemia as for other autoimmune disorder.

Conclusion
Our case confirms that, Thiazides can induce hyponatremia, especially in elderly female patients. Chronic hyponatremia, must be seriously evaluated, to find out the cause and but stationing to be corrected if possible. Correction of hyponatremia can improve cognitive performance and life quality. We must be careful while treating an older female patient with Thiazides.

DOI: 10.1530/endoabs.49.EP765

EP766
Raynaud phenomenon in a young PCOS patient
Martina Eva Leczycky1, Johannes Ohrman1 & Hisham Maksood2
1Medical University of Gdansk, Gdansk, Poland; 2Nottingham Woodthorpe Hospital, Nottingham, UK.

Polycystic ovarian syndrome presents in 4–8% of women worldwide, making it the most common reproductive age endocrinopathy. Rheumatological concomitant diseases are extremely rare in PCOS patients, especially Raynaud’s phenomenon. Condition that, lowers the quality of life in patients, suggesting hormonal imbalances despite years of treatment. Studies show that oestrogen plays a role in the vasculature, it is exogenous administration increases the endothelium dependent dilatation. Treatment of the phenomenon is symptomatic, wearing gloves, avoiding triggering factors, and lastly pharmacotherapy or sympathetic blockade in severe cases to avoid digital ischemia. We are presenting a rare case of dermato-rheumatological involvement in a PCOS patient. 24-year-old woman, diagnosed with PCOS in 2010 was treated with multi drug therapy including Metformin up to 1500 mg daily, oral contraceptive pill, spironolactone up to 150 mg daily. Topiramate 50 mg daily for migraine headaches and Liraglutide 0.6 mg with varying regimens throughout the years. In winter 2014 she presented with the first symptom of Raynaud’s phenomenon (RP). However that has been ignored until 2016 – 1 year after the discontinuation of oral contraception, the patient reported; pain upon dishwashing, hand washing, and increased frequency of the phenomenon despite wearing double winter gloves. She was then referred to a rheumatology department, underwent capilaroscopy exam, which revealed dilated capillary nail beds. The following laboratory tests; ANA-Hp2 was elevated – 1:640 (<1:80 norm) of a granular type. Antibody panel characteristic for connective tissue diseases was all negative except for – DFS 70 being mildly elevated. The antibody is typical for an autoimmune rather than rheumatological ethology. No other abnormalities were found in the blood morphology, rheumatoid factor nor erythrocyte sedimentation rate. Syndrome as common as PCOS should be of a concern across different hospital departments, the complexity of the pathomechanism and treatment regime should alert us for further clinical consequences.

DOI: 10.1530/endoabs.49.EP766

EP765
Chronic hyponatremia caused by Thiazide diuretic: A case report
Marjeta Kermaj1, Dorina Ylli1, Anisa Zeqja4, Violeta Hoxha1, Thanas Ferera1, Rentza Sancakh1, Ernira Muc4, Adela Shkurt1, Enalda Demaj1 & Agron Ylli1
1UCH Mother Teresa, Endocrinology Department, Tirana, Albania; 2UCH Mother Teresa, Department of Infectious Diseases, Tirana, Albania; 3Vila Maria Hospital, Endocrinology Department, Tirana, Albania; 4UCH Mother Teresa, Department of Psychology, Oncologic Hospital, Tirana, Albania; 5Kucova Hospital, Endocrinology Department, Tirana, Albania.

Introduction
Hyponatremia (defined as a serum sodium level < 135 mmol/l), is seen in in 15–30% in hospital setting, especially in intensive care units. Certain drugs (e.g. Thiazides diuretics) used in everyday clinical practice, may induce hyponatremia, more frequently in elder women.

Case report
A 76-year-old woman presented at emergency unit with complaints: physical weakness, nausea, vomiting, extreme fatigue and abdominal pain. She was under arterial hypertension treatment with Valsartan/Hydroclortiazide 160/25 mg daily. After normalization of blood electrolytes, we looked for the cause of improvement, she was transferred to Endocrinology Unit for further treatment. Following laboratory test were performed:

- TG 207.1 IU/ml; antiTPO 141.0 IU/ml) without disorders of thyroid function and morphology, rheumatoid factor nor erythrocyte sedimentation rate.
- Syndrome as common as PCOS should be of a concern across different hospital departments, the complexity of the pathomechanism and treatment regime should alert us for further clinical consequences.

Conclusion
The term polyglandular autoimmune syndrome (PAS) is used when there is a dysfunction of two or more endocrine glands associated with circulating antibodies directed at organ specific included glands. Neufeld and Blizzard classified PAS into two categories: type I and type II with the newly added category, type III, which does not include the adrenal cortex. PAS III includes several autoimmune diseases (autoimmune thyroiditis, immune-mediated diabetes mellitus, pernicious anemia, vitiligo, alopecia areata, and many others) and is divided into four sub-categories. We report a 44-year-old patient who was hospitalized in August 2016 at our department with suspected polyglandular autoimmune syndrome. In 2013 he was repeatedly evaluated at gastroenterology department where he was established the diagnoses of primary hemochromatosis (hemolytic anemia mutation in the gene p C282Y HFE), Crón’s disease and celiac disease, as well as candidiasis in May 2016. In 2016, the endocrinological testing establish the existence of autoimmune thyroiditis (anti-TG 207.1 IU/ml; antiTPO 141.0 IU/ml) without disorders of thyroid function and the presence of insulin resistance.

DOI: 10.1530/endoabs.49.EP767
EP768
Resistance of SIAD to tolvaptan despite initial control in progressive small cell lung cancer
Aoiise Garrathy & Chris Thompson
Academic Department of Endocrinology, Beaumont Hospital/ RCSI Medical School, Dublin, Ireland.

A 58-year-old male was admitted through the emergency department with symptomatic severe euveloric hyponatremia. Biochemistry was consistent with SIAD (plasma sodium (pNa) 107 mmol/l, plasma osmolality 230 mOsm/kg, urine sodium 36 mmol/l, urine osmolality (UOsm) 638 mOsm/kg, 0900 h plasma cortisol 434 nmol/l and thyroid function tests were normal but CT thorax confirmed a lung mass suspicious for malignancy. As the patient had symptoms of cerebral irritation, including drowsiness and confusion, he was treated with hypertonic (3%) saline infusion; pNa rose by 13 mmol/l over the 48 h and symptoms resolved. Water deprivation caused no further rise in pNa so the patient underwent tolvaptan challenge; pNa rose from 121 to 125 mmol/l over 12 h, associated with a rise in plasma vasopressin (pAVP) from 4.4–9.3 pmol/l. Tolvaptan 7.5 mg daily was commenced on day 5 and pNa rose gradually to 130 mmol/l with an eventual tolvaptan dose of 15 mg daily. Over 6 weeks, the patient developed persistent hyponatremia despite escalating doses of tolvaptan to 60 mg daily. UOsm while on tolvaptan was > 800 mOsm/kg and AVP levels between 8 and 16 pmol/l indicating unopposed action of AVP. Systemic chemotherapy led to temporary improvement in plasma sodium and tolvaptan dose was reduced to 15 mg over the subsequent three months. Six months after initial presentation, pNa fell again and tolvaptan dose was increased to 60 mg; noncompliance was excluded by supervised imaging of the spleen using 99mTC-colloid failed to reveal a functional spleen. The case is the first report of escape of SIAD from tolvaptan therapy, despite increasing doses. With progression of malignancy, and rising pAVP concentrations tolvaptan may have been insufficient to compete with tumour associated AVP for renal receptors.

Overestimation of HbA1c by an unusual hemoglobin variant
Fernando García Pérez1, Sandra Isabel Villanueva-Herráiz1, José Ignacio Fernández Peña1, Inés Camacho Benítez2, Juan Manuel García de Quirós1, Guillermo Martínez de Pinillos Gordillo1, Antonio Moro Ortiz1, Maritana Tomé Fernández-Ladreda2 & María Victoria Cozar León1
1Hospital Universitario de Valme, Sevilla, Spain; 2Hospital Punta de Europa, Gibraltar, Spain.

Glycosylated haemoglobin (HbA1c) is considered the Gold Standard parameter for evaluating long-term glycemic control in individuals with Diabetes Mellitus (DM). The presence of hemoglobin variants or other conditions that modify its glycosylation, can affect the veracity of its measurement. The detection of these hemoglobinopathies and his knowledge by the clinicians is very important for the correct diagnosis and follow-up. We present the case of a patient who presented a glycosylated hemoglobin that interferes with the determination of HbA1c by HPLC. One of the methods most used in laboratories is the Glycosylated haemoglobin (HbA1c) meassurement. The diagnosis of subclinical Hashimoto’s thyroiditis presents HbA1c of 6.5% with repeated blood fasting glucose between 70 and 75 mg/dl. A new HbA1c with a result of 7.0% and other exams were requested, which were normal: oral glucose tolerance test, negative autoantibodies (GAD, IA-2 and insulin), plasma C peptide and insulinemia. Blood count parameters were also normal. He had no family history of DM to suspect Monogenic Diabetes. Levels of fructosamine (alternative marker for assessing glycemic control of the last 2–3 weeks, based on glycoproteins measurement) were requested, resulting in 240 μmol/l, which correlated with a calculated HbA1c of 5.6%. In addition to the incongruity between the HbA1c values and the rest of the study, an abnormal peak in the HbA1c chromatogram (HPLC assay) was observed. HbA1c was measured again by a different method (boronate affinity chromatography) resulting in a very different result (HbA1c 5.3%). Due to the suspicion of hemoglobinopathy that overestimates HbA1c, it was sent to the reference laboratory for molecular characterization. Finally, the patient presented hemoglobin J-Camagüey heterozygous (Arg>Gly; HBA1: c.424C>G). The mother also presented the same hemoglobinopathy in heterozygous.

Conclusions
Many patients may present simultaneously a hemoglobinopathy and DM. Some hemoglobinopathies, without clinical repercussion are detected incidentally during the measurement of HbA1c. It is important for clinicians to be aware of its existence, because some may falsify the results (underestimating or over-estimating HbA1c, such as J-Camagüey). The use of alternative glycemic markers may be helpful in these cases.

Myasthenia gravis associated with Graves’ disease and adrenal insufficiency
Mouna Elleuch, Hamza Elfekih, Faten Hadjkacem, Mahdi Kalthoum, Mouna Annmar, Nabila Rekik, Wajdi Safi, Mouna Mnif & Mohamed Abid Hedi-Chaker University Hospital, Sfax, Tunisia.

Introduction
Multiple autoimmune syndrome (MAS) is a rare condition, first described by Humbert and Dupond in 1988 and characterized by three or more autoimmune disorders in the same individual.

Case description
Here we present a case of 14-year-old female patient diagnosed with ocular myasthenia gravis. The diagnosis of Graves’ disease was suspected on the basis of hyperthyroidism symptoms and confirmed by undetectable TSH level (<0.01 mU/l) with high FT4 level (27.8 mU/l). The adrenal insufficiency was suspected also clinically (extreme fatigue, weight loss, hyperpigmentation and low blood pressure) and accepted with a low cortisol level (37.4 ng/ml). The patient has improved after taking an anticholinesterase agent and corticosteroid replacement therapy. For the hyperthyroidism, a radical treatment is recommended and the Beta-blockers should be avoided.

Conclusion
The MAS-3 in our case is characterized by the association of myasthenia gravis, Graves’ disease and adrenal insufficiency in which every condition has a different treatment and prognosis in addition to a multidisciplinary care.

Incidental asplenia in a patient with presumed type 2 autoimmune polyglandular syndrome (APS-2): misclassification or overlap?
Thomas Georgiou, Fotini Adamidou, Geshthamni Mintziari & Marina Kita Ippokrateion General Hospital of Thessaloniki, Thessaloniki, Greece.

Introduction
Asplenia has been reported in 10% of patients with type 1 APS (APS-1), but has never been reported in APS-2. We describe a patient with presumed APS-2 and asplenia.

Case report
A 69-year-old woman was diagnosed with B12 deficiency with severe anemia at age 21 and insulin dependent diabetes mellitus at age 33, following routine testing. At 59, she was hospitalized with salt wasting and a diagnosis of Addison’s disease was made, which was subsequently confirmed by an inadequate response to tetracosactide stimulation. The diagnosis of subclinical Hashimoto’s thyroiditis was concurrently made. The patient had chronic onychomycosis of one fingernail and multiple toenails, but never of the mucous membranes and has never reported tetany. The diagnosis of APS-2 was made, based on the presence of the complete tri-glandular syndrome. The patient was under active surveillance for other autoimmune manifestations, but none has so far been detected. Her past history is negative for serious illnesses or infections and has never had abdominal surgery. Of note, she had never received a pneumococcal vaccine. Her family history is negative for autoimmune disorders. An abdominal CT scan was requested for complaints of non-specific abdominal discomfort and an incidental observation regarding the absence of an orthotopic spleen was made. An abdominal ultrasound found evidence of a hypoplastic splenic vessel. Functional imaging of the spleen using 99mTc-collodide failed to reveal a functional spleen. Relevant laboratory investigations including peripheral blood smear revealed Howell-Jolly bodies. Parathormone and electrolytes were normal. Quantitative measurements of major immunoglobulin classes and T lymphocyte sub-populations were normal. HLA-II haplotypes DQB1*05 and DQA1*01 were indentified, AIRE sequencing is pending.

Conclusion
Asplenia in the context of well-defined APS-2 and in the absence of clinical immunodeficiency, is a novel finding that challenges our current understanding of APS and needs to be further investigated.

Immune checkpoint inhibitors related thyroiditis – a report of two cases
Sara Donato, Pedro Antunes, Joana Simões-Pereira & Hélder Simões
Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal.

Introduction

Immune checkpoint inhibitors (ICPIs) are recent approved drugs used in malignant melanoma, non-small-cell lung cancer and renal cell cancer. They act by activating host T cell against malignant antigens. Immune checkpoint blockade can lead to breaking of immune self-tolerance, thereby inducing autoimmune/autoinflammatory side effects, such as endocrinopathies. It may affect thyroid, adrenal and pituitary. We present two ICPIs induced thyroiditis cases.

Case 1

Sixty-eight-year-old female diagnosed with a conjunctival malignant melanoma at the age of 64. She was first surgery treated and then submitted to radiotherapy. Due to bone, lung and hepatic metastasis she started Ipilimumab 3 mg/kg on 21-day cycle. Eleven days after the third Ipilimumab administration she was asymptomatic but was found to have thyrotoxicosis (TSH 0.04 μU/ml; FT3 1.31 ng/dl). Thyroid peroxidase and thyroglobulin antibodies were elevated and thyroid stimulating immunoglobulin was low. Four months after suspension of Ipilimumab a spontaneous recovery of the thyroid axis was seen.

Case 2

Sixty-two-year-old female diagnosed with a foot malignant melanoma one year before. She was first surgically treated. Due to lung, breast and lymph node metastases she started Nivolumab 3 mg/kg on 15-day cycle. Before starting this drug she had a diffuse thyroid uptake on PET-scan with normal thyroid function. Twelve days after the first administration of Nivolumab she described a painless increase of anterior cervical volume, fatigue and had thyrotoxicosis on the blood test (TSH 0.02 μU/ml; FT3 2.50 ng/dl). One month after she was found to have asymptomatic hypothyroidism (TSH 9.96 μU/ml; FT3 0.49 ng/dl). Thyroid ultrasound showed a thyroiditis pattern. She started levothyroxine therapy and one month after stopping Nivolumab she was still on hypothyroidism.

Conclusions

ICIs may induce autoimmune thyroiditis or may worsen a pre-existing one. These patients should be monitored for signs and symptoms of thyroid dysfunction, since it can cause significant morbidity if not promptly recognized and treated.

Nivolumab-associated pituitary, adrenal and thyroid autoimmune disorders
Rita Bettencourt-Silva1,2, Joana Oliveira1,2, César Esteves1,2, Venceslau Hespanhol2,3, Gabriela Fernandes3, Cláudia Caeiro4, Joana Queirós1 & Davide Carvalho1,2
1Department of Endocrinology, Diabetes, and Metabolism, Centro Hospitalar São João, E.P.E., Porto, Portugal; 2Faculty of Medicine, University of Porto, Porto, Portugal; 3Department of Pulmonology, Centro Hospitalar São João, E.P.E., Porto, Portugal; 4Department of Medical Oncology, Centro Hospitalar São João, E.P.E., Porto, Portugal.

Background

Nivolumab is an immunotherapeutic strategy for human cancer, but it can interfere with endocrine system. We report four cases regarding nivolumab-associated endocrinopathies: (i) Male, 55-year-old, with previous normal cortisol and adrenocorticotropic hormone (ACTH) levels, treated with nivolumab for metastatic lung epidermoid carcinoma. After 14 cycles, he developed adrenal insufficiency with morning cortisol <1.0 μg/dl; hydrocortisone treatment was started with clinical improvement. (ii) Male, 78-year-old, with previous normal cortisol and ACTH levels, treated with nivolumab for stage 3B lung epidermoid carcinoma. After 15 cycles, he developed adrenal insufficiency with morning cortisol <3.0 μg/dl and ACTH <5.0 ng/l. He had recent weight loss, but was hemodynamically stable, without electrolyte imbalance. He started hydrocortisone with clinical improvement. (iii) Male, 70-year-old, without previous thyroid disease, treated with nivolumab for metastatic clear cell renal carcinoma. After 2 cycles, he developed thyrotoxicosis with thyroid-stimulating hormone (TSH) 0.01 μU/ml (ref:3.50–4.94), free thyroxine (FT4) 1.82 ng/dl (ref:0.70–1.48), free triiodothyronine (FT3) 3.68 pg/ml (ref:1.71–3.71), positive thyroid globulin antibody (TgAb), negative peroxidase (TPOAb) and TSH-receptor antibodies (TRAb). He was treated with methimazole for 3.5 months. He maintains normal thyroid function since antithyroid drug withdrawal. (iv) Male, 64-year-old, without previous thyroid disease, treated with nivolumab for metastatic lung adenocarcinoma. After 5 cycles, he developed thyrotoxicosis with TSH 0.003 μU/ml and normal FT3 and FT4. He had spontaneous remission of thyrotoxicosis within 2 months and then developed hypothyroidism with TSH 7.78 μU/ml, FT3 0.48 ng/dl, FT4 2.19 pg/ml and positive TPOAb and TgAb. Levothyroxine was initiated, compatible with the possible diagnosis of nivolumab-associated thyroiditis.

Conclusions

Health providers must be aware of endocrine disorders that may be associated with immunomodulatory therapies for a timely diagnosis and correct treatment.

Meigs’ syndrome in a 63 year-old woman – case report
Alina Mihaela Pascu, Mircea Daniel Hogea, Marius Alexandru Moga, Lorena Dima, Petru Iulian Iften & Claudia Gavris
Faculty of Medicine, Transilvania University of Brasov, Brasov, Romania.

Introduction

Meigs’ syndrome is defined as the presence of a benign ovarian tumour (fibroma), in association with ascites and hydrothorax. The characteristic feature of this condition is the resolution of the effusions once the tumour is surgically removed.

Case report

A 63-year-old female patient was admitted to the Surgery Clinic with metrorrhagia, abdominal distention, and a recent history of minor breath shortness. Pulmonary clinical examination showed all the signs of right pleural effusion, which was also confirmed by the chest X-ray. The abdominal examination revealed a round irregular mass arising from the right pelvic cavity. Abdominal ultrasound showed a large pelvic mass (23 cm in diameter) more on the right pelvic cavity, a polyfibrinomatous uterus, and a small quantity of ascites. A complete blood count was carried out, with normal results. Surgical intervention was decided and the laparotomy confirmed a large pelvic mass which was part of the left ovary, dislodged in the right side of the peritoneal cavity. Also, 100 ml of ascitic fluid and a polyfibrinomatous uterus were found. The ovarian mass was removed and also a hysterectomy with bilateral adnecsectomy was performed. The macroscopic appearance: giant polynodular tumoral mass (23 cm in diameter), with compact structure, microcysts, and haemorrhagic areas. No residual ovarian tissue was observed in the subcapsular portion of the tumour. Microscopically, a compact tissue, consisting of pleomorphic fusiform cells, and discrete mitotic activity (less than 3 divisions/10 fields) was described. The cells were arranged in fascicles, with hyaline and myxomatous areas. Dilated vessels with thrombotic material were noted. The absence of malignancy of the tumour and of the ascitic and pleural effusions was confirmed by cytomorphologic study. In conclusion, the histopathological examination demonstrated an ovarian tumour with a fibroma aspect. Postoperative evolution was favorable and the patient was discharged after 12 days. The control chest X-ray revealed the resolution of the hydrothorax.

Conclusions

Even though Meigs’ syndrome mimics an aggressive malignant ovarian tumour, in the presence of pleural and peritoneal effusions, after surgical removal of the tumour the patient has a good prognosis and the life expectancy is similar to normal healthy population, even if recurrence was also reported.

Developmental Endocrinology

GHI influences plasma fasting adropin concentration in patients with Turner syndrome
Beata Wikiera1, Magdalena Krawczyk2, Anna Noczynska1 & Jacek Daroszewski3
1Department of Endocrinology for Children and Adolescents, Medical University, Wroclaw, Poland; 2Department of Developmental Endocrinology, Diabetes and Isotope Therapy, Wroclaw, Poland.

Background

Increased adiposity and insulin resistance are conditions frequently observed nowadays. Many hormones are involved in the pathogenesis of the condition but...
therapeutic options we can offer to the patients are still scant. Each newly discovered peptide give us hope. Adropin (Ad) is a newly discovered metabolic hormone involved in energy homeostasis. This homeostasis is frequently disturbed in patient with Turner Syndrome (TS). Patient with Turner syndrome are unique model for studies of an effect of the treatment with supraphysiological doses of growth hormone (rGH).

Objective and hypotheses
We studied adropin dependence and response in a group of TS patients treated with supraphysiological doses of growth hormone (rGH).

Method
The study group consisted of 36 TS patients aged 3.2-16.07 years (mean 8.2 years) diagnosed by karyotyping. rGH was applied in a dose 0.03 mg/kg per day Prior to and following the treatment anthropometrical data were recorded as well as biochemical parameters were measured: adropin, OGTT, insulin levels, IGF-1, and IGFBP-3.

Results
The increase of IGF-1 concentration at the end of observation was significant (from 119.4 ±62.46 to 413.37±204.38 ng/ml, mean ± s.d., P=0.000). The GH treatment influenced insulin resistance revealed by increased HOMA values (median 0.64±0.45 before and 0.92±0.97 after, P=0.02). rGH treatment cause a significant rise in Ad level. The correlation between adropin and IGF-1 and IGF-1 SDS levels was not significant neither before nor on the treatment (r=0.17 and r=0.004 respectively). Adropin concentration correlated with IGFBP3 level before rGH treatment but not on rGH therapy. Ad also correlated with insulin level before GH applying. Correlation with glucose levels at 30' of OGTT was stable and even rise on GH treatment (P=0.33 vs P=0.48). Similar observation was noticed for lipids, but close correlations between Ad adropin and total cholesterol, LDL cholesterol, triglycerides (TG) before GH applying changed on GH treatment. The only correlation noticed in GH treated patients was noticed for lipids, but close correlations between Ad adropin and total cholesterol, LDL cholesterol, triglycerides (TG) before GH applying changed on GH treatment.

Conclusion
Result of the study showed an increase in adropin level following rGH application is not mediated by IGF-1; rGH treatment changes adropin influence on lipid metabolism, but ameliorates insulin action.

The comparison of cardiovascular events in kidney transplant recipients with and without type 2 diabetes mellitus
Alparslan Ersoy1 & Canan Ersoy2
1Department of Nephrology, Uludag University Medical Faculty, Bursa, Turkey; 2Uludag University Medical Faculty, Endocrinology and Metabolism, Bursa, Turkey.

Diabetes mellitus (DM) presents particular challenges after kidney transplant (KT). These challenges contribute to cardiovascular diseases among diabetic recipients. We assessed frequency of posttransplant cardiovascular events in diabetic patients.

Methods
This retrospective study conducted in 399 kidney recipients at our center. The patients were divided into two groups: DM (n:69, 52.5% females) and non-DM (n:340, 46.5% females).

Results
The median KT duration was 4 years. The median age and BMI of DM group were higher than those of non-DM group (51 vs 42 years and 28.6 vs 25.8 kg/m2, respectively, P<0.001). The mean creatinine levels of both groups were similar. Hypertension (76.3 vs 62.4%, P=0.04), coronary artery disease (15.3 vs 4.1%, P=0.001), obesity (39.7 vs 20.9%, P=0.007) and dyslipidemia (32.3 vs 15.4%, P=0.002) co-morbidities in DM were more frequent than those of non-DM groups. There was no significant difference between the ratios of myocardial infarction (3.4 vs 2.6%), cardiac arrhythmia (3.4 vs 9.4%), congestive heart failure (3.4 vs 1.2%), stroke (1.7 vs 0.6%), transient ischemic attack (1.7 vs 4.1%) and peripheral vascular disease (3.4 vs 0.6%) in DM and non-DM groups. The ratio of patients underwent angioplasty was higher than that of non-DM group (25.7 vs 12.1%, P=0.016) while the ratios of patients underwent coronary stenting (1.7 vs 1.8%) and coronary by-pass operation (3.4 vs 1.2%) were similar. The graft loss and mortality rates in DM and non-DM groups did not differ (5.1 vs 5.6% and 5.1 vs 1.8%, respectively).

Conclusion
We observed that there was no difference in new cardiovascular events, graft loss and mortality between recipients with or without DM after KT. DOI: 10.1530/endoabs.49.EP778

The adrenal gland after diosgenin application in a rat model of the menopause
Vladimir Ajdzanovic1, Ivana Jarić1, Jasmina Zivanovic1, Marko Miler1, Natasa Ristic1, Dragana Milijc1, Florina Percicin-Popovska1 & Verica Milosevic1
1Institute for Biological Research “Sinisa Stankovic”, University of Belgrade, Belgrade, Serbia; 2Department of Neuroendocrinology, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; 3Faculty of Veterinary Medicine, Ss. Cyril and Methodius University in Skopje, Skopje, Macedonia.

Diosgenin, a steroidal sapogenin of natural origin, demonstrated some therapeutic effects when it comes to the treatment of cardiovascular issues, malignancies and the menopausal symptoms. In this study, we have investigated histological changes and corticosterone secretion of the adrenal gland after diosgenin application in a rat model of the menopause. Middle-aged, acyclic female Wistar rats were divided into control (C; n = 6) and diosgenin treated (D; n = 6) groups. Diosgenin (100 mg/kg b.w./day) was orally applied for 4 weeks, while C group received the vehicle alone. Our approach considered using the design-based stereology, histochemistry and the hormonal assay. The adrenal cortex volume decreased in D females by 15% (P < 0.05) while the volume of adrenal medulla increased (P < 0.05) by 64%, compared to the same parameters in C group. Volume density of zona glomerulosa (expressed per absolute adrenal gland volume) in D rats increased (P < 0.05) by 22% in comparison with C animals. Diosgenin treatment decreased (P < 0.05) volume density of zona fasciculata (expressed per volume of adrenal cortex) by 15% and caused vasodilatation within this zone, when compared to C females. Circulating corticosterone was also decreased by 16% compared to the C group. Absolute volume of zona reticularis in D group decreased (P < 0.05) by 38% in comparison with the same parameter in C rats. Also, after diosgenin application, volume density of zona reticularis (expressed per absolute adrenal gland volume) and zona reticularis cell volume were decreased by 40% and 20% (P < 0.05) respectively, compared to C animals. Our results, reflecting a decrease of the numerous adrenocortical stereological parameters, indicate that diosgenin took over the role of corticosteroid precursors and got incorporated into the steroidogenesis.

Characterization of murine Leydig cell lines as tools to study androgen synthesis disruption by xenobiotics
Roger Engeli, Cornelia Fürstenberger, Denise Kratschmar & Alex Odermatt
University of Basel, Basel, Switzerland.

Mammalian Leydig cells produce the majority of the systemic levels of the primary male sex hormone testosterone. Testosterone plays a crucial role during development of male reproductive tissues, onset of puberty, and maintaining health state. The final step of testosterone synthesis is catalyzed by 17β-hydroxysteroid dehydrogenase 3 (17β-HSD3). Disruption of testosterone synthesis is associated with many diseases. Due to the lack of a human Leydig cell line, two different murine Leydig cell lines (MA10, BLTK1) were studied for their suitability as screening tools for testosterone synthesis disruption by xenobiotics. The endogenous expression and activity of murine 17β-HSD3 was studied in both cell lines. Further, cells were stimulated using br-8-cAMP and forskolin to study testosterone production. Cell supernatants were analyzed using LC-MS. Unstimulated cells showed no or very low endogenous 17β-HSD3 activity. Stimulated MA10 cells showed low but concentration-dependent increases of testosterone levels in supernatants after 24 h. BLTK1 cells did not produce any testosterone. This study emphasizes the necessity of analyzing steroid using sensitive MS-based methods and shows that MA10 and BLTK1 cells produce a variety of steroids but only low amounts or no testosterone.

Identification of chemicals disrupting adrenal steroid production by steroid profiling in H295R cells
Petra Strajhar1, David Tonoli2, Fabienne Jeanneret2, Raphaella Imhof1, Vanessa Malagnino1, Melanie Pat1, Denise Kratschmar1, Julien Boccard2, Serban Rudaz* & Alex Odermatt1
1University of Basel, Basel, Switzerland; 2University of Geneva, Geneva, Switzerland.

Human adrenal H295R cells are applied according to the validated OECD test guideline 456 to identify potential endocrine disrupting chemicals. Testosterone and estradiol production serves as read-out although these are not steroids typically produced by the adrenals. The current study attempted to optimize conditions for using H295R cells to detect chemicals disturbing the synthesis of key adrenal steroids. Culture supernatants of H295R cells were analysed by LC-MS. Unstimulated cells showed no or very low endogenous 17β-hydroxy-5α-pregnan-3α,20α-diol-3β-ol (17β-HSD3). Disruption of testosterone synthesis is associated with many diseases. Due to the lack of a human Leydig cell line, two different murine Leydig cell lines (MA10, BLTK1) were studied for their suitability as screening tools for testosterone synthesis disruption by xenobiotics. The endogenous expression and activity of murine 17β-HSD3 was studied in both cell lines. Further, cells were stimulated using br-8-cAMP and forskolin to study testosterone production. Cell supernatants were analyzed using LC-MS. Unstimulated cells showed no or very low endogenous 17β-HSD3 activity. Stimulated MA10 cells showed low but concentration-dependent increases of testosterone levels in supernatants after 24 h. BLTK1 cells did not produce any testosterone. This study emphasizes the necessity of analyzing steroid using sensitive MS-based methods and shows that MA10 and BLTK1 cells produce a variety of steroids but only low amounts or no testosterone.

Endocrine dysfunctions associated with Hodgkin Lymphoma treatment
Daniela Dias, Joana Simões-Pereira, Sara Donato & Conceição Pereira
Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal.

Introduction
Hodgkin lymphoma (HL) survivors may develop a range of long-term complications that arise after therapy. Among these, the endocrine dysfunctions are a major concern. Aim: To investigate the long-term endocrine effects of HL treatment.

Methods
Revision of the HL patients’ medical files who were followed at our Endocrine Late-effects Clinics.

Results
We studied 178 patients (86 (48.3%) were female), whose mean age at HL diagnosis was 18.07±7.97 (2–56) years. Chemotherapy was offered to 177 (99.4%) patients and radiotherapy to 157 (88.2%). Hypothyroidism was identified in 76 (42.7%) patients; women were not more affected than men (P=0.083). Mean time between radiotherapy and hypothyroidism diagnosis was 7.76±6.96 (1–39) years. Seven patients who developed hypothyroidism did not receive directed cervical radiotherapy and only 3 of them evidenced positive thyroid antibodies. Thyroid nodules were present in 41 (23%) patients. Mean time between radiotherapy and thyroid nodules development was 13.41±7.90 (1–35) years. Although women were more affected (P=0.001), they were not diagnosed earlier (P=0.842). Six (3.4%) patients developed thyroid cancer. Mean age at thyroid cancer diagnosis was 24.2±8.36 (17–34) years. Patients who developed thyroid cancer were significantly younger when they underwent radiotherapy (10.2±2.9 vs 20.3±9.8; P=0.024). Mean time between radiotherapy and thyroid cancer diagnosis was 16.25±5.5 (11–21) years. Ten (11.6%) women developed breast cancer, 16.7±6.03 (7–25) years after HL therapy. Hypogonadism was observed in 32 women and 12 men; mean age at hypogonadism diagnosis was 28.07±8.92 (13–48) and 40.5±17.19 (14–66) years, respectively. Women (P<0.0001) and men (P=0.001) who developed hypogonadism were older when they received HL therapy. Median time between HL therapy and hypogonadism was significantly shorter in women (10.18) vs (11.5±3.39) years; (P<0.0001). Women who recovered their gonadic function were younger when they received lymphoma therapy (17.5±7.0 vs 20.46±9.8; P=0.026).

Conclusion
Given the high relevance of endocrine dysfunctions in these patients, in order to early identify and manage them, a long-term endocrine follow-up is needed, with adequate protocols.

Endocrine Tumours and Neoplasia

EP784
Multidisciplinary committee on endocrine tumors: an analysis of 6-year experience
Juan J Diez1,2, Pedro Iglesias1, Teresa Alonso-Gordoa1, Enrique Grande1 & Pablo Gajate1
1Hospital Universitario Ramón y Cajal, Madrid, Spain; 2Universidad de Alcalá de Henares, Madrid, Spain.

Aim
Multidisciplinary approach is mandatory in the management of endocrine tumors. Herein, we summarize the healthcare activity performed during the last 6 years at the multidisciplinary committee for endocrine tumors of a tertiary and University Hospital. Methods
A search of clinical-care activity of the endocrine tumors committee of our hospital from 2011 to 2016 was performed. Clinical and demographic data of all patients were recorded. The committee’s decisions were analyzed by tumor type and the type of decision (diagnostic or therapeutic). Clinical protocols approved by the committee were quantified.

Results
Two hundred and sixty seven decisions, affecting 205 patients (72.2% women; mean age 53.3±16.9 years) with endocrine tumors, were made. Thyroid tumors accounted for the main workload of the committee, with 61.8% of all decisions, a percentage that has not substantially changed over the years. The rest of decisions dealt with neuroendocrine (14.6%), pituitary (13.5%), adrenal (6.0%) and parathyroid tumors (4.1%). Most cases came from the Departments of Endocrinology (52.3%) and General Surgery (18.0%). 75.7% of the committee’s decisions were therapeutic and 15.7% diagnostic. The committee developed 29 clinical protocols for local use. 65.5% of them were therapeutic and 34.5% diagnostic. When studying the relationship between the department of origin and tumor type, we found a statistically significant difference between the cases presented by the department of Endocrinology and the surgical departments (General Surgery and Otolaryngology) and the remaining departments (χ²=46.55; P<0.001). No significant association between the type of decision and tumor type was found (χ²=9.79; N.S.).

Conclusion
Multidisciplinary teams are feasible and needed to make reliable, shared, patient-centered and evidence-based decisions. Endocrinology department remains the cornerstone that allows the flow of patients across the team.

ER status heterogeneity in breast cancer: role in response to endocrine treatment
Teresa Gagliano, Angeliki Ditiou, Arnhild Grothey & Georgios Giannas
Department of Biochemistry and Biomedicine, University of Sussex, Brighton, UK.

Tumor heterogeneity affects diagnosis, prognosis and response to therapy. Heterogeneity is found in both normal and neoplastic human mammary gland. For example, luminal estrogen receptor (ER)-negative cells can give rise to various phenotypes, including ER-negative and ER-positive mammary tumors, suggesting that the cell-of-origin does not necessarily reflect the tumor type. Regarding ER status, heterogeneity can challenge endocrine therapies; elimination of responsive clones can increase resistance of the survived ones and ultimately reduce treatment efficacy leading to tumor relapse. The aim of our study is to investigate breast tumor heterogeneity and its role in breast cancer resistance onset. For this purpose, we co-cultured ER-positive (T47D, CAMA1) and triple negative breast cancer (TNBC) (MDA-MB231, HCC70) cell lines, using 2D and 3D models. CAMA1 were sensitive to tamoxifen in term of cell viability, however this sensitivity was reduced when CAMA1 were co-cultured with TNBC cells. Interestingly, following co-culture with TNBC cells, the expression of ER in CAMA1 decreased while the anti-estrogenic protein Mcl-1 increased. On the other hand, T47D are slightly sensitive to tamoxifen; however, this sensitivity was completely abolished when T47D were co-cultured with TNBC. In addition, the expression of ER in T47D was significantly increased following co-culturing with TNBC cells, while the doubling-time of T47D was significantly reduced, suggesting an increase in cell proliferation rate. Our results demonstrate that ER status appears to be modulated when ER positive cells are co-cultured with TNBC cells, leading to a different response to endocrine therapy. In addition, ER positive cells’ doubling time is modified after exposure to TNBC cells. Further experiments are needed to fully understand the molecular mechanisms behind these findings.

EP786
Potential role of vitamin D in restoring sensitivity to mTOR inhibitors in hepatocellular carcinoma (HCC): 1,25(OH)vitamin D (VitD) reverses everolimus (EVE) resistance in a hcc cell line
Claudia Pivonello1, Dominga Patrao Provisiero1, Mariarosaria Negri1, Gilda Di Gennaro1, Cristina de Angelis2, Chiara Simeoli3, Giacomo Gallieo1, Maria Cristina De Martino1, Annamaria Colao1 & Rosario Pivonello1
1Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Università Federico II di Napoli, Naples, Italy; 2I.O.S. and COLEMAN S.r.l., Naples, Italy.

HCC is a difficult-to-treat- cancer with poor prognosis. Despite EVOLVE-1 trial demonstrated that EVE did not improve overall survival in molecularly and clinically unselected patients with advanced sorafenib resistant HCC, in selected patients, the established antitumor effect of EVE could make this drug a potential adjuvant therapy. Unfortunately, the acquired EVE resistance due to the tumour adaptation to chronic drug use is a current challenge. VitD has been deemed as potential regimen to treat a variety of cancers alone or in combination with other drugs. The aim of this study was to assess the antiproliferative effect of the combined treatment with EVE and VitD in JHH-6 cell line resistant to EVE (JHH-6 EveR). JHH-6 EveR were obtained after 4 months of EVE 10-8M treatment. Messenger and protein VitD receptor (VDR) expression was confirmed by RT-qPCR and immunofluorescence. DNA assay
Endocrine health problems detected in 764 patients evaluated in a late effects clinic
Conceição Pereira, Joana Pereira, Daniela Dias, Sara Donato & Duarte Salgado
Portuguese Cancer Institute, Lisbon, Portugal.

Context
Many pediatric cancer survivors have endocrine conditions. After alkylating agents, steroids, methotrexate and radiation, several endocrine dysfunctions may appear. Surveillance for late effects is recommended by worldwide guidelines.

Objective
The outcome of the study was to describe the endocrine outcomes of 764 patients followed during a 20 years period in our out-patient clinic.

Design
The design was a retrospective medical records review.

Patients
The study included 764 patients whose oncological or hematological dangerous diseases appeared before 18 years old. Larger groups were constituted by Leukaemias, Central Nervous Tumors and Lymphomas.

Outcome measures
The frequency and types of endocrine conditions were measured.

Results
One thousand and ninety one endocrine conditions were observed in all groups. The most common types of endocrine conditions were problems with growth and thyroid. We found puberty abnormalities and bone problems in third and fourth places of frequency. ACTH insufficiency was found in seventh place.

Conclusion
Endocrine dysfunctions are very common in survivor’s population. Endocrinologists should be aware of international guidelines and to make an effort to optimize screening and treatment of endocrine effects of cancer therapy. The crucial period is the pubertal with growth spurrt failure and acceleration puberty maturity which of them can bring future social and professional difficulties.

Comparison of subtraction and two-phase parathyroid scintigraphy concerning histological type of hyperfunctioning parathyroid tissue
Sanja Dugonjic, Boris Ajanovic, Snezana Ceric & Zoran Hajdukovic
1Military Medical Academy, Institute of Nuclear Medicine, Belgrade, Serbia; 2Military Medical Academy, Institute of Pathology and Forensic Medicine, Belgrade, Serbia; 3Military Medical Academy, Institute of Nuclear Medicine, Belgrade, Serbia; 4Military Medical Academy, Institute of Pathology and Forensic Medicine, Belgrade, Serbia; 5Military Medical Academy, Clinic of Endocrinology, Belgrade, Serbia.

The aim of this study was comparison of sensitivity of subtraction parathyroid scintigraphy (SBPS), vs. two-phase parathyroid scintigraphy (2FPS), related to histological type of hyperfunctioning parathyroid tissue.

Materials and methods
Fifty patients, thirty with primary hyperparathyroidism and twenty on dialysis and secondary hyperparathyroidism underwent parathyroid scintigraphy (PS) before surgery. Static scintigrams of neck and chest were performed, fifteen minutes and two hours after iv. injection of 740 MBq of Tc99m-MIBI. Four hours latter, after iv. injection of 185 MBq Tc99m, thyroid scintigraphy was performed. After normalization and motion correction, subtraction Tc99m from Tc99m-MIBI scintigrams was done. Scintigraphic results of both PS methods were graded from one to five: grade 1-normal finding, grade 2-probable normal finding, grade 3-suspicious finding, grade 4-probable abnormal finding and grade 5-abnormal finding. Scintigraphic findings graded 3, 4 and 5 were considered as pathologic.

Pathohistological analyses were done microscopically on standard haematoxylin-eosin stained slides to determine the substrate: adenoma and type of hyperplasia.

Results
Postoperatively 96 hyperfunctioning parathyroid glands (PG): 24% adenomas, 62.5% with nodular hyperplasia (NHPL) and 13.5% with diffuse hyperplasia (DHPH), were found. Overall sensitivity of SBPS was 74%; 91.3% for adenoma, 70% for NHPL and 61.5% for DHPH, with no statistically significant difference in sensitivity between groups of PG. Overall sensitivity of 2FPS was 67.7%; 100% for adenoma, 61.5% for NHPL, and 38.5% for DHPH. Statistically significant difference was found in sensitivity of 2FPS findings between these three groups, P<0.0001. SBPS had statistically significantly higher sensitivity of 61.5% for diffuse hyperplasia, comparing to 2FPS, with sensitivity of 38.5%, P<0.0001.

Conclusion
SBPS and 2FPS showed similar sensitivity in detection of PG adenoma and nodular hyperplasia of parathyroid glands. Superiority of subtraction parathyroid scintigraphy in detection of PG with diffuse hyperplasia is important finding, knowing that these glands are the smallest one and often remain undetected prior surgery, both in secondary, and importantly in primary hyperplasia.

Magnas modulates chemoresistance in endocrine-related cancers
Eleonora Riva, Federico Tagliati, Teresa Gagliano, Claudio Trapella, Sonia Missirolì, Paolo Pinton, Cristiano Bertolucci, Ettore degli Uberti & Maria Chiara ZateLLi
1Section of Endocrinology, Department of Medical Sciences, University of Ferrara, Ferrara, Italy; 2Department of Chemical and Pharmaceutical Sciences, University of Ferrara, Ferrara, Italy; 3Department of Morphology, Surgery and Experimental Medicine, University of Ferrara, Ferrara, Italy; 4Department of Life Sciences and Biotechnologies, University of Ferrara, Ferrara, Italy.

Magnas, a gene encoding for the mitochondrial import inner membrane translocase subunit, Tim16, protects different cell lines from the antitumoral effects of several pro-apoptotic stimuli (i.e. chemicals and chemotherapeutic agents). The synthetic Compound 5 is capable of sensitizing chemoresistant tumor cells overexpressing Magnas to proapoptotic stimuli, indicating that this molecule may be useful to overcome tumor chemoresistance. The aim of our study was to evaluate whether Compound 5 targets Tim16 and is cytotoxic in vivo. We found that Compound 5 enhances the antiproliferative effects of doxorubicin in MCF7 cells, while it fails to do so in two independent MCF7 cell clones where Magnas was silenced by specific shRNA. Then, the normal breast MCF12 cells were transfected with two differently tagged vectors, tim16-diktag encoding for Tim16 and tim14-hatag, encoding for its partner Tim14. We found that Tim16 co-immunoprecipitates with Tim14 and that their interaction is reduced in the presence of Compound 5. However, Tim16 levels appear to be reduced in cells treated with Compound 5. The toxicity of this molecule was then tested in vivo by the Fish Embryo toxicity assay, employing Zebrafish eggs: Compound 5 is not toxic in vivo at the concentrations employed in vitro (5 and 10 μM), while its toxicity increases dose-dependently at higher concentrations. These data support the hypothesis that Compound 5 targets Tim16 and that Tim16 levels modulate the chemosensitizing effects of Compound 5, that need to be confirmed by in vivo studies.

Altered expression of the components of the splicing machinery is associated to increased malignancy and expression of aberrant splicing variants in prostate cancer
Juan M Jimenez-Vacas, Manuel D Gahele, Sergio Pedraza-Arévalo, Mercedes del Río-Moreno, Daniel Hormaechea-Agulla, Enrique Gómez-Gómez, Julia Carrasco-Valiente, María del Mar Moreno, María José Requena-Tapia, Justo P Castaño & Raúl M Luque

Context
Many studies have demonstrated that alterations in the splicing machinery can arise during cell transformation and contribute to cancer progression by generating novel protein isoforms. The splicing machinery is composed by pre-mRNA splicing factors (SFs), which are dysregulated in different human diseases, including cancer. Therefore, the assessment of clinical samples for SFs expression can provide insights in the molecular mechanisms of cancer progression. In prostate cancer, SFs expression is altered, suggesting that aberrant splicing may play a role in prostate cancer progression. In this study, we analyzed the expression of SFs in a large set of prostate cancer clinical samples and compared it with expression in normal prostate tissues and control cells.

Materials and methods
We collected a series of prostate cancer clinical samples and normal prostate tissues. We also analyzed the expression of SFs in control cells. We used quantitative real-time PCR to measure the expression of SFs. We compared the expression of SFs in prostate cancer clinical samples and normal prostate tissues using statistical analysis.

Results
The expression of SFs was significantly different between prostate cancer clinical samples and normal prostate tissues. The expression of specific SFs was higher in prostate cancer clinical samples than in normal prostate tissues. The expression of specific SFs was lower in prostate cancer clinical samples than in normal prostate tissues. The expression of specific SFs was similar in prostate cancer clinical samples and normal prostate tissues.

Conclusion
The results of this study suggest that the expression of SFs is altered in prostate cancer clinical samples compared to normal prostate tissues. This alteration in SFs expression may contribute to the increased malignancy of prostate cancer. Furthermore, the expression of specific SFs may be associated with the expression of aberrant splicing variants in prostate cancer. These findings highlight the potential role of SFs in prostate cancer progression and suggest the possibility of using SFs as biomarkers for prostate cancer.

DO: 10.1530/endoabs.49.EP790
Prostate cancer (PCa) is the most common cancer among men in developed countries. Unfortunately, the heterogeneity of this malignancy hinders the finding of new biomarkers and therapeutic tools. A potential factor contributing to PCa is alternative splicing, which can generate the appearance of oncogenic variants involved in PCa aggressiveness. Thus, we hypothesized that the alteration of the splicing machinery (spliceosome components and splicing factors (SFs)) could be associated to the expression of tumorigenic splicing variants and malignancy of PCa. Accordingly, we characterized the expression pattern of key components of the spliceosome responsible for the recognition of and binding to the branching site of some of these SFs. Altogether, these results indicate that the splicing machinery is drastically dysregulated in PCa, which could help to explain the predominance of intron retention events and the appearance of tumorigenic splicing variants in this pathology, providing novel tools to develop diagnostic markers or therapeutic targets.

EP791 Polyglandular autoimmune syndrome type III b Raquel Vaz de Castro1, José Maria Aragüés2, Florbela Ferreira3, Vânia Gomes3, Ana Wessling1, Lurdes Tavares1, Joana Ribeiro3, Irina Alves1, Afonso Camilo Fernandes & Maria João Bugalho1
1Santa Maria Hospital, Lisbon, Portugal; 2Beatrix Angelo Hospital, Lisbon, Portugal.

We report the case of a 57-year-old female diagnosed with Grave’s disease fifteen years before (TSH <0.001 U/ml; FT4 2.3 ng/dl; FT3 7.2 ng/dl, TSAbs 17 U/l). Persistency of hyperthyroidism despite antithyroid therapy led to total thyroidectomy three years after the diagnosis. Thereafter, thyroid function remained normal under hormonal replacement with levothyroxine. The patient had also been diagnosed with Pernicious Anemia at 47 years of age after investigation for complaints like fatigue and shortage of breath. Hemoglobin levels were 10.2 g/dl and Intrinsic Factor antibody titer was positive. She was treated with cobalamin and folic acid and hemoglobin levels became stable in the years before (TSH 2.12 mU/l; FT4 1.7 ng/dl; FT3 9.6 ng/dl, TSAbs 17 U/l; MCV 88.1 fl). Pernicious Anemia diagnosis was confirmed by the presence of high titers of gastric parietal cells antibodies (1:1280). 13 years later, persistency of hyperthyroidism despite antithyroid therapy led to total thyroidectomy. The postoperative course was uneventful and thyroid function remained normal under hormonal replacement with levothyroxine (TSH 0.35 mU/l; FT4 1.7 ng/dl; FT3 9.6 ng/dl, TSAbs 17 U/l; MCV 88.1 fl). After 19 months, the patient was referred to our hospital due to complaints of fatigue and myalgia. The patient was a 57-year-old female with a history of Grave’s disease and Pernicious Anemia. She was admitted to our hospital due to complaints of fatigue and myalgia. Physical examination revealed a woman with a body mass index of 21.5 kg/m². The patient had a history of chronic thyroiditis and pernicious anemia, as well as a family history of autoimmune diseases. The patient was diagnosed with Polyglandular autoimmune syndrome type III b. The patient was treated with replacement therapy for thyroid and gastric deficiencies. The patient’s condition improved with replacement therapy and she was followed up for a period of 3 years. The patient was referred to our hospital due to complaints of fatigue and myalgia. Chronic stress and somatotroph axis in breast cancer more than a simple association Iulia Crumpei1, Ioana Armasu2, Mihai Danciu1,3, Mariana Tofan1, Constantin Volovat1, Alina Bălăceanu1, Felicia Crumpei1, Valentina Adomniaci2 & Carmen Vulpoi2,3
1University of Medicine and Pharmacy, Iasi, Romania; 2Department of Endocrinology, Sf. Spiridon Hospital, Iasi, Romania; 3Department of Oncology, Victoria Hospital, Iasi, Romania; 4Department of Radiology, Sf. Spiridon Hospital, Iasi, Romania; 5Department of Morphopathology, Sf. Spiridon Hospital, Iasi, Romania.

Introduction
Epidemiological and clinical studies have proven direct correlations between chronic stress, inflammation and cancer progression. The inflammatory environment preexisting the malignant change and elevated IGF-1 levels are associated with higher cancer risk, especially through GH effects on cell proliferation and inhibition of apoptosis.

Aim
To evaluate the relationship between biological and hormonal stress markers, growth factors and breast cancer (BC).

Patients and Methods
Biological markers (tibrinogen, C-reactive protein (CRP), endocrine stress markers (urinary free cortisol, ACTH and urinary metanephrines)) and somatotroph axis; growth hormone (GH), insulin-like growth factor-1 (IGF1) were determined in a population-based sample of 79 female patients diagnosed and treated for breast cancer.

Results
Among the inflammatory markers the increase of fibrinogen has been connected to high levels of IGF1 (r=0.231, P=0.045), low GH (r=-0.220, P=0.062) and low cortisol (r=-0.226, P=0.058); elevated ESR correlates with the increase in GH secretion (r=0.243, P=0.039) and high CRP was directly linked to higher values of ACTH (r=0.417, P=0.00). Both cortisol (r=-0.265, P=0.025) and urinary metanephrines (r=-0.311, P=0.016) have proven to negatively correlate to IGF-1. While advancing in age, both ACTH levels (r=-0.225, P=0.052) and IGF1 (r=-0.223, P=0.051) tend to decrease.

Conclusion
The chronic inflammatory status, frequently found in patients suffering from breast cancer, seems to be linked to the increase of the endocrine stress and growth markers. This augmentation of IGF1 levels could be a negative predictive factor for the further evolution and prognostic for the disease. However, our study has shown that high levels of stress hormones correlate to lower IGF1.

Cynicism and common endocrine diseases in pregnancy Ioannis Ilia1, Anastasia Linardi1, Charalambos Milionis1, Evangelia Venaki2, Athanasios Tsleibis2, Stamatina Nikopoulou1 & Efthia Koukou1
1Department of Endocrinology, Diabetes & Metabolism, El. Venizelou Hospital, Athens, Greece; 2Department of Psychiatry, Sotiria Hospital, Athens, Greece.

Introduction
Cynicism (or cynical distrust) is described as a state of mind and belief that most people are selfish. Cynicism is an attitude characterized by general distrust of the motives of others, and some experts describe it as a form of chronic anger. Negative emotions, especially cynicism, may be harmful to physical health.

Aim
The assessment of cynicism in pregnant women with common endocrine diseases. Subjects – Methods
We examined 54 Greek pregnant women (mean age + S.D.: 35±5 years), 18 with hypothyroidism diagnosed during pregnancy (HT), 18 with gestational diabetes mellitus (GDM) treated with medical nutrition therapy and 18 with HT+GDM. They all responded to the validated Greek version of the Cook-Medley questionnaire (by T Anagnostopoulou & G Kosogiouli) (minimum possible score: 8, maximum: 40). The validity of the responses was assessed by calculating Cronbach’s alpha and the differences between the three groups of women, taking into account their age, were assessed with analysis of covariance (ANCOVA).

Results
The validity of the questionnaire was satisfactory (Cronbach alpha = 0.77). Women with HT had mean cynicism score = SE: 19.4 + 1.3, with GDM: 21.6 +

**Thyroid ultrasonography findings in patients with polycystic ovary syndrome**

Anice Bergamim, Cristiane Perazo, Ivan Cruz, Simone Austgulen, Patricia das Oliveiras, Roberto Perrotta & Flávia Conceição

Federal University of Rio de Janeiro, Rio de Janeiro, RJ, Brazil.

Polycystic ovarian syndrome (PCOS) affects 6–10% of women of childbearing age. The pathophysiology of PCOS is related to increased insulin resistance (IR). Obesity, the leading cause of high IR, is present in 50% of women with PCOS, but lean women with PCOS also have higher IR than women with the same BMI without PCOS. Recent studies have correlated high IR with presence of thyroid nodules (TN), which motivated us to evaluate the occurrence of TN in patients with PCOS. 50 women with 18–45 years with PCOS according to the Rotterdam criteria were submitted to: evaluation of BMI and presence of acanthosis nigricas (AN); laboratory tests for blood glucose and thyroid hormones; and thyroid ultrasound (made by the same examiner with the same device). Laboratory and imaging results were compared between patients with (group 1) and without (group 2) TN through the Student’s T-test. The prevalence of TN was 36%. We observed that weight, BMI and glycemia were significantly higher in group 1 with the following p-values, respectively: 0.003; 0.01; and 0.028. The prevalence of AN was also higher in group 1 (50% vs. 37.5%). Among patients with TN, 13 had a single nodule and 5 had multinodular disease (2 patients with 4 and 3 with 3), totaling 30 nodules identified. 13 of these were ≤1 cm and 7 were suspicious, indicating that further investigation would be necessary. Our prevalence of TN was higher than that found by other authors in obese women at the same age without PCOS (21.4%). Although prevalence of TN increases with age, a Finnish study evaluating healthy middle-aged women (49–58 years) also showed a lower prevalence (30.6%). These data suggest that patients with PCOS have a higher risk of developing TN.

**Comparison of free testosterone results by a radioimmunoassay and a chemiluminescent assay**

Conceicaco Godinho & Isaura Rodrigues

Centro Hospitalar Lisboa Central, Lisboa, Portugal.

Introduction

Radioactive assays are widely used in clinical laboratories for measuring free testosterone. The appearance of a non-isotopic, chemiluminescent automatic assay, may be an interesting alternative if the performance of the assay remains the same or higher.

Objective

To compare the free testosterone results by radioimmunoassay (RIA) and chemiluminescent assay (CLIA) and to analyze the clinical impact taking into account the % concordance.

Material and Methods

We studied 76 patients, aged 13–73 years old, and observed at CHLC medical appointments, in Lisbon. The serum samples were analyzed by “Free TESTO-RIA-CT”, Diasource (0.2–22.1 pg/ml) and “Maglumi Free Testosterone (CLIA)” Snibe (1.52–40.62 pg/ml). An excel tool was used for statistical treatment and the clinical concordance of the results were analyzed according to the reference values of both.

Results

A strong correlation was observed \( r = 0.95 \) and linear regression was calculated: \( y = 1.51x + 0.072 \). The % concordance found was:

<table>
<thead>
<tr>
<th>n</th>
<th>Age</th>
<th>Agreement</th>
<th>Disagreement</th>
<th>% concordance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Female</td>
<td>50</td>
<td>16–73</td>
<td>49</td>
<td>1</td>
</tr>
<tr>
<td>Male</td>
<td>26</td>
<td>13–60</td>
<td>19</td>
<td>7</td>
</tr>
</tbody>
</table>

Conclusion

There is a good agreement between the two methods. The absence of age-stratified reference values by CLIA’s method may explain the discordant results. Despite the small sample size, Maglumi free testosterone may be considered a good alternative to the RIA assay, although it is fundamental to have reference values according to age and gender since the concentration of free testosterone varies throughout life from childhood to adulthood.

**Comparison of new standardization IGF-I assay IMMULITE 2000 with IGF-I assay currently used in CHLC**

Isaura Rodrigues & Conceicao Godinho

Centro Hospitalar Lisboa Central, Lisboa, Portugal.

Introduction

IGF-I is a clinically relevant protein in the diagnosis and monitoring of treatment of growth disorders. The Growth Hormone Research Society and the International IGF Research Society have encouraged the adoption of a universal calibration for immunoassays to improve standardization of IGF-I measurements.

Objectives

Comparison of new standardization IGF-I assay with IGF-I assay currently used in CHLC, Lisbon; To study whether the introduction of the new assay would lead to different clinical interpretations, verifying the concordance of results.

Material and Methods

A random sample of 186 patients regularly assisted at CHLC, mostly in Endocrinology Departments, comprising both genders, ages 2 months–85 years. Determinations on IMMULITE 2000 (Siemens). Chemiluminescent assays: new standardization (1st IS WHO, 02/254 NIBSC) and old (1st IRR WHO, 87/518 NIBSC); An Excel tool was used for statistical treatment. For comparison statistics we excluded 9 patients.

Results

Comparison statistics: \( r = 0.994 \); Slope = 0.63; interception (ng/ml) = 22.4; \( n = 177 \); range 27.2–938.0 ng/ml. According to assay and age-specific reference values specified by the manufacturer, we found concordance between 78.3 and 90.4%, regardless of gender, with the exception of 0–3 year age group, in which concordance fell below 33.3 and 50%.

Conclusions

Comparison statistics revealed data overlapping with those of the manufacturer. Although there was a good agreement between assays results, caution should be exercised in the interpretation of a single IGF-I value and of the impact of the new standardization. Discrepancies require posterior evaluation in the evolution of the disease, mainly in group 0–3 years. Clinicians should be aware of the tendency to reduce IGF-I values with the new calibration, so that they do not attribute it to a change in patient status.

**Rare case of manifestation of erectile dysfunction soon after thyroidectomy because of thyroid cancer in 56-year-old man with diabetes mellitus type 2 and diabetic neuropathy**

Nata Katamadze & Zurab Marshana

V Iverieli Endocrinology, Metabology, Dietology Center, “ENMEDIC”, Tbilisi, Georgia.

Introduction

Erectile dysfunction (ED) is common among men with diabetes mellitus (DM). Early diagnosis for such patients is essential in case of other multiple serious
endocrine disorders like thyroid cancer (TC). The aim of our presentation is to
demonstrate the case of 56-year-old male with DM and TC when the
manifestation of ED had been observed only after thyroidectomy.
Clinical presentation
A 56-year-old man attended our clinic with complaints of ED and loss of libido.
He also represented the complaints characteristic to diabetic neuropathy. The
symptoms of diabetic neuropathy appeared approximately 10 years ago. The
patient was diagnosed with diabetes mellitus type 2 since the age of 46. So diabetes
mellitus and diabetic neuropathy was diagnosed at the same time. In November
2016, total thyroidectomy was performed because of papillary microcarcinoma.
After several days of surgical intervention the patient represented complaints of
ED. Laboratory investigations were performed: HBAlc=6.0%, prolactin and total
testosterone within normal range. It had carried out a comprehensive, phased
process, which included treatment of diabetic neuropathy and hypothyroidism
with carrying out non-specific stimulation (Yohimbine Hydrochlorid and
L-arginin) as well as the therapy by PDE-5 inhibitor. Above-mentioned treatment
led positive results because the treatment of ED was initiated in a timely manner.
In our clinical case DM and DN was diagnosed at the same time. It is interesting
that the patient underwent to thyroidectomy and soon after he attended our Clinic.
The question is: does thyroidectomy and high level of TSH could be the reason of
early manifestation of ED?
Conclusion
The early diagnosis of ED is important for successful treatment especially among
men who had ED and multiple serious endocrine disorders. So it is important to
reveal it in the early stage. The easiest way not to miss ED in diabetic patients is
the questionnaires, which we use successfully in our clinic.

Dissecting the androgen excess phenotype of women with idiopathic intracranial hypertension
Michael O’Reilly1, Catherine Hornby1, Connar Westgate1, Hannah Bottlefield1, Keira Markey1, Carl Jenkinson1, Lorna Gilligan1, Mark Sherlock1, Justin Gibney2, Jeremy Tomlinson1, Wiebke Adt1 & Alexandra Sinclair1

1University of Birmingham, Birmingham, UK; 2Tallaght Hospital and Trinity College, Dublin, Ireland; 3University of Oxford, Oxford, UK.

Abstract
Idiopathic intracranial hypertension (IIH) is a devastating neurological condition, with elevated intracranial pressure of unknown aetiology. IIH is largely a disease of obese females of reproductive age. The clinical phenotype of IIH overlaps with polycystic ovary syndrome (PCOS), with prevalent obesity, hyperandrogenism and anovulation. In this study, we aimed to delineate the androgen excess phenotype of IIH women compared to those with PCOS and simple obesity. Women with III (n = 70), alongside age- and BMI-matched cohorts with PCOS (n = 60) and simple obesity (n = 40), were recruited to an in vivo study. Serum classic and 11-oxygenated androgens were measured by liquid chromatography–mass spectrometry (LC-MS/MS) and urinary steroid excretion by gas chromatography-mass spectrometry. Cerebrospinal fluid (CSF) androgens were quantified by LC-MS/MS in IIH women (n = 49) and a female cohort with non-IIH neurological disease (n = 30). PCOS patients had increased insulin resistance, as measured by HOMA-IR (P < 0.05), while HOMA-IR in IIH and controls did not differ. Serum testosterone was higher in IIH compared to both PCOS and control women (P < 0.001 for both); conversely, serum androstenedione was higher in PCOS women than in IIIH (P < 0.001) and controls (P < 0.01). Serum levels of the 11-oxygenated androgen precursors 11β-hydroxysteroidinedione and 11-ketoandrostenedione were increased in PCOS (P < 0.0001), while levels in IIH patients did not differ from controls. Systemic 5α-reductase activity, as measured by the ratio of 5α-tetrahydrocortisol/tetrahydrocortisol, was higher in IIH women compared to both PCOS and controls (P < 0.05 for both). IIH women had increased CSF androstenedione and testosterone compared to controls (all P < 0.0001). Using mass spectrometry-based analysis, we show that women with IIH have a distinct androgen excess phenotype compared to PCOS and simple obesity, with higher active serum androgens, 5α-reductase activity and increased
CSF androgens. Further studies are needed to understand the role of androgen excess in the pathogenesis of IIH.

EP799
Epileptic seizures in patients with large and giant prolactinomas
Yuliya Sidneva, Luidmila Astafeva, Maksim Katin & Pavel Kalinin
The Burdenko Neurosurgical Institute, Moscow, Russia.

Objective
To study epileptic seizures in patients with large and giant prolactinomas.

Patients and methods
The study group included 45 patients with large prolactinoma (more 36 mm in
 diameter) and 23 patients with giant prolactinoma (more than 60 mm in diameter).
55 men and 13 women aged 16–67 years (mean 39). Patients were followed by
hormone measurements, magnetic resonance imaging (MRI), electroencephalo-
gram (EEG) and endocrinological, psychopathological, neurologic examinations.

Results
Mean serum prolactin level ranged between 12 990 and 1 038 000 mIU (mean
198 000 mIU). Epileptic syndrome was revealed in 14 patients (21%): partial
seizures with secondary generalization (64%), complex (28%) and simple (14%)
seizures or their combinations. Seizures differed in structure depending on growth
of the tumor. Partial seizures with secondary generalization were mostly revealed
in patients with growth of adenoma to temporal region on left (50%) and right
(14%). Complex partial seizures were revealed in patients with growth of the
adenoma to temporal region on left (21%) and into the III ventricle (7%). Simple
partial (psychomotor) seizures were in patients with growth of adenoma into
diencephalic region (14%). Diagnosis of epileptic seizures was based on the
detection of typical pathological patterns in EEG.

Conclusion
21% patients with large and giant prolactinomas have epileptic syndrome.
Structure of epileptic seizures depends on extension of the adenoma and intrusion
in different regions of the brain.

Prednisolone reinforces the food reward system by bilateral amygdala activation – an MRI study
Georg Serfling1, Macia Buades-Rotger2,3, Birgit Harbeck1, Ulrike Krämer2,3 & Georg Brabant1

1Department of Internal Medicine I, University of Lübeck, Lübeck, Germany; 2Department of Psychology II, University of Lübeck, Lübeck, Germany; 3Department of Neurology, University of Lübeck, Lübeck, Germany.

Introduction
A well known side effect of glucocorticoid treatment is abdominally centred
weight gain due to increased sensation of hunger but the underlying mechanism is
still only incompletely clarified. To elucidate whether the brain reward system is
involved in this regulation we studied here the effects of an acute prednisolone
infusion on brain centres responding to food stimulation by fMRI in healthy males
and correlated these findings to the 24 h food intake of the subjects.

Methods:
20 healthy normal-weight men were tested in a prospective randomized cross-
over setting after an overnight fast respectively. They were either infused for 30
min with 250 mg prednisolone or placebo. fMRI scans were taken 4 h later
while presenting food and object pictures. At the following morning participants
had a supervised breakfast at a standardized buffet. All were restricted from eating
during the four hours until fMRI and kept a food diary until the next morning.

Results
When presenting palatable food pictures in contrast to object pictures we obtained
a significant activation in brain regions known to be part of the food reward
system like the hippocampus, anterior cingulate cortex, bilateral amygdala and
insula. Application of prednisolone significantly increased the activity in the
bilateral amygdala and right insula in comparison to placebo. The buffet test did not
reveal any significant difference in calorie intake or preferences of different
macronutrients nor did the food diary.

Discussion
The present imaging results support a direct stimulatory, prednisolone specific
interaction may represent an increased anticipated reward value of high calorie
food mediated by glucocorticoids, an effect which most likely needs to be present
for a prolonged period of time to relate to a measurably increased food intake
(supported by DFG).

18β-glycyrrhetinic acid reduces VLDL secretion as a modulator for HNF4α.

Qingli Liu, Meng Yang, Minyi Zhang & Min Guan
Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, Guangdong, China.

Glycyrrhizin (GL) is a major bioactive triterpene glycoside of licorice root, a traditional Chinese herbal medicine. GL and primary metabolite 18β-glycyrrhetinic acid (GA) have been developed as anti-inflammatory and antiviral drugs for liver diseases in China and Japan. Hepatic VLDL secretory pathway is not only responsible for lipid homeostasis but also associated with viral particles assembly and secretion. Hepatocyte nuclear factor 4α (HNF4α) together with its downstream targets, namely, secreted phospholipase A2 G12B (PLA2G12B) and microsomal triglyceride transfer protein (MTP), regulate VLDL production and secretion. We hypothesized that GA may act through HNF4α to mediate some of its beneficial effects. We found that GA inhibits the transcriptional activity of HNF4α. Specifically, promoter reporter expression of PLA2G12B, MTP and ApoB activated by HNF4α are dose-dependently suppressed by GA. Through lipid droplet analysis in vitro, we further found that GA tended to elevate intracellular triglycerides levels in a dose dependent manner in HepG2 cells, indicating that VLDL production and secretion is suppressed. To investigate GA effects in vivo, we fed mice a high-fat diet for 19 weeks. These mice were then gavaged with GA 60 mg/kg (HFD-GA) or vehicle (HFD-ctrl) every day for 6 weeks. We found that VLDL secretion rate was lowered significantly by GA treatment in HFD mice compared to HFD-ctrl mice. Data from blood biochemistry analysis revealed that treatment with GA significantly reduced blood TG, TC, ALT, AST, and glucose. While hepatic TG and TC levels were increased by HFD feeding, GA blunted the amount elevated by HFD. Oil red O staining showed that the amount of fat droplets in HFD-GA hepatocytes were reduced noticeably compared to HFD-ctrl, indicating that GA treatment reduced neutral lipid accumulation in the liver. These evidence collectively suggested that GA acts as a modulator of HNF4α, not only alleviating hepatosteatosis but also reducing hepatic secretion of TG-rich VLDL implying an underlying mechanism for antiviral and hepatoprotective properties.

5z-THB as a novel anti-inflammatory drug: The roles of the glucocorticoid and mineralocorticoid receptors

Amber Abernethie1, A Gastaldello1, RA Morgan2, C Mitchell1, KJ McIntyre1, K Beck1, A Odorment3, R Houtman1, D Melchior5, OC Meijer4, PWF Hadoke1, DEW Livingstone1, BR Walker1 & R Andrew1
1University of Edinburgh, Edinburgh, UK; 2University of Amsterdam, Amsterdam, The Netherlands; 3PamGene International, Den Bosch, The Netherlands; 4University of Basel, Basel, Switzerland.

Glucocorticoids (GCs) are potent anti-inflammatory compounds, acting mainly through the glucocorticoid receptor (GR). GC therapy, however, has debilitating side-effects, necessitating safer new alternative therapies. The natural GC metabolite 5z-Tetracosahydrocortisosterone (5zTHB) is anti-inflammatory in vivo in mice, but with fewer side-effects. Its mechanism of action is unknown, and here we test signalling via GR and the mineralocorticoid receptor (MR). 5zTHB displaced dexamethasone (Dex) from primary rat hepatocytes (n=6, Kd (nM): Dex 37±8, corticosterone 153±59, 5zTHB 268±78) but only negligibly from isolated human GR (n=3, EC50 (µM): Dex 0.004, cortisol 0.019, 5zTHB 480). GR nuclear translocation was quantified by western blot after nuclear (N) and cytoplasmic (C) separation of steroid-treated A549 cells. Dex (100 nM) increased the N/C GR ratio, after 30 minutes (0.59±0.26 to 2.97±0.50, P<0.0001) and 24 h (0.47±0.29 to 2.23±0.72, P<0.05). In contrast, GR translocation was not observed with 5zTHB (1, 3 or 10 µM) at either time (n=6). Similarly, GR Ser211 phosphorylation was increased by (1 µM) corticosterone (B); 0.19±0.05 fold vs vehicle, P<0.0001) but not by (10 µM) 5zTHB (2.74±0.35 fold vs vehicle, not significant). MARCoNi (Pamgene) peptide array analysis (n=3) demonstrated that Dex altered the interaction of GR ligand binding domain (LBD) with 75 co-regulator peptides, whereas 5zTHB induced weak changes with only 3. Interestingly, interactions between the MR LBD and its co-regulator peptides were altered to a comparable extent by F and 5zTHB treatment (76 vs 41 interactions altered, respectively). In addition, both aldosterone (10 nM) and 5zTHB (5 µM) increased transcriptional activity of a luciferase construct in HEK293 cells (13.50±1.09 fold and 11.20±1.24 fold vs vehicle, respectively, both P<0.0001, n=4). Both effects were antagonised by spironolactone. In conclusion, the mechanisms underlying the action of 5zTHB differ from those of classical GCs, consistent with its reduced side-effect profile, and may involve MR as much as GR.

Development of novel human stable reporter cell line for the assessment of PPARγ transcriptionsal activity

Peter Illes, Aneta Grycova & Hana Preichystalova
Department of Cell Biology and Genetics, Faculty of Science, Palacky University, Slechtitelu 27, 783 71 Olomouc, Czech Republic.

Endocrine disrupting chemicals (EDCs) are exogenous compounds that affect the endocrine system, disrupt the hormonal balance and consequently cause the adverse health effects in humans. These compounds persist and accumulate in the environment and can easily gain entry to the food chain. Peroxisome proliferator-activated receptor gamma (PPARγ) and its heterodimeric partner retinoid X receptor alpha (RXRα) are very often targets of EDCs. PPARγ plays crucial role in lipid and glucose metabolism and disturbing of PPARγ signaling leads to serious diseases such as obesity, diabetes, insulin resistance and cardiovascular diseases. Therefore, it is of topical interest to develop reliable, high throughput in vitro system allowing screening and identification of compounds affecting PPARγ activity. In the current work, we developed the unique stably transfected human reporter cell line T24/83-PPARgamma for the assessment of PPARγ transcriptional activity. Reporter cell line was prepared by transfecting the human bladder carcinoma cell line T24/83 with reporter plasmid pNL2.1[Nluc/Hygro] containing three copies of PPARγ response element, coupled with minimal promoter. Design of response element was based on the sequences of promoter region of human acyl-CoA-oxidase. In the cells treated with PPARγ ligand 15-deoxy-d12,14-prostaglandin J2 and prostaglandin D2 for 24 h, luciferase activity ranged from 20-fold to 50-fold and from 70-fold to 80-fold, respectively (RLU 10^4–10^5). Application of PPARγ selective antagonist T0070907 resulted in inhibition of luciferase activity, indicating specific response of T24/83-PPARgamma cell line. The inducibility of luciferase activity remained unaffected after cryopreservation and even after prolonged cultivation for more than 2 months. Based on these results, the novel human reporter cell line T24/83-PPARgamma can be considered as a potential tool for screening of compounds affecting PPARγ activity, applicable in various toxicological and environmental studies.

Functional characterization of inherited S127F substitution in V2 vasopressin receptor revealed a loss-of-function mutation leading to nephrogenic diabetes insipidus

László Erdélyi1, András Balla1,2 & László Hunyadi1,2
1Department of Physiology, Semmelweis University, Budapest, Hungary; 2MTA-SE Laboratory of Molecular Physiology, Hungarian Academy of Sciences and Semmelweis University, Budapest, Hungary.

The V2 vasopressin receptor (V2-R) mediates the effect of vasopressin on the water reabsorption in the kidney and several mutations in the V2-R have been identified causing nephrogenic diabetes insipidus (NDI). In this study, we investigated a previously not characterized mutation of the. We obtained genomic DNA of a young male patient with NDI, the AVPR2 gene was amplified with PCR and a missense mutation (S127F) was identified. We monitored the cellular localization of the S127F mutant V2 receptor using

Endocrine Abstracts (2017) Vol 49
HA-tagged receptors in confocal microscopy experiments. The S127F V2 receptor was detected only in the endoplasmic reticulum but not in the plasma membrane. We also measured the CAMP signaling capability of the mutant receptor with BRET measurements. The S127F receptor was not able to increase the intracellular cAMP levels in response to vasopressin stimulation. Certain ER retention mutations can be rescued by pharmacological chaperones, which cause misfolded mutant receptors to present in the plasma membrane. We examined the effect of tolvaptan (V2R antagonist) on the S127F V2 receptor. HEK293 cells were transiently transfected with the plasmid of the mutant receptor and after one day the cells were incubated for 18 hours with tolvaptan. After the pretreatment, the cells were exposed to vasopressin and we were able to detect cAMP signal generation of the mutant receptor. We checked whether the result after tolvaptan pretreatment was due to restored plasma membrane location of the receptor. We were able to demonstrate significant increase of the mutant receptors in the plasma membrane using flow cytometry. Since the tolvaptan is already used in the treatment of multiple diseases, we plan to carry out clinical studies to assess the potential therapeutic usage of this drug in the NDI patients with S127F V2R mutation. This work was supported by National Research, Development and Innovation Fund (NKFI K116954).

Effects of human interleukins on transcriptional activity of vitamin D receptor in transgenic gene reporter cell lines IZ-VDRE and IZ-CYP24

Iveta Bartonková, Aneta Grycova & Zdenek Dvorak

Department of Cell Biology and Genetics, Faculty of Science, Palacky University, Slechtitelu 27, 783 71 Olomouc, Czech Republic.

Vitamin D receptor (VDR) signalling can be affected with a variety of compounds, both endo- or exogenous. However, any disruption of VDR transcriptional activity can exert severe physiological or pathophysiological outcomes. It is therefore of a great importance to have a reliable in vitro screening technique that would provide a tool for efficient identification of agonists and antagonists of human VDR. In the current work, we described two novel human reporter cell lines IZ-CYP24 and IZ-VDRE, constructed for the purpose of VDR transcriptional activity detection. Parental human adenocarcinoma cell line LS 180 was stably transfected with a reporter construct CYP24_minP-PNL2.1[Nuc/Hygro] containing a sequence from the promoter region of human CYP24A1 gene (IZ-CYP24), or VDREI3_SV40-PNL2.1[Nuc/Hygro] containing three copies of VDREI from the promoter region of human CYP24A1 gene (IZ-VDRE), respectively. Both our cell lines remained fully functional in the cell culture for more than 2 months (corresponding to 30 passages) and even after cryopreservation. Luciferase inductions ranged from 10-fold to 25-fold (RLU 106–107) and from 30-fold to 80-fold (RLU 103–104) in IZ-VDRE and IZ-CYP24 cell lines, respectively. Time-course analyses revealed the possibility to detect VDR activators as soon as after 8 hours of incubation. Both our cell lines were highly selective towards VDR agonists, no cross-talk with retinoids, thyroids or steroid was observed. As a proof of concept, the effect of 13 human interleukins on VDR transcriptional activity was examined. Luciferase assays showed an inhibition of VDR transcriptional activity by interleukin-4 and interleukin-13, reaching approximately 60% of calcitriol-induced luciferase signal in concentrations about 1 ng/ml after 24 h of incubation in IZ-CYP24 cell line. Similar results were obtained from expression analyses of human CYP24A1 mRNA. Taken together, both of these cell lines provide a tool for reliable, high-throughput and selective identification of VDR ligands, with possible implications in toxicological and environmental studies.

3-Iodothyronamine (3-T1AM) induces transient receptor potential melastatin 8 (TRPM8) channel activation in human corneal endothelial cells and human corneal keratocytes

Nina Ljubojević, Nounshafarin Khajavi, Katharina Lobse, Monika Valtink & Stefan Mergler

1Klinik für Augenheilkunde – Charité Universitätsmedizin Berlin, Berlin, Germany; 2Institut für Experimentelle Pädiatrische Endokrinologie, Charité – Universitätsmedizin Berlin, Berlin, Germany; 3Institute of Anatomy, Faculty of Medicine Carl Gustav Carus, TU Dresden, Dresden, Germany.

3-Iodothyronamine (3-T1AM) is an endogenous metabolite of thyroid hormone (TH) for which was shown to have various effects. One of the effects is body temperature decline, which may be related with menthol receptor TRPM8. Normally, this ion channel is expressed in neuronal tissue, where it has a nociceptive role. Functional TRPM8 expression has also been shown in non-neuronal cells of the eye such as corneal and conjunctival epithelial cells, corneal endothelial cells as well as human corneal keratocytes. Furthermore, we could demonstrate in previous studies that 3-T1AM acts as a cooling agent in human corneal epithelial and conjunctival epithelial cells and that it is suppressing TRPV1 channel (capsaicin receptor), which plays an important role in dry eye disease. Here, we determined in a human corneal endothelial cell line (HCEC-12) and a human corneal keratocyte cell line (HCK) if 3-T1AM also acts as a cooling agent to directly affect TRPM8 at a constant temperature. Functional activity was evaluated by comparing the effects of 3-T1AM with those of TRPM8 known agonists on intracellular Ca2+ currents and whole-cell currents using fluorescent Ca2+ imaging and planar patch-clamping. Menthol (500 µM), a specific TRPM8 activator, evoked a Ca2+ influx as well as an increase of whole-cell currents. This effect could be blocked by BCTC (20 µM) and AMTB (20 µM), both selective TRPM8 antagonists. Notably, comparable effects were observed with 1 µM 3-T1AM. Overall, our study complements our previous studies of human corneal and conjunctival epithelial cells. Interestingly, the effect of 3-T1AM has a similar Ca2+ response pattern and similar whole-cell current pattern in all three layers of the cornea. Therefore, this might represent a general biological phenomenon. Further investigation of 3-T1AM effects on the cornea should be performed in order to better characterize a potential benefit of 3-T1AM on the treatment of dry eye disease.

Cytotoxicity of plant extracts from Brazilian biome in prostate cancer cell lines

Sarah Cardoso, Mathews Andrade, Vinicius Cunha, Cristiana Silva, Patrícia Rodrigues, Mayra Leão, Christopher Fagg, Eliete Guerra, Francisco Neves, Luiz Simeoni, Dâmaris Silveira & Adriana Lofranco-Porto

University of Brasilia, Brasilia, Brazil.

Prostate cancer is a public health problem worldwide. The cure is unlikely and therapeutic alternatives are limited. The Brazilian biodiversity represents a huge source of potential discovery of new drugs derived from plants. We therefore aimed to conduct a biomonitoring chemical study of plant extracts from Pouteria sp., previously shown to be cytotoxic in androgen-sensitive (LNCaP) and androgen-resistant (PC3) human prostate cancer cell lines. Methods The crude ethanolic extract of Pouteria caimito leaves and hexanic extract of Pouteria ramiflora were tested in PC3 and LNCaP human prostate adenocarcinoma cells. The crude extract of P. ramiflora branches and stem was then pre-fractionated through sintered funnel. The pre-fraction hexane: ethyl acetate 1:1 was fractionated by column chromatography into 649 fractions, grouped according to the profile in thin layer chromatography into 49 samples. Among those, four samples were selected for Nuclear Magnetic Resonance (NMR) spectroscopy, based on their abundance and cytotoxicity biomonitoring by MTT. Results The ethanolic extract of P. caimito showed a dose-dependent cytotoxic effect in PC3 cells (>50%), with a statistically significant inhibitory effect on the cell cycle. The hexanic extract of P. ramiflora showed a dose-dependent cytotoxic effect in LNCaP, with a high selectivity index (5.5 after 48 h of treatment), as compared to a non-cancerous human cell line (HaCaT). Among the 49 samples obtained from this extract, fraction “8” was purified and the compound epifriedelanol was isolated, whose bioactivity is under evaluation in prostate cancer cell lines. Conclusion Our biomonitored analysis of Pouteria sp. extracts has provided the purification of a number of cytotoxic fractions. Among those, a triterpenic bioactive compound (epi-friedelanol) was identified by RMN spectroscopy, and deserve
Further studies regarding its specific cytotoxicity. Triterpenes have been shown to exert cytotoxic effects on different types of cancer at low activity towards normal cells, including prostate cancer.

Obesity

Evolution of patients with amyotrophic lateral sclerosis followed in a nutrition and endocrinology specific unit during 3 years

Inmaculada Gonzalez-Molerio, Monserrat Gonzalo, Viyu Doulatram, Jose Abuin, Francisco Tinahones & Gabriel Oliveira
Hospital Regional de Malaga, Malaga, Spain.

Introduction

A high percentage of patients diagnosed with Amyotrophic Lateral Sclerosis (ALS) have malnutrition. The nutritional treatment in ALS is essential, affecting muscle strength, quality of life and survival.

Objective

To describe the nutritional characteristics of patients evaluated in a specific nutritional Unit in patients with ALS during 3 years.

Material and methods

A descriptive study of all patients diagnosed with ALS and evaluated in this specific consultation since October 2013. The nutritional status is assessed by anamnesis, 24-h ingestion count, physical examination (BMI, % lost weight, Picometry, dynamometry), evaluation of dyphagia by EAT-10 (if positive, volume viscosity test) and analytical tests.

Results

Data were obtained from 60 patients. Mean age at diagnosis: 57.5 years (26–79 years), 65% male. Bulbar: 28.6%, spinal: 61.2%. The mean time until the evaluation in nutrition Unit was 22.1 month (12.6 in bulbar vs 24.7 in spinal, P < 0.05). The initial BMI: 26.4 (18.1 to 36.2), in 78.3% > 25. The nutritional status in the first consultation was (VSG): 23% of patients with moderate malnutrition, 17.1% of severe malnutrition (30.8% of bulbar vs 5.9% of spinal, P < 0.05). The most frequent analytical disturbances were vitamin D insufficiency/deficiency (58.3%) and hypercholesterolemia (50%). The most frequent analytical disorders were vitamin D deficiency/insufficiency (58.3%) and hypercholesterolemia (22.5%). Nutritional intervention at the first visit was only diet in 46% (7.1% bulbar vs 69% in spinal, P < 0.05), thickening prescription in 34%, nutritional supplements in seven patients, gastrostomy in three patients (all of them bulbar). Of the patients who were offered gastrostomy during follow-up (56.8%), 68.4% accepted. The main reason for this was weight loss (83%). The hormonal modulation was performed by one same practitioner and the diameters of each lobe was given as a single parameter that is expected to change over postsurgical period.

Conclusions

– 40.1% of patients with ALS present moderate/severe malnutrition in the first assessment.
– BMI and analytical parameters are not early markers of malnutrition, being weight loss the best marker.
– Patients with bulbar ALS present malnutrition more frequently than spinal forms and require an earlier and more aggressive nutritional intervention.

Obesity, gonadotrophic axis and breast cancer – is ghrelin the connexion?

Ioana Armasu1,2, Iulia Crumpei1,2, Constantin Volovat3, Mariana Tofan3, Valentin Zaharia1, Adrian Aancutei1, Ioana Vasiliu1, Ionela Lacramioara Serban1 & Carmen Vulpoi1,2
1University of Medicine and Pharmacy, “Gr.T. Popa”, Iasi, Romania; 2County Emergency Hospital, “Sf. Spiridon”, Iasi, Romania; 3Victoria Hospital, Iasi, Romania.

Introduction

Obesity and insulin resistance have been identified as risk factors for breast cancer and are associated with late-stage diagnosis and poor prognosis. Ghrelin is a unique gut-derived peptide that has major impact in energy homeostasis and weight regulation, with new emerging implications in tumorigenesis process, especially in hormone-dependent cancers.

Aim

To evaluate the relationship between ghrelin, clinico-biological parameters of obesity and gonadotropic axis in breast cancer patients.

Patients and Methods

We assessed the relationship between fasting ghrelin and anthropometric measures, insulin-resistance, lipid and glucose metabolism parameters, hypothalamic-pituitary-gonadal axis (HPG): FSH, testosterone/estriadiol-ratio, SHBG, and body composition (evaluated by dual-energy X-ray absorptiometry) in 64 breast cancer patients. Both acyl-ghrelin (AG) and des-acyl-ghrelin (DAG) were evaluated through ELISA; total ghrelin (TG) was calculated as the sum of the two.

Results

DAG, but not AG, negatively correlates with BMI (r = −0.280, P = 0.013), waist circumference (r = −0.335, P = 0.006) and waist/hip ratio (r = −0.302, P = 0.015). Concerning body fat distribution, DAG negatively correlates with sub-total (r = −0.326, P = 0.005) and truncal fat mass (r = −0.273, P = 0.02).

Even stronger association of these parameters was observed with TG. Also, DAG negatively correlates with insulin 1 (r = −0.354, P = 0.003) and HOMA-IR (r = −0.343, P = 0.004). Concerning HPG, AG but especially AG/TG-ratio were positively correlated with FSH (r = 0.354, P = 0.004) and SHBG (r = 0.272, P = 0.03). Even though no direct correlations were found between ghrelin and HPG, we observed that insulin positively correlates with testosterone/estriadiol-ratio (r = 0.247, P = 0.039) and that the hip circumference was positively correlated with free-testosterone levels (r = 0.251, P = 0.044).

Conclusions

Ghrelin has definitely indirect effects in breast cancer through its roles in obesity and insulin-resistance. We described different connections between ghrelin-obesity-gonadotropic axis in these patients, underlying discreet metabolic and hormonal modifications. However, ghrelin may also play a direct role in breast cancer pathogenesis due to its recently discovered anti-aromatase effect in adipocytes.

Differences in calcium and thyroid homeostasis and thyroid volume after bariatric surgery

Ilker Dagdelen Duran1, Nese Ersöz Gülçekil2, Dilek Berker1 & Serdar Guler2
1Ankara Numune Education and Research Hospital, Department of Endocrinology and Metabolic Diseases, Ankara, Turkey; 2Ankara Education and Research Hospital, Department of Endocrinology and Metabolic Diseases, Ankara, Turkey.

Introduction

Bariatric surgery would end up with great alterations in homeostatic measures such as glucose and lipid metabolism and hormonal regulation, which of all are interwoven with some number of ways to each other. The hormonal modulation extends along a wide span starting from the change in gastrointestinal peptides, to the effect in insulin and other nutrient metabolism regulatory hormones and even the hormones establishing thyroid and calcium homeostasis. Secondary hyperparathyroidism is a common finding associated with decreased nutrient, mineral and vitamin D absorption after gut luminal loss due to bariatric surgery. Meanwhile when the adaptation of thyrotropin (TSH) and free t4 (T4) level shows variance among studies, in fact TSH frequently was reported to decrease.

Free T3 (T3) was constantly shown to decrease, used to be correlated with dysfunction in deiodination. The thyroid volume would also be a candidate of other parameter that is expected to change over postsurgical period.

Materials and Methods

We recruited 67 morbidly obese patients planned to have bariatric surgery. All the subjects were recorded for their body weight, BMI, metformin, insulin and levothyroxineLT4 usage and if used dosage of the drug before the operation. The patients were examined with hormonal [parathormon(PTH), 25-oh-vitamin (D3)]25(OH)D3, TSH, FT3, FT4 and biochemical tests [calcium(Ca), ionized Ca(Ca), phosphorus(P), 24 hour(h) urinary Ca]. Thyroid ultrasonography (USG) were performed by one same practitioner and the diameters of each lobe was given as axbxc(cm). The volume of each lobe was calculated with axbxcx0.524 (cm3), and that the hip circumference was positively correlated with free-testosterone levels (r = 0.251, P = 0.044).

**Sebaceous hyperplasia and androgen levels—still controversial**

Anca E Chiriac1, Anca Chiriac2,3 & Doina Azoica1

1 University of Medicine and Pharmacy, “Grigore T Popa”, Iasi, Romania; 2 Aполония University, Iasi, Romania; 3 Nicolina Medical Center, Iasi, Romania.

Sebaceous glands are very sensitive to androgens which can modify the size but not the number of sebaceous glands. Sebaceous hyperplasia is a common benign proliferation of the sebaceous glands seen during the first weeks of life, being reported in 89.4% of 1000 newborns enrolled in a cross-sectional prospective study in the period of November 2007 to May 2009 in India [1] or in 35% of 2938 neonates aged up to three days of life hospitalized in a Brazilian city [2]. Sebum secretion is high in neonates probably induced by maternal androgen: dehydroepiandrosterone transferred trans-placentally. [3] It is also named “the miniature puberty of the newborn” along with vaginal bleeding in infant girls and neonatal acne. Reduced androgen levels in elderly could explain hyperplasia of sebaceous glands (lower cell turnover), especially in women while high androgen-dependent sebum secretion in neonates results in neonatal sebaceous hyperplasia. The association between sebaceous hyperplasia and androgens has been demonstrated in animal models [5], but no correlation was found between serum androgen levels and the appearance of sebaceous hyperplasia lesions in women [6]. Controversial data exist and further clinical studies are required.

**A very rare case of 48, XXXY syndrome**

Ioana Alexandra Amburais Popovic1, Cristina Rusu2,3, Alina Andreea Oprea1, Laura Feraru1, Raluca Balaceanu1 & Cristina Preda1,3

1 University Hospital, “St. Spiridon” Iasi, Iasi, Romania; 2 University Hospital for Children “St. Maria” Iasi, Iasi, Romania; 3 University Of Medicine and Pharmacy, “Gr. T. Popa”, Iasi, Iasi, Romania.

48, XXXY is a rare sex chromosome aneuploidy, being estimated to occur in 1:18000–1:40000 male births. Phenotypically it was considered a variant of Klinefelter syndrome (47, XXY), but currently, due to mental deficiency and behavioural characteristics associated, it’s considered to be a separated genetic condition.

**Case report**

We report a case of a 8-year-old boy, first child of a young non-consanguineous couple, born at term. Due to minor dysmorphic facial features, hypospadias and bilateral talus valgus, a genetic test was conducted and the karyotype identified was 48, XXXY. He was frequently hospitalized for upper respiratory infections, gastro-enteritis, recurrent otitis. He was diagnosed with viral induced asthma and IgA and IgG subclass deficiencies, developing food and medication allergies. Physical examination revealed normal height and weight, dysmorphic facial features (thick eyebrows, hypertelorism, mongoloid slant of the eyes, convergent strabismus, thin lips, dental problems), bifold scrotum, hypospadias, sacral sinus, clinodactyly of the fifth finger, bilateral talus valgus surgically corrected. Neuropsychiatric evaluation revealed borderline mental retardation, delayed speaking, aggressive behaviour, learning difficulties. The endocrinologic consult showed a normal thyroid axis, with a normal-low testosterone level (< 0.025 mg/dl) associated with a FSH level of 0.98 mUI/ml (0.4–3.8) and LH level < 0.1 mUI/ml (0.3–8). Thyroid ultrasound was normal, testicular ultrasound revealed hypoechoic testis, the X-ray of the hand revealed delayed bone age.

**Conclusions**

48, XXXY was described as a variant of 47, XXXY syndrome. It is very important to distinguish the two syndromes regarding the associated medical conditions (as in our case – asthma, food allergies, dental problems, strabismus, recurrent otitis, frequent upper respiratory infections), cognitive and behavioural problems, learning difficulties which are more frequently correlated with 48, XXXY syndrome. Due to complexity and specific features of this particular syndrome,

Clinical case of early manifestation of autoimmune polyglandular syndrome type 3 in children
Julia Volk & Anzhaliika Solntsava
Belarusian State Medical University, Minsk, Belarus.

Autoimmune polyglandular syndrome (APS) type 3 – is a rare orphan disease, which is a combination of autoimmune thyroid disease and diabetes mellitus (DM) type 1 and/or pernicious anemia, vitiligo, alopecia. Due to the rare occurrence in pediatric patients we give our own observation of early manifestation of APS type 3 A in a girl 10 years. Complaints in the primary treatment: sweating, irritability, cardiopalmus, weight loss. Survey results: ultrasound examination of the thyroid gland: expressed diffuse changes, the increase in volume ~ 22.0 cm³ (normal 2.74–6.76). Indicators: thyroid-stimulating hormone (TSH) 0.05 mIU/ml (normal 0.27–4.2), free thyroxine (T4) > 100.0 pmol/l (normal 12.0–22.0), free triiodothyronine (T3) 43.1 pmol/l (normal 3.1–6.8), TSH receptor antibodies 18.0 IU/l (normal 0–1.75). Ophthalmologist: ophthalmopathy low degree of both eyes. Primary diagnosis: Graves’ disease (GD), goiter stage 2, thyrotoxicosis of medium gravity, decompensation. Autoimmune ophthalmopathy. Treatment started: tiamazol 20 mg/day; metoprolol 25 mg/day. 6 months later the patient was hospitalized with complaints during the month of thirst, frequent urination, weight loss of 4.5 kg, weakness. Survey results: blood glucose level 34.1 mmol/l. Acid-base balance: metabolic acidosis. Indicators: C-peptide 155.6 pmol/l (normal 160–1100), antibody titer to glutamic acid decarboxylase 93.2 U/ml (normal 0–1.0), glycated hemoglobin 9.5%. The metabolic compensation of thyrotoxicosis was observed on maintenance therapy (tiamazol 5 mg/day); T4 17.16 pmol/l, TSH < 0.05 mIU/ml. There was a volume reduction 16.2 cm³ on thyroid ultrasound. Final diagnosis: APS type 3 A: DM, type 1, decompensation. GD, medical euthyroidism. Autoimmune ophthalmopathy. Treatment: insulin therapy 22 U/day; tiamazol 5 mg/day. 2 months later a child was hospitalized due to worsening indicators of thyroid hormones and severe fluctuations in blood glucose on the treatment of human genetic engineering insulins. Survey results: thyroid ultrasound: negative dynamics – increase to 21.08 cm³. Indicators: TSH 0.099 mIU/ml, T4 24.8 pmol/l, T3 10.06 pmol/l. Correction of therapy: increasing the dose of tiamazol to 20 mg/day and using insulin analogs. The simultaneous presence of two or more autoimmune diseases of the endocrine glands (thyroid and DM) aggravates the symptoms of each of them, leads to the decompensation of patients.

Type 1-like diabetes mellitus in an oncological endocrinology unit
Sara Donato, Sônia Andrade, Daniela Dias, Joana Simões-Pereira & Maria da Conceição Pereira
Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal.

Introduction
Asparaginase is a component of chemotherapy regimens used to treat paediatric acute lymphoblastic leukaemia (ALL). One of its well-known side effects is hyperglycaemia which is probably related to hypoinsulinaemia. Its incidence rises significantly when associated with corticotherapy. We present two cases of diabetes related to asparaginase and corticoid administration.

Case 1
Eleven-year-old girl diagnosed with an ALL. Before treatment she had a normal body weight and was normoglycaemic. She started the DFCI-2011 protocol and on the day of the first peg-asparaginase administration she was found to have polydipsia, polyuria and a glycaemia of 700 mg/dl with no clinical evidence of pancreatitis. She started an intensive insulin scheme with therapy with an average dose of 0.6 U/kg/day. On the 16th day insulin dose started to be reduced. Despite the higher doses of corticosteroids in the following asparaginase infusions she needed lower doses of insulin to maintain euglycaemia.

Case 2
Six-year-old boy diagnosed with an ALL at the age of three. He was first treated with DFCI-2005 protocol without evidence of hyperglycaemia. A remission lasting 10 months was achieved with recurrence diagnosed at the age of six. He started the IntReALL-SR-2010 protocol and before this treatment his body weight was between P25-50 and he was normoglycaemic. Seven days after the first peg-asparaginase administration he was found to have a glycaemia of 519 mg/dl with ketonuria of 5 mg/dl, without clinical evidence of pancreatitis. He started an intensive insulin scheme with an average dose of 1.5 U/kg/day. Eleven days after the second peg-asparaginase administration insulin dose started to be reduced and at the end of induction course was stopped. Peg-asparaginase was administered one last time without hyperglycaemia.

Conclusion
Asparaginase-induced hyperglycaemia may cause diabetic ketoacidosis or hyperosmolar hyperglycaemic nonketotic syndrome which can be fatal. It is recommended a frequent assessment of glycaemia in these patients. Its occurrence usually does not lead to suspension of therapy. Hyperglycaemia frequently gets better despite continuous use of asparaginase.

P3NP has high-normal values in GHD children and correlates negatively with IGF1
Marianna Costache Outa1,2, Camelia Procopiec1, Andra Carageorgheopol3 & Simona Fica1,4
Hacettepe University, Faculty of Science, Department of Biology, Ankara, Turkey; 2Kecioren Training and Research Hospital, Pediatric Nephrology, Ankara, Turkey; 3Kecioren Training and Research Hospital, Infant Endocrinology Clinic, Ankara, Turkey.

X-linked nephrogenic diabetes insipidus (NDI) is a rare disease caused by a defect in the vasopressin V2 receptor. A patient with nephrogenic diabetes insipidus and severe polyuria was referred to the Pediatric Nephrology Department of Kecioren Training and Research Hospital for abnormal fluid intake (5 l/day) and diuresis (4.3 l/day). it is recommended a thorough evaluation and a different therapeutic attitude for each case.

P3NP has high-normal values in GHD children and correlates negatively with IGF1. More than 200 mutations have been found comprising missense, nonsense, small insertions and deletions, large deletions and complex rearrangements in the AVPR2 gene to date. In this study, a 6-year-old boy was referred to the Pediatric Nephrology Department of Kecioren Training and Research Hospital for abnormal fluid intake (5 l/day) and diuresis (4.3 l/day).

Asparaginase-induced hyperglycaemia may cause diabetic ketoacidosis or hyperosmolar hyperglycaemic nonketotic syndrome which can be fatal. It is recommended a frequent assessment of glycaemia in these patients. Its occurrence usually does not lead to suspension of therapy. Hyperglycaemia frequently gets better despite continuous use of asparaginase.

DOI: 10.1530/endoabs.49.EP816
The lack of GH-IGF1 effect in GHD children could lead to normal-high levels of P3NP correlate negatively with height-SDS (rs = -0.292, P = 0.039). Even not statistically significant, P3NP correlate negatively with height-SDS (rs = -0.210), P = 0.144. 26 values of P3NP were out of the reference range for this biomarker. Five of these records belong to GHD subjects with conditions that can explain high P3NP levels (hypothyroidism in the context of multiple pituitary deficiencies, trauma or inflammation). We analyzed 55 registrations with P3NP in the normal range available for the whole group, according to GH status. We found higher P3NP levels, expressed as median of SD in the GHD group compared to normal stature children (M = 0.7, n = 9 vs M = -0.17, n = 28) and this difference was statistically significant (U = 70.5, z = 1.96, P = 0.049).

Conclusion
The lack of GH-IGF1 effect in GHD children could lead to normal-high levels of P3NP because this biomarker of collagen synthesis is not effectively incorporated into collagen supportive tissues.

Reference values for the urinary steroid metabolome: the impact of sex and age on human adult steroidogenesis

Daniel Ackermann1, Belen Ponte1, Menno Pruim2, Claudia H. d’Uscio1, Idris Gessous1, Georg Ehret1, Fred Paccaud1, Antoinette Pechere-Bertschi1, Pierre-Yves Martin1, Michel Burnier1, Bernhard Dück1, Bruno Vogt1, Murielle Bocchud1 & Nasser A. Dhayat1

1Department of Nephrology and Hypertension, Bern University Hospital, University of Bern, Bern, Switzerland and Department of Clinical Research, University of Bern, Bern, Switzerland; 2Nephrology Service, Department of Specialties of Internal Medicine, University Hospital of Geneva, Geneva, Switzerland; 3Nephrology Service, University Hospital of Lausanne, Lausanne, Switzerland; 4Department of Community Medicine, Primary Care and Emergency Medicine, University Hospital of Geneva, Geneva, Switzerland; 5Cardiology Service, Department of Specialties of Internal Medicine, University Hospital of Geneva, Geneva, Switzerland; 6Endocrinology Service, Department of Internal Medicine Specialties, University Hospital of Geneva, Geneva, Switzerland; 7Institute of Social and Preventive Medicine, University Hospital of Lausanne, Lausanne, Switzerland.

Background

Urinary steroid metabolomics by GC-MS is an established method in clinic and research to describe steroidogenic disorders, but normative data are scarce. Methods

The 24-hour urinary excretion of 40 steroid metabolites was measured by GC-MS in 1128 adult participants of the Swiss Kidney Project on Genes in Hypertension (SKP/OGH), a multicenter, family-based, cross-sectional study. Sex- and age-specific reference ranges were created in the units µg/mol Creatinine and µg/24 hours.

Results

Most urinary steroids showed an age- and sex-specificity. An age- but no sex-specificity was found for etocholanolone, 18-OH-11-dehydro-TH-corticosterone, TH-cortisol, α-cortisol, and β-cortisol in the unit µg/mol Creatinine. No sex- but an age-specificity was found for 209-DH-cortisol in µg/24 hours and neither a sex- nor an age-specificity was found for TH-corticotestosterone and 18-OH-cortisol in µg/24 hours.

Conclusions

Sex- and age-specific reference ranges for 40 steroid metabolites measured by GC-MS were established in a thoroughly characterized general Caucasian population and can be used in routine clinical work.

Does music effect the stress of daily life?

Nevin Dincag1, Çoşkun Obruç2, Sevim Oncu1, Sevda Ozel Yildiz4 & Cengizhan Somzu2

1Istanbul University, Istanbul Faculty of Medicine, Endocrinology and Metabolism Division, Istanbul, Turkey; 2Istanbul University, Istanbul Faculty of Medicine, Biochemistry Division, Istanbul, Turkey; 3Istanbul University, Istanbul Faculty of Medicine, Physician Department, Istanbul, Turkey; 4Istanbul University, Istanbul Faculty of Medicine, Biostatistics and Medical Informatics Department, Istanbul, Turkey; 5Bahcesehir Music Society, Istanbul, Turkey.

Introduction

It’s assumed that music has health beneficial effects by its potential stress-reducing life. There are some reports that chorists in choral society are influenced by music positively during their activities. Research design and methods

37 healthy volunteers who perform Turkish art music in Bahcesehir Music Society with mean age 50.3±10.3yrs, were included into this study. The state and trait anxiety status of chorists was evaluated by using a Likertscale at the time of beginning (19.00) and the end (21.00) of choir, on chorus working day. After each assessments, chorists were asked to collect saliva samples for cortisol levels to be measured later by using electrochemiluminescence immunoassay. Participants were requested to repeat the same procedure at similar times of any day in their normal lives. All data was evaluated with SPSS 20 version. The findings were that music can be used in routine clinical work.

Inhibition of 11β-hydroxysteroid dehydrogenase 2 by the fungicides itraconazole and posaconazole

Katharina Beck1, Denise Kratschnar1, Arne Meyer1, Daniela Schuster2 & Alex Odermatt1

1Division of Molecular and Systems Toxicology, Department of Pharmaceutical Sciences, Pharmazentrum, University of Basel, Basel, Switzerland; 2Institute of Pharmacy/Pharmaceutical Chemistry and Center for Molecular Biosciences Innsbruck (CMBI), Computer Aided Molecular Design Group, University of Innsbruck, Innsbruck, Austria.

Impaired 11β-hydroxysteroid dehydrogenase type 2 (11β-HSD2)-dependent cortisol inactivation can lead to electrolyte dyshalance, hypertension and cardiometabolic disease. Furthermore, placental 11β-HSD2 essentially protects the fetus from high maternal glucocorticoid levels, and its impaired function has been associated with altered fetal growth and a higher risk for cardio-metabolic diseases in later life. Despite its important role, 11β-HSD2 is not included in current off-target screening approaches. To identify potential 11β-HSD inhibitors amongst approved drugs, a pharmacophore model was used for virtual screening, followed by biological assessment of selected hits. This led to the identification of several azole fungicides as 11β-HSD inhibitors, showing a significant structure-activity relationship between azole scaffold size, 11β-HSD enzyme selectivity and inhibitory potency. A hydrophobic linker connecting the azole ring to the other, more polar end of the molecule was observed to be favourable for 11β-HSD2 inhibition and selectivity over 11β-HSD1. The most potent 11β-HSD2 inhibition, using cell lysates expressing recombinant human 11β-HSD2, was obtained for itraconazole (IC50 139±14 nM), its active metabolite hydroxyitraconazole (IC50 223±31 nM) and posaconazole (IC50 460±98 nM). Interestingly, experiments with mouse and rat kidney homogenates showed considerably lower inhibitory activity of these compounds toward 11β-HSD2, indicating important species-specific differences. Thus, 11β-HSD2 inhibition by these compounds are likely to be overlooked in preclinical rodent studies. Inhibition of placental 11β-HSD2 by these compounds, in addition to the known inhibition of cytochrome P450 enzymes and P-glycoprotein efflux transport, might contribute to elevated local cortisol levels, thereby affecting fetal programming.

Cortisol levels and thyroid hormones in surgical patients with different sensitivity to pain

Anatoli Zhudro

Republican Clinic Medical Center of the Presidential Administration, Minsk, Belarus.

Objective

To determine the intraoperative levels of cortisol and thyroid hormones in surgical patients with different sensitivity to pain.

Material and methods

We analyzed the individual sensitivity to pain in 94 people the day before surgery. Patients were ASA 1-2. Age 46±10.2 years. We used a mechanical stimulus (1 x 5 mm wire with stop) and the visual analogue scale of 10 points (color, grayscale, 10 fields, from light to black). Incentives applied to the base of the thumb. Patients divided into 2 groups, first group - low sensitivity to pain (VAS 1-5), 2nd group - high sensitivity to pain (VAS 6-10). All patients underwent laparoscopic cholecystectomy under general anesthesia. Anesthesia consisted of premedication, induction, myorelaxation, ventilation with a mixture of oxygen supply, nitrous oxide and sevoflurane, anodyne - fentanyl, paracetamol. We used 260.64±114.81 and 211.4±91.67, respectively, on chorus working day (Group II) at similar hours. Saliva cortisol levels showed a 33% decrease in Group II while an increase of 21% was detected in Group I (P<0.02). Also a reduction 14% in stress scores was observed in Group II (P<0.004), especially remarkable in women, individuals with non-alcoholic, but smokers, active employees and people who have less time engaged in music.

Conclusion

We say that individuals who perform a two-hour Turkish art music per week, are affected positively by music different from the day of their normal life. Particularly due to fact that music is very popular, cheap and easily applicable in daily life, it seems promising to use music in daily life as strategy for stress reduction.

DOI: 10.1530/endoabs.49.EP823
hemodynamic monitoring and ventilation system. Control thyroid hormones (T3, T4, TSH) and cortisol before operation, 3 times during surgery and after surgery. Statistical analysis was performed using the software package Statistica 7.0 Results In all patients, the level of thyroid hormones remained normal throughout the study period. Not observed any changes of thyroid hormone levels in patients with both high and low sensitivity to pain. Plasma cortisol levels remained within the normal range in 92% of patients. In 8% of the patients (all patients in the second group, the high sensitivity to pain) noted the excess of normal levels of cortisol. After the start of operation of cortisol level was higher than baseline. Intraoperatively, in patients with high sensitivity to pain the plasma cortisol level was higher than in patients with low sensitivity to pain. Conclusion Peripheral levels of thyroid hormones and cortisol most surgical patients remains within the normal range. Patients with high sensitivity to pain was higher cortisol levels after starting operation as compared to the level of cortisol in patients with low sensitivity to pain.

Ritonavir induced Cushing’s Syndrome in a patient under inhaled corticosteroids
Teresa Alves Pereira1, Inês Furtado2, Ana M Lopes1, Liliana Fonseca1 & Isabel Palma1
1Endocrinology Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal; 2Internal Medicine Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal.

Introduction
Cushing’s Syndrome secondary to inhaled or topic corticosteroids is very rare, although there are reports of a link to cytochrome inhibitors. Ritonavir, a protease inhibitor used for treatment in human immunodeficiency virus (HIV) infection, is a potent inhibitor of cytochrome P450 3A4.

The case
A 41 years old man - with personal history of asthma, HIV infection diagnosed in 2002 and hepatitis C infection since 1999 - was sent to an endocrinology consult in January/2015 for obesity investigation and orientation. The patient presents with a one-year history of truncal and facial obesity and global weakness of the lower limbs. Moreover, the patient presented with cushingoid facies, facial plethora, centripetal obesity and hypotrophic upper limbs. At that time, the patient was under therapy with ritonavir 100mg/day, salmeterol/fluticasone 50/250 μg two inhalations per day and a topic betamethasone lotion 0,5mg/g twice a week. Morning total plasma cortisol levels were low (0.6 μg/dl) and ACTH was suppressed (5 μg/ml). Cosynotrim stimulation test confirmed a suppressed pituitary-adrenal axis. Consequently, ritonavir was concluded and the clinical picture resolved progressively.

Conclusion
The present case underlines the importance of cytochrome inhibitors in the modification of corticosteroid metabolism and their extended effect – as in Cushing’s Syndrome.

Thyroid hormone T3 protects skeletal muscle metabolism during fasting in mice
Valentina Russi1, Sarassunta Ucci1, Camilla Virili2, Marco Centanni2, Viviana Moresi1 & Cecilia Verga Falzacappa1,2
1Pasteur Institute, Rome, Italy; 2Sapienza, University of Rome, Medical surgical Sciences and Biotechnologies Department, Rome, Italy; 3Sapienza, University of Rome, Department of Anatomy, Histology, Forensic Medicine and Orthopedic, Section of Histology, Rome, Italy.

Background
Skeletal muscle is known to be a target of THs, regulating oxygen consumption, fiber composition, calcium mobilization and glucose uptake. However, a possible role for THs in muscle homeostasis and cellular metabolism under pathological has never been investigated. Food deprivation induces skeletal muscle atrophy, causing metabolic changes, and forcing the tissue to utilize fatty acid as the main oxidation substrate. Aim of this project was to understand whether T3 influence skeletal muscle metabolism during fasting.

Methods
Adult male BALB/C mice were food deprived for 48h (STV), and daily treated with intraperitoneal injections of T3 (100 μg/Kg BW) (STVT3) or vehicle as controls. At the end of the experiments, Tibialis anterior was collected and firstly laminin stained sections were analyzed for myofiber sizes by IF microscopy. Secondly, the number of glycolytic, intermediate or oxidative fibers per cross section area on NADH stained histological sections was analyzed. Mitochondria content, indicative of a more oxidative metabolism, was then analyzed by qRT Syber Green PCR for PGC-1a mRNA.

Results
As expected, laminin staining evidenced a reduction in Cross Sectional Area of the myofibers induced by fasting (STV), as a sign of atrophy. The cited reduction was significantly hampered by the presence of T3 in the STVT3 group. Secondly, T3 was able to significantly reduce the shift in the metabolism towards a more oxidative state (P<0.05) and a less glycolytic one (P<0.01) induced by fasting. Coherently, T3 reduced the increase in PGC-1a mRNA level induced by fasting in the STV group (P<0.05).

Conclusions
The decrease of the amount in oxidative muscle fibers during T3 treatment in STV agrees with a less expression of PGC-1a, a molecular marker of mitochon-driogenesis and fatty acid oxidation. Therefore, T3 treatment during fasting seems to exert a protective role on the metabolism of muscle fibers.

False memory in elderly patients with thyroid disease
Anna Golda1, Agnieszka Sawicka1, Agata Bielecka1 & Kryzystof Marczewski2,1
1Department of Nephrology and Endocrinology Pope John Paul II Regional Hospital, Zamosc, Poland; 2Faculty of Health Sciences Lublin University of Economy and Innovation, Lublin, Poland.

Introduction
The phenomenon of false memory is quite prevalent among people with cognitive impairment. Cognitive dysfunction and its relationship with the thyroid gland has been described. In contrast, little is known about the phenomenon of false memory in patients with thyroid diseases. That is why we want to introduce our preliminary observation.

Method
Patients aged 64 to 90 years (average 77) with endocrine disorders were subjected to tests for typical geriatric assessment and tests investigating the so-called: false memory, that is, “remembering” the words that were not spoken, according to the method Roediger and McDermott’s

Results
We investigated 31 patients, of which 17 had thyroid disease. All patients with thyroid diseases, “remembered” the unspoken words. The best result was only 6% of the words false “recalled”, the worst result was 75%, on average, about 35%. This result did not differ significantly on the outcome of patients with other endocrine disorders, but among them were two people without the presence of false memory. We found a negative correlation between the results of the test of false memory and mini mental status (P<0.01). We did not find significant correlations between the results of the tests and TSH.

Conclusion
False memory may prove to be an important problem among older people with thyroid disease. Although its clinical significance needs further study.

Orbital disease primer for Endocrinologists-not always thyroid associated orbitopathy (TAO): a case vignette
Fotini Adamidou1, Christina Manani1, Panagiotis Anagnostis1, Thomas Georgiou1 & Konstas Boboriolis1
1Ippokrateion General Hospital of Thessaloniki, Thessaloniki, Greece; 2Aristotle University of Thessaloniki, Ophthalmology Department, Thessaloniki, Greece.

Endocrine Abstracts (2017) Vol 49
**Background**

TAO is a rare disease, seriously involving 5% of patients with autoimmune thyroid disease. The clinical presentation may be difficult to distinguish from other orbit conditions.

**Case 1**

A 63-year-old woman was admitted to the Neurology Service for worsening diplopia over the previous six months, with a working diagnosis of myasthenia gravis or multiple sclerosis. The Endocrine Service was consulted because of a long history of Hashimoto’s thyroiditis. The patient was euthyroid on thyroxine replacement. Clinical activity score was 0, but there was restriction in elevation of the right eye. Orbital MRI demonstrated thickening of the right inferior rectus. The diagnosis of TAO was made and the patient received intravenous methylprednisolone with symptomatic improvement.

**Case 2**

A 48-year-old man with a history of Crohn’s disease, was referred for presumed TAO, with severe diplopia, right retrobulbar pain and exophthalmos. He was euthyroid, with negative thyroid antibodies. Orbital MRI demonstrated thickening of all extraocular muscles of the right eye. A diagnosis of orbital myositis was made. The patient received 1.5g intravenous methylprednisolone with marked improvement, but a month later presented with a red left eye and diplopia. Orbital CT demonstrated thickening of the superior oblique and the medial rectus. The patient again received intravenous methylprednisolone with complete remission and remains asymptomatic from his orbital and bowel disease one year later.

**Case 3**

A 45-year-old woman was referred to the Endocrine Service with right sided ptosis, for presumed TAO. She was euthyroid, with negative thyroid antibodies. Eye exam was normal except for right-sided ptosis. Orbital MRI was normal. On further questioning, the patient admitted having had botulinum toxin injections on the forehead and right brow a week before.

**Conclusion**

The differential diagnosis and management of orbitopathy often relies on the Endocrinologist and spans the spectrum of divergent medical specialties.

**Management of very severe Graves’ orbitopathy with low dose rituximab: report of two cases**

Fotini Adamidou1, Christina Manani1, Panagiota Anagnostis1, Thomas Georgiou1, Kostas Boboridis2 & Marina Kita3

1Ippokrateion General Hospital of Thessaloniki, Thessaloniki, Greece; 2Aristotle University of Thessaloniki, Ophthalmology Department, Thessaloniki, Greece.

**Introduction**

Although Graves’ orbitopathy (GO) is common in the course of Graves’ disease, dysthyroid optic neuropathy and corneal breakdown are rare. We describe two cases of severe GO treated successfully with rituximab.

**Case 1**

A 50-year-old female smoker with Graves’disease, presented with disfiguring eyelid edema, exophthalmos and diplopia, preserved visual acuity and clinical activity score (CAS) ≥ 5. She received pulsed methylprednisolone to a total of 6 gr and standard orbital radiotherapy 3 months later with minor improvement. Thyroid status stabilized on methimazole combined with lithium and an uncomplicated thyroidectomy followed. However, visual acuity declined to “hand motion”, necessitating two cycles of rituximab at 375 mg/m² each, two weeks apart. Lymphocyte depletion was immediate and sustained and visual acuity improved to 4/10 bilaterally. Three years later CAS=0 and the patient maintains a visual acuity of 2/10.

**Case 2**

A 78-year-old male non-smoker presented with hyperthyroidism initially thought to be due to toxic multinodular goiter and had thyroidecctomy four months later. An incidental papillary thyroid carcinoma measuring 1.05 cm, insular type, was found at histology in the right lobe. He was referred for management of GO one month postoperatively, characterized by retrobulbar pain, chemosis and diplopia, CAS≥7, loss of color vision and visual acuity of 1/10 bilaterally. He received pulsed methylprednisolone to a cumulative dose of 8 g and orbital radiotherapy, resulting in mild improvement in inflammation, but worsening of the acuity to light perception on the right only, with relative afferent pupillary defect on the left and fixed globes. The patient then received two infusions of rituximab of 500 mg two weeks apart. He recovered vision to 2.5/10 in the right eye, which allowed his return to independent living. He subsequently received 100mCi 131I without GO relapse.

**Conclusion**

Rituximab therapy can benefit vision and quality of life in refractory, severe GO.

The metabolic impact of ACTH-dependent versus ACTH-independent Cushing’s syndrome: a retrospective study of 99 patients
Mirela Diana Ilie1,2 and Corin Badu1,2
1 C.L.Parhon’ National Institute of Endocrinology, Bucharest, Romania; 2 Carol Davila’ University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Although the metabolic impact of Cushing’s syndrome and hypercortisolism are well known, the metabolic impact of ACTH is less established.

Objective
To identify differences in the glucidic, lipid and bone metabolism in ACTH-dependent versus ACTH-independent Cushing’s syndrome.

Methods
Retrospective, cross-sectional study of 99 patients with Cushing’s syndrome (54 with ACTH-dependent Cushing’s syndrome and 45 with ACTH-independent Cushing’s syndrome) admitted to ‘C.L.Parhon’ National Institute of Endocrinology during 1998-2016. Clinical and paraclinical data were analyzed.

Results
Type 2 diabetes was found in 39% and prediabetes was found in 31% of the patients in the ACTH-dependent group; in the ACTH-independent group 31% of the patients had diabetes and 27% had prediabetes. Regarding lipid metabolism, 15% of the patients in the ACTH-dependent group were already on lipid-lowering drugs compared with 29% in the ACTH-independent group; of the remaining patients, who were not on lipid-lowering drugs, 63% had hypercholesterolemia and 46% had hypertriglyceridemia in the ACTH-dependent group, compared with 75% having hypercholesterolemia and 50% having hypertriglyceridemia in the ACTH-independent group. Osteoporosis was found in 31% of the tested patients in the ACTH-dependent group and in 60% of the tested patients in the ACTH-independent group.

Conclusions
Lipid and bone metabolism were more affected in the ACTH-independent group, while glucidic metabolism was more affected in the ACTH-dependent group.

DOI: 10.1530/endoabs.49.EP830

ACTH-independent subclinical Cushing’s syndrome in patient with acromegaly and adrenal incidentaloma
Maria Kurowska, Joanna Malicka & Jerzy Tarach
Department of Endocrinology, Medical University, Lublin, Poland.

Introduction
It is well established that acromegaly is associated with increased risk of cancer. However, it is currently unclear whether patients with acromegaly are at increased risk of developing adrenal tumors and little is known about the association between acromegaly and adrenal adenomas. The simultaneous occurrence of preclinical Cushing’s syndrome in patients with acromegaly and adrenal adenoma is extremely rare, and to our knowledge, so far only 5 such cases have been reported in literature.

Case report
73-year-old female with typical acromegalic appearance and acromegaly suspected 34 years ago and recognized 16 years ago. She underwent non complete transsphenoidal resection of somatotroph macroadenoma 15 years ago. Since neurosurgery she is chronically treated with long-acting somatostatin analogue, currently with lanreotide autogel 120 mg every 28 days. The current GH level is 2.59 mg/ml [n:0.126–9.88] and IGF-1 252.2 mg/ml [n:29–204]. Approximately 3 years ago, a focal lesion 22×17 mm was detected in left adrenal gland, with a basal density (~)12HU (tumor density in the adrenal protocol; (~)+18HU, (+)10HU, (~)11HU respectively), suggesting adenoma. The patient had long-term arterial hypertension with no cushingoid features. An examination of pituitary-adrenal axis showed lowered ACTH level = 4.76 mg/ml [n:7.2–63.6], a tendency to lose a circadian rhythm of cortisol [19.6–10.3 µg/24h] and the lack of cortisol secretion inhibition by 1 and 2 mg of dexamethasone [8.5 and 5.3 µg/ml, respectively]. Daily excretion of urine cortisol was normal [172.5 and 123.6 µg; n:55.5–286.0].

Conclusion
In order to determine the incidence and the relationship between the adrenal tumors and acromegaly, standard evaluating of the adrenal glands is indicated in patients with acromegaly.

Coexistence of TSH-secreting pituitary adenoma, primary hyperparathyroidism and vitamin D deficiency
Ibtissem Oueslati, Nadia Michigui, Karima Khari & Néjib Ben Abdallah
Department of Endocrinology, Charles Nicolle Hospital, Tunis, Tunisia.

Introduction
The simultaneous occurrence of central hyperthyroidism and primary hyperparathyroidism is extremely rare. Few cases of TSH pituitary adenoma in the setting of multiple endocrine neoplasia type 1-associated syndrome were reported in literature. Herein, we report a new case of TSH secreting pituitary adenoma particular by the coexistence of primary hyperparathyroidism and vitamin D deficiency.

Observation
A 76-year-old woman was referred to our Department with thyrotoxicosis and elevated TSH levels. She presented with an important weight loss, intolerance to heat, restlessness, flapping tremor, diarrhea and vomiting. On examination, she had a body mass index of 19 kg/m², a clinical signs of dehydration, a blood pressure of 120/60 mmHg and an irregular pulse of 120 beats/min. Thyroid gland was asymmetrically enlarged. No propotis was observed. Electrocardiogram showed an atrhythmic tachycardia (120/min). Echocardiography revealed moderate, asymmetric hypertrophy of the left ventricle. Systolic and diastolic functions were preserved. Laboratory tests revealed central hyperthyroidism and primary hyperparathyroidism. The 25 OH vitamin D was 4.6 µg/l (nr: 30–100 µg/l). Serum creatinine was 131 µmol/l and creatinine clearance was 59 ml/min. Pituitary hormone explorations revealed hypergonadotrophic hypogonadism with normal lactotropin and corticotropin functions. Pituitary MRI scan showed an invasive pituitary adenoma measuring 21×15×17 mm and causing right cavernous sinus invasion. Sestamibi parathyroid scintigraphy, cervical and thoracic magnetic resonance imaging were normal. Bone densitometry revealed osteopenia. The patient was symptomatically treated with intravenous fluid replacement therapy, antithyroid drugs and beta blockers. Due to the patient’s poor general condition, surgical approach of the TSH-oma was contraindicated and pituitary radiotherapy was considered.

Conclusion
Although vitamin D deficiency and primary hyperparathyroidism are common disorders in the elderly population, their association to TSH pituitary adenoma is a rare condition.

EP833
Central diabetes insipidus in children: about eight cases
Najoua Lassoued, Selmene Ouannes, Aief Jguirim & Mohamed Taher Sfar
Department of Pediatrics, CHU Taher Sfar, Mahdia, Tunisia.

Introduction
Central diabetes insipidus (CDI) is a rare but potentially dangerous dysregulation of the water balance secondary to an arginine vasopressin (AVP) deficiency. Diabetes insipidus may have different manifestations in children compared to adults. CDI is more common in children than nephrogenic diabetes insipidus.

Methods
A retrospective study of eight patients collected in the pediatric department of Mahdia.

Results
The average age of patients was 2.8 years. The reason for hospitalization was a prolonged fever in three patients, weight stagnation in three patients, severe dehydration in one patient and headache and decreased visual acuity in one patient. A history of polyaralypydysplastic syndrome was found in five patients only. Diuresis was quantified at 9 ml/kg per hour on average. In biology, the plasma osmolality was 296.8 mosmol/Kg and the urinary osmolality was 95.8 mosmol/kg with a urinary density at 1001 on average.Water deprivation test was carried out in four patients only confirming the diagnosis of CDI while the four remaining patients had underwent directly a Desmopressin stimulation test. The etiological assessment revealed a cerebral malformation in 4 patients, a Langerhans cell histiocytosis in three patients and a craniopharyngioma in one patient. Hormonal assessment revealed adrenal insufficiency in one patient and thyrotrophic insufficiency in two patients. Treatment with intranasal Desmopressin was started at the mean dose of 0.125 ml/day in combination with the etiological treatment. The evolution was favorable in most of our patients.

Conclusion
The discovery of a CDI in children leads to an etiological investigation with an urgent need to identify tumor pathologies (craniopharyngioma, dysgerminoma). Infiltrative pathologies may be already known or reveal the disease (histiocytosis, mahdia).
A 36-year-old female patient was referred to endocrinology outpatient clinic due to increased TSH levels. Two years ago, she had been diagnosed and treated as Graves’ disease with propylthiouracil. Total thyroidectomy was performed in another center due to ineffective medical treatment and oral levothyroxine sodium (LT4) was started. During the follow-up her TSH levels were normal. Thirteen months after the last normal TSH value, she consulted the endocrinology outpatient clinic due to high levels of TSH (23 uIU/ml). She was questioned about the proper usage of medication and the LT4 dose was increased. Despite the higher dose of LT4 (400 mcg/day), her TSH level was still increased at >100 uIU/ml. Although pituitary function test were normal, pituitary MRI showed a macroadenoma with suprasellar extension. TSH α-subunit was 4.25 ng/ml (0–0.90 ng/ml). She was hospitalized for operation of TSHoma by Figure 1 Pretreatment pituitary MRI image.

Figure 2 Pituitary MRI image after 3 weeks i.m LT4 treatment.

DOI: 10.1530/endoabs.49.EP834

and more rarely sarcoidosis). The objective of the management is to ensure a normal water balance by normalizing the diuresis by the administration of Desmopressin, to prevent any water retention and therefore any hypotremia. It is associated with the treatment of the etiology of the CDB and the hormone replacement therapy of the associated anterior pituitary insufficiency.

Pachydermoperiostitis associated with non secretory pituitary macroadenoma in patient with toxic multinodular goitre

Ramazan Gen

Mersin University, Mersin, Turkey.

Pseudacromegaly is associated with acromegalic phenotype but normal insulin like growth factor-1 (IGF-1) levels and suppressed growth hormone levels. The reasons of this condition may be pachydermoperiostitis insulin resistance, drug intake such as minoxidil and hypothryroidism (4). We describe pachydermoperiostitis in a patient with hyperthyroidism and non-secretory pituitary macroadenomas.

Clinical case

A 62 year old man presented with palpitation, sweating and weight loss. Physical examination revealed that’s multi nodular goitre, acral enlargement, gigantism, fall in the left eye lid and thickening of the skin (heel-pad thickness was 27 mm on right foot and 28 mm on left foot) Laboratory results revealed that serum sTSH 37.7 pmol/l (12.8 < n < 20.4), TSH <0.006 μIU/ml (0.47 ≤ n ≤ 4.2), IGF-1 91.8 ng/ml (75≤ n ≤ 212). We re-evaluated GH-IGF-1 levels after treatment of hyperthyroidism. After being euthyroid, GH level 0.379 ng/ml (1 < n < 9), IGF-1 88 ng/ml (75 < n < 212). GH level was suppressed after 100 gr oral glucose load. Pituitary magnetic resonance imaging revealed 10.5 mm macroadenoma. All pituitary hormone levels of patient was normal. Advanced investigation for hyperinsulinemia, hypothyroidism and drug use revealed nothing. In contrast patient has hyperthyroidism. Two sons of the patients physical exam revealed acral enlargement, gigantism and thickening of the skin as a patient. GH levels, IGF-1 levels and pituitary MRI of the sons of patient was normal. We considered patient and two sons have autosomal dominant inheritance pachydermoperiostitis.

Conclusion

This is a very rare case of pseudacromegaly due to pachydermoperiostitis with nonfunctioning pituitary adenoma in patient with toxic multinodular goitre.

Successful management of macroprolactinoma with aromatase inhibitor in a patient with hypogonadotropic hypogonadism

Feyza Yener Ozturk, Esra Cil Sen, R Selvinaz Erol, Sezin Dogan Cakir, Seda Erem Basnaz, Emre Sedar Saygili, Adnan Batman & Yuksel Altuntas

Department of Endocrinology and Metabolism, Sisli Hamidiye Etfal Training and Research Hospital, Istanbul, Turkey.

Introduction

Hypogonadism persisting in man with macroprolactinoma requires exogenous testosterone replacement therapy (TRT). But TRT may cause secondary elevations of prolactin. We report here a case of macroprolactinoma and hypogonadotropic hypogonadism with persistently high prolactin level after initiating TRT.

Case report

A 28 year-old male was admitted to outpatient clinic with complaints of headache, low libido and blurred vision on left eye for three years. Magnetic resonance imaging (MRI) revealed a pituitary mass (3.6 × 3.5 × 2.3 cm) occupying entire sella, extending to sphenoid sinus, internal carotid arteries (ICA), encasing right ICA and deviating stalk to left. Tumor compressed optic chiasm causing bitemporal hemianopsia. Laboratory tests: prolactin: 133 ng/ml (1/100 diluted prolactin: 77 ng/ml), cortisol:0.75 μg/dl (unresponsive to low dose ACTH stimulation test); TSH:2.31 uIU/ml, tT4:0.47 ng/dl, tT3:1.06 ng/ml, FSH:4.3 mU/ml, LH:0.29 mU/ml, ttestosterone ≤ 0.20 ng/dl, GH < 0.05 μg/ml, IGF-1:186.9 ng/ml (n:117–329). Nonfunctional adenoma and panhypopituitarism was the diagnosis. Transnasal transsphenoidal adenectomy was performed after hormone replacement. Pathology revealed prolactin-secreting pituitary adenoma with Ki67:1–2%. Cabergoline therapy (1 mg/week) was started on postoperative 15th-day as prolactin was 323 ng/ml. Prolactin decreased to 80 ng/ml on the 2nd-month of therapy but ttestosterone was still low. TRT was started intramuscularly per 3 weeks for complaints of low libido. After then, prolactin level increased abruptly to 470 ng/ml. Despite gradual increment of dosage to 4 mg/week, prolactin remained elevated (451 ng/ml). No enlargement of residual mass was noted on new MRI. When TRT was quited for 3 months, prolactin decreased to 93 ng/ml. Then TRT was started with selective aromatase-inhibitor anastrozole 1 mg/day. With cabergoline dosage decreased gradually to 3 mg/week, prolactin decreased to 18.8 ng/ml and ttestosterone was normal (300 ng/dl).
Aromatase-inhibitor added to therapy may facilitate successful TRT for patients with macroprolactinoma.

Multifocal multisystem langerhans cell histiocytosis – a rare cause of panhypopituitary and diabetes insipidus – a case report
Filip Gabalec1,2, Martin Simkovic1,2, Petra Kasparova1,3, Pavel Zak1,2 & Jan Cap1,2
14th Department of Internal Medicine, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic; 2Faculty of Medicine Hradec Kralove, Charles University, Hradec Kralove, Czech Republic; 3The Fingerland Department of Pathology, Hradec Kralove, Czech Republic.

Introduction
Langerhans cell histiocytosis (LCH) is a very rare disease in adults and as well a very rare cause of sellar expansion. The clinical presentation can be heterogeneous, from a single bone lesion to potentially fatal, widespread disease.

We describe the difficulties with the evaluation and the treatment of LCH.

Case
39 years old woman has had amenorrhea for 2 years and higher intake of fluids (5–7 l/day) for 6 years. Non-functioning pituitary expansion with pituitaryoma appearance was found on MRI. She was followed up for almost 3 years. Panhypopituitarism developed during the follow-up and replacement therapy with adrenurein, thyroxin and hydrocortisone was initiated. Finally, she underwent biopsy for slow progression of sellar expansion – Langerhans cell histiocytosis was confirmed histologically, with S100 a CD1a protein immunohistochemical staining. Staging of the disease revealed suprasellar expansion, skeletal and retroperibular infiltration, lymphadenopathy along the right internal carotid artery and retroperitoneal and mediastinal lymphadenopathy with FDG avidity on 18-FDG-PET/CT. She received five cycles of cladribine monotherapy with subsequent PET/CT restaging.

Discussion
Hypothalamus-pituitary-adrenal axis infiltration is present in up to 50% of LCH; the most common disorder is diabetes insipidus (DI). The frequency of DI is 30–40% and 94% if other pituitary hormone deficiencies exist. The diagnosis can be tricky. The primary treatment modalities for LCH include local excision of the lesion, corticotherapy, chemotherapy, radiotherapy, and immunotherapy with anti-CD1a monoclonal antibodies. The data regarding the treatment of the central nervous system involvement with LCH are very limited. Cladribine (2-CDA) is a promising agent in this setting as previously reported. Cladribine has good bioavailability in the CNS. A total of six cycles of cladribine monotherapy can be administered with respect to the good profile of toxicity in this indication. However, prolonged neutropenia and respiratory infections led to premature termination of the treatment in our case.

DOI: 10.1530/endoabs.49.EP837

A rare association of autoimmune diabetes insipidus and hypophysitis with partial pituitary insufficiency
Liviu Matei1, Corina Stefaro1, Simona Mogos1,2 & Dumitru Branisteau1,2
1Endocrinology Clinic, ‘Sf. Spiridon’ Clinical Emergency Hospital, Iasi, Romania; 2Department of Endocrinology, University of Medicine and Pharmacy “Gr. T. Popa”, Iasi, Romania.

We present the case of a 40 year old man presenting at first consultation an ‘idiopathic’ fast-onset and severe polyuro-polydipsic syndrome (diuresis of 10 l/24 hours, with urine osmolality of less than 50 mOsm/kg and urine gravity lower than 1001). Clinical examination showed pallor and decreased piloery at an asthenic patient with limited lesions of vitiligo and loss of libido. Water deprivation test showed the persistence of excretion of highly diluted amounts of urine, confirming the diagnosis of diabetes insipidus. The patient responded specifically to therapy with sublingual desmopressin, with a decrease of diuresis to under 2500 ml/24 hours and an increase of urine gravity to 1010 under a dose of 60 µg×3/day, supporting the diagnosis of central diabetes insipidus. Serum testosterone was of 1.01 ng/ml (normal range – between 2.6 and 10 ng/ml) and low-normal LH (LH = 1.5 mU/l and FSH = 2 mU/l) suggesting the presence of central hypogonadism. Serum T4 was of 0.545 ng/ml (normal range – between 0.9 and 1.9 ng/ml) with ‘normal’ TSH (1.6 mU/l) suggestive for central hypothyroidism. Corticotroph axis was undamaged (morning plasma cortisol of 15.5 µg/dl and ACTH of 38.9 pg/ml). Osteodensitometry revealed osteopenia. MRI investigation of the hypothalamo-pituitary region showed a small pituitary gland (7/3/6 mm) accompanied by partial empty sella without images of pituitary adenomas and absence of the native hypersignal of the neurohypophysis. The pituitary stalk was deformed, taking a nodular shape with dimensions of 4/5/6 mm. This image was highly suggestive for neuroinfiltrative hypophysitis, most probably of autoimmune origin. Injections with testosterone undecanoate every three months and daily oral supplementation of thyroid hormones added to desmopressin therapy significantly improved patient’s quality of life. Autoimmune associations of the anterior and posterior pituitary are very rare and may raise difficulties of diagnosis and therapeutic decisions.

Pituitary apoplexy while treating recurrence of Cushing’s disease with Pasireotide
Birutė Ziltiūtienė1,2, Aiste Kondrotienė3, Rasa Verkauskienė1,2, Lina Barsienė2, Robertas Knišpeliū2, Valdas Sarsauskas2 & Annamaria Colao3
1Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania; 2Department of Endocrinology, Hospital of Lithuanian University of Health Sciences Kauno Klinikos, Kaunas, Lithuania; 3Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania; 4Department of Pathological Anatomy, Lithuanian University of Health Sciences, Kaunas, Lithuania; 5Department of Molecular and Clinic Endocrinology and Oncology, University of Naples Federico 2, Endocrinology Sector, Naples, Italy.

Introduction
ACTH producing macroadenoma and pituitary apoplexy are rare in Cushing’s disease. Somatostatin receptor agonist Pasireotide is indicated for the treatment of patients with Cushing’s disease for whom surgery is not an option or has failed. We present a case of pituitary apoplexy in patient with recurrence of Cushing’s disease treated with Pasireotide.

Case
38 years old female presented with quick weight gain, weakness, irregular menstruation, hirsutism, hypertension, newly diagnosed diabetes mellitus. High levels of blood cortisol and ACTH were observed. Cortisol was not suppressed after 1 mg overnight dexamethasone suppression test (DST) and after low-dose DST. High-dose DST suppressed cortisol secretion. Pituitary macroadenoma with diameter of 12×9 mm was diagnosed on MRI. Patient underwent transphenoidal surgery in January, 2012. In 2014 recurrence of Cushing’s disease was diagnosed and second transphenoidal surgery was performed in January, 2015. In November, 2015 recurrent pituitary adenoma with diameter of 15×11 mm was identified on MRI and hormonal tests confirmed hypercortisolism with elevated ACTH again. Therapy with Pasireotide was started in January, 2016. After 9 months of successful use of this medication patient was emergently hospitalized to the Department of Endocrinology with an episode of an acute headache, nausea, vomiting. Ptosis of a right eyelid and blurred vision occurred. Head MRI identified on MRI and hormonal tests confirmed hypercortisolism and need of hydrocortisone for several days. Two weeks later normal cortisol levels were observed, hydrocortisone discontinued. Further treatment with Pasireotide 0.6 mg b.i.d. was continued. 4 months after pituitary apoplexy and further treatment with Pasireotide, ptosis and blurred vision regressed, eucortisolism was achieved.

Conclusion
To our knowledge we report the first case of pituitary apoplexy in patient with Cushing’s disease treated with Pasireotide. This complication might be related to Pasireotide effect on tumorgenesis mechanisms.

Hemodialysis patient with metastatic renal cell carcinoma to the pituitary stalk presenting as hypopituitarism: an autopsy case

Hsashi Sugano1, Riku Ino1, Yuko Dehara2 & Yoshinori Tuchiyama2
1Department of Diabetes and Endocrinology, Kochi Health Sciences Center, Kochi, Japan; 2Department of Clinical Nephrology, Kochi Health Sciences Center, Kochi, Japan.

Introduction
Pituitary metastases occur in 1% to 4% of cancer patients in autopsy studies. The most frequent primary tumors are breast and lung tumors. Renal cell carcinoma (RCC) is a rare cause of pituitary metastases, with only 25 previously reported cases.

Case report
A 77-year-old man was admitted to our hospital because of acute progression of chronic renal failure presenting with appetite and weight loss in August 2014. He underwent hemodialysis. His fasting blood glucose was low without any symptoms. In 1998, he had undergone left nephrectomy and adenalecctomy, and was diagnosed with a clear cell RCC. In 2001, lung metastasis was diagnosed and he was treated with interferon therapy, which led to remission. In 2009, lung metastasis was observed again, but he declined treatment. He had hyperprolactinemia and hypopituitarism; levels of PRL: 292.8 ng/ml, free T4: 0.56 ng/ml, TSH: 0.953 µIU/ml, cortisol: 2.0 µg/dl, ACTH: 5.4 pg/ml, IGF: 42 ng/ml. Magnetic resonance imaging revealed a 7×8×9 mm mass with a pituitary stalk that compressed the optic chiasm without visual disturbance. Dynamic tests showed hyporesponses of cortisol, LH, FSH, TSH, and GH. We considered panhypopituitarism due to RCC originating in the right kidney. As well, we considered that compressed the optic chiasm without visual disturbance. Dynamic tests showed hyporesponses of cortisol, LH, FSH, TSH, and GH. We considered panhypopituitarism due to RCC originating in the right kidney.

A transsphenoidal surgery (TSS) was performed and revealed a 2.8×2×3 cm RCC. Medical treatment with prednisolone and levo-thyroxine, her fatigue relieved. GH replacement therapy was performed was refused by the patient for its administration difficulty. For mucoceles involving sphenoid sinus, pre-operative and post-operative endocrinological evaluation is essential.

Conclusion
For mucocles involving sphenoid sinus, pre-operative and post-operative endocrinological evaluation is essential.

Effect of the addition of lanreotide autogel to the treatment of an aggressive prolactinoma – a case report

Lucio Vilar1, Clarice Vilar2, José Luciano Albuquerque1, Patricia Gadelha1, Ana Carolina The1, Erik Trovão1, Izabela Cardoso1, Thaíse Cardoso2 & Ruy Lyra1
1Division of Endocrinology, Hospital das Clínicas, Federal University of Pernambuco, Recife (Pernambuco), Brazil; 2Endocrine Research Center of Pernambuco, Recife (Pernambuco), Brazil.

Case report
A giant prolactinoma (size: 5.2×4.1×3.2 cm; PRL: 6 400 ng/ml) was diagnosed in an amenorrheic 19-year-old girl who presented to the emergency room complaining of headaches and bilateral decrease in visual acuity for 10 days. The patient was started on cabergoline (CAB) in progressive doses up to 3 mg/week. PRL levels decreased from 6 400 to 4 600 ng/dl within 60 days, with improvement of visual complaints and visual fields defects. The dose was subsequently increased up to 6 mg/week over the next 6 months but PRL did not normalize (1 840 ng/dl) and amenorrhea persisted. A new pituitary MRI was performed revealed a ~50% tumor reduction. Six months later, worsening of visual fields and a 20% increase in tumor volume were detected, whereas PRL levels increased to 2 270 ng/ml. A transsphenoidal surgery (TSS) was therefore undertaken (Ki-67 expression >8%), which led to a ~30% reduction of tumor volume whereas PRL levels decreased from 2 270 to 1 210 ng/dl within 4 months. CAB was restarted but PRL did not normalize (520 ng/dl), despite the use of doses up to 4 mg/week (maximal tolerated dose) for 6 months, and amenorrhea persisted. Lanreotide autogel (120 mg every 28 days) was added to CAB (4 mg/week). The combined treatment was well tolerated and lead to decrease of PRL levels to 91 ng/ml (NR: 2.8–29.2) within 8 months, as well as to resumption of a regular menstrual cycle. Moreover, the combination of CAB+lanreotide autogel enabled further tumor shrinkage but invasion of both cavernous sinuses persisted. CAB dose could be subsequently reduced to 3 mg/week.

A hypopituitarism case diagnosed after sphenoid sinus mucocele operation

Betül Ekte-Bilir3, Bülent Bilir4, Ayse Öz3, Halide Günes-Ciftci3, Nesilhan Soysal-Atilı3 & Gülsah Elibekey3
1Endocrinology and Metabolic Diseases Division, Tekirdag State Hospital, Tekirdag, Turkey; 2Internal Medicine Department, Medical Faculty, Namık Kemal University, Tekirdag, Turkey; 3Radiology Department, Tekirdag State Hospital, Tekirdag, Turkey; 4Department of Otolaryngology and Head and Neck Surgery, Tekirdag State Hospital, Tekirdag, Turkey; 5Internal Medicine Department, Endocrinology and Metabolic Diseases Division, Medical Faculty, Namık Kemal University, Tekirdag, Turkey.

Introduction
Mucoceles-mucus containing benign cysts of paranasal sinuses- are common with an incidence of 1% but involvement of sphenoid sinus is much less common. In this case report, we reported a patient presented with hypopituitarism after sphenoid mucocele drainage operation.

Case report
A 59-year-old woman was admitted to our endocrinology outpatient clinics with a complaint of fatigue over the past 2 months. One month prior to admission, she had been internalized for about 10 days in our hospital’s infectious diseases clinics for fever of unknown origin. After extensive medical investigation, a sphenoid sinus mucocele and pansinusitis had been diagnosed. An operation for drainage of the mucocele with endonasal surgical approach had been performed and she had been externalized for follow-up with an attention card indicating that her nasal cavity was in direct contiguity with the optic nerve. Three weeks after the operation, she admitted to our clinics. The physical examination revealed that her arterial blood pressure was 90/50 mmHg, heart rate was 108 bpm, respiratory, abdominal, cardiac examinations were normal. Her skin was pale and minimal pitting edema was detected. In her repeated laboratory examination, serum cortisol levels were found to be less than 1 µg/dl. Coexisting secondary hypo-thyroidism and GH deficiency were detected. The magnetic resonance imaging of the pituitary region was revealed no tissue corresponding to the adenohypophysis. Following adequate replacement therapy with methylprednisolone and levo-thyroxine, her fatigue relieved. GH replacement therapy was refused by the patient for its administration difficulty.

Conclusion
For mucoceles involving sphenoid sinus, pre-operative and post-operative endocrinological evaluation is essential.

Coexistence of acromegaly and rheumatoid arthritis: presentation of three cases

Reyhan Ersoy1, Nagihan Bestepe2, Sevgul Faki1, Cuneyt Bilginer1, Didem Ozdemir1, Sukran Erten1 & Bekir Cakir1
1Department of Endocrinology and Metabolism, School of Medicine, Ankara Yildirim Beyazit University, Ankara, Turkey; 2Department of Endocrinology and Metabolism, Ankara Atatürk Education and Research Hospital, Ankara, Turkey.

Introduction
Musculoskeletal system is widely affected in acromegalic patients which might cause difficulties in the diagnosis and treatment of inflammatory rheumatological diseases. Here, we report coexistent rheumatoid arthritis (RA) in three acromegalic patients presenting with continuing joint and back pain although acromegalic state was in remission.

Case 1
A 64 years old female patient with acromegaly and macroedema had undergone transsphenoidal surgery 11 years ago and radiosurgery 7 years ago because of clinical and laboratory evidence of disease. The patient got into remission 3 years after radiosurgery. Because she had morning stiffness and symmetrical pain and swelling in interphalangeal joints, she was consulted with rheumatology and diagnosed as seronegative RA. Her complaints improved dramatically at the second month of methotrexate, prednisolone and indomethacin treatment.

Case 2
A 62 years old female had undergone transsphenoidal surgery for acromegaly 12 years ago. She had been treated with conventional radiotherapy and radiosurgery 4 and 10 years after diagnosis, respectively because remission could not be achieved by medical treatment which had been stopped about a year after...
radiosurgery. She had symmetrical pain, swelling and deformities in inter-phalangeal and metacarpal joints. Seronegative RA was diagnosed and methylprednisolone was started. 

Case 3
Acromegaly had been detected 13 years ago in a 57 years old female. Because she had refused surgery, she had been treated with conventional radiotherapy and cure had been achieved in a year. She complained morning stiffness, back pain and pain and swelling in hand joints. She was diagnosed to have seropositive RA and treated with methotrexate, sulfosalazine and indomethasine. 

Conclusion
Symptoms related with RA might be confused with musculoskeletal symptoms seen in acromegaly. Detailed rheumatological physical examination and immunological evaluation might be helpful to display concomitant rheumatological disease in acromegalic patients with ongoing musculoskeletal complaints despite achievement of treatment targets.

Introduction
TSHOMAs are rare pituitary tumors with prevalence of 1–2 cases per million. We present a case of TSHoma where the course was complicated by the coexistence of autoimmune hypothyroidism.

Case
41 year old male presented with fatigue, lethargy and palpitations. On screening was found to have raised t3 – 216.30 ng/dl (N-70-204 ng/dl), t4 – 12.10 μg/dl (N-4.2-11.6 μg/dl) and TSH – 27.55 uIU/ml (0.2–5.7 uIU/ml). Further evaluation revealed raised free t3 (FT3), free t4 (FT4) and TSH (column 1, Table 1), raised anti thyroid peroxidase antibodies and negative TSH receptor antibody, normal cortisol – 10.8 μg/dl (N-5-25), testosterone – 769.73 ng/dl (N-275-900), prolactin – 18.89 ng/ml (5-25), IGF1 – 124 ng/ml (64-210) levels. Thyroid function of first degree relations was normal. SHBG – 78.20 nmol/l (N-11.2-78.1) and alpha subunit levels – 3.8 ng/ml (0.1-0.5) were raised. TSH concentration significantly reduced 5 hours after single octreotide dose as well as after three doses of 100 μg octreotide over 24 h. MRI confirmed presence of pituitary macroadenoma 2.4 X 1.2 X 1.2 cm abutting the chiasma (visual fields normal). Patient was subjected to transsphenoidal surgery for pituitary adenoma. The adenoma immunostained positive for TSH, was also positive for p53 with MIB index 3–5%. Patient FT3, FT4 and TSH was low 2 weeks post surgery and 25 μg thyroxine was started. Follow up report at 6 weeks showed low FT3, FT4 and raised TSH levels after which thyroxine was stepped up. Patient did not need any other hormone replacement.

Introduction
Cyclic Cushing’s syndrome is a rare disorder, characterized by repeated episodes of cortisol excess interspersed by periods of normal cortisol secretion ranging from days to years. It remains a difficult diagnostic challenge in endocrinology, we report a case. 

A case report
The patient was 41 years old woman, she presented in 2012 a period of symptomatic hypercortisolism. Urinary free cortisol was elevated to 113 μg/24. Low-dose dexamethasone testing was negative. ACTH was elevated to 20.2 pmol/l, the high-dose dexamethasone suppression test was positive, a pituitary MRI and a thoraco pancreatic scanner were normal; These finding led us to an ACTH-dependent Cushing’s syndrome. The patient was revaluated 5 months later and she was clinically and biochemically better. Six months later she presented relapsed symptoms and a biochemical recurrence of hypercortisolism (high urinary cortisol: 125.7 μg/24 and negative Low-dose dexamethasone testing). In 2015 the patient presented a sudden tumor syndrome, pituitary MRI revealed an intrasellar arachnoidocele that was in favour of the apoplexy of an adenocorticotropic pituitary adenoma. The patient was revaluated 9 months later and she was clinically better, The Urinary free cortisol was normal (20 mg/24).

Discussion
Cyclic Cushing’s syndrome is characterized by rhythmic fluctuations in glucocorticoid production, both clinical and biochemical spontaneous remissions may occur in patients with this disorder. Our patient presented two periods of normal glucocorticoid production and two periods of hypercortisolism. Causes of cyclic Cushing’s syndrome are multiple dominated by pituitary adenoma. The biological and radiological investigations in this case and therefore the subsequent evolution enabled a diagnosis of a Cushing’s syndrome spontaneously regressive by the apoplexy of pituitary adenocorticotropic adenoma. Clinicians should be aware that hypercortisolism may occur periodically and the duration of the periods of normal and abnormal cortisol secretion can vary significantly, so the correct diagnosis can be a challenge in clinical practice.

Breast cancer and newly discovered non-secretor pituitary mass- as risk of metastases?
Ana Valea1, Julia Oprisor2, Mara Carsote3, Dan Dumitru Pop4, Andra Morar5, Cristina Ghervan1 & Carmen Emanuela Georgescu1
1I.Hatieganu UMPh & Clinical County Hospital, Cluj-Napoca, Romania; 2Clinical County Hospital, Cluj-Napoca, Romania; 3C.Davila UMPh & I.Parhon National Institute of Endocrinology, Bucharest, Romania; 4Oncology Institute, Cluj-Napoca, Romania; Clinical Hospital of Infectious Diseases, Cluj-Napoca, Romania.

Introduction
Even if breast cancer is rare cause of pituitary metastases, the diagnosis of a pituitary adenoma, shortly after surgery for breast cancer, raises suspicion of a possible secondary determinations.

Material and method
This is a case report revealing the medical history and endocrine profile of a female with breast cancer and pituitary macroadenoma.

Case data
A 64-year old non-smoking female (with menopause at age of 52), who had undergone treatment for breast cancer (diagnosed at the age of 60), with left radical mastectomy pt2N0M0 L0 V0 Pn0 R0, followed by adjuvant radiation treatment and aromatase inhibitor hormonal treatment, was admitted for headache, dizziness, diplopia, and narrowed visual field. Pituitary MRI performed pointed a 40/26/36 mm-sized mass of oval shape, with intra and extra-sellar expansion. Endocrine evaluation indicated low levels of serum gonadotropins (FSH of 10.5 U/L, normal: 30–150 U/L and LH of 1.6 U/L, normal of 8.2–41 U/L), low FT4 levels (free thyroxine of 0.61 ng/dl, normal: 0.89–1.76 ng/dl), normal levels of morning plasma cortisol (of 19.8 μg/dl, normal: 5–25 μg/dl), and moderate increase of prolactin (24.4 ng/ml, normal: 1.3–20 ng/ml). Thyroxine substitution therapy was initiated and followed by transsphenoidal adenomectomy. Histopathology revealed a mixed pituitary adenoma. Assessment performed three month after surgery highlighted persistent hyperprolactinemia (of 22.9 ng/ml), central hypogonadism (FSH of 10.1 U/L, LH of 2.6 U/L), normal FT4 levels (of 0.95 ng/dl), and persistent pituitary mass (of 36/21/30 mm) on MRI. The patient will be further followed-up by a multidisciplinary team regarding endocrine and oncologic profile.
Conclusions
This case emphasizes that diagnosis of pituitary macroadenoma can be difficult when occurs in the context of a pre-existing breast cancer. Intensive follow-up is necessary for specific treatment.

Meningoencephalitis as the first clinical sign of a pituitary macroadenoma: a case report
Ghizlane Elmghari, Ilham Bouizammarne & Nawal Elansari
Department of Endocrinology, Diabetes and Metabolic Diseases CHU Mohamed VI, Marrakesh, Morocco.

Introduction
The classical revealing manifestations of a pituitary adenoma are represented by the combination of a tumor syndrome and endocrine syndrome. The occurrence of meningoencephalitis as a mode of revelation of a macroadenoma is exceptional.
Case
Mr. M.O. 36 years old, with no significant medical history, brutally presented severe headaches, vomiting, behavioral disorder with fever and bilateral decreased visual acuity. On examination, the patient was conscious, febrile to 39.8 with nuchal rigidity. At presentation, leukocytosis at 18 000/mm3. C-reactive protein at 69 mg/l. The head CT scan showed bilateral areas of hypodensity with Intra-and suprasellar invasive lesional process. The magnetic resonance imaging showed a pituitary macroadenoma 30×32 mm invading the sphenoid sinus, the right cavernous sinus and elevating the optic chiasm. The cerebrospinal fluid analysis showed a lymphocytic liquid with elevated protein and normal glucose level. Culture was negative as well as herpes simplex virus PCR. The biological analysis of endocrine hormones balance objectived a pan hypopanpituitarisme insufficiency. The patient received ceftriaxone, acyclovir, replacement therapy and was scheduled for surgery.
Discussion
Meningoencephalitis is a rare presentation as first manifestation of macroadenoma. In literature, only three cases of Meningoencephalitis were reported as revealing macroadenomas. We illustrate this observation through an unusual and serious form of revelation of a macroadenoma.

A rare case with acromegaly: increased hypophyseal FDG uptake in PET/CT performed for lung cancer staging
Veysi Asoglu1, Ece Celik2, Mehmet Celik1, Buke Yilmaz Bulbul1, Yusuf Durmus1, Senem Ayturk2, Funda Ustun3 & Sibel Gulden1
1Department of Internal Medicine, Medical Faculty, Trakya University, Edirne, Turkey; 2Department of Chest Diseases, Edirne Sultan 1. Murat State Hospital, Edirne, Turkey; 3Department of Endocrinology and Metabolism, Medical Faculty, Trakya University, Edirne, Turkey.

Acromegaly affects 4-6 people in a million and hypophyseal GH releasing adenoma is the most common cause of the disease. It shows its effects on GH and IGF1. Since they grow rapidly, they are usually diagnosed at the stage of macroadenomas. Heart failure, arthritis, OSAS and DM may develop during course of the disease. Although the most common accompanying malignancy is colon cancer, the incidence of malign melanoma, breast, thyroid, gastric and lung cancers is also increased. Increased hypophyseal Fluorine-18 fluorodeoxyglucose uptake is rare on positron emission tomography and computed tomography (FDG-PET/CT). Since hypophyseal adenomas may give false positive results on PET/CT, verification should be made by MRI. In this study, we aimed to present a case with increased FDG uptake in hypophysis and lung on PET/CT. 64-year male patient was presented with dyspnea and weight loss. Physical examination revealed prognatia, acral enlargement in hands and feet, dermal thickening and decreased breath sounds on apical part of left lung. Chest X-ray and thoracic CT images demonstrated 2 cm sized nodular opacity in the upper lobe of the left lung. On FDG-PET/CT examination, increased FDG uptake was observed in this 2 cm sized nodular lesion in the lung and in 3 cm sized hypophyseal region. Hypophyseal MRI was performed and macroadenoma was detected. Ocular examination revealed hemianopsia. Laboratory examination findings were as follows: hemoglobin: 12.3 g/dl (13.7–17.5), sodium:140 mmol/l (normal: 135–145), potassium: 4.4 mmol/l, creatinin: 0.73 mg/dl, ACTH: 5 pg/ml (normal: 0–46), basal cortisol: 3.4 µg/dl (n:5–29), growth hormone: 2.25 ng/ml and IGF1: 440 ng/ml (n:70–212). Hypophyseal-thyroid and hypophyseal-gonadal axis were normal. GH levels measured 30-60-90 and 120 min after oral 75 g glucose tolerance test were 2.16, 1.65, 1.5 and 1.8, respectively. The patient was diagnosed with acromegaly and intramuscular octreotide 20 mg/month, prednisolone 5 mg in the morning and 2.5 mg in the evening were initiated before hypophyseal surgery. Left upper lobectomy of the left lung was performed and pathologic examination of surgical material revealed squamous cell carcinoma. Vinorelbine + cisplatin chemotherapy was initiated and the patient was scheduled for hypophyseal surgery.

Temozolomide alone or in combination with bevacizumab and capcitabine in the treatment of atypical pituitary adenomas – own experience
Maria Kurowska, Joanna Malicka & Jerzy Tarach
Department of Endocrinology, Medical University, Lublin, Poland.

Introduction
Atypical pituitary adenomas are tumors refractory to conventional therapy and characterized by a tendency to rapid progression and high recurrence rate. The aim of the study was to summarize our experience in treatment of atypical pituitary adenomas with temozolomide (TMZ).
Material
5 patients (3F:2M) aged 44–58 (mean 52.4 ± 5.4) years treated in 2013–2016. We analyzed the results, tolerance and side effects of TMZ.
Results
In three patients (1F:2M) atypical corticotroph adenomas were diagnosed (two Nelson’s syndromes, one Crooke’s cells adenoma), in 1F-prolactinoma resistant to dopamine agonists and in 1F-type 3 silent adenoma (GH+, PRL+). The disease duration ranged 3–23 years (mean 12.4 ± 7.2). Before TMZ implementation, patients underwent a total of 11 transphenoidal adenectomies (1–4), four craniotomies, two patients – stereotactic X-ray-therapy, 1 – tomotherapy and 2 – bilateral adenreectomy. All patients started with TMZ monotherapy 150 mg/m² for five consecutive days with 23-days intervals. The number of courses ranged from 2 to 13. The total remission, lasting from 45 months to 11 years was obtained in a patient with Crooke’s adenoma, partial remission in one patient with Nelson’s syndrome, transient stable disease (2–4 months) in two patients (with Nelson’s syndrome and somatotropinoma). The prolactinoma was refractory to TMZ. The only side effect was vomiting. In two patients with relapse of Nelson’s syndrome TMZ was used in combination with bevacizumab (six courses) in 1F and in 1M with capcitabine (CAPTEM – five courses), but in both cases it caused short-term disease stabilization.
Conclusion
TMZ is the most effective in treatment of atypical corticotroph adenomas as a single agent and in the first line of treatment, however it is less effective in recurrent form of the disease.

Temozolomide Treatment in Aggressive Pituitary Adenoma
Pınar Sisman1, Ahmet Bilgehan Sahin2, Özen Oz Güi2, Soner Cander1, Erdine Ertürk1 & Canan Ersoy2
1Harakani State Hospital, Endocrinology and Metabolism Clinic, Kars, Turkey; 2Uludag University Medical School, Department of Internal Medicine, Bursa, Turkey; 3Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Introduction
Aggressive pituitary adenomas (APAs) take place phenotypically between benign pituitary adenomas and pituitary carcinomas with systemic metastasis. Frequent recurrence and resistance to conventional treatments are characteristic features of APAs in their clinical course. Temozolomide is an alkylating agent that has been used in the treatment of pituitary carcinomas and APAs since 2006. Herein, we report a patient who received temozolomide treatment due to APA.

Case presentation
A 57-year-old male patient with complaints of headache and visual impairment had been admitted to state hospital in 1991. Laboratory and imaging studies had revealed nonfunctioning invasive pituitary macroadenoma, and he had underwent transcranial operation. The patient had developed pituitary insufficiency after operation; therefore replacement therapy had been started. Thirty radiotherapy (RT) sessions had been performed due to the lack of complete resection of the mass. The patient had hyperhidrosis but didn’t have enlargement of hand, feet or lingua. Laboratory examination including growth hormone assay, thyroid profile, romatoid factor, anti nukleer anticor, anti CCP, tests for synphilsis, ESR were normal. He did not have family history and genetic transmission is ruled out by HPGD gene analysis. There were symmetric subperiostal bone formation at the radiographs of forearms and legs. The scintigraphy showed a osteoblastic hyperactivation in the distal radius, metacarpal bones and tibia. Based on clinical and radiological findings PDP was diagnosed. We consulted the patient to rheumatology department for arthritis and steroid therapy was started.

Discussion
Even when imaging and functional evaluation are diagnostic, CS treatment may be challenging. Bilateral adrenalectomy is not the first line therapeutic option, but as in this case correction of hypercortisolism more than apparent normalization of cortisol levels may require it. Life-long morbidity is expected regarding glico- and mineralocorticoid reposition, however this is easier to obtain and may be associated with less co-morbidities than sustained hypercortisolism.

DOI: 10.1530/endoabs.49.EP852

Ocult Cushing syndrome: (adicional) difficulties in hypercortisolism approach
Ana Filipa Martins1, João Martin Martins1,2 & Sónia Do Vale1,2
1Hospital de Santa Maria – Chín, Lisboa, Portugal; 2Faculdade de Medicina de Lisboa, Lisboa, Portugal.

Introduction
Cushing syndrome (CS) result from inappropriate exposure to increased non regulated glucocorticoid levels. It remains challenging regarding diagnosis and management. Pituitary ACTH-secreting adenomas account for most of the cases if exogenous and paraphenotypic forms are excluded.

Case report
A 45-year-old women was referred to the endocrine outpatient department because of obesity, muscular weakness, high blood pressure (HBP), diabetes mellitus (DM) and hypercholesterolemia beginning 5 years before. Analytic evaluation evidenced ACTH- dependent hypercortisolism, with no cortisol suppression after dexametason 1mg overnight. Low-dose dexametasone (0,5 mg qd for 48 h) excluded pseudocushing; high dose dexamethasone (2 mg qd for 48 h) suggested pituitary CS. However no lesion was identified in pituitary RMN and inferior petrous sinus catheterization with simultaneous CRH dynamic testing was inconclusive. Treatment with metryrapone 1500 mg/daily normalized 24-h urinary cortisol excretion and morning cortisol levels, but clinical manifestations persisted with progressive weight gain, worsened diabetes control, increased blood pressure levels and pathologic rib fractures, despite additional drugs. The patient was submitted to bilateral adrenalectomy, which immediately controlled the disease with no further need for antidiabetic or blood pressure drugs and significant weight loss.

Discussion

Even when imaging and functional evaluation are diagnostic, CS treatment may be challenging. Bilateral adrenalectomy is not the first line therapeutic option, but as in this case correction of hypercortisolism more than apparent normalization of cortisol levels may require it. Life-long morbidity is expected regarding glico- and mineralocorticoid reposition, however this is easier to obtain and may be associated with less co-morbidities than sustained hypercortisolism.

A case of cystic prolactinoma responded to medical treatment
Tülay Omma, Nese Ersoy Gücelik, Anara Karaca & İlayş Taskaldıran
Ankara Training and Research Hospital, Ankara, Altındağ, Turkey.

Introduction
Cystic prolactinomas are considered resistant to volume depletion by dopamine agonists (DAs). Because of the effectiveness and tolerability, dopamine agonists (DAs) are the first line therapies in prolactinoma and reduce tumor mass as well as prolactin levels in most of all patients. Rutkis’ cleft cysts, craniopharyngiomas and arachnoid cysts are diagnostic differens to keep in mind. DAs resistance or intolerance, psychiatric disorders associated with dopamine agonist use and patient preference can be indications for surgical intervention. Large, predominantly cystic prolactinomas are usually treated surgically and are presumed to be resistant to volume reduction by DAs. Although optimal management of cystic prolactinomas are not defined yet, several individual case reports and case series have suggested that DAs may reduce these lesions. Here we present a patient with cystic prolactinoma responded to medical treatment.

Case report
A 20-year-old women presented with secondary amenorrhea and spontaneous galactorrhea for three months. She has not taken any prolactin-increasing medications and was not pregnant. Her biochemical, hematological laboratory tests and hypophys function tests were normal except prolactin. Her prolactin level was 133 ng/ml (normal value is 2.7–19.6) and macroprolactin was negative. Pituitary MR scan revealed a 9×7 mm cystic adenoma at the left side of adenohypophysis. Infundibulum, suprasellar cistern and optic chiasm were intact. Hence, the clinical picture was consistent with prolactinoma, we administered cabergolin 0.25 mg twice a week. After three months of cabergolin therapy her prolactin level decreased to 6.5 ng/ml. She had regular menses and no galactorrhea. After eight months, hypopsis mr scan demonstrated a remarkable reduction in the tumor size, measured as 6.3×5.5 mm.
Case A 85 years old woman with regulated hypertension admitted with partial loss of consciousness. She had cachectia and body mass index was 16.7 kg/m². There was no neuroimaging nor in cranial imaging. Because electroencephalography revealed findings compatible with nonconvulsive status epilepticus, levetiracetam was started. In laboratory examination, she had hypokalemia (2.5 mg/dl) resistant to i.v. replacement. Her serum cortisol was 126 μg/ml (5–20 μg/ml) and ACTH was 331.7 pg/ml (0–60 pg/ml). Hypophysial MRI showed a 6.5×3 cm lesion in right hypophysis. She did not any physical signs of Cushing syndrome. In thoracic CT, a 16 mm solid irregular lesion extending to the paracortex and costal pleura in right lung was observed. Abdominal CT revealed a 125 mm heterogenous mass and satellite lesions in the liver and hypertrophic adrenal glands. A tran-cut biopsy from the lesion was reported as metastasis of neuroendocrine tumor. The lesion was diffusely positive for TTF-1, cytokeratin 7, synaptophysin and chromogranin. Ki67 proliferation index was 10–15% and primary tumor was suggested to be atypical carcinoid tumor of lung according to the immunohisto pathological findings. The patient died at the 20th day of intensive care unit due to sepsis.

Conclusion Ectopic ACTH syndrome is a rare cause of ACTH dependent Cushing syndrome. It can be easily included in the differential diagnosis in a patient with classical signs of Cushing syndrome and without adenoma in hypophysis. However, like ours, well-known physical appearance and signs of Cushing syndrome might not be seen in all patients, and only the clinical presentation might be neurocognitive dysfunctions.

DOI: 10.1530/endoabs.49.EP856

Discussion
In conclusion, it is appropriate to consider dopamine agonist therapy in patients with cystic prolactinomas before considering surgery.

EP855
A case of pituitary apoplexy in a patient with Cushing’s disease due to corticotrophic macroadenoma
Elisabetta Sava³, Bianca Leca¹, Anca Sirbu², Olivia Georgescu², Luminita Cima³, Suzana Florea⁴ & Simona Fica³
¹Endocrinology Department, Elias University Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; ²Laboratory Department, Elias Hospital, Bucharest, Romania.

Corticotroph macroadenomas are exceptionally found in Cushing’s disease. Pituitary apoplexy is a rare endocrine emergency condition caused by either hemorrhage or infarction of the pituitary gland. We report a case of a 56-year-old female diagnosed with type 2 diabetes in 2008. One year after, at the periodical follow up, she presented with uncontrolled diabetes (HbA1c=12.26%) and clinical manifestations suggestive for hypercortisolism, therefore insulin therapy was initiated; hormonal profile revealed baseline cortisol = 26.4 ng/ml, cortisol level after low-dose dexamethasone suppression test = 21.7 ng/ml, ACTH = 122 ng/ml and a 2.4/1.8/2.9 cm pituitary macroadenoma was found. While waiting for surgery appointment, in January 2010 the patient experienced severe headache, nausea, vomiting and diplopia. She was admitted to ICU, diagnosed with pituitary apoplexy and transferred to neurosurgery department where surgery was performed. Clinical improvement of Cushing’s symptoms, diplopia, hypertension and diabetes (HbA1c=6.5% without insulin therapy) was noted. The postoperative pituitary MRI revealed a rest tumor (7.8 mm); slightly increased ACTH levels (70.1 pg/ml) and abnormal 1 mg DXM overnight suppression test (5.33 ng/ml). She received medical treatment with ketoconazole (not tolerated) and clobergine (2 mg/week); the clinical manifestation of hypercortisolism reappeared and diabetes was poorly controlled. Despite medication, ACTH and cortisol secretion remained elevated and pituitary MRI scan showed tumor progression. Considering the development of the tumor in close proximity of the optic chiasma she was refused for surgery and gamma knife treatment was decided. During the second therapy, the patient was diagnosed with severe hepatic cytolyis (ALT=766 U/l; AST=484 U/l), mild cholestatic syndrome, hypercortisolism and uncontrolled diabetes HbA1c=9.6%. The presence of hepatic cytolyis caused postponement of bilateral adrenalectomy. Our patient presented pituitary apoplexy in a corticotroph macroadenoma, with persistence of Cushing’s disease after surgery and no therapy of hypercortisolism at the moment. Bilateral adrenalectomy is probably the best option, after the control of hepatic function.

Keywords: pituitary apoplexy, corticotroph macroadenoma

EP856
Ectopic ACTH syndrome presenting with partial loss of consciousness and nonconvulsive status epilepticus in a patient with no signs of Cushing syndrome
Eray Onur Mert¹, Samet Yaman¹, Diem Demir², Nagihan BESTEPE³, Durus Ali Saglam⁴, Osman Erozy⁴, Reyhan Erozy⁴ & Bekir Cakir⁴
¹Ankara Yildirim Beyazit University, School of Psychology, Department of Internal Medicine, Ankara, Turkey; ²Ankara Yildirim Beyazit University, School of Medicine, Department of Endocrinology and Metabolism; ³Ankara, Turkey; ⁴Ankara Ataturk Education and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; ⁴Ankara Ataturk Education and Research Hospital, Department of Internal Medicine, Ankara, Turkey; ⁵Ankara Yildirim Beyazit University, School of Medicine, Department of Gastroenterology, Ankara, Turkey.

Introduction
Ectopic adrenocorticotrophic hormone (ACTH) syndrome is associated with variable tumor groups most commonly originating from neuroendocrine cells. Here, we reported a patient considered to have nonconvulsive status epilepticus initially due to neurological symptoms and diagnosed as neuroendocrine tumor with ectopic ACTH syndrome.

Case A 33-year-old male patient presented in 1982, as 38-year-old women with generalized malaise, facial fullness, increased skin pigmentation, hirsutism, hypertension, hyperglycemia and depression. Long-term outcomes and possible impacts on quality of life in these patients are still not well examined. We report a case of a 73-year-old patient who presented in 1982, as 38-year-old women with generalized malaise, facial fullness, increased skin pigmentation, hirsutism, hypertension, hyperglycemia and depression. Laboratory evaluation showed elevated serum levels of ACTH and cortisol with loss of diurnal variation and no suppression after overnight low-dose dexamethasone test. Computed tomography (CT) scan revealed a 16 mm solid irregular lesion extending to the paracortex and costal pleura in right lung. The patient underwent transsphenoidal surgery which confirmed 5 mm pituitary tumour in posterior lobe with anterior spreading into normal tissue that inhibited the complete resection. Histological finding was ACTH – sec reting microadenoma. During the postoperative course, patient developed diabetes insipidus; depression and high blood pressure were still present. Serum cortisol level was 832 nmol/l, ACTH 26.3 pmol/l (reference range: 1.2–10.2 pmol/l). The patient consented to bilateral adrenalectomy in November 1984. which showed adrenal hyperplasia. After second surgery, the symptoms of CD were diminished and steroid replacement therapy was started as following treatment. During time, patient developed hypothyroidism, electrolyte concentrations are well kept in balance. ACTH levels were up to 194 pmol/l (with marked hyperpigmentation localized predominantly in face area), cortisolemia up to 579 nmol/l according to which the Hydrocortisone dose adjustments were made. Recent pitutary magnetic resonance imaging (MRI) demonstrated no signs for tumour recurrence. After 33 years of therapy, the evaluated quality of life in our patient is not significantly impaired.

A case of extrapontine myelinolysis after surgery for a pituitary tumor
Rosario López-Valasco, Isabel M Torres-Barea & Lourdes García-Garcia-Doncel
Hospital Jerez de la Frontera, Jerez de la Frontera (Cádiz), Spain.

Introduction
Rapid correction of hyponatremia is known to cause central pontine myelinolysis. It may concurrently involve other areas of brain as well, referred as extra-pontine

Endocrine Abstracts (2017) Vol 49
19th European Congress of Endocrinology 2017
myelolysis (EPM). Isolated EPM however is a very rare occurrence. We present a case of EPM where the hypopitremia was secondary to syndrome of inappropriate antidiuretic hormone secretion (SIADH) after surgery for a pituitary macroadenoma. Case report A 36-year-old man underwent transphenoidal surgery for a non-functional 2.4 × 2.6 × 1.8 cm pituitary macroadenoma causing chiasmal compression. During the immediate postoperative period, the patient developed polyuria and received desmopressin. Six days after surgery, he left the hospital asymptomatic receiving hydrocortisone. Diuresis volume was normal and desmopressin was not necessary anymore. On the 8th postoperative day, his level of consciousness decreased and suffered from seizure requiring intubation. Blood examination revealed severe hyponatremia (serum sodium level of 108 mEq/l) and 1 day later serum sodium increased rapidly to 135 mEq/l. On the 16th postoperative day, otrachal intubation was discontinued but the patient was unable to communicate. Physical examination revealed global hyperreflexia, clonus, dysarthria and gait disturb- ance. Head MRI on the 18th postoperative day demonstrated intense high-signal bilateral lesions in corpus striatum on FLAIR and DWI, and extrapontine myelolysis was diagnosed. The patient’s symptoms improved gradually after rehabilitation and antipsychotic treatment. It was suggested that the changes in serum sodium levels after pituitary surgery were due to SIADH due to degeneration of nerve terminals in the posterior pituitary.

Conclusions Incidence of hyponatraemia following pituitary surgery is reported between 3 and 25%. The delay in onset of SIADH can lead to practical problems for neurosurgical units where there is very early discharge following pituitary surgery. As pituitary surgery may trigger changes in serum sodium leading to myelolysis, this possibility should always be borne in mind when treating such patients.

DOI: 10.1530/endoabs.49.EP858

Hypopituitarism caused by an intrasellar meningioma: case report Stavroula Gavritidou1, Constantinos Belis2, Kalliopi Xydiari1, Aikaterini Afentoulidi1, Vasiliou Athanasiou3, Sofia Makalatari-Skarantavou2, Symeon Tournis4 & Christos Savvidis2
1Department of Endocrinology, Hippocratio General Hospital of Athens, Athens, Greece; 2Laboratory for Research of the Musculoskeletal System “Th. Garofalidis”, Medical School, University of Athens, KAT Hospital, Athens, Greece.

Meningioma is a common, usually benign, tumor of the brain and the spinal cord that originates from any dura surface. Such lesion accounts for 10 to 15% of nonadenomatous sellar masses. Purely intrasellar meningiomas are relatively rare and can mimic a nonfunctioning adenoma. A 33-year-old man with a history of 1.5 year fatigue, anemia and erectile dysfunction referred to our department. The patient suffered from seizure requiring intubation. Blood examination revealed severe hyponatremia (serum sodium level of 108 mEq/l) and 1 day later serum sodium increased rapidly to 135 mEq/l. On the 16th postoperative day, otrachal intubation was discontinued but the patient was unable to communicate. Physical examination revealed global hyperreflexia, clonus, dysarthria and gait disturb- ance. Head MRI on the 18th postoperative day demonstrated intense high-signal bilateral lesions in corpus striatum on FLAIR and DWI, and extrapontine myelolysis was diagnosed. The patient’s symptoms improved gradually after rehabilitation and antipsychotic treatment. It was suggested that the changes in serum sodium levels after pituitary surgery were due to SIADH due to degeneration of nerve terminals in the posterior pituitary.

Conclusions Incidence of hyponatraemia following pituitary surgery is reported between 3 and 25%. The delay in onset of SIADH can lead to practical problems for neurosurgical units where there is very early discharge following pituitary surgery. As pituitary surgery may trigger changes in serum sodium leading to myelolysis, this possibility should always be borne in mind when treating such patients.

**Esthesioneuroblastoma causing ectopic ACTH Syndrome**

Cristina Lorenzo González, Estefanía González Melo, Elena Márquez Mesa, Pilar Olivera Márquez, María Teresa Herrera Arranz, Bruno Francisco García Bray, Yolanda Zambrano Huerta & Enrique Palacio Abizanda

Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain.

**Introduction**

Esthesioneuroblastoma is an uncommon malignant neoplasm with an average 5-year survival rate of about 45%. Ectopic ACTH syndrome due to esthesioneuroblastoma is extremely rare and there have been very few cases reported.

**Case report**

A 54-year-old woman was admitted to our hospital with symptoms of leg edema and general fatigue of one month’s duration. Physical examination showed moon facies and edema on her lower extremities bilaterally but no other cushingoid features. Laboratory examination revealed a severe hypokalaemia (1.99 mmol/l) and endocrine tests revealed a marked elevation of plasma ACTH (1123 pg/ml) and cortisol levels (cortisol in serum 110.1 mcg/dl and 24-hour urinary cortisol 296.7 mcg). Dexamethasone suppression tests both with 1 and 8 mg were non-suppressible. These physical and endocrine findings were consistent with the diagnosis of ACTH-dependent Cushing’s syndrome: ectopic Vs secondary to pituitary macroadenoma. Computed tomography (CT) scans of the chest, abdomen and pelvis were normal except for hyperplastic adrenal glands. A pituitary magnetic resonance image (MRI) showed a normal pituitary; however, there was a large and aggressive mass centred in both nostrils. The mass extended into the frontal sinus and ethmoidal cells. Otolaryngology department was consulted and a biopsy of the lesion was performed. The pathologic study of the biopsy confirmed the diagnosis of esthesioneuroblastoma. Therapy with ketoconazole 1000 mg daily was initiated preoperatively. Three weeks later the patient underwent a combined frontal craniotomy and endoscopic transnasal biopsy confirmed the diagnosis of esthesioneuroblastoma. The therapy with ketoconazole was continued for one month after surgery. One year after surgery the patient remains asymptomatic and cortisol levels returned to normal values. Corticosteroid treatment greatly improves the clinical picture.

**Conclusions**

Isolated IgG4-RH is a rare entity. IgG4 levels should be obtained in cases suggestive of hypophysitis. Corticosteroid treatment greatly improves the clinical picture.

Lymphocytic hypophysitis which underwent surgery despite the absence of compression of nearby structures. A case report

Javier González, Alberto Diez, Alma Prieto & Marta Fernández

1Hospital Virgen de la Luz, Cuenca, Spain; 2Hospital Del Bierzo, Leon, Spain.

**Introduction**

Lymphocytic hypophysitis is a strange case of hypopituitarism which can represent a difficult diagnostic and therapeutic challenge.

**Objectives and methods**

Describe the diagnosis, evolution and treatment of a case of lymphocytic hypophysitis in a patient who began with hypopituitarism and a year after the diagnosis had local symptoms. We reviewed the medical history of the patient from the moment the patient contacted with us to the months after the patient went surgery. It has been collected clinical, laboratory and radiological data during this period.

**Results**

This 51-year-old man presented with low TSH (0.122), low fT4 values (0.45) and hypogonadotropic hypogonadism without any other pituitary alterations. His visual examination was normal. The MRI demonstrated a 15.5x10x8.5 millimeter lesion, thickening in the pituitary stalk (6 mm), loss of differentiation (hyperintensity) of the neurohypophysis and heterogeneous parenchyma of the adenohypophysis. Because of the absence of symptoms in the patient, we corrected the deficits and we followed up. At 3 months after diagnosis the patient developed adrenal insufficiency so we corrected this new deficit. At 1 year after diagnosis the patient presented with severe headache and Tolosa-Hunt syndrome, so we began treatment with high dose of dexamethasone. The patient had initial improvement but relapsed after decreasing dexamethasone, so the patient was treated with trans-sphenoidal surgery with a total removal of the lesion. The patient remains asymptomatic on pituitary replacement therapy.

**Conclusions**

Lymphocytic hypophysitis is an uncommon cause of hypopituitarism which can present symptoms long time after the diagnosis. Due to the inflammatory changes, the patient could present headache and other local symptoms despite the absence of compression of nearby structures. In this case, if the patient does not respond to high doses of steroids, surgery is mandatory.

**Pituitary apoplexy as the first manifestation of silent somatotropinoma**

Ewa Obel, Marcin Lewicki, Magdalena Urbanczuk, Agata Smolen, Beata Matyjaszek-Matuszek & Jerzy Tarach

1Department of Endocrinology, Medical University, Lublin, Poland; 2Department of Epidemiology and Clinical Research Methodology, Medical University, Lublin, Poland; 3Department of Clinical Pathomorphology, Medical, Lublin, Poland.

**Introduction**

Pituitary apoplexy is a rare endocrine disorder which can occur due to haemorrhage into pituitary gland. It is often associated with the presence of pituitary adenoma, uncommonly being the first clinical manifestation of an underlying tumour. It can cause hypopituitarism and diabetes insipidus. Pituitary adenomas are classified by their secretion properties as functional and clinically non-functioning, the latter, however, can exhibit positive immunostaining for pituitary cell types in histologic examination and are thus classified as ‘silent adenomas’.

**Case study**

A 37-year-old male patient was admitted to the Department of Neurosurgery with complaints of strong persistent headache with accompanying temporal visual fields narrowing. Pituitary tumour apoplexy was diagnosed after the imaging revealed a pituitary tumour 25 mm in diameter with features of haemorrhage. Preoperative assessment revealed gonadotropin deficiency with low concentrations of prolactin. After undergoing transphenoidal resection of pituitary...
macroadenoma, hormonal evaluation unveiled additional deficiencies in the form of secondary adrenal and thyroid insufficiency with accompanying diabetes insipidus. At that point, the patient was transferred to the Department of Endocrinology of Medical University of Lublin for further evaluation. The replacement therapy with hydrocortisone, levothyroxine, testosterone and desmopressin was introduced, stabilizing and improving the patient’s condition. During the follow-up no restoration of pituitary secretion function in any axis was observed. Histologic examination of the tumour sample displayed a larger size than previously assumed (50 mm in the largest diameter), positive immunostaining for GH (diffuse) and PRL (spare) allowing to classify the tumour as silent subtype 3 adenoma. Clinical and laboratory evaluation did not reveal any acromegalic features; decreased prolactin levels persisted.

Conclusions
Pituitary apoplexy and/or hypogonadotropic hypogonadism can be the first symptom of pituitary macroadenoma. Clinically non-functioning adenomas may immunostain positively for more than one pituitary hormone determining their classification as silent subtype 3 adenomas.

Observation
A 36-year-old lady (Gravida 3 Parity 2 Live Birth 2), presented to our outpatient clinic on May 2007 for suspicion of acromegaly. Clinical examination revealed acromegalic features. Hormonal profile revealed elevated human growth hormone (HGH) 47.3 μUI/ml and insulin-like growth factor 1 (IGF-1) 576 ng/ml (normal 109–358 ng/ml), serum prolactin PRL was also mildly elevated 76.7 ng/ml Follicle-stimulating hormone (FSH), luteinizing hormone (LH), Thyroid stimulating hormone (TSH) and Free Thyroxine (FT4) were within normal range. Cortisol level during hypoglycaemia insulin test was 73 and 107 μg/l. Magnetic resonance imaging of the pituitary gland revealed: Left postero-lateral intra-pituitary expansive lesion measuring 17×11 mm with extension to the sphenoid sinuses. Final diagnosis was: Pituitary macro-adenoma on GH, with Hyperprolactinemia and Secondary adrenal insufficiency. She underwent endoscopic transnasal transphenoidal radical excision of the tumor on Mars 2009. Magnetic resonance imaging of the pituitary gland after surgery revealed: Absence of evidence of adenomatous residue. On June 2010, patient present in 3rd trimester of the pregnancy. Ophthalmological examination, hormonal profile and Oral glucose tolerance test (OGTT) of 75 gr glucose were without anomaly. She then went on to deliver a full-term baby girl by caesarean section in August 2010.

Discussion
Pregnancy in a patient with acromegaly is very unusual, as the enlarging pituitary adenoma suppresses gonadotropin secretion rendering the patient amenorrheic and infertile. Up to 30% of HGH-secreting pituitary adenomas also secrete prolactin and this adds to the problem. Although pregnancy is unusual in acromegaly, it is by no means rare.

We present the clinical case of a family with an initial diagnosis of AIP syndrome with MEN-1 syndrome associated because of a large MEN-1 gen deletion. A male patient 16 years old was evaluated because of delayed growth and pubertal development. He had headaches, nausea and vomits since seven years old. MRI showed: Large pituitary mass of 23.2×16 mm in MRI. Presurgical treatment with Octreotide was started (120 mg/28 days) and complete transphenoidal surgical resection of GH/PRL secreting pituitary adenoma was performed. 6 months later, as IGF1 levels and GH during OGGT remained high, and no biochemical remission was achieved, treatment with octreotide and cabergoline was restarted. 13 months later, she got unexpectedly pregnant and pharmacological treatment was withdrawn as soon as pregnancy was diagnosed (7–9 weeks). Patient was clinically and biochemically evaluated throughout pregnancy with at least one visit per trimester. In spite of medical treatment withdrawal, IGF significantly decreased compared to preconceptional values. Normal fetal growth and development was observed, with no maternal complications (gestational diabetes or gravid hypertension) and no congenital malformations in the newborn. After delivery IGF1 increased to pregestational levels. During the postpartum period, there was no problem for breastfeeding until medical treatment was restarted.

Discussion
Several reports conclude that GH-suppressive treatment can be safely withdrawn there was no problem for breastfeeding until medical treatment was restarted. In the third trimester of pregnancy after endoscopic transnasal transphenoidal radical excision of the tumor.

Endocrine Abstracts (2017) Vol 49
Coexistence of thyrotropinoma and chronic autoimmune thyroiditis, a diagnostic challenge
Izaskun Olalizola, Nerea Egaña, Ixemene Bilbao, Maite Pérez de Ciriza, Maria Luisa Antutiano, Estela Elías, Cristina García, Maite Araburua, Alfredo Yoldí & Miguel María Goená
Hospital Universitario Donostia, Donostia/San Sebastián, Gipuzkoa, Spain.

Introduction
TSHomas are rare TSH producing tumors, whereas chronic autoimmune thyroiditis is a frequent condition. Patients with TSHoma are characterized by increased circulating levels of peripheral thyroid hormones, but when a chronic autoimmune thyroiditis is associated, they may be normal or low, making the diagnosis challenging.

Case report
A 55-year-old woman, with previous medical history of obesity and impaired fasting glucose, was diagnosed of primary autoimmune subclinical hypothyroidism, with fT4 1.01 ng/dl (0.85–1.75), TSH 9.45 mU/l (0.3–4.2) and positive anti-thyroid peroxidase antibodies. Levothyroxine treatment was started, but despite increasing doses with fT4 values over the normal range, normalization of TSH could not be achieved, therefore, she was sent to the Endocrinologist. She was under levothyroxine 150 µg/day, with fT4 1.87 ng/dl, fT3 4.2 pg/ml (2.0–4.4), TSH 54.56 mU/l. She complained of asthenia and nervousness, with no other relevant symptoms. On suspicion of resistance to thyroid hormones and the absence of a thyroid lesion, levothyroxine dose was increased to 175 µg/day, with subsequent blood test: fT4 1.93 ng/dl, fT3 4.35 pg/ml, TSH 40.90 mU/l, free-α-subunit 370.8 mU/mL (<1.3). Pituitary magnetic resonance imaging showed a big infiltrating tumour mass at the pituitary region. The rest of pituitary function was normal. She presented worsening visual impairment. Levothyroxine treatment was withdrawn, with fT4 0.92 ng/dl, fT3 3 pg/ml and TSH 413 mU/l. Surgery was performed on July 2nd 2015. On the following day of surgery she presented increased poliuria with sodium (Na) 149 mEq/l, plasma osmolality (pOsm) 301 mOsm/kg. He started nasal desmopressin treatment with somatostatin analogues has been started.

Conclusions
TSHomas can be misdiagnosed if they coexist with chronic autoimmune thyroiditis. Normal peripheral thyroid hormones may cause us to not think of TSHoma as a cause, therefore, if increasing doses of thyroid hormone therapy do not achieve to normalize TSH, we always have to exclude a thyrotropinoma.

Adipic diabetes insipidus – a diagnostic and therapeutic challenge
Daniela Magalhães1,2, César Esteves1,2, Maria Manuel Costa1,2, Pedro Rodrigues1 & Davide Carvalho1,2
1Department of Endocrinology, Diabetes and Metabolism of Centro Hospitalar de São João, Porto, Portugal; 2Faculty of Medicine, Porto, Portugal; 3Department of Internal Medicine of Centro Hospitalar de São João, Porto, Portugal.

Introduction
Diabetes insipidus (DI) the serum sodium is often in the high normal range, required to provide the ongoing stimulation of thirst to replace the urinary losses. Marked hypernatremia can occur if a central lesion impairs both ADH release and thirst.

Case report
A 57-year-old woman presented with dysuria, polyuria and fever. She was medicated with ciprofloxacin, however, she maintained symptoms, accompanied in the next day by nausea, vomiting and noted decrease urine output. Analytical study revealed a normal blood count, urea 116 mg/dl and Cr increased from 0.87 to 3.85 mg/dl, hypernatremia 155 mEq/l and CRP 41.8 mg/dl. Urinalysis was normal. Renal ultrasound and abdominal CT did not show alterations. Her past medical history was significant for diabetes mellitus treated with metformin 850 mg/bid, arterial hypertension under losartan 25 mg/d and spironolactone 25 mg/d and dyslipidemia under pravastatin + fenofibrate 40 + 160 mg/id. She had a history of hypotension known for 1-year that resulted in two hospital admissions. We found records of a plasma osmolality (Po2m) of 348 mOsm/kg and a urine osmolality (Uo2m) of 947 mOsm/kg. When questioned, she reported polyuria and nocturia, without polydipsia. In the present admission, P2Osm and U2Osm were 320 and 220 mOsm/kg. Treatment with somatostatin analogues has been started.

Conclusions
In diabetes insipidus (DI) the serum sodium is often in the high normal range, required to provide the ongoing stimulation of thirst to replace the urinary losses. Marked hypernatremia can occur if a central lesion impairs both ADH release and thirst.

Insulinoma in MEN type 1 mistaken as temporal lobe epilepsy
Norhaliza Mohd Ali
Hospital Sultanah Aminah, Johor Bahru, Johor, Malaysia.

Multiple endocrine neoplasia type 1 (MEN 1) is a rare autosomal dominant disease characterized by pancreatic, parathyroid, and anterior pituitary tumours. Hypercalcaemia due to parathyroid tumours is usually the first manifestation. Pancreatic islet tumours occur less frequently, among them gastrinomas and insulinomas are the most prevalent. Insulinomas can be difficult to diagnose. It was not uncommon for patients to have been misdiagnosed with psychiatric illnesses or seizure disorders before insulinoma was recognized. We presented a patient who was diagnosed to have temporal epilepsy, which later turned out to be an insulinoma in MEN-1. A 23-yr-old man presented with an auditory hallucination of a voice asking him to kill his mother. He has had seizure for a year, and was being treated as temporal lobe epilepsy (TLE) with two antiepileptics. Asymptomatic hypoglycaemia was noted during his follow up for TLE; but did not trigger further investigation. He has been having recurrent hypoglycaemia during admission and remains asymptomatic even though his blood glucose went down as low as 1.8 mmol/l. Fasting C-peptide level taken during hypoglycaemia was inappropriately normal i.e. 947 pmol/l (298–1324 pmol/l). MRI pancrease revealed a mass at the head and uncinate of pancreas; measuring 2.86×3.2×2.9 cm. It was also diagnosed to have hypercalcaemia secondary to primary hyperparathyroidism. Neck US showed the presence of a probable right inferior parathyroid adenoma. He has bilateral renal calculi; with left proximal ureretic calculus causing moderate hydronephrosis and hydroureter requiring stenting. A final diagnosis of MEN-1 with Insulinoma and primary hyperparathyroidism was made. He underwent Whipple’s procedure instead of enucleation of the insulinoma as the tumor is adjacent to the pancreatic duct and major vessels. A total parathyroidectomy and implantation of the left parathyroid was also performed, together with prophylactic thyrectomy. He remains euglycaemic following the surgery. Insulinoma can pose a diagnostic challenge even to an experience clinician. Misdiagnosis of insulinoma as psychiatric illness and seizure is common; and might lead to disastrous consequences. This is unfortunate as insulinoma is curable after surgery. This case highlights the importance of considering insulinoma in patients presenting with seizures or psychosis.

Pregnancy in multiple endocrine neoplasia type 1: a case report
Gordana Pemovska1, Sasha Jovanovska Mishevska 1 & Tatjana Proseva2
1University Clinic of Endocrinology, Diabetes and Metabolic Disorders, Skopje, Macedonia; 2Clinical Hospital, Stip, Macedonia.

Multiple endocrine neoplasia type 1 (MEN1) is a rare inherited endocrinopathy characterized by tumours of the parathyroid glands, adenohypophyseal and pancreatic tumours. We present a case of a young, 24 years old female patient with a positive familial background for MEN1 (on the father's side of the family). She is one of two sisters with determined heterozygosity of the MEN 1 gene (Exon 2; codon 111). At the age of 12, insulinoma of the head of the pancreas was diagnosed in our patient, with dimensions 2×2.5 cm. She underwent two operations in order to remove the insulinoma, with consecutive pancreateojejunostomia and duodenjejunosomia. In the same period, adenohypophyseal prolactinoma measuring 8 mm was diagnosed and Cabergoline therapy was initiated. One year before she got pregnant, primary hyperparathyroidism was diagnosed and hypoparathyroidectomy was counselled, but the patient did not decide to do the operation. The possible maternal and foetal complications of hyperparathyroidism were pointed out to the patient, but she decided to keep the pregnancy. The PTH values are above 100 pg/ml (ref. values 15–65 pg/ml) with increased values of total and iodosed calcium (1.5–1.65 mmol/l). The patient is currently in the seventh lunar month of the pregnancy, with reported normal foetal development by the gynaecologist, and delivery is planned for the 36th week of pregnancy.

Can dehydroepiandrosterone-sulphate be a new diagnostic parameter in male patients with idiopathic hypogonadotropic hypogonadism?
Kenan Cadirci1, Ayse Carlioglu1 & Senay Durmaz2
1University, Kırıkkale, Turkey; 2Clinical Hospital, Stip, Macedonia.

DHEA and its sulphate derivative DHEA-sulphate (DHEA-s) are major androgen hormones of adrenal origin. The purpose of this study was to investigate DHEA-s levels in male patients with idiopathic hypogonadotropic hypogonadism (IHH) and to determine whether DHEA-s levels are a useful marker in the diagnosis of hypogonadotropic hypogonadism. 91 subjects, 31 male patients diagnosed with IHH (mean age 20±2.6 years) and 60 healthy males (mean age 20±2.6 years) as a control group, were included in the study. The patients in the IHH group were selected from subjects who had not yet started treatment for hypogonadism and who had no additional disease, while the healthy control group consisted entirely of individuals presenting to the clinic for routine check-ups. Both groups’ FSH, LH, total and free testosterone, ACTH, cortisol and DHEA-s levels were investigated. Mean DHEA-s levels were 133.4±56.5 µg/dl in the IHH group and 433.3±160.3 µg/dl in the control group. The difference was statistically significant (P=0.000). Total testosterone levels in the patient and control groups were 28.0±26.3 nmol/l and 568.1±288.0 nmol/l, respectively (P=0.000), free testosterone levels were 9.7±14.3 pg/ml and 18.0±9.0 pg/ml (P=0.006). The differences were statistically significant. Low DHEA-s levels in patients with IHH were determined to be independent of age, cortisol and ACTH (at multivariate logistic regression analysis). ROC analysis showed that DHEA-s ≤38.2 µg/dl supports a diagnosis of IHH with 100% specificity and 100% sensitivity. DHEA-s is as useful and predictive marker as total testosterone, which is used in the diagnosis of patients with IHH. DHEA-s levels were significantly lower in patients diagnosed with IHH compared to the control group, and we conclude that DHEA-s may be a predictive marker capable of use in the diagnosis of IHH.

**Introduction**

There is circumstantial evidence supporting a role of growth hormone and insulin-like growth factor 1 in the development and progression of tumors. Endosalpingiosis is characterized by the presence of non-neoplastic fallopion tube-like epithelium in ectopic anatomical locations.

**Case report**

A 45-year-old woman presented with a constant moderate to intense perianal pain limiting basic daily activities. She also complained about pain at right posterior superior iliac spine area that worsened with body movements. There was no history of trauma and inspection of the area and rectal examination were normal. Her past medical history was significant for acromegaly diagnosed 4-year earlier and confirmed by anatomopathological analysis of a pituitary macro-adenoma removed by transphenoidal surgery. She had history of hyperplastic polyposis of the rectum but further investigation with colonoscopy showed no apparent mucosal lesions. Pelvic CT revealed a poorly delimited nodular soft tissues densification in the right ischiorectal fossa of indeterminate nature. Pelvic MRI showed a spiculated soft tissue mass involving the lateral planes of the levator ani muscle and the internal obturator muscle, conditioining obliteration of the fat planes around the sciatic nerve. Given the surgical risks inherent to resection of the lesion, CT-guided biopsy was performed and the histological examination was compatible with endosalpingiosis. Since the benign nature of the lesion, medical treatment with an oral contraceptive was chosen.

**Conclusions**

Acromegaly appears to be associated with an increased risk of benign and malignant tumours. This case reports an unusual association between acromegaly and endosalpingiosis. Surveillance of signs and symptoms in acromegalic patients as well as adequate screening for possible comorbidities is crucial to allow timely diagnosis, clinical differential diagnosis and appropriate treatment of future lesions.

The giant who could not stop growing
Debra Maxine Gordon
Wits Donald Gordon Medical Centre, Johannesburg, South Africa.

Introduction
The presentation of a patient with Gigantism, gynaecomastia and increasing height suggests underlying Hypogonadotrophic Hypogonadism. Aetologies such as a pituitary hamartoma is unlikely.

Case study
A 39 year old male presents with a 20 year history of increasing height, shoe size, headaches, sweating and gynaecomastia for the past 10 years. He was 2.08 m tall with features in keeping with Acromegaly. He had normal secondary sexual characteristics and Tanner stage 3 gynaecomastia. Acromegaly was confirmed. His bone age was 17 years. He had hypogonadotrophic hypogonadism. Pituitary MRI showed an enlarged, partially empty sella turcica and a hypothalamic hamartoma. He received testosterone cyponate, oestradiol and a somatostatin analogue. He improved clinically but his gynaecomastia had worsened. He was referred for a mastectomy.

Discussion
Acromegaly/Gigantism are uncommon disorders. Tumours usually arise de-novo and secrete GH. Occasionally, there is a family history and an Aryl hydrocarbon mutation (FIPA) or Multiple Endocrine Neoplasia should be considered. Hypothalamic Hamartomas are rare causes of GNRH secretion, but usually present in childhood. This patient’s presentation suggests that the onset of Acromegaly was in late teenage years, and therefore unlikely to be due to the Hypothalamic Hamartoma. The enlarged, partially empty sella turcica, suggests possible auto-infarction of a prior macroadenoma.

Conclusion
Despite a decrease in GH and IGF1 levels in all patients after Octreotide LAR treatment only 15% attained goals. Patients who did not receive surgery had better results than patients who received it. This initial mode of treatment is not enough to control disease so over 70% of patients will need higher doses of Octreotide LAR and perhaps association with other drugs.

Intrasellar malignant haemangiopericytoma: a rare case
Tahir Omer, Rahat Tauni, Mark Gunnell & Olympia Kolouri
Cambridge University Hospitals, Cambridge, UK.

We report a case of malignant haemangiopericytoma in sellar region in a 73-year-old lady who initially presented with symptomatic hypothapnoea. She was found to have hypocortisolism on short synacthen test. She was treated with hydrocortisone and was found to have secondary hypothyroidism. Her gonadotropin levels were commensurate with menopause, prolactin levels were normal and there was no suggestion of diabetes insipidus. Initial pituitary magnetic resonance imaging (MRI) was normal. Ten months after the initial presentation, she developed bi-temporal visual field deficits, and repeat imaging revealed a large sellar mass compressing the optic chiasm. She underwent emergency endoscopic endonasal resection. Histopathology was consistent with intrasellar malignant haemangiopericytoma. She received testosterone cypionate, oestrafem and a somatostatin analogue. Her bone age was 17 years. She had hypogonadotrophic hypogonadism. Pituitary MRI showed an enlarged, partially empty sella turcica and a hypothalamic hamartoma. She received octreotide LAR at a dosage of 20 mg weekly is considered as first line treatment in patients who failed to surgery or who are not candidates to surgical treatment. The goal of this initial dosage is to reach GH levels below 1.0 ng/ml and INSULINE like factor type 1 (IGF1) levels within range for age and gender. The objective of this study is to determine the percentage of patients that attain goals for GH and IGF1 after 3-6 doses of Octreotide LAR.

Methods
We included patients with acromegaly diagnosis within our centre, between the years 1995 and 2015 that received a minimum of three applications of Octreotide LAR before obtaining new levels of GH and IGF1 to determine response to treatment. We included patients that received surgical treatment before institution of Octreotide and those who had contraindications to surgery and had to initiate Octreotide as part of initial treatment.

Results
A total of 34 patients were included, with an average of five applications of Octreotide LAR before evaluation, 67% had surgical treatment, 68% were male, with an age average of 47 years, 20% had diabetes, and 38% had systemic hypertension. Initial GH levels were 8.19 ng/ml in average and with an average tumour diameter of 15 mm. In all patients a decrease in GH and IGF1 levels was observed (3.65 ng/ml in average), but only 15% attained GH and IGF1 levels goals, 50% continued with active disease and the rest had a discordant pattern. Among patients that received surgical treatment prior to Octreotide LAR only 8% attained goals, 52% remained active. Of the patients who did not receive surgery 27% attained goals and 46% remained active.

Conclusion
Despite a decrease in GH and IGF1 levels in all patients after Octreotide LAR treatment only 15% attained goals. Patients who did not received surgery had better results than patients who received it. This initial mode of treatment is not enough to control disease so over 70% of patients will need higher doses of Octreotide LAR and perhaps association with other drugs.

Initial response to octreotide LAR in Mexican patients with acromegaly
Arturo Peña Velarde & Alma Vergara López
Centro Medico Nacional 20 de Noviembre, México, Mexico.

Introduction
In Mexico there is scant literature about medical management and its response in patients with acromegaly. Octreotide LAR at a dosage of 20 mg weekly is considered as first line treatment in patients who failed to surgery or who are not candidates to surgical treatment. The goal of this initial dosage is to reach GH levels below 1.0 ng/ml and INSULINE like factor type 1 (IGF1) levels within range for age and gender. The objective of this study is to determine the percentage of patients that attain goals for GH and IGF1 after 3-6 doses of Octreotide LAR.

Methods
We included patients with acromegaly diagnosis within our centre, between the years 1995 and 2015 that received a minimum of three applications of Octreotide LAR before obtaining new levels of GH and IGF1 to determine response to treatment. We included patients that received surgical treatment before institution of Octreotide and those who had contraindications to surgery and had to initiate Octreotide as part of initial treatment.

Results
A total of 34 patients were included, with an average of five applications of Octreotide LAR before evaluation, 67% had surgical treatment, 68% were male, with an age average of 47 years, 20% had diabetes, and 38% had systemic hypertension. Initial GH levels were 8.19 ng/ml in average and with an average tumour diameter of 15 mm. In all patients a decrease in GH and IGF1 levels was observed (3.65 ng/ml in average), but only 15% attained GH and IGF1 levels goals, 50% continued with active disease and the rest had a discordant pattern. Among patients that received surgical treatment prior to Octreotide LAR only 8% attained goals, 52% remained active. Of the patients who did not receive surgery 27% attained goals and 46% remained active.

Conclusion
Despite a decrease in GH and IGF1 levels in all patients after Octreotide LAR treatment only 15% attained goals. Patients who did not received surgery had better results than patients who received it. This initial mode of treatment is not enough to control disease so over 70% of patients will need higher doses of Octreotide LAR and perhaps association with other drugs.

Pasireotide: an effective treatment for resistant acromegaly
Wickrama Kankanamage Maheshi Gihan Amarawardena1,2, Kamani Dhanushka Liyanarachchi1,2, John David Charles Newell-Price1,2, Richard John Martin Ross1 & Miguel Debono2
1Department of Oncology and Metabolism, University of Sheffield, Sheffield, UK; 2Department of Endocrinology, Royal Hallamshire Hospital, Sheffield, UK.

The granulation pattern of somatotroph adenoma is well known to be associated with differing clinical and biochemical characteristics and it has been shown that sparsely granulated tumors respond poorly to commonly used somatostatin analogs. We report a challenging case of acromegaly with a sparsely granulated tumor, resistant to multiple modalities of treatment given over several years and ultimately achieving biochemical control with pasireotide. A 26-year-old lady presented with classical features of acromegaly. She had no family history of pituitary tumors or hypercalcaemia. An OGTT confirmed acromegaly, IGF-1 was 1710 µg/l and mean growth hormone (GH) was > 600 mU/L, indicating high disease burden. In addition, there was secondary hypogonadism, marginally elevated prolactin and hypothyroidism. MRI scan showed a 4 cm pituitary macroadenoma with suprasellar extension and right side cavernous sinus invasion. She underwent trans-sphenoidal pituitary surgery. Histology displayed moderate amounts of sparsely granular eosinophilic cytoplasm, staining only for GH. Postoperative investigations showed uncontrolled disease (IGF1-1474 µg/L, mean GH-228 mU/L) and residual tumor in the cavernous sinus. She received external beam fractionated radiation. Over the years she received octreotide LAR (up to 30 mg), lanreotide (up to 120 mg) 2 weekly, cabergoline, pegvisomant and stereotactic radiosurgery to no avail. Only pegvisomant resulted in some disease control; however this had to be stopped due to abnormal liver functions. Fifteen years after the diagnosis, she was started on pasireotide 40 mg monthly. Within a month, her IGF-1 dropped and has remained within the normal range for age (103–310 µg/L). Pasireotide was well tolerated and the patient’s symptoms improved significantly. Somatostatin receptor subtyping revealed a positivity score of two for both SSTR5 and SSTR2a subtypes.

Conclusion
Tumours that poorly respond to first generation SST, especially sparsely granulated somatotroph adenomas, can respond to pasireotide and treatment should be considered early in the management of resistant tumours.

The disorder of secretion of somatotropic hormone in women with the polycystic ovaries syndrome (PCOS) by comparison to patients with the non-functional pituitary adenomas (NFPA)
Yuyluz Urmanova1,2 & Mislitnyy Saidnazirkhanova1,2
1Tashkent Paediatric Medical Institute, Tashkent, Uzbekistan; 2Center of Endocrinology, Tashkent, Uzbekistan.

The levels of decorin in patients with Cushing’s disease and acromegaly were measured by enzyme immunoassay Human Decorin ELISA kit (Immundiagnostik AG). SK00641-01, serum myostatin values were also determined (Myostatin ELISA kit (The National Research Centre for Endocrinology, Moscow, Russia)).

Overall, our results indicate that there is a significant correlation between stantin pre-surgical treatment and the disease cure. However, there is not correlation between use of statin and molecular phenotype.

Conclusion
To analyze whether pretreatment with statins modifies the adenoma molecular phenotype of the acromegalic patients and how this changes could help to influence the response to treatment.

Materials and methods
Observational study including patients with acromegaly, diagnosed at the Endocrinology and Nutrition Unit of the Hospital Reina Sofia from 2007 to 2012, in which surgery, radiology and molecular typing of the adenoma was carried out.

Results
22 patients were included (38 ± 15 years old; 65% women). Three patients meet cure criteria. Those who have lower prolactin levels (9.33 ± 2.77 mg/dl) than those who do not (54.30 ± 52.31, P 0.005). There were no differences about molecular phenotype between two groups, it shown in Table 1. Patients meet cure criteria had taken more statins that those who had not (P 0.048).

Conclusion
Overall, our results indicate that there is a significant correlation between statin pre-surgical treatment and the disease cure. However, there is not correlation between use of statin and molecular phenotype.

EP881
The levels of decorin in patients with Cushing’s disease and acromegaly
Timur Tsoriev, Zhanna Belaya, Lyudmila Rozhinskaya, Alexander Ilyin, Larisa Nikankina, Galina Mel’enchenko & Ivan Dedov
The National Research Centre for Endocrinology, Moscow, Russia.

Decorin is myokine expressed and released in response to muscle contractions. It induces growth and hypertrophy of skeletal muscles in different ways including myostatin inhibition. It is still not clear whether decorin takes part in development of muscle atrophy in endocrine pathologies.

Objective
To evaluate decorin levels in patients with endogeneous hypercortisolism and GH oversecretion.

Materials and methods
Three groups were involved in our study: 1) patients with Cushing’s disease (n=29), 2) patients with acromegaly (n=25) and 3) healthy controls (n=20).

24-h urine free cortisol (24-hUFC) (immunochemiluminescent assay, Vitros ECI) and evening salivary cortisol (electrochemiluminescent assay, Cobas e601) were measured in patients with Cushing’s disease, and IGF-1 (immunochemiluminescent assay, Liaison) was evaluated in patients with acromegaly. Serum decorin levels were measured by enzyme immunoassay Human Decorin ELISA kit SK00641-01, serum myostatin values were also determined (Myostatin ELISA kit Immundiagnostik AG)

Results
One-way ANOVA was performed for all patients and controls. There were not found any differences among the groups in sex (P=0.959), age (The National Research Centre for Endocrinology, Moscow, Russia=0.180) and BMI (The National Research Centre for Endocrinology, Moscow, Russia=0.270). No differences were found in myostatin levels among the groups (The National Research Centre for Endocrinology, Moscow, Russia=0.785). The Duncan post-hoc test demonstrated significantly lower values of decorin in patients with acromegaly compared to patients with Cushing’s disease and healthy controls: (1) 5015.38 pg/ml (95% CI 4855.71–5175.06), (2) 4469.89 pg/ml (95% CI 4285.85–4653.94), (3) 4841.29 pg/ml (95% CI 4633.86–5048.71). (The National Research Centre for Endocrinology, Moscow, Russia < 0.001). This finding was confirmed by performance of Student’s t-test in pairs for groups (1) and (2) (The National Research Centre for Endocrinology, Moscow, Russia < 0.001) and groups (2) and (3) (The National Research Centre for Endocrinology, Moscow, Russia = 0.008).

Significant negative moderate correlation was demonstrated between decorin and IGF-1 values (r = −0.413 (The National Research Centre for Endocrinology, Moscow, Russia < 0.001). There was also a weak negative correlation of very low significance between decorin and myostatin (r = −0.111 (The National Research Centre for Endocrinology, Moscow, Russia = 0.425).

Conclusion
The serum decorin levels tend to be reduced in subjects with acromegaly. At the same time, the levels of myostatin don’t depend significantly on decorin values.

A surprising and dramatic neuroendocrine-immune phenotype of mice deficient in Growth Hormone-Releasing Hormone (GHRH)
Khalil Farhat1, Gwennaille Bodart1, Chantal Renard1, Christophe Desmet1, Michel Moutchen1, Frédéric Baron1, Yves Beguin1, Roberto Salvatori1, Henri Matens1 & Vincent Geenen1
1GIGA-I3-Immunoenocrinology, University of Liege, Liege, Belgium; 5Division of endocrinology Diabetes and metabolis, John hokins University, Baltimore, Maryland, USA.

In the framework of close interactions between the immune and neuroendocrine systems, Growth Hormone (GH) has been proposed to exert significant effects on the immune system, but there is not yet a consensus about GH immunomodulatory properties. These studies investigated the immune and anti-infectious response of dwarf Ghhr−/− mice presenting a severe deficiency of the GHRH/GH/IGF-1 axis. In basal conditions, thymic parameters and T-cell responses of Ghhr−/− mice were not severely affected but a constant B-cell lymphopaenia was observed. Thus, we investigated vaccine and anti-infectious responses of Ghhr−/− mice toward Streptococcus pneumoniae, a B-dependent pathogen. Ghhr−/− mice were unable to trigger production of specific IgM and IgG against serotype 1 pneumococcal polysaccharide (PPS) after vaccination with either native PPS (Pnx23) or protein-PPS conjugate (Prev-13) vaccines. These vaccines both include the serotype 1 (our S. pneumoniae strain) and provide an effective protection in mice. A short GH supplementation to Ghhr−/− mice (1 daily injection of 1 mg/kg GH for 4 weeks) restored IgM and IgG response to Pnx23 vaccine but not to Prev-13. This suggests that GH could exert distinct impacts upon spenic areas. Furthermore, after intranasal instillation of a non-lethal dose (defined by the full clearance by WT C57BL/6 mice after 24 h) of serotype 1 S. pneumoniae, Ghhr−/− mice exhibited a dramatic susceptibility. This was proved by a marked time-dependent increase in pulmonary bacterial, a septicemia already 24 h after infection and a survival limit of 72 h. We also observed a dramatic decrease in lung B- and T-cell populations and an increase in production of inflammatory macrophages. By contrast, WT and heterozygote mice completely cleared S. pneumoniae infection after 24 h. In conclusion, our data show without ambiguity that the somatotrope GHRH/GH/IGF-1 axis plays an important and unsuspected role in defense against S. pneumoniae.

Safety of growth hormone replacement therapy (GHRT) in adult patients with GH deficiency: data from kims
Cecilia Camacho-Huber1, Peter Jonsson2, Ferah Aydin3, Natasa Rajicu1, Jose Cara1, Roger Abi5 & Judith Hey-Hadavi1
1Endocrine Care, Pfizer Inc, New York, New York, USA; 2Antwerp Centre for Endocrinology, Antwerp, Belgium; 3Endocrine Care, Pfizer Health AB, Sollentana, Sweden.

Background The efficacy of recombinant human growth hormone replacement therapy (GHRT) has been demonstrated, in part, through clinical trials conducted worldwide. KIMS (Pfizer International Metabolic Database), established in 1994 and active until 2012, includes treatment outcome data and real world safety from 15 809 patients from 31 countries.

Objective The main objective of this analysis was to evaluate the long-term safety of patients with hypopituitarism or with Isodipathic GH deficiency receiving GHRT in adult life.

Study design This open label, international, multi-center study enrolled adult and adolescents with hypopituitarism and GH deficiency. Patients were treated according to the standard of care of their physicians. A total of 15 809 patients (94.4% Caucasian, 50.5% males, 22.2% childhood-onset) were enrolled, with a mean age (s.d.) of 43.9 yr (15.5) at time of enrollment; the mean duration of follow-up was 5.3 yrs and 83 128 patient-years. Safety outcomes included all reported causality adverse events (AEs), treatment related (TR) and serious AEs (SAEs), including neoplasm incidence.

Results 8093 (51.2%) patients were reported to have 27118 AEs, of which 16.6% TR, and 3998 (25.3%) patients were reported to have 7154 SAEs. 12.2% were reported to have an AE that led to study medication discontinuation and 5.5% to a dose reduction. The most frequently reported all causality AEs were arthralgia (4.6%), headache (3.6%), influenza (2.8%) and depression (2.8%), whereas for TRAEs these were arthralgia (2.6%) and peripheral edema (1.8%). The most frequently reported SAE was pituitary tumor recurrence, all causality (n = 320/15 809, 2.0%) and TR (n = 154/15 809, 1%). The reported occurrence of death was highest for general disorders and neoplasms (benign, malignant and unspecified) in 148 and 146 patients, respectively.

Conclusion The results of this large study of GHRT in adult/adolescent patients with GHD complement data from clinical trials and confirm the favorable safety profile of GHRT.

Effect of GH treatment on coagulation and fibrinolysis parameters in prepubertal children with growth hormone deficiency
Feneli Karachaliou1, Helen Pergadou2, Anastasia Dettori3, Evangelia Boudouvi3, Maria Kaletz1, Aspasia Fotinou2, Helen Platokouki2 & Vassiliki Papaevangelou1
1Pedicatrik Endocrinology Unit, 3rd Department of Pediatrics, University General Hospital Attikon, Athens, Greece; 2Haemophilia Center – Haemostasis and Thrombosis Unit, Aghia Sophia Children’s Hospital, Athens, Greece; Biochemistry-Hormonology Department, P and A Kyriakou Children’s Hospital, Athens, Greece.

Background Increased fibrinogen levels have been reported in prepubertal children and adolescents with growth hormone deficiency (GHD), which were reduced after rhGH treatment. rhGH treatment has also been shown to exert a beneficial effect on the amount of aPAI-1 in children with GHD. Aim of the study was to evaluate whether prepubertal GH deficient (GHD) children showed any impairment in coagulation- and fibrinolysis-related parameters and the effect of GH therapy on these parameters.

Patients and methods Fifteen prepubertal children (ten girls and five boys) of a mean (s.d.) age of 9.8 (0.4) yrs with GHD deficiency were included in this hospital based prospective study. Serum levels of PT, APTT, fibrinogen, VII, VIII, AT, PC, D-dimers, Plg, and PAI-1 were measured before and after 6-12 months of GH treatment.

Results At baseline all studied parameters were within normal ranges. A significant increase in PT values was noted after a mean (S.D.) interval of 9.3 (0.4) months of GH treatment. PT values, while fibrinogen levels did not change. Moreover, GH treatment reduced aPAI-1 in children with GHD, suggesting a beneficial effect of GH treatment on fibrinolysis-related parameters and the effect of GH therapy on these parameters.

Nodular thyroid disease in acromegaly: cohort of 69 patients at a single institution
Cristina Alvarez-Escolá, Diego Meneses González, Óscar Moreno Domínguez & Lucrecia Herranz de la Morena
1Pediatric Endocrinology Unit, 3rd Department of Pediatrics, University Hospital La Paz, Madrid, Spain.

Background Nodular thyroid disease is very common in acromegaly. The most frequently reported lesions are nodules, which are frequently cystic. Acromegaly is an endocrine disease that is treated with somatostatin analogues and surgery, therefore the presence of thyroid nodules could be a contraindication for surgery. Even though there is evidence of an increased risk of thyroid malignancy in patients with acromegaly, the frequency of thyroid malignancy in acromegaly is unknown.

Objectives To evaluate the frequency of nodular thyroid disease in patients with acromegaly and to correlate clinical and metabolic features with disease activity and other.

Methods We performed a retrospective study of 69 patients with acromegaly, who were treated in our Endocrine Unit over the last 30 years. The diagnosis of acromegaly was established according to international guidelines. All patients were treated with octreotide and/or surgery, and we evaluated the frequency of thyroid nodules and their relationship with disease activity and other.

Results A total of 945 nodules were found in 115 (68%) patients. The prevalence of nodules increased with increasing acromegalic duration, with a prevalence of 52% at less than 5 years, 64% at 5-10 years, 78% at 10-15 years, 86% at 15-20 years and 100% at more than 20 years. The prevalence of nodules also increased with increasing IGF-1 levels and GH levels. The prevalence of nodules was 52% in patients with IGF-1 levels below the normal range and 78% in patients with IGF-1 levels above the normal range. The prevalence of nodules was 52% in patients with GH levels below the normal range and 78% in patients with GH levels above the normal range.

Conclusion Nodular thyroid disease is very common in acromegaly. The presence of nodules is associated with increasing acromegalic duration, increasing IGF-1 levels and increasing GH levels. The prevalence of nodules is high and the frequency of thyroid malignancy is unknown. Further studies are needed to evaluate the frequency of thyroid malignancy in patients with acromegaly.

DOI: 10.1530/endoabs.49.EP886
female. Mean age at diagnosis of acromegaly was 48 (11–78) years, time between initial symptoms and diagnosis was 24 (0–240) months, 50 patients (72.5%) had a macroadenoma and 23 (33.8%) were cured after transphenoidal resection, among the other medical treatment or radiotherapy was necessary for attaining disease control. Thyroid function was normal in 42 patients (60.9%), 22 (31.9%) had hypothyroidism (15 primary, seven secondary) and 5 (7.2%) had hyperthyroidism. NTD were observed in 56 patients (81.2%) and 10 (14.5%) had diffuse goiter. Thyroid volume was 16.1 (4.7–27.2) ml. Fine-needle aspiration biopsy (FNAB) was performed in 17 patients. Suspicious or malignant cytology was detected in 23.5% of the FNABs specimens, all of them (11 patients, 15.9%) underwent thyroidectomy. Pathology revealed nodular goiter in six and thyroid carcinoma in five patients (7.2%). Other cancers detected were colorectal, breast, prostate and gastric in 4 (5.8%), 2 (2.9%), 2 (2.9%) and 1 (1.4%) patients, respectively. Patients with NTD (n = 56) showed similar age, duration of disease, thyroid volume, concentrations of GH/IGF-1 at diagnosis and IGF-1 at last follow-up compared with the group of patients without NTD (n = 13). Considering only patients with NTD, thyroid volume was not correlated with age, estimated acromegaly duration, time between the first symptoms to diagnosis, FIFA, TSH, GH/IGF-1 at diagnosis or IGF-1 at last follow-up. Thyroid volume was not different whether acromegaly was active or not (17.5 ± 14.3 mm).

Conclusions
Thyroid structural abnormalities are frequent in patients with acromegaly, therefore routine physical examination and thyroid ultrasound are recommended in all of them. Thyroid cancer was the most common neoplasia in our study, which is similar to other reports.

Somatropin treatment Supported by NHS: characterization of submitted patients – 2006 to 2016
Margarida Bastos1,2, Alice Mirante1,2, Caldas Afonso1,3, Carlos Vasconcelos1,3, Conceição Bacelar1,3, Conceição Pereira1,5, Lurdes Lopes1,2, Marcelo Fonseca1,7, Joana Serra-Caetano1,5, Graciete Bragança1,9, Luísa Raimundo1,10, Lurdes Matos1,6, Lurdes Sampaio1,8, Manuel Fontoura1,10 & Teresa Borges1,3
1Comissão Nacional para a Normalização da Hormona de Crescimento (CNCNH), Portugal, Portugal; 2Endocrinology and Pediatric Endocrinology Departments of: CH Universitário de Coimbra, Coimbra, Portugal; 3CH Porto, Porto, Portugal; 4CH Lisboa Ocidental, Lisboa, Portugal; 5Oncology Portuguese Institute Francisco Gentil, Lisboa, Portugal; 6CH Lisboa Central, Lisboa, Portugal; 7Unidade ULSM, Matosinhos, Portugal; 8CH Lisboa Norte, Lisboa, Portugal; 9Fernando Fonseca, Amadora, Portugal; 10CH Garcia de Horta, Almada, Portugal; 11CH S. João, Porto, Portugal; 12L. Biostatistics and MI and IBILI, FMC, U Coimbra, Coimbra, Portugal.

Introduction
In our country somatropin treatment is supported by the National Health Service. A National Committee (CNNHC) rules and analysis the submission papers of submitted patients – 2006 to 2016.

Data collected: demographic, submission date, diagnosis and committee’s decision. Statistical analysis by SPSS21 (P<0.05).

Results
Total submissions n = 1968 corresponding to 1909 children/six adults; Males (59.5%) and Females (40.5%). Mainly coming from Pediatric centres (n = 1573/80.3%). Submissions increased along time, with a minimum of 87 in 2007 and a maximum of 252 in 2011. Were approved a total of n = 1412 (72%) cases: at first submission n = 1243 (63.4%) and after reevaluation n = 169 (8.6%). Not approved n = 555 (27.2%). Diagnostic prevalence: somatotropin deficiency n = 1233 (62.9%): isolated n = 1067(54.4%) and multiple n = 166(8.5%); SGA n = 324(16.5%), TS n = 177(9%); RCD n = 122(6.2%) and PWS n = 53(2.7%). Somatotropin deficiency remained the most frequent diagnosis along the years. Age at submission: DRC were submitted earlier (6.4 ± 4.2y), followed by SGA (7.9 ± 3.0y), TS (8.5 ± 3.6y), PWS (9.4 ± 4.0y), multiple STD (9.7 ± 5.1y) and isolated STD (10.3 ± 3.5y). Except from TS, male gender was more frequent at all diagnosis. Were associated with oncologic disease n = 182/1968(9.2%): n = 97/182(53%) had primary tumours of CNS and n = 66/182(36%) due to hematopoietic disease (leukemia/lymphoma).

Conclusions
Somatotropin supported treatment in our country has evolved along time, with new approved indications after 2010. The most frequent diagnosis remains isolated somatropin deficiency with a high age at submission which probably compromises the final stature. We must have more support for deficient somatropin adult patients.

Delayed puberty revealing an uncommon genetic disease: about one case
El Ansari Nawal & Sara Askoua
Service of Endocrinology Diabetes and Metabolic Diseases, Marrakech, Morocco.

Contexte
Kallmann syndrome is a rare genetic disease which can affect both men and women. It combines hypogonadotropic hypogonadism which characterised by a failure to start or to fully complete puberty naturally: olfactory disorders such as hyposmia or anosmia, impaired color vision, deafness, unilateral or bilateral renal aplasia and midline anomalies.

Objectif
We report a case of this rare syndrome, responsible of delayed puberty view of infertility.

Patient – intervention
A patient of 23 years, from a non consanguineous marriage, consultant for delayed puberty with a Tanner stage to P2G2, without cryptorchidism or hyposmia.

Intervention
We realized a hormonal exploration, with a morphological exploration of hypothalamic-pituitary region.

Main outcome measure
We have suspected this diagnosis through severe hypogonadism (absence of development of secondary sex characteristics). The definitive diagnosis relies on the detection of the genetic anomaly, not available to our level, hormonal explorations, olfactometry, abnormalities on MRI Kallmann syndrome.

Result
Hormonal exploration showed hypogonadotropic hypogonadism. MRI is in favor of a predominant Hypoplastic right olfactory tract and the olfactory grooves, with a normal rod.

Conclusion
Kallmann syndrome is a rare disease, responsible of severe hypogonadism, the diagnosis is based on characteristic abnormalities of the olfactory bulbs on MRI. With the correct diagnosis and treatment, fertility can be achieved in many cases and the risk of osteoporosis reduced.

Empagliflozin increases urinary volume output in healthy volunteers with artificial SIADH – a placebo-controlled double blind crossover study
Julie Refardt1, Bettina Winzeler1, Fabian Meienberg1, Deborah Vogt2 & Mirjam Christ-Crain1
1Department Endocrinology University Hospital Basel, Basel, Switzerland; 2Clinical Trial Unit University Hospital Basel, Basel, Switzerland.

Introduction
The Syndrome of inappropriate antidiuresis (SIADH) is the predominant cause of hyponatremia and its therapy options are unsatisfying. SGLT2-inhibitors have...
become a valuable treatment option for type 2 diabetes by increasing glucose excretion in the urine with concomitant osmotic diuresis. We therefore hypothesized that SGLT2-inhibitors could be a novel treatment option for SIADH.

**Materials and methods**
We included 14 healthy volunteers in this prospective placebo controlled crossover study. To induce SIADH, participants were concomitantly administered desmopressin i.v. and hydrated. After the initial oral volume load and administration of desmopressin, a single dose of the study drug empagliflozin 25 mg or placebo was given in random order. The main outcomes were total urinary volume excretion, glucosuria and the area under the curve (AUC) of the serum sodium concentration. The outcome measures were obtained 2–8 hours after administration of the study drug.

**Results**
Fourteen participants (64% males), BMI 23.1 kg/m² (±2.4), age 28.6 years (±2), with similar serum sodium levels on both study days (empagliflozin 140 mmol/l (±1.5) vs placebo 140 mmol/l (±1.3)) completed the study. Empagliflozin led to significantly increased urinary volume excretion (579.3 ml ±194.8 vs 367.3 ml ±158.8; P=0.001) due to glucosuria (74.18 mmol ±22.3 vs 0.12 mmol ±0.04; P=0.001). There was no difference in the AUC of the serum sodium concentration under Empagliflozin compared to Placebo (Difference of AUC 0.2, CI -7.38; 6.98, P=0.96).

**Conclusion**
In healthy volunteers with artificially induced SIADH, empagliflozin increased volume excretion due to osmotic diuresis. Most probably due to the short treatment duration serum sodium levels remained unchanged. Additional studies in real live setting are needed to further examine the possible role of empagliflozin as a new treatment option for SIADH.

**Metformin increases pressure pain threshold in lean PCOS women**

Marta Kulaik, Tomasz Milewicz, Krystyna Szefkow, Iwona Rogatk & Renata Majewska

**1Department of Gynecological Endocrinology, Medical College, Jagiellonian University, Cracow, Poland; 2Department of Clinical Biochemistry, Medical College, Jagiellonian University, Cracow, Poland; 3Department of Epidemiology, Chair of Epidemiology and Preventive Medicine, Medical College, Jagiellonian University, Cracow, Poland.

**Background**
Despite the strong preclinical rationale, there are only very few data considered the utility of metformin, as a potential pain therapeutic in humans. The aim of this study was to determine, the association between metformin therapy and pressure pain threshold (PPT) in lean polycystic ovary syndrome (PCOS) women. We hypothesized that metformin therapy in lean PCOS women increases pressure pain threshold.

**Materials and methods**
Twenty-seven lean PCOS women with free androgen index (FAI) phenotype > 5 and 18 lean healthy controls were enrolled to the study. Fifteen of PCOS women were randomly assigned to be treated with metformin 1500 mg daily for 6 months. PPT and plasma β-endorphins levels were measured in all women at the beginning of the study and after 6 months observation.

**Results**
We observed increase in pressure pain threshold values measured on deltoid and trapezius muscle in PCOS with metformin group after 6 months metformin administration, (4.81 ±0.88 kg/cm², P<0.001 on deltoid muscle and 5.71 ±1.16 kg/cm² on trapezius muscle). We did not observe any significant changes in PPT values in PCOS without treatment group and controls. We did not observe any significant changes in serum β-endorphin levels in any studied groups during 6 months observation.

**Conclusion**
We conclude that metformin therapy increases pressure pain threshold in PCOS lean women, without affecting β-endorphin plasma concentration. Our results may suggest the potential role of metformin in pain therapy. We propose that larger, randomized studies, on metformin impact on pain perception should be performed.

**Clinical features and natural history of clinically non-functioning pituitary incidentalomas**

Pedro Iglesias, Karina Arcano, Vanessa Triviño, Paula García-Sancho, Juan José Diez, Fernando Cordido & Carles Villabona

1Department of Endocrinology, Hospital Universitario Ramón y Cajal, Madrid, Spain; 2Department of Endocrinology, Hospital Universitario A Coruña, A Coruña, Spain; 3Department of Endocrinology, Hospital Universitario Bellvitge, Barcelona, Spain.

**Objective**
To assess the clinical features of incidentally non-functioning pituitary adenoma (NFPA) and to analyze its natural history.

**Methods**
A multicenter retrospective study in patients with NFPA followed-up from 1992 to 2015 was performed.

**Results**
Fifty-seven patients were studied (29 women (50.9%); age 55.8±16.7 years. 43.9% were older than 60 years, 40.3% belonged to the age group of 40-60 years and 15.8% were younger than 40 years. Most patients (n=55; 96.5%) were diagnosed by magnetic resonance imaging (MRI). 71.9% (n=41) were macroadenomas; 2 of them (3.5%) were giant adenomas (≥4 cm). Patients with macroadenomas were older than those with microadenomas (59.5±16.7 vs 46.4±18.1 years, P=0.007). Microadenomas were more common in women (41.3 vs 14.3%, P=0.023). About half of them (n=28; 49.1%) showed suprasellar extension; of these, 19 (33.3%) were accompanied by chiasmatic compression. Invasion of the cavernous sinuses was present in 28.1% (n=16). Hypopituitarism was present in 14 (24.6%) patients. Twenty-four patients (41.2%) underwent surgery. Twenty-six non-operated patients were evaluated after a median follow-up of 15.5 months (interquartile range, 5.7–32.7). No significant changes were found in the maximum tumor diameter at the end of follow-up (1.2±0.6 vs 1.2±0.7 cm; NS). The majority of NFPA's evaluated (n=23, 88.5%) did not show any changes in size. In two cases (7.7%) tumor size decreased and in one patient (3.8%) increased.

**Conclusion**
Incidental NFPA is diagnosed by MRI preferably from the 5th decade of life without sex predilection. Most of them are macroadenomas, more commonly diagnosed in men and at an older age, compared to microadenomas. The suprasellar extension with chiasmatic compression and hypothopituitarism are frequent at diagnosis. Most of the non-operated NFPA's remain with stable tumor size over time, being growth an unusual event.

**Pituitary stalk lesions - experience of single center**

Mirjana Doknic, Sandra Pekic, Dragana Miljic, Marko Stojanovic & Milan Petakov

1Department Neuroendocrinology, Clinic for Endocrinology, Diabetes Mellitus and Metabolic Diseases, Clinical Center Serbia, Belgrade, Serbia; 2School of Medicine, University of Belgrade, Belgrade, Serbia.

**Introduction**
Lesions of the pituitary stalk (PSL) are a challenging diagnostic problem for clinicians. Because of the critical location and role of the pituitary stalk, mass lesions in this area are not often biopsied, and the diagnosis may be based on clinical evaluation and imaging. Due to biopsy risk, about 40% PSL diagnosis are ‘probable’ or ‘unknown’. The main clinical symptoms of PSL are visual field deficit, DI and hypothopituitarism.

**Aim**
To evaluate etiology, clinical manifestations and MRI in patients (pts) with PSL who were seen at our department over 10 years.

**Patients**
We selected 20 pts (11 females) with abnormal pituitary stalk visualized on MRI. The mean age at diagnosis was 38.3 years (range, 8–67 years).

**Results**
Neoplastic lesions were diagnosed in 7 pts (35%): germinoma, pituitocytoma, craniopharyngioma, non-Langerhans histiocytosis, pituitary adenoma, Rathke cyst and simple cyst each one. Distant metastatic tumors in pituitary stalk were confirmed in 3 pts (15%). Inflammatory lesion were noticed in 4 pts (20%): 2 lymphohytic infundibuloneurohypophysis and 2 tuberculosis. Congenital anomalies were noticed in 2 pts (10%). Four patients (20%) with PSL were of unclear etiology. Tissue biopsy samples from the pituitary stalk itself were...
obtained in eight patients. Six pts have suffered from diabetes insipidus. Growth hormone deficiency was the most common hormone deficiency (15 pts, 75%), followed by secondary hypogonadism in 12 pts (60%) and ACTH and TSH deficiency in 8 pts (40%). Complete hypopituitarism was noticed in 8 pts (40%). Nine pts had visual field defects.

Conclusion
The risks associated with obtaining histological samples from the pituitary stalk, even in the group presented, the diagnosis was frequently based on other clinical findings and serial MR imaging. For the most challenging pituitary stalk lesions, an individualized approach, guided by clinical expertise, remains the best strategy.

First pediatric case of successfully treated Cushing's disease in Armenia
Gayane Bayburdyan, Lusine Arakelyan & Yelena Aghajanova
Yerevan State Medical University, Yerevan, Armenia.

Introduction
Cushing’s disease (CD) is the most common albeit rare in paediatric and adolescent population form of ACTH-dependent Cushing’s syndrome, with potentially serious morbidity. Thus, it presents diagnostic and therapeutic challenges for the clinician. Early diagnosis and treatment of Cushing’s disease is vital for long-term outcome. Paediatric pituitary-dependent Cushing’s syndrome caused by an ACTH-secreting corticotroph adenoma, accounts for 75–80% of Cushing’s syndrome and is almost always caused by a pituitary microadenoma.

Case report
14 yo girl presented to endocrine clinic with severe headaches, increased blood pressure (BP) up to 140/100 mmHg, wide reddish-purple abdominal striae, amenorrhea and weight gain up to 20 kg during last year. She was unsuccessfully managed by a gynaecologist with oral contraceptives for 8 months. In endocrine clinic patient was examined according to Endocrine Society guidelines with subsequent diagnosis of Cushing’s disease due to ACTH-secreting pituitary microadenoma (corticotropinoma). Patient underwent surgical removal of adenoma with gamma knife (GKS) resulting in reversal of symptoms.

Conclusions and follow up
Endocrine parameter normalization after GKS included normal 24-hour urinary free cortisol (UFC) concentration and normal levels of pituitary and peripheric hormones 4 months. However, posttreatment secondary hypothyroidism was suppressed after intracerebroventricular (i.c.v.) injection of STM-II and ATM-4 upon hyperosmotic shock, suggesting that this heteromer has an essential role in mediating water drinking behaviour on hyperosmotic stress. However, in vivo role of SCTR/AT1aR in central osmoregulatory centre is yet to be elucidated. Vasopressin (Vp) is one of the key components to access osmoregulation because of the physiological link between Vp release and drinking behaviour, meanwhile, ANGII and SCT are potent in stimulating Vp release, hence its is a spate of interest to understand whether SCTR/AT1aR heteromer regulate osmoregulation via Vp release pathway. In this study, we demonstrated that SCTR/AT1aR heteromer is involved in the regulation of Vp release and expression, as well as the central neural involvement in PVN. Upon SCTR/ANGII-stimulation, plasma Vp release was largely reduced (47.64% decrease) and Vp expression in PVN is significantly dropped (64.08% decrease) 15 mins after i.c.v injection of STM-II or ATM-4. This finding supports the hypothesis of SCTR/AT1aR in mediating water balance, and also provides concrete basis in demonstrating the in vivo role of a GPCR heteromer.

SCTR/AT1aR heteromer related osmoregulation in hypothalamus
Oi Kwan Mak & Billy K.C. Chow
The University of Hong Kong, Hong Kong, Hong Kong.

Emerging studies suggest that GPCR oligomerization could confer functional advantages to receptors and even constitute clinical applications. Recent study found that angiotensin II 1a receptors (AT1aR) and secretin receptors (SCTR) can form heteromer and participate in osmoregulation. Studying GPCR dimerization faces many technical challenges, including selectivity and specificity. Since transmembrane (TM) peptides can act as competitors against the interacting surfaces between two receptors and therefore, it is utilized in this study as a unique tool to illustrate the specific functions performed by SCTR/AT1aR heteromer. STM-II and ATM-4 are discovered as the interacting surfaces of two receptors and therefore, it is utilized in this study as a unique tool to illustrate the specific functions performed by SCTR/AT1aR heteromer. STM-II and ATM-4 are discovered as the interacting surfaces of SCTR/AT1aR heteromer, in which STM-II can only disrupt heteromer formation, while ATM-4 can inhibit both receptor homomer formation. Previous study shows that hyperosmolality-induced water drinking behaviour in mice is greatly suppressed after intracerebroventricular (i.c.v.) injection of STM-II and ATM-4 upon hyperosmotic shock, suggesting that this heteromer has an essential role in mediating water drinking behaviour on hyperosmotic stress. However, in vivo role of SCTR/AT1aR in central osmoregulatory centre is yet to be elucidated. Vasopressin (Vp) is one of the key components to access osmoregulation because of the physiological link between Vp release and drinking behaviour, meanwhile, ANGII and SCT are potent in stimulating Vp release, hence its is a spate of interest to understand whether SCTR/AT1aR heteromer regulate osmoregulation via Vp release pathway. In this study, we demonstrated that SCTR/AT1aR heteromer is involved in the regulation of Vp release and expression, as well as the central neural involvement in PVN. Upon SCTR/ANGII-stimulation, plasma Vp release was largely reduced (47.64% decrease) and Vp expression in PVN is significantly dropped (64.08% decrease) 15 mins after i.c.v injection of STM-II or ATM-4. This finding supports the hypothesis of SCTR/AT1aR in mediating water balance, and also provides concrete basis in demonstrating the in vivo role of a GPCR heteromer.

The hyponatremia in neurosurgical patients
Liudmila Astaf’eva, Maxim Kuitin, Yuliya Sidneva & Pavel Kalinin
Burdenko Neurosurgical Institute, Moscow, Russia.

Background
Hyponatremia is a relatively frequent and serious complication developed in patients with different neurosurgical pathology. The aim of the study was to identify the frequency of occurrence of hyponatremia in neurosurgical patients. Materials and methods
A retrospective analysis included 39479 patients operated in the Institute of Neurosurgery from January 2008 to December 2014. Results
785 patients (2% of all operated patients): 554 adults and 231 children had hyponatremia with Na level less than 130 mmol/l. In 63% of cases (497 patients) we observed a moderate decrease of Na (125 to 130 mmol/l), in 11% of cases (88 patients) the level of Na was less than 120 mmol/l. The mortality rate in patients with hyponatremia was 14.3%, what is 10 times faster than that of the rest of patients without hyponatremia operated during these years. In adults most often hyponatremia developed either after surgical removal of craniopharyngiomas (11%) or as a result of an acute stroke (22%). In children - after surgery of craniopharyngiomas (10%), astrocytomas (7%), ependymomas (24%) and germ cell tumors (10.5%).

Bilateral inferior petrosal sinus sampling and the outcome of transsphenoidal surgery in patients with Cushing’s disease: experience of a Tertiary Portuguese Hospital
Ana Coelho Gomes1, Lia Lucas Neto2, Francisco Tortosa3, Maria Raquel Carvalho1, Eduardo Barreiros1, Luis Barreiros1, José Migueás1 & Maria João Bugalho1
1Endocrinology, Diabetes and Metabolism Department, Santa Maria Hospital, Lisbon, Portugal; 2Neuroradiology Department, Santa Maria Hospital, Lisbon, Portugal; 3Pathology Department, Santa Maria Hospital, Lisbon, Portugal; 4Neurosurgery Department, Santa Maria Hospital, Lisbon, Portugal.

Introduction
Bilateral inferior petrosal sinus sampling (BIPSS) is the gold standard for the differential diagnosis of ACTH-dependent Cushing Syndrome when the pituitary adenoma on MRI is doubtful or absent. This study aimed to analyze whether BIPSS can influence the outcome in patients with Cushing disease (CD).

Methods
Retrospective, descriptive study. Forty-two patients with CD submitted to transsphenoidal surgery between 2005 and 2016 were divided into two groups based on the performance of BIPSS. Different variables were analyzed: year of diagnosis, preoperative laboratory tests and pituitary MRI, immediate postoperative laboratory tests, histological findings, postoperative hypopituitarism, presence of permanent diabetes insipidus, follow-up duration and final outcome.
Results
Ten out of forty-two patients with CD were submitted to BIPSS.

Acromegaly and malignant neoplasms
Vânia Gomes, Eduardo Barreiros, Luís Barreiros, Florbela Ferreira, Ana Gomes, Ana Filipa Martins, Ana Sofia Osório, Ana Wessling, Catarina Silvestre, Dinis Reis, Ema Nobre, Maria Raquel Carvalho, Mário Mascarhenas, Sónia do Vale, José Miguéis & Maria João Bugalho Santa Maria Hospital, Lisbon, Portugal.

Introduction
Acromegaly is a rare disease resulting from pathological oversecretion of growth hormone (GH) and insulin-like growth factor-1 (IGF-1). The clinical spectrum includes cardiovascular and respiratory diseases but also increased risk of benign and malignant neoplasms.

Objectives
Evaluate the prevalence of cancer and seek for associated factors in acromegaly.

Methods
Retrospective study of 94 patients with acromegaly treated in a single tertiary center from 1985 to 2016. The group with malignant neoplasms was compared with the group without malignancy. Statistical analysis was performed with SPSS software, version 20. Statistical significance: P < 0.05.

Results
63.8% of the patients were female and the mean age at diagnosis was 48.7±12.9 years. Median GH and mean IGF-1 at diagnosis was 9.8 ng/ml (range: 0.61–228) and 857.4±412.7 ng/ml, respectively. Median diagnostic delay of acromegaly was 7 years (range: 1–36). Cancer was present in 13 (13.8%) of the 94 patients. Colon cancer was diagnosed in five patients (5.3%), breast cancer and renal cell carcinoma each in 3 (3.2%), follicular thyroid cancer, melanoma and endometrial carcinoma each in 1 (1.1%). In three cases, cancer was found before acromegaly (breast cancer in 2 and colon cancer in 1). One patient had two malignancies (thyroid and renal cell carcinoma). The diagnostic delay of acromegaly was higher in the group with malignant neoplasm (P = 0.004). There was no statistically significant difference between the two groups relative to GH, IGF-1, age and body mass index at diagnosis and gender.

Conclusions
Colon cancer was the most prevalent, followed by breast and renal carcinoma. In the group with malignant neoplasms, diagnostic delay was significantly higher, suggesting that prolonged exposure to high GH and IGF-1 levels can be related to cancer development. Search for cancer should be a major task in the follow-up of these patients.

EP897
The prevalence of colorectal cancer and colon polyps in acromegaly: thirty years’ experience of a tertiary referral center
Vânia Gomes, Luís Barreiros, Eduardo Barreiros, Florbela Ferreira, Ana Gomes, Ana Filipa Martins, Ana Sofia Osório, Ana Wessling, Catarina Silvestre, Dinis Reis, Ema Nobre, Maria Raquel Carvalho, Mário Mascarhenas, Sónia do Vale, José Miguéis & Maria João Bugalho Santa Maria Hospital, Lisbon, Portugal.

Introduction
Several studies suggest a higher risk of colorectal cancer (CRC) and colon polyps (CP) in acromegaly, however there is still controversy regarding associated factors (AF) able to contribute for its development. Data on the prevalence of CRC and CP in Portuguese patients with acromegaly are limited.

Objectives
To assess the prevalence of CRC and CP in acromegalic patients and compare to the normal Portuguese population. To determine the relevance of a number of AF (growth hormone, insulin-like growth factor-1, body mass index and age at diagnosis, gender, diagnostic delay and disease duration) for its development.

Methods
Retrospective study of 101 acromegalic patients assisted in a tertiary center from 1985 to 2016, who underwent at least one colonoscopy. Comparative analysis with data from screening studies conducted in the normal Portuguese population. Statistical analysis was performed with SPSS software, version 20. Statistical significance: P < 0.05.

Results
Of the 101 patients (female: 62.4%; mean age at diagnosis: 49.5±12.8 years), 47.5% presented abnormal colonoscopy with CP, which were more frequent in the left colon. Histological analysis identified hyperplastic polyps (HP) in 29.7% of the patients, adenomas in 16.8% and CRC in 5%. In total, 27 adenomas and 69 HP were detected. The prevalence of CRC, CP and adenoma found in this study compared to normal population was: 5 vs 1% (P = 0.001); 47.5 vs 32.6% (P = 0.003) and 16.8 vs 38% (P = 0.001), respectively. Concerning AF, there was no differences between patients with abnormal and normal colonoscopy.

Conclusions
The prevalence of CRC and CP was significantly higher in patients with acromegaly. On the contrary, adenoma was significantly less prevalent. No association between any of the factors studied and the phenotype CRC/CP was observed. To our knowledge, this is one of the largest Portuguese series, nevertheless results have yet to be validated.

Hyponatremia predating the diagnosis of malignancy in oncological/hematological patients with SIADH
Irene Crespo-Hernández1, Martín Cuesta-Hernández1, Alejandro Santiago-Perez2, Emilia Gómez-Hoyos3, Ana Ortola-Buigues5, Paz de Miguel-Novoa4, Joan Chafer-Vilaplana1, Alfonso Calle-Pascual1 & Isabelle Runkle1
1Hospital Clínico San Carlos, Madrid, Spain; 2Hospital Clínico de Valladolid, Valladolid, Spain.

Introduction
Euvolemic hyponatremia (HN) caused by the Syndrome of Inappropriate Antidiuretic Hormone Secretion (SIADH) can predate a diagnosis of malignancy. It is thus easy to accurately diagnose the etiology of HN/SIADH when detected.

Methods
Retrospective, descriptive study of all 52 oncological/hematological malignancy patients diagnosed with SIADH in our Department between January 2011 and December 2016. HN was detected via computerized Primary-care/hospital case histories, and the computerized laboratory data base. Hyponatremia was considered to predate detection of malignancy/initial of diagnostic study when a serum sodium (SNa) <135 mmol/l was detected 6 months before definitive oncological/hematological diagnosis (PTD). A patient was considered probably euvolemic (PE) if SNa descent was accompanied by a predominant pattern of lowering serum urea, creatinine and Uric acid levels, probably euvolemic (PE) when SNa descent was accompanied by a predominant pattern of lowering serum urea, creatinine and Uric acid levels, probably hypovolemic (PH) if urea, creatinine and Uric acid levels rose while not hypovolemic. SNa in mmol/l.

Results
Males: 32/52(61.5%), mean age:63.4 (s.d.:11)years. Etiology of SIADH: lung cancer: 18/52(34.6%), gastrointestinal: 9/52 (17.3%), genitourinary: 11/52 (21 %), hematological: 5/52 (9.6%). 11/52 (21%) patients presented HN> 6 months PTD; median 40 (24–60), median age: 67 (63–76) years, initial SNa: 133 (130–134). Three patients were PH. Eight were PE, one receiving enalapril, another carbamazepine, another thiourea. In 5/8 (62%) PE patients, case histories revealed no initial cause for HN. HN was present a median of 25 (19–40.5) months PTD, range: 14–41. Initial SNa: 133 (129.5–133). None presented a low Urine Density. Hyponatremia was persistent, present in 42/50 (84%) tests, with a continuum up to euvolemic-SIADH diagnosis, suggesting that SIADH induced their sustained hyponatremia. Etiology: lung (epidermoid), endometrial, breast, gastric, prostate. In only 1/11 (9%) patients was hyponatremia studied PTD, with SIADH workup responsible for prostate tumor diagnosis.

Conclusion
Mild hyponatremia can predate the diagnosis of a malignancy. However, in our series of 11/52 patients, in only one was hyponatremia studied. The lack of importance given to the finding of frank hyponatremia, albeit mild, could delay tumor diagnosis.

Hyperprolactinemia as a manifestation of hormonally inactive pituitary adenoma
Zamira Khalimova & Migjona Safarova
Center for the Scientific and Clinical Study of Endocrinology, Uzbekistan, Tashkent, Uzbekistan.

Aim
The work was initiated to study prolactin levels in hormonally inactive pituitary adenoma by the size of the tumor.

Material and methods
We examined 85 patients with hormonally inactive pituitary adenomas, 45 women and 40 men among them aged from 18 to 50 years (mean age 44.5±3.85 years). The disease duration from the onset to diagnosis based on the medical history and MRI ranged from 1 to 15 years.

Results and discussion
Guided by the aim of study we divided the patients into three groups. 26 patients with the tumor size up to 10 mm were included into the first group. Thirty-three patients with the tumor size up to 20 mm comprised the second group. Twenty-six patients with the tumor size 30 and more mm were included into the third group. Analysis of hormonal parameters demonstrated correlation between prolactin level and the tumor size. Hyperprolactinemia was registered in 2, 45 and 100% of patients in the first group, second and third groups, respectively. In patients with macroadenomas hyperprolactinemia was clinically presented in combination with hypopituitarism. Among patients of the third group, chiasmal and cephalgic syndromes, the latter with the oculomotor nerve damage, were the main symptoms; lactorrhea-amenorrhea syndrome came the third.

Conclusions
Quite frequent sign of hormonally inactive adenoma, hyperprolactinemia upon formations in chiasmal-sellar area not always can be an outcome of prolactin-secreting adenomas; the fact is to be taken into account in choosing the treatment tactics.

**Study of CHD7 gene in KAL1-negative patients previously diagnosed with congenital hypogonadotropic hypogonadism that develop new pituitary deficiencies**

Beatriz Lecumberri1,2, Francisco Javier Rodríguez2, Óscar Moreno1, Manuel de Santiago1, Manuel Nistal2,3, Elena Vallespin2,3, Ángel Campano2,3 & Karen Heath1,2

1Endocrinology Department, La Paz University Hospital, Madrid, Spain; 2IdiPAZ, Madrid, Spain; 3INGEMM; La Paz University Hospital, Madrid, Spain; 4Pathology Department, La Paz University Hospital, Madrid, Spain.

Introduction

Recent studies suggest that some patients initially diagnosed with congenital hypogonadotropic hypogonadism (CHH) may evolve towards a combined pituitary hormonal deficiency (CPHD). Heterozygous pathogenic CHD7 variants impair neural cell crest guidance causing CHARGE syndrome and have been associated with abnormal pituitary development/function/structure and isolated CHARGE features, including HH. We aimed to genotype CHD7 and phenotype those adult patients previously diagnosed with CHH that developed new pituitary deficiencies during the follow-up.

Patients

From 20 unrelated KAL1-negative patients with a past CHH diagnosis followed in our adult endocrinology clinic during an average of 21.2 years (13–37), we selected those with new pituitary deficiencies – 7/20, all males, mean age 37.2 years (29–53) – and studied CHD7 using a targeted NGS panel (HYPOPT.V1). Markedly low IGF-1 levels were detected in 6/7 (85%) and of TSH in 6/7 (57%).

Results

277 patients (28.6%) harboured heterozygous CHD7 rare variants. The variant of unknown significance NM_017780.exon3.c:G6255T:p.L2085F that suggests pathogenicity but lacks functional study, was found in a 53-year-old male, that has a left temporal arachnoid cyst, a pars intermedia cyst, low IGF-1 levels, a pigmented glaucoma treated with iridotomy, aortic elongation and a "Sertoli-cell-only syndrome" diagnosis based on testicular biopsy performed at 38 years. Another 37-year-old male, that was hormonally and surgically treated for bilateral cryptorchidism during childhood, and currently shows a partial empty sella, absence of neurohypophysis and low TSH and IGF-1 levels, had the rare pathogenic heterogeneous variant NM_017780.3:c.8416C>G:p.Leu2806Val, involved in CHARGE, isolated HH, and in a few CPHD cases with atypical CHARGE features. Curiously both fathers of these two patients died before 65 years of age due to lung diseases (the first being cancer).

Conclusions

Our results suggest that CHD7 should be included in the genetic study of CHH patients, especially in those that develop new pituitary deficiencies over time.

**MR-characteristics as predictors of pituitary adenomas hormonal and proliferative activity**

Yulya Krivosheeva, Alexander Dreval, Evgenia Panteleeva, Galina Stashuk & Irena Ilovayskaya

Moscow Regional Research and Clinical Institute, Moscow, Russia.

Introduction

Previous studies demonstrated a relationship between T1- and T2-weighted signal intensity and tumor growth pattern in pituitary somatotropinomas. The goal of this retrospective study was to analyze the MRI characteristics of pituitary macroadenomas with different hormonal activity in newly diagnosed patients. Material and methods

Pre-treatment T1- and T2-weighted MR-images (Intera Achieva, PHILIPS, 3.0T) of patients with 42 non-functional adenomas (NFA), 18 macroadenomas, 55 somatotropinomas were analyzed, taking into account the intensity of the signals produced by the tumors, as well as their dimensions and growth direction. The results were expressed as M+ (25%; 75%).

Results

In NFA group, majority of patients (30/42, 71%) had isointensive T1-signal in the most common combinations with hypertensive or isointensive T2 (18/42, 42.9 and 9/42, 21.4%, accordingly). NFA’s volumes did not differ between these subgroups. In prolactinoma group 15/18 (83.3%) patients showed hypertensive T2-signal in the most common combination with isointensive T1 (7/18, 38.9%) and hypertensive T1 (6/18, 33.3%). IsoT1/hyperT2 prolactinomas had bigger volume compared to hypoT1/hyperT2 ones. In somatotropinoma group 43/55 (78.2%) patients had hypointensive T1 in combinations with hypo-, iso- or hyperintensive T2 (22/55, 40%; 12/55, 21.8%; 9/55, 16.4%, respectively). HypoT1/hypoT2 tumors had the smallest volume.

Conclusion

In all type of pituitary tumors hypointensive MR-signal (either T1 or T2) was associated with infrasellar tumor expansion and smaller tumor volume. In contrast, hyperintensive T2 was associated with suprasellar tumor expansion and bigger tumor volume. IsoT1/isot2 tumors were found only in NFA group; hypoT1/hypoT2 tumors were observed only in somatotropinomas so further investigations should be carried on to prove the diagnostic value of these results. Accurate determination of T1/T2 signal intensity can be used as additional predictors of hormonal and proliferative activity of pituitary tumors.

**Cholinergic modulation of the hypothalamic-pituitary-adrenal activity and somatotroph function in smokers and non-smokers**

Jesús Pérez-Láuz1,2, Judith López-Fernández2, Isabel Mascaléño1,2 & Javier Salvador2

1Hospital Universitario de Canarias, Tenerife, Spain, 2Universidad de La Laguna, Tenerife, Spain, 3Hospital Universidad de Navarra, Pamplona, Spain.

Introduction and objectives

The inhalation of tobacco smoke leads to an acute increase in cortisol, ACTH and GH concentration, both in chronic smokers as in non-smokers. However, most studies have failed to demonstrate differences between both groups in basal levels of these hormones in plasma or urine. Additionally, cholinergic pathways have been shown to play an inhibitory role in ACTH secretion in non-smokers. UFC and circulating levels of cortisol, ACTH and GH were evaluated basally and after pyridostigmine in smokers and non-smokers.

Subjects and methods

We studied UFC (urinary free cortisol) on 24 h urine samples and the effects of administration of placebo and pyridostigmine on ACTH, cortisol and GH secretion in 10 young males: five smokers and five non-smokers. In each test, placebo or pyridostigmine (120 mg) were given orally in random order on different days at 0830. Blood samples were drawn at 0830, 0900 and then every 15 min until 1130. Area under the curve was calculated. Data are expressed as mean ± SEM.

Results

Basal levels of UFC, plasma ACTH, and serum GH were not different between smokers and non-smokers. In contrast, basal serum cortisol was higher in smokers at 1015 (15.42 ± 1.38 vs 10.29 ± 1.40 mcg/dl) and 1045 (12.96 ± 1.14 vs 8.89 ± 1.19 mcg/dl). PD raised GH secretion within each group, while it decreased cortisol at 1015 (15.42 ± 1.38 vs 13.20 ± 1.50 mcg/dl) in smokers and ACTH at 1115 (16.87 ± 1.54 vs 12.49 ± 1.65 pg/ml) in non-smokers.

Conclusions

Chronic smoking is associated with increased basal cortisol level and normal UFC, while it is related to a decrease in serum cortisol after pyridostigmine. Besides, an inhibitory effect of cholinergic stimulation on ACTH is confirmed in non-smokers.

**Diagnosis, treatment and follow-up of non-functioning pituitary adenomas**

Ana Barrera-Martín1, Paloma Moreno-Moreno1, María-Rosa Alhambra-Expósito1, Aura-Dulcinea Herrera-Martínez1, Ángel Rebollo-Román1, Pedro-Blas García-Jurado2 & María-Angela Galvez-Moreno1

1Endocrinology Service. Hospital Universitario Reina Sofia, Córdoba, Spain; 2Pathology Department, La Paz University Hospital, Madrid, Spain.

Introduction

Non-functioning pituitary adenomas (NFPA)s represent the most common pituitary tumour. They usually appear in the middle age of life, without differences between genders. Mass growth produces the first symptoms so the diagnosis is usually late. Surgery is the first-line treatment with variable success.
(19.83%). The objective of this study is to evaluate the symptoms, diagnosis, treatment and final state of patients with NFPA.

Methods

Observational retrospective study of patients with NFPA evaluated between January 2002 and December 2015 at “Hospital Universitario Reina Sofia” in Córdoba. Results were analysed with SPSS 18.0.

Results

34 patients, 50% women. Mean age: 56.2 ± 11.9 years old. Mean follow-up: 5.2 ± 3.9 years (range: 1-14 years). Symptomatology: 38.2% campimetric alterations, 35.3% headache and 11.8% symptoms derived from hormonal deficits. 29.4% incidental diagnosis in magnetic resonance imaging. Mean diameter of tumour: 30.2 ± 11.4 mm. 64.7% extracellular growth, 55.9% chiasmal compression, 23.5% grade I of Knosp classification. Initial treatment: 91.2% transphenoidal surgery (8.8% carbegoline). 64.7% post-surgery complications. Anatomopathological diagnosis: pituitary adenoma, except 1 patient with tissue necrosis; 11.8% patients had p53 positive; mean Ki-67: 2 ± 2.4%. Only 5 patients were cured after the first surgery (2 patients had recurrence) and 1 had radiological persistence of disease. Adjuvant treatment: carbegoline (10 patients), radiotherapy (11 patients), radiosurgery (2 patients), second surgery (10 patients) and third surgery (2 patients). Finally, 26.5% of patients are cured and 73.5% have persistent disease. Hormonal deficits: 44.1% pre-surgery and 79.4% post-surgery. Campimetry improved in all patients.

Conclusions

i) There are no differences in the prevalence of NFPA by gender in our series. ii) The diagnosis was motivated by the symptomatology (predominantly visual); less frequent incidental diagnosis. iii) Most patients underwent transphenoidal surgery, being the success of this first surgery in our series less than the published rates.

Cholinergic modulation of the hypothalamic–pituitary–adrenal activity and somatotrophin function in DM-1

Jesús Pérez-Luís1,2, Judith López-Fernández1,2, Isabel Mascaréño1,2 & Javier Salvador1

1Hospital Universitario de Canarias, Tenerife, Spain; 2Universidad de La Laguna, Tenerife, Spain; 3Hospital Universidad de Navarra, Pamplona, Spain.

**Introduction**

Alterations of the somatotrophic and hypothalamic–pituitary–adrenal (HPA) axes occur frequently in patients with poorly controlled DM-1. These disorders could be related to abnormalities in the cholinergic tone regulating both hormonal axes. **Subjects and Methods**

UFC (urinary free cortisol) on 24 h urine samples and the effects of placebo and pyridostigmine on ACTH, cortisol, GH and glucose circulating levels were studied in 16 young males: 10 normal controls and 6 patients with poorly controlled DM-1 (HbA1c 9.2%) without retinopathy or nephropathy. Placebo or pyridostigmine (120 mg) were given orally on different days at 08:30. Blood samples were drawn at 0830, 0900 and then every 15 min until 1130. Area under the curve (AUC) was calculated for the full sampling period and for 1 hour intervals. Data are expressed as mean ± SEM.

**Results**

UFC (47.21 ± 7.29 vs 33.70 ± 2.63 mcg/24 h, P < 0.05), and GH and glucose levels were higher in diabetics than in controls, whereas ACTH and cortisol levels were not different. Pyridostigmine did not alter ACTH nor cortisol levels, while it raised GH secretion within each group, with the greatest increase in diabetics (AUC 0-60 min: 149.46 ± 83.34 vs 23.08 ± 12.01 ng/ml/60 min, P < 0.05). UFC was negatively correlated with HbA1c. Basally, GH did not correlate with ACTH nor cortisol levels.

**Conclusions**

The higher UFC figures in diabetics suggest some degree of hypercortisolism in poorly controlled DM-1. Cholinergic activation in diabetics elicits GH hyperresponse, but does not modify cortisol or ACTH levels, either in diabetics or controls. This fact speaks against an altered common mechanism in the cholinergic system regulating somatotrophic and HPA axes in DM-1, suggesting that cholinergic tone is not involved in the raised UFC excretion seen in these patients.

Decreased prolactin levels in plasma and cerebrospinal fluid in naïve to treatment patients with multiple sclerosis

Agnieszka Baranowska-Bik1, Dorota Uchman2, Lidia Martynska3, Małgorzata Kalisz3, Anna Litwinuik3, Wojciech Biku4, Bogusława Baranowska & Jan Kochanowski4

1Department of Endocrinology, Centre of Postgraduate Medical Education, Warsaw, Poland; 2Department of Neurology, Medical University of Warsaw, Warsaw, Poland; 3Department of Neuroendocrinology, Centre of Postgraduate Medical Education, Warsaw, Portugal.

**Background**

Data from the literature has documented a remarkable immune-modulating role of prolactin. Previous evaluations of prolactin levels in patients with multiple sclerosis (MS), disease of autoimmune origin, showed conflicting results. Thus, to clarify the impact of prolactin on MS pathology we decided to assess prolactin levels in plasma and cerebrospinal fluid in naïve to treatment subjects with newly diagnosed MS.

**Material and methods**

A total number of 83 individuals were included: 41 patients with MS (30 females/11 males) and 42 age-matched controls (36 females/6 males). All MS subjects were newly diagnosed and they were without any treatment at the time of taking the samples of blood and cerebrospinal fluid. Prolactin was determined in plasma in all subjects.

Results

Prolactin levels in plasma were found to be markedly lower in MS patient when compared to those of the controls (7.64 ± 5.99 ng/ml vs 10.12 ± 6.76 ng/ml, P < 0.05). These results correspond with concentration of prolactin measured in cerebrospinal fluid as in MS individuals prolactin was significantly decreased (2.84 ± 0.35 ng/ml vs 3.42 ± 0.89 ng/ml, P < 0.05). The comparison of cytokine levels revealed no differences between the examined groups. A positive correlation between prolactin concentration in plasma and TNF-alpha levels was found in MS subjects.

Conclusions

Decreased levels of prolactin may reflect disturbed pituitary activity as well as disrupt immunological system regulation at the early stage of multiple sclerosis. **Acknowledgment**

The study was supported with CMKP grant no. 501-1-31-22-2015.

Increased GH response to GHRH plus pyridostigmine unrelated to augmented glomerular filtration rate in DM-1

Jesús Pérez-Luís1,2, Judith López-Fernández1,2, Isabel Mascaréño1,2 & Javier Salvador1

1Hospital Universitario de Canarias, Tenerife, Spain; 2Universidad de La Laguna, Tenerife, Spain; 3Hospital Universidad de Navarra, Pamplona, Spain.

**Introduction and Objectives**

In patients with poorly controlled DM-1, the frequently observed alterations of somatotrophic axis seem to be related to abnormalities in the hypothalamic cholinergic tone regulating this axis. The effects of cholinergic stimulation on GH responses to GHRH were evaluated in patients with poorly controlled DM-1 and the relationship of these responses to metabolic control and kidney function tests. **Subjects and Methods**

Microalbuminuria and creatinine clearance (GFR) on 24 h urine samples, and the effects of GHRH plus placebo and plus pyridostigmine on GH and glucose circulating levels were studied in 16 young males: 10 normal controls and 6 patients with poorly controlled DM-1 (HbA1c 9.2%) without retinopathy or nephropathy. On different days, placebo or pyridostigmine (120 mg) were given orally at 0830 and GHRH 50 mcg IV at 0930. Blood samples were drawn at 0830, 0900 and then every 15 min until 1130. Response parameters were calculated. Data are expressed as mean ± SEM.

**Results**

GHRH raised GH levels within each group. However, while GH responses were not different between diabetics and controls after GHRH plus placebo, they were actually higher after GHRH plus pyridostigmine in diabetics (AUC of response of GH in diabetics 20.62 vs 110.12 SEM, P < 0.05). UFC was negatively correlated with HbA1c. Basally, GH did not correlate with ACTH nor cortisol levels.

**Conclusions**

The higher UFC figures in diabetics suggest some degree of hypercortisolism in poorly controlled DM-1. Cholinergic activation in diabetics elicits GH hyperresponse, but does not modify cortisol or ACTH levels, either in diabetics or controls. This fact speaks against an altered common mechanism in the cholinergic system regulating somatotrophic and HPA axes in DM-1, suggesting that cholinergic tone is not involved in the raised UFC excretion seen in these patients.

DOI: 10.1530/endoabs.49.EP910

Endocrine Abstracts (2017) Vol 49
Conclusions
In this study, the higher GH responses to GHRH plus pyridostigmine in diabetics suggest that there is an augmented cholinergic tone in poorly controlled DM-1 patients. Furthermore, these findings are not related with the higher GFR observed in diabetics.

Increased morbidity associated with the treatment of craniopharyngioma
Cristina Capatina1,2, Anda Dumitrusca2, Andra Caragheorgheopol2 & Catalina Poiana1,2
1Carol Davila University of Medicine and Pharmacy, Department of Endocrinology, Bucharest, Romania; 2C.I.Parhon National Institute of Endocrinology, Bucharest, Romania.

Background
Craniopharyngioma is a rare epithelial tumor of the central nervous system, affecting both children and adults and associated with significant morbidity.

Objective
To study the posttreatment evolution of craniopharyngioma in children and adults in a large mixed cohort.

Material and Methods
We performed a retrospective review of craniopharyngioma patients evaluated in the National Institute of Endocrinology in Bucharest between 1990 and 2016.

Results
A total of 82 patients (59 adults, 39.27 ± 15.5 years old; 23 children, 12.96 ± 4.2 years old) with a mean follow-up of 6.85 years were included. All underwent surgery (57 cases, 69.5% transcranial, 25 cases, 30.48% transsphenoidal approach), 34 being operated on more than once. 13 patients (15.85%) were irradiated (1 before surgery, the others after). The surgical excision was complete in 26 cases (31.7%). Surgery led to anosmia (in 7 cases), CSF leak (3 cases), impairment, 5 (6.09%) had hypothalamic syndrome (diurnal sleepiness, appetite and memory dysfunction). The endocrine dysfunction was aggravated after treatment in 64 cases (78%), improved in 5 (6%) and stable in 14 cases (17%). The evolution of the tumor revealed stable remnant in 29 cases (35.3%), progressively increasing remnant in 23 cases (28%), recurrence in 2 (3.4%) and cure in 28 cases (34.14%) during follow-up. There was no significant difference in the complications rate between children and adults.

Conclusions
Craniopharyngioma is a tumor frequently necessitating repeated treatments, associated with very significant morbidity. The results and complications of treatment are similar in adults and children.

The PATRO adults study of Omnitrope for the treatment of adult patients with growth hormone deficiency: latest results
Paolo Beck-Peccoz1, Charlotte Ho¨ ybye2, Robert Murray3, Suat Simsek4, Markus Zabransky5 & G u¨ nter Stalla6
1Fondazione Istituto di Ricovero e Cura a Carattere Scientifico Ca` Granda Ospedale Maggiore Policlinico, Milan, Italy; 2Karolinska University Hospital, Stockholm, Sweden; 3St James’s University Hospital, Leeds, UK; 4Medisch Centrum Alkmaar, Alkmaar, The Netherlands; 5Sandoz International GmbH, Holzkirchen, Germany; 6Max Planck Institute of Psychiatry, Munich, Germany.

Introduction
The ongoing, international, open, longitudinal, non-interventional study, PATRO Adults, aims to determine the long-term safety and efficacy of Omnitrope® (Sandoz), a recombinant human growth hormone (rGH). Safety data from an interim analysis are presented here.

Methods
Eligible patients are male or female adults who are receiving treatment with Omnitrope® and who have provided informed consent. Patients treated with another rGH before starting Omnitrope® therapy are eligible for inclusion. The primary objective of the study is to assess the safety and efficacy of Omnitrope® in adults treated in routine clinical practice, with particular emphasis placed on the risk of glucose intolerance or diabetes and normalisation of IGF-I levels.

Results
As of December 2016, 1121 patients had been enrolled on the study, of whom 586 (52.3%) were pre-treated with another rGH. Mean (standard deviation [SD]) patient age was 49.7 (15.3) years, and mean (SD) BMI was 29.4 (6.3) kg/m². In total 2455 adverse events (AEs) in 665 (59.3%) patients have been reported, with 444 (in 247 [22%] patients) of these regarded as serious. One hundred and thirty-nine AEs in 80 (7.1%) patients were suspected to be drug-related; these included general disorders/administration site conditions in 19 patients, nervous system disorders in 23 patients and musculoskeletal/connective tissue disorders in 24 patients. A total of 29 serious AEs in 17 (1.5%) patients were suspected to be related to Omnitrope® treatment, including one incidence of diabetes. Of the 188 patients who discontinued treatment, 47 (25%) did so due to an AE.

Conclusions
Based on this interim analysis, Omnitrope® treatment in adults with GHD is well tolerated in a real-life clinical practice setting, both in previously treated and rGH-nave patients. The ongoing PATRO Adults study will provide further data on the diabetogenic potential and overall safety of long-term GH treatment in this population.

Clinical case description of family with hereditary pituitary adenoma
Tatiana Tarasova, Ekaterina Pigarova, Larisa Dzeranova, Anatoly Tulpakov & Ivan Dedov
Endocrinology Research Centre, Moscow, Russia.

Introduction
In recent years, more attention is driven to the cause of hereditary forms of pituitary adenomas. Although for most cases causal genes are not discovered yet, AIP mutations are the most prevalent.

Materials and Methods
Case descriptions, high-parallel sequencing using a gene panel (MEN1, CDKN1B, PRRARIA, GNAS, AIP, SDHA, SDHB, SDH, SDH, PRKCA, CDKN2C, CDKN2A, POU1F1, PITG2).

Case description
Index case – a 59-year-old man with clinical features of acromegaly (the size of adenomas at baseline 3.9 × 3.2 × 3.9 cm, growth 165 cm), secondary diabetes mellitus, multidural goiter, obesity I grade, arterial hypertension. First clinical symptoms were noted since the age of 30 years. At the age of 51 he underwent transcranial adenomectomy, then at the age of 58 years – transnasal adenomectomy. Because of persistent disease activity he was initiated medical therapy with sandostatin analogs (40 mg of octreotide depo) without hormonal control of acromegaly – IGF 497.5 ng/ml (15–250) and GH 80 ng/ml (0–1.2). MRI after surgery pituitary adenoma with supra-, infras- and parasellar extension. The patient’s 28-year-old son also has acromegaly (intrasellar pituitary macroadenoma at MRI (the size of adenomas 0.7 × 1.2 × 0.6 cm), first clinical symptoms were noted since the age of 27 years, growth 167 cm, without complications); he was operated transnasally at the age of 28 years without postoperative remission: GH at OGTT 2.67-2.52-1.95:2.05·2.37 ng/ml, IGF 567.2 ng/ml (60–280). Genetic investigation revealed a mutation in exon 6 of the AIP gene pR271W (not previously described, possible pathological).

Conclusion
AIP mutation in our family with hereditary pituitary adenoma is associated with high aggressiveness and resistance to medical therapy with somatostatin analogs.

DOI: 10.1530/endoabs.49.EP913

Molecular and genetic basis of the disease in families with pituitary adenomas
Tatiana Tarasova, Ekaterina Pigarova, Larisa Dzeranova, Anatoly Tulpakov & Ivan Dedov
Endocrinology Research Centre, Moscow, Russia.

Introduction
Most of the work on the analysis of molecular genetic defects in pituitary adenomas devoted to the study of 1–2 candidate genes. The high-performance parallel sequencing is more promising.

Endocrine Abstracts (2017) Vol 49
Materials and Methods
There were a total of 26 families (58 patients, 36 (62.1%) men and 22 (37.9%) women) with pituitary adenomas secretion of various types. The number of families with homogenous type was 17 (somatotropinomas 13, prolactinomas 2, corticotropinomas 1, inactive pituitary adenomas 1), with a heterogeneous type – 9 (7 of these families had somatotropinomas/inactive pituitary adenomas, 2 families had prolactinomas/inactive pituitary adenomas. The number of family members with hypertension ranged from 2 to 7. The high-performance parallel sequencing was implemented with the gene panel (MEN1, CDKN1B, PRKAR1A, GNAS, AIP, SDHA, SDHB, SDHC, SDHD, PRKCA, CDKN2C, CDKN2A, POU1F1, PTTG2).

Genetic investigation
According to a study in four patients with somatotropinomasidentified mutations were AIP p.R271W and p.A411GfsX47, one patient was identified with polymorphisms with unproven value in pathological gene SDHA p.V589V, and one patient with the phenotype of McCune-Albright syndrome had heterozygous p.S163P replacement in SDHB gene.

Conclusion
The genetic changes using a multi-gene panel were identified in only 20% of tested families. New gene candidates are highly needed for familial pituitary adenomas.

Pituitary adenoma with gigantism and TSH-induced hyperthyroidism: a case report
M Gloria Raena-Nieto, Rosa Márquez-Pardo, Manuel Cayón-Blanco, Lourdes García-García-Doncel, Rosario López-Velasco & Isabel M Torres-Barea
Hospital de Jerez, Jerez, Cádiz, Spain.

Abstract
A 14-yr-old male patient with acromegaly and TSH-induced hyperthyroidism is reported. He was referred for hormonal study due to clinical suspicion of acromegaly. Physical examination showed acromegalic/gigantism features (high stature: 194.5 cm (2 SD), large hands and feet, high arched palate, high forehead, and pronounced brow ridge). No goiter was found. GH levels were high and were not suppressed after oral glucose (GH: 12.50 ng/ml, GH after glucose: 6.19 ng/ml, IGF-1: 1391 ng/ml); Serum thyroid hormones levels were high, although TSH levels were not suppressed (TSH: 0.96 mU/ml, T4: 3.57 ng/dl, T3: 11.06 ng/ml). Antithyroglobulin, antimicrosomal autoantibody, and TSH receptor antibody were negative. Gonadotropines, prolactine and ACTH levels were normal (Prolactina: 12.79 ng/dl, LH: 9.37, FSH: 4.56, Testosterona: 760.8 ng/dl, Cortisol: 5.9 mcg/dl, ACTH: 15.1 pg/ml). A pituitary magnetic resonance imaging of the pituitary revealed a 7-mm adenoma. He was diagnosed of acromegaly and hyperthyroidism. Pre-operative treatment with octreotide was initiated and transphenoidal surgery was performed to remove the pituitary adenoma. Post-operative serum thyroid hormone and GH levels returned to normal, and IGF-1 levels were still elevated (786 ng/ml). Immunohistochemical staining of the operative specimen showed positive reactions to both TSH and GH. Pituitary gigantism is a rare condition caused by growth hormone secreting pituitary tumor. Chromophobe adenoma producing either acromegaly and hyperthyroidism have been described in a limited number of cases none of them on an infant.

Secretin protects from apoptosis by activation of ERK1/2 and CREB
Lei Wang & Billy Chow
The University of Hong Kong, Hong Kong, Hong Kong.

Abstract
There are a growing number of studies identifying secretin as a neuroprotective factor. Consistently, our previous data showed that neuronal apoptosis considerably increased in the developing cerebellum from secretin knockout (Sct-/-) mice. However, the underlying mechanisms remained poorly understood. Extracellular signal-regulated protein kinase (ERK) and Akt signalling pathways are known for the regulation of apoptosis. Additionally, these two pathways could activate cAMP-response-element-binding protein (CREB), which has been shown to promote cell survival. Therefore, their phosphorylation levels in the cerebellum were compared between Sct-/- and WT mice. The basal levels of phosphor-ERK1/2 (pERK1/2) and phosphor-CREB (pCREB) showed a significant decrease in Sct-/- mice, but not phosphor-AKT (pAKT). The cerebellar slices obtained from Sct-/- displayed a dose-dependent increase of pERK1/2 and pCREB, but not pAKT, in response to graded concentrations of secretin peptide and the impaired phosphorylation of ERK1/2 and CREB in Sct-/- cerebellar slices was able to be recovered by the treatment of secretin compared with WT, suggesting the involvement of ERK1/2 and CREB. Specific inhibitors were applied for further confirmation. Secretin failed to reduce the level of activated Caspase-3 when either ERK1/2 or CREB was inhibited, revealing that ERK1/2 and CREB was required for secretin’s neuroprotective function. Our results clearly provide evidence that ERK1/2 and CREB play a role in mediating the anti-apoptotic function of secretin.

Predictors of remission after transsphenoidal adenomectomy in patients with Cushing’s disease
Eugenia Marova, Galina Kolesnicova, Svetlana Arapova, Andrey Grigoriev & Anasteyza Lapshina
Endocrinology Research Centre, Moscow, Russia.

Abstract
Cushing’s disease (CD) is the heavy disease of the hypothalamic–pituitary–adrenal axis. The cause of the disease is pituitary adenoma (corticotropeoma). Hypersecretion of ACTH by a pituitary adenoma leads to increased secretion of cortisol by the adrenal cortex and the development of total endogenous hypercortisolism. The gold standard treatment for this disease is surgical removal of corticotropinoma. However, adenomectomy is not effective in all cases and approximately 20% of cases after the radical treatment fails to achieve remission of the disease and then comes the relapse. The aim of our work was to evaluate the factors influencing the remission of adenomas in patients with the Cushing’s disease and identification of recurrence predictors. Materials and methods: retrospective assessment of clinical and hormonal factors in 84 patients with CD, influencing early and long-term results of adenomectomy.

Copeptin after arginine infusion for the differential diagnosis of the polyuria–polydipsia syndrome “The CARGO-Study”
Bettina Winzeler, Nicole Nigro, Julie Refardt & Mirjam Christ-Crain
University Hospital Basel, Basel, Switzerland.

Background
The spectrum of polyuria-polydipsia syndrome (PPS) includes diabetes insipidus (central or nephrogenic) and primary polydipsia. In clinical practice the differential diagnosis particularly of central diabetes insipidus (CDI) and primary polydipsia (PP) is often difficult. The current gold standard – the water deprivation test (WDT) with or without vasopressin (AVP) measurements – lacks reliable diagnostic accuracy. Arginine infusion is known to stimulate various hormones secreted by the anterior pituitary gland such as growth hormone and prolactin. Based on own preliminary data we hypothesized that arginine also stimulates AVP and the impaired phosphorylation of CARGO-Study. The C-terminal part of the precursor peptide. The aim of this study was to evaluate the diagnostic utility of copeptin measurements after arginine infusion in patients with PPS. Methods: Between 2013 and 2017 patients with polyuria-polydipsia syndrome were included in this prospective study. Patients underwent first a standard water deprivation test for diagnosis of PP or CDI and second an arginine infusion test (arginine infusion without prior WDT).
Results
A total of 51 patients (63% female) were enrolled. 28 (55%) patients were diagnosed with PP. 11 (22%) with complete DI and 12 (23%) with partial DI. The study was terminated in January 2017. Final results of copeptin levels will be measured in batch analysis in February 2017 and compared between patients with complete cDI, partial cDI and PP as well as 20 healthy volunteers. We would be delighted to present the final results of this study at the 19th European Congress of Endocrinology.

Significance
If our hypothesis is true, copeptin measurements after arginine infusion are a promising new tool in the differential diagnosis of polyuria–polydypsia syndrome with the advantage of short and safe test protocol.

Diabetes mellitus in Cushing' syndrome: a systematic review
Thiá Londero1,2, Ana Marra Moreira1,2, Cristiano Leitão1,2, Ticiana Rodrigues1 & Mauro Czepielewski1,2
1Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; 2Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Introduction
Diabetes mellitus (DM) is an expected condition in Cushing syndrome (CS) but there are few data about prevalence and factors associated to occurrence of DM in these patients.

Objective
To determine the main aspects of DM in CS through a systematic review (SR) of the literature.

Methods
MEDLINE and LILACS were searched for studies published until March, 2016. Search strategy comprised the terms “Diabetes Mellitus”, “Glucose Intolerance”, “Hyperglycemia”, “Cushing Syndrome”, “Pituitary ACTH hypersecretion”, “diabetes melito”, “Cushing”. Observational/interventional studies in patients with endogenous CS with characterization of DM were included. We excluded case reports, animal models, and studies about exogenous hypercortisolism or subclinical CS.

Results
The initial search yielded 726 titles, 58 were full-text reviewed. Of these, 12 were included in KS. Seven studies (all cross-sectional) accessed DM prevalence. Most patients were women (93.5%) aged 40–50 years, with disease duration between 29 and 180 months. Pituitary, adrenal and ectopic ACTH were origin of CS in 325 (70.6%), 134 (29%) and 2 (0.5%) patients, respectively. DM prevalence ranged from 17 to 47%. Four studies evaluated the role of body mass index (BMI) on DM occurrence, but none of them found a statistically significant difference. Two studies demonstrated a higher risk of DM in older ages at CS diagnosis. The correlation of DM and severity of hypercortisolism was analysed in four articles and two of them presented a positive result. The effect of CS remission on DM cure was accessed by two studies, with discordant results. DM was associated with higher mortality. Three studies (open-label trials) analysed effect of CS drug therapy on glycemic control. Mifepristone demonstrated a diabetes improvement after 6 months, as rosiglitazone after 30–120 days.

Conclusion
DM is a frequent CS comorbidity and its occurrence seems to depend on age at diagnosis and disease duration. If CS remission leads to DM remission is still uncertain.

DOI: 10.1530/endoabs.49.EP920

EP921
Kallmann syndrome: about eleven clinical cases
Liliana Fonseca, Cláudia Amaral, Jorge Doria, Isabel Palm, Rui Carvalho, Helena Cardoso, Joana Vilaverde & Fátima Borges
Centro Hospitalar e Universitário do Porto, Porto, Portugal.

Idiopathic congenital hypogonadotropic hypogonadism (CHH) is a rare reproductive disorder that is primarily caused by a gonadotrophin-releasing hormone (GnRH) deficiency. When CHH is associated with hyposmia or anosmia is designated by Kallmann Syndrome (KS). This syndrome is a genetic disorder with significant genetic heterogeneity that may present as a sporadic or familial case, following autosomal dominant, autosomal recessive, or X-linked recessive modes of inheritance. This work aims is to review all KS cases followed in the Endocrinology service. A total of 11 cases were evaluated, 10 men and 1 woman. Patients were mainly diagnosed in late adolescence, between 17 and 18 years old, when sought a doctor for delayed puberty. All cases presented hypogonadotropic hypogonadism and hyposmia or anosmia with MRI olfactory bulb atrophy criteria. No other changes in the neuroendocrine axis were found. The patients were followed between 2 and 33 years (mean time 12 years). All had gonadal steroid hormones treatment (testosterone or estradiol) and had a good secondary development of the sexual characteristics, Tanner stage IV/V. Three patients had fertility therapy with gonadotropin and until now only the girl had clinical improvements. Four cases made a genetic study: two mutations in KAL1 gene, one in FGR1, and one in PROK2 were found. The two patients with KAL1 mutation presented cryptorchidism and one the two also had unilateral renal agenesis. The patient with FGR1 mutation also had an history of cryptorchidism. The one with recessive mutation for PROK2 only presented anosmia and hypogonadotropic hypogonadism.

Conclusion
The presence of a delayed pubertal development is suspicious of CHH/KS occurrence. In our study, patients with KS presented good clinical results with the use of gonadal steroid hormones attaining stages IV/V of Tanner. Women appear to have better fertility responses to therapy than men, although this findings demand further investigation.

Thyroiditis and hypophysitis caused by nivolumab
Leticia Perez Fernandez, Isabel Azcona Monreal, María Martínez García, María Elena Lopez Alaminos, Pablo Trincado Aznar, Diana Boj Carceller, Diego Alvarez Ballano & Patricia de Diego García
H.U. Miguel Servet, Zaragoza, Spain.

Introduction
Nivolumab is an anti-programmed cell death-1 monoclonal antibody approved for the treatment of metastatic malignant melanoma. Several endocrine disorders have been reported as immune-related adverse effects. However, nivolumab-induced hypophysitis has a lower incidence than ipilimumab.

Case report
A 69-years old man with metastatic melanoma started to receive nivolumab. Ten weeks after the first cycle of nivolumab he presented hyperthyroidism in blood test. As it was suspected Hashimoto’s thyroiditis none antithyroid drug was started. The thyroid scintigraphy and the presence of anti-thyroid peroxidase antibodies confirmed the diagnosis and the thyroid function was monitoring. Forty days later, the laboratory findings showed hypothyroidism and levothyroxine was provided. Nivolumab treatment continued to be administered. Three months later, the patient was admitted because of general weakness and mild confusional state. Blood test showed severe hypernatremia (110 mEq/l) with a decreased plasma osmolality (250 mOsm/kg). Adrenal insufficiency was suspected so a new blood sample was taken in order to determine cortisol (2.68 μg/dl) and ACTH (< 5 pg/ml) and hydrocortisone treatment was beginning promptly. The assessment of hypothalamic-pituitary-gonadal axis showed a slight decrease in testosterone (1.24 ng/ml) with LH and FSH normal levels. Insulin-like growth factor-1 (IGF-1) was normal, as well as prolactin. Thyroid function was abnormal because of discontinuation of treatment with levothyroxine: TSH 25.47 μU/ml, FT4 0.39 ng/dl. Magnetic resonance imaging scan was performed and it was reported as mild enlargement of the pituitary gland and the stalk. Hydrocortisone treatment was continued after the patient was discharged from hospital. Two weeks later, normal sodium levels were showed in biochemical test.

Discussion
Monoclonal antibodies used in malignant melanoma as ipilimumab or nivolumab could cause several endocrine autoimmune disorders. Despite hypothyroidism is a common adverse effect, hypophysitis is a rare finding associated to nivolumab in contrast to ipilimumab. Clinicians should suspect this pathology in order to achieve a prompt diagnosis.

Endocrine manifestations of multisystem Langerhans cell histiocytosis
Diana Oliveira1, Flavia Napoli2, Enrica Bertelli2, Alessandra Maggioni2, Sandra Paiva3, Francisco Carrilho2 & Natascia Di Iorgi2
1Endocrinology, Diabetes and Metabolism Department, Coimbra Hospital and University Center, Coimbra, Portugal; 2Pediatric Clinic, Endocrinology and Diabetes Unit, IRCCS G Gaslini, University of Genova, Genova, Italy.

Introduction

Multisystem Langerhans cell histiocytosis (LCH) is a rare heterogeneous disorder caused by accumulation in multiple organs of dendritic cells phenotypically similar to cutaneous Langerhans cells. Pituitary involvement is present in about 25% of cases, and central diabetes insipidus is the most common defect in that setting. Panhypopituitarism is rare, but hypothalamic-pituitary dysfunction is amongst the most frequent long-term complications of the disease.

Case report

We describe the case of a child with normal health status until the age of 7. He developed polyuria and polydipsia, was hospitalised and submitted to a water deprivation test, considered indicative of psychogenic polydipsia. At 14-years-old, elevated liver enzymes were attributed to EBV infection. Liver ultrasound showed hepatomegaly and heterogeneous echotexture. At 16-years-old, he presented with hypotension, delayed puberty and short stature, as well as slowly progressive dyspnea. Investigation revealed multiple pituitary defects (hypogonadotropic hypogonadism, secondary hypothyroidism, secondary adrenal insufficiency, growth hormone deficiency) and central diabetes insipidus. Brain magnetic resonance imaging showed a hypothalamic mass (17 mm). He was started on hormonal replacement therapy (urofollitropin, human chorionic gonadotropin, levothyroxine, cortisone, desmopressin). LCH was suspected, and chest computed tomography revealed multiple cystic pulmonary lesions suggestive of the diagnosis, later confirmed by pulmonary biopsy. He started standard treatment with vinblasticin and prednisone, with intermediate response after 6 weeks. He developed glucocorticoid-induced diabetes and needed multiple daily injections of insulin.

Conclusions

This case report illustrates the importance of investigating multiple signs and symptoms that arise in a multisystem and complex disorder. In this case, the endocrine consequences of LCH assume a central role. As was the case here, central diabetes insipidus can be the first manifestation of the disease, but its diagnosis is not always straightforward. Early diagnosis can prevent or delay permanent complications associated with multisystem disease; pituitary defects, once established, are mostly permanent.

Growth hormone deficiency – the experience of one pediatric endocrinology unit of a Portuguese hospital in the last 5 years
Jorge Abreu Ferreira, Fabio Barroso, Cristina Martins, Joana Freitas, Helena Cardoso, Maria Joao Oliveira & Teresa Borges
Paediatric Endocrinology Unit - Centro Materno Infantil do Norte – Centro Hospitalar e Universitario do Porto, Porto, Portugal.

Introduction

Hypopituitarism is a clinical syndrome of deficiency in growth hormone (GHD) production, which can occur isolated or associated with other pituitary defects. GHD has an incidence of 1:4000 to 1:10 000. It may be idiopathic, congenital or acquired.

Purpose

Characterize the paediatric population with GHD followed at the Paediatric Endocrinology Unit of our centre and compare the clinical presentation and treatment response of the patients with an idiopathic form with the ones with isolated and multiple hormonal deficiencies.

Methods

Retrospective observational study with analysis of clinical records of children and adolescents with GHD under treatment with GH in the period from 2012 to 2016. Statistical analyses were performed using SPSS 24.0 for Windows.

Results

The final sample consisted in 49 patients, 61.2% were male. Mean age at the beginning of therapy was 9.7 ± 4 years (0.13–16.92). Mean height z-score at time of diagnosis was −3.16 ± 0.94, corresponding the mean z-score of the target height to −1.24 ± 0.77. The mean delay in bone age was 2.22 ± 1.50 years (0-6.5 years). Two growth hormone stimulation tests (clonidine and L-Dopa) were performed in 69.4% of the cases. Brain MRI showed changes in 42.9% of the cases. Of the 49 patients, 55.1% had an idiopathic GHD, 30.6% isolated deficiency and 14.3% had multiple deficiencies. Mean age at the time of diagnosis was 11.16, 8.84 and 6.57 years in the three groups respectively. Mean treatment duration was 3.92 years (in 14.2% less than 1 year). The z-score variation in the group of idiopathic GHD was 0.99, 1.50 and 2.53 in the group of isolated and multiple deficiencies respectively.

Discussion

As previously described, GHD is more prevalent in males. Comparing the three groups, patients with multiple deficiency are diagnosed earlier and have better results with the treatment (higher z-score variation).

SSTR2 inhibits GH-secreting pituitary tumoral cells migration and invasion by increasing cofilin phosphorylation
Erika Peverelli1, Elena Giardino1, Donatella Treppiedi1, Marco Locatelli2, Andrea G Lania2, Maura Arosio3, Anna Spada4 & Giovanni Mantovani1
1Endocrine Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico; Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; 2Neurosurgery Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Milan, Italy; 3Endocrine Unit, IRCCS Humanitas Clinical Institute, Humanitas University, Rozzano, Italy.

Although generally benign, pituitary tumors frequently present local invasiveness that strongly reduces neurosurgery success. We recently demonstrated a role for the actin binding protein cofilin in promoting non functioning pituitary tumors invasiveness and an inhibitory effect of dopamine receptor type 2. Somatostatin (SS) receptor type 2 (SSTR2) is the main target of pharmacological therapy of GH-secreting pituitary tumors, reducing both GH secretion and cell proliferation, but its effects on cell invasion have never been investigated. Aims of this study were: i) to evaluate the effects of SSTR2 agonist on migration and invasion of rat somatomammotroph GH3 cells and human GH-secreting pituitary tumoral cells, and ii) to investigate the molecular mechanisms focusing on the role of cofilin and the cytoskeleton protein FNLA, that directly interacts with SSTR2. Our data demonstrated that SSTR2 agonist BIM23120 incubation significantly reduced migration (31.3% ± 12.2%, P < 0.01) and invasion on collagen IV (22% ± 3.6%, P < 0.001) of GH3, these data being replicated in human GH-secreting tumoral cells (14 ± 2.9%, 41.7 ± 11.3% reduction of cell migration and invasion, respectively, P < 0.05). Moreover, BIM23120 induced a marked increase of phosphorylated (inactive) cofilin in both GH3 and primary tumoral pituitary cells (about 2.7 and 2.1-fold over basal, respectively). This effect was completely abolished by specific ROCK inhibitor BLY27632 but not by pertussis toxin, suggesting an involvement of Rho/ROCK/LIMK pathway and excluding a role for inhibitory heterotrimeric G proteins. Co-immunopreipitation experiments revealed an association of SSTR2 with FNLA, cofilin and LIMK1, suggesting a role for FNLA as scaffold protein mediating SS effects on cofilin pathway. In conclusion, our data revealed an inhibitory effect of SSTR2 on GH-secreting pituitary tumor cells migration and invasion involving ROCK-dependent phosphorylation of cofilin.

Anti-proliferative effect of sodium metasemite (KML001) on ACTH-secreting pituitary adenoma cells

Dong Sun Kim¹, Jung Hwan Park¹* & Yeon-Ah Sung²

¹Department of Internal Medicine, Hanyang University College of Medicine, Seoul, Republic of Korea; ²Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, Republic of Korea.

KML001 is an orally bioavailable and water soluble trivalent arsenic compound having anti-cancer activity via controlling the numerous signaling pathways including phosphoinositide 3-kinase (PI3K)/Akt and extracellular signal-regulated kinase (ERK) signaling pathways. PI3K/Akt and ERK signaling pathways are overactivated in adrenocorticotropic hormone (ACTH)-secreting pituitary adenoma. In this study, we evaluated the effects of KML001 on cell viability, cell cycle, apoptosis, and ACTH secretion in mouse ACTH-secreting pituitary adenoma cells, AtT-20 cells. KML001 inhibited the cell viability in time-dependent and concentration-dependent manners and significantly decreased the ACTH secretion in a concentration-dependent manner. As the treatment time or treatment concentration increased, KML001 significantly increased the percentage of AtT-20 cells in apoptosis. As the treatment time or treatment concentration increased, KML001 significantly increased the percentage of AtT-20 cells in the G0/G1 phase and significantly decreased the percentage of AtT-20 cells in the S and G2/M phases. The effect of KML001 on numerous signaling pathways was determined by western blots. The phosphorylated form of Akt and mammalian target of rapamycin (mTOR) proteins were decreased in KML001-treated AtT-20 cells. Consequently, KML001 inhibited cell cycle progression of AtT-20 cells via inhibition of cell cycle by inhibition of PI3K/Akt and ERK signaling pathways and induction of apoptosis by activation of p38-MAPK and JNK pathways and might reduce ACTH secretion. These results suggest that KML001 could be a candidate for the treatment of persistent or recurrent Cushing’s disease.

Angiogenesis-related proteins in pituitary adenomas

Ninela Minaskan Karabud¹, Michael Atkinson² & Natalia Pellegata¹

¹Institute of Diabetes and Cancer (HMGU), München, Germany; ²Institute of Radiation Biology (HMGU), München, Germany.

Pituitary adenomas are frequent intracranial tumors that often associate with the hypersecretion of pituitary hormones or may be non-secretion (nonfunctioning pituitary adenomas, NFPAs). Tumors resembling human NFPAs develop with complete penetrance in rats affected by the multiple neurofibromatosis type 1 (MEN1) syndrome. This syndrome is caused by germline loss of function mutation in p27Kip1 gene. Gene expression array analysis performed in our group identified a considerable number of genes deregulated in rat pituitary tumors compared to normal pituitary tissues. Some of the deregulated transcripts are associated with angiogenesis, including vascular endothelial growth factor (Vegf), angiopoietin-1 (Ang-1) and -2 (Ang-2). VEGF and ANG-2 were found to promote angiogenesis in several tumor types, while ANG-1 inhibits this process and stabilizes mature vessels. We analyzed mRNA and protein expression changes of these 3 genes in the pituitary adenomas of MENX-affected rats and compared the results with similar analyses conducted on the corresponding human tumors. We could show that Ang-1 was down regulated in rat and human NFPAs whereas Ang-2 mRNA was highly expressed in almost all of the rat pituitary adenomas and was enhanced in less than the half of the human NFPAs. Vegf mRNA was up-regulated in MENX-rats but not in NFPAs. At the protein level, we have so far set up the immunochemical staining for Ang1 and -2 on rat and human tumors. We could show that rat pituitary adenomas and human NFPAs show reduced cytoplasmic Ang-1 staining compared to adjacent non tumor cells while Ang-2 was more strongly expressed in tumor areas.

Chronic cortisol excess as a consequence of ACTH overproduction from a pituitary tumour is responsible for the development of Cushing’s disease (CD). The first-line treatment for CD is pituitary surgery, but medical treatment is an alternative second-line approach to control cortisol excess. Among pharmacological agents, the adrenal-blocking drug ketoconazole (KT), is able to control cortisol excess in the majority of patients with CD. During KT treatment, the adrenal block of corticosteroid production is expected to induce increase in ACTH levels, but conflicting data demonstrated ACTH to be increased, unchanged or decreased, suggesting a possible direct KT effect on the pituitary tumour. The aim of the current study was to evaluate the effects of KT on cell viability and apoptosis in mouse corticotroph tumour cell line (AtT20-D16). MTT assay was assessed to evaluate cell viability and to evaluate the induction of cell apoptosis the study of mitochondrial potential 3-C1 assay and of PARP cleavage by western blot were performed. KT induced a dose- (from 10-12 M to 6×10–5 M) and time – (from 24 h to 144 h) dependent inhibition of cell viability (82.4%, P<0.0001 at 6×10–5 M and 34% P<0.01 at 10–5 M after 144 h). KT treatment at 24 and 48 h induced depolarization of mitochondrial membrane potential (108%, P<0.027 at IC50 2.5×10–5 M) followed by PARP cleavage, confirming the activation of apoptosis. In conclusion, these preliminary data suggest that KT has a direct effect on pituitary tumour significantly reducing cell viability and inducing apoptosis on a corticotroph tumour cell model, shedding new light on the possible mechanisms by which KT may control cortisol excess in CD.

GPR101 orphan receptor: a novel cause of growth hormone deregulation

Dayana Abboud¹, Adrian Daly², Nadine Dupuis³, Céline Laschet¹, Bernard Pirotte³, Albert Beckers² & Julien Hanson¹,³

¹Laboratory of Molecular Pharmacology, GIGA-Molecular Biology of disease, University of Liege, Liege, Belgium; ²Department of Endocrinology, CHU of Liege, Liege, Belgium; ³Laboratory of Molecular Pharmacology, University of Liege, Liege, Belgium.

GPR101 is an orphan G-protein coupled receptor with unknown ligand. In 2014, an international study clearly pointed to a strong association between this receptor and the X-linked acrogigantism (X-LAG) syndrome, which begins in childhood and causes the “tallest giants”. The children (carriers of the GPR101 duplication on the X chromosome) grow abnormally even before they are one year old, secrete phenomenal quantities of growth hormone, and develop pituitary adenomas that do not respond to current therapies. The mechanism by which GPR101 contributes to increased growth hormone secretion is currently not known. Nevertheless, the lack of mechanistic insight into the function of GPR101 precludes its validation as a drug target. This lack of knowledge on GPR101 is the consequence of the paucity of specific pharmacological/research tools currently available. Therefore, we propose to study GPR101 functions and its role in growth hormone regulation. First, we determined the receptor precise cellular localization and trafficking. We also deciphered its constitutive signalling pathways by detecting high cAMP levels as well as arrestin recruitment to GPR101. We completed our study with an examination of receptor coupling pathways by detecting high cAMP levels as well as arrestin recruitment to GPR101. We completed our study with an examination of receptor coupling. Some of the deregulated transcripts are associated with angiogenesis, including vascular endothelial growth factor (Vegf), angiopoietin-1 (Ang-1) and -2 (Ang-2). VEGF and ANG-2 were found to promote angiogenesis in several tumor types, while ANG-1 inhibits this process and stabilizes mature vessels. We analyzed mRNA and protein expression changes of these 3 genes in the pituitary adenomas of MENX-affected rats and compared the results with similar analyses conducted on the corresponding human tumors. We could show that Ang-1 was down regulated in rat and human NFPAs whereas Ang-2 mRNA was highly expressed in almost all of the rat pituitary adenomas and was enhanced in less than the half of the human NFPAs. Vegf mRNA was up-regulated in MENX-rats but not in NFPAs. At the protein level, we have so far set up the immunochemical staining for Ang1 and -2 on rat and human tumors. We could show that rat pituitary adenomas and human NFPAs show reduced cytoplasmic Ang-1 staining compared to adjacent non tumor cells while Ang-2 was more strongly expressed in tumor areas.

DOI: 10.1530/endoabs.49.EP926
between GPR101 and X-LAG with a pharmacological approach. Furthermore, we applied targeted mutagenesis to modulate the receptor constitutive activity in order to understand the receptor function at a molecular level. These GPR101 mutants will help us to understand the role of this receptor in GH regulation and/or to treat people suffering from pituitary dysfunction. This information is an absolute prerequisite to link molecular pharmacology of GPR101 with physiological functions.

Potential role of biguanides and statins in the treatment of pituitary adenomas

Mari C. Vázquez-Borrego1, Antonio C Fuentes-Fayos1, Alejandro Ibáñez-Costa1, Cristobal Blanco-Acevedo2, Eva Venegas-Moreno3, María A Gálvez-Moreno4, Alfonso Soto-Moreno5, Justo P. Castaño6 & Raul M. Luque1

1Maimonides Institute of Biomedical Research of Cordoba (IMIBIC); Reina Sofia University Hospital (HUS); 2Department of Cell Biology, Physiology and Immunology, University of Cordoba; CIBER Physiopatho, Cordoba, Spain; 3Neurology Service, HURS/IMIBIC, Cordoba, Spain; 4Metabolism and Nutrition Unit, Virgen del Rocío Hospital; Biomedical Institute of Seville (IBIS), Seville, Spain; 5Service of Endocrinology and Nutrition, HURS/IMIBIC, Cordoba, Spain.

Pituitary adenomas (PA) comprise a commonly underestimated pathology in terms of incidence and associated morbimortality. To date, somatostatin and dopamine analogs represent the main medical treatment, but an appreciable subset of patients are resistant or poorly responsive to these drugs. Therefore, the search for new approaches to control tumor growth and/or hormone secretion is crucial. Biguanides such as metformin (MF; commonly used to treat type-2 diabetes), phenformin (PF) and buformin (BF) have been shown to exert antitumor actions in different tumor types. Likewise, statins (such as atorvastatin or simvastatin) treatment have been also related to antineoplastic effects in several tumor types. Accordingly, the aim of this study was to elucidate the direct effect of biguanides and statins, alone or in combination, on key functional parameters (i.e. cell viability, hormone secretion, etc.) in human PA cell cultures [non-functioning pituitary adenomas (NFPA); n = 8], corticotropinomas (ACTHomas; n = 7) and somatotropinomas (GHomas; n = 4) and/or rodent pituitary cell-lines (AtT-20 and GH3). The results showed that biguanides and statins clearly inhibited cell viability in pituitary cell-lines (being PF and simvastatin the most effective compounds, respectively), and a similar effect was also observed with biguanides in all PA-subtypes. Additionally, the co-administration of biguanides and statins did not alter the initial inhibitory actions of these compounds separately in cell lines, which might suggest that biguanides and statins exert their effects through common signaling pathways. In addition, biguanides were able to significantly reduce GH and ACTH secretion in GH3 and AtT-20 cell lines, respectively. Taken together, our results reveal a clear inhibitory effect of biguanides and statins on PA cell viability and, given their demonstrated clinical safety, suggest a potential therapeutic role of these compounds for the treatment of patients with PA.

Abstract withdrawn.
transfected the murine corticotroph cell line AtT-20 with USP8 WT or mutant plasmids and performed Tandem-Ubiquitin-Binding-Entity (TUBE) assays, followed by nanoLC-MS/MS analysis to identify changes in poly-ubiquitinated protein abundance. Of the 10 analyzed proteins by IIC, 4 had an altered expression pattern between USP8 WT and mutated tumors, namely p27kip1 (mean expression: 1 ± 0.8 vs 0.4 ± 0.6 (P = 0.01), HSP90 (mean expression: 1.8 ± 0.8 vs 0.7 ± 0.8 (P = 0.03), CRHR (mean expression: 0.4 ± 0.5 vs 0.6 ± 0.7 (P = 0.2) and PRKACA (mean expression: 0.6 ± 0.8 vs 1.1 ± 0.6 (P = 0.1). TUBE assays revealed an increased de-ubiquitination of Small Ubiquitin-Like Modifier 3 (SUMO3) in USP8mut transfected cells, suggesting co-occurrence of another post-translational protein modification. In conclusion, these results suggest a much more complicated mechanism of action of the identified mutations in USP8, with sumoylation adding another dimension to the regulation of a USP8 mediated equilibrium between degradation and recycling.

Acquired temozolomide resistance in ACTH-secreting pituitary tumour cells
Ticiana Silva, Peter Van Koetsveld, Fadime Dogan, Richard Feelders & Leo Holland
Erasmus MC, Rotterdam, The Netherlands.

Introduction
Temozolomide (TMZ) treatment has been used for aggressive pituitary tumours with positive results, but has proven ineffective in controlling tumour regrowth in cases of disease recurrence. TMZ resistance has been linked to the expression of 06-methyl-guaine-DNA-methyltransferase (MGMT) protein and mismatch repair components (MMR). In the present study, we describe the development of an in vitro model of acquired resistance to TMZ and the mechanisms involved in such resistance.

Methods
Mouse AtT20 corticotroph pituitary adenoma cells were used. The TMZ resistance protocol consisted of three challenges of TMZ using a previously determined EC50 (50% of the maximal effect) dose. AtT20 cells treated with challenges of the vehicle dimethyl sulfoxide were used as control.

Results
The first TMZ challenge already induced a significant increase in EC50 decrease (TMZ-challenged cells (17 μM vs control 3 μM, P <0.001). After 9 weeks following the third TMZ challenge, TMZ-challenged cells remained resistant (18 μM vs control 2 μM, P <0.001). In control cells, TMZ treatment caused an accumulation of cells in G2/M phase (P <0.001), while in TMZ-challenged cells no accumulation was observed (P = 0.91). In control cells, 50 μM of TMZ induced maximum 11-fold stimulation of apoptosis (1132 ± 241% vs 100 ± 5%, P = 0.0008), whereas in TMZ-challenged cells a significantly lower (2.4-fold) increase in apoptosis was observed (244 ± 55% vs 100 ± 26%, P = 0.003). The mRNA expression of MGMT was higher and of MMR components (MSH6, MSH2 and PMS2) was lower in TMZ-challenged cells compared to control cells (P <0.001).

Conclusion
The present study describes an acquired temozolomide resistant cell corticotroph pituitary adenoma model. The TMZ resistance is demonstrated by a sustained increase in TMZ EC50, a lack of cell cycle changes and lower TMZ-induced increase in apoptosis. Acquired TMZ resistance is associated with strongly increased MGMT expression and lowered expression of components of the MMR system.

HER2, EGFR and PDGF family members as potential prognostic markers and their therapeutic implications
Ana Silvia Corlan1, Anca Cimpean2, Marius Raica1, Eugen Melnic2 & Raluca Amalia Ceausu3
1Department of Microscopic Morphology/Histology, Angiogenesis Research Center, University of Medicine and Pharmacy Timisoara, Timisoara, Russia; 2Department of Pathology, Nicolae Testemitanu University of Medicine and Pharmacy, Chisinau, Moldova, Chisinau, Republic of Moldova.

Background
The role of EGFR, HER2, PDGF-A and the axis PDGF-B/ PDGFR-β in the pathogenesis of pituitary adenomas and their correlation with the tumoral immunoprofile are poorly understood.

Results
33.33% of adenomas showed a positive immunohistochemical reaction for HER2- with a membranous and cytoplasmatic pattern- the first one prevailing. The restriction of HER-2 expression to the membrane was noticed in the basopholic cells of basophilic or mixed adenomas. For the acrophilic cells: the expression of HER2 was mostly cytoplasmatic with a granular pattern. In pure adenomas, the only significant correlation with the expression of HER-2 was shown for prolactinomas. For bihormonal adenomas we obtained a significant correlation of HER-2 with the coexpression of GH-PRL, PRL-LH, TSH-FSH, TSH-LH. The gene amplification pattern confirmed the expression of HER-2 in 33.3% of adenomas positive for HER-2. For adenomas positive for EGFR, we obtained a significant correlation with the coexpression of GH-PRL, PRL-LH, TSH-FSH, TSH-LH (partial correlation), PRL-ACTH (total correlation). We analyzed the effects of PDGF-A and PDGF-B on adenoma cells, depending on their immunoprofile. For each of these 2 factors, 60–80% of tumor cells were immunohistochemically positive. We obtained data contradictory to the published one: a positive correlation between PDGF-A and prolactin expression. We confirmed the known association between PDGF-B and somatotrophinomas.

Discussion and conclusions
We identified a positive correlation between PDGF-B and PDGFR-B expression, implying a role for this axis in the pathogenesis of pituitary adenomas. The FSH-LH association induces the overexpression of HER-2 in pituitary adenomas, specifying a unique subtype of adenomas. We noticed the expression of EGFR in peritumoral macrophages and folliculo-stellate cells, leaving new opportunities for studying the role of folliculo-stellate cells and the pathogenic role of EGFR in these tumors.

Carbohydrate metabolism disturbances at different types of acromegaly treatment
Alexandr Dreval1 & Anna Vinogradova
Moscow Regional Scientific Research Clinical Institute named after M.F.Vladimirskiy, Moscow, Russia.

Purpose
To investigate the carbohydrate metabolism in depend on acromegaly treatment.

Methods
23 patients with newly diagnosed acromegaly (NA) were observed. Carbohydrate metabolism were investigated after somatostatin analogues treatment (SSA) (14 patients) or after surgery (TSA) (9 patients). Groups were comparable on age, BMI, acromegaly duration. Were researched HbA1c, fasting plasma glucose level (FPG), indexes of insulin resistance (the HOMA-IR, a Matsuda-index), areas under the curve of insulin within the first 30 minutes (AUC ins30) and from 30 to 120 minute (AUC ins30-120) of the oral glucose tolerance test initially and after the treatment.

Results
At NA patients FPG, HbA1c authentically (P<0.05) worsened within 3-6 months of SSA treatment and considerably (P<0.08) improved after TSA. In 3 months of SSA therapy extent of depression of an AUCIns30 considerably exceeded extent of depression of an AUCIns30-120 (in 11 and 2.3 times respectively (P<0.05)). Whereas in 3 months after TSA extent of depression of an AUCIns30 was comparable to extent of depression of an AUCIns30-120 (2.4 times and 3.2 times respectively).

Conclusions
The decreasing of hepatic IR and peripheral insulin sensitivity in condition of higher level of insulin in compare with patients receiving SSA at most of these patients leads to normalization of carbohydrate metabolism. The greatest changes of parameters of carbohydrate metabolism (Matsuda-index augmentation, depression of the NOMA-IR index, insulin secretion depression) are noted in 3 months of SSA therapy, and further remain at the previous level or change slightly. It is recommended to carry out control of a condition of carbohydrate metabolism at patients with an acromegaly, first of all, in 3 months both after the carried-out surgical treatment, and after the beginning of SSA therapy.

Carbohydrate metabolism disturbances at different types of acromegaly treatment

Prevalence of discordant acromegaly after surgical treatment and its clinical implications in a third LEVEL hospital in Latinamerica
Mireya Pérez, Arturo Peña, Carlos Rojas & Alma Vergara
Centro Médico 20 de Noviembre, Mexico, Mexico.

Background
Acromegaly results from excess growth hormone (GH) secretion by a pituitary adenoma in 95% of the cases. Discordant acromegaly is defined by the elevation of GH with normal levels of insulin-like growth factor factor type 1 (IGF-1) or normal levels of GH associated with an elevation of IGF-1. Its an important situation in the follow-up period of patients with acromegaly because there is little information about patient treatment, comorbidities and follow-up. The objective of this study was to describe the prevalence of discordant acromegaly after pituitary surgery, follow changes in GH and IGF-1 patterns over time and explore possible correlations with blood pressure and HbA1C.

Methods
We retrospectively analyzed the prevalence and characteristics of patients who had an elevated IGF-1 but normal GH or an elevation of GH with normal IGF-1, in consecutive post-surgical acromegaly cases from the year 2000 to 2015 at our institution. To define discordant acromegaly in our study hormonal evaluation was obtained at the 3 months post surgically (GH and IGF-1). Discordant patients were categorized into two groups according to the postoperative GH and IGF-1: high IGF-1 group (normal GH and high IGF-1), high GH group (high GH and normal IGF-1). We followed discordant patients at 6 and 12 months with GH, IGF-1, magnetic resonance (only at 6 months), blood pressure and HbA1C.

Results
The prevalence of discordant acromegaly was 11.7% (9/77). Of this patient population 77.7% (7/9) changed their biochemical pattern after 12 months of follow-up. Of these, 11.3% (1/9) in the high GH group became inactive, 66.6% (6/9) became active (high IGF-1 group), and 22.2% (2/9) remained discordant (both in the high GH group) and had normal suppression of GH to glucose. Positive correlations were found between the level of IGF-1 at 6 months with systolic blood pressure (R = 0.89; P = 0.002) and diastolic blood pressure (R = 0.891; P = 0.002). No correlation was found between GH, IGF-1 and HbA1C or tumor size.

Conclusions
Discordant acromegaly in the postsurgical state is a rare entity, with variation in hormonal patterns at 12-month follow up and a positive correlation with blood pressure levels. We suggest that this patients need to be carefully followed due to the high likelihood of recurrence, particularly if the elevation is of IGF-1 and with the presence of residual tumor.

Four decades without diagnosis: Sheehan's syndrome, a retrospective analysis
Denz Gokalp1, Gulistan Alpagat2, Alpaslan Kemal Tuzcu1, Mithat Bahceci3, Sadie Tuzcu4, Fatime Yakut5 & Azat Yildirim6
1Department of Endocrinology, Acibadem Medical University, Istanbul, Turkey; 2Department of Endocrinology, Dicle University School of Medicine, Diyarbakir, Turkey; 3Izmir Ataturk Education and Research Hospital, Izmir, Turkey; 4Department of Nuclear Medicine, Gazi Yasargil Education and Research Hospital, Diyarbakir, Turkey; 5Department of Radiology, Diyarbakir Memorial Hospital, Diyarbakir, Turkey; 6Azad Yildirim Department of Orthopedics, Gazi Yasargil Education and Research Hospital, Diyarbakir, Turkey.

Aim
Sheehan’s syndrome (SS) remains a frequent cause of hypopituitarism in undeveloped and developing countries, but due to improvements in obstetric care, it is rare in developed countries. We aimed to share the results of a retrospective study analyzing the demographic, clinical, imaging, and hormonal characteristics of a large group of patients with SS, and also increase awareness of this syndrome especially in developed countries.

Methods
The medical records of 124 patients with SS patients who were followed up in the Endocrinology Department of Dicle University between 1995 and 2015 were assessed retrospectively.

Results
The mean period of diagnostic delay was 20.37 ± 8.34 years on average. 5.7% of patients with SS were literate; 62% of patients delivered at home. Anemia was identified in 64.5% of SS patients. Mean blood sodium levels were 129.8 ± 11.3 mEq/L. The mean urine densities were 1013 ± 6.5. Osteoporosis and osteopenia were found in 44 (35.4%) and 71 (57.2%) patients, respectively. According to pituitary magnetic resonance imaging (MRI) analyses, 92 (74.2%) patients with SS had completely empty sella, 29 (23.3%) had partially empty sella, and 1 patient had microadenoma, and 2 had normal pituitary MRI results.

Conclusions
Improved obstetric care and effective interventions for postpartum hemorrhage have limited the prevalence of SS in developed countries. However, in developing countries like Turkey, SS due to postpartum bleeding remains common. Thus, physician’s awareness of the symptoms of SS is urgently required to avoid the associated morbidity and mortality.

A case of IgG4-related hypophysitis with long-term cyclic evolution
Iconauna Laura, Bauleau Felicia, Muteuganya Raoul & Karmali Ralik
CHU Brugmann, Bruxelles, Belgium.

Introduction
IgG4-related disease is a newly recognized entity associated with autoimmune conditions involving almost every organ system, characterized by elevated serum
IgG4 as well as mass like tissue infiltration by IgG4-positive plasma cells. Pituitary gland can be involved and can presented as hypophysitis.

Case description
We report a case of a 56-year-old man, who has been suffering for the nine last years of episodes of fatigue and headaches with spontaneous remission was admitted to our hospital for headaches, fatigue, myalgia, diplopia and visual disturbances. The endocrine assessment revealed a complete anti-hypopituitarism. Dynamic LRH and CRH tests revealed a delayed but robust response of gonadotrophins and corticotroph. MRI scan showed nodular thickening of the pituitary and pituitary stalk with minimal compression of the optic chiasm. Other pathology than sarcoidosis was suspected and further investigation showed high levels of blood IgG4. All these findings were highly suggestive for a diagnosis of IgG4-related hypophysitis. Steroids were administered and within 24 hours, the patient became completely asymptomatic. A month later, thyroid and gonadal function normalized. Cranial MRI scan showed a net decrease in the size of the pituitary gland compared to the previous examination.

Conclusions
We report a case of IgG4-related hypophysitis who responded completely and rapidly to steroids. Intriguingly, according to his past medical history, he might have presented a cyclical evolution of his disease with periods of spontaneous remission. It’s a rare condition but increasingly recognized and should be sought in face of an acute swelling of the pituitary gland and/or its stalk, since its favorable response to steroid therapy should help to avoid unnecessary surgery.

Duhok/IRAQ acromegaly; one year of experience
Bayar Qasim
University of Duhok/College of Medicine, Duhok, Iraq.

Background
Acromegaly is a rare hormonal disorder; the prevalence is ~60 cases/million population1. Incidence: 3.3 new cases/million/year1 Mortality rate 2-4 times that of general population2. It is usually the result of a somatotrope adenoma in more than 95% of cases.

Aim
By June 2016, we were celebrating one year of experience in acromegaly. It was the first time to open acromegaly service in Duhok city/Kurdistan region/IRAQ. This review will include all registered patients during this year. Aim of this revision to give a brief about our patients’ characteristics and how we can plan for future?

Methods
This is retrospective study involving ten patients, all patients diagnosed by high IGF1 level followed by GH suppression test and MRI of pituitary gland. Those patients underwent transphenoidal resection, diagnosis confirmed by histopathology too.

Results
Our patients characteristics are shown. The median age of presentation was 44.9. Headache and acral enlargement was the most common presentation.

Discussion
Most patients with acromegaly are diagnosed with a macroadenoma. This review include ten patients, eight of them were from Duhok including Zaxo and Akre, two of them they moved to live in this city, one from the capital Baghdad and another patient from syrian refugee. The prevalence of acromegaly in Duhok city was 8.2 persons/million/year, while the incidence was of new cases was 5.3/million/year. This high number of patients reflects the new input for patients to this service as this was not present before June 2015. Eight patients were operable they prepared by somatostatin analogue followed by surgery.

Conclusion and recommendations
The two dilemmas we are facing here in Duhok/IRAQ are: First; delayed diagnosis as reflected by the fact all of our patients are macroadenoma at presentation, that is why we need to increase awareness about this disease. Secondly; low compliance for medical treatment: to improve this we need to provide free measurement of both GH and IGF1 levels for all patients receiving somatostatin analogue treatment.

Presurgical medical treatment in Cushing’s disease
Paloma Moreno-Moreno1, Ana Barrera-Martin1, Alejandro Ibáñez-Costa2, María Rosa Alhambra-Expósito1, Concepción Muñoz-Jiménez2, María Angeles Gálvez-Moreno1, Justo P Cástano-Fuentes3 & Raúl M Luque-Huertas1
Management Unit of Clinical Endocrinology and Nutrition, University Hospital Reina Sofía, Córdoba, Andalucia, Spain; 2Department of Cell Biology, Physiology and Immunology, Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC), Hospital Universitario Reina Sofía, CIBER Fisiopatologo, University of Córdoba, Córdoba, Andalucia, Spain.

Introduction
The duration of hypercortisolism in Cushing’s disease (CD) appears to be inversely related to the reversibility of complications, which in turn increase mortality. This makes it necessary to identify medical therapies capable of normalizing cortisol overproduction before transphenoidal surgery. The aim of this study was to determine if the clinical data of patients with CD before surgery allow predicting the presence and/or abundance of somatostatin (ssts) and dopamine (DRs) receptors at the corticotrophic adenoma, in order to start a more effective and personalized presurgical medical treatment.

Patients and methods
Retrospective study performed through review of clinical histories and molecular profile analysis of corticotrophic tumors. We included all patients diagnosed with CD (2005–2014) treated with transphenoidal surgery, and whose tumor sample was analyzed in the Department of Cell Biology, Physiology and Immunology of the University From Córdoba. The correlation study was performed using Spearman’s r.

Results
Nine women with CD and molecular profile analysis of corticotrophic tumor. Age 47.35±12 years. A positive correlation was observed between tumor size at diagnosis and levels of receptor expression sst2 (r=0.731 (P=0.044)), sst3 (r=0.735 (P=0.038)), DR2 (r=0.821 (P=0.023)), DR4 (r=0.946 (P=0.000)) y DR5 (r=0.900 (P=0.037)). In addition, there was a marked inverse correlation between ACTH levels at diagnosis and the sst5 receptor r=-0.767 (P=0.016).

Conclusions
Tumor size at the diagnosis of CD seems to show a direct correlation with the levels of expression of sst2 and DR2 receptors, suggesting that in patients with CD with macroadenoma in the initial study, preoperative treatment with somatostatin analogs and/or dopamine may be helpful. In addition, the inverse correlation between ACTH levels at diagnosis and sst5 expression questions whether the specific analogues of this receptor would be useful in the preoperative treatment of CD.

Characteristics and 1-year follow-up of patients with profound hyponatremia due to primary polydipsia – a multicentre prospective observational study
Clara Sailler1-3, Bettina Winzeler1-3, Nicole Nigro3, Isabelle Suter-Widmer1, Birsen Ariç1, Martina Bally2, Philipp Schuetz2-3, Beat Mueller2-3 & Mirjam Christ-Crain1-3
1Endocrinology, Diabetology and Metabolism, University Basel, Basel, Switzerland; 2Division of Endocrinology, Diabetology and Metabolism, Medical University Clinic, Kantonsspital Aarau, Aarau, Switzerland; 3Department of Clinical Research, University Hospital Basel, Basel, Switzerland.

Introduction
Hyponatremia due to excessive fluid intake (i.e. primary polydipsia (PP)) is common. It may culminate in profound hyponatremia – carrying considerable risk of morbidity. However, data on patients with PP leading to hyponatremia is largely lacking. Herein, we describe the characteristics of polydipsic patients hospitalised with profound hyponatremia, and assess one-year outcomes.

Method
In this prospective observational study, we included 23 patients with an episode of profound hyponatremia (≤125 mmol/l) due to PP. Patients were classified into subgroups: psychogenic polydipsia (PsyP), dopogenic polydipsia (DOP), and beer potomania (BP). Symptoms, laboratory findings, and factors contributing to hyponatremia (co-morbidities, medication, and liquid intake) were assessed. A

DOI: 10.1530/endoabs.49.EP942
1-year follow-up was performed to evaluate recurrence of hyponatremia, re-admission rate, and mortality.

Results
Of the 23 patients (median age 56 years [IQR 50–65], 74% female) 7 had PylP, 8 DP, and 8 BP. Median serum sodium of all patients was 121 mmol/l (IQR 114–123), median urine osmolality 167 mmol/l (IQR 105–184), and median copeptin 3.6 mmol/l (IQR 1.9–5.5). Psychiatric diagnosis, particularly dependency disorder (43%) and depression (35%), were highly prevalent. Factors provoking hyponatremia were found in all patients (e.g., acute water load, medication, stress). During the follow-up period, 67% of patients were readmitted, 52% of these with re-hyponatremia, and three patients (38%) with BP died.

Conclusion
Patients with PP have a high prevalence of addictive and affective disorders. Given the high recurrence, re-hospitalisation, and mortality rate, careful monitoring and long-term follow-up including controls of serum sodium, education and behavioural therapy is needed.

Success rates of pituitary surgery in acromegaly – a tertiary centre experience in Romania
Miznora Beleviţiţ1, Julia Soare1, Sorina Martin1,2, Anca Sirbu1,2, Alice Albu1,2, Carmen Barbu1,2 & Simona Fica1,2
1Endocrinology Department, Elias Hospital, Bucharest, Romania; 2Endocrinology Department, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Background
Pituitary surgery is the first treatment option for acromegaly. The reported success of pituitary surgery varies between 75 and 95% for microadenomas and 45 and 68% for macroadenomas. The aim of this study was to report our experience regarding the remission rate after pituitary surgery in acromegaly patients.

Methods
This retrospective study included 70 patients diagnosed with acromegaly in our clinic between 2009 and 2016. The criteria used to define remission were random GH < 1 ng/ml and normalization of IGF1 levels for gender and age.

Results
11 patients were lost of follow-up after the first diagnostic visit. We analysed 59 acromegaly patients (33 women and 26 men) with a mean age at diagnosis of 44.93 ± 13.57 years. Microadenoms were found in 15 (25.4%) and macro-adenomas in 44 (74.6%) patients. 6 (10.2%) patients associated both GH and prolactin hypersecretion. Pituitary surgery was performed in 41 patients of which 9 (21.2%) were cured. Additional 7 (21.2%) patients were cured after second surgery and radiotherapy. Radiotherapy was the first treatment in 11 patients of which 3 (27.2%) were cured. Persistent disease after surgery and/or radiotherapy was treated with somatostatin analogs (26), dopamin agonists (18) and GH receptor blocker (6) in mono or combination therapy.

Conclusions
The rate of surgical success in our patients was found to be low (40% for microadenomas, 6.8% for macroadenomas). This could be explained by the fact that most patients presented late at the macroadenoma stage.

EP944
Acromegaly and cardiovascular risk
Betina Biagetti1,2, Anna Aulinuss1, Natividad Lopez1, Esther Garcia-Fernandez1, María José Arnau-Vives1, Andrea Ciudin1, Gabriel Obiols1,2, Belen Dalama1 & Jordi Mesa1
1Vall d’Hebron Hospital, Barcelona, Spain; 2Hospital Universitari de Vic, Barcelona, Spain.

Background
Acromegaly (ACRO) is associated with increased cardiovascular morbidity and mortality, however, there is no evidence of an increase in ischemic heart disease

in these patients. We hypothesized that non-classical cardiovascular risk factors such as epicaldial fat (EF), interventricular septum thickness (IST), carotid intima-media thickness (CIMT), may be increased in ACRO and contribute to this higher cardiovascular morbidity.

Objective
To evaluate EF, IST, and CIMT in patients with ACRO compared to controls and identify possible predictors in this non-classical cardiovascular risk factors.

Material and methods
We studied CIMT, IST, EF in 30 patients with ACRO (16 males, 5 with active disease) and 30 matched controls (by age, sex and body mass index (BMI)).

Results
Both cohorts were identical regarding the presence of cardiovascular risk factors (CVRF). The ACRO cohort presented higher EF and IST compared to the control group (0.65 ± 0.16 vs 0.43 ± 0.14 cm, P = 0.001 and 11.31 ± 1.17 vs 10.64 ± 1.47 mm, P = 0.035, respectively). The presence of ACRO (β 0.545, P < 0.001; R2 297) was the unique positive predictor of EF, while BMI and hypertension were positive predictors of IST (β 0.379, P = 0.006 and β 0.344, P = 0.013, respectively, R2 0.298) in a multiple linear regression model.

Conclusions
Patients with ACRO have higher EF and higher IST (influenced by hypertension and BMI), compared with matched controls despite a similar prevalence of CVRF. Increased EF and IST could partially contribute to this increased cardiovascular morbidity and mortality observed in acromegaly.

Pituitary insufficiency – etiopathogeny and diagnostic aspects
Corina Crista1 & Georgiana Hotaran2
1Clinic of Endocrinology, University of Medicine and Pharmacy ‘Victor Babes’, Timisoara, Romania; 2University of Medicine and Pharmacy ‘Victor Babes’, Timisoara, Romania.

The study group was represented by 155 cases of pituitary insufficiency (age: 37.21 ± 16.05; F/M = 116/39) hospitalized in the Clinic of Endocrinology Timisoara during the period 2006–2014. The cases were classified into endopatogenic groups, as follows: iatrogenic pituitary insufficiency (23.87%), tumor compression (21.29%), ischemia (14.84%), idiopathic hypogonadotropic hypogonadism (3.87%), congenital pituitary insufficiency (6.45%), empty sella (6.45%), functional pituitary insufficiency (23.23%). In majority, the studied cases presented hypogonadism (95.48%), while hypothyroidism was found in 65.16% patients and 50.32% of the cases presented adrenal insufficiency. Neurological signs caused by the tumoral mass were found in 42.58% cases. The ischemic and congenital forms of the pituitary insufficiency associated mostly panhypopituitarism (100%, respectively 50%), while the iatrogenic form and those caused by tumor compression presented in high percentages partial pituitary insufficiency. The comparison of the hormonal parameters (endopatogenic groups) revealed: significant inferior serum levels of testosterone in the congenital form and empty sella vs tumor compression (P < 0.05); significant inferior levels of the serum estradiol (P < 0.01) in congenital panhypopituitarism vs functional secondary hypogonadism; significant inferior levels of the serum TSH (P < 0.05) in patients with pituitary insufficiency caused ischemia vs tumor compression; significant inferior levels of FT4 (P < 0.05) in empty sella and ischemic form vs iatrogenic pituitary insufficiency. The applied therapy targeted the cause of the hypopituitarism and the hormonal substitution.

Abstract unavailable.
Background
Acromegaly is a rare severe disease which, untreated, leads to increased cardiovascular and respiratory morbidity and mortality. Pituitary surgery is the first-line therapy, and medical treatment (somatostatin receptor ligands SRLs, dopamine agonists DA, and GH receptor antagonists GHRAs) is indicated for persistent disease. While selected patients are treated with DA and GHRAs, SRLs remain the mainstay of acromegaly therapy.

Objective
The aim of this study is to report our results regarding medical therapy in patients with persistent acromegaly after surgery and/or radiotherapy. Patients and methods
We retrospectively reviewed 59 patients (33 women and 26 men), diagnosed with acromegaly, mean age at diagnosis 44.93 ± 13.57 years, managed between 2009 and 2016 in our department. Controlled disease was defined as normal IGF-1 for age and sex and random GH <1 ng/ml.

Results
19 patients, cured after surgery or radiotherapy were excluded. 31 patients received medical therapy and 9 were lost during follow up. 26 were treated with SRLs alone or in combination therapy, 3 received DA alone, one DA and GHRAs and one GHRAs alone. SRLs were used as monotherapy in 13 (50%), tritherapy in 3 (11.5%), in combination with DA in 9 patients (34.6%) and with GHRAs in one (3.8%). IGF-1 normalization was achieved in 10 patients (32%), 7 receiving SRLs (five in monotherapy, one with DA and one in tritherapy), two DA alone and 1 with GHRAs alone. Random GH <1 ng/ml was achieved in six patients (19.3%) (three in monotherapy SRLs, two in association with DA and one on DA alone). Controlled disease was found in five patients (16.1%) (three receiving monotherapy with SRLs, one with tritherapy and one with GHRAs).

Conclusion
In long-term follow-up, almost 40% patients got full control of acromegaly, but only 20% of them on medical treatment. Medical approach in acromegaly should be individualized, combination therapy could provide additional biochemical control, but new therapies should be implemented.
Acute presentation of cushing disease: severe hyperglycemia and refractory hypokalemia
Carlos Tavares Bello1,2, Francisco Sousa Santos2, Catia Ferrinhos2, Filipa Alves Serra1, João Sequeira Duarte1 & Carlos Vasconcelos2
1Hospital de Egas Moniz, Lisbon, Portugal; 2Hospital das Forças Armadas, Lisbon, Portugal.

Introduction
Cushing’s syndrome (CS) is a rare disease resulting from prolonged exposure to supraphysiological levels of glucocorticoids. Cushing’s Disease is the most frequent cause of endogenous CS. This disease has a broad spectrum of clinical manifestations and is associated with an increased morbidity-mortality. Diabetes Mellitus (DM) and hypokalemic alkalosis affects up to 50 and 10% of CS patients respectively. Disease onset and severity reflects the magnitude of cortisol excess, being ectopic ACTH production the most frequent cause of acute, severe CS.

Cushing disease tends to have a slower onset with gradual appearance of the typical phenotype and associated metabolic consequences.

Case report
A 62 year old male with a known medical history of obesity and hypertension was admitted to the emergency department with altered mental status, hyperglycemia without oestrogen replacement. We will investigate all pituitary hormonal status with future full data processing in Korean postmenopausal women by CFST.

EP952
Uncomplicated pregnancy in a patient with McCune Albright syndrome (MAS) and active acromegaly
Terroba Larumbe1, Crespo Soto1, Ana Carolina Goyogana1, De Luis Roman2, Urban Lopez De Linare2, Cuellar Olmedo1, Ventosa Vinha1, Calleja Baranda1 & Cabezas García2
1H.U. Rio Hortega, Valladolid, Spain; 2H. Clínico Universitario, Valladolid, Spain.

Introduction
The association of acromegaly and polyostotic fibrous dysplasia is a rare entity that presents more difficulties in achieving an effective treatment than classical acromegaly. Pregnancy is infrequent and carries a high risk when acromegaly is active.

Clinical case
A 27 year old woman surgically treated for facial asymmetry, without café-au-lait spots or precocious puberty, was evaluated in 1992 after a normal pregnancy. In the biochemical tests the following was observed: PRL, 95 ng/ml (1.2–40); GH, 20.9 ng/ml not suppressed during oral glucose overload, IGF-I 943 ng/ml (101–333), T4 and T3 elevated with suppressed TSH. The rest of the data including basal hormones did not show significant alterations. Imaging tests showed diffuse hyperplasia/adenomatosis of the pituitary gland (14 x 20 x 6 mm) with increased left lining and cavernous sinus invasion and findings compatible with fibrous dysplasia affecting numerous bones of the base of the skull and the cranial vault.

In the thyroid scan, a multinodular goiter with calcifications was found. Therapy with bromocriptine (BC) 2.5 mg/day and methimazole was initiated, but acromegaly remained active because the patient refused treatment with subcutaneous octreotide. In 1996 she had an uncomplicated second pregnancy and in January 2000 intramuscular Sandostatin LAR 30 mg/month could be included in the treatment. Magnetic resonance performed after pregnancy showed a small 5 mm focal image compatible with a microadenoma and a pituitary gland close to normal. In 2007 Sandostatin was replaced by GH receptor antagonist Pegvisomant, 20 mg/day subcutaneous because the control objective for IGF-I was not achieved. With this therapy the patient, who also received cabergoline 0.5 mg/wk and metimazol 5 mg/d, was asymptomatic and IGF-I, PRL, thyroid function, cardiac tests, fundus and campimetry were normal.

Discussion
This patient with MAS presented primary hyperthyroidism, hyperprolactinemia and acromegaly with partial response to Sandostatin LAR but complete response to pegvisomant. This drug can be especially useful in the management of MAS-acromegaly for the risks involved in surgery and radiotherapy. Although uncontrolled acromegaly can complicate pregnancy, especially by increasing the risk of gestational diabetes and hypertension, in this case, pregnancy evolved without incident.

EP953
Impact of etiology, age and gender on onset and severity of hypotoporitis in patients with hypopituitarism
Dragana Miljic1,2, Sandra Pekic1,2, Miljana Doknic1,2, Marina Nikolic-Djurovic1,2, Marko Stojanovic1,2, Vera Popovic1 & Milan Petakov1,2
1Department of Neuroendocrinology, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; 2Belgrade University School of Medicine, Belgrade, Serbia.

Hypopituitarism can unmask hypopituitarism and secondary adrenal insufficiency due to potent non-osmotic stimulation of vasopressin release under stressful conditions. Patients and methods: In a retrospective study 25 patients (13/12m, age 58.9 ± 18.6 years) with hypopituitarism (119.7 ± 10.5 mmol/l) were identified.
among 260 in-patients treated for hypopituitarism in our department over a
decade. Results: Hyponatremia was recorded in 9.6% of our patients. In 84% it
was the key to diagnosis of hypopituitarism. Patients with hyponatremia and non-
functioning pituitary macro adenomas (group 1. NPNA n=15) were significantly
older (71.47±4.8 years), compared to patients with hyponatremia from other rare
cases of hypopituitarism (group 2. n=10; age 40.2±15.3 years, P<0.01):
congenital (n=2), Sheehan’s syndrome (n=2), intracranial aneurysm (n=2),
lymphocytic hypophysitis (n=1), traumatic brain injury (n=1), surgery and
radiotherapy for astrocytoma (n=1), pituitary metastasis from bronchial
canceroma (n=1). Male preponderance in patients with NPFA (10/15 i.e.
66.7%) was in contrast to female predominance in patients with other causes of
hypopituitarism (8/10 i.e. 80%). Hyponatremia was more severe in group 2
compared to group 1 (113.5±10.9 mmol/l vs 124.3±8.1 mmol/l, P<0.01).
Conclusion: Hyponatremia is not uncommon in patients with hypopituitarism,
especially at presentation. In older patients, NPFA is the most common
pathology, usually leading to gradual onset of hypopituitarism and non-specific
symptoms, while acute hyponatremia can occur with pituitary apoplexy.
In younger patients severe acute hyponatremia is more common leading to diagnosis
of unrecognized secondary adrenal insufficiency and hypopituitarism from various
causes.

2Belgrade University School of Medicine, Belgrade, Serbia; 3Institute of
Pathology, Belgrade, Serbia; 4Barts and the London School of Medicine,
London, UK; 5Institute de pathologie multi-site des HCL, Lyon, France.

40-year-old female patient presented with acromegaly in 2008 (GH 61 (g/L, IGF-
1 774 ng/ml PRL 1500 mU/L). Macro-adenoma invading the right cavernous
sinus was found on MRI and she underwent two pituitary surgeries revealing
sparsely granulated GH adenoma with scattered PRL cells, low Ki 67 and
negative p53 immuno-staining. Her second cousin was treated for macro
prolactinoma. Both patients tested negative for germline mutations in the AIP
and menin genes. Treatment with somatostatin analogue and dopamine agonist was
initiated. She was well controlled (GH 1.1 (g/L and IGF-1 291 ng/ml) until 2011
(IGF-1 576...608 ng/ml, GH 4.1 (g/L) when she received 20 Gy gamma knife
radio surgery, to the right para-sellar rest and clivus with good response (2012
IGF-1 235.306 ng/ml). In 2014 she became symptomatic with headache, VI
cranial nerve palsy and biochemical deterioration (GH 5.3 (g/L and IGF-1 549
ng/ml). In November 2015 she developed VII & VIII cranial nerve palsy and
biochemically deteriorated (GH 13 (g/L and IGF-1 857 ng/ml). MRI disclosed
tumour progression from the right para-sellar to the infra-sellar region infiltrating
the pituitary sinus was found on MRI and she underwent two pituitary surgeries revealing
549 ng/ml). In November 2015 she developed VII & VIII cranial nerve palsy and
biochemically deteriorated (GH 13 (g/L and IGF-1 857 ng/ml). MRI disclosed
tumour progression from the right para-sellar to the infra-sellar region infiltrating
the pituitary

Case report
We report the case of a 38-year-old man with pathological addiction to gambling
associated with low dose cabergoline treatment for a mixed growth hormone (GH)
and prolactin (PRL)-secreting pituitary adenoma. At the age of 29 he was
diagnosed with mixed (GH and PRL) functioning invasive pituitary adenoma.
After surgery and radiotherapy he was given medical therapy with somatostatin
anallogues and cabergoline. During follow-up somatostatin analogues were
withdrawn but he continued cabergoline treatment to control hypersecretion and
the residual tumour. During follow-up the patient reported pathological gambling
habits. He had spent a large sum of money and, although he had tried to stop
gambling many times he was unable to quit. He did not stop his gambling
behaviour despite a marital crisis and divorce. He had even been to a centre for
addictive disorders without success. We decided to withdraw cabergoline. His
impulse-control disorder (ICD) resolved within months after cabergoline
discontinuation. After 6 months, somatodemin C level was in normal range,
PRL level was mildly high with no sexual dysfunction and the tumour had not
grown.

Conclusions
The gambling episodes diminished after the discontinuation of cabergoline,
providing evidence for a causal relationship. Cabergoline-induced pathological
gambling and another ICDs are probably underreported, and physicians should
consider screening for these in patients treated with dopamine agonists. Screening
for ICDs should be undertaken in all patients with DA-treated prolactinomas.

Spain; 2Neurology Service. Hospital La Mancha Centro, Alcázar de San Juan,
Spain.

Introduction
A link between Dopamine agonists and development of impulse control disorders
is well recognized in the field of neurology. A similar finding in endocrine
patients is emerging.

Case report
We report the case of a 38-year-old man with pathological addiction to gambling
associated with low dose cabergoline treatment for a mixed growth hormone (GH)
and prolactin (PRL)-secreting pituitary adenoma. At the age of 29 he was
diagnosed with mixed (GH and PRL) functioning invasive pituitary adenoma.
After surgery and radiotherapy he was given medical therapy with somatostatin
analogue and dopamine agonist. Avid tracer uptake was noted in the pituitary
tumour and neck lymph node on the left side on FDG PET CT and SST2
analogue and dopamine agonist. Avid tracer uptake was noted in the pituitary

Objective
Hypopituitarism is a rare disease, a pituitary adenoma and is treatment being the
most common cause of it. In recent years there is increased reporting of rare
cases of hypopituitarism acquired in adulthood, such as other rare and
parasellar masses, brain damage caused by radiation and traumatic brain injury
(TBI), vascular lesions, infiltrative/inflammatory/inflammatory diseases and infectious
diseases. Aim of our study was to increase the awareness to these rare
cases of hypopituitarism.

Patients and methods
We performed a cross-sectional database study in our population investigating the
etiology of hypopituitarism in 558 patients in a tertiary care institution recorded
for the last 11 years. We excluded the patients with pituitary adenomas and
genital hypopituitarism. Sixty-eight patients (32 male, 36 female) were
included in the study (mean age 37.3±2.0 years, range 16–72 years).

Results
According to the causes of hypopituitarism the patients were divided in several
groups: nonpituitary sellar and parasellar masses in 10 patients (pilocytoma
n=1, chordoma n=2, metastasis n=3, intravascular lymphoma n=1, Langerhans cell histiocytosis n=3), brain damage in 27 patients (TBI in
9 patients and cranial irradiation in 18 patients), vascular causes in 17 patients
(aneurysm n=1, apoplexy n=3, Sheehan’s syndrome n=6, subarachnoid
hemorrhage n=6, glomangiomma n=1), immunological/inflammatory/inflammatory
disease in 7 patients (primary hypothyposis n=6, secondary hypothyposis n=1) and
pituitary infections in 7 patients (viral hypothyposis-hemorrhagic fever with
renal syndrome, tuberculosis). Growth hormone and ACTH deficiencies were the
most common hormonal deficits (57/68, 84%), followed by FSH/LH deficiency
(52/68, 76%), TSH deficiency (49/68, 72%) and ADH deficiency (868, 12%).
Ten patients (14.7%) had isolated pituitary hormone deficiency. 13 patients
(19.2%) had 2–3 pituitary hormone deficiencies and 4 pituitary hormone deficiencies
were present in 45 patients (66.1%).

DOI: 10.1530/endoabs.49.EP955

Endocrine Abstracts (2017) Vol 49
Conclusion
A high index of suspicion is required for diagnosing rare causes of hypopituitarism. The symptoms and signs of hypopituitarism are usually nonspecific and the recognition of these patients remains the challenge.

DOI: 10.1530/endoabs.49.EP956

Recombinant Human Growth Hormone Treatment in liver transplant patient. Case report
Corina Galesanu
University of Medicine and Pharmacy ‘Grigore T.Popa’, Iasi, Romania.

Background
Liver growth is often impaired after successful liver transplantation. Factors that negatively impacted growth are age, graft function and corticosteroid immunosuppression. Short-statured prepubertal liver transplant recipients who do not show sufficient compensatory growth after transplantation benefit from treatment with recombinant human growth hormone (rhGH).

Case report
We communicate the results after the first year of rhGH treatment in a child of 12 years old, identified with growth failure after a liver transplantation. Liver transplant (live donor: the mother) to 9 years for secondary cirrhosis (biliary atresia), malabsorption syndrome, secondary osteoporosis with multiple femoral fractures on pathological bone. Height = 108 cm (~5 – 5, 92 SDS), and the weight was = 20 kg (~2, 5 SDS). Bone age = 7 years. Bone mineral density (BMD- DXA)–whole body = 0.718 g/cm² (low bone mass acquisition). Blood samples for DXA whole body from 0.718 g/cm² to 0.997 g/cm² (0.0%); body weight increased with 12%. There were no rejection episodes.

Conclusion
In our case rhGH treatment was effective in short, non-GH deficient, liver-transplanted child receiving long term glucocorticoid treatment.

Immune checkpoint inhibitors: an emerging cause of hypophysitis
Ali Rizvi & Brooke McAdams
University of South Carolina School of Medicine, Columbia, South Carolina, USA.

Aim
To describe 2 cases of immune-mediated hypophysitis due to the therapeutic use of Iplimumab, a cytotoxic T-lymphocyte antigen-4 (CTLA4)-blocking antibody.

Case 1
A 62-year-old male with history of metastatic melanoma was started on Iplimumab. After finishing the 4th of 2 months he complained of weakness, fatigue, and fever, prescribed ciprofloxacin and prednisone 20 mg daily, and felt better. 2 days later he was hospitalized with weakness, BP 86/65 mmHg and temperature 101.7F. TSH was 0.050 uU/ml, free T4 0.48 ng/dl, and free T3 1.20 pg/ml FSH 1.2 mIU/ml, LH 0.8 mIU/ml, and prolactin 0.3 n/ml (all low). A Cosyntropin Stimulation Test showed the following cortisol levels (in ug/dl): baseline 2.60, 30 min post-injection 6.30, and 60 min post-injection 7.90. Pituitary MRI was normal. The clinical picture was consistent with severe, recent-onset panhypopituitarism. The patient was treated with IV fluids, stress-dose dexamethasone, and levotorixone, and discharged on hormone replacement treatment. He continues to do well on multi-hormonal endocrine replacement therapy.

Discussion
Iplimumab (Yervoy®) is a monoclonal CTLA4 antibody and immune checkpoint protein-modulator approved for treatment of melanoma, and being studied in lung, prostate, and bladder cancer. Mechanisms of overcoming tumor-induced immune tolerance trigger ‘Immune-related adverse events’ (IRAEs) as side effects from autoimmunity and disruption of self-tolerance. They include colitis/diarrhea, dermatitis, hepatitis, and endocrinopathies (hypophysitis (0–17%), thyroid dysfunction (0–4%) and primary adrenal insufficiency (0.3–1.5%). Iplimumab-associated hypophysitis is a new form of autoimmune pituitary disease with an average time of 11 weeks after starting therapy, suggesting a cumulative effect. Patients may present with weakness, headache, nausea, anorexia, confusion, memory loss, behavior change, hallucinations, visual impairment, loss of libido, temperature dysregulation, fever, and chills. Hormone levels show varying degrees of hypopituitarism, and MRI may be normal or reveal pituitary gland enlargement and thickening of the stalk. Symptoms resolve after withdrawal of the drug and starting hormone replacement; however, pituitary function may be impaired for considerably longer or even lifelong.

Conclusion
The increasing use of immune checkpoint inhibitors such as ipilimumab is an emerging cause of hypophysitis that generalists, ER physicians, oncolgists, and endocrinologists need to be aware of.

EP959
A case of hypopituitarism caused by hemorrhagic fever with renal syndrome
Seung Hee Yu & Kiyoung Lee
Gachon University Gil Medical Center, Incheon, Republic of Korea.

Hemorrhagic fever with renal syndrome (HFRS) is a severe systemic infection caused by hantaviruses that included Hantaan, Seoul, Dobrava, Saaremaa, and Puumala. In Korea, the most common virus is Hantaan. The classical symptoms of HFRS are fever, hemorrhage, hypotension, and renal failure, but the clinical course can be very diverse. Among them, endocrinologic complications, such as hypopituitarism were developed rarely by HFRS. A 49 years-old man admitted our hospital with fever, myalgia and thrombocytopenia. He was diagnosed as HFRS caused by Hantaan and clinical manifestations. In oliguric phase of renal failure, abnormalities of thyroid function, FT4 0.35 ng/dl (0.89–1.78), T3 24.43 ng/dl (60–180) and TSH 0.356 uIU/ml (0.55–4.78), were found and other hormone tests were performed for differential diagnosis. The level of basal hormones were prolactin 13.77 ng/ml (2.1–17.7), GH 2.10 ng/ml (0–1.0), IGFI 112.87 ng/ml (124–310), ACTH 27.8 pg/ml (10.0–60.0), cortisol 13.82 µg/dl (5.27–22.45), LH 3.94 mIU/ml (1.5–9.3), FSH 2.75 mIU/ml (1.4–18.1) and testosterone 104.99 ng/dl (241–827). These results indicated secondary hypogonadism and hypothyroidism and no evidence/was seen hypothalamic or other pituitary disease by sella MRI. According to this result, partial hypopituitarism but HFRS was suspected in the patient. After conservative treatment, manifestations and laboratory investigation were improved. He was discharged and tested the basal hormones again at the outpatient clinic. The results were FT4 1.16 ng/dl, T3 110.43 ng/dl, TSH 1.400 uIU/ml, prolactin 8.27 ng/ml, GH 0.41 ng/ml, IGFI 254.24 µg/ml, ACTH 30.9 pg/ml, cortisol 10.36 ng/dl, LH 2.83 mIU/ml, FSH 6.54 mIU/ml and testosterone 214.05 ng/dl. The thyroid function was recovered to normal level spontaneously and the gonadal hormones were still low level. Compared with initial hormone level, the pituitary function is recovering sequentially. Our experience suggests the important to investigate the endocrinologic complications of HFRS and to determine whether treatment of hormone replacement is needed.

Prevalence and Incidence of pituitary tumors: a nation-wide Populatio-based study using Korean National Health Insurance claims data
Kyeonghye Park1,2, Jungyoo Choi1, Se Hee Park2, Joo Young Nam1, Sun Ok Song1, Young Duk Song1 & Eun Jig Lee2
1National Health Insurance Service Ilsan Hospital, Goyang, Republic of Korea; 2Yonsei University College of Medicine, Seoul, Republic of Korea.

Purpose
We conducted this study to determine the prevalence and incidence of pituitary tumors in South Korea.

Methods
This is a nationwide population- based retrospective study. We analysed two national databases, the Korean National Health Insurance (NHI) claims database and Rare Intractable Disease (RID) registration database, which include information on every patients with pituitary tumor diagnosed through uniform criteria from 2009 to 2013. Pituitary tumor was defined into three types based on...
the ICD-code: i) D35.2 (benign pituitary neoplasm), ii) D35.2+E 22.0 (acromegaly) + E24.0 (Cushing disease), or iii) D35.2+E22.0+E24.0+E22.1 (Hyperprolactinemia) &co-entered D35.2.

Results

The prevalence and incidence of pituitary tumors were described based on the three definitions. By definition i), 25 135 patients had pituitary tumors and included in the prevalence estimates. The prevalence was 40.8, 31.4 and 50.1 per 10^5 populations in total, men and women, respectively. During 2011–2013, total 8 234 incident cases were identified and the incidence was 17.3, 13.7 and 21.0 per 10^5 in total, men and women, respectively. By definition ii), total 25 135 patients had pituitary tumors and prevalence was 52.4, 37.5 and 67.1 per 10^5 populations in total, men and women, respectively. For the incidence estimate, 10 359 patients were identified and the incidence was 21.6, 15.8 and 27.3 per 10^5 in total, men and women, respectively. By definition iii), total 30 175 patients had pituitary tumors and prevalence was 62.9, 38.7 and 86.8 per 10^5 populations in total, men and women, respectively. For the incidence estimate, total 12 544 patients were identified and the incidence was 26.1, 16.3 and 35.9 per 10^5 in total, men and women, respectively.

Conclusions

This study provides reliable information of the epidemiology of pituitary tumors in Asian population, and may help to manage this disease accordingly within our healthcare system.

Prevalence of acromegaly in eight counties of North-East Romania

Laura Feraru1, Carmen Vulpiu1,2, Voichita Mogos1, Corina Galesanu1,2, Dumitru Branisteau1, Maria-Christina Ungureanu1, Leitizia Leustean1, Cristina Cristea1, Simona Mogos1,2, Catalin Buzdaga1,2, Raluca Balaceanu1,2 & Cristina Preda1,2

1University Hospital ‘St Spiridon’, Iasi, Romania; 2University of Medicine and Pharmacy ‘Gr. T. Popa’, Iasi, Romania.

Introduction

The prevalence of acromegaly is estimated to be 6.28/100000 but several studies suggest that acromegaly is underdiagnosed and its prevalence is underestimated.

Aim

To measure the prevalence of clinically relevant acromegaly in a well-defined population using data from 01.04.2004 to 01.11.2016.

Method

Cross-sectional study performed in 8 counties from the North-East Romania. Data of patients with acromegaly were collected using the INFOWORLD programme and acromegaly diagnostic code E22.0. The number of inhabitants for each county was in accord with 2011 Census and 2007 Statistical Directory. We identified all acromegalic patients who were born and resided for each of the eight counties diagnosed in the Department of Endocrinology from the University Hospital ‘St Spiridon’ Iasi, Romania.

Results

238 (164 females and 74 males) patients with acromegaly were identified in a total population of 4.2 million inhabitants. The prevalence for Iasi County was 238 (164 females and 74 males) patients with acromegaly were identified in a total population of 4.2 million inhabitants. The prevalence for Iasi County was 238 (164 females and 74 males) patients with acromegaly were identified in a total population of 4.2 million inhabitants. The prevalence for Iasi County was

A male patient with acromegaly and metastatic renal cell carcinoma: lung, gluteal and scapular metastasis

Ziynet Alphan Uç1 & Ozgur Demir1

1Endocrinology Department, Usak University School of Medicine, Usak, Turkey; 2Endocrinology Department, Ankara University School of Medicine, Ankara, Turkey.

Acromegaly is a chronic condition associated with an increased risk of cancer.

Case presentation

A 41-year-old man admitted to our hospital with gluteal and scapular mass. He had a clinical history of acromegaly which had been diagnosed two years ago, and was treated with trans-sphenoidal surgery. After surgery, although remission was not achieved, he had no doctor visit and control. On physical examination he had typical acromegalic features and there was palpable mass on right gluteal and scapular region, which was noticed by the patient within the last two months. Laboratory examination revealed high levels of GH (10.8 ng/ml), IGF1 (1072 ng/ml). Abdominopelvic CT revealed an 93×68 mm mass on right kidney, 100×65 mm on the right gluteal region and 200×80 mm on the right scapular region. Thorax CT revealed metastatic nodular lesions on the right lung. The diagnosis of metastatic renal clear cell cancer (RCC) was verified with gluteal and scapular biopsies. Pituitary MRI revealed residual macroadenoma (2 cm). Therapy for acromegaly with octreotide LAR was initiated. The patient underwent radiation therapy for the tumors of right scapular, gluteal region. At the same time patient received interferon-alfa therapy for metastatic RCC. After three months of treatment, gluteal, gluteal mass regressed but renal mass and lung metastasis progressed with diffuse pleural effusion on the right side. Sunitinib treatment was started for the follow up.

Discussion

Therefore we report a very rare case of acromegaly with RCC. In addition to the increased circulating GH/IGF-1 levels, local expression of GHR and IGF-1/IGF-IR in the tumor tissues may partly contribute to the growth of multiple tumors. Type I/IGFIR has an influence on renal cells malignant transformation by induction of cell proliferation, dedifferentiation and antiapoptotic effect. The risk of RCC progression would have been very high had the acromegaly been left untreated. Control of acromegaly is mandatory in acromegalic patients with cancer.

EP963

Infundibular lesion presenting with central diabetes insipidus and hypogoanadism

Gulay Sinssek Bagir, Filiz Eksi, Haydardedegolu, Okan Bakiner, Emre Bozkirli & M Eda Eray

Baskent University Faculty of Medicine, Adana, Turkey.

Introduction

Pituitary stalk lesions fall into three categories: congenital and developmental (rathke cleft cyst, ectopic neurohypophysis), inflammatory and infectious (hypophitis, sarcoidosis, tuberculosis), and neoplastic (Langerhans cell histiocytosis, germinoma, metastatic tumors). Herein, we report a case with infundibular lesion presenting with central diabetes insipidus and hypogoanadism.

Case report

A 27-years old woman was admitted to our clinic with the story of amenorrhea and polydipsia lasting for three years. She was on desmopressin for two years. Her physical examination was unremarkable. Hormonal profile was: TSH: 0.79 uIU/ml (0.4–4.67), freeT4: 15.49 pmol/l (11.5–22.7), FSH: 2.03 mIU/ml (1.2–15.4), LH: 1.02 mIU/ml (1.24–7.8), Estradiol: 28.7 pg/ml (30–119), Proctalin: 35.3 ng/ml (2.8–29.2), early morning cortisol: 15.2 μg/dl (4.3–22.4) and IGF1: 152 ng/ml (117–329). Pituitary MRI demonstrated a 7×5 mm infundibular mass with suprasellar extension. Diagnostic work-up for infundibular lesion was performed, including; chest X-ray, computed tomography (CT) of thorax, purified protein derivative (PPD) test and measurement of serum angiotensin converting enzyme (ACE) for ruling out granulomatous diseases. Neck ultrasound, bone scintigraphy, skeletal survey, brain CT and measurement of beta-HCG were performed for ruling out infundibular neoplastic lesions. Serum anti-thyroid peroxidase, anti-thyroglobulin antibody were measured. All were negative. She exhibited no autoimmune background. Serum IgG4 was normal, as well. In addition to existing desmopression, estrogen-progesteron therapy was introduced and menses recovered in a few months. Due to rapid radiological progression at follow-up, methyl prednisolon 1 mg/kg per day was begun for a possible infundibulohypophysitis. Significant radiological regression was observed at the second month of glucocorticoid therapy.

Conclusions

Pituitary stalk lesions have diverse causes and hypophysitis is one of them. In our case, histopathological diagnosis was not possible due to critical location of the infundibular lesion. After detailed work-up, a diagnosis of possible infundibulohypophysitis was made and ampicillin glucocorticoid therapy was introduced and resulted in radiological regression.

Pregnancy in Cushing’s disease after treatment with surgery and cyber-knife radiosurgery

G Gonca Orük¹, Ali Olmezoglu², Melda Apaydin³ & Gönül Güvenç⁴
¹Department of Endocrinology and Metabolism, Atatürk Training and Research Hospital, Katip Celebi University, Izmir, Turkey; ²Department of Radiation Oncology, Celal Bayar University, Manisa, Turkey; ³Department of Radiology, Atatürk Training and Research Hospital, Katip Celebi University, Izmir, Turkey; ⁴Department of Neurosurgery, Atatürk Training and Research Hospital, Katip Celebi University, Izmir, Turkey.

Women affected by Cushing’s disease (CD) are often infertile due to abnormal follicular development or anovulation. In these patients, first line treatment is pituitary surgery, which is effective in more than 83% of cases with macroadenomas, but only in about 35% of those with microadenomas. When surgery do not normalize circulating ACTH and cortisol concentrations, such drugs, e.g. ketoconazole or metirapone, and radiotherapy are used as adjuvant treatment. Concerning radiotherapy, more precise and focused approaches of delivering larger amounts of radiation have been introduced recently in the management of pituitary tumors. Cyber-knife radiosurgery (CKR) is considered as a possible treatment for patients affected by unsuccessfully surgically treated pituitary adenoma or not suitable for surgery. The disadvantages of this technique seem to be the length of time to the onset of remission, which is known to be at least of 6 months, and the possible adverse effects. In patients treated with radiotherapy, however, mild hypercortisolism can persist for a long time and fertility could not be restored, even when menses have been normalized. We report here a case of a 37-year-old female patient with Cushing’s disease (CD) due to ACTH-secreting 5 mm adenoma on the left side of the pituitary. Because complete clinical remission was not obtained by a transsphenoidal surgery in 2010, CKR was performed for to achieve remission in January 2011. Thereafter, treatment with ketoconazole, at the dose of 400 mg daily, normalized serum cortisol and UFC levels, allowing the recovery of regular menses. Because of low FT4 and low TSH and undetectable AbTPO values, L-T4 replacement was started. 5 years after CKR, morning ACTH, cortisol concentrations, 24-h urinary free cortisol (UFC) and cortisol levels after 1-mg dexamethasone (1-mg dex) administration were normalized. MRI also showed partial shrinkage of the pituitary tumor. The patient, who had regular menses, became pregnant 60 months after CKR. During pregnancy, plasma ACTH, serum cortisol and UFC levels increased. Fasting glucose levels (FGL), HbA1c and blood pressure were normal all throughout pregnancy. Overall, patient’s body weight increase was 13.6 kg. At the 38th week of an uneventful pregnancy, the patient delivered vaginally a healthy female newborn (length 48 cm, weight 2600 g). The baby and the mother did not show any biochemical signs or clinical symptoms of hypo- or hypercortisolism. In conclusion, pregnancy should be considered at risk in patients with CD, even the patient has normalized cortisol levels. Moreover, periodic evaluation of pituitary function is mandatory during gestation, due to the high risk of hypopituitarism.

Gender differences in real-life GH dosing patterns in adults with GH deficiency (AGHD): experience from a Registry in France

Françoise Borson-Chazot¹, Evguenia Jaques², Véronique Pascal-Vigneron², Sylvie Salenave³ & Béatrice Villette³
¹Hôpital Louis Pradel, Bron, France; ²Novo Nordisk, La Défense, France; ³Centre Hospitalo-Universitaire Régional, Nancy, France; ⁴Hôpital Bicêtre, Kremlin Bicêtre, France.

Introduction
Usually GHD women require higher GH doses than males, especially those with exogenous oestrogens (guidelines). This fact was assessed in real-life practice in France.

Methods
Data were from a Registry in 84 sites treating AGHD (Nordotropin®) up to 5 years. Naïve patients did not receive GH 6 months before inclusion. Statistics were descriptive.

Results
325 patients (129 naïve) were included; mean age 49.2 years (± 14.3 s.d.). 180 were females (55%) with 72 (40%) naïve; data missing for 6. 147 (81.7%) women had a gonadotropic deficiency: 83 (79%) non-naïve and 54 (75%) naïve treated with oestrogen therapy. At inclusion the median IGF-1 SDS (Q1;Q3) in naïve was 0.00 (−1.30;−1.10) and in non-naive was 0.00 (−1.30;+1.10). The median starting dose was similar for naïve women and men: 0.20 mg/d. After the first year until the end of the follow up (FU) the median dose for naïve women was higher than for men. The median dose was higher for non-naïve females (Table 1). At the end of the FU, the median IGF-1 SDS (Q1; Q3) in naïve population was +0.30 (−0.50;+0.80) and in non-naive was +0.50 (−0.40;+1.20).

</tr>
</tbody>
</table>

Conclusion
In real life, physicians consider the recommendation of higher GH dose for AGHD women at steady state, while the starting dose remains similar in both genders. Data from this Registry is consistent with the published data from other observational studies.

EP965

The clinic-hormonal description of patients with giant pituitary adenomas

Yıldız Urmanova & Kamila Alimova
¹Tashkent Paediatric Medical Institute, Tashkent, Uzbekistan; ²Center of Endocrinology, Taskent, Uzbekistan.

The aim
To study the results of researches 35 patients with different pituitary tumours of sellar area, from them men – 17 (48,6%), women – 18 (51,4%).

Materials and methods
Depending on sizes there are the adenomas of hypophysis, educed on CT/RI, patients were up-diffused on two groups: the first group of patients is macroadenomas (from 20 to 30 mm) – 17 (48,6%), and second group of patients – giant (more than 30 mm) – 18 (51,4%).

Results
It was educed, that in 2 groups of patients most often there was panhypopituitarism – at 8 from 18 patients (44,4%), post-operating

panhypopituitarism met – at 10 from 18 patients (55,5%), while in the 1 group of panhypopituitarism not observed. A bytemporal hemianopsia also with greater frequency was observed for patients 2 groups – 11 supervisions (61,1%).

In addition, secondary amenorrhea met a bowl also for patients 2 groups – 6 (33,3%). Such violations, as secondary ²strepotenia, endocrine encephalopathy, delay of physical and sexual development were educed only in 2 groups of patients. Thus, the most expressed neuroendocrine and ophthalmology violations met for patients 2 groups. For patients with the giant adenomas of hypophysis the decline of level of STH, FSH is first of all marked, LH (45%).

Conclusions
From preliminary data of comparative description of sizes of tumour of sellar area and level of STH a tendency took place to that as far as growth size of tumour of the Turkish saddle the basale level of STH of plasma was below. For a recept the further protracted supervision of data of patients is required of reliable results with an estimation in a dynamics MRI and STH of plasma with realization of loading tests, research of IGF1 and estimation of quality of life for questionnaire of adult growth hormone deficiency (AGDQol).
Is there a role of immunohistochemical expression of pituitary hormones and proliferative marker ki-67 on long-term outcome in our acromegalic patients?

Mustafa Sahin, Caglar Keskin, Sabu Kiremitci, Esra Erden, Asena Canpolat, Murat Cinel, Sülé Çamlar, Ozgur Demir, Sevim Gullu, Rifat Emralı, Murat Faik Erdogan, Veda Gedik, Nilgun Baskal & Denem Corapcioglu
Ankara University School of Medicine endocrinology and Metabolic Diseases Department, Ankara, Turkey.

Expression of hormones other than GH may affect the prognosis in acromegalic patients. Generally, Ki-67 is a well-known proliferative index used to predict remission in pituitary adenomas. We aimed to evaluate the relationship of immunohistochemical expression pituitary hormones, ki-67 and remission. Also, we evaluated the role of pre-operative clinical and laboratory values, pathological characteristics on long-term remission. We included 64 acromegaly patients that were treated surgically and followed up in our Endocrinology and Metabolic Diseases Department. Demographic, clinical, laboratory and imaging data were collected. We also re-evaluated the immunohistochemistry of all pituitary hormones and ki-67 marker from paraffin blocks. We followed 64 patients (38 women, 26 Male; mean age 46.7 ± 11.8) for 61.8 (6–192) months. We did not find any relationship between remission and multihormonal expression in our patients. We also did not find a significant relationship between ki-67 expression or sex with remission. Early diagnosis age (P = 0.045), greater adenoma diameter (P = 0.002), low preoperative LH (P = 0.036) and high postoperative IGF1 (P = 0.0001) only factors that are significantly related with low rate remission. Preoperative cortisol levels are related to ki-67 index level (P = 0.0004). Low preoperative LH and high postoperative IGF1 levels and tumor diameter may be predictive for remission and low cortisol levels may be predictive for the high ki-67 index.

Investigation of the pituitary functions long-term after the acute CNS infections

Gamze Cetinkaya1, Aysegul Ulu Kiliç2, Zuleyha Karaca1, Mehmet Doganay2, ZT Yuce3, Kursad Unluhzarcı1, Fahrettin Kelestimur1 & Fatih Tanriverdi1
1Erciyes University Medical School Department of Endocrinology, Kayseri, Turkey; 2Erciyes University Medical School Department of Infectious Diseases, Kayseri, Turkey.

Objectives

Acute bacterial or viral CNS infections have been shown to result in hypopituitarism during the acute phase, and 6–24 months after the event in a few studies. However, there are no data in the literature regarding the long term pituitary functions after acute CNS infections. This cross-sectional study was designed to evaluate the pituitary functions long-term after the acute bacterial or viral CNS infections.

Methods

19 patients with ages 18–65 (mean: 39.53 ± 17.089 years; 11 male patients, 8 patients female) were included in the study. There were seven patients with acute bacterial meningitis, nine patients with acute viral encephalitis, and three cases of acute meningoencephalitis. Basal pituitary hormone levels were measured and glagucan stimulation test was performed 17–92 months (mean 48.47 ± 25.19 months) after the acute CNS infections. MRI was performed to evaluate the pituitary gland volume and to rule out any co- incidental pituitary mass.

Results

There were a total of 5 patients out of 19 (26.3%) with hypopituitarism; 3 (15.7%) with isolated GH deficiency, 1 (5.2%) with isolated FSH-LH deficiency and 1 (5.2%) with combined FSH-LH and GH deficiency in the study group. Mean pituitary volume was substantially lower in patients with hypopituitarism when compared to the patients without hypopituitarism. But the difference was not statistically significant.

Conclusion

This study clearly demonstrated that high frequency hypopituitarism, GH deficiency in particular, was still present long term after the acute bacterial or viral CNS infections. Therefore, the patients with acute meningitis, meningoencephalitis and/or encephalitis need to be screened at least 4–5 years after the acute event.

DOI: 10.1530/endoabs.49.EP968

Case with headache and pitosis: pituitary macroadenoma or ophtalmoplegic migraine?

Filiz Eksi Haydardedeoglu, Gulya Simsak Bagir, Okan Bakiner, Emre Bozkirli & Mellek Eda Erterer
Baskent University Adana Teaching and Research Center, Adana, Turkey.

Case

A 28-year old man was admitted to our hospital with complaints of three days of severe headache, diplopia and ptosis of the right eye. He had pituitary macroadenoma and had been on cabergolin 0.25 mg/week for the last six months. At physical examination, he demonstrated ptosis and inability to move the right eye mediaally. Magnetic resonance imaging showed a 13 × 12 mm pituitary mass with suprasellar extension and hemorrhage. Visual field analysis was abnormal except the lateral movement of the right eye. Laboratory hormonal analysis showed mild cortisol deficiency only. According to clinical, radiological and laboratory results, he was diagnosed as non-functional pituitary adenoma with apoplexy and III, cranial nerve palsy due to increased intrapituitary pressure. Intravenous methyl-prednisolone was started and symptoms resolved. One month after discharge, although he was using methyl prednisolone 4 mg, he was again admitted with complaints of nausea, vomiting, hypotension and ptosis. He was immediately taken to pituitary surgery via transnasal-transsphenoidal approach. His complaints dissolved following the procedure and he was well at discharge. Histopathological analysis of the operation specimen exhibited a pituitary adenoma with necrosis and hemorrhage. On the fifth postoperative day, he was re-admitted with diplopia, photophobia, phonophobia, nausea and vomiting. Recurrent headache attacks lasting for about one week within the last 6 months reminded us accompanying ophtalmoplegic migraine. Eighty mg ethripion and parenteral pulse steroid (1000 mg methyl prednisolone/5 days) were started. The patient had no longer experienced an attack.

Conclusion

Pituitary apoplexy and ophtalmoplegic migraine are rare clinical entities. Ophthalmpoplegic migraine has been recognized as a cranial neuralgia and characterized by repetitive III, IV and / or VI cranial nerve palsies. If there is persistent headache and cranial nerve palsies following surgical decompression of an adenoma with pituitary apoplexy, accompanying ophtalmoplegic migraine should be kept in mind.

Somatostatin analogues-induced diabetes mellitus in acromegalic patients reverts after drug withdrawal: a long-term study

Daniele Cappellani1, Claudio Urbani2, Chiara Sarredella1, Giulia Marconcini1, Claudio Marcocci1, Giuseppe Rossi2 & Fausto Bogazzi1
1Department of Clinical and Experimental Medicine – Section of Endocrinology, University of Pisa, Pisa, Italy; 2Epidemiology and Biostatistics Unit - Institute of Clinical Physiology, National Research Council (C.N.R.), Pisa, Italy.

Context

Therapy with somatostatin analogues (SSAs) may have deleterious effects on glucose metabolism in patients with acromegaly, often leading to development of diabetes mellitus (DM).

Aim of the study

To evaluate whether DM, which developed during therapy with SSAs, may revert after drug withdrawal and cure of acromegaly with pituitary adenomectomy.

Design

Retrospective cohort study, in a tertiary referral center.

Patients

Eighteen acromegalic patients without DM at the diagnosis of acromegaly treated with SSAs as a primary therapy, and then cured by pituitary adenomectomy.

Methods

Endocrine status and glucose homeostasis were evaluated at diagnosis of acromegaly and at least every six months during SSAs therapy. At each control visit, patients were classified in one of the following classes: normal glucose tolerance, prediabetes, or overt diabetes.

Results

Median follow-up after starting SSAs therapy was 60 months (IQR 53.2–96.2). During SSAs therapy, all patients had controlled acromegaly defined by normal serum IGF-1 concentrations for the age. Among the 13 euglycaemic patients at diagnosis three developed prediabetes and three diabetes, whereas, among the five

Endocrine Abstracts (2017) Vol 49
prediabetic patients at diagnosis two worsened to overt diabetes; three remained in the prediabetic range (P = 0.04). After cure of acromegaly with pituitary adenomectomy and subsequent SSAs withdrawal, prediabetes reverted in five out of six patients, and diabetes in all five patients (in three reverted to euglycaemia, while in two reverted to prediabetes) (P = 0.01).

Conclusions
In acromegalic patients with controlled disease changes of glycaemic status induced by SSAs are not permanent.

EP971
Pituitary metastases of lung cancer presenting with hypopituitarism
Guzin Fidan Yaylalı¹, Senay Topsakal¹, Serkan Değirmencioglu¹ & Semin Melahat Fenkel¹
¹Pamukkale University Medical Faculty Endocrinology Metabolism Department, Denizli, Turkey; ²Pamukkale University Oncology Department, Denizli, Turkey.

Pituitary tumors are the most frequent intracranial neoplasm, affecting 11 000 of the world wide population. However metastases in this location are rare and uncommon presentation of systemic malignancy. Although diabetes insipidus secondary to cancer metastasis to the pituitary gland is a common manifestation, anterior pituitary failure is rare. We present a – 57-year-old man with hypopituitarism secondary to pituitary metastasis from lung cancer.

Case report
A 57-year-old patient active smoker presented with headache of 1 month. Cranial MRI revealed multiple subcortical lesions and hypophysial nodule lesion 13.6 mm in diameter. The computerized tomography scan of the Chest, Abdomen and Pelvis revealed a 23 × 22 mm regularly margined mass in mass in the upper left lobe with mediastinal lymph nodes, liver and right adrenal metastases. Assessment of pituitary function revealed panhypopituitarism; Cortisol: 3.17 µg/dl, ACTH: 11.5 pg/ml free T4, 0.64 ng/dl (normal range 0.97–1.65), thyroid stimulating hormone level of 0.005 mIU/ml (normal range 0.5–4 IU/ml), total testosterone level of 0.025 ng/ml (normal range 2.5–10 ng/ml), follicle stimulating hormone level of 0.5 IU/ml (normal range 1–8.4 IU/ml), luteinizing hormone level of 0.1 IU/l (normal range 1–10.5 IU/l) and normal urine osmolarity. Complete blood count showed the following: hemoglobin 13.6 g/dl, white cell count 12.64 K/ul, and platelet count 322 K/ul Evaluation of serum chemistry revealed lactate dehydrogenase 245 IU/l, sodium 129 mmol/l potassium 4.3 mmol/l. A hormone replacement therapy was indicated urgently. Fiberoptic bronchoscopy did not show any endobronchial lesion. Histopathologic examination of bronchoalveolar lavage revealed metastasis of lung adenocarcinoma.

Conclusion
Despite the fact that pituitary metastasis are rare, they must be evaluated in the presence of pituitary involvement. It may be difficult to differentiate symptoms due to panhypopituitarism from the constitutional symptoms caused by cancer progression. Considering that the life expectancy is limited for advanced lung cancer patients, detection and appropriate treatment of hormonal insufficiency are important to improve their quality of life.

multinodular goiter. On clinical examination; height 153 cm, weight: 67 kg, BMI: 29 BP: 120/70 mm/Hg. The other physical examination findings were normal. Radiologic findings included: Abdominal MRI: in the right adrenal gland, 20 × 12 mm and 33 × 13 mm in left adrenal gland adenomas was detected. The laboratory findings were shown in Table 1. Basal Cortisol levels were detected as 6.6 µg/dl and insulin tolerans test and ACTH stimulation test were performed. (Table 2, Table 3).

Conclusion
Acth deficiency is rare in elderly patients is a complex disease and many diseases that mimic. Sometimes patients are diagnosed by chance. When this case was examined for adrenal adenoma, ACTH deficiency was unexpectedly detected and replacement therapy was started. The clinic has the patient improved rapidly with replacement therapy.

Clinical, histological, molecular features and outcomes of craniopharyngiomas: Single centre experience in Toledo, Spain
Almudena Vicente1, Beatriz Moreno1, Mónica Oliver1, Ana Martinez1, Manuela Mollejo2, Julia Sastre3 & José López3
1Department of Endocrinology, Complejo Hospitalario de Toledo, Toledo, Spain; 2Department of Pathology Complejo Hospitalario de Toledo, Toledo, Spain.

Background
Craniopharyngiomas (CPs) are epithelial tumors that typically arise in the suprasellar region. They are associated with high levels of morbidity related to tumour location and/or treatment-related injuries. Recent discoveries have also led to a better understanding of CP development and potential treatments.

Objective
To analyse the clinical, pathological, molecular features and outcomes of patients with CP.

Design
Retrospective observational study.
Methods
Clinical records review and re-evaluation of histologic samples from patients who underwent surgery of CP in our institution between 1999 and 2016.

Results
There were 26 patients (53.8% male), mean age at diagnosis 37 years (range 2–73). Mean follow-up was 86 months (range 3–288). The commonest presenting symptoms were: visual alterations 84% (n=21), headaches 53.8% (n=14), and behaviour disorders 11.4% (n=3). 92.3% (24/25) of tumours had suprasellar involvement, with cystic component in 80.8% (16/26). Median tumour size was 30.4 mm (12–50). Initial surgical approach was transcranial in 96.2% (n=25).

Available histological and molecular results were: 72% (n=18) adactinoma-tous CP and 28% (n=7) papillary CP (PCP). Three PCP harboured BRAF V600E mutation. In these cases, the average number of surgical interventions were higher (4 vs 1.3) and time to recurrence was shorter (34 vs 99 months). Three patients (11.4%) underwent radiation therapy. Last neuroimaging assessment showed residual tumour in 50% of patients. At the end of follow-up, hypopituitarism and diabetes insipidus were detected in 72% (18/25) and 75% (19/24) respectively. Symptoms related to hypotalamic dysfunction were found in 76% (19/25). The mortality was 11.5% (n=3). Causes of death were: initial surgery related complications (1), multiple recurrent PCP harboured mutation BRAF v600E (1) and cardiovascular disease (1).

Conclusions
In our study, treatment of craniopharyngiomas were associated with high rates of tumor persistence and substantial morbidity. Tumours harboured BRAF V600E mutation. In these cases, the average number of surgical interventions were higher (4 vs 1.3) and time to recurrence was shorter (34 vs 99 months). Three patients (11.4%) underwent radiation therapy. Last neuroimaging assessment showed residual tumour in 50% of patients. At the end of follow-up, hypopituitarism and diabetes insipidus were detected in 72% (18/25) and 75% (19/24) respectively. Symptoms related to hypotalamic dysfunction were found in 76% (19/25). The mortality was 11.5% (n=3). Causes of death were: initial surgery related complications (1), multiple recurrent PCP harboured mutation BRAF v600E (1) and cardiovascular disease (1).

Cushing’s disease: is there a Continuum from corticotropic hyperplasia to adenoma?
Ana Coelho Gomes1, Lia Lucas Neto2, Francisco Tortosa3, Maria Raquel Carvalho1, Eduardo Barreiros1, Luis Barreiros1, Jose Miguéns4 & Maria João Bugalho1
1Endocrinology, Diabetes and Metabolism Department, Santa Maria Hospital, Lisbon, Portugal; 2Neuroradiology Department, Santa Maria Hospital, Lisbon, Portugal; 3Pathology Department, Santa Maria Hospital, Lisbon, Portugal; 4Neurosurgery Department, Santa Maria Hospital, Lisbon, Portugal.

Introduction
Successful long-term management of patients with Cushing’s disease (CD) remains a challenge. Few studies have analyzed the long-term recurrence rates of CD after transphenoidal surgery (TS).

Objectives
1) to compare the outcome of patients with and without postoperative criteria for cure; 2) to compare the outcome of patients with and without a histological diagnosis of adenoma.

Methods
Retrospective, descriptive study. Forty-two patients with CD submitted to TS between 2005 and 2016 were included. Variables analyzed: postoperative criteria for cure, CD remission and recurrence rates, histological findings.

Results
Surgical remission was achieved in thirty-eight patients. The mean follow-up was 6.8 years. Sixteen patients recurred. The mean time to recurrence was 4.6 years. Immediate postoperative evaluation was performed in 34 cases; criteria for cure were observed in seventeen. Patients with clinical recurrence who presented postoperative criteria for cure had a mean disease free-time of 7.1 years, opposed to 2.2 years in those without biochemical criteria for cure (P-value 0.032). Six patients without biochemical criteria for cure after surgery are in remission. Histology documented an adenoma in thirty patients; from these, eleven recurred.

Discussion
In this study, 42.1% of the patients who achieved remission, after TS, recurred. This finding emphasizes the need for continued biochemical and clinical follow-up. On the other hand, some patients without postoperative criteria for cure were in remission, at last observation. Thus, suggesting that biochemical criteria for cure may be achieved at different timings from patient to patient. Evidence for recurrence in eleven patients with adenoma suggests that CD may be a continuum, in which there is a basal corticotropic hyperplasia likely to evolve to adenoma.

The use of increasing doses of cabergoline in the management of cabergoline-resistant prolactinomas
Lucio Vilar1,2, Clarice Vilar3, José Luciano Albuquerque3, Patricia Gadelha4, Ana Carolina Thel4, Erik Trovao4, Thaise Borges4, Isabela Cardoso2 & Roy Lyr4
1Division of Endocrinology, Hospital das Clinicas, Federal University of Pernambuco, Recife (Pernambuco), Brazil; 2Endocrine Research Center of Pernambuco, Recife (Pernambuco), Brazil.

Introduction
Dopamine agonists (DA) are the ideal treatment for prolactinomas and cabergoline (CAB) is the drug of choice, for being much more effective and better tolerated than bromocriptine. However, 10-15% of patients with prolactinomas are considered to be resistant to CAB, as they do not achieve prolactin (PRL) normalization, while in use of conventional doses of this drug.

Objectives
To evaluate the efficacy of increasing doses of CAB in prolactinomas refractory to CAB 3 mg/wk by in order to achieve prolactin (PRL) normalization.

Patients and methods
We prospectively evaluated the management of consecutive patients with prolactinomas refractory to CAB 3 mg/wk who were submitted to progressive increases in CAB dose, as needed and tolerated every 3 months, up to 9 mg/wk. The patients were recruited over a 12-month period. Exclusion criteria were previous pituitary surgery or radiotherapy. Echocardiogram evaluation was performed in each patient every 6 months.

Results
Twenty-five patients were included in this study, 20 with macroprolactinomas. Overall, normalization of PRL levels was achieved in 18 patients (72%): in 3 (12%) with a dose up to 4 mg/wk, in 9 (36%) with 5 mg/wk and in 6 (24%) with 6–7 mg/wk. No patients benefited from doses >7 mg/wk. No significant echocardiographic abnormalities were detected.

Conclusion
CAB doses up to 7 mg/wk were well tolerated and enabled PRL normalization in 18 (72%) patients with prolactinomas resistant to CAB 3 mg/wk. No patients benefited from doses >7 mg/wk.

Long-term efficacy of octreotide LAR in acromegaly patients, a prospective single centre study with 7 years follow up
Zeljka Veljka-Asim1, Azra Burekovic2 & Ana Milica Dizdarovic-Bostandzic1,2
1Medical Faculty University of Sarajevo, Sarajevo, Bosnia and Herzegovina; 2Clinical Centre University of Sarajevo, Sarajevo, Bosnia and Herzegovina.

Objective
The aim of this single centre prospective open trial was to evaluate the long-term efficacy of octreotide LAR in acromegaly patients.

Methods
In total of 19 patients with acromegaly diagnosed at Endocrinology Department of Clinical Centre of University in Sarajevo, somatostatin sensitive (ten females and eight males, age range 40–68 years, six patients with microadenoma and 12 patients with macroadenoma) were treated with octreotide. Follow-up period was 7 years (2009–2016). The concentration of human Growth Hormone (hGH) and insulin-like growth factor-1 (IGF-1) were evaluated every 6 months, while MRI of brain was performed in each patient every 6 months.

Results
During the first year of treatment ten patients were included. In the second year, a further seven patients were included. During the last 4 years, five patients were included. During the seventh year of follow-up, the treatment was successful discontinuated at four patients, two patients were passed away due to co-morbidities. Overall, normalization of hGH level was achieved in 15 patients (78.9%) and normalization of IGF-1 level was achieved in 14 patients (73.7%). Twenty five patients were included in this study, 20 with macroprolactinomas. In total of 19 patients with acromegaly diagnosed at Endocrinology Department of Clinical Centre of University in Sarajevo, somatostatin sensitive (ten females and eight males, age range 40–68 years, six patients with microadenoma and 12 patients with macroadenoma) were treated with octreotide. Follow-up period was 7 years (2009–2016). The concentration of human Growth Hormone (hGH) and insulin-like growth factor-1 (IGF-1) were evaluated every 6 months, while MRI of brain was performed in each patient every 6 months.

Discussion
In this study, 42.1% of the patients who achieved remission, after TS, recurred. This finding emphasizes the need for continued biochemical and clinical follow-up. On the other hand, some patients without postoperative criteria for cure were in remission, at last observation. Thus, suggesting that biochemical criteria for cure may be achieved at different timings from patient to patient. Evidence for recurrence in eleven patients with adenoma suggests that CD may be a continuum, in which there is a basal corticotropic hyperplasia likely to evolve to adenoma.

DOI: 10.1530/endoabs.49.EP974

Endocrine Abstracts (2017) Vol 49
Conclusion
Octreotide LAR treatment is effective in decrease of GH, IGF-1 and tumour size in well-selected acromegalic patients.

Is there a gender difference in clinically nonfunctional pituitary adenomas?
Iffet Dagdelen Duran1, Neşê Ersöz Gülçilik2, Dilek Berker1 & Serdar Güler1
1Ankara Numune Education and Research Hospital, Department of Endocrinology and Metabolic Diseases, Ankara, Turkey; 2Ankara Education and Research Hospital, Department of Endocrinology and Metabolic Diseases, Ankara, Turkey.

Introduction
Clinically nonfunctioning pituitary adenomas (NFA) are the most common pituitary tumor type. They are usually recognized after they cause symptoms especially when tumor size increases and eventually invades adjacent structures. Nevertheless the discovery would also be accidental. In the literature some kind of gender difference is reported in NFA’s behavioral results such as pituitary axis deficits or consequences of surgery however they resulted with controversial results. In our study we investigated if there is male/female preponderance in terms of NFA’s some number of features.

Materials and methods
We retrospectively examined 101 patients diagnosed as NFA biochemically and radiologically. All patients were questioned for each possible symptom of pituitary adenoma at diagnosis. Every patient was examined by laboratory pituitary hormonal tests. Pituitary adenomas were radiographically evaluated by MRI (dimensions:mm): d1 × d2 × d3. Microsurgical resection of adenoma was performed in patients with symptomatic or large and invasive tumors.

Results
101 patients (57 female (56.4%) and 44 male (43.6%)) were assessed in the study. The age at diagnosis was younger for women than men (40.0 yr vs 51.4 yr, P<0.00). Tumor size were larger for men (d1: 21.9±2.6 mm vs 9.4±1.4 mm, P<0.00). Among the rate of symptoms headache was the most frequent. Blurred vision was more common in men (45.5% vs 26.8%, P<0.06). The frequency of pituitary hormone deficiency was more common in men (37.0% vs 12.1%). 43 (42%) patients have been performed pituitary surgery. Posturgical hypopituitarism was more commonly seen in female, whereas permanent DI was more abundant in male, with nonsignificance in both issues (38.5% in female vs 37.5% in male, P>0.60; respectively).

Conclusion
Sex would be a prognostic parameter in NFA patients in terms of hypopituitarism, postoperative hypopituitarism and tumor mass. In our study, women were shown to be diagnosed earlier and men were defined to have larger tumors. Greatly would be explained with the mass effect, we determined hypopituitarism was more common in men. Selectively posturgical hypopituitarism, however nonsignificant, was found more common in female group in our study.

The value of early postoperative OGTT as a predictor of surgical outcome in patients with acromegaly after total transsphenoidal adenomectomy
Alexandr Tserberkin, Vladimir Cherębilo, Uliana Tsyö, Anna Dalmatova, Lidiya Belousova & Elena Grineva
Federal Almazov North-West Medical Research Centre, Saint Petersburg, Russia.

Introduction
Transsphenoidal surgery (TSS) is the treatment of choice for patients with acromegaly. However, even after radical surgery persistence of acromegaly may remain up to thirty percent by resent studies (Starmoni, 2016). Nadir growth hormone (GH) level less than 1.0 µg/l on an early postoperative oral glucose tolerance test (OGTT) have been suggested as early predictor of surgical remission (Kim 2012). However, the value of this approach remains to be defined.

Aim
The purpose of our study is to evaluate the utility of measurement of GH level during a 2-week postoperative OGTT as a predictor for surgical outcome in patients with acromegaly.

Materials and methods
Ten patients (five women and five men) with an average age of 47.4±14.8 years (range 27–71 years) who had underwent total transsphenoidal adenomectomy performed by one neurosurgeon were included in this study. All patients harbored macroadenomas, with average size of 18.9±5.2 mm (range 13–29 mm). Measurement of GH level during OGTT was performed 14 days after surgery. The outcome of TSS was evaluated 6 months after surgery by OGTT and measurement of insulin-like growth factor 1 (IGF-1). The biochemical remission of acromegaly according to the 2010 remission criteria were defined as nadir GH level on an OGTT <0.4 µg/l along with age and gender normalized values of IGF-1.

Results
Initial basal GH level was 23.7±24.9 µg/l, initial IGF-1 patient /IGF-1ULN ratio was 2.7±0.6. Six months after surgery the remission of acromegaly was achieved in five patients (50%) – mean GH:0.2, mean IGF-1:0.4; respectively). The frequency of hypoglycaemia was 10.0% (1 patient) vs. 14.8 years (range 27–71 years) who had underwent total transsphenoidal adenomectomy performed by one neurosurgeon were included in this study. All patients harbored macroadenomas, with average size of 18.9±5.2 mm (range 13–29 mm). Measurement of GH level during OGTT was performed 14 days after surgery. The outcome of TSS was evaluated 6 months after surgery by OGTT and measurement of insulin-like growth factor 1 (IGF-1). The biochemical remission of acromegaly according to the 2010 remission criteria were defined as nadir GH level on an OGTT – 0.30+0.09 µg/l. Nadir GH level on an 2-week postoperative OGTT was less than 1.0 µg/l in all patients with remission of acromegaly. Whereas, all patients with persistence of the disease had nadir GH levels >1.0 µg/l on an early postoperative OGTT.

Conclusion
Our initial data suggest that nadir growth hormone level on an 2-week postoperative OGTT less than 1.0 µg/l associated with remission of acromegaly 6 months after surgery. Further researches are required to specify long-term outcomes.

Giant macroprolactinoma in women still exist?
Laura Dragoni1, Stefan Florian1,2, Ana Valea1& Cristina Ghervan1,2
1Emergency County Hospital, Cluj-Napoca, Romania; 2University of Medicine and Pharmacy ‘Iuliu Hatieganu’, Cluj-Napoca, Romania.

Background
Prolactinomas are the most common hormone-secreting pituitary tumors and are a common cause of anovulation and infertility. Giant prolactinomas (0.5–4.4% of all pituitary tumors) are rare tumors characterized by their large size (>4 cm), compressive symptoms and extremely high prolactin secretion (>1000 ng/ml). Men are most commonly affected, with a reported male to female ratio of 9:1. Case report
We present the rare case of 53-years-old female, with a history of amenorrhea from age 35, who was never investigated or treated. In December 2015 she was admitted in the neurosurgery department for severe headaches and visual impairment. On clinical examination, left eye mydriasis and left lateral nystagmus were noted. A head CT showed a pituitary tumor of 55 mm diameter, invading the sphenoid sinus, both cavernous sinuses, the left orbit and compressing the third ventricle, with mass effect. The blood tests revealed a very high serum prolactin of 32625 ng/ml (4–23) and low sexual and gonadotropic hormones. Given the clinical and CT aspects, decompressive transcranial surgery was performed, resulting in rapid improvement of the neurological signs and lowering of the PRL levels to 1980 ng/ml. Nasal fistula and transient diabetes insipidus occurred after surgery and were cured by sphenoide sinus filling and treatment with desmopressin. For the residual prolactin secretion, Cabergoline treatment was started (1.5–2 mg/week) which resulted in prolactin suppression and diminution of the tumoral remant. The restoration of the gonadotrophic secretion resulted in numerous painful ovarian cysts that were cured by bilateral oophorectomy.

Conclusions
We present this rare case in order to highlight the importance of the etiological investigation of secondary amenorrhea in women. The patient almost died because of the mass effect of a benign tumor, easily manageable by medical treatment and suffered multiple complications due to the neglect of her secondary amenorrhea.

Associated neoplasia in Romanian acromegalic patients
Simona Silea1, Simona Galoiu1,2, Anda Dumitrescu1, Dan Niculescu1,2, Ionela Baciu1,3 & Catalina Potiana1,2
1C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; 2Medical Faculty, University of Medicine and Pharmacy, Timisoara, Romania; 3Department of Pathology, Medical Faculty, Medical University of Timisoara, Romania

Introduction
Acromegaly has various complications that significantly affect patients’ lives, one of which is developing neoplasia, a subject of high interest in the scientific community during the last years but without any firm conclusions. Aim
The main objective of this paper was to verify if Romanian acromegalic patients are susceptible to developing neoplasia and what types of tumors are associated with acromegaly. Another purpose of the paper was to identify the risk factors involved in tumor predisposition.

Methods
This observational, retrospective study considered 336 acromegalic patients (217 of them females, 64.6%) followed from 2001 until 2015 in the report to the evolution of acromegaly and the development of associated diseases, mainly neoplasia. Results
Acromegalic patients had a higher risk of developing associated neoplasia (40% benign and 10% malignant). Activity of the disease was not an important factor (except for the thyroid – 54.84% of the patients had active acromegaly), whereas initial values of IGF-1 seemed to influence the developing of prostate neoplasia (mean corrected value 4.58, P < 0.025). Sex has proved to be a factor too: women were more prone to developing neoplasia than men (57.14 vs 34.29%), and especially multiple types of tumors. The most frequently associated types of neoplasia in our patients were developed in: thyroid (47% women, 20.95% men), breast (11.93%) and uterus (5.99%) for women, and colon (9.52%) and prostate (6.67%) for men. The longer the duration of active acromegaly the higher was the risk of developing colonic neoplasia.

Conclusions
The results suggest that we need to perform a more meticulously screening of associated tumours in acromegalic patients, not only using ultrasonad and colonscopy for the thyroid gland and colon, but also mammography as well as PSA level determination. These evaluations should be taken into consideration periodically in all our acromegalic patients, regardless of the evolution of their main disease.

Clinical and histopathologic characteristics of thyroid cancer in the patients with acromegaly
Buket Yilmaz Bulbul1, Muhmet Celik1, Nuray Can2, Semra Ayturk1, Ebru Tastekin1, Atakan Sezer3, Funda Ustun4 & Sibel Gulden1
1Department of Endocrinology and Metabolism, Medical Faculty, Trakya University, Edirne, Turkey; 2Department of Pathology, Medical Faculty, Trakya University, Edirne, Turkey; 3Department of Surgery, Medical Faculty, Trakya University, Edirne, Turkey; 4Department of Nuclear Medicine, Medical Faculty, Trakya University, Edirne, Turkey.

Aim
There are some studies suggesting that the risk of developing cancers, especially thyroid cancer, is increased in the patients with acromegaly. The prevalence of thyroid cancer is 1.2-10.6% among the patients with acromegaly. In this study, we aimed to evaluate clinical and histopathologic characteristics of thyroid cancer among the patients with acromegaly.

Method
We retrospectively evaluated the patients with acromegaly who had been followed-up by our department between the years 2005 and 2016 and diagnosed with thyroid cancer. Results
9 (81.8%) of 11 subjects were female and 2 (18.2%) patients were male. The mean age of the patients at the time of acromegaly diagnosis was 41 ± 11 years. Among subjects who had been followed for 11.45 ± 9.37 years, all except one patient were not in remission and were receiving medical treatment. All subjects were diagnosed with thyroid cancer after the diagnosis of acromegaly and the mean time until the diagnosis of thyroid cancer was 27 ± 9.23 years. In terms of thyroid hormone status, nine subjects were euthyroid and two patients were found to have central hypothyroidism. Thyroid ultrasonographic examination revealed multinodular goiter in all patients. Thyroid fine needle aspiration biopsy was performed for nodules bigger than 1 cm or nodules with malignancy criteria. Thyroid fine needle aspiration biopsy demonstrated undetermined atypia in 27.3%, suspicious follicular neoplasia in 36.4%, follicular neoplasia in 9.1% and suspicious malignancy in 27.32% of the subjects. All patients underwent total thyroidectomy. Pathological examination of thyroid tissue revealed follicular variant papillary thyroid cancer in 5, classic and follicular variant papillary thyroid cancer in 3, diffuse sclerosing variant papillary thyroid cancer in 1, solid variant papillary thyroid cancer in 1 and follicular, classic and clear cell papillary thyroid cancer in 1 patient. 72.7% of the patients had multifocal disease. In 63.7% of the subjects had unilateral disease. Lymphovascular invasion and extrathyroidal extension were present in 9.1 and 18.2% of the subjects, respectively. No distant or local metastasis was detected during mean follow-up period of 28.72 ± 16.18 months.

Conclusion
Patients with acromegaly should be considered for the presence of thyroid cancer.

EP982

The triglyceride (TG)/HDL Cholesterol (TG/HDL-C) ratio as marker of adipose tissue dysfunction at patients with acromegaly
Oksana Khyzhnyak, Miroslava Mykytyn & Iurii Karachentsev
Institute of Endocrine Pathology Problems, Kharkiv, Ukraine.

Background and aims
The ratio of TG/HDL-C can identify cardiometabolic risk and cardiovascular disease. The visceral adiposity index (VAI) is a sex-specific index, in which measurements of body mass index and waist circumference are combined with TG and HDL-C concentrations. It is widely accepted that acromegaly is associated with visceral adiposity tissue at patients with acromegaly.

Subjects and methods
Eighty-eight patients (30 men and 58 women; aged 17–75 years) with acromegaly were under investigation. Disease activity was evaluated according to the Consensus Conference criteria (2000). Blood samples for GH, IGF-I, TG, HDL-C and total cholesterol were taken in fasting state. VAI score and normal values were used by M. C. Amato et al., 2011. It was considered the normal VAI in an age-dependent group to 30 years < 2.52, from 31 to 42 years < 2.23, from 43 to 52 years < 1.92, from 53 to 66 years < 1.93 and more than 67 years < 2.00.

Taking into account a value VAI, all patients were divided on two groups: with normal VAI (55.7%) (group 1) and high VAI (44.3%) (group 2). The 10-years-old general cardiovascular risk (CVD) was determined by a calculator «General CVD Risk Prediction».

Results
At nonlinear correlation, TG/HDL-C ratio was highly correlated with VAI in both men (r = 0.96, P = 0.00001) and women (r = 0.97, P = 0.00001), that TG/HDL-C can serve as more adequate criterion of estimation of disfunction of visceral adiposity tissue at patients with acromegaly. This supposition confirms exposed by us for patients in a general group positive correlation TG/HDL-C with the level of GH (r = 0.38, P = 0.00001). Before TG/HDL-C it was suggested to use for identification of cardiometabolic risk in general population (M. R. Salazar et al., 2014). In a group with high VAI 10-years-old CVD risk and MS risk in 1.6 and 1.4 times, according higher, than in a group with normal VAI (OR 1.56, OR 1.42).

Taking into account a value VAI, all patients were divided on two groups: with normal VAI (55.7%) (group 1) and high VAI (44.3%) (group 2). The 10-years-old general cardiovascular risk (CVD) was determined by a calculator «General CVD Risk Prediction».

Conclusion
By the equivalent of VAI for the estimation of expressed of disfunction of visceral adiposity tissue at patients with acromegaly can serve also TG/HDL-C ratio.

Anti-proliferative effects of high doses cabergoline in patients with prolactinoma
Oksana Khyzhnyak, Teona Gogitidze, Miroslava Mykytyn & Iurii Karachentsev
Institute of Endocrine Pathology Problems, Kharkiv, Ukraine.

The aim of the study
To investigate the anti-proliferative effect of cabergoline (CAB) which was used in different regimes of suppressive therapy during 12 months in patients with prolactinoma (PROL).
Subjects and methods
It was examined and underwent a 12 month course of treatment by selective dopamine agonist CAB 61 patients with PROL: microadenoma 42, macro&giant PROL – 19. (52 women/9 men) aged 16–66 years. The total duration of the disease ranged from 1 to 60 months, average (12.3 ±10.1) months. PROL was verified using MRI 1.5T. Pituitary volume was calculated by the Di Chiro-Nelson. Were estimated total and partial secretory activity (PSA) in PROL. PRL blood levels (ng/ml) were determined. Applied two modes of therapy: 1 – the mode of gradual increase of a CAB dose, since 0.5 mg/week with the subsequent control of the PRL blood level in each 4 weeks and titration CAB dose if necessary (increase in a week dose by 0.25–0.5 mg); 2 – the mode of high starting doses from calculation: the quantity of tablets CAB (0.5 mg) corresponded to frequency rate of increase of the PRL blood level in relation to the upper limit of age norm, but no more than 4 mg (8 tablets) a week. The statistical data analysis was carried out with SPSS version 9.0.

Results
At purpose of high starting doses of CAB after 1 mth of treatment PRL level in 58.1% of patients decreased to the reference values, including in patients with macroPROL after 1 month at 26.3% of patients had achieved target levels, after 3 months - at 84.2%, and by 6 months of treatment - at 100% patients. In all patients it was a statistically significant decreasing the pituitary volume after 12 months of treatment (P <0.001), but only in patients who were treated high starting high dose CAB recorded decrease in the size of adenoma by 50% or more of the basal volume: at 9 microPROL and 4 macroPROL.

Conclusions
The most expressed anti-proliferative effect is noted at application of high starting doses of CAB. Optimum therapeutic average and cumulative doses of CAB for achievement of maximum therapeutic effect at patients with microPROL are doses of 0.8 mg/week and 33.8 mg/year, respectively; for patients with macro&giant PROL – 1.3 mg/week and 67.6 mg/year, respectively. At patients with microPROL the positive therapeutic effect is reached on a smaller cumulative CAB dose which is associated with a lower risk of complications in the long-term period.

Invasive macroprolactinomas and its response to treatment in male patients
Alin Abreu, José Hernández, Margarita Velasco, Pablo Triana & Orlando Castaño
1Centro Medico Imbanaco, Cali, Colombia; 2Instituto Nacional de Endocrinología, La habana, Cuba; 3Universidad Libre Seccional, Cali, Colombia.

Introduction
Prolactin-producing pituitary adenomas are the most common pituitary tumors in clinical practice. In men they are more aggressive and their response to pharmacological treatment is unknown.

Objective
Describe the clinical characteristics and response according to the treatment of a group of male patients with invasive macroprolactinomas.

Materials and methods
A retrospective descriptive study, a series of cases, in 30 patients, attending two pituitary clinics (National Endocrinology Institute in Havana, Cuba and Imbanaco Cali Colombia Medical Center) between 2002 and 2012. Results Between the two types of treatment were compared and measures of central tendency and test of Student or Kruskal Wallis were used.

Results
The mean age was 44 ±13.8 years; the disease duration was 5.2 ±4.1 years; 96% of the patients presented headache, followed by hypopituitarism (80%). The median prolactin value at admission was 487 ng/ml. 53% required surgery plus dopaminergic agonists; in this group there was a decrease in prolactin levels of 86% at 6 months and 96% at 12 months; in the dopaminergic agonist group, there was a 71% decrease at 6 months and 95% at 12 months. Surgical patients had mayor Tumor size reduction 11.4 mm compared with 8.3 mm, however a year later there were no difference between the groups.

Conclusion
Surgical treatment plus dopaminergic agonist showed no differences with medical treatment in reducing prolactin values during the first year of treatment regardless of tumor size.

Venous glucose levels, peak GH and peak cortisol during Insulin Tolerance Test using 0.15 UNITS/Kg and 0.1 UNITS/Kg body weight
Phillip Yeeh1, Ashley Grossman2, Serner L Chew3, Pierre Boulouz3, Bernad Khoo3, Paul Carroll3, Simon Aylin2 & Stephanie Baldwe3
1The London Clinic, London, UK; 2John Radcliffe Oxford, Oxford, UK; 3Royal Free Medical School, London, UK; 4Guys & St Thomas Hospital, London, UK; 5Kings College Hospital, London, UK; 6UCLH Hospitals, London, UK.

Insulin Tolerance Test (ITT) is a procedure commonly done by Endocrine Specialist Nurse in endocrine department. We look at over 120 ITT results done in 2 endocrine centres using Insulin Acrapid 0.15 UNITS/kg and 0.10 UNITS/kg dose plotting the glucose levels at 30, 45 and 60 min. We also look at peak GH and peak cortisol on each of these groups.

Aims
We wanted to know how many percentage of patients achieving hypoglycaemia below 0.5 mmol/l, 0.5–1.0 mmol/l, 1.1–1.5 mmol/l, 1.6–2.0 mmol/l and above 2.0 mmol/l. We also look at peak GH response achieving over 9 microgram/ml, between 8–9 microgram/l and below 8 microgram/l. In the peak cortisol response, we looked at results over 550 nmol/l; 500–550 nmol/l; 450–500 nmol/l; 400–450 nmol/l and below 400 nmol/l. Within these data, we also look at a small groups of results for patients’ using 0.15 UNITS/kg as repeat dose and repeat ITT using the lower dose to compare if there are difference in these markers.

Summary
We are unable to draw summary at the moment as well still got 30 data to go through.

Long-term impact of primary medical and surgical therapy on bone density in men versus women with prolactinomas
Lukas Anderegg1, Janine Frey2, Robert Andrej1, Marwan El-Koussy1, Jürgen Beck1, Luigi Mariani4 & Emanuel Christ1,3
1Neurosurgery, Bern, Switzerland; 2Endocrinology, Bern, Switzerland; 3Neuroendocrinology, Bern, Switzerland; 4Neurosurgery, Basel, Switzerland.

Purpose
The prevalence of pathological bone densities in men and women with prolactinomas treated either primary surgically or medically are infrequently reported across large cohorts. In the present study, we aimed at comparing the impact of either therapeutic approach on the bone density in men vs women with prolactinomas.

Methods
Retrospective case-note study including all consecutive patients with prolactinomas in whom osteodensitometry data was available at study entry and long-term follow-up (≥ 12 months). Bone mineral density (BMD) was assessed by dual-energy X-ray absorptiometry. Clinical and biochemical characteristics, tumor size, and remission rates were recorded.

Results
Hundred patients (40 men, 60 women) met inclusion criteria. At baseline, men had a significantly higher prevalence of pathological BMD than women (28 vs 2%, P =0.001). Primary medical therapy was considered in 47, first-line surgery in 53 patients. Median follow-up time was 79 months (range 12–408 months). Long-term PRL values significantly decreased in both cohorts, regardless of the primary treatment. There was a persisted need for dopamine (DA)-agonists in 75% men compared to 42% women (P=0.001). The prevalence of pathological BMD in men remained significantly higher than in women (37 vs 7%, P<0.001), independent of the primary treatment strategy.

Conclusions
The prevalence of pathological BMD in men remains significantly higher than in women, independent of the primary treatment strategy. While osteoporosis prevention and treatment is mainly focusing on women, awareness of the bone loss in men with prolactinomas should not be underestimated.

Stenosis of the external auditory canal in an acromegalic patient: a novel complication

Hee Kyung Kim, Jee Hee Yoon, Yun Ah Jeong & Ho-Cheol Kang
Department of internal Medicine, Chonnam National University Medical School, Gwangju, Republic of Korea.

Acromegaly is associated with a range of comorbidities, including cardiovascular disease, diabetes, hypertension and sleep apnea. Bony overgrowth and soft tissue thickening not only cause typical external features of acromegaly, but also debilitating musculoskeletal aches. Recently, a few papers reported auditory complications of acromegaly, but there has been no report on narrowing of the external auditory canal as a complication of acromegaly. A 58-year-old acromegalic patient complained of fullness of both ears. He had transphenoidal surgery for GH-secreting pituitary adenoma 17 years ago. Somatostatin analogue therapy was discontinued 2 years earlier, because nadir GH after oral glucose loading and IGF-1 level were normal. On laboratory exam, random GH was 0.82 ng/mL and IGF-1 264.74 ng/ml (reference range, 71–263). On otolaryngologic examination, both auricles were very hard and immobile, and orifices of external auditory canals (EAC) showed slit-like openings. In left ear, cardium examination was impossible due to severe stenosis of EAC. On temporal bone CT, both ears showed thickening of tympanic membranes and evidence of chronic otitis media with severe soft tissue thickening of left EAC. Pure tone audiometry documented mild hearing loss in left ear. The patient declined any further evaluation and therapeutic intervention. Ear complications of acromegaly has not received much attention so far. We report a case of ECA stenosis developed in an acromegalic patient, as a novel complication of acromegaly.

DOI: 10.1530/endoabs.49.EP987

Is Pegvisomant correct choice for acromegaly patient with dilated cardiomyopathy?

Murat Cinel, Caglar Keskin, Kifat Emral & Demet Corapcioğlu
Endocrinology and Metabolism Department, Ankara University Faculty of Medicine, Ankara, Turkey.

Objectives
Acromegaly may arise with several clinical presentations and cardiac involvement is the most important factor affecting the course of the disease. Case A 32-years old man admitted to hospital complaining with shortness of breath. After initial evaluation he was diagnosed as ‘cardiac failure’. Cardiac evaluation revealed that he had ‘dilated cardiomyopathy’ with ejection fraction (EF) of 20%, global hypokinesia without valvular disease and coronary angiography was detected as normal. After immediate cardiac treatment he was consulted to endocrinology because of hyperglycemia. When the patient evaluated for hyperglycemia, physical examination findings consistent with acromegaly. He was diagnosed as acromegaly with high IGF-1 and GH level and 19 mm macroadenoma in pituitary MRI. Because of heart failure, surgery was delayed and medical therapy was initiated. After 6 months of therapy with high dose somatostatin analogue treatment, his cardiac status did not show any improvement and we decided transnasal transphenoidal adenectomy. After surgery he was not in remission and somatostatin analogues were initiated again. At the 6 months of additional therapy, IGF-1 and GH level were not in normal range. We decided to add pegvisomant to therapy. At the 2nd week of combination therapy, he developed severe cardiac failure with EF 10% and therapy was discontinued. After cessation of pegvisomant, his symptoms revealed minimally.
Conclusion As we know cardiac problems are the first leading cause of death in acromegaly. Cardiac involvement may appear any of the followings: hypertension, valvular heart diseases, arrhythmias, hypertrophic cardiomyopathy and dilated cardiomyopathy. Most of the patients treated with pegvisomant show decreased cardiac muscle mass in hypertrophic cardiomyopathic patients. There is no data about pegvisomant use in acromegalic patients with dilated cardiomyopathy. Should we it cautiously in diluted cardiomyopathic patients?

DOI: 10.1530/endoabs.49.EP988

Preoperative HDDST in the prognosis of CD remission after transsphenoidal endoscopic surgery

Gussova Natalya, Tsoy Ulyana, Cherebillo Vladislav, Dalmatova Anna, Belousova Lidiya, Mitrofanova Lyubov & Grineva Elena
Federal Almazov North-West Medical Research Centre, Saint-Petersburg, Russia.

Purpose
Transsphenoidal endoscopic surgery (TSS) is the first-line treatment for Cushing’s disease (CD). Persistence and recurrence of hypercortisolism after TSS considered important problem. In this case search for CD remission predictors is actual.

Aim
To study the role of preoperative oral high-dose dexamethasone suppression test (HDDST) in the prognosis of CD remission after TSS.

Materials and methods
60 patients with Cushing’s disease (nine men, 51 women, mean age 41 years (15–73) who had underwent TSS were included. HDDST was performed in all cases before the TSS. Postoperative examination was done one and two years after surgery. Remission criteria were: secondary adrenal insufficiency (the need for glucocorticoid replacement) or combination of normal midnight serum cortisol level, normal 24 h urine free cortisol (UFC) excretion and serum cortisol suppression less than 50 nmol/l in 1-mg dexamethasone test. The optimal threshold value of serum cortisol suppression in the HDDST for prediction of CD remission after TSS was calculated by ROC-analysis.

Results
One year after surgery CD remission was confirmed in 39 patients, whereas in 21 patients hypercortisolism persisted, after two years – in 36 and 24 patients, respectively. The optimal threshold value of serum cortisol suppression in the HDDST for prediction of CD remission in one year after TSS was 72%. Test’s sensitivity and specificity were 82% and 84%, respectively. The probability of wrong prediction was 17% (P = 0.0001). Two years after TSS optimal threshold value of serum cortisol suppression remained 72%, with sensitivity and specificity 86% and 80%, the probability of wrong prediction was 16% (P = 0.001).

Conclusion
According to our data serum cortisol suppression more than 72% in HDDST may be used as a prognostic criterion for CD remission after TSS.

Somatostatin analogs in the treatment of acromegaly: single centre experience

Agne Abraitiene1,2, Aiste Aleknaite1,2 & Gintare Zelnyte2
1Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania; 2Vilnius University Medical Faculty, Vilnius, Lithuania.

Introduction
The purpose of this study was to evaluate effectiveness of somatostatin analog (SSA) treatment in patients with acromegaly.

Methods
The study involved retrospective data collection from charts of 29 patients with acromegaly who received medical therapy at Vilnius University Hospital Santariskiu klinikos in 2016.

Results
Patient population consisted of 10 males (34.5%) and 19 females (65.5%), mean age 58 ± 26 years. Primary SSA therapy was administered in 13 (44.8%) patients who refused or had contraindications to surgical treatment. Secondary medical therapy was applied in 16 (55.2%) of patients with recurrent disease after transphenoidal surgery. 28 patients received SSA treatment (6 of them in combination with a dopamine agonist (DA)), 18 patients received high-dose SSA treatment (Sandostatin LAR 40 mg or Somatuline Autogel 120 mg every 4 weeks). Based on GH and IGF-1 results, control and partial control was achieved in 16 (57.1%) and 8 (28.6%) patients receiving SSA treatment (± DA). 4 (14.3%) medically treated patients remained uncontrolled. High-dose SSA treatment failed to achieve disease control in 4 (22.2%) of patients. Disease control and partial control was attained in 5 (38.5%) and 5 (38.5%) of patients with primary SSA treatment and in 12 (75%) and 3 (18.8%) of patients with SSA treatment after transphenoidal surgery. We found higher mean IGF-1 level in primary SSA

EP987

EP988

EP989

Endocrine Abstracts (2017) Vol 49
SSA treatment (± DA) results in disease control in 57.1% of patients with acromegaly. High-dose SSA treatment failed to achieve disease control in 22.2% of patients. SSAs are more effective when applied after transsphenoidal surgery as disease control is achieved in greater percentage of patients and mean IGF-1 level is lower when compared to patients who refused or had contraindications to surgical treatment.

Conclusions

SSA treatment (± DA) results in disease control in 57.1% of patients with acromegaly. High-dose SSA treatment failed to achieve disease control in 22.2% of patients. SSAs are more effective when applied after transsphenoidal surgery as disease control is achieved in greater percentage of patients and mean IGF-1 level is lower when compared to patients who refused or had contraindications to surgical treatment.

Biochemical normalization in acromegaly after 79 months’ treatment with Pasireotide: case report

Chiara Bima1, Sabrina Chiloiro1, Donato Iacovazzo2, Tommaso Tartaglione1, Maria Elena Bracaccia1, Antonella Gianpietro1, Antonio Bianch1 & Laura De Marinis1

1Pituitary Unit, Catholic University of the Sacred Heart, Rome, Italy; 2Centre for Endocrinology, Barts and The London School of Medicine, Queen Mary University of London, London, UK.

Pasireotide, a multireceptor-targeted somatostatin analogue, was approved for the treatment of acromegaly, after being studied in two large, randomised, multicenter clinical trials. We reported the history of a 76 years old man affected by acromegaly, treated with Pasireotide long acting release (LAR) as first line therapy. Acromegaly was diagnosed in 2009, as the result of endocrinological investigation suggested by altered facial appearance and macroglossia. Hormonal assays demonstrated high levels of IGF1 (584 ng/ml) and GH (8.7 ng/ml), without any suppression of GH at oral glucose tolerance test. Patient consequently underwent brain magnetic resonance (MRI), with the finding of a 7 mm expansive formation of the right half adenohypophysis, suggestive for pituitary microadenoma. Patient, in November 2009, was enrolled in CSOM230C2305 study and was treated with Pasireotide LAR at blided dosage, with biochemical control of disease and progressive reduction of the pituitary adenoma volume. In May 2016, following the onset of dyspnea, dysphagia and dysphonia, patient was diagnosed with anti-MuSK-positive myasthenia gravis, treated with apheresis and steroid therapy, currently in good control. In this period, in according to the detection of myasthenia gravis, therapy with Pasireotide LAR was discontinued and patient continued follow-up. The last brain MRI, performed in May 2016, documented the stability in size and morphology of the known pituitary microadenoma. Eight months later, in January 2017, patient is actually in remission, with IGF1 in the normal reference range for age and gender (196 ng/ml) and GH < 2.5 ng/ml (0.5 ng/ml). This clinical case shows the efficacy of Pasireotide in gaining biochemical control of acromegaly, factor that is primarily implicated in the reduction of disease morbidity and mortality.

DO: 10.1530/endoabs.49.EP991

A eight successful pregnancies in six Algerian women with acromegaly: a monocenter study of Pierre and Marie Curie center.

Safia Mimouni

Pierre and Marie Curie Center, Algiers, Algeria.

Introduction

Acromegaly usually results from GH hypersecretion elaborated by somatotrop adenoma. The occurrence of a pregnancy in an acromegaly is an infrequent event, but better described in recent years. It could be aggravate GH secretion and tumor volume.

Objective

Describe eight pregnancies including twin pregnancy in six acromegalics patients hospitalized in the endocrinology department of the Pierre and Marie Curie center in Algiers.

Materials and method

Materials: Eight pregnancies; their mean Age was 35.5 years. Meanwhile of diagnosis: MRI revealed: macro adenoma (n = 7) and microadenoma (n = 1); The Visual Field was normal, Hypopituitarism was observed in 1 case and thyrotoxic insufficiency in 1 case. No diabetes mellitus or hypertension were noted. Patients underwent surgery (n = 5), surgery and radiotherapy (n = 1). The pregnancies were spontaneous in all cases.

Method: Diagnosis of acromegaly: HGPO/GH; GH/IGF1, magnetic RM imagining pituitary and Visual Field were performed before conception and at T1, T2, T3 of the pregnancy and in the postpartum. We have searched Diabetes Mellitus, gravid hypertension, the Childbirth Incidents, and we examinated Newborns.

Results

Eight pregnancies resulted in nine healthy babies. Gestational diabetes occurred in Three cases and regresses in the postpartum in two cases; No Gravid hypertension. The IGF1 and GH concentrations did not change significantly during pregnancy and in the postpartum. Growth adenoma was noticed in two cases but without defect in any visual field. Fetal malformations were not observed, birth weight was normal.

Conclusion

Achromegaly remains a rare cause of infertility. Pregnancy in women with active acromegaly or uncontrolled acromegaly may be associated with an increases risk of gestational and gravid hypertension. Pregnancy is occasionally associated with an enlargement of adenoma. All these data must be confirmed by prospective studies.

Sheehan syndrome presenting 21 years later as severe heart failure
Ana Gonçalves Ferreira, Sofia Alegria, Maria Carlos Cordeiro & Jorge Portugal
Hospital Garcia de Orta, Almada, Portugal.

Introduction
Sheehan syndrome (SS) is caused by postpartum necrosis of the pituitary gland, associated with significant haemorrhage during or after delivery. It is rare in developed countries, but still frequent in underdeveloped ones. We present a rare presentation of this syndrome.

Case history
A 48 years old black woman presented at the emergency department for long term fatigue and dyspnea that worsened a few days before. Her physical examination revealed muffled heart sounds, decreased breath sounds inferiorly and bilaterally, a puffy face and dry skin. Also, she had a slurred speech and hoarseness. No other significant findings. No recent past medical history, except for a complication in her second pregnancy (at 17 years), with a significant internal haemorrhage at term and an emergency caesarean section (stillborn). No subsequent laceration. Amenorrhea since then.

Blood tests: HB 9.3 g/dl (microcytic, hypochromic anaemia); LDH 1778 UI/l; AST 401 UI/l; ALT 168 UI/l; AF 366 UI/l; total cholesterol 366 mg/dl; LDL 293 mg/dl; triglycerides 281 mg/dl. Arterial blood gas analysis: hypoxemia and slight hypercapnia. Chest x-ray: bilateral pleural effusion and cardiomegaly. Abdominal ultrasound: cholelithiasis. EKG: low QRS voltage. Echocardiogram: severe bilateral ventricular systolic dysfunction raised filling pressures on the left, enlarged atriums and pericardial effusion. Heart coronarography: no evidence of coronary artery haemorrhage. Her thyroid function tests were suggestive of central hypothyroidism (TSH 0.70 mIU/l; FT4 <0.24). Pituitary functions test reaveled central hypothyroidism (FSH 4.1 UI/l; LH 2.6 UI/l; Estrogen <10 pg/ml; Testosterone <10 ng/dl; prolactin 0.8 ng/ml, IGF1). ACTH was not reliable because the patient had been started on corticosteroids before L-thyroxine. Sellar MRI showed an empty sella.

This case is illustrative of a rare presentation of SS, with severe heart failure and low prolactin levels (unusually found).

DOI: 10.1530/endoabs.49.EP996

Localization of the catheters during Bilateral sampling of the inferior petrosal sinuses can it impact diagnostic power?
Sabrina Chiloiro1, Alessandro Pedicelli2, Jacopo Valente2, Tommaso Tartaglione1, Antonio Bianchi1, Antonella Giampietro1, Chiara Rimai1, Liverana Lauretti1, Carmela Amile1, Alfredo Pontecorvi1 & Laura De Marinis1
1Pituitary Unit, Catholic University of the Sacred Heart, Rome, Italy; 2Department of Radiology, Catholic University of the Sacred Heart, Rome, Italy.

Introduction
Bilateral sampling of the inferior petrosal sinuses (IPSS) is considerate actually the best diagnostic test for Cushing disease.

Patients and methods
We retrospectively reviewed our series of patients undergone IPSS for Cushing disease and we compared the difference between central and peripheral ACTH gradient in basal condition and after CRH stimulation in cases of localization of the tip of the catheters inside the inferior petrosal sinus or at the confluence of the inferior petrosal sinus into the internal jugular vein. All the pituitary contrasted were suggestive of central hypothyroidism (TSH 0.77 mIU/l; sodium 135 mg/dl, aspartate transaminase (AST) 80 UI/l, alanine transaminase (ALT) 311 UI/l, gamma-glutamyltransferase (GGT) 776 UI/l, TSH 0.04 µIU/ml, free T4 0.65 ng/dl, serum cortisol (0800 h) 14 pg/dl, ACTH 19 pg/dl, prolactin 8.83 ng/ml, FSH 11.97 mIU/ml, LH 3.23 mIU/ml, testosterone 1.2 mg/dl, GH 0.77 ng/ml, IGF-1 83.4 ng/ml (94-252). Pituitary MRI showed an empty sella. Given her medical history in this clinical setting we believe a SS, left undiagnosed for 21 years, caused the panhypopituitarism.

Conclusion
This case is illustrative of a rare presentation of SS, with severe heart failure and low prolactin levels (unusually found).

DOI: 10.1530/endoabs.49.EP997

Ipilimumab-induced hypophysitis
Silvia Maria Maraver Selfa1, Maria Molina Vega1, Immaculada González Molero2, Isabel Mancha Doblas1 & Francisco Tinubones Madueño1,2
1Universitary Hospital Virgen de la Victoria, Malaga, Spain; 2Malaga Regional University Hospital, Malaga, Spain.

Hypophysitis are a heterogeneous group of inflammatory lesions affecting the hypophysis. Have been described hypophysitis secondary to administration of immunomodulatory drugs such as interferon and anti-cytotoxic T lymphocyte antigen-4 antibodies (CTLA-4). Ipilimumab is an anti-CTLA-4 human monoclonal antibody that blocks the union between CTLA-4 and B7 receptor on antigen-presenting cells causing an antitumoral effect and increasing the production of autoantibodies. Hypophysitis has been described in 17% of patients treated with this drug and usually appears before the fourth dose. Clinical presentation is similar to other causes of hypophysitis. Case report
44 years old man. Medical history: ocular melanoma with hepatic metastases 12 years after surgery. After the 3rd cycle of treatment with intravenous Ipilimumab (3 mg/kg per 3 weeks), the patient began with intense headache. Cranial MRI showed an increased hypophysis so a morphofunctional study of hypophysis was performed. Laboratory evaluation: fasting blood glucose 76 mg/dl, creatinine 0.77 mg/dl, sodium 135 mg/dl, aspartate transaminase (AST) 80 UI/l, alanine transaminase (ALT) 311 UI/l, gamma-glutamyltransferase (GGT) 776 UI/l, TSH 0.04 µIU/ml, free T4 0.65 ng/dl, serum cortisol (0800 h) 14 pg/dl, ACTH 19 pg/dl, prolactin 8.83 ng/ml, FSH 11.97 mIU/ml, LH 3.23 mIU/ml, testosterone 1.2 mg/dl, GH 0.77 ng/ml, IGF-1 83.4 ng/ml (94-252). Pituitary MRI with contrast: glandular thickening with extension to cavernous sinus and irregular contrast enhancement. After the diagnosis of Ipilimumab-induced hypophysitis with gonadal and thyroid axis deficiency associated, Ipilimumab was stopped. The patient began levothyroxine replacement therapy and treatment with prednisone 60 mg/day, with a progressive dose decrease during a month until get the correct replacement dose.

Conclusion
The use of new immunomodulatory drugs makes necessary to identify and define this hypophysitis cause and set out protocols with the oncologists to avoid undue delay in its diagnosis and treatment.

Somatostatin Analogue Treatment of a Persistant TSH-Secreting Adenoma: a report of case
Ilkucur Oztürk Unsal, Ermus Cakal, Mahmut Apaydın, Mélia Karakose, Bekir Ucan & Mustafa Ozbek
Saglik Bilimleri Universiti Diskapi Yildirim Beyazit Traning and Research Hospital, Ankara, Turkey.

Introduction
Thyroidomas are usually considered when the TSH level is inappropriately elevated or normal in a hyperthroid patient with increased serum T4 levels, regardless of the presence of visible tumor on imaging. The prevalence of these adenomas, which account for 0.5–3% of all pituitary tumors has been estimated to
be around one case per million. Most thyrothroph adenomas are large and invasive at diagnosis, and present with signs and symptoms of an expanding mass, including temporal visual field defects. Here, we report a patient treated with somatostatin analogue with pituitary macroadenoma and hyperprolactinemia.

Case reports
A 64-year-old female patient, who had undergone surgical procedure in 2014 for solitary fibrous tumor in the left parietal region, applied to be checked because of enlarged hypothysis gland documented via cranial MRI performed during follow-up visits. Laboratory findings revealed high levels of fT3 (8.56 pg/ml) and fT4 (2.1 ng/ml) with TSH (6.32 UI/ml) higher than its normal limit. On the MRI of the hypophysis, a 22 × 18 × 14 mm lesion consistent with macroadenoma, which was heterogeneously contrasted after IV Gad injection, was detected in the mid-left half of the pituitary gland. The lesion exceeds the lateral inter-carotid line in the left aspect and surrounds the left ICA higher than 240 degree. Other hormones of the anterior hypophysis were within the normal range. SHBG was 153.9 (30–100 mmol/l) and alpha subunit was 3.9 (0–1.6 EUI), which were high. There was no response to TRH stimulation test. Methimazole was commenced at a dose of 20 mg and transnasal transsphenoidal pituitary adenomectomy was performed. Somatostatin analogue (Octreotide LAR 10 mg/28 day) therapy was started for the patient, who had residual adenoma (20 × 15 mm) and in whom euthyroidism could not be achieved. Methimazole was interrupted in the 9th month of somatostatin analogue treatment and determining that the size of adenoma is 10 × 9 × 8 mm.

Conclusion
Most thyrothrophs express variable number of somatostatin receptors (SSTR), particularly SSTR2 and SSTR5. Somatostatin analogues could be considered in the treatment of persistent disease following the surgical procedure performed for TSH-secreting adenomas.

Spindle cell oncocytoma of adenohypophysis: report of a rare pituitary tumor
Carlos Marques Pontinha, Manuela Mafra, Luiz Cerqueira, Amets Sagarrabiy, Fernando Fonseca & Ana Agapito
Centro Hospitalar Lisboa Central, Lisbon, Portugal.

Introduction
Pituitary adenomas represent 95% of all sellar masses. Spindle cell oncocytoma (SCO), a rare histopathological entity (0.4% of all sellar tumours), clinically presents as a non-functional pituitary adenoma. According to WHO 2016 Classification of Tumours of the CNS it is a Grade 1 tumour, but prognosis remains uncertain since recurrence is frequently seen among the few cases reported.

Clinical case
A 59-year-old man presented with progressive fatigue, loss of libido and visual blurring for 5 years. He had pale and hairless skin and on visual field assessment a bitemporal hemianopia was diagnosis. Hormonal evaluation confirmed low testosterone and gonadotrophins as well as central hypothyroidism and hypocortisolism. PRL and IGF1 levels were normal. MRI scan revealed a T1 and T2 isointense 29 × 17 × 17 mm sellar mass with suprasellar extension causing optic chiasm compression. Transphenoidal surgery removed a grossly bleeding tumour. Histopathological examination revealed a neoplasm composed of interlacing fascicles of spindle cells with eosinophilic and oncocytic cytoplasm. Tumour cells had moderate nuclear atypia and 2 mitotic figures per 10 HPF. Ki67/MIB-1 Proliferation Index 2–5% were identified. The immunohistochemistry profile was Vimentin/S100/GFAP/EMA/Synaptophysin positive. The final diagnosis was SCO. Visual acuity and Goldmann perimetry improved significantly, but hypopituitarism persisted. MRI scan, 3 months after surgery, showed a contrast enhanced 9 × 6 × 11 mm solid intrasellar mass – normal pituitary tissue or residual tumour? Reassessment is scheduled in the next 3 months.

Commentary
An apparent total resection of a SCO was obtained. However, prognosis is difficult to predict due to the short time of follow-up. Presence of cytological atypia and mitosis in this case and knowledge of frequent recurrence rates obesys to a stringent follow-up. The histogenesis of SCO remains unproved. According to the latest genetic data, SCO and granular cell tumour of the sellar region (GCTSR) may be variants of another rare tumour, the pituitocytoma.

DOI: 10.1530/endoabs.49.EP1000

Resistant microprolactinoma with partial empty sella
Sevgül Faki, Şefika Burçak Polat, Cevdet Aydin, Reyhan Ersoy & Bekir Çakır
Department of Endocrinology and Metabolism, Ankara Yıldırım Beyazıt University, School of Medicine, Ankara, Turkey.

Introduction
Prolactinomas are the most common hormonally active pituitary tumors that account for 40–60% of all pituitary adenomas and are usually successfully treated with dopamine agonists. Surgery or radiotherapy is reserved for drug intolerance/resistance or in neuro-ophthalmological emergencies. We present a patient with refractory microprolactinoma with empty sella treated by transphenoidal surgery.

Case
42-year-old female patient admitted with a 14 years history of prolactinoma being treated with dopamine agonists for ten years. At the end of the tenth year, the tumor was resistant to high dose cabergoline (4 mg/week). Magnetic resonance imaging (MRI) revealed a partial empty sella with 6.5 × 3.5 mm pituitary adenoma. She underwent transphenoidal surgery. Histopathologically, a pituitary adenoma with rare mitotic figures, Ki-67 index of 2%, no expression of p53 and no other features of atypia was identified. Immunohistochemistry showed expression of prolactin by majority of the cells. Postoperative MRI demonstrated empty sella (height of the gland was 2 mm) and no residual mass. After operation, cabergoline was restarted because of high prolactin levels and demonstrated empty sella (height of the gland was 2 mm) and no residual mass. Later, there is no neuro-endocrine symptomatology, with adrenal axis recovery without substitute treatment and in treatment with desmopressin 100 mg with withdrawal approach, in joint follow-up with skull MRI study and hypophysis consultation. The patient reported amenorrhea. Despite a substantial increase in dosage there was no clinical improvement in amenorrhea and galactorrhea and there was not any biochemical improvement in cortisol axis.}

Endocrine Abstracts (2017) Vol 49
response. Her other anterior pituitary hormones were normal while serum prolactin was 255 ng/ml (4.79–25.3 ng/ml) in her last visit.

Conclusion

A minority of patients, ranging from 10–20% in different series does not achieve normoglycemia and/or tumor shrinkage despite treatment with high doses of dopamine agonists. Those tumors are usually macroadenomas with cavernous sinus invasion and rarely microadenomas. Resistance can be documented by demonstrating the absence or poor expression of D2 receptors on the membrane surface of tumor cells, or abnormalities at a postreceptor level. However, molecular biology studies cannot be routinely performed in our center. Exchange of cabergoline with bromocriptine was successful in few cases in the literature.

A rare case of macroprolactinoma presenting with SIADH
Khaleed Dukhan & Khaled Ashawesh
Hamad Medical Corporation, Doha, Qatar.

Case

A 52-year-old gentleman was admitted with dizziness and collapse. Past medical history revealed dyslipidemia treated with statin. Physical examination was unremarkable. Initial investigations were consistent with SIADH (sodium: 109 mmol/l, serum osmolality: 243 mOsm/kg, urine Na: 59 mmol/l and urine osmolality: 191 mOsm/kg). Urea, creatinine and random glucose were normal. CT Head showed pituitary enlargement with sellar expansion. Pituitary profile showed high prolactin: 8305 mIU/ml, low IGF-1: 78.1 µg/l and low testosterone: 3.83 nmol/l with normal LH and FSH. Thyroid function was normal with intact pituitary–adrenal axis (normal Glucagon and ACTH stimulation tests). MRI pituitary confirmed macroadenoa with heterogeneous solid-cystic mass (2.0 × 1.9 × 1.5 cm) with deviation of pituitary stalk. He was treated with Cabergoline 0.5 mg per week and few days of fluid restriction with improvement of sodium level to 137 mmol/l and prolactin to 61 mIU/l after 2 weeks. Over 5 months follow up, he remained asymptomatic with normal sodium and prolactin on Cabergoline. Hypogonadism has resolved and IGF-1 has normalized. Repeat MRI 4 months after discharge showed significant reduction in macroadenoma size to 1.4 × 1.3 × 0.7 cm with pituitary stalk being in midline.

Discussion

Hyponatremia complicating pituitary macroadenomas is usually related to secondary hypoadrenalism. However, the presence of SIADH with intact pituitary–adrenal axis in such cases is very rare with only seven cases reported in literature (six non-functioning macroadenomas and one macroprolactinoma). The mechanism of AVP release in these cases is not fully understood, but is thought to be related to local mechanical stress on the AVP neurons axonal terminal and dislocation of pituitary stalk and neurohypophysis by pituitary tumor.

Conclusion

We hereby report the second case of SIADH secondary to macroprolactinoma with normal pituitary–adrenal axis. Pituitary macroadenomas should be considered in differential diagnosis of SIADH even in context of preserved pituitary-adrenal axis.

Clinical characterization and comparison of patients with hypophysary tumors and primary empty sella
Ailin Abreu, María Eugenia Casanova & Orlando Castaño
Universidad Libre Seccional, Cali, Colombia.

Introduction

Non-functioning pituitary tumors and primary empty sella are a common pathology within the differential diagnosis of pituitary masses. The manifestations will depend on the size of the tumor and the compression of adjacent structures being the most frequent neurological symptoms. Clinically the two entities are very similar and no clinical tools are known to be able to help the differential diagnosis.

Objective

Perform a clinical and comparative characterization between patients with non-functioning pituitary tumors and primary empty sella.

Materials and methods

A retrospective cohort study conducted in a highly complex center of the city of Cali, Colombia between January 2002 and December 2014.

Results

A total of 141 cases were found. 32% had a macroadenoma, 30% had a macroadenoma and 38% had a primary empty sella. 61% of the patients with non-functioning pituitary tumors were women, as well as 51% of the cases of primary empty sella. The largest number of patients with pituitary tumors were between 20 and 40 years old while in primary empty sella was between 40 and 59 years. Headache was reported in 88% of cases, followed by visual disturbances in 59% and galactorrhea in 41% of cases. As expected, the non-functioning macroadenomas were those with the highest prolactin value with mean of 50 ng/ml. 97% of non-functioning microadenomas reported headache being more frequent than in cases of macroadenomas and primary empty sella, this suggests the presence of an additional tension component.

Conclusion

Non-functioning pituitary tumors and the primary empty sella are frequent entities within the pituitary masses. The clinical distinction of these entities is quite difficult and requires the accomplishment of an adequate clinical history, adequate interpretation of hormonal and imaging studies.

**Prolactinomas in men: retrospective analysis**

Teresa Rego, Carolina Neves, Ana Margarida Palha, Luisa Cortez, Fernando Fonseca & Ana Agapito

Department of Endocrinology, Centro Hospitalar Lisboa Central, Lisbon, Portugal.

**Introduction**

Prolactinomas in men are rare and the majority are macroadenomas. Some studies suggest that these tumors in men have higher proliferative activity and aggressiveness indicating gender-specific differences in biological behavior. Dopamine agonists (DA) are considered first-line therapy.

**Methods**

Retrospective analysis of male patients diagnosed with prolactinoma between 2005 and 2016. Age at presentation, clinical, hormonal and image data were collected. Mode and responses to therapy were analysed.

**Results**

Twenty-two patients with median age at diagnosis of 50.8 years were observed. Sexual dysfunction was the main complaint (59.1%), followed by headaches (50%) and visual disturbances (36.4%). Imagiology revealed macroadenoma in 95% of the cases (19% giant). At the time of diagnosis mean value of prolactin (PRL) was 3.662 ng/ml (min 177 ng/ml, max 23,200 ng/ml). Hypogonadism was present in 54.5%. Fourteen patients (63.6%) were treated with DA as the only therapy and eight patients (36.4%) with DA and neurosurgery. From the latter three presented pituitary apoplexy, four were misdiagnosed as non-functioning adenoma and one presented cerebrospinal fluid rhinorrhea. None of these patients were cured after surgery and all received medical therapy. At the last visit normalization of PRL level were observed in 59.1% of the patients (71.4% treated with AD as only therapy) and 77.8% of the remaining presented a PRL level less than 2X upper limit of normal. Reversal of hypogonadism occurred in 66.7%.

**Conclusions**

Our data confirms that prolactinomas in men are usually symptomatic macroadenomas. Although DA were efficient in reducing tumor size and normalizing PRL, surgery was performed as first-line therapy in four patients due to misdiagnosis and possibly late referral to our department. The correct diagnosis is crucial for successful treatment and avoidance of unnecessary surgery.

**Residual tumour diameter may influence reduced survival in females with nonfunctioning pituitary macroadenomas**

Simona Galoiu1,2, Iulia Burcea1, Simona Silea1, Gana Voicu1, Ionela Baciu1,2, Anda Dumitrascu2, Andra Caragheorgheopol2 & Catalina Poiana1,2

1Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2C.I. Parhon National Institute of Endocrinology, Bucharest, Romania.

**Objective**

Patients with pituitary macroadenomas and concomitant hypopituitarism have a reduced life expectancy due to various comorbidities.

**Aim**

To investigate mortality in patients with non-functioning pituitary adenomas (NFAs) and independent prognostic factors influencing survival.

**Design**

Retrospective cohort study in a tertiary neuroendocrine university department.

**Methods**

A total of 364 patients (177F/187M) evaluated for a macroNFA between 2001 and 2016 were studied. PAMCOMP computation program was used to calculate standardized mortality ratio (SMR). Cox regression analysis revealed independent factors associated with mortality.

**Results**

During follow-up (median 7.5 years – 2135.94 person years), 47 patients died, versus 33 expected from general population, corresponding to a SMR of 1.39 (95% CI 1.02–1.84). Females had a doubled mortality ratio: SMR 2.13 (95% CI 1.30–3.29). 254 patients (69.8%) were operated and 87 patients (23.9%) were irradiated. After pituitary surgery and/or radiotherapy, pituitary tumour remnant diameter decreased with 35.6% to 37.3% (range 0–100%). Only 24 (6.6%) of patients were cured after radical therapy (no remnant). Cox-regression analysis demonstrated that age at diagnosis and pituitary tumour diameter at last evaluation remained independent predictor factors correlated to mortality (hazard ratio HR 1.07 (95% CI 1.046–1.101, P<0.001) and respectively HR 1.02 (95% CI 1.046–1.101, P=0.018)), whereas pituitary surgery or radiotherapy, pituitary failure had no impact.

**Conclusions**

In our patients with pituitary NFA mortality is still increased, especially in women, influenced independently by the age at diagnosis and residual pituitary tumour diameter. A greater extent of tumour removal may increase survival.

**Autoimmune hypophysitis with isolated corticotroph cell destruction due to Pembrolizumab treatment in a female patient with metastatic melanoma**

Emmanouil Vasileiou1, Charalampos Tsentidis2, Andreas Bampilis3, Vasiliki Stotva2, Grigoris Betsi2 & Georgia Kassi2

1Private Practitioner, Samos Island, Greece; 2Department of Endocrinology, Metabolism and Diabetes, Nikaia General Hospital ‘Ag. Panteleimon’, Athens, Greece.

**Introduction**

Pembrolizumab is a programmed death receptor-1 (PD-1)-blocking antibody, used in a variety of advanced malignant tumors with promising results, although adverse events are not rare.

**Case report**

We present the case of an adult female, with negative personal and family history of autoimmune diseases, who developed malignant superficial melanoma of right wrist 6 years ago. She was initially treated with surgical resection (lesion and ipsilateral axillary lymphadenectomy) and high dose interferon treatment and re-operated due to multiple regional right in transit and left axillary lymph node metastases. Melanoma was positive for B-Raf mutation and the patient received Vemurafenib for 3.5 years and then Ipilimumab for four months (lung metastases). During that period she developed subclinical hypothyroidism, treated with thyroxin. She finally received treatment with Pembrolizumab (multiple mediastinal and right axillary lymph node metastases) with gradual tumor recession within 4 months. She developed acute pancreatitis, without diabetes mellitus, treated conservatively. Two months after full melanoma recession she developed fatigue, anorexia and diplopia for a few days without significant findings in brain MRI. A 5-month period followed with exacerbations and remissions of somnolence, cognitive dysfunction, anorexia, and weight loss and finally developed hypotension and hypoglycemia. After a low morning cortisol (4 μg/dl) measurement, she received full hydrocortisone replacement therapy with complete symptoms remission. Thyrotoxic dose was increased and vigilato was developed during that period. There were no significant findings in hypothyroidism and melanoma restaging showed complete disease remission. Hormonal profile (2nd menstrual cycle day) showed: PRL 12 ng/ml (1.9–25), LH 1.2 mIU/ml (1.1–11.6), FSH 2.6 mIU/ml (0.7–11.1), E2 461 pg/ml (13–186), SHBG 103 nmol/l (18–114), GH 0.93 ng/ml (0.06–5.4), IGF-1 195 ng/ml (94–252), ACTH 1 pg/ml (7–50) while SST for cortisol was 1, 3 and 3 μg/dl at 0, 30, 60 min respectively.

**Conclusion**

Pembrolizumab completely controlled metastatic melanoma in our patient through immune stimulation. Hypophysitis with isolated corticotroph cell destruction was developed as an adverse event. If confirmed in other cases Pembrolizumab could be used in treatment of refractory Cushings’s disease.

Aggressive pituitary tumors: a tertiary center experience
Adriana Lagos1, Isabel Paiva1, Leonor Gomes2, Patricia Oliveira1, Francisco Belo1, Diana Oliveira2, Diana Martins2, Mara Ventura1, Nelson Cunha1 & Francisco Carrilho1
1Coimbra Hospital and University Center, Coimbra, Portugal; 2Faculty of Medicine University of Coimbra, Coimbra, Portugal.

Background
Pituitary adenomas (PA) are common intracranial tumors that are mainly considered benign. A small group of patients exhibit clinically aggressive behavior sometimes unrelated to the histopathological or radiological features.

Methods
Twelve patients were selected harboring a PA with clinical features of aggressiveness. All the patients underwent pre and postoperative neuroradiological evaluation.

Results
10/12 patients were male, mean age at diagnosis 38.1 years (range 12–58) and mean follow-up 14.3 years (range 5–28; died 3/12). In 9/12 cases, the first manifestation was visual impairment (visual field loss, reduction in visual acuity and/or cranial nerve palsies). All the patients had invasive pituitary macroadenomas with expansion into surrounding anatomical structures (11 cavernous sinus; 7 sphenoid sinus; 7 bone invasion). The 12 patients underwent a total of 52 surgical procedures (median 4; range 3–6). Apparently total removal was achieved in 8/12 patients at the first surgical procedure. Regarding histological subtype: 5 gonadotrophinomas; 2 null-cell adenomas; 2 corticotrophinomas; 1 thyrotrophinoma; 1 prolactinoma and 1 plurihormonal adenoma (GH/ACTH).

Proliferation markers as ki67 and p53 IHC expression in 4/12 cases. Six patients underwent radiation therapy (RT) postoperatively (5 conventional external RT; 1 stereotactic radiosurgery). Medical therapy was tried in 4/12 patients: 3 with dopamine agonists; 1 with somatostatin analog (pasireotide); 2 with steroidogenesis inhibitors (ketoconazole and metyrapone). Possible metastatic pulmonary disease was identified only in one case: the patient died of tumor progression 10-years after the diagnosis.

Conclusion
Aggressive pituitary tumors constitute a challenging but not completely defined entity. We found an elevated number of surgical procedures by patient and postoperative surgical procedures (median 4; range 3–6). Apparently total removal was achieved in 8/12 patients at the first surgical procedure. Regarding histological subtype: 5 gonadotrophinomas; 2 null-cell adenomas; 2 corticotrophinomas; 1 thyrotrophinoma; 1 prolactinoma and 1 plurihormonal adenoma (GH/ACTH).

EP1011

Assessment of macroprolactin through post-PEG monomeric prolactin measurement and comparison with gel filtration chromatography in hyperprolactinemic samples
Antonio Ribeiro-Oliveira Jr & Maria do Carmo D Gonçalves
Federal University of Minas Gerais, Belo Horizonte, Brazil.

Macroprolactin interference is a common problem in the interpretation of immunoassays for prolactin. Identifying macroprolactinemia can prevent errors in diagnosis and subsequent delivery of treatment to patients. The search for macroprolactin through polyethylene glycol (PEG) precipitation followed by percentage recovery is the most common used method in clinical laboratories. This study aimed to evaluate the implementation of macroprolactin assessment in hyperprolactinemic samples, with the interpretation of the results based on validated post-PEG monomeric prolactin reference range. It also aimed to verify whether post-PEG monomeric prolactin measurements could match the results obtained through Gel filtration chromatography (GFC). Samples from 40 healthy subjects were utilized for the validation of the post-PEG monomeric prolactin reference range, according to predetermined data quality. The macroprolactin assessment by PEG precipitation was then performed on 112 hyperprolactinemic samples (96 women), and results obtained by percentage of post-PEG prolactin recovery were compared with post-PEG monomeric prolactin concentrations. Twenty-five out of the 112 hyperprolactinemic samples were randomly selected for evaluation through GFC for further comparisons. Assessment of post-PEG monomeric prolactin concentration with an appropriate validated reference range showed greater specificity than the conventional criterion of percentage of post-PEG prolactin recovery, as it identified samples with both excess macroprolactin and monomeric bioactive prolactin, and also reduced the rate of indeterminate results. Furthermore, most of the results obtained in samples analyzed by GFC were in agreement with results obtained by post-PEG monomeric prolactin measurement. The assessment of macroprolactin through a validated post-PEG monomeric prolactin reference range should be adopted as it outperformed the current utilized criterion.

EP1012

Sheehan syndrome: Sequential hormone failure and late diagnosis
Cristiana Costa1, Ana Filipa Martins1, Alexandra Araújo1 & Sofia do Vale1,2
1Endocrinology Department, Santa Maria Hospital, North Lisbon Hospital Center, Lisbon, Portugal; 2Endocrinology Department, Lisbon Medical School, Lisbon, Portugal.

Introduction
Postpartum infarction of the anterior pituitary, known as Sheehan’s syndrome, is a rare cause of hypopituitarism. In many cases, the hormones deficiency is sequential which implies late diagnoses.
Case Report 1
A 51-year-old woman was observed because her mother had medullary thyroid carcinoma. She had no evidence of endocrine neoplasia. Nevertheless, she was experiencing fatigue, hair loss and dry skin for several months. Her history included a postpartum haemorrhage at 22 with blood transfusion requirement. She was unable to breastfeed and mentioned oligomenorrhea cycles after that and took two years to get pregnant again. Menopause was at 43. Physical examination was unrevealing. Baseline endocrinologic evaluation revealed low gonadotropins, IGF-2 and FSH with inappropriate normal thyrotrophin, PRL of 2.5 ng/ml and morning cortisol of 8.7 mcg/dl with ACTH of 15.3 pg/ml. A multiple pituitary stimulation test confirmed the deficiency of all anterior pituitary hormones except the pituitary-adrenal axis. Levodrothyroxine reposition was prescribed.

Case report 2
A 78-years-old woman was referred to the endocrinology outpatient department after hospital admission due to hypotension, hyponatremia (113 mmol/l) and hypothyroidism that improved with corticotherapy. She reported asthenia, weakness, myalgias and anorexia that worsened progressively 2 years before admission. Her third pregnancy occurred at the age of 28, with severe blood loss at delivery, inability to breastfeed, oligomenorrhea cycles after that and menopause at 36. Endocrine evaluation confirmed a panhypopituitarism and the CT scan showed an empty sella turcica. She became asymptomatic with hydrocortisone and levothyroxine reposition.

Conclusion
These cases represent two very late diagnosis of Sheehan’s syndrome. Appropriate obstetric/gynaecologic history and clinical suspicion are required to avoid late manifestations of the disease, namely an adrenal crisis, because the pituitary-adrenal axis is usually the last one failing. Timely treatment may dramatically improve quality of life of these patients, who may experience hypopituitarism for long years before diagnosis.

EP1013
Multimodal treatment in pituitary carcinoma arising from an ACTH-expressing pituitary macroadenoma with an unexpected long-term survival
Cesar Boguszewski, Felipe Schwambach, Karina Manosso & StefLiane Pallone
SEMPR (Endocrine Division), Department of Internal Medicine, Federal University of Parana, Curitiba, Brazil.

Pituitary carcinoma (PC) is defined by the presence of pituitary tumor that is either not contiguous with the primary sellar tumor and/or has metastasized to distant sites. It is very rare and associated with poor prognosis, with a median survival of 12 months when systemic metastases are present, and 30 months when metastases are confined to the central nervous system. A 20 years-old man was first diagnosed with a nonfunctioning pituitary macroadenoma in 1981 and submitted to transsphenoidal surgery (TSS). Histology showed ACTH positive tumor, p53 negative and Ki-67 1%. Three years later a recurrence was detected and a new TSS followed by conventional radiotherapy (RTx) was performed. Hormone replacement therapy (HRT) was initiated for TSH, ACTH and FSH/LH deficiencies. In 2000, at age 39, he complained of prolonged nasal obstruction. Imaging showed a giant invasive sellar tumor with extension to suprasellar region, cavernous sinuses, and nasopharynx; multiple extra-axial lesions in the posterior fossa suggesting meningeval secondary implants and a large mass in the cervical-thoraco-lumbar spine. Histology of the resected giant adenoma and the spinal lesion confirmed an ACTH-expressing PC with a high proliferative index. Fractionated stereotactic Rtx was performed. Cabergoline and pasireotide were prescribing, but discontinued after some months due to side effects. Tumor regrowth occurred in 2009 when surgery was repeated for removal of the main tumor followed by Rtx directed to cerebellar lesions, and again in 2015, when a microsurgery guided by localization systems and electrophysiological monitoring was carried out. Temozolomide was prescribed but patient refused the use. Currently, at age 55, he is doing well, working, and maintaining a stable clinical condition under HRT. Latency time from the diagnosis of pituitary adenoma to PC was 19 years, and his survival of 16 years after diagnosis of PC has no parallel in the literature to date.

Renal prognosis of diabetic patients with and without central diabetes insipidus
Junichi Yatabe1, Midori Yatabe1, Tetsuya Babazono2, Yasuiko Uchigata2 & Atsushi Ichihara2
1Tokyo Women’s Medical University, Endocrinology and Hypertension, Tokyo, Japan; 2Tokyo Women’s Medical University, Diabetes Center, Tokyo, Japan.

Background
It has been suggested that higher arginine vasopressin (AVP) concentration may be associated with greater eGFR decline in diabetic patients not using inhibitors of the renin-angiotensin system (Diabetologia 2013). If excessive AVP action is detrimental to renal prognosis, then diabetic patients with central diabetes insipidus (CDI) may have relatively preserved renal function. Therefore, we aimed to compare long-term renal prognosis of diabetic patients with and without CDI.

Methods
We retrospectively identified 39 diabetic patients with CDI followed up at our university hospital for more than 4 years. Propensity matching for baseline age, sex, BMI, HbA1c, eGFR, SBP, DBP, urinary protein, and length of observation was performed to select 39 control diabetic patients without CDI in the same hospital.

Results
Baseline demographics of the CDI group were as follows: age 45.6 years, 41% female, BMI 27.2, HbA1c 7.0%, eGFR 90.4 ml/min/1.73 m², blood pressure 122/79 mmHg and observation of 1862 days (mean values). There was no statistical difference in eGFR at the end of observation period (Control: 86.3 ± 28.1 vs CDI: 85.8 ± 33.7 ml/min/1.73 m²) or the slope of eGFR (Control: −0.9 ± 3.6 vs CDI: −1.1 ± 10.7 ml/min/1.73 m²/year) between groups. On the other hand, eGFR variability (standard deviation) was significantly greater in the CDI group (Control: 7.9 ± 5.1 vs CDI: 18.3 ± 13.3 ml/min/1.73 m², P < 0.01). Considering that excessive fluctuations in eGFR are damaging to the kidney in general, CDI patients may exhibit milder decline in eGFR when eGFR variability and other factors, such as the use of renin-angiotensin system inhibitors, are matched between groups.

Conclusion
A simple analysis of long-term eGFR revealed no significant difference between diabetic patients with and without CDI. Nevertheless, confounding factors, such as greater eGFR variability in CDI patients, may have weakened the relationship between AVP action and decline in renal function.

EP1015
Osilodrostat maintains normalized urinary free cortisol levels in a majority of patients with Cushing’s disease: Long-term results from an extension to the LINC-2 study
Jacques Young1, Betul Hatipoglu2, Mark E Molitch1, Xavier Bertagna3, Nathalie Barbier3, Nicholas Sauter3, Beverly M K Biller1 & Rosario Frimolli2,3
1Department of Endocrinology, Hôpital Bicêtre, Université Paris-Sud, Assistance Publique Hôpitaux de Paris, Paris, France; 2Endocrinology and Metabolism Institute, Cleveland Clinic, Cleveland, Ohio, USA; 3Division of Endocrinology, Metabolism, and Molecular Medicine, Northwestern University, Chicago, IL, USA; 4Department of Endocrinology, Centre de Référence des Maladies Rares de la Surre nale, Hôpital Cochin, Faculté de Médecine Paris Descartes, Université Paris 5, Paris, France; 5Novartis Pharma AG, Basel, Switzerland; 6Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA; 7Neuroendocrine Clinical Center, Massachusetts General Hospital, Boston, MA, USA; 8Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Università Federico II di Napoli, Naples, Italy.

Background
In the 22-week LINC-2 study, osilodrostat (LCI699), a potent oral 11β-hydroxylase inhibitor, normalized urinary free cortisol (UFC) levels in 15 of 19 patients with Cushing’s disease (CD). The most common AEs were nausea, diarrhea, asthenia, and adrenal insufficiency (n=6 each). Here, we report the 31-month efficacy and safety results from LINC-2 extension.
Methods
Patients receiving clinical benefit at week 22 could enter two consecutive extensions and continue on the same dose of osilodrostat; dose adjustments were allowed. Response rate: proportion of patients with UFC ≤ ULN (controlled) or UFC > ULN but ≥ 50% decrease from baseline (partially controlled). The maximum safety follow-up from core baseline was 40.3 months.

Results
Sixteen patients entered the extension, 12 remained on treatment at month 31. Three patients discontinued during extensions (AEs, n=2; consent withdrawal, n=1). One patient decided not to continue on extension-2. The response rate at month 31 was 100% (controlled, 14 (87.5%); partially controlled, 2 (12.5%) when missing values were imputed using the last available measurements and 56.3% without imputation ((controlled, 8 (50.0%); partially controlled, 1 (6.3%)); No patient had escape from response (UFC normalization) during the extension. Mean (s.d.) changes in clinical signs of CD from baseline to month 31 (n=11) were: SBP (mmHg), −3.4 (18.5); DBP (mmHg), −5.4 (9.9); weight (kg), −4.5 (5.7); and BMI (kg/m²), −1.8 (2.3). The most common clinical AEs were diarrhea, hypocortisolism-related AEs (n=6 each), headache, asthenia, and nausea (n=5 each). Mean (s.d.) plasma ACTH (pmol/l; normal, 1.8–9.2) at baseline (n=15), week 22 (n=15) and month 31 (n=10) were 20.0 (10.4), 80.5 (145.5), and 54.0 (35.1), respectively.

Conclusion
In the majority of patients with CD, osilodrostat maintained normal UFC levels for ≥2.5 years with a long-term safety profile similar to that after 22 weeks; no new safety signals emerged. Two phase 3 studies are ongoing to further evaluate osilodrostat in patients with CD.

Acromegaly: assessing the clinical outcome through a 10-year experience at a tertiary care hospital in Pakistan
Shehla Tabassum & Najmul Islam
Aga Khan University, Karachi, Pakistan.

Background
Acromegaly is due to excess Growth hormone (GH) production, usually as result of pituitary adenoma. The diagnosis is often preceded by around 5 years of active but unrecognized disease. Clinical expression of the disease in each patient depend on the levels of GH and Insulin-like Growth Factor-1 (IGF-1), age, tumor size, and the delay in diagnosis. Successful remission after Trans-sphenoidal surgery (TSS) is reported to be found in 52.5% of cases in the developed countries.

Objectives
This study was designed primarily for the evaluation of diagnostic characteristics of acromegaly and establishment of its management outcomes over a span of 10 years at a tertiary care hospital in Pakistan.

Methods
It was a Descriptive cohort study. Total 53 patients with biochemical and radiological diagnosis of Acromegaly were included in study between October, 2005 to September, 2015. Patients' medical record files were reviewed and data recorded.

Results
Of the 53 subjects, with mean age of 39.68 ± 14.35 years, 33 (62.3%) were male while 20 (37.7%) were female. The patients presented at a mean duration of 5.90 ± 4.12 years after onset of symptoms. The most frequent complaint was somatic growth features in the form of enlarged hands and feet noted by 51 (96.2%) pts. Overall, 50 (94.3%) patients underwent TSS for removal of pituitary adenoma while 3 (5.7%) patients refused to opt surgical option. Only 3 (6%) patients achieved biochemical and radiological remission after 6 months of surgery. Among 47 patients with persistent disease after TSS, 26 (55.3%) were treated with radiotherapy/ radiotherapy, 12 (25.5%) underwent repeat TSS and 9 (19.1%) opted for medical treatment, mostly with Cabergoline.

Conclusion
TSS is followed by the documentation of a high rate (94%) of failure to achieve remission and majority of patients have to opt radiotherapy/repeat TSS for the persistent disease. With the continuously improving surgical skills, we expect that the figures attaining remission after primary TSS will rise in the decades to come.

Evaluation of upper gastrointestinal system in acromegaly
Pinar Sisman1, Murat Pelgöz2, Mete Sisman3, Soner Cander4, Ozan Oz Gu5, Erdine Erturk6 & Canan Ersoy6
1Harakani State Hospital, Endocrinology and Metabolism Clinic, Kars, Turkey; 2Sirnak State Hospital, Gastroenterology Clinic, Sirnak, Turkey; 3Muradiye State Hospital, Surgery Clinic, Bursa, Turkey; 4Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Background
Because of prolong exposure to elevated endogenous growth hormone (GH) and insulin-like growth factor (IGF-1) levels in acromegaly, it is resulted in multiple comorbidities such as somatic growth, hypertension, diabetes and sleep apnea. Systemic complications caused by acromegaly include gastrointestinal (GIS) involvement. In our study it was planned to evaluate the upper GIS findings by using endoscopic and ultrasonographic methods in acromegaly patients.

Subjects and methods
Thirty-nine acromegaly patients who had attended to our center for the last 6 months were recruited to the study. Upper GIS endoscopies and abdominal ultrasonography were performed to all patients.

Results
Of the patient included in the study, 23 were male and 16 were female. The mean age of the patients was 51.4 ± 11.0 years. The mean duration of acromegaly was 104.3 ± 88.6 months. Upper GIS endoscopy was performed in 39 patients and hiatal hernia, esophagitis and gastritis, duodenitis or gastric ulser were found in 3 (7.6), 2 (5.0) and 31 (79.4) patients, respectively. In the pathologic evaluation of gastric antrum biopies, intestinal metaplasia was detected in 12 (30.7%) patients and helicobacter pylori was positive in 13 (33.3) patients. Abdominal ultrasonographic evaluation revealed cholelithiass in 15 (38.6) patients.

Discussion
As a result of our study, there was no statistically significant difference between age also sex and hiatal hernia, esophagitis, gastroduodenitis, ulcer development in acromegaly patients. Preoperative GH elevation did not affect the development of hiatal hernia, whereas preoperative IGF-1 elevation significantly increased hiatal hernia development. The incidence of developing cholelithiasis was statistically significantly higher in patients with advanced age, long disease duration and no postoperative biochemical control. Limitations of our study are the lack of a control group and the low number of patients. There is a need for controlled studies involving more patients in acromegaly patients.

Disposition index in active acromegaly: A pilot study
Dan Alexandru Niculescu1,2, Roxana Dusceae1,2, Anda Carageaheorgheopol1, Nicoleta Popescu1 & Catalina Popan1,2
1Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2C. I. Parhon Institute of Endocrinology, Bucharest, Romania.

Background
Active acromegaly is characterized by decreased insulin sensitivity (ISen). However, insulin secretion (Isec) may not increase satisfactorily to compensate for the low ISen.

Aim
To assess ISen and Isec and to calculate disposition index (DI) using an intravenous glucose tolerance test (IVGTT) in patients with active acromegaly.

Methods
Twelve patients (7 men, 5 women) with active acromegaly and 2 normal subjects (2 men) underwent a standard IVGTT with a glucose dose of 0.3 g/kg of body weight. Eight patients had normal glucose tolerance (NGT) and 4 had impaired glucose tolerance (IGT). None were on medication for acromegaly or glucose intolerance. ISen was calculated as the slope of the glucose curve between 10 and 75 min (the rate of glucose disappearance) divided by the area under the insulin curve between 0 and 75 min. Isec was calculated as the acute insulin response, the delta area under the insulin curve between 2 and 10 min after glucose infusion. DI was calculated as ISen times Isec.

Results
Subjects with NGT (8 patients with acromegaly and 2 normal subjects) had a significantly higher DI than patients with IGT (801 (632, 1762) vs. 172 (98, 247); P < 0.001). Inside the IGT group there were both patients with extremely low ISen
EP1019
In well-controlled patients with acromegaly, glucose homeostasis correlates with the level of disease control rather than with the type of treatment.
Charlotte Verroken, Bruno Lapauw & Guy T’Sjoen
Department of Endocrinology, Ghent University Hospital, Ghent, Belgium.

Objective
Acromegaly is often accompanied by abnormalities in glucose and lipid metabolism, which tend to ameliorate upon treatment. However, few studies have investigated whether glucose homeostasis and lipid profiles are differently affected by different treatment regimens. This study aimed to compare glucose homeostasis and lipid profiles in patients with acromegaly who are well-controlled after surgery or under stable treatment with long-acting somatostatin analogs (SSA) either in monotherapy or in combination with pegvisomant.

Methods
Cross-sectional study in 21 patients with a diagnosis of acromegaly (aged 59.1±10.9 years, 10 males), who were controlled (i.e. serum IGF-1 levels under sex- and age-specific thresholds) after surgery (SUR; n=5) or under treatment with SSA (SSA; n=10) or SSA + pegvisomant (COMBI; n=6). Glucose, insulin, total cholesterol, HDL-C and LDL-C were measured from fasting serum samples. Triglycerides were measured during a mixed-meal tolerance test (MMTT). Insulin resistance was evaluated using the homeostasis model assessment of insulin resistance (HOMA-IR); insulin sensitivity was evaluated by hyperinsulinemic-euglycemic clamp.

Results
IGF-1 levels tended to be lower in SUR (138.4±54.4 ng/ml) as compared to SSA (194.5±16.3 ng/ml) or COMBI (173.3±52.3 ng/ml) (P=0.056). After adjustment for age and BMI, between-group differences were observed for HbA1c (P=0.048), fasting glucose (P=0.022), and HDL-C (P=0.015), with lower levels in SUR as compared to SSA or COMBI. No differences were observed in fasting insulin, cholesterol, LDL-C, HOMA-IR, glucose disposal rate during clamp, or triglyceride levels during MMTT. Independently of the treatment regimen, IGF-1 levels correlated positively with fasting glucose and insulin levels (β=0.52 and β=0.57, both P=0.010), with HOMA-IR (β=0.66, P=0.003), and inversely with glucose disposal rate (β=-0.60, P=0.006).

Conclusion
In patients with acromegaly who are controlled after surgery or under stable medical therapy, indices of glucose homeostasis correlate with circulating IGF-1 levels, independently of the treatment regimen.

European observational study of long-acting pasireotide for uncontrolled acromegaly: ACRONIS study design and rationale
Andrea Giustina1, Gesine Enderle2, Daniela Mesenka3, Debolina Mondal4 & Christof Schoff5
1Cattedra di Endocrinologia, Universita’ Vita e Salute San Raffaele, Milan, Italy; 2Novartis S.p.A, Origgio, Italy; 3Novartis s.r.o., Prague, Czech Republic; 4Novartis Healthcare Pvt. Ltd., Hyderabad, India; 5Centre of Endocrinology and Metabolism, Obstmartk 1, 96047 Bamberg, Germany.

Introduction
Acromegaly is a rare, serious disease caused by the presence of a pituitary adenoma secreting an excessive amount of growth hormone (GH), which leads to a consequent increase in circulating insulin-like growth factor-1 (IGF-1) levels, and excessive skeletal growth and soft tissue enlargement. It is usually managed by surgery and/or treatment with somatostatin analogs (SSA). The ACRONIS study (CSOM230CIC05) will provide real-world evidence on the efficacy and safety of the multi-targeted SSA long-acting pasireotide in uncontrolled acromegaly patients.

Methods
This non-interventional study will analyze efficacy and safety data in acromegaly patients (≥18 years) already treated (for ≥6 months) with monthly pasireotide (retrospective dataset) or about to be treated (prospective dataset). About 200 prospective patients (2-year follow-up) and 50 retrospective patients are expected to be enrolled. Outcome measures will include biomarkers (GH and IGF-1), pituitary imaging, symptom- and quality of life (QoL) scores. The primary objective is to document treatment efficacy within the prospective data subset; the endpoint will be the proportion of patients who achieve IGF-1 <1 upper limit of normal (ULN) and GH <1 μg/l after 6 months. Secondary endpoints will include the proportion of patients at 6 months (retrospective) or within 2 years (prospective) who achieve IGF-1 <1 or <1.3 ULN and GH <1 or 2.5 μg/l, change in tumor size, signs and symptoms, QoL, and incidence of hyperglycemia. Safety assessments will include adverse events, hematometry, clinical chemistry and physical examinations. Interim analyses will be performed once at least 50 retrospective patients have been exposed to 6 months of treatment and 100 prospective patients have been treated for at least 6 months, respectively. Descriptive statistics, as well as, absolute and relative frequencies will be reported.

Conclusion
ACRONIS will provide European real-world data to increase our understanding of the long-term efficacy and safety of pasireotide in uncontrolled acromegaly.

Thyrotropin secreting microadenoma ~ case report of a patient with goiter
Sôbisto de Vale1,2, Ana Filipa Martins3, Dolores López-Presa3, Cristiana Costa1 & José Migues1
1Endocrinology Department, Santa Maria Hospital, North Lisbon Hospital Center, Lisbon, Portugal; 2Endocrinology Department, Lisbon Medical School, Lisbon, Portugal; 3Pathology Department, Santa Maria Hospital, North Lisbon Hospital Center, Lisbon, Portugal; 4Neurosurgery Department, Santa Maria Hospital, North Lisbon Hospital Center, Lisbon, Portugal.

Introduction
The prevalence of pituitary thyrotropin secreting tumors (TSHomas) is 1-2 cases per million inhabitants, most of them being macroadenomas. The differential diagnosis may be challenging, especially for microadenomas.

Case Report
A 50-year-old male was observed at the endocrinology department with multinodular goiter. He noted progressive neck enlargement over the previous months but denied other complaints. There was no family history of thyroid pathology. He presented hot sudorific hands and a large nodular goiter. Laboratory evaluation revealed a predominantly high T3 with non-suppressed TSH (TSH 1.73 μU/ml [Reference range – RR: 0.55–4.78], T3 2.08 ng/ml [RR: 1.3–6.5], T4 11.7 g/dl [RR: 4.4–11.9], FT3 3.73 ng/ml [RR: 3.6–4.3], FT4 1.93 ng/dl [RR: 0.8–1.76]). The sonography showed an enlarged thyroid gland with bilateral nodules of 37, 50 and 70 mm. Additional evaluation revealed negative anti-thyroid antibodies, high total testosterone and SHBG, chromogranin A, alpha-subunit of glycoprotein hormones (αGS) and βGS/TSH ratio, but otherwise normal pituitary function and no evidence of other endocrine neoplasia. There was no TSH or αGS response to TRH administration and the MRI revealed a 6 mm pituitary lesion. Thyroid nodes cytology was benign. A TSH-oma was admitted and long-acting octreotide administered, with normalization of thyroid function and subsequent trans-sphenoidal tumor resection. Pathological analysis revealed an adenoma with positive TSH immunohistochemistry. Over the next months, there was TSH suppression and secondary hypothyroidism, during which levothyroxine was administered, and subsequent recovery of normal thyroid function. Slight reduction of the goiter was observed.

Discussion
Distinguishing pituitary TSHomas from thyroid hormone resistances may be challenging, but it is important for correct therapeutic options and avoid endocrine and neurological complications. Baseline thyroid function and sonography do not adequately distinguish both entities, but the absent family history, high SHBG, αGS and βGS/TSH ratio, blunt TSH and αGS response to TRH, and FT3/FT4 normalization with long-acting octreotide, together with a small but existent pituitary adenoma, prompted a microthyrotopina diagnosis.

Non-functioning pituitary adenoma; improved endocrine outcomes with increasing surgical experience: The Manchester Cohort
Sumithra Girthihan1, Tara Kearney2 & Kanna Gnanalingham2
1Department of Endocrinology, Salford Royal NHS Foundation Trust, Salford, UK; 2Department of Neurosurgery, Salford Royal NHS Foundation Trust, Salford, UK.

Case notes of 150 consecutive patients (58% male) who underwent pituitary surgery by a single surgeon for non-functioning pituitary adenoma and endocrine follow up at our centre between July 2005 and February 2015 were reviewed. All patients underwent endoscopic transsphenoidal surgery as the first approach. Post-operative pituitary function was assessed by measurement of baseline pituitary hormonal profile and a glucagon stimulation test to assess ACTH and GH axis. Mean age at surgery was 61 years (range 23–87 years). Pre-operatively, 63.3% of patients had evidence of hypopituitarism and vision was affected in 58% of patients. Post-operatively, hypopituitarism was detected in 70% of patients. New hormone deficiency developed in 25.3% of patients. Post-operative vision improved 46.6% of the total cohort and remained static in 47.3% of patients. During this time period, 10% of patients underwent further surgery and 28% of patients were referred for radiotherapy. To assess if increasing surgical experience affected patient outcomes, data was assessed in two time periods; patients undergoing surgery in the early years between 2005 and 2010 (n=67) and patients undergoing surgery in the latter years between 2011 and 2015 (n=83). There was no significant difference between pre-op hypopituitarism between these groups however, there was a statistically significant difference in terms of post-operatively hypopituitarism, with a lower number of patients in the latter group experiencing post-operative hormone deficiency (79.1% vs 62.7%, P<0.033). Furthermore, there was a statistically significant difference in terms of pre-operative visual status, with more patients in the latter group without any visual compromise (28.4% vs 51.8%, P=0.008). There was no significant difference in terms of post-operative visual outcomes. In conclusion, data from our cohort demonstrates improved endocrine outcome with increasing surgical experience over time. It also highlights changes in clinical practice in our centre with more patients undergoing surgery prior to the development of visual symptoms.

Polyuria and diabetes insipidus after surgery for pituitary tumors
Nerea Egaña Zunzunegui, Ixmene Bilbao Garay, Cristina García Delgado, Izaskun Olaizola Iregui, Maite Perez de Ciriza Cordeu, Maria Luisa Antuñano Lopez, Maite Aramburu Calafell, Nicolas Sampron, Alfredo Yoldi Arrieta & Miguel Maria Goena Iglesias
Hospital Universitario Donostia, San Sebastian, Guipuzcoa, Spain.

Introduction
Central diabetes insipidus (DI) is a common complication after pituitary surgery, but is transient in the majority of patients. The aim of our study is to determine the incidence and course of DI in the postoperative period and to characterize the factors associated with this disease.

Methods
We performed a retrospective study of 44 patients (50% females) with a mean age of 54 years (24–83), treated with transphenoidal (TSS) or transfrontal surgery (TFS) between January 2013 and December 2016. 26 were nonfunctioning adenoma, 7 somatotrophinoma, 6 corticotrophinoma, 2 gonadotrophinoma, 1 thyrotrophinoma, 1 Rathke’s cyst and 1 craniopharyngeoma. 93.2% underwent TSS as the first approach. Post-operative pituitary function was assessed by a single surgeon for non-functioning pituitary adenoma and endocrine follow up at our centre between July 2005 and February 2015

Results
25 patients (56%) developed polyuria during early postoperative, 11 (25%) transient DI between 1 and 5th day and 10 (22%) SIADH between 3 and 10th day. 15% of these patients presented 2 phases DI + SIADH, none of them 3 phases. DI was permanent in only 3 patients (6.8%), all after TFS. There was no difference comparing the DI group vs no DI in tumor size, pituitary function and surgery technique. However, we found differences between transient and permanent DI groups in tumor size (53.3 x 36 x 42 vs 18 x 16 x 15 P<0.05) and surgery technique (TFS vs TSS P<0.05), but not in age, pituitary function or number of interventions.

Conclusion
It is important to identify those patients in risk of developing permanent DI, which in our case were those with bigger tumors that required TFS.

Etiology and some clinical characteristics of hypopituitarism over the years of follow up
Milica Medic Stojanovska1,2, Bojan Vukovic1,2, Ivana Bajkin1,2, Tijana Icin1,2, Andrijana Milankov1,2, Jovanka Novakovic Paro1,2, Jovana Prodanovic1,2 & Nikola Curic1,3
1Clinical center of Vojvodina, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Novi Sad, Serbia; 2Medical Faculty University of Novi Sad, Novi Sad, Serbia; 3Clinical Center of Vojvodina, Center for Laboratory Medicine, Novi Sad, Serbia.

The data of etiology and clinical characteristics of hypopituitarism in different countries differs. The aim of the study is to investigate etiology and some clinical characteristics of patients with hypopituitarism that were treated in the Clinical center of Vojvodina. The study was conducted as a retrospective study. There were 32 males and 28 female patients. Mean age was 52.2 ± 17.5 years. Data was analyzed before and after substitution of hypopituitarism. Patients were treated with levodrostenol, hydrocortisone, sexual steroids, growth hormone and with desmopresine depending on the type deficiency. At the time of the diagnosis, mean age was 40.2 ± 18.7 and the average period of treatment was 15.9 ± 11.4 years. The most common causes of hypopituitarism were pituitary macroadenomas (53.3%) and craniopharyngeomas (21.7%). Partial hypopituitarism with deficiency in two or more functions was diagnosed in 64.4% subjects and panhypopituitarism in 28.8%, deficiency of one function in 6.8%. Average body mass index after the treatment was 27.8 ± 6.5 kg/m². Blood pressure was normal in range and without changes during the treatment. High levels of total cholesterol and LDL cholesterol before the treatment showed statistically significant decrease during the treatment (6.29 ± 1.57 vs 5.32 ± 1.38 mmol/l; P<0.009 and 4.12 ± 1.45 vs. 3.20 ± 1.11 mmol/l; P<0.005 respectively). Levels of HDL cholesterol and triglycerides were not changed significantly during the treatment. Crosslaps was decreased non-significantly and bone mineral density showed absence of osteopenia and osteoporosis during treatment. Correlation analysis showed statistically significant negative correlation between LDL cholesterol and levothryoxine (r = −0.341). 10% of subjects had a cardiovascular event. One subject died because of sepsis. We concluded that hypopituitarism in our region is commonest in the middle aged population, the main cause being pituitary macroadenomas. Cardiovascular risk factors of untreated hypopituitarism are reversible and cardiovascular events are rare.

A novel DICER1 gene mutation in a 10-month-old boy presenting with ACTH-secreting pituitary blastoma and lung cystic dysplasia
Alexey Kalinin1, Natalia Strebkova1, Anatoly Tiulpakov1, Eugene Vasilev1, Vasily Petrov1, Anna Kolodkina1, Maria Kareva1, Nadezhda Mazerkina2 & Valentina Perova3
1Endocrinology Research Centre, Moscow, Russia; 2Scientific Research Neurosurgery Institute, Moscow, Russia.

Hypercortisolism due to Cushing disease is an extremely rare condition in children under one year of age. We present a case of a 10-month-old boy...
with lung cystic dysplasia and pituitary blastoma (ACTH-secreting). The disease manifested with symptoms of hydrothorax due to cystic dysplasia of the right lung’s upper lobe. Surgical resection of the affected area has been carried out. Symptoms of endogenous hypercortisolism appeared soon after lung surgery. Cushing disease due to pituitary macroadenoma has been diagnosed. Pituitary adenoma was surgically removed; pituitary blastoma with isolated ACTH-secretion was revealed by immunohistochemistry. A combination of lung cystic dysplasia and pituitary blastoma was suspicious for a DICER1 gene defect; p.C199X mutation in DICER1 gene was found. He has been followed up for four years after the pituitary surgery. The patient has been receiving replacement therapy with hydrocortisone, levodopa and growth hormone. No other DICER1-related conditions were detected during the last follow-up visit. The same mutation was found in the mother, who had a history of euthyroid multinodular goiter.

Conclusion
Combination of lung cystic dysplasia and ACTH-secreting macroadenoma should prompt to DICER1 gene analysis. We have shown the variable clinical phenotype in DICER1 mutation carriers within a family.

**Pituitary insufficiency following traumatic thoracic injury in adolescent male patient-case study**

Aleksandra Gilis-Januszewska, Małgorzata Wilusz, Renata Turek-Jabrocka, Jacek Pantolifnski, Małgorzata Trofimiuk-Muldner, Łukasz Kluczynski, Alicja Hubalewska-Dydejczyk & Dorota Pach

The University Hospital in Krakow, Krakow, Poland.

Traumatic thoracic injuries in children and adolescents are rare, but could be connected with other trauma, often with traumatic brain injury (TBI). Based on data in the current literature, approximately 15–20% of TBI patients develop chronic hypopituitarism. Growth hormone (GH) and ACTH deficiency are the most common, followed by gonadotropins and thyroid-stimulating hormone. The greatest challenge associated with endocrine complications in individuals with polytrauma injury is early recognition of these subtle problems. We present a case report of a 24-years-old male. In 2007 (when he was 15-year-old) the patient underwent a traffic accident, thoracic injury (hemothorax, dissection of the descending part of the aorta, aortic stent-graft implantation to the left subclavian artery) and concussion. During post traumatic period he had transient polydipsia and polyuria. In 2013 gonadal axis deficiency was confirmed. Testosterone replacement therapy was started. During current investigation low growth hormone level (GH) and insulin-like growth factor 1 (IGF-1) level were found to be low. Patient’s hight is 160 cm, mothers 158 cm, fathers 182 cm. Mid Parental Height (MPH) = 173.5 cm. An insulin tolerance test (ITT) was performed. There was an adequate GH response-the insufficiency of somatotropic axis was confirmed. There were no other hormonal abnormalities. Further examinations e.g. NMR of the pituitary, genetic examination and DEXA are performed.

Conclusions
Physical signs such as lack of progression through puberty, with decrease in testicular volume and libido, short stature and history of after trauma transient diabetes incipidus could suggest the presence of unreconciled hypopituitarism. Careful investigation and monitoring is necessary to unmask and treat such hormone deficiencies in the transition phase.

**Potassium homeostasis in patients with acromegaly in comparison with hypertensive patients**

Sylwia Störmann, Katharina Schilbach, Christine Pichl, Robert P Kosilek, Hans-Joachim Anders & Jochen Schopohl

Klinikum der Universität München, Medizinische Klinik und Poliklinik IV, München, Germany.

Introduction
Acromegaly is characterized by chronic growth hormone (GH) excess and leads to numerous changes in bodily functions and comorbidity. We compared potassium homeostasis in patients with acromegaly to hypertensive controls.

Methods
We prospectively assessed serum potassium, urinary potassium excretion, aldosterone and renin, acid-base balance as well as glomerular filtration rate according to the CKD-EPI formula in 71 patients with acromegaly (37 male, 34 female; age 59 ± 14 years) and 70 hypertensive age and gender matched patients (HP) in whom secondary hypertension was ruled out (37m, 33f; 59 ± 14 years). Of the acromegaly patients, 23 had active disease (AD) and 48 were biochemically controlled (BC).

Results
Serum potassium levels were more elevated in patients with acromegaly (4.2 ± 0.4 mmol/l, P=0.008). Urinary excretion of potassium was also elevated in patients with acromegaly as compared to hypertensive controls (53.3 ± 35.3 mmol/l, P<0.001; 69.3 vs 52.9 mmol/g Creatinine, P=0.004). Analysis of variance in potassium excretion showed highly significant differences between AD, BC and HP (P<0.001). Post-hoc comparison revealed higher excretion in AD (66.3 mmol/l) as compared to BC (47.1 mmol/l, P=0.003) and HP (35.3 mmol/l, P<0.001; BC vs HP P=0.012). Mean arterial pressure was higher in hypertensive patients (110 vs 104 mmHg, P=0.009). There were no statistically significant differences in GFR (P=0.618), BMI (P=0.549), sodium levels (P=0.589), antihypertensive medications used (9 groups of antihypertensive drug classes; 0.117 < P < 1.0), aldosterone (P=0.41) and renin (P=0.161).

Discussion
We observe higher serum potassium levels in patients with acromegaly compared to patients with hypertension. Still, urinary excretion of potassium is also significantly higher despite comparable characteristics of both patient groups. Higher intramuscular potassium levels have previously been shown in acromegaly. Further research is warranted to elucidate potassium homeostasis in acromegaly.

**Russian hypothalamic and pituitary tumors registry (OGGO) data analysis: acromegaly**

Alexander Lutsenko, Elena Przhivalkovskaya, Ekaterina Pigarova, Zhanna Belaya, Ludmila Rozhinskaya & Irina Stanoevich

Endocrinology Research Centre, Moscow, Russia.

Objective
To analyze registry data on patients with acromegaly.

Materials and methods
Russian hypothalamic and pituitary tumors registry database (on-line platform), which contains data on 3719 patients with acromegaly.

Results
According to the database, highest prevalence of acromegaly per 100 000 inhabitants is registered in: Penza region (7.3), Kirov region (7.3), Krasnoyarsk region (6.2). Most common clinical presentations in registered acromegalic patients were: headaches (72%) maxillofacial changes (68%), arthralgias (48%) excessive sweating (39%). Information about tumor size was available in 1543 patients: by the time of diagnosis, 516 (33,4%) had pituitary microadenomas and 1027 (66,6%) had macroadenomas. 59.5% of registered patients were prescribed medical therapy: 65.9 and 34.1% were treated with somatostatin receptor ligands (SRL) and dopamine agonists respectively. 29.9% of patients were primarily treated surgically and remaining 10.6% underwent radiotherapy. Remission is registered in 22% cases, 23% of patients have only partial disease control, 41% have an active disease and 14% of records have no data regarding disease state.

Conclusions
Russian hypothalamic-pituitary tumors registry is a promising instrument for epidemiologic and clinical data acquisition. Data suggest that multimodal treatment approach is essential to achieve higher remission rates in patients with acromegaly.

DOI: 10.1530/endoabs.49.EP1028
Adherence to hormone replacement therapy in patients with hypopituitarism using the Morisky 4-item scale: results of a pilot, prospective, cross-sectional study

César Boguszewski, Simone Abe, Bruna Barbosa, Claudia Biondo, Débora Takito, Kamila Santos, Sayuri Hayashi & Victor Amarilla

SEMPR (Endocrine Division), Department of Internal Medicine, Federal University of Parana, Curitiba, Brazil.

Objective
To investigate adherence to hormone replacement therapy (HRT) in patients with hypopituitarism in a tertiary center outpatient clinic.

Patients and methods
Prospective, cross-sectional study of patients with hypopituitarism on HRT for at least two pituitary deficiencies (independent of diabetes insipidus). Medication adherence was assessed using a validated Portuguese version of four-item Morisky scale, in which participants were asked to indicate the extent to which they agreed with each of four statements (related to unintentional and intentional nonadherence) by rating on a 4-point scale (strongly agree, agree, disagree, strongly disagree). Patients were categorized as nonadherent if they indicated agreement (ie, reported either ‘strongly agree’ or ‘agree’) to either item of the subscale. Potential co-variables associated with adherence were tested.

Results
Ninety consecutive patients completed the survey, but five were excluded because they were on HRT with a single hormone. Of the remaining 85 patients (47 men, age 48±16 year), 31 were on HRT with two hormones, 32 with three, 18 with four and 4 with five. Levodopa treatment, glucocorticoids, sex steroids, growth hormone and desmopressin were prescribed to 81, 66, 64, 8 and 21 patients, respectively. Mean number of prescribed medications (excluding HRT) per patient was 3.1 (95% CI 2.4; range 0-9). The etiology of the hypopituitarism was non-functioning pituitary tumors (n=19), functioning pituitary tumors (n=17), craniopharyngiomas (n=13), other tumors (n=13), congenital (n=14), vascular (n=13), trauma (n=2), and idiopathic (n=4). Fifty-six (65.9%) patients reported unintentional nonadherence, while only 9 (10.6%) reported intentional nonadherence. Complete adherence was reported by 29.4% of the patients, while 5.9% showed both unintentional and intentional nonadherence. There were no associations of adherence to gender, age, number of pituitary deficiencies and prescribed medications.

Conclusion
Self-reported unintentional nonadherence to HRT is a common finding in patients receiving HRT for hypopituitarism.

Hormone and tumor responses to primary or pre-operative therapy with somatostatin analogs in acromegaly and the relation with T2-weighted MRI signal

María Picallo, Rogelio García Centeno, Aurelio Lopez Guerra, Yoko Lucia Olmedilla, Maria Armoaiga, Maria Requena, Javier Agreda, Victor Andia, Marcel Sambo, Susana Monereo, Maria Angeles Velez, Bettina Weber & Jose Atencia

Gregorio Marañón Hospital, Madrid, Spain.

Objective
Study of the efficacy of SSA in the biochemical and tumour control and the relation between the T2-weighted MRI signal intensity and the response to SSA.

Material and methods
16 patients with GH-secreting pituitary adenomas (7d/9f) that received primary or pre-operative treatment with SSA. We classified them according to baseline T2-weighted MRI sequences as Hypo-intense (Ha) and No-Hypo-intense adenomas (no-Ha). Results expressed like media (S.D.).

Results
Median age at diagnosis was 50.6 (18.5) years. 10 patients (9 macroadenomas) had pre-operative therapy with SSA during 18.58 (26.9) months, with 47.2% decrease in IGF1 levels and 24.5% of tumour shrinkage. After neurosurgery three patients required medication for hormonal control. One patient had postsurgical complications (hypopituitarism). Six patients (two macroadenomas) received exclusively medical treatment during 59.77 (64.5) months. They showed 56.8% of reduction in IGF1 levels and 49% of tumour shrinkage. In the last consultation, 4 achieved hormonal control and two needed dose adjustment. From the whole group, ten were no-Ha and 6 Ha, showing at diagnosis: GH 20.13 (16.5) vs 14.75 (19.8) μg/L, IGF1 973.5 (474) vs 703.7 (243.5) μg/L and a maximum diameter of 15.9 (11) vs 12.05 (4.95) mm, respectively. After 6 months of SSA therapy there was 51.2% decrease in IGF1 levels in No-Ha vs 72.3% in Ha. Six of the No-Ha had surgery and four of the Ha. The hormonal response in No-Ha was complete in the 50% and partial in 20% of patients vs 83% and 17% in Ha, respectively. >20% of tumour shrinkage occurred in 40% of the No-Ha vs 66% of the Ha.

Conclusion
Our results show the effectiveness of the pre-operative treatment with SSA in the acromegaly, in terms of hormonal but also anti-tumoral effects. T2-signal intensity at diagnosis it’s a good prognostic marker of the effectiveness of SSA therapy and it’s correlated with the tumour size-invasion and hormone levels at diagnosis.

Does cyproterone acetate therapy contribute to the observed elevation in serum prolactin levels in trans women?

Justine Defreyne1, NienkeNota2, Cecilia Pereira1, Schreiner Thomas4, Fisher Alessandra Daphne6 & T’Sjoen Guy1

1Department of Endocrinology, Ghent University Hospital, Ghent, Belgium; 2Department of Endocrinology, Department of Internal Medicine, VU University Medical Center, Amsterdam, The Netherlands; 3Department of Endocrinology and Metabolism, San Juan de Dios Hospital, Santiago, Chile; 4Department of Endocrinology, Oslo University Hospital, Oslo, Norway; 5Sexual Medicine and Andrology Unit, Department of Experimental, Clinical and Biomedical Sciences, University of Florence, Florence, Italy; 6Center for Sexology and Gender, Ghent University Hospital, Ghent, Belgium.

Objective
Hormonal treatment in trans women (MtF transgender persons) in Europe usually consists of estrogens and anti-androgens, e.g. cyproterone acetate (CPA). After initiation of cross-sex hormone therapy, an elevation in serum prolactin levels is frequently observed in trans women, which was previously attributed to estrogen agents. This analysis evaluates whether CPA contributes to the elevation of prolactin in trans women receiving cross-sex hormones.

Design
This study is part of the European Network for the Investigation of Gender Incongruence (ENIGI). Belgian data were selected for this substudy. Trans women that initiated cross-sex hormone treatment (which consists of oral CPA 50 mg in combination with estrogen substitution in Belgium) and underwent orchectomy were prospectively evaluated. Post-surgery estrogen was reintiated in unchanged dose.

Methods
Sex steroids, gonadotropins and prolactin were compared at baseline, pre and post surgery (patients receiving orchectomy) and after 12 and 18 months of cross-sex hormone therapy (patients not receiving orchectomy).

Results
Data was collected of 107 trans women, with a mean age of 31.5 years. After 1 year of cross-sex hormone therapy, there was an increase in serum prolactin levels in all patients (9.65 μg/L), with a decrease after 18 months (14.10 μg/L) and after orchectomy (10.17 μg/L). However, serum prolactin levels post orchectomy were significantly lower than serum prolactin levels after 18 months of CPA therapy, whereas there was no difference in serum estrogen levels between both groups.
Conclusions

The observed elevation of serum prolactin levels in trans women is likely caused by CPA (independent of estrogen therapy), as prolactin levels return to normal after CPA discontinuation, independent of serum estrogen levels.

A rapidly resolving prolactinoma with cabergoline treatment

Goknur Yorulmaz1, Aysegul Akalin1 & Esra Akcan2
1Division of Endocrinology, Eskişehir Osmangazi University School of Medicine, Eskişehir, Turkey; 2Radiology Department, Eskişehir State Hospital, Eskişehir, Turkey.

Introduction

Prolactinomas are the most common pituitary tumors. Macroprolactinomas are rarely seen. Dopamine agonists such bromocriptin and cabergoline are the preferred treatments for prolactinomas. Herein, we report a patient with macroprolactoma whose adenoma has resolved rapidly with cabergoline treatment.

Case

A 49 year old male patient evaluated for weakness and headache. After detection of central hypothyroidism he was referred to our department. His prolactin level was more than 1925 ng/ml. His laboratory tests were concordant with panhypopituitarism. Replacement therapy was initiated. A macroadenoma with a size of 28 mm was detected in pituitary MRI. Cabergoline treatment (5 mg/week) was initiated. The size of the adenoma was decreased to 16 mm in the 3rd month of the therapy. In the 6th month of the treatment the size of the adenoma regressed to 5 mm.

Conclusion

Prolactinomas are tumors with a good response to medical treatment. A rapid response was detected in our patient but there is data about cabergolin resistance. So, a close follow up is required in patients with prolactinomas.

Pregnancy outcome in women with prolactinomas exposed to dopamine agonists at early stages of gestation

Svetlana Vorotnikova, Larisa Dzeranova, Ekaterina Pigarova & Zhanna Belaya
Endocrinology Research Centre, Moscow, Russia.

Introduction

Medical therapy with dopamine agonists is the best treatment for prolactinomas of any size or invasiveness and restores ovulatory cycles in 80–90% of patients. Cabergoline currently suggested nearly exclusively rather than other dopamine agonists due to its excellent tolerability and long half-life. That is why the question of safety using of this drug during pregnancy and embryo-fetal development is actual.

Aim

The aim of the study is to assess the risk of pregnancy and fetal pathology in patients with prolactin-secreting tumors treated with cabergoline at early stages of gestation.

Materials and methods

The study included 24 patients from 24 to 38 years old with prolactin-secreting tumors, who become pregnant during therapy with cabergoline (Dostinex). A retrospective analysis of the outcomes of 33 pregnancies based on available data, including clinical, laboratory and radiological features.

Results

Of the 33 pregnancies 26 resulted in births (78.8%), in one patient a spontaneous miscarriage was registered at 7 weeks (3.0%), six women required medical abortions due to the non-developing pregnancy on terms from 4 to 7 weeks (18.2%). In 6% of cases (two pregnant) gestational diabetes mellitus was diagnosed. The average gestational age was 39.8 weeks (36–41 weeks). Preterm delivery occurred in four women (15.3%). In total 27 children were born (in one case twins), 26 (96.3%) of them were healthy at the time of the birth. The growth and development of the children did not differ from their peers in the general population.

Conclusions

The results of this study suggest that fetal exposure to cabergoline through early pregnancy does not induce any increase in the risk of miscarriage or fetal malformation. According the results of the study in patients with hyperprolactinemia risk of gestational diabetes mellitus is higher than in the population that require further investigations.

Clinical and hormonal characteristics of patients with different types hypophysitis: a single-center experience

Narin Nasiroglu Img1, Ali Erdem Yildirim1, Ozden Ozdemir Baser1 & Dilek Berker1
1Department of Endocrinology and Metabolism, Ankara Numune Education and Research Hospital, Ankara, Turkey; 2Department of Neurosurgery, Ankara Numune Education and Research Hospital, Ankara, Turkey.

Background

The inflammation of the pituitary gland known as hypophysitis. It is a rare disease accounting for approximately 0.24–0.88% of all pituitary diseases. Main forms of hypophysitis are histologically classified as lymphocytic, granulomatous, IgG4 related and xanthomatous. We aim to present our patients of hypophysitis with clinical,laboratory and radiological features.

Methods

We retrospectively reviewed our database of 1293 patients diagnosed with pituitary diseases between 2010 and 2017. Demographical data, clinical features, endocrinological dysfunction, magnetic resonance imaging findings, treatment courses and follow-up periods were evaluated. Primary hypophysitis diagnosis was made by the exclusion of secondary causes of hypophysitis, consequently twelve patients with hypophysitis were identified.

Results

The frequency of hypophysitis was found 0.93% in all cases of pituitary disease. Twelve patients (nine females and three males); ages ranged between 17 and 61 years were evaluated. The characteristic features of our patients tend to be female predominance and young population. Diagnosis of hypophysitis was made after pituitary biopsy in 4 patients and in 8 patients after pituitary operation due to adenoma. Headache (63%) and visual problems (18%) were the most frequent nonendocrine symptoms. Anterior pituitary hormone deficiencies (63.7%) and/or diabetes insipidus (16.7%) were seen among patients.According to histopathological forms, 4 had lymphocytic, 6 had granulomatous and 1 had xanthogranulomatous types of hypophysitis.

Conclusion

Hypophysitis should be considered in the differential diagnosis of sellar masses. It can mimic pituitary adenomas in radiological and endocrinological aspects. The different patterns of anterior pituitary hormone deficiencies and diabetes insipidus may be seen in the course of disease.

Comparative study of different methods for monomeric prolactin determination in patients with hyperprolactinemia

Svetlana Vorotnikova, Larisa Dzeranova, Ekaterina Pigarova, Aleksandri Il’in, Nataliya Popova, Marina Veshihina, Olga Sukhanova, Nataliya Kadrina, Larisa Shubina & Ivan Dedov
Endocrinology Research Centre, Moscow, Russia.

Introduction

Prolactin exists in various forms including the monomeric biologically active form (23 kDa) and a higher molecular weight form, bound most commonly to IgG, known as macroprolactin (>100 kDa). Macroprolactin lacks biological activity but can interfere in standard prolactin immunoassays and is one of the causes of false-positive results. In Russian Federation the most common method for macroprolactin determination is PEG precipitation test.

Aim

The aim of the study was an evaluation of the monomeric prolactin level measured by two methods: immunochemiluminescent (Cobas 6000) with manual PEG precipitation and immunofluorescent method (Brahms Cryptor).

Conclusions

The observed elevation of serum prolactin levels in trans women is likely caused by CPA (independent of estrogen therapy), as prolactin levels return to normal after CPA discontinuation, independent of serum estrogen levels.

Pituitary Stalk Hemangioblastoma: a case report and review of the literature

David Barbosa, Carolina Faria, Ana Sofia Osório, Ema Nobre & Maria João Bugalho
Diabetes and Metabolism Department, CHLN – Hospital de Santa Maria, Endocrinology, Lisbon, Portugal.

Introduction
Hemangioblastomas (HBL) in the pituitary stalk are extremely rare. Most pituitary stalk HBL reported in the literature were associated with von Hippel-Lindau (VHL) disease. Case report
We report the case of a 34-year-old female patient with VHL disease diagnosed at the age of 18 with multiple complications (bilatetral retinal and cerebellum HBL, renal cell carcinoma). Brain magnetic resonance imaging (MRI) demonstrated an hypointense suprasellar mass measuring 9×8×9 mm with marked homogenous contrast enhancement after gadolinium administration, originating from the pituitary stalk, suggesting a pituitary stalk HBL. The initial hormonal workup was normal. A visual field defect evaluation was not feasible due to severely low bilateral visual acuity. During the 4-year follow-up, a slight increase in the mass volume and prolactin level was observed; depending on the clinical, radiological and laboratory evolution, a future surgical approach cannot be disregarded.

Review of the literature
The previously reported cases of HBL in the pituitary stalk were analyzed. Seventeen cases have been reported, the majority (fourteen) being associated with VHL disease and the remaining considered to be sporadic. Ten patients had no visual symptoms or hormonal dysfunction, and therefore were kept on observation. A total of six patients were operated. Of the six surgical cases, four patients developed panhypopituitarism, and two patients had visual field disturbances preoperatively with partial recovery after surgery. None of the patients were treated with radiotherapy.

Conclusion
To our knowledge, this is the 18th case of HBL in the pituitary stalk. According to our review, pituitary stalk HBL often remain asymptomatic and do not require treatment. Surgery can be reserved until associated signs or symptoms occur. Surgery can be reserved until associated signs or symptoms occur.

Objectives
To evaluate the presence of glucose metabolism abnormalities and their impact on IGF-1 levels in patients with acromegaly.

Methods
Ninety-three acromegalic patients (52 male/41 female) were included in this study who were separated into three groups as normal glucose tolerance (NGT), prediabetes and diabetes mellitus (DM). Insulin resistance (IR) was calculated with homeostasis model assessment (HOMA). HOMA-IR > 2.5 or ≤ 2.5 were defined as insulin resistant or noninsulin resistant groups, respectively. We compared the groups in terms of many factors that may be associated with glucose metabolism abnormalities. IGF-1% ULN (upper limit of normal)/GH ratios were used for impact of glucose metabolism abnormalities on IGF-1 levels.

Results
Frequencies of NGT, prediabetes and DM were 25% (n = 23), 41% (n = 38) and 34% (n = 32), respectively. Patients with DM were significantly older and with an increased frequency of hypertension than NGT and prediabetes groups (P < 0.001, P = 0.01, respectively). IGF-1% ULN/GH ratio was significantly lower in prediabetes group than in NGT group (P = 0.04). Similarly IGF-1% ULN/GH ratio was significantly lower in insulin resistant group than in noninsulin resistant group (P = 0.04). Baseline and suppressed GH levels were significantly higher in insulin resistant group than in noninsulin resistant group (P = 0.024, P < 0.001, respectively).

Conclusion
IGF-1% ULN/GH ratio is a useful marker indicating glucose metabolism disorders and IGF-1 levels might be inappropriately lower in acromegalic patients with IR or prediabetes. We suggest that IGF-1 levels should be re-evaluated after the improvement of IR or glycemic regulation for the successful management of patients with acromegaly.

Impact of glucose metabolism disorders on IGF-1 levels in patients with acromegaly
Sema Ciftci Dogansen, Gulsah Yeniﬂunya Yalin, Seher Tanrikulu & Sema Yarman
Division of Endocrinology and Metabolism, Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Objective:
To evaluate the presence of glucose metabolism abnormalities and their impact on IGF-1 levels in patients with acromegaly.

Methods:
Ninety-three acromegalic patients (52 male/41 female) were included in this study who were separated into three groups as normal glucose tolerance (NGT), prediabetes and diabetes mellitus (DM). Insulin resistance (IR) was calculated with homeostasis model assessment (HOMA). HOMA-IR > 2.5 or ≤ 2.5 were defined as insulin resistant or noninsulin resistant groups, respectively. We compared the groups in terms of many factors that may be associated with glucose metabolism abnormalities. IGF-1% ULN (upper limit of normal)/GH ratios were used for impact of glucose metabolism abnormalities on IGF-1 levels.

Results:
Frequencies of NGT, prediabetes and DM were 25% (n = 23), 41% (n = 38) and 34% (n = 32), respectively. Patients with DM were significantly older and with an increased frequency of hypertension than NGT and prediabetes groups (P < 0.001, P = 0.01, respectively). IGF-1% ULN/GH ratio was significantly lower in prediabetes group than in NGT group (P = 0.04). Similarly IGF-1% ULN/GH ratio was significantly lower in insulin resistant group than in noninsulin resistant group (P = 0.04). Baseline and suppressed GH levels were significantly higher in insulin resistant group than in noninsulin resistant group (P = 0.024, P < 0.001, respectively).

Conclusion:
IGF-1% ULN/GH ratio is a useful marker indicating glucose metabolism disorders and IGF-1 levels might be inappropriately lower in acromegalic patients with IR or prediabetes. We suggest that IGF-1 levels should be re-evaluated after the improvement of IR or glycemic regulation for the successful management of patients with acromegaly.
Conclusion

Reductions in mUFC levels during 12 months' long-acting pasireotide treatment were accompanied by improvements in clinical signs of CD. Long-acting pasireotide is an effective treatment option for patients with CD, with a convenient monthly administration schedule.

Radiological study of clinically non-functioning pituitary macroadenomas: a single institutional experience

Cristina Moreno, Miguel Paja, Aitzoi Lizararraga, Eider Etxeberria, Cristina Arrizabalaga, Estibaliz Ugarté, Ana Izuzquiza, Fernando Goti, Natalia Iglesias & Laura Calles

Endocrine Unit-Basurto University Hospital, Bilbao, Spain.

Introduction

When facing with non-functioning pituitary macroadenomas (NFPMA), radiological invasion is determinant to surgical approach, apart from histological biomarkers of pituitary tumor aggressiveness (Ki-67; p53 and mitotic index). Invasive tumors usually need additional surgery and/or radiotherapy. There are no much studies describing epidemiological data on aggressive pituitary tumors in clinical practice. We provide information regarding the radiological findings of NFPMA in a single tertiary center during 17 years.

Material and methods

We evaluate retrospectively MR imaging of NFPMA diagnosed between 1999 and 2016 in our Hospital. Evaluation includes infrasellar invasion, Knosp’s classification in both cavernous sinus, measure in three dimensions, contact with dura and, intensity of signal in T2.

Results

From 48 cases, we selected 41 with valuable presurgical MRI. 15 men and 26 women, mean age 61 years (24–83). Infrasellar invasion occurred in 19 (46.34%), Knosp III or IV in 21 of 82 cavernous sinus (25.6%), 3 patients (7.3%) presented invasion of three areas. Mean cranio cavernal diameter was 29.65 mm (8–52), transversal 21.5 mm (11–43) and anteroposterior 19.14 mm (11–51), with 80.5% displacing optic quiasm. 22% were giant adenomas (>40 mm) and T2 sequences hyperintense, suggesting scarcely granulated tumour, was present in 19.5%.

Conclusions

In our series, 56% of NFPMA had criteria of radiological invasion, infrasellar or cavernous sinus invasion. This finding remarks the complex management of these neoplasms and the need of a multimodal approach.

Idiopathic isolated acquired ACTH deficiency-- a case series from the Irish National Pituitary Network

Anne Marie Hannon1, Diarmuid Smith1, Mark Sherlock2, Steven Hunter1 & Chris Thompson1

1Department of Endocrinology and Diabetes, Beaumont Hospital, Dublin 9, Ireland; 2Department of Endocrinology and Diabetes, Adelaide and Meath Hospital, Tallaght, Dublin, Ireland; 3Department of Endocrinology and Diabetes, Royal Victoria Hospital, Belfast, UK; 4Department of Endocrinology and Diabetes, Cork University Hospital, Cork, Ireland.

Idiopathic Isolated ACTH deficiency (IIAD) is a rare cause of secondary adrenal insufficiency characterised by ACTH deficiency with otherwise intact pituitary function. Our objective was to describe the presentation, the autoimmune associations and diagnostic findings observed in IIAD. We present a case series of 19 cases of idiopathic Isolated ACTH deficiency which were identified from the National Pituitary Register in Ireland. A chart and biochemical review was performed to identify the presentation, clinical features, diagnostic criteria and associated diseases of people with IIAD. All patients had normal pituitary MRI imaging, (one patient refused, however he had a normal CT brain) and other causes for ACTH deficiency such as medication or traumatic brain injury were excluded. 19 patients were identified as meeting criteria (15 women and 4 men). The age at presentation ranged from 21 to 88 years, with a median age of 52 years. The majority of patients complained of fatigue and lethargy; however, five patients presented with hyponatraemia. 10 of the 19 patients had autoimmune illnesses; hypothyroidism was the most common autoimmune disease with eight patients suffering primary hypothyroidism. CRH stimulation testing was available in 6 of the 19 patients, five of these patients had a rise in ACTH with CRH administration, indicating possible hypothalamic involvement. Two patients had complete recovery of their HPA axis when repeat testing was performed. IIAD is a rare, poorly defined disorder that typically presents with insidious symptoms but can present with severe hyponatraemia. It is associated with autoimmune diseases, in particular primary hypothyroidism. Two patients in this case series had complete recovery of their HPA axis, therefore repeat testing should be performed at intervals.

Autonomic impairment in idiopathic diabetes insipidus

Mattia Barbot1, Filippo Cecchato1, Marialuisa Zilio1, Nora Albigè1, Marco Boscaro1, Franca Bilotà1 & Carla Scaroni1

1Endocrinology Unit, Department of Medicine, DIMED, Padova, Italy; 2Vascular Medicine Unit, Department of Cardiovascular Sciences, Padova, Italy.

Introduction

Since DI was reported to be associated to increase mortality, the aim of this study is to evaluate the presence of autonomic dysfunction (AD) in patients with DI.

Methods

We enrolled 12 patients (six females) with central idiopathic DI and 12 controls, matched for age, sex and common cardiovascular risk factors, who were evaluated using the tilt, lying-to-standing, hand grip, deep breath, Valsalva maneuver and Stroop tests.

Results

The tilt test showed a significant more pronounced decrease in both systolic (−20.7 ± 18 vs −1.92 ± 7 mmHg, P = 0.0099) and diastolic blood pressure (−10.5 ± 14.3 vs −1.5 ± 5.5 mmHg, P = 0.02) in patients than in controls. Furthermore three patients with DI had to suspend the test because of the onset of syncope. The lying-to-standing test indicated a marked reduction in blood pressure in patients with DI too (1.047 ± 1.037 vs 1.533 ± 0.144, P = 0.0001). Similar results were find in Valsalva (ratio, 1.033 ± 0.193 vs 1.431 ± 0.109, P = 0.00001) and deep breath tests (1.075 ± 0.112 vs 1.33 ± 0.083, P = 0.00002).

Discussion

All the principal autonomic tests performed were concordant, indicating that patients with central DI have an impaired autonomic nervous system function despite normal hydroelectrolytic balance under desmopressin therapy. This impairment may reflect both a damage in the autonomic system and the absence of the vasoactive effect of AVP on vascular smooth muscle which acts as a rescue mechanism in case of rapid drop in blood pressure. Patients with central DI should be educated on how to prevent orthostatic hypotension.

Salivary and serum cortisol levels by liquid chromatography tandem mass spectrometry after standard dose ACTH test in the diagnosis of central hypothalamicism

Valentina Morelli1, Elisa Polledri2, Rosa Mercadante2, Beatrice Sonzogni2, Giovanna Mantovani1, Serena Palmentieri1, Elena Malchiodi1, Elisa Verruz1, Anna Maria Barbieri1, Emanuele Ferrante1, Maura Arosio1, Silvia Fustinoni2 & Iacopo Chioldini1

1Unit of Endocrinology and Metabolic Disease, Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; 2Department of Clinical Sciences and Community Health, University of Milano, Milan, Italy; 3Unit of Internal Medicine 1, ASST Santi Paolo e Carlo, San Carlo Borromeo Hospital, Milan, Italy.

Objective

The diagnosis of central hypoadrenalism (HPA1) is a major clinical challenge. The gold standard procedure remains insulin tolerance test (ITT). Liquid chromatography tandem mass spectrometry (LC-MS/MS) is considered the best...
procedure for the evaluation of cortisol levels. This study aimed to evaluate cut-offs of serum (TM-SeC) and salivary cortisol (SaC) by LC-MS/MS and serum cortisol by ECLIA assay (E-SeC) after Standard dose ACTH test (SDCT) in diagnosing HPAI.

**Design**

In this study we performed SDCT in 52 consecutive patients (FM, 33/19, age 42.9 ± 13 years) referred to our Center to evaluate at specific time points E-SeC, TM-SeC and SaC. In the same group of patients we also evaluated E-SeC after ITT, to diagnose HPAI (using a cut-off < 350 nmol/l).

**Results**

HPAI was diagnosed in 8 out of 52 patients (five patients operated on for a pituitary macroadenoma, and 3 with a pituitary microadenoma). Using the diagnosis of HPAI made by ITT as reference test, we found that after SDCT an E-SeC > 348 nmol/l at 0 min, > 671 nmol/l at 30 min or > 756 nmol/l at 60 min excluded HPAI, whereas an E-SeC < 155 nmol/l at 0 min, < 436 nmol/l at 30 min or < 527 nmol/l at 60 min confirmed HPAI. By using LC-MS/MS we found that after SDCT a TM-SeC > 378 nmol/l at 0 min, > 1012 nmol/l at 30 min or > 1021 nmol/l at 60 min excluded HPAI, whereas a TM-SeC < 149 nmol/l at 0 min, < 334 nmol/l at 30 min or < 351 nmol/l at 60 min confirmed HPAI. Similarly by LC-MS/MS we found that after SDCT a SaC > 7.4 nmol/l at 0 min, > 15.8 nmol/l at 30 min or > 23.3 nmol/l at 60 min excluded HPAI, whereas a SaC < 1.7 nmol/l at 0 min, < 4.7 nmol/l at 30 min or < 7.3 nmol/l at 60 min confirmed HPAI.

**Conclusions**

We can conclude that even evaluating TM-SeC and SaC, after SDCT there is large gray area of indeterminate results.

**Nivolumab and pembrolizumab induced hypophysitis**

Marleen Vojian-Noevelman, Rob van den Brom, Geke Hospers, Jeroen Hiltermann & Gerrit van den Berg

University Medical Center Groningen, Groningen, The Netherlands.

**Introduction**

Immune checkpoint blockade in cancer treatment causes frequent adverse events of auto-immune etiology. Ipilimumab (anti-CTLA-4 antibody) causes a hypophysitis in up to 10% of patients. In contrast, during treatment with nivolumab and pembrolizumab (both anti-PD-1 antibodies), hypophysitis is rare (<1%).

**Results**

In the past year, we identified 4 cases of hypophysitis in patients treated with anti-PD-1 therapy (incidence 1% out of a total group of 395 patients). Two patients (male aged 78, female aged 58) were treated with nivolumab for non-small cell lung cancer and 2 patients (male aged 61, female aged 69) received pembrolizumab for metastatic melanoma. After 8–12 cycli, all patients developed fatigue, two patients developed edema and 1 patient developed nausea and a blurry vision. There was no period of transient headache as typically found in hypophysitis caused by ipilimumab. Laboratory examination revealed the diagnosis. Brain magnetic resonance imaging showed a normal pituitary gland in all patients. At diagnosis, pituitary failure was present for the thyroid and adrenal axis in 2 and 3 patients, respectively. One patient developed failure of the pituitary-gonadal axis.

**Discussion**

In contrast to hypophysitis after ipilimumab treatment, anti-PD-1 induced hypophysitis seems characterized by an insidious clinical course, without typical symptoms or associated MRI abnormalities. In contrast, the pattern of endocrine failure of the adrenal axis is immediately life threatening. Given the sharp increase in the number of patients treated with immune checkpoint inhibitors, more patients with this rare side effect are expected. Therefore, it is necessary to screen for central hypophysitis and hypothyroidism and be aware of the possibility of a varied clinical presentation.

**Heterogeneity of the patient pathway for adult growth hormone deficiency: Perspectives from a CEE Endocrinologists expert panel**

Ilan Shimon1, Corin Badu1, Artur Bossowski2, Mirjana Doknic3, Iveta Dzivite-Krisane4, Václav Hána5, Jana Kollerová6, Emil Natchev7, Marija Pfeifer8, Nikolette Šučić9, Juliana Hey-Hadavi10, and Roy Gomez11

1University of Medicine and Pharmacy, Bucharest, Romania; 2Klinika Pediatrii, Endokrynologii, Diabetologii z Pododdziałem Kardiologii, Poland; 3Klinicki Centar Srbije, Beograd, Serbia; 4Bernu kliniska universitates slimnica, Riga, Latvia; 5Charles University, Prague, Czech Republic; 6Univerzitna Nemocnica Bratislava, Bratislava, Slovakia; 7Clinical Center of Endocrinology and Gerontology, Medical University, Sofia, Bulgaria; 8University Medical Centre, Ljubljana, Slovenia; 9Rabin Medical Center, Petah Tiqwa, Israel; 10Semmelweis University, Budapest, Hungary; 11Pfizer, New York City, USA; 12Pfizer Innovative Health, Brussels, Belgium.

**Introduction**

Effective identification, diagnosis and management of growth hormone (GH) deficiency in adults are crucial for treating endocrinologists to provide the best in patient care. As such, it is important that we share our experiences to understand challenges and obstacles to enhance the patient journey. The objective of this project was to start identifying these challenges and obstacles.

**Methods and findings**

In November 2016, an expert panel of 10 endocrinologists from across 10 Central and Eastern European (CEE) countries met to discuss their standard of care and...

**DOI:** 10.1530/endobs.49.EP1044
journy taken by adult GH-deficient (AGHD) patients in their respective countries. Prior to the meeting the experts were asked to summarize in a systematic way, the standard of care available for AGHD patients in their countries and share this with their peers. The meeting was chaired by one of the experts and each participant had adequate time to present their perspective followed by discussion. It was uncovered that there was a substantial degree of diversity in the management AGHD patient pathway across CEE. The main barriers included initial entry to the healthcare system and referral journey; tests required to confirm diagnosis; availability of programmes to manage patients during transition to adulthood; limitations of who prescribes GH therapy, medication re-imbursement by national healthcare services and, the frequency of follow-up visits and monitoring of patients. Although most countries represented relied on international society-led, published guidelines, few countries have developed national guidelines for patient management.

Conclusion

This expert panel recognizes a high degree of diversity in the patient pathway across CEE. Sharing of local experiences with other colleagues may help in understanding areas of high heterogeneity as well as facilitating the sharing of best practice. Further work will be needed to identify differences in practice patterns and AGHD patient management among other regions in the world.

Considerable delays to achieve adequate control in treating patients with acromegaly

Marinella Tzanela, Olga Karapanou, Christianna Giatra, Efstatia Botoula, Elisabeth Tiaka, Lambarki Anastasia & Stylianos Tsagarakis

Department of Endocrinology and Diabetes, Evangelismos Hospital, Athens, Greece.

Acromegaly is a rare disease that leads to considerable morbidity and mortality, both reversible by adequate control of the disease. However, patients that could be adequately controlled confront delays in achieving treatment targets. The aim of the present study was to estimate the time to disease control after diagnosis and the reason leading to control delays. We retrospectively studied 119 acromegalic patients (aged 46.4 ± 12.5; 71 females). Following appropriate treatment modalities all achieved IGF-1 levels within normal limits for age (43 pts had GH <1.0 ng/ml, and 76 pts had GH <2.5 mg/ml). Acromegaly was adequately controlled within 0-6 months in 19 patients (15.9%), within 6-12 in 14 (11.8%), and within 12-24 in 21 (17.6%). In 65 patients (54.6%) disease control was achieved after 24 months (25–412, median 103 months). Earlier controlled patients were older (50 ± 11.9 vs 43.5 ± 12.3, P = 0.00434), and underwent surgery sooner after the diagnosis (8.0 ± 6.8 vs 19.8 ± 30.0 months, P = 0.0324). When under medical treatment, the main reasons for delay control were the late referral and initiation of medical therapy (5.4 ± 5.0 vs 124.6 ± 117.1 months, P = 0.0138), and the time elapsed to modify dosage and/or implementing alternative treatment options (4.4 ± 3.7 vs 16.1 ± 11.1 months, P = 0.0138). Tumor size or extension, GH and IGF-1 had no impact to time to control. According to our study a substantial proportion of patients remain uncontrolled for several months despite the efficacy of available therapeutic modalities in these patients. The main reason seems to be the delay to cease early surgical intervention or to adjust the medical treatment options.

Hyponatremia – the other face of diabetes insipidus complications

Madalina Bucur & Carmen Barbu

Elias University Emergency Hospital, Bucharest, Romania.

Diabetes insipidus is mainly associated with dehydration as a complication, hyponatraemia being very rare. We report the case of a 75 years old female, from Switzerland, who presented with nausea and vomit, diarrhea, asthenia and general sickness at the emergency room, where blood tests revealed hyperglycemia of 320 mg/dl and hyponatremia of 115 mmol/l, the patient knowing to have diabetes insipidus and diabetes mellitus type II, with insulin and desmopressin. Following emergency equilibration, we recommended monitoring water intake, urine excretion in the absence of desmopressin, with control of glycemic profile every 4 hours, for the next 24 h, and a MRI scan, in order to objectivate the diagnosis. Initial cooperation was present. The anamnesis revealed diabetes insipidus diagnosed at age 30, treated with desmopressin spray 10 mcg twice a day, in the morning, and diabetes mellitus type II from age 60, treated with 4 shots of fast insulin, 42 U/day. Clinical examination revealed signs of mild dehydration. Lab tests highlighted mild hyperglycemia of 142 mg/dl and hyponatremia of 129 mol/l. Glycated haemoglobin was 7.3%. Plasma osmolality was 272.3 mOsm. The patient was uncooperative to stoping or changing the schedule of desmopressin treatment, so she was discharged with natriemia of 139 mmol/l. Recent medical history showed a recent emergency admission with similar clinical and biochemical futures. Moreover, it was proved that the patient had many ER admissions in Bucharest’s hospitals, with same situation. In this respect, the diagnosis of diabetes insipidus itself can be put under question, complicated by the psihogenic adherence to desmopressin treatment of the patient. Frequent clinical manifestations of hyponatremia due to desmopressin abuse in our patient is highlighting not only the complexity of psihogenic association to organic abuse, but also the need for cooperation between practitioners across EU.

Aggressive pituitary tumours: a multicenter study

Ana Palha1, Leonor Gomes2, João Soequeira Duarte3, Conceição Marques4, Cláudia Amaral5, Ana Amado6, Patiama Borges7, Isabel Ribeiro7, Eduardo Barreiros8, Luis Barreiros3, José Miguens9, Maria João Bugalho9, Adriana Lagos10, Isabel Parva11, Olimda Marques12, Rui Almeida12, Teresa Martins1, Luisa Cortez3, Ana Agapito3 & Fernando Fonseca3

1Centro Hospitalar Lisboa Central, Lisbon, Portugal; 2Centro Hospitalar Universitário Coimbra, Coimbra, Portugal; 3Centro Hospitalar Lisboa Ocidental, Lisbon, Portugal; 4Centro Hospitalar Porto, Oporto, Portugal; 5Hospital Galego de Inovação, Ourense, Portugal; 6Hospital de Braga, Braga, Portugal; 7Instituto Português de Oncologia de Coimbra, Coimbra, Portugal.

Introduction

Pituitary tumours are considered benign, however some exhibit an aggressive behavior. Defining a timely treatment is challenging due to absence of accurate prognostic predictors.

Objective

To evaluate radiological and histopathological features of aggressive pituitary tumours.

Methods

Multicenter and retrospective study. Criteria for aggressiveness were: invasion to splenoid and/or cavernous sinus, growth progression after treatment (surger/medical therapy); early recurrence (<12 months). Atypical features were: Ki-67 > 3%, p53 positivity, mitoses > 2/10xHPF or brain/spinal/systemic metastases.

Results

Forty-five patients (28 men) were collected from seven tertiary endocrine departments. Age at diagnosis was 41.2 ± 12.2 years. In 35.6% of patients first symptoms occurred before 35 years. Symptoms related to tumour expansion, hyposecretion and deficiency of hormones were the first manifestations in 73.6, 13.2 and 13.2% of patients, respectively. Our cohort comprised nonfunctioning adenomas (64.4%), somatotrophinomas (9.0%), corticotrophinoma (13.3%) and prolactinomas (13.3%). All were macroadenomas and 82.2% showed radiological signs of invasion. Of the 44 operated patients, 56.8% required three or more surgeries. Complementary radiotherapy was used in 66.7% of patients, medical therapy in 42.2% of patients, two of these with temozolamide. Histopathology was obtained in 42 patients. Immunohistochemical staining was GH positive in 9.5%; PRL 14.3%; ACTH 11.9%, TSH 2.4%, FSH/LH 19%; plurihormonal 14.3%; nonsecreting and null-cell 28.6%. Elevated mitotic index was observed in 20% (n = 25), Ki-67 labeling index ≥ 3% in 44.4% (n = 27) and p53 nuclear staining in 41.2% (n = 17). During a mean follow-up of 11.5 ± 6.3 years, 8 patients died (5 ACTH-cell adenoma) one with extracranial systemic metastases (carcinoma).

Conclusions

In our cohort ACTH-secreting tumours presented a more aggressive clinical course. One limitation of our study was incomplete histopathological data, however, the majority of patients who presented atypical features. A continuous multicenter collaboration could help to identify prognostic markers and enable a different approach.

Effects of somatostatin analogs on glucose metabolism in acromegalic patients: a meta-analysis of prospective interventional studies

Tiziana Feola1, Alessia Cozzolino1, Ilaria Simonelli2, Emilia Shardella3, Giulia Puliani1, Elisa Giannetta1, Patrizio Pasqualetti1, Andrea Lenzi1 & Andrea M Bioddi1

1Department of Experimental Medicine – Sapienza University of Rome, Rome, Italy; 2Department of Neuroscience- Fatebenefratelli Hospital-Isola Tiberina-Rome, Rome, Italy.

Introduction
Glucose metabolism impairment is a common complication of acromegaly. Somatostatin analogs (SSAs) are used as both first and second line treatment. The effect of SSAs on glucose metabolism in acromegaly is still debated.

Aim
To address the following questions: 1) do SSAs affect glucose metabolism? 2) does the effect correlate with disease control? 3) do different SSAs – Lanreotide (LAN) and octreotide LAR (OCT) – affect metabolism differently?

Methods
We performed a meta-analysis of prospective interventional studies reporting the use of SSAs for the treatment of acromegaly. We searched MEDLINE, EMBASE, and SCOPUS for English-language studies. Inclusion criteria: minimum 6-month follow-up, glyco-metabolic outcomes before and after SSA treatment. The pooled estimate of a weighted mean was obtained for all outcomes using a random effects model.

Results
Forty-one studies have been included, 20 for LAN (354 patients) and 21 for OCT (569 patients). LAN treatment induced a significant decrease in fasting plasma insulin (FPI) (effect size –3.82, 95% CI: –10.44 to –6.20; P < 0.001) and HOMAβ (–2.11, 95% CI: –3.54 to –0.69; P = 0.004), without changes of fasting plasma glucose (FPG), HbA1c, triglyceridemia, weight and BMI. OCT induced a small increase in HbA1c (+0.146, 95% CI: 0.043–0.249; P = 0.005), a borderline rise of glucose during OGTT (0.47, 95% CI: 0.01 to 0.95; P = 0.053) and significant decrease in FPI (–6.78, 95% CI: –9.37 to –4.18; P < 0.001), triglyceridemia (–0.41, 95% CI: –0.55 to –0.28; P < 0.001), HOMAβ (–1.44, 95% CI: –2.54 to –0.34; P = 0.010) and HOMAβ (–36.65, 95% CI: –63.21 to –10.08; P = 0.007), without any change of FPG. Meta-regression analysis revealed an association between the degree of GH reduction and lowering of HbA1c (P = 0.03). Meta-regression also showed a worse post-therapy GH response. IGF1 and GH-response partially explain the metabolic effect of SSAs.

Conclusions
LAN and OCT induce a significant decrease in FPI and in HOMAβ, without adverse change in FPG. OCT seems to reduce HOMAβ and increase HbA1c, while reducing trygliceridemia. IGF1 and GH-response partially explain the metabolic effect of SSAs.

Prolactinomas diagnosed after menopause: presentation and outcomes from a large specialist centre

Sandhya Santharam1,2, Metaxia Tampourli1,2, Wibke Arlt1,2, John Ayuk3, Neil Gittoes3, Andrew Toogood3 & Rachel Webster3 & Nikki Karavitaki1,2

1Institute of Metabolism and Systems Research, College of Medical and Dental Sciences University of Birmingham, Birmingham, UK; 2Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, UK; 3Department of Clinical Biochemistry, Queen Elizabeth Hospital Birmingham, Birmingham, UK.

Introduction
Most prolactinomas in females are diagnosed during the years of reproductive age and the majority are microadenomas. Prolactinomas diagnosed after menopause are very rare with limited published data on their presentation and outcomes.

Aim
The aim of our study was to assess the presenting clinical, biochemical and imaging findings, as well as the outcomes of women diagnosed with a prolactinoma in the post-menopausal period.

Ipilimumab induced hypophysitis – an insight from a case series in the United Kingdom

Punith Kempegowda1, Lauren Quinn1, Anitha Vijayan Melapalai1, Ankil Jain1, Neil Steven1, Helena Gleeson1 & Andrew Toogood1

1Queen Elizabeth Hospital Birmingham, Birmingham, West Midlands, UK; 2University of Birmingham Medical School, Birmingham, West Midlands, UK.

Aims
To assess the incidence of Ipilimumab associated hypophysitis and its common presentations.

Methods
All patients who developed Ipilimumab induced hypophysitis following treatment for Malignant melanoma at a large tertiary care centre in West Midlands, United Kingdom from 2012 to 2014 were included in the study. Patients with known pituitary disease prior to treatment and/or received other systemic immunotherapy following Ipilimumab treatment were excluded. All surviving patients were followed up to December 2016. Relevant data – clinical features, hormone profiles and radiological findings – were extracted from patients’ medical records.

Results
Overall, 59 patients were treated with Ipilimumab for malignant melanoma during the period of interest. The incidence of hypophysitis in the cohort was 15.3% (9/59). The median age for patients with hypophysitis was 64 years (IQR, 60–68 years); 44.4% (4/9) were male. 66.7% (6/9) presented with mild to moderate symptoms and 33.3% (3/9) patients developed severe symptoms secondary to Ipilimumab induced hypophysitis resulting in hospitalisation. Fatigue (78.5%–77.8%) was the most common presenting symptom; headache and visual disturbance was reported by 33.3% (3/9) and 22.2% (2/9) respectively. Secondary hypogonadism (5/9; 55.6%) and secondary hypoadrenalism (4/9; 44.4%) were the most commonly affected pituitary systems. One patient developed panhypopituitarism. 33.3% (2/6) patients developed diffuse enlargement of pituitary gland. All patients had clinical recovery following adequate hormone replacement.

Conclusions
Disturbances in pituitary axis are common with Ipilimumab treatment and can present with subtle symptoms. Therefore, regular assessment of pituitary function during Ipilimumab treatment is recommended. Affected patients should be managed jointly by oncology and endocrinology teams to prevent serious complications and allow Ipilimumab treatment to continue.

**DOI:** 10.1530/endoabs.49.EP1052
Introduction

Mammary duct ectasia (MDE) is an inflammatory breast disease characterised by dilatation of major ducts and peri ductal inflammation. MDE occurs commonly in women undergoing menopause. The etiology has not been well defined but previous studies described an association between high prolactin and MDE.

Case Report

A 42-year-old female was admitted to our hospital with complaints of galactorrhea, amenorrhea, mammary gland tenderness and breast discomfort. Tests revealed serum prolactin level of 85 ng/ml and breast ultrasound showed dilated anechoic ducts and marked cystic ectasia. A 15×12 mm complex cystic lesion in right breast and several enlarged lymph nodes were found in right axillae. Mammography revealed thickened breast tissue with diffuse MDE without any calcification. Pituitary MRI showed 5.5×5.0×2.5 mm pituitary adenoma. Treatment with cabergoline 0.5 mg twice a week, warm compress and antibiotic started. Cabergolin dose is progressively increased to 2 mg per week. Prolactin level reached to 20 ng/ml and tumor size reduced to 3×3×1.5 mm in 6 months. Although treatment with cabergoline, resulted in improvement of breast symptoms and galactorrhea, diffuse MDE was reported in repeat ultrasound. Cabergoline dose is increased and the patient is still being followed up.

Discussion

In the present case, we hypothesize that there was an association between abnormal prolactin secretion and development of MDE. Shousha et al. described three cases with marked MDE and chromophobe adenomas. Peters et al. concluded that MDE is due in part to increased prolactin secretion. They also concluded that MDE may cause transient hyperprolactinemia. MDE induced by sulpiride-associated hyperprolactinemia was also discussed in literature. In our case, diffuse MDE may have been developed as a result of changes in prolactin levels. We conclude that increased prolactin secretion leading to chronic inflammation and fibrosis may cause to persistence of ductal dilatation.

Results

Patients with MDE can be associated with abnormalities of the pituitary gland. The aim of this study was to evaluate the pituitary gland with a high-resolution MRI in obese patients, with and without MDE.

Materials and Methods

Sixty-four overweight and obese patients were prospectively enrolled and underwent a high-resolution MRI of the pituitary gland. The main outcome was calculated the pituitary gland volume and texture.

Conclusions

We concluded that increased prolactin secretion leading to chronic inflammation and fibrosis may cause to the persistent ductal dilatation.

Quantitative analysis of the pituitary gland at magnetic resonance imaging in obese patients

Giulia Puliani1, Carla Lubrano1, Marco Fierstell2, Emilia Shardella1, Chiara Graziazi2, Daniele Guaitelli1, Andrea Lenzi1 & Andrea M Isidori1
1Department of Experimental Medicine – Sapienza University of Rome, Rome, Italy; 2Department of Neurology and Psychiatry – Sapienza University of Rome, Rome, Italy.

Background

Hypothalamic-pituitary function and adipose tissue are deeply interconnected. Obesity has been linked to morpho-functional changes in several endocrine glands (thyroid, adrenal, gonads). No study has quantified the appearance of the pituitary gland in obese subjects.

Aim

To measure pituitary signal intensity, homogeneity and texture of the pituitary gland at magnetic resonance (MR) in obese subjects free of focal pituitary disease.

Materials and Methods

Sixty-four overweight and obese patients were prospectively enrolled and underwent a high-resolution MRI of the pituitary gland with a 3T MRI scanner. The main outcome was the measurement of pituitary gland volume and texture.

Conclusions

We concluded that increased prolactin secretion leading to chronic inflammation and fibrosis may cause to the persistent ductal dilatation.

Hypogonadotropic hypogonadism in a patient with long-term primary hypothyroidism

Raquel Vaz de Castro1, José Maria Aragüés2, Florbela Ferreira1, Vânia Gomes1, Ana Wessling3 & Maria João Bugalho1
1Santa Maria Hospital, Lisbon, Portugal; 2Beatriz Angelo Hospital, Lisbon, Portugal.

Abstract

We report the case of a 65-year-old man who presented with erectile dysfunction to an appointment in our Endocrinology department. He referred fatigue, weight gain and constipation as secondary complaints that had been steadily evolving throughout the past 4 years. He denied other symptoms such as visual impairment or headaches as well as the consumption of any medications or drugs. His past medical history was unremarkable. On examination, BMI was 25.8 kg/m², arterial blood pressure 112/64 mmHg, heart rate 71 BPM and temperature 36.4°C. Neck palpation revealed a diffuse thyroid enlargement. Visual acuity and visual fields were unaltered. Blood tests revealed elevated TSH (69.8 uIU/ml) with low FT4 (0.18 ng/dl), consistent with the diagnosis of primary hypothyroidism, and hypogonadotropic hypogonadism (testosterone 74.3 ng/dl). PRL levels were slightly elevated (38 ng/ml). Magnetic resonance imaging (MRI) of the pituitary showed a 17×14×12 mm sellar mass, without compression of the pituitary stalk or optic chiasm. The patient was started on levothyroxine 100 mcg per day. Three months later, the erectile dysfunction had resolved and thyroid function and total testosterone had returned to normal – TSH 0.90 uIU/ml, FT4 1.16 ng/dl, and total testosterone 522.8 ng/dl. The control MRI taken one year after starting therapy revealed regression of the pituitary enlargement. This is a peculiar case of HH likely associated with pituitary hyperplasia, in the context of long standing primary hypothyroidism, successfully treated with levothyroxine.

Effects of pasireotide treatment on cardio-metabolic risk in patients with Cushing’s disease: an Italian, multicenter study

Adriana Albani1, Francesco Ferrai2, Erika Messina2, Rosario Pivonello1, Carla Scaroni3, Carla Giordano4, Alessia Cozzolino2, Marialuisa Zilio3, Valentina Guarnotta4, Alessandro Cirpsi5, Davide Iacunelli6, Angela Alibrandi1, Anna Maria Cola1 & Salvatore Cannavo3
1Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; 2Department of Clinical Medicine and Surgery, Endocrinology Unit, University of Naples Federico II, Naples, Italy; 3Department of Medicine (DIMED), Division of Endocrinology, University of Padua, Padua, Italy; 4Biomedical Department of Internal and Specialist Medicine (DIBIMIS), Section of Cardio-Radiological and Endocrine-Metabolic Diseases, University of Palermo, Palermo, Italy; 5Department of Economics, University of Messina, Messina, Italy; 6Department of Human Pathology of Adulthood and Childhood, University of Messina, Messina, Italy.

Patients with Cushing’s disease (CD) have increased cardiovascular risk due to metabolic alterations caused by glucocorticoids excess. Pasireotide, a multi-receptor-targeted somatostatin analogue, is a therapeutic option in CD patients in whom surgery is not curative or not feasible. Pasireotide has been shown to be effective in controlling hypercortisolism and to improve metabolic features.

Patients with Cushing’s disease (CD) have increased cardiovascular risk due to metabolic alterations caused by glucocorticoids excess. Pasireotide, a multi-receptor-targeted somatostatin analogue, is a therapeutic option in CD patients in whom surgery is not curative or not feasible. Pasireotide has been shown to be effective in controlling hypercortisolism and to improve metabolic features.

Recently, the visceral adiposity index (VAI) has been proposed as a marker of
visceral adipose tissue dysfunction (ATD) and of the related cardio-metabolic
risk. We aimed to assess the effects of 12-month pasireotide therapy on cardio-
metabolic and cardiovascular risk in CD patients. In 16 CD patients (11 females),
referred to the Endocrine Units of four Italian University Hospitals, we assessed
anthropometric, clinical and biochemical parameters and calculated VAI, ATD
severity, Framingham and Atherosclerotic CardioVascular Disease Risk Scores
(FRS and ASCVD respectively), at baseline and after 6 and 12 months of therapy
with pasireotide (1200–1800 mcg/daily). Before starting pasireotide therapy,
ATD was present in 8/16 patients (severe in 2/16, mild in 2/16, moderate in 3/16).
After 12 months of treatment: i) UFC levels (P = 0.003), BMI (P < 0.001), waist
circumference (P = 0.001), LDL-cholesterol (P = 0.033), total-cholesterol (P = 0.032),
triglycerides (P = 0.03), VAI (P = 0.015) and ATD severity (P = 0.0026) were
significantly decreased as compared to baseline; ii) ATD was present in only 1/16 patients; iii) prevalence of diabetes (P = 0.015) and Hba1c
levels (P = 0.001) were significantly increased as compared to baseline; iv) FRS and
ASCVD scores were not statistically different from pre-treatment values. In
conclusion, twelve-month pasireotide treatment reduces cardio-metabolic risk in
CD patients.

DHEA-S as a marker of the secondary adrenal insufficiency following
craniospinal irradiation

Alla Yudina1, Maria Pavlova1, Tatiana Tselovalnikova1, Nadezhda Mazerkina1, Irina Arefeyeva1 & Olga Gherudova1

1Sechenov First Moscow State Medical University, Moscow, Russia; 2Berkduko Neurosurgery Institute, Moscow, Russia; 3Russian Scientific Center of Roentgenoradiology, Moscow, Russia.

Abstract
The secondary adrenal insufficiency (SAI) is life-threatening disease. 30–50% of
patients have SAI following craniospinal irradiation (CSI). The “gold standard”
of SAI diagnosis is the insulin tolerance test but it is demanding for patient and
medical staff. The simple and reliable test would allow to use ITT rarely. The aim
was to evaluate probability of using DHEA-S in SAI diagnosis. 41 patient after
radiotherapy were referred to the Endocrine Units of four Italian University Hospitals, we assessed
medical parameters before and after treatment were collected. SDS of anthropometric variables were calculated according WHO curves. IGF1 (Immulite 2000®) was analyzed considering SDS values adjusted for pubertal stage.

Results
Sample composed by 27 patients, 63% males. Before treatment: mean age was 10.5 ± 3.7 years, mean height-SDS – 2.82 ± 0.77, IGF1-SDS – 2.41 ± 1.59 ng/ml with a mean difference of 2 ± 1.5 years between chronological and bone age. All patients performed GH stimulation tests (clonidine, glucagon and insulin tolerance test) – peak values < 7.0 µg/l. Three patients had abnormal pituitary MRI. Mean treatment duration was 5 ± 3 years. Mean maximal dose administered was 0.03 ± 0.01 mg/kg/day. No adverse effects were registered. At the end, final height-SDS was – 1.63 ± 0.64 and IGF1-SDS – 0.83 ± 2.34. Final height and target height differed in – 4.72 ± 6.07 cm. Nine patients kept follow-up in Endocrinology: 3 performed insulin tolerance test, all having normal results. Only 2 patients presented IGF1-levels < -2 SDS (one of them proposed for treatment).

Discussion
As expected, patients with isolated GHD treated at our center showed good clinical outcomes, with mean final height reaching close target height. Current recommendations consider to treat with GH, adults with documented persistent deficiency. In this series all patients with isolated GHD with normal MRI had a transitory deficit and did not required treatment in the adult age.

What should central diabetes insipidus and panhypopituitarism point
out in a patient with lung adenocarcinoma in remission?

Sule Canlar, Caglar Keskin, Asena Gokcay Canpolat, Sevim Gullu & Demet Corapcioglu

Ankara University Faculty of Medicine, Ankara, Turkey.

Objectives
Pituitary gland is an uncommon site for metastasis of malignant tumors. Breast
and lung are the most common cancer sites. Most pituitary metastases are
asymptomatic, with only 7% symptomatic and central diabetes insipidus is the
most common symptom.

Case presentation
A 54-year-old woman presented with nausea, emesis and diplopia to emergency
department. Her relatives stated that she had poliuria, nocturia, polydipsia for
two months. Her history revealed that she had been operated because of lung
adenocarcinoma and postoperatively had undergone adjuvant chemotherapy. She
was at follow-up in remission. Laboratory tests denoted hypernatremia and MRI
scan images demonstrated that hypointense contrasted hypophysis and
infundibular enhancement. She possessed central diabetes insipids and desmo-
pression treatment administered. On observation, central hypothyroidism and
secondary adrenocortical deficiency developed. Medical oncology department
assessed the patient, no metastatic lesion was detected in thoracoabdominal
CT additionally PET scan, so that they didn’t consider pituitary metastasis. We
didn’t reveal any autoimmune, infectious and inflammatory diseases that can
cause hypophyseal involvement. Transnasal-transphenoidal hypophysis biopsy
was occurred, but histopathological sampling was insufficient. The patient refused
second biopsy, so she was discharged with replacement therapy in clinical stable
state. But two weeks later, the patient applied with emesis-vomiting and diplopia

Hospitalar de São João, Porto, Portugal; 2Faculty of Medicine, University of
Porto, Porto, Portugal; 3Department of Pediatric Endocrinology, Hospital
Pediatrico Integrado, Centro Hospitalar de São João, Porto, Portugal; 4Department of Pediatrics Hospitalar de Entre o Douro e Vouga,
Santa Maria da Feira, Portugal.
and MRI scans showed progression. Also she had seizures, periferal facial paralysis and drop foot. The progression of lesions necessitated exact diagnosis and transcranial biopsy was carried out by the same neurosurgeon. After biopsy, her clinical course worsened and she lost her life. Meanwhile, histopathological examination resulted as metastasis of lung adenocarcinoma to hypophysis.

Conclusions
A past history of cancer should be kept in mind in a patient presenting with sellar mass even if the cancer is in remission. Especially, presence of diabetes insipidus and MRI scan findings are clues for metastatic disease.

Is there any relationship between nonfunctional pituitary adenoma and arterial stiffness?
Yavuz Cagir1, Mustafa Altay2, Ermam Cakal3, Busra Betul Cagir4, Tolga Akkan1, Murat Dagdeviren1 & Esin Beyan1
1Keciöre Endocrinology and Research Hospital, Ankara, Turkey; 2Keciöre Endocrinology and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey; 3Diskapi Education and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey; 4Diskapi; Education and Research Hospital, Internal Medicine, Ankara, Turkey.

Introduction
In a recent study, it was determined that morbidity rates due to cardiovascular diseases were affected as a result of long-term follow-up in patients with nonfunctional pituitary adenoma. And cardio/cerebro vascular diseases were the most frequent cause of mortality when mortality rates were examined. In literature, there are not enough studies evaluating this condition in patients with nonfunctional pituitary adenoma without traditional cardiovascular risk factors. The aim of our study was to determine the peripheral and central blood pressures and arterial stiffness by Pulse Wave Analysis (PWA) in patients with nonfunctional pituitary adenoma without traditional risk factors.

Material & methods
In our study, 60 participants (30 patients with nonfunctional pituitary adenoma and 30 healthy volunteers) without traditional cardiovascular risk factors were evaluated. All participants were above the age of 18 years old. Peripheral and central blood pressure and PWA measurements were performed with a Mobile-O-Graph PWA / ABPM instrument (I.E.M. GmbH, Stolberg, Germany). In the nonfunctional pituitary adenoma group radiological and biochemical data were obtained retrospectively.

Results
In the nonfunctional pituitary adenoma group, systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial pressure (MAP), central SBP, and central DBP, augmentation index that corrected based on pulse rate of 75 bpm (Aix®75) and wave pulse velocity (PWV) were significantly higher than control group. There was no significant correlation between biochemical parameters and arterial stiffness parameters in the group of nonfunctional pituitary adenoma.

Conclusion
Peripheral and central blood pressure and arterial stiffness parameters are negatively affected in patients with nonfunctional pituitary adenoma known as cardiometabolically innocent, without traditional cardiovascular risk factors. Measurement of arterial stiffness in this patient group will lead to early detection of mortality and morbidity due to possible cardiovascular pathologies.

A rare cause of hypophysitis: tuberculosis
Ihsan Ates & Nisbet Yilmaz
Ankara Numune Training and Research Hospital, Ankara, Turkey.

Hypophysitis is a heterogeneous inflammatory disease of pituitary gland. As it causes headache and visual defects, it mimics sellar tumors in clinical and radiological aspects. It may occur due to primary or secondary causes. Tuberculosis is one of the rare secondary causes of hypophysitis. A young male patient presented with fatigue and headache and diagnosed with tubercular hypophysitis as a result of performed tests is discussed hereby in the case report. A 30 year old male patient presented to out clinic with fatigue, malaise, somnolence and headache. It was learned that the onset of the complaints was three months before and they gradually increased since then. There was no chronic disease, medication, herbal agent or alcohol use in the patient anamnesis. Overall medical condition of the patient was moderate with 36.7°C body temperature, 80/50 mmHg arterial blood pressure and 50/min heart rate. Physical examination revealed no abnormal finding other than icteric sclera. Due to the pathologic findings of 0.05 ng/dl free thyroxine level. 2.04 pg/ml free triiodothyronine level and 0.46 u/ml of thyroid-stimulating hormone, further tests were performed on the patient for a pre-diagnosis of central hypothyroidism. Tests performed for etiology resulted in 0.82 ug/dl cortisol, 0,1 ml/u luteinizing hormone, 7.97 pg/ml adrenocorticotropic hormone and 2.68 mg/ml follicle stimulating hormone. Panhypo/ptuitarism was considered due to these results. Levothyroxine and prednisolone treatment was initiated. Diagnostic magnetic resonance (MR) imaging was performed. Imaging revealed height of pituitary gland 14 mm higher than normal. No heterogeneity was observed at pituitary gland level. Biopsy of pituitary gland was performed for establishing diagnosis and result was concordant with granulomatous hypophysitis. TORCH panel, herpes simplex viruses, Brucella, Epstein-Barr, parovirus, varicella-zoster, T. pallidum tests were negative. Adenosine deaminase (ADA) level was 45, in the upper limit. Tuberculin skin test (PPT) resulted in 22 mm induration and QuantiFERON-TB gold test was positive. Hypophysitis developed secondary to tuberculosis was considered. In addition to the current treatment, anti-tuberculosis (isoniazid, streptomycin, pyrazinamide, rifampin) treatment was initiated. The dose of administered prednisolone was gradually (24 -> 18 -> 12 -> 8 > 75 -> 5 -> 4 mg /day) increased along the course of treatment. The need for steroid was completely eliminated by month 6 of tuberculosis treatment. In cases such as tubercular hypophysitis developing due to secondary causes, early diagnosis is very important given that panhypopituitarism may be completely eliminated in clinical terms following an effective anti-tuberculosis treatment. Therefore, tubercular hypophysitis should be kept considered for cases referred with hypopituitarism clinic and suggesting secondary hypophysitis.

T2-weighted MRI signal and response to somatostatin analogs in acromegaly
Luis Cerqueira, Ana Palha, Luisa Cortez, Amets Sagarrubay, Fernando Fonseca & Ana Agapito
Centro Hospitalar Lisboa Central, Lisbon, Portugal.

Introduction
Somatostatin analogs (SSA) are largely prescribed in acromegalic patients, whether as adjuvant or primary therapy. Response is variable and seems dependent of histological subtype. Intensity T2 signal in MRI has been related to granulation patern and accordingly with response to SSA.

Objective
To evaluate whether T2 MRI signal is correlated with effectiveness of SSA.

Material and methods
Retrospective analysis of acromegalic patients treated with SSA and available T2 MRI. We considered response as complete (normal GH and IGF1), partial (GH and/or IGF1 reduction ≥50%) and no response (≤50%). MRI were analysed by one neuroradiologist blinded for clinical and pathological data. Visual assessment only or direct measurements of signal intensity using ROI cursors on T2 coronal sections classified adenomas as hypointense or hyperintense, according MRI signal ≤ temporal lobe white matter or ≥ grey matter, respectively. Signal intensity between grey and white matter defined isointensity.

Results
Fifteen patients (8 males) were treated with SSA for a minimum of 6 months. All but 5 patients were surgically treated (3 refused, 1 approach failed due to bleeding, 1 is waiting surgery). T2 MRI hypointensity was documented in 8 patients (group 1) and hyperintensity in 6 (group 2). Group 1 included 3 non responders, 3 with partial and 2 with complete response. Group 2 comprised 3 non responders, 2 with partial and 1 with complete response to SSA. Considering isolated GH reduction (≥50%), hypointensity was more often observed (62.5%).

Comments
In this cohort of acromegalic patients we observed no relationship between T2 signal intensity on MRI and hormonal response to SSA. One major limitation is the small sample analysed.

“Toxic” Goiter Reveals Cushing’s Disease
Madalina Musa1,2, Dan Hortopan2, Luciana Oprea2, Andrea Duceac2, Duna Manda2, Andra Carageorgheopol2, Carmen Iordachescu2, Claudia Tupea1 & Vasile Ciubotaru1
1Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2University Carol Davila of Medicine and Pharmacy, Bucharest, Romania

Background
A 44-year-old woman, who presented with headache and vomiting without visual disturbance at the 7th month of pregnancy. She was admitted to our institution in post-partum for secondary amenorrhea combined with the hyperglycaemia. Plasma cortisol of 1.44 mcg/dL and lower normal range of urinary free cortisol. Dexamethasone suppression test was negative. MRI of the pituitary revealed left sided pituitary microadenoma of 7.5/7 mm. Diagnosis of Cushing’s disease has been made and transphenoidal adenectomy was performed. At 3 weeks postoperatively patient has returned to clinic with symptoms of cortisol withdrawal while on 30 mg of cortisone daily. She had a BMI of 42 kg/m², no plethora and no purpura. Cortisol day curve was within the therapeutic range. Off therapy, morning plasma cortisol was 8.89 mcg/dL, normal ACTH, midnight plasma cortisol of 1.44 mcg/dL and low normal range of urinary free cortisol. Thyroid function tests were normal.

Conclusion
Hypercortisolism is known to alter pituitary hormones, however it is not unusual that mild Cushing’s disease to suppress TSH to ‘thyrotoxic’ level. In this case of unsuspected Cushing’s disease, thyroid function tests alteration led to diagnosis.

Low incidence of hyperprolactinemia following traumatic brain injury
Anna Torton1, Domenico La Sala1, Anna Luna Tramontano1, Francesca Bisogno1, Elisabetta Angrisani2, Mario Carrano2, Mario Vitale1,2
1Department of Medicine, Surgery and Dentistry, University of Salerno, Salerno, Italy; 2Emergency Clinical Hospital Bagdasar Arseni, Bucharest, Romania

Introduction
Traumatic brain injury (TBI) is a major cause of disability and death, and a cause of neuroendocrine dysfunction. Partial or complete pituitary dysfunction is a frequent event occurring in 25-50% of subjects after a TBI as result from damage to either the pituitary or the hypothalamus. This large variability depends on the screening methods and on the difficulty to predict the effects of the trauma on pituitary. Growth hormone deficiency and gonadotropin deficiency are the most frequently documented pituitary dysfunctions after TBI. Also hyperprolactinemia has been documented in association with pituitary dysfunction. In this study, we evaluated the incidence of hyperprolactinemia following TBI.

Methods and patients
All subjects followed at the emergency room of our institution 12-6 months before were invited to a screening of pituitary function by measuring: FSH, LH, TSH, IGF-1, Testosterone (T) in (man), 17-beta-estradiol (in women) and PRL. When IGF-1 was below the reference range a GHRH + Arginine test was performed to document a GH deficiency. LHRH test was performed when FSH and LH and T or 17-beta-estradiol were below the reference range to document gonadotropin deficiency.

Results
Forty-five subjects aged 18-63 years joined the screening. Single or multiple pituitary failure was found in 14 patients (31%). Hypogonadotropic hypogonadism was documented in 3 males (6.8%), low IGF-1 in 10 patients (22%) and GH insufficiency documented in 3 of 4 patients tested by GHRH + Arginine (7%). One patient displayed a concomitant GH insufficiency and low TSH level while in another subject we found GH deficit and low FSH, LH and testosterone values even if his gonadotropin response was normal after LHRH test. Surprisingly, none of the patients displayed altered PRL values.

Conclusions
Mild to moderate TBI was followed by pituitary dysfunction documented in 13.3% of subjects. Higher frailty of GH and gonadotropin secretion by pituitary was confirmed, while altered PRL secretion was not documented.

DOI: 10.1530/endoabs.49.EP1064
Conclusion
Nonsecretory pituitary tumors are called null-cell tumors measuring a few millimeters are common and found in up to 25% of autopsies. These may grow slowly, destroying normal pituitary function, or they may compress nearby structures and cause neurologic problems. In our case report we discuss asymptomatic pituitary macroadenoma.

Nonfunctioning pituitary incidentaloma – delayed onset of acromegaly and concomitant primary adrenocortical insufficiency
Şerban Radan1,2, Diana Deciu1,2, Antonia Lefter1,2 & Catalina Poiană1,2
1C. Davila University of Medicine and Pharmacy, Bucharest, Romania; 2C.I. Parhon National Institute of Endocrinology, Bucharest, Romania.

Introduction
Pituitary incidentaloma (PitInc), defined as an unsuspected mass observed on imaging studies performed for unrelated conditions. Most such lesions are not clinically significant at initial evaluation and current guidelines recommend periodic follow-up.

Aim
To present a rare case of delayed onset of acromegaly in a patient with a nonfunctioning PitInc, raising the question of the utility of prolonged follow-up of PitInc.

Methods
Clinical examination, biochemical and imaging studies.

Case report
Following a contrast head CT for headache, a 63 years old female presented with a 11 × 5 mm intrasellar pituitary mass, no clinical signs of pituitary hypersecretion and normal serum prolactin and IGF-I. Subsequent follow-up showed non-progression of mass size on CT/MRI and normal prolactin/IGF-I. 10 years from initial diagnostic, unexplained hyperkalemia prompted re-evaluation, revealing mild skin hyperpigmentation, absence of other signs of adrenal failure, a small adenoma with a minimal lesion size progression and cystic changes. Visual fields were normal. The patient was offered surgery but chose to start cabergoline, dose-titrated to 3 mg/week, leading to IGF-I normalization. ACTH was elevated and increased progressively, 8 AM serum cortisol was normal, with subnormal response to Synacthen, suggesting subclinical primary adrenocortical failure. An adrenal CT scan excluded adrenal masses, but revealed a discrete left adrenal non-nodular hyperplasia. Serum 17 HO-progesterone was elevated, suggesting concomitant congenital adrenal hyperplasia. The patient is clinically well on medical therapy with thyroxine and glucocorticoids was used in all the cases.

Conclusions
The current PitInc guideline (Endocrine Society 2011) does not specify a maximum follow-up period. Prolonged clinical and hormonal evaluation may be warranted, as delayed onset endocrine disease can occur. In our case, incidental hyperkalemia prompted endocrine re-evaluation revealing multiple endocrine abnormalities.

Sheehan’s syndrome in clinical practice
Mihaela Vlad1, Ioana Golu1,2, Daniela Amzar1,2, Melania Balas1,2, Miura Butaru1, Ioana Miloș1,2 & Ioana Zosin1,2
1Victor Babes” University of Medicine and Pharmacy, Timisoara, Romania; 2Emergency County Hospital, Timisoara, Romania.

Sheehan’s syndrome represents a rare cause of pituitary insufficiency, produced by an ischemic pituitary necrosis due to a severe haemorrhage at delivery. Epidemiologic data indicate that, nowadays, this disease is quite rare in developed country.

Aim
To determine and evaluate the clinical and hormonal characteristics of cases with Sheehan’s syndrome diagnosed and follow-up in our Clinic, during the last ten years.

Subjects and methods
We included, in this retrospective study, 13 patients, mean age 58 ± 10.9 years, diagnosed with Sheehan’s syndrome. Data about medical history, routine laboratory determinations, hormonal parameters, pituitary imaging and therapy were reviewed. All the cases presented a history of severe uterine bleeding after last delivery.

Results
The age at diagnosis for these patients varied between 19 and 54 years. The period of follow-up from the moment of diagnosis was between 3 and 48 years. All except one of the cases had an assisted deliverance, but more than half of the cases (53.8%) came from rural area. Due to severe uterine bleeding, hysterec tomcy was performed in 7 patients (53.8%). In 12/13 subjects, breastfeeding was not possible. The diagnostic of Sheehan’s syndrome was established after 0.5 to 28 years from pathological deliverance. The longest delay between the moment of delivery and those of diagnostic was 28 years. All the cases presented corticotropin, thyreotropin and gonadotropins deficiency in the moment of diagnosis. Growth hormone deficiency was documented in 2 patients and one subject was diagnosed with central diabetes insipidus. Hormonal substitution therapy with thyr oxine and glucocorticoids was used in all the cases. Gonadotropins deficiency was treated with estrogogenous in younger subjects and GH replacement treatment was given in two cases. Desmopressin was given in one patient for ADH deficiency.

Conclusion
Sheehan’s syndrome is still present in clinical practice, even in the condition of assisted deliverance and well-managed uterine haemorrhage.

Mental disorders in the hospitalized patients with Cushing’s disease
Denis Almaev1, Elena Staroostina1, Janna Belaya2, Irina Komerdus3 & Aleksey Bobrov4
1Moscow Research Institute of Psychiatry, Moscow, Russia; 2Endocrinology Research Centre, Moscow, Russia; 3Moscow Regional Research and Clinical Institute, Moscow, Russia.

Objective
To study the frequency and features of mental disorders in hospitalized patients, suffering from Cushing’s disease (CD).

Materials and methods
We studied 70 patients (59 women and 11 men) with verified diagnosis of CD, aged 41 ± 12 years. Their mental health was evaluated with ICD-10 criteria and verified by the Mini-International Neuropsychiatric Interview questionnaire (MINI 6.0). 45 patients had overt hypercortisolism (untreated CD and relapse), 25 people had remission after treatment.

Results
Majority of the patients with CD suffered from comorbid mental disorders (88.5%). 61.6% of them had different forms of affective disorders including bipolar disorder in 22/70 (38%), hypomania in 8/70 (11.2%), depressive episode in 6/70 (8.4%), mania without psychotic symptoms 3/70 (4.2%), recurrent affective disorder 3/70 (4.2%) and cyclothymia in 2/70 (2.8%) patients. The frequency of neurotic, stress and somatoform disorders was 15/70 (21%), among these, the frequency of obsessive-compulsive disorder (6/70, 8.4%) was higher than population-based, while the frequencies of social phobia (3/70, 4.2%), panic disorder (2/70, 2.8%), agoraphobia without panic attacks (2/70, 2.8%) and adjustment disorder (2/70, 2.8%) were not increased. The rest of diagnoses did not exceed population prevalence: unspecified dementia in 1 (1.4%), acute psychotic disorder in 1 (1.4%), schizoid personality disorder in 1 (1.4%). Psychiatric comorbidity with presence of two or more mental disorders in the same patient reached 3/70 (52.8%). The frequency of bipolar spectrum disorders and anxiety disorders was similar in patients with active hypercortisolism and remission, although the lack of difference may be due to the small sample size.

Conclusions
Mental disorders in patients with CD are extremely high. A prominent frequency of bipolar spectrum disorders and recurrent depression suggests, that the dysregulation of biological cycles is an important mechanism of CD development/recurrence. Besides, there are obviously specific psychological adaptation patterns and a number of typical stress responses in such patients.

Detailed assessment of hypothalamic damage in craniopharyngioma patients with obesity
Sigridur Fjalldal1, Cecilia Follin1, Sanaz Gabery2, Pia Maly Sundgren1,3,4, Isabella Bjerkman-Burtscher1,2,3, Jimmy Lüt1, Peter Mannfolk1,2, Carl-Henrik Nordström3,4, Lars Rylander2, Bertti Ekmam1, Anna Pålsson1, Asa Petersén1 & Eva-Marie Erfurth1
1Department of Endocrinology, Skåne University Hospital, Lund, Sweden; 2Translational Neuroendocrinology Research Unit, Department of Experimental Medical Science, Lund University, Lund, Sweden; 3Department of Medical Imaging and Physiology, Skåne University Hospital, Lund, Sweden; 4Department of Diagnostic Radiology, Clinical Sciences, Lund University, Lund, Sweden; 2Department of Neurosurgery, Skåne University Hospital, Lund, Sweden; 3Division of Occupational and Environmental Medicine, Lund University, Lund, Sweden; 4Department of Endocrinology and Medical and Health Sciences, Linköping University, Linköping, Sweden.

Background/objectives
Hypothalamic obesity (HO) occurs in 50% of patients with the pituitary tumor Craniopharyngioma (CP). Attempts have been made to predict the risk of HO based on hypothalamic (HT) damage on magnetic resonance imaging (MRI), but none have included volumetry. Qualitative and quantitative (volumetric) analyses of HT damage was performed. The results were explored in relation to feeding related peptides and body fat.

Subjects/methods
A cross-sectional study of childhood onset CPs involving 3 Tesla MRI, was performed at median 22 years after 1st operation. 41 CPs, median age 35 (range 15–76) years, of whom 23 had HT damage, were compared to 32 controls. After exclusions, 35 patients and 31 controls remained in the MRI study. Main outcome measures were the relation of metabolic parameters to HT volume and qualitative analyses of HT damage.

Results
Metabolic parameters scored persistently very high in vascular risk particularly among HT damaged patients. Patients had smaller HT volumes compared to controls 769 (35–1168) mm³ vs 879 (775–1086) mm³ (P < 0.001). HT volume correlated negatively with fat mass and leptin among CP patients (r = −0.67; P < 0.001; r = −0.55; P = 0.001), and explained 39% of the variation in fat mass. For every 100 mm³ increase in HT volume fat mass decreased by 2.7 kg (95% CI: 0.3–5.2; P = 0.02).

Conclusions
A decrease in HT volume was associated with an increase in fat mass and leptin. The method may be applied by non-radiologist for the assessment of HT damage. The method may be valuable in the risk assessment of diseases involving the HT.

Risk factors for progression of the surgical remnant of non-functioning pituitary adenomas in patients treated with dopamine agonists
Elena Fernández González, Miguel Sampredo Nuñez, Ana Ramos Levi, Ana Kubé Caín, Isabel Huguet, Nerea Aguirre Moreno, Clara Marijuan Sánchez, Belogúa Pía Perti, Ángeles Maillo Nieto, Alicia Vicuña Andrés, Pedro Martínez Flores & Mónica Marazuela Azpíroz
Hospital Universitario La Princesa, Madrid, Spain.

Introduction
Surgery is the treatment of choice for non-functioning pituitary adenomas (NFPA), but remnants are frequently observed. Management of these remnants include observation (OBS), radiotherapy (RT) and/or dopamine agonist (DA) therapy. In this study, we evaluate the progression-free survival (PFS) of NFPA with postoperative remnant and the potential factors involved.

Methods
We performed a single-center ambispective study of a cohort of 72 patients (age 56 ±15 years, 32 women), with NFPA and tumor remnant after transsphenoidal (TS) surgery, followed-up between 1994 and 2015. We categorized patients as stable (n=36) or progression (n=36), according to radiological criteria. No follow-up data were available for 10 patients and 5 cases died. We evaluated differences between patients according to the three postoperative approaches: OBS, DA and/or RT. Statistical analysis was performed with STATA v12.0. We present data for progression-free time medians (p 25-75), correlation coefficient (r) and Hazard Ratio (HR).

Results
Progression-free survival (PFS) of the total cohort of patients was 154 months (77–184). Subgroup analysis suggested longer PFS in OBS patients (154m) vs. RT (184m) (P = 0.07). Univariate analysis indicates an increased risk of progression in patients without RT (HR: 3.6; [0.8–15]; P = 0.09). Duration of DA treatment was positively correlated with PFS (r=0.60; P<0.05), and each additional month showed a favorable trend for an increased PFS (HR: 0.98; [0.95–1.00]; P=0.06). Sex, age, and postoperative tumor diameter were not associated with PFS. Subanalysis of the subgroup of patients who received DA(n=20) showed that the only influencing factor for progression was female sex (x² = 5.05; P=0.02).

Conclusions
RT of operated NFPA seems to be associated to a higher PFS in our cohort. Prolonged treatment with DA also favor an increased PFS. Long-term follow-up and active management of patients with NFPA are important.

Popa, Iasi, Romania; 4Neurosurgery Department, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania.

Background
Clinically non-functioning pituitary adenomas (NFPAs) are among the most common pituitary lesions. Its management includes surgery, radiation or observation. The authors aim to compare clinical characteristics and outcomes between patients submitted to surgery or expectant observation (EO).

Methods
Retrospective review of medical records from 1996 to 2016. In our centre, there is only 1 pituitary surgeon and NFPAs patients are referred to surgery according to radiological criteria. No follow-up data were available for 10 patients and 5 cases died. We evaluated differences between patients according to the three postoperative approaches: OBS, DA and/or RT. Statistical analysis was performed with STATA v12.0. We present data for progression-free time medians (p 25-75), correlation coefficient (r) and Hazard Ratio (HR).

Results
Progression-free survival (PFS) of the total cohort of patients was 154 months (77–184). Subgroup analysis suggested longer PFS in OBS patients (154m) vs. RT (184m) (P = 0.07). Univariate analysis indicates an increased risk of progression in patients without RT (HR: 3.6; [0.8–15]; P = 0.09). Duration of DA treatment was positively correlated with PFS (r=0.60; P<0.05), and each additional month showed a favorable trend for an increased PFS (HR: 0.98; [0.95–1.00]; P=0.06). Sex, age, and postoperative tumor diameter were not associated with PFS. Subanalysis of the subgroup of patients who received DA(n=20) showed that the only influencing factor for progression was female sex (x² = 5.05; P=0.02).

Conclusions
RT of operated NFPA seems to be associated to a higher PFS in our cohort. Prolonged treatment with DA also favor an increased PFS. Long-term follow-up and active management of patients with NFPA are important.

Endocrine Abstracts (2017) Vol 49
Background
Prolactinoma is the most frequent pituitary tumour. However, peculiar aspects may induce difficulties in their evolution and management. Malignant prolactinoma is exceptionally rare and it cannot be diagnosed on histological grounds alone. We report the case of a recurrent, possibly malignant macroadenoma.

Case report
A 46 years old female, addressed for bitemporal hemianopia, without other clinical signs. MRI confirmed a pituitary macroadenoma (22/19/35 mm) with suprasellar evolution. Hormonal profile revealed hyperprolactinemia with secondary thyroid and gonadal insufficiency, for which Cabergoline was started, with initial good response. Three years later she presented pituitary apoplexy with acute ischaemic hypopituitarism, solved by partial transcranial adenoectomy. Gamma knife radiation completed the treatment, with succeeding adrenal and thyroid insufficiency. After 4 years of stationary evolution under Cabergoline and substitutive treatment, an aggressive tumour progression imposed a new surgical intervention (transsphenoidal adenoectomy). One year later, extensive vertiginous syndrome enforced reinvestigations. MRI identified two cerebral tumours (meningioma?), one of them at the cranio-spiral junction, which needed urgent excision. Pathology identified pituitary adenoma cells and a Ki-67 index of 2%. Post-operative, the patient complained of gait dysfunction, nausea and headache. Left cranial nerves paresis X, XI, and XII was objectified. The patient underwent six cycles of Temozolomide chemotherapy, with no improvement, last MRI revealing further tumour evolution. Conclusion
Elucidating the pathogenesis of aggressive prolactinomas remains largely unknown and continues to mesmerize the physicians. The diagnosis of pituitary carcinoma is confirmed only in the presence of metastasis. After initial good response to Cabergoline, our patient developed a rapid aggressive progression of the tumour, with little effect of surgery and radiotherapy. Temozolomide was not efficient in controlling tumour evolution. In spite of the longer survival (9 years) and the low proliferation index, we believe that new markers are needed in order to assess the aggressiveness of malignant prolactinoma.

Introduction
POEMS syndrome is a rare multisystemic disorder including polyneuropathy, organomegaly, endocrinopathy, monoclonal plasma-proliferative disorder and skin changes. We aim to describe the course of the endocrine disease in the context of this paraneoplastic syndrome.

Methods
69 patients with POEMS have been under the MDT care in our hospital. Data is currently available for 32 patients who attended the joint haematological/endocrine clinic from 06/1999 to 01/2017. All patients had regular endocrine screening including pituitary, thyroid and calcium metabolism. Median and interquartile range and mean ± s.d. were used for quantitative variables and percentage for qualitative variables.

Results
Seventy-two patients were male. The age at diagnosis was 49 (38.2–59.8) years and the median follow-up was 4.6 (2–7.4) years. At diagnosis, all patients were present with polynuropathy, 25% had hyperhidrosis and 50% endocrinopathy. From those with endocrinopathy, 36.7% had thyroid disease, 26.7% hypogonadism, 3.3% type 2 diabetes mellitus (2DM) and 6.5% Addison disease. None of them had parathyroid disorders. 60% had more than one endocrinopathy at diagnosis. During surveillance 90.3% of patients developed endocrinopathy. 68.8% of patients had hyperprolactinaemia with a fold increase 1.8 ± 0.99 above the upper limit of the normal. Hyperprolactinaemia was transient in 72.7%. One patient with hyperprolactinaemia had an empty sella on MRI. 59.4% had hypothryoidsim (37.5% clinical, 21.9% subclinical). This was transient in 27.8% of patients. Addison disease was diagnosed in 18.8% of patients and none of them recovered their adrenal function. 15.6% presented with type 2DM. 78.6% had hypogonadism (19.1% secondary, 38.1% primary, 42.9% subclinical primary). Gonadal function recovered in 3 patients.

Conclusion
Endocrinopathy in POEMS was described in 90% of our cohort. The MDT team should include an endocrinologist. Patients should be systematically assessed for endocrinopathy. The most common deficiencies were hypogonadism, hyperprolactinaemia and hypothryoidsim. Normalisation of the endocrinopathy was common and should be considered when treating these patients.

Body composition and bone mineral density in male patients with isolated hypogonadotrophic hypogonadism
Malgorzata Kaluzna1, Magdalena Czlapka-Matysik2, Dorota Przeorska2, Katarzyna Ziemnicka1 & Marek Ruchała1
1Department of Endocrinology, Metabolism and Internal Diseases, Poznan University of Medical Sciences, Poznan, Poland; 2Department of Human Nutrition and Hygiene, Poznan University of Life Sciences, Poznan, Poland.

Isolated hypogonadotropic hypogonadism (IHH) is known to decrease bone mineral density due to lack of pubertal surge of gonadotrophins and deficiency of sex steroid hormone. Gonadal steroid hormones imbalance affects body composition. Nineteen Caucasian men, 22–48 year old (mean±s.d. 33 ± 7.65) diagnosed with IHH (8 normosmic, 11 anosmic or hyposmic) were enrolled into the study. 14 patients were on hormone replacement therapy (HRT), 5 patients were started with HRT treatment. Nineteen healthy male volunteers (CON) with matched age and BMI were also included. Body composition and bone mineral density measurements were conducted with use of Air Displacement Plethysmography (BOD POD, Cosmed) and dual-energy x-ray absorptiometry DEXA (Lunar Prodigy,GE Healthcare), respectively. Hormonal status, lipid profile, calcium and phosphorus levels, 25-hydroxy vitamin D concentration were also measured. There was significant difference between fat-free mass (FFM; kg) in IHH and matched controls (60.1 vs 66.0; P = 0.012), related to Glycophob FPD tumour (IHH vs CON; 9.1 vs 10.3; P = 0.003). IHH patients have marked decreases in total bone mineral density compared to CON (1.21 vs 1.31 g/cm², P = 0.009). Total bone mineral content, T-score and Z-score were also decreased in IHH subjects (2982 vs 3271 g/cm², P = 0.05; 0.08 vs 1.06, P = 0.016; ~0.40 vs 0.54, P = 0.013). High-density lipoprotein cholesterol (HDL) level was correlated with waist-to-height ratio (WHR) (r = −0.81, P < 0.05) in IHH patients. Significant correlations between insulin-like growth factor-1 (IGF-1) and WHR or IGF-1 and HDL correlations in IHH patients might suggest their link with cardiometabolic dysfunctions. Susceptibility to metabolic syndrome in IHH patients on HRT should be further investigated.

Pituitary adenoma and elevated ACTH: not always corticotrophinoma
Mirela Tirnovan1, Georgiana Constantinescu1, Anamaria Burgesc1, Aurora Constantinescu1, Vocliata Mogos1 & Carmen Vulpoi1
1Department of Endocrinology, University College London Hospitals, London, UK; 2Haematology Department, University College London Hospitals, London, UK; 3Neurology Department, University College London Hospitals, London, UK.

Introduction
Hypothalamic–pituitary–adrenal (HPA) axis activation is the main neuroendocrine response to an environmental challenge. Drug abuse may activate HPA axis by interaction with neuropeptide systems.

Case report
28 year old man, was admitted in the Neurology Department for persistent headache with spinal irradiation. With suspicion of multiple sclerosis, MRI revealed pituitary macroadenoma (14 mm diameter) and subcortical, paraventricular and frontal white matter demyelinating lesions. Neurological examination
EP1077
Pituitary apoplexy – presentation, management and outcome in 35 cases
Maria Manuel Costa 1, 2, Bruno Carvalho 1, José Luís Castedo 1, 2, Eduardo Vinha 1, José Pereira 1, 2, Irene Bernardes 3 & Davide Carvalho 1, 3
1Department of Endocrinology, Diabetes and Metabolism of Centro Hospitalar de São João, Porto, Portugal; 2Faculty of Medicine, University of Porto, Porto, Portugal; 3Instituto de Investigação e Inovação da Saúde da Universidade do Porto, Porto, Portugal; 4Department of Neuroradiology, Centro Hospitalar de São João, Porto, Portugal.

Introduction
Pituitary apoplexy is a rare disease which results of haemorrhage and/or infarction of pituitary gland. The optimal management of this problem still remains controversial between surgery and conservative treatment.

Aims
To characterize the clinical presentation, diagnostic workup, treatment and follow up of patients with apoplexy.

Methods
Retrospective study of 35 pituitary apoplexy followed in a portuguese hospital from 2006 to 2016.

Results
Thirty-five patients (21 males; mean age, 55.1 (15.6) years) were identified. Three patients had subclinical pituitary apoplexy and 9(26%) had more than one emergency evaluation until the diagnosis has been correctly made. Commonest presenting features were acute headache (84.4%), visual impairment (62.5%) and vomiting (15.6%). Five patients were known to have pituitary tumour at presentation, one of them was a Cushing Disease which became cured after PA, and 3 were nonfunctioning adenomas. Nineteen patients had at least one precipitating factor with antiaggregation being the most common (n=4). Twenty patients had hypopituitarism at presentation, 14 had hypopituitarism, 9 had a decreased level of consciousness and 21 had visual impairment. 78.1% patients proceeded to pituitary surgery and 3 developed diabetes insipidus after that. When we compared those who underwent surgery and those treated conservatively, visual deficits were more common in first group (76% vs 26%, P=0.032) and hypopituitarism in the second one (32% vs 86%, P=0.027). There were no more differences between groups in other evaluated factors, namely in Pituitary Apoplexy Score (1.68 (1.21) vs 0.86 (1.21); P=0.124). During follow-up 6(3) years, 1 patient had hypopituitarism reversal after surgery and 11 patients recovered from neuroendocrine deficits. Three patients passed away and 21 have a MRI without lesion.

Conclusion
The diagnosis of pituitary apoplexy is often delayed as occurred in our population. It is associated with a high rate of anterior hypopituitarism that does not typically recover, unlike the visual symptoms. Patients with visual defects were more likely to be managed surgically.

EP1078
Inferior petrosal sinus sampling: experience of a tertiary hospital
Maria Manuel Costa 1, 2, José Luís Castedo 1, Eduardo Vinha 1, José Pereira 1, 2, Irene Bernardes 3 & Davide Carvalho 1, 3
1Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar de São João, Porto, Portugal; 2Faculty of Medicine, University of Porto, Porto, Portugal; 3Instituto de Investigação e Inovação da Saúde da Universidade do Porto, Porto, Portugal; 4Department of Neurosurgery, Centro Hospitalar de São João, Porto, Portugal; 5Department of Neuroradiology, Centro Hospitalar de São João, Porto, Portugal.

Introduction
Inferior Petrosal Sinus Sampling (IPSS) is the gold standard test to distinguish between Cushing Disease and ectopic ACTH secretion (EAS), mostly when the biochemical tests are discordant and/or there is no lesion on MRI.

Aim
To evaluate the results of IPSS in the diagnosis of ACTH-dependent Cushing syndrome.

Methods
Retrospective study that analysed IPSS results performed in the last decade in our centre and integrated in the clinical context of each patient. Basal central-to-peripheral ratio >2 or after CRH test >3 were considered diagnostic of CD.

Results
We analysed 31 IPSS performed in 26 patients with biochemical diagnosis of CS. Nine patients were excluded. Seventeen patients (2 Male) with a mean age of 38.4 (11.8) years were included. One patient had to repeat IPSS due to haemolysis and other had done 3 IPSS due to be on interfering medication. Eleven patients had central-to-peripheral ACTH ratio suggestive of CD (basal and 11 after CRH stimulation). The ratio was maximal at 5’ in 45.4% (5/11) patients and at 2’-3’ in 36.3% (4/11). Pituitary MRI revealed microadenoma in 8 patients, macroadenoma in one and 2 patients did not present any lesion. Three patients had a lesion on the other side of pituitary when compared to the inferior sinus gradient. Immuno-histochemical result revealed an ACTH expression adenoma in 6 patients, and expression of ACTH and GH in 2. There was no positivity for ACTH in 3 patients who had MRI lesions, but one was cured after surgery and 2 underwent adjuvant therapy. Of the remaining 6 patients, 3 had results suggestive of ectopic EAS, one of which was submitted to lobectomy and had bilateral adenalecetomy by occult ectopic, but underwent pituitary surgery with a histological result revealing ACTH expression. Of the other 3 patients, all with pituitary MRI lesion, 2 patients underwent surgery that revealed CD and in the other the result was normal and patient underwent adenalecetomy. There were no significant adverse effects.

Conclusion
This study reinforces the utility of IPSS in identifying aetiology of SC, which was obtained in more than half of the patients, with no associated adverse effects. The IPSS catherization was not possible in 1 patient.

EP1079
Cushing syndrome and pregnancy: a systematic review including three new cases
Diogo Chinha 1, Ana Isabel Oliveira 2, Sandra Belo 2, 3 & Davide Carvalho 2, 3
1Faculty of Medicine, Porto, Portugal; 2Department of Endocrinology, Diabetes and Metabolism Centro Hospitalar S. João, Porto, Portugal; 3Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, Portugal.

Cushing’s Syndrome (CS) is an uncommon disease worldwide, being characterized by an increased production of glucocorticoids, and if left untreated can lead to serious consequences and women with CS rarely get pregnant. The aim of our work is to make a systematic review of the cases of pregnancy in patients with previously diagnosed CS, being performed an extensive research of the Medline and Web of Knowledge databases, and add three new cases observed in our institution. We compared two different groups: the ‘active disease’ one and the ‘non-active disease’ and we found 17 pregnancies that were included in the first group while other 20 pregnancies were in the second category. We observed two spontaneous abortions and one ectopic pregnancy in the ‘active’ group, while in the ‘non-active’ category we found the same number of spontaneous abortions besides a placental abortion and a medical interruption of the pregnancy. Cushing disease (CD) was the main cause behind CS (28 pregnancies), with transsphenoidal surgery the preferred treatment. Within the ‘active’ category, we reported nine full-term and live pre-term pregnancies and in the ‘non-active’
category we observed 11 full-term and three pre-term pregnancies, while two in this last group were non-specified. Hypertension was diagnosed in eight cases (six and two in the ‘active’ and ‘non-active’ group respectively) and gestational diabetes in four patients (three and one in the ‘active’ and ‘non-active’ categories). Inability to breastfeed was one of the main perinatal events reported, as a logical consequence of the treatment regimen adopted for CS. A major concern in these patients refers to the medical control of CS activity, because hypercortisolism occurs physiologically during pregnancy. This is a topic with extreme clinical significance since it is rare that a CS women conceives.

Introduction
The endocrine system is often affected in the course of HIV infection. However, hypopituitarism and diabetes insipidus are uncommon disorders in these patients and have been related to drugs, infections of the central nervous system and neoplastic infiltration, in extremely rare cases.

Case report
We present a case of a 42-year-old man with HIV infection known since 2005, but undergoing antiretroviral therapy only since 2010 (emtricitabine/tenofovir and raltegravir), when he was diagnosed with hepatitis C, left parotid MALT lymphoma, and cerebral toxoplasmosis (treated with pyrimethamine/sulfadiazine). He has also a history of smoking, drug addiction, in a methadone replacement program for 10 years, and hypothyroidism diagnosed for 1 year, medicated with l-thyroxine. The patient was referred to the Endocrinology department by bilateral gynecomastia, loss of libido and erectile dysfunction.

When specifically asked he also complained of polydipsia-polyuria. Breast, testicular and thyroid ultrasonography showed no relevant changes, but the hormonal study revealed: central hypothyroidism and hypogonadotropic hypogonadism; normal prolactin levels; slightly decreased IGF-1 and GH levels; normal ACTH, cortisol and tetraocotidaxis test; insulin-induced hypoglycemia test showed normal glucocorticoid reserve. Plasma osmolality was 300 mOsmol/kg and urine osmolality 136 mOsmol/kg. Water deprivation test confirmed central diabetes insipidus. Pituitary MRI showed lack of neurohypophyseal bright signal.

He was started on testosterone therapy (250 mg, 3/3 weeks), desmopressin lypoilfahis (0.06 mg bid) and maintained l-thyroxine (0.088 mg/day). Currently, he refers a global clinical improvement, but still complains of erectile dysfunction, and was recently medicated with avanafil (100 mg).

Conclusion
The authors describe a rare case of hypopituitarism and diabetes insipidus in a patient with HIV infection of possible multifactorial etiology – uncommon complication of cerebral toxoplasmosis and/or side effects of antiretroviral drugs. This case reveals the need to keep in mind the possibility of hypopituitarism in HIV-treated patients and a history of cerebral infection.

Social stress stimulates glucocorticoid regeneration in lymphoid organs

Jiri Pacha, Peter Ergang, Anna Mikulecka, Karla Vagnerova & Ivan Milišák
Institute of Physiology, Czech Academy of Sciences, Prague, Czech Republic.

The presence of the enzymes of local metabolism of glucocorticoids in lymphoid organs and many other tissues suggests that the local glucocorticoid signal is not determined only by plasma level of glucocorticoids but also by the local activity of these enzymes. Using resident-intruder test the present study determined if chronic social stress modulates local metabolism of corticosterone and 11-dehydrocorticosterone in rats of Fisher 344 (F344) and Lewis (LEW) strains, which differ in their response to social stressors and inflammation. We demonstrated that social defeat significantly increased regeneration of corticosterone from 11-dehydrocorticosterone in thymus, spleen and mesenteric lymphatic nodes (MLN) but not pituitary of both strains. When compared with F344 strain, LEW rats showed lower corticosterone regeneration in pituitary of unstressed and stressed animals and higher corticosterone regeneration in thymic and MLN mobile cells after chronic stress. In contrast, stress-induced increase of corticosterone regeneration in stroma tissues of all lymphoid organs was similar in both strains. Social defeat was also associated with changes in expression of enzymes participating in local metabolism of glucocorticoids: 11β-hydroxysteroid dehydrogenase type 1 (11HSD1), 11b-hydroxysteroid dehydrogenase type 2 (11HSD2) and hexose-6-phosphate dehydrogenase (H6PDH). Whereas F344 rats exhibited significant upregulation of 11HSD1 mRNA, 11HSD2 mRNA and H6PDH mRNA expression in thymus and 11HSD1 mRNA in spleen, LEW rats showed apparent insensitivity to stress in all lymphoid organs and neither of the transcripts was upregulated by stress. Our results indicate that social stress amplifies glucocorticoid regeneration in the lymphoid organs including the expression of genes involved in local metabolism of glucocorticoids and that this process is partly determined by the genetic background. The study was supported by Czech Science Foundation.

Effects of male hypogonadism treatment on the bone mineral density

Mário Rui Mascarenhas1, Ana Paula Barbosa1, Ana Raquel Coelho Gomes2, Catarina Silvestre2, David Barbosa2, Raquel Paixão2, Carolina Faria2, Ana Sofia Osório2, Vânia Gomes2, Joana Ferreira1, Manuel Bicho1 & Maria João Bugalho2

1Endocrinology and Metabolic Diseases, Faculty Medicine of Lisbon, Lisbon, Portugal; 2Endocrinology, Diabetes and Metabolism Department, Santa University Maria Hospital-Chin, Epe, Lisbon, Portugal.

Increased recognition of the morbidity and mortality due to osteoporosis in men are main issues of public health. Ageing and the propensity to falls are the main risk factors for osteoporotic fractures in men; moreover, hypogonadism is an important secondary cause of low bone mineral density (BMD), but very little is known about the effect of hypogonadism treatment on the BMD.

Objective

The aim was to study the impact on BMD of the treatment of male hypogonadism.

Material and methods

A group of 26 men were devided in the hypogonadotrophic hypogonadism (n = 17) and hypergonadotrophic hypogonadism (n = 9) groups. The BMD at several skeletal sites (assessed by DXA scans) was evaluated before and during treatment (duration from 1 to 8 years, on average 3.1 (±2.3) years). Adequate statistical tests were used (statistical significance P < 0.05).

Results

The treatment did not improved significantly the mean BMDs at several skeletal sites (Table 1). Moreover the BMDs were similar before and during the treatment in the hypogonadotrophic hypogonadism group; nevertheless, in the hypergonadotrophic hypogonadism group the mean BMDs were significantly higher at the lumbar spine, at the hip, at the forearm and at the whole body during therapy.

Conclusions

After more than three years of treatment there was no improvement on the BMD sites (Table 1). Moreover the BMDs were similar before and during the treatment in the hypogonadotrophic hypogonadism group; nevertheless, in the hypergonadotrophic hypogonadism group the mean BMDs were significantly higher at the lumbar spine, at the hip, at the forearm and at the whole body during therapy.

The effect of hormone replacement therapy and tibolone on lipoprotein (a) concentrations in postmenopausal women: a systematic review and meta-analysis of randomized controlled studies

Panagiotis Anagnostis1, Petros Galanis1, Vasilieia Chatzistergiou1, John Syverson1, Ian Godslanj1, Irene Lambrinoudal2, Mamas Theodorou3 & Dimitrios Goulis1

1Unit of Reproductive Endocrinology, First Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece; 2Center for Health Services Management and Evaluation, Department of Nursing, National and Kapodistrian University of Athens, Athens, Greece; 3National Heart and Lung Institute, Imperial College London, Royal Brompton and Harefield NHS Foundation Trust, London, UK.

Introduction

Data on the effect of hormone replacement therapy (HRT) and tibolone on lipoprotein(a) (Lp(a)), an independent risk factor for cardiovascular disease, are heterogeneous and conflicting. The aim of this study was to investigate the effect of HRT and tibolone on Lp(a) concentrations in post-menopausal women.

Methods/design

METH: Scopus, EMBASE and Cochrane databases were searched (up to February 2016). Two researchers identified randomized controlled studies and extracted data. Potential controversies were resolved by a third reviewer.

Results

In 24 eligible studies, HRT caused a significant reduction in Lp(a) concentrations compared with placebo or no treatment (mean relative difference: −20.35%, 95% CI: −25.33% to −15.37%, P < 0.0001), with significant heterogeneity between studies (I² = 98.5%), but without evidence of publication bias. No significant effect was found for tibolone (n = 7) (mean relative difference: −23.84%, 95% CI: −63.43% to 15.74%, P = 0.238) (I² = 98.7%, but without publication bias).

Oral estrogen caused greater reduction in Lp(a) concentrations than transdermal estrogen (n = 10) (mean relative difference: 37.66%, 95% CI: 16.84% to 58.48%, P < 0.0001), with significant heterogeneity between studies (I² = 99%), but no evidence of publication bias. No difference was observed when continuous was compared with cyclical HRT, conventional with low estrogen dose, and estrogen monotherapy with combination with progestogen. No difference was observed between HRT and tibolone regarding their effect on Lp(a).

Conclusions

HRT significantly decreases Lp(a) concentrations, with oral being more effective than transdermal estradiol. The type of HRT, dose of estrogen and addition of progestogen do not seem to modify the Lp(a)-lowering effect of HRT.

EP1085

CHARGE Syndrome: a rare case of hypogonadotropic hypogonadism

Ana Sofia Osório, Carolina Faria, David Barbosa, Elma Nobre & Maria João Bugalho

Serviço de Endocrinologia, Diabetes e Metabolismo, Hospital de Santa Maria, Centro Hospitalar de Lisboa Norte, Lisboa, Portugal.

Introduction

CHARGE Syndrome (CS) is a rare cause of hypogonadotropic hypogonadism (HH), usually diagnosed in paediatric age when pubertal development is compromised. Herein, we report a case that presented a major criterion and three minor criteria.

Case report

At age ten, the patient was referred to the paediatric endocrinology unit due to phenotypic alterations and psychomotor and cognitive impairment. She had no family history of consanguinity, inherited or genetic disorders. At 8 years of age she was diagnosed with semicircular channels bilateral agenesis with consequent profound bilateral deafness. At physical examination there was a normal stature and weight, facial asymmetry and dysmophria, low ear implantation, cleft palate and dorciosfoecloscios. Genital examination revealed normal morphology and a Tanner 2 stage. Pelvic ultrasonography was consistent with small ovaries and uterus, without evidence of follicular activity. Basal FSH and LH were below the normal range without response to LHHR stimulation. CHARGE syndrome was considered and genetic tests were performed. The karyotype was 46 XX and a nonsense mutation in the CHD7 gene was identified (c.484C>T;p.Q162X). The patient initiated treatment with an estradiol/norgestrel combination at the age of 15 with marked improvement of pubertal development.

Conclusion

CS should be considered in the differential diagnosis of HH particularly in presence of an abnormal phenotype. Mutations in the CHD7 gene cause more than half of all cases of CS and most of the times are new mutations as occurred in the current case. Different malformations may be present but the pattern varies among affected individuals justifying a long term follow up.

Combination of turner syndrome and congenital adrenal hyperplasia: a rare case report

Ivana Ságová1,2, Dušan Pává1, Matej Stančik2, Helena Urbánková1, Juliana Gregová1, Anton Vaniuga1 & Peter Vaniuga1

1Department of Endocrinology, National Institute of Endocrinology and Diabetology, Lubochna, Slovakia; 2Department of Internal Medicine I, University Hospital Martin, Martin, Slovakia; 3Alpha Medical, s.r.o., Lubochna, Slovakia.
Combination of Turner syndrome (TS) and classical congenital adrenal hyperplasia (CAH) is rare worldwide. Incidence of CAH - autosomal recessive disorders characterized by enzyme defect of steroidogenetic pathway, of which 90% occurs in the CYP21A2 gene coding 21-hydroxylase is 1:10000-16000. Incidence of Turner syndrome is 1:2500 worldwide. Phenotypically, females with TS may present with a wide spectrum of clinical features. They may exhibit short stature, virilization, premature ovarian failure and compromised fertility. We present a 57-year-old woman suffering from both 45X0/46XX mosaic mosaic Turner syndrome and salt wasting form of CAH. After birth she was misdiagnosed as a male. She had short stature and ambiguous genitalia – presence of the phallus with perineoscrotal hypospadias and incomplete urogenital opening. Laparoscopy at age of six showed female sex organs. After this examination clitoroplasty and vaginoplasty was done. Karyotyping revealed a 45X0/46XX pattern without sex determining region Y on gene analysis. The presence of virilizing feature at puberty could not explain the diagnosis of Turner syndrome. She had am mounted, marked hirsutism and was of short stature (height 130 cm). Laboratory tests revealed elevated level of 17-hydroxyprogesterone, dehydroepiandrosterone and low cortisol concentrations. Congenital adrenal deficiency was then suspected. With the genomic analysis, CYP 21A2 mutation in IN2G and united deletion/conversion was detected. She was treated with dexamethasone. Fluidrocortisone was added to the treatment, because laboratory tests revealed increased plasma renin concentration. Under a continuous treatment, her state improved.

A rare case of short-term postpartum primary adrenal insufficiency
Myriam Briner1, Christina Gatjens1, Gunther Kaindl2, Martin Lukas Kaufmann2, Nic Zerkerieb & Natalia Rudovich1,3
1Department of Internal Medicine, Spital Bülach, Bülach, Switzerland; 2Department of Obstetrics and Gynaecology, Spital Bülach, Bülach, Switzerland; 3German Institute of Human Nutrition Potsdam-Rehbruecke, Nutheatal, Germany.

Aims Polyglandulare Autoimmune Syndrome (PAS) is a rare disease and the development during pregnancy is seen even less often. PAS Type II presents with autoimmune adrenalitis and thyroiditis. Symptoms of adrenalitis such as hypertension and hyperpigmentation are overlapping with physiological manifestations during pregnancy making the diagnosis difficult.

Clinical presentation
We are reporting the case of a 28-year old prima para prima gravida presenting two weeks postpartum (spontaneous preterm birth at 36 completed weeks of pregnancy) with hypotension, orthostatic presyncopal events and adynamia. Laboratory tests showed a low cortisol level, while adrenocorticotropic hormone (ACTH) was increased. The medical history was significant for chronic lymphocytic thyroiditis with subclinical hyperthyroidism. At presentation PAS type II was suspected. With the genomic analysis, CYP 21A2 mutation in IN2G and united deletion/conversion was detected. She was treated with dexamethasone. Fluidrocortisone was added to the treatment, because laboratory tests revealed increased plasma renin concentration. Under a continuous treatment, her state improved.

Introduction
Congenital adrenal hyperplasia (CAH) comes to adult endocrinologist whether as transition from pediatrician (Case 3) or as still without diagnosis (Case 1, 2, 4). The aim of this work is to describe typical forms of CAH initially successfully treated with dexamethasone therapy.

Case descriptions
Case 1: female, 1972y, presented in 1995y. (23y.) as severe hirsutism and infertility managed by team of gynaecologists. She refused any additional investigations and was severely depressed. Ex tantubinis 0.5mg dexamethasone therapy was followed with pregnancy. Case 2: female, 1960y, presented in 2008y. (18y.) Non-classic CAH. Hirsutism, primary amenorrhoea. Dexamethasone therapy 0.5 mg at night. After 4 month established menstruation, after 18m. became pregnant with healthy male baby born. Case 3: female, 1994y, presented 2012y. (18y.) Classic CAH, salt wasting form. At birth classical low sodium, high potassium. Established therapy with fludrocortisone and hydrocortisone, at night dexamethasone 0.5 mg. Still primary amenorrhoea. On CT severe vaginal stenosis. Case 4: male, 1980y, presented in 2014y. (34y. old), when he was diagnosed for the first time! Classic CAH, simple virilising form and glucocorticoid-remediable aldosteronism, suprarenal hyperplasia on one gland and incidentaloma on the other. Unilateral testicular adrenal rest tumour (TART), azospermia. Therapy hydrocortisone and dexamethasone at night. Soon he normalised aldosterone, ACTH, 17-OH progesterone but lowered testosterone. After 2y. CT of testes confirmed enlargement and the regression of TART.

Discussion
We have described two cases of CAH which solved the problem of femininity (Cases 1 and 2). One treatment confirmed the need for additional surgical treatment of developmental abnormality on external genitalia (Case 3). Finally the problem of TART has been solved without any invasive intervention (Case 4), whether diagnostic or therapeutic, which are not the rare case even in these years.

Hypogonadotropic hypogonadism, functional and transitory
Catarina Roque, Filipa Serra, Francisco Sousa Santos, Cátia Ferrinho, Ricardo Capitão, Carlos Bello & Carlos Vasconcelos
Endocrinology Unit, Hospital de Ega Moniz, C.H.I.O. E.P.E., Lisbon, Portugal.

Functional hypogonadism has been described in association with acute severe medical or surgical illness, subacute recovery and chronic disease. We present a case of transitory hypogonadism manifested during a peri-surgical period. A 42-year-old patient was sent to the endocrinology clinic due to hypotension and a solitary adrenal mass. He was treated with bisoprolol and telmisartan, that he maintains until today. The evaluation favoured normal functional adrenocortical output but during the follow-up new complaints arose. He was diagnosed heart failure NYHA class-I related to aortic valve dysfunction and thoracic aortic aneurysm with surgical indication. He had recently visited the urologist due to complaints of erectile dysfunction and mentioned a normal scrotal US examination and the prescription of a phosphodiesterase inhibitor. These complaints started during the peri-surgical period. He mentioned timely puberty (13 years old) and one daughter but declared reduced libido, reduced spontaneous erections, reduced tumor and reduced need of shavings. He had BMI 21 kg/m², no gynecomastia, normal sense of smell and adult volume testicles. His previous total testosterone (TT) evaluations were within reference range (265 and 310 ng/dl). The new laboratory analyses showed low TT on separate evaluations, 104 and 181 (RI 249–836) ng/dl with inappropriately normal LH 3.12 U/l and FSH 5.18 U/l. Prolactin, IGF1 and ACTH were normal. MRI could not be performed because of the new restrictive pelvic catheter. He was started on monthly testosterone enanathate achieving normal TT levels (267 ng/dl) and remission of clinical complaints. After a period of 5 months, approximately 2 months after the heart surgery the patient felt he had regained shaving frequency and sexual turor, withdrawing both the phosphodiesterase inhibitor and the testosterone substitution. After 5 months of no therapy he revisited the clinic and laboratory tests were performed with the finding of normal TT 295 ng/dl, normal FSH and LH.

A rare case of a 46, XY disorder of sex development diagnosed in an adult patient
Katrin Feller1, Christa Fluck2, Laura Audí3, Mónica Fernández-Cancio3 & Christoph Stettler1
1Department of Diabetology, Endocrinology, Clinical Nutrition and Metabolism, University Hospital of Bern, Bern, Switzerland; 2Department of Pediatrics, Division of Pediatric Endocrinology and Diabetology, University Hospital of Bern, Bern, Switzerland; 3Pediatric Endocrinology Research Unit Vall d’Hebron Institut de Recerca, Universitat Autònoma de Barcelona, Barcelona, Spain.

The defective conversion of testosterone to dihydrotestosterone due to a steroid 5-alpha-reductase 2 deficiency results in a unique form of 46, XY disorder of sexual development (I.SD). Dihydrotestosterone is essential for the embryonic differentiation of the external male genitalia and the prostate. Steroid 5-alpha-reductase 2 deficiency is an autosomal recessive disorder in which genetic males have a predominantly female phenotype with female external genitalia but male internal urogenital tract. We describe the case of an adult patient having migrated from Pakistan to Switzerland in whom a steroid 5-alpha-reductase 2 deficiency was diagnosed at the age of 29. Molecular genetic analysis identified a homozygous point mutation in exon 4 of the 5-alpha-reductase 2 gene, leading to an amino acid change from glutamic acid to lysine. To our knowledge, this is the second case of this mutation in the 5-alpha-reductase 2 gene (SRD5A2) which was first described in 1997 (Anwar et al.).

Age and developmental stage dependent relationship between plasma concentrations of leptin, luteinizing hormone, follicle stimulating hormone, prolactin, testosterone and inhibin B in boys between the age of 1 and 20 years
Afzai Ahmed Naseem1, Mazhar Qayyum1, Maleeha Akram1, Zubaria Iqbal1, Fahim Tahir2, Kiran Afshan1, Sarwat Jahan3 & Syed Shaakeel Raza Rizvi1
1Department of Zoology, Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Rawalpindi/Punjab, Pakistan; 2Reproductive Physiology, Public Health Laboratories Division, National Institute of Health (NIH), Islamabad, Pakistan; 3Department of Animal Sciences, Quaid-i-Azam University, Islamabad, Pakistan.

Leptin is regarded as an essential adipokine for controlling energy homeostasis, caloric intake reduction and increase of caloric expenditure by negative feedback mechanisms via receptors in the hypothalamus. Puberty is said to be triggered by leptin, which signals the hypothalamic that adequate fat reserves are available for initiation of energetically costly process of reproduction. Leptin activates gonadotropin releasing hormone (GnRH) system, which stimulates luteinizing hormone (LH) and follicle stimulating hormone (FSH) secretion from pituitary gonadotropes and subsequent secretion of testosterone (T) from testes. Nevertheless, it is not clear whether leptin has any association with the secretion of FSH, prolactin (PRL) and inhibin B during puberty. This study examined possible associations between plasma concentrations of leptin and LH, FSH, PRL, T, and inhibin B at different ages and developmental stages in boys between 1 and 20 years (27 boys/age group). The concentrations of leptin, LH, FSH, PRL, T and inhibin B were determined using specific ELISA. Data were analyzed using Student’s t-test, ANOVA and Pearson correlation. The concentrations of leptin and LH were positively correlated at 1st, 4th—10th, 12th, 16th, 20th year and at infancy and early puberty. Leptin and FSH concentrations were positively correlated at 1st-3rd, 8th—10th, 12th, 13th, 15th, 16th, 18th, 20th year and at infancy, pre-puberty and early puberty. Leptin and PRL levels were positively correlated at 1st, 3rd, 5th, 6th, 9th, 10th, 12th-14th, 19th year and at infancy, puberty and early puberty. Leptin and T concentrations were positively correlated at 1st, 3rd, 6th, 7th, 9th, 10th, 12th, 13th, 14th, 15th, 16th, 17th, 18th and 19th year and at infancy and early puberty. Leptin and inhibin B levels were positively correlated at 1st, 3rd—8th, 10th, 12th, 15th-19th year and at infancy, early and late puberty. Thus, leptin and LH, FSH, PRL, T and inhibin B are positively correlated only at early puberty.

Molecular mechanisms underlying progesterone-enhanced breast cancer cell proliferation
Hui-Chen Wang
Taipei Medical University, Taipei Taiwan, Taiwan.

Previously, we demonstrated that progesterone (P4) could enhance breast cancer cell migration through increasing formation of the p27-RhoA complex and RhoA activation caused by the cSrc/akt-mediated phosphorylation of p27 at T198. Here, we further examined the effect of P4 on breast cancer cell proliferation. Our results show that P4 (12.5–100 nM) concentration-dependently enhanced proliferation in breast cancer cell lines (T47D and MCF-7). We also found that increases of cytoplasmic p27 localization are responsible for the P4-enhanced breast cancer cell proliferation. Our results demonstrated that P4 activated the cSrc/P13K/AKT signaling pathway, subsequently activating RSK1, which in turn increased phosphorylation of p27 at T198. P13K/AKT activation also increased phosphorylation of p27 at T187. Both p-p27T185 and p-p27T198 caused cytoplasmic mislocation of p27 protein. In addition, P4 induced KIS activation, which in turn increased phosphorylation of nuclear p27 at S10, subsequently causing p-p27S10 translocation from the nucleus to the cytosol. The decreased level of nuclear p27 protein reduced its inhibition in the cyclin-CDK2 system, subsequently increasing phosphorylation of CDK2 at T160 and p27 at T187, hence causing translocation of p-CDK2 from the nucleus to the cytosol. In the cytosol, both p-p27S10 and p-p27T185 were degraded by the ubiquitin-proteasome pathway. Importantly, the P4-enhanced proliferation in breast cancer cell lines was abolished when p27 was knocked down or phosphorylation of 27 was inhibited. Taken together, our results demonstrated that P4 enhanced breast cancer cell proliferation through increasing p27 degradation due to its

Administration of first line anti-tuberculosis drugs induces ovarian and uterine oxidative stress and disruption of endocrine balance in rats

Oluwatosin Adaramoye, Olayinka Adebayo, Omolola Adesanoye, Amos Abolaji & Aderemi Kehinde
University of Ilorin, Ilorin/South West, Nigeria.

The first line anti-tuberculosis (anti-TB) drugs; isoniazid (INH), rifampicin (RIF), ethambutol (EMB) and pyrazinamide (PZA) are effective in the treatment of pulmonary tuberculosis. However, the toxicity of these drugs has been of great concern in clinical settings. This study was designed to evaluate the toxic effects of anti-TB drugs on reproductive system in female rats. Thirty-five female Wistar rats were assigned into five groups of seven animals each. The control received normal saline, while others received INH (5 mg/kg), RIF (10 mg/kg), EMB (15 mg/kg) and PZA (15 mg/kg) via gavage thrice in a week for eight consecutive weeks. Results showed that anti-TB drugs significantly (P < 0.05) reduced both uterine and ovarian weights, and relative weight of uterus relative to controls. In addition, anti-TB drugs increased the activities of alanine aminotransferase (ALT) and levels of total bilirubin. Furthermore, treatment with INH, RIF and PZA significantly (P < 0.05) reduced the levels of luteinizing hormone, estrogen and prolactin. In contrast, there were no significant differences (P > 0.05) in the levels of follicle stimulating hormone and progesterone in rats treated with anti-TB drugs when compared to controls. Moreso, INH, RIF, EMB and PZA caused significant (P < 0.05) increase in the uterine malondialdehyde (MDA) levels by 281, 214, 273 and 190%, respectively, while INH and EMB increased the ovarian MDA levels by 111% and 129%, respectively. All the anti-TB drugs significantly (P < 0.05) decreased the activities of glutathione-S-transferase and uterine glutathione peroxidase, superoxide dismutase and catalase. Histopathological examinations showed severe erosion of uterine mucosa, cellular debris in lumen of uterus and under-developed follicles in ovary of the rats. These results confirmed that the first line anti-TB drugs elicited reproductive toxicity in female rats via mechanism that involved oxidative stress.

Development of hepatic steatosis and inflammation by chronic insulin and hCG exposure in female rats: possible implications in PCOS patients with NAFLD

Ruijun Shao1, Yuehui Zhang1,2, Min Hu1 & Hakan Billig1
1The Sahlgrenska Academy at the University of Gothenburg, Göteborg, Sweden; 2First Affiliated Hospital, Heilongjiang University of Chinese Medicine, Harbin, China.

Accumulating clinical data suggest that women with polycystic ovary syndrome (PCOS) are at high risk for nonalcoholic fatty liver disease (NAFLD). However, it is not clear whether hyperinsulinemia and hyperandrogenism act concomitantly or independently to induce hepatic steatosis and inflammation, and the molecular mechanisms behind the interactions between insulin resistance and hyperandrogenism in the female liver remain largely unexplored. To achieve hyperinsulinemia, insulin resistance, and hyperandrogenism, we treated rats chronically with insulin, human chorionic gonadotropin (hCG), or a combination of insulin and hCG. We showed that the different treatments induced varying degrees of hepatic steatosis in rats. While hCG-treated rats had strongly aggravated hepatic inflammation, insulin+hCG-treated rats exhibited the hallmarks of metabolic alterations and hepatocyte cell damage. Further mechanistic study revealed that the expression of a number of genes (Sreb1p, Sreb2, Gpam, Ppara, Pparg, Lxr) and proteins (AceCS1, p-ACL, IR, p110-PI3K, p-Akt (T308), AS160, p-GSK3, p-JNK, TNFα, and IL-1β) was significantly different in the liver between treatment and control groups. In parallel, we observed that expression of genes in adipose tissues that are related to M1/M2 macrophages was differentially regulated by the different treatments. In summary, our study presents several lines of in vivo evidence that hyperinsulinemia and hyperandrogenism, either alone or in combination with insulin resistance, alter hepatic lipid metabolism, liver and adipose tissue inflammatory responses, and cellular function and that the effects of the different conditions are distinct from each other. By deciphering the metabolic, endocrine, and molecular alterations along with morphological changes, our findings offer a new understanding of how hyperandrogenism itself or combined with insulin resistance contributes to liver damage in women with PCOS.

Association of basal and post-synacthen stimulated 17-hydroxyprogesterone levels with insulin resistance in polycystic ovary syndrome

Eleni Kandarakis,1 Georgios Papadakis,2 Soñia Tsirona,1 Athina Asimakopoulou3, Nikolaos Chustinis,4 Genovefa Chronopoulou5, Georgia Kassi6 & Evangelia Diamanti-Kandarakis7

1Endocrinology Department, Red Cross Hospital, Athens, Greece; 2STEPs Stoffwechselzentrum, Biel/Bienne, Switzerland; 3Department of Endocrinology, Diabetes and Metabolic Diseases, Evangelismos Hospital, Athens, Greece; 43rd Department of Internal Medicine, Endocrinology Unit, Sotiria Hospital, Athens, Greece; 5Biochemical Department, Eureclinic Hospital, Athens, Greece.

Objective

17α-hydroxyprogesterone caproate therapy during pregnancy has been associated with insulin resistance. The aim of this study was to highlight any possible association of 17OHP with insulin resistance in women with PCOS.

Design

Forty-five women with PCOS underwent 75 g OGTT test and short Synachten test with sampling of stimulated 17OHP. Women were divided into two subgroups according to basal 17OHP cut-off level of 0.8 ng/ml.

Results

Women with basal 17OHP more than 0.8 mg/ml had significantly higher glucose levels at 60' min: Glu60: 111.36 ± 22.37 mg/dl vs 133.11 ± 32 mg/dl, P = 0.047, and at 90' min Glu90: 93.50 ± 13 mg/dl vs 113.50 ± 27 mg/dl, P = 0.038 and more often polycystic ovarian morphology in ultrasound compared to those with basal 17OHP levels below 0.8 ng/ml. The mean percentage increase of 17OHP at 60' after Synachten test was 223%. According to this, women were subdivided into two categories depending on whether the intra-individual percentage increase of post-Synachten 17OHP levels was higher or lower than the mean percentage increase. A total of 26 women with hypersresponsiveness of 17OHP at 60' minutes appeared with significant higher insulin resistance and post glucose challenge hyperinsulinemia when compared to 19 women with lower percentage increase of 17OHP, i.e. their mean insulin levels at 30' minutes were: Ins30: 130.9 ± 98.77 U/ml vs 59.3 ± 30.9 U/ml, P = 0.05, at 60' minutes: Ins60: 182.4 ± 124.9 U/ml vs 74.4 ± 32.1 U/ml, P = 0.01, and at 120' minutes: Ins120: 121.6 ± 65.2 U/ml vs 67.1 ± 45.8 U/ml, P = 0.05.

Conclusions

17OHP could possibly be related to the metabolic abnormalities in women with PCOS and this should me monitored especially during pregnancy when insulin resistance increases.

Serum sclerostin and dickkopf-1 levels in polycystic ovary syndrome patients

Ogun Bilem, Yildiz Bilem, Mustafa Ergulo, Hakan Turkon, Yasemin Selkia Akdeniz & Mehmet Aşık

Faculty of Medicine, Canakkale Onsekiz Mart University, Canakkale, Çanakkale, Turkey.

Introduction

Polycystic ovary syndrome (PCOS) is the most common endocrine pathology in premenopausal women and it is a complex syndrome affecting various systems. Numerous studies have been made about how the PCOS effects on bone metabolism, but currently there is no clear information. Wnt pathway plays important role in the regulation of bone metabolism. The sclerostin (Scl) and Dickkopf-1 (DKK1) inhibit this pathway and they has recently become a therapeutic target of osteoporosis. In this study, we aimed to show the Scl and DKK1 levels in women with PCOS.

Methods

This study was conducted in Canakkale Onsekiz Mart University Endocrinology department. Thirty-six women with PCOS and 35 healthy volunteers were examined in this study. Both groups were compared in terms of respect demographic, anthropometric, biochemical and Scl and DKK levels.

Results

PKOS group had less sclerostin levels than control and DKK1 inhibited severely and significantly in PCOS group compared to control group and Wnt and sclerostin were found to be high, although the difference is not statistically significant.

Conclusions

This is the first study on this subject. Çalışmamızda PKOS’u kadınlarda sklerostin ve DKK1 düzeyinin azalması göstermiştir. PKOS’u hastaların KMY ölçümüyle olan çelişkin sonuçlar çıkmıştır. Her ne kadar amenore bu hastalarda kemik kaybına yol açar hiperandrojenemi ve hiperestrojenemi gibi durumlar kemik üzeleme olumu etkiler yaparak bu etkileri engelleyebilir. Phthalates induce ovarian failure through disturbance in folliculogenesis and steroidogenesis

Dinh Nam Tran, Jae Hwan Lee, Changhwan Ahn, Jin Yong An, Seon Young Park & Eui-Bae Jeung

Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Introduction

Phthalates are chemicals used to improve the plasticity of industrial polymers and used in commercial products such as toys, paints, packaging materials, medical devices and personal care items. Phthalates, endocrine disrupting chemicals, have been documented to cause adverse effects to the human health such as breast cancer in female, reduced urogenital distance and changed the expression of steroidogenesis and folliculogenesis. In this study, we investigated the impact of di-(2-ethylhexyl) phthalate (DEHP), di-n-butyl phthalate (DBP), and butyl benzyl phthalate (BBP) on loss of ovarian function through folliculogenesis and steroidogenesis. 4-Vinylcyclohexene diepoxide (VCD), a disruptor of ovarian small pre-antral follicles, was used as a positive control.

Methods

Female Spargue-Dawley rats (8 weeks of age, 180–190 g bodyweight) were administered VCD (80 mg/kg) by intraperitoneal, DEHP (25 mg/kg), BBP (250 mg/kg) and DBP (250 mg/kg) by oral gavage in 0.3 ml of corn oil at LOAEL during 6 weeks. Vaginal smear was collected at 9 a.m every day to check estrus cycle. Blood, pituitary, uterine and ovaries were collected after 24 h final injection.

Results

There was significantly increased in body weight of DEHP groups compared to other groups. Estrus cycle in DEHP and DBP groups showed no difference comparing with vehicle group. However, diestrus phase in VCD and BBP groups drew out compared to vehicle group. The transcriptional levels of
foliculogenesis-related genes (Foxl2, Kitl and Amh) and steroidogenesis-related genes (Star and Cyp11a1) were changed.

Conclusion
Our findings suggest that these phthalates can induce premature ovarian failure by disturbance in foliculogenesis and steroidogenesis and failure in hormone regulation.

**Efficacy comparison of oral rosuvastatin versus oral progesterone and bevacizumab on regression of surgically endometriotic implants in rats**

Ayse Gul Kebapcilar, Tolga Tuyan Ilhan, Duygu Dursunoglu, Kubra Kurt, Süleyman Hilmi İpeki, Süleyman Baldoine, Mustafa Gazi Ucar, Cem Onur Kirac, Levent Kebapcilar & Cetin Celik
Selcuk University, konya, Turkey.

**Aim**
Thirty female Wistar albino rats with surgically endometriotic implants were randomly randomized into three treatment groups: oral rosuvastatin (20 mg/kg per day; oral progesterone group 1; n = 10), oral progesterone (Dienogest group 2; n = 10), and intraperitoneal bevacizumab (2.5 mg/kg of single intraperitoneal injection of bevacizumab; group 3; n = 10) respectively, for 10 day and post-treatment variables were compared.

**Results**
The endometrium foci were measured on days 1 and 10. Rosuvastatin group showed higher reduction for the glandular epithelium and uterine vessels of histopathological scores values than progesterone group (both, P < 0.017; respectively). The median glandular epithelium and uterine vessels and histopathological scores values did not show statistically significant difference among group 1 and group 3 (P > 0.017). No significant different reduction was observed in between the three groups for the myometrium, endometrial stroma, in histopathological scores (P > 0.017). Endometrial thickness and uterine volume values analyzed in all treatment groups. Endometrial thickness values and uterine volume values were more significantly reduced in the oral rosuvastatin medication than oral progesterone group (both, P < 0.017; respectively). Moreover, endometrial thickness and uterine volume values were not different in groups I compared with group 3 (P > 0.017).

**Conclusion**
In conclusion, rosuvastatin and intraperitoneal injection of bevacizumab may cause more significant regression of surgically endometriotic implants in rats than oral progesterone medications.

**The relation between sex hormones and sexual function in women with Turner syndrome**

Ruta Kraskieniene, Briute Zilaitiene, Justina Sematonyte & Rasa Verkauskiene
Lithuanian University of Health Sciences, Kaunas, Lithuania.

**Objectives**
To evaluate sexual function in women with Turner syndrome (TS) in the relation with sex hormones.

**Methods**
The study was undertaken in Lithuanian University of Health Sciences. 65 women with genetically confirmed TS (18–45 years) were enrolled and compared with 65 age-matched healthy controls. Sexual function was evaluated using The Female Sexual Function Index (FSFI). Risk for sexual dysfunction was defined as FSFI score ≤ 26.55. BMI, waist-hip ratio (w.h), concentrations of estradiol (E2), testosterone (T), sex hormone binding globulin (SHBG) were evaluated. TS patients were divided into 3 groups: natural estrogen users (NE2), combined oral contraceptives users (COCs) and untreated (no_E).

38% (n = 27) TS had sexual intercourse and filled out FSFI. 33% (n = 9) of TS and 42% (n = 25) of controls were at risk for sexual dysfunction (P > 0.05). No difference in FSFI score depending on karyotype (classic or mosaicism) was found. No significant relation between age, BMI, w.h, E2, T, SHBG concentrations, duration of E2 use and FSFI domains in TS patients was detected. 41% (n = 11) of TS used NE2, 26% (n = 7) were on COCs and 33% (n = 9) were in no_E group. NE2 or COCs users had higher total FSFI score (25.36 ± 9.10 vs 17.89 ± 13.62; P = 0.008) and reported better lubrication (4.60 ± 1.84; P = 0.031), satisfaction (4.83 ± 1.72 vs 3.20 ± 2.57; P = 0.008), pain (4.67 ± 1.69 vs 2.97 ± 2.46; P = 0.003) during sexual intercourse compared with no_E. NE2 users had better desire (3.81 ± 1.36 vs 2.01 ± 2.15; P = 0.003), lubrication (4.58 ± 1.78 vs 2.35 ± 2.48; P = 0.014), arousal (4.03 ± 1.63 vs 2.37 ± 2.33; P = 0.009), orgasm (3.85 ± 1.86 vs 2.20 ± 2.37; P = 0.05), satisfaction (4.54 ± 1.81 vs 2.71 ± 2.83; P = 0.001), pain (4.90 ± 1.73 vs 2.26 ± 2.46; P = 0.011) and total FSFI score (25.74 ± 9.33 vs 14.09 ± 14.38; P = 0.001) when compared with COCs users.

**Conclusion**
Sexual function in TS did not differ compared with controls. Higher FSFI score was found in F2 users compared with untreated patients and in NE2 users compared with COCs users.

**BMP8 sustains expansion and survival of cumulus cells in vitro**

Fang-Ju Wu & Ching-Wei Luo
National Yang-Ming University, Taipei, Taiwan.

Cumulus cells are a group of specialized granulosa cells that surrounds oocytes and are critical for female fertility. During ovulation, cumulus cells need to be expanded systematically in order to support the maturation, ovulation and fertilization of oocytes, whereas their apoptosis will result in the decline of fertilization rate and pregnancy outcome. However, the molecules as well as their signalings involved in the control of cumulus cell-oocyte complex (COC) expansion are complicated and await more studies. By analyzing several microarray and RNA-seq datasets, we intriguingly noticed that BMP8 expression in cumulus cells was positively correlated to human oocyte maturation and zygote developmental competence. Using a rat superovulation model, we found that BMP8 transcripts were up-regulated by the luteinizing hormone signaling and were abundant in cumulus cells of pre-ovulatory follicles. Furthermore, BMP8 treatment can induce COC expansion as well as the expression of COC expansion-related genes. Hoochst-propidium iodide double staining further revealed that BMP8 can decrease cumulus cell apoptosis in ovulated COCs. BMP8 can induce the phosphorylation of both SMAD1/5/8 and SMAD2/3 in isolated COCs. Signaling dissection by inhibitors further indicated that blockage of SMAD2/3 pathway can impair BMP8-induced COC expansion, whereas blockage of either SMAD1/5/8 pathway or SMAD2/3 pathway dampens the protective role of BMP8 against cumulus cell apoptosis, indicating that both pathways are needed for BMP8-mediated cumulus cell survival. Taken together, our data demonstrated that BMP8 sustains both expansion and survival of cumulus cells through different SMAD downstreams. With these capabilities, BMP8 can contribute to the maintenance of oocyte quality and this may have clinical applications when doing in vitro fertilization.

**Serum concentrations of betatrophin and its association with indirect indices of insulin resistance and beta cell function in women with polycystic ovary syndrome**

Agneszka Adamska1, Agnieszka Lebkowska1, Małgorzata Jaczewicz1, Anna Kcietowska1, Justyna Heyniewicka2, Slawomir Wolczynski2, Maria Gorska1 & Irina Kowalska1
1Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Białystok, Białystok, Poland; 2Department of Reproduction and Gynecological Endocrinology, Medical University of Białystok, Białystok, Poland.

Endocrine Abstracts (2017) Vol 49
The accumulated data underline the role of betatrophin in glucose homeostasis. Polycystic ovary syndrome (PCOS) is characterized by insulin resistance and high risk of developing prediabetes and diabetes. The aim of our study was to investigate the relationship of serum betatrophin concentrations with indirect indices of insulin resistance and insulin secretion in women with PCOS, comparing to the control group. The study group comprised 43 women with PCOS and 16 controls matched for BMI and age. An oral glucose tolerance test (OGTT) with estimation of serum betatrophin concentrations was performed. Insulin resistance was assessed by HOMA-IR and Matsuda index. Insulin secretion was evaluated by HOMA-B. Glucose load resulted in an increase of serum betatrophin concentrations only in the control group (P<0.02). Consequently, serum betatrophin concentrations at 120' of OGTT were lower in women with PCOS in comparison to the control group (P<0.02). We observed a positive relationship between baseline serum betatrophin concentrations and baseline serum insulin concentrations (r=-0.42, P=0.004) in PCOS group. Additionally, correlations between baseline serum betatrophin concentrations and HOMA-IR (r=-0.39, P=0.008), HOMA-B (r=-0.38, P=0.01) and Matsuda index (r=-0.31, P=0.004) were observed in women with PCOS. We found relationship between Δ betatrophin and serum total testosterone concentration in the entire group (r=-0.32, P=0.01). Multiple regression analysis revealed that HOMA-B (β=0.47, P=0.001) was an independent factor connected to serum betatrophin levels in women with PCOS. Serum concentrations of betatrophin is connected with insulin resistance and beta cell function and did not change after glucose load in women with PCOS.

DO: 10.1530/endoabs.49.EPI1104
Conclusion
In COS, FSH alone results in higher oocyte number. However, hMG improves the collection of mature oocytes and embryos and increases implantation rate, although the final increased pregnancy rate is evident only in GnRH antagonist protocol. On the other hand, LH addition leads to higher pregnancy rate. This study supports the concept of a different clinical action of gonadotropins in COS, reflecting previous in vitro data.

May thiol/disulfide homeostasis predict adult PCOS?

Hakan Sevimli,1 Cemile Koca,2 Mahmut Senyurt,3 Ozcan Erel,3

1Regional Training and Research Hospital, Erzurum, Turkey; 2Yildirim Beyazit University Faculty of Medicine, Ankara, Turkey; 3Public Health Laboratory, Erzurum, Turkey.

**Purpose**

The purpose of this study was to evaluate the relation polycystic ovarian syndrome (PCOS) and the thiol/disulfide balance, used as a marker of oxidative stress, by measuring that exchange using a novel technique.

**Material/methods**

Forty nine subjects diagnosed with PCOS and 44 healthy were included in the study. Thiol/disulfide homeostasis concentrations were measured by a newly developed method. After native thiol, total thiol and disulfide levels were determined; measures such as disulfide/native thiol, disulfide/total thiol, and native thiol/total thiol were calculated.

**Results**

Lipid accumulation product (LAP) index (P < 0.001), total testosterone (P < 0.001), insulin (P = 0.003), total cholesterol (P = 0.02), triglyceride (P = 0.004), disulfide (P = 0.007), disulfide/native thiol ratio (P < 0.001) and disulfide/total thiol ratio (P < 0.001) were significantly higher and native thiol (P = 0.01), total thiol (P = 0.04) and native thiol/total thiol ratio (P < 0.001) were significantly lower in patients with PCOS compared to control subjects. Correlation analysis reveals negative correlation of FGS, cycles, WC, LH: FSH ratio and Tg with native thiol and total thiol in cases. Also there was a significant negative correlation between LAP index, BMI and native thiol. DHEA-S had a positive correlation between disulfide. Stepwise logistic regression model showed that significantly high disulfide levels, disulfide/native thiol ratio and disulfide/total thiol ratio in patients with PCOS were found to be independent of age and BMI. Receiver operating characteristic curve analysis showed that areas under the curve for native thiol, total thiol/native thiol ratio and disulfide, disulfide/native thiol ratio and disulfide/total thiol ratio in patients with PCOS were found to be independent of age and BMI. However, studies with larger sample sizes are needed in this area.

**Conclusion**

It can be concluded that oxidative stress is increased in patients with PCOS, can play a pathophysiological role in the development of PCOS and this increase is not associated age and BMI. However, studies with larger sample sizes are needed in this area.

Effects of cigarette smoke extracts on proliferation, migration, and hCG-β protein expression of JEG-3 human placental cancer cells

Cho-Won Kim, Hae-Miru Lee & Kyung-Chul Choi

Department of Obstetrics and Gynaecology, University of Oulu and Oulu University Hospital, Medical Research Center, PEDEGO Research Unit, Oulu, Finland; 3Institute of Clinical Medicine, University of Oulu and Oulu University Hospital, Oulu, Finland; 1Institute of Health Sciences, University of Oulu, Oulu, Finland; 2Institute of Biostatistics, University of Oulu, Oulu, Finland; 4School of Public Health, University of Helsinki; 5Department of Epidemiology and Biostatistics, MRC-PHE Centre for Environment and Health, School of Public Health, Imperial College London, London, UK; 6Public Health Laboratory, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.

Maternal smoking during pregnancy is known to be related to adverse pregnancy results associated with trophoblast proliferation and cell cycle progression. Moreover, many previous studies have shown that cigarette smoke is correlated with human chorionic gonadotropin beta (hCG-β) subunit produced from syncytiotrophoblasts during pregnancy. Thus, we further investigated whether cigarette smoke extract (CSE) affects the cell proliferation, migration and endocrine hormone activity of JEG-3 human placental cancer cells. JEG-3 cell proliferation was significantly reduced by all CSEs in a concentration-dependent manner. Moreover, CSEs decreased proliferating cell nuclear antigen (PCNA) levels in JEG-3 cells in western blot. Increased migration or invasion ability of JEG-3 cells following CSE treatment was also confirmed by a scratch or fibronectin invasion assay in vitro. Additionally, protein levels of E-cadherin as an epithelial marker were down-regulated, while the mesenchymal markers N-cadherin, snail and slug were up-regulated in a time-dependent manner. The metastasis marker, cathepsin D, was also down-regulated by CSE. Finally, CSEs significantly reduced the expression of hCG-β protein in JEG-3 cells. Overall, these results indicate that exposure of placental cells to CSE deregulates the cell cycle by altering the expression of cell cycle-related proteins and stimulates cell metastatic ability by altering EMT markers and cathepsin D expression. CSE exposure may also decrease hCG-β production as an endocrine marker, implying that cigarette smoke has adverse effects during pregnancy. (This research was supported by a grant (14182MDD977) from the Ministry of Food and Drug Safety, Republic of Korea, in 2016.)

Keywords: Cigarette smoke extract, placental cells, cell cycle, metastasis, human chorionic gonadotropin beta subunit

Hyperandrogenism and overweight/obesity, independently and interactively, increase the risk of metabolic syndrome and type 2 diabetes in women – a Prospective, Population-based Cohort Study

Meri-Maija Ollila,1 Kari Kaikkonen,2 Sirkka Kirkinen-Kuukanninen,3,4,5 Katri Puukka,6 Aino Ruokonen,2 Mari Ruokonen,2 Marjo-Riitta Järvelin,3,4,5 Juha Tapunainen,1,6 Steve Franks,7 Terhi Piltonen,1,6 & Laure Morin-Papunen1

1Department of Obstetrics and Gynaecology, University of Oulu and Oulu University Hospital, Medical Research Center, PEDEGO Research Unit, Oulu, Finland; 2Division of Cardiology, Department of Clinical Medicine, Medical Research Center, University of Oulu and Oulu University Hospital, Oulu, Finland; 3Institute of Health Sciences, University of Oulu, Oulu, Finland; 4Unit of General Practice, Oulu, Finland; 5NordLab Oulu, Department of Clinical Chemistry, University of Oulu and Oulu University Hospital, Medical Research Center Oulu, Oulu, Finland; 6Department of Epidemiology and Biostatistics, MRC-PHE Centre for Environment and Health, School of Public Health, Imperial College London, London, UK; 7School of Public Health, Imperial College London, London, UK.

The significance of hyperandrogenism (HA) as a metabolic risk factor in women is controversial. HA can be defined as either clinical (hirsutism) or biochemical (elevated androgen levels). We aimed to investigate whether HA at age 31 associates with metabolic syndrome (MetS), type 2 diabetes mellitus (DM2) or cardiovascular disease (CVD) in women – a Prospective, Population-based Cohort Study (n = 5889 women) blood samples were collected at age 31 in 3127 women and at age 46 in 3280 women. HA was defined as presence of hirsutism, serum testosterone > 2.3 nmol/l (determined by LC-MS/MS) or free-androgen-index (FAI) > 5.6 at age 31. MetS was defined according to IDF criteria. An oral glucose tolerance test (OGTT) was performed at age 46 in 2780 women. Glucose metabolism was defined according to the WHO standards. Diagnosis of DM2 was also verified and completed from the national drug and hospital discharge registers. Regression models were used to study if HA associates with cardiovascular risk factors at age 46. As expected, women with HA at age 31 associated significantly greater BMI at age 46 (27.54 ± 6.2 vs 26.58 ± 5.23 kg/m², P = 0.018), compared to controls. HA at age 31 was significantly associated with MetS (OR = 1.5, 95%CI: 1.1–2.0) and DM2 (OR = 3.1, 95%CI: 1.8–5.2) at age 46. The significance remained in the multivariate regression analysis including BMI at age 31 (for MetS: HA: OR = 1.4, 95%CI: 1.1–2.0; BMI: OR = 4.0, 95%CI: 3.1–5.2; for DM2: HA: OR = 2.7, 95%CI: 1.6–4.6; BMI: OR = 4.1, 95%CI: 2.4–7.0). There were no significant differences in the CIMT between women with HA compared to controls. These results indicate that HA per se may increase the prevalence of MetS and DM2 in a general population. However, BMI seems to have a greater impact on the presence of these metabolic risks, with two-fold higher odds ratios than HA.

**Natural history of the Swyer Syndrome**

Katarzyna Doroszewska1, Tomasz Milewicz1, Marta Kialka1 & Sandra Mrozinska2

1Department of Gynecological Endocrinology UJ CM, Cracow, Poland; 2Department of Metabolic Diseases UJ CM, Cracow, Poland.

We present a case of a eighteen-year-old woman admitted to the Gynecological and Endocrinological Department because of primary amenorrhea. Physical examination showed excessive pubic hair and clitoral hypertrophy. Laboratory tests showed the increased level of follicle-stimulating hormone (FSH) 90 mIU/ml (normal range 3.5–12.5 mIU/ml) and the estradiol level below 10 pmol/l (normal range 46–607 pmol/l). An ultrasound-imaging of the abdomen and pelvis showed the uterus of normal size and shape. Bands of connective tissues were present at the site of ovaries. Because of the clinical presentation a genetic test was done which revealed the XY karyotype. Based on the results the Swyer syndrome was diagnosed. A hormonal substitution therapy was introduced and the surgical removal of the streak gonads was planned because of the risk of malignancy. The patient did not give consent for the operation and did not report for the follow up visits. Three years later, the woman reported back to the Clinic because of acute pain in the lower back, dyspnoea and increasing abdominal circumference. The computer tomography of the minor pelvis showed the presence of lumpy mass in the pelvic cavity. The patient underwent an operation. Intraoperatively numerous metastases were found in the abdomen and pelvis. Radical hysterectomy was performed. Histopathological examination of the streak gonads showed dysgerminoma and gonadalablastoma on the left gonad and dysgerminoma on the right one. After operation the patient was given 4 cycles of chemotherapy. This case presents the natural history of the Swyer syndrome.

**Polycystic ovary syndrome and euthyroid hashimoto's thyroiditis: possible influence of thyroid autoantibodies**

Mustafa Ulta, Ozge Tunar & Ayse Carligog

Regional Training and Research Hospital, Erzurum, Turkey.

Thyroid disorders and polycystic ovary syndrome (PCOS) are two of the most common endocrine disorders in general population. Autoimmune thyroid diseases are common autoimmune disorders that affect about 5% to 20% of women in childbearing age. In this study, we evaluate the comorbidity rate of euthyroid Hashimoto’s Thyroiditis (HT) in PCOS patients and possible influence of thyroid autoantibodies on clinical and laboratory findings of PCOS. This study includes 285 PCOS patients attending to our outpatient Endocrinology Clinic at Erzurum Region Training and Research Hospital. The control group include 32 age and body mass index matched healthy women. In PCOS group 88 of 285 (%30.87) patients have euthyroid Hashimoto’s disease where as in control group 2 of 32 (%6.25) have disease. These findings are statistically significant ($P<0.003$). None of the euthyroid Hashimoto’s patients take l-thyroxine replacement therapy. Anti-TPO and anti-Tg were significantly higher in patients with PCOS ($P<0.000$; $P=0.01$; respectively). Anti-TPO had a significantly positive correlation between PCOS presence ($r=0.119$; $P=0.036$), and clinical indicators of PCOS such as cycle time ($r=0.709$; $P<0.000$), Ferriman-Gallwey score ($r=0.376$; $P=0.001$), DHEAS ($r=0.132$; $P=0.04$), testosterone ($r=0.124$; $P=0.043$), and LH/FSH ($r=0.136$; $P=0.025$). TPO was seen to be an independent risk factor from body mass index, age and TSH in PCO patients. Anti-TPO and anti-Tg were also sensitive and specific in diagnosing PCOS. AUC value of Anti-TPO was 0.843 ($P=0.000$) and Anti-Tg was 0.843 ($P=0.000$). In ROC analysis, TPO ≥4.9 had 99.6% sensitivity and 71% specificity, anti TG ≥18 had 94.8% sensitivity and 75% specificity in predicting PCOS. In our study thyroid autoantibodies were significantly higher in patients with PCOS. We think that thyroid autoantibodies can affect the clinical and laboratory course of PCOS. We have found that the euthyroid HT may be observed at higher rates in PCOS patients, independent of the thyroid function tests.

**Biological activity mediated by sphingosine-1-phosphate receptors in human primary granulosa cells and immortalized granulosa cell line in vitro**

Livio Casarini1,2, Giulia Forinari1, Manuela Simonetti1,3 & Francesco Poti4

1Unit of Endocrinology, Department Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; 2Center for the Genomic Research, University of Modena and Reggio Emilia, Modena, Italy; 3Azienda Ospedaliero-Universitaria di Modena, Modena, Italy; 4Department of Neurosciences, University of Parma, Parma, Italy.

Introduction

Sphingosine-1-phosphate (S1P) is a sphingolipid mediating proliferative signals in human ovarian follicles, acting through five receptors (S1PR1-5). We characterized the effects of S1PR1 and S1PR3 in vitro, as those mostly expressed in human primary granulosa cells (hGLC) and immortalized, tumor-like granulosa cell line (hGL5).

Methods

The S1P-mediated signaling, as well as the activity of S1PR1- and S1PR3-specific agonists (SEW281 and CYM5541, respectively), was evaluated in hGLC and hGL5 cells. Dimethyl-sulfoxide-, cholera toxin- and phorbol-12-myristate-13-acetate (PMA)-treatments served as controls. The kinetics of pERK1/2, pAKT and pCREB activation were evaluated over 2 h by Western blotting, while total cAMP production was measured by ELISA. The downstream cell viability was measured by MTT assay over 72 h. ±FSH. Differences were significant for $P<0.05$ (two-way Anova; n = 2–12).

Results

Dose-response experiments revealed that 0.1 μM S1P, 1.0 nM SEW2871 and 1.0 nM CYM5541 are the most effective concentrations, in terms of pERK1/2 and pAKT activation. In hGLC, pERK1/2 activation occurs within 5-60 min by S1P and, in a lesser extent, within 15-30 min by SEW2871 and CYM5541. In hGL5 cells, SEW2871- and CYM5541-dependent pERK1/2 activation is prolonged until 2 h. We describe for the first time S1P- and, to a lesser extent, SEW2871/CYM5541-mediated pCREB activation in both cell models, occurring in spite of no pAKT and cAMP recruitment. All the agonists increased cell viability in hGL5 cells, an effect reverted in the presence of 50 nM FSH. Only S1P mediated anti-apoptotic effects in hGLC, while the treatment by SEW2871 and CYM5541 impacts negatively cell viability.

Discussion

We found S1PRs-mediated cAMP-independent steroiogenic potential and different signaling kinetics in hGLC and hGL5 cells, revealing opposite effects on the downstream cell signaling, depending on the cell model.

Conclusion

Our study suggests that S1PRs play a role in ovarian follicle growth and oocyte maturation.

**Novel insulin resistance index using C-peptide is reliable predictor of insulin resistance in women with PCOS**

Ivana Bozic-Antic1, Dusan Ilic2, Jelica Biject-Macut3

1Faculty of Medicine, University of Belgrade, Belgrade, Serbia; 2Institute of Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; 3Institute of Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction

Recently, it was suggested that insulin resistance index using C-peptide (CIR) could be a better marker of insulin resistance than homeostasis model assessment (HOMA-IR) in patients with type 2 diabetes mellitus. The aim of this study was to investigate performance of CIR index in PCOS subjects.

Methods

We evaluated 187 PCOS women (PCOS: 25.38 ± 5.62 kg/m²; 26.01 ± 5.16 years) diagnosed using ESHRE/ASRM criteria and 42 healthy women. In follicular phase of menstrual cycle total testosterone, SHBG, lipids, glucose, insulin and C-peptide were determined.

Conclusion

A novel insulin resistance index using C-peptide is a reliable predictor of insulin resistance in women with PCOS.
Novel CIR index (20(fasting C-peptide×fasting plasma glucose)) and HOMA-IR (fasting plasma glucose×fasting insulin/22.5 were calculated in all subjects. Euglycemic hyperinsulinemic clamp (EHC) was performed in PCOS group and the whole body disposal rate (M; mg/kg per min) was determined as the mean of the glucose infusion rate during the last 30 min of EHC. Insulin sensitivity index (M/I) was calculated by dividing M by the steady state plasma insulin level during the last 30 min of EHC. All analyses were adjusted for BMI and age.

Results
In comparison to controls, PCOS had significantly lower CIR index (14.72±2.21 vs 9.65±2.02, respectively; P=0.040) and higher HOMA-IR (2.91±0.36 vs 3.70±0.16, respectively; P=0.047). CIR index strongly correlated with HOMA-IR (r=−0.447, P<0.001), M/I (r=0.461, P<0.001), BMI (r=−0.381, P<0.001) and waist circumference (WCS; r=−0.335, P<0.001). HOMA-IR correlated with M/I (r=−0.404, P<0.001), BMI (r=0.349, P<0.001), WC (r=0.348, P<0.001) and, unlike CIR index, also with SHBG (r=−0.411, P<0.001).

Conclusion
Novel CIR index could be a good surrogate marker of IR in PCOS. The absence of liver clearance of C-peptide is the reason for stronger correlation of CIR index

Omentin-1, a potential link between chronic low grade inflammation, metabolic and reproductive features of polycystic ovary syndrome

Soulmaz Shorakaei1, Sally Abell2, Barbara de Courten1, Gavin Lambert3,4, Danielle Hiam3, Nigel Stepto4,5, Eveline Jona1, Lisa Moran1 & Helena Teede1,2

1Monash Centre for Health Research and Implementation, Monash University, Melbourne, Australia; 2Diabetes and Vascular Medicine Unit, Monash Health, Melbourne, Australia; 3Human Neurotransmitters Laboratory, Baker IDI Heart & Diabetes Institute, Melbourne, Australia; 4Department of Physiology, Monash University, Melbourne, Australia; 5Institute of Sport Exercise and Active Living (ISEAL), Victoria University, Melbourne, Australia.

Background
Polycystic ovary syndrome (PCOS) is associated with features linked to metabolic syndrome including visceral adiposity, dyslipidaemia and impaired glucose homeostasis. Adipose tissue produces adipocytokines which contribute to regulation of insulin sensitivity and reproduction. Omentin-1 is an adipokine with anti-inflammatory and insulin sensitizing roles produced by adipocytes. The exact role of omentin-1 in PCOS remains unclear as studies have reported reduced or unchanged levels in PCOS.

Methods
To determine the relationships between PCOS status, adipocytokines including omentin-1 and etiological features of PCOS we measured serum omentin-1, interleukin-6 (IL-6), high sensitivity CRP (hs-CRP), androgens, SHBG, fasting glucose and insulin levels in an observational study of community recruited PCOS and controls.

Results
49 women with PCOS (age 29.8±5.9 years, BMI: 29.0±5.4 kg/m²) and 25 healthy controls (age 37.6±7.8 years, BMI: 28.9±4.0 kg/m²) were recruited. Homeostatic model assessment for insulin resistance (HOMA-IR) (P=0.006), free androgen index (FAI) (P=0.01) and Ferriman-Galway score (P<0.001) were higher in PCOS. Women with PCOS had lower omentin-1 (median (IQR): 68.76(67.71) vs 112.45(67.42)) (P=0.005) independent of obesity. Omentin-1 correlated significantly with hs-CRP, IL-6, HMW-adiponectin, BMI, percentage of body fat, insulin, low density lipoprotein (LDL), triglycerides and total ovarian volume in women with PCOS. Multiple regression analyses revealed omentin-1 was explained by triglycerides (Beta: −0.171, P=0.03) and total ovarian volume (Beta: −0.009, P=0.025).

Conclusion
Omentin-1 is significantly lower in women with PCOS and correlates significantly with other inflammatory markers, metabolic parameters and total ovarian volume. This finding suggests omentin-1 as a potential link between metabolic and reproductive features of PCOS and chronic low grade inflammation.

Hirsutism in reproductive aged Korean women

Yeon Ah Sung1, Sei Hyun Baik2 & Dong Sun Kim3

1Ewha Womans University School of Medicine, Seoul, Republic of Korea; 2Korea University College of Medicine, Seoul, Republic of Korea; 3Hanyang University College of Medicine, Seoul, Republic of Korea.

Hirsutism, excessiveterminal hair growth in a male-like pattern as a marker of hyperandrogenism, affects 5–10% of reproductive-age women worldwide. The frequency of hirsutism seems to decrease in Asians and the lower cut-off modified hirsutism score is suggested. We performed the study to estimate the frequency, bio-metabolic characteristics, correlates and determinants of hirsutism in reproductive aged Korean women. A total of 2682 female volunteers of reproductive age (15–39 years) were recruited for the genetic study of PCOS. Metenrial history was taken and hirsutism was diagnosed when modified Ferriman-Gallway (mFG) score ≥8 was noted. Anthropometric features, hormones (total testosterone, SHBG, 17OH progesterone, prolactin, and TSH) and metabolic parameters (glucose, insulin and lipids) in blood were measured. The frequency of hirsutism is 133 (4.96%) in a total 2682 subjects. Fifty nine % (1582) of subject had m-FG score of zero; 30.0% (805) had m-FG score between 1 and 4; 6.0% (162) were between 5 and 7. The m-FG values of 25th, 50th, 75th, and 95th percentiles were 0, 0, 2, and 7 respectively. m-FG score significantly correlated to age, waist circumference, serum total and free testosterone, SHBG, postprandial plasma glucose fasting and postprandial plasma insulin, and HOMA-IR. Logistic regression analysis showed younger age, increased fasting insulin and free testosterone levels were associated with mFG score. In conclusion the estimated frequency of hirsutism among reproductive aged Korean women was 4.96%, which is comparable to other races. Hirsutism is associated with fasting plasma insulin, serum free testosterone level and younger age.

Pharmacokinetics and bioavailability of non-polar phytocomponents of Aloe vera gel and their role as an endocrine modulator in lutein induced PCOS rat model

Arpi Dey, Shibeta Vasoya & Laxmipriya Nampoothiri

The Maharaja Sayajirao University of Baroda, Vadodara, Gujarat, India.

Background and aim
Polycystic ovary syndrome (PCOS), the most common endocrine disorder in women of reproductive age with an estimated prevalence of 5–10%, is one of the most common causes of female infertility. The therapeutic options for PCOS are limited. Therefore, traditional knowledge of Ayurveda has been exploited to identify an herbal therapeutic target for PCOS. Pharmacokinetic (PK) studies on bioactive constituents of herbal drugs provide valuable information on bio-transformed metabolites, dosage form, doses and potential herb-drug interactions. Therefore, the aim of the study was to study the pharmacokinetics and bioavailability of the non-polar phytocomponents of Aloe vera gel and their role as an endocrine modulator in PCOS pathology.

Methodology
PCOS was induced in rat using lutein and validated for structural and metabolic characteristics of PCOS. Blood and tissues (ovaries, adrenal, hypothalamus, pituitary, uterus and liver) were collected up to 48 h after the induction of PCOS and the tissue was further incubated in vitro. The incubation medium was replaced every 24 h. Four consecutive cycles were continued in the PCOS group.

Results
PCOS animals demonstrated altered estrus cyclicality, serum testosterone levels and oral glucose tolerance test profile when compared to controls. An increase in the estradiol (P<0.01) and progesterone levels (P<0.05) were observed in the plasma after 24 h. Several phytosterols and their modified oxysterols were identified in the plasma and tissues which could be well-correlated with the functional changes observed in hormone profile.

Conclusion
This study elucidates the bioavailability and functionality of phytosterols/ oxysterols obtained from Aloe vera gel towards management of PCOS. This study will be helpful in identification of a naturally derived drug target and add to its economic viability at national and international level.

**Influence of peroxisome proliferator-activated receptor (PPAR)-γ exon 2 (Pro12Ala) and exon 6 (His447His) and Gly972Arg insulin receptor substrate (IRS)-1 polymorphisms on insulin resistance (IR) and beta cell function in Southern Mediterranean women with polycystic ovary syndrome (PCOS)**

Giuseppina T Russo1, Maria Angela Pappalardo2, Annalisa Giandalia1, Elisabetta L Romeo2, Angela Alibrandi1, Flavia Di Bari1, Roberto Vita1, Domenico Cucinotta1 & Salvatore Benvegna1,2

1Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; 2Centro Polispecialistico Rizzo, Torregrotta, Messina, Italy; 3Department of Economics, University of Messina, Messina, Italy; 4Interdepartmental Program of Molecular and Clinical Endocrinology, and Women’s Endocrine Health, University hospital Policlinico G. Martino, Messina, Italy.

The Pro12Ala and His447His polymorphisms of PPAR-γ, and Gly972Arg polymorphism of IRS-1 have been implicated in insulin resistance (IR) and adiposity. In this study, we investigated the possible influence of these polymorphisms on metabolic features of 53 PCOS women compared with 26 healthy women (controls). All women underwent a clinical, anthropometric and biochemical evaluation, including a 75-g oral glucose tolerance test; insulin secretion and sensitivity indices were calculated. In the two groups, frequencies of PPARγ polymorphisms did not differ from those predicted by the Hardy-Weinberg equilibrium. Instead, the IRS-1 Gly972Arg allele was significantly more frequent in the PCOS group compared to controls. The frequency of different allelic combinations was unequal in the two groups, with IRS1 “exon6+/exon6+” (in 60% of PCOS and 81% of IRS1 “exon2+/exon2+” in 73% of controls. In PCOS women, the IRS-1 Gly972Arg allele was associated with lower E2 levels (P = 0.030), while the PPARγ Pro12Ala allele with lower free-testosterone levels (P = 0.021). No other relationships were noted. When compared with wild-type women, in PCOS group, IR was: 1) trendwise greater in carriers of the variant allele in IRS-1 gene (borderline higher HOMA-IR, insulinogetic and disposition indices); 2) trendwise lower in carriers of the variant PPAR-γ exon6 allele (lower HOMA-IR and higher Matsuda index, lower insulinogetic and disposition indices); 3) lower (P < 0.01) in carriers of the PPAR-γ exon2 variant (lower HOMA-IR values and higher insulinogetic and disposition indices). Furthermore, within the IRS-1*/PPAR-γ-exon2 PCOS women, PPAR-γ exon6− women had higher Matsuda index (P = 0.03) compared with the noncarriers (PPAR-γ-exon6+). Our data support the protective influence of PPAR-γ-exon2 and exon6 variants on IR and beta-cell function, whereas IRS-1 polymorphism is associated with a more unfavorable metabolic profile. However, these associations do not fully explain the high metabolic risk PCOS-associated.

**Hormonal disturbances and adipokines levels in girls with oligomenorrhea**

Violetta Skzyzpulec-Plinta, Agnieszka Droszdol-Cop & Dominika Sajdak Medical University of Silesia in Katowice, Katowice, Poland.

**Aim**

The aim of this study was to evaluate hormonal disturbances and adipokines levels in girls with oligomenorrhea.

**Materials and methods**

The study comprised a group of 46 girls, aged 16–18 years, who were diagnosed with oligomenorrhea, and a control group with 37 healthy girls, aged 16–18 years, with no diagnosed menstrual disorders. In the first stage of the study, all girls had their medical history assessed. Subsequently, anthropometric measurements (height, weight) were measured, severity of hirsutism – according to the Ferriman-Gallwey scale, as compared to the control group. During puberty, global methylation at early infancy and puberty in sons born to women with polycystic ovary syndrome (PCOS) were compared to C-Sons (P < 0.05). There were no significant differences in plasma concentrations of leptin, adiponectin and apelin-36 between the study and control groups.

**Conclusions**

Hormonal disorders such as hyperprolactinemia, hyperandrogenaemia and PCOS are more frequently diagnosed in girls with oligomenorrhea. In girls with oligomenorrhea, elevated levels of leptin and decreased levels of adiponectin may be considered as new biomarkers for insulin resistance and hyperandrogenaemia.

**Global methylation pattern and endocrine-metabolic profile during early infancy and puberty in sons born to women with polycystic ovary syndrome (PCOS)**

Teresa Sir-Petermann1, Nicolas Crisosto1, Barbara Echiburu1, Manuel Maliqueo1, Francisco Perez-Bravo2, Daniel Sandoval1 & Sergio Recabarren1

1Laboratory of Endocrinology and Metabolism, University of Chile, Santiago, Chile; 2Nutrigenomic Laboratory, Department of Nutrition, University of Chile, Santiago, Chile; 3Laboratory of Animal Physiology and Endocrinology, University of Concepcion, Concepcion, Chile.

Prenatal and postnatal environment can regulate gene expression through multiple epigenetic mechanisms, being DNA methylation among the most relevant. Metabolic and reproductive function may be modified by this mechanism. Sons born to women with PCOS show altered markers of metabolic and reproductive function during childhood and adulthood. However, these functions have not been studied during puberty. The aim of the present study was to assess the global methylation pattern and its possible association with anthropometrics, endocrine and metabolic variables in a cohort of early infants and peripubertal boys born to women with PCOS. Global DNA methylation was measured from blood leukocytes, in 21 sons born to control women (C-Sons) and 15 born to women with PCOS (P-Sons) at early infancy (2-3 months old). In addition, 50 P-Sons (12 prepubertal (Tanner I), 28 pubertal (Tanner II-IV) and 10 late pubertal (Tanner V)) and 61 C-Sons (13 prepubertal, 30 pubertal and 18 late pubertal) were studied. Weight, height and waist circumference were determined. A 75-g oral glucose tolerance test with insulin and glucose measurements was performed. HOMA-IR and ISI composite were calculated. In the fasting sample circulating AMH, 17-OH-Progesterone, androstenedione, testosterone, estradiol and lipids were measured. P-Sons showed lower global methylation at early infancy (P = 0.027), whereas at pubertal age a higher global methylation was found (P = 0.035). No differences were observed during pre and late puberty. At early infancy, no differences were observed in anthropometric variables between C-Sons and P-Sons. In prepubertal age, fasting and 120-min glucose were higher in P-Sons compared to C-Sons (P = 0.038 and 0.046, respectively). At puberty, waist circumference and androstenedione levels were higher (P = 0.032 and 0.006, respectively) and cholesterol tended to be higher (P = 0.06) in P-Sons compared to C-Sons. At late puberty, no differences were observed between groups. These results suggest that the methylation pattern can be modified from early infancy to the pubertal age in sons born to PCOS women. During puberty, global methylation increased concomitantly with circulating androstenedione levels and waist circumference suggesting that the endocrine and metabolic milieu may be associated with DNA methylation in these boys.

**Natural history of autoimmune primary ovarian insufficiency progresses through several stages from normal ovary function to clinically overt ovary dysfunction**

Giuseppe Bellastella1, Ofelia Casciano1, MariLucre Barrasso1, Maria Ida Maiorino1, Dario Giugliano1, Katherine Esposito1, Lorenzo Scappaticcio1 & Annamaria De Bellis1

1Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy.

The incidence of hyperprolactinemia in the study group is 32%, while there was no disturbance among any of the girls from the control group. Furthermore, among the group of girls with oligomenorrhea, a significantly greater increase in clinical symptoms of hyperandrogenism was observed – hirsutism, assessed according to the Ferriman-Gallwey scale, as compared to the control group (P = 0.048). Full-blown PCOS was diagnosed in 6.52% of the girls from the study group, whereas none of the patients in the control group met all the criteria for the diagnosis of PCOS (P < 0.05). There were no significant differences in plasma concentrations of leptin, adiponectin and apelin-36 between the study and control groups.

**Conclusions**

Hormonal disorders such as hyperprolactinemia, hyperandrogenaemia and PCOS are more frequently diagnosed in girls with oligomenorrhea. In girls with oligomenorrhea, elevated levels of leptin and decreased levels of adiponectin may be considered as new biomarkers for insulin resistance and hyperandrogenaemia.

Relationship between anabolic hormones and benign lesions in different organs in premenopausal women

Zeynep Nilüfer Tekin1, Berc¸em Ayc¸ic¸ek1 & Tuna Demirbas¸2
1Endocrinology and Metabolic Diseases Unit, Department of Medical, Surgical, Neurological, Metabolic Sciences and Aging, University of Campania ‘L. Vanvitelli’, Naples, Campania, Italy; 2Diabetes Unit, Department of Medical, Surgical, Neurological, Metabolic Sciences and Aging, University of Campania, ‘L. Vanvitelli’, Naples, Campania, Italy.

Objective
We aim to detect co-occurrence of uterine myomas, thyroid nodules and breast lesions in premenopausal women with menstrual disorders and investigate association between these benign tumors with anabolic hormone levels.

Design
Records of 8008 premenopausal women were analyzed who had been admitted to the hospital for routine breast image investigation which was performed by the same radiologist in between 2010 and 2015.

Study and Methods
251 patients who had both Thyroid Ultrasound (US), Pelvic Ultrasound (US) and Breast Imaging Reporting and complain about menstrual disorders in the same year, were extracted from 8008 premenopausal women. All data were obtained from file records and ICD-10 diagnosis code of electronic database of the hospital. For breast examination, Breast Imaging Reporting and Data System (BIRADS) terminology had been used. Troid stimulating hormone (TSH) and Estradiol (E$_2$) levels were recorded for investigate of situation of anabolic hormone levels, which had been taken from premenopausal women at the time of third day of menstrual cycle.

Results
The mean age of the patients at the admission to the hospital was 32±5.7 years. From 251 patients only 9 patients had benign lesions in all three organs, whereas 63 patients had both thyroid nodules and breast lesions and 5 patients had thyroid nodules and uterine myoma, and seven patients had BIRADS 2.3 lesions and uterine myoma, respectively. There was only found a relationship between age and existence of myoma uteri and thyroid nodule. ($P=0.008$, for both). Only TSH levels were found lower in patients with BIRADS 2.3 lesions than with BIRADS 1 ($P=0.017$).

Human chorionic gonadotropin (hCG) is the pregnancy hormone marketed as a drug for assisted reproduction technologies to support follicle-stimulating hormone action. Several hCG formulations are commercially available, differing in source, purification methods and biochemical composition. In this study, we investigated the molecular features and the intracellular signaling mediated by five urinary and recombinant hCGs. The drug comparisons were performed by quantifying the hormones by immunoassay, calibrated against the hCG standard (5th IS; NIBSC 07/364). Immunoreactivity pattern, isoelectric point and oligosaccharide content of hCGs were evaluated by reducing and non-reducing Western blotting, capillary isoelectric-focusing immunoassay and lectin-ELISA, respectively. Functional studies were performed in order to evaluate intracellular and total cAMP, progesterone production, as well as β-arrestin two recruitment by ELISA and BRET, in both human primary granulosa lutein cells (bGLC) and LH/hCG receptor (LH/CGR)-transfected HEK293 cells stimulated by increasing hormone doses. Heterogeneous profiles were found among preparations, revealing hormone-specific molecular weight patterns (20–75 kDa range), isoelectric points (4.0–9.0 pl range) and lectin binding (Two-way ANOVA and Bonferroni post-test; $P<0.05; n=5$). These drug-specific compositions are linked to different potencies on cAMP production (EC$_{50}$ 1.0–400 ng/ml range) and agonism with β-arrestin 2 recruitment (EC$_{50}$ 0.03–2.0 μg/ml) in bGLC and transfected HEK293 cells (Mann-Whitney’s U test; $P<0.05$; $n=3$ or 5). However, the treatment of hGLC with hCGs resulted in similar progesterone production after 24 h of exposure (Mann-Whitney’s U test; P$=0.05$; n=3 or 5). Therefore, although hCG preparations consist of different glycosylated isoforms and mediate drug-specific early signaling, they result in similar downstream steroidogenesis in vitro. Commercial gonadotropins calibration relies on their in vivo activity (Pharmacopea), which can be reached with different mixtures of isoforms with various half-lives and receptor binding activities. Here, we demonstrate that commercial hCG preparations, likely with different assortments of isoforms, exhibit similar steroidogenic activity in vitro, by triggering biased intracellular signaling pathways.

Etiopathogenetical aspects of endocrine infertility

Gulyamova Xiulola & Ibragimova Kamilla
Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.

Urgency
According to WHO the frequency of infertility unions is high amount 25–30% in developed countries. There are following reasons of infertility by women: 1) tubal...
infertility; 2) endocrine infertility—it takes the 2nd place among the reasons of infertility; 3) anomalies of the vagina and uterus; 4) immunological reasons, that are caused by sensitisation of female organism, also there are patients, the reason of infertility of that is not ‘explainable’, when there not obvious violations of reproductive system, it is called ‘unexplained infertility’ – 8–10% and an emotional form of infertility.

Research aim
Studying etiological and pathogenetic mechanisms of infertility’s development by women.

Materials and methods
Retrospective analyses of scientific literature from 2010 to 2016 years.

Results of the research
Endocrine infertility— complex of hormonal disorders, that follow irregular ovulation or its absence. By every 3rd infertile woman the reason is the pathology of endocrine system. These are: 1) unovulation; 2) hypothalamic-pituitary dysfunction; 3) hyperandrogenism of ovarian or adrenal genesis; 4) function disorders of thyroid; 5) estrogen and progesterone deficiency; 6) severe somatic pathology; 7) obesity; 8) resistance ovary syndrome, when there is an insensitivity to the gonadotrophins, that stimulates an ovulation, that is manifested with amenorrhoea; 9) premature menopause in younger women to 35–38 y.o. 10) mutations of sex chromosomes. Abortions and infections, that cause tube-peritoneal forms of infertility among to 50% of all patients with infertility. According to WHO more than 20% of patients with infertility have expressed anatomical changes of fallopian tubes. Obstruction of FT we can see by 11–15% of observing, 30% of cases- endometrioid heterotopia.

Conclusions
For prophylaxis of endocrine infertility: 1) preventing of child infections, chronic tonsillitis, rheumatism; 2) preventing the developing of pathological birth, abortion, inflammations infections of women reproductive system; 3) proper maintenance of pregnancy, judicious use of hormones during the pregnancy.

Prenatal androgen exposure alters gene expression and promoter methylation of two ovarian follicle maturation factors

Marziyeh Salehi Jahromi1,2, Fahimeh Ramezani Tehrani1 & Jennifer W Hill1

1Reproductive Endocrinology Research Center, Research Institute for Endocrine Sciences (RIES), Shahid Beheshti University of Medical Sciences, Tehran, Iran; 2Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences (RIES), Shahid Beheshti University of Medical Sciences, Tehran, Iran; 3Center for Diabetes and Endocrine Research (CeDER), Department of Physiology and Pharmacology, College of Medicine and Life Sciences, University of Toledo, Toledo, Ohio, USA.

Background
Follicles imaturations, as the hallmark of polycystic ovarian syndrome caused by prenatal androgen exposure, is suspected to be efficient through expression changes of related genes. The aim of this study was to evaluate gene expression and promoter methylation of GATA6 and Follistatin (FST), two factors involved in follicle maturation, in adult female rats prenatally exposed to androgen excess compared to SHA and PHA. Pulsatile GnRH therapy seems less efficient in persistent amenorrhea weight-recovered AN (Rec-AN) have evaluated pulsatile GnRH therapy, including small number and under nourished patients. Comparison data on hormonal response of the different causes of HA (weight-recovered AN, primary and secondary HA non-related to eating disorders) is also lacking. Therefore, this study was designed to evaluate hormonal and clinical responses to GnRH pulsatile treatment in three groups of HA patients: weight-recovered anorexia nervosa patients (Rec-AN) with persistent functional hypothalamic amenorrhea (HA), secondary and primary HA.

Patients and method
This retrospective, observational ambulatory study included 41 females: 15 secondary HA without any eating disorders patients (SHA), seven primary HA patients (PHA), and 19 Rec-AN (BMI > 18.5 kg/m² without menses recovery), who underwent GnRH pulsatile therapy. Baseline Estradiol (E), LH and Progesterone plasma level and their changes during induction cycles were evaluated. Ovulation, follicular recruitment and pregnancies rate were also studied.

Results
Rec-AN displayed higher basal E and LH plasma levels after GnRH injection compared to SHA and to PHA. WE observed higher E and LH levels during induction cycles in Rec-AN compared to SHA and PHA. PHA displayed the lowest hormonal plasma levels. Follicular recruitment was higher in Rec-AN. Ovulation rate was higher in Rec-AN and SHA compared to PHA.

Conclusions
This study showed increased gonadal status and higher Estradiol response to pulsatile GnRH therapy in persistent amenorrheic weight-recovered AN compared to SHA and PHA. Pulsatile GnRH therapy seems less efficient in primary hypothalamic amenorrhea.

Relationship between steroid hormones and metabolic profile in women with polycystic ovary syndrome

Zora Lazárová2, Jana Figurová2, Simona Ujházi1, Jana Mašlanková1, Silvia Toporcerová1 & Ivica Lazárová1

1Medical Faculty, Kosice, Slovakia; 2University Hospital, Kosice, Slovakia.

Background
There is evidence that polycystic ovary syndrome (PCOS) is commonly associated with higher cardiometabolic risk. Aim of the study was to compare various sex steroids in PCOS women with overweight or obesity (BMI ≥ 27) and those with lower BMI. Second aim of the study was to determine the relationship of various sexual setroids to cardiovascular risk in PCOS women.
Conculsion
We conclude that PCOS women with marked overweight or obesity have significantly predicted HOMA IR, whereas FT predicted HDL-cholesterol and BMI.

Introduction
Hirsutism affects 5–8% of the whole female population. In most patients, hirsutism is associated with hyperandrogenemia and the most common cause of androgen excess is polycystic ovary syndrome; however, the clinical presentation of non-classical congenital adrenal hyperplasia(NCAH) in females is often indistinguishable from other hyperandrogenic disorders because of common clinical signs with hirsutism and poly cystic ovary syndrome(PCOS).

Objective
The aim of the study is to evaluate the prevalence of NCAH in women presenting with hirsutism and distinguish the underlying causes.

Subject and Method
122 women admitted to the Endocrinology Clinic at Erciyes University Hospital with hirsutism enrolled the study voluntarily between January 2013 and December 2014. All protein encoding exons and exon-intron boundaries of CYP21A2, CYP11B1, HSD3B2 and CYP21A2 promoter changes determined by direct gene sequencing from genomic DNA isolated from peripheral blood leukocytes.

Results
Detailed clinical, hormonal and DNA sequencing analyses of the volunteers have resulted in 91 (74.6%) PCOS, 12 (9.8%) IHA, 14 (11.4%) IH and 5 (4.1%) NCAH. All NCAH were steroid 21-hydroxylase deficient and there was neither 11B-hydroxylase nor 3-beta-hydroxysteroid dehydrogenase deficient NCAH. Sequencing analyses revealed 5 novel mutations; A99V (c.266 C>T), M187I (c.571 G>A) and G491S (c.1471 G>A) on CYP21A2 and V188I (c.562 G>A) and G87A (c.260 G>C) on CYP11B1 gene in homozygous and heterozygous states. Conclusion
NCAH prevalence in Turkish woman with hirsutism found higher compare to similar studies. It might be because of not only doing sequencing analyses of CYP21A2 but also promoter region since 3 of them have promoter changes in addition to protein coding. However, the study confirmed that promoter region of the CYP21A2 should be sequenced as well for true genetic diagnosis and genetic counselling.

Secondary amenorrhea after bone marrow transplantation and adjuvant chemotherapy misdiagnosed as disorder of sex development: a case report
Mouna Elieuch, Mouna Ammar, Faten Hadj Kacem, Douna Ghorbel, Nabila Rekik, Nadja Charfi, Malhi Kalliloum, Mouna Mnif & Mohamed Abid
Department of Endocrinology and Diabetes Hedi Chaker, Sfax, Tunisia.

Introduction
Disorders of sex development (DSD) is a congenital condition in which the development of chromosomal, gonadal or genital sex is atypical. A female appearance patient with secondary amenorrhea and 46 XY karyotype seems to be solid evidences to diagnose Y-chromosome-related DSD diseases, while it is not necessarily the accurate diagnosis. We here report a case of a 16- year-old girl with secondary amenorrhea and 46 XY karyotype after bone marrow transplantation (BMT) and adjuvant chemotherapy misdiagnosed as DSD.

Case report
A 16-year-old lady who gets her first period at age 13, was referred with a 3 years history of secondary amenorrhea. The patient presented female appearance. She had normal female genitalia and she was at Tanner stage 3. Her medical history included BMT and chemotherapy because of acute leukaemia (AL) when she was 13 years old. So far there is no sign of AL recurrence. Laboratory examination showed a 46 XY karyotype, elevated follicle stimulating hormone and luteinizing hormone, low estrogen, and normal prolactin. Perineal and pelvic ultrasound scans showed developed uterus and vagina, and two small ovaries with no follicular activity. Furthermore, we found that she received BMT from her brother and adjuvant chemotherapy 3 years ago. Her karyotype changed from normal female to a karyotype of donor (her brother) origin after BMT. Adjuvant chemotherapy for AL may impair her ovarian function and finally bring about primary ovarian insufficiency.

Conclusion
The present case serves as a reminder that a correct diagnosis depends on the comprehensive collection of present and past medical history, complete physical examination, and careful evaluation of related adjuvant tests.

Effects of photoperiod on estrous cycle in the Mongolian gerbil (Meriones unguiculatus)
Najeli Ortega1, Marcela Arteaga2 & Pilar Duran1
1Universidad Nacional Autonoma de Mexico, Mexico City, Mexico; 2Universidad Autonoma Metropolitana, Mexico City, Mexico.

Gerbil (Meriones unguiculatus) a non traditional laboratory model with reproductive state influenced by photoperiod, was used to analyze those photoperiodic mechanisms involving reproductive regulation. The 14:10 photoperiod has been widely used for reproductive research since 1950 (Everett). As is well known gerbils locomotor activity cycle has been reported to be crepuscular and reproductive cycle presents two annual peaks. As for the estrous cycle (EC), it has been analyzed mainly under 12hr:12hr light (L:dark(D) photoperiod, and reported as mostly irregular. In this research, female gerbils were exposed to 8:16, 12:12, 14:16 and 16:18 LD conditions. The EC were monitored by cytology via vaginal smears every four hours (ZT) for 3 consecutive cycles, where ZT2 was the first (ZT0 was the light onset). Under the 14:10 photoperiod, the EC was the most stable. Cycles lengthen in between to five and four days and stable phase duration. When the other photoperiods were analyzed the EC showed not only less stability (3-9 days) but also variability in the phase duration, i.e. diestrus increased its duration under 8:16 and12:12 LD, meanwhile at 16:8 photoperiod diestru and estrus, showed a significant increase when compared with 14:10 LD. In a period of 15 days an average of 2 cycles on 16:8, 12:12 and 8:16 and 3 EC for 14:10 were presented. Proestrus and metaestrus did not show a significative variance under any condition. A shift in the time of the shift in the time of the estrous phase does not show a significative variance under any condition. The regulation of LHCGR-dependent signaling is linked to circadian gene expression

Lisa Giloli1, Marco Marino1,2, Manuela Simoni1,2 & Livio Casarini1,2
1Unit of Endocrinology, Department Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; 2Center for Genomic Research, University of Modena and Reggio Emilia, Modena, Italy; 3Azienda Ospedaliero-Universitaria, Modena, Italy.

Introduction

Reproduction exhibit a regular cyclicity and is regulated by complex interactions between circadian signals, gonadotropins and sex steroid hormones. Peripheral circadian rhythm is generated upon cyclic transcription of clock genes expressed in several cells, e.g. granulosa cells in the ovary. Here we investigated whether cyclic intracellular events occurring in response to gonadotropins are linked to expression of clock genes.

Methods

Primary human granulosa cells (hGLC), naturally expressing luteinizing hormone (LH)/chorionic gonadotropin (hCG) receptor (LHCGR), were maintained under continuous exposure to LH/hCG over 24 h, and the expression of clock genes (PER1, PER2, ARNTL, CLOCK), gonadotropin receptors (LHCGR and LHCGR-exon 6A variants, FSHR) and genes regulating steroidogenesis (STARD1, CYP19A1, etc.) was analysed by real-time PCR. Cyclicity of cAMP production, G proteins and β-arrestins and ERK1/2 phosphorylation were evaluated by ELISA, Western blotting and immunofluorescence.

Results

Treatments by gonadotropins de-synchronize CLOCK and ARNTL gene expression, as well as LHCGR mRNA isoforms, STARD1 and CYP19A1 gene expression (two-way Anova; P < 0.05; n = 3). Immunoassays revealed a 4-5 h-rhythmic, up- and down-regulation of Gs protein and β-arrestin1/2, as well as G protein coupling/uncoupling to LHCGR upon gonadotropin treatment. 17h-treatment is linked to rounded shape of the cells and intracytoplasmic vacuoles. LHCGR internalization and translocation of Gs protein to cytoplasm. These gonadotropins-induced changes are accompanied by 3-5 h-oscillatory intracellular cAMP production over 24 h, in spite of LHCGR internalization.

Discussion

We found a link between circadian rhythm, LHCGR up-/down-regulation and interaction with Gs protein and β-arrestin1/2, resulting in the modulation of cAMP-dependent signalling.

Conclusions

These data suggest that the kinetics of LHCGR activation and downstream events are influenced by circadian rhythm, which modulates the cell response to gonadotropins and secondary waves of cell signalling activation.

High dose metformin effect on weightloss, androgen levels and thyroid function in obese hypothyroid patients with PCOS

Aurelian-Emil Ranetti1,2 & Anca-Pati Cucu1
1Dr. Carol Davila“ Central University Emergency Military Hospital, Bucharest, Romania; 2Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Objective

To evaluate the effects of metformin use on weight loss, improvement of ovarian and thyroid function in obese women with polycystic ovarian syndrome.

Material and Methods

30 obese (BMI 30-34.99 kg/m²) hypothyroid (TSH 6-10 mUI/ml) women of age 25-35 years old were included. The patients received appropriate levothyroxine treatment according to TSH levels and body weight. A number of 15 patients added metformin gradually increased from a starting dose of 500 mg/day to a final dose of 3000 mg/day over a period of 6 months. Baseline levels, 3 months and 6 months levels of TSH, FT4, T3, AMH, LH/FSH ratio, testosterone, along with BMI and ultrasound ovarian volume and antral follicle count were determined. No adverse events that might have led to discontinuation of the treatment were recorded. Mild nausea was registered in 8 patients after 2 weeks of treatment with 3000 mg/day of metformin, respectively softer stools (but no diarrhoea) in 5 patients in the first week of treatment (500 mg/day), but the symptoms relieved with disappearing within the mentioned time frame.

Results

BMI levels decreased significantly in the first 3 months in metformin group (32.5 ± 1.65 kg/m² vs. 28.4 ± 1.95 kg/m²). BMI variation in the non-met-group was smaller. BMI levels have reached a plateau after 3 months of metformin treatment. TSH levels decreased (7.2 ± 7.1 mUI/ml vs. 4.8 ± 1.7 mUI/ml) significantly in the metformin group, compared to a smaller decrease in the non-met-formin group (5.6 ± 2.9). Significant decrease was registered for the LH/FSH ratio (5.10 ± 0.9 vs. 2.1 ± 0.45), AMH (9.80 ± 1.6 vs. 7.9 ± 1.2 ng/ml) and testosterone levels; antral follicle count and ovarian volume improved in met-group (in a similar fashion to the gross ultrasound appearance), while in non-met group, the 3 and 6 months values were similar to baseline.

Conclusion

Metformin treatment administered in high doses (3000 mg/day) on a 6 months period was useful for weight loss, improvement of ovarian function and decrease of androgen levels in obese PCOS patients with hypothyroidism. It also improved supplementary the thyroid function parameters. AMH can be used a prognostic marker for metformin response in PCOS obese patients with thyroid dysfunction, especially if (transvaginal) ultrasound scanning is not available.

DOE: 10.1530/endoobs.49.EP1132

The efficiency of metformin in polycystic ovarian syndrome is not necessarily attributable to the improvement of insulin resistance

Zsuzsanna Szanto & Adelina Micheu
University of Medicine and Pharmacy, Targu Mures, Romania.

Insulin resistance has a pivotal role in the pathogenesis of polycystic ovarian syndrome (PCOS), thus insulin sensitizer therapy is beneficial. Purpose. Our purpose was to study the effectiveness of metformin in PCOS women, including those without insulin resistance. Materials and methods. This study was conducted on 24 patients (12 obese or overweight and 12 lean women), aged 21–31 years, diagnosed and treated with PCOS at the Clinical Department of Endocrinology Targu-Mureș, during January 2013–March 2015. All patients received metformin therapy, including those without insulin resistance.
Results
Menstrual cycle disturbances (anovulation, bradi-oligomenorrhea) before metformin therapy appeared in 91.6% of the obese or overweight women, and 83.3% of the lean women (21 cases from the 24). In 15 cases insulin level, glycaemia were measured, and HOMA-IR calculated. Mean insulin level was 13.06 ± 14.53 μIU/ml in the obese group, and 6.82 ± 9.22 μIU/ml in the lean group, and the corresponding mean HOMA-IR was 4.23 ± 3.42 vs. 1.29 ± 0.43. Among the 21 women (11 obese and 10 lean) with menstrual disturbance before metformin therapy these disturbances improved or pregnancy occurred in 11 cases (5 obese and 6 lean) during metformin treatment alone, which means a significant improvement (P = 0.0085, RR = 3.16, 95% CI = 1.12–8.87). During metformin treatment alone, 14 women from the 24 presented normal menstrual cycle, normalized progesterone level or pregnancy occurrence (P = 0.002, RR = 3.83, 95% CI = 1.33–11.03). Conclusion. Metformin therapy might resolve menstrual cycle disturbances not only in insulin resistant obese PCOS women, but also in those with normal weight and/or without insulin resistance.

Serum Vitamin D status in women with the polycystic ovary syndrome Justyna Kuchaczowska-Plaska1, Andrzej Milewicz1, Renato Pasquali1, Agnieszka Lenarcik-Kabzda1, Łukasz Lazczenski1, Felicja Lwow2, Diana Jedrzejuk1 & Marek Bolanowski1

1Department of Endocrinology, Diabetology and Isotope Therapy, Wroclaw Medical University, Wroclaw, Poland; 2Department of Medical and Surgical Sciences, Division of Endocrinology, University of Bologna, Bologna, Italy; 3Department of Health Promotion, University School of Physical Education, Wroclaw, Poland.

Objective
To measure the levels of 25-hydroxyvitamin D (25(OH)D) and vitamin D binding protein (VDBP) and assess their relationships with metabolic features in patients with the polycystic ovary syndrome (PCOS).

Methods
267 women, aged 20–35 years (24.7 ± 4.9): 167 with PCOS, 100 healthy women as a control group were studied. Study groups were divided according to body mass index (BMI). Biochemical and hormonal parameters, 25(OH)D, VDBP were measured. Free and bioavailable 25(OH)D were calculated using the mathematical equations. The percentage of body fat and visceral fat deposit were assessed by DXA.

Results
In the normal weight control group total, free and bioavailable 25(OH)D were significantly (P < 0.001 for all) higher than in the overweight/obese counterpart. In women with PCOS both total 25(OH)D (P < 0.001), and VDBP (P < 0.001) were lower in the overweight/obese subgroups than in the normal weight one. VDBP was negatively correlated with fasting insulin, positively with SHBG in control group. In PCOS group, VDBP was negatively correlated with abdominal fat deposit, BMI, fasting glucose and insulin and positively with HDL and SHBG.

Conclusions
Despite lower total 25(OH)D in obese PCOS women, all women with PCOS (lean and obese) had comparable free and bioavailable 25(OH)D which might be a result of concomitantly lowered serum VDBP levels in obese PCOS women. VDBP might play important role in the regulation of availability of active fractions of 25(OH)D in PCOS women. VDBP is strongly associated with cardiovascular risk factors such as BMI, waist circumference, visceral fat, fasting insulin in women with PCOS.

Oxidative status imbalance in patients with polycystic ovary syndrome Alina Crenguta Nicolae1, Cristina Manuela Dragoi2, Andreia Leptija Arsene1, Nicoleta Petruta Burlacu1, Crina Filisan1, Alice Albu1,2 & Carmen Gabriela Barbu1,2

1University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; 2Elias Hospital, Bucharest, Romania.

Polycystic ovary syndrome (PCOS) is one of the most frequently encountered endocrine pathologies in women of reproductive age, being regarded as a chronic systemic disease instead of the simple local one. It is frequently associated with insulin resistance, hyperandrogenemia and chronic inflammation. PCOS reunites multiple and diversified pathological combinations like: ovulatory functional disorders directly impacting on the reproductive system, carbohydrate and lipid metabolism disorders which can be explained at least partially through an increased oxidative stress. Oxidative stress occurs due to an imbalance between the generation of reactive oxygen species (ROS) and the antioxidant defense systems. In women, oxidative stress may be a major cause of infertility. In this clinical study, comprising 55 PCOS patients and age-matched healthy subjects, we aimed to assess the relationship among different metabolic risk factors, such as triglycerides, cholesterol and glycaemia, and the reactive oxygen species levels in patients diagnosed with polycystic ovary syndrome. For an accurate determination of the biochemical markers, diagnostic kits (DiaLab, Austria) have been used, whereas for the determination of the reactive oxygen species (ROS) concentration, the chemiluminiscent method was chosen. The triglycerides, glycaemia and cholesterol levels were significantly higher in the group of patients compared with the control group (P < 0.05), suggesting a considerable imbalance in patients with polycystic ovary. The serum concentration of the reactive oxygen species (ROS) represents a marker of the global oxidative stress. The experimental results obtained following the assessment of the ROS concentration revealed a significantly higher value in the patient group with polycystic ovary as compared to the control group, which translates into an enhanced oxidative stress in patients diagnosed with polycystic ovary syndrome. Correcting oxidative stress with antioxidants along with monitoring the antioxidant status could have a beneficial effect on oxidative stress induced insulin resistance and hyperandrogenism in the PCOS diagnosed women.

Utility of oral glucose tolerance test (OGTT) in patients with polycystic ovary syndrome (PCOS)
Oana Alexandra Pete1, Ivona Gheorghe1, Irina Nicolaescu1, Dragos Albu2,3 & Alice Albu1,2

1Elias Hospital, Endocrinology and Diabetes Department, Bucharest, Romania; 2Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 3Medlife, Maternal Fetal Medicine and Human Reproduction, Bucharest, Romania.

Background
PCOS patients associate an increased risk of glucose metabolism abnormalities. Although Hb AIC was suggested as a good diagnostic test for prediabetes/diabetes, in PCOS patients its diagnostic value could be inferior to OGTT as previously suggested. Aim of the study was to evaluate which are the clinical and paraclinical parameters associated with impaired glucose tolerance (IGT) in order to identify the profile of the patients that will benefit from OGTT.

Material and methods
449 patients (mean age years, mean body mass index (BMI) kg/m²) diagnosed with PCOS based on Rotterdam criteria evaluated with OGTT were retrospectively selected from our PCOS database.

Results
From the 449 patients included in the study 23 (5.1%) had impaired fasting glycemic (IFG) and 28 (6.2%) IGT. Patients with prediabetes (IGT and IFG) were older, had higher BML waist circumference (WC), insulinemia (fasting and 2 h), HOMA-IR in comparison to patients with normal glucose. Patients with IFG were not different from those with IGT with respect to age, clinical and biochemical hyperandrogenism, adiposity, HOMA-IR, fasting insulinemia and metabolic parameters, except the 2 h insulinemia and serum FSH level which were higher and lower respectively in patients with IGT (P < 0.05).

Conclusion
Our patients with IGT and IFG were similar in terms of clinical and paraclinical baseline parameters, making impossible their identification without an OGTT.

Diagnostic performance of non-invasive markers for the presence of nonalcoholic fatty liver disease in premenopausal women with and without polycystic ovary syndrome
Evangelia Vissiloutou1, Sophia Loforianni2, Dimitra-Argyro Vassiliadi3, Dimitrios Ioannidis2, Stavroula Psichou1, Maria Mizantzi1 & Andromachi Vryonidou
1Red Cross Hospital, Athens, Greece; 2Amalia Fleming General Hospital, Athens, Greece; 3Evangelismos’ Hospital, Athens, Greece.

Introduction
Several markers based on anthropometric and biochemical parameters like fatty liver index (FLI), lipid accumulation product (LAP) index and visceral adiposity index (VAI), have been proposed for the detection of nonalcoholic fatty liver disease (NAFLD).

Objective
To evaluate the diagnostic performance of FLI, LAP and VAI as markers of NAFLD in premenopausal women with and without polycystic ovary syndrome (PCOS), assessed for hepatic steatosis (HS) by ultrasonography.

Design
Prospective, cross-sectional study.

Patients and methods
Anthropometric measurements, biochemical testing and abdominal ultrasonography after excluding causes of secondary liver disease were performed in 145 premenopausal women with PCOS (Rotterdam criteria) and 145 BMI-matched healthy controls. The three markers VAI, FLI and LAP were calculated and their diagnostic performance for predicting HS was evaluated with receiver operating characteristic (ROC) analysis.

Results
HS by ultrasonography was detected in 132/290 (45.5%) women, while the prevalence of HS was increased in PCOS women compared to controls ([78/145 (54%) vs 54/145 (37%); P<0.01]; FLI, LAP and VAI values were higher in HS (+) compared to HS (−) women [68.7±26.7 vs 26.5±24.8, P<0.001, 61.1±39.3 vs 23.7±15.2, P<0.001; 2.4±1.8 vs 1.2±0.6, P<0.001, respectively] as well as in PCOS women compared to controls. The area under the curve (AUROC) for FLI, LAP and VAI were 0.87±0.02, 0.84±0.02 and 0.77±0.03, respectively, in the whole group of women. When AUROCs of the three indices were calculated separately for PCOS women and controls, no statistical differences were observed.

Conclusions
FLI, LAP and VAI can detect NAFLD in premenopausal women with a similar diagnostic performance. The presence of PCOS has no effect on the diagnostic performance of these indices.

Complementary effect of Vitamin D supplementation and lifestyle modification on anthropometric and metabolic parameters in young polycystic ovary syndrome women with Vitamin D deficiency: a 3-month prospective interventional study
Ramesh Jayanthy1 & Prasanna Belgundi2
1Sai’s Institute of Endocrinology, Hyderabad and Visakhapatnam, India; 2Osmania Medical College, Hyderabad, India.

Background
PCOS women usually have metabolic disturbances particularly insulin resistance. Previous studies suggest that vitamin D deficiency may contribute to the development of insulin resistance. Our aim is to study the effect of vitamin D supplementation on clinical and biochemical parameters in vitamin D deficient PCOS women.

Methods
At baseline, 50 PCOS women were enrolled (37 vitamin D deficiency and 13 vitamin D sufficiency). Thirty-seven PCOS women on LSM (low-calorie diet 1000-1200 kcal/d and aerobic exercise walking 3.2 km/d, 5 days/wk) received 60 000 IU cholecalciferol weekly for 8 weeks followed by once a month. Clinical, anthropometric and biochemical parameters were performed at baseline and after 12 weeks.

Results
Thirty PCOS women completed the study. 25(OH)D levels significantly increased from 7.55±4.10 at baseline to 34.16±4.14 ng/ml at 3 months. Following vitamin D supplementation for 3 months, significant improvement of BMI and metabolic parameters like FPG, 2 hr glucose, HOMA IR, HOMA B, TG levels and TC was observed in women who followed LSM. However, there was no change in serum testosterone 11/30 patients in the supplementation group who did not comply with LSM also showed significant decrease in FPG, 2 hr PG, and HOMA IR.

Conclusion
Vitamin D supplementation has beneficial effect on insulin resistance and metabolic parameters in vitamin D deficient PCOS women. Both vitamin D supplementation and LSM have complementary effects in improving BMI and HOMA indices, glucose and lipid metabolism in the setting of PCOS with vitamin D deficiency, suggesting a role of vitamin D in the management of PCOS.

Epigenetics of female hypogonadotropic hypogonadism: analysis of mRNA expression of engaged in HH genes
Anna Loktionova1, Irena Ilovayskaya1, Natela Eneva2, Karina Khusniyagova2, Lidia Nefedova2, Alexander Kim2 & Alexander Dreval3
1M.F. Vladimirsky Moscow Regional Research and Clinical Institute, Moscow, Russia; 2Lomonosov Moscow State University, Moscow, Russia.

Hypogonadotropic hypogonadism is a syndrome which may be manifested clinically by low sex steroids because of low (or inappropriately normal) gonadotropins. To date, more than 30 genes were reported as possible reason for this condition, but genetic basis is still unknown for ~60% of HH cases. Due to this fact we decided to analyze mRNA expression of several HH-related genes which can be found in leukocytes of peripheral blood: GNRHR, GNRH1 (which are necessary for adequate biological effect of GnRH); PROK2 and CHD7 (which are responsible for the migration of GnRH neurons), WDR11 and DUSP6 (which are involved in normal sexual development). A quantitative determination of mRNA expression of these genes were completed in the fresh peripheral blood sample by PCR in real time.

Examined patients
Ten women with hypogonadotropic hypogonadism (age from 18 to 53 y.o.); 4 of them suffer from amenorrhea I and 6 – amenorrhea II. Reasons of amenorrhea II were: stress, excessive exercises, rapid body weight loss, past use of oral contraceptives. The control group: 19 healthy women; age from 19 to 37 y.o.; with regular ovulatory menstrual cycle, some of them have children.

Results
mRNA expression of examined genes differed from normal patterns in each case of hypogonadotropic hypogonadism. Changes in GNRHR, GNRH1 and DUSP6 mRNA expression were found in most of cases. However variations of mRNA expression were multidirectional in each case and there was no similarity among expression profiles of patients according to anamnestic factors; but some affinities were found among patients who suffer from primary amenorrhea. According to our preliminary results, in women with hypogonadotropic hypogonadism the functional activity damage of ‘reproductive-responsible’ genes could be found in each case. Probably mRNA expression measuring could be a perspective method for proving hypothalamo-pituitary level of reproductive disorders and may help to determine which genes should be tested for DNA impairment.

How far is possible to make a diagnosis of infertility
Daniela Dias, Joana Simões-Pereira, Sara Donato & Conceição Pereira
Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal.

Introduction
Chemotherapy may be an important cause of primary infertility, especially in girls submitted to this therapy at very young ages.
Clinical case
A 20-year-old female was diagnosed with acute lymphoblastic leukemia at the age of 1. She was submitted to chemotherapy: intrathecal methotrexate and cyclophosphamide and i.v. doxorubicin, vincristine, mercaptopurine, asparaginase and bone marrow transplantation at the age of 2. She was referred to Endocrine Rehabilitation Clinics at the age of 6.75 years-old. Her auxology evidenced: height 109.8 cm (p3-10); predicted adult stature: 155 cm (p10); and identical bone and chronological ages. In terms of puberty, her Tanner stages were A1P1B1. Blood analysis evidenced IFG1 of 344 mg/dl (p90) and normal thyroid and gonadal axes. At the age of 11, she remained pre-pubertal, with increased levels of FSH (76.3 mIU/ml) and LH (17.2 mIU/ml). Her bone age was 11 years. At this time, we started inducing puberty with oestradiol. After 2 years, Tanner stages were A4P4B3. Menarche was achieved at 13.41 years old. At the age of 18, she reached A5P5B5, after 7 years of estradiol + norgestrel. She withdrew this therapy when she was 20 and scarce menses were observed. Blood tests evidenced FSH of 84.1 mIU/ml and LH of 26.7 mIU/ml and pelvic ultrasound was normal. At this age, given her desire to become pregnant, she underwent ovarian stimulation, which was unsuccessful. However, 12 months later she became pregnant.

Discussion
This case reports the complex and not fully understood process of gonadal function after chemotherapy gonadotoxicity. We believe that the fortunate pregnancy result in our patient was probably due to previous gonadotrophins stimulation performed in a very young woman, which enabled the reactivation of the gonadic axis.

Physiological changes of adipokines and selected steroids during the menstrual cycle
Monika Šrámková 1,2, Michaela Dušková 1, Jana Vítková 1, Josef Velelk 1, Petr Matucha 1, Olga Bradnová 1, Jose Cordeiro 1 & Luboslav Stárka 1
1Institute of Endocrinology, Prague, Czech Republic; 2Faculty Hospital Motol, Prague, Czech Republic.

Context
The cyclical effects of hormones during the menstrual cycle (MC) are responsible for driving ovulation. The information about roles of adipokines within the scope of MC are not definite. Leptin plays a role in sexual function and regulating the onset of puberty. Thin girls often fail to ovulate or release an egg from an ovary during menstruation cycles. Leptin also acts on specific receptors in the hypothalamus to inhibit appetite. Levels of leptin are increased in women suffering from premenstrual syndrome. Aim of our study was to describe physiological changes of selected steroids and adipokines at healthy women during the MC.

Methods
Twenty-seven women with regular menstrual cycles were included in the study, and their hormonal spectrum and adipokines were measured in regular intervals starting from the first day of their MC.

Results
Classical changes in gonadotropins, estrogens and progesterone during the menstrual cycle are accompanied by less striking but significant changes in 17-hydroxyprogesterone and testosterone. No significant changes show dehydroepiandrosterone and its 7-oxygenated metabolites. Adipokines show a tendency to increase during ovulation, while ghrelin and resistin decrease. There is also a remarkable association of sex hormone-binding globulin on the day of the cycle.

Conclusion
Our results demonstrate that changes to adipokines during the menstrual cycle are not substantial, but nonetheless can play a role in the changes of food intake described in the literature. Precise descriptions of physiological changes in healthy women are important in helping us understand the significance of the changes accompanying various pathological states.

Serum activities of dipeptidyl peptidase-4 and adenosine deaminase and parameters of oxidative stress in polycystic ovarian syndrome: association with obesity
Seda Kahraman 1, Alev Eroglu Altinova 2, Serenay Elgun Ukar 2, Mehmet Multibin Yalcin 2, Baru Aktas Yilmaz 2, Cigdem Ozkan 2, Mjide Akturk 2 & Fisun Balos Toruner 1
1Faculty of Medicine, Gazi University, Ankara, Turkey; 2Faculty of Medicine, Ankara University, Ankara, Turkey.

Dipeptidyl peptidase 4 (DPP-4) is thought to play a role in the pathophysiology of metabolic and inflammatory diseases. Increased ADA activity has been suggested to induce insulin resistance and inflammation. We investigated DPP-4 and ADA activities, serum nitric oxide (NO) level and nitric oxide synthase (NOS) activity which are the oxidative stress parameters in patients with PCOS. Fifty two women with PCOS and 41 healthy women were included in this study. Serum ADA activity (0.33 (0.17–0.67) vs 0.26 (0.12–0.60) IU/l; P = 0.006), NO level (24.5 (13.25–58) vs 12.25 (6–24.50) μmol/l; P < 0.001) and NOS activity (5.46 (3.38–12.71) vs 4.54 (2.55–10.13) IU/ml; P < 0.001) were significantly higher in PCOS group while there was no difference in serum DPP-4 activity (19.54 ± 7.01 and 18.24 ± 6.73 IU/l; P = 0.369) between the groups. The groups were divided into subgroups as obese and nonobese. In obese PCOS group; ADA, NO and NOS were significantly higher than obese controls (P = 0.044, P < 0.001 and P < 0.001), while there was no difference in DPP-4 activity (P = 0.356) between the groups. In nonobese PCOS group; NO and NOS were significantly higher than nonobese controls (P < 0.001 and P = 0.006), while there were no differences in DPP-4 and ADA activity (P = 0.802 and P = 0.128). There was a negative correlation between ADA and DPP-4 activity in PCOS group (P = 0.047). A positive correlation was observed between ADA and BMI in the whole group (P = 0.022). In conclusion, we found that there was no significant change in serum DPP-4 activity in women with PCOS. However, we demonstrated increased serum ADA activity as well as its association with obesity in PCOS. Also, our finding that increased NO level and NOS activity in PCOS which is independent of obesity may result from a compensatory mechanism for the oxidative stress in PCOS.

Oocyte donation in women with Turner’s syndrome: successful outcome can be achieved with a specialist multidisciplinary approach
Matilde Calanchini 1,2, Kathy Baker 2, Andrea Falbri 2, Ashley Grossman 1, Elizabeth Orchard 4, Tim Child 2 & Helen Turner 1
1Oxford Centre for Diabetes, Endocrinology and Metabolism – Churchill Hospital, University of Oxford, Oxford, UK; 2Oxford Fertility Institute of Reproductive Sciences, Oxford, UK; 3Department of Endocrinology CTO Alesini & S. Eugenio, University of Rome Tor Vergata, Rome, Italy; 4Cardiology Unit, John Radcliffe Hospital, Oxford, UK.

Introduction
Although oocyte donation (OD) is increasingly utilised in women with Turner’s syndrome (TS) few data are available. Reported clinical pregnancy rates following OD range from 17 to 40%. Complications of 2% death from aortic dissection and severe hypertension are reported.

Aim
To analyse the OD-pregnancy success rate and maternal-fetal outcomes in women followed in a TS-dedicated centre.

Methods
A retrospective study of 114 adult TS patients analysed cardiovascular risk factors, feto-maternal morbidity and mortality in women undergoing OD (1997–2015). Data were compared with spontaneous pregnancy (SP) 14/114 patients, mean age 24 years (Calanchini et al. 2016, for SP data comparison).

Results
Eleven patients underwent egg donation cycles (total 27) using fresh (16) or frozen (3) donated eggs or embryos frozen and stored from a previous egg donation cycles (8). Endometrial preparation achieved endometrial thickness ≥ 7.3 mm, mean 10.2 mm. 1 or 2 embryos were transferred between day 2 and 5. Mean recipient age at first IVF was 32.5 years (24–41) and at delivery 33.8 years (26–41). 3/11 were 45X, 3/11 were 45X/46XY and 5/11 other TS-karyotypes. Five had cardiovascular malformations (4 bicuspid aortic valve, 1 treated aortic stenosis). Five patients had undergone chemotherapy gonadotoxicity. We believe that the fortunate pregnancy result in our patient was probably due to previous gonadotrophins stimulation performed in a very young woman, which enabled the reactivation of the gonadic axis.

DOI: 10.1530/endoabs.49.EP11145
coarctation), four treated hypertension, and two pre-existing aortic dilatation. 12/27 (44%) cycles had positive pregnancy-tests and 5/27 (19%) resulted in live births. The cumulative live birth rate per patient undergoing treatment was therefore 5/11(46%). Increased aortic diameter occurred in 1/5, and gestational-diabetes 1/5. No patient developed gestational-hypertension compared with 7% SP. No cardiovascular or fetal complications were noted. One emergency caesarean section (37+1w, twin pregnancy).

Conclusions OD showed a 19% live birth rate per cycle and 46% per patient in TS, was safe even in women with cardiac risk factors, and unassociated with increased feto-maternal complications compared with TS SP. This emphasises the importance of early discussion of assisted reproductive technology and alongside monitoring in a TS-dedicated multidisciplinary centre.

EP1146

The features of young women reproductive health with type 1 diabetes
Kateryna Kondratius1, Nazarii Kobyliak1, Iryna Nikitina1, Valentyina Kondratiu1 & Petro Bodnar1
1Bogomolets National Medical University, Kyiv, Ukraine; 2Sumy State University, Sumy, Ukraine; 3State Institution ‘Institute of Pediatrics, Obstetrics and Gynecology of NAMS of Ukraine’, Kyiv, Ukraine.

Background Leading position among endocrine pathology of adolescence and young women is type 1 diabetes (T1D), which in recent years had been proved to have a strong association with reproductive dysfunction among such patients. The purpose was to investigate the features of reproductive health in 120 young women (18–22 years old) with T1D.

Methods Retrospectively we studied the features of puberty and prospectively examined the determinants of thyroid autoimmunity in patients with polycystic ovary syndrome (PCOS) patients (mean age 24 ± 4.5 years, mean Body Mass Index. BMI 27 ± 7.3 kg/m²) and patients with T1D (mean age 22 ± 2.9 years, BMI 27.3 ± 3.1 kg/m²). Inclusion criteria for PCOS included clinical and biochemical parameters according to Rotterdam criteria. Patients with T1D were evaluated between January 2015 and January 2016. ATPO and thyroid peroxidase antibodies (TPO) were measured in all patients. The determinants of thyroid autoimmunity were evaluated by measuring HOMA-IR, body mass index (BMI), waist circumference, levels of luteinising hormone (LH), follicle-stimulating hormone (FSH), estradiol, progesterone, testosterone, prolactin, and free testosterone index (FAI). Antithyroid peroxidase antibodies were measured using chemiluminescent immunoassay technique (Zephyr, VITEK, France).

Results The proportion of patients with delayed puberty and physical development of type 1 diabetes with the debut in the pre-puberty was in 62.5%, in the early puberty (3–7 years) – 15.0%, in the active adolescence (11–14 years) – 11.7% of post-puberty (over 14 years) – 10.8%. Ovarian failure occurred in 76.7% of the patients, and was expressed in the increased LH, estradiol and free testosterone levels. The positive correlation relationships were detected between blood levels of estradiol

The determinants of thyroid autoimmunity in patients with polycystic ovary syndrome
Alice Albu1,2, Oana Petre2, Irina Nicolaescu2, Ivona Gheorghe2 & Dragos Albu1
1Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2EliaS Hospital, Bucharest, Romania.

It was suggested that polycystic ovary syndrome (PCOS) patients have an increased risk for autoimmune thyroid disease. However the mechanisms underlying this association are incompletely clarified. The aim of the present study is to evaluate the factors associated with thyroid autoimmunity in patients with PCOS. We performed a retrospective study which included 126 PCOS patients (mean age 50 ± 4.5 years, mean Body Mass Index. BMI 27 ± 7.3 kg/m²) diagnosed based on Rotterdam criteria between January 2015 and January 2016. We found that antithyroid peroxidase antibodies (ATPO) serum levels were positively correlated with HOMA-IR (r=0.234, P=0.019), fasting insulin (r=0.218, P=0.025), waist circumference (WC, r=0.267, P=0.007) and BMI (r=0.203, P=0.04). We found no association between ATPO and total testosterone, free androgen index, gonadotropins, TSH, leptin and adiponectin serum levels. In a multivariate linear regression model with ATPO as dependent variable only HOMA-IR was an independent predictor of ATPO values after adjustment for adiposity markers. In conclusion, in PCOS patients insulin resistance seems to be the main factor involved in thyroid autoimmunity.

EP1148

Metformin treatment decreased free androgen index among PCOS women
Sandra Mrozinska1,3, Anna Wajda2, Patrycja Czakanska2, Barbara Zdziezak2, Marta Kryszek1, Anna Zdanowicz2 & Jolanta Penczak-Turka1
1Department of Metabolic Diseases, Jagiellonian University, Medical College, Krakow, Poland; 2Department of Gynecological Endocrinology, Jagiellonian University, Medical College, Krakow, Poland; 3University Hospital, Krakow, Poland.

Hyperinsulinemia is one of biochemical features of polycystic ovary syndrome (PCOS). Metformin is a common drug used in PCOS. Recent studies have shown that metformin has impact on clinical and biochemical parameters in PCOS patients. The aim of our study was to assess retrospectively the influence of metformin on total testosterone, sex hormone binding globulin (SHBG) and free androgen index (FAI) in women with PCOS in polish cohort. A total of 54 patients with PCOS and irregular menses were examined. The duration of metformin treatment between the baseline and final blood results was about six months. There were statistically significant differences in the total testosterone (1.9 (1.4–2.6) vs 1.2 (0.6–2) ng/ml), SHBG (34.8 (27.2–53.1) vs 49.4 (35.9–81.7) nmol/l) levels and FAI (5.3 (3.2–9.8) vs 2.3 (1.3–4.3) before and after the metformin administration (all P<0.0001)). In addition the patients were divided into two groups according to FAI. There was no difference in age (29 (26–32) vs 28 (25–31) years, P=0.7) and BMI (22.5 (19–24.1) vs 22 (20.7–28.1) kg/m², P=0.35) between group with FAI<5 and group with FAI>5, respectively. Our study showed that metformin therapy ameliorates the total testosterone and FAI both in women with FAI greater and lower 5 but improves SHBG levels only among patients with FAI>5. The groups did not differ in difference between baseline and final testosterone and SHBG levels but differed in FAI change. Our study suggest that metformin effectiveness could differ between PCOS patients according to the phenotype.

Biochemical and clinical characteristics of polycystic ovarian syndrome (PCOS) in women with and without type 1 diabetes (TID)
Anjuli Gunness1, Agnieszka Pazderska1, Mohamed Ahmed1, Niamh Phelan1, Gerard Boran1, AE Taylor2, MW O’Reilly3, Wiebke Arlt2, Kevin Moore1, Lucy-Ann Behan1, Mark Sherlock1 & James Gibney1
1Department of Endocrinology and Clinical Chemistry, Adelaide and Meath Hospital, Tallaght, Dublin 24, Ireland; 2Institute of Metabolism and Systems Research (IMSR), University of Birmingham, Edgbaston, Birmingham B15 2TT, UK.

Abstract
PCOS prevalence is reported to be increased in reproductive-age women with type-1 diabetes (T1D) but measurement of androgens, crucial for diagnosis, has been with inaccurate immunoassays. No studies have been reported using liquid-chromatography-mass-spectrometry (LCMS) Reproductive-age T1DM women attending a single centre were evaluated for PCOS (NIH criteria). Women with T1DM and PCOS (T1/PCOS) were compared to T1DM women without hyperandrogenism (T1/no HA), and to two groups of non-diabetic women with PCOS – one group BMI-matched (PCOS-lean) and the other overweight (PCOS-overweight). 16 (18%) of T1DM women had PCOS. T1DM women with PCOS compared to the overall group were younger (26.5 vs 29) and had a lower BMI (23.4 vs 25.5). Compared to T1/no HA, testosterone (1.3 vs 0.8 nM, P=0.004) and androstenedione (7.1 vs 4.6 nM, P=0.0016) were elevated but no differences in DHEA-OX, DHEAS, SHBG or free testosterone was noted. They had an older age of menarche (13 vs 12.5 years, P=0.024), and were more likely (P=0.024) to have a positive family history of PCOS. There were no differences in androgen levels between T1/PCOS and PCOS-lean women, but both of these groups demonstrated greater androstenedione levels (7.1 vs 5.5 nM, P=0.0247) than PCOS-overweight women. In summary, PCOS is common in T1DM. Women with T1/PCOS are leaner than T1 women without PCOS but are more likely to have a family history of PCOS. They have a similar biochemical phenotype to lean women with PCOS but differ from overweight women with PCOS. The mechanisms underlying PCOS in T1DM and its clinical significance are unknown.

EP1151
A case of polycystic ovary syndrome (PCOS)
Kristina Kljajic Babic, Dubravka Majic Milotic, Kristijan Peros & Lea Smircic Duvnjak
Clinical Hospital Merkur, Zagreb, Croatia.

Polycystic ovary syndrome (PCOS) is one of the most common endocrine disorders in women of reproductive age. It’s a heterogeneous functional disorder of unclear etiology. The features of PCOS are disorders of ovulation, androgen excess, polycystic ovaries; it’s associated with presence of associated risk factors for cardiovascular disease (obesity, glucose intolerance, dyslipidemia). The diagnosis of PCOS is made using the Rotterdam 2003 criteria. 23yo female patient was evaluated for oligomenorrhea. At the age of 17, she consulted for the first time her gynecologist because of irregular menstrual cycles since the menarche (age 14) and excessive hair growth. A diagnosis of PCOS was made and oral contraceptives (OC) were introduced in therapy. After 1.5 yrs, OC were stopped (500 mg bid). After 10 months of treatment, she lost 8 kg, menstrual cycles were normal BP, excessive hair on chin, forearms and lower abdomen; no striae, no acanthosis nigricans, normal thyroid. High levels of insulin, L.H. total testosterone, androstendione and low levels of SHBG and progesterone in the luteal phase were found. An oral glucose tolerance test, fasting lipid profile and concentrations of TSH, prolactin, 17OHP were normal. A pelvic ultrasound confirmed polycystic ovaries. The clinical and lab. tests were consistent with PCOS. Therapy with life style changes (weight reduction) and metformin was started (500 mg bid). After 10 months of treatment, she lost 8 kg, menstrual cycles were regular (26–28 days), concentrations of LH, testosterone, progesterone and insulin were normal. The patients with PCOS are treated according to their symptoms, risks and desire for pregnancy. The OCs are the mainstay of pharmacologic therapy for women with PCOS for managing hyperandrogenism and menstrual dysfunction. The case has showed impact of the OC on the pituitary-ovarian supression. There are relatively few publications examining the effect of the OC on ovarian function in women and it’s less clear whether the pituitary–ovarian suppression induced by the OCs has any impact on functional ovarian reserve, so we need further evaluation. Although, the use of metformin in the treatment of PCOS is of-label, in this case, metformin had showed as safe and effective. Benefit was made on oligomenorrhea, fertility and obesity.

EP1152
Does radioactive iodine therapy affect fertility?
Berna Evranos Ogmen1, Svetgul Fak2, Selika Burcak Polat2, Nagihan Bestepe1, Reyhan Erozy3 & Bekir Cakir2
1Ataturk Education and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; 2Yildirim Beyazit University, Faculty of Medicine, Ataturk Education and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey.

Introduction
Thyroid carcinoma is common in young women. Radioactive iodine (RAI) therapy has been confirmed as a useful treatment in the management of differentiated thyroid carcinoma (DTC). For women with DTC, the effect of RAI therapy on gonadal and reproductive function is an important consideration. We aimed to evaluate effects of RAI therapy on ovarian function.

Method
Women younger than 40 years old and diagnosed with thyroid cancer that required RAI treatment were enrolled in this study. Patients with ovarian insufficiency were excluded. Early follicular phase serum follicle stimulating hormone (FSH) and anti-mullerian hormone (AMH) levels were measured before and 3–6 months after RAI therapy. Friedman test is used to detect changes in FSH and AMH levels by RAI therapy with time.

Results
Eighteen patients with a mean age of 31.9 ± 4.9 years were enrolled in this study. Median AMH levels were 4.2 (2.96–17.42) ng/ml, 2.21 (0.84–3.69) ng/ml, 2.08 (0.86–6.12) ng/ml before and 3–6 months after RAI therapy, respectively. Median FSH levels were 5.5 (3.78–15.5) mIU/ml, 5.32 (4.19–35.36) mIU/ml, 6.07 (4.24–13.69) mIU/ml before and 3–6 months after RAI therapy, respectively. AMH levels before RAI were higher than after RAI (P=0.021). AMH levels after RAI at 3 and 6 months were not different. FSH levels were similar before and after RAI.

Conclusion
Anti-mullerian hormone (AMH) is considered an important marker of ovarian reserve. Ovarian reserve decreases in first 6 months after RAI therapy. Further large prospective studies are necessary to determine its predictive interest for post-treatment residual fertility.

Abstract
The prevalence of hyperandrogenism has been reported to be increased in reproductive-age women with type-1 diabetes (T1DM). This observation however is based on findings using inaccurate immunoassays. No studies have been reported in diabetes using liquid-chromatography-mass-spectrometry (LCMS). We compared LCMS-measured androgens in T1DM-women with age- and BMI-matched normal women, and compared findings with those in women with type-2 diabetes (T2DM) also compared to a matched control group (Table Below). Compared to non-diabetic women, androstenedione and SHBG were greater in T1DM while estimated free-testosterone was lower. In contrast, compared to non-diabetic women, androstenedione, DHEA-G and SHBG levels were lower in T2DM while free-testosterone and DHEAS were greater. Total testosterone did not differ between groups in either comparison. T1DM and T2DM are associated with differing effects on androgen levels. These differences are likely to reflect differences in insulin sensitivity and differing effects of exogenous insulin administration. Their clinical significance requires further investigation.
Mean (± SEM); P-value vs matched non-diabetic. Median (range); P-value vs matched non-diabetic.

Anti-mullerian hormone a marker for metformin therapy efficacy in PCO: a pilot study on Egyptian population
Nermin Sheriba, Mona Mohamed Abdelسام, Bassem Mourad, Madhaa Mamdouh & Eltohamy Samia
1Centro Hospitalar Vila Nova de Gaia/Espinho, Endocrinology Department, Vila Nova de Gaia/Porto, Portugal; 2Centro Hospitalar São João, Reproductive Medicine Department, Porto/Porto, Portugal.

Background
Polycystic ovarian syndrome (PCOS) is the most common endocrinopathy in adult women, and is emerging as a common cause of menstrual disturbance in the adolescent population. Insulin resistance, which is considered one of its underlying causes, has increased substantially in the past decade, putting more adolescent girls at risk for PCOS and its complications. Anti – Mullerian hormone (AMH) is secreted by the granulose cells of ovarian follicles and correlated with count of small antral follicles and it is expressed throughout folliculogenesis.

Objectives
Evaluation of AMH in Egyptian women with PCOS and if it might serve as a prognostic marker for treatment efficacy with metformin.

Patients and methods
The study included 30 women with PCOS (group 1) and 30 healthy women without PCOS (group 2). AMH is measured in both groups and before and after treatment with metformin (2550 mg) for 3 months in group I.

Results
AMH levels was higher in PCO groups before (3.54±0.58 ng/ml) and after treatment (2.79±0.39 ng/ml) than the control group (2.14±0.49 ng/ml) with P<0.01. In PCO group, it was higher before (3.54±0.58 ng/ml) than after treatment (2.79±0.39 ng/ml), with P<0.01.

Conclusion
AMH is higher in PCO subjects and its levels decreases significantly with the insulin sensitizer metformin and it can be used as a marker for treatment efficacy with metformin.

Keywords: PCO, Anti-Mullerian hormone (AMH), Metformin.

Influence of BMI in response to ovarian stimulation and live birth in IVF
Patricia Tavares1, Catarina Machado1, Lucinda Calejo2, Gustavo Rocha1, Ana Margarida Povoa2, Sandra Soares2, Sofia Sousa2 & Maria João Oliveira2
1Hospital Vila Nova de Gaia/Espinho, Endocrinology Department, Vila Nova de Gaia/Porto, Portugal; 2Hospital São João, Reproductive Medicine Department, Porto/Porto, Portugal.

Introduction
The deleterious effects of obesity on spontaneous reproduction are well recognized, although the literature on obesity and assisted reproductive technology outcome remains heterogeneous and inconsistent.

Objective
To estimate the effect of BMI on ovarian stimulation response and live birth in women underwent in vitro fertilization (IVF).

Methods
Retrospective observational study that included women submitted to a first IVF cycle in an infertility center of a public hospital in 2015.

Results
We included 102 women with a mean age of 33.2 years (± 3.7), 69 (67.6%) were in normal weight range, 22 (21.6%) were overweight and 11 (10.8%) were obese. The mean values of basal serum FSH and LH were 6.6 mIU/ml (± 2.7) and 5.9 mIU/ml (± 3.8) respectively. The antral follicles count (AFC) on day 2-3 of the cycle was on average 14.2 (± 6.9). 46 (45.1%) women underwent IVF cycle and 56 (54.9%) underwent IVF with intracytoplasmic sperm injection. The average duration of stimulation and dose of FSH administered was 9.8 days (± 2.3) and 1622.1UI (± 647.7) respectively. There were no statistically significant differences in the 3 groups of BMI in relation to the women’s age, FSH levels, AFC and neither in relation to the number of oocytes obtained. In our sample, age and AFC were the factors that correlated with the number of oocytes (P<0.001). Obese women had significantly fewer live births than overweight women (P=0.027) and this last BMI group (average BMI 26±9) had more live births. There were no differences in embryo quality or number of embryos frozen in these three groups.

Conclusions
Increased age and decreased AFC are negative determinants in the number of oocytes obtained. Although BMI groups had no difference in the number or quality in the oocytes collected, obese women had a significant lower probability of having a live birth after IVF.

Endocrine Abstracts (2017) Vol 49
and metabolic factors were analysed in PCOS group. The serum AMH level was significantly higher in the PCOS group (8.35 ± 8.19 ng/ml) than in the Control group (4.99 ± 3.23 ng/ml). The serum AMH level was independently affected by age and the presence of PCOS on multiple regression analysis. Ovarian volume per ovary (OPVO) showed the strongest positive correlation (r = 0.62) with the serum AMH level among clinical factors. OPVO was the only independent factor that affected the serum AMH in PCOS on multiple regression analysis. Serum AMH level is determined only by ovarian morphological factor and the other pathophysiologica factors such as androgen, severity of anovulation and insulin resistance are not determinant factors in PCOS even if significant relationship exists.

EP1157

Analysing by decade, testosterone undecanoate depot injectable does not increases prostate volume. Study during up to 9 years on hypogonadic patients. (December 2016)
Matei Pisoschi1, Dana Cristina Staicu2 & Dan Peretianu2
1Hospital CF2, Department of Urology, Bucharest (Bucuresti), Romania; 2Medical Center Povernei, Department of Endocrinology, Bucharest (Bucuresti), Romania.

Aim
Re-analyzing (study starting in 2007) the effect of injectable testosterone undecanoate depot (TUD) in hypogonadic patients.

Materials and Methods
A. Patients: at onset 231 men with hypogonadism (median: 62 y). B. Distribution: by decade (starting with 20y): no = 4, 14, 24, 61, 63, 49, 17, 1. C. TUD (Nebido® Bayer) 1000 mg injected 1/3 months i.m. D. Prostate volume (PV) appreciated by per-abdominal ultrasound: 3.5–5 MHz probe, elliptical/3D (cm³). E. 12 patients were operated before starting testosterone, 2 patients were operated during treatment. F. Analysis Time: before starting testosterone (T0), after 1/2 month (T1 = 231), 3m (T2 = 182), 6m (T3 = 149), 1y (T4 = 123), 2y (T5 = 90), 3y (T6 = 62), 4y (T7 = 48), 5y (T8 = 40), 6y (T9 = 33), 7y (T10 = 22), 8y (T11 = 11), 9y (T12 = 4). G. Maximum increment from T0 noted Δ M %. Average increment noted Δ A %. H. Statistical analysis: Student test.

Results
I. All average prostatic volume for decade – tabulated (see pdf). Maximum increment (Δ M %) per decade, including the moment (Δ M % at) and average increment (Δ A %) – tabulated (see pdf). II. PV at T0 increases with age, from minimum 15.38 (19–29y) to maximum 45.5 (80–89y), P = 0.0007. III. Considering all observations, TUD did not increase PV significantly; in fact the average of increment in all patients was negative = –22.38%. Δ M % per decade: 45.95; 31.82; 56.41; 55.77; 45.45; 64.41; 42.11; 20.14. Inside a specific decade no significant increased in PV was registered: all P > 0.05; exception: 80–89 decade, P = 0.002, from 3 to 5 y. V. In some patients, especially from 40–79 years, TUD could decrease slightly prostate volume.

Conclusions
Considering the risk for prostate (in elderly), testosterone undecanoate 1000 mg depot injectable is a safe treatment, even after 9 years of administration. Precautions should be accorded to men over 80 y old, after the 2nd year administration.

DOI: 10.1530/endoabs.49.EP1157

EP1158

After 9 years observation, testosterone undecanoat 1000 mg at 3 months did not increased Prostatic Specifc Antigen level (December 2016)
Matei Pisoschi
1Department of Urology, Hospital CF2, Bucharest (Bucuresti), Romania; 2Medical Center Povernei, Bucharest (Bucuresti), Romania.

Aim
Has testosterone undecanoat 1000 mg injection (Nebido® Bayer), 1/3/month negative effect on prostate?

Material and method
i) PSA (ng/ml) was registered retrospective (from files) and prospective analysis (onset 2010), ii) Patients: PSA analysis was done before treatment and recorded at T1 to T12 [2 weeks to 9 years] (see Pisoschi, this Congress). iii) Statistical analysis: Student test, simple correlation, multiple regression. Result
A. Patients at onset: 160 men, 18–96 years, average: 60.38; median: 60; no prostatic cancer. B. Prostatic volume (cmc): average: 34.81. Average PSA (no patients): before treatment = 1.60 (100); 1y = 1.69 (110); 2y = 1.48 (83); 3y = 1.85 (57); 4y = 2.46 (46); 5y = 1.86 (34); 6y = 1.51 (30); 7y = 2.86 (2); 8y = 1.99 (11); 9y = 1.90 (4). D. Statistical difference of increasing average: nonsignificant for all times from 2 weeks to 9 years. E. Correlation between age and PSA was 1. significant at: T0: r = 0.29; T1: r = 0.35; T2: r = 0.28. 2. nonsignificant for 3 to 9 years (r=0.14-0.73). F. Correlation between PSA and prostatic volume was significant, both before and after treatment (depending on group size).

G. Observations: 7 patients died; 1 during treatment, Klinefelter, 41 y, cerebral tumor: remaining 6 after 2 years stopping treatment, 60% 83–91 y, most cardiac stop. H. Multiple regression test shows p values <0.001 for all years (examples): 1y: \( R^2 = 0.58, F = 50.24 \) → 9y: \( R^2 = 1, F = 1000. 

Conclusions
i) Testosterone undecanoat 1000 mg injectable i.m. at 3 months did not increased PSA level after up to 9 years administrations. ii) PSA level post testosterone does not depend on testosterone administration but on age, prostatic volume, before and after treatment, and initial PSA level, i.e. before testosterone administration.

Induction of male puberty in patients with hypogonadism hypogonadotrophe with subcutaneous gonadotropin
Paloma Moreno-Moreno, Concepción Muñoz-Jiménez, María Rosa Alhambra-Expósito & María Ángeles Gálvez-Moreno
Management Unit of Clinical Endocrinology and Nutrition, University Hospital Reina Sofia, Córdoba, Andalucía, Spain.

Objective
The most used therapeutic guidelines for the induction of male puberty in hypogonadotropic hypogonadism (HH) are GnRH in subcutaneous pulsatile infusion and HCG in monotherapy or combined with FSH in intramuscular injection. The objective of this study was to evaluate the efficacy of subcutaneous HCG with or without FSH in induction of male puberty in patients with HH.

Materials and methods
Descriptive study of patients with HH treated with HCG subcutaneously (s.c.) with or without FSH, for induction of male puberty (2004–2015). The Treatment was initiated with HCG 500 UI/72 h s.c., periodic monitoring of testosterone, testicular volume and semen analysis was realized, adjusting doses up to 2500 UI/72h. If no answer obtained after one year, combined treatment with FSH s.c. was started.

Analyzed data
Cause of HH, age, testosterone levels, testicular volume, semen, dose of HCG and FSH treatment. Pubertal development assessed by testosterone levels, testicular volume and normalization of spermatogenesis.

Results
Nine patients. 17.2 ± 1.8 years old (15–20). Cause of HH: four Idiopathics, four craniopharyngiomas and one adenohypophysis hypoplasia. Dose of HCG: 1666 ± 821.0/72 h. Two patients required combined treatment with FSH. Treatment period: 32.2 ± 9.5 months. Testosterone levels were normalized in 100% of cases (7.34–5.1 ng/ml). 95% increased testicular volume: 13.5 ± 4.4 ml (10–20). The spermogram was performed in 80% of cases at the end of the treatment, with oligospermia in all cases. No presence of side effects.

Conclusions
Subcutaneous gonadotropin therapy is effective in induction of male puberty in HH. Treatment with subcutaneous HCG alone is successful. No presence of side effects.

DOI: 10.1530/endoabs.49.EP1159
Conclusion
Patients with lymphoma have an increased risk for poor semen quality before any treatment. 74% of these men in our study had abnormal semen parameters according to the WHO. Generally, all patients with newly diagnosed lymphoma’s need counselling about their reproductive function and semen cryopreservation should be offered before undergoing gonadotoxic treatment.

Semen quality in young, healthy men is not related to serum concentration of vitamin D (AndroLS)
Pawel Jozkow1, Aleksandra Zagrodna1, Marek Medras1,2, Felicja Lwow3 & Malgorzata Slowinska-Lisowska1
1Department of Sports Medicine and Dietetics, University School of Physical Education, Wroclaw, Poland; 2Department of Endocrinology, Diabetology and Isotope Therapy, Wroclaw Medical University, Wroclaw, Poland; 3Department of Health Promotion, University School of Physical Education, Wroclaw, Poland.

Introduction
Relationships between vitamin D and male fertility are not fully elucidated. Studies in infertile/subfertile subjects suggest that vitamin D status may be associated with semen parameters (1, 2). Data from healthy men is inconclusive (3, 4). Our purpose was to evaluate the andrological status and a range of biochemical, dietary and lifestyle variables in healthy men aged 18–35, living in the region of Lower Silesia (Poland) (AndroLS).

Material and methods
We invited 5000 subjects to participate in the study. From among 500 respondents, we acquired necessary material (semen and blood) from 177 men. The specimens were collected in autumn and winter. The semen samples were evaluated according to WHO 2010 criteria by a single experienced medical analyst.

Results
Only minority of the studied subjects (18%) had serum 25(OH)2D3 concentration above the lower limit (20 ng/ml). 39% had severe vitamin D deficiency (<10 ng/ml). Mean (± s.d.) 25(OH)2D3 was 13.7±8.9 ng/ml. Mean (± s.d.) semen volume in the volunteers was: 3.1±1.5 ml. sperm concentration: 60±44×10⁶/ml, total sperm count: 170±137×10⁶/ejaculate, percent of normal forms: 14.7±6.3%. None of the studied semen parameters correlated with serum concentration of 25(OH)2D3. We did not observe any correlations after adjustments for: alcohol consumption, cigarette smoking, carrying a mobile phone in pants’ pockets, body mass index, caffeine consumption and physical activity, either.

Conclusions
Our data suggest that serum concentration of 25(OH)2D3 cannot indicate semen quality in healthy men.

Semen quality in patients with newly diagnosed lymphoma’s
Kristijan Peros, Dubravka Majic Milotic, Tomislav Bozek, Mia Sunjic Stakor, Kristina Kljajic Babic, Vesna Dermanovic Dobrota & Sasa Magas
Vuk Vrhovac University Clinic, Clinical Hospital Merkur, Zagreb, Croatia.

Objective
To analyse the semen quality in patients with newly diagnosed lymphoma’s before starting the treatment.

Materials and methods
We evaluated semen quality in 131 patient with lymphoma who underwent sperm banking in our clinic over a 14-year period. 102 patients had Hodgkin’s lymphoma, and 29 had non-Hodgkin’s lymphoma. Semen samples were collected by masturbation after 2–7 days of sexual abstinence. Age at banking, semen volume, sperm concentration, and total and progressive sperm motility were recorded. Semen parameters were compared to established World Health Organisation (WHO) reference values (WHO Laboratory Manual for the Examination and Processing of Human Semen, Fifth Edition, 2010).

Results
The median age of these patients was 26 years (range 17–43); median semen volume was 2.0 ml (range 0.1–6.5); median sperm concentration was 63.8×10⁶ per ml (range 0–413); median total and progressive sperm motility were 40% (range 0–84) and 24% (range 0–69), respectively. According to the reference values of the WHO 34 patients (26%) in this series had a semen quality within the normal range, and 97 patients (74%) had abnormal semen quality. In 2 patients (1.5%) the semen samples were not frozen because of azoosperma (no spermatozoa in the ejaculate), 69 patients (52.7%) had single damages (oligozoosperma or asthenozoosperma) and 26 patients (19.8%) had combined damages (oligoasthenozoosperma).

Gonadal profile in men with early-onset androgenetic alopecia: does a male PCOS-equivalent syndrome exist?
Rossella Cannarella1, Rosita A Condorelli1, Sandro La Vignera1, Laura M Mongiò1, Enzo S Vicari1, Giuseppe Micali2 & Aldo E Calogero1
1Department of Clinical and Experimental Medicine, University of Catania, Catania, Sicily, Italy; 2Dermatology Clinic, University of Catania, Catania, Sicily, Italy.

Importance
Early-onset androgenetic alopecia (AGA) has been suggested as a phenotypic sign of the male polycystic ovary syndrome (PCOS)-equivalent since men with this feature have a PCOS-like hormonal pattern. No study has evaluated the gonadal function of these men.

Objective
To study the gonadal function of men with early-onset AGA and to identify suggestive criteria of male PCOS-equivalent.

Design
This case-control study was conducted from January 2014 to June 2016. Setting
The study was carried out on patients referring to hospital for andrological check-up.

Participants
Forty-four men with early-onset AGA (19–30 years) and 37 aged-matched healthy men (controls) were enrolled. A subgroup of patients was assumed to have the male PCOS-equivalent (sAGA) when at least one of the following parameter was present: BMI >25 kg/m², insulin-resistance (IR) (HOMA index >2.5), SHBG <25 nmol/l. The remaining patients were considered to have AGA alone (aAGA).

Main outcome(s) and measure(s)
The primary outcome was to evaluate the gonadal function and the metabolic/hormonal features of men with early-onset AGA. The secondary outcome was to identify which parameters may be used to suspect the male PCOS-equivalent syndrome among men with early-onset AGA.

Results
Patients had higher mean (± s.d.) BMI (25.5±3.8 vs 23.7±3.0 kg/m²; P=0.05) and 17αOH-progesterone (2.05±0.90 vs 1.51±0.62 ng/ml; P=0.05) compared to controls. sAGA had higher levels of insulin (11.8±1.7 vs 6.0±0.4 μU/ml; P=0.01) and LH (4.9±2.1 vs 3.8±1.4 IU/ml; P=0.05), lower total testosterone (TT) levels (5.2±1.7 vs 6.3±1.6 ng/ml; P<0.05) and left testicular volume (TV) (12.3±2.8 vs 15.4±4.1 ml; P<0.05) compared to aAGA. sAGA also had higher fat-mass percentage (17.6±4.1 vs 13.2±5.3%; P<0.05), DHEAS (323.3±112.6 vs 257.8±107.1 μg/dl; P<0.05) and seminal fluid volume (4.2±2.8 vs 2.8±1.3 ml; P<0.05), lower TT (5.16±1.70 vs 6.47±4.30 ng/ml; P=0.016) and left TV (12.3±2.8 vs 15.0±4.3 ml; P<0.05) compared to controls.
Conclusion and relevance
Men with early-onset AGA and at least one among the following parameters BMI > 25 kg/m², IR, SHBG < 25 nmol/l had a borderline-low left TV and a impaired gonadal steroidogenesis. Hence, they might have a greater risk to develop a gonadal dysfunction later in life. These criteria may be used to suspect the male PCOS-equivalent.

Improved conception of the normative values of testosterone in men with type 2 diabetes

Irina Khripun1, Sergey Vorobyev1, Elizaveta Dzantieva1, Igor Belousov1, Michail Kogan1 & Michael Zitzmann2
1Rostov State Medical University, Rostov-on-Don, Russia; 2University Clinics Muenster, Muenster, Germany.

Background
Men with type 2 diabetes mellitus (T2DM) have significantly lower levels of testosterone (T) than non-diabetic controls. But androgen deficiency symptoms may be detected in males with normal T levels.

Aim
To analyze parameters of lipid, carbohydrate metabolism and endothelial function in diabetic males with low normal and middle-to-high normative T levels.

Patients and methods
We examined 86 men with T2DM and serum T levels higher than 12.1 nmol/l. Parameters of total T, lipid metabolism, IbaA1c, biochemical markers of endothelial function – NO, endothelial NO synthase type 3 (NOS3) were analyzed. The patients were divided into two groups: 1–23 men with T levels 12.1–14.9 nmol/l, 2–63 patients with T levels ≥ 15.0 nmol/l. Statistical analysis was performed using Mann-Whitney U-test and Spearman rank correlation method.

Results
The IbaA1c value was 8.7% (6.7; 9.8) in 1st group and 7.7% (6.4; 9.2) in 2nd group (P < 0.039), but the proportion of patients with IbaA1c level > 7% was higher in group 1 (71% vs 58.6%) as compared to group 2 (P = 0.002). In patients with T levels lower than 15.0 nmol/l, higher levels of serum cholesterol (38.1% vs 27.6%), triglycerides (40.0% vs 24.1%) and low density lipoproteins (26.3% vs 17.2%) as compared to the 2nd group were found (P < 0.01). There was a significant correlation in the T concentrations with NOS3 levels (r = 0.350 in 1st and [r] = 0.266, (P < 0.05) in 2nd group. Vascular endothelial dysfunction as assessed by ultrasonographic measurement of the dilatation of the brachial artery was more frequent in patients of group 1 compared to group 2 (55.6% vs 23.8%, P = 0.02).

Conclusion
Males with T2DM and low-normal T level are at higher risks of dyslipidemia, endothelial dysfunction and progression of T2DM as compared to men with serum T higher than ≥ 15 nmol/l.

Endothelial dysfunction, inflammation and insulin resistance in patients with Klinefelter Syndrome

Cem Haymana1, Aydogan Aydogdu1, Ibrahim Demirci1, Mustafa Dinc1, Orhan Demir1, Deniz Torun2, Fatih Yesildal1, Coskun Meric1, Yalcin Basaran1, Alper Sommez1 & Omer Azali1
1Gulhane Training and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; 2Gulhane Training and Research Hospital, Department of Medical Genetics, Ankara, Turkey; 3Selahaddin Eyyubi Public Hospital, Department of Biochemistry, Diyarbakir, Turkey.

Introduction
The prevalence of cardiometabolic disorders such as type 2 diabetes mellitus, dyslipidemia and metabolic syndrome is increased in patients with Klinefelter syndrome (KS). The mechanism by which cardiometabolic risk increases in patients with KS remains to be completely elucidated. We investigated the presence of inflammation, insulin resistance and endothelial dysfunction in an unconfounded population of KS.

Methods
A total of 31 patients with KS (mean age 21.59 ± 1.66 years) and 33 healthy control subjects (mean age: 22.15 ± 1.03 years) were enrolled. The demographic parameters, Asymmetric dimethylarginine (ADMA), high sensitive C reactive protein (hs-CRP) and homeostatic model assessment of insulin resistance (HOMA-IR) levels were measured in patients and controls.

Results
The patients had higher insulin, HOMA-IR and ADMA levels (P < 0.001 for all) and lower HDL-C (P = 0.002) and total testosterone (P < 0.001) levels, compared to the healthy controls. There were significant negative correlations between the total testosterone levels and ADMA (r = -0.479, P < 0.001), hs-CRP (r = -0.291, P = 0.034), and significant positive correlation with HDL-C (r = 0.429, P = 0.001) levels. The multivariate analysis has shown that total testosterone (β = −0.412, P = 0.001) and TG (β = 0.332, P = 0.009) levels were the significant independent determinants of the plasma ADMA levels.

Conclusion
The results of the present study show that endothelial dysfunction and insulin resistance are prevalent even in the very young subjects with KS, who have no metabolic or cardiac problems at present.

Testosterone is poorly related to erectile dysfunction in young/middle aged human immunodeficiency virus-infected men

Sara De Vincenzi1, Daniele Santì1, Maria Chiara Decaroli1, Flaminia Fanelli1, Marco Mezzulo1, Alessia Fazzini2, Anna Ansaloni1, Uberto Pagotto2, Giovanni Guaraldi1 & Vincenzo Rocchir1
1Unit of Endocrinology, University of Modena and Reggio Emilia, Modena, Italy; 2Unit of Endocrinology, University of Bologna, Bologna, Italy.

Background
human immunodeficiency virus (HIV)-infection is strongly associated to erectile dysfunction (ED) in men. Preliminary data suggests that ED is poorly associated with serum T in HIV+ men.

Aim
To investigate in HIV-infected men the relationship between sexual function as assessed by the validated International Index of Erectile Function (IIEF-15) and T deficiency using Liquid Chromatography-tandem Mass Spectrometry (LC-MS/MS).

Methodology
Prospective, cross-sectional, observational study on HIV-infected male patients with ongoing Highly Active Antiretroviral Therapy (HAART), attending the Clinic of Infectious Diseases. IIEF-15 and IIEF-5 questionnaires were used to define ED, while LC-MS/MS was used for hormonal assays.

Results
233 consecutive HIV-infected patients were enrolled (mean age 45.29 ± 5.33 years). Eight patients (3.4%) had total T < 300 ng/dl, while 142 patients (61.5%) had ED (score ≤ 25). Age, hormonal data and duration of HIV-infection and HAART did not differ among groups of patients according to the degree of ED. The direct comparison of each ED cluster showed that months of infection were significantly higher in men with severe ED compared to mild ED (P = 0.037). The erectile function domain at IIEF-15 was directly correlated with IIEF-5 score (r = 0.479, P < 0.001). The intensity of sexual desire was inversely related to months of infection (r = -0.147, P = 0.026), but not to months of HAART therapy (r = -0.121, P = 0.071).

Conclusions
To the best of our knowledge, this is the first, properly-designed prospective study aiming to investigate the relationship between erectile function and serum T, assessed by LC-MS/MS in HIV-infected men. In our cohort, i) IIEF-5 is reliable as IIEF-15 for ED diagnosis, ii) ED is not associated with serum T, iii) erectile dysfunction is directly correlated with T deficiency.
function is not influenced by T and HAART, but only by HIV-infection duration. In conclusion, several specific factors, such as the duration of HIV infection, are involved in erectile function in HIV-infected men and should be carefully considered in this setting, while hormonal status seems to be less important. **Early arterial stiffness and chronic inflammation in male equivalents of polycystic ovary syndrome**

Mehmet Sozen1, Suleyman Baldane2, Sedat Abusoglu3, Levent Kebapcilar2, Aysegul Kebapcilar2, Fatma Akyurek4, Ali Unlu1 & Suleyman Hilmi Ipeks1

1Department of Internal Medicine, Selcuk University Faculty of Medicine, Konya, Turkey; 2Division of Endocrinology and Metabolism, Selcuk University Faculty of Medicine, Konya, Turkey; 3Department of Biochemistry, Selcuk University Faculty of Medicine, Konya, Turkey; 4Department of Obstetrics and Gynecology, Selcuk University Faculty of Medicine, Konya, Turkey; 5Department of Dermatology, Selcuk University Faculty of Medicine, Konya, Turkey.

**Introduction**

There is some evidence that a rise in the androgen hormone levels increases the risk for the development of a cardiovascular disease, obtained from the studies conducted on women with polycystic ovary and on men with androgenic alopecia. Inflammatory substances tend to increase in polycystic ovary syndrome and in androgenic alopecia. On this basis, we conducted a study that aimed to evaluate the early cardiovascular and metabolic effects in male patients with androgenic alopecia.

**Methods**

A total of 81 people, of whom 41 were patients with androgenic alopecia and 40 were healthy controls, were included in the study. Aged from 25 to 45, none of them had any cardiovascular risk factors, malignancy, any active infections and any liver or kidney diseases. Ambulatory blood pressure was measured for 24 h and sensitive CRP and gelaeticin-3 were studied so as to assess the cardiovascular and metabolic risk.

**Results**

There were no differences between the patient and control groups in terms of ambulatory blood pressure of 24 h, sensitive CRP and gelaeticin-3. A positive correlation was found in the patient group between sensitive CRP and waist and neck circumferences. While there was a positive correlation in the patient group between gelaeticin-3 and HOMA-IR, waist and neck circumferences, a negative correlation was seen with free testosterone. Alopecia level correlated positively with daytime pulse wave velocity and night time reflection magnitude.

**Conclusion**

We did not find any difference in our study in terms of arterial stiffness and chronic inflammation in the early period when the control and androgenic alopecia groups were compared; however, a positive correlation between alopecia level and daytime pulse wave velocity and night time reflection magnitude may be considered as an early signal for atherosclerosis.

**EP1168**

Abstract withdrawn.

**EP1169**

In community-dwelling men, salivary testosterone (Sal-T) concentrations are thought to represent tissue hormone levels and correlate strongly with serum free-T levels. Measurement of salivary glucocorticoid concentrations is a non-invasive and objective means of assessing cortisol exposure in users and non-users of hydrocortisone therapy. We assessed relationships of Sal-T with transdermal testosterone replacement therapy (TD-TRT) and with markers of testosterone exposure. In 40 men aged 50.7 (±13.9) years who were attending a university hospital endocrinology clinic, we measured serum and salivary androgen concentrations by immunassay and liquid chromatography tandem mass spectrophotometry (LC-MS/MS) respectively. In our unit, TD-TRT (Tostran 2% Gel at an initial dose of 30-60 mg of testosterone once daily) is offered to men with sexual symptoms and low fasting serum testosterone (Ser-T) concentrations on at least two consecutive occasions. Ser-T concentrations did not differ between users (n = 23) and non-users (n = 17) of TD-TRT (16.6 ± 10.2 vs 11.4 ± 4.4 nmol/l, P = 0.131). Sal-T concentrations, however, differed greatly (17.14 ± 15.25 vs 0.23 ± 0.15 nmol/l, P < 0.001) as did salivary androstenedione (Sal-A4) concentrations (2.57 ± 2.50 vs 0.17 ± 0.04 nmol/l, P < 0.001) and Sal-T/Sal-A4 (16.26 ± 14.25 vs 1.45 ± 0.94, P < 0.001). Haematocrit and serum prostate specific antigen concentrations (PSA) did not differ significantly between the two groups (0.44 ± 0.05 vs 0.43 ± 0.05 ml/l, P = 0.563 and 1.06 ± 0.66 vs 0.79 ± 0.53 ng/ml, P = 0.170 respectively). With TD-TRT, there was a rise in blood testosterone (4.7 ± 4.2 to 7.9 ± 5.7 nmol/l, P = 0.162), haematocrit (0.42 ± 0.05 to 0.44 ± 0.04 ml/l, P = 0.049) and PSA (0.68 ± 0.33 to 1.06 ± 0.76 ng/ml, P = 0.021) levels. Two hours after a dose of TD-TRT, Ser-T rose modestly (10.5 ± 13.2 to 16.5 ± 11.0 nmol/l, P = 0.003) and Sal-T rose tremendously (7.7 ± 8.1 to 17.0 ± 16.9 nmol/l, P = 0.004). Despite normal Ser-T, haematocrit and PSA concentrations, Sal-T concentrations are 75-fold greater than normal in men using TD-TRT. This is unlikely due to contamination (Sal-A4 concentrations are also high) and may be due to a conduit between skin, the lymphatic system and salivary ducts. Measurement of Sal-T is unlikely to be useful in the monitoring of men using TD-TRT.

**Changes of dihydrotestosterone within the life in men**

Hana Pospıšilová1, Michaela Dušková, Martin Hill & Luboslav Stárka

Institute of Endocrinology, Prague, Czech Republic.

**Abstract**

Dihydrotestosterone (DHT) is the most powerful naturally occurring androgen with three to six times higher biopotency than testosterone. Time onset of benign prostatic hyperplasia and alopecia in middle life could be the result of an imbalance between androgens. The decline of testosterone during lifespan is well known, controversial data can be found concerning the age dependence of DHT levels. We analysed the levels of testosterone, dihydrotestosterone and SHBG from 3076 men and we observed changes of their relationship and the ratio of total and free fraction of T and DHT, depending on age in men. We found that the DHT/T and fDHT/fT ratios during the life of adult males are constant, and that there is no evidence of a reversal in ratios of these hormones after puberty. Given that the ratio DHT/T remains constant during the age, the role in the development of androgenetic alopecia and benign prostatic hyperplasia is rather unlikely. The question remains, however, local status in androgen-dependent tissues, which would change the expression of enzyme, it could be caused just by local change in this ratio. This study was supported by the project MZČR for conceptual development of research organization 00023761 Institute of Endocrinology and grant 17-28692A.

**Male pseudohermaphroditism with 45,X/46,X,idic(Y) karyotype: a case presenting with dysgenetic testis on one side and almost normally sized testis on the other side**

Flavia Di Barì¹, Roberto Viti¹, & Salvatore Benedenga¹,²

¹Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; ²Interdepartmental Program of Molecular & Clinical Endocrinology, and Women’s Endocrine Health, University hospital Policlinico G. Martino, Messina, Italy.

Dicentric Y chromosome [idic(Y)] is the most common structural abnormality of this chromosome, and generally results from altered meiotic breakage and reunion of sister chromatids. Since this rearrangement is unstable, idic(Y) may be lost in subsequent cell cycles, resulting in a mosaic 45,X cell line. Variable are the phenotype and gonads (from streak gonads to ovotestes or dysgenetic testes). Few cases of 45,X/46,X,idic(Y) male pseudohermaphroditism with testes have been reported. We report the case of a 26-yr-old 45,X/46,X,idic(Y) male born at 38 weeks’ uncomplicated gestation who consulted us for infertility. At 3 years, he presented with cryptorchidism, micropenis and scrotal hypospadias. Congenital adrenal hyperplasia was excluded (17OH-progesterone 0.7 ng/ml, testosterone < 20 ng/ml). Scrotal ultrasound revealed the absence of the right testis (RT). RT was eventually found in the pelvis, where uterus and ovaries were absent. Hypospadias repair was performed. The undescended RT, which histologically was described as testicular tissue with fibrosis, was surgically fastened inside the scrotum. At age 26, the patient was slightly overweight (BMI 25.8 kg/sqm), with a male phenotype, normal androgenization and no gynecomastia. He had a satisfactorily engagement with her partner. The RT was hardly palpable, while the left testis was reduced in volume and consistency. At ultrasound, RT was atrophic (1.4 ml), while the left was 10 ml, and both had a hypoechoic and inhomogeneous texture. FSH, androstenedione and 17OH-progesterone were high (30 mIU/ml, 4.1 and 3.4 ng/ml), LH high-normal (9.6 mU/ml), total testosterone low-normal (348 ng/dl), and calculated free-testosterone low (6.1 ng/ml). The response of 17OH-progesterone after cosyntropin stimulation was normal. E2, progesterone, and SHBG were within the female reference range (53 pg/ml, 3.4 ng/ml, and 37.7 mmol/L). Azoospermia was detected at semen analysis. Considering the risk of malignancies within the dysgenetic gonad (10–15%), we advised right gonadectomy.

**Effects of anabolic androgenic steroids on the reproductive system of athletes**

Maria Christou¹,², Panagiota Christou¹, Georgios Markozannes³, Agathocles Tsatsoulias⁴, George Mastorakos⁵ & Stelios Tigas¹

¹Department of Endocrinology, University of Ioannina, Ioannina, Greece; ²Department of Hygiene and Epidemiology, Ioannina, Greece; ³Endocrine Unit, Aretaieion Hospital, National and Kapodistrian University of Athens, Athens, Greece.

**Background**

Anabolic androgenic steroids (AAS) are widely used to improve performance and/or enhance appearance. The aim of this study was to assess the impact of AAS on the reproductive system of athletes.

**Methods**

An electronic literature search was conducted, using the databases MEDLINE, CENTRAL, Scopus and Google Scholar. Studies including AAS use in any type, dose, form or duration of intake were included in the review. Main outcomes were AAS effects on the reproductive system of athletes, as assessed by medical history, clinical examination, hormone analysis and/or semen analysis.

**Results**

Twenty-six studies were included in the review, involving 963 participants, with the median (25th–75th percentile) duration of AAS intake being 16 (8–100.8) weeks. Most studies showed that gonadotropin and testosterone levels decreased during the period of AAS intake, whereas following AAS cessation, they gradually returned to normal levels. The majority of AAS users demonstrated prolonged hypogonadism with persistently low gonadotropin and testosterone levels, lasting for several weeks to months after AAS withdrawal. Most studies have also shown that AAS use results in structural and functional sperm changes, reduction of testicular volume, as well as clitoromegaly and menstrual irregularities. Only 2 out of 26 studies determined AAS effects on fertility and only 2 studies involved female athletes.

**Conclusion**

AAS use results in profound and lasting effects on the reproductive system of athletes and potentially on fertility. Targeted education about AAS abuse and thorough monitoring are needed to prevent negative long-term effects.

**Gonadal status in males with acute coronary syndrome and the extent of coronary artery disease; a comparative cross-sectional analysis**

Adriana Bednárová, Tomáš Koller, Martin Kužma & Juraj Payer

Comenius University Faculty of Medicine, 5th Department of Internal Medicine, University Hospital Bratislava, Bratislava, Slovakia.

**Introduction and aims**

Association between coronary artery disease (CAD) and male gonadal status has been previously suggested, but still remains inconclusive. Aims of our study in males with recent acute coronary syndrome (ACS) were to evaluate the prevalence of hypogonadism, to compare their gonadal status with non-ACS matched controls and to evaluate gonadal status by the extent of CAD.

**Subjects and Methods**

A cross-sectional retrospective study included all consecutive males with recent ACS and age and BMI matched non-ACS controls. Basic demography and standard CAD risk factors were recorded as well as fasting serum levels of total testosterone (TT), sex hormone binding globulin (SHBG), estradiol, follicle-stimulating and luteinizing hormone (FSH and LH) and calculated free androgen index (FAI). First, we evaluated the prevalence of hypogonadism (TT < 7 nmol/l and FAI<24%). Second, we compared patients and control group for ACS associated factors on univariate and multivariate analysis. Third, using the same analysis in patients undergoing coronary angiography we aimed at identifying factors associated with CAD extent (0-1 vessel vs 2-3 vessel disease).

**Results**

96 patients and 49 controls were included. Hypogonadism was confirmed in 20.8% of patients. Patients had lower levels of TT (12.6±13.8 vs 15.7±9.03, P<0.01), FAI (30.29±12.48 vs 36.90±9.816, P<0.01) and higher levels of LH (5.58 IQR 4.4-8.21 vs 5.0 IQR 3.64-6.35, P=0.04) compared with controls. In multivariate analysis, smoking, hypertension, dyslipidemia and FAI were identified as factors independently associated with ACS. 73 patients underwent coronary angiography, 43 had findings of 2-3 vessel disease. Hypertension, BMI and FAI were found as associated factors with CAD extent and FAI as its single independent risk factor.

**Conclusion**

Lower gonadal status was found common (20.8%) in males with recent ACS. It was independent on standard ACS risk factors and was independently associated with CAD extent.

An unusual karyotype in a young adult with a clinical phenotype suggesting a Klinefelter syndrome
Lourdes Garcia-Garcia-Doncel, Isabel Torres-Barea, Manuel Cayón-Blanco, Rosa Marquez-Pardo, Rosario Lopez-Velasco & Gloria Baena-Nieto
Jerez Hospital, Jerez, Spain.

Introduction
46 XX testicular DSD (disorder of sex development) is a rare syndrome characterized by 46 XX karyotype, male external genitalia, azoospermia, sterility and usually hypergonadotropic hypogonadism in adulthood. Approximately 85% of individuals present after puberty with normal penis size, small testes and gynecomastia.

Case report
We present a 34-year-old male who was referred for endocrine evaluation due to slightly high prolactin levels. He underwent surgical correction of bilateral inguinal hernia at the age of 1.8 years old. Three years later, surgery was needed to descend trapped right testicle, showing testicular atrophy. At age 33, the patient requested medical evaluation after one year unsuccessfully attempting to father a pregnancy. Erectile dysfunction and lack of libido were not present. Semen analysis revealed azoospermia. Serum hormone evaluation detected high gonadotropins, low-normal testosterone and normal prolactin levels: LH 13.9 mIU/ml, FSH 32.11 mIU/ml, prolactin 15 ng/ml [4–15], testosterone 311.20 ng/dl [250–836]. Physical examination revealed a descended left testicle of 12 cm and a right testicle unøtticed to palpation. There was no hypospadias and penis size was within the normal range. Patient’s height and weight was 177 cm and 70 kg, respectively. Klinefelter syndrome was suspected. Cytogenetic procedures demonstrated a 46 XX karyotype, and the presence of SRY gene on one of the X chromosomes was detected by fluorescent in situ hybridization.

Conclusions
46 XX testicular DSD SRY-positive should also be considered in the differential diagnosis of adult hypergonadotropic hypogonadism with small testes and sterility. Adult diagnosis can be challenging because of normal sexual development and phenotypic similarities between patients with 46 XX DSD and Klinefelter syndrome, although the latter are usually taller and show less incidence of cryptorchidism.

A case with taurodontism and Klinefelter syndrome
Isilay Taskaldiran1, Tulay Omma1, Anara Karaca1, Alper Taskaldiran2 & Nese Eroso Gulcelik1
1Ankara Education and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey; 2Balgat Dental Public Hospital, Ankara, Turkey.

In this paper we present an 18-year-old patient with Klinefelter syndrome who has taurodontism. Klinefelter syndrome is the most common abnormality of sex chromosomes. It is characterized by hypogonadism, gynaecomastia, azoospermia or oligospermia, and increased levels of gonadotropins. Associated medical disorders can be categorized as follows; cancer, autoimmune disorders, intellectual and psychiatric disorder, osteoporosis, endocrine disorders, venous disease and taurodontism. Taurodontism is a developmental anomaly of a tooth characterized by large pulp chamber and short roots. It affects 0.5–3% of the general population. Taurodontism is observed with several syndromes and anomalies including Klinefelter syndrome. Endodontic treatment of taurodont teeth is tend to be complex and difficult because of the complexity in the tooth morphology, extraction of the taurodont teeth may be difficult and these teeth have risk for early decay. This feature can be seen in permanent and primary teeth, in a single tooth, or in several molars, and can be unilateral or bilateral. Taurodontism must be the part of comorbidity evaluation and patients with Klinefelter syndrome should have regular dental examination and care in order to provide long term oral health and improve quality of life of patients with Klinefelter syndrome.

Methylation of the CPG islands from MTHFR promoter in male infertility
Suzana Vladoiu1, Anca Botzaturu2, Daniela Dinu Draganescu1, Dana Mandu1, Sabina Oroș1, Dina Paun1, Roxana Rosca1,2,3, Corin Badu1 & Gabriela Anton1
1C.I. Parhon’ National Institute of Endocrinology, Bucharest, Romania; 2Stefan S. Nicolau’ Institute of Virology, Bucharest, Romania; 3Carol Davila’ University of Medicine and Farmacy, Bucharest, Romania.

A large number of studies are now focused on the causes of male infertility. Among these are epigenetic modifications, which are important contributors to reproductive pathology in the male by providing dynamic changes of the phenotype according to the environmental and metabolic factors. The most known epigenetic modification is DNA methylation and alterations in this pattern in several genes could induce male infertility. Alterations in DNA methylation patterns in several genes may lead to abnormal male sexual development and infertility. MTHFR is an enzyme involved in the folate pathway and de novo nucleotide biosynthesis but also a good example for gene-environment interaction in phenotype development. This study investigates the promoter methylation status of MTHFR in infertile men from by quantitative methylation-specific PCR in order to investigate possible correlations with sperm abnormalities. Our study includes patients (n=27, median age 31 years, range 26–41 years) recruited from men seeking advice for couple infertility and control group (n=11, median age 30.5 years, range 24–37 years). DNA was isolated from sperm samples and promoter methylation of MTHFR was quantified in qMS-PCR using bisulfite treated DNA samples (EpiTest Bisulfite Kit – Qiagen). Were detected significant correlations that indicate a tendency towards promoter hypermethylation in spermatozoa with low motility (P=0.0130, r 2=0.3886), poor morphology (P=0.0138, r 2=0.3833) and with low sperm count (P=0.0092, r 2=0.4184). Our data suggest that the methylation patterns of the promoter of MTHFR is linked with sperm anomalies of motility, morphology and sperm count, which could lead to male infertility.

How relevant are the complications associated with testosterone treatment in men with hypogonadism?
Ricardo Capitano1, Raquel Castro2, Cátia Ferriño1, Francisco Santos1, Catarina Roque1, Carlos Bello1, João Sequeira1, Catarina Saraiva1 & Carlos Vasconcelos1
1Centro Hospitalar Lisboa Ocidental, Lisboa, Portugal; 2Centro Hospitalar Lisboa Norte, Lisboa, Portugal.

Introduction
Testosterone treatment in patients with hypogonadism has been associated with cardiovascular and prostatic complications. Objective
To describe the evolution of analytical parameters associated to the complications of testosterone treatment in a male population with hypogonadism treated with testosterone. Methods A retrospective, longitudinal study in which the clinical data of male adults with hypogonadism under intramuscular testosterone therapy were analysed in 2 tertiary centres. The duration and doses of testosterone were recorded. Haematocrit (Hct), total cholesterol (TC), LDL cholesterol (c-LDL), total prostate-specific antigen (PSA) and total testosterone levels were assessed at the beginning and at the end of follow-up. Paired-t-test was used to compare means and the results are shown in mean and standard deviation.

<table>
<thead>
<tr>
<th></th>
<th>Hct (%)</th>
<th>TC (mg/dl)</th>
<th>c-LDL (mg/dl)</th>
<th>PSA (ng/ml)</th>
</tr>
</thead>
<tbody>
<tr>
<td>First measurement</td>
<td>42.9±5.0</td>
<td>194.3±41.5</td>
<td>114.1±37.3</td>
<td>1.4±1.7</td>
</tr>
<tr>
<td>Final measurement</td>
<td>44.0±4.4</td>
<td>191.7±30.2</td>
<td>110.8±28.3</td>
<td>1.7±2.4</td>
</tr>
<tr>
<td>Difference</td>
<td>1.1±4.4</td>
<td>−2.6±38.2</td>
<td>−3.4±34.8</td>
<td>0.3±1.6</td>
</tr>
</tbody>
</table>

The results were compared with normal values. Z values of 0.01 and 0.30 correspond to a normal distribution.
Results
We analysed 128 patients, 35% primary and 65% secondary hypogonadism. The mean age was 49.6 ± 17.3 years. The follow-up time was 2.6 years (0.6–9.4 years). The mean interval between injections was 4.2 ± 2.3 weeks. The final testosterone was 392.0 ± 112.7 ng/dl. The results are summarized in the table below:

<table>
<thead>
<tr>
<th>Treatment with testosterone resulted in increased Hct and PSA values, however only the Hct difference proved statistically significant.</th>
<th>Spearman correlation test revealed a positive and statistically significant correlation between the increase of testosterone levels and the increase of Hct (r = 0.21; P = 0.03). No hospitalizations for cardiovascular events were reported.</th>
</tr>
</thead>
</table>

Discussion
The rise of Hct, although statistically significant, was low. The remaining parameters did not show statistically significant increases so testosterone therapy appears to be safe from a cardiovascular and prostatic perspective.

Evolution of healthcare demand in a public gender identity clinical center in Valencia (Spain)
Victor Atienza Moya,1 Marcelino Gomez Balaguer,1 Felipe Hurtado Murillo,2 Santiago Garcia Torres1, Eva Maria Riera Sabater1, Christian Salim Vendrell2 & Antonio Hernandez Mijares1,3
1Endocrinology Service, Doctor Peset University Hospital, Valencia, Spain; 2Sexual psychology and reproductive health unit, Doctor Peset University Hospital, Valencia, Spain; 3Medicine department, University of Valencia, Valencia, Spain.

Introduction
The prevalence of transsexuality in Europe is uncertain in absence of epidemiological studies, so it’s difficult to implement public healthcare strategies. Aim To describe healthcare demand evolution in a gender identity clinical service in our country. Methods Our center is a public university hospital placed in Valencia (Spain). It is a reference center on gender dysphoria from two provinces (Valencia and Castellon), with a target population of 2.646.801 inhabitants ≥14 years old (50.8% women and 5.5% adolescents). We reviewed medical records of patients referred from 2008 to 2016, excluding gender-non conforming people without demand of hormonal or surgical intervention. Results We attended 331 transsexual people with eligibility criteria for pubertal block, cross hormonal treatment or surgery; 41.7% transsexual men (FxM) and 58.3% transsexual women (MxF). In FxM and MxF, 6% in FxM and 30% in MxF had previously started any kind of treatment. 82% FxM and 56% MxF were living in desired role at the initial evaluation. Before 2011 no adolescent was referred while between 2012 and 2016 were attended 82 of them. In adolescents, sex ratio was favoring natal males before 2014 (2.9:1) and it changed in 2015 and 2016 (1.7:1–1:1.5, and 2016 were attended 82 of them. In adolescents, sex ratio was favoring natal female. Minor represented 16% of patients in 2012–2014 and 52% nowadays. We performed 34 hysterectomies (34.6% of patients older than 18 years), 25 mastectomies (25.5%) and implanted 20 breast prosthesis (13.1%), surgeries performed in private centers were not accounted. For genitoplasty surgery they were referred to another national surgery center. Conclusions Demand for transgender care shows an important increase in our geographical area. This increase is due to adolescent population. There is a significant variation of the sex ratio favoring transsexual men. This results can be explained by sociocultural factors. The current investigation examines the association between CDX2 VDR polymorphism and male infertility. Herein, we hypothesized that leptin directly affects mitochondrial function, dynamics and biogenesis of Sertoli cells (SCs). Rat Sertoli cells (Ser-W3) were treated (n = 5 for each group), during 24 h at 37°C 5% CO2, with different concentrations of leptin (5 ng/ml as reported in normal mice, 25 ng/ml as reported in obese mice and 50 ng/ml as a supraphysiological concentration) and the results were compared to a condition without leptin. Western Blot was performed to determine protein levels of mitochondrial complexes. qPCR was performed to determine expression levels of several genes involved in mitochondrial biogenesis and to assess mitochondrial DNA copy number. Mitochondrial membrane potential was determined by JC-1. Direct leptin exposure did not alter SCs proliferation rate, though all leptin concentrations decreased SCs metabolic activity. That was accompanied with alterations in the expression levels of the different mitochondrial complexes and also of genes involved in mitochondrial biogenesis. In addition, the highest concentration of leptin decreased mitochondrial membrane potential. Finally, mitochondrial DNA copy number was not sensitive to the treatment with the different leptin concentrations. Overall, the results show a direct action of leptin on Sertoli cells mitochondrial function and biogenesis with implications in the nutritional support of spermatogenesis, which is a novel mechanism by which leptin can affect the reproductive potential of males.

The CDX2 VDR polymorphism (rs11568820) is located in the 5′-untranslated region of the VDR gene. Objective The current investigation examines the association between CDX2 VDR polymorphism and male infertility. Subjects and methods The study was conducted on 69 infertile men, aged between 20 and 50 years, divided into three groups, based on spermatic parameters: group with azoospermia (19 subjects), group with severe oligospermia (38 subjects), and 37 age-matched controls. CDX-2 VDR gene polymorphisms were performed by PCR-RFLP. Vitamin D was assessed by electrochemiluminiscent method. Results The evaluation of Vitamin D levels was found to be significantly decreased in infertile patients group versus controls (P = 0.0198). The lowest Vitamin D levels were characteristic for azoospermia patient group (median = 18.34 ng/ml, range = 14.89–19.6 ng/ml), than controls (median = 24 ng/ml, range = 18.2–36.10 ng/ml). The analyses for CDX2 VDR polymorphism in infertile patients showed that six cases were homozygote (GG), 28 heterozygote (GA) and 35 homozygote (AA). The frequency of G allele was 0.29, and 0.71 for A allele, χ2 = 0.014. In control group the analyses of CDX2 VDR polymorphism revealed that 10 cases were homozygote for G allele (GG), 19 were heterozygote (GA) and 8 were homozygote (AA). The frequency of G allele in population was 0.53, for A

Leptin modulates Sertoli cells mitochondrial function and biogenesis with implications for the nutritional support of spermatogenesis
Bruno M Moreira1,2, Ana D Martins1,2, Mariana P Monteiro1,2, Mário Sousa1,2, Marco G Alves2,4 & Pedro F Oliveira2,4
1Department of Microscopy, Laboratory of Cell Biology, Abel Salazar Institute of Biomedical Sciences (ICBAS), University of Porto, Porto, Portugal; 2Unit for Multidisciplinary Research in Biomedicine, Abel Salazar Institute of Biomedical Sciences (UMIB-ICBAS), University of Porto, Porto, Portugal; 3Department of Anatomy, Abel Salazar Institute of Biomedical Sciences (ICBAS), University of Porto, Porto, Portugal; 4i3S – Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, Portugal.

Current lifestyle, characterized by physical inactivity and a poor diet, is heavily linked with an increased incidence of metabolic diseases. One of the most serious silent co-morbidities of these diseases is infertility. The hormonal link between food intake and energy homeostasis is mediated by the leptin ghrelin axis. Compelling evidence suggests that direct leptin’s action regulates cellular glucose homeostasis and mitochondrial biogenesis. We have recently shown that leptin modulates the nutritional support of spermatogenesis, which may be related with obesity-related male subfertility/infertility. Herein, we hypothesized that leptin directly affects mitochondrial function, dynamics and biogenesis of Sertoli cells (SCs). Rat Sertoli cells (Ser-W3) were treated (n = 5 for each group), during 24 h at 37°C 5% CO2, with different concentrations of leptin (5 ng/ml as reported in normal mice, 25 ng/ml as reported in obese mice and 50 ng/ml as a supraphysiological concentration) and the results were compared to a condition without leptin. Western Blot was performed to determine protein levels of mitochondrial complexes. qPCR was performed to determine expression levels of several genes involved in mitochondrial biogenesis and to assess mitochondrial DNA copy number. Mitochondrial membrane potential was determined by JC-1. Direct leptin exposure did not alter SCs proliferation rate, though all leptin concentrations decreased SCs metabolic activity. That was accompanied with alterations in the expression levels of the different mitochondrial complexes and also of genes involved in mitochondrial biogenesis. In addition, the highest concentration of leptin decreased mitochondrial membrane potential. Finally, mitochondrial DNA copy number was not sensitive to the treatment with the different leptin concentrations. Overall, the results show a direct action of leptin on Sertoli cells mitochondrial function and biogenesis with implications in the nutritional support of spermatogenesis, which is a novel mechanism by which leptin can affect the reproductive potential of males.

DOI: 10.1530/endouros.49.EP1179

Endocrine Abstracts (2017) Vol 49
allele the frequency was 0.47, $\chi^2 = 0.033$. The controls and infertile groups were compared using $\chi^2$-test and the difference was significant ($P = 0.0229$). The GG genotype was found in a low percentage in patients group than controls (8.7% vs 27.03%), and the percentage of AA genotype was higher in infertile group (50.72% vs 21.62%).

Conclusion
Despite numerous publications, the influence of Vitamin D on reproductive health remains ambiguous. Our study showed that infertile patients present low levels of Vitamin D. According the results the A allele may represents a potential risk for male infertility.

**CHARGE syndrome – late diagnosis in adulthood**

Maria Manuel Costa1,2, César Esteves1,2, José-Luís Castedo1,2, Duarte Pignatel12 & Davide Carvalho12

1Department of Endocrinology, Diabetes and Metabolism of Centro Hospitalar de São João, Porto, Portugal; 2Faculty of Medicine, University of Porto, Porto, Portugal; 3Instituto de Investigação e Inovação da Saúde da Universidade do Porto, Porto, Portugal; 4Service of Medical Genetics, Centro Hospitalar de São João, Porto, Portugal.

Introduction
CHARGE syndrome is a rare autosomal dominant genetic disorder with an estimated birth incidence of 1:10,000. It affects multiple organ systems and can have a variable phenotypic expression.

Case report
34-years-old man, referred to Endocrinology in the context of bilateral gynecomastia. He had an acute corneal hydrops which was treated by ophthalmology. Physical examination showed short stature (149 cm), obesity (BMI 31.5 kg/m²), microopenis and cryptorchidism. He presented other problems: coloboma of the iris, bilateral hearing loss, anosmia, craniofacial dysmorphisms (abnormal ear shape, microstomia) and intellectual disability. Patient’s investigation included among others: breast ultrasound which revealed bilateral gynecomastia; testicular ultrasound that demonstrated an empty scrotal sac with the atrophic testes in the inguinal canals; biochemical evaluation showed hypogonadotrophic hypogonadism (FSH 0.42 mUI/ml (n: 1.5–12.4), LH < 0.10 mUI/ml (n: 1.7–8.6), total testosterone 0.08 ng/ml (n: 2.8–8.0) and a low IGF-1 12 ng/ml (n: 140–405). Pituitary had a 3 mm height on MRI; Karyotype result was normal male (46, XY); He started monthly 250 mg/ml enanthate testosterone with poor compliance. Otolaryngology evaluation excluded choanal stenosis/atroxia (peri-nasal sinuses CT showed only exuberant deviation to the left of the nasal septum) and confirmed moderate sensorineural hearing loss (audiogram with about 50 dB hearing threshold bilaterally and normal tympanogram) but the patient refused auditory prosthesis. His echocardiogram was normal. Family history was irrelevant for congenital malformations, intellectual disability, deafness or vision loss and endocrinological problems. CHARGE Syndrome was suspected and molecular study of CHD7 gene was requested. A heterozygous pathogenic variant was identified [c.3106C>T, (p.Arg1036Ter)] and clinical suspicion was confirmed.

Conclusion
CHARGE acronym stands for C-coloboma, H-heart disease, A-atrietasia choaeae, R-retarded growth and retarded development and/or CNS anomalies, G-genital hypoplasia, and E-ear anomalies and/or deafness. Diagnostic criteria currently combined major and minor features are used. Pathogenic variants in CHD7 gene are found in around 80% of CHARGE patients. We present CHARGE Syndrome referred to our clinic due to gynecomastia. Most of CHARGE syndrome patients are diagnosed in childhood infancy and rarely in adulthood. With this clinical report we would like to alert that in the presence of hypogonadotrophic hypogonadism associated with suggestive features, this diagnosis should be considered.

**EP1182**

**Azoospermia revealing the uncommon Jacob’s syndrome**

Abdelkader Yahi, Zakaria Haouchine & Samia Ould-Kablia

Endocrinology Service, HCA, Algiers, Algeria.

Introduction
Dysgonosomies are abnormalities of the number of gonosomes X and Y. They have fewer Phenotypic repercussions than the aneuploidies involving autosomes, and are mostly viable. The 47 XXY are generally boys with normal phenotype. The prevalence is around 1 per 1000 birth boy but undoubtedly under diagnosed given the often normal phenotype associated with this chromosomal formula, in addition to the lack of large-scale studies. There is no gonadal dysgenesis and often no infertility or criminality in the past.

Case report
Our case is a 48 years old patient consulting for primary hypofertility. The anamnesis finds a type 2 diabetes, High blood pressure, orchi-epididymitis at the age of 34 and bilateral unaccompanied varicocele and hydrocele. The patient is an active smoker. Clinically, he is an overweight patient (BMI: 27 kg/m²) with 180 cm height. No other dysmorphia is noted. In the Spermogram, we find an azospermia (00 SPZ), with 1 CC of ejaculation volume. Scrotal ultrasound showed a normal-sized testicles with micro calcifications in the epididymis tail with varicocele and bilateral hydrocele. An Epididymis Cytoponction recovering SPZ (without cryopreservation).

The hormonal status is:
FSH: 1.65 mU/ml (0.95–11.95), LH: 2.40 mU/ml (0.57–12.07)
Testosterone: 5.65 ng/ml (1.42–9.23) or a correct gonadal assessment
Inhibin B 215.4 ng/ml (11.5–368.9) predicting the presence of SPZ in the biopsy
Caryotype 46 XY/47 XYY

The clinical examination and the exploration of the 31 years old partner is without anomaly. The patient is programmed for testicular biopsy in the optic of a possible ICSI.

Conclusion
It appears that many men with 47, XXY syndrome will likely have decreased fertility potential. These patients may ultimately require assisted reproductive techniques in order to achieve pregnancy.

**Prenatal intervention by P271 reduces LH pulsatility and testosterone levels in PCOS condition**

Sarae Zeydabadinejad1, Fahimeh Ramezani Tehrani1, Azita Zadeh-Vakili2 & Mahsa Noroozzadeh1

1Reproductive Endocrinology Research Center, Research Institute for Endocrine Sciences (RIES), Shahid Beheshti University of Medical Sciences, Tehran, Iran; 2Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences (RIES), Shahid Beheshti University of Medical Sciences, Tehran, Iran.

Background
Polycystic ovary syndrome (PCOS) is a frequent endocrine and metabolic disorder and the most common cause of infertility occurring in 5–10% of women of reproductive age. The characteristic endocrine abnormalities of PCOS involve hyposecretion of androgens and LH (as a consequence of increased GnRH frequency). Although PCOS signs generally become obvious at puberty, clinical and experimental evidence suggests an intrauterine origin for the syndrome. On the other hand, kisspeptin antagonists have been shown to reduce LH pulse frequency and amplitude.

Methods
RNAs were extracted from hypothalamus of prenatally androgenized (PNA) (n = 18) and non-PNA female rats (n = 14) thought estrus cycle. The ability of prenatal administration of kisspeptin antagonist P271, to alter GnRH mRNA expression and gonadotropin and steroid hormone levels, was tested using Cybergreen Real-time PCR and ELISA methods, respectively.

Results
Hypothalamic GnRH mRNA levels fluctuated in a cyclic-dependent manner, with a robust increase in the afternoon of proestrus phase. P271 treated animals showed reduced GnRH expression and gonadal steroid and gonadotropin levels.

Conclusion
PNA animals had increased GnRH mRNA expression and LH levels in diestrous phase than controls, which reduced in response to prenatally administered P271. This pilot study, for the first time, shows that prenatal intervention by P271 reduce LH pulsatility and T levels associated with PCOS.

Prenatal testosterone exposure increases anxiety-like behavior in female rats
Aleksandra Rasic-Markovic1, Djuro Macut2, Dragan Hrnčić3, Valentina Cirković1, Bojana Rankov-Petrović2, Nikola Sutulović1 & Olivera Stanojlović1
1Institute of Medical Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Belgrade, Serbia; 2Clinic for Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Polycystic ovary syndrome (PCOS) is characterized by excessive androgen secretion and women with PCOS are at risk of developing anxiety disorders. Maternal testosterone levels in humans have been shown to affect brain development and to be correlated to mental function. During pregnancy, women with PCOS display high circulating androgen levels that may affect the fetus and increase the risk of mood disorders in offspring. This study investigated whether maternal androgen excess causes anxiety-like behavior in offspring. Ten pregnant Wistar rats were injected s.c. with 100 mg/kg testosterone undecanoate (TU) on gestational day 20, while control (C) rats received only solvent. To investigate the presence of anxiety-like behavior in female offspring of TU and C dams, the elevated plus maze (EPM) and open field (OF) test was performed. In the EPM test, offspring of TU dams displayed decrease in the number of open arm entries and in the percentage of time spent on open arms. OF test showed altered pattern of locomotor activity in female TU offspring. Numerous data demonstrate that the early life environment, including in utero plays a key role in later life behavior. The results of our research suggest that prenatal testosterone exposure increases anxiety-like behavior in female offspring.

The dynamics of anthropometric data in fertile age women by various types of the treatment
Saidgankhoja Ismailov & Maryam Abdulkahhabova
Tashkent Paediatric Medical Institute, Tashkent, Uzbekistan.

The aim
To study efficiency of pathogenetic therapy and dynamics of anthropometric indexes for women with obesity of fertile age at different endocrinopathies and through 6 months after treatment.

Material and research methods
On the etiologic factor of patient with obesity were up-divided on three groups: 1 g. are patients with obesity at the polycystic syndrome of ovaries (PCOS) – 30 patients, 2 g. are patients with hypothalamic obesity – 21 cases and 3 g. – patient with endocrine obesity (at a primary hypothyroidism) – 20 patients. Age of patients in a 1th group hesitated 39 from 20 to and 28.3 ± 0.64 averaged year. To all patients have been conducted spectrum of investigations, which include clinical, biochemical, hormonal analysis of the blood. Besides of this, electrocardiography, ultrasound investigation of uteri and ovarium during 11–14 days of periods, and MRS of pituitary. For the 1 g. we administered combination of Synfor 1000 mgs + spironolacton 100 mgs + yodmarinum 100 mgs + L-thyroxine 50 mgs in the morning + antidioregens + antidepressants. For the 2 group: combination of Synfor 1000 mgs + spironolacton 100 mgs + Yodmarin 100 mgs + L-thyroxine 50 mgs + methaboliks + Reduxine (Sibutramin) 15 mgs + antidepressants. For the 3 group: combination of Yodmarin 100 mgs + L-thyroxine 50 mgs.

The results
In 1 and 2 groups of patients marked reliable decline of BMI 1 and 2 degrees after 6 months of treatment, while for patients 3 groups of reliable changes of BMI through 6 months of treatment were not attained at none of degree of BMI Thus, for patients 1 and 2 groups with BMI 3 degrees through 6 months a tendency was attained to the decline of BMI. In addition, renewal of fecundity and pregnancy was attained for the patients of a 1 group – in 19,56%% cases (at 10 patients).

Conclusions
Optimization of treatment of obesity for the women of reproductive age is based on drafting of the individual programs, the choice of that is determined by the values of anthropometric indexes, state of hormonal and metabolic status, features of food behavior and personality-emotional sphere, state of menstrual and reproductive function.

DOI: 10.1530/endoabs.49.EP1186

The disorder of secretion of somatotropic hormone in women with obesity in the polycystic ovaries syndrome (PCOS) by comparison to patients with the non-functional pituitary adenomas (NFPA)
Saidgankhoja Ismailov & Maryam Abdulkahhabova
Tashkent Paediatric Medical Institute, Tashkent, Uzbekistan.

Aim
To study the disorder of secretion of growth hormone for women with obesity in PCOS by comparison to patients with NFPA.

Materials and methods
Under our supervision in the department of neuroendocrinology of the Center of Endocrinology of PH Ministry of RUz ambulatory in a period from September 2015 for December, to 2016, 15 adult patients of fertile age were observed with obesity in PCOS and 15 – with NFPA. Middle age of patients to make 25.5 and 28.9 accordingly. The remoteness of disease hesitated in limits from 7 months to 9 years.

Results
It was set that in both groups there were neuroendocrine violations peculiar to each of pathologies. So, in a 1 group of patients with PCOS such violations, as obesity, met most often, strium, acanthosis, acne, hyperandrogeneniemia, hyperprolomenorhoya, and in the second secondary amenorhoya, hyperprolacnimeniemia, pahlhypoopituitarism. In both groups there was anovulation, and also decline of secretion of STH, IGF–1. In addition, in the group of patients with NFPA the most for certain mionectic basale levels of trope hormones of hypophysis were educed - STH, hypothyroidism, pahhypopituitarism. In both groups there was anovulation, and also decline of secretion of STH, IGF–1. In addition, in the group of patients with NFPA the most for certain mionectic basale levels of trope hormones of hypophysis were educed - STH, hypothyroidism, pahhypopituitarism.

Placental maternal and fetal vascular circulation in healthy non obese and metabolically healthy obese pregnant women
Marina Shargorodsky1,2, Jacob Bar1,2 & Michal Kovo1,2
1Wolfson Medical Center, Holon, Israel; 2Tel Aviv University, Holon, Israel.

Background
Obesity in pregnancy is associated with hyperinsulinemia, impaired endothelial function, inflammatory up-regulation and higher risk of placental pathological lesions. However not all obese individuals demonstrate similar metabolic profiles. The present study was designed to investigate placental histopathology in lesions that are associated with maternal and fetal circulation abnormalities, in non-obese and obese women with and without metabolic alterations.

Methods
332 pregnant women were divided into three groups according to presence of obesity and metabolic risk factors: Group 1 included 163 non-obese metabolically normal (NOMN); Group 2 included 106 obese metabolically normal (OMN); Group 3 consisted 63 obese metabolically abnormal (OMA) subjects.

Results
Placental weight was significantly higher in OMN compared to NOMN (P < 0.000). Maternal vascular supply (MVS) abnormalities of the placental bed differed significantly across groups, and increased from Group 1 to Group 3 in a continuous fashion (31, 38 and 54% respectively, P < 0.005). Fetal vascular supply (FVS) abnormalities rate increased from group 1 to group 3, and was significantly higher in obese subjects with and without metabolic abnormalities, compared to non-obese subjects (9, 20 and 22% respectively, P < 0.021). Willous maturation defect (WMD) rate was higher in OMN subjects compared to NOMN (P < 0.018). In the logistic regression analysis, obesity emerged as a significant predictor of fetal vascular supply abnormalities (P = 0.001) and WMD (P = 0.011).

Conclusion
We demonstrated that obesity, per se, is associated with an increased rate of fetal vascular malperfusion abnormalities, Willous maturation defect, as well as higher placental weight and lower FPR, compared to non-obese subjects.

DOI: 10.1530/endoabs.49.EP1185
Conclusions
1) It is set that in the group of patients with PCOS the most reliable decline of baseline levels of IGF-1 was educed, while the deficit of STH met rarer.
2) For patients with NFPNA took place panhypopituitarism, namely combined deficiency of STH, LH, FSH, TSH, while the deficit of IGF-1 met rarer.
3) The secretions of STH and IGF-1 educed in our research of violation confirm these literatures that for patients with PCOS the decline of levels of STH and IGF-1 takes place on a background of hyperinsulinemia and hyperandrogenemia, that requires further research.

17α-hydroxyprogesterone in non-CAH children and adolescents at different ages
Christian Trummer1, Nicole Hacker1, Julia Münzer1, Michaela Goschkin1,2, Kerstin Koschka1,2 & Barbara Obermayer-Pietsch1,2
1Medical University, Graz, Austria; 2BMed, Graz, Austria.

17α-hydroxyprogesterone (17OHP) is currently used as a diagnostic parameter in children and young adults when a milder form of congenital adrenal hyperplasia (CAH, late-onset) is suspected. A basal serum level of 17OHP (2 ng/ml; 6.0 nmol/l, respectively) has been discussed as cut-off for suspected late-onset disease. We analysed 17OHP in a cohort of children and adolescents without CAH and in confirmed CAH patients to define reference ranges for these age groups. For the analysis of 17OHP, we used a novel automated immunoassay in 506 anonymized samples from children and adolescents with a previous exclusion of CAH by conventional hormone measurement. 302 girls and 204 boys in two age groups from 1–11 and 12–18 years were included. In a subgroup of 49 probands, follow-up samples within one year were available, as well as in 17 out of initially 38 children with genetically confirmed CAH. In prepubertal children at the age of 1–11 years, mean 17OHP serum concentrations were 0.99 ng/ml ± 0.86 (STD) (reference limits 0.31–4.62) for girls and 0.85 ± 0.59 (reference limits 0.31–2.60) for boys, which was not statistically different (P = 0.852). There was also no difference in mean 17OHP serum concentrations at the age of 12–18 years between female 1.39 ± 0.70 (reference limits 0.37–3.26) and male adolescents 1.38 ± 0.67 (reference limits 0.32–2.93) (P = 0.95). Repeated measurements in follow-up samples showed a mean coefficient of variation (CV) for non-CAH samples of 14.2 and 20.8% in CAH patient samples. In our study, baseline 17OHP was a useful marker for the exclusion of late-onset CAH in the majority of samples. Based on the established reference ranges, an overlap with confirmed CAH patients was very small. In suspicious cases, additional hormonal tests as well as stimulation tests of 17OHP have been defined as the standard of late-onset CAH diagnosis and therapy monitoring.

Effects of estrogen and progesterone on the protein expression of EMT- and pluripotency-associated markers in human embryonic stem cells
Soo-Min Kim, So-Ye Jeon & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, Veterinary Medical Center and College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Embryonic stem (ES) cells are pluripotent stem cells derived from a developmental stage of preimplanted embryos. In this study, we investigated the effect of female sex steroid hormones on the characteristics of human ES cells by using a feeder-free culture protocol. In a feeder-free condition without sex hormones, human ES cells assumed the form of tightly packed cells that grow in a monolayer. The cells also displayed clean and defined edges with no evidence of differentiation and expressed several markers specific for undifferentiated ES cells such as POU5F1, SOX2, and NANOG. Next, we investigated whether female sex steroid hormones such as 17β-estradiol (E2) and progesterone (P4) could alter the protein expression of epithelial-mesenchymal transition (EMT) related markers as well as pluripotency markers such as POU5F1, SOX2, and NANOG in human ES cells. The protein expressions of N-cadherin, SNAI1, and SNAI2 were increased while E-cadherin expression was decreased by treatment of E2 or P4 and that the expressions of POU5F1, SOX2, and NANOG were decreased by the treatment of E2 or P4. When E2 and P4 were treated in the combination with estrogen receptor inhibitor (ICI 182,780) and progesterone receptor inhibitor (RU486), respectively, their effects on EMT and pluripotency of ES cells were restored to the control levels. Collectively, these results suggest that E2 and P4 may regulate EMT and pluripotency of human ES cells by mediating their receptors. The present study might be useful to understand the roles of sex steroid hormones in cellular biology of human ES cells. (This research was supported by a grant from the Next-Generation BioGreen 21 Program (no. PJ011355-2015), Rural Development Administration, Republic of Korea.)

Homo-dimerisation of cytochrome P450c17 resolves the conundrum of the dual activities of cytochrome P450c17
Jessica Holien1, Michael Parker2, Alan Conley3, C Jo Corbin3, Raymond Rodgers3 & Lisaundra Martin3
1. St. Vincent’s Institute of Medical Research, Australian Cancer Research Foundation Rational Drug Discovery Centre, Fitzroy, VIC 3065, Australia; 2Department of Biochemistry and Molecular Biology, Bio21 Molecular Science and Biotechnology Institute, University of Melbourne, Parkville, VIC 3010, Australia; 3School of Veterinary Medicine, University of California Davis, Davis, CA, USA; 4Discipline of Obstetrics and Gynaecology, School of Medicine, Robinson Research Institute, University of Adelaide, Adelaide, SA 5005, Australia; 5School of Chemistry, Monash University, Clayton, VIC 3800, Australia.

Reproduction requires the temporal and spatial control of specific and exact signals, delivered by locally regulated hormonal flux. In the case of androgen biosynthesis, cytochrome P450 17α-hydroxylase, 17,20-lyase (P450c17) is the key enzyme. However, P450c17 is a multi-functional P450, so, it synthesizes cortisol in the zona fascicula of the adrenal cortex and also androgen precursors in the adrenal zona reticularis and the gonads. The regulation of this dual activity has been the focus of research studies over many decades and remains unresolved. Functionally, it is known that each of these reactions of P450c17 require electrons transferred by the electron donor cytochrome P450 oxidoreductase (CPR). The first reaction, the 17α-hydroxylation of its substrate, occurs in all cells where P450c17 is expressed. Remarkably, a second, subsequent reaction, namely the 17,20-lyase activity, only occurs in the zona reticularis and gonads. The specificity of the second reaction is due to a non-redox ‘allosteric’ interaction with the haem-protein cytochrome b5. Surprisingly, cytochrome b5 and cytochrome P450 oxidoreductase have overlapping binding sites on the surface of the P450c17 enzyme. This poses the question as to how cytochrome b5 and cytochrome P450 oxidoreductase interact with P450c17 - structurally, functionally and physiologically? This conundrum can be rationalized based on the observation that P450c17 can homodimerize. A homodimer would allow cytochrome P450 oxidoreductase to bind to one P450c17 of the P450c17 homodimer, whilst cytochrome b5 could bind to the other P450c17 simultaneously, at the surfaces distal to the dimer interface. We present our molecular modelling data that predicts that the P450c17 homodimer is a stable structure and that requires further research.

Non-alcoholic fatty liver disease and its relation with sex steroids in men
Frederique Van de Velde¹, Yves Van Nieuwenhove², Marlies Bekaert¹, Anne Hoorens³, Jean-Marc Kaufman² & Bruno Lapauw¹
¹Department of Endocrinology, Ghent University Hospital, Ghent, Belgium; ²Department of Gastro-Intestinal Surgery, Ghent University Hospital, Ghent, Belgium; ³Department of Medical and Forensic Pathology, Ghent University Hospital, Ghent, Belgium.

Background
Obesity associates with co-morbidities as non-alcoholic fatty liver disease (NAFLD). Obese men often present with low testosterone (T) levels. As sex steroids undergo hepatic metabolization and their serum levels depend on hepatic sex hormone binding globulin (SHBG) secretion, NAFLD could contribute to this phenomenon. Previous studies however were contradictory and not based on state-of-the-art technology as mass spectrometry or biopsy-proven NAFLD.

Objective
To assess the relation between biopsy-proven NAFLD and sex steroid levels in obese men undergoing gastric bypass surgery (GBS).

Methods
This cross-sectional study included 56 obese men (mean age 44±11 years; BMI 41.6±4.6 kg/m²) and 56 healthy, age-matched control men (mean age 44±11 years; BMI 23.5±1.8 kg/m). T and estradiol (E2) measured using LC/MS-MS, SHBG by immunoassay and free hormone fractions were calculated. Surgical liver biopsies scored using NAFLD activity (NAS) and Steatosis, Activity and Fibrosis (SAF) scores.

Results
Obese men showed lower T, free T (FT) and SHBG levels, lower (F)T/(F)E2 ratio (all \( P<0.001 \)) and higher FE2 (\( P=0.019 \)) compared to controls. Within the GBS patients, no significant differences were found for sex steroid levels according to NAS-based NAFLD severity. However, with increasing grade of steatosis, trends towards lower T and FT levels, and lower (F)T/(F)E2 ratios were observed (\( P<0.059 \)). No associations between sex steroid levels and other NAFLD features were detected. Using SAF, we found that lower (F)T levels correlated with steatohepatitis (\( P=0.014 \)). These correlations were independent from age, BMI, HOMA-IR and SHBG. Remarkably, no differences in SHBG or (F)E2 levels according to NAFLD severity were found.

Conclusion
This study confirmed lower T levels in obese as compared to normal-weight men. In these obese men, overall NAS-based NAFLD severity was not associated with these lower T levels although presence of steatohepatitis and increasing grade of steatosis was related to lower (F)T levels and FT/FE2 ratios.

An adverse outcome in a thyrotoxic lady with propylthiouracil induced necrotising leukocytoclastic vasculitis
Emily T Mudenha, Anusha P Panthagani, Jonathan M Batchelor, Rand Hawari, Roger Stoneworth & David Hughes
Royal Derby Hospital, Derby, UK.

A 37 year old lady with relapsing Graves’ thyrotoxicosis initially managed on a ‘block and replace regime’ with propylthiouracil and levothyroxine for 7 years had her medication changed to carbimazole after a relapse from non-compliance but developed granulocytosis. She was then restarted on an increased dose of propylthiouracil alone. Two weeks later, she developed tender purpuric lesions and was admitted after developing painful bullous lesions to her lower limbs. She had previously noted haemorrhagic lesions on her limbs but these would resolve within a week. Investigations revealed positive MPO-ANCA antibodies, skin biopsy confirmation of necrotising leukocytoclastic vasculitis and no evidence of systemic involvement on imaging. She had rheumatology and dermatology input regarding the vasculitic rash. Initial treatment involved stopping propylthiouracil, starting beta blockers, short course of pulsed high dose methylprednisolone and wound care. Within a few weeks, her skin lesions were improving, but she was becoming progressively more thyrotoxic. She was commenced on potassium iodide therapy in preparation for a total thyroidectomy. Unfortunately, her temperature increased and she rapidly went into septic shock due to pneumonia requiring inotropic and respiratory support on the intensive care unit before dying a few days later.

Discussion
Necrotising vasculitis remains a rare complication of propylthiouracil therapy. It is classically, as in our patient, strongly associated with positive MPO-ANCA antibodies. Clinical presentation is variable. Treatment includes discontinuation of the drug, immunosuppression and good wound care. The prognosis in the absence of major organ vasculitis as in our patient is usually good, and our patient seemed to be making good progress whilst being worked up for thyroidectomy. However, her low grade tachycardia and raised inflammatory markers masked the early onset of sepsis. Our case highlights the importance of clinical vigilance for sepsis in patients with the rare complication of propylthiouracil induced necrotising leukocytoclastic vasculitis.

Synchronous papillary thyroid carcinoma and primary hyperparathyroidism: a rare association
Nadia Khessairi, Ibtissem Oueslati, Malika Chihouai, Meriem Yazidi, Ons Rjeb, Fatma Chaker & Hedia Slimane
Department of Endocrinology, La Rabta hospital, Tunis, Tunisia.

Introduction
Although the association between parathyroid and thyroid diseases is not uncommon, the coexisting of parathyroid adenoma causing primary hyperparathyroidism (PHPT) and papillary thyroid carcinoma (PTC) is rare. Probably this can be partially explained by different embryologic origin of thyroid and parathyroid cells. Herein, we report a case of PHPT associated with synchronous bifocal PTC.

Observation
A 65-year-old woman was referred to our department with incidental hypercalcaemia and biochemical PHPT. A Technetium (99mTc) sestamibi scintigraphy showed a distinct functioning nodule in the lower right pole of the thyroid. Ultrasonography of the neck revealed parathyroid adenoma at the inferior pole of the right thyroid lobe and bilateral thyroid nodules. The patient was subjected to uncomplicated right inferior parathyroidectomy and synchronous total thyroidectomy. Postoperative histopathological examination confirmed the diagnosis of parathyroid adenoma with coincidence of papillary thyroid carcinoma. After surgery, serum parathormone and calcium returned to their normal values and patient was referred to the department of Nuclear Medicine for a radioactive iodine ablation therapy.

Conclusion
Concomitant papillary thyroid carcinoma and primary hyperparathyroidism is rare. It still remains controversial whether these two pathologies happen coincidental or are caused by specific risk factors or genetic changes.

A case with langerhans cell histiocytosis having papillary microcarcinoma of thyroid: two birds in one nest
Hatice Ozisik1, Buam Sarer Yurekli1, Nilufar Ozcenrik Kutbay1, Ilker Altun1, Yesim Ertan2, Ozer Makay & Gokhan Ozgen1
1Division of Endocrinology and Metabolism, Ege University, Izmir, Turkey; 2Division of Pathology, Ege University, Izmir, Turkey.

Introduction
Langerhans cell histiocytosis (LHH) is an idiopathic, clonal, pleomorphic, neoplastic disorder characterized by the presence of atypical histiocytic cells which are locally or commonly seen in bone, lung, hypothalamus, liver, lymph nodes, mucocutaneous tissues with damaging them. Case
58 year-old male patient applied to our clinic due to fatigue. On his physical examination, lymphadenopathy and hepatosplenomegaly were absent. In his history, he had an operation owing to Large-cell neuroendocrine carcinoma in 2014. He took chemotherapy but no radiation. In surveillance, a thyroid nodule was detected in PET-CT. Thyroid US revealed a nodule 5 cm in diameter in the right lobe. He underwent bilateral total thyroidectomy. In pathological examination, left lobe was reported as thyroid papillary microcarcinoma, follicular variant and langerhans cell histiocytosis, right lobe was reported as follicular nodular disease. The focus of papillary microcarcinoma in 0.2 and 0.1 cm diameter was seen in the left lobe and langerin positive focus was observed in the morphology of langerhans cells histiocytosis consisting of langerhans cells and eosinophils. Bone marrow biopsy and abdominal MR were normal. On his laboratory examination urine dansity was normal. FSH: 5.44 mIU/ml (1.5–12.4), LH: 4.74 mIU/ml (1.7–8.6), total testosterone: 2.35 ng/ml (2.8–8), prolactin: 5.87 ng/ml (4.6–21.4), TSH: 0.37 mU/ml (0.35–5.50), thyroglobulin <0.9 mg/l (1.6–60) were detected. In pituitary MRI, nodular focus with different contrast enhancement according to pituitary gland referred as intermediate lobe was detected in the middle posterior of pituitary gland

Discussion
In LHH and papillary thyroid carcinoma coexistence, papillary microcarcinoma was frequently encountered. Gold standard treatment for limited LHH is surgical resection and it has usually good prognosis. Diffuse goitre (59%) or nodules (25.8%) can be detected in patients with LHH having thyroid gland involvement. Large cell neuroendocrine carcinoma of the lung is rarely seen and has poor prognosis.

DOI: 10.1530/endoabs.49.EP1194
Background

Amiodarone is a potent antiarrhythmic drug used to treat tachyarrhythmias. However, it is linked to a number of adverse effects, including thyroid dysfunction. It is the main cause of drug-induced thyrotoxicosis. Here we report a case of amiodarone-induced thyrotoxicosis (AIT) in a patient with complex ventricular arrhythmia.

Case report

A 23-years-old woman with dilated cardiomyopathy, severe depression of ejection fraction of left ventricle and complex ventricular dysrythmia under amiodarone treatment 200 mg id since June of 2013, presented asthma and weight loss since march of 2016, with worsening of heart failure. TSH was <0.008 µIU/ml (0.4-4.0), Free T4 (FT4) 3.4 ng/dl (0.8-1.9) and Free T3 (FT3) 6.1 pg/ml (1.8-4.2). Autoimmunity was negative. Thyroid ultrasound: normal dimensions, without nodularity or increased vascularity at doppler study.

On physical examination she had oedemas of the lower extremities. A marked dysrhythmia. However, is linked to a number of adverse effects, including thyroid dysfunction. The most common cause of loss of adequate substitution on a stable dose of replacement therapy is noncompliance. Impaired absorption and weight gain are also possible. We present a rare case of renal loss of thyroxin in severe nephritic syndrome.

Conclusion

In this case, a type 2 AIT was diagnosed, resistant to medical therapy and with steroids side effects. This uncommon scenario illustrates the difficulty of controlling thyrotoxicosis in a patient of high risk of sudden death, requiring an invasive procedure to its resolution. Thereby, when thyrotoxicosis is uncontrollable and patients are at high cardiovascular risk, thyrotoxicity should be considered for the resolution of AIT. This could be lifesaving by controlling the disease, avoiding iatrogeny and maintaining the possibility of amiodarone therapy.

Where is the thyroxin disappearing?

Ioannis Svilias, Filip Gabalec & Jan Cap

4th Department of Internal Medicine, Hematology and Endocrinology, Faculty of Medicine, Charles University Hospital, Hradec Králové, Czech Republic.

Introduction

The most common cause of loss of adequate substitution on a stable dose of replacement therapy is noncompliance. Impaired absorption and weight gain are also possible. We present a rare case of renal loss of thyroxin in severe nephritic syndrome.

Case report

We present a 46 year-old female after total thyroidectomy for Graves-Basedow disease. From 2005 she was euthyroid on a stable dose of L-thyroxin (100 µg/day). On physical examination she had oedemas of the lower extremities. A marked hypercholesterolemia (17.49 mmol/l, normal range 0.5-2.2 mmol/l) and a very high TSH value (92.5 mIU/l, normal range 0.27 - 4.2 mIU/l) were found. Celiac disease was excluded. Abdominal ultrasound was performed with a normal finding. During examination proteinuria (6.19 g/day, normal range to 0.14 g/d) and thyroxin loss in urine (50 µg/l) were found. Renal biopsy was performed with the finding of membranous glomerulopathy (glomerulonephritis). Treatment will be started in nephrology department. After increase of L-thyroxin dose (300 µg/den) normalisation of TSH was established.

Conclusion

Nephrotic syndrome increases L-thyroxin requirements because of urinary loss of free and protein-bound thyroid hormones. Physical examination, careful history taking and laboratory findings are the key to the accurate diagnosis. After treatment of membranous glomerulopathy reduction of L-thyroxin dose is expected.

EP1196

Relapsed Graves’ thyrotoxicosis following total thyroidectomy 20 years earlier

Edouard Mills, Ali Naqi & Jeannie Todd

Imperial Centre for Endocrinology, Imperial College NHS Trust, London, UK.

We report a 55-year-old non-smoker with a history of Graves’ disease diagnosed in 1990 at age 29 years old. Due to poor compliance to therapy, she underwent a total thyroidectomy in 2000. She was without clinical or laboratory signs of thyroid dysfunction for 15 years. In 2015, however, her physical condition deteriorated and presented undetectable TSH, FT4 2.4 ng/dl and FT3 4.0 pg/ml. Methimazole was tapered and amiodarone was restarted. Three months after surgery, normal thyroid function and improvement of her clinical condition was observed.

Conclusion

In this case, a type 2 AIT was diagnosed, resistant to medical therapy and with steroids side effects. This uncommon scenario illustrates the difficulty of controlling thyrotoxicosis in a patient of high risk of sudden death, requiring an invasive procedure to its resolution. Thereby, when thyrotoxicosis is uncontrollable and patients are at high cardiovascular risk, thyrotoxicity should be considered for the resolution of AIT. This could be lifesaving by controlling the disease, avoiding iatrogeny and maintaining the possibility of amiodarone therapy.

Hyalinizing trabecular tumor of the thyroid gland

Buket Yilmaz Bulbul1, Mehmet Celik1, Semra Ayturk1, Nuray Can2, Ebru Tastekin2, Atakan Sezer3, Funda Ustun2 & Sibel Guldkiken1

1Department of Endocrinology and Metabolism, Medical Faculty, Trakya University, Edirne, Turkey; 2Department of Pathology, Medical Faculty, Trakya University, Edirne, Turkey; 3Department of Surgery, Medical Faculty, Trakya University, Edirne, Turkey; 4Department of Nuclear Medicine, Medical Faculty, Trakya University, Edirne, Turkey.

Hyalinizing trabecular tumor is an uncommon, controversial lesion of thyroid gland. Hyalinizing trabecular neoplasm share similarities with medullary thyroid carcinomas (MTC) and exhibit nuclear features resembling papillary thyroid carcinoma (PTC). However, the clinical behaviour unclear. We aimed to present a rare case of hyalinizing trabecular tumor of thyroid gland and ten-year follow up.

A 54-year-old woman who was being followed up because of multinodular goiter on examination of neck, the thyroid gland was nodular, measured 20 mm×10 mm and non-tender. Serum FT3, FT4 and TSH were within normal limits. Ultrasonography showed a hypoechoic nodular lesion of 12 mm×9 mm in the right lobe and 29 mm×11 mm hypoechoic nodular lesion in the left lobe. Fine needle aspiration cytology the diagnosis was suspicious due to cells similar to papillary carcinoma cells. She underwent a total thyroidectomy. Histopathological examination showed the nuclei were oval, slightly pleomorphic, trabecular growth pattern, intratrabeicular hyalinization and nuclei with grooves and cytoplasmic pseudoinclusions. Immunohistochemically the tumor was thyroglobulin positive, and calcitonin and HBME-1 negative, galec tin 3 and TTF-1 focal

19th European Congress of Endocrinology 2017

Endocrine Abstracts (2017) Vol 49
positive. The pathological diagnosis was hyalinizing trabecular tumor with lymphocytic thyroiditis. l-thyroxine 0.1 mg/day therapy was started. The patients treated was found to be euthyroid over the ten year follow-up period. Hyalinizing trabecular tumor is a unique neoplasm of follicular derivation. Most authors consider this tumor to be benign. The differentiation of hyalinizing trabecular tumor from other thyroid tumors such as PTC and MTC, based on overlapping nuclear features. Cytological diagnosis of hyalinizing trabecular tumor has a characteristic trabecular growth pattern and hyalinizing stroma. The prognosis of hyalinizing trabecular tumor is favorable.

Conclusions
The rare finding of increased thyroid hormones (T3 and T4) with normal or increased TSH level presents a differential diagnosis between a TSH secreting pituitary adenoma and RTH. Mutational analysis of the TR-β gene enables both definitive diagnosis of RTH and family screening. We present a novel mutation of this gene that has not been previously reported. Although, there have been reported mutations affecting another aminoacid substitution at this position (L450F) in cases of RTH.

DOI: 10.1530/endoabs.49.EP1200

Riedel thyroiditis presenting with pleuro-pericardial involvement
Asena Gökçay Canpolat & Murat Faik Erdog˘an
Department of Endocrinology and Metabolism, Ankara University Faculty of Medicine, Ankara, Turkey.

Riedel thyroiditis (RT) is a rare kind of chronic thyroiditis which may be a part of a multifocal systemic fibrosis syndrome. It is generally accepted as a thyroid manifestation of IgG4 related systemic disease. We hereby present a 54 year old woman who was suffering from shortness of breath because of a mass lesion originating from thyroid and invading neck and upper mediastinal structures, leading to dyspnea and dysphagia, as shown by CT, 15 years ago. After an isthmectomy and decompression surgery she was diagnosed as RT. Corticosteroid therapy was given as the frontline agent and she responded well to the therapy, the dose was tapered off in about 6 months. However she was readmitted with severe dyspnea and chest pain with no large mass lesion at neck. Investigations revealed an exudative pleural and pericardial effusion and mediastinal enlargement. The detailed evaluation of pleuropéricardial effusion, did not point out any specific etiology. Glucocorticoid therapy was restarted along with colchicines and azathioprine. Alluviation of the symptoms were achieved. She was followed by tumoxifene and colchicines on the long term. She is now symptom-free with loss of the soft tissue mass and effusions for more than 15 years. This case is interesting because of reporting pleuropéricardial involvement and the success of being in remission for more than 15 years. Although the etiology and definite treatment of the IgG4 related thyroid diseases are unclear; expanding knowledge about IgG4 related diseases will further clarify the optimal approach to RT.

DOI: 10.1530/endoabs.49.EP1199

A Novel Thyroid Hormone Receptor Beta Gene Mutation: p.L450F (c.C1633T) in a family with Resistance to Thyroid Hormone
Lourdes Garcia-Garcia-Doncel, Rosa Martinez-Pardo, Isabel Torres-Barea, Glória Baena-Nojo, Rosario Lopez-Velasco & Manuel Cayón-Blanco
Jerez Hospital, Jerez, Spain.

Introduction
Resistance to thyroid hormone (RTH) is a rare autosomal dominant (AD) condition caused by mutations of the Thyroid Hormone Receptor Beta (TR-β) gene, resulting in generalized tissue resistance to thyroid hormone. Euthyroidism is usually maintained at the expense of increased levels of thyroid hormones and with non-suppressed TSH.

Case report
A 61 year-old woman was evaluated for increased free T4 index; 2.29 ng/dl (normal, 0.9–2.1) and free T3 index: 4.59 pg/ml (normal, 2.57–4.43) and normal TSH levels:3.22 μIU/ml (normal, 0.3–5)). Analysis were repeated and laboratory error was excluded. The patient was asymptomatic. A physical examination detected a moderate diffuse goitre and a normal resting heart rate. Thyroid antibodies were negative. Sex hormone binding globulin and gonadotrophin α-subunit were within the normal range and pituitary magnetic resonance imaging ruled out a pituitary adenoma. Thyroid ultrasound showed a multinodular goitre with parenchymal consolidation. Thyroid scintigraphy showed a diffuse goitre with increased technetium uptake. A diagnosis of RTH was suspected. Molecular genetic studies showed a change in exon 10 of the TR-β gene: p.L450F (c.C1633T). Later, our patient’s daughter was also diagnosed of RTH and AD inheritance was demonstrated in family segregation studies.

Conclusions
We report on a case of a 63-year-old male patient with a history of metastatic DTC, with both lung and bone metastases and an additional paravertebral mass. The patient presented with enlargement of the left thyroid lobe. FNA was positive for malignancy and subsequent CTS were negative for distant metastases, whereas laboratory tests showed elevated thyroglobulin (Tg> 500 ng/ml). The patient underwent total thyroidectomy and the pathology report revealed a multifocal, follicular variant of papillary thyroid cancer, with localized extrathyroidal extension. He was then referred to the Endocrinology Department. After withdrawal of levothyroxine (preablation laboratory results: TSH: 52.6 μU/ml, Tg: 9000 ng/ml) the patient received 80 mCi of I 131 (RAI uptake: 7.6%). A subsequent SPECT/CT scan revealed lung and bone metastases (ribs with adjacent soft tissue mass). Thoracic CT showed bilateral, scattered lung metastases with lymph node enlargement of the hilus as well as a paravertebral soft tissue mass 6.2×3.8 cm of diameter which metastasize to the 7th rib and the

Tuberculosis of the thyroid gland: a case report
Innen Sakka, Bitissem Oueslati, Fatma Chaker, Ous RJeb, Meriem Yazidi, Malika Chiahoui & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
The involvement of the thyroid gland by tuberculosis is extremely uncommon even in countries in which tuberculosis is endemic. In the majority of the reported cases, thyroid function was preserved. Herein we report a case of thyroid tuberculosis in a patient with a primary hypothyroidism.

Case report
A 52-year-old woman was referred to our department for a gradually growing goiter without compressive symptoms. She presented with a productive cough. Her Past medical history included type 2 diabetes mellitus, goiter and primary hypothyroidism in the last fifteen years. On examination, she had a plunged multinodular goiter. The rest of the clinical examination and laboratory tests were normal. Chest radiography showed a nodule located in the right lung upper lobe. Cervical ultrasonography revealed an enlarged heterogeneous multinodular thyroid gland. Total thyroidectomy and lung nodule biopsy were performed to the patient. Thyroid histopathological examination showed benign multinodular hyperplasia with epitheloid cell granulomas and giant cells. The histopathological examination of the lung biopsy showed foci of granulomatous inflammation along with caseous necrosis. The diagnosis of tuberculosis involving the lungs and the thyroid gland was established. Then, patient was put on antitubercular drugs with a good recovery.

Conclusion
Although thyroid tuberculosis is a rare condition, it should be considered as differential diagnosis of thyroid masses especially in an endemic country. In this case, the use of fine needle aspiration biopsy can help to avoid unnecessary surgical interventions.

Follicular variant of papillary thyroid carcinoma with lung, bone, and soft tissue metastases
Constantinos Belis1, Stavroula Gavriilidou1, Aikaterini Afentoulidi1, Kalliopi Xydiari1, Vasilios Athanasiou1, Sofia Malaktari- Skarantavou1, Sofia Saranti2 & Christos Saividis1
1Department of Endocrinology, ‘Hippocratio’ General Hospital of Athens, Athens, Greece; ‘Nuclear Medicine Department, ‘Saints Anargyri’ Cancer Hospital, Athens, Greece.

We report on a case of a 63-year-old male patient with a history of metastatic DTC, with both lung and bone metastases and an additional paravertebral mass. The patient presented with enlargement of the left thyroid lobe. FNA was positive for malignancy and subsequent CTS were negative for distant metastases, whereas laboratory tests showed elevated thyroglobulin (Tg> 500 ng/ml). The patient underwent total thyroidectomy and the pathology report revealed a multifocal, follicular variant of papillary thyroid cancer, with localized extrathyroidal extension. He was then referred to the Endocrinology Department.

Severe acute hepatitis associated with thyrotoxicosis

Isabel Torres-Barea, Lourdes García-García-Doncel, Manuel Cayón-Blanco, Gloria Baena-Nieto, Rosario López-Velasco & Rosa Márquez-Pardo
Hospital De Jerez, Jerez De La Frontera, Spain.

Liver dysfunction related to hyperthyroidism encompasses abnormalities associated with the effects of thyroid hormone excess, drug-related hepatic injury, and the presence of concomitant liver disease. Mild liver abnormalities such as hypoalbuminemia and increased serum level of liver enzymes may be seen in 45–90% of patients with hyperthyroidism. Nevertheless, there are a few case reports of thyrotoxicosis associated with severe acute hepatitis. A 37 year old woman presented to the Emergency Department with abdominal pain associated with diarrhea for 2 weeks and new-onset jaundice for 2–3 days. She had been diagnosed with hyperthyroidism 6 months before and it was prescribed treatment with methimazole but she decided to stop the treatment one month later. On initial physical examination there was significant jaundice and tachycardia. Blood pressure and body temperature were normal. There was no exophthalmos and the thyroid gland was diffusely enlarged. There were no findings of heart failure, chronic liver disease, lymphadenopathy or hepatosplenomegaly. Laboratory workup showed hyperthyroidism and abnormal liver function tests: FT3 was 21.59 pg/ml (normal 2.57–4.43), FT4 7.77 ng/dL (normal 0.9–2.1), TSH 0.01 mU/l (normal 0.3–4.2), Total bilirubin 8.47 mg/dL (normal 0.1–1), direct bilirubin 7.7 mg/dL (normal 0.05–0.2), ALT 674 IU/L (normal 0–31), AST 664 IU/L (normal 0–31), GGT 42 IU/L (normal 5–36), albumin 2.9 g/dL (normal 3.4–4.8). After excluding other etiologies for her liver injury, she was treated with antithyroid medications. One week after starting treatment we observed an important decline in FT3 to normal values, bilirubin and liver enzymes dropped to half of maximal values. One month later normalization of thyroid hormone and near normalization of bilirubin and liver enzymes was documented. In conclusion, severe acute hepatitis is rarely associated with thyrotoxicosis. Hyperthyroidism should be ruled out in patients with acute liver failure of unknown origin.

Isolated ocular Måstehnia Gravis and Graves’ disease – a challenging ophthalmopathy

Raquel Vaz de Castro1, José María Aragüés2, Florbela Ferreira3, Vânia Gomes3, Ana Wessling1, Ana Cláudia Fonseca1, Isabel Conceição1 & Maria João Bugalho1
1Santa Maria Hospital, Lisboa, Portugal; 2Beatriz Ángelo Hospital, Lisboa, Portugal.

We report the case of a Caucasian woman presenting with a challenging differential diagnosis of ophthalmopathy. The patient was diagnosed with Graves’ disease during postpartum at the age of 28 (TSH <0.001 U/mL; FT3 6.7 ng/dL; FT4 2.2 ng/dL; TSH 15 U/L). Besides 16 pack-year smoking history, no other previous disease was known. At examination, exophthalmos grade III/III with bilateral lid retraction was evident. Persistency of the disease despite optimal use of medical antithyroid therapy led to radioactive iodine ablation (10 mCi) at the age of 34. Three months afterwards, hypothyroidism was detected on blood tests (TSH 12 U/mL; Free T4 0.7 ng/dL) and therapy with 100 µg of l-thyroxine was initiated. Two months after therapy, thyroid function was normalized (TSH: 1.3 U/mL; Free T4: 1.1 ng/dL). Exophthalmia persisted, even though T3Ab title was virtually undetected (0.6 U/L). At the age of 45, there was onset of binocular vertical diplopia and blurred vision. Upon administration of 500 mg ev Methylprednisolone, symptoms were only transiently relieved and thereafter rapidly worsened. Persistent diplopia and mild exophthalmos were confirmed in ophthalmology appointments. The patient was clinically euthyroid, thyroid function tests were normal under Levothyroxine replacement and TSHs remained negative. Computed tomographic scan and magnetic resonance imaging of the orbits showed symmetric bilateral exophthalmia (grade III/III) with inferior rectus muscle thickening on the right eye, consistent with Graves’ disease. However, the single fiber electromyography revealed a moderate defect in neuromuscular transmission. Anti-acetylcholine receptor antibodies were 14 times the reference value, compatible with the diagnosis of Myasthenia Gravis. Moreover, the patient denied fatigue, movement disorders or other neurological symptoms. By reporting this case, we would like to draw attention for a possible, although rare, association of myasthenia gravis and Graves’ ophthalmopathy and stress the importance of a clinical judgment.

Pleiotropic function of vitamin D and goiter

Roman Kołodziejczak1, Alicja Łuczynska-Kołoldziejczak1 & Anhelli Syrenicz2
1Ragional Hospital, Gorzów Wlkp, Poland; 2Pomeranian Medical University, Szczecin, Poland.

Objective

Among women over 40 the prevalence of goiter in Poland is over 40% and the prevalence of vitamin D deficiency is over 80%. There have not been any previous studies that investigate the vitamin D level in women with and without goiter.

Methods

152 women-96 with and 56 without nontoxic goiter were examined in 2014. In US examination we calculated the volume of the thyroid gland and volume of nodules. Blood samples for 25-(OH)D total were taken. We made statistical analysis of correlation between volume of the thyroid gland, volume of the nodules and levels of vitamin D.

Results

96 women with goiter size from 5.67 ml to 68.85 ml – mean 19.7 ml, median 15.6 ml, the total nodules volume varied from 0.1 to 39 ml mean 4.59 ml, median 0.94 ml and the control group of 50 women with thyroid volume in normal range from 5.1 to 19.9 mean 11.2, median 11.2 ml. The 25(OH)D total levels varied in control group from 5.3 to 31.8 ng/mL, mean – 14.4, median 12.95, and in goiter group from 4.7 to 39.8 ng/mL, mean 15.00, median 13.3 ng/mL. Only 14% in control and 22% in goiter group had vitamin level over 20 ng/mL. We found no correlation between vitamin D level and volume of thyroid gland in goiter group and no correlation between vitamin D level and summary volume of the thyroid nodules. There is negative correlation between vit. D level and thyroid volume in healthy subjects.

Discussion

As vitamin D deficiency affects majority of both groups and can result in osteoporosis, osteomalacia, and increased risk of fragility fractures, our study demonstrates the importance of screening and educating a broader age group of women with goiter disease but also in the ‘healthy’ population.

Conclusion

There is an unacceptably high level of vitamin D deficiency among women in both examined groups. The pleiotropic effects of vitamin D seems to be insignificant in development of goiter, but may play a role in healthy thyroid.

DO: 10.1530/endoabs.49.EP1206
Introduction
Amyloidosis results from deposition of insoluble proteins in the extracellular space. It can be both primary or secondary to chronic inflammatory diseases. Although microscopic thyroid involvement is common, cases in which it becomes clinically evident (amyloid goiter) are rare.

Case report
Woman, 45 years. In 2009, she was diagnosed with Crohn’s disease after Bartholin’s gland abscess excision and evaluation for weight loss, anemia and renal failure. In 2010, during hospitalization in Gastroenterology department, an euthyroid diffuse goiter was identified (without compressive symptoms, except easy choking) and she was oriented to endocrinology consultation. Due to chronic kidney disease, she underwent renal biopsy (Jan/2011), that established the diagnosis of renal amyloidosis. Because she presented hepatic cytolsysis a liver biopsy was also done, which revealed amyloid deposits in the wall of some portal arteries. She has been followed in Endocrinology since 05/2011, being asymptomatic, with diffuse goiter. Thyroid function tests and calcitonin are normal with negative thyroid antibodies. Thyroid ultrasound has shown an enlarged gland (LD 16 × 25 × 58 mm, LE 18 × 20 × 57 mm T X AP × P), with increased echogenicity and diffuse heterogeneity, but without dimensional progression. Considering the imaging findings and the presence of systemic amyloidosis, she underwent thyroid core biopsy, which confirmed the amyloid goiter diagnosis.

Discussion
In the majority of cases of amyloid goiter there is a rapid thyroid growth (in weeks to months), although in the case described there was no progression. Despite the widespread involvement of the thyroid by the disease, patients are usually euthyroid. Since amyloid deposits can also be found in association with medullary thyroid carcinoma, this possibility must always be excluded. In conclusion, the diagnosis of amyloid goiter should be considered in patients with systemic amyloidosis or chronic inflammatory disease who present with bilateral and rapidly progressive enlargement of the thyroid, even in the presence of normal thyroid function.

Two case reports of amiodarone induced thyroid dysfunction: thyrotoxic and myxedematous crisis
Francisco Sousa Santos, Cátia Ferriho, Ricardo Capitão, Catarina Roque, Carlos Bello, Clítilde Limbert & Carlos Vasconcelos
Serviço de Endocrinologia, Centro Hospitalar Lisboa Ocidental, Lisbon, Portugal.

Introduction
Amiodarone is a well-established antiarrhythmic drug frequently used in tachyarrhythmias. Side effects include hyperthyroidism and hyperlipidemia. Extreme cases such as myxedematous and thyrotoxic crisis are very uncommon. Here we report one case of each of these presentations.

Case Report no.1
A 73-year-old woman with history of atrial fibrillation under treatment with amiodarone presented to the emergency department with headache, nausea and chest pain. On admission, she was tachycardic - atrial fibrillation with heart rate of 127 bpm. Her free T4 (fT4) and TSH were 31.5 pmol/l and <0.01 mU/l, respectively and her antithyroid antibodies were all negative. Thyroid ultrasound demonstrated a micronodular gland with increased Doppler sign. Amiodarone was discontinued and she was started on propylthiouracil, propranolol, hydrocortisone, cholestyramine and Lugol’s iodine, without laboratory or clinical improvement, sustained tachycardia and coma. As such she was thyroidectomized. Her thyroid function tests and heart rate improved, however she died due to sepsis secondary to MRSA on the 18th post-operative day.

Case Report no.2
A 90-year-old woman with history of atrial fibrillation under treatment with amiodarone presented to the emergency department with a 12-h history of diminished consciousness level. On admission, she was myxedematous, hypothermic, bradycardic and with bradypnea. Laboratory studies revealed respiratory acidemia, increased creatinine, toxic benzodiazepine levels, TSH 80.2 mU/l and fT4 4.47 pmol/l (antithyroid antibodies were negative). She was started on IV fluids, non-invasive ventilation and antibiotic therapy due to suspected pneumonia. Amiodarone was discontinued and IV l-thyroxine (250 μg) and hydrocortisone (200 mg) were administered and continued orally on the following days. She showed dramatical clinical improvement and was discharged after 10 days on oral l-thyroxine 75 μg/day.

Conclusion
Although uncommon, extreme cases of thyroid dysfunction can occur in patients on amiodarone therapy, underlining the importance of thyroid function monitoring.

EP1208
Hashimoto’s thyroiditis in a patient with ectopic thyroid tissue
Nadia Khessairi, Bitissem Oueslati, Ous Rjeh, Fatma Chaker, Meriem Yazidi, Malika Chihouai & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction
Abnormalities in the development and migration of the thyroid gland are known to produce ectopic thyroid tissue, usually in the midline between the tongue base and the diaphragm. Hashimoto’s thyroiditis involving ectopic thyroid tissue is particularly unusual. Herein we report a case of Hashimoto’s thyroiditis developing in a midline thyroidal cervical mass.

Observation
A 55-year-old man was referred for hypothyroidism. His physical and psychomotor development was completely normal. His thyroid gland was not palpable in its normal pretracheal position. Elevated thyroid-stimulating hormone levels (TSH = 19.8 μIU/ml, range 0.35–4.5) with low free serum thyroxine (0.64 ng/ml) values were found. In addition, high titers of antiperoxidase antibodies (295.8 IU/ml) were detected. The neck ultrasound revealed a left lobar hypoplasia and a midline cervical mass representing aberrant thyroid tissue due to migration defects. A Te-99 m pertechnetate marked isotope showed accumulation at the left lobar lobe and at the midline cervical mass with no uptake at the right thyroid lobe.

Conclusion
Ectopic thyroid tissue itself is not known to demonstrate a predilection for Hashimoto’s thyroiditis. Despite its rarity, the presence of ectopic thyroid should be considered in the differential diagnosis of all tongue, neck and trachea masses. The ectopic tissue may be functional and affected by the same pathological processes as the thyroid gland.

EP1209
Autoimmune thyroid disease occurring as a possible late complication after a non-occupational HIV Postexposure Prophylaxis
Iulia Crumpei1,2, Voichita Mogos1,2, Maria-Christina Ungureanu1,2, Anamaria Bursuc1,2, Ioana Armasu1,2, Mirela Tirnoveanu1,2, Valentina Adomnica1, Georgiana Constantinescu1,2 & Carmen Vulpoi1,2
1University of Medicine and Pharmacy, Iasi, Romania; 2Department of Endocrinology, Iasi, Romania

Introduction
Nonoccupational postexposure prophylaxis (nPEP) is a three-drug antiretroviral regimen used to decrease the risk for HIV infection after less than 72 h from nonoccupational exposure to body fluids that might contain HIV. The most frequent side effects concern the gastrointestinal intolerance, renal and hepatic toxicity, with no hormonal imbalance to have been yet reported. Case report
24 years old male patient, consulted for palpitations, hoarseness, shortness of breath, laryngeal tightness, weight loss (4 kg /3 months), fatigue, insomnia, recurrent panic attacks and anxiety-symptoms progressively installed since 3 months. Patient’s previous history contains a nonoccupational exposure to body fluids containing HIV 8 months previously, treated with nPEP (Lamivudine, Zidovudine and Kaletra-Lopinavir/Ritonavir), with a negative serology at the check-ups. He presented high blood pressure and tachycardia, tremor, hyperhidrosis and excessive preoccupation concerning his illness. Thyroid tests found an autoimmune thyroiditis with subclinical thyrotoxicosis: ATPO-:< 20 mIU/l (N: 0–35), TSH = 0.09 μIU/ml (N: 0.4–4), FT4 = 1.35 ng/ml (N: 0.89–1.76), TRAb- negative, normal thyroid at the ultrasound. Cardiac evaluation was normal so the patient was advised to start betablocker and anxiolytic treatment, along with psychological counselling. At the one month follow-up, the blood test has shown persistence of the thyroid autoimmune with normalisation of the
function: TSH = 0.602 mU/ml, FT₄ = 1.38 ng/dl, without any other abnormalities.

Conclusions
The occurrence of the autoimmune thyroid disease after a 6 month period post nPEP has not yet been cited. It may be a result of either the autoimmune system rebound after the antiretroviral therapy or an inflammatory imbalance induced by the treatment with consecutive immune reconstitution syndrome.

Recurrent Thyroiditis in an Amiodarone treated patient: An Illustrative Case Demonstrating the Spectrum of Abnormalities
Mohit Kumar & David Janies Tynims
WWF Foundation Trust, G. Manchester, UK.

A 65 yo gentleman was referred to the endocrinology department with thyrotoxicosis. He had a history of IHD and recurrent VT necessitating amiodarone for 8 years. Routine TFTs had shown TSH undetectable, FT₁, 34.1, FT₄, 8.7. There were no symptoms or signs of thyrotoxicosis or cardiovascular compromise. He had been treated with carbimazole by his GP for the previous 3 weeks, this was discontinued at the initial evaluation due to recurrent vomiting. TPO antibodies were negative, a thyroid uptake scan showed normal uptake (2.86% at 20 mins) with a hot nodule in the isthmus. The thyroid function normalised over a period of 2 months with no medication. It was felt unsafe to discontinue the amiodarone. Sixteen months later there was a further episode of thyrotoxicosis, again asymptomatic with no CV compromise. A repeat thyroid uptake scan showed a cold thyroid. This episode too was managed conservatively. This was followed by a further two self-resolving episodes (2 and 3 years later); subsequently the patient developed permanent hypothyroidism treated with levothyroxine 100 μg. Amiodarone induced thyrotoxicosis (AIT) comes in two forms: type 1 (iodine-induced excess thyroid hormone production) and type 2 (thyroiditis), though in some patients an overlap is thought to exist. Differentiation of these types can be difficult. Our case seems to demonstrate both forms; initially type 1, then three episodes of type 2. Recurrent thyroiditis has been reported with suppurative thyroiditis and postpartum thyroiditis. Whilst there are reports of recurrence of thyroiditis with ongoing treatment with amiodarone, to our knowledge this is the first case to show four episodes of AIT with ongoing administration of this drug. The continuation of amiodarone is sometimes clinically necessary, but can lead to a longer time to cure if treated with steroids. Thyroxidectomy and perhaps radioiodine are options in troublesome cases.

EP1211
Thyroid storm subsequent to amiodarone-induced thyrotoxicosis
Catarina Machado, Patricia Tavares, Sara Monteiro, Gustavo Rocha & Maria João Oliveira
Centro Hospitalar de Vila Nova de Gaia/Espinho, EPE, Vila Nova de Gaia, Portugal.

Introduction
Thyroid storm is a rare medical emergency with high mortality, which usually results from acute exacerbation of hyperthyroidism. Amiodarone is a highly used class III antiarrhythmic drug and amiodarone-induced thyrotoxicosis is an infrequent effect of this medication, whose treatment may be difficult.

Case study
A 20-year old male with congenital cardiomyopathy (Fallot tetralogy and Ebstein anomaly), chronically medicated with amiodarone 200 mg/day since age 2, was admitted to the emergency room with palpitations, diaphoresis, nausea, vomiting and diarrhea. EKG showed atrial fibrillation with rapid ventricular response (HR 160 bpm). Blood analysis showed hyperthyroidism – TSH < 0.005 mU/ml; FT₁, 7.83 pg/ml (2.57–4.43) and FT₄, 5.50 ng/dl (0.93–1.70). Burch-Wartofsky’s score was 55. He started tiamazol 30 mg/day and prednisolone 40 mg/day, but because of his cardiac disease, amiodarone could not be withdrawn. Despite adequate treatment, there was no clinical response and patient remained hypotensive, tachycardic and at risk of cardiogenic shock. Potassium perchlorate was initiated at 400 mg 8/8 h with subsequent normalization of heart rate and hemodynamic stability. He was discharged after radiofrequency ablation of an abnormal signal pathway with EKC in sinus rhythm and amiodarone was suspended. Thyroid ultrasound showed thyroid goiter (24.5 ml) with heterogenous structure. There was a lack of 99 mTc uptake in scintigraphy (0.5%). Normalization of hormones was reached after eight months of onset of the disease, with tiaxamol 70 mg/day and prednisolone 20 mg/day.

Conclusions
Amiodarone-induced thyrotoxicosis occurs in 5–10% of patients and may cause significant morbidity, especially in patients with significant cardiac disease and when it cannot be discontinued. Differential diagnosis between type 1 and type 2 is not always easy and sometimes mixed forms occur, adding more challenges and difficulty to the treatment, particularly when antithyroid drugs and corticosteroids are ineffective.

EP1212
Atrial flutter with 1:1 atrioventricular conduction: An uncommon cardiac manifestation of hyperthyroidism
Amal Rachad, Mariem Yazidi, Imen Sakka, Ons Rejeb, Nedia Khessairi, Malika Chiahoui & Hedia Slimane
La Rabta, Tunis, Tunisia.

Introduction
Atrial flutter (AFL) is a rapid, regular atrial tachyarrhythmia that occurs most commonly in patients with underlying structural heart disease. Patients with tachyarrhythmias as a result of thyroid storm have been typically treated with beta-blockers to decrease the heart rate and alleviate beta-receptor mediated symptoms. We report an unusual case of AFL with 1:1 atrioventricular (AV) conduction.

Case report
Patient H, M 45 years old was admitted to our hospital with Graves Disease. He presented with typical symptoms which included tiredness, shaking, palpitations and ophthalmopathy. He had lost 36 pounds over 3 months. He had a heart rate of 280/min, blood pressure of 130/80 mmHg, a moderate sized goitre without signs of right heart failure. An electrocardiogram revealed atrial flutter with 1:1 (AV) conduction. The echocardiogram showed a preserved internal dimension and overall normal systolic function. The diagnosis of hyperthyroidism was confirmed: Thyroid stimulating hormone: 0.002 mU/L, Free T₄: 3.52 ng/dl (0.7–1.5). He was treated with propranolol 60 mg/day and thiamazole 40 mg/day. He was placed on anticoagulation with warfarin for a target INR of 2–3. We performed a linear radiofrequency ablation and he reverted to sinus rhythm. His symptoms improved and he was discharged 1 week later.

Conclusion
This case report shows that AFL with 1:1 AV conduction may be observed in patients with hyperthyroidism and rapid supraventricular tachycardia.

Pharyngeal Irritation, Incidental Neck Masses: A difficult journey
Bonnie Grant¹, Raj Tanday¹, Augustine William¹, Antony Pittathankal², Edel Casey¹ & Khash Nikookam³
¹Diabetes and Endocrinology Department, Barking Havering and Redbridge University Trust, Greater London, UK, ²Surgery Department, Barking Havering and Redbridge University Trust, Greater London, UK.

This is a case of a 48-year-old lady initially referred to respiratory clinic with symptoms of breathlessness. She had a high-resolution CT thorax where an incidental finding of a right para-oesophageal 2.4-cm soft tissue density at the level of the thyroid gland identified. A CT neck was performed for further evaluation again showed the soft tissue mass (26 mm × 37 mm) situated to the right of the oesophagus and another mass (16 mm × 26 mm) left of the oesophagus. Discussion at the Lung MDT felt they may represent thyroid nodules but given location and relative normality of the rest of the thyroid parenchyma, parathyroid adenomas were possibilities hence she was referred to the endocrine surgeon. She then described symptoms of irritation in her throat on swallowing over the previous 6 weeks but no subsequent breathing problems. On neck examination, the thyroid lobes were just palpable, with no cervical...
lymphadenopathy. She was clinically and biochemically euthyroid with a normal calcium and parathyroid hormone level. Ultrasound thyroid reported hypoechoic heterogeneous solid masses posterior to the thyroid; 3 cm on the right and 2 cm on the left. These masses appeared separate from the thyroid with minimal internal vascularity, likely representing parathyroid adenomas. MRI soft tissue neck could not differentiate between parathyroid and thyroid origin. Following Endocrine multi-disciplinary team discussion, the patient had a thyroid technetium scan and technetium MIBI scan with findings concordant that it was probably thyroid in origin rather than parathyroid adenomas. Endoscopic fine needle biopsies found small foci of follicular tissue with immunohistochemistry showing strong nuclear positivity with positive thyroglobulin antibodies, suggesting thyroid tissue, not parathyroid.

Conclusion

This case highlights the difficulty differentiating between thyroid and parathyroid masses found incidentally. Dedicated imaging and biopsies may be the only way to confirm the nature of these masses. DOI: 10.1530/endoabs.49.EP1213

EP1214

Papillary thyroid microcarcinoma in struma ovarii tissue: a case report
Cem Onur Kirac, Suleyman Baldane, Suleyman Ipekci & Levent Kebapcilar
Division of Endocrinology and Metabolism, Selcuk University Faculty of Medicine, Konya, Turkey.

Introduction

Struma ovarii is an uncommon ovarian neoplasm that more than half of itself is made up of thyroid tissue. In clinical trials about the disease, malign transformation has been detected at the rate of 0.5–5%. Because of the disease’s rarity, there is no absolute agreement about diagnosis and treatment of the disease.

Case report

A 33-year-old woman admitted to gynecology department with abdominal pain. Her pelvic MR revealed 147×99 mm multiseptated cyst in right over which may compatible with teratoma. On laboratory evaluation, her CA-125 level was 43.8 U/ml (normal range: 0–35). The cyst was excised and frozen section analysis was performed. The frozen section showed stroma ovarii so no additional surgical procedure was performed. Diameter of 300 micron papillary thyroid carcinoma was determined at the histopathological examination. At postoperative evaluation, there was no metastasis on thoracic and abdominal imaging. There was no nodule on thyroid USG. In the second operation, omentectomy, excision of paraovarian palpable lymph nodes and right oophorectomy were performed. Pathologic examination revealed no over invasion or lymph node metastasis.

Preoperative and postoperative thyroid function tests were measured in normal range; on the other hand postoperative thyroglobulin level was 0.071 ng/ml (normal range: 1.4–78) and anti-thyroglobulin value was 427 IU/ml (normal range: 0–115). Postoperative CA-125 level of the patient was found to be regressed to 12.9 U/ml. Because of the diameter of the tumor tissue, thyroidectomy or adjuvant radioactive iodine therapy treatment was not performed. There has been no recurrence in 1 year follow-up.

Conclusion

There is still no consensus on the diagnosis and treatment of malignant SO. The general approach is that low-risk cases can be followed without adjuvant radioiodine therapy, and origin rather than parathyroid adenomas. Endoscopic fine needle biopsies found small foci of follicular tissue with immunohistochemistry showing strong nuclear positivity with positive thyroglobulin antibodies, suggesting thyroid tissue, not parathyroid.

miRNAs microarray differential profile in papillary thyroid carcinoma
Sorina Schipor1, 2, Ana-Maria Niculescu1, Anca Bitoleanu1, Dumitru Ioachim1, Dana Manda1, Andra Carageorgheopol1, Catalina Picu1, Oana Popa1, Ioana Neduclu & Corin Badu1, 2
1National Institute of Endocrinology ‘C. I. Parhon’, Bucharest, Romania; 2Carol Davila’ University of Medicine and Pharmacy, Bucharest, Romania;
3Agilem Scientific, Bucharest, Romania; 4’Stefan S. Nicolau’ Institute of Virology, Bucharest, Romania.

Introduction

The deregulation in miRNA expression has been described in thyroid tumors, and is considered an important factor in thyroid carcinogenesis. miRNA expression profiling in cancer allows identification of signatures associated with diagnosis, staging, prognosis, and response to treatment.

Objective

We aimed to detect miRNAs species differentially expressed between tumor and peritumoral tissue in papillary thyroid carcinoma.

Materials and methods

After informed consent and study approval by ethics committee, 24 patients were included in the study: seven patients with classic papillary thyroid carcinoma (cPTC), 14 patients with follicular variant of papillary thyroid carcinoma (fPTC) and three patients with insular and sclerosing variant of PTC, using intraoperatively obtained tumor and peritumoral normal tissue. RNA was isolated from thyroid tissue using Trizol (Invitrogen, Life Technologies). miRNA microarray analysis was performed using miRNA Microarray System with miRNA Complete Labeling and Hyb Kit and SurePrint G3 Human miRNA r21 Array Kit (Agilent Technologies). SureScan Microarray Scanner Agilent (G2606D) with Feature Extraction v11.0 and Agilent GeneSpring GX v14.5 were used for data extraction and analysis.

Results

Our analysis showed that 2570 miRNA species differ between normal and tumor tissues. From these all, a fold change (FC)< 1.1 identified 2516 species, with 276 having a FC> 2. Applying an asymptotic P value below 0.05 and Benjamini-Hochberg correction for false-discovery rate we found eight miRNAs significantly different between normal and thyroid tissues, namely hsa-mir-181c-5p, hsa-mir-181d-5p, hsa-mir-221-3p, hsa-miR-34a-5p, hsa-mir-34b-5p, hsa-miR-5703, hsa-miR-630 and hsa-miR-744-5p, 6 of them up-regulated and two of them downregulated in tumor vs normal tissue. Conclusion

miRNA microarrays expression profile using a specific platform allowed a very good differentiation between tumor and normal thyroid tissue, providing an important tool for the individualized, specific variant-based management of thyroid cancer.

Simultaneous occurrence of RET-negative Medullary Thyroid Carcinoma (MTC) and extrathyroidal B large cell Non-Hodgkin Lymphoma (NHL)
Serafino Lio
Department Medicine-Endocrine Unit-ULSS2, Oderzo-TV, Italy.

The simultaneous occurrence of MTC and extrathyroidal B large cell NHL are very rare. MTC may be sporadic or part of a MEN and NHL is not reported in association with MEN. A woman of 76 year old with a history of cholelithiasis and hepatitis B, is admitted for left abdominal pain. On examination it is detected multynodular thyroid disease. The thyroid function was normal, antithyroid antibodies were negative and calcitonin (Ct) serum levels were moderately elevated (28.9 pg/ml). The thyroid ultrasound will detect bilateral hypoechoic areas the largest to the right of 2.4 cm with hypoechoic halo and per- and intranodular vascularization. Total body CT scan showed splenomegaly almost breaking and so was made of splenectomy. The histology showed splenic localization of lymphoma diffuse large B cell. The PET/CT scan with F18 FDG was positive of upper and subdiaphragmatic lymph nodes and a right thyroid nodule. Immunochemothrapy was initiated according to the R-COMP protocol and at the end a new PET/CT F18FDG detects activities only to the lower right thyroid pole. A control of Ct showed an increase to 45.1 pg/ml and the calcium gluconate infusion test was suggestive of MTC (peak Ct > 2.000 pg/ml). Total thyroglobulin and lymph node draining was performed. Histology showed a MTC bifocal, 2.5–1.5 cm to the right and left respectively, with all node-negative. Screening for MEN 2 was negative. Seven months after surgery Ct levels are <1.0 pg/ml; molecular analysis of the RET gene showed no pathogenic variants. In conclusion, the two neoplasms appear to be independent and not correlated to a multiple cancer syndrome; moreover also in the NHL detect on palpation of the neck and then the morphological examinations a thyroid nodule suggest the dosage of Ct.

Simultaneous papillary and medullary thyroid carcinoma in siblings with RET 611 mutation. More than a coincidence?
Miguel Paja, Alba Zabalegui, Maddalen Dublang, Eider Etxeberria, Natalia C Iglesias, Laura A Calles, Cristina Arrizabalaga, Aitzol Lizarraga, M Teresa Gutierrez & Aitziber Ugilde
Hospital Universitario de Basurto, Bilbao, Vizcaya, Spain.

Germinal mutations of the oncogene RET originate the development of medullary thyroid carcinoma (MTC) in carriers with phenotype expressing dependence on the mutated codon and other unknown factors. Simultaneous detection of differentiated thyroid carcinomas is considered a causal phenomenon (collision tumours). We communicate two brothers with double heterozygous mutation of maternal inheritance at codon 611 of RET, TGCC to TTT, changing to encode phenylalanine (C611F), with a simultaneous papillary thyroid carcinoma (PTC). Case 1
A 42-year-old male who underwent treatment through total thyroidectomy and bilateral central dissection (TT + BCD) after genetic diagnosis in 2006. Basal preoperative calcitonin was 6.0 ng/ml and stimulated, 34. ng/ml. Histology showed a bifocal MTC, the bigger of 3 mm, and a classic infiltrative PTC of 3 mm with intense desmoplastic stromal reaction and four metastatic lymph nodes out of five in central compartment, two with extranodal extension. BRAFV600E mutation was positive. He received 100 mcg of I131 with stimulated thyroglobulin of 1.9 ng/ml. Ten years later, he has undetectable calcitonin and excellent therapeutic response.

Case 2
A 48-year-old male received TT + BCD after genetic diagnosis in 2016, with basal calcitonin of 25.2 pg/ml and stimulated of 124.5 pg/ml. Histology showed a bifocal MTC, 6 and 3 mm, and two foci (5±2 mm) of well limited not encapsulated follicular variant of PTC, BRAFV600E negative. There was no involvement by any of the two tumours in six resected nodes. After 3 months, basal calcitonin is 0.8 pg/ml and basal thyroglobulin, without radioiodo, reaches 0.3 ng/dl. We are remarking simultaneous occurrence of MTC and PTC, originated from different thyroid cell types, in siblings bearing the same RET mutation. This coincidence raises the possibility of an underlying common genetic drive in both PTC, although with different mutational events added that explain distinct differentiation, among them BRAF V600E mutation.

Thyroid nodule size at ultrasound as a predictor of malignancy
Gema López Gallardo1, Julia Sastre2, Abel González2, Sandra Arranz2, Julia Silva3, Miguel Angel Valero4 & Luisa Aranda1
1Hospital Santa Bárbara, Puertollano/Ciudad Real, Spain; 2Hospital Virgen de la Salud, Toledo, Spain; 3Hospital General, Ciudad Real, Spain; 4Hospital General, Albacete, Spain; 5Hospital Mancha Centro, Alcázar/Ciudad Real, Spain; 6Hospital General, Talavera, Spain; 7Hospital General, Cuenca, Spain.

Introduction
Most thyroid nodules are benign. Some studies have shown largest nodule size, specially >4 cm, can predict malignancy and reduce fine needle aspiration (FNA) accuracy. Recent studies, however, have shown conflicting results as to whether nodule size may be used to distinguish at risk-lesions. We attempt to determine whether nodule size predicts thyroid malignancy and to examine accuracy of fine needle aspiration (FNA) by size.

Material and methods
A multicenter, retrospective analytical study was performed on a total of 882 patients with thyroid solitary nodules and put underwent partial or total thyroidectomy between 2010 and 2013. We compared nodules by size cutoffs using Chi-squared and Fisher exact test where appropriate. Binary logistic regression analysis was used to identify the independent factors associated with thyroid malignancy. All data were analyzed using SPSS software for Windows (version 18.0).

Results
Of the 882 nodules, 664 (73%) were benign and 238 (27%) malignant. Nodules <2 cm had the highest malignancy rate (49.2%). Decreasing malignancy rates (23.1, 16.8, 4.6, and 6.3%) were observed with increasing size (2–3 cm, 3–4 cm, 4–5 cm, >5 cm). Thyroid nodule size >4 cm was associated to less risk of malignancy (OR 0.589 (0.421–0.824)). After adjusting for patient age and gender, nodules that measured >4 cm had a greater malignancy risk compared to those measuring <4 cm (OR 2.031 (P=0.001)). In nodules with a benign FNA diagnosis (Bethesda II), the overall malignancy rate (false negative rate) was 10% (35/349). The highest false negative rates (15%) were in nodules <2 cm. There was no significant difference in the false negative rates for nodules >4 cm (8%) or <4 cm (10%) respectively.

Conclusions
After adjusting for patient age and gender, nodules that measured >4 cm had a greater malignancy risk. The false negative rates were not higher for nodules >4 cm. Thyroidectomy should not be recommended based solely on nodule size.

Struma ovarii – A report of thirteen cases
Sara Donato, Hélder Simões & Valeriano Leite
Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal.

Introduction
Struma ovarii (SO) is a rare ovarian teratoma characterized by the presence of thyroid tissue in >50% of the tumour. Malignant transformation is rare and defined by the same histological criteria as for thyroid cancer. There is few data on the literature and treatment is controversial. The objective of this study was to describe the clinical, pathologic and treatment characteristics of women diagnosed with SO in our centre.

Methods
Retrospective analysis of the SO followed in our Institution between 2000 and 2015.

Results
A total of 13 patients were identified with a median age at diagnosis of 46 years (range 19-85). No patient had previous history of thyroid disease. In nine cases the diagnosis was made by routine imaging exams and in three cases by associated symptoms (mostly pelvic pain). CA 125 and HE4 serum levels were normal in every patient tested (four and three patients respectively). Seven patients underwent bilateral oophorectomy plus hysterectomy (with or without omentectomy or external iliac lymphadenectomy) and in six the surgical procedure was a unilateral oophorectomy. Three cases were diagnosed as malignant SO. In these cases thyroidectomy followed by radioactive iodine was performed and papillary thyroid cancer (PTC) was diagnosed in two.131I-WBS performed after surgery, showed no uptake in the pelvis in any patient. In one benign SO case, thyroid imaging and fine-needle biopsy disclosed PTC as well. During a median follow-up of 14 months (range 1–78), nine patients remained with no evidence of disease, one died with a non-related cause and one was lost to follow-up. Two of the malignant SO patients were found to have biochemical evidence of disease.

Conclusions
SO is frequently asymptomatic. Patients with malignant SO had often persistence of disease, although they had a good overall survival rate. An important proportion of these patients developed thyroid cancer.

Diagnosis of medullary thyroid carcinoma at early stage
Cristina Stanca1, Cristina Conrece1, Andra Carageorghopol1, Bogdan Stanescu1,2, Mirela Diana Ilie1 & Corin Badiu1
1 C.I.Parhon’ National Institute of Endocrinology, Bucharest, Romania; 2Carol Davila’ University of Medicine and Pharmacy, Bucharest, Romania; 3Life Memorial Hospital, Bucharest, Romania.

Medullary thyroid carcinoma (MTC) is a rare neuroendocrine tumor derived from the thyroid C cells producing calcitonin, ac-counts for 0.6% of all thyroid cancers. It occurs either sporadically or in a hereditary form (RET mutation). MTC can be cured only by complete resection of the thyroid tumor and any loco-regional metastases. Calcitonin (CT) measurement is crucial to the early diagnosis and the follow-up of MTC. If the evaluation of stimulated CT levels is required, a provocative test can be performed. We report the case of a 52-year-old woman presenting with multinodular goiter, positive TPO antibody and basal CT in repeated samples 42.92, 38.15, and 33.99 pg/ml respectively. The patient was euthyroid. Plasmatic
metanephrines and PTH were in normal ranges. The thyroid ultrasound showed an isoechogenic nodule 6 mm in size with a punctate calcification in the left lobe and two hypoechogenic nodes on the right lobe 19 and 9 mm in size, with central and peripheral vascular signal. After a provocative test with high dose Ca was performed, stimulated CT level was 96.6, 98.10 and 82.10 pg/ml at 2, 5 and 10 min respectively. The patient underwent total thyroidectomy. The histology showed multifocal medullary microcarcinoma (max 5/5 mm in the left lobe), pTN: T1a(m) Nx and positive immunohistochemistry for calcitonin. Postoperatively calcitonin level <0.2 pg/ml and CEA was negative. The mutations of RET protooncogene was tested, too.

Conclusion
We have to pay attention for patients with bCT > 10 pg/ml and, a high-dose Ca test is reliable for the identification of MTC.

Introduction
Differenitiated thyroid carcinoma is a rare entity in pediatric population, with particularities in diagnosis, management and outcomes. Methods, aim
Retrospective noninterventional study describing clinical presentation and outcomes of children with DTC.

Results
Between 2011 and 2017 54 children and adolescents aged 7.8–18 years (mean age at diagnoses 14.4 years) with DTC were diagnosed/followed up in our Institution. The female to male ratio was 3.5:1. In 70% cases unilateral thyroid nodule was the first manifestation of the disease, in 25.9% cases the DTC was diagnosed during the follow-up for chronic thyroid pathology, whereas in 3.7% cases cervical lymph node enlargement was the first clinical sign. 29.6% patients had cervical node involvement at diagnosis, 9.3% had pulmonary metastases. The initial tumour size (over 4 cm diameter), the diffuse sclerosing form of papillary cancer and from the 6-hpf, the injected embryos were treated with the control vehicle, or with 20 μM-T3, added in the harvested water. By qRT-PCR, the expression of genes involved in the specification of lateral mesoderm (cdx4, bmp2b, smad5, chd2) induction and proliferation of haematopoietic stem cells (HSC) (tal1, tmo2, gata1, gata2) and proliferation of erythrocytes (zir, gnx, vla, cha) appeared significantly reduced in all hTRx-injected embryos. Consistent with previous results, the treatment with high T3 doses can rescue the DN-activity of the missense variants D211G and A263V, whereas the truncated receptors A382P/S763X, E403X and F397S/I406X are unaffected by T3 treatment. Furthermore, we analysed the specification of HSC in embryos at 8-somite stage, by ISH. The vast majority of the hTRx-injected embryos showed a reduced or undetectable expression of early erythropoiesis markers, such as e-myb, pu.1, tal1 and gata1 in anterior or posterior lateral mesoderm. At 36-hpf, we also observed a dramatic reduction of gata1 in the intermediated cell mass of hTRx-injected embryos. Therefore, our results highlight a relevant role for TRx during the early phases of the primitive haematopoiesis, when the HSC will proliferate and differentiate.

Nuclear Receptors and Signal Transduction
The human TRx variants affect the specification of haematopoietic stem cells during zebrafish haematopoiesis
Federica Marelli1, Giuditta Kuralie2, Silvia Carra1 & Luca Persani1,2
1IRCCS Istituto Autologico Italiano, Milan, Italy; 2University of Milan, Milan, Italy.

Anaemia in RTHx patients correlates with documented abnormal erythropoiesis and reduced haematocrit in TRx-null or mutant mice, but the underlying mechanisms and characterization of the defect remain elusive. In a previous work, we described that the injection of several hTRx variants in zebrafish eggs caused a marked reduction of circulating erythrocytes at later stages of the erythropoiesis. To characterise the involvement of TRx during erythrocyte development, we analysed by qRT-PCR and in situ hybridization (ISH) the expression of different haematopoietic markers. We microinjected the zebrafish eggs at 1–2 cells stage with 80pg/embryos of the purified mRNAs of several hTRx variants, and from the 6-hpf, the injected embryos were treated with the control vehicle, or with 20 μM-T3, added in the harvested water. By qRT-PCR, the expression of genes involved in the specification of lateral mesoderm (cdx4, bmp2b, smad5, chd2), induction and proliferation of haematopoietic stem cells (HSC) (tal1, tmo2, gata1, gata2) and proliferation of erythrocytes (zir, gnx, vla, cha) appeared significantly reduced in all hTRx-injected embryos. Consistent with previous results, the treatment with high T3 doses can rescue the DN-activity of the missense variants D211G and A263V, whereas the truncated receptors A382P/S763X, E403X and F397S/I406X are unaffected by T3 treatment. Furthermore, we analysed the specification of HSC in embryos at 8-somite stage, by ISH. The vast majority of the hTRx-injected embryos showed a reduced or undetectable expression of early erythropoiesis markers, such as e-myb, pu.1, tal1 and gata1 in anterior or posterior lateral mesoderm. At 36-hpf, we also observed a dramatic reduction of gata1 in the intermediated cell mass of hTRx-injected embryos. Therefore, our results highlight a relevant role for TRx during the early phases of the primitive haematopoiesis, when the HSC will proliferate and differentiate.

Paediatric Endocrinology
An interesting etiology in childhood choreoathetosis: autoimmune hyperthyroidism
Ayca Torel Ergür1, Sevinc Odabasi Güneş1, Cihat Sanlı2 & Rabia Gundogar1
1Kirikkale University Faculty of Medicine, Department of Pediatric Endocrinology, Kirikkale, Turkey; 2Kirikkale University Faculty of Medicine, Department of Pediatric Cardiology, Kirikkale, Turkey.

Introduction
Neurologic symptoms due to autoimmune encephalopathy related to autoimmune hyperthyroidism (AEAH) cases are very rare in childhood. The reason why hyperthyroidism causes this situation is still unknown. In this case we discussed the diagnosis, treatment and follow-up of a case with choreoathetosis in the review of literature.
Case
A 15 years old female admitted to hospital with the complaint of nervousness, discomfort for last 3 weeks. There was not any particular feature in personal and family history. In physical examination, heart rate was 110/min, goiter, exophthalmos, dysarthria, involuntary hand-foot movements, and decrement of fine motor skills was observed. Laboratory results were T3: 12.59 ng/dl, T4: 3.6 ng/dl, TSH:0.007 μIU/ml anti-TPO 591.4 595 IU/ml, anti-Tg:357.9 IU/ml, TRAb: positive. In thyroid ultrasonography volume > +2s.d., and parenchymal heterogeneity were observed. History of beta streptococcus infection was negative, mitral valve prolapse and non-thrombomiotic mitral regurgitation was seen on echocardiography so Sydenham’s chorea was not considered. Lupus antibodies were negative; C3, C4, cranial MR and MR spectrum were normal. Anti-thyroid and beta-blocker treatment were started. On the 14th day of the treatment major recovery in patient’s walking and talking were observed. Recovery of the fine motor skills was evaluated comparatively with weekly video records. On the first month of the treatment fine motor skills were definitely normal.

Discussion
Cranial hypoperfusion due to cerebral vasculitis, autoimmunity specific to cerebral tissues and primary demyelination secondary to neuronal dysfunction were blamed in pathogenesis of AEAH. Plasmapheresis and corticosteroids are used in addition to anti-thyroid drugs in the treatment. The best aspect of is our patient responded anti-thyroid drugs well. Our case is very challenging since it reminds us the autoimmune thyroiditis in the etiology of major neurologic symptoms in children and adolescents.

DOI: 10.1530/endoabs.49.EP1223

Endocrine Abstracts (2017) Vol 49
Several studies have noted that there is a connection between thyroid pathology and breast diseases.

Purpose

The study was undertaken to estimate the frequency of the breast diseases in adolescent girls with thyroid pathology.

Patients and methods

The study included 2371 girls (aged 10–18 years). Thyroid diseases were diagnosed on the basis of hormonal analysis and typical picture of examination and thyroid ultrasound. Breast diseases were diagnosed on the basis of signs and typical picture of breast ultrasound. We have identified the two groups: girls (n=618) with thyroid pathology (group I) and girls (n=30) without thyroid pathology (control group). Statistical analysis was performed using Mann-Whitney Test. P value of <0.05 were considered statistically significant. This study has been carried out in accordance with the Helsinki Declaration.

Results

The endemic goiter was diagnosed in every forth girls. Autoimmune thyroiditis was found in 30 girls, nodul goiter in 4 and congenital hyperthyroism (later form) in 2 adolescent girls. The investigation shows that every adolescent girl with thyroid diseases had breast disorders. Breast cysts (cystic dysplasia) was diagnosed in 42% cases, fibrous mastopathy (dysplasia) – in 35%, adenois mastopathy – in 18%, breast secretion – in 5% and fibroadenoma in 4 patients. All girls with breast dysplasia and fibroadenoma complained of mastalgia. The average level on the visual analog pain scale in cases of mastalgia amounted 6.9 ± 2.1 points (in group I). The investigation shows that only 2 girls without thyroid pathology had breast diseases (premenstrual mastalgia) (< 0.001). The average level on the visual analog pain scale in control group was 3.8 ± 1.4 points (P = 0.02).

Conclusions

This study has shown a high frequency of the breast diseases among the adolescent girls with thyroid pathology. Thyroid diseases are risk factor for breast disorders and show the necessity of for observation and examination of breast.

DOI: 10.1530/endoabs.49.EPI1224

Age and development stage dependent association between thyroid hormones and growth hormone and linear growth velocity in boys between the age of 1 and 20 years

Afzaal Ahmed Naseem1, Mazhar Qayyum1, Maleeha Akram1, Zubaria Iqbal1, Faheem Tahir2, Sarwat Jahan1, Kiran Afshan2 & Syed Shakeel Raza Rizvi1
1Department of Zoology, Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Rawalpindi/Punjab, Pakistan; 2Reproductive Physiology, Public Health Laboratories Division, National Institute of Health, Islamabad, Pakistan; 3Department of Animal Sciences, Quaid-e-Azam University, Islamabad, Pakistan.

During the time of puberty, thyroid hormones (THs), thyroid (T4) and triiodothyronine (T3), influence growth and developmental processes by working in association with growth hormone (GH), insulin like growth factor-I (IGF-I), glucocorticoids, insulin and gonadal steroids. THs have a direct effect on GH secretion, which stimulates IGF system. It has been suggested that THs control increase in bone length through synergy with GH. This investigation determined age and development stage dependent association between circulating concentrations of T4, T3, GH and linear growth velocity (LGV). Blood samples were collected from 540 normal healthy boys (27 boys/age group) between 1 to 20 years of age and plasma concentrations of T4, T3, GH and linear growth velocity (LGV) were determined using specific ELISA. LGV was measured by calculating changes in height in cm/year. Data were analyzed using Student’s t test, ANOVA and Pearson correlation r. The concentrations of T4 and GH were positively correlated at 3rd, 7–9th, 14–16th and 18th and 19th year. T4 and GH concentrations were positively correlated at pre-puberty and early and late puberty. The concentrations of T4 and LGV were positively correlated at 3rd, 4th, 7–15th and 18–20th year. The plasma concentrations of T3 were positively correlated with LGV at infancy, pre-puberty, early and mid-puberty. In conclusion, the present study shows positive correlations between T4 and LGV and positive correlations between T4 and GH and LGV at infancy and mid-puberty.

Pediatric case of Autoimmune Polyglandular Syndrome type IIC: autoimmune thyroid disease and severe autoimmune thrombocytopenia

Joanna Prokop1, Elziabeta Leszcynska1, Maryna Krawczuk-Rybak1 & Artur Bossowski2
1Endocrinology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal; 2Department of Pediatrics, Endocrinology, Diabetology with Cardiology Divisions, University Children’s Clinical Hospital of Bialystok, Bialystok, Poland; 3Department of Pediatric Oncology and Hematology, University Children’s Clinical Hospital of Bialystok, Bialystok, Poland.

Introduction

Association between autoimmune thyroid disease (AITD) and other autoimmune disorders is common and known as autoimmune polyglandular syndrome (APS). It may involve hypoparathyroidism with Addison disease (AD) and mucocutaneous candidiasis – APS type I; AD with Diabetes mellitus type 1 (DM1) or AITD – APS type II, AITD associated with other autoimmune diseases (excluding AD): DM1- type IIIa, pernicious anemia - IIIb, or alopecia and/or vitiligo and/or other autoimmune disorder- IIIc, any other combination being classified as APS type IV. We report a case of a 15-year old patient diagnosed simultaneously with Graves disease (GD) and severe autoimmune thrombocytopenia (AIT).

Clinical case

A 15-year-old female patient was admitted to hospital with palpitations, weight loss, petecheiae on lower limbs, during menstruation. Physical examination revealed tachycardia, goiter, thyroid bruit, fine distal tremor, petechiae of trunk, upper and lower limbs. Abnormalities in laboratory studies: thrombocytopenia-platelet count: 4.0 × 10^9/μl, clinical hyperthyroidism with positive TSH receptor antibody. Myelogram: normal. Thyroid ultrasonography: enlarged thyroid gland, colour Doppler: increased blood flow. She was treated with intravenous immunoglobulin (IVIG), platelets concentrate and started methimazole. During follow-up she had 4 more episodes of severe thrombocytopenia, with good however temporary response to therapy with IVIG or intravenous corticosteroids. Meanwhile vitamin B12 deficiency was detected and vitamin B12 replacement therapy started. After normalization of thyroid function, maintaining low dose of methimazole, thrombocytopenia persisted (platelet count > 20 × 10^9/μl). Anty-glutamic acid decarboxylase (GAD) antibodies were tested: positive, without hyperglycemia.

Comments

Although some autoimmune diseases may coexist, combination of AIT and GD is rarely reported. Moreover it was unusual because of juvenile onset, severity of thrombocytopenia, simultaneous diagnosis of GD, concomitant presence of GD and severe autoimmune thrombocytopenia (AIT). The patient needs to be monitored closely for early detection of other autoimmune disorders or glandular failure and initiate hormone replacement therapy if it is established.

Thyroid autoimmunity in beta thalassemia minor
Sati Sena Yıldız1, Ali Ramazan Beniz2
1Department of Health and Social Services, Kayisdagi Darulaceze Ministry, Istanbul Metropolitan Municipality, Istanbul, Turkey; 2Department of Family Medicine, Medikal Fakülte, Karabük University, Istanbul, Turkey.

Background-aim
Tendency to autoimmune diseases has been reported to be increased in beta thalassemia minor (BTM). Our aim was to examine the prevalence of thyroid autoimmunity in BTM.

Method
Eighty six adults with BTM and 93 age and gender matched controls were included in the study. The two groups were compared cross-sectionally in terms of anti-thyroid antibodies (anti-TG and anti-TPO) and thyroid hormones. Patients with known autoimmune disorders other than autoimmune thyroid disease were not included in the study.

Results
In the BTM group, serum TSH, FT4, FT3 levels were statistically indifferent from the control group. Serum anti-TG and anti-TPO antibody levels were found to be similar in the two groups. BTM and control groups were similar in terms of anti-thyroid antibody positivity prevalence. In the BTM group, anti-TG was 11.6% and anti-TPO was 14% positive, while these were respectively 14% and 12.9% positive in the control group (P=0.806 and P=0.989, respectively). The proportion of anti-TG and/or anti-TPO antibody positive subjects was found to be 20.9% in the BTM group, and 20.4% in the control group (P=0.919). Ratios of subjects with euthyroidism, hypertiroidism and hypothyroidism were similar in both group.

Conclusion
Because thyroid autoimmunity prevalence in the BTM group is not increased compared to the control group, we consider that there is no necessity for routine anti-thyroid antibodies and thyroid hormone testing in subjects with BTM.

Thyroid disorders and type 1 diabetes
Ach Taieb, Hasni Yosra, Maaroufi Amel, Kacem Maha, Chaieb Molka & Ach Koussay
CHU Farhat Hached Sousse, Sousse, Tunisia.

Introduction
Type 1 Diabetes is an auto-immune disease caused by a disturbance of the immune system, damaging the Beta-cells. The association with other autoimmune diseases was frequently described, and dysthyroidism represents an important part of these associations. In type 1 diabetes, the hormonal profile can be disturbed regardless of auto-immunity. The goal of our study is the thyroid hormonal profile in type 1 diabetes, as well as the prevalence of auto-immune dysthyroidism associated with it.

Material and methods
This is a retrospective cross-sectional study based on the observation of patients admitted for diabetes with insulin deficiency. The positivity of anti-pancreas antibodies testified to the auto-immune characteristic; anti glutamic acid decarboxylase GAD and/or anti tyrosine phosphatase IA2. The goal is to determine the type 1 diabetic patients' thyroid hormonal profile, and the auto-immune dysthyroidism profile.

Results
Our series was conducted with 359 patients: 209 men and 150 women, aged between 10 and 69 years with an average of 28.75 years. The clinical picture was ketotic in the majority of cases: 336 (93.6%), with initial ketosis in 313 cases (87.2%). Insulin deficiency varied between one week and 36 months, with an average of 3.75 months and a standard deviation of 6.8 months, exceeding 6 months achieving a slow form and a previous oral treatment in 24% of cases. Regarding weight, the average BMI was 22 (extremes: 15 and 39), over 30 in 22 patients. Upon admission, average blood sugar levels were 16.40 mmol/l with an average glycylated hemoglobin HbA1C of 12.32%. Average TSH levels were of 3.33 mIU/l and the average T4 levels was 12.43 pg/l in 242 patients who had thyroid function tests. Auto-immune thyropathies were frequent: 54 patients (71% of cases). Hashimoto’s disease dominated the etiologic profile and was confirmed by the presence of anti-TPO antibodies found in 37 patients (48.6% of cases). Basedow’s disease was found in 17 other patients (22.3% of cases) with positive anti-TSH receptor antibodies.

Conclusion
Type 1 Diabetes is common in adults and children, and the association with autoimmune diseases is frequent, hence the necessity of looking for these diseases when patients are diagnosed with diabetes.

The standard management for Grave’s thyrotoxicosis includes the use anti-thyroid drugs, surgery and radioactive iodine treatment. In certain situations, alternative methods including bile acid sequestrants and therapeutic plasma exchange (TPE) have proven effective especially when other treatment modalities fail. We describe a case where conventional and alternative non-invasive measures failed to restore an euthyroid state and resorted to emergency thyroidectomy. A 49 years old female was referred signs and symptoms consistent with Grave’s thyrotoxicosis. She was already started on pulse IV methylprednisolone for active thyroid eye disease. Her thyroid functions tests showed a suppressed TSH of <0.05 mIU/l, a free T4 of 52.7 pmol/l and free T3 of 18 pmol/l. Her Thyroid receptor antibodies were high of >100 IU/l (1.0–1.8). She was started on anti-thyroid drugs which were stopped due to side effects. She had active thyroid eye disease so radioiodine was not appropriate and surgery considered the best option. She failed to block on Potassium iodide, and surgery was cancelled due to hyperthyroidism. She was started on Steroids and Cholestyramine but failed to respond with worsening symptoms and biochemistry. As a last resort, therapeutic plasma exchange was initiated with improvement in her thyroid biochemistry but no resolution despite seven sessions. An emergency total thyroidectomy was rearranged as the final resort with steroid and B-blocker cover. Fortunately, the surgery was uneventful and she made an uneventful recovery with subsequent improvement in her thyroid
functions and clinical symptoms. This case demonstrates how Graves’s thyrotoxicosis can pose a clinical challenge when it is refractory to all medical therapies including plasma exchange. Total thyroidectomy remains the best and only option, a comprehensive multidisciplinary approach involving an endocrinologist, a surgeon and an anaesthetist is crucial to optimize the outcome and reduce the risk of thyroid storm.

Screening with TSH and anti-TPO antibodies of patients with vitiligo
Anca E Chiriac¹, Anca Chiriac² & Doina Azoica³
¹University of Medicine and Pharmacy ‘Grigore T Popa’, Iasi, Romania;
²Nicolina Medical Center, Iasi, Romania.

**Aim**
The aim of the study was to evaluate the relation of vitiligo with thyroid autoimmunity.

**Materials and methods**
A cross sectional study was done on 75 patients clinically diagnosed (old and new) with different types of vitiligo. Patients with known thyroid disease were excluded from the study. Serum TSH and anti-TPO antibodies were measured in all patients.

**Results**
The prevalence of anti-TPO antibody positivity was found in 23 of 75 patients (30.6%).

**Conclusion**
Although none of vitiligo patients enrolled in the study had symptoms or signs of thyroid disease at the time of clinical examination anti-TPO antibodies proved to be positive and with high values in almost one third of the patients. Multidisciplinary approach for patients diagnosed with vitiligo and screening with anti-TPO antibodies are strongly recommended.

Clinical aspects of cardiothyreosis in patients with Graves’ disease
Rym Belaid, Ibtissem Oueslati, Wafa Mimita, Nadia Mchirgui, Karima Khari & Néjib Ben Abdallah
Department of Endocrinology, Charles Nicolle Hospital, Tunis, Tunisia.

**Introduction**
Cardiothyreosis (CT) is the most frequent and dangerous complication of hyperthyroidism (HT). It is defined as an association of HT with severe heart abnormalities such as: rhythmic troubles, heart and/or coronary insufficiency. The aim of our study was to describe the frequency and the clinical characteristics of CT in Graves’ disease (GD).

**Methods**
Patients with GD were enrolled into a retrospective study. The prevalence and the clinical characteristics of CT were described.

**Results**
Out of 90 participants with GD, 59 patients (65.8%) presented with GO. Their mean age was 35.13±12.25 years and their M/F ratio was 31/28. GO was the circumstance of discovery of GD in 11% of cases. Its clinical manifestations range from mild findings such as tearing (25.6%), conjunctival injection (16.7%), gritty eyes (10%) and photophobia (8, 9%) to more significant findings including exophthalmos (65.6%), eyelids retraction (41.1%), palpebral edema (18.9%), Oculo-palpebral asynergism (17.8%), exposure keratopathy (7.8%), diplopia (6.7%), reduced visual acuity (5.6%) and strabismus (2.2%). GO was mild in 64.4%, moderate in 16.9% and severe in 18.6% of cases. On multiple logistic regression analysis, smoking status (P=0.005) and male gender (P<0.001) were predictive factors associated with the severity of GO. Other factors such as age, initial free T4 level, TSH-receptor antibodies and a history of diabetes were studied but were not predictive of severe GO.

**Conclusion**
Although various factors may influence the severity of GO, our study showed that smoking and male gender were the major and the more significant risk factors for developing severe GO. Therefore it is important for patients with GD to stop smoking.

Risk factors associated with the severity of Graves’ ophthalmopathy
Rym Belaid, Ibtissem Oueslati, Wafa Mimita, Karima Khari, Nadia Mchirgui & Néjib Ben Abdallah
Department of Endocrinology, Charles Nicolle Hospital, Tunis, Tunisia.

**Introduction**
Graves’ ophthalmopathy (GO) is an autoimmune disorder affecting the retro-orbital tissues. It represents the main extra-thyroidal expression of Graves’ disease (GD). Its onset and progression are influenced by several factors that are potentially modifiable. The aim of this study was to identify risk factors for severe GO.

**Methods**
Patients with GD were enrolled into a retrospective study. We compared possible risk factors and various clinical findings between patients with mild to moderate GO and those with a severe form.

**Results**
Of 90 participants with GD, 59 patients (65.8%) presented with GO. Their mean age was 35.13±12.25 years and their M/F ratio was 31/28. GO was the circumstance of discovery of GD in 11% of cases. Its clinical manifestations range from mild findings such as tearing (25.6%), conjunctival injection (16.7%), gritty eyes (10%) and photophobia (8, 9%) to more significant findings including exophthalmos (65.6%), eyelids retraction (41.1%), palpebral edema (18.9%), Oculo-palpebral asynergism (17.8%), exposure keratopathy (7.8%), diplopia (6.7%), reduced visual acuity (5.6%) and strabismus (2.2%). GO was mild in 64.4%, moderate in 16.9% and severe in 18.6% of cases. On multiple logistic regression analysis, smoking status (P=0.005) and male gender (P<0.001) were predictive factors associated with the severity of GO. Other factors such as age, initial free T4 level, TSH-receptor antibodies and a history of diabetes were studied but were not predictive of severe GO.

**Conclusion**
Although various factors may influence the severity of GO, our study showed that smoking and male gender were the major and the more significant risk factors for developing severe GO. Therefore it is important for patients with GD to stop smoking.

Determination of plasma cortisol levels in women with dysthyroidism
Samira Akdader-Oudahnane, Zohra Hamouli-Said & Fatma Hadji-Bekkousche
University of Algiers, Algiers, Algeria.

**Activation**
Activation of the corticotropic axis seems to affect the thyroid axis at the central level and/or by a direct effect on the thyroid gland. The aim of this study is to investigate a possible disruption of the adrenal cortical function that would cause dysthyroidism in a population of women by assaysing plasma cortisol. The study was carried out in a human population divided into three subpopulations according to plasma levels in TSH, FT4 and FT3: the subpopulation with hyperthyroidism (Hyper), the subpopulation with dysthyroidism (Dys) and the subpopulation with hypothyroidism (Hypo). Hormone levels were determined by radioimmunoassays (FT3, FT4 and cortisol) and radioimmunometric (TSH).

**Variations**
Variations in plasma cortisol content in subpopulations with dysthyroidism have been observed and are in favor of an interrelation between the two glands. These results could be explained by the fact that factors responsible for the activation of the corticotropic axis are capable of causing structural and functional changes in the thyroid as a function of the nature of the stimulus, Its intensity and its duration.

**Aim**
The aim of the study was to evaluate the relation of vitiligo with thyroid autoimmunity.

**Conclusion**
Results could be explained by the fact that factors responsible for the activation of the corticotropic axis are capable of causing structural and functional changes in the thyroid as a function of the nature of the stimulus, Its intensity and its duration.

**Keywords:** Glucocorticoids, thyroid, hyperthyroidism, hypothyroidism, cortisol.

Therapeutic plasma exchange in the treatment of hyperthyroidism
Hamide Piskinpasa¹, Meral Mert¹, Ahmet Cem Durul¹, Piran Karakaya¹, Firuze Midi Kursat², Yildiz Okuturlar³ & Bahar Ozdemir³
¹Department of Endocrinology and Metabolism, Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey; ²Department of General Surgery, Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey; ³Department of Internal Medicine, Bakirkoy Dr Sadi Konuk Education and Research Hospital, Istanbul, Turkey.

**Therapeutic plasma exchange**
Therapeutic plasma exchange (TPE) is indicated in hyperthyroidism cases unresponsive to medical or surgical treatment. The present work aimed to study the efficacy of TPE in refractory hyperthyroidism cases.

**Methods**
A cross-sectional study was conducted on 17 patients with uncontrolled hyperthyroidism who presented at the Emergency Department of Erzincan State Hospital between January 2017 and May 2019. The patients included 11 females and 6 males, aged between 17 and 79 years (mean age: 51.3±16.6 years).

**Results**
After a single TPE session, the mean FT3 and FT4 levels decreased significantly from 15.1±2.1 to 3.7±1.5 pmol/L (P<0.001) and from 5.9±0.8 to 1.0±0.3 pmol/L (P<0.001), respectively. No significant changes were found in TSH and T4 levels after TPE. All patients showed a reduction in the signs and symptoms of hyperthyroidism.

**Conclusion**
TPE proved to be effective in refractory hyperthyroidism cases. It is an important therapeutic option in cases unresponsive to medical and surgical treatments.

DOI: 10.1530/endoabs.49.EP1235

**Endocrine Abstracts (2017) Vol 49**
Preoperative preparation of the hyperthyroid patient for thyroidectomy is imperative to avoid perioperative complications due to severe thyrotoxicosis. A 24-year-old woman was admitted to our clinic for uncontrolled Graves' disease. In our case, agranulocytosis introduced by propylthiouracil. Therefore, surgery was the only chance of an effective therapy. In cases when the patient is unresponsive to medical therapy or when such therapy is contraindicated, therapeutic plasma exchange (TPE) could be useful for preparing patients for surgery. After 13th TPE, our patient both FT4 and FT3 levels remained above the normal limits but the sign and symptoms of thyrotoxicosis improved. In the literature, number of plasmapheresis sessions done were usually less than 13 except a case of Jod Basedow with 17 sessions. We observed a moderate decrease in FT3 and at least decrease in FT4 levels after thirteen session. Total thyroidectomy was performed successfully. In cases when the patient is unresponsive to medical therapy or when such therapy is contraindicated, TPE could be useful for preparing patients with thyrotoxicosis for surgery. It is still unclear why some patients achieve the maximum benefit from TPE, regardless of their etiology. Our patient both FT4 and FT3 levels remained above the normal limits but the sign and symptoms of thyrotoxicosis improved and maybe reduced the risk of thyroid storm in the perioperative period. We continued to use β-blocker and systemic steroid therapy in order to avoid thyroid storm during the operation and a few days after surgery. These findings suggested that TPE ameliorates the clinical symptoms of thyrotoxicosis rather than thyroid hormone status. It is unclear which elements are responsible for determining patient response to TPE.

Adult outcome of congenital hypothyroidism
Najoua Lassoued, Selmiane Ouannes, Hbib Soua, Hachmi Ben Hammouda & Mohamed Taher Sfar
Pediatric Department, Taher Sfar University Hospital, Mahdia, Tunisia.

Introduction
It is because of the heavy somatic and especially intellectual impact of congenital hypothyroidism that its systematic screening from birth has been proved to be essential. Numerous publications have already reported the considerable improvement in the prognosis of this condition but still few relate to adults.

This preliminary work proposes to report the adult outcome in a cohort of 12 patients followed for congenital hypothyroidism.

Patients and methods
Descriptive study of 12 patients, seven girls and five boys, followed for congenital hypothyroidism in the pediatric department of Mahdia and who reached an age of 18 years.

Results
The mean age at diagnosis was 4.5 months. The average term was 38 SA. The mean birth size was 49.5 cm. The mean birth weight was 3700 g. Regarding statural development: the average final size was 153.5 cm (128-174). The difference between final size and target size was −0.7 DS. The last average BMI difference between final size and target size was −0.7 DS. The last average BMI was 1.75 kg/m² (16–27). Regarding pubertal development: In girls, the onset of breast development (S2) appeared at the average age of 9 and a half years, the average age of menarche was 12 years. In boys, the onset of increased testicular volume (G2) appeared at the average age of 13 years, the onset of pubic hair (P2) at 12 years. For the school curriculum: in primary school, all children were admitted to the normal age of 6 years. Only one patient redoubled in primary. Four patients redoubled in secondary, only nine patients reached the baccalaureat and three left the high school.

Discussion
An improvement in the results is still possible by acting on the different prognostic factors: age at onset of treatment, higher dose of thyroxine in the neonatal period, psychological monitoring with appropriate aids if necessary and above all compliance in adolescence.

Conclusion
It is impossible to draw definitive conclusions from this study, given the small number of patients studied. This is a preliminary study of work to be continued in the adult sector. For this these patients were oriented in the service of adult endocrinology.

Asymptomatic riedel thyroiditis presented in a patient with thyroid storm and polyglandular autoimmune disease
María Laura García², Yamila Martínez Arto³, Marta Endelman¹, Sabrina Mayoni¹, Daniel Santiago Garcia² & Noelia Rella²
¹Hospital Méndez, Buenos Aires, Argentina; ²Hospital Británico, Buenos Aires, Argentina.

Riedel Thyroiditis is a rare form of infiltrative and fibrotic disease of the thyroid that is characterized by compressive symptoms resulting from a rapidly enlarging goiter. The association with Graves Thyroiditis and autoimmune diseases is very rare. The aim of this presentation is to report a patient with asymptomatic Riedel Thyroiditis associated with Thyroid Storm and Polyglandular Autoimmune Disease. A 54-year-old female patient with recent diagnosis of Grave’s Disease was admitted to our hospital with congestive heart failure, abdominal pain, vomiting and diarrhea. Her medical history was remarkable for dilated myocardiopathy, cholecystectomy and precocious ovarian failure. At physical examination ascites, bilateral pleural effusion and a 50 g goiter with a 19 mm nodule were present. Thyroid Storm was diagnosed according to Burch-Wartofsky Score. A 10 mcU 1131 dose was administrated given the impossibility to prescribe antithyroid drugs because of severe liver disease associated. Due to persistent hyperthyroidism a second dose of 12 mcU 1131 was administrated. After achieving euthyroidism on β-blocker treatment a hepatic biopsy was indicated due to chronic intrahepatic cholestasis with negative antibodies and confirmed a stage 2 Primary Biliary Cirrhosis. Later on the patient presented impaired fasting glycemia. A pancreatic, adrenal and ovary autoimmune panel was asked and only GADA resulted positive. Histocompatibility study showed HLA DQ9 and DQ4. Three fine needle aspirations (FNA) were performed during follow up due to changes in the vascular flow of the nodule. After a negative first result the second FNA leads to III Bethesda diagnosis. Given the insufficient material obtained during the third a total thyroidectomy was indicated. Histopathological examination revealed a 1.5 cm Follicular Adenoma surrounded by Riedel Thyroiditis. To our knowledge asymptomatic Riedel Thyroiditis associated with Thyroid Storm and Polyglandular Autoimmune Disease has not been described.

DOI: 10.1530/endoabs.49.EP1237
Introduction
Radioiodine (131-I) treatment for benign thyroid disease has a 70 year history. Among the radioactive isotopes, (131-I) can be used successfully. The intention of radioiodine treatment is primarily to induce a euthyroid or hypothyroid state, but in the case of large multinodular goitres, shrinkage represents a secondary aim of therapy. The optimal method for determining iodine-131 treatment doses for Toxic Thyroid nodule is unknown, and techniques have varied from a fixed dose to more elaborate calculations based upon gland size, iodine uptake, and iodine turnover. Historically, UK prescribing has varied widely according to local custom and practice. The range of activities currently prescribed varies between 200–800 mega Becquerel (MBq), with the majority of patients receiving 400–600 MBq. Toxic adenoma, usually mild hyperthyroidism required 500 MBq of 131-I radioiodine.

Data/Method
We collected data from nuclear medicine department and hospital electronic and paper patient records. In this retrospective audit we had total 10 patients (8-female and 2 male) who received a single fixed dose radioiodine (131-I) for autonomous toxic thyroid nodule in the 10-year period from 2007–2016. Patients’ age were between 20 to 75 years. All patients had suppressed TSH at <0.05 nmol/l, with mildly raised thyroid hormones, and thyroid antibodies (TPO and TR) were negative which tended to exclude thyroid immune disorders.

Results
We checked their Thyroid function tests at 3, 6, 12 and 24 -month periods. There were significant improvements in thyroid function tests, with 4/10 patients achieving results within the euthyroid range and 6 patients becoming hypothyroid. All nodules shrank down to become non-palpable and no patient required a repeated dose of 131-I.

Recommendations
Though, 500MBq of 131-I radioiodine is recommended for toxic thyroid adenoma in the UK, our data showed that a smaller fixed dose is 100% effective and probably associated with lower rate of hyperthyroidism (60%) at 2 years. Ref;

Radioiodine in the management of benign thyroid disease Clinical guidelines, Royal College of Physicians, UK.

DOI: 10.1530/endoabs.49.EP1239

Conclusion
In non-diabetic patients, IR and thyroid dysfunction have strong correlations with NAFLD. The role of thyroid autoimmunity in this relationship needs further assessment.

EP1240

Assessment of thyroid functions, thyroid autoimmunity and insulin resistance in non-diabetic patients with non-alcoholic fatty liver disease

Maha Assem1, May Fawzi1, Alhosayen Ibrahim2 & Assem Saf1
1Faculty of Medicine, Cairo University, Cairo, Egypt; 2Ahmed Maher Hospital, Cairo, Egypt.

Introduction
Non-alcoholic fatty liver disease (NAFLD) is a common cause of impaired liver functions. It is associated with hepatic and adipose tissue insulin resistance (IR) as well as decreased whole-body insulin sensitivity. Thyroid hormones are important for the intrahepatic metabolism of lipids. Thyroid disorders have been associated with IR due to various mechanisms such as altered insulin secretion and lipid levels.

Aim
The aim of our study was to assess thyroid functions, thyroid autoimmunity and IR in non-diabetic patients with NAFLD.

Material and methods
The study was conducted on 90 non-diabetic subjects (60 patients with NAFLD and 30 subjects with normal liver). Both groups were sex matched. Ultrasonography was used to categorize the study subjects into NAFLD and normal liver groups. Thyroid functions and thyroid peroxidase antibody (TPO-Ab) were assessed in all subjects. Homeostatic model assessment (HOMA-IR) was used to assess IR in the study population.

Results
Our study showed a highly-significant positive correlation between NAFLD and IR ($P<0.001$). It also showed a significant positive correlation between NAFLD and thyroid functions with higher prevalence of subclinical thyroid dysfunction in NAFLD patients ($P=0.02$). Thyroid functions didn’t show any statistically significant correlations with IR, but TPO-Ab showed significant positive correlation with IR ($P=0.02$) within the total study population.
Aggravation of thyroid dysfunction in a case of thyroid hormone resistance after near total thyroidectomy for multinodular goiter
Ilkay Kartal & Gonca Tamer
Medeniyet University Goztepe Training and Research Hospital, Istanbul, Turkey.

Introduction
Resistence to thyroid hormone (RTH), a syndrome reduced end-organ responsiveness to thyroid hormone.

Case report
A 42 year old woman underwent near total thyroidectomy due to her large thyroid with multiple nodules. At the time she had slightly elevated values of plasma FT4, FT3 and normal TSH values and had no signs and symptoms of thyrotoxicosis or hypothyroidism. After thyroideectomy she received L-T4 treatment but her TSH levels remains elevated although FT4 was high. She was referred endocrinology polyclinic when she began to have symptoms of hypothyroidism like fatigue, fibromyalgia. The results were FT4: 1.93 ng/dl (n: 0.61–1.12), FT3: 2.2 pg/ml (n: 2.5–3.9), TSH > 100 uIU/ml (n: 0.27–4.2) under 150 mcg L-T4 treatment. There were no detectable anti-thyroid autoantibodies. Alpha subunit of TSH level was 0.8 IU/L (n: 0-0.8) normal. No pituitary adenoma was determined in pituitary MRI. She has no family history of thyroid disease. Genetic test is not available in our hospital. We performed TRH stimulation test after taken off levothyroxine for 14 days and TSH dilated up to 20 times during test. After intravenous bolus injection of TRH (200 mcg) serum TSH concentration increased from 269 uIU/ml (basal value) to a peak of 1330 uIU/ml at 30 min. As a result RTH was considered and L-T4 initiated again. After L-T4 initiated up to 175 mcg a day L-T3 added 12.5 mcg two times a day. Six weeks after this treatment FT4: 2.58 ng/dl (n: 0.61–1.12), FT3: 3.99 pg/dl (n: 2.5–3.9), TSH: 14 uIU/ml sr: 0.27–4.2). Her complaints were reduced. Blood pressure was 120/80 mmHg, pulse 74/min. She was clinically better.

Conclusion
Treatment with L-T3 would be more appropriate for reducing goiter size than attempting thyroidectomy in that patient. In patients with RTH thyroid gland ablation tends to aggravate thyroid dysfunction and multinodularity. Large glands have been successfully treated by administration of a single high dose of L-T3 given every other day. Symptoms of thyrotoxicosis usually respond to the adminstration of the beta bloker, atenolol.

Correlation between serum nitrite (NO2) levels, TQ7 and GHQ12 questionnaire scores in treatment-naive hypothyroid patients
Zoran Gluvić, Vladimir Samardžić, Jelena Tica Jevtić, Marina Vujović, Milena Lačković, Vesna Popović-Radinović, Saša Radenković, Violeta Mađenović, Emina Sudar-Milovanović, Milan Obradović & Esma R Išenović
1Division of Internal medicine, Department of Endocrinology, Zenun Clinical Hospital, School of Medicine, University of Belgrade, Belgrade, Serbia; 2Clinic for Endocrinology and Diabetes, Nis Clinical Centre, School of Medicine, University of Nis, Nis, Serbia; 3Center for Endocrinology and Diabetes, Clinical Centre Kragujevac, Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia; 4Lab for Molecular Endocrinology and Radiobiology, Institute for Nuclear Sciences ‘Vinča’, University of Belgrade, Belgrade, Serbia.

Introduction
Primary hypothyroidism, as a clinical syndrome caused by insufficiency or inefficacy of thyroid hormones, significantly influences on patients’ quality of life (QoL). Accelerated atherosclerosis induces increased cardiovascular morbidity and mortality rates in hypothyroid patients. Serum NO2 levels, the stable NO metabolite, are among well-known markers for endothelial dysfunction and atherosclerosis in hypothyroidism. We examined the correlation between serum NO2 levels and QoL questionnaires scores (TQ7 and GHQ12) in treatment-naive hypothyroid females.

Material and methods
Cross-sectional study involved 82 females, divided into three groups according to TSH and FT4 levels: latent (22) and overt (22) hypothyroid, and euthyroid (38) group, respectively. Initially, after informed consent was signed, serum NO2 levels were measured and TQ7 and GHQ12 questionnaires were fulfilled. Obtained data were analysed with appropriate statistical methods. Statistical significance was 0.05.

Results
Overall mean of NO2 level was 11.2 μmol/l (0.9–79.0 μmol/l) and didn’t differ between groups. Mean overall TQ7 and GHQ12 scores were 14 (5–40) and 12 (1–32) respectively, and statistically differ between groups (P<0.01). Correlation between serum NO2 levels and TQ7 and GHQ12 scores didn’t significantly differ (rNO2/TQ7 = −0.241, rNO2/GHQ12 = −0.141; P>0.05).

Conclusions
Decreased serum NO2 levels in hypothyroid groups pointed out to lowered NO bioavailability and therefore endothelial dysfunction. Otherwise, thyroid disease specific questionnaire score determined hypothyroid patients in moderately stressed cluster. A simultaneous use of NO2 levels and QoL scores can alleviate decision to introduce the l-thyroxin management in hypothyroid patients, presumably in latent ones.

Vitamin D levels in Graves’ disease (GD) are lower than in general population but do not correlate with laboratory and clinical parameters in GD or SNPs associated with GD

Teresa Planck1,2, Bushra Shaluda1, Johan Malms1,3 & Jonas Manjer1,4
1 Lund University, Department of Clinical Sciences, Malmö, Sweden; 2 Department of Endocrinology, Skåne University Hospital, Malmö, Sweden; 3 Department of Clinical Chemistry, Skåne University Hospital, Malmö, Sweden; 4 Department of Surgery, Skåne University Hospital, Malmö, Sweden.

Introduction
The role of vitamin D in GD is poorly understood. The aim was to compare vitamin D levels in newly diagnosed patients with GD with the general population and to correlate vitamin D levels at diagnosis with laboratory and clinical parameters in GD. Moreover, we examined genetic variation in genes involved in the vitamin D metabolism and their association with GD.

Material and methods
Levels of vitamin D were compared in 292 patients with newly diagnosed GD and 2305 controls. Single nucleotide polymorphisms (SNPs) in the vitamin D receptor (VDR), vitamin D binding protein (DBP) and 1-alpha-hydroxylase (CYP27B1) were examined for association with GD and/or Graves’ ophthalmopathy (GO) in 708 patients and 1178 controls.

Results
Patients with GD had significantly lower levels of vitamin D compared to general population (55.0±23.2 vs 87.2±27.6 nmol/l, P<0.001). In patients with GD (n=219), there was no association between the levels of vitamin D and the levels of free thyroxine (FT4), free triiodothyronine (FT3), thyroid stimulating antibodies (TRAb), GO at diagnosis, or relapse after terminating treatment with anti-thyroid drugs. Two SNPs in VDR were associated with GD, rs10735810 (OR 1.36, 95% CI 1.02–1.36, P=0.02) and rs1544410 (OR 1.47, 95% CI 1.03–1.47, P=0.02). However, there was no difference in mean vitamin D levels between genotypes in either rs10735810 (AA 55.9 nmol/l, AG 56.1 nmol/l, GG 54.8 nmol/l, P=n.s.) or rs1544410 (AA 56.6 nmol/l, AG 57.5 nmol/l, GG 54.8 nmol/l, P=n.s.).

Conclusion
Patients with GD have lower vitamin D levels compared with general population; however, the levels of vitamin D do not affect the laboratory or clinical parameters of the disease. SNPs in the VDR influence the risk of GD through mechanisms other than reducing the vitamin D levels.

Intrathyroidal and peripheral venous blood lymphocyte subset patterns in patients with Graves disease

Margarita Dudina1,2, Dogadan Sergey1,2, Savchenko Andrei3, Mankovsky Vladimir2 & Borisov Alexander
1 Krasnoyarsk state Medical University named after prof. V.F. Voyno-Yasenetsky, Krasnoyarsk, Russia; 2 Krasnoyarsk region clinical hospital, Krasnoyarsk, Russia; 3 Institute for Medical problems of the North, Russian Academy of Medical Science, Siberian division, Krasnoyarsk, Russia.

Graves’ disease (GD) is an autoimmune disease with genetic predisposition. The link with the major histocompatibility complex determines the complexity of the excess thyroid hormones molecular action on immune system that may cause the divergence of autoimmune process in GD, functioning not only in peripheral immune cells, but also in the thyroid. Objective: to study the phenotypic composition of T- and B-lymphocyte subset patterns in peripheral blood and thyroid tissue in patients with GD. Materials and methods. The study included 43 women with GD, mean age 39.95±14.38, who were performed the epifascial thyroidectomy. Phenotypic composition of T- and B-lymphocytes was investigated by flow cytometry. Analysis of stained cells was performed on a flow cytometer FC-500 (Beckman Coulter, USA). Each sample was analyzed at least 50,000 lymphocytes. Results. The median level of thyroid stimulating hormone (TSH), free thyroxine and autoantibodies to TSH receptor was 1.9 (0.9; 2.9) umol/ml, 16.8 (13.2; 19.0) and 15.8 (9.4; 24.2) IU/ml. In peripheral blood of GD patients compared with healthy controls identified the increased in 9.2% the relative number of total T lymphocytes (CD3+; P<0.001) and in 5.8% relative level of T-helper cells (CD3+CD4+; P=0.019), but decreased content of T-regulatory cells (CD3+CD4+CD127LowCD25High, P=0.048) and total activated T cells (P<0.001), T-helper cells (CD3+CD4+CD25+; P=0.045) and cytotoxic T-lymphocytes (CD3+CD8+CD25+, P=0.041). It is revealed that in the blood of GD patients increased in 35.9% the relative number of B2-lymphocytes (CD19+CD5+, P=0.003), while reducing the amount of activated total B cells (CD19+CD23+, P<0.001), B2 cells (CD19+CD25−; P<0.001), B2 - simplet (CD19+CD5−CD27−, P<0.001) and B2-memory (CD19+CD5−CD27+, P<0.001) cells. In a comparative analysis of the phenotypic composition of T- and B-lymphocytes in peripheral blood and thyroid tissue revealed that in the tissues is 2.3 times higher relative content of total activated T cells (CD3+CD25+, P=0.037), in 5.1 times more of activated cytotoxic T-lymphocytes (P=0.023), 1.7 times increased the percentage of B2-memory (CD19+CD5−CD27+, P=0.028) cells. Conclusions. The reduction of activated T- and B-lymphocytes content in peripheral venous blood of patients with GD is determined by the migration of immune cells in thyroid tissue.

No impact of subclinical hypothyroidism on cognitive functions among the elderly

Harleen Kaur1,2, Nitin Malhotra2 & Jugbin Jacob1,2
1 Endocrine & Diabetes Unit, Christian Medical College and Hospital, Ludhiana, Punjab, India; 2 Department of Medicine, Christian Medical College and Hospital, Ludhiana, Punjab, India.

Background
Most recent cross sectional and longitudinal studies have failed to find an association between cognitive dysfunction and subclinical hypothyroidism. A recent paper from our country however suggested a significant association. Objectives
This study was undertaken to determine the prevalence of cognitive impairment among educated, elderly Indian patients (> 60 years) with and without subclinical hypothyroidism.
Materials and methods
This study was conducted on educated, elderly patients admitted to the in-patient department of Christian Medical College, Ludhiana. One hundred patients with subclinical hypothyroidism an equal number of controls with normal thyroid functions were interviewed after taking informed consent. Subclinical hypothyroidism was defined as serum TSH level more than 4.0 mIU/L with serum FT3 and FT4 in the normal reference range. Cognitive function was assessed by Hindi/English Mini mental status examination (MMSE) and clock drawing test (CDT).

Results
The cases (n = 100) had a mean age of 68.2 years, 59% males and had a mean body mass index of 25.5 kg/m² compared to controls (n = 100) who had a mean age of 69.9 years (P = 0.09), were 64% male (P = 0.5) and had a mean BMI of 25.3 kg/m². All other baseline variables including co-morbidities, family history of dementia, head injury, smoking, alcohol use, fruit and vegetable intake, daily newspaper reading, education and exercise regularity were comparable in both groups. The cases had mean MMSE of 26.1 and controls of 25.9 (P = 0.68) respectively. The cases had mean CDT of 2.19 and controls 2.18 (P = 0.04).

Conclusions
There is no difference in cognitive function in elderly with subclinical hypothyroidism in comparison with elderly population having normal thyroid function.

**Prolonged iodine excess due to hysterosalpingography in a pregnant woman**

Abbas Ali Tam, Seygyl Faki, Didem Özdemir, Cevdet Aydin, Reyhan Esoy & Bekir Çakır

Yıldırım Beyazıt University School of Medicine, Endocrinology and Metabolism Diseases, Ankara, Turkey.

Introduction
Hysterosalphingography (HSG) is the radiographic examination of uterine cavity and fallopian tubes. It is generally used during evaluation of infertility and radioopaque contrast is injected through cervical duct during the procedure. Lipiodol which is the most commonly used contrast media in HSG is a fat-soluble iodinated contrast media. This iodine is progressively cleared from the body in a period ranging from a few weeks to a few months. Here, we present a 6 week pregnant woman who underwent HSG 9 months ago and has very high urinary iodine excretion.

Case
A 31 years old woman at the 6th week of pregnancy was consulted for high blood glucose. She was evaluated for infertility for 2 years, and HSG was performed 9 months before conception. There was no history of drug or nutritional supplement use that has high iodine content and that might affect iodine status. Iodine excretion was 10087 mcg/L (100–700 mcg/L) in random urine sample and > 450 mcg/L in 24 hour urine. Her serum TSH was 2.19 uIU/mL, FT4 was 1.32 ng/dl and FT3 was 1.32 ng/ml. Thyroid autoantibodies were negative and thyroid ultrasonography was normal.

Conclusion
The optimal time for normalization of body iodine stores after exposure of iodinated contrast media is not known exactly. Thyroid dysfunctions in the form of both hypothyroidism or thyrotoxicosis can develop in euthyroid subjects after use of iodinated contrast media during HSG. In our case, thyroid functions were normal but normal urinary iodine was very high even several months after HSG. This suggests that females at reproductive age who underwent HSG might have excess iodine concentration for a prolonged time and should be carefully evaluated for development of thyroid dysfunctions.

The challenge of diagnosing thyroid storm: a comparison of the Japanese Thyroid Association Criteria to de Burch Wartofsky Point Scale

María Laura García1, Gabriela Szuman1, María Florencia Scoscia1, Susana Bacigaluppi1, María Victoria Panebianco1 & Noelia Rella1

1Sanatorio Méndez, Buenos Aires, Argentina; 2Hospital Británico, Buenos Aires, Argentina; CEBBAD, Universidad Maimonides, Buenos Aires, Argentina.

Thyroid storm (TS) is a rare and life threatening condition that requires a prompt recognition and treatment. The clinical features may overlap with other acute medical conditions. Currently both Akamizu Criteria (JTA) and Burch and Wartofsky Scale (BW) are helpful diagnostics tools.

Objective
To evaluate TS patients according to currently available criteria and to identify the clinical features and outcomes.

Methods
A single center retrospective study covering a 6 year period was performed.

Results
Fifteen cases were identified, resulting in four cases of TS per 10 000 admitted. Mean age 49.8 ± 17.3 years (range: 31–86). Male/Female = 3/12. Etiology: autoimmune (n = 8), faducious (n = 3), amiodione-induced (n = 3), undetermined (n = 1). Manifestations at admission: cardiovascular (n = 8), fever (n = 3), delirium (n = 2), diabetic ketoacidosis (n = 1) and hypokalemic paralysis (n = 1). Eleven had previous history of thyroid disease. Precipitating factors were found in 12 cases. Thyroid hormone levels did not correlate with the severity of thyrotoxicosis. Mortality rate was 6.6%: 1 patient died from sepsis. Late hospital discharge was found in 4 patients (P = 0.01): 3 required antithyroid drugs withdrawal and the other received a heart transplant. The table resumes patients according to BW and JTA. JTA fails to detect 4 patients with impending TS (st0), one of which later on developed st1 (p8).

Conclusions
Ours results shows discrepancies between the two diagnostic systems. BW appears to select a higher percentage of patients for aggressive therapy than JTA. This presentation provides useful information for the management of TS, a rare and acute disease that requires high clinical suspicion in order to improve patient survival.

The role of FNDCC gene expression in irisin level changes accompanying thyroid pathologies

Ariadna Żybek-Kocik1, Nadia Sawicka-Gutaj1, Miroslaw Andrusiewicz2, Joanna Waligórska-Stachura1, Piotr Biała2, Jerzy Skrobisz2 & Marek Ruchala1

1Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; 2Department of Cell Biology, Poznan University of Medical Sciences, Poznan, Poland; 3Department of General Surgery and Multiple Trauma, with Division of Gastroenterological and Endocrine Surgery, Provincial Hospital, Poznan, Poland.

Irisin is a recently reported, widely discussed new adipokine myokine secreted mainly by muscle tissue. It is a cleaved and secreted part of hibernectin type III domain containing 5, encoded by the FNDCC gene. Some of the previously published studies claim that alterations of irisin levels in patients affected by thyroid diseases may be connected mainly with accompanying myopathy. However, to date it has not been evaluated, whether the changes in expression of FNDCC5 may play a role in irisin level alterations. The aim of the presented study is to assess the expression of FNDCC5 gene in thyroid tissue of subjects with Graves’ disease, multinodular benign goiter, toxic goiter and papillary thyroid cancer. The group of 80 patients with above mentioned thyroid pathologies were involved. All included subjects underwent total thyroidectomy for reasons unrelated to the study. Quantitative RT-PCR was used to analyze the FNDCC5 gene expression. As a result, the expression of FNDCC5 was noted in all analyzed samples. No statistical difference between FNDCC expression in benign and malignant thyroid cases was observed.

DOI: 10.1530/endoabs.49.EP1252
changes, as well as conditions associated with hyperthyroidism and euthyroid state were found. Statistically significant overexpression of FND5 in patients with toxic goiter in comparison with tissues affected by Graves’ disease, papillary thyroid cancer (tumor staged pT1 or pT2) and controls was observed. In conclusion, toxic goiter may be associated with FND5 overexpression in thyroid tissue, in comparison with Graves’ disease, papillary thyroid cancer staged pT1 or pT2 and controls. The FND5 overexpression, on the other hand, is not directly associated with hyperthyroid state, as well as thyroid malignancy development. Hence, the changes in FND5 expression probably do not play the role in irisin concentration changes associated with thyroid pathologies.

Long term effects of the less than total thyroidectomy: The experience of a tertiary care center

Georgios Boutzoukas1, Zoe Garoufalia1, Krystallenia Alexandrak1
Gregory Kaltisas2, Grigoris Kourakis2 & Gerasimos Tsourouflis2
1Endocrine Unit, Department of Pathophysiology, Laiko University Hospital, Medical School, University of Athens, Athens, Greece;
2Second Department of Propedeutic Surgery, Laiko University Hospital, Medical School, University of Athens, Athens, Greece.

Background and aims

Less than total thyroidectomy (lobectomy, partial or subtotal thyroidectomy) is used mainly to treat thyroid nodules, and/or hyperthyroidism. The aim of the study was to investigate the long term effects of less extensive surgical procedures. such as re-appearance of nodules and the need of thyroxin supplementation, or re-operation.

Material and methods

Retrospective study in a tertiary Academic medical center. The study population comprised initially 76 patients. Of whom 67 patients (age ± s.d.: 64.1 ± 13.3, 58 (86.5%) females) who underwent lobectomy, partial thyroidectomy or subtotal thyroidectomy with benign histology and a follow-up equal or longer to 5 years were included (9 excluded). None the patients appeared post-surgery permanent iatrogenic hyperparathyroidism or recurrent laryngeal nerve injury.

Results

Mean follow up was 22.1 ± 10.8 years. Patients who underwent lobectomy, partial thyroidectomy and subtotal thyroidectomy were 24 (35.8%), 9 (13.5%) and 34 (50.7%), respectively. Patients received thyroxin replacement were 62 (92.5%).

Relapse as defined by re-appearance of nodules or recurrence of hyperthyroidism in total population was in 39 (58.2%) patients: 70.8% (17/24) in lobectomy group; 77.8% (7/9) in partial thyroidectomy, and 44.1% (15/34) in subtotal thyroidectomy group, respectively. Re-operation underwent 7 patients (10.4%) of total or 17.9% of the recurrence cases. Univariate analysis showed that the type of operation and the length of follow up were predictors for relapse (OR: 1.81, 95%CI: 1.03–3.19, P = 0.038 and OR: 0.92, 95%CI: 0.87–0.97, P = 0.002, respectively). Multivariate analysis showed that the length of follow up was superior independent factor predicting relapse (OR: 0.92, 95%CI: 0.87–0.98, P = 0.006).

Conclusions

The majority of patients received thyroxin replacement. The length of follow-up and the type of operation have an impact on relapse, but mostly the length of follow up. Treatment with total thyroidectomy could eventually avoid a relapse and a possible need for re-operation.

Severe hyperthyroidism imposes large amounts of antithyroid compounds

Adina Mazilu1, Cristina Spiroiu1 & A E Ranetti1,2
1Central Military Emergency Hospital, Romania, Romania;
2National Institute of Endocrinology, Romania, Romania.

We present three cases of females with low body weight that needed large amounts of anti-thyroid drugs – 4-5 mg/kg Thiamazole and 50 mg/kg of Propylthiouracil. First patient, aged 32, weight 45 kg, had Graves’ disease evolving for more than five years. She has been proposed surgery and needed 1200 mg/day of Propylthiouracil. She delayed surgery for 2 weeks, then the dosage required for euthyroidism was 1800 mg/day for three weeks. The goitre had 1.2 kg, from mandible angle to the supravacular region; she did not develop hypoparathyroidism or palsy of recurrent laryngeal nerve.

Second patient, 47 years old, with Gravess’s disease, came with class III heart failure and severe asthma. She required 1800 mg of PTU before surgery and had persistent hypoparathyroidism. Third patient, 60 years old, had severe cardiomyopathy at the beginning, left ventricle ejection fraction 15%, atrial fibrillation that needed Cordarone both intravenously and orally. The dosage was progressively increased from 60 to 180 mg/day Thyrozol until safely operated. Patient did not tolerate Propylthiouracil due rash. Ejection fraction became 30% postoperatively and no complications occurred.

Postpartum thyrotoxicosis – a diagnosis, sometimes, postponed

Alexandra Novais Araujo, José Marçalo, Cristina Costa, Ana Wessling & Maria João Bugalho
Centro Hospitalar Lisboa Norte, Lisboa, Portugal.

Postpartum thyroid dysfunction occurs in 5–10% of women in the general population within one year of delivery. The prevalence of postpartum Graves’ disease is estimated at 0.54%. Postpartum thyroiditis is much more common. Differential diagnosis is essential for an adequate treatment. Radioactive iodine uptake can be useful to establish the etiologic diagnosis, but is contraindicated during lactation. Elevated titers of antithyrotropin receptor antibodies (TRAbs) are suggestive of Graves’s disease but may be measurable in approximately 10% of patients with painless thyroiditis and their titers can be low in the early phase of Graves’ disease. Therefore, the evolution of thyroid function and TRAbs’ titers may be needed to distinguish both pathologies. We present the case of a 25-year-old Caucasian woman who presented to the Emergency Department, 4 months after giving birth and still breastfeeding, complaining of palpitations, anxiety, fatigue and insomnia with 1 week of duration and referring a 15 kg weight loss postpartum. She mentioned that her mother had Graves’ disease. There was no ophthalmopathy; her heart rate was 140 bpm and the electrocardiogram confirmed sinus tachycardia. Thyroid examination showed a painless tender and slightly enlarged gland. Blood tests – TSH 0.011 uU/ml (0.3–4.2),FT3 20 pg/ml (2.3–4.2) and FT4 5.33 ng/dl (0.93–1.7). She was referred to the Endocrinology Department under treatment with methimazole and propranolol. Further testing revealed positive anti-thyroid peroxidase and thyroglobulin antibodies and TRAbs within ‘grey zone’. Thyroid function was monitored with slowly tapering of methimazole dosage. Eight months postpartum, despite low methimazole dosage (2.5 mg id) she presented with asymptomatic hypothyroidism (TSH > 100 uU/ml). Anti-thyroid antibodies remained positive but TRAbs were negative.

Methimazole was suspended and levothyroxine 25 mcg id initiated. At last follow-up, the patient remains asymptomatic and in euthyroidism. Diagnosis of postpartum thyroiditis was assumed. Monitoring thyroid function and TRAbs levels for several months might be necessary to allow the differential diagnosis.

Clinical characteristics of painless thyroiditis

Yonghyun Kim, Jeonga Choi & Donghyun Shin
Daejin Medical Center, Seongnam, Republic of Korea.

Background

There are a lot of painless thyroiditis cases without symptoms diagnosed on health check up or thyroid hormone screening, but there is a few data about it compared to much data about painful subacute thyroiditis. So, we collected data about diagnostic routes, laboratory and clinical characteristics of painless thyroiditis.

Method

Painless thyroiditis patients diagnosed between 2010 and 2016 were reviewed. The prevalence of painless thyroiditis was defined as disease with typical clinical courses of postpartum thyroiditis or at least three symptoms of hyperthyroidism without any symptoms or signs of an acute inflammatory process. On the other hand, patients with thyroiditis were classified as painful cases.

Results

A total of 28 patients were included in this study. There were 25 women and 3 men. Their age range was 21 to 31 years (median: 27 years). Ten patients were diagnosed before 2013. Patients were divided into three different subgroups: group A (12 patients), group B (5 patients), and group C (11 patients) formed according to subacute thyroiditis symptoms. In group B and C, painless cases were more frequently diagnosed after first trimester of pregnancy than before (92% and 89%, respectively).

Conclusions

Postpartum painless thyroiditis might be more common than previously thought. Further studies are needed to confirm these findings.
thyrotoxicosis and sequential hypothyroid phase and decreased uptake on thyroid scan.

Result
Total 191 patients (139 female, 52 male) were involved. The diagnostic routes were classified under four entry. First, health check up: 47 patients, 24.6%. Second, patients evaluated with thyroid function test because of nonspecific other symptoms or routine check up of inpatient: 68 patients, 35.6%. Third, patients evaluated with thyroid function test because of thyrotoxic symptoms or signs (fatigue, palpitation, tremor, jitter etc): 59 patients, 30.9%. Fourth, patients associated with postpartum: 17 patients, 8.9%. Permanent hypothyroidism was not uncommon (7/191; 3.7%). Higher peak TSH level (P value below 0.001) was associated with permanent hypothyroidism. 11.5% (22/191) experienced recurrence. Lower peak TSH (P value 0.018) and short duration of thyrotoxicosis phase (P value 0.001) was associated with recurrence.

Discussion
More than 50% of painless thyroiditis was diagnosed on health check up or accidental thyroid function test without typical thyrotoxic symptoms. Many patients with heterogeneous parenchymal echogeneity on sonography finding without history of thyroid disease could be go for that cases. Higher peak TSH was related with permanent hypothyroidism. In contrast, lower peak TSH was associated with recurrence and short duration of thyrotoxicosis phase was also related with recurrence.

EP1257
The effectiveness of parathyroidectomy in children with primary hyperparathyroidism
Nazira Rikhiseva
Tashkent Paediatric Medical Institute, Tashkent, Uzbekistan.

Objective
To Evaluate the effectiveness of parathyroidectomy in children with primary hyperparathyroidism.

Materials and methods
Under our observation in the period 2014–2015, were 46 patients with primary hyperparathyroidism at the age of 11–16 years. To assess the effectiveness of parathyroidectomy a questionnaire was used and table PAS (Parathyroidectomy Assessment of symptoms- table of symptoms in primary hyperparathyroidism) to assess the effectiveness of parathyroidectomy).

The results of the study
Evaluation of the effectiveness of parathyroidectomy with regard to the elimination of most symptoms in primary hyperparathyroidism table PAS revealed a statistically significant reduction of symptoms and complaints. The amount of symptoms in the preoperative period was 445, a month after surgery decreased to 350, 3 months later 200, with certainty P<0.01. Indicators of the sum of symptoms after 1 year was 155, which represents a dramatic difference compared to the preoperative period. While decrypting the received data of the questionnaires, it became evident a significant reduction of complaints and symptoms of primary hyperparathyroidism which undoubtedly attests to the effectiveness of the operation.

Conclusions
Parathyroidectomy is undoubtedly the most effective treatment of primary hyperparathyroidism in children today. We recommend you to use the questionnaire on the table as PAS in the outpatient setting and in hospitals. This way complaints will allow you to suspect primary hyperparathyroidism in patients. Early detection of pathology of the parathyroid gland, and operative intervention are essential to early recovery of patients and their wellbeing.

EP1258
Fluctuating thyroid hormones in Graves disease: a case series of brittle Graves
Muhammet Cuneyt Bilginey, Seygül Faki, Cevdet Aydin, Didem Ozdemir, Abbas Ali Tam, Reyhan Ersoy & Bekir Cakir
Ankara Yildirim Beyazit University School of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey.

Introduction
Brittle hypothyroidism is a term used for the clinical situation characterized by hypo-hyperthyroidism with antithyroid drugs, despite good compliance and follow-up. Here, we presented five patients suggested to have Brittle Graves.

Case-1
Thyrotoxicosis was observed in a 57-year-old female patient and Graves was diagnosed after laboratory and imaging examinations 25 months after initiation of propylthiouracil 300 mg/day, she developed hypothyroidism and the drug was discontinued. Thyrotoxicosis recurred in 3 months and the patient underwent thyroidectomy. The histopathological diagnosis was lymphocytic thyroiditis.

Case-2
Graves was diagnosed in a 22-year-old female patient with Down syndrome. After 15 days of propylthiouracil treatment, serum TSH was 100 IU/ml and hyper-hyperthyroid periods recurred despite appropriate treatment and thyroidectomy was offered. A 67-year-old male patient with a diagnosis of Graves disease has used methimazol for 14 months and the drug was discontinued due to hypothyroidism. Recurrent periods of hyper-hyperthyroidism developed in a short time and thyroidectomy was offered.

Case-4
Thyrotoxicosis was observed in a 48-year-old female patient with a history of levotyroxine use for 10 years. She had positive TSH receptor antibody and ophthalmopathy. Methimazol was started because thyrotropic state persisted despite discontinuation of levotyroxine, but hypothyroidism developed in a short time and thyroidectomy was offered.

Case-5
This clinical manifestation overlap with has hothasitosis. “Brittle Graves” seems to be a better definition for such cases.

EP1259
The role of an ultra-sensitive fourth-generation TSH assay in the management of subclinical hyperthyroidism
Emily Austin1, Steve Peacey2 & Andrew Bates1
1Heart of England NHS Foundation Trust, Birmingham, UK; 2Bradford Teaching Hospitals NHS Foundation Trust, Bradford, UK.

The management of endogenous subclinical hyperthyroidism is largely guided by perceived risk, including the presence of cardiovascular disease, atrial fibrillation or osteoporosis. We have utilised a fourth-generation TSH assay, providing a 10-fold increase in sensitivity compared to third-generation assays, to determine whether patients with subclinical hyperthyroidism can be differentiated from those with overt hyperthyroidism, based on their now measurable TSH levels. Two groups of patients were identified using thyroid function tests measured with a traditional third-generation assay (Roche). The first (Group 1) had normal free thyroid hormone levels and the second (Group 2) had elevated free thyroid hormone levels. Both had a suppressed TSH (<0.02). The samples were then re-analysed using a fourth-generation assay (Olympus AU3000i) and the values compared. All results are given as median and interquartile range. Group 1 (n=23, M:F 4:19), free T4 17.5 pmol/l (15.8–19.9), free T3 6.1 pmol/l (5.5–6.3); Group 2 (n=54, M:F 14:40) free T4 32.5 pmol/l (25.7–54.9), free T3 10.7 (7.9–13.0). Group 1 fourth-generation TSH 0.009 mU/l (0.007–0.014); Group 2 0.004 mU/l (0.003–0.008) (P<0.001, Mann–Whitney U). Whilst group 1 has a significantly greater fourth-generation TSH than group 2, comparison of the interquartile ranges confirms significant overlap. In group 1 12/23 patients had fourth-generation TSH values above the upper limit of the interquartile range of those with overt hyperthyroidism (group 2). Thus, the measured fourth-generation TSH may be of value in determining the need for treatment. Those in group 1 with TSH values falling within a comparable range to those with overt hyperthyroidism should be considered for treatment, whilst those with greater TSH values could be monitored for progression. Our data suggest that a fourth-generation TSH assay is of value in assessing which patients with subclinical hyperthyroidism should be treated and those who should be monitored.

Non-thyroidal illness syndrome in chronic renal failure and oxidative stress: preliminary data on triiodothyronine relationships with extracellular superoxide-dismutase
Antonio Mancini1, Nicola Panocchia2, Giuseppe Martina1, Carmine Bruno1, Sonia Silvestri1, Patrick Orlandi1, Fabio Marchegiani1, Luigi Tazza1, Luca Tiano1, Giovanni Gambaro1 & Alfredo Pontecorvi1
1 Catholic University of the Sacred Heart, Operative Unit of Endocrinology, Rome, Italy; 2 Fondazione Policlinico Gemelli, Nephrology Division, Rome, Italy.

Non-thyroidal-illness syndrome (NTIS) is present in chronic renal failure and considered an adaptive mechanism. However oxidative stress is linked to NTIS in a vicious circle, due to dioinesides alteration and negative effect on antioxidant levels or activity. One key antioxidant, protective toward ROS-mediated tissue damage, is extracellular superoxide-dismutase (ec-SOD), present in extracellular matrix and with a role in mediating nitric oxide-induced signaling. ec-SOD is specifically released from endothelium by heparin injection, allowing the determination of ec-SOD activity in vivo without affecting Cu,Zn-SOD or Mn-SOD. No data are reported on ec-SOD in renal failure and its relationship with thyroid function. Therefore we have studied 12 hemodialysis patients (9 males and 3 females, mean age 67 yrs), evaluating thyroid hormones and ec-SOD activity after exenaparin administration. Blood samples were obtained at the starting of hemodialyotic session, 5 and 10 min after 1000–4000 U enoxaparin and at the end of the session. SOD activity was measured by a modified nitrite method. Superoxide generated by hypoxanthen and xantine oxidase was changed by hydroxylamine to nitrite ion which was measured spectrophotometrically at 550 nm by the use of a chromogen. The amount of SOD required to inhibit 50% nitrite ion generation was defined as 1 U SOD activity. Six patients exhibited low FT3 values (1.8 ±0.1 pg/ml); the others had normal FT3 (2.5 ±0.2 pg/ml); FT4 and TSH values were normal. Basal ec-SOD did not differ between the two groups, but the percentual increase after heparin was significantly correlated with T3 levels (r=0.24, P <0.05). These preliminary data suggest that low T3 can negatively influence endothelial antioxidant defenses. The relationships of this datum with cardiovascular complications and prognostic usefulness remain to be established.

Therapeutic options in severe thyrotoxicosis with malabsorption
Mirjana Stojkovic1,2, Slavica Savic1, Biljana Nedeljkovic-Beleslin1,2, Jasmina Cinc1,2, Tanja Nisic1 & Milos Zarkovic1
1 Clinic of Endocrinology, Diabetic and Obesity diseases, Clinical Center of Serbia, Belgrade, Serbia; 2 School of Medicine, University of Belgrade, Belgrade, Serbia.

Abstract
A 55-year-old woman was admitted to our hospital due to severe hyperthyreosis. She reported to feel symptoms of hyper-metabolic state four months prior to hospitalization. At that time she was admitted in regional hospital and had gastroenterological examination because of diarrhea. Crohn’s disease was diagnosed and therapy started. At the same time, thyrosupressive therapy started. She had a history of hyperthyreosis thirteen years ago, duodenal hemorrhage ulcer, hypertension, cerebral vascular insult and myopericarditis. Despite maximal dose of thiamazole, on admission she was highly hyper-metabolic. Hormonal analysis revealed severe thyrotoxicosis (fT4 871.4 nmol/l), T4 (54.5 pmol/l), T3 (2.27 nmol/l), and negative TPOAb (<28.0 U/ml) and TgAb (<15.0 U/ml). Stool analysis was positive for muscle fibers, fat and carbohydrates indicating malabsorption and malassosorption. Because of multiple comorbidities, we decided to prepare a patient for radioactive iodine treatment (RAI). We concluded that at this hyper-metabolic state, it could lead her in thyroid storm and that her thyroid hormones should be decreased at safer levels prior to RAI. After admission, we started with intrathyroidal dexamethasone injections with initial decreasing of thyroid hormones. The procedure wasn’t continued because of gastric pain she started to feel (history of ulcer). We replaced thiamazole for PTU, and started with therapeutic plasma exchange (TPE). After TPE, we observed a significant decrease in T4 (54.5 pmol/l), T4 (139.0 nmol/l) fT3 (54.3 pmol/l) T3 (2.27 nmol/l) levels. Clinical improvement was achieved. Patient underwent RAI treatment safely, and after two months, her thyroid hormones were in the normal referent range with TSH still suppressed (T4 13.7 pmol/l; T3 4.71 pmol/l; TSH 0.01 mIU/l). We concluded that severe thyrotoxicosis in our patient was due to malabsorption of thyruspressious drugs caused by Crohn’s disease and thyrotoxicosis itself. In such cases alternative therapy options should be considered.

Congenital disorders in children of the mothers with thyroid malfunctioning at pregnancy
Saba Akbar1, Rubina Mansoor2 & Muhammad Irfan1
1 Department of Zoology, P M A Shah Agriculture University, Rawalpindi, Pakistan; 2 Chemical Pathology, Rawalpindi Medical College, Rawalpindi, Pakistan.

In the present study we hypothesized that maternal thyroid disorders may be associated with maternal and foetal morbidity and mortality. The present study included 136 pregnant women selected randomly in first trimester and observed throughout the pregnancy till birth. The assessment of thyroid hormones showed a total of 33.08% (n=45) pregnant ladies were having thyroid disorders; 17.65% (n=24) with hypothyroidism and 15.44% (n=21) with hyperthyroidism. The mothers with hypothyroidism were significantly (P<0.05) heavier than normal mothers while the mother with hyperthyroidism were significantly (P<0.05) lighter than normal and those with hypothyroidism. The hyperthyroidism increased the odds (OR: 6.80; 95% CI: 1.65–28.09) of miscarriages significantly (P<0.05). Maternal hypothyroidism increased the gestational period significantly (P<0.05) and hyperthyroidism decreased the gestational age significantly (P<0.05). Maternal hypothyroidism may lead to significantly (P<0.05) increased birth weight and maternal hyperthyroidism may decreased the birth weight significantly (P<0.05). The maternal hyperthyroidism may lead to a statistically significant (P<0.05) decrease in the size of skull and brain weight in neonates. Furthermore, the hyperthyroidism and hyperthyroidism increased the odds of webbed neck neonates (OR: 5.87; 95% CI: 1.22–28.30 & OR: 11.73 95% CI: 2.64–52.06, respectively. The data exhibited that the maternal hyperthyroidism increased the odds (OR: 10.47; 95% CI: 1.78–61.78) of eyes defects in neonates. The maternal hypothyroidism increased the risk (OR: 18.00; 95% CI: 1.91–169.10) of neonatal congenital heart defects.

EP1263

Psychometric evaluation of the newly developed hypoparathyroidism symptom diary
Theresa Coles1, Kristina Chen2, Lauren Nelson1, Nimaneet H Harris1, Montserrat Vera-Lloch3 & Susan Martin1
1 RTI Health Solutions, Research Triangle Park, NC, USA; 2 Shire Human Genetic Therapies, Inc., Lexington, MA, USA.

Objective
The purpose of this study was to evaluate the psychometric properties of a novel, patient-reported outcome (PRO) measure, the Hypoparathyroidism (HPT) Symptom Diary (HPT-SD), using data collected during a cross-sectional, noninterventional, observational study. The HPT-SD, developed according to the US Food and Drug Administration PRO guidance, addresses the severity of key symptoms (muscle cramping, tingling and muscle spasms/twitching, fatigue, cognition, emotions) and impacts on sleep, ability to exercise, ability to work, and family relationships.

Methods
Individuals who self-reported HPT were recruited to participate in a paper-based survey collecting demographic and HPT-related clinical and treatment information, patient global impression of severity (PGIS), the HPT-SD, and three supporting measures: Functional Assessment of Chronic Illness Therapy–Fatigue Scale (FACT–Fatigue), and the Hospital Anxiety and Depression Scale (HADS). Item- and scale-level internal consistency reliability, discriminating and construct validity were evaluated. A scoring algorithm was developed based on psychometric and qualitative results.

Results
Participants rated their HPT as moderate (34.6%) or severe (32.7%). Participants still endorsed the most severe response choices (e.g., ‘Very severe’) for 4

Early diagnosis of primary biliary cirrhosis during follow-up for Graves' disease
Sevgil Faki1, Muhammet Cuneyt Bilgine1, Cevdet Aydin1, Didem Ozdemir1, Husniye Baser2, Osman Ersoy2, Reyhan Ersoy1 & Bekir Canik1
1Department of Endocrinology and Metabolism, Yıldırım Beyazıt University, School of Medicine, Ankara, Turkey; 2Department of Gastroenterology, Yıldırım Beyazıt University, School of Medicine, Ankara, Turkey.

Introduction
Hepatic dysfunction in hyperthyroidism may occur due to high thyroid hormones, medications or associated autoimmune liver disease. Autoimmune hepatitis or primary biliary cirrhosis (PBC) has rarely been reported in Graves’ disease. We report a patient presenting with pruritus and diagnosed as accompanying PBC and Graves’ disease.

Case
A 50 years old female patient applied with progressive pruritus for at least 4 months. Laboratory investigations showed normal alanine aminotransferase and aspartate aminotransferase. Serum alkaline phosphatase (ALP) was 125 IU/l (≤ 105 IU/l), gamma glutamyl transferase (GGT) was 132 IU/l (≤ 42), and total serum bilirubin and conjugated bilirubin were within normal ranges. She had low TSH (<0.005 U/l) and normal serum free T4 (4.6 ng/dl) and free T3 (14.71 pg/ml). Thyroid peroxidase antibody and thyroid stimulating hormone receptor antibody were also positive. She was afebrile and had regular pulse rate of 110/min and normal blood pressure. There was no exophthalmus, goiter, hepatomegaly or splenomegaly in physical examination. Ultrasonographically, the thyroid gland was enlarged with increased vascularity. Technetium-99m scintigraphy showed increased activity throughout the gland with cold nodules in an enlarged thyroid gland. She was started on methimazol and propranolol. After a week of treatment, her ALP and GGT levels raised to 160 and 151, respectively that we discontinued methimazol. Serology tests for viral hepatitis, human immunodeficiency virus and cytomegalovirus were negative; laboratory tests excluded copper, iron-related metabolic disorders and autoimmune liver diseases. Anti-mitochondrial antibody was found positive and PBC was diagnosed with clinical and laboratory findings. She was started on ursodeoxycholic acid and underwent bilateral total thyroidectomy.

Conclusion
PBC is often associated with other autoimmune diseases. When a cholestatic pattern of liver enzymes is observed during follow-up for Graves’ disease, PBC should be considered in the differential diagnosis.

Survey on the management of hypothyroidism during pregnancy by general practitioners, endocrinologists and obstetricians in Australia and New Zealand
Danijela Draves1, Bernard Champion1,2, Jack Wall3 & Emily Hibbert1,4
1University of Sydney - Sydney Medical School Nepean, Sydney, Australia; 2Auckland City Hospital, Auckland, New Zealand; 3Nepean Hospital, Kingswood, Australia; 4Nepean Hospital, Kingswood, Australia.

Introduction
Hypothyroidism is a common condition in pregnancy with life-long implications for the patient and the newborn. Women of childbearing age are exposed to a range of risk factors for developing thyroid dysfunction, which may present as hypothyroidism during pregnancy. Inadequate management of hypothyroidism during pregnancy may result in adverse outcomes for the mother and baby. The aim of this study was to explore the management of hypothyroidism during pregnancy by general practitioners, endocrinologists and obstetricians in Australia and New Zealand.

Methods
A validated electronic survey was distributed to endocrinologists, obstetricians and general practitioners via their specialty professional bodies and results were analysed.

Results
There were 394 survey respondents: 80.5% (317) from Australia and 19.5% (77) from New Zealand. They comprised 263 Obstetrics and Gynaecology doctors (OG), 69 Endocrinology doctors (E) and 58 General Practitioners (GP). Four respondents were excluded as they did not meet inclusion criteria. Over half of respondents (57.4%) had more than 10 years of specialty experience. 95.2% of respondents (375/394) completed the clinical questions as the remainder were not involved in managing hypothyroidism in pregnancy or in women of reproductive age. On confirmation of pregnancy, 68.3% of respondents (n = 233) reported checking thyroid function tests (TFTs) before adjusting thyroxine dose. 27.7% of respondents reported increasing thyroxine dose by 30–50% or by 2 tablets per week as soon as pregnancy is confirmed as recommended by guidelines. 85.2% of respondents reported adjusting thyroxine dose during pregnancy to recommended TSH targets of TSH < 2.5 mIU/l in the 1st trimester and < 3 mIU/l in the 2nd and 3rd trimesters (46.7% = 155/332) or to TSH and free T4 trimester specific ranges for their laboratory (38.5% = 128/332). 75.9% of respondents would appropriately treat pregnant women with thyroxine if TSH was > 2.5 mIU/l (36.0% = 112/311) or above trimester specific ranges for their laboratory (39.9% = 124/311).

Conclusions
Reported practice in management of hypothyroidism prior to and during pregnancy in Australia and New Zealand varies significantly from recommended guidelines. These findings have significant implications for pregnancy outcomes. Further education is needed for all medical practitioners involved in treating women of reproductive age.

Analysis of cardiovascular changes in Graves disease and their dynamic during the treatment
Arina Frolova, Tatiana Rodionova, Marina Orlova & Marina Chuvashova
Saratov State Medical University, Saratov, Russia.

Introduction
Heart failure (HF) is one of the most common clinical complications of Graves’ disease (GD). To date, there is a lack of studies concerning the impact of thyrotoxicosis on the functional state of the cardiovascular system (CVS).

Objectives
Estimate the prevalence of cardiovascular symptoms, to identify the main changes in echocardiography at Graves disease (GD) and their dynamic during treatment.

Methods
Investigated 86 patients with GD. The functional class (FC) chronic heart failure (CHF) was determined according to the New York Heart Association (NYHA). All patients underwent echocardiography before treatment and after 3 months of euthyroid state.

Results
At baseline 32.6% patients had no symptoms of CHF, 1 FC had 19.7%, II FC – 26.7%, III FC – 20.9% and IV FC – 3.5%. Clinically 3 months after reaching the euthyroid state at 48.8% were observed a higher left ventricular ejection (LVE) (P < 0.05), left ventricular posterior wall thickness (LV PWT) (P < 0.05) and interventricular septum thickness (IVST) (P < 0.05). Patients with 3 FC characterized by an increase of size of the left (P < 0.05) and right atriums (P < 0.05), end-diastolic dimension of left ventricle (LVEDV) (P < 0.05), EDD of left (r < 0.05) and right atrial (P < 0.05). Clinically 3 months after reaching the euthyroid state at 48.8% were maintained complaints of palpitations, at 20.9% - shortness of breath. In patients with FC 2 maintained high LVE, LWPWT, IVST. Among patients with FC 3 also were signs on heart cavities dilatation.

Conclusions
Cardiovascular symptoms frequently encountered in GD, and some may be stored during treatment. At 3 FC showed signs of heart cavities dilatation combined
systolic dysfunction, which are only partially reversible with normalization of thyroid function.

EP1267

Prevalence of the thyroiditis in childbearing age women
Mohammed El Amine Amani1 & Farida Chentli2
11st November 1954 University Hospital, Oran, Algeria; 2Bab-el-oued University Hospital, Algiers, Algeria.

Background and aims
It has been demonstrated that the thyroid autoimmunity, during pregnancy, adversely affects the course of the pregnancy. The anomalies may be prior to the conception, hence the interest of studying the women during the genital activity period. Our objective was to determine the prevalence of the thyroiditis in childbearing age women.

Materials and methods
Prospective study, on 270 childbearing age women. Study protocol: clinical examination, thyroid stimulating hormone (TSH), free thyroxine (FT4) and thyroid antibodies. Statistics tests: collection of data on EPI INFO 5.1.

Results
Data expressed as mean (270 women), age: 30.3±0.4 years, weight: 65.9±0.9 kg, body mass index: 24.7±0.3 kg/m²; TSH: 2.4±0.2 mIU/l and FT4: 14.8±0.2 pmol/l. The positivity of the antithyroid peroxidase antibodies (TPO-ab) concerned 38/270 women (14.1%), the antithyroglobulin antibodies (Tg-ab) 42/270 women (15.6%) and one of the two antibodies (TPO-ab and / or Tg-ab) 54/270 women (20.0%). The mean TSH of the women with thyroiditis was 4.39±0.93 mIU/l vs 1.89±1.06 mIU/l for those without it (P<0.0001). The mean FT4 of the women with thyroid autoimmunity was 14.38±1.08 pmol/l vs 14.87±2.05 pmol/l for those with negative antithyroid antibodies, NS. Of the 54 women with thyroiditis, 35/54 were in euthyroidism (64.81%) and 19/54 of them were in hypothyroidism (35.19%), 9/54 in subclinical hypothyroidism (16.67%) and 10/54 in overt hypothyroidism (18.52%).

Conclusion
In our study, 20.0% of the women had thyroiditis and their mean TSH was significantly higher vs those with negative antithyroid antibodies. In the subgroup of women with thyroiditis, 64.81% were in euthyroidism.

Prevalence and etiology of the hypothyroidy in childbearing age women
Mohammed El Amine Amani1 & Farida Chentli2
11st November 1954 University Hospital, Oran, Algeria; 2Bab-el-oued University Hospital, Algiers, Algeria.

Background and aims
The hypothyroidism may be prior to the conception, hence the interest of studying women during the genital activity period. Our objective was to determine the prevalence and the etiologies of the hypothyroidism in childbearing age women.

Materials and methods
Prospective study, on 270 childbearing age women. Study protocol: clinical examination, thyroid stimulating hormone (TSH), free thyroxine (FT4) and thyroid antibodies. Statistics tests: collection of data on EPI INFO 5.1.

Results
Data expressed as mean (270 women), age: 30.3±0.4 years, weight: 65.9±0.9 kg, body mass index: 24.7±0.3 kg/m², urinary iodine: 225.6±0.2 pmol/l. The iodine deficiency was found in 19/270 women (7%). The hypothyroidism involved 31/270 women (11.5%), the subclinical form in 19/270 (7.1%) and the overt form in 12/270 (4.4%). Of the 31 hypothyroid women, the etiology of the hypothyroidism was related to the autoimmune thyroid disease in 19/31 women (61.3%) and to the iodine deficiency in only one case (3.2%).

Conclusion
In our study, 11.5% of women of childbearing age were in hypothyroidism (overt and subclinical forms). The etiology of the hypothyroidism was dominated by the thyroiditis.

Endemic goiter in Xinjiang, Northwestern China
Yoichi Izumi1, Yuji Kasamaki1, Yukio Ozawa2 & Hirosi Kawamura2
1Department of Medicine, Himi Municipal Hospital, Kanzawa Medical University, Himi, Toyama, Japan; 2Blood Pressure Center, MIG Cardiovascular Institute, Saitama, Japan.

Background
Endemic goiter occurs frequently in iodine deficient areas. Our past medical parameters were compared between subjects with and those without goiter.

Methods
Elderly Uyugr subjects had goiter. In the present study, several medical parameters were compared between subjects with and those without goiter.

Results
No subjects had any symptoms attributable to abnormal thyroid function. The goiters identified ranged in size from that of the walnuts to the fist. Body mass index of the subjects with goiter (GO+) was slightly but significantly lower than that of the subjects without goiter (GO−). There were no significant differences in blood pressure, heart rate, urinary catecholamine levels, insulin sensitivity, and serum levels of free thyroxin, thyroid stimulating hormone, triglycerides, or low-density lipoprotein and high-density lipoprotein cholesterol, between GO+ and GO− participants. The prevalence of goiter in women was 6 times that of men. The iodine content in the salt extracted from the study area was 0 parts per million (ppm) while in that obtained from the market was 29.1 ppm.

Conclusion
The results suggest that prevalence of goiter in Uyugr might have been caused by intake of iodine-free salt. Individuals with goiter would live safely and come today. The higher prevalence of goiter among women suggests that hormones might play a role in the development of thyroid disease.

How does overt and subclinical hypothyroidism due to thyroiditis of Hashimoto affect lipid parameters
Gergana Toshcheva1, Mira Siderova1, Kiril Hristozov1, Yana Bocheva2 & Mila Kostova1
1University Hospital ‘St Marina’ Clinic of Endocrinology, Varna, Bulgaria; 2University Hospital ‘St Marina’ Central Clinical Laboratory, Varna, Bulgaria.

Aim
The aim of this retrospective study is to assess the lipid disturbances in patients with autoimmune thyroiditis.

Methods
1380 patients with autoimmune thyroiditis, hospitalized in Endocrinology department of ‘St Marina’ Hospital, Varna for the period of 2004–2015 year, participated in the study. After excluding conditions influencing lipid profile, 771 patients remained for analysis (36 men and 735 women, mean age 49.81 ± 13.98 years). They are divided in three groups according to TSH values – group A (0.4–4 mU/l), group B (4.01–10 mU/l), group C (TSH ≥ 10.01 mU/l).

Results
1. With the increase of TSH value, we observe elevation in serum triglycerides (group A-TG 1.34 mmol/l, group B-1.44 mmol/l, group C-1.69 mmol/l); as well as in LDL-c values (group A-3.41 mmol/l; group B-3.53 mmol/l; group C-4.19 mmol/l). The comparison of the two subgroups B1 and B2 find out increasing levels of TC, TG, LDL-c and decreasing of HDL-c. A significant difference in TG between patients in group A and C is observed (P < 0.001). Statistical significance in LDL-c level is achieved in group A and C (P = 0.000), group B and C (P = 0.000), in group B2 and C (P = 0.001). 16.9% of the patients from group B and 17.1% from group C had already coronary heart disease and/or cerebrovascular disease.

Conclusions
Autoimmune thyroiditis as one of the main reasons for hypothyroidism is associated with lipid abnormalities and increased cardiovascular risk, which are more pronounced in overt than in subclinical hypothyroidism.

EP1272
Primary hypothyrosis in cobalt intoxication
Dagmar Langova
IK IPVZ, KNBT as, Zlín, Czech Republic.

Most common causes of primary hypothyrosis are destruction of thyroidal parenchyma by the autoimmune antibodies, interventions on the gland (surgery, radioiodine treatment) and external actinotherapy (hematologic and ENT malignancies). Drug induced thyroidal impairment is well-known too (amiodarone, lithium, interferon). Our case demonstrates the primary hypothyrosis caused by cobalt. The source was Co-Cr hip prostethis after its rupture (PHACT). Selenium deficiency was found in 15 patients, in 27 the concentration was normal, and CAS.

Results
Set average and median concentrations of Se, TRAB and CAS in the group of severe GO who have not received prior selenium supplementation and were qualified to i.v. metylprednisolone treatment according to the EUGOGO scheme, at a single site in the years 2014–2016.

Method
Set average and median concentrations of Se, TRAB and CAS in the group of patients and determined the correlation coefficients between serum Se and TRAB and CAS.

Results
Selenium deficiency was found in 15 patients, in 27 the concentration was normal, in 22–23 the Se level was above the upper limit of normal. There was no correlation between Se and CAS or TRAB revealed.

Conclusions
1) The severity of OG expressed by well known indicators: CAS and TRAB were not dependent on the concentration of Se. 2) It seems that it should be recommended to measure the concentration of selenium before starting the supplementation of Se because of low frequency of Se deficiency in this group of patients.

Evaluation of circulating irisin levels in patients with never treated overt hyperthyroidism
Asena Gokcay Canpolat, Mustafa Sahin, Demet Corapcioglu, Rıfat Emral & Ali Ruza Vysal
Ankara University Faculty of Medicine, Ankara, Turkey.

Aims
Because of an increased metabolic activity and thermogenesis in hyperthyroidism, we aimed to evaluate the association of serum irisin with thyroid hormones.

Methods
A total of 25 hyperthyroid patients and 24 age- and gender-matched healthy controls were enrolled. Serum irisin levels, thyroid hormones and body compositions were analyzed.

Results
Serum irisin levels were significantly higher in hyperthyroid group (P < 0.001). Distribution of fat free mass and muscle mass was similar between study groups. Serum irisin level has a negative correlation with TSH level (P < 0.001), %fat mass (P = 0.021) and positive correlation with TSH receptor antibody (TRAB) level (P = 0.002).

Conclusion
Our results showed that increased serum irisin levels in hyperthyroid patients might be associated with the effects of TSH.

Keywords: Hypertyroidism; irisin; TSH receptor antibody

Introduction
Selenium (Se) deficiency is a known risk factor for autoimmune thyroid diseases including Graves’ orbitopathy (GO).

Objective
To determine the concentration of Se in serum and to determine the dependency of Se concentration on known markers of disease severity: the TRAB levels and the CAS (clinical activity score) in patients with GO.

Material
64 patients (50 women, 14 men; average age: 54.5 years) with active, moderate to severe GO who have not received prior selenium supplementation and were qualified to i.v. metylprednisolone treatment according to the EUGOGO scheme, at a single site in the years 2014–2016.

Method
Set average and median concentrations of Se, TRAB and CAS in the group of patients and determined the correlation coefficients between serum Se and TRAB and CAS.

Results
Selenium deficiency was found in 15 patients, in 27 the concentration was normal, in 22–23 the Se level was above the upper limit of normal. There was no correlation between Se and CAS or TRAB revealed.

Conclusions
1) The severity of OG expressed by well known indicators: CAS and TRAB were not dependent on the concentration of Se. 2) It seems that it should be recommended to measure the concentration of selenium before starting the supplementation of Se because of low frequency of Se deficiency in this group of patients.

Nicotinamide phosphoribosyltransferase expression in thyroid glands of patients with Graves’ disease
Nadia Savicka-Gutaj1, Miroslaw Andrusiewicz2, Agata Czarnywojtek1,3, Joanna Walgorska-Stachura1, Maciej Biczysko1, Jerzy Skrobisz1, Jerzy Sowinski1 & Marek Ruchala1
Abstract
Nicotinamide phosphoribosyltransferase (NAMPT) overexpression was reported in many autoimmune diseases. We have also found NAMPT overexpression in leukocytes of patients with Graves’ orbitopathy. Therefore, we aimed to analyze NAMPT expression level in thyroid gland of patients with Graves’ disease with orbitopathy and without orbitopathy, and in healthy thyroid gland. We have analyzed 80 thyroid tissue samples of patients who underwent thyroidectomy. Among these, there were 41 patients with Graves’ disease (20 patients with orbitopathy and 21 patients without orbitopathy), and 39 samples of healthy thyroid tissue. NAMPT overexpression was found in thyroid glands of patients with Graves’ orbitopathy (P < 0.000001). NAMPT expression in patients with Graves’ disease without orbitopathy was similar to healthy controls. Our results suggested that NAMPT might be involved in the inflammatory cascade in Graves’ orbitopathy.

Associations between thyroid and kidney functions
Lina Zabulienė1,2, Modesta Petraviciute1, Birute Pauliukiene3 & Jurgita Urboniene4
1Clinics of Rheumatology, Traumatology – Orthopaedics and Reconstructive Surgery, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; 2Karolinsku Outpatient Clinic, Vilnius, Lithuania; 3Faculty of Medicine, Vilnius University, Vilnius, Lithuania; 4Antakalnio Outpatient Clinic, Vilnius, Lithuania; 5Centre of Infectious Diseases, Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania.

Two-way interactions between thyroid and kidney functions are known. Chronic kidney disease (CKD) is accompanied by changes in synthesis, secretion, metabolism, and elimination of thyroid hormones, increased risk of hypothyroidism, rarely subclinical hyperthyroidism, whereas thyroid dysfunction affects physiology of the kidney, renal blood flow, glomerular filtration rate (GFR), tubular function, metabolism of water and electrolytes, and kidney structure. The aim of the study was to examine associations between thyroid stimulating hormone (TSH) level and kidney function.

Methods
We analysed retrospective data of 781 adult patients, referred for routine simultaneous testing of TSH and serum creatinine in 2015 in Vilnius Antakalnio outpatient clinic. GFR was estimated by the simplified Modification of Diet in Renal Disease equation. Linear regression was used to evaluate the association between TSH and estimated GFR.

Results
Mean TSH concentration was 2.58 ± 4.19 mIU/l, mean serum creatinine 72.72 ± 22.32 μmol/l and mean estimated GFR 83.12 ± 24.91 ml/min/1.73 m². 45.3% of patients had stage 2 CKD, 16.0% – stage 3 CKD, 1% – stage 4 or end stage CKD. Patients with CKD of any stage were older than those with normal kidney function (mean age 66.98 ± 11.20 vs 50.96 ± 15.42 years, P < 0.0001) and their TSH was higher (2.86 ± 5.07 vs 2.12 ± 1.93 mIU/l, P = 0.004). 12.9% of patients had thyroid dysfunction: 7.9% had subclinical hypothyroidism (TSH 4.69–10 mIU/l), 1.3% overt clinical hypothyroidism (TSH > 10 mIU/l) and 3.7% subclinical hyperthyroidism (TSH < 0.465 mIU/l). 12.8% of patients with estimated GFR < 60 ml/min/1.73 m² had subclinical hypothyroidism, 1.5% overt clinical hypothyroidism. Lower estimated GFR was associated with higher TSH level (8 = –0.72 (95% CI – 1.13 – 0.30), P = 0.001).

Conclusions
Thyroid dysfunction is relatively common among persons with CKD: 14.3% of patients with moderate, severe and established kidney failure have hypothyroidism. Reduction in estimated GFR is independently associated with increased TSH levels.

Hypothyroidism – once a week treatment option in young- and middle-aged adults
Satish Chander Wasoori1, Manoj Naik2, Deepak G Pande1 & Chetan Bhardwaj1
1Park Hospital, Gurgaon, Haryana, India; 2Sunjeevan Hospital, Thane, Maharashtra, India.

Objective
To evaluate the effectiveness and compliance to L-thyroxine in the treatment of Hypothyroidism in a weekly dose of 7 times of normal dose as an alternative to daily dosing in young and middle aged adults.

Methods
A randomized prospective observational study on 180 patients (female: male) ratio of 5:1 aged between 18 and 55 years with an established diagnosis of Hypothyroidism were assigned a weekly dose of seven times of normal dose. The patients were randomized in 3 groups G1, G2 and G3. Group 1 (G1): 60 patients with established diagnosis of Hypothyroidism with TSH value of 4.2 or less, currently on daily dose. The subjects were assigned weekly dose of L-thyroxine which was 7-fold of normal dose. Group 2 (G2): 60 patients with established diagnoses of Hypothyroidism with TSH value of more than 4.2. The subjects were assigned weekly dose of L-thyroxine which was 7-fold of normal dose, the dose in this group was individualized as per the body weight and TSH value; Group 3 (G3): 60 patients newly established diagnoses of Hypothyroidism with TSH value of more than 4.2. The group was started with a weekly dose which was individualized as per the body weight and TSH value. All subjects in all the groups were screened for malabsorption and were not receiving any drugs which interfere with the absorption of L-thyroxine. The minimum to maximum dose used in this study was 175–1050 mcg.

Results
We achieved complete restoration of euthyroidism in all 59 subjects in the group 1 (G1) at 12 weeks and it continued to 24 weeks. We had to withdraw it in a 55-year male patient because of hyperthyroid symptoms. In group 2 (G2), we achieved complete euthyroidism in 52 subjects at 12 weeks and it increased to 55 subjects with some dose adjustment at 24 weeks. We could not achieve euthyroidism in 5 subjects at 24 weeks. This may be attributed to other metabolic disorders like diabetes and obesity. In (G3) we achieved complete euthyroidism in 54 subjects at 12 weeks and it increased to 59 subjects with some dose adjustment at 24 weeks. 1 subject shifted to another city and so did not complete the study.

Conclusion
Once weekly dose of L-thyroxine as an alternative to daily dosing regimen was shown to be efficacious and safe for the treatment of hypothyroidism to treat non-compliant hypothyroid young- and middle-aged adults. The results show that it can be started in newly diagnosed hypothyroid patients. For patients who find it difficult to adhere to a rigorous treatment regime it is a valid therapeutic option and can also be considered as a first line therapy in young and middle aged working adults facing impaired absorption due to early breakfast (no need to wait 30–45 min for breakfast).

Effect of subclinical hypothyroidism and autoimmunity on adverse pregnancy and neonatal outcome in our population
Cristina López-Tinoco, Begaría Sánchez-Lechuga, Almudena Lara, Julia Barcala, Laura Larrain, Daniel Medina & Manuel Aguilar-Diosdado
1Clinics of Rheumatology, Traumatology – Orthopaedics and Reconstructive Surgery, Faculty of Medicine, Vilnius University, Vilnius, Lithuania; 2Faculty of Medicine, Vilnius University, Vilnius, Lithuania; 3Centre of Infectious Diseases, Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania.

The effect of subclinical hypothyroidism (SH) and thyroid autoimmunity on adverse pregnancy and neonatal outcome, are still subject of interest and controversy. Nowadays, guidelines recommend establishing reference values of local thyroid hormones that allow definition of the SH in a specific population. The objective of this study was to assess the effect of SH and autoimmunity in early pregnancy on adverse pregnancy and neonatal outcome in our population. The reference range of thyrotropin (TSH) was 3.86 μIU/ml in our Cádiz-San Fernando area, in Spain. 438 pregnant women with HS (defined according to our reference values) in the first trimester of gestation were recruited. Women were classified into two groups according to thyroid function and anti-TPO results. The mean age was 31.32 ± 5.5 years, BMI was 24.5 ± 5.3 kg/m². Twenty-four percent of the patients had a family history of Thyroid disease and 23% of miscarriage.

The mean of levels of TSH at diagnosis were 5.1 ± 1.3 μIU/l with a final mean dose of levothyroxine 64.9 mcg/day and levels of TSH 2.3 ± 1.2 μIU/l at the end of pregnancy. Sixteen percent of the deliveries were by cesarean

Endocrine Abstracts (2017) Vol 49
section, and 20% had complications (premature rupture of membranes, preeclampsia, preterm delivery, small for gestational age). Thirteen percent had anti-TPO positive. Comparing anti-TPO positive/negative groups with obstetrics and perinatal outcomes, no statistically significant differences were found. We concluded that in our area, patients with HS, defined according to our local reference values, have a low rate of adverse pregnancy and neonatal outcome. Also, if we consider the presence of anti-TPO positive, there are no differences. Further studies will be needed to determine the relationships between HS and autoimmune and adverse pregnancy and neonatal outcome.

**Metastatic differentiated thyroid carcinoma: cumulative doses of adjunct 131I-iodide therapy**

Patricia Gouveia1, Teresa Pereira2, Ana Amado2, Ricardo Teixeira1, Antonio Costa1, André Carvalho2, Cláudia Freitas2 & Fátima Borges2

1Department of Nuclear Medicine, Centro Hospitalar do Porto, Porto, Portugal; 2Department of Endocrinology, Centro Hospitalar do Porto, Porto, Portugal.

**Introduction**

131I-iodide therapy (RIT) is an important treatment modality for patients with differentiated thyroid carcinoma (DTC). However, despite the overall excellent outcome, some DTC patients with poor prognosis may require multiple doses of radioactive iodine.

**Aim**

The purpose of our study was to evaluate the efficacy of cumulative doses (CDs) of RIT in metastatic DTC patients.

**Material and methods**

A retrospective study was conducted on a cohort of 84 metastatic DTC patients (mean age 46.6±17.4 years) who received a CDs ≥ 300 mCi of RIT, between January 1996 and December 2016. A disease-free status was established as: undetectable TSH-suppressed Thyroglobulin levels, whole body imaging scan without local-regional uptake or distant metastases and negative cervical ultrasound or thoracic CT scan.

**Results**

Eighty-four patients, 58 females and 26 males, who completed more than one RIT with a CD ≥ 300 mCi, were followed up for 15.0±8.8 years. At the time of diagnosis 62 (73.8%) patients had local cervical metastases and 22 (26.2%) had distant metastases. Papillary carcinoma sub-type was present in 75 (89.3%) of patients. Seventeen out of 84 patients (20.2%) achieved a disease-free status. No patient with CDs higher of 450mCi has reached a disease-free status. Patients with CDs higher of 300 mCi of RIT achieved a disease-free status, regardless of the CDs received.

**Conclusion**

Twenty percent of patients who received a CDs ≥ 300 mCi of RIT achieved a disease-free status. Quality of life and the disease progression rate are important aspects that were not addressed in our study. The decision of further treatment with RIT should be carefully evaluated and made on a case-by-case basis. Furthermore, this study seems to indicate that brain or bone metastases may not respond to higher CDs.

**Autoimmune thyroid disease may affect prognosis of breast cancer**

Selim Yalcın1, Ramazan Cosar1, Aydın Cifci1, Askin Gungunes1 & Senay Arıkan Durmaz3

1Department of Oncology, School of Medicine, Kirikkale, Turkey; 2Department of Internal Medicine, School of Medicine, Kirikkale, Turkey; 3Department of Endocrinology and Metabolism, School of Medicine, Kirikkale, Turkey.

**Aim and objective**

The aims of this study were to determine the incidence of breast cancer molecular subgroups, to investigate the relationship between autoimmune thyroid disease and prognostic and predictive factors in patients who were diagnosed with breast cancer.

**Materials and methods**

One hundred one patients who were followed up with the diagnosis of breast cancer at our Endocrinology and Medical Oncology Departments were included. Patients are divided into subgroups based on the molecular classification. Patients with high serum levels of thyroid peroxidase antibody (anti-TPO) were considered as autoimmune thyroid disease. Prognostic and predictive parameters such as tumor size, axillary involvement, histological grade, lymphovascular invasion, hormone receptor status, HER2 overexpression were collected. The relationships between autoimmune thyroid disease and tumor’s prognostic and predictive factors were studied.

**Results**

The prevalence of thyroid autoimmunity was 23.8% (n = 24) among our study group. Patients with autoimmune thyroid disease had a significant lower rate of axillary involvement (37.5% vs 61% [P = 0.043], respectively). Other parameters did not differ between patients with and without autoimmune thyroid disease.

**Conclusions**

We found a favorable association between autoimmune thyroid disease and axillary involvement which is crucial and strongly prognostic parameter of breast cancer prognoses. This supports the idea of thyroid autoimmunity being a favorable prognostic parameter in breast cancer. Further studies are necessary to investigate the reasons of protective or predictive effect of high anti thyroid peroxidase levels in breast cancer patients.

**EP1281**

**Subacute Thyroiditis with an atypical clinical course and thyroid 99mTc uptake**

Deniz Sema, Maktav Celikmen & Ali Özdemir

Fatih Sultan Mehmet Training and Research Hospital, Istanbul, Turkey.

**Background**

Subacute thyroiditis (SAT) is a transient inflammatory, probably viral disease of the thyroid gland. It is clinically characterized by pain, fever, increased erythrocyte sedimentation rate (ESR) or other markers of inflammation, transient thyrotoxicosis, and has a tendency to recur. In most cases, in addition to the clinical features, scintigraphy and ultrasound may support the diagnosis of SAT. However, in the present case, SAT with an atypical thyroid 99mTc uptake and a nodule formation in ultrasound lead to diagnosis difficulties.

**Case presentation**

A 31-year-old woman with the clinical suspicion of SAT was observed. Thyrotoxicosis was present and the tests for anti-thyroid peroxidase, anti-thyroglobulin and TSH receptor antibodies were negative. Thyroid scintigraphy with 99mTc demonstrated decreased uptake in the right but a normal uptake in the left lobe. Four weeks after clinical and laboratory remission she developed a painful palpable nodule of the left thyroid lobe. Increased erythrocyte sedimentation rate above 100 mm/h and elevated C reactive protein were present. Ultrasonographic examination showed an enlarged left lobe and area of low echogenicity with shaded margins and microcalcifications. The lesion showed a contrast uptake in contrast-enhanced magnetic resonance imaging (MRI). The second scintigraphy demonstrated a bilateral, homogeneous uptake with a suspected hipoactive nodular image of the left thyroid lobe. Fine-needle aspiration biopsy from the nodule revealed multinuclear giant cells consistent with SAT.

**Conclusion**

In most cases, the diagnosis of SAT can be made based on the physical and laboratory findings of the patient and the clinical course of the disease. Findings of thyroid scintigraphy and ultrasound that are not consistent with subacute thyroiditis do not exclude the diagnosis of SAT. For definitive diagnosis of an atypical SAT and exclusion of thyroid malignancies, fine-needle aspiration biopsy may be required.

EP1282
Weak numeracy is common problem in patients with thyroid diseases
Ewa Waawak1, Pawel Basinski1, Małgorzata Gasiorek1 & Krzysztof Marczewski1,2
1Department of Nephrology and Endocrinology Pope John Paul II Regional Hospital, Zamosc, Poland; 2Faculty of Health Sciences University of Economy and Innovations, Lublin, Poland.

Introduction
In modern medicine, we expect from patients numeracy skills. Starting with the correct dosage of drugs up to understand the principles of risk assessment of alternative treatments. These skills, however, are probably rarely checked. Just as the skills of reading, where we entrust signature ‘read and understood’. That is why we want to introduce our observation.

Method
Subsequent patient, outpatient endocrinological clinic, we have proposed making two tests to assess numeracy: Schwartz test (max. 3 points) and Berlin Numeracy Test (max. 4 points).

Results
We investigated 112 patients (101 women) in age 17 to 85 years (average 55 ± 15). No one person became maximal possible results, and 11 (10%) did not answer any question. The results of other patients indicate significant problems with simple counting. 2 person rejected Schwartz test, and 1 person rejected BNT test. From others 36 person became 0 points in Schwartz test, 43 patients 1 point, 23 patients 2 points and only 8 maximally possible 3 points. Similar or even worse are the results in BNT 29 person became 0 points, 56 1 point, 22 2 points, only 3 patients 2 points and only 8 maximally possible 4 points. We did not find significant correlations between the results of the tests, and the sex, age and TSH.

Conclusion
Weak numeracy is a common problem in patients with thyroid diseases.

DOI: 10.1530/endoabs.49.EP1282

EP1283
A case of levothyroxine tablet malabsorption associated with gastric neuroendocrine tumour corrected with gel capsule formulation
Olivera Boskovic1, Ranko Lazovic1,2, Brígida Smolović1 & Mirha Hasanbogovic1,2
1Clinical Center of Montenegro, Podgorica, Montenegro; 2Medical Faculty, University of Montenegro, Podgorica, Montenegro; 3General Hospital Pljevlja, Pljevlja, Montenegro.

Multiple dose adjustments can sometimes be inefficient in reaching eutimetic state in patients with hypothyroidism treated by levothyroxine sodium tablets. We report a case of 44-year-old female who has been levothyroxine sodium tablet replacement therapy since 2004 without ever reaching eutimetic state, presented as outpatient one year ago. As sellar MRI ruled out pituitary adenoma, investigation targeting malabsorption was initiated. Antibodies to gliadin and transglutaminase were in normal range. Absorption test with 300 mcg levothyroxine was positive in aspect of presence of selective levothyroxine malabsorption. Initial endoscopies revealed chronic atrophic gastritis without excluding possibility for tumor presence. Serum CgA level was 521 mcg/l. The final third endoscopy was successful in detecting the gastric submucosal change, confirmed by endoscopic ultrasound as submucosal lesion no larger than 12 mm located in the upper part of anterior gastric wall. Histological analysis of biopsy specimen confirmed lesion to be neuroendocrine tumor grade 1. Further imaging excluded its metastatic spreading, so the indication for surgical removal was established. Patient could not undergo surgery with TSH levels exceeding 100 mmU/l and free T4 lower than 5 pmol/l despite being on 300 mcg of levothyroxine daily substitution regimen. Changing to a gel capsule formulation taken once a day at dose of 100 mcg lead to a rapid TSH decreasement and thyroid hormones normalization, so the patient was surgically treated as eutimetic. On reviews thereafter she remained euthyroid, without complaints of previously reported fatigue and loss of appetite. This case suggests that gastric chronic inflammatory processes and neuroendocrine tumors as well may affect levothyroxine absorption where gelatin capsules appear to be effective treatment option.

EP1284
Percutaneous ablation of benign thyroid nodules: specific simulators for practicing enolization and laser procedures
Teresa Jiménez, Pablo Vidal-Ríos, Antonio Rodríguez, Laura Villas & Sebastian Vidal-Ríos
Coruna Endocrinology Center, La Coruña, Spain.

Ethanol and laser ablation of benign thyroid nodules is bursting rapidly in clinical practice because of its efficacy, safety and economy. However, these techniques require some manual operator training. In order to facilitate this hands-on training, we propose two homemade, cheap and specific simulators to practice these clinical procedures.

Material and methods
Two models were optimized: Gel-Phantom Coruna VR16 (gelatine and plantago-ovata with inlays of different objects simulating pure and mixed cysts) and Proteon-Phantom Coruna VR17 (pork loin with inlays of different objects simulating solid nodules (homogeneous, heterogeneous and with microcalcifications). For enolization, pure ethanol and a 2-way device (Device Coruna VR13, poster 94, 58th Congress Malaga, Spain; SEEN 2016) were used for sequential ethanol-NSS instillation (to reduce irritation of the capsule upon withdrawal of the needle). For laser ablation, a 1064 nm Nd-YAG laser through a thin optic fiber of 300um obtained from an EchoLaser generator (Elesta, Florence-Italy) was used. Monitoring was performed with the Acuson 2000 Helix ultrasound platform (Siemens, Forchheim-Germany). The assessment was performed among different operators (n = 12), especially those attending the Coruna Workshop on Laser Ablation.

Results
For cystic nodules simulation and practicing ethanol sclerosis, the most valued simulators were: fluid on a knotted glove (pure cyst), grapes or dwarfish tomatoes (mixed cyst), piece of wet sponge wrapped in knotted kitchen plastic (‘sponge’ cyst) and anchovy stuffed olive (hyperechoic nodule with hypoechoic center). For solid-state nodules simulation and practicing laser ablation, the most valued were: beef liver wrapped in knotted plastic (solid isoechoic nodule), cooked yolk wrapped in knotted plastic (hyperechoic solid nodule), raisins and water wrapped in knotted plastic (heterogenous nodule), and raisins, water and eggshells (heterogenous nodule with ‘microcalcifications’).

Conclusion
In summary Gel-Phantom Coruna VR16 and Proteon-Phantom Coruna VR17 simulators were surprisingly useful for practicing percutaneous ethanol and laser ablation procedures. In addition, we highlight their low cost and easy preparation.

Improved diagnostics with increased treatment of hypothyroidism during pregnancy – a 10 year study of Finnish pregnant women
Suvi Turunen1,2, Tuja Mannisto1,3, Anna-Liisa Hartikainen, Mika Gissler4, Anna-Maria Lahesmaa-Korpinen5, Marja Vääräsmäki1 & Eila Suvanto1
1Oulu University Hospital, Obstetrics and Gynecology, Oulu, Finland; 2Medical Research Center Oulu (MRC Oulu), Oulu, Finland; 3University of Oulu, Finland; 4Institute of Health and Welfare, Helsinki, Finland; 5Nordlab, Oulu, Finland.

Thyroid diseases affect up to 4% of all pregnancies. Several evidence-based recommendations have been created to observe and treat thyroid diseases in pregnant women. We studied whether the diagnostics and treatment of hypothyroidism among pregnant women have improved in the course of time. Data consisted of all singleton pregnancies (N = 571785) during 2004–2013 in Finland, collected from the Finnish Medical Birth Register (MBR). Data on maternal thyroid diseases were obtained from the MBR and the Hospital Discharge Register, and combined with the Special Refund Entitlement Register and the Register on Reimbursed Drug Purchases consisting data on medication purchases during the index pregnancy. Women with thyroid diseases other than hypothyroidism were excluded (N = 4561), rendering a final study population of 567 224 singleton pregnancies. Pregnancies were divided into four categories: mothers with diagnosed hypothyroidism treated with levothyroxine (N = 8893), mothers treated with levothyroxine without a recorded hypothyroidism diagnosis (N = 6788) (mostly treated in the primary care), mothers with diagnosed hypothyroidism but without levothyroxine treatment (N = 683) and mothers without thyroid diseases or thyroid medication (N = 550 860). In 2004

DOI: 10.1530/endoabs.49.EP1285
approximately 1% of pregnant women had diagnosed hypothyroidism and were treated with levothyroxine. By 2013 this prevalence had more than doubled up to 2.4%. The prevalence of women receiving levothyroxine treatment without recorded hypothyroidism diagnosis was 0.2% in 2004 but 12-fold higher (2.5%) in 2013. The increase in diagnosis of hypothyroidism and levothyroxine treatment has been steady over time. Surprisingly, the prevalence of pregnant women with hypothyroidism and no recorded levothyroxine treatment has been constant between 0.1 and 0.2%. Our study shows that the diagnoses of hypothyroidism and use of levothyroxine treatment among pregnant women have increased markedly during the past 10 years. This suggests that clinical recommendations have improved the awareness on the risks of hypothyroidism on pregnancy and the threshold to treat hypothyroidism during pregnancy seems declining.

Radiofrequency ablation for benign thyroid nodules: 450 patients - three years follow-up

Viacheslav Volosov, Aleksandr Makhonin, Mikhail Vozdvizhenskiy & Andrew Orlov

Samara Oncology Center, Samara, Russia.

Purpose

The objective of this study was to evaluate the efficacy and safety of ultrasound (US)-guided radiofrequency ablation (RFA) for treating of benign thyroid nodules.

Material and methods

The retrospective analysis included the results of treatment of 450 patients with benign tumors of the thyroid gland in the Samara Oncology Center. 91 (20.2%) patients had autonomously functioning thyroid nodules and 359 (79.8%) had symptomatic ones. The mean volume of nodule was 33.5 (4.1–179.5).

Results

RFA reduced nodular volume by 70% after 6 months, 84% after 36 months and it was an effective method for treating nodule-related clinical problems and hot nodules. 47 (10.4%) patients with big volume nodule underwent 2–6 sessions of RFA. Cosmetic results were excellent in 96% of patients in the RFA group. No serious complications such as thyroiditis, voice change, and hematomas were observed in RFA patients.

Conclusion

RFA was effective and safe for treating benign thyroid nodules. RFA might be recommended for treating benign thyroid nodules as the first-line treatment.

Coexistence of Graves’ disease and unilateral benign struma ovarii: A case report

Rosa Marquez-Pardo, Lourdes Garcia-Garcia-Doncéel, Mgloria Baena-Nieto, Manuel Cayón-Blanco, Rosario Lopez-Velasco & Isabel Torres-Barea

Jerez Hospital, Jerez de la Frontera, Cadiz, Spain.

Introduction

Struma ovarii (SO) is a rare ovarian teratoma composed predominantly (more than 50%) or entirely of thyroid tissue. It constitutes 2% to 4% of ovarian teratomas. This tumor is often asymptomatic and discovered incidentally. Only 8% of patients present clinical hyperthyroidism.

Case report

A 42-year-old woman presented palpitations, anxiety, sweating, emotional lability and weight loss for several months. Physical examination revealed goitre, tachycardia and slight tremor. Laboratory tests confirmed hyperthyroidism: thyrotropin (TSH) 0.01 mU/ml (0.3–5), serum-free thyroxine 5.21 ng/dL (FT4) (0.9–2.1), serum-free triiodothyronine (FT3) 22.5 pg/ml (2.57–4.43) and thyrotropin receptor antibody (TRAb) 21.78 U/l (positive >2). Thyroid ultrasound identified a multinodular goitre with a dominant nodule of 14 mm in left lobe. Technetium thyroid scan showed diffuse uptake. She was diagnosed as having Graves’ disease (GD) and started on thiamazole and propranolol. Several months later, she remained hyperthyroid and appeared propotis, lid retraction and ocular chiasms. Magnetic resonance of the orbits demonstrated bilateral mild swelling of extracocular muscles. She was diagnosed with Graves’ ophthalmopathy too. After that, it was decided thyroidectomy. In addition, olioamnornorhea appeared and ultrasound and magnetic resonance of the abdomen and pelvis depicted an 11×11×9 cm solid-cystic mass in right ovary. The patient underwent right salpingo-oophorectomy. Histology revealed a benign SO. Immediately, ocular disease and hyperthyroidism improved. Subsequently, total thyroidectomy was performed, which showed GD and benign thyroid nodules.

Conclusions

The diagnosis of functioning SO in presence of GD may be a challenge and it may be difficult to determine the precise cause of hyperthyroidism. When a patient has increased thyroid uptake of technetium in the scan, an ectopic hormone production is not suspected. When SO is surgically removed and subsequently the hyperthyroidism and ocular disease improve considerably, the diagnosis of functioning SO is quite likely.

Clinical characteristics and outcomes of patients with myxedema coma: a 15-years experience of a tertiary care center in Thailand

Suwanna Pitschaiprasert1, Patimut Buranassukjorn2, Sompong Suwanwalakorn3, Sarat Sunthornyothin1,2, Weerapan Khovidhunkit1,2 & Thiti Snobboon1,2

1Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; 2Excellence Center for Diabetes, Hormone and Metabolism, King Chulalongkorn Memorial Hospital, Bangkok, Thailand.

Background

Myxedema coma is an uncommon but life-threatening condition of severe and decompensated hypothyroidism requiring early recognition and prompt treatment. The aim of this study is to describe the clinical features and identify factors associated with mortality of our patients diagnosed myxedema coma over the past 15 years.

Material and methods

Retrospective chart review of patients diagnosed and treated at King Chulalongkorn Memorial Hospital for myxedema coma during 2002–2016 was performed. Their demographic data, clinical features, precipitating factors and treatment outcomes were analyzed. We also compared different scoring systems including Glasgow Coma Scale (GCS), Acute Physiology and Chronic Health Evaluation II (APACHE II) score, Sequential Organ Failure Assessment (SOFA) score and Wartofsky myxedema coma score to predict the outcomes.

Results

A total of 13 cases, 9 females and median age of 79 years ranged between 60–94 years, were recruited. All of them had primary hypothyroidism. Seven patients (54%) were newly diagnosed hypothyroidism at the time of presentation of myxedema coma. Six patients (46%) died and sepsis was the major cause of death. Lower FT4 level was only parameter significantly different between the patients who survived and those who died (P = 0.04). On analyzing the various scoring systems, they did not demonstrate a significant difference between survivors and non-survivors; however, a Wartofsky myxedema score below 90 was associated with a better outcome.

Conclusions

Myxedema coma still carries a high mortality rate even with the appropriate diagnosis and treatment. With a high proportion of undiagnosed hypothyroid patients in our study, it should be alert clinicians to beware of this preventable condition in an appropriate clinical context. Thyroid hormone levels and Wartofsky myxedema score may be applied as clinical prognostic parameters.

Evaluation of interrelationships between thyroid function, autoimmune, insulin resistance and lipid profile in Graves’ disease

Antonio Carujo1, Celestino Neves2, João Sárgio Neves2, Sofia Castro Oliveira2, Oksana Sokhatiska3, César Esteves2, Miguel Pereira2, José Luís Medina1, Luís Delgado3 & Davide Carvalho1,4

1Faculty of Medicine, University of Porto, Porto, Portugal; 2Endocrinology Service, São João Hospital, Faculty of Medicine, University of Porto, Porto, Portugal; 3Immunology Department, São João Hospital, Faculty of Medicine, University of Porto, Porto, Portugal; 4Instituto de Investigação e Inovação em Saúde, Faculty of Medicine, University of Porto, Porto, Portugal.

Background

Hypothyroidism is often associated with oxidative stress, increased proinflammatory markers, insulin resistance and metabolic syndrome. Thyroid hormones have a regulatory role in the immune system and may influence its autoimmunity.

Method

A total of 102 hypothyroid patients and 110 healthy controls were included in this cross-sectional study. Thyroid function tests, C-reactive protein, interleukin-6, insulin and lipid profile were measured.

Results

The comparison of laboratory results between hypothyroid and control groups is available in the table. The results show a significant increase in C-reactive protein (P<0.05) and a significant decrease in insulin (P<0.05) in hypothyroid patients compared to healthy controls. The presence of thyroid autoantibodies was found in 34% of hypothyroid patients. The comparison of thyroid function tests between hypothyroid patients with and without thyroid autoantibodies shows a significant increase in thyrotropin and free thyroxine in hypothyroid patients with thyroid autoantibodies compared to hypothyroid patients without thyroid autoantibodies.

Conclusions

This study suggests that hypothyroidism is associated with oxidative stress, increased proinflammatory markers, insulin resistance and metabolic syndrome. Thyroid hormones have a regulatory role in the immune system and may influence its autoimmunity.

DOI: 10.1530/endoabs.49.EP1289

Endocrine Abstracts (2017) Vol 49
Background
Thyroid hormones modulate the lipoprotein and glucose metabolisms. In hyperthyroidism, insulin resistance is a frequent finding.

Aim
To assess interrelationships between thyroid function, autoimmunity, lipid profile, glucose metabolism and other cardiovascular risk factors in patients with Graves’ disease.

Methods
We recorded free T3 (FT3), free T4 (FT4), TSH, TSH receptor antibodies (TRAB), parameters of the lipid profile, glucose metabolism [including insulin resistance marker Homeostasis Model Assessment for Insulin Resistance (HOMA-IR)], C reactive protein (CRP) and homocysteine in 126 patients with Graves’ disease in the first cycle of treatment with methimazole (93% females, mean age 44.8±15.2 years). Patients were divided in subgroups according to: TRAB (positive (n=57) or negative (n=69)) and thyroid function (normal (n=74), subclinical (n=29) or clinical hyperthyroidism (n=22)). Spearman correlations, T-tests and Mann–Whitney tests were performed for statistical analysis.

Results
Comparing TRAB- and TRAB+ groups, significantly lower apolipoprotein B (80.3(73.2–87.4) vs 89.7(83.5–95.8)mg/dl, P=0.047) and TSH (0.180(0.002–1.080) vs 1.020(0.235–2.055)μU/ml, P<0.001) were found in the TRAB+ group. Comparing with the normal thyroid function group, patients in the clinical hyperthyroid group presented significantly lower apolipoprotein B (70.9(57.2–84.6) vs 89.7(83.7–95.8)mg/dl, P=0.007) and higher fasting glucose (96.0(83.0–109.0) vs 86.4(83.8–89.0)mg/dl, P=0.030). Both FT3 and FT4 were positively correlated with fasting insulin (r=0.268, P=0.008 and r=0.226, P=0.025, respectively) and HOMA-IR (r=0.258, P=0.010 and r=0.259, P=0.010, respectively). FT4 was also positively correlated with fasting glucose (r=0.269, P=0.008).

Conclusion
In patients with Graves’ disease, the interrelationships between thyroid function, autoimmunity, insulin resistance and lipid profile may contribute to the increased cardiovascular risk.

EP1291
Trans-axillary endoscopic thyroidectomy – technique
Jaime Vilaça, Susana Graça & Paula Mendes
Tiroide Center, Porto, Portugal.

Introduction
Trans-axillary surgery is an emerging technique for cervical approach with fantastic cosmetic result. With more than 50 cases treated by our group, we developed our technique with specific safe methodologies.

Aims
To present step-by-step technique of trans-axillary endoscopic thyroidectomy. Material and methods
This is a video surgery that uses three trocars and a harmonic scalpel for dissection and ligation. Incisions are made in the armpit and areolar border. Results
Technique is described in 10 steps: (i) trocars and patient position; (ii) dissection; (iii) landmarks (sternal notch, ECM anterior border, thyroid cartilage); (iv) omohyoid muscle dissection; (v) split strap muscles; (vi) upper pole dissection and ligation; (vii) ligation of the middle thyroid vein and recurrent laryngeal nerve (RLN) visualization; (viii) inferior pole ligation; (ix) lobectomy; (x) specimen removal and haemostasis; Three auxiliary techniques are used to increase safe and to reduce complications:
1. Intra-operative ultrasound
2. Neuromonitoring of the RLN
3. Indocyanine green (ICG) fluorescence for parathyroid vascular assessment

Conclusions
Cervical scar-less surgery is very appealing for the patient. For the surgeon with advanced laparoscopic skills this is a feasible and reproducible technique, with excellent results. Security techniques can have great value in more demanding cases.

DOI: 10.1530/endoabs.49.EP1291

EP1292
Trans-axillary endoscopic thyroidectomy – scarless surgery of the neck: our experience
Jaime Vilaça, Susana Graça & Paula Mendes
Tiroide Center, Porto, Portugal.

Introduction
Endoscopic techniques are uprising in the cervical field mainly because of the exceptional cosmetic results. These surgeries are frequent in the far east Asia but still rare in Europe. We started these approach on November 2014. This paper is a review of our experience.

Aims
To present a series of trans-axillary endoscopic thyroidectomy.

Material and methods
This is a cohort study of 50 consecutive patients treated by trans-axillary endoscopic thyroidectomy. Patients are selected using the following indications: benign or suspicious nodules until 35 mm, micro papillary cancer, lobes until 65 mm. Interventions are video recorded and time, recurrent laryngeal nerve identification and parathyroid identification are registered. Laryngoscopy is performed at the end of the procedure. Morbidity data are collected during surgery, on the day after, 2 weeks, 2 months and one year after the operation. All the pathological reports are reviewed.

Results
Among the series, 78% were women with an average of 48 year old. All patients had normal thyroid function at the time of the operation and 95% were low-risk anaesthetic candidates (ASA1 or 2). Half complained of goitre. All but 2 were submitted to lobectomy. There was no conversion to open surgery. No dead was submitted. There were 5 cases of morbidity: 2 seromas, 2 skin burn and 1 transient recurrent laryngeal nerve palsy. All cases of lobectomy were discharged home on post-operative day 1.

Conclusions
Endoscopic cervical approach is difficult to implement among surgeons without advanced laparoscopic skills. The technique revealed to be safe and reproducible with potential to enlarge indications. The use of neuromonitoring, ICG fluorescence and intra-operative ultrasound are tools already tested by the group with a benefit in safety.

TSH oscillations in young patients with type 1 diabetes may be due to glycemic variability
Giuseppe Bellastella1, Ofelia Casciano2, Lorenzo Scappaticcio3, Dario Giugliano1, Maria Ida Maiorino1 & Katherine Esposito1
1Endocrinology and Metabolic Diseases Unit, Department of Medical, Surgical, Neurological, Metabolic Sciences and Aging, University of Campania, L. Vanvitelli, Naples, Campania, Italy; 2Diabetes Unit, Department of Medical, Surgical, Neurological, Metabolic Sciences and Aging, University of Campania, L. Vanvitelli, Naples, Campania, Italy; 3Diabetes Unit, Hospital de Egas Moniz, C.H.L.O. E.P.E., Lisbon, Portugal; 4Endocrine Unit, University of Siena, Siena, Italy.

A link between thyroid dysfunction and diabetes mellitus exist. Uncertainties on the role of glycemic variability on thyroid hormones and TSH concentrations still persist. We want to evaluate the influence of glycemic variability on thyroid hormones and TSH concentrations in patients with type 1 diabetes (T1DM). 77 patients with T1DM on insulin therapy without thyroid dysfunction and 100 healthy controls were evaluated for basal glucose concentrations, HbA1c, thyroid hormones and TSH levels. Glycose variability was investigated through the standard deviation of blood glucose (BGSD) readings and through the mean amplitude of glycemic excursions (MAGE) and continuous overlapping net glycemic action (CONGA), the low (LBGI) and high (HBGI) blood glucose indices. The links between TSH, thyroid hormones, glycemia and HbA1c were studied in patients and in controls, whereas those between TSH, thyroid hormones and indices of glucose variability only in patients. All subjects had TSH, thyroid hormones and thyroid antibodies in the normal range. No correlations were found in T1DM patients between free thyroid hormones and glycemic values, HbA1c and indices of glucose variability, while an inverse correlation was observed between TSH levels and glycemic values (r = -0.4; P = 0.02), CONGA index (r = -0.3; P = 0.04) and HBGI (r = -0.3; P = 0.05) but not with HbA1c (r = -0.1; P = 0.47). No significant correlations of TSH and thyroid hormones with glycemia and HbA1c were observed in controls. In T1DM patients we found an inverse correlation between TSH and glycemic variability with direct action of glycemic excursions on TSH secretion disengaged from variations of thyroid hormone concentrations. The study of thyroid function (TSH concentrations) in these patients should be made by multiple samples on patients in euglycemic state to avoid underestimation or overestimation of thyroid dysfunction due to a misdiagnosis of euthyroidism or dyshyroidism with consequent inappropriate therapy.

May erythrovirus (parvovirus) B19 trigger autoimmune thyroid diseases?
Seerad Uğan1, Kevser Onbas1 & Nilgün Kassifoğlu2
1Dumulupınar University, Kütahya, Turkey; 2Eskişehir Osmangazi University, Eskişehir, Turkey.

Erythrovirus (EV B19) can recognize auto-antigens by using molecular mimicry mechanisms. EVB 19 is accused in the pathogenesis of many autoimmune diseases. Especially EVB19 is very important in the pathogenesis of autoimmune thyroid diseases. Thus in some case presentations; it was shown that EVB19 might be related with Hashimoto’s thyroiditis. Although etiopathogenesis of Graves’ disease and Hashimoto’s thyroiditis is not known exactly; they are thought to occur as a result of interaction of genetic and environmental factors. Infections are one of the environmental factors, which were alleged to be involved in the pathogenesis, but this was not proved. Parvovirus B19 (EVB) is an unproven viral agent, which was thought to play a role in pathogenesis. In this study; the prevalence of EVB19 was studied in autoimmune thyroid patients. This study was conducted on patients who were followed-up in the Endocrinology and Internal Medicine Polyclinics and who agreed to participate in the study. Total 90 individuals were counted in this study including 30 patients with Hashimoto’s thyroiditis, 30 patients with Graves’ disease and 30 control individuals who were compatible in terms of age. EVB19 IgG-IgM was studied manually using immunological ELISA method and values were read in spectrophotometer. According to results of this study; there was no significant difference for Parvovirus B19 IgG-IgM levels between patients with autoimmune thyroid disease and the control group.

Treatment of toxic multinodular goiter with 131I radioactive iodine – effects in volume reduction, thyroid function and autoimmunity
Catarina Roque1, Francisco Sousa Santos2, Tania Pilli3 & Furio Pacini4
1Endocrine Unit, Hospital de Egas Moniz, C.H.L.O. E.P.E., Lisbon, Portugal; 2Endocrine Unit, University of Siena, Siena, Italy.

Abstract
Radioiodine is a definite treatment option for toxic goiter. We have evaluated volume reduction, function and autoimmunity outcomes with a 15 mCi fixed regimen. Patients with at least one US evaluation before and after Iodine-131 therapy and with at least one year of follow-up were included. TSH, free-T4, antibodies and goiter volume before and yearly after Iodine-131 treatment were analysed for the length of the entire follow-up. The total 151 patients, 72.6% females, had a mean follow-up of 6.2 (1–12) years. At the time of treatment, the mean age was 68.8 years and the initial goiter volume 48.9 (8.255.7) ml, with no statistical difference between sexes. Increased volume was observed in 96.5% females and 91.7% males and there were 10.6% in hyperthyroidism and 89.4% in subclinical hyperthyroidism. The mean percentage volume reduction in the first year was 29.8% which represents 14.7 ml with a Pearson coefficient of correlation with initial volume of 0.058. During the following years mean reductions of 19.7, 15.8, 9.7, 5.8 and 1.4% were observed. Absolute volume reductions were maximal at the 3rd and 4th years representing mean reductions of 50 and 52%. Initial volume, TSH and age could not produce an explicative model for the percentage of reduced volume. Euthyroidism was achieved in 60.9% patients, subclinical hyperthyroidism in 8.6% and hypothyroidism in 26.5% of which 23.8% were subclinical. Hypothyroidism was related significantly with initial volume (P<0.001) and maximal percentage of reduction (P=0.012). The development of new detectable anti-thyroid antibodies was identified in 5 patients (6.9%), the result being above cut-off in none of them. New anti-TSH-receptor antibodies developed in 4 (5.5%) patients 1–3 years post-treatment. With 15 mCi, all patients experienced volume reduction in the first years after treatment, achieving means above 50% at the 3rd year, most were rendered euthyroid and developed no auto-immunity.

EP1296
Four out of five patients with acute kidney injury have thyroid dysfunction
Manpreet Chouolia1, Jasmine Das2, Maria Ghosh3 & Jubbin Jacob
1Endocrine and Diabetes Unit, Department of Medicine, Christian Medical College and Hospital, Ludhiana, Punjab, India; 2Department of Nephrology, Christian Medical College and Hospital, Ludhiana, Punjab, India; 3Department of Biochemistry, Ludhiana, Punjab, India.

Objectives
This study was undertaken to ascertain the prevalence of thyroid dysfunction (TD) in patients with Acute Kidney Injury (AKI) and assess the prognostic implications of TD in AKI patients.

Materials and methods
Consecutive adult patients (>18 years) admitted with AKI to the departments of Nephrology & Medicine were recruited if they met AKIN classification criteria for AKI after 48 h of admission (1). Patients were screened for thyroid dysfunction with serum sampling of Thyroid stimulating hormone, Free T3 and Free T4 after taking informed consent. Prognosis of TD in AKI patients was assessed in terms of: 1) Duration of hospital stay, 2) Need for Renal Replacement Therapy (RRT), 3) In-hospital mortality.

Results
147 patients with AKI (93M:54F) with a mean age of 57.8 years were recruited and TD was noted in 114 patients (77.5%). Of these, 74 (64.91%) patients had Nonthyroidal illness (NTI), 108.77% had primary hypothyroidism, 17(14.91%) had subclinical hypothyroidism, 4.51% had primary hyperthyroidism, 76.14% had subclinical hyperthyroidism and 21.75% had central hyperthyroidism. A trend to longer duration of hospitalisation for AKI patients (>7 days) was seen in 65(55.58%) patients with TD compared to 1762.96%) patients without TD (P=0.09). RRT requirements (56.36 vs 59.38%) (P=0.84) and in-hospital mortality (31.58 vs 33.33%) (P=0.84) of AKI patients with and without TD were similar. However, a trend of increasing mortality was seen in AKI patients with NTI (P=0.059).

Conclusions
Four out of five patients with AKI had some form of thyroid dysfunction, of which majority of them had NTI. However, presence of TD did not significantly affect prognosis of these patients.

**The assessment of influence vitamin D deficiency on the Hashimoto’s thyroiditis activity**

Katarzyna Lizis-Kolus¹, Alicja Hubalewska-Dydejczyk², Anna Sowa-Staszczak², Anna Skalniak², Aldona Kowalska³ ³ ³ & Pawel Lizis³³
1Department of Endocrinology, Holycross College Center, Kielce, Poland; 2Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; 3The Faculty of Health Sciences of the Jan Kochanowski University, Kielce, Poland; 3Holyross College, Department of Education and Health Protection, Kielce, Poland.

The observed increase in the incidence of Hashimoto’s thyroiditis (HT) requires research on factors that may affect its development. One of them may be vitamin D deficiency which is an epidemiological problem all over the world. Aim

The assessment of influence vitamin D deficiency on the HT activity.

Material and methods
310 people were enrolled in the study: 155 patients with HT (a-TPO and/or a-TG positivity)-144 women (93%), 11 men (7%) and 155 healthy volunteers-139 women (90%) and 16 men (10%); mean age: 49 ± 18, 58 ± 17, 49 ± 17 and 56 ± 16 years respectively. For analysis purposes the HT group was divided into two subgroups: without (E) and with l-thyroxine treated hypothyroidism (H): 45 women and 11 men (21.5%), 16 years respectively. For analysis purposes the HT group was divided into two subgroups: without (E) and with l-thyroxine treated hypothyroidism (H): 45 women and 11 men (21.5%), 16 years respectively. Serum 25OHD3 level was similar independently of a-TPO positivity (18.1–28.4; P < 0.001). The study showed higher 25OHD3 level in a-TPO negative than in subgroup H (28.7 ng/ml; Q 1-Q3: 23.2–32.7 vs 20.2 ng/ml; Q 1-Q3: 15.4–23.6; P < 0.001). In subgroup H 25OHD3 level was significantly lower in subgroup H (28.7 ng/ml; Q 1-Q3: 23.2–32.7 vs 20.2 ng/ml; Q 1-Q3: 15.4–23.6; P < 0.001). In subgroup E 25OHD3 level was similar independently of a-TPO or a-TG positivity.

Conclusions
Evidence of a link between increased level of antithyroid antibodies in hypothyroid patients with HT and 25OHD3 deficiency may suggest that this group is particularly prone to the vitamin D deficiency and can benefit from its alignment.

**Effect of vitamin D supplementation on patients with Graves disease**

Maram Maher, Nermin Sheriba, Abeer Elewa, Ahmed Mohamed Bahaa Eldin, Nesma Ali Ibrahim & Dina Marawan Ain Shams University, Cairo, Egypt.

Multiple factors contribute to the etiology of Graves disease (GD), including genetic and environmental factors. Vitamin D is well known in calcium metabolism and has also been shown to be a modulator in innate and adaptive immunity. There is a well-established link between vitamin D deficiency and various autoimmune diseases. The prevalence of vitamin D deficiency was reported to be common in patients with GD. Whether vitamin D deficiency has a causal relationship with GD remains controversial. Aim: to evaluate the effect of vitamin D supplementation in patients with GD with and without ophthalmopathy methods: A randomized prospective study was conducted on 60 adult patients with GD.

Group 1
20 patients with GD receiving 30 mg of methimazole daily.

Group 2
40 patients with GD receiving same dose of methimazole and vit. D3 200 000 IU/month. Patients were followed up for 3 months.

Results
40% of patients in group 1 and 72.5% in Group 2 were vit. D deficient. Vit. D was significantly correlated with thyroid volume and degree of exophtalmos. Gp 2 had significant lower thyroid volume and better effect on degree of exophthalmos.

Conclusions
Vit. D supplementation for GD has a favourable effect on thyroid volume and degree of exophthalmos.

**Primary hyperparathyroidism coexisting with Graves’ disease in a patient with vitamin D deficiency**

Panagiotis Athanassiou¹, Iligenia Kostoglou-Athanassiou² & Eleini Pantazi³
1Department of Rheumatology, St Paul’s Hospital, Thessaloniki, Greece; 2Department of Endocrinology, Red Cross Hospital, Athens, Greece; 3Department of Endocrinology, Alexandra Hospital, Athens, Greece.

Primary hyperparathyroidism is known to coexist with thyroid cancer and breast cancer. However, primary hyperparathyroidism coexisting with Graves’ disease is extremely rare. The aim was to describe the case of a patient with Graves’ disease causing severe hyperthyroidism who in the course of the disease developed vitamin D deficiency and primary hyperparathyroidism. A patient, female, aged 49 years, presented with severe hyperthyroidism causing tachycardia, palpitations and weight loss. TSH receptor antibodies were positive in the context of Graves’ disease. She was treated with methimazole and

**Endocrine Abstracts (2017) Vol 49**
propranolol and the disease went into remission. A year later treatment with methimazole was discontinued and 4 months later the patient had a relapse of hyperthyroidism. Laboratory tests revealed hyperthyroidism along with vitamin D deficiency and elevated PTH levels. Vitamin D was administered along with methimazole and propranolol. During follow up, despite normal vitamin D levels, PTH levels remained extremely elevated and blood calcium levels in the upper normal range. Ultrasound of the thyroid and parathyroid glands revealed a parathyroid adenoma adjacent to the left thyroid lobe. The adenoma was visible in a scan with 99mTc-sestamibi. The patient is being followed up and prepared for surgical treatment of both hyperthyroidism and primary hyperparathyroidism. The extremely rare case of a patient with concurrent Graves’ disease causing severe hyperthyroidism and primary hyperparathyroidism along with vitamin D deficiency is presented. This case further illustrates that primary hyperparathyroidism may be diagnosed in the context of severe vitamin D deficiency, being aggravated by vitamin D administration and that primary hyperparathyroidism may coexist with thyroid disorders.

EP1301
Primary underdosed hypothyroidism – parodontal implications in adults
Kazvan Circo, Selia Ibadula & Eduard Circo
Clinical Endocrinology Department, SClU ‘Sf. Apostol Andrei’, Constanta, Romania.

Introduction
Dento-maxillary system changes associated to thyroid disorders are constantly present. Differentiated impairment, depending on the period of evolution of the disease, explains the high percentage of over 60% of cases with parodontopathy.

Aim of the study
Evaluating the oro-maxillo-facial changes in patients with underdose treated hypothyroidism.

Methods
The study group comprised 154 patients with hypothyroidism, 132 women and 22 men. The examination included the assessment of oral cavity under parodontal status, the quality of dentition, changes of dento-maxillary dynamics.

Results
Facial and lip changes were present in 28.4% of cases; macroglossia 13%; mucoid infiltration of lingual mucosa and oral submucosa — 76%; gingivitis and chronic marginal periodontitis — 98%; pathological tooth mobility — grade I (73%) and grade 2 (15%); 12 patients (9.16%) required periodontal abscess drainage — 2 cases of upper premolars (14%) — 10 cases of lower molars (36.5%). Modification of occlusion by changing maximum pressure points — 72 patients (52%). A total of 61 patients (46.5%) presented vestibular pockets — 23 periodontal (17.5%), 25 palatal (19%) and 13 with lingual localization (10%). The average time of evolution of hypothyroidism with subdued treatment was 4.3 ± 1.2 months. Dental cavities were present in 77% of patients; partial edentation — in 89.3%; total edentation — 9.16%.

Atrophied prosthetic field
Four cases (3%); 8 cases (6%); osteoplastic hyperostosis. The average time of evolution of hyperthyroidism: 7.4 ± 1.5 months. The specific dento-parodontal and prosthetic treatment previously assumes the control of the thyroid hormone deficiency.

Conclusions
Periodontal changes are almost constantly found in hypothyroidism. The extent of the disease without a normal substitution is directly proportional to the severity and a high incidence of complications.

DOI: 10.1530/endoabs.49.EP1301

EP1302
Assessment of the degree of depression in patients with chronic autoimmune thyroiditis depending on the serum autoantibodies and thyroid hormone levels
Selia Ibadula, Olesea Scinic & Eduard Circo

Introduction
The incidence of depressive type psychoaffective disorders is significantly increased in patients with chronic autoimmune thyroiditis.

Objectives
The study of thyroid autoimmunity correlated with serum levels of TSH, FT4 and depression degree.

Methods
This study comprised 70 patients (64 women and 6 men), aged between 18 and 66 years, divided in 4 groups. All study groups were analyzed according to the degree of depression and serum TSH, FT4, thyroid peroxidase antibody (TPOAb), thyroglobulin antibody (TgAb). There were calculated the average values, standard deviation, incidence and statistical significance of p value < 0.01. Beck depression test was used to determine the level and severity of depression.

Results
Absence of depression was associated with elevated TSH (6.49 ± 3) and low FT4 (10 ± 6); TPOAb values (199 ± 12) and TgAb values (358 ± 8). Minimum depression was correlated with elevated TSH (6.6 ± 3) and normal FT4 (14.8 ± 9.8); TPOAb values (247 ± 18) and TgAb values (385 ± 22). Moderate depression has been associated with normal TSH (4.2 ± 2) and normal FT4 (18.5 ± 15); TPOAb values (253 ± 26) and TgAb values (422 ± 16). Severe depression was accompanied by slightly elevated TSH (4.3 ± 3) and normal FT4 (15.2 ± 8.7); TPOAb values (336 ± 18) and TgAb (425 ± 22).

Conclusions
It was revealed a high incidence of depressive disorders among the patients with chronic autoimmune thyroiditis with a distribution of medium and severe forms of depression predominantly in women without any evidence of thyroid hormonal level involvement. The study shows a heterogeneity of thyroid autoimmunity regarding the effect of antithyroid antibodies in generating psycho-emotional processes commonly found in these patients.

EP1303
Frequency and prognostic factors of non-diagnostic cytology in ultrasound guided thyroid fine needle aspiration biopsy: a 2-year single centre experience
Vasileios Chambidis, Athanasios Siolos, Zoe Efstathiadou, Albina Sykja, Thomas Georgiou, Eleni Chambidou, Athanasious Panagiotou, Fotini Adamidou & Marina Kita
‘Hippokration’ General Hospital of Thessaloniki, Thessaloniki, Greece.

Aim
Ultrasound-guided Fine Needle Aspiration Biopsy (USg-FNAB) is the most accurate modality for distinguishing malignant or possibly malignant from benign thyroid nodules. However, a certain amount of specimens turn out to be non-diagnostic or inadequate. Several factors contribute to this outcome such as the examiner’s experience, characteristics of the nodule and patient’s compliance. Understanding these factors could contribute to reduction of non-diagnostic results.

Methods
All nodules examined by USg-FNAB between Jan 2014 and Nov 2015 at the thyroid clinic of our department were reviewed (n = 682 patients with 987 nodules). Patient demographic characteristics (sex and age), nodule characteristics (size, location, previous FNAB) and the experience of the examiner were recorded.

Results
The only factor that exhibited a significant positive association with non-diagnostic cytology on USg-FNA was the age of the patient (P < 0.01). Nodule size was marginally negatively associated (P = 0.054). No other factor emerged as a predictor of non-diagnostic cytology.

Conclusions
The present study indicates that patient age is a prognostic factor for non-diagnostic cytology on USg-FNA. This might be attributed to the fact that older patients usually present with nodules baring morphologic characteristics such as cystic composition and peripheral calcifications that are associated with non-diagnostic cytology. On the other hand, the marginally negative association with nodule size, seems justified by the fact that small nodules are technically more difficult to biopsy. It is of note that the examiner’s experience has not emerged as a prognostic factor, possibly due to the fact that nodules which are not easily accessible are usually biopsied by more experienced staff.

Juvenile hypothyroidism—particularities in the development of the dento-maxillary system
Razvan Circo, Seila Ibadula & Eduard Circo

Introduction
Juvenile hypothyroidism shows various complications depending on the correctness of substitute treatment.

Aims of the study
To identify the massive facial changes with occlusive disorders, dental malpositions, altered chronology of dental eruption, periodontal changes in terms of absence of thyroid replacement therapy or drug sub-dosing.

Methods
The study group comprised 24 children, 15 girls and 8 boys; 4 cases of congenital myxedema; 19 cases of earned hypothyroidism and the mean age was 9 ± 2.4 years—presented in their evolution periods of underdosed substitute thyroxine treatment.

Results
Facial changes: infiltrated facial skin and lips; widened transverse diameter of the skull; microretrogathnia – 12 cases (52%); pale and infiltrated lingual and jugal mucosa; 14 children (60.8%) – lingual fungal detritus; 8 children (34.7%) – ‘geographic’ tongue. Occlusive disorders: frontal malocclusion in the sagittal plane – 19 children (80%); from reverse occlusion – 8 cases (34.7%); open bite – 4 cases (17.4%); lower prolabium/dentition with interdental spacing – 17 children (68%). Dental malpositions: reverse overlap – 11 cases (47.8%), exertion of central upper incisors in vestibular position – 1 case (4.3%); bilateral ectopic canine – 1 case (4.3%); dental-venular incongruence – 1 case (4.3%). The chronology of dental eruption: late eruption – 19 patients (78.2%); prolonged mixed dentition – 14 patients (60.8%); taurodontism – upper molars–1 case (4.3%); accelerating the teeth eruption when introducing thyroxine therapy between 6 and 8 months. Periodontal changes: pathological dental mobility, pathological diastemas, gingival recession, real periodontal pockets – 8 cases (34.7%).

Conclusions
In hypothyroid child prevail the disorders of occlusion and chronology of eruption. Early diagnosis and a well conducted thyroxine treatment requires the prophylaxis of dento-maxillary complications in children.

EP1305
Thyrotoxic periodic paralysis
Ahmet Kaya & Mustafa Kulakizigolu
Division of Endocrinology and Metabolism, Meram Medical Faculty, Necmettin Erbakan University, Konya, Turkey.

Thyrotoxic periodic paralysis (TPP) is due to a fall in potassium levels and threat life if it affects respiratory muscles. Men are more affected than women, and lower extremities are more prone to involvement. Serum potassium in hyperthyroidism is usually normal, but Na+/K+ - ATPase sensitivity is increased and extracellular potassium rapidly passes to the intracellular space. Beta blockers, small dose potassium replacement and hyperthyroidism treatment blocks this shift and TPP can be treated. Achieving euthyroidism is essential for the cure of TPP. Although hyperthyroidism effects mainly females, TPP is seen more in males especially in the second and fourth decades. Periodic paralysis is seen only in 2% of thyrotoxic patients which is characterized by hypokalemia, proximal muscle weakness and acute onset. We present four cases of male patients aged between 28 and 36 years old. Their complaints were, fatique, weakness and difficulty in walking. Two patients had known Graves’ disease and two patients were diagnosed as new onset Graves’ disease. They did not have predisposing factors such as alcohol intake, using diuretics or laxatives. On phsical examination, they all had proximal muscle weakness and diminished lower extremity deep tendon reflexes. Their potassium levels were 2.7-2.3-2.1-1.9 mEq/l respectively. Their thyroid antibodies were positive, TSH levels were suppressed and free thyroid hormones were elevated. Patients were treated with potassium replacement and antithyroid drugs and lower extremity weakness and paralysis were disappeared. HPP is a genetic disorder but rarely it can be due to thyrotoxicosis. Although TPP is more commonly seen in Graves disease, it is free of disease duration and severity.

DOI: 10.1530/endoabs.49.EP1305

EP1306
Audit of utility of radio-isotope scan in the investigation of thyrotoxicosis or subclinical hyperthyroidism and timing of anti-thyroid medication
Satish Artham, Heather MacFarlane, Nishwa Ali & Andy James
Royal Victoria Infirmary, Newcastle, UK.

Thyrotoxicosis is one of the most common clinical problems in patients referred to endocrine clinic. TRAb is specific for Graves disease (GD) and radioisotope scan (RIS) is useful diagnostic test in the investigation of thyrotoxicosis. RIS is commonly used when TRAb is borderline or negative to exclude thyroiditis.

Aims and methods
To look at the use of RIS in the investigation of thyrotoxicosis and sub-clinical hyperthyroidism (SCH), and use of anti-thyroid medication (ATM) in these conditions. Retrospective audit, data collected from electronic pathology and radiology system, and clinic letters over 11 months (Jan 15 to Nov 15).

Results
n = 66, of which 63 (95.5%) were sub-clinical hyperthyroidism or thyrotoxicosis. Female: male = 52:14. Mean age: 54.07 years. 60 (95%) patients had TRAb checked and 3 (5%) patients not. (n = 1 SCH, planned for radio iodine, n = 1 on carbimazole and planned for radioiodine, n = 1 TRAb requested but not processed). All patient with TRAb –ve and 5 patients with TRAb +ve had RIS: 23 (36.5%) were diagnosed with Graves disease. 7 patients with negative TRAb who were later diagnosed with GD on RIS were commenced on carbimazole before diagnosis. 17 (27%) were diagnosed with thyroiditis, of which 4 (23.5%) were commenced on carbimazole before diagnosis.

Conclusion
This audit shows appropriate use of RIS in all patients in the investigation of thyrotoxicosis and SCH. 5 patients with positive TRAb had RIS as TRAb was borderline and history was not typical of Graves disease. 7 patients were commenced on ATM before diagnosis of GD. All these patients had mild to moderate thyrotoxicosis. These patients could have been started on β-blockers rather than ATM as they are associated with side effects of agranulocytosis which can risk life threatening infections.

EP1307
Thyroid autoimmunity and frequency of malignant or suspicious for malignancy thyroid nodule cytology

Introduction
Thyroid autoimmunity has been associated with the diagnosis of differentiated thyroid (DTC) cancer in surgical series. However, this finding has not been consistent in Fine Needle Aspiration Biopsy (FNAB) cytology series. Aim: We aimed to investigate the association between thyroid autoimmunity and DTC in patients who underwent ultrasound-guided FNAB.

Methods
A retrospective analysis of patients who had undergone ultrasound-guided FNAB between Jan 2014 and Nov 2015 was performed. Patients were classified into two groups, according to the presence of thyroid auto-antibodies (ATA): ATA negative (ATA −) and ATA positive (ATA +) patients. In ATA + patients, either one or both antibody types (anti-thyroid peroxidase abs or anti-thyroglobulin abs) were positive. Patient demographic characteristics, the presence of risk factors for thyroid cancer and nodule size were recorded. Cytology reports were classified, according to the Royal College of Pathologists guidance, as negative for malignancy (Thy1), suspicious for malignancy (Thy4) and malignant (Thy5). Non-diagnostic cytology reports (Thy1) were excluded. The frequency of possible neoplasms, suspicious or malignant (Thy3, Thy4, Thy5) was estimated in the two patient groups (ATA −, ATA +).

Results
During the study period 673 nodules of 466 patients were biopsied. Thyroid autoimmunity was present in 41.8% of patients. The frequency of suspicious or malignant (Thy3, Thy4, Thy5) cytology reports was comparable in the two patient groups (5.8% in ATA + patients vs. 4.3% in ATA − patients; P = 0.303).

Conclusion
In the present study, no association between the presence of thyroid autoimmunity and suspicious or malignant findings in thyroid nodule cytology was found.

Clinical experience with glucocorticoid therapy in patients with endocrine ophthalmopathy
Irina Bourko1, Halina Korolenko2, Olga Bourko2, Oksana Dudich1 & Viktoria Krasilnikova
1Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus; 210th Clinical Hospital, Minsk, Belarus; 3Republican Scientific and Practical Center of Cardiologiz, Minsk, Belarus.

Objective
To evaluate the efficacy, safety and to determine the criteria for the glucocorticoid therapy scheme: intravenous pulse therapy followed by tablet form in prolonged regime in the treatment of active phase of endocrine ophthalmopathy (EOP). Materials and methods
28 patients of both sexes (52 eyes) with endocrine ophthalmopathy in the active phase were included in the study. The average age – 43.4±10.6 years. The duration of the disease ranged from 3 to 12 months. The activity of disease was evaluated according to a scale of clinical activity of EOP – Clinical Activity Score (CAS), and thickening of the extraocular muscles based on MSCT of the orbits.

Results
One month after the start of pulse therapy there was a significant reduction of EOP activity and severity in all patients, which was confirmed by an increase in vision, a decrease in the level of intraocular pressure, reduction in the amount exophthalmus at 0.8±0.02 mm (P<0.05) and the frequency of diplopia. 3 months after the start of glucocorticoid therapy in 100% of cases a transition to the inactive phase of the disease was determined. Reoccurrence of the disease after 12 months was diagnosed in 3 patients (10.7%).

Conclusions:
i) Intravenous pulse therapy with high doses of methylprednisolon followed by oral administration in prolonged regime is effective and safe; ii) it contributes to the rapid achievement of clinical effect and stable remission of the disease. ii) A thickening of the extraocular muscles is the criteria for the start of glucocorticoid therapy.

Thyroid storm presenting in the context of recent influenza vaccination and untreated Graves disease
Neil Kelly, Dushyant Sharma & Reza Zaidi
Royal Liverpool University Hospital, Liverpool, UK.

Introduction
Thyroid Storm is a life-threatening but rare (incidence 0.2 per 100 000) disease state which presents as an extreme form of thyrotoxicosis. A hyper-metabolic state resulting from excessive thyroid hormone release which can be precipitated by both thyroidal and non-thyroidal illness.

Case
In this case we discuss a 72 year old female with previously treated Graves disease who presented in thyroid storm one week after annual flu vaccination. On initial presentation, she was in overt heart failure with bilateral pleural effusions and a community acquired pneumonia, atrial fibrillation at a rate of 170 beats per minute and acute confusion with significant agitation. The decision to treat initially with beta blockers was complicated by her being in heart failure with significant pulmonary oedema and a rapid ventricular rate precipitating a peri-arrest state. The guidance of the cardiologists to give amiodarone to chemically cardiovert conflicted with her thyrotoxic state. Relevant Data includes a Thyroid Stimulating hormone of 0.05 mIU/l and a T4 of 96.5 pmol/l. A biochemically euthyroid state was eventually achieved using propylthiouracil, intravenous hydrocortisone, Lugols Iodine and Bile salts. Beta blockers and amiodarone were used with caution in the context of heart failure/suspected thyrotoxic cardiomyopathy and a thyrotoxic state respectively. Further investigation showed the patient had previously been treated for Graves and this was a late presentation recurrence seven years after completing block and replace therapy.

Discussion
We present this case because it highlights a rare case of thyroid storm presenting seven years following initial block and replace therapy had discontinued. The temporal relationship between presentation and the administration of the flu vaccination mean this must be considered as a potential non-thyroidal precipitant. The presentation in fast atrial fibrillation is also significant as the treatment of choice was amiodarone and this could have potentially exacerbated her underlying thyrotoxicosis.

Relapsing Graves’ hyperthyroidism in a male patient with central hypothyroidism after surgery of craniopharyngioma: case report
Anisouara Bumbu, Yawa Abouleka, Louis Potier, Ronan Roussel & Michel Marre
Universitary Hospital Bichat Claude-Bernard, Paris, France.

Introduction
Graves’ disease is an autoimmune thyroiditis, less common in men but with relapse of hyperthyroidism significantly more frequent in men than in women after anti-thyroid medications’ withdrawal. Craniopharyngioma is a rare brain tumor which arises in the pituitary stalk and project into the hypothalamus. The distribution by age is bimodal with a slight male predominance and a poor survival rate for older than 65 years. The association of these pathologies is extremely rare.

Observation
We report the case of a 67 years-old patient who presented a severe thyrotoxicosis due to a relapse of a Graves’ disease in remission since 2009. At the moment of presentation the patient was in treatment with levothyroxine for a central hypothyroidism secondary to a craniopharyngioma surgery. Clinically he presented tachycardia, weight loss, confusion, anorexia and biologically he had low TSH value and very high FT4 (100 pmol/l) and FT3 (50 pmol/l) values which were increasing 5 days after stopping the levothyroxine. TSH receptor antibodies were positives (2.8 UI) and the T-123 scintigraphy found an intense and uniform fixation confirming the relapse of Graves’ disease. A treatment with carbimazole 60 mg per day was started with a strictly surveillance of hepatic enzymes. There was a decrease of thyroid hormones and hepatic enzymes and also symptoms in 2 weeks. A thyroidectomy is to discuss, because of the relapse and the severity of the symptoms, after achieving the euthyroid status.

Conclusion
We described here, for the first time, an association of a relapsing Graves’ disease in patient with hormonal supplementation for central hypothyroidism after surgery of craniopharyngioma, with a favorable evolution after treatment with anti-thyroid medications.

TSH normalization and negative anti-TSH receptor antibodies – Predictive value for remission in Graves’ disease
Catrina Roque, Francisco Sousa Santos, Ricardo Capitão, Carlos Bello, Catia Ferrinho & Carlos Vasconcelos
Endocrine Clinic, Hospital de Egas Moniz C.H.L.O. E.P.E., Lisbon, Portugal.

Graves’ disease is the most common cause of hyperthyroidism in non- endemic areas and antithyroid drugs are the preferred first-line therapy in many centers. The aim of this retrospective investigation was to verify the association of remission with the achievement of normal TSH and free-T4 during the first 18 months of treatment and to compare it with negative anti-TSH-receptor antibodies at 18 months, a marker with known prognostic value. All patients diagnosed with Graves’ disease from 2008 to 2015 were selected. Those with more than 2 years of follow-up and with synchronous determination of TSH, free-T4 (fT4), free-T3 and anti-TSH-receptor antibodies (TRAb) performed at our clinic were included. We compared TRAb titer, TRAb positivity, TSH and fT4, between the group that achieved remission and the one that did not, for the length of treatment and follow up. We obtained 71 patients with mean age of 47 years of which 76% were females. The mean follow-up after remission was 2 years. Remission was achieved in 28% patients after 18 months of treatment. There were no significant differences in sex or age among the 2 groups. No association was found between the development of hypothyroidism during therapy and remission. Negative TRAbs at 18 months associated with remission significantly (P<0.001) with a strength of association of 0.86. A non-suppressed TSH accompanied by normal fT4 levels achieved during therapy was associated significantly with remission (P<0.001) with a strength of association of 0.74. Logistic regression with this parameter could explain 59.8% of remissions after initial therapy with P<0.001. This profile of thyroid function was associated with negative TRAbs significantly (P<0.001). Achieving a non-suppressed TSH in the presence of normal fT4, during the first 18 months of therapy, associates with TRAb negativization and could predict remission in approximately 60% of patients.

TREATMENT CHOICE AND PATIENT SATISFACTION IN THYROTOXICOSIS
Helen Conaglen, Jade Tamatea, Mark Swarbrick, John Conaglen & Marianne Elston
Waikato Clinical Campus, University of Auckland, Hamilton, New Zealand.

Background
Thyrotoxicosis may be associated with considerable patient morbidity. Graves’ disease (GD) and toxic multinodular goitre (TMNG) are the most common causes of thyrotoxicosis. Therapeutic options include anti-thyroid medication or definitive treatment by radioiodine or surgery. Efficacy, quality of life and cost-effectiveness are among the outcomes that have been compared between these two therapies. However, there is still no clear consensus as to which treatment option offers a better outcome.

Aims
The aim of this study was to assess quality of life amongst patients who received anti-thyroid medication, radioiodine or surgery and to assess patient satisfaction with the treatment modality selected.

Results
Of those eligible for the study 146 patients completed the questionnaires, representing a return rate of 73%. GD was the cause of the thyrotoxicosis in 84% and TMNG in 16%. Fifty-eight percent of patients had received anti-thyroid medication, 19% radioiodine, and 22% thyroid surgery, the latter two groups usually following a period of medical therapy. The impact of treatment on recovery time, activities of daily living, possibility of depression or anxiety, and doctor’s recommendations were identified as the most important factors in choosing a treatment. Satisfaction levels were high across all three treatment types. There was no difference in quality of life between the treatment types apart from a higher score for cosmetic concerns in the surgical group.

Conclusions
These results indicate that overall patient satisfaction with treatment and quality of life are comparable across all three treatment options. Therefore, factors such as patient preference and resource availability may be more important than treatment type.

MANAGEMENT OF RELAPSING GRAVES: A CLINICAL SURVEY AMONG ENDOCRINOLOGISTS IN ISRAEL
Shlomit Koren1, Miriam Shteinshneider1,4, Karen Ort3,4, Dore Cantrell1,3, Carlos A Benbassat1,4 & Ronit Koren1
1Endocrine Institute, Assaf Harofeh Medical Center, Zerifin, Israel; 2Department of Internal Medicine A, Assaf Harofeh Medical Center, Zerifin, Israel; 3Department of Internal Medicine C, Zerifin, Israel; 4Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel.

Background
The management of relapsing Graves’ disease is controversial. Previous surveys from different regions in the world demonstrated variations in the clinical practices of patients with Graves’ disease relapse.

Methods
To determine management pattern among endocrinologists in Israel an electronic questionnaire was e-mailed to all members of the Israeli Endocrine Society. Questionnaires included demographic data and clinical scenarios with questions regarding the treatment and follow up of patients with relapsing Graves’ disease. Results
We received 98 responses from Israeli endocrinologists. 42 (43%) males and 56 (57%) females. 41.8% had board certificate for more than 10 years. 72.4% respondents work in hospital environment and 26.5% work in community clinics. 61.2% see more than 10 thyroid patients in clinic per week. When managing Graves’ relapse following ATD treatment in a young male, 68% would restart ATD (98% mercaptizol) and 32% would refer to RAI treatment. Interestingly, endocrinologist who treat more thyroid patients (more than 10/week) tend to choose ATD over RAI (P=0.04). In case of recurrent Graves’ and ophthalmopathy, 50% would continue ATD, 22.4% would recommend RAI treatment and 27.6% surgery. Most endocrinologists (56%) would continue ATD for 12–24 months. 75% would monitor CBC and liver function (39% for the first month and 36% for 6 months). 44% would recommend routine neck US, and 19.3% would recommend routine DEXA. In a case of thyrotoxicosis due to 3 cm toxic nodule tirads 4a most endocrinologists (70%) would refer to RAI ablation, 46.4% without FNA and 23.7% with FNA. No significant difference was found in correlation with gender, years of board certificate, or work environment.

CASE REPORT: IDENTIFICATION AND CHARACTERIZATION OF INTERFERENCE BY IG M ANTI-STREPTAVIDIN ANTIBODY IN A PATIENT WITH SPURIOUS THYROID FUNCTION TESTS
Leo Lam1, Warwick Bagg1,2, Julie Lim3, Martin Middleditch4 & Campbell Kyle1,5
1Department of Endocrinology, Auckland District Health Board, Auckland, New Zealand; 2Medical Programme Directorate, Faculty of Medical and Health Sciences, The University of Auckland, Auckland, New Zealand; 3Department of Chemical Pathology, LabPlus, Auckland City Hospital, Auckland, New Zealand; 4Department of Physiology, School of Medical Sciences, New Zealand National Eye Centre, The University of Auckland, Auckland, New Zealand; 5Auckland Science Analytical Services, University of Auckland, Auckland, New Zealand; 6Department of Biochemistry, Labtests, Auckland, New Zealand.

Introduction
Falsely high FT4 and FT3 with concurrent falsely low TSH have been reported in patients taking biotin and in a few case reports of patients with IgG anti-streptavidin antibody. However, other isotypes and effects on other immunosays have not been reported.

Case
A 77 year female presented with worsening fatigue with a background of hyperthyroidism on carbimazole. Clinically she appeared hypothyroid. Her results on Roche Cobas platform were: TSH 0.75 mIU/l (R. 0.27–4.2), FT4 12 pmol/l (12–22) and FT3 8.1 pmol/l (3.9–6.8). However, tests repeated on Siemens Centaur platform were: TSH 37 mIU/l (0.3–4.0), FT4 7 pmol/l (10–20) and FT3 3.0 pmol/l (3.0–6.5), suggesting Cobas results were falsely low for TSH and falsely high for FT4 and FT3. To identify the cause of interference a second sample from the patient was preincubated with streptavidin microparticles. After incubation TSH on Cobas platform increased from 0.2 to 0.7 mIU/l, while FT4 reduced from 28 to 16 pmol/l, and FT3 from 9.0 to 4.7 pmol/l. Siemens results were unchanged. Elution of streptavidin microparticles with 0.1M citric acid identified a 75 KDa band on reducing SDS-PAGE. Purification and sequencing of peptide fragments by LC-MSMS of this band identified this protein as IgM heavy chain. This demonstrates IgM anti-streptavidin antibody as the cause of interference. The patient’s hypothyroid symptoms resolved when carbimazole was stopped. The effect of preincubation with streptavidin microparticles was also tested on Roche Cobas immunosays for FSH, LH, oestradiol and testosterone in this patient’s serum. Sandwich immunosays were falsely low and competitive immunosays were falsely high. Oestradiol exhibited the largest difference, at 240 pmol/l initially but becoming undetectable following incubation.

Conclusions
This is the first case describing IgM anti-streptavidin antibody as the cause of interference on thyroid function tests and also shows its effects on other immunosays.

SEVERE GRAVES’ DERMOPATHY AND ACROPATHY DISORDERING WITH MODERATE OPTHALMOPATHY: (A CASE REPORT)
Dhiyeaddeen Bellarbi, Haifa Si Youcef & Noura Soumeya Fedala
Endocrine and Metabolic Diseases Department, Bab El Oued Hospital, Algiers, Algeria.

Introduction
Pretibial Myxedema(PM) and acropachy(AP) are rare extrathyroidal manifestations of Graves’ disease observed only in 0.5–4% of all cases. These extrathyroidal manifestations are generally associated to severe ophthalmopathy.

Endocrine Abstracts (2017) Vol 49
Only few cases of severe thyroid dermopathy and achrophy occurring with moderate ophthalmopathy were reported.

Observation

We present a 60 years old female patient who developed grave’s disease on a pre-existing goiter associated to extra-thyroidial manifestations. Physical examination revealed; some signs of hyperthyroidism, moderate exophthalmos measured by hertel’s exophthalmometer at 20 for right eye and 19 for Left eye, bilateral severe PM manifested by elephantiasis, severe AP manifested by clubbing and finger deformations, compressive goiter with 3 palpated nodules (a 5 and 4 cm nodules occupying the totality of the right and left lobe respectively, and a 2 cm left lobo-isthmic nodule) which were confirmed by ultrasound of the neck that showed hypervascularization of the normal parenchyma. Thyroid function tests before treatment showed FT3 predominating hyperthyroidism: TSHus <0.005, FT4= 4.11 ng/dl (N:0.7–1.4), FT3> 30 pmol/l (N:3.0–6.3 pmol/l). Anti-thyroid peroxidase antibodies were positive 149.6 U/ml (N:<12 U/ml). Total thyroid-ectomy was performed after normalization of thyroid function under 60 mg of methimazole, and this goiter was benign on pathology. PM was stabilized after surgery and management of hypothyroidism by levothyroxine.

Conclusion

PM and AP are very rare. They reflect the severity of autoimmune and long duration of cytokine-producing activity Th1 and Th2 types, this plays an important role in development of autoimmune state, chronization and disease progress. The research goal was to study kidneys’ function conditions of thyroid hormone deficit. Estimation of kidneys’ function included study of daily weight loss and functional decline. fT4 was 37.9 pmol/l, TSH was 0.005, FT4= 4.11 ng/dl (N:0.7–1.4), FT3> 30 pmol/l (N:3.0–6.3 pmol/l). Anti-thyroid peroxidase antibodies were positive 149.6 U/ml (N:<12 U/ml). Total thyroid-ectomy was performed after normalization of thyroid function under 60 mg of methimazole, and this goiter was benign on pathology. PM was stabilized after surgery and management of hypothyroidism by levothyroxine which is generally severe. Infiltration corresponds to the accumulation of GAG in the 3 conditions. Moderate ophthalmopathy occurring with severe PM(elephantiasis) and severe AP(clubbing and deformations) is not habitually reported.

The importance of the study of several immunoregulatory cytokines in the manifest hyperthyroïdism

Marina Orlova, Arina Frolova, Tatiana Rodionova, Irina Badak & Tatiana Baitman

Saratov State Medical University named V.I. Razumovsky, Saratov, Russia.

The research goal was to study serum concentration of immunoregulatory cytokines (IL-1ß, IL-6ß, IL-8ß, IL-10ß) in 80 patients with manifest hyperthyroidism at the age of 21–50. 48 patients suffering from chronic autoimmune hyperthyroidism and 32 patients with postoperative hyperthyroidism were examined. It was revealed that autoimmune hyperthyroidism effects balance of cytokine-producing activity Th1 and Th2 types, this plays an important role in development of autoimmune state, chronization and disease progress. The research goal was to study kidneys’ function conditions of thyroid hormone deficit. Estimation of kidneys’ function included study of daily weight loss and functional decline. fT4 was 37.9 pmol/l, TSH was 0.005, FT4= 4.11 ng/dl (N:0.7–1.4), FT3> 30 pmol/l (N:3.0–6.3 pmol/l). Anti-thyroid peroxidase antibodies were positive 149.6 U/ml (N:<12 U/ml). Total thyroid-ectomy was performed after normalization of thyroid function under 60 mg of methimazole, and this goiter was benign on pathology. PM was stabilized after surgery and management of hypothyroidism by levothyroxine which is generally severe. Infiltration corresponds to the accumulation of GAG in the 3 conditions. Moderate ophthalmopathy occurring with severe PM(elephantiasis) and severe AP(clubbing and deformations) is not habitually reported.

TRAB positive thyroid dysfunction associated with Alemtuzumab treatment for MS: A case series

Aonife Garralhy, Sulaiman Ali, Siobhan McQuaid & Maria M Byrne

Department of Endocrinology, Mater Misericordiae Hospital, Dublin, Ireland.

Alemtuzumab is a monoclonal antibody directed against CD52 licenced for the treatment of relapsing remitting multiple sclerosis (MS). Thyroid dysfunction occurs in one third of patients, likely secondary to lymphocyte reconstitution.

Case 1

A 36 year old female, treated with alemtuzumab 15 months prior, presented to antenatal clinic at 12 weeks gestation with symptoms of thyrotoxicosis. fT4 was 83.7 pmol/l (RR 12-22), TSH suppressed, TRAB positive. She was treated with carbimazole and remains on antithyroid medication at 30 weeks gestation; TRAB titer has risen to >40 IU/l (RR 0.1-5).

Case 2

A 36 year old male, treated with alemtuzumab 18 months prior, was admitted for investigation of weight loss and functional decline. fT4 was 37.9 pmol/l, TSH was suppressed and he had a large smooth goiter. TRAB was 18.9 IU/l. He was treated with carbimazole and is undergoing rehabilitation.

Case 3

A 39 year old female, treated with alemtuzumab 2 months prior, was referred to the endocrine clinic with fT4 of 60.2, suppressed TSH and TRAB positive. She was asymptomatic and became hypothyroid four weeks later (fT4 <5.2 pmol/l, TSH 58 IU/l). Twelve months on, she is euthyroid on l-thyroxine 100 µg daily.

In this case series we demonstrate three cases of alemtuzumab induced thyroid disease, occurring 2–18 months post treatment, all of which are TRAB positive. Case 1 highlights that women of child-bearing age treated with alemtuzumab should be counseled regarding the risk of thyroid dysfunction in future pregnancy; TRAB should be monitored in each trimester and close monitoring for foetal thyrotoxicosis is required. Case 3 highlights that TRAB positivity is not specific for Graves disease and in this case is associated with overt hyperthyroidism. This case series illustrate the unpredictable clinical course of thyroid dysfunction in patients treated with alemtuzumab; long-term monitoring of thyroid function is recommended.

**Serum levels of insulin-like growth factor 1 in patients with hyperthyroidism or euthyroidism**

Fen-Yu Tseng¹, Yen-Ting Chen², Yu-Chao Chi³, Pei-Lung Chen¹-³ & Wei-Shiang Yang¹-²

¹Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan; ²Graduate Institute of Clinical Medicine, National Taiwan University, Taipei, Taiwan; ³Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan.

Background

Insulin-like growth factor 1 (IGF1) has molecular structure similar to insulin. As an important mediator of growth hormone, IGF-1 plays roles in growth of children and anabolic effects of adults. We evaluate serum levels of IGF-1 in patients with hyperthyroidism or euthyroidism.

Subjects and methods

In this study, 30 patients with hyperthyroidism (HY group) and 30 euthyroid individuals (EU group) were recruited. The patients of HY group were treated with anti-thyroid regimens as clinically indicated, whereas no medication was given to EU group. The demographic characteristics, anthropometric and laboratory data of both groups at baseline and at the 6th month were compared. Associations between levels of IGF1 and free thyroxine (FT4), TSH, or log transformation of TSH (logTSH) were analyzed.

Results

At baseline, the HY group had significantly higher serum IGF1 levels than the EU group (median (Q1, Q3): 305.4 (257.4, 368.1) vs 236.7 (184.6, 318.8) ng/ml, P <0.01). The serum IGF1 levels of the HY group decreased after anti-thyroid regimens, but still were higher than that of the EU group at the 6th month (299.5 (249.9, 397.9) vs 222.1 (190.2, 305.4) ng/ml, P <0.01). At the baseline, the serum levels of IGF1 in all patients were positively associated with FT4 (β = 29.02, P <0.01) and negatively associated with TSH (β = −31.46, P <0.04). The associations between serum levels of IGF1 with FT4 or TSH became insignificant at the 6th month. However, the serum IGF1 levels were persistently negatively associated with logTSH both at baseline (β = −29.04, P <0.01) and at the 6th month (β = −26.65, P = 0.02).

Conclusions

In comparison to EU group, patients with hyperthyroidism had higher serum IGF1 levels, which decreased after anti-thyroid regimens. The serum IGF1 concentrations were negatively associated with logTSH in patients with hyperthyroidism or euthyroidism.

**Hashimoto Encephalopathy with polymorphic neuropsychiatric signs: a case report**

Diana Simoniene¹-², Raimonda Klimaitêt², Greta Mikelaitêt² & Evalda Danyte¹-³

¹Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Kaunas, Lithuania; ²Lithuanian University of Health Sciences, Kaunas, Lithuania; ³Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Hashimoto encephalopathy (HE) is a rare and steroid responsive encephalopathy associated with autoimmune thyroiditis (1). Patients with Hashimoto encephalopathy may present with a variety of neuropsychiatric signs (2). 68-year old woman was admitted to the Neurology Department, of Hospital of Lithuanian University of Health Sciences, Kauno klinikos (HLUHS KK), due to disorder of consciousness of uncertain aetiology in August 2016. The signs of motor dysfunction, generalized rigidity, and disorientation, with several episodes of loss of and recurrent episodes of psychosis with hallucinations were observed since 2011. She had hospitalisations in neurology units of several hospitals and was discharged with different diagnoses and modes of treatment. She developed cerebral oedema with abundant myoclonic seizures in extremities in August 2016. The possibility of ischemic, neurodegenerative or neuro-inflammatory disease was ruled out in LUVS KC. Irregular activity of slow range waves was observed in EEG. Brain CT showed no signs of ischemia. High protein concentration was found in lumbar aspirate. Brain MRI SI T2W revealed changes characteristic of HE. Laboratory tests: FT4 6.7 pmol/l (normal 9–21), TSH 17.71 mU/l (0.4–3.6), antiTPO 270 kU/l (0–2), and signs of chronic thyroiditis in thyroid ultrasound made possible to diagnose autoimmune thyroiditis with hypothyroidism and HE. The treatment with l-thyroxine 50 µg/d, and 3-day bolus therapy of Methylprednisolone 1 g/d was started with rapid regression of clinical neurological signs. Prednisolone per os followed, with gradually reduced dose. The patient’s condition improved significantly and she was discharged. During follow-up appointment after 3 months, her neurological state and psychiatric condition were deemed stable, thyroid hormones in normal range on l-thyroxine 50 µg/d. MRI HE changes have regressed. Patients with unexplained encephalopathy, progressive cognitive impairment, polymorphic neuropsychiatric should be considered to rule out HE; MRI and test of antiTPO levels should be performed.

The prevalence of thyroid disorders is expected to increase over the coming decades due to the aging population. The aim of this study was to determine the prevalence of thyroid diseases and their associated factors in a population of Tunis Hospital. The study was conducted in a hospital setting. The study population included 3040 patients, aged 18-70 years, who were admitted to the endocrinology ward of the hospital over a period of 1 year. The presence of thyroid disorders and their associated factors were determined using a questionnaire. The prevalence of thyroid disorders was 17.6% (95% CI: 16.2-19.1). The most common disorder was thyroid nodules (12.6%), followed by hypothyroidism (4.6%) and hyperthyroidism (2.3%). The prevalence of thyroid disorders was significantly higher in females (21.1%) than in males (13.1%) (P < 0.05). The prevalence of thyroid disorders was also significantly higher in patients with diabetes mellitus (20.0%) than in patients without diabetes mellitus (14.5%) (P < 0.05). The prevalence of thyroid disorders was also significantly higher in patients with hypertension (21.0%) than in patients without hypertension (12.5%) (P < 0.05). The prevalence of thyroid disorders was also significantly higher in patients with obesity (22.5%) than in patients without obesity (13.1%) (P < 0.05). The prevalence of thyroid disorders was also significantly higher in patients with smoking (22.0%) than in patients without smoking (13.1%) (P < 0.05).

Endocrine Abstracts (2017) Vol 49
**Background**
Cardiothyreosis (CT) or thyrotoxic heart is associated with higher morbidity and mortality than the other forms of hyperthyroidism. Its risk factors have been investigated in a limited number of studies. The aim of our study was to identify risk factors of CT in patients with hyperthyroidism.

**Methods**
We identified 538 patients with a hospital discharge diagnosis of hyperthyroidism from January 2000 to December 2015. Thirty five patients were diagnosed with CT. Their demographic, clinical and biological characteristics were retrospectively studied and compared with those of 72 controls randomly selected, using univariate and multivariate analysis.

**Results**
The prevalence of CT in patients hospitalised for hyperthyroidism was 6.5%. The cardiac complications were atrial fibrillation (AF) in 33 cases (6.1%) and cardiac heart failure (CHF) in 11 cases (2%). The risk factors of CT were age greater than 50 years (OR=13.1 (95% CI, 4.9–34.4)), low socioeconomic status (OR=2.8 (95% CI, 1.2–6.7)), low educational level (OR=3.1 (95% CI, 1.2–8.3)), history of hypertension (OR=3.5 (95% CI, 1.1–11.2)) and a multinodular toxic goiter as the etiology of hyperthyroidism (OR=4.6 (95% CI, 1.6–13.9)). After multivariate analysis, age greater than 50 years was the only independent risk factor of CT (adjusted OR=11.6 (95% CI, 2.7–49.5)). Severe biological hyperthyroidism (FT4> 3 times normal) was associated with a lower risk of CT (adjusted OR=0.2 (95% CI, 0.1–0.9)).

**Conclusions**
The prevalence of CT in patients with hyperthyroidism was 6.5%. The two types of cardiac disease observed were CHF and AF with a clear predominance of the latter. Advanced age was the only independent risk factor of CT.

Takotsubo cardiomyopathy associated with thyrotoxicosis
Helena Vitorino, Joana Costa, Filipa Moleiro, Cláudia Jesus, Ana Afonso, Nadine Monteiro, Sofia Santos, Eduarda Comenda & Helena Cantante
Hospital Lusíadas Lisboa, Lisboa, Portugal.

**Background**
Takotsubo cardiomyopathy is a rare, acute, nonischemic cardiomyopathy causing transient systolic dysfunction of the apical and/or mid segments of left ventricle and is commonly associated with emotional and physical stress. Thyrotoxicosis is a rare cause of this condition, resulting from direct and indirect action of thyroid hormones on the cardiovascular system.

**Case presentation**
A 43-year-old woman presented at emergency room with chest pain, shortness of breath, palpitations, nausea, anxiety, slurred speech and myalgia. Two months earlier she had been admitted in another hospital with chest pain and a diagnosed Takotsubo cardiomyopathy, based on normal cardiac catheterization and compatible echocardiographic changes. At admission, diagnosis of recurrent Takotsubo cardiomyopathy in the context of thyrotoxicosis was assumed (TSH < 0.05 µIU/l, FT4 65 µg/dl). Further evaluation confirmed Graves’ disease. Recomended treatment was started and follow-up at 5 weeks revealed improvement of cardiac function and near normalization of thyroid hormone levels.

**Conclusions**
Takotsubo cardiomyopathy could be the presenting manifestation of thyroid storm. Awareness of this possible association is important in establishing the diagnosis and instituting proper management.

Therapeutic and evolutionary characteristics of subclinical hypothyroidism
Meriez Yazidi1,2, Imed Mezghani1, Faïma Chaker1,2, Ois Rejeh1,2, Melika Chihoua1,2 & Hedia Slimane1,2
1Faculté de médecine de Tunis, Université de Tunis El Manar, Tunis, Tunisia; 2Hôpital La Rabta, Tunis, Tunisia.

Subclinical hypothyroidism (SCH) is a common disorder and indications of treatment are still being debated. The aim of our study was to describe the therapeutic and evolutionary characteristics of SCH.

**Methods**
We undertook a longitudinal retrospective study in 110 patients with SCH biologically defined by increased serum thyroid-stimulating hormone (TSH) levels (>4 mIU/l) and normal FT4. Pregnancy, age less than 18 years, personal history of partial thyroidectomy or radioactive iodine therapy were exclusion criteria.

**Results**
Sixty-one (55.5%) patients were put under l-thyroxine therapy. The TSH level of treated subjects was significantly higher than that of untreated subjects (8.1 mIU/l vs 5.9 mIU/l, P < 0.001). Thyroid peroxidase antibodies were more frequently positive in treated subjects (93% vs 7%, P < 0.001). The dose of l-thyroxine which allowed the normalization of the TSH level was on average 63.9 µg ± 39.4 µg/day. There was no significant difference between the results of the metabolic parameters (weight, blood pressure, fasting glucose, total cholesterol, triglycerides and HDL cholesterol) before and after normalization of TSH level.

In untreated patients, spontaneous TSH normalization occurred in 27% of cases after an average time of 3.5 ± 3.1 months.

**Conclusions**
l-thyroxine replacement in patients with SCH concerned almost half of our patients. Higher TSH level and positive thyroid peroxidase antibodies were more frequently associated with l-thyroxine requirement. Spontaneous TSH normalization was relatively frequent (one quarter of untreated patients); hence repeating measurement of FT4 and TSH is necessary before starting l-thyroxine therapy.

The manner of performing the thyroid ultrasound examination and the reliability of assessment of the thyroid size in school-aged children
Arkadiusz Zygmunt1, Zbigniew Adamczewski2, Malgorzata Karbowiak-Lewinska2 & Andrzej Lewinski2
1Department of Endocrinology and Metabolic Diseases, Medical University of Lodz, Lodz, Poland; 2Department of Oncological Endocrinology, Lodz, Poland.

Goiitre incidence in school-aged children evaluated by the use of ultrasonography (US), apart from reflecting urine iodine concentration and percentage of households consuming iodized salt, is an essential indicator for assessing iodine intake in a given area. The position in which the US examination is being performed can also be an important problem in terms of its result interpretation. The aim of the study was to examine what is the difference between the thyroid volume measured in the supine and sitting position and to determine the coefficients of variation between measurements performed by the same observer (intra-observer variation), between two (2) observers (inter-observer variation) and between two different positions (inter-position variation). The survey included 87 children (56 girls and 31 boys, aged 7–13 years). The US tests were carried out by two (2) examiners (AZ and ZA). Thyroid volume measured in a sitting position was significantly lower than in the supine position. The intra-observer variations equalled 9.7% (CI – 8.1–11.13) for ZA and 9.56% (CI – 7.66–11.45) for AZ. The inter-observer variations amounted to 34.53% (CI – 31.9–37.1) and 35.7% (CI – 32.5–38.9) for measurements performed in the supine and the sitting position, respectively. We have concluded that the size of the thyroid gland depends on the position in which it is examined. The manner the US evaluation is being performed is important for the analysis of the results. It is crucial to aim at the smallest value of inter-observer variation, which can be achieved by strictly defining the methods of measurement of the thyroid and comparing one’s measuring techniques with the reference technique. Conclusions: The use of standards in US evaluation performed in the supine position, as well as those without a strict determination of the study method, including body position during examination, can lead to erroneous conclusions.

Which thyroid or architectural characteristics are associated with malignancy in AUS/FLUS cytologies according to subgroups?

Oya Topaloglu1, Aysegul Alinboga2, Fatma Neslihan Cuhaci1, Ceslet Aydin3, Husniye Basel4, Onur Yazicioglu1, Afra Alkan1, Buyhan Ensoy4 & Bekir Cakir1
1Department of Endocrinology and Metabolism, Yildirim Beyazit University Faculty of Medicine, Ankara, Turkey; 2Department of Pathology, Ataturk Education of Research Hospital, Ankara, Turkey; 3Department of Endocrinology and Metabolism, Ataturk Education of Research Hospital, Ankara, Turkey; 4Department of General Surgery, Ataturk Education and Research Hospital, Ankara, Turkey; 5Department of Biostatistics, Yildirim Beyazit University Faculty of Medicine, Ankara, Turkey.

Aim
Atypic/follicular lesion of undetermined significance(AUS/FLUS) is a category of thyroid cytology with features that are neither definitely benign or malignant. We aimed to determine whether specific cytologic or architectural features are associated with malignancy in AUS/FLUS category of Bethesda system according to subgroups.

Methods
The specimens of patients who underwent surgery with preoperative thyroid fine needle aspiration (FNA) biopsies of Bethesda Category III (AUS/FLUS) were reanalyzed. An experienced cytopathologist who blinded to original cytology and final histopathology was reevaluated the specimens and numerated the cytology from 1 to 7 according to Bethesda system as follows: Group 1: cells producing microfollicles, Group 2: containing predominantly Hurthle cells with rare cells and colloid, Group 3: difficulty in evaluation of atypia due to smear artifacts, Group 4: cellular smears containing benign Hurthle cells, Group 5: focal cells with nuclear changes like papillary carcinoma but generally benign appearance, Group 6: cells with atypic features but generally benign appearance, Group 7: rare follicular cells with nuclear enlargement and frequently apparent nuclei.

Results
Specimens of one hundred and ninety five patients (153 females, 42 males) with a mean age of 47.37 ±12.18 years were included to the study. Of these 195 patients, 148 had AUS and 47 had FLUS cytopathy. Nuclear groove formations are found as higher in malignant group in overall study population and in also AUS subgroup (P=0.005 and P=0.023, respectively), but not in FLUS subgroup (P=0.164). Nuclear enlargement, overlapping, elongation, inclusions, and papilloroid features were similar between malignant and benign groups in all patients, and AUS and FLUS subgroups (P>0.05, for all).

Conclusion
Patients in Bethesda Category III particularly in AUS subgroup with cytologic interpretation of nuclear grooves are at higher risk of malignancy and should undergo surgery.

Relationship between thyroid volume and baseline vitamin D levels in new-onset Graves disease

Gulsah Y Yalin1, Fuat Cenik2, Huseyin Celik3 & Abdulbaki Kumbasar2
1Department of Internal Medicine, Division of Endocrinology and Metabolic Diseases, Kanuni Sultan Suleyman Research and Training Hospital, Istanbul, Turkey; 2Kanuni Sultan Suleyman Research and Training Hospital Department of Internal Medicine, Istanbul, Turkey.

Introduction
Serum 25(OH) vitamin D levels are shown to be significantly lower and associated with lower remission rates in Graves disease. In this study we aimed to investigate the impact of baseline vitamin D levels on thyroid volume in patients with new-onset Graves disease.

Materials and methods
This is a monocenter cross sectional study with a total of 61 new-onset Graves disease patients (n=61; F: 40, M:21) who were divided into two groups according to baseline serum vitamin D levels, as Group-1 (D vit <20; n=22) and Group-2 (D vit ≥20; n=19). Plasma fT4, fT3, TRAb, TPOAb and PTH levels were analysed and thyroid volume (ml), isthmus thickness (mm) were measured by the same physician with thyroid ultrasonography at the time of diagnosis for each patient. The results were compared between the two groups. Categorical variables were processed with the chi-square test. Pearson and spearman correlation analysis were performed for normally and non-normally distributed data, respectively.

Results
There was an inverse correlation between baseline serum vitamin D levels and thyroid volume, TRAb, fT3 and PTH levels (P=0.02, r=-0.31; P=0.005, r=-0.36; P=0.04, r=-0.26; P=0.02, r=-0.32; respectively). Thyroid volume was also correlated with serum fT4, fT3, TRAB and TPOAAb (P=0.001, r=0.426; P=0.001, r=0.50; P=0.004, r=0.26; P=0.001, r=0.42; respectively). Low vitamin D and high TgAb levels were independently associated with thyroid volume in logistic regression analysis (P=0.03, OR:18.7, CI 95% 1.34–260.91 and P=0.04, OR: 16.6, CI 95% 1.07–255.64; respectively).

Conclusion
Baseline serum vitamin D levels are inversely related with thyroid volumes, fT3 and TRAB levels in new-onset Graves disease. In addition to several advantages, optimization of vitamin D levels would also be beneficial in the surveillance of these patients. However larger scale studies are required in order to make further suggestions.

A novel mutation in thyroid hormone receptor-beta gene causing resistance to thyroid hormone in a tunisian female

Ous Rejeb, Melika Chihaoui, Meriem Yazidi, Ibtsissem Oueslati, Fatma Chaker & Hedia Slimane
University of Tunis El Manar, Faculty of Medicine of Tunis, La Rabta Hospital, Department of Endocrinology, Tunis, Tunisia.

Introduction
The syndrome of resistance to thyroid hormone is a rare inherited disorder characterized by elevated circulating thyroid hormones, failure to suppress pituitary thyroid stimulating hormone (TSH) and variable tissue target hyporesponsiveness to thyroid hormone action. We reported the case of a RTH syndrome with a novel mutation.

Case report
A 15-year-old girl was investigated for visual hallucinations and behavior disorders. Her medical history was unremarkable except for a learning disability and a hyperactivity disorder in childhood. There was no family history of thyroid diseases and she was not taking any regular medication. She was found to have abnormal thyroid function tests with increased plasma free T3, free T4 of 2.51 ng/dl (reference range: 0.71–1.85 ng/dl) with non-suppressed TSH of 7.7 µU/ml (reference range: 0.12–3.4 µU/ml). On examination, weight was 48 kg, height was 141 cm, blood pressure was normal and pulse rate was 92 beats/min. She had clinical symptoms of thyroid hormone excess: moist skin, insomnia and agitation. She had no goiter or dysthyroid eye disease. Repeated thyroid function tests confirmed previous findings. Thyroid antibodies (anti-peroxidase and anti-TSH receptor) were negative. The level of TSH α-subunit was normal 0.54 µU/ml (range: 0.05–0.9) and the ratio TSH α-subunit/TSH was less than 1. TSH-secreting tumor was ruled out by normal pituitary magnetic resonance imaging (MRI). Genetic analysis yielded a novel mutation in the THRβ gene, c.1369 A>G in exon 10, due to a base pair substitution of glutamic acid by lysine in position 457.

Discussion
We reported a novel mutation in the THRβ gene that has not been previously described and discussed the clinical presentation of the thyroid hormone resistance syndrome according to the different mutations.

Measurement of anti-thyroglobulin antibodies, a matter of equipment?

Ricardo Capitão1, Susana Prazeres2, Ana Font3, Conceição Godinho4, Isaura Rodrigues5, Frederico Cerveira6, Graça Belo1, João Viana7 & Deolinda Madureira8
1Hospital Egas Moniz, Centro Hospitalar Lisboa Ocidental, Lisboa, Portugal; 2Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal; 3Centro Hospitalar Lisboa Central, Lisboa, Portugal; 4Centro Hospitalar do Baixo Vouga, Aveiro, Portugal; 5Sociedade Portuguesa de Endocrinologia Diabetes e Metabolismo, Lisboa, Portugal.

Introduction
The presence of anti-thyroglobulin antibodies (ATG) can induce falsely lower thyroglobulin (Tg) values. The methods characteristics used for ATG measurement vary according to the equipment/agent used. ATG at our centre is measured by Unicap.

Objectives
To assess if patients with negative ATG by Unicap have different results with other equipment.

Methods
A cross-sectional retrospective study was conducted in February-March of 2016, in which blood samples from patients followed at our Centre, with negative ATG, were selected and separated into three groups: 1) differentiated thyroid carcinoma (DTC), total thyroidectomy, Tg < 0.2 μg/ml; 2) without DTC and positive TPO-Ab; 3) without DTC and negative TPO. ATGs were measured by Immulite®, Cobas® and Advia®. ATG’s classification was based on the cut-off of each manufacturer. Q-Chrocan test was used to calculate the p-values (P<0.05 were considered statistically significant).

Results
A total of 141 samples were analysed. The results are described in the table below: high significant differences were found between the various methods in all groups. The Architect and the Immulite had the highest and lowest rate of ATG positives, respectively, compared to Unicap.

Discussion
ATG results depend on the equipment used. This can influence the follow-up strategy of patients with DTC. These results also raise the question of which method is more reliable for ATG detection and how a result of ‘ATG positive’ actually influences the Tg measurement.

References
1) without DTC and negative TPO. DO: 10.1530/endoabs.49.EP1329
Optimization of iodine intake aims to prevent the irreversible damage that iodine deficiency (ID) can cause in the central nervous system during its development, as well as thyroid disorders that can be induced by both ID and excessive micronutrient intake. The Spanish legal regulation stipulates that iodized salt (IS) must contain 60 mg of iodine per kg of salt, allowing a tolerance of ±15%. The aims of this study is to address the iodine content of different commercially available IS in Spain.

Methods
162 different IS lots from 51 different product presentations were collected from Spanish food stores in Andalusia, Aragon, Asturias, Balearic Islands, Catalonia, Madrid and Basque Country between 2014 and 2016. Iodine concentration in these samples was assessed by HDL-chromatography (HPLC).

Results
The mean (s.d.) and median (P25–P75) iodine concentration for these 162 samples was 61.2 (19.7) and 59 (50–70) µg I/g salt, respectively. Iodine concentration dispersion was mainly attributable to iodate-fortified IS (n=67). The analysis of these fortified IS revealed that 67.2% of them had iodine levels out of the legal threshold (51–69 µg I/g salt), whereas only 43.2% of the iodate-fortified IS (n=95) were outside this limit (P<0.05).

Conclusions
IS, having an average 60 µg I/g salt, is an important alimentary source of iodine in Spain. The use of iodate instead of iodide for the fortification of the salt allows a greater proportion of IS with iodine concentration within the legal limits. Public Health and Consumer Affairs authorities should closely monitor IS production processes and eventually check IS sale points in order to homogenize the iodine content of commercially available IS packages and thereby optimize their intake by the population.

Low DHEAS levels predict rheumatism in primary hypothyroidism: preliminary data from tertiary hospital
Ravindra Shukla, Praveen Sharma, Vikram Singh & Gopal Vohra
AIIMS, Jodhpur, Jodhpur, India.

Introduction
DHEAS is weak androgen with specific role in human physiology illdefined. Various studies have implicated role of DHEAS in autoimmune arthritis including SLE and RA. Recently EULAR consensus statement has approved CSA (clinically significant arthralgia) for incipient RA.

Methods and material
34 follow up patients of primary hypothyroidism rated their symptom score on CSA (clinically suspect arthralgia) as given by EULAR.1) Their DHEAS levels were divided into quartiles while CSA was graded from 100 sensitivity (when one component is positive) to 100 specificity (when all seven component are positive), Kendal tau test of correlation was run using SPSS 21. ROC curve for DHEAS to predict at least one symptom of CSA was run. SPSS version 20 was used for analysis.

Results
Anti TPO Ab were available for 19 subjects, out of which 16 were Anti TPO Ab+. 25(OH) vitamin D levels were available for only seven patients hence excluded from analysis. Kendal’s tau correlation test yielded strong negative correlation between DHEAS and CSA score,(P<0.01; r = −0.512).

Discussion
This the first study evaluating role of DHEAS in rheumatism of primary hypothyroidism. Musculoskeletal abnormalities are common in primary autoimmune thyroid disease (AITD); 2) AITD is also associated with rheumatoid arthritis (RA); 3) There has been recent acknowledgement of role of local androgen in molecular pathogenesis of autoimmune arthritis; 4) We found inverse correlation between serum DHEAS and rheumatism. The serum DHEAS levels seemed to predict grade of rheumatism in these patients. The finding and strength of association is significant and opens further avenues for research regarding role of DHEAS in musculoskeletal manifestations of AITD. DHEAS supplementation has been evaluated in SLE (4) but not in hypothyroidism. Although association between Rheumatoid arthritis (RA) and DHEAS is not well defined, improvement in RA is associated with increase in DHEAS levels (5) Does DHEAS supplementation early in RA or pre –RA alters its natural history, in background of hypothyroidism? Well designed studies are needed.

Conclusion
Rheumatism as evaluated by CSA criteria bears strong inverse correlation with DHEAS. Further trials examining role of DHEAS in such group of patients can be explored.

A thyroid storm in a context of diabetic ketoacidosis: case report
Ghizlane El Mghari, Loubna Oukit & Nawal El Ansari
Endocrinology Department, CHU Mohammed VI, Marrakesh, Morocco.

Introduction
The association of a thyroid storm and diabetes ketoacidosis is relatively rare. We report two cases.

Observations
The first one is a 20 years old woman, with no history of diabetes, who came with ketoacidosis, a history of non medicated thyrototoxicosis, and she was complaining about fever, a thyrotoxicosis syndrome, a vascular goiter, and exophthalmos. Her general condition had improved significantly after the treatment in emergency and under maintenance therapy. The second one is a 54 years old female, with a case of diabetes mellitus, who presented a ketoacidosis. But despite the control of this situation, the patient’s consciousness level became disturbed and she presented hyperthermia. The thyroid function tests revealed hyperthyroidism. Thus, thyroid storm was evocated and managed. The patient finally passed away despite the prompt medical care.

Discussion
In these two cases, a thyroid storm, associated with Graves’ disease covered by diabetic ketoacidosis was the final diagnostic. Thereby, for patients having diabetic ketoacidosis one should seek an eventual thyroid storm, and vice versa: in fact, there are some symptoms in common. But there are scores to help systematize the diagnosis. The management is controlled, acutely based on antithyroid drugs in high doses, beta-blockers and corticosteroids. We should not disregard the search for and treatment of precipitating factors: ketoacidosis in our cases. And identify the thyroid underlying disease: most commonly Graves’ disease.

Hyalinizing trabecular adenoma of the thyroid
Ozen Oz Gul1, Soner Candyer1, Pinar Susman1 & Canan Erozy1
1Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey; 2Kars State Hospital, Department of Endocrinology and Metabolism, Kars, Turkey.

Introduction
Hyalinizing trabecular adenomas (HTA) of the thyroid gland is a rare neoplasm of follicular cell origin. HTA can be present as a thyroid nodule or incidental finding in a thyroids specimens. HTA is generally accepted to be a benign tumor,
endocrine disorder, due to its potentially dangerous consequences, especially if it is caused by amiodarone. Hyperthyroidism is difficult to cure if caused by amiodarone but in this case, it may occur during amiodarone therapy and in some patients, it can be a persistent and problematic situation caused by amiodarone cure. In recent cases, thyroid function was assessed in patients with a history of amiodarone therapy. Thyroid function tests were performed, including thyroid-stimulating hormone (TSH), free thyroxine (fT4), and free triiodothyronine (fT3). Thyroid function tests were performed, including thyroid-stimulating hormone (TSH), free thyroxine (fT4), and free triiodothyronine (fT3). In this study, we report a case of amiodarone-induced hyperthyroidism and recurrent ventricular tachycardia. We describe the case of a 52-year-old woman who was admitted to our hospital for the first time with symptoms of hyperthyroidism. She was diagnosed with amiodarone-induced hyperthyroidism and recurrent ventricular tachycardia. Reversible thyrotoxic pulmonary hypertension with heart failure: 2 cases
Aftab Khattak1, Eleanor Wong1, George Mak1 & James A O’Hare1,2
1University Hospital Limerick, Limerick, Ireland; 2University of Limerick, Limerick, Ireland.

Introduction
Heart failure is a complication of thyrotoxicosis. We present 2 unusual cases presenting with pulmonary hypertension with isolated right heart failure that reversed after treatment.

Case description
Case 1: A 55-year-old man presented with weight loss, dyspnoea and leg swelling. HR: atrial fibrillation 51/min. He had a raised JVP, tricuspid regurgitation and severe pitting oedema. Pro-BNP: 4995 pg/ml, TSH: 0.06 mU/l, FT4: 34.1 pmol/l, FT3: 10.5 pmol/l. TSH receptor antibodies (TRAb) were positive. CTPA: no pulmonary embolism. Echo: PAP 45 mmHg, LVEF preserved. Carbinizemole, diuretics, ACE inhibitors and Apxiban were commenced. Right heart catheterization showed non-obstructive coronary artery disease and pulmonary hypertension. Repeat ECHO 7 months later revealed normal right heart pressure and size when euthyroid. Tricuspuid regurgitation and Pulmonary Hypertension were resolved.

Case 2: A 34-year-old male presented with oedema, elevated JVP, tricuspuid regurgitation and atrial fibrillation. Pro-BNP: 2064 pg/ml, TSH: 0.05 mU/l. Free T4: 72.6 pmo l/l, TRAb positive. CTPA negative for PE. ECHO: PAP 60 mmHg. Right cardiac catheterisation when euthyroid demonstrated a RVSP of 32 mm Hg, pulmonary artery systolic pressure of 27 mm Hg and a wedge pressure of 14 mmHg indicating a resolution of his RHF.

Learning point
Selective right heart failure may occur in thyrotoxicosis perhaps due to altered metabolism of pulmonary vasodilators resulting in raised pulmonary vascular resistance.

Peripheral neuropathy in hypothyroidism - a clinical case
José Marçalo, Alexandra Araújo, Carolina Faria, Ana Wessling, Maria Raquel Carvalho, Ema Nobre & Maria João Bugalho
Hospital de Santa Maria, Lisbon, Portugal.

Introduction
Hypothyroidism can affect the nervous system, commonly causing mono and polyneuropathies which show a variable frequency and pattern. Its mechanisms are not fully understood. Symptoms usually correlate better with the duration of the dysfunction rather than with its severity and typically improve significantly after medical therapy.

Case report
A 58-year-old woman was admitted at our hospital with a one-year history of progressive weakness of both lower extremities, more evident on her left limb. The patient reported a 20-year history of hypothyroidism medicated with levothyroxine 25 mcg id and type 2 diabetes medicated with metformin 1000mg bid, without proper follow-up. She denied other relevant long-term medication or addictions. Fifteen days prior to admission, she was paraparetic and had lost her ability to walk. No other relevant personal or familial medical history was found. Neurological examination showed painless sensorimotor polyneuropathy and lower muscular strength on both legs. Laboratory results revealed hypothyroidism: TSH 37.1 mU/l and FT4 0.5 ng/dl. Serologic studies were negative and TSH receptor antibodies (TRAb) were positive. CTPA: no pulmonary embolism. Echo: PAP 45 mmHg, LVEF preserved. Carbinizemole, diuretics, ACE inhibitors and Apxiban were commenced. Right heart catheterization when euthyroid demonstrated a RVSP of 32 mm Hg, pulmonary artery systolic pressure of 27 mm Hg and a wedge pressure of 14 mmHg indicating a resolution of his RHF.

Conclusions
In general, sensorimotor peripheral neuropathy is common in diabetes and occasional in hypothyroidism. In the described case, it is difficult to ascertain the relative contribution of each nosological entity. Nevertheless, the clinical presentation, the EMG and the prompt response to levothyroxine, favor hypothyroidism as the main cause.

Is Levothyroxine requirement the same for tablet and soft gel formulation in postsurgical hypothyroidism?
Vincenzo Di Dona1, Rosa Maria Paragiola1, Chiara De Waure2, Annapina De Rosa1, Giampaolo Pap1, Alfredo Pontecorvi1 & Salvatore MariaCorsello1
1Endocrinology, Università Cattolica del Sacro Cuore, Rome, Italy; 2Institute of Public Health, Università Cattolica del Sacro Cuore, Rome, Italy.

Background
In a previous publication we identified the major predictive factors of levothyroxine (LT4) requirement and proposed an efficient nomogram to calculate LT4 substitutive starting dose after total thyroidectomy for benign disease. The aim of this study was to assess whether the LT4 requirement differs between the tablet and the soft gel capsules formulations.

Methods
One hundred and three consecutive patients submitted to total thyroidectomy for benign disease and were receiving substitutive therapy with LT4 were enrolled. All patients received the LT4 tablet formulation. The specific substitutive starting dose was calculated using the previously described nomogram and was aimed at achieving normal TSH levels (0.4–2.5 mU/L). Exclusion criteria were: malignancy at histological examination, symptoms or signs of malabsorption, assumption of drugs or habits interfering with LT4 absorption, impaired renal function, pregnancy, poor compliance with drug administration. TSH, FT4 and FT3 were assessed three months after the switch from tablet to soft gel capsule formulation at the same dose of LT4. Mean and standard deviation (SD) were used for quantitative variables. The paired t-test was applied in order to compare the thyroid function tests with different formulations of LT4.

Results
Serum TSH was significantly lower during treatment with soft gel capsules [1.3 mU/l (SD 0.9) and 1.8 mU/l (SD 1.2) respectively, P = 0.02]. There were no statistically significant differences for FT4 and FT3.

Conclusions
Levothyroxine substitutive dose is not significantly different between soft gel capsules and tablets in patients without malabsorption but TSH is significantly lower with the first one. This datum must be considered in clinical practice, particularly for patients with TSH at limits of the therapeutic range or if a strict therapeutic goal is needed.

Immune reaction to food antigens in Graves’ disease (GD) patients: role of gliadin and other food antigens
Danila Covelli1, Giuseppe Colucci1, Mario Salvi1, Ulrike Kaiser2, Anja Eckstein2, Maria Cristina Burlacu2, Chantal Daumerie2, Gez Richelle1, Petros Perros1, Mohd Shazli Draman1, Marian Ludgate2, Giulia Masetti2 & Filippo Biscarini3
1Graves’ Orbitopathy Centre, Endocrinology, Fondazione IRCCS Cà Granda, and University of Milan, Milan, Italy; 2Center for Ophthalmology University Clinic, Essen, Germany; 3Medecin specialiste hospitalier Service d’Endocrinologie, Diabetologie et Nutrition Cliniques universitaires St-Luc (ULC), Bruxelles, Belgium; 4Diabetes & Endocrine Royal Victoria Infirmary, Newcastle Upon Tyne, UK; 5Division of Infection and Immunity School of Medicine, Cardiff University, Cardiff, UK; 6PTP Science Park, Lod, Italy.

As known, an imbalance of the gut microbiota is associated with a higher risk for autoimmune diseases. Moreover the increased rates of autoimmunity reported in urban residential areas worldwide suggest a possible influence of diet. We report
on the antibody response to food antigens in GD patients. Since 10% of celiac patients develop an autoimmune thyroidopathy we focused on gliadin (DGP), transglutaminases (tTG) and 40 other food antigens (FA). Commercially available ELISA assays were performed according to the manufacturer’s instructions. 105 and 108 sera from 5 European endocrine centres have been tested for IgG and IgA to tTG and DGP. Results have been compared to epidemiological data. 71 sera have also been tested for IgG to FA and compared to 25 healthy controls. 6 out of 105 sera (5.7%) showed positive tTG; 16 and 7 out of 108 (15 and 6.5%) positive DGP-IgA and IgG, respectively; a higher prevalence compared to the worldwide prevalence of celiac disease (1%) (chi-squared test; p-value < 0.001). Prevalence of smokers and ocular involvement was not higher in patients with positive sera compared to negative. 23 out of 71 (32.3%) GD sera showed sensitivity against a food antigen, compared to 25% (6 out of 24) positive results among healthy controls (chi-squared test; P-value = 0.4). Interestingly, some antigens (cow’s milk, egg white, wheat, yeast) are more frequently positive than others. The distribution of antibodies against TSH receptor (TRAb) values was not different in positive or negative sera. In conclusion, the prevalence of positive tTG antibodies is higher in GD patients than worldwide. Even though autoantibodies to DGP and tTG were equally available ELISA assays were performed according to the manufacturer’s instructions. However, the increased sensitivity. More studies are needed to confirm these data.

The prevalence of thyreoid diseases eg hyperthyreosis and hypothyreosis in patients with thyroid disease varies in different parts of the world. Hyperthyreosis and hypothyreosis had a significant impact on patients’s QoL mostly hyperthyreosis. There are a significant differences in duration of disease and symptoms, disability of work and professional visits – hyperthyreosis had greater impact. Information about the disease, evaluation of medical and nursing care and willingness to pay had no statistical differences.

Methods

The primary method used for the analysis of QoL was the original combined questionnaire. Statistical methods from Excel 2010 were used in results evaluation.

Results

There were 214 patients in the examined group: 34 patients with hyperthyreosis (10 men, 24 women) – group A, and 180 patients with hypothyreosis (25 men, 155 women) – group B. QoL was evaluated on numeric scales from 0 – the worst to 10 – the best. Present level of QoL was 6.4 vs 7.25, when in the time of diagnosis it was 4.6 vs 6.0, in the time without disease – 7.6 vs 8.3 and in the time excellent health – 8.0 vs 9.2. The average duration of disease was 6.5 vs 11.30 years and the duration of symptoms before diagnosis was 0.74 vs 0.99 years. Patients were very satisfied with the level of information about their disease: 4.6 vs 4.3, with medical care – 4.8 vs 4.7 and with nursing care 4.8 vs 4.7 (1- the worst, 5- the best). Disability of work was 0.8 vs 4.9 days in employed patients (19 in group a and 79 in group B) per year. Patients visited endocrinologic outpatient department 5.1 vs 2.2 times per year. Willingness to pay was 55 vs 48 € per month.

Conclusions

Hyperthyreosis and hypothyreosis had a significant impact on patients’s QoL mostly hyperthyreosis. There are a significant differences in duration of disease and symptoms, disability of work and professional visits – hyperthyreosis had greater impact. Information about the disease, evaluation of medical and nursing care and willingness to pay had no statistical differences.

The association of gene polymorphisms with the clinical outcome of Graves’ disease

Dalia Dauksiene¹, Narseta Mickuviene² & Albertas Daukas³

¹Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; ²Behavioral Medicine Institute, Medical Academy, Lithuanian University of Health Sciences, Palanga, Lithuania; ³Institute for Digestive Research, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania.

The aim

Of this study was to investigate the association between two common CTLA-4 gene SNPs (49A/G in exon 1 and CT60 A/G in 3’UTR) and Graves’ disease outcome in Lithuanian population.

Methods

This case-control study was performed in the Hospital of Lithuanian University of Health Sciences. Graves’ disease patients (n=105) were divided into remission and failed treatment groups according to the final outcome of the disease. The remission group (n=49) – patients with euthyroid status minimum 1 year after antithyroid drugs (ATD) withdrawal. The failed treatment group (n=56) – patients submitted radioiodine therapy or surgery due to poor response to ATD therapy. Genomic DNA was extracted from the peripheral blood leukocytes with kit Qiagen GmbH, Hilden, Germany.

Results

The patients in failed treatment group had significantly higher frequency of GG genotype and a lower frequency of AA genotype than patients in remission group. Patients with GG homozygous genotype had more than four-fold (OR 4.94, 95% CI 1.38–17.65) and more than sixteen-fold (OR 16.91, 95% CI 1.83–156.62) increase in risk of ATD treatment failure compared to patients with homozygous genotype AA for 49A/G SNP and for CT60 SNP, respectively. When association of 49A/G and CT60 genotypes on the outcome of Graves’ disease was analyzed separately it provided significant prognostic information but after multivariate logistic regression analysis these genetic markers were not independent of other factors. Only TRAb levels before treatment was independently associated with elevated odds of failure (OR 1.05, 95% CI 1.02–1.08).

Conclusion

The data shows significant association of two polymorphisms (49A/G at position 49 and CT60 in 3’UTR) in the CTLA-4 gene with Graves’ disease in Lithuania and suggest that these genetic markers may provide important information in predicting high risk patients for failure to ATD therapy.

The impact of levothyroxine sodium treatment on dynamic thiol/disulphide homeostasis in overt hypothyroidism

Cemile Bicer¹, Ihsan Ates², Murat Aydin³, Mustafa Altay³, Canan Topcuoglu⁴, Salim Neselioglu⁵, Ozcak Maciejewski¹, Michal Kowalczyk⁶, Adam Maciejewski¹, Teresa Gasinska⁷ & Katarzyna Lacka⁸

¹Yildirim Beyazit University Medical Faculty, Ankara, Turkey; ²Ankara Numune Training and Research Hospital, Department of Internal Medicine, Ankara, Turkey; ³Namik Kemal University Medical Faculty, Department of Biochemistry, Ankara, Turkey; ⁴Ankara Numune Training and Research Hospital, Department of Biochemistry, Ankara, Turkey.

Objective

Thiols are organic compounds that contain sulphhydryl group (-SH) and have important role in preventing oxidative stress especially in cells. The aim of our study is to investigate the relationship between hypothyroidism due to HT and the thiol/disulphide homeostasis, the effect of treatment on this homeostasis and to demonstrate the utility of thiol/disulphide homestasis as a marker for assessing the damage to functional group of proteins and the oxidative balance in this group of patients.

Design, patients and measurements

Thirty-five patients with a new diagnosis of hypothyroidism due to HT who were not yet under treatment is enrolled in the study. Serum samples were taken prior to the treatment and 6 months after initiation of levothyroxine sodium treatment to compare clinical and laboratory parameters of patients. Thiols/disulphide homeostasis is evaluated by Erel & Neselioglu method.

Results

After 6 months of treatment the native thiol and total thiol levels were significantly increased (P=0.001 and P=0.001). The disulphide level, the disulphide/native thiol and the disulphide/native thiol ratios showed a significant decline (P=0.001, P=0.001, P=0.001 respectively).

Conclusion

Decrease in the disulphide/thiol ratio after levothyroxine sodium treatment in hypothyroidism may suggests that treatment plays a role in reducing both oxidative stress and free radical mediated damage to the functional groups of proteins. Thus, it may be possible to avoid the complications caused by oxidative stress. As a result disulphide/thiol ratio may contribute to the management of treatment in hypothyroid patients.

The role of vitamin D receptor gene FokI (rs2228570) polymorphism in the pathogenesis of thyroid associated orbitopathy

Adam Maciejewski¹, Michal Kowalczyk⁶, Adam Czyzyk⁷, Teresa Gasinska⁷ & Katarzyna Lacka⁸

¹Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; ²Department of Dermatology and Venerology, Poznan University of Medical Sciences, Poznan, Poland; ³Department of Gynecological Endocrinology, Poznan University of Medical Sciences, Poznan, Poland; ⁴Department of Internal Diseases and Oncologic Chemotherapy, Silesian Medical University, Katowice, Poland.

Introduction

Vitamin D, known mainly as a calcium-phosphorus homeostasis regulator, turned out to play also a significant role in the immune system modulation. Vitamin D deficiency has been reported in some autoimmune disorders. It is also suspected that polymorphisms of vitamin D-related genes comprise a risk factor for different autoimmune diseases. Therefore the aim of our study was to assess vitamin D receptor (VDR) gene FokI polymorphism in thyroid associated orbitopathy (TAO) in comparison to the controls among the Caucasian-Polish population.

Patients

The study was performed in the Hospital of Lithuanian University of Health Sciences. Graves’ disease patients (mean age 53.8) and 142 healthy age and sex matched controls. TAO was diagnosed by clinical examination, TRab assessment and orbit MRI or CT. TAO group was further divided into: A- orbitopathy from the onset of Grave’s disease, B- later development of TAO. In the control group both TAO and autoimmune thyroid diseases were excluded by clinical examination and thyroid ultrasound.

Methods

FokI polymorphism of the VDR was studied by PCR-RFLP analysis, randomly selected patients were additionally analyzed by direct sequencing. The statistical significance of differences between the allele and genotype frequencies in TAO vs controls, as well as in subgroups of TAO were evaluated by χ² or Fisher’s exact test. A P-value of <0.05 was considered significant.

Results

Observed allele frequencies were in Hardy-Weinberg equilibrium. C allele and CC genotype were more frequent in TAO compared to the controls (59.50 vs 55.28% and 34.00 vs 31.69%, respectively), although differences were not statistically significant (P=0.36 and P=0.50). CC+CT genotypes (dominant inheritance model) were more frequent in the subgroup A compared to B (89.70% vs 75.00%), P=0.07.

Conclusions

There is no statistically significant difference in allele or genotypes distribution of VDR FokI polymorphisms between TAO and the control group among the Caucasian-Polish population.

Effects of hypothyroidism on nutritional status: which impact?
El Mghari Ghizlane, Naima Bouznad & Nawal El Ansari
Department of Endocrinology, Diabetology, Metabolic Diseases and Nutrition, PCIM Laboratory, FMMP, Mohamed VI CHU, Marrakech, Morocco.

Introduction
Hypothyroidism is a common disease in Morocco because of the iodine deficiency frequency. The metabolic and nutritional effects of hypothyroidism are known in the literature. The hypothyroidism is classically described as causes of secondary obesity. The aim of the study is to evaluate the nutritional status and anthropometric parameters in patients having hypothyroidism.

Patients and methods
Patients were recruited from the out-patients clinics. All the patients with the diagnosis of hypothyroidism and not receiving yet the L-thyroxin were included. All the patients were examined by the dietician and the clinical and laboratory evaluation were carried on in all patients.

Results:
A total of .... were included. The mean age was 41 years. The sex ratio is 6/1. Weight gain was found in 67% of patients with a mean gain of 8kg. The mean weight was 80 kg for men and 68 kg for women for an average ideal weight of 64 and 54 kg respectively. The BMI was normal in 43, 30% of cases, 26.60% were overweight and 23.20% were obese. Waist circumference was pathological in 92% of women and 80% of men. The body fat percentage was high in 60% of female patients and 80% of male patients. The average daily caloric intake for women was 2138.77 Cal while the caloric intake was 1856.6 Cal in men. High caloric intake in macronutrients was found in all patients.

Conclusion
Hypothyroidism is responsible for an important increase in body fat leading to overweight and obesity. The hormonal replacement is an efficient way to overcome these nutritional and metabolic changes. The nutritional evaluation is necessary to complete with exhaustive etiology investigation in front of this clinical presentation.

An unusual case of subacute thyroiditis after alemtuzumab treatment
Philippe Baltzinger, Alina Dumitrescu, Clothilde Wagner, Nicolas Collongues, Jerôme De Seze, Thibault Bahougne & Nathalie Jeandidier
University Hospital of Strasbourg, Strasbourg, France.

Introduction
Alemtuzumab, a humanized monoclonal antibody against CD52, is effective in the treatment of early relapsing-remitting multiple sclerosis (MS). Thyroid side-effects such as Graves’ disease have been already described. We describe one case of unusual subacute thyroiditis after alemtuzumab treatment.

Clinical case
A 38 year-old-female was treated by alemtuzumab for 2 years. She was referred for hyperthyroidism with 10 kg weight loss, diarrhea and palpitations. Clinical examination found cervical pain and fever. Thyroid function tests revealed low fT3: 18.2 pmol/l (N: 3.84–7.07). Thiamazol (20 mg bid) and propranolol (20 mg 3 times a day) were started in front of a urinary infection suspicion. Finally, bacteriological analyses (blood and urine) were negative and ceftriaxone was discontinued. After 2 weeks, fT3 and fT4 were in the normal ranges.

Discussion
Although subacute thyroiditis is not known as an auto-immune disease, an increase of its incidence rate is found after alemtuzumab or INF-alpha treatment. Although subacute thyroiditis is not known as an auto-immune disease, an increase of its incidence rate is found after alemtuzumab or INF-alpha treatment. Alemtuzumab, a humanized monoclonal antibody against CD52, is effective in the treatment of early relapsing-remitting multiple sclerosis (MS). Outcome of radiodine therapy in patients with hyperthyroidism
Catarina Machado1, Patricia Tavares1, Sara Monteiro1, Gustavo Rocha1, Fernando Silva1, José Manuel Oliveira2 & Maria João Oliveira1
1Centro Hospitalar de Vila Nova de Gaia/Espinho, EPE, Vila Nova de Gaia, Portugal; 2HPP-MM-Lenitudes, Porto, Portugal.

Introduction
Radioiodine treatment (RAIT) is an effective definitive treatment for Graves’ Disease (GD) and Toxic Nodular Goiter (TNG). The aim of this study was to analyze demographic and clinical factors affecting the outcome of RAIT in patients with hyperthyroidism.

Methods
Retrospective review of patients treated with RAIT for hyperthyroidism. A fixed dose of 10 mCi was administered to patients with GD and 15 mCi to patients with TNG. Treatment success was defined as euthyroidism or hypothyroidism (subclinical/overt hypothyroidism) 12 months after RAIT.

Results
217 patients were included; 122 with GD and 95 with TNG (52 patients with toxic multinodular goiter and 43 with Toxic Adenoma). RAIT was more effective in TNG than in GD (94.7% vs 71.3%, P<0.05). Gender, previous thyroid function and thyroid volume were significantly associated with an effective outcome in patients with GD (P<0.05). No clinical or demographic factors affected the outcome in patients with TNG, although a higher Tc99 uptake on scintigraphy was associated with persistent hyperthyroidism. Hyperthyroidism was more common in GD (62.3% vs 41.1%, P=0.001). Hypothyroidism was significantly more frequent in smaller nodules (26±8 mm vs 32±11 mm, P<0.05) and in lower thyroid volumes (24.3±14 ml vs 37.7±19 ml, P<0.05).

Conclusion
Thyroid volume seems to have a significant influence on the development of hypothyroidism after the treatment and, in patients with GD, the efficacy of RAIT.

Pattern of amiodarone-induced thyrotoxicosis before and after universal salt iodization
Raluca Trifianescu1, Cristina Popa2, Andrei Goldstein3, Florin Alexiu4, Martina Punic5 & Catalina Poisiana2
1Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2C.I. Parhon’ National Institute of Endocrinology, Bucharest, Romania.

Background
Prevalence and type of amiodarone-induced thyroid dysfunction in a population depend on geographical iodine intake.

Aims
To assess differences in amiodarone-induced thyrotoxicosis pattern before and after iodine supplementation.

Patients and methods
84 patients (41M/43F) with amiodarone-induced thyrotoxicosis, aged 60.1 ± 11.9 years, were retrospectively reviewed. 28 patients were resident in former iodine-deficient areas. TSH, FT4 and total T3 were measured by chemiluminescence; 2 h and 24 h radioiodine (131I) uptake and color flow Doppler were performed.

Results
Type 1 amiodarone-induced thyrotoxicosis (AIT) was diagnosed in 21 cases (25%), type 2 in 26 cases (30.9%) and mixed type in 37 cases (44%). Before universal salt iodization were diagnosed 38 cases (type 1 AIT in 12 cases – 31.6%; type 2 in 14 cases – 36.8% and mixed type in 12 cases – 31.6%); after universal salt iodization were diagnosed 46 cases (type 1 AIT in 9 cases – 19.6%, type 2 in 12 cases – 26% and mixed type in 25 cases – 54.3%); Patients with type 1 AIT were significantly younger (62.5 ± 9.6 years vs 56.1 ± 12.8 years, P = 0.05), with significantly higher radioiodine uptake at 24 h (median 7% vs median 1%, P = 0.022) and had higher thyroid volume (29.2 ± 14.8 ml vs 19.2 ± 8.6 ml, P = 0.015) than patients with type 2 AIT. Patients with type 1 AIT had higher total T3 levels than patients with type 2 AIT (340.9 ± 157.4 vs 246.7 ± 135.9 ng/dl, P = 0.06) and type 3 AIT (216.4 ± 111.8 ng/dl, P = 0.003, respectively). There were no statistically significant differences in body mass index, amiodarone treatment duration, amiodarone cumulative dose, FT4 levels between AIT type 1, 2 and mixed type.

Conclusion
After universal salt iodization, AIT type 2 and mixed type prevailed in our geographical area.

They think it’s all ovar(ii)
Raj Tandan1, Bonnie Grant1, Premila Kollipara2, Edel Casey1 & Khash Nikokam1
1Department of Endocrinology, King George Hospital, London, UK; 2Department of Obstetrics and Gynaecology, King George Hospital, London, UK.

A 37 year old woman was referred to the endocrinology clinic from the gynaecologists. She was awaiting an 8 cm left ovarian cyst removal and found to be hyperthyroid (T3 7.8 pmol/l, FT4 of 19.0 pmol/l, TSH <0.1 mU/l). She described 4 months of palpitations, change in bowel habit and menstrual irregularity. She had no tremor or tachycardia. She had no palpable goitre or eye signs. She had a past medical history of asthma on inhalers. There was no family history of thyroid disease. Repeat bloods confirmed T3 toxicity, negative TPO and TSH receptor antibodies. She was commenced on carbimazole 10 mg od. She had no palpable goitre or eye signs. She underwent abnormally high radioiodine uptake at 24 h (median 7% vs median 1%, P = 0.022) and had higher thyroid volume (29.2 ± 14.8 ml vs 19.2 ± 8.6 ml, P = 0.015) than patients with type 2 AIT. Patients with type 1 AIT had higher total T3 levels than patients with type 2 AIT (340.9 ± 157.4 vs 246.7 ± 135.9 ng/dl, P = 0.06) and type 3 AIT (216.4 ± 111.8 ng/dl, P = 0.003, respectively). There were no statistically significant differences in body mass index, amiodarone treatment duration, amiodarone cumulative dose, FT4 levels between AIT type 1, 2 and mixed type.

Conclusion
After universal salt iodization, AIT type 2 and mixed type prevailed in our geographical area.

Perinatal outcome in Graves-basedow disease during pregnancy
Snezana Mihajlovska & Marija Mihajlovska
1Department of Nuclear Medicine, Clinical Center ‘D-R Trifun Panovski’, Bitola, Macedonia; 2Department of Endocrinology, General Hospital ‘8-MI Septemvri’, Skopje, Macedonia.

The purpose of this study is to assess the treatment outcome of pregnant patients with Graves-Basedow disease. In the period of 20 years 59 pregnancies in hyperthyroid patients were registered with Graves-Basedow disease in the Department of Nuclear Medicine in Clinical Hospital Bitola. Thyrostatic therapy was applied in 29 (56.5%) pregnant patients divided into 2 groups. The first group were patients who used methimazole therapy (MMT) or 50–400 mg propiltiuracil (PTU). Of this group, 19 were born healthy infants (74.3%), 2 (5.12) with low birth weight, 5 (12.8) were premature but with no fetal malformations. The second group were patients who were not regularly controlled and treated. Of them all three babies were born with malformations (two newborns died shortly after birth and one newborn died six months after birth).

Conclusion
Our study suggests that patients treated with Graves-Basedow disease during pregnancy with a low dose of thyrostatic therapy, provides a significant reduction of fetal complications. Our study also indicated no significant difference in the effects of both drugs - PTU and MMT in these doses although preferably PTU because of reduced transplancental passage compared to MMT. In our study observed complications and mortality in newborns of mothers with uncontrolled or inadequate and irregular treated hyperthyroidism.

TSH receptor stimulating immunoglobulins – performance of an automated immunoassay
Patricia Tavares1, Catarina Machado1, José Carlos Pedroso1, Joana Vieira2, Gustavo Rocha1, Sara Monteiro1, Ana Margarida Sousa1, Pedro Rodrigues1, Agostinho Lira2 & Maria João Oliveira1
1Endocrinology Department, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova Nova de Gaia/Porto, Portugal; 2Clinical Pathology Department, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova Nova de Gaia/Porto, Poland.

Introduction
Graves’ disease (GD) hyperthyroidism is caused by autoantibodies against TSH receptor (TRAb). Three varieties of TRAb are now recognized: stimulating (TSI), blocking and neutral antibodies. Current TRAb immunosays detect and quantify serum immunoglobulins that interact with the TSH receptor but without discriminating their function. An automated immunoassay for the detection and quantification of TSI is available.

Objective
Our study objective was to determine the performance of TSI assay in patients with thyroid autoimmune disease, nodular disease, and healthy individuals.

Methods
59 subjects were enrolled in the study: 37 samples of consecutive individuals referred to the endocrinology consultation with thyroid pathology and 22 healthy subjects. The Immulite® 2000 TSI (Siemens) was used to measure TSI.

Results
Of the 37 patients, 30 (81.1%) were female and 7 (18.9%) were male, with a mean age of 58 (± 14) years. 18 patients were diagnosed with autoimmune thyroid diseases (10 with untreated GD and 8 with Hashimoto thyroiditis (HT)) and 19 with nodular thyroid disease (12 with non-toxic goiter and 7 with toxic adenoma). Healthy subjects and those with nodular thyroid disease had a negative TSI assay but one patient with HT had a positive TSI assay (specificity 98%). Of the ten patients with diagnosis of Graves’ disease 10 had positive TSI assay (sensitivity of 100%) with a median value of 3.6 IU/L (maximum of 90.1, minimum of 1.2). There was a positive correlation between the value of TSI assay and the amount of the free fractions of thyroid hormones.

Conclusion
This easy to perform assay method of TSI revealed high sensitivity and specificity in the diagnosis of Graves’ disease.

Genetic variation in NFE2L2 and SEPS1S associated with increased risk of Hashimoto’s thyroiditis
Liliana R Santos1,2, Cecilia Duarte1,2, Ana Pestana1,2, César Esteves2, Celestino Neves2,3, David Carvalho2,3, Manuel Sobrinho Simões1,2 & Paula Soares1,2

1Institute of Molecular Pathology and Immunology of University of Porto (IPATIMUP), Porto, Portugal; 2Internal Medicine Department, Hospital de Santa Maria, Centro Hospitalar Lisboa Norte, Lisboa, Portugal; 3Faculty of Medicine of the University of Porto, Porto, Portugal; 4Department of Endocrinology, Hospital of S. João, Porto, Portugal.

Hashimoto’s thyroiditis (HT) is the most common chronic autoimmune thyroid disease, which is characterized by alteration of the thyroid function. HT is a multifactorial disorder and several candidate genetic loci have been identified as contributing to HT. The transcription factor NF2, encoded by the NFE2L2 gene, is an important regulator of the cellular protection against oxidative stress. The relevance of selenoproteins in follicular thyroid cell physiology and in molecular physiology have pointed to a putative role of the interaction of NF2 with selenoproteins in the pathogenesis of autoimmune thyroid diseases. In order to evaluate the role of a promoter variation in NRF2 and SEPS1 in the risk for developing Hashimoto’s thyroiditis (HT), we performed a case-control study comprising 997 individuals (HT patients and unrelated controls). Genetic variants were discriminated by real-time PCR using TaqMan SNP genotyping assays. Three polymorphisms (– 653A/G: rs35652124; – 651G/A: rs6706649 and – 617C/A: rs6721961 SNPs) in the NRF2 gene promoter were studied and no significant difference were found between HT patients and controls with regard to genotypic or allelic frequencies of the three NRF2 SNPs (p>0.05). The joint effect of genetic polymorphisms in NFE2L2 and SEPS1 was assessed considering the high-risk genotypes of NFE2L2 and SEPS1. Our findings suggest that the risk to develop Hashimoto’s thyroiditis is not associated to a single NFE2L2 polymorphism but increases with the combined effect of the number of risk alleles in NFE2L2 and SEPS1. Individuals carrying two high-risk genotypes present a significant increased risk for HT.

Safety and efficacy of cholestyramine in the adjuvant management of Graves thyrotoxicosis
Tammur Guliam & Sath Nag
James Cook University Hospital, Middlesbrough, UK.

Introduction
Graves’s disease is an autoimmune condition both cell and antibody-mediated, which is associated with thyrotoxicosis and extra thyroid features.

Case report
A 27 years old woman, normopondal, presented from the age of 11 years for short stature. Further investigations found pluritrope pituitary insufficiency (somatotroph, gonadotroph, corticotroph and tireotroph) and substitutive treatment was started. After 20-year history of a slow-growing nontender neck mass. She became euthyroid after a few weeks of starting the treatment and then prednisolone 40 mg once a day in order to improve her thyrotoxicosis. Eventually a 35-year-old female presented with symptomatic hyperthyroidism due to graves disease is an autoimmune condition both cell and antibody-mediated, which is associated with thyrotoxicosis and extra thyroid features.

Thyroid nodules are a common clinical finding, with an estimated prevalence of palpable thyroid nodules to be approximately 5% in women and 1% in men. The clinical importance of thyroid nodules rests with the need to exclude thyroid cancer. The prevalence of malignancy reported for palpable thyroid lesions ranges from 5.0% to 6.5%. Patients with benign thyroid nodules are unlikely to suffer morbidity or mortality due to thyroid cancer. A 53 aged man presented with a 20-year history of a slow-growing nontender neck mass. He denied any compressive symptoms, such as dysphagia, dyspnea or hoarseness. On physical examination of the thyroid, the patient had a right-sided soft, elastic nodule larger than 10 cm of diameter. TSH, T4 were within normal range and thyroid antibodies were negative. CT scan of the neck indicated a solitary dominant nodule of the right thyroid lobe measuring 140×78×84 mm without invasion of adjacent structures. A minor compression and tracheal deviation to the left was also reported. Thyroid ultrasound indicated a large, heterogeneous nodule, solid with some cystic component and well-defined contours, occupying the entire right lobe of the thyroid gland. Left lobe also had a 1.4 cm solid nodule. FNAB of both nodules were benign. The patient remained asymptomatic throughout. Natural growth behaviour of thyroid nodules is controversially discussed. In our clinical case, the slow progression and the absence of compressive signs was suggestive of a benign lesion. However, the large dimensions and the progressive growth of the nodule might also be indicative of malignancy. There are few studies about long-term prognosis of thyroid nodules, including their malignant transformation. Although well established that approximately 90% of non-functioning thyroid nodules are benign, even in slow growth big nodules with benign FNAB, surgery is crucial to the final diagnosis.

Introduction
Many causes of malabsorption of levothyroxine (LT4) in patients with hypothyroidism have been thoroughly described in literature. Pseudomaldabsorption, poor compliance of the patient is most common cause of failure of LT4 and/or liothyronine (LT3) treatment.

Case report
27 years old woman, normopondonal, presented from the age of 11 years for short stature. Further investigations found plurirotic pituitary insufficiency (somatotroph, gonadotroph, corticotroph and tireotroph) and substitutive treatment was started (GH-treated off 17 years, actual height 168 cm, cortisol, esosogestative and thyroid hormones). MRI described a small pituitary. Despite of increasing dose of LT4, ulterior in association with LT3, and vitamin C for better absorption, THS remained high (13 UI/ml, reference 0.4–4 mU/L) with constantly low fT 4.

Endocrine Abstracts (2017) Vol 49
excluded drugs and dietary interactions; To evaluate the hypothesis of pseudomalabsorption, the patent was submitted to rapid LT₄ absorption test. After an overnight fasting, it was administrated 1000 µg LT₄. We measured FT₄ at 30’, 2, 4, 6 h. Immediately FT₄ serum increase, with the maximum serum level after 2 h (basal FT₄ = 0.56 ng/dl, 2 h = 1.72 ng/dl, peak FT₄ > 2.5). The test showed a normal absorption of LT₄, and malabsorption was excluded.

Conclusion
Our case showed an inadequate thyroid hormone supplementation (3.3 µg/kg); the literature suggested that after excluding organic cause or drug interaction, is useful to make a malabsorption test, which confirms the diagnostic pseudomalabsorption; based on his historical attempts to stop the treatment, a psychological counseling may be necessary. Once weekly oral thyroxine treatment, supervised, can be a safe, well-tolerated, and effective therapy for patients with non-compliance.

Oxidative profiles in patients with autoimmune thyroid diseases
Fatma Mnif, Hamza Ellekhi, Mouna Elleuch, Faten Hadjkacem, Houcem Elomma Mrabet, Nabilah Rekik, Dorra Ghorbel, Mouna Mnif & Mohamed Abdal
Hedi-Chaker University Hospital, Sfax, Tunisia.

Introduction
Autoimmune thyroid diseases are known to be associated with oxidative stress.

Objectives
We studied the oxidative profiles in plasma and thyroid tissue of 82 patients having Graves’ disease (GD) or Hashimoto thyroiditis (HT) or Hashitoxicosis (HTX) vs 65 healthy controls in order to evaluate the antioxidant enzymes’ activity and the lipid peroxidation.

Results
The lipid peroxidation was objected with a significant higher level of Malondialdehyde (MDA) in the plasma of our patients vs healthy controls (P < 0.01 for HT, P < 0.001 for GD and HTX). A very low antioxidative activity of Glutathione peroxidase (GPx) was found in our patients vs healthy controls (P < 0.001 for HT and HTX, P < 0.01 for GD). The Selenium which is GPx cofactor and the Catalase were found to be reduced as well. For the proteins oxidation, we found a higher level in Carbonyl-group, MDA and a lower level of thiol-group in our patients vs healthy controls. Similar results were found in the thyroid tissue samples.

Conclusion
This study shows clearly the presence of an oxidative stress in both plasma and thyroid tissue in patients with autoimmune thyroid diseases.

Levothyroxine absorption test in the management of a patient with persistent hypothyroidism
Joana Monteiro, Marta Ferreira, Miguel Pires, Alexandra Vieira, Daniela Guelho, Teresa Pereira, Fernanda Pinhal & Célio Fernandes Centro Hospitalar de Leiria, Leiria, Portugal.

Nonadherence to levothyroxine therapy is one of persistent hypothyroidism. To distinguish nonadherence from malabsorption, a levothyroxine absorption test (LAT) is sometimes required. The authors report a case of a 60-year-old female patient suffering from hypothyroidism resistant to oral levothyroxine (LT₄) substitution after radioiodine therapy for Graves’ disease. Despite the continuous increases of LT₄ over 10 years, to a maximum of 1 mg/day, she remained with high thyrotopin (TSH) and low free thyroxine (FT₄). Extensive investigation excluded disease of the small bowel, liver and pancreas as well as drugs interactions. After careful consideration was decided to conduct a LAT. Serum levels of TSH, FT₄, and free triiodothyronine (FT₃) were drawn at 0, 60, 120, 180 e 240 min after 1mg of LT₄. The results are presented in the graphic below. The patient remained with normal heart rate and normotensive along LAT. The results showed a normal absorption of LT₄, so pseudo-malabsorption was proven. Based on this diagnosis was prescribed 1 mg of LT₄ weekly to improve therapeutic compliance. Nowadays, patient present normal TSH and FT₄ serum levels. In conclusion, pseudo-malabsorption is an important differential diagnosis in persistent hypothyroidism to achieve therapeutic success and LAT is a simple, secure and useful tool in this cases.

Serum irisin level in different thyroid dysfunction states and its relation to markers of muscle dysfunction
Mohamed Reda Halawa, Mona Mohamed Abdelsalam, Bassem Mourad Mostafa & Amira Galal Ahmed Ain Shams University, Cairo, Egypt.

Introduction
Irisin is a myokine secreted by myocytes responsible for transmission of signals from muscles to other body tissues. It improves systemic metabolism by increasing energy expenditure and has a significant influence on the body metabolism and thermogenesis. Thyroid disorders are characterized by a disrupted thermo-metabolic state and muscular damage, and the underlying mechanisms still not clear.

Aim
To evaluate serum Irisin levels in patient with hypothyroid and hyperthyroid disease and its relation to creatinine kinase (CK) a marker of muscle damage.

Method
90 subjects participated in the study. They were divided into three groups: Group 1: 30 hypothyroid patients, Group 2: 30 hyperthyroid patients, Group 3: 30 normal persons. They were submitted to history, medical examination (Weight, Height and BMI) and measurement of fasting serum Irisin, TSH, Free T₃, Free T₄, CK.

Results
Irisin hormone level was lower in hypothyroid patients (16.60 ± 4.07) pg/ml than hyperthyroid patients (26.83 ± 7.95) pg/ml and controls (25.70 ± 5.29) pg/ml (P < 0.01). However, it was higher in hyperthyroid than (P > 0.05). Creatine kinase (CK) level decreased in hyperthyroid patients (33.80 ± 1.49) µl/ml than hypothyroid patients (196.26 ± 4.53) µl/ml and controls (62.86 ± 1.63) µl/ml (P < 0.01). However, creatine kinase increased in hypothyroid patients (196.26 ± 4.53) µl/ml in comparison with control (62.86 ± 1.63) µl (P < 0.01). There is a negative correlation between Irisin, TSH, Weight, BMI and CK (P < 0.01), and a positive correlation with freeT₃ and free T4 (P < 0.01) in hyperthyroid patients.

Conclusion
Lower Irisin hormone level was found in patients with hypothyroidism which might be explained by muscles destruction demonstrated with high CK levels, however the higher level of Irisin in hyperthyroidism might explained by hypermetabolic state.

Popa University of Medicine and Pharmacy, Iasi, Romania; 4 University of Medicine and Pharmacy, Targu Mures, Romania; 5 H. Hateganu University of Medicine and Pharmacy, Cluj Napoca, Romania; 6 Alesandrescu Rusecuc National Institute for Mother and Child Care, Bucharest, Romania; 7 L. Blaga University, Faculty of Medicine, Sibiu, Romania; 8 University of Medicine and Pharmacy, Craiova, Romania; 9 V. Babes University of Medicine and Pharmacy, Timisoara, Romania; 10 Campulung Hospital, Campulung, Romania; 11 Astra Clinic, Sibiu, Romania.

**Introduction**

Even mild to moderate maternal iodine deficiency during pregnancy is associated with impaired child cognition. Iodine deficiency is especially problematic in pregnant women, who have a higher iodine requirement (250 μg/day) than non-pregnant women (150 μg/day).

**Objective**

To assess iodine status (median urinary iodine concentration, UIC) in pregnant women from multiple endemic or non-endemic areas in Romania, 13 years after implementation of the Universal Salt Iodization (25–40 mg iodine/kg salt).

**Subjects and methods**

Median UIC in the morning urine was evaluated by spectro-photometry in 409 pregnant women in the third trimester from seven geographical regions in Romania (age range 16–44 years, median age 29 years, none treated with thyroxine, 80% from endemic regions, 59% from urban regions). Data regarding iodized salt intake, bread intake (usually containing 6–9 g iodine/slice) and iodine supplements were assessed. The study was approved by the local Ethics Committee.

**Results**

Iodized salt was consumed by 87% of women, iodine supplements during pregnancy by 48% of women. Median UIC in the study group was 131 μg/l, reflecting iodine deficiency during pregnancy (normal values ≥150 μg/l). Lower median UIC (μg/l) were recorded in the endemic regions of Transylvania (92), Oltenia (114), Moldova (129) and Muntenia (149) as compared to Bucharest area (206) and other non-endemic regions (206.6), except Timis (140); 55.7% of women had values below 150 μg/l, 13% below 50 μg/l, 1.7% had values over 500 μg/l. Higher median UIC was recorded in women with a daily intake of ≥5 slices of bread, 166 vs 111 μg/l, P < 0.01. Similar UIC were found in women taking prenatal vitamins containing iodine and in those with no supplements. In Transylvania region there is a discrepancy between schoolchildren (normal median UIC) and pregnant women (low median UIC). Urinary iodine/creatinine ratio was not significantly different from urinary iodine levels.

**Conclusions**

Mild iodine deficiency is still prevalent in Romanian pregnant women from historical endemic regions after 13 years of universal salt iodization. Iodine supplementation during pregnancy should be encouraged in these regions.

**The potential of smartphone applications in management and compliance to recommended lifestyle in Hashimoto’s patients**

Vedrana Ho¨gqvist Tabor & Mikael Ho¨gqvist Tabor

Boost by VLM Health UG, Berlin, Germany.

**Background**

Hashimoto’s thyroiditis (HT), a chronic autoimmune disease caused by an interaction between genetic factors and the environmental is treated by thyroid supplementation as the first line of treatment. However, many of the symptoms are unrelated to the failing thyroid function, but seem to be connected to the autoimmune disease, remain. Literature has reported on many of the environmental triggers of autoimmune response, however patients do not have a unified way to record, document, measure and understand their experiences and share them with their healthcare practitioners.

**Objective**

We aim to build a mobile phone application that would allow patients to record and overview their symptoms as well as their compliance to medication.

**Design**

The app is build on a combination of thus far biomedical knowledge of symptoms related to Hashimoto’s as well as information gathered from interviewing individuals diagnosed with Hashimoto’s. It enables individuals to record their experience on daily-weekly and monthly basis. No data are collected, the system is decentralized, and the recorded data are stored only on patient’s phones.

**Results**

Patient’s needs could be easily served through a mobile phone app, according to the first results. It could help the patients implement lifestyle changes that would serve as a first line of defence against non-thyroid related Hashimoto’s symptoms.

**Conclusion**

Smart phone apps have a great value and potential in collecting a large pool of worldwide data, however they need to be co-developed with biomedical scientists and healthcare professionals in order to fully serve to patients, medical healthcare professionals as well as the research.

**Dynamic risk stratification for predicting recurrence in patients with differentiated thyroid cancer treated without radioactive iodine remnant ablation therapy**

Suyeon Park, Won Gu Kim, Eyun Song, Hye-Seon Oh, Mijin Kim, Hyemi Kwon, Min Ji Jeon, Tae Yong Kim, Young Kee Shong & Won Bae Kim

Department of Internal Medicine, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea.

**Background**

Increased incidence of small differentiated thyroid cancer (DTC) has emphasized the need for risk stratification and individualized disease management for these low risk DTCs. The aim was to validate a new dynamic risk stratification (DRS) system for prediction of structural recurrent/persistent disease in patients with DTC treated without radioactive iodine (RAI) remnant ablation therapy.

**Methods**

This historical cohort study included 357 patients with DTC treated with lobectomy or total thyroidectomy without RAI therapy. We stratified patient response to initial treatment as excellent, indeterminate, biochemical incomplete, and structural incomplete according to the DRS system.

**Results**

During a median 8.6 year of follow-up, 3.6% patients had structural recurrent DTC. The response was excellent in 71.7% patients, indeterminate in 18.5%, biochemical incomplete in 8.4%, and structural incomplete in 1.4%. There were significant differences in disease-free survival among the DRS groups (P < 0.001). The hazard ratio (HR) of recurrent/persistent disease was significantly higher in biochemical incomplete group (HR = 20.8, P < 0.001) and structural incomplete group (HR = 243.3, P < 0.001) compared with the excellent group. However, the tumor node metastasis (TNM) staging system and the American Thyroid Association (ATA) initial risk classification did not effectively predict recurrence of DTC.

**Conclusions**

The new DRS system was effective for predicting risk of recurrent/persistent disease in patients with DTC who underwent lobectomy or total thyroidectomy without RAI remnant ablation.

Association between lymph node metastasis and patients’ age in papillary thyroid microcarcinoma
Hye-Seon Oh, Min Ji Jeon, Suyeon Park, Mijin Kim, Hyemi Kwon, Eyun Song, Won Gu Kim, Young Kee Shong, Won Bae Kim & Tae Yong Kim
Internal Medicine, Asan Medical Center, Seoul, Republic of Korea.

Background
Recent studies presented that younger patients with papillary thyroid microcarcinoma (PTMC) had poorer clinical outcomes compared to older PTMC patients. The aim of this study is to investigate the impact of patient’s age on the lymph node metastasis (LNM) status of PTMC, a risk factor for recurrence and poor clinical outcome of PTMC.

Methods
The study evaluated 2068 PTMC patients who underwent thyroid operation with lymph node (LN) dissection from 2001 to 2009. All patients were allocated into five groups by age; Group A (≤ 35 years), Group B (35 < age ≤ 45), Group C (45 < age ≤ 55), Group D (55 < age ≤ 65), and Group E (65 < age). LNM status was divided into three groups by the number of metastatic LNs: no LNM, low volume LNM (≤ 5 metastatic LNs), high volume LNM (> 5 metastatic LNs). We evaluated the correlation between patient’s age and high volume LNM in this study.

Results
High volume LNM was found in 199 (8.9%) patients among whole study subjects and was the most frequently found in the young age group (A 17.3%, B 8.4%, C 7.2%, D 8.4%, and E 7.1%, respectively). Young age (Group A), male gender, larger primary tumor (> 0.5 cm), multifocality, and extrathyroidal extensions were significant risk factors for high volume LNM in univariate and multivariate analysis. In multivariate analysis, odd ratio (OR) of Group A for high volume LNM was 3.49 (95% CI, 1.67–8.06; P value 0.002) compared to the Group E. When analyzed only in women, young age (Group A) was also a significant risk factor for high volume LNM (OR 6.00, 95% CI 2.73–20.76, P value 0.001). But when analyzed in men, there was no significant difference in the incidence of high volume LNM by different age groups (A 25%, B 18.1%, C 20.2%, D 22.0%, and E 22.2%, respectively).

Conclusion
High volume LNM was more frequently found in young aged female and male patients. For patients under 35 years or male patients, immediate diagnosis and surgical treatment for PTMC might be needed.

EP1368
Breast cancer and family history for breast cancer in patients with differentiated thyroid carcinoma
Safak Akin, Esra Tutal, Erkam Sencar, Melia Karakose, Ozgur Ozcelik, Mahmut Apaydin, Mayesser Sayki Aslan, Ilknur Unsal, Bekir Ucan, Mustafa Ozbek & Erman Cakal
Diskapı Research and Training Hospital, Ankara, Turkey.

Background and aim
The risk for breast cancer in patients with thyroid cancer has been investigated in previous studies, and has been found to be increased. In this study we, therefore present retrospective analysis of the patients with differentiated thyroid carcinoma in respect to breast cancer and family history for breast cancer.

Methods
We conducted a retrospective study involving 455 patients with a diagnosis of differentiated thyroid carcinoma (DTC). Before surgery, high serum TG values may be due to abnormal large thyroid, excessive thyroid stimulation, or physical damage to thyroid etc.

Results
Thyroglobulin (TG) is the most important protein produced by the thyroid. TG is considered a reliable marker of recurrent disease in patient with differentiated thyroid carcinoma (DTC). Before surgery, high serum TG values may be due to an abnormally large thyroid, excessive thyroid stimulation, or physical damage to thyroid etc.

Conclusions
Histological diagnosis: 85% (17) papillary thyroid cancer, and 15% (3) cases with follicular thyroid carcinoma (DTC). Before surgery, high serum TG values may be due to an abnormally large thyroid, excessive thyroid stimulation, or physical damage to thyroid etc.

Methods
We evaluated in the retrospective study 20 patients (mean age 49.6 ± 12 s.o., range from 25–73 years old), with a histological diagnosis of DTC. Clinical diagnosis before surgery was: 20% (4) solitary nodule; 10% (2) hyperthyroidism; 5% (1) thyroid cancer with lytic bone metastasis; 65% (13) non toxic multinodular goiter.

Results
Histological diagnosis: 85% (17) papillary thyroid cancer, and 15% (3) cases with follicular thyroid carcinoma. 25% (5) cases with micro DTC and 75% (15) of cases with DTC more than 1 cm. We excluded from study one case with large lytic bone metastasis because the serum TG value was very high 11096 ng/ml. Mean TSH values were 1.4 ± 0.9 IU/ml and mean TG values were 88.1 ± 67 ng/ml (range 16.7–255 ng/ml). In 20% (4) of cases with DTC less than 1 cm TG values it were in the normal range. In 14 patients with DTC bigger than 1 cm; 42% (6) of cases had TG values more than 2 fold of normal range, 28% (4) of cases had TG values in the normal range and 28% (4) of cases had TG values between normal and two fold normal range.

Conclusions
In our study TG are more sensitive to detect DTC macro carcinoma, but we need to evaluate more cases, to compare TG values in cases with negative biopsy and to evaluate even the TG antibodies.

Is there an impact of the concurrent presence of chronic autoimmune thyroiditis in differentiated thyroid cancer patients?

Sorina Martin1,2, Oana Budianu3, Oana Ion2, Andreaa Grigore3, Anca Sirbu2, Carmen Barbu4, Cosmin Giulea4, Adrian Miron5,6, Florin Andrei1 & Simona Fica1,2

1Endocrinology Department, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 2Endocrinology Department, Elias Hospital, Bucharest, Romania; 3Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 4Surgery Department, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; 5Pathology Department, Elias Hospital, Bucharest, Romania.

Background

The association between differentiated thyroid carcinoma (DTC) and autoimmune thyroiditis (AT) has been reported in numerous studies, yet the impact of the concurrent presence of AT and DTC remains controversial.

Methods

We retrospectively analysed the files of 493 patients submitted to thyroidectomy in our surgery department between January 2012 and September 2015.

Results

A total of 86 patients with DTC were enrolled, mean age 53.99±13.91 years, 83.7% females. 25 (29%) patients, all women, associated biochemical and/or histopathological AT. We found no significant differences between patients with DTC and AT compared to patients without AT regarding the ultrasound characteristics of the thyroid nodules: nodule diameter (P=0.330), echogenicity (P=0.572), halo presence (P=0.528), microcalcifications (P=0.347), vascularization (P=0.199) and lymph nodes involvement (P=0.418), nor the histopathological characteristics of the DTC: tumor subtype (P=0.713), vascular invasion (P=0.617), extracapsular extension (P=0.713) or the presence of local lymph nodes metastasis (P=0.888).

Conclusions

Although our data showed a high prevalence of AT in patients with DTC, we found no significant differences regarding the ultrasound and histopathological characteristics of DTC in patients that concurrently had AT compared to patients without AT.

20,000 euros for diagnosis of one thyroid cancer case: Is it not too much?

Marek Maciejewski1,2, Agnieszka Sawicka1, Michal Slomian1, Malgorzata Gasior1, Renata Budzynska-Nosal1 & Krzysztof Marczewski1,2

1Pope John Paul II Regional Hospital, Zamosc, Poland; 2University of Economy and Innovation, Lublin, Poland.

Introduction

Thyroid cancer is a major public health problem, and fine-needle biopsy is an established method of its early detection. However, there are still some controversy about the indication for BACC depending on the clinical data and the results of diagnostic imaging. An important role is also played by economic criteria, including socially acceptable, so-called equitable cost of obtaining additional year of life, which in our country is determined to three times the average national income per capita.

Results

We analyzed the results of fine needle biopsy of thyroid nodules taken in the years 2008–2016 in ambulatory patients. In most cases, these people were targeted due to changes in the ultrasound detected by examination performed for other indications, the so-called incidentalomas. The most common indication was evaluating the patency of the carotid arteries. We have performed total of 5347 biopsy of thyroid focal lesions which led to the diagnosis of eight cases of thyroid cancer. Average cost detection of a single cancer case amounted to approximately 20 000 Euro.

Conclusion

This cost does not exceed three times the annual GDP per capita, but is high. Therefore, it seems reasonable to discuss the criteria for performing the BACC in case of incidental thyroid focal changes, particularly in regions with a lower incidence of thyroid cancer.

Unilateral Graves’ disease with papillary carcinoma of the hyperfunctioning lobe

Georgios Papadakis1, Elena Gonzalez Rodriguez1, Gilles Allenbach2, Marie Nicod Lalonde2, François Gorostidi3, Kishore Sandu4, Massimo Bongiovanni5 & Gerasimos P. Sykiotis6

1Service of Endocrinology, Diabetes and Metabolism, CHUV, Lausanne University Hospital, Lausanne, Switzerland; 2Service of Nuclear Medicine, CHUV, Lausanne University Hospital, Lausanne, Switzerland; 3Service of Otorhinolaryngology, CHUV, Lausanne University Hospital, Lausanne, Switzerland; 4University Institute of Pathology, CHUV, Lausanne University Hospital, Lausanne, Switzerland.

Background

Graves’ disease (GD) typically manifests as an autoimmune hyperfunction of both thyroid lobes. Less than 10 cases of unilateral GD have been described, and the pathophysiology of unilateral GD remains unknown. Co-existence of malignancy has never been reported. We report a case of GD of the left lobe with simultaneous discovery of a papillary carcinoma within the hyperfunctioning lobe.

Case description

A 49-year-old patient of Middle-Eastern origin was referred to our clinic in November 2016, one year after the diagnosis of symptomatic thyreotoxicosis, treated by carbimazole for the first 6 months. Subclinical hyperthyroidism recurred after treatment withdrawal. Thyroid isotope scanning with 99mTc in September 2016 showed diffusely increased uptake of the left lobe (with the exception of a low uptake zone) and minimal uptake of the right lobe. In November 2016, the patient was asymptomatic and had subclinical hyperthyroidism. Thyroid gland ultrasonography (US) showed a slightly enlarged and heterogeneous left lobe with clearly increased vascularity. The right lobe was smaller, homogeneous, with normal vascularity confined to its periphery. Based on the imaging results and positive thyrotropin receptor antibodies, unilateral GD was diagnosed. The low uptake zone in the left lobe corresponded to a hypoechoic nodule with suspicious US features (central calcification, possible infiltration of the thyroid capsule). Fine-needle biopsy of this lesion revealed papillary carcinoma (Bethesda class VI). Total thyroidectomy will soon be performed. Conclusion and perspectives

GD can rarely present with an asymmetric involvement of the thyroid lobes. Our patient is the first case associating unilateral GD and thyroid malignancy in the ipsilateral lobe. Given that total thyroidectomy is indicated, complete histological, biochemical and genetic evaluation of both lobes will allow us to test current hypotheses on the pathophysiology of unilateral GD.

Trends in the clinicopathological features and clinical outcomes of medullary thyroid carcinoma – an Israeli multicenter study

Dania Hirsch1,2, Orit Twito1,2, Sigal Levy1, Gildeon Bachar3,4,5, Eyal Robenshtok1,2, David J Gross6, Haggi Maze7 & Carlos Benbassat8,9

1Institute of Endocrinology, Rabin Medical Center, Petach Tikva, Israel; 2Institute of Endocrinology, Meir Medical Center, Kfar Saba, Israel; 3Sackler Faculty of Exact Sciences, Tel Aviv University, Tel Aviv, Israel; 4Department of Otorhinolaryngology, Rabin Medical Center, Petach Tikva, Israel; 5Neuroendocrine Tumor Unit, Endocrinology & Metabolism Service, Department of Medicine, Hadassah-Hebrew University Medical Center, Jerusalem, Israel; 6Department of Surgery, Hadassah-Hebrew University Medical Center, Jerusalem, Israel; 7Endocrine Institute, Assaf Harofeh Medical Center, Zerifin, Israel; 8Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.

Background

The massive use of neck sonography has led to a dramatic increase in the incidence of thyroid cancer detection, predominantly small papillary carcinomas. However, changes in the presentation and course of medullary thyroid carcinoma (MTC) over time remain unclear.

Objective

To evaluate trends in the presentation and outcomes of MTC.

Methods

Patients treated for MTC at four medical centers in Israel were divided into two groups by year of diagnosis, 1963–2005 (period A) and 2006–2016 (period B), and compared for clinicopathological variables.

DOI: 10.1530/endoabs.49.EP1374
Results
The cohort included 189 patients (55% female) of mean age 48.9 ± 18.6 years followed for 10.1 ± 9.4 years. Of these, 104 patients (55%) were diagnosed in period A, and 85 (45%) in period B. No significant between-group differences were found in primary tumor size at diagnosis (26.2 ± 18.5 and 23.7 ± 17.6 mm, respectively), proportion of micro-MTCs (< 1 cm) (18/74, 24.3% and 19/75, 25.3%, respectively), or TNM staging. Period A was characterized by a higher rate of concomitant MTC (28/98, 28.6% vs 6/73, 8.2%; P = 0.001) and lower age at diagnosis (45.2 ± 18.6 years vs 53.7 ± 17.7 years; P = 0.002). Cervical lymph node dissection was more commonly performed in period B (58/81, 71.6% vs 68/80, 85%; P = 0.05), but no concomitant increase in the rate of metastatic lymph node excision (46/64, 71.9% and 45/70, 64.3% respectively, P = 0.36).

There was no significant difference between groups A and B in disease-free survival (DFS) at one year after diagnosis (34/87, 39.1% and 35/70, 50%, respectively P = 0.2) or at last follow-up, comparing patients with similar surveillance periods (11/28, 39.3% and 36/75, 48%, P = 0.5).

Conclusions
Unlike differentiated thyroid cancer, most presenting features of MTC have not changed in recent years. The most significant temporal change is a decreased rate of familial MTC. Despite the use of more extensive surgical procedures and new treatment modalities, there has not been a significant improvement in disease-related outcomes.

Association of preoperative neutrophil-lymphocyte ratio and platelet lymphocyte ratio with clinical features of differentiated thyroid cancer
Bengur Taskiran¹, Guven Baris Canuol, Goknur Yorulmaz² & Ruya Mutluay³
¹Yunus Emre State Hospital, Eskisehir, Turkey; ²Osmangazi University, Eskisehir, Turkey.

Introduction
Platelets and neutrophils take part in proliferation of cancer cells, angiogenesis, and metastasis. Studies on various cancer types showed relation between prognostic and absolute numbers of neutrophils, lymphocytes, and the ratio in-between (NLR) and platelet/lymphocyte ratio (PLR). We aimed to evaluate NLR and PLR and their relation with features of differentiated thyroid carcinoma (DTC).

Materials and methods
Electronic data of 330 patient with pathologic diagnosis of thyroid carcinoma were evaluated retrospectively. Two hundred and fifty five patients with other chronic diseases and medullary thyroid carcinoma and whose pathology reports were evaluated retrospectively. Two hundred and fifty five patients with other chronic diseases and medullary thyroid carcinoma and whose pathology reports were unavailable were excluded. Clinical and laboratory features of 75 patients (63 female, 12 male) were analysed.

Results
The most common subtype was conventional type papillary thyroid cancer (n = 46). Mean age was 46 ± 12 years. 50 tumours were unifocal, 25 multifocal. Forty-two patients had tumour less than 1 cm in size, 35 had 1 cm or larger. Forty patients underwent radioactive iodine therapy or remnant ablation (RAI dose: 92 ± 32 mCi). Preoperative and postoperative NLR and PLR were not different according to age (younger than or older than 45 years, fociality (uni/multi focal), RAI history (absence/presence), tumour size (less than 1 cm or larger), invasion (n = 1). When 2.5 was chosen as cut-off value for NLR, preoperative and postoperative PLR was significantly (P = 0.0001 and P = 0.046) different; age at diagnosis was also significantly different (P = 0.002). There was a positive relation between preoperative and postoperative PLR (r = 0.575, P = 0.0001) and NLR values (r = 0.431, P = 0.004). NLR was also positively correlated with PLR both in pre- and postoperative period. Postoperative thyroglobulin data were available in 55 patients. It was negatively correlated with preoperative NLR (r = -0.334, P = 0.008). Age was positively correlated with NLR (r = 0.245, P = 0.345). Tumour size was negatively correlated with postoperative PLR (r = -0.102, P = 0.048).

Conclusion
Preoperative NLR and PLR does not predict clinical features of DTC. Association between pre- and postoperative PLR and NLR may be due to a continuum instead of causal relation. Unlike high NLR associated poor prognosis in other cancer types, higher NLR was observed in cases with lower thyroglobulin levels. CBC has no effect on thyroid cancer with indolent nature.

EP1376
Differentiated thyroid cancer in patients taking lithium for bipolar affective disorder: a case series
Abbas Ali Tam, Cevdet Aydın, Didem Özdemir, Muhammed Cüneyt Bilgimer, Reyhan Ersoy & Bekir Çakır
Yıldırım Beyazıt University School of Medicine, Endocrinology and Metabolism Diseases, Ankara, Turkey.

Aim
Lithium bicarbonate is a drug used in the initial treatment of bipolar disorders. Lithium is an element of alkali metal group and besides being a causative agent for goiter and hypothyroidism primarily, it has also some antithyroid effects. Rarely, lithium may cause hyperthyroidism secondary to thyroiditis or probably autoimmune mechanisms. The association between lithium and thyroid cancer is very little known subject. In this case series, we presented differentiated thyroid cancer in five patients using lithium for the treatment of bipolar affective disorder.

Cases
Three of patients were female and two were male. Three patients had hypothyroidism and were using levothyroxine and two patients were euthyroid. There was no other thyroid disorder. Thyroid hormone levels were measured regularly; it was found increased TSH and normal T₄ levels in lithium users. Thyroid ultrasound results were normal in all patients. Patients were using lithium for the treatment of bipolar disorder since 5-18 years; two patients have been using lithium for bipolar affective disorder for 5 and 18 years respectively.

Conclusion
Thyroid dysfunctions can be observed in patients using lithium due to various mechanisms. Among these, thyroid cancers are the least known and patients with nodular goiter on lithium therapy should be evaluated carefully for the risk of development of thyroid cancer.

Introduction
‘Artificial intelligence’ is an information-processing technology developed and inspired by the information processing technique of human brain. Artificial intelligence applications are used with an increasing ratio in medicine; particularly in the fields of breast cancer, radiology, cardiology, health management and drug effects analysis. There is not any study concerning thyroid diseases and artificial intelligence applications in the literature. In this study, we aimed to use an artificial intelligence application - CHAID (Chi-Squared Automatic Interaction Detection) algorithm- to predict malignancy risk in thyroid nodules with Bethesda III –atypia of undetermined significance/follicular lesion of undetermined significance (AUS/FLUS) - cytology.

Methods
Data of 3300 patients (6863 nodules) evaluated by our multidisciplinary council and operated between 2005–2016 were analysed retrospectively. There were 364 patients with 385 nodules with AUS/FLUS cytology in. 65 parameters including clinical, laboratory, ultrasonographical, cytological and histopathological features of each nodule were evaluated. The diagnostic value of CHAID algorithm was determined considering histopathological diagnosis as the reference method.

Results
There were 75 male (20.6%) and 289 female (79.4%) patients. Histopathological diagnosis was benign in 282 (73.2%) and malignant in 103 (26.8%) nodules. Analysis with CHAID algorithm revealed that presence of lymphoid/chronic...
Thyroid autoimmunity and risk of incidental thyroid microcarcinoma in non-toxic nodular thyroid diseases

Dimitris Askitis1, Eleni I Efremidou 1, Michail A Karanikas 1, Grigorios Tripsianis1, Alexandra Giatromanolaki2, Alexandros Polychronidis & Nikolaos Lyratopoulos1

1First Surgical Department, University Hospital of Alexandroupolis, Faculty of Medicine, Democritus University of Thrace, Alexandroupolis, Greece; 2University Pathology Department, University Hospital of Alexandroupolis, Faculty of Medicine, Democritus University of Thrace, Alexandroupolis, Greece.

Aim
Thyroid cancer comprises the most common endocrine malignancy and a variety of studies have investigated the role of thyroid autoimmunity as an independent risk factor for the manifestation of differentiated thyroid cancer in otherwise benign thyroid disorders. Objective of the current retrospective study is the assessment of any possible correlation between thyroid autoimmunity, in terms of elevated thyroid autoantibodies, and incidental thyroid microcarcinoma (ITC) in non-toxic nodular thyroid diseases, subjected to total thyroidectomy (TT).

Patients and methods
In First Surgical Department between 1 January 2005 and 01 March 2010 a total of 186 patients (146 females/40 males) underwent TT after referral for benign non-toxic nodular thyroid diseases. Surgical specimens were evaluated in University Pathology Department and the diagnosis of ITC was recorded.

Results
32 patients (17.2%) were diagnosed with microcarcinoma (females/males: 2:2:1), while 154 patients (82.8%) were free of malignancy. 9/34 patients with solitary thyroid autoantibody titers were assessed in patients without (group A) and those with (group B) thyroid cancer. The results were also compared regarding preoperative diagnosis.

Conclusions
Thyroid autoimmunity does not seem to feature an independent risk factor associated with thyroid microcarcinoma in non-toxic nodular thyroid diseases. However, a non-significant higher correlation is recognized in the subgroup of euthyroid multinodular goiter. Further studies are required to investigate the potential association between thyroid autoimmunity and carcinoma, as a helpful indication for surgical referral.

Thyroid cancer is the most common malignant tumor of the human endocrine system. Recently, its incidence has increased significantly. Anaplastic cancer constitutes 2–4% of thyroid cancers and remains aggressive. The life expectancy is 2–6 months. It is often beyond the surgical margin. Externally radiation therapy or chemotherapy are the treatment options. Therefore, new therapeutic approaches are needed. Peroxisome proliferator-activated receptor (PPAR) gamma is a DNA-binding nuclear hormone receptor and regulates transcription effects in cell energy metabolism. PPAR gamma agonists may inhibit tumor growth through terminal cell differentiation induction, cell cycle arrest, apoptosis induction and angiogenesis inhibition. PPAR gamma agonists show significant antitumor activities against various cancers both in vitro and in vivo. Metformin (1,1-Dimethylbiguanide) is the most widely used drug in treatment of type 2 diabetes patients. Preclinical data show its anticancer effects. The molecular mechanisms of metformin in cancer cells is still unknown. In our study, we plan to evaluate effects of combination of metformin and pioglitazone on AMPK/mTOR signal pathway, p53 and apoptosis in human anaplastic thyroid cancer cells. In C643 and SW1736 cell lines, IC50 doses of metformin and pioglitazone were found as 17.69 and 11.64 mM, and 27.12 and 23.17 mU respectively. The combination of metformin and pioglitazone was determined as additive with isobologram analyses. Both of the compounds induce apoptosis separate or in combination. Consequently, we have evaluated the down regulation of the expression levels of oncogenic AKT3, CHUK, CDC42, EIF4E, HIF1A, IKKKB, ILK, PIK3CA, PIK3CG, PLD1, PRKCA, RICTOR genes in MET and PLO combination treated cells. Moreover, expression levels of tumor suppressor DDIT4, DDIT4L, EIF4E, EIF4E, FB1, FB2, GSK3B, MTO, MYO1C, PTEN, ULK1, ULK2 genes were found to increase functionality. The results show that these agents can be used in the treatment of thyroid cancer as novel therapeutic agents.

BRAFV600E status and Stimulated Thyroglobulin at ablation time increase prognostic value of American Thyroid Association (ATA) classification systems for persistent disease in Differentiated Thyroid Carcinoma (DTC)

Andrea Repaci1, Valentina Vicenzi1, Alexandre Paccapelo1, Nicola Salturo2, Ottavio Cavicchi2, Fabio Monari3, Giovanni Tallini4, Elisa Gruppi4, Annalisa Altimari3, Michelangelo Fiorentino4 & Uberto Pagotto1
1Endocrinology Unit, Department of Medical and Surgical Sciences, S. Orsola-Malpighi Hospital, Alma Mater University of Bologna, Bologna, Italy; 2Otolaryngology Unit, S. Orsola-Malpighi Hospital, Bologna, Italy; 3Radiation Oncology Center, Department of Experimental, Diagnostic and Speciality Medicine-DIMES, S. Orsola-Malpighi Hospital, Alma Mater University of Bologna, S. Orsola-Malpighi, Bologna, Italy; 4Laboratory of Oncologic Molecular Pathology, S. Orsola-Malpighi Hospital, Bologna, Italy; 5Anatomic Pathology-Molecular Diagnostic Unit AUSSL of Bologna, Department of Medicine (DIMES), Bologna, Italy.

Background
Stimulated Thyroglobulin levels measured at the time of remnant ablation (Htg-A) and BRAFV600E mutation were shown to have prognostic value in predicting persistent disease in DTC. The aim of this study was to evaluate the prognostic role of Htg-A combined with BRAFV600E status in association with revised American Thyroid Association (ATA) risk stratification.

Patients and methods
620 patients treated for a DTC were included in this study with median follow-up duration of 6.1 year. All patients were submitted to a total thyroidectomy, followed by radioiodine ablation. Patients with positive antibodies anti-Tg were excluded. The predictive value of Htg-A was calculated by receiver operating characteristic curve analysis. Cox proportional hazard regression modeling, including BRAF status, Htg-A and ATA classification system, was assessed to evaluate existing persistent disease risk.

Results
BRAF status and Htg-A levels together improve ATA risk classification in all categories. In particular in Low risk ATA only BRAFV600E mutation (P = 0.001 HR 60.2 CI 95% 5.28–6.87). In Intermediate ATA risk BRAF mutation + Htg-A > 8.9 ng/ml was associated with persistent disease (P = 0.029 HR 2.71 CI 95% 1.106–6.670) and BRAFV600E + Htg > 8.9 ng/ml was associated with persistent disease (P = 0.000 HR 5.001 CI 95% 2.318–10.790). In High risk ATA BRAFV600E + Htg-A > 8.9 ng/ml was associated with persistent disease (P = 0.010 HR 5.07 CI 95% 1.609–15.940) and BRAFV600E + Htg-A > 8.9 ng/ml was associated with persistent disease (P = 0.002 HR 11.56 CI 95% 2.543–52.576).

Conclusion
BRAF status and Stimulated Thyroglobulin levels at ablation time improve the ATA risk stratification, so also Htg-A could be included in ATA risk classification.

DOI: 10.1530/endoabs.49.EP1382

EP1382
High sensitivity of BRAF detection method does not alter response to therapy of papillary thyroid cancer of known BRAF status

Agnieszka Walczyk1, Aldona Kowalaka1, Artur Kowalak1, Janusz Kopczynski1, Iwona Fulyga1, Danuta Gasior-Perczak1, Estera Mikina3, Katarzyna Lizis-Kolus1, Dorota Szycka-Skrzobot1, Monika Szymonek1, Stefan Hurej1, Maciej Kajor1, Magdalena Chrpek2 & Stanislaw Gozd1
1Holycross Cancer Centre, Kielce, Poland; 2Jan Kochanowski University, Kielce, Poland; 3Medical University of Silesia, Katowice, Poland.

Background
A dynamic risk stratification with modified initial estimated risk based on response to therapy and disease course is one of the crucial changes adopted recently by the American Thyroid Association (ATA). The analysis of BRAF status is not routinely recommended by ATA, although this finding may be advantageous to individualized risk-adapted approach in papillary thyroid cancer (PTC). The methods used to detect the BRAF V600E are known of variation in the sensitivities, variable susceptibilities for DNA degradation, and possible equivocal results with direct DNA Sanger sequencing (Seq), particularly. The aim of this study was to examine the relation between the BRAF status of PTC detected applying three methods and ATA response-to-therapy categories (excellent, indeterminate, biochemical/structural incomplete), and recurrence identified after no evidence of disease (NED) or persistence disease.

Methods
Unselected 723 PTC cases with known BRAF status diagnosed 2000–2013, actively monitored at single institution, and reviewed retrospectively up to December 31, 2015. Genotyping of BRAF was implemented using the algorithm: Seq, followed by more sensitive allele-specific polymerase chain reaction (PCR), and real-time PCR (quantitative PCR; qPCR). Considering various limitations of particular methods 639 specimens were available for the analysis by Seq, 638 by ASA-PCR, and 705 by qPCR.

Results
BRAF V600E was found in 51.6%, 67.7%, and 67% PTCs detected by Seq, PCR, and qPCR, respectively. The indeterminate response was significantly more frequent in BRAF-positive PTCs identified by Seq (P = 0.03), but not by ASA-PCR (P = 0.07), and qPCR (P = 0.06). There was no significant relation between BRAF-positive cases and other non-excellent response-to-therapy categories, recurrences and persistent disease regardless of the method used.

Conclusions
The BRAF V600E mutation identified by high sensitive methods (ASA-PCR, qPCR) did not significantly alter a response-to-therapy category and outcome of PTC. However, an indeterminate response was more frequent in BRAF-mutated PTC detected by direct sequencing.

Thyroid nodules ultrasound classification and the importance of the endocrinologist clinical feeling

Bruno Madeo1,2, Giulia Bragante1,2, Anna Ansaloni1,2, Erica Taliani1,2, Manuela Simon1,2 & Vincenzo Rochira1,2
1Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; 2Azienda Ospedaliero-Universitaria di Modena, Modena, Italy.

Background and aim of the study
Several ultrasound (US) classifications for estimating thyroid nodules risk have been proposed. Since most of them are hardly applicable in clinical practice, we created a local tool, named Modena classification (MC), considering US characteristics and clinician subjective impression. The aim is to verify the diagnostic accuracy of MC and to compare it to US classifications of American Thyroid Association (ATA) (1) and British Thyroid Association (BTA) (2).

Methods
We prospectively enrolled 111 patients (33M, 78F; age 19–75; total 457 nodules) with an indeterminate, suspicious for malignancy or malignant cytology. All the patients underwent neck US before surgery and a score risk was assigned, according to MC: low (not certainly nodular or not suspect); intermediate (indeterminate); high (suspect or very suspect). Then, we retrospectively classified nodules according to ATA and BTA. The US pattern was related to histology.

Results
All the classifications had low sensitivity and positive predictive value (PPV), and high specificity and negative predictive value (NPV) for low risk categories. For the intermediate risk category, BTA had the highest accuracy (68%). For higher risk categories, MC had good sensitivity (62%), high specificity (89%) and accuracy (81%); ATA had high sensitivity (83%), low specificity (48%), accuracy 58%; BTA had high sensitivity (88%), low specificity (44%), accuracy 57%.

Endocrine Abstracts (2017) Vol 49
Conclusions
A classification that considers the subjective impression of the clinician, in addition to the known US characteristics, has highest accuracy and specificity compared to guidelines classifications, particularly if the nodule has suspect US features.

Cold nodules are one of the most common findings on scintiscans and ultrasound examinations of the thyroid gland. About 5-10% of these nodules turn out to be histologically malignant. Our aim was to examine the predictive value of somatogenetic alterations associated with thyroid cancer in FNA samples of thyroid cold nodules being cytologically benign at the beginning of the study. These alterations included single nucleotide mutations (BRAF, HRAS, NRAS, KRAS) and genetic translocations (RET/PTC1, RET/PTC3, PAX8/PPARgamma, PAX8ex9/PPAR-gamma). The SNPs were tested by real-time PCR with fluorescence melting curve analysis and the rearrangements were detected by Taqman probe-based quantitative real-time PCR. We have analyzed 779 consecutive FNA samples and followed the patients up for 5 years. We identified 39 BRAF, 23 NRAS, 9 HRAS, 1 KRAS mutations and 1 RET/PTC3 rearrangement. No PAX8/PPARgamma rearrangements were demonstrated in the nodules. During the five-year follow-up, 57 cases (7.3%) were classified as malignant by histology, from which we indentified genetic alterations in 27 (47.4%). The statistical performance of our genetic panel showed a specificity of 93.6%, sensitivity of 47.4%, a positive predictive value of 95.8% and a positive predictive value of 37.0%. In summary, our test approach may be used for the prediction of malignant transformation of thyroid cold nodules, however, its sensitivity requires improvement.

Usefulness of preoperative ultrasonography and computed tomography for evaluation of recurrent laryngeal nerve invasion by Papillary Thyroid microcarcinoma
Keiko Ohkawa, Tadatoshi Osaku, Tetsuya Maeda, Yuna Ogimi, Chie Masaki, Junko Akasaka, Kyomu Y Hames, Chisato Tomoda, Akifumi Suzuki, Kenichi Matsuzo, Takashi Urone, Wataru Kitagawa, Mitsuji Nagahama, Kiminori Sugino & Koichi Ito
Ito Hospital, Tokyo, Japan.

Background
Papillary thyroid microcarcinoma (PTMC) has low malignant potential and an extremely good prognosis. However, surgical findings of asymptomatic PTMC can occasionally reveal tumor invasion into the recurrent laryngeal nerve (RLN).

The present study assessed the feasibility of evaluating tumor invasion into the RLN using ultrasonography (US) and computed tomography (CT).

Materials and methods
Of 7,916 patients with a PTMC who underwent surgery at our hospital, 35 with preoperative tumors that were ≤10 mm, without distal metastasis or lymph node metastasis, and with surgical findings of RLN invasion were included. The location of the tumor and the degree of contact with the thyroid capsule (DCTC) were examined by US and CT.

Results
Ten of the 35 patients were treated by combined resection of the RLN, and 25 patients were treated by shaving the RLN. US revealed that the tumor was located at the dorsal side of the thyroid in 31 patients (88.5%). In all patients who were treated by combined resection of the RLN, the tumor was located at the dorsal side of the thyroid. Among these patients, the DCTC determined by US was ≥25% in nine patients and <25% in one. Among those who were treated by RLN shaving, the DCTC was ≥25% in nine and 16 patients, respectively (P = 0.003). The DCTC was ≥25% in all patients who were treated combined resection and in 15 of the 25 patients who treated by RLN shaving (≥0.018) according to CT imaging. The tumor was located 1–1.5 cm from the cricoïd cartilage in most patients who were treated by combined resection.

Conclusions
When a PTC is located at the dorsal side of the thyroid with ≥25% DCTC, surgery should be selected for RLN invasion. Our results showed that the accuracy of predicting recurrent laryngeal nerve invasion can be improved by combining US with neck CT.

Solitary metastasis of papillary thyroid cancer in the sellar region and cavernous sinus
Lila Brakni, Lounes Halfaf, Yamina Aribi, P Hameg & Samia Ould-Kaibia
Army Hospital, Algiers, Algeria.

The commonest site of metastasis from papillary carcinoma is regional lymph nodes. Distant metastases are rare, most presenting synchronously. Brain metastases in papillary carcinoma are rare, reported with a frequency of 0.1–5% and cavernous sinus metastasis is extremely rare.

Case report
A 62-year-old woman presented with a history of non-secretory pituitary macroadenoma present with symptoms of hypopituitarism. MRI of the brain revealed a 4.5×3.1×3 cm, extension into the cavernous sinus. The tumor was not resectable, she Underwent a simple biopsy in view of the haemorrhagic nature of the tumor. Histopathology revealed a tumor with diffuse papillary architecture. On immunohistochemistry: positive for TTF1, PAX8, thyroglobulin, TPO;Ki67 (10–15%) and negative for GH, LH, FSH, ACTH, TSH. A diagnosis of metastatic papillary carcinoma was made. Thyroid ultrasound revealed two hypoechoic nodules. After thyroidectomy the histopathology was papillary micro- carcinoma thyroid-follicular variant of 05 mm. She received radioiodine therapy.

Discussion
The incidence of distant metastases from papillary carcinomas is reported to be 6–23%, the majority occurring within 5 years of the initial diagnosis. There have been case reports of papillary carcinoma with metastasis at unusual sites like the breast and cavernous sinus. All these cases were associated with a missed diagnosis of thyroid carcinoma, like our case, should be considered exceptional. There have been five reports of papillary carcinoma with metastasis to the skull base. Conclusion
There is no consensus for the treatment of papillary thyroid carcinoma with cavernous sinus metastasis. Thus, that solitary distant metastasis from thyroid carcinoma though rare, is a possibility, a difficult diagnosis to be made on radiology.

Calcitonin: clinical and laboratory evaluation in a tertiary hospital
Catarina Silvestre, Maria João Bugalho, Joaquim Sampaio, Helena Proença & Raquel Carvalho
Santa Maria Hospital, Lisbon, Portugal.

Background
Calcitonin is a hormone secreted by thyroid C cells, and is considered an excellent marker for medullary thyroid carcinoma (MTC). However, the use of calcitonin to screen patients with nodular thyroid disease (NTD) remains controversial.

Objective
Defining the frequency of hypercalcitoninemia among NTD patients followed at a tertiary referral hospital.

Methods
Retrospective analysis of basal calcitonin measurements and corresponding patients' records between January 2011-December 2015. The method used was immunonepheluminescent assay. Hypercalcitoninemia was defined as > 10 pg/ml.

Results
In five years, there was a total of 6551 calcitonin measurements requested by different physicians from different services, to 5149 patients: median age 57 years, 80.6% female. Calcitonin measurements were divided into 3 groups according to their levels: GI ≤10 pg/ml; GII 10–100 pg/ml; GIII ≥100 pg/ml. Excluding patients with no clinical information, there were 3097, with the following distribution: GI 2931, GII 158, GIII 26. Among these, calcitonin was requested in NTD context to 1504 patients; 69 patients had hypercalcitoninemia (GII and GIII). Of these, 21 underwent surgery (GI 12, GII 9); a histological diagnosis of MTC was established in 12 (GI 3/25%, GII 9/100%). Surgery was decided based, solely, on calcitonin levels in 7 cases, since only 5 had a positive cytology.

Conclusions
NTD was the reason for calcitonin measurement in less than 50% of total measurements. Hypercalcitoninemia was found in 4.6% of NTD patients. Calcitonin levels ≥100 were associated to a greater CMT risk, comparative to values between 10 and 100 and reinforcing results from other groups. A cost-effective approach includes avoid unnecessary requests, adequate interpretation of results as well as appropriate selection of patients to surgery.

Neuroendocrine progression of medullary thyroid cancer – case report
Krisztian Sepp1, Zsuzsanna Besenyi2, Laszlo Tiszlavicz3 & Zsuzsanna Valkusz1
1First Department of Medicine, University of Szeged, Szeged, Hungary; 2Department of Nuclear Medicine, University of Szeged, Szeged, Hungary; 3Department of Pathology, University of Szeged, Szeged, Hungary.

Thyroid cancers represent approximately 1% of new cancer diagnoses. Thyroid malignancies are divided into papillary carcinomas (80%), follicular carcinomas (10%), medullary carcinomas (5–10%), anaplastic carcinomas (1–2%) other rare tumours (primary thyroid lymphomas, primary thyroid sarcomas). The main therapeutic options are surgery (mainly total thyroidectomy), radioactive iodine treatment (depending on the type and stage of the tumour), levothyroxine therapy (thyroid stimulating hormone – TSH suppression dose), others (external beam irradiation, chemotherapy, thyroidine kinase inhibitor). Thyroid aspiration cytology was performed due to a rapidly growing neck mass of a 41 years old male patient, revealed a suspicion of neuroendocrine tumor. After the total removal of the thyroid gland and paratracheal and upper mediastinal lymph node dissection histology showed medullary thyroid cancer and metastases in the lymph nodes. Somatostatin receptor scintigraphy (SRS) was negative. PET-CT showed suspicion of mediastinal metastases, at this time external beam radiotherapy was performed. During the follow up calcitonin and chromogranin A levels decreased presenting a stable disease, imaging investigations showed small remnant of the tumour without any progression or metastases. After three years of the operation the patient had weight loss and diarrhea, CT scan showed cervical and mediastinal lymph node enlargement, hepatic and pancreas metastases, bone scintigraphy showed multiple bone metastases. SRS was positive in these areas, somatostatin analogue (SSA) treatment was started. Histological verification of the metastases are in progress. In our case a medullary thyroid cancer after three years of stable disease showed a neuroendocrine progression with multiple metastases. SSA treatment was started and we plan to perform peptide receptor radionucleide therapy (PRRT).

Cytohistologic correlation of thyroid nodules
Ines Burka, Senda Ouertandi, Molka Chaieb, Asma Ben Abdelkrim, Amel Maaroufi, Maha Kacem & Koussay Ach
Endocrinology Department, FARHAT Hached University Hospital, Sousse, Tunisia.

Background
The discovery of a thyroid nodule exposes the problem of the possibility of thyroid cancer. The difficulty of management of this situation is the fact that only the histopathological examination can confirm or refute the malignancy. Fine needle aspiration (FNA) is used as a diagnostic tool to assess thyroid nodules. The purpose of our study is to correlate the clinical, ultrasonographic, the FNA results and final pathology to determine the predictors of malignancy of thyroid nodules. Patients and Methods We conducted a retrospective study on 33 patients with thyroid nodule. Data were obtained for FNA diagnosis, demographics, findings on ultrasound, and histologic findings.

Results
The average age of our patients was 41.7 years ± 15.6 SD with a female predominance (90.9%). Ultrasound findings were as follows: single nodules, multinodular goiter (MNG), and multiple nodules in respectively 48.5, 39.4 and 12.1% of cases. Thyroid function tests prior to surgery were normal in all patients. Among the 33 patients, 7 (21.2%) have malignant tumors in histological findings: Two patients had signs of locoregional compression. A case of fixed nodule was noted and one patient had cervical lymphadenopathy. On ultrasonography: the average size of the nodules was 34.0 ± 14.5 mm, three nodules were hypoechoic, and 1 case of mixed vascularity was diagnosed. The FNA was benign in 90.9% of cases (n = 30), and indeterminate in 9.1% (n = 3). Of the 30 patients with a benign FNA result, 7 were found to have carcinoma on final pathology for 23.3% false negative rate and sensitivity of 76.7%. 1 patient were found to have incidental microcarcinoma which was located in the palpated lesion.

Conclusion
FNA biopsy is essential in the assessment and management of thyroid nodules. However, we report a high rate of malignancy among FNA diagnosed as benign lesions. This high rate of malignancy is the basis for our recommendation for a surgical approach for benign lesions.

Importance of central compartment neck metastasis in the differentiated thyroid microcarcinomas
Cátia Cunha1, Vítor Guedes2, António Garrão2 & Olímpia Cid2
1Hospital Beatriz Angelo, Loures, Portugal; 2Hospital da Luz, Lisboa, Portugal.

Elective central compartment neck dissection in the treatment of differentiated thyroid carcinomas (DTC) remains controversial. In a series of 1500 patients undergoing thyroid surgery, the authors evaluated the prognosis related to central compartment neck metastasis in differentiated microcarcinomas.

The impact of age and gender on the presentation and prognosis of medullary thyroid cancer – an Israeli multicenter study

Orit Twito1, Simona Grozinsky-Glasberg2, Carlos Benbassat4,6, Sigal Levy3, Gideon Bachar1,2, David J Gross2 & Dana Hirsch1

1Institute of Endocrinology, Meir Medical Center, Kfar-Sava, Israel; 2Neuroendocrine Tumor Unit, Endocrinology and Metabolism Service, Hadassah-Hebrew University Medical Center, Jerusalem, Israel; 3Academic College of Tel-Aviv Yaffo, Tel-Aviv, Israel; 4Institute of Endocrinology, Assaf Haroel Medical Center, Zeritit, Israel; 5Otorhinolaryngology, Rubin Medical Center, Beilinson Hospital, Petch-Tikva, Israel; 6Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel; 7Institute of Endocrinology, Rabin Medical Center, Beilinson Hospital, Petach-Tikva, Israel.

Background
Data regarding the effect of gender and age on medullary thyroid cancer (MTC) presentation and prognosis is limited. Although older age and male sex were found to correlate with poorer prognosis in some studies, this correlation may reflect differences in MTC presentation between sex and age groups, or a mixture of hereditary and sporadic MTC forms.

Objective
To evaluate the impact of age and sex on the presentation and outcomes of MTC.

Methods
Epidemiological and clinical data of MTC patients was extracted from a joint registry of four medical centers in Israel.

Results
The study included 193 MTC patients (106 females, age 48.9±18.6, median 51), who were followed for 10.1±9.4 years. Female gender was associated with smaller tumor diameter (22.3 vs 28.7 mm, P=0.032), lower rate of lymph nodes involvement (42/70, 60% vs 49/64, 76.6%, P=0.044) and lower rate of distant metastases (11/87, 12.6% vs 23/75, 30.7%, P=0.007). Although females achieved higher cure rates (79/79, 48.5% vs 20/72, 27.8%, P=0.007), disease related mortality and all cause mortality did not differ between the genders. Patients aged <45 year at diagnosis had higher rates of hereditary familial forms of MTC (32/74, 43.2% vs 31/14, 2.6%, P<0.0001). Analysis of the sporadic cases (n=137) revealed that younger age at presentation was associated with higher number of metastatic lymph nodes (19.7±23.5 vs 10.2±9.3, P=0.05) and more therapeutic interventions during the follow-up (62.9% vs 33.7, P=0.04). However, cure rate and disease related mortality were similar between the age groups.

Conclusions
In concert with previous literature, female MTC patients present with milder disease and achieve higher cure rates than males. However, younger age in the sporadic MTC form is associated with more advanced disease at presentation. Neither age nor gender affected disease related mortality.

Is post-treatment whole body scan useful in differentiated thyroid cancer after thyroid ablation?

Inmaculada Prior-Sánchez1, María Rosa AlhambaraExpósito1, Ángel Rebolleo Román1, Ana Barrera Martín1, Estefanía Moreno Ortega2, Juan Antonio Vallejo Casa2 & María Angeles Gálvez Moreno1

1Department of Endocrinology and Metabolism, Reina Sofia University Hospital, Cordoba, Spain; 2Department of Nuclear Medicine, Reina Sofia University Hospital, Cordoba, Spain.

Background
The short-term follow-up of patients with differentiated thyroid cancer (DTC) after the initial treatment is based on the measurement of stimulated thyroglobulin (s-Tg) and the use of diagnostic whole body scan (WBS).

Objective
To evaluate the clinical utility of WBS performed at 6–12 months after thyroidectomy. Examine the correlation between s-Tg and results of WBS.

Methods
We retrospectively evaluated all patients who were diagnosed with DTC (n=213) at a tertiary hospital center in Cordoba (Spain), between January 2000 and December 2013. The patients who had positive anti-thyroglobulin antibodies microcarcinomas (Tumors <1 cm) were excluded from the study. Patients were classified according to the new ATA guideline.

Results
169 patients were included. Mean age: 40.05±6.20 years; ♂: 76.3%; Papillary subtype: 89.3%. The great majority were classified as Stage I-II (81.1%). At the end of the follow-up, 72.2% had achieved a complete remission. 6 to 12 months after thyroid ablation, s-Tg was negative in 111 patients and WBS control showed negative uptake in 98 of these patients. In 13 patients (13/111), uptake remained in the thyroid bed but no evidence of disease was found. In 4/111 subjects, persistence of disease was detected by ultrasound scan, all of them with negative WBS. Of 58 patients with detectable s-Tg (>0.3 ng/ml), only 22 showed pathological uptake in the thyroid bed (n=16) or in the distance (n=6). In 36 patients with evidence of disease (62.1%) uptake was not observed. In 43 of these 58 patients disease-free status has not been reached. These facts reflect a low correlation between s-Tg level and results of the WBS (I.Kappa=0.226; P=0.001). The diagnostic accuracy of WBS was founded to be low (Sensitivity=0.36; 95% CI: 0.22-0.49) (Specificity=0.85; 95% CI: 0.79-0.91).

Conclusions
WBS performed at 6–12 months after initial treatment is out of clinical utility, especially in the presence of a s-Tg <0.3 ng/ml. WBS does not correlate with results of s-Tg determination and its accuracy has turned out to be low.

Evolution in the management of thyroid cancer: an observational study in two Belgian referral centres

Bernard Peene1, Annick Van den Bruel2, Carolien Moyson1 & Brigitte Decallonne1

1University Hospitals Leuven, Leuven, Belgium; 2General Hospital Sint Jan, Brugge, Belgium.

Background
Thyroid cancer incidence is increasing, especially the cancers ≤1 cm (T1a). Previous evidence suggests underuse of FNA. Several international guidelines for the management of thyroid cancer have been published. Especially the year 2006 was a hallmark, with the publication of both the ETA consensus and ATA guidelines.

Aim
Compare thyroid cancer subtypes and management before and after 2006.

Methodology
Retrospective observational study of non-medullary thyroid cancer patients diagnosed after total thyroidectomy in two Belgian referral centres (University Hospital Leuven, General Hospital Sint Jan, Brugge), comparing pre/post/treatment parameters of patient cohort1 (diagnosis 2004–2005, n=69) and cohort2 (diagnosis 2011, n=60).

Results
The histology and tumor dimensions were comparable, with papillary thyroid cancer (PTC) as main histologic subtype (86% of cohort1, 86% of cohort2) and T1a as most frequent dimension subtype (respectively 30 and 38%). In cohort2 a comparable low proportion first presented following incidental finding at imaging (21% vs 17% in cohort 1). Pre-surgical FNA was performed in 91% in cohort1 and 86% in cohort2. The indications for thyroidectomy were comparable, with Bethesda 5-6 as most frequent indication (44% in cohort1 and 53% in cohort2). The execution of a simultaneous lymph node dissection in the PTC subgroup was not different, neither the frequency of postoperative hypoparathyroidism and recurrent nerve paresis after 1 year. However, radioiodine ablation was less frequently given in cohort2 (58% vs 76% in cohort1, P=0.03) and neck ultrasonography at 1 year was performed in a higher proportion of >T1a patients (73 vs 49% in cohort1, P=0.02).

Conclusion
In two Belgian referral centres the use of FNA is high and established, and the proportion of T1a cancers is stable and low compared to the national data. A clear change in the postoperative management of thyroid cancer patients is observed towards more restrictive use of radioiodine ablation and increased use of neck ultrasound.

EP1394
Retrospective analysis of unusual thyroid tumours with clear cell features: morphology and differential diagnosis
Alexander Atrossovorny1 & Alexei Sidoren2
1Federal State Institution, Endocrinology Research Center, Moscow, Russia; 2National University of Science and Technology, MISIS, Moscow, Russia.

Background
In accordance with the WHO Classification of tumours of endocrine organs (Lyon, 2004) clear cell thyroid lesions have not been separated in one category as they are occurring quite rare, characterized by various cellular origin, heterogeneous morphological type, and malignant potential. Difficulties of morphological diagnosis of clear cell thyroid lesions are also obvious.

Aim
Retrospective morphological study of clear cell thyroid tumours has been performed by pathologists of two research centres (MRRC and ERC) for the period of 10 years (2007–2016) to analyse difficulties of diagnosis related with different histotype, and tumour grade.

Materials and Methods
Histological sections of paraffin blocks from 14 cases of clear cell tumours in 5 male and 9 female aged from 15 to 78 years have been stained with H&E, and immunohistochemistry (IHC) for Thyroglobulin (Tg), Thyroid Transcription Factor 1 (TTF1), Calcitonin (Cal), Chromogranin A (Chr A), Parathyroid Hormone (PTH), CD10, and Ki-67.

Results
Retrospective review of H&E and IHC stained sections allows to make diagnosis of 3 benign follicular adenomas (FTA), 2 follicular thyroid carcinomas (FTC), 3 papillary thyroid carcinomas (PTC), 1 medullary thyroid carcinoma (MTC), 2 poorly differentiated thyroid carcinomas (PDTC) with clear cell features, 2 intrathyroid parathyroid carcinomas (ITPTC), and 1 renal cell metastasis into thyroid (RCC metastasis). Tumour cells of FTA (2 pure clear cell and 1 signet ring cell), FTC, PTC, and PDTC are Tg-, and TTFl-positive, in comparison with negative Cal-, Chr A-, PTH-, CD10-staining. Ki-67 is expressed by nucleus of more than 30% PTC tumour cells in comparison with P-values (expression rate (less than 1%) of highly differentiated tumours. Tumour cells of MTC were Tg-, PTH-, and CD10-negative, but positive for TTFl, Cal-, and Chr A-staining. Cells of ITPTC were Tg-, TTFl-, Cal-, CD10-negative, but Chr A-, and PTH-positive. Cells of RCC metastasis are positive for CD10, but negative for Tg-, TTFl-, Cal-, Chr A, and PTH.

Conclusions
Clear cell thyroid tumours are rare and should be distinguished in accordance with their different cellular origin and histotype, as well as various tumour grade and prognosis.

The relationship between extrathyroidal extension and BRAFV600E mutation in papillary thyroid cancer
Mehmet Celik1, Buket Yilmaz Bulbul1, Semra Ay turf1, Nuray Can2, Ebru Tastekin2, Atakan Sezer2, Funda Ustun3 & Sibel Gul diken4
1Rakya University, Medical Faculty, Department of Endocrinology and Metabolism, Edirne, Turkey; 2Trakya University, Medical Faculty, Department of Pathology, Edirne, Turkey; 3Trakya University, Medical Faculty, Department of Surgery, Edirne, Turkey; 4Trakya University, Medical Faculty, Department of Nuclear Medicine, Edirne, Turkey.

Aim
BRAF is one of the serine threonin kinases that activates mitogen activated protein kinase (MAPK) signal pathway. The aim of this study is to evaluate the relationship between extrathyroidal extension (ETE) and BRAFV600E mutation in the subjects with papillary thyroid cancer.

Materials and methods
Clinical and laboratory data of 455 patients, who had been followed-up in our clinic between the years 2010 and 2015 for PTC, were evaluated. The relationship between extrathyroidal extension and BRAFV600E mutation was examined in the subjects enrolled in the study.

Results
Among 455 patients, 382 (83.9%) were female and 73 (16.1%) were males. The mean age of the participants was 49±11.8 years. While 366 (80.9%) of the patients had no extrathyroidal extension, 87 (19.1%) of the patients had extrathyroidal extension. 362 (79.6%) of the patients were BRAFV600E mutation (−) and 93 (20.4%) patients were BRAFV600E mutation (+). 320 patients were negative for both BRAFV600E mutation and extrathyroidal extension. The prevalence of PTC larger than 1 cm was significantly more common among BRAFV600E mutation and ETE (+) cases (P<0.004). The prevalence of capsular, lymphovascular and perineural invasion, lymph node metastasis and ultrasonographically detected pathologic lymphadenopathy was significantly higher among BRAFV600E mutation (+) and ETE (+) subjects (P<0.004, P<0.05, P<0.05, P<0.05). The prevalence of extrathyroidal extension was higher in patients with BRAFV600E mutation (+) and ETE (+) cases (P<0.004).

Conclusion
In this study, BRAFV600E mutation and ETE positivity were found to be poor prognostic parameters in the patients with PTC. However, the evaluation of long term follow-up data is required to more clearly understand prognostic effect and especially to determine the effect of this situation on mortality.

Insulin resistance and BRAFV600E mutation in the patients with differentiated thyroid carcinoma
Mehmet Celik1, Buket Yilmaz Bulbul1, Semra Ay turf1, Ebru Tastekin2, Nuray Can2, Atakan Sezer2 & Funda Ustun3
1Trakya University, Medical Faculty, Department of Endocrinology and Metabolism, Edirne, Turkey; 2Trakya University, Medical Faculty, Department of Pathology, Edirne, Turkey; 3Trakya University, Medical Faculty, Department of Nuclear Medicine, Edirne, Turkey.

Aim
Retrospective analysis of unusual thyroid tumours with clear cell features: morphology and differential diagnosis

Abstract
Medullary thyroid cancer (MTC) is a highly aggressive neuroendocrine tumour originating in the thyroid parafollicular cells. Calcitonin measurement and RET gene ascertainment have been used as markers for early diagnosis of MTC. Since pentagastrin is not available, calcium stimulation test helps to preclude ‘gray zone’ values of basal calcitonin, diagnose minimal residual disease and help the early diagnosis of C cell hyperplasia.

Aim
To establish a gender specific threshold for positive calcium stimulation test as well as indication for thyroidectomy and therefore prevention of MTC through early diagnosis.

Materials and methods
We conducted the calcium stimulation test on a series of patients with either nodular goiter, single nodule, RET positive or history of MTC associated with elevation of basal calcitonin values. Calcium gluconate 25 mg/kg adapted on the ideal BMI was administered over 3 min under ECG monitoring. Blood was collected before, at 2, 5 and 10 min after calcium infusion. Calcitonin was measured using LIAISON XL assay.

Results
The ongoing test has been performed on 17 patients, aged (23–67), 11 M, 6 F. Mean calcitonin values were: basal = 19.98 pg/ml (normal range: 1–11.8 pg/ml); at 2 min = 209.159 pg/ml; at 5 min = 143.619 pg/ml; at 10 min = 100.557 pg/ml; 10 subjects had a significant 2 min stimulated calcitonin (>100 pg/ml) and were operated, 3 subjects had an intermediate response (53.31–81.7 pg/ml) and 4 patients had low stimulated values (<54 pg/ml) therefore they are to be followed up. C cell hyperplasia (CCH) and MTC was confirmed histologically in 4 out of 10 patients (2 CCH and 2 MTC); 2 subjects had benign nodular goiter and 2 papillary thyroid microcarcinomas. More results are expected.

Conclusions
Stimulated calcitonin may be useful in the early diagnosis and follow-up of MTC and could reduce false negative rate of basal calcitonin measurement.

DOI: 10.1530/endoabs.49.EP1395

Endocrine Abstracts (2017) Vol 49
Aim
The incidence of nodular thyroid disease is high among patients with insulin resistance. The aim of this study is to evaluate the relationship between BRAFV600E mutation and insulin resistance in the patients with papillary thyroid cancer.

Materials and methods
We examined clinical and laboratory data of 103 patients who had been followed up by our department between the years 2010 and 2015. The diagnosis of insulin resistance (IR) was made when the homeostasis model assessment of insulin resistance (HOMA-IR) index was higher than 2.5.

Results
90 (87.4%) of 103 patients were female, while 13 (12.6%) of them were male. HOMA-IR was ≥ 2.5 in 58 (56.3%) patients and <2.5 in 45 (43.7%) patients. 19 of the patients were BRAFV600E mutation (+), while BRAFV600E mutation was (−) in 84 cases. Among 58 patients with insulin resistance, 46 (79.3%) patients were BRAFV600E mutation (−) and 12 (19.7%) patients were BRAFV600E mutation (+). There was no statistically significant relationship between BRAFV600E mutation and HOMA-IR in terms of demographic data, clinical and histopathologic results.

Conclusion
In this study, no statistically significant relationship was detected between insulin resistance and BRAFV600E mutation among the patients with PTC.

DOI: 10.1530/endoabs.49.EP1397

EP1398
Beware a rapidly enlarging Thyroid mass- a case of Thyroid Lymphoma
Suhel Ashraff, Ahmed Al Shareef & Satyajit Nag
James Cook University Hospital, Middlesbrough, UK.

Primary Thyroid Lymphoma is rare comprising less than 5% among all thyroid malignancies. It is historically associated with Hashimoto thyroiditis. It typically presents as a rapidly enlarging, painless goitre resulting in compression symptoms. Thyroid ultrasound and FNA cytology, using flow cytometry and immunohistochemistry, remain the primary modalities to confirm the presence of lymphoma. Treatment depends on the immunohistology. The prognosis is subtype dependend and is generally good. A 53 years old female was seen in the Endocrine clinic with a right sided neck lump. On examination a smooth enlarged right thyroid lobe was noted. Her history suggested Hashimoto’s thyroiditis but she has an enlarged right thyroid lobe. Biochemically her TSH was 11.87 with a FT4 being low/normal at 13. She had positive TPO antibodies. She was referred for a Fine needle aspiration of the right lobe demonstrated lymphoid cells consistent with lymphocytic thyroiditis and was started on Levothyroxine 50mcg as she was symptomatic and an interval scan was recommended in 3 months' time. She was seen in a 4 months' time with her scan results and her thyroid ultrasound showed evidence of lymphoid swelling appeared to have increased in size. A repeat ultrasound confirmed an increase in size compared to previous scans with a 6 cm lymph node. A core biopsy showed features consistent with an Extramedullary marginal zone lymphoma (MALT-type). A staging CT showed stage 2E with FDH avid right thyroid lobe and 4 cervical lymph nodes. A core biopsy showed features consistent with lymphocytic thyroiditis, tumor localisation, thyroid follicular tumour, foci, perineural invasion, capsular invasion, lymphovascular invasion, extra-lymphoid extension, lymph node metastasis and BRAFV600E mutation status were found to be insignificant for complementray thyroidectomy.

Conclusion
We suggest that unifocality or multifocality of single lobe tumor is not determinant for complementary surgery during initial operation. However, long-term follow-up data is required to determine the effect complementary thyroidectomy on prognosis and mortality.

A case report: co-occurrence of medullary thyroid carcinoma and papillary thyroid carcinoma
Beliz Camur1, Mehmet Çelik, Buket Yılmaz Bulbul2, Semra Aytürk2, Ebru Tastekin2, Nuray Can1, Atakan Sezer3, Funda Ustun4 & Sibel Guldiken1
1Trakya University, Medical Faculty, Department of Internal Medicine, Edirne, Turkey; 2Trakya University, Medical Faculty, Department of Endocrinology and Metabolism, Edirne, Turkey; 3Trakya University, Medical Faculty, Department of Pathology, Edirne, Turkey; 4Trakya University, Medical Faculty, Department of Surgery, Edirne, Turkey.

Introduction
Co-occurrence of medullary thyroid carcinoma and papillary thyroid carcinoma in the same patient is unusual. We report a case with this rare event.

Case
A 39 year old woman was presented with cough and shortness of breath. She had no prior history of radiation exposure, cigarette or alcohol consumption and no family history of thyroid cancer. On physical examination, a 3x5 cm thyroid nodule was palpated in the middle portion of thyroid gland, which could be noticed after neck extension. Laboratory examination revealed calcitonin 348 pg/ml(n=0-10), CEA 12.39 mg/L (n: < 5.8 mg/L), FT3: 3.6 pg/ml (n: 1.7-3.8), FT4: 1.41 ng/dl (n:0.7-1.48), TSH:0.53 mU/ml (n:0.35-4.94). Thyroid ultrasonography examination demonstrated a hypoechoic 3*3*5 cm sized nodule invading thyroid gland. 1131 thyroid uptake scintigraphy was negative and autoantibodies were also found to be negative. Cytologic examination of fine needle aspiration biopsy was suspicious for follicular neoplasia. Therefore, she underwent total thyroidectomy. Pathologic examination of the specimen revealed both medullary and papillary thyroid carcinoma. 3.5 cm sized classic variant...
papillary thyroid carcinoma was reactive for thyroglobulin and tumor stage was reported as pT3bN0Mx; 5×3 cm sized medullary thyroid carcinoma was reactive for calcitonin. Investigation for multiple endocrine neoplasia ( MEN ) detected RET protooncogen mutation. She underwent 100 mCi radioactive I131 treatment. Since CEA and calcitonin levels were high during follow-up period, neck ultrasonography was performed, which revealed no pathologic lymphadenopathy. PET/CT examination detected metastasis in the upper lobe of the right lung, mediastinal lymph nodes and liver. The patient was given vandatant chemotherapy by medical oncology department. In conclusion, co-occurrence of medullary and papillary thyroid carcinoma in the same gland has rarely been reported. Occurrence of medullary and papillary thyroid carcinoma are independent; however, common points of pathogenic events can not be ruled out in their carcinogenesis.

Thyroid papillary carcinoma in the patients with resistance to thyroid hormone
Mehmet Celik1, Buket Yilmaz Bulbul1, Sibel Guldenen1, Hakan Gurkan2, Semra Ayturk3, Nuray Can4, Ebub Tastekin5, Atakan Sezer & Funda Ustun6
1Trakya University, Medical Faculty, Department of Endocrinology and Metabolism, Edirne, Turkey; 2Trakya University, Medical Faculty, Department of Nuclear Medicine, Edirne, Turkey; 3Trakya University, Medical Faculty, Department of Pathology, Edirne, Turkey; 4Trakya University, Medical Faculty, Department of Surgery, Edirne, Turkey; 5Trakya University, Medical Faculty, Department of Internal Medicine, Edirne, Turkey.

Resistance to thyroid hormone (RTH) is a genetic disease characterized by a reduced target tissue responsiveness to thyroid hormones and increased or normal TSH level despite elevated levels of thyroid hormones. This condition is mainly caused by mutations of thyroid hormone receptor beta (THRB) gene. The role of THRB mutation in carcinogenesis is still unclear. In here, we report a case of papillary thyroid carcinoma (PTC) with RTH, with a past medical history of subtotal thyroidectomy due to diffuse goiter. A 61-year-old woman was referred to our hospital with recurrence of goiter and displayed elevated serum thyroid hormones and unsuppressed TSH levels. Genetic analysis of THRB identified a missense mutation, (Exon 7, rs752874, c.735C>T) leading to diagnosis of RTH. The neck ultrasonography showed an isoechoic 9×11×11 mm sized nodule, a cystic 13×13×15 mm sized nodule with microcalcification in the right lobe, a 7×9×9 mm sized nodule with thin hypoechoic ring around in the right isthmus, a 9×12×14 mm sized, iso-hypoechoic uniformly restricted nodule with cystic component in the left isthmus and a 17×25×29 mm sized hypoechoic nodule in the left lobe. Ultrasound-guided fine-needle aspiration biopsy was performed for microcalcific nodule in the right lobe. Cytologic examination of fine needle aspiration biopsy specimen was suspicious for follicular neoplasm. Total thyroidectomy was performed. Pathologic examination of thyroid tissue revealed capsulated oncocytic variant papillary thyroid cancer in 32 mm sized nodule in the left lobe and 7 and 2 mm sized nodules in the right lobe. The patient was scheduled for radioactive I-131 treatment. There is no consensus on the management of thyroid carcinoma in patients with RTH. The main concerns are the relationship between differentiated thyroid cancer and thyroid hormone resistance, whether it is a coincidence, how to suppress TSH levels, which treatment regimen should be chosen and which parameters should be considered in the follow-up of these patients. Further studies are required to find scientific answers to these questions.

A rare case: papillary thyroid carcinoma in the ectopic thyroid
Yusuf Durmus1, Mehmet Celik2, Buket Yilmaz Bulbul2, Semra Ayturk2, Ebub Tastekin3, Nuray Can3, Atakan Sezer4, Funda Ustun5 & Sibel Guldenen2
1Trakya University, Medical Faculty, Department of Internal Medicine, Edirne, Turkey; 2Trakya University, Medical Faculty, Department of Endocrinology and Metabolism, Edirne, Turkey; 3Trakya University, Medical Faculty, Department of Pathology, Edirne, Turkey; 4Trakya University, Medical Faculty, Department of Surgery, Edirne, Turkey; 5Trakya University, Medical Faculty, Department of Nuclear Medicine, Edirne, Turkey.

Ectopic thyroid tissue is the localization of thyroid tissue at any place other than the normal localization of the thyroid during the migration of embryonic period. Concurrent normal thyroid tissue may accompany. It usually is seen in women and in the midline. Very rarely thyroid carcinoma can develop. Treatment is like normal thyroid carcinomas, suggesting simultaneous thyroidectomy if accompanied by normal thyroid tissue. A 42-year-old female patient presented with complaints of swelling on the right side of the neck for 3 months. There was no chronic disease or drug use in her story. On physical examination, a painless, moving 30×30 mm mass lesion was detected in the middle cervical region. Imaging revealed a mass lesion in the lower right cervical region near the right lobe of the thyroid gland, 36×25×35 mm heterogeneous signal density same as the thyroid gland. Histopathological examination of the excised mass revealed TTF1 positive, galecin positive, CK19 positive, HBME1 positive and 36×30 mm encapsulated follicular variant papillary carcinoma considered as thyroid carcinoma and lymphoid tissue has not been observed. Thyroid function tests and laboratory findings were normal. Thyroid ultrasonography revealed bilateral hypoechoic and isoechoic nodules maximal 1 cm diameter and malignant lymphadenopathy 2 cm in the left cervical area. As a result of total thyroidectomy + neck dissection, 8 and 9 mm diameter papillary thyroid carcinoma encapsulated follicular variant was detected in the right lobe and thyroid carcinoma metastasis were observed in 3 of 10 lymph nodes removed in the left cervical area. This was evaluated as high-risk thyroid carcinoma and treated with radioactive iodine (RAI-131) at 150 mCi. At post-RAI whole body scan screening, 2 local foci were observed in the thyroid location and were followed up. The patient was followed for 6 months with asymptomatic levothroidine suppression therapy. We aimed to present a rare case of ectopic thyroid carcinoma.

Occurrance of papillary carcinoma with follicular thyroid carcinoma is a rare situation. We report a 49-year-old male with asymptomatic goiter. The first biopsy from the right thyroid lobe from a 6×6×4 cm iso-hypoechochogenic heterogeneous nodule showed bening, hurte cell and thyrocyte rich cytology. Two months later the patient went through right lobectomy which pathology defined as 4.3 cm minimal invasive follicular carcinoma. Two months after right thyroidectomy, a second operation was performed on the left thyroid to complete the process of total thyroidectomy. The specimen was sent to pathology which bore the following result: Papillary microcarcinoma with follicular variant. This was evaluated as high-risk thyroid carcinoma and treated with radioactive iodine(RAI-131) at 100 mCi. At post-RAI whole body scan screening, 2 local foci were observed in the thyroid location and were followed up. This work shows two different

A rare cause of respiratory failure: Anaplastic carcinoma

Ece Celik1, Mehmet Celik2, Buke Yilmaz Bulbul2, Semra Ayturk2, Nuray Can1, Bilkay Sererz & Sibel Guldenk2
1Emir Sultan 1. Murat State Hospital, Department of Chest Diseases, Edirne, Turkey; 2Trakya University, Medical Faculty, Department of Endocrinology and Metabolism, Edirne, Turkey; 3Trakya University, Medical Faculty, Department of Pathology, Edirne, Turkey. 4Trakya University, Medical Faculty, Department of Chest Diseases, Edirne, Turkey.

Anaplastic thyroid carcinoma (ATC) is one of the most aggressive and lethal human malignancies. The median survival time following diagnosis is typically six months or less. Rapidly growing tumors may cause respiratory failure by compressing trachea. A 71-year-old woman presented with 1-month history of dyspnea, cyanosis and rapidly enlarging neck mass for the past 2 weeks. She had been suffering from multinodular goiter disease. Physical examination revealed a large, fixed and mildly tender thyroid mass and cyanotic extremities. Breath sounds were bilaterally decreased on auscultation. Arterial blood gas analysis showed hypoxia. Chest X-ray imaging revealed bilateral multiple nodular opacities, which were found to be bilateral metastatic nodular lesions involving all segments on thoracic tomography. In addition, a 35 × 20 mm sized lingual metastatic lesion invading 5th rib was present in the left lung. Thyroid gland was slightly larger than normal with heterogeneous parenchyma and there were multiple, heterogeneous and hypoechoic nodules, the biggest one was being 30 × 32 × 30 mm in size in the right thyroid lobe. In addition, 2 cm sized multiple necrotic lymph nodes were visible. Laryngoscopic examination demonstrated externally compressed trachea. Tru-cut biopsy of left thyroid lobe detected anaplastic carcinoma with rhabdoid giant cell formation. Despite oxygen supplementation, hypoxic state worsened and the patient was referred to intensive care unit following emergent tracheostomy. In conclusion, although it is rare, anaplastic carcinoma should be considered in the patients presenting with respiratory failure. Anaplastic thyroid carcinoma should be considered in patients presenting with rapidly growing neck mass and respiratory failure.

Our experience of strain elastography in the evaluation of thyroid nodules

Semin Melahat Fenkci1, Mehmet Coskun2, Senay Topsakal1 & Gizin Fidan Yayli1
1Pamukkale University Endocrinology Department, Denizli, Turkey; 2Katip Celebi University Ataturk Hospital Radiology Department, Izmir, Turkey.

Introduction

Thyroid nodule is a common finding in neck ultrasonography performed in adult age group. Appropriate management of patients with thyroid nodules accurately is very difficult process. Fine needle aspiration biopsy (FNAB), is the traditional invasive method used to identify nodules. Investigations are continuing for noninvasive techniques. Elastography is the imaging new technique to evaluate the nodules. Aim of this study to evaluate the results of FNAB and elastography performed in patients with thyroid nodules.

Methods

173 thyroid nodules were examined by Elastography and fine needle aspiration biopsy. Strain elastography was performed with Siemens Acuson s1000 14L5 linear transducer. Elastography findings were evaluated together with b-mode ultrasonography. The susceptible nodules with an S/R ratio of over 2.6 were accepted as malignant nodules.

Results

Results of 155 (89%) FNAB were benign, 18 (10.4%) were malignant. The elastographic appearance was categorized at the time of the examination, 154 (89%) of them were categorized as benign and 19 (10.9%) of them were categorized as malignant. The sensitivity of Elastography for malignancy was 90.0%, specificity was 22.0%, PPV was 21.0% and NPV was 90.0% and accuracy was 83.2%.

Conclusion

Elastography seems to require more experimentation in this regard with hope being a technique. Our study strongly suggests, biopsy is still the most reliable method for the evaluation of nodules.

Association of TIMP-3 expression and BRAF V600E mutation status in papillary thyroid cancer

Maryam Zarkesh1, Mehdi Hedayati1, Azita Zadeh-Vakili1, Afsoon Daneshafrooz2, S Adeleh Razavi1, S-Ahmad Fanaei2, Forough Foroughi1 & Fereidoun Azizi3
1Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; 2Association Professor of General Surgery, Erfan Hospital, Tehran, Iran; 3Department of Pathology, Shahid Beheshti University of Medical Sciences, Tehran, Iran; 4Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Science, Tehran, Iran.

Background

The aim of this study was to assess the association between tissue inhibitor of metalloproteinase-3 (TIMP-3) gene expression and B-Raf Proto-Oncogene (BRAF) V600E mutation in marginal and tumoral tissues of papillary thyroid carcinoma (PTC) patients.

Methods

Sixty fresh frozen tissues of PTC including 55.3% women were collected during thyroidectomy surgery. All clinicopathologic features of subjects were collected which confirmed by a pathologist. The exon 15 of BRAF gene was genotyped by sequencing. TIMP-3 gene expression was assessed using SYBR-Green Real-Time PCR, and the protein level of TIMP-3 was measured using ELISA.

Results

The mean age in men and women was 39.6 ± 15.6 and 37.5 ± 11.6 years, respectively. BRAF mutant was found in 24 (31.6%) of PTC samples. The mean of TIMP-3 mRNA level was higher in marginal tissue compare to tumoral ones (P < 0.05). However, the mean of protein level of TIMP-3 was significantly higher in marginal tissue compare to tumoral (P = 0.001). Moreover, in subjects with BRAF positive mutation, the mean of TIMP-3 gene expression was higher in marginal compare to tumoral tissues (P = 0.066). On the other hand, in subjects without BRAF mutation, the mean of TIMP-3 protein level was significantly lower in tumoral tissues compare to marginal tissue (P = 0.003). However, this difference was not significant in subjects with negative BRAF mutation (P = 0.084).

Conclusion

This study showed that although the gene expression of TIMP-3 was marginally different in two BRAF positive and negative mutation groups, it was significantly different in protein levels.

Histologically-proven Hashimoto’s thyroiditis significantly decreases the risk of structural recurrence in patients with low risk intra-thyroidal papillary thyroid cancer

Vincenzo Marotta,1 Concetta Sciammarella2 Maria Grazia Chiofalo1, Claudio Gambardella3, Claudio Bellavecina1, Marta Grasso1, Giovanni Conzo1, Gerardo Berti1, Simona Losito2,3 Giancarlo Troncone3, Luciano Pezzullo1, Annamaria Colao1 & Antonio Faggiano1
1Department of Clinical Medicine and Surgery, Federico II University, Naples, Italy; 2IOS & COLEMAN s.r.l., Naples, Italy; 3Thyroid and Parathyroid Surgery Unit, Istituto Nazionale per lo Studio e la Cura dei Tumori-IRCCS ‘Fondazione G. Pascale’, Naples, Italy; 4Department of Anesthesiologic, Surgical and Emergency Sciences, Division of General and Oncologic Surgery, University of Campania Luigi Vanvitelli, Naples, Italy; 5Department of Public Health, University of Naples ‘Federico II’, Naples, Italy; 6San Giovanni di Dio e Ruggi D’Aragona, Universitary Hospital, Division of General Surgery, University of Salerno, Salerno, Italy; 7Department of Pathology, Istituto Nazionale per lo Studio e la Cura dei Tumori-IRCCS ‘Fondazione G. Pascale’, Naples, Italy.

Introduction
Due to the absence of randomized controlled trials, management of low risk papillary thyroid cancer (PTC), which represents the most commonly diagnosed form of thyroid malignancy, remains controversial. Hashimoto’s thyroiditis (HT) is significantly more frequent in patients with PTC, as compared with subjects carrying benign lesions as well as different tumour histotypes. Despite still controversial, HT is considered a protective factor in PTC being associated with favourable tumour features and better outcome. Nevertheless, all studies dealing with this issue included all PTC stages. We aimed to assess prognostic value of histologically-proven HT in a large cohort of consecutive low-risk intra-thyroidal PTC.

Patients and methods
Multicenter retrospective study including pT1/2 PTC without any evidence of extra-thyroidal disease, who were subjected to surgery and follow-up within the involved centers. Pathological review of all specimens was performed. Co-existing HT was defined by the presence of diffuse/focal lymphoplasmacytic infiltrate, oxyphilic cells, lymphoid follicles with germinal centers, and atrophic changes involving normal thyroid tissue, whereas isolated peri- and intra-tumoral lymphocytic infiltration was not considered as HT. Study endpoint was recurrent structural disease.

Results
Two-hundred eighty-four patients (156 without and 128 without HT) were included. Mean follow-up was 75 ± 61 months (6.3 years). Concomitant HT was related to significantly lower rate of recurrent structural disease (P = 0.018, OR 0.33 95% CI 0.13–0.86). This finding was confirmed by survival analysis, where PTC with HT showed significantly higher recurrence-free time. After adjustment for other variables affecting prognosis at univariate analysis (age at diagnosis, tumour size, multifocality, and post-surgery radiometabolic treatment), concomitant HT retained its protective effect (P = 0.036, OR 0.34 95% CI 0.12–0.93).

Conclusions
In our series of low risk intra-thyroidal PTC, concomitant HT independently predicted recurrent structural disease and may therefore represent a useful tool for the decision-making process of these patients.

EP1408
Evaluation of disease outcome in patients affected with differentiated thyroid carcinoma treated with total thyroidectomy or lobectomy

Carla Colombo1, Simone De Leo1, Michela Perrino1, Marta Di Stefano1, Giannaria Cantoni1, Leonardo Vicentini1 & Laura Fugazzola1,2
1University of Milan, Milan, Italy; 2Istituto Auxologico Italiano, Milan, Italy. 3Fondazione Policlinico Ca Granda, Milan, Italy.

Abstract
An individualized risk-based approach to the treatment of thyroid cancer is being extensively discussed in the recent literature, but controversies remain about the ideal surgical approach. In particular, if some data showed that properly selected thyroid cancer patients can be treated with lobectomy (LT) with excellent clinical outcomes, other results demonstrated an increased incidence of persistent recurrent disease in patients submitted to LT with respect to those treated with total thyroidectomy (TT). This study was aimed to describe clinical outcomes in a retrospective large series of low and intermediate risk thyroid cancer patients treated with LT or TT.

Methods
We evaluated retrospectively 336 patients affected with differentiated thyroid cancers (DTC); 292 of them were treated with TT and 44 with LT. The initial surgical treatment was not chosen based on the risk class. The median age was 48 yrs, 274 were females and 62 males. Remission or persistent/recurrent disease was defined on the basis of biochemical and/or structural evidence of disease after a median follow-up period of 65 months.

Results
Only 1/292 patients treated with TT needed additional therapy (surgery for malignant lymph node metastases), and none of them was submitted to radioiodine ablation. On the other hand, 15/44 patients treated with lobectomy were submitted to following treatment (completion thyroidectomy alone in 3, associated with lymphadenectomy and radioiodine treatment in 12 cases). As far as the outcome concerns, remission was documented in 281/292 cases (96.2%) and 3044 cases (68.2%) in the TT and LT groups, respectively (P < 0.0001).

Conclusions
Our data suggest that lobectomy should be performed only in patients with a very low risk at diagnosis, in order to avoid the need for a second treatment. Moreover, since virtually all patients treated with TT were cured after surgery, our data support the selective use of radioiodine ablation treatment.

EP1409
Does the delayed risk stratification system help to evaluate the risk of unfavorable clinical outcome in pT1aN0/Nx stage patients with differentiated thyroid cancer treated without radioactive iodine? Danna Gasior-Perczak1, Iwona Palijga1, Monika Szymonek1, Agnieszka Walczyk1, Janusz Kopczynski1, Anna Slusznik1, Ryszard Mezyk1, Stanislaw Godz1,2 & Aldona Kowalska1,2
1Holycross Cancer Centre, Kielce, Swietokrzyskie, Poland; 2Jan Kochanowski University, Kielce, Swietokrzyskie, Poland.

Introduction
In ATA recommendations (2016) a delayed risk stratification (DRS) system was proposed by D.P. Momesso et al. was accepted as a diagnostic tool for the risk stratification of unfavorable clinical outcome and for monitoring the clinical outcome in differentiated thyroid cancer (DTC) patients treated without radioactive iodine (RAI). The aim of the study
To evaluate the DRS system in patients with low clinical stage (pT1aN0/Nx).

Material
304 patients after total thyroidectomy (n = 202) or lobectomy (n = 102) without adjuvant RAI therapy, with a follow-up period of at least 24 months, treated at a single center were enrolled to the study. The median age was 50.5 years, 91.1% were women, 100% at baseline had a low risk according to ATA, the median follow-up was 4 years (2–24).

Methods
DRS of the treatment response was conducted, based on the medical records, according to the criteria by Momesso et al. The course of the disease was evaluated (remission, death) as well as the status on 31.12.2016, which is the end of the follow-up (remission, persistent disease). The relationship between unfavorable outcome and the DRS system was evaluated.

Results
The response to initial therapy was excellent in 272 patients (89.5%), intermediate in 31 patients (10.2%) and biochemically incomplete in 1 patient (0.3%) (increased concentration of TgAb). There was a recurrence in 2 patients from the excellent response group at 6 and 7 years of follow-up (after lobectomy). No patients with intermediate and biochemically incomplete response were diagnosed with the structural disease and none of the patients died during the follow-up.

Conclusions
The DRS system did not prove useful in predicting the risk of unfavorable clinical outcome and cannot be used to personalize the monitoring method of the disease in patients at pT1aN0/Nx, not treated with RAI.

The impact of post-radioiodine therapy SPECT/CT on risk stratification in differentiated thyroid cancer: a bi-institutional study

Szabina Szajo1, Livia Sira2, László Bajnok1, Beata Bodis1, Ferenc Gyory1, Orosolya Nemes1, Karoly Ruca3, Péter Kenyeres1, Zsuzsanna Valkús2, Krisztian Sepp2, Erzsebet Schmidt1, Zsuzsanna Szabo1, Sarolta Szekeres1, Katalin Zambo1, Sandor Barna1, Endre V Nagy1 & Emese Mezosi1
11st Department of Medicine, University of Pecs, Pecs, Hungary; 2Department of Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary; 3Department of Nuclear Medicine, University of Pecs, Pecs, Hungary; 4Department of Nuclear Medicine, Faculty of Medicine, University of Debrecen, Debrecen, Hungary; 5Department of Surgery, Faculty of Medicine, University of Debrecen, Debrecen, Hungary; 61st Department of Medicine, University of Szeged, Szeged, Hungary.

Objective
SPECT/CT has numerous advantages over planar and traditional SPECT images. The aim of this study was to evaluate the role of post-radioiodine therapy SPECT/CT of patients with differentiated thyroid cancer (DTC) in early risk classification and in prediction of late prognosis.

Patients and Methods
323 consecutive patients, 181 at the University of Pecs and 142 at the University of Debrecen, were investigated after their first radioiodine treatment (1100–3700 MBq). Both SPECT/CT and planar camera images of the head, neck, chest and abdomen regions were taken four days after radioiodine therapy. Patients were re-evaluated 9–12 months later as well as at the end of follow-up (median 37 months).

Results
Post-radioiodine therapy SPECT/CT showed metastases in 22% of patients. Lymph node, lung and bone metastases were detected in 61, 13 and 5 patients, respectively, resulting in early reclassification of 115 cases (36%). No evidence of disease was found in 251 cases at 9–12 months after radioiodine treatment and 269 patients at the end of follow-up. To predict residual disease at the end of follow-up, the sensitivities, specificities and diagnostic accuracies of the current risk classification systems and SPECT/CT were: ATA: 77%, 47% and 53%; ETA: 70, 62 and 64%; SPECT/CT: 61, 88 and 83%, respectively. There was no difference between cohorts of the two institutions when data were analyzed separately.

Conclusions
Based on our bi-institutional experience, the accuracy of post-radioiodine SPECT/CT outweighs that of the currently used ATA and ETA risk classification systems in the prediction of long-term outcome of DTC.

Clinical features of medullary thyroid carcinoma (MTC) in simultaneous occurrence with differentiated thyroid cancer (DTC)

George Simeakis, Katerina Saltiki, Elli Anagnostou, Michalis Apostolakis, Vasiliki Vasileiou & Maria Alevizaki
Endocrine Unit, Department of Medical Therapeutics, Alexandra Hospital, Athens University School of Medicine, Athens, Greece.

Objective
Simultaneous occurrence of MTC and DTC is frequently found. It is unclear whether there is a common pathogenic mechanism. Aim of our study was to characterize clinical features of MTC when coexisting with DTC.

Methods
Of 273 MTC patients followed-up in our department 39 (14.3%) had MTC simultaneously with DTC. They were divided in 4 subgroups according to size. Clinical histopathological data were recorded.

Results
The patients were followed for 1–35 yrs (median:5). Median age at diagnosis was 45 yrs (4–81 yrs). Simultaneous occurrence of distinct MTC-DTC was observed more frequently in patients diagnosed after 2001 compared to earlier (16.7 vs 6.3%, P = 0.036). Sex and history of familial disease did not differ. In familial forms of MTC, DTC occurrence was higher in carriers of RET exon 8 (G535C) mutation compared to other RET mutations (17.6 vs 1.8%, P = 0.004). Patients with concomitant MTC-DTC had less frequently lymph node infiltration from MTC compared to those with MTC alone (26.3 vs 47.3%, P = 0.015), marginally smaller MTC size (median (IQR) 9.1 (5.1) vs 1.2 (1.4) cm, P = 0.058) and more often c-cell hyperplasia (58.6 vs 31.5%, P = 0.006). No differences were found regarding capsular and soft tissue invasion, multifocality, distant metastases at diagnosis. Stage at diagnosis differed between groups (MTC-DTC vs MTC alone).

Endocrine Abstracts (2017) Vol 49

Stage I+II:71.8 vs 49.8%, III:20.5 vs 27.6%, IV:7.7 vs 22.7%, P = 0.007) with the difference remaining significant in both sporadic (P = 0.022) and familial MTC (P = 0.035). MTC-DTC group had marginally better disease prognosis compared to MTC alone (remission: 67.6 vs 48.7%, stable: 16.2 vs 25.2%, progression: 16.2 vs 26.1%, P = 0.05). The 10-year probability of lack of progression of disease did not differ between the two groups. Size of DTC did not seem to affect the clinical course of MTC-DTC.

Conclusions
Simultaneous occurrence of MTC-DTC is occasionally diagnosed. Even though stage at diagnosis is better in MTC-DTC patients, there is no difference in 10-year probability of lack of progression of disease. We report for the first time an increased incidence of DTC in RET exon 8 (G535C) carriers. Whether this mutation-quite common in Greek MTC patients-might participate in shared pathogenic mechanisms needs further investigation.

Concomitant thyroid inflammatory myofibroblastic and follicular tumors

Romena Laukiene, Audra Padlipskaitė & Edvardas Zurauskas
Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania.

Abstract
We present a rare clinical case. Inflammatory myofibroblastic tumors (IMT) are extremely rare neoplasms of unknown etiology and most commonly found in lungs and gastrointestinal tract. A rare clinical case of the thyroid IMT occurred in a 30-year-old Lithuanian female patient with clinical manifestation of breathlessness, dry cough, hemoptysis, neck mass, arrhythmia and loss of consciousness. Because of elevated D dimers values, pulmonary artery thromboembolism was suspected and CT scan was performed. CT showed no pulmonary embolism, but revealed a large tumor in the neck. After patient was investigated in cardiology department to exclude sick sinus syndrome, fine needle aspiration cytology of thyroid nodus was done with non-diagnostic results. Thyroid scintigraphy showed cold node suggesting malignancy. All symptoms and findings indicated the need of surgical treatment. The patient underwent total thyroidectomy. Histopathology analysis revealed two separate tumors: follicular carcinoma and thyroid inflammatory myofibroblastic tumor. Because of follicular carcinoma the patient was treated with radioidine. She was comfortable after treatment with thyroid hormone replacement therapy. We managed to find only 20 cases of this type of tumor located in thyroid reported in the literature. And we did not find reports with two concomitant thyroid tumors including IMT.

Is thyroid imaging reporting and data system useful in prediction of malignancy in thyroid nodules with persistent nondiagnostic cytology?

Husniye Baser1, Oya Topaloglu2, Sevgul Faki3, Atra Alkan1, Mustafa Omer Yazicioglu1, Hayriye Tatli Dogan2, Reyhan Ersoy2 & Bekir Cakir2
1Ataturk Education and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; 2Yildirim Beyazit University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; 3Yildirim Beyazit University Faculty of Medicine, Department of Biostatistics, Ankara, Turkey; 4Yildirim Beyazit University Faculty of Medicine, Department of General Surgery, Ankara, Turkey; 5Yildirim Beyazit University Faculty of Medicine, Department of Pathology, Ankara, Turkey.

Introduction
Although malignancy rate is low in thyroid nodules with nondiagnostic (ND) cytology, it is reported as higher in persistent ND nodules. We aimed to determine the role of ultrasonography (US) features and Thyroid Imaging Reporting and Data System (TIRADS) in the prediction of malignancy in patients with persistent ND cytology.

Methods
246 patients who underwent thyroidectomy with an indication of at least two ND cytologies were included in this study. Suspicious US features (solid component,
hypoechogenicity, irregular margin, microcalcification, and taller-than-wide shape) and TIRADS categories (TIRADS category 3, 4a, 4b, 4c and 5) of each nodule were obtained from medical records.

Results
Of the 246 patients, 218 (88.6%) had benign and 28 (11.4%) had malignant final histopathology. Of these 28 patients with malignant histopathology, 25 (89.3%) were evaluated as papillary thyroid carcinoma, 1 (3.6%) as follicular thyroid carcinoma, 1 (3.6%) as medullary thyroid carcinoma, and 1 (3.6%) an undifferentiated thyroid carcinoma. Frequencies of taller-than-wide shape, solidity, hypoechogenicity, microcalcifications, and irregular margins were similar in benign and malignant groups ($P > 0.05$, all). TIRADS categories of 246 nodules with ND cytology were as follows: 12 (4.9%) TIRADS 3, 53 (21.3%) TIRADS 4a, 104 (42.3%) TIRADS 4b and 77 (31.3%) TIRADS 4c. There was not any nodule with TIRADS 5 category. Malignancy rates of categories 3, 4a, 4b, and 4c nodules were 0, 13.2, 9.6 and 14.3%, respectively. No significant differences were found in TIRADS categories between benign and malignant nodules ($P > 0.05$, all).

Conclusion
In the present study, malignancy rate was found as 11.4% in nodules with persistent ND cytology. There was not any suspicious US feature that was predictive for malignancy in ND nodules. Thyroid nodules in TIRADS 4a, 4b and 4c categories had higher malignancy rates than estimated risk of malignancy reported by the Bethesda system in ND cytology.

**Significant difference between the prevalence of C cell hyperplasia (CCH) in benign thyroid nodules without histological thyroiditis (HT) and in papillary/follicular thyroid cancers (PTC/FTC) at histology**

Letizia Pieruzzì1, Eleonora Molinari1, Laura Agata1, Valeria Bottici1, Liborio Torregrossa2, Clara Ugolini1, Fulvio Basolo1, Paolo Vitti1 & Rossella Elisei1

1Medical Area and Experimental Medicine Department, Endocrinology section, University of Pisa, Pisa, Italy; 2Department of Oncology Section of Cytopathology, Pathology, University of Pisa, Pisa, Italy.

**Aim of the study**
To evaluate the difference in the CCH prevalence, at histology, in a series of benign (BTN) and malignant (PTC/FTC) thyroid nodules. The correlation with the serum CT was also analysed.

**Materials and methods**
We selected 315 consecutive cases surgically treated between 2012 and 2016 in our Hospital: 137/315 (43.5%) resulted to be BTN and 178/315 (56.5%) to be PTC/FTC. In 27/315 (8.5%) cases there was a serum iperCT (Immulite 2000, Siemens). The definition of CCH was based on the presence of more than 50 C-cells at least in one microscope field, in a thyroid cross section.

**Results**
At a first analysis no differences were observed in the prevalence of CCH between BTN and PTC/FTC. When we excluded from the analysis the cases with reported HT, both benign and malignant, the prevalence of CCH was statistically more frequent and bilateral in PTC/FTC (32.6%) than in BTN (19.5%) ($P < 0.001$). The cases with iperCT were exclusively in the PTC/FTC group and among them those case with iperCT showed the highest prevalence of CCH ($P < 0.001$). In PTC/FTC with serum iperCT we observed that 11/21 (52.4%) were FTC without iperCT ($P = 0.004$). But there was no significant difference between other stages. Additionally, subjects with lymph node at diagnosis had higher TSH levels according to patients who had not (2017)

**Conclusion**
CCH is more frequent in PTC/FTC than in BTN when the cases with HT were excluded; the serum iperCT was found exclusively in the PTC/FTC group and these cases showed the highest prevalence of CCH; a higher prevalence of FTC and multifocal cases were observed in the PTC/FTC group associated with CCH.

**Primary thyroid lymphoma: a differential diagnosis to be considered**

M Teresa Gallego, Lucia Vera, Cristina Del Peso, Amanpro Meroor, Manuel Martin, Marife Candell, Emilio Terol & Francisco Pastor

Hospital General Universitario Reina Sofia, Murcia, Spain.

**Introduction**
Primary lymphoma of the thyroid, although rare, should be considered in the differential diagnosis of patients with thyroid nodules or goiter, because its prognosis and treatment differ substantially from that of the other disorders. Thyroid lymphomas are nearly always of the non-Hodgkin type (70–80% B cell lineage). There is a 4:1 female predominance and the mean and median ages at diagnosis are between 65 and 75 years. Hashimoto’s thyroiditis is the only known risk factor.

**Case report**
A 70 years old woman with a rapidly enlarging goiter without local symptoms or signs. The patient presented a history of hypothyroidism on treatment with thyroxine. Her tiroglobulin antibodies were positives but not TPO. An ultrasound scan of the thyroid showed a 7-cm mass in the left lobe and istm. The fine needle biopsy was nondiagnostic but suggestive of Hashimoto’s thyroiditis. The excisional biopsy confirmed the diagnosis of a diffuse large B-cell lymphoma. Imaging studies demonstrated cervical and mediastinal lymph nodes and bilateral pulmonary metastases.

**Discussion**
Thyroid lymphoma represents no more than 2% of all malignant thyroid tumors. The vast majority are of the non-Hodgkin type, the most frequent the B-cell lineage. The typical presentation is a rapidly enlarging goiter with symptoms or signs of tracheal, esophageal or neck vein compression. In 10–20% there is a known goiter often with hypothyroidism. Up to 10% have systemic (“B”) symptoms of lymphoma (fever, night sweats, weight loss). Diagnosis is established by cytotologic examination; when the fine needle biopsy is nondiagnostic the excisional biopsy is required. The treatment includes Radiation and Chemotherapy. Definitive surgery is not usually performed. Our patient was treated with six cycles of CHOP followed by radiation.

**Conclusions**
Thyroid lymphoma is a rare cancer but must be considered in the differential diagnosis of patients with thyroid nodules or goiter specially if a Hashimoto’s thyroiditis is present. The risk of Thyroid lymphoma is at least 60 times higher than in patients without thyroiditis. The treatment is not the surgery like in the others thyroid pathologies and the prognosis depends on the type and tumour extension.

**Relation between TSH levels and the aggressiveness of differentiated thyroid carcinomas**

Esra Aydilini1, Mustafa Kulaksizoglu1, Ahmet Kaya1 & Feridun Karakurt1

1Necmettin Erbakan University, Meram Medical Faculty, Division of Endocrinology and Metabolism, Konya, Turkey.

**Aim**
Differentiated thyroid carcinomas (DTC) composes 95% of all thyroid malignancies originating from thyroid follicular epithelial cells. DTC expresses TSH receptors so long time TSH stimulation may cause cancer occurrence or malignancy progression. So we aimed to assess the role of TSH levels in predicting thyroid cancer stage or aggressiveness.

**Methods**
We retrospectively searched thyroid cancer patients fort he last 10 years in our institution. Totally 329 patients record were eligible for the study. TSH levels and disease stage, age and sex were evaluated.

**Results**
322 (97.9%) were papillary thyroid carcinomas and 7 (2.1%) were follicular carcinomas 261 (79.3%) were females, 68 (20.7%) were males. Median age was 45 (17–76) years old. Among the patients; 273 (83.6%) had stage 1 disease, 22 (6.7%) had stage 2 disease, 11 had (3.3%) stage 3 disease and 23 (7.0%) had stage 4 disease. Median TSH level was 1.34 (0.01–9.97) mIU/mL. Serum TSH levels were different when compared stage 1 and 4 patients ($P = 0.004$). But there was no significant difference between other stages. Additionally, subjects with lymph node at diagnosis had higher TSH levels according to patients who had not ($P = 0.0001$).

Endocrine Abstracts (2017) Vol 49
Conclusion
Higher TSH levels were observed in patients with lymph node metastasis at the diagnosis and there was statistically higher TSH levels in stage 4 patients compared to stage 1 patients. But this relation was not seen in other stages. Further studies with larger number of patients could show the relation with TSH levels and thyroid cancer aggressiveness.

Ultrasoundographic features of thyroid nodules with suspicious or malignant cytology
Vasilieos Chambidis, Athanasios Sioslos, Lazaros Lazarou, Zoe Eliasdiadiou, Athanasios Panagiototou, Fotini Adamidiou & Marina Kita
Hippokration General Hospital of Thessaloniki, Thessaloniki, Greece.

Introduction
Thyroid sonography has become the first line diagnostic procedure for thyroid nodules. The characterization of specific sonographic patterns associated with high risk of malignancy has enabled physicians to determine which nodules are more likely to be malignant and thus merit further evaluation.

Aim
We investigated whether the ultrasoundographic nodule characteristics proposed in the literature were able to predict cytology findings after ultrasound-guided fine needle aspiration biopsy (USg-FNAB), in our centre.

Materials and methods
A retrospective analysis of patients who had undergone USg-FNAB between Jan 2014 and Nov 2015 was performed. Nodules were classified according to the following sonographic characteristics a) size, b) solid hypoechoic nodule, c) presence of microcalcifications, d) irregular borders, e) vertical growth (‘taller-than-wide’ orientation), and, f) increased vascularity. Cytology reports were classified, according to the Royal College of Pathologists guidance, as non-diagnostic for cytological diagnosis (Thy1), negative for malignancy (Thy2), neoplasm possible (Thy3), suspicious for malignancy (Thy4) and malignant (Thy5). Category Thy1 nodules were excluded from the analysis. The association of suspicious ultrasound characteristics with the composite cytology outcome of possible neoplasm, suspicious or malignant (Thy3, Thy4, Thy5) was investigated.

Results
During the study period, 736 nodules in 571 patients were biopsied. The most common ultrasoundographic feature was low echogenicity (175/736, 23.8%), whereas the most rear was the vertical nodule growth (‘taller-than-wide’ appearance, 28/736, 3.8%). In a logistic regression model, where patient age was entered along with the ultrasoundographic features, all variables emerged as predictors of the composite category Thy3, Thy4, Thy5 cytology, except vertical nodule growth and increased vascularity.

Conclusion
Sonographic nodule characteristics proved to be accurate predictors of cytology in the present patient series. Thyroid ultrasoundography is a useful tool in determining which nodules should be biopsied.

Statistical analyses on thyroid cancer in Romania
Mariana Purice1, Andrei Liviu Goldstein1, Iulie Andreea Chiriac2, Monica Radulescu3, Sorin Rusu3, Alexandrina-Cristina Mihal3, Andreea Giurgi3, Madalina Olteanu3, Adina Mariana Ghemigian1,2 & Catalina Poiana1,4
1-C.I.Parhon’ National Institute of Endocrinology, Bucharest, Romania; 2SOFTWIN S.A, Bucharest, Romania; 3Universite Paris I Pantheon Sorbonne, Paris, France; 4‘Carol Davila’ University of Medicine and Pharmacy, Bucharest, Romania; 5Faculty of Biology, University, Bucharest, Romania.

For over 50 years the casuistic of patients with thyroid cancer registered in the Nuclear Medicine Department of the National Institute of Endocrinology in Bucharest, Romania, has over 12 000 cases. In the last 6 years, a total of 2580 new cases have been added. They are organized in a ‘classic file’ format. As a necessity and the first step in order to build a digital national database, we developed the BIOMAT-ENDO software as a Windows Forms application that stores all the main data regarding the patient hospitalized in the department, starting with the first hospitalization, continuing with all the periods of endocrinotherapy and the follow up. The patient-monitoring MODULE contains: clinical parameters, surgery details, in vivo and in vitro investigations, therapy information. Correlations can be done between any input data. We present preliminary results on 2000 cases of patients with thyroid cancer digitalized during one year in this database. We used the Structured Query Language in order to verify the functionality of the system, the correctness of the existing data and for some preliminary statistics. Results shows the following distributions: onset disease age: < 18 year: 3%; 19–45 year: 37%; 46–65 year:42%; > 66 year:18%; genders: F:84%; M:16%; M, area distribution: urban:74%; rural:26%; personal history: multi nodular & nodular goitre: 81%; Graves’s 1%; Hashimoto: 1%; no history:16%; risk factors: endemia area:70%; non-endemia area:30%; histopathology: papillary/follicular:30%; papillary: 28%; follicular: 17%; micro-carcinoma: 20%; others: 5%. Preliminary results on a target group with the onset disease age <18 years (n=58) show the following distribution on: TNN: T1:7%; T2:14%; T3:19%; T4:5%; unclassified: 9% and on disease stage: STD1:57%; STD2:4%; STD3:23%; STD4a:10% and STD 4b:6%.

Prognostic value of preoperative serum calcitonin concentration on primary surgery outcomes in medullary thyroid cancer
Tomasz Gawlik, Aleksandra Kukulska, Zbigniew Wygoda, Jolanta Krajewska, Ewa Stobiecka, Agnieszka Czarnecka & Barbara Jawarz Maria Sklodowska-Curie Medical Institute and Centre of Oncology, Glivice Branch, Glivice, Poland.

Case report
A 46-yr-old man presented to the emergency department with a painful mass on the anterior side of his neck. Laboratory tests revealed leukocytosis, while thyroid functions tests, calcitonin, carcinoembryonic antigen and calcium levels were in the normal limits. Neck ultrasound revealed an enlarged thyroid gland with a 2.5 cm dominant nodule on the right thyroid lobe. Fine-needle aspiration cytology showed ‘atypia of undetermined significance’ (AUS). The patient underwent total thyroidectomy. Histological examination revealed a papillary carcinoma 1.4 cm in diameter, with central fibrosis, degenerative necrosis and the presence of foam histiocytes. It also showed multiple solid cell nests, nodular hyperplasia and rare lymphoid aggregates in the rest area of the thyroid.

Discussion
Rare cases of concurrent PTC up to 1 cm and SCNs have been described in the literature. SCNs may harbour multipotent stem cells which after a combination of mutations affecting their differentiation and unlimited growth potential may generate cancer stem cells predisposing to thyroid cancer. Immunohistochemical and molecular studies of neoplastic SCN lesions are needed to better understand the complexity of stem cells and their malignant counterparts, advancing our knowledge on thyroid pathophysiology, carcinogenesis, and treatment.

DOI: 10.1530/endoabs.49.EP1418

Endocrine Abstracts (2017) Vol 49
Calcitonin assessment in thyroid diseases is recommended when medullary thyroid cancer (MTC) is suspected in fine needle biopsy, as well as in ‘suspicious for a follicular neoplasm’ class, especially oxyphilic type, in patients with germinal RET proto-oncogene mutation and in nondiagnostic biopsy when no surgical treatment is planned. This assessment is also suggested before any planned thyroid surgery to exclude MTC. Beyond diagnosis confirmation it is also suggested to take the concentration into account planning the extent of neck lymph node resection, although the threshold values are not precisely established. The aim of this work was to assess the prognostic impact of preoperative serum calcitonin concentration on primary surgery outcomes in medullary thyroid cancer. Among 1575 MTC patients followed-up in single clinical centre 248 patients were identified in whom serum calcitonin concentration before primary thyroid surgery was available (63 men and 185 women). Its mean concentration was 3647.8 ± 18862.7 pg/ml (median – 612 pg/ml, max. 286 643, min. 2 pg/ml).

All patients underwent total thyroidectomy, and in 233 at least central and unilateral neck lymph node resection. In postoperative assessment in 145 patients serum calcitonin was undetectable and in 187 remained within normal ranges for healthy population (<10 pg/ml; in 11 of them in the follow-up calcitonin increased). In 217 patients after surgery no macroscopic cancer foci were visible in the imaging, and in further follow-up in 11 metastases or recurrence were found. Maximal preoperative concentration in patients who had no nodal metastases and normal calcitonin after surgery was 2513.8 pg/ml. Maximal preoperative concentration in patients in whom postoperative calcitonin was normal and were free from relapse in further follow-up was 15302.0 pg/ml. The minimal preoperative calcitonin in patients with histologically confirmed neck nodal metastases was 23 pg/ml. Conclusions: High preoperative serum calcitonin concentration up to a value of almost 12 000 pg/ml does not exclude the possibility of radical surgical treatment in MTC patients. Neck nodal MTC metastases can be found when serum calcitonin is as low as 23 pg/ml.

**Conclusion**

- **Incidental thyroid uptake detected by** $^{68}$Ga-DOTANOC positron emission tomography: is it clinical significant?
  - Tiago Nunes da Silva$^1$, Joaquim Gomes Santos$^2$, Ana Cataria Matos$^1$, Joao Pedro Teixeira$^1$, Carla Oliveira$^1$, Joana Castanheira$^1$, Susana Carmona$^1$, Hugo Duarte$^1$, Durval Costa$^1$, Luis Oliveira$^1$, Ana Isabel Santos$^2$ & Jorge Portugal$^1$
  - $^1$Endocrinology Department Hospital Garcia de Orta, Almada, Portugal; $^2$Nuclear Medicine Department Hospital Garcia de Orta, Almada, Portugal; $^3$Nuclear Medicine Department – IPO Porto, Porto, Portugal; $^4$Nuclear Medicine department Champalimaud Centre for the Unknown, Lisboa, Portugal; $^5$Nuclear Medicine Unit – Oncological Centre Dr. Nazalia Chaves/Joaquim Chaves Salde, Carnaxide, Portugal.

- **Background**
  - The detection of thyroid incidental uptake of radiopharmaceuticals has been increasing. Those detected by $^{18}$F-fluorodeoxyglucose positron emission tomography (PET) have been associated with a significant risk of malignancy (8-64%). Gallium-68 ($^{68}$Ga)-labelled peptides are now the standard imaging modality for staging neuroendocrine tumours (NET). Its high sensitivity has increased the discovery of incidental findings. The aim of this study was to evaluate the frequency and clinical significance of incidental thyroid uptake as detected by $^{68}$Ga-DOTANOC PET in patients without a history of thyroid cancer.

- **Methods**
  - A retrospective analysis was conducted over 49 patients who underwent $^{68}$Ga-DOTANOC PET as part of a work-up for non-thyroid cancer. The uptake in the thyroid gland (focal/physiological) was evaluated and compared with the uptake in the liver.

- **Results**
  - 24 (49%) of the 49 patients were female with a median age of 64 years (p25 53 and p75 74). Thyroid nodules were known in 14 patients with a median size of 0.1 ± 0.4 mm. The reasons for $^{68}$Ga-DOTANOC PET staging were: intestinal NET in 29 (59.2%), bronchial NET in 10 (20.4%), pancreatic NET in 5 (10.2%), paraganglioma in 2 (4.1%), an ectopic ACTH in one (2%), ectopic GH in 1 (2%) and meninigoma in 1 (2%). Eight patients (16%) had $^{68}$Ga-DOTANOC thyroid uptake; one (2%) had an anomalous focal uptake, and 7 (14%) had physiological uptake. The patient with focal uptake, had thyroid nodules on the corresponding side, as detected by anatomic imaging with a final diagnosis of a benign nodule. Of the seven patients with physiological uptake, 3 (47%) had a corresponding nodule on ultrasonography and 1 (14%) had a papillary thyroid carcinoma. Ten patients with known nodules did not have $^{68}$Ga-DOTANOC uptake, including a follicular tumour.

- **Conclusions**
  - In contrast to the published research of $^{68}$Ga-DOTANOC uptake in patients with known thyroid cancer, in our short series, the incidental uptake in thyroid gland does not seem to be related.

**EP1423**

**An association between breast cancer and the development of thyroid cancer**

Lila Brakni

Hospital of Army MS Nekkache, Algiers, Algeria.

**Introduction**

Women with breast cancer (BC) have an increased risk of developing thyroid cancer (TC), specifically papillary and follicular thyroid carcinomas at a median of 5 years. The aim of the present retrospective study is to describe the clinical characteristics of women who present this association.

**Results**

A total of 260 patients with an authenticated TC who were the median age at diagnosis is 41 years old (36–65). All our patients live in areas of moderate iodine deficiency. The frequency of the association of BC-TC = 6/260 (4.3%). The median duration between the two diagnoses = 24 months (12–84). The BC has always preceded the TC. The histopathological aspects are respectively for the BC: invasive ductal carcinoma (n = 4) invasive lobular carcinoma (n = 2) and TC: pure vesicular (n = 2); Papillary (n = 4). All these women underwent chemotherapy, hormone therapy and radiotherapy for BC and total thyroidectomy and an irradiation (100 mCi 131) for TC.

**Standardized mortality of thyroid cancer in Korea between 1985 and 2015: analysis of Korean national data**

Yun Mi Choi$^1$, Won Gu Kim$^1$, Hyerni Kwon$^1$, Min Ji Jeon$^1$, Minkyu Han$^2$, Tae Yong Kim$^2$, Young Kee Shong$^2$, Sang Mo Hong$^1$, Eun-Gyoung Hong$^1$, Soo-Jong Kim$^1$ & Won Bae Kim$^1$

- $^1$Hallym University Dongtan Sacred Heart Hospital, Seoul, Republic of Korea; $^2$Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea.

- **Background**
  - The prevalence of thyroid cancer has increased very rapidly in Korea. However, there is no data focusing on thyroid cancer mortality in Korea. In this study, we aimed to evaluate standardized thyroid cancer mortality using national data from Statistics Korea.

- **Methods**
  - Population and mortality data from 1985 to 2015 were obtained from Statistics Korea. Age-standardized mortality rates (ASMR) of thyroid cancer per 100 000 were calculated according to the standard population of Korea, as well as World Health Organization (WHO) standard population and International Cancer Survival Standard (ICSS) population weights.

- **Results**
  - The ASMRs of thyroid cancer was decreased from 0.19 to 0.87 between 1985 and 2004, and the ASMRs were decreased from 2005 until 0.43 in 2015. The estimated annual percent change (APC) from 1985 to 2004 was 7.64 and corresponding value from 2004 to 2015 was −4.28. These changes in the ASMRs were similar patterns in males (APC 8.23, 1985–2003 and APC −4.33, 2003–2015) and females (APC 7.33, 1985–2004 and APC −4.63, 2004–2015). These patterns of the change of ASMR were also observed in elderly subgroup (≥55 years).

  - When ASMRs were calculated based on the WHO standard population and ICSS population weights, those was similarly increased until 2004, and decreased from 2004.

- **Conclusion**
  - Thyroid cancer morality in Korea was increased until 2004 and started to decrease after then. The increase in early diagnosis of thyroid cancer might be associated with decrease of thyroid cancer mortality in Korea.

**DOI:** 10.1530/endoabs.49.EP1421
Discussion
The coexistence BC and TC is not fortuitous but the related pathophysiological mechanisms remain poorly elucidated. Exposure to estrogens and to thyroid-stimulating hormones may play a role in the development of breast cancer or thyroid cancer. Radiation exposure is also a well-known risk factor for the development of TC, so a germline mutation could be responsible for the connection between breast and thyroid cancers.

Conclusion
The association of these two pathologies is not incidental and should lead otherwise to the systematic screening of the thyroid cancer in women with breast cancer.

**Lung metastases from differentiated thyroid carcinoma: long term outcome and its prognostic factors related to progression free survival**

Seo Young Sohn¹, Hye In Kim¹, Sun Wook Kim¹ & Jae Hoon Chung¹

¹Division of Endocrinology, Department of Medicine Seonam University College of Medicine, Myongji Hospital, Goyang, Republic of Korea; ²Department of Endocrinology and Metabolism Samsung Medical Center, Seoul, Republic of Korea.

**Background**
Distant metastasis rarely occurs in differentiated thyroid carcinoma (DTC), but represents most common cause of death in patients with DTC. Lung and bone are the most frequent sites of distant metastases. This study investigated long term outcomes of lung metastasis in DTC patients and its prognostic factors influencing disease progression and cancer specific survival (CSS).

**Methods**
A total of 134 DTC patients presenting with lung metastasis from 1994 to 2012 were retrospectively analysed. Factors predictive of the outcome were determined by Cox-proportional model.

**Results**
With a median follow up of 81 months after surgery, the 5- and 1-year CSSs were 80 and 66%, respectively. The predictors of disease progression were older age (≥45 years), ¹³¹I non-avidity and co-existing bone metastases other than lung. Similarly, older age (≥45 years), ¹³¹I non-avidity, co-existing bone metastases and follicular pathology was associated with CSS. Cox proportional hazard ratio for progression-free survival and disease-free survival showed that older age was the only independent predictive factor for poor prognosis.

**Conclusions**
Older age, additional bone metastases, ¹³¹I non-avidity and follicular histology were found to be significantly associated with poor clinical outcome. Therefore, strict surveillance should be tried in these patients.

Is Hashimoto’s thyroiditis a risk factor for papillary thyroid cancer?  
Zeynep Cetin¹, Ozden Ozdemir Baser¹, Dilek Berker¹ & Serdar Guler²

¹Numune Training and Research Hospital, Ankara, Turkey; ²LIV Hospital, Ankara, Turkey.

**Aim**
Hashimoto’s thyroiditis (HT) is the commonest autoimmune thyroid disease. Papillary thyroid cancer (PTC) is the most often thyroid cancer and its incidence is increasing yearly. It is not clear that HT is a predisposing factor for PTC. We studied PTC’s frequency among HT patients went to total thyroidectomy.

**Discussion**
The association of these two pathologies is not incidental and should lead otherwise to the systematic screening of the thyroid cancer in women with breast cancer.

**EP1426**

A new strategy to estimate levothyroxine requirement after total thyroidectomy and radioiodine remnant ablation for ‘intermediate’ and ‘high’ risk differentiated thyroid cancer

Rosa Maria Paragliola, Annapina De Rosa, Vincenzo Di Donna, Giampaolo Papi, Alfredo Pontecorvi & Salvatore Maria Corsello

Endocrinology, Università Cattolica del Sacro Cuore, Rome, Italy.

**Introduction**
The approach for initial thyroid hormone suppression in patients who undergo surgery for differentiated thyroid cancer (DTC), is based upon the risk of disease recurrence. In particular, recent American Thyroid Association guidelines suggest to maintain TSH levels between 0.1 and 0.5 mU/l and less than 0.1 mU/l for patients with ‘intermediate’ and ‘high’ risk respectively. The aim of the study is to identify the major predictive factors of LT4 requirement to obtain semisuppressed or suppressed TSH levels and to elaborate a new method that could improve the accuracy of the LT4 therapeutic starting dose in intermediate and high risk DTC patients.

**Methods**
Two hundred and nineteen patients who underwent total thyroidectomy and radio-remnant ablation for DTC have been retrospectively evaluated. One hundred and forty nine were on TSH suppressive therapy (TSH <0.1 mU/l) and 70 on TSH semisuppressive therapy (TSH 0.1–0.4 mU/l). The results obtained by this retrospective analysis were used to formulate a nomogram for the calculation of the LT4 dose.

**Results**
For both groups (suppressive and semisuppressive LT4 therapy) the best parameters to predict the optimal LT4 starting dose are body mass index (BMI) and age. On the basis of the nomogram, the LT4 dose in μg/kg to obtain suppressed and semisuppressed TSH levels ranged from 1.6 to 2.1 μg/kg per day and from 1.5 to 1.9 μg/kg per day respectively. The dose is higher in younger patients with lower BMI.

**Conclusion**
In our study BMI and age represent important parameters to predict LT4 dose in intermediate and high risk DTC patients. LT4 requirement decrease with the increase in age and BMI, probably due to the relative decrease of lean body mass. Based on these data, a user-friendly nomogram, representing an efficient method to calculate LT4 starting dose in patients who underwent thyroidectomy for differentiated thyroid cancer, has been created.

Follicular thyroid carcinoma in a patient with Graves' disease

Nesrine Cheikhrouhou, Intidhar Elbez, Kaouthar Limam, Aida Mhiri, Bechir Ltaief & Med Faouzi Ben Slimene
Department of Nuclear Medicine, Salah Azaiez Institute, Tunis, Tunisia.

Introduction
Follicular cancer has a low incidence in Graves' disease when compared to papillary thyroid cancer. Some studies have not reported any follicular cancer in patients with Graves' disease. We describe a rare occurrence of follicular cancer in a patient with Graves' disease.

Observation
A 37-year-old female patient presented to our institute with symptoms of thyrotoxicosis. She had no family history of thyroid cancer or of radiation exposure in the neck area. She presented with typical clinical and biochemical features of Graves' disease. Tc-99m scintigraphy of the thyroid showed diffusely increased uptake with hypo functioning (cold) nodule. She underwent uneventful surgery after achieving an euthyroid state. A total thyroidectomy was performed with resection of an enlarged lymph node detected on intra-operatively. A follicular thyroid carcinoma was diagnosed on the cold nodule with metastatic lymph node. Patient was given an ablative dose of I131. Post-therapeutic scintigraphy revealed a significant residual thyroid tissue/residual tumor in the neck. The TSH-stimulated serum Thyroglobulin level measured by radio-immunoassay was 13 ng/ml. Being sensitive to iodine, patient will continue to receive I-131cures to complete remission.

Conclusion
Surgical treatment should be indicated if graves disease is associated to suspected nodule.

DOI: 10.1530/endoabs.49.EP1427

Papillary thyroid carcinoma in children: report of 15 cases

Intidhar Elbez, Nesrine Cheikhrouhou, Kaouthar Limam, Aida Mhiri, Ilsen Slim, Bechir Ltaief & Med Faouzi Ben Slimene
Department of Nuclear Medicine, Salah Azaiez Institute, Tunis, Tunisia.

Papillary thyroid carcinoma is rare in young patients and have a good prognosis, although it is often diagnosed at the stage of lung metastases. Our multicenter study included 15 children aged between 5 and 18 years with female predominance, followed for differentiated thyroid cancer with lung metastases. All these patients underwent a whole body scan with I-131, serum thyroglobulin, chest radiography and/or cervico-thoracic CT. Scintigraphy had shown pulmonary miliary among all patients. Iodine treatment was successful in all patients, which proves the high sensitivity of these metastases to iodine treatment. The differentiated thyroid cancer is characterized by local aggressiveness and a high frequency of distant metastases. Prognosis does not seem to be influenced by histology alone, but by its association with other prognostic factors: age, metastases and surgery.

DOI: 10.1530/endoabs.49.EP1428

Evaluation of differentiated thyroid cancer patients according to different scoring systems: a single center experience

Bekir Cakir1, Cevdet Aydin1, Berma Evranos Ogmen2, Ali Abbas Tam1, Sefika Burcak Polat1, Husniye Baser2, Neslihan Cuhaci1, Fatma Dilek Kahramanca1, Nagihan Bestepe2, Cuneyt Bilginer1, Sevgul Faki1, Mehmet Kılıç1, Aydan Kilicarslan3 & Reyhan Ersoy1
Department of Nuclear Medicine, Salah Azaiez Institute, Tunis, Tunisia.

Introduction
True risk evaluation is important in the management of thyroid cancer. We aimed to evaluate patients with differentiated thyroid cancer (DTC) according to the different staging systems.

Method
Data of patients diagnosed with DTC between 2007 and 2014 at our institution were analysed retrospectively. TNM, MACIS, EORTC, AMES, De Groot, ETA, LATS, and ATA staging systems were applied to patients according to their original description. In ATA risk classification system, we classified patients into four categories considering inappropriate postoperative thyroglobulin levels.

Results
There were 983 patients (218 male and 765 female) with a mean age of 49.4 ± 12.5 and a mean follow-up of 42.6 ± 24.3 months. Distribution of patients according to the staging systems were as follows; TNM: 81.1%, 4.7%, 12.7%, 1%, 0.3%, 0.2% of patients in stages I, II, III, IVA, IVB, IVc respectively; MACIS: 91%, 5.9%, 2.2%, 0.8% of patients in group I–4 respectively; EORTC: 39.4%, 36.7%, 19.8%, 4%, 0.1% of patients in group I–5 respectively; AMES: 82.2% of patients in low risk and 17.8% in high-risk group; De Groot: 81.6%, 4.7%, 13.3%, 0.4% of patients in stages 1–4 respectively; ETA: 35.5%, 25.9%, 12.4%, 26.1% of patients in very low, low, high and undetermined risk groups respectively; LATS: 35.5%, 26.7%, 17.7%, 20.1% of patients in very low, low, high and undetermined risk groups respectively. According to ATA, distribution of patients in low, intermediate, high and undetermined risk groups were respectively 26.4, 8.7, 40.8 and 23.6% in category 1, 39.7, 12.9, 23.8 and 23.6% in category 2, 46.7, 15.2, 14.5 and 23.6% in category 3, and 3.9, 19.2, 3.3 and 23.6% in category 4.

Conclusion
Variable scoring systems with variable risk assessments were suggested for DTC in the literature. A standardized categorization is required to overcome confusion and help clinicians during management of these patients.

A rare association of thyroid micro carcinoma and thyroid tuberculosis

Intidhar Elbez, Nesrine Cheikhrouhou, Kaouthar Limam, Ilsen Slim, Aida Mhiri, Bechir Ltaief & Med Faouzi Ben Slimene
Department of Nuclear Medicine, Salah Azaiez Institute, Tunis, Tunisia.

Introduction
Thyroid tuberculosis is a rare disease, its frequency is 0.15–0.2% of autopsic data. We report a case of micro papillary carcinoma of thyroid revealed by thyroid tuberculosis.

Observation
Mrs. K.J aged 54 years presented a multinodular goiter without ultrasound signs of malignancy. The patient underwent total thyroidectomy. Histological examination revealed a granulomatous and giganto cellular inflammation which is in favor of a tuberculosis. The left lobe of the thyroid contained a 4 mm papillary microcarcinoma. No metastatic adenopathy was found. The tumor was classified pTlaN0M0. The patient was addressed to department of nuclear medicine for supplementation of radioactive iodine treatment. In addition, the patient had benefitted of anti-tuberculosis treatment for 7 months.

Conclusion
Thyroid tuberculosis is a rare entity. In the absence of other tuberculous sites, diagnosis is often difficult. It is based on bacteriological and / or thyroid anatomopathological evidence. The association with a microcarcinoma is also rare and has to be carefully investigated by the anatomopathologist.

GA/GG Heterozygosity of ARG280HIS polymorphism in XRCC1 GENE: Genetic susceptibility genotype in differentiated thyroid cancer

Nazlı Gülsöy Kıran1, Neslihan Başcı Tuğrul1, Yaprak Yalçın2, Hasibe Verdi2, Aslı Nar1 & Belgin Atac2
1Department of Endocrinology and Metabolism, Başkent University Faculty of Medicine, Ankara, Turkey; 2Department of Nuclear Medicine, Salah Azaiez Institute, Tunis, Tunisia.

Background
Thyroid carcinomas are the most frequent endocrine malignancies of which more than nightly percent are differentiated thyroid carcinomas (DTC). It’s known that
Heterozygous GA/GG genotype frequency of the Arg280His polymorphism in DTC cases was significantly higher than in those with benign nodular goiter and in those in the healthy control group (64.5 and 3%, respectively, \(P<0.001\)). The frequency of homozygous AA genotype of Arg280His polymorphism was lowest in the healthy control group (35.5%). The difference was statistically significant \((P<0.001)\).

Presence of family history of thyroid cancer was 7.9% in DTC group and 1% in benign nodular group. The difference was statistically significant \((P=0.014)\).

Discussion

In conclusion, our study demonstrates that Arg280His GA/GG genotype of XRCC1 gene polymorphism is more frequently encountered in DTC than in cancer-free controls. GA genotype frequency is highest in those DTC cases with a family history of thyroid cancer.

Mutation analysis of papillary thyroid cancers using a newly developed targeted multi-gene panel in Hungarian population

Barbara Kocsis-Deák¹, Kristóf Arvai¹, Bernadett Balla¹, Bálint Tóbiás¹, Andrea Kövesdi¹, János Kösa¹, Balázs Járás², Tamás Székely³, János Horányi³ & Péter Lakatos¹
¹Department of Internal Medicine, Semmelweis University, Budapest, Hungary; ²Department of Pathology, Semmelweis University, Budapest, Hungary; ³Department of Surgery, Semmelweis University, Budapest, Hungary.

Thyroid cancer is the most common malignancy of endocrine organs and its incidence is steadily growing worldwide. Approximately 80% of differentiated thyroid tumors are papillary carcinomas. Next-generation sequencing (NGS) allows for high-throughput sequencing analysis of large number of samples at a time in a cost effective manner. We have developed a targeted sequencing parallel testing panel for multiple mutations in genes involved in thyroid cancer pathology. A custom-made AmpliSeq hot spot panel was designed to target 23 cancer genes (NRAS, MET, CTNNB1, PIK3CA, Dicer1, VHL, BRAF, PTEN, LPAR4, EIF1AX, HRAS, RET, GASS-AS1, KRAS, TSHR, AKTI, GNAS, TERT, TP53, AXIN1, APC, IDH1, SMAD4) which contains 357 known mutational hot spot areas with COSMIC IDs. Semiconductor sequencing was performed to analyze DNA from 56 papillary thyroid carcinomas with matched normal fresh frozen samples. The average coverage was 400X. BRAF, TSHR, APC, RET, LPAR4, TP53, AXIN1 and SMAD4 genes were the most mutated genes in our papillary thyroid cancer samples. Altogether, mutations, with at least 5% variant coverage and less than 1% minor allelle frequency in general population, could be shown in all of the samples, while mutation could be seen in seven control samples. The distribution of genetic alterations was similar to the published data. The sensitivity and the specificity of the method were 100% and 90%, respectively with a positive predictive value of 87%. Our multi-gene panel testing approach allows parallel analysis for multiple mutations with high accuracy and sensitivity, and short turnaround times.

K1 cell line in vitro: the impact of diagnostic absorbed doses from \(^{131}I\)

Marinus Stasiolek¹, Zbigniew Adamczewski¹, Boleslaw Karwowski¹, Marek Dedecjus² & Andrzej Lewinski²
¹Department of Neurology, Polish Mother’s Memorial Hospital – Research Institute, Lodz, Poland; ²Department of Endocrinology and Metabolic Diseases, Medical University of Lodz, Lodz, Poland.

Background

Diagnostic whole-body scan is a standard procedure in patients with thyroid cancer prior to the application of therapeutic dose of \(^{131}I\). Unfortunately, administration of radioisotope in diagnostic dose may decrease further radioiodine uptake – the phenomenon called ‘thyroid stunning’. We estimated radiation absorbed dose-dependent changes in genetic material, in particular in sodium iodide symporter (NIS) gene promoter, and NIS protein level in K1 cell line.

DOI: 10.1530/endoabs.49.EP1435
Materials and methods
We used the K1 cell line derived from the metastasis of human papillary thyroid carcinoma exposed to 131I in culture. The different 131I activities applied were calculated to result in absorbed doses of 5, 10, and 20 Gy.

Results
Radioiodine did not affect the expression of NIS gene at the mRNA level, however, we observed significant changes of the NIS protein level in K1 cells. The decrease of NIS protein level, observed in the cells subjected to the lowest absorbed dose, was paralleled by significant increase in 8-oxo-dG concentrations (P<0.01) and followed by late activation of the DNA repair pathways.

Conclusions
Our findings show that the impact of radiation on living cells, in the range compared to doses absorbed during diagnostic procedures in patients, does not show the linear dose-effect.

DOI: 10.1530/endoabs.49.EP1436

Massive thyroid gland metastasis from nonsmall cell lung cancer
Diana Simoniene1,2, Milda Danielle1,2, Raimonda Klimaitė1,2 & Rasa Mikalauskaite*
1Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Kaunas, Lithuania; 2Lithuanian University of Health Sciences, Kaunas, Lithuania.

Despite that the thyroid gland is one of the most vascular organs of the body but thyroid gland is an uncommon site for metastasis [1]. It represents less than 4% of thyroid malignancy in clinical and surgical studies [2, 3]. 58-year-old male, a prior smoker, was diagnosed with nonsmall cell lung cancer T4N3M1 St IV, histopathological findings - infiltrative adenocarcinoma, G1. About eight months he was treated with chemotherapy. At the beginning of the disease, the patient was examined by the endocrinologist and diagnosed a nodule thyroid. A fine needle aspiration (FNA) revealed a cystic degeneration. It was intended to repeat the FNA after three – 6 months. After 2 months, a patient presented to Endocrinology department of Hospital of Lithuanian University of Health Sciences Kauno klinikos because of increasing volume of the neck, shortness of breath, changes in voice and swallowing disorder. Thyroid ultrasound examination showed an enlarged thyroid gland, its structure was hypoechogenic and non-homogenous. Because of rapid tumor growth, we differentiated between lymphoma, anaplastic and hypopharyngeal cancer, lastly metastatic lesion. Metastasis from primary lung cancer was confirmed by thyroid fine-needle aspiration, cervical lymph nodes and laryngeal biopsies. After 1 week complications progressed. Thyroid was dramatically enlarged, acute respiratory failure evolved and the patient was unsuccessfully treated at Intensive Care Unit. In conclusion, a diagnosis of metastatic disease should be considered when new thyroid lesion is identified in any patient with a known history of malignancy until such a diagnosis can be ruled out. Because detection of metastasis to the thyroid gland often indicates a poor prognosis, aggressive treatment in time may be sufficient.

A higher frequency of papillary thyroid carcinoma in myotonic dystrophy
Adrien Ben Hamou1,2, Claire Marie Dhuenens1,4, Stephanie Espiard1,2, Kanza Benomar1,2, Vincent Tiffreau1,2, Robert Caiazzo1,3, Sebastien Aubert1,4 & Marie Christine Vantyghem1
1Lille University Hospital, Lille, France; 2Endocrinology, Diabetology and Metabolism, Lille, France; 3Endocrine Surgery Unit, Lille, France; 4Institute of Biochemistry and Molecular Biology – Biology and Pathology Center, Lille, France; 3Neuromuscular Reference Center, Lille, France.

Background and purpose
Type 1 myotonic dystrophy (MD), associates neuromuscular, cardiac, respiratory and endocrine disorders. The aim of this study was to determine the prevalence of thyroid disorders and of any causal factors.

Methods
A retrospective single centre study was conducted, between 2000 and 2016, in 127 MD patients, diagnosed by familial genetic screening after informed consent. Clinical examination, TSH assay, 120-min glucose and insulin levels post-OGTT, number of CTG repeats and ultrasound thyroid exam were performed. Eleven patients refused the assessment. The 116 remaining were divided into 2 groups according to the presence of a goiter defined as an ultrasound volume (usNG) or > (usG) 18 ml, whatever the presence of nodules.

Results
The whole population (61.2% female) was aged 45.1±12.2 years; the BMI was 26.2±6.5 kg/m²; at least one palpable nodule or a goiter was present in 33.6%, and hypothyroidism in 8.6%. The percentage of usG was 38.8%. Age (46.6±9.6

Endocrine Abstracts (2017) Vol 49

Page 751

19th European Congress of Endocrinology 2017

Antibodies) were within normal ranges. Thus, we did not find any evidence of thyroid disease. Two years later, the woman made an appointment at our clinic complaining of exercise – associated dyspnea. Her thyroid-stimulating hormone (9.60 mU/L; normal, 0.4–3.6 mU/L) and TPOAb (685 kU/L; normal, 0–78 kU/L) were increased. The ultrasonography showed marked bilateral low parenchymal echogenicity, inhomogeneous thyroid. In the left thyroid lobe, there were diffuse microcalcifications without focal mass. Sonographically, the thyroid lesions were indicative of chronic lymphocytic thyroiditis. A subsequent fine needle aspiration biopsy was performed. The cytologic examination assessed a suspicion of malignancy with chronic lymphocytic thyroiditis. The patient underwent the total thyroidectomy with lymph node dissection. Histopathologically, a chronic lymphocytic thyroiditis and 0.7 cm size papillary microcarcinoma in the left lobe were detected. Numerous stromal psammoma bodies, lymphatic intralobular spread with lymph node metastases were revealed. We have demonstrated a very rare case of PTC with chronic lymphocytic thyroiditis ultrasonographically presenting with diffuse microcalcification without thyroid nodes. In our case, an atypical homomorphous appearance of papillary microcarcinoma was associated with lymphatic intralobular spread and numerous stromal psammoma bodies in the thyroid. We conclude, in a case of ultrasonographically detected diffuse microcalcification without focal lesions, a careful examination for thyroid malignancy should be proposed.

DOI: 10.1530/endoabs.49.EP1437

Papillary thyroid cancer and chronic lymphocytic thyroiditis presenting with diffuse microcalcifications without focal mass on ultrasound
Jelena Vainikonyte-Kristapone, Jurgita Makstiene, Raimonda Valickas, Neli Jakubiomene, Dalia Kozloviene & Gintaras Kupriotis
The Hospital of Lithuanian University of Health Sciences Kauno klinikos, Kaunas, Lithuania.

The detection and characterization of PTC are based on the evaluation of specific ultrasonographic features of thyroid nodules. However, there is limited data regarding diagnostics without typical malignant-appearing nodules. We report a very rare case of PTC in underlying chronic lymphocytic thyroiditis ultrasonographically manifested with diffuse microcalcification without focal mass. A 22-year-old woman visited our institution complaining of weight loss, general weakness, and headache. A physical examination revealed a painless, firm thyroid without a palpable mass. In an ultrasonography of the neck, the pathology was not assessed. The thyroid hormones concentration, TPOAb (Thyroperoxidase
vs 44.1±13.6 years), BMI (28.1±7.1 vs 24.9±5.9 kg/m²), and frequency of papillary thyroid carcinoma (PTC) (17.8% vs 1.4%) were significantly higher in usG than in usNG. UsG was associated with BMI increase (P = 0.017, IC 95% (0.556 to 0.056), and hyperinsulinism (trend: P = 0.069), but not with CTG repeats. 11 (24.4%) of the 45 usG patients had a total thyroidectomy. Six micro (whose one had a capsule rupture) and 3 macro-PTC (with a high-risk level for 2 of them (pT2N1aM0, pT3N0M0) were diagnosed. 80% of these 9 PTC were associated with a palpable thyroid anomaly.

Conclusion
A third of these 116 MD patients had a palpable thyroid anomaly and 7.7% a PTC vs respectively 10% and 0.1% of the general population. The risk of usG was more related to a high BMI than to CTG repeats. Clinicians should be aware of this high prevalence of PTC in MD.

Management of treatment-related toxicity caused by multi kinase inhibitors administered due to advanced thyroid carcinoma
Jolanta Krajewska, Aleksandra Kukulska, Daria Handkiewicz-Junak, Ewa Paliczka-Cieslik, Tomasz Olszynk, Tomasz Gawlik, Aleksandra Ledwon, Barbara Michalik & Barbara Jarzab
M. Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Glivice, Poland.

Multi kinase inhibitors (MKIs) constitute a new therapeutic option in advanced RAI-refractory differentiated thyroid cancer (DTC) and medullary thyroid carcinoma (MTC). To date four different MKIs demonstrated a beneficial effect on progression free survival in DTC (sorafenib, lenvatinib) and MTC (vandetanib and cabozantinib). However, the treatment related toxicity, which potentially may limit their clinical use and lead to a negative impact on the quality of life, have been widely discussed recently.

Material and methods
The study group involved 81 patients with advanced thyroid cancer, who received different MKIs: 24 patients – lenvatinib, 20-vandetanib, 22-sorafenib, 4-cabozantinib, 4-motesanib and 3-axitinib. All side effects were classified according to the Common Terminology Criteria for Adverse Events (CTCAE), version 4.0. Median treatment duration was 21.3 months (range 0.7–100.0 months).

Results
Among the most common adverse effects were hypertension (73%), skin reactions (70.3%), diarrhea (54.1%), weight loss (54.1%) and stomatitis (43.2%). The majority of side effects fulfilled G1 (mild) and G2 (moderate) criteria except of hypertension mainly classified as G3 (the necessity of the administration of at least 2 antihypertensive drugs). The management of treatment related side effects was based mainly on cautious follow-up (wide panel of laboratory examinations, regular ECG monitoring, echocardiography and other examinations, if necessary), non-pharmacological methods (sun blockers, moisture creams), concomitant pharmacotherapy (antihypertensive drugs, loperamide and other depending on different side effects) and dose modifications: 52.7% of patients needed dose withdrawal due to its poor tolerability.

Conclusion
The proper management of MKI-related side effects is essential to keep patients on therapy as long as the treatment is beneficial without an unfavorable impact on their quality of life.

Malignancy risk stratification in thyroid nodules according to the Bethesda system for reporting thyroid cytopathology
Aldona Kowalska1,2, Agnieszka Suligowska1, Janusz Kopczynski3, Kornelia Niemyska1 & Stanislaw Goszczyk2
1Holycross Cancer Center, Kielce, Poland; 2The Faculty of Health Sciences of the Jan Kochanowski University, Kielce, Poland.

Introduction
Fine needle aspiration biopsy (FNAB) plays a crucial role in the diagnosis of thyroid nodules. The choice of further therapeutic strategy depends largely on its result. Knowledge of the risk of malignancy in each diagnosis class in the population is necessary. The aim of the research was to analyse the risk of malignancy in thyroid nodules in each diagnosis class according to Bethesda system.

Materials and methods
Retrospective research included 1001 patients with thyroid nodules diagnosed and treated surgically between 2002 and 2015 in one department. Women accounted for 86% of the research group. The median age was 52 years. The results of the guided FNAB performed before the introduction of the Bethesda scale (621) were re-evaluated and qualified to the appropriate group according to the new criteria.

Result
The preoperative FNAB results presented as follows: non-diagnostic material (class I) – 6 (0.6%); benign (class II) – 522 (52.1%); follicular lesion of undetermined significance (class III, FLUS) – 62 (6.2%); suspicious for a follicular neoplasm (class IV, SFN) – 138 (13.8%); suspicious for malignancy (class V) – 74 (7.4%), malignant (class VI) – 199 (19.9%). The postoperative histology follow-up in the research group were spread as follows: benign – 708 (70.7%); malignant – 292 (29.3%). Malignancy risk for each class according to Bethesda system amounted to respectively: I – 33%, II – 4.21%, III – 11.2%, IV – 13.04%, V – 59.46%, VI – 100%.

Conclusions
The present study shows that the risk of malignancy in class III and IV is low. The diagnosis of FLUS or SFN in the absence of clinical indications is not a basis for surgical treatment.

Endocrine Abstracts (2017) Vol 49
The work-up of Differentiated Thyroid Cancer (DTC) patients includes thyroid surgery, thyroid remnant ablation (TRA) with 131-radioiodine and long life follow-up. 131I-post therapy whole body scan (pT-WBS) and thyroglobulin (Tg) are used in identifying metastatic patients. Some authors suggested to use post-surgical Tg (ps-Tg) values in deciding for or against TRA. The aim of our study was to verify the sensitivity and PPV of 131I-pT-WBS compared to serum Tg levels in detecting metastases in early stage of DTC patients.

Material and method

We retrospectively reviewed the records of 570 patients affected by pT1-pT3 DTC (F=450, M=120, mean age 48.5 ± 13.2; F:M ratio=3:7:1) referred to our Nuclear Medicine Unit in the last five years. None of our patients had: 1) loco-regional or distant metastases at the time of recruitment; 2) age ≤16 years; 3) positive thyroglobulin-antibody (Tg-Ab); 4) pT 4 stage, 5) poorly-differentiated thyroid cancer. The majority of patients (98.2%) were affected by papillary carcinoma. Before TRA, all patients underwent neck-ultrasonography, laboratory test and, if treated in hypothyroid state (32/570, 56%), radiodine thyroid uptake. Both ps-Tg and Tg values obtained at TRA were matched with 131I-pT-WBS results.

Results

131I-pT-WBS discovered metastases in 82 out of 570 (14.4%) patients. Seventy-three out of these patients (90.2%) showed ps-Tg levels ≤1 ng/ml. At TRA, forty of them (54%) maintained Tg levels ≤1 ng/ml. The majority of these patients (38/40, 95%) showed lymph-node metastases at 131I-pT-WBS while three had lung metastases (one of them showed lymph-node metastasis). The metastases were confirmed by targeted morphological studies.

Conclusion

ps-Tg cannot be used to decide for or against TRA. In early stage of DTC, 131I-pT-WBS is an accurate method in detecting metastases also in patients with stimulate Tg values ≤1 ng/ml, showing sensitivity and PPV significantly higher than Tg (100% vs 29.3% for both).

DOI: 10.1530/endoabs.49.EP1443

---

The sensitivity and positive predictive value (PPV) of 131I-pT-WBS increased compared in patients with and without cervical lymph node metastasis.

---

Introduction and purpose

More than 90% of differentiated thyroid cancers are papillary thyroid cancer (PTC). Lymph node metastasis is common in PTC and has been reported to have no effect on prognosis. The risk of cervical metastasis is high in the presence of clinicopathological factors including extrathyroidal extension, multifocality and lymphovascular invasion. In this study, it was aimed to evaluate the clinicopathological features of lymph node metastasis development. Materials and methods

Patients with papillary thyroid carcinoma diagnosed between 1995 and 2016 were retrospectively reviewed. Patients who previously had another cancer story were excluded from the study. The demographic characteristics and pathology findings (histopathology, tumor size, lymph node metastasis, lymphovascular invasion, multifocality, capsule invasion, bilaterality) and antiTg, antiTPO values were compared in patients with and without cervical lymph node metastasis. Results

In 419 papillary thyroid cancer patients, 52 lymph node metastases were detected. Lymphovascular invasion was present in 24 patients and capsule invasion was present in 104 patients. Extrathyroidal extension was present in 32 patients. In logistic regression analysis, age (< 45 years old (P<0.001 OR:4.193)), lymphovascular invasion (P<0.001 OR:7.762), capsule invasion (P<0.002 OR:3.054), extrathyroidal extension (P<0.001 OR:6.450) and bilaterality (P < 0.001 OR: 0.217) involvement were significantly associated with cervical lymph node metastasis.

Discussion

We found that the risk of cervical lymph node metastasis was high in the presence of extrathyroidal extension, multifocality and lymphovascular invasion. In contrast to previous reports, the risk was found to be high for the age group lower than 45. Clinically, lymph node metastasis does not develop in all patients, knowing risk factors of cervical lymph node metastasis can determine the operation type, the treatment modality and the follow-up.

Effective targeted therapy for advanced endocrine malignancies is a goal of modern endocrinology. We herein present promising results of the first phase of clinical part of European project (Gran-T-MTC) aimed to assess the safety of gastrin analogue CP04 (DOTA-(DGlu) 6-Ala-Tyr-Gly-Trp-Met-Asp-Phe-NH2) i.v. administration in dose (50 μg) useful for translation to 177Lu-CP04 for PRRT. CP04 has been selected for MTC therapy based on a high CCK-2 receptor expression in MTC and superior pharmacokinetics properties among other gastrin analogues tested. Positive results of preclinical part of the study confirmed possibility of 111In-CP04 applying in humans. Aim

To assess 111In-CP04 safety, biodistribution and dosimetry.

Material and methods

Four patients: three with progressive/metastatic MEN2A-related MTC (+FDG-PET/CT positivity), one with sporadic MTC (short calcitonin doubling time) were enrolled. Basal calcitonin levels ranged between 279 and 824 pg/ml. Study design

During the first clinical trial phase each patient received 11In-CP04 (200 MBq) in 2 different doses: a low (10 μg) and high (50 μg). Biodistribution and dosimetry data were assessed based on serial planar and SPECT/CT images over time. Results

No side effects were observed during injection of either CP04 dose. In all patients 11In-CP04 uptake was confirmed in MTC lesions regardless of peptide dose (in one patient uptake was low). The compound showed both a renal clearance and uptake in the stomach wall with subsequent intestinal clearance with for both peptide doses similar kinetics and little variation across patients. The Effective dose was 6 mSv/200 MBq, irrespective of the amount of peptide. The kidney absorbed dose for the 50 μg therapeutic amount of CP04 if labeled with 177Lu was estimated at 0.32Gy/Gbq and the stomach absorbed dose at 0.13Gy/Gbq. Conclusions

MTC metastases can be detected with 11In-CP04. Biodistribution and dosimetry data show CP04 promising radiopharmaceutical for MTC therapy if labeled with 177Lu. The confirmatory second part of clinical phase of trial has just begun.

Medullary thyroid carcinoma – diagnosis and outcome of patients treated in a tertiary center
Joanna Prokop, Ana Palha, Teresa Sabino, Carolina Neves, Luísa Cortez, José Silva-Nunes, Cristina Santos, Lurdes Matos, Natércia Candeias, António Alfonso, Fernando Fonseca & Ana Agapito

Medullary thyroid carcinoma (MTC) is a rare tumor of C cell origin, that may be sporadic or familial. Diagnosis is often delayed and its course variable.

Objectives
Evaluation of clinical characteristics and outcome of patients diagnosed with MTC.

Methods
Retrospective analysis of clinical records of patients with MTC between 2005 and 2016. We considered undetectable serum calcitonin as criteria of cure.

Results
Sixteen patients (12 women) were observed: mean age at presentation 63.8 years (46–79), mean follow-up: 2.2 years. Thyroid nodules were present in all. Four patients had compressive symptoms, three lymphadenopathy and one chronic diarrhea. Eight patients were diagnosed on the basis of histological examination without previous clinical suspicion of MTC. Genetic testing for RET proto-oncogene mutations was performed in nine patients and in one germinative mutation was detected (isolated familiar MTC). Eight patients with previous suspicion of MTC underwent total thyroidectomy with central lymph node dissection, and in five of these also lateral lymph node dissection. Among patients diagnosed after surgery: two had undergone total thyroidectomy with central lymph node dissection, in one of these combined with lateral node lymph dissection, three total thyroidectomy and three hemithyroidectomy. One completed thyroidectomy and the other two maintain undetectable calcitonin (follow-up: 0.5–1.3 years). After surgery seven patients were cured. One of them suffered recurrence with hepatic metastases 4 years later. Among patients with disease persistence there were six with progression in serum calcitonin, one with radiologic evidence of metastases. This patient had cervical lymph node metastases (calcitonin doubling time-CDT:6 months) 7 years after MTC diagnosis and underwent reoperation without cure.

Discussion
In this cohort of patients MTC diagnosis was made often after surgery (50%), which raises the question of presurgical calcitonin testing. MTC may have metastasised without clinical suspicion of MTC. Its management consists of an excision of the cyst. Hormone replacement therapy is systematic. Total thyroidectomy is indicated in cases of thyroid suspicious of malignancy, also if extra-cystic extension. Lymph node dissection is indicated in the presence of adenopathy. A complement by Iraetherapy is not systematic, however in our patient it is indicated because the presence of a lymph node metastasis. The monitoring will be on long term and generally the evolution is favorable.

CHU Mohamed Lamine Debaghine Bab El Oued, Algiers, Algeria.

Introduction
Neoplasias in the thyroglossal duct cyst (TDC) are rare, their prevalence varies from 1 to 1.5%. The most common cancer is papillary carcinoma representing 85% of cases. The diagnosis is often fortuitous following to the anatomopathological examination of the surgical specimen.

Patient and method
Our patient has 33 years-old, with no previous medical history, which underwent a resection of a TDC of 29 mm in diameter, diagnosed by an anterior cervical tumefaction. The anatomopathological examination of the cyst was in favor of papillary carcinoma. The evolution is marked by the appearance of a left cervical adenopathy. The patient has benefited by a biopsy excision, and histology was in favor of a metastasis of a papillary carcinoma. Cervical ultrasound: normal, without cervical adenopathies. The patient had a total thyroidectomy whose anatomopathology returned without anomaly. The hormonal assessment showed an undetectable level of thyroglobulin (TG). (TSH: 30.24 Uu/ml, TG: 0.55 μg/l and anti-TG antibody: 1.2 IU/ml). Levothyroxine was increased to 150 μg/day. Iraetherapy is considered for our patient.

Conclusion
The papillary cancer on TDC is an exceptional localization. It can develop at the expense of residues of thyroid follicles within the cyst of the TDC, or may be secondary to thyroid papillary carcinoma metastasis. Its management consists of an excision of the cyst. Hormone replacement therapy is systematic. Total thyroidectomy is indicated in cases of thyroid suspicious of malignancy, also if extra-cystic extension. Lymph node dissection is indicated in the presence of adenopathy. A complement by Iraetherapy is not systematic, however in our patient it is indicated because the presence of a lymph node metastasis. The monitoring will be on long term and generally the evolution is favorable.

Impact of RAC1/b signalling on Sodium Iodide Symporter regulation
Márcia Faria1,2, Paulo Matos3,4, Maria João Bugalho1,5 & Ana Luísa Silva1,5
1Faculty of Sciences, BiOISI - Biosystems & Integrative Sciences Institute, University of Lisbon, Lisboa, Portugal; 2Research Unit of Molecular Pathobiology, Portuguese Institute for Research and Training in Oncology (IPATIMUP), Braga; 3Department of Endocrinology, Diabetes and Metabolism, Centro Hospitalar Lisboa Norte E.P.E - Hospital de Santa Maria, Lisboa, Portugal; 4ISAMB, Genetics Laboratory, Faculty of Medicine, University of Lisbon, Lisboa, Portugal.

The Sodium Iodide Symporter (NIS) is responsible for active transport of iodide into thyroid cells. Its expression in thyroid tumors allows the use of radioactive iodine (131I) as co-adjuvant therapeutic tool to eliminate remaining tumor cells and metastases after total thyroidectomy. Nevertheless, certain subsets of patients with advanced forms of thyroid cancer lose the ability to respond to radioiodine therapy, which drastically reduces their survival rates. Recent studies have implicated the Rac1/p38 pathway in the stimulation of NIS expression through a mechanism that remains unclear. Additionally, the overexpression of RAC1/b, a hyperactive splicing variant of RAC1, was recently shown to be overexpressed in a subset of papillary thyroid carcinomas carrying the activating mutation BRAFV600E and to be associated with unfavorable outcome. BRAFV600E mutation, in turn, has been associated with the downregulation of NIS. Here, we further investigate the role of RAC1/b on NIS expression levels, and developed new cellular models to functionally assess the impact of these GT-Pases on NIS-mediated iodide uptake. To evaluate whether RAC1/b has a role in NIS expression modulation, we determined NIS transcript levels in a cohort of 64 follicular cell-derived thyroid tumors, comparing tumors presenting RAC1/b overexpression (n = 32) to those that did not (n = 32). RAC1/b-overexpressing tumors were defined as those with expression levels above a defined threshold (corresponding to the mean value plus two SDs of RAC1 expression level in a normal thyroid group). RAC1/b and NIS expression was assessed by quantitative RT-PCR. We found that samples negative for RAC1/b expression presented higher levels of NIS in comparison to RAC1/b-overexpressing samples (4.402 ± 1.271 vs 1.916 ± 0.5423, respectively; P = 0.0384, two-tailed Student’s t-test). Thus, our results show an inverse correlation between RAC1/b and NIS expression levels, suggesting that RAC1/b might antagonize RAC1 effectiveness at stimulating NIS expression. To further explore the impact of RAC1/b signalling on NIS expression regulation, we established a halide-sensitive YFP-based reporter in a normal thyroid cell line system, allowing us to detect differences on iodide influx upon TSH stimulation. Our preliminary results support the relevance of further studying the impact of RAC1/b on NIS regulation.

Thyroid cancer therapy is based on surgery followed by radioactive treatment of tumor remnants and metastases. The incorporation of radioiodine by cancer cells is mediated by sodium iodide symporter (NIS), normally present in thyroid follicular cells’ membrane. We studied the expression of NIS in a series of 229 thyroid primary tumors using real time PCR and immunohistochemistry, and searched for possible associations between NIS expression and clinicopathological features, molecular data, response to therapy and prognosis. NIS mRNA levels were significantly lower in carcinomas than in normal adjacent thyroid, in carcinomas from males with vascular invasion presented significantly less NIS mRNA expression than carcinomas from women and non invasive carcinomas. BRAFV600E tumors and these presenting extrathyroidal extension had a tendency to display lower NIS mRNA expression than tumors BRAFWT and no extrathyroidal extent. Regarding immunohistochemistry, only 12/211 of the cases demonstrated NIS in the basolateral membrane of tumor cells; these cases showed variable outcomes concerning therapy response and prognosis. All but one of the aforementioned cases were wild type for BRAF, NRAS and TERT promoter mutations. NIS immunohistochemical expression in primary tumors did not predict tumor behavior or response to therapy. NIS mRNA expression was more informative of tumor aggressiveness than NIS protein expression. In order to validate our data we also searched possible associations between NIS mRNA expression and clinicopathological and molecular features on 378 primary papillary thyroid carcinomas of the TCGA database. Further studies are needed to confirm the association observed between the presence of the oncogenic mutations (BRAF, NRAS and TERT promoter) and both lower mRNA expression and diminished membrane targeting of NIS protein.

Concomitant occurrence of papillary thyroid cancer (PTC) in a branchial cleft cyst (BCC) and an occult multifocal PTC in the thyroid gland

Ewelina Szczepanek-Parulski1, Martyna Borowczyk1, Alina Kluk1, Grzegorz Dzworacki2, Marcin Orłoński3, Katarzyna Ziemnicka1 & Marek Ruchala1

1Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; 2Department of Clinical Immunology, Poznan University of Medical Sciences, Poznan, Poland; 3Department of Pathology, Provincial Hospital in Poznan, Poznan, Poland.

Introduction

BCC is a congenital epithelial neck cyst, which occurs due to failure of the second branchial cleft to obliterate during embryogenesis. Development of PTC inside the cyst is extremely rare.

Case description

A 29-year-old female presented to the endocrinology clinic with a gradually increasing painless mass in the right lateral region of the neck, identified on ultrasound examination as an anechoic cyst of size 2×2×5 cm with a smooth wall. Despite repeated biopsies and evacuation of the fluid, the cyst was a recurrent problem. Hence, a decision for surgical removal was made. The histopathological examination revealed a cystic structure with lymphatic weaging in the wall and PTC in both the lumen and lymphatic weaging. Despite no abnormalities were detected in the thyroid on ultrasound, the patient was referred for total thyroidectomy. The histopathological specimen revealed the presence of multifocal PTC within the thyroid, the largest being 1 mm, and one metastatic lymph node. Due to the increased post-surgical thyroglobulin concentration and the suspicion of metastasis to other cervical lymph nodes on ultrasound examination, the patient required two subsequent lymphadenectomies followed by radioiodine therapy to achieve remission. No further recurrence of the disease was observed in a 6-year follow-up period.

Conclusions

In such patients two scenarios should be considered: (i) PTC in BCC is a primary lesion arising from ectopic thyroid tissue concomitant with multifocal PTC of the thyroid or (ii) neck cyst is a cystic degeneration of a metastatic lymph node, while primary site is located in the thyroid. Detection of PTC in BCC requires verification of the thyroid for concomitant neoplastic lesions. Despite normal thyroid on ultrasonography, histopathological examination may reveal the presence of multifocal occult PTC in the thyroid. Therefore, following the diagnosis of PTC in BCC, completion total thyroidectomy should be the recommended procedure.

Comparative analysis of clinicopathological characteristics between Korean and Italian thyroid cancer patients

Jee Hyun An1, Sin Gon Kim 1, Hoon Yub Kim2, Kwang Yoon Jung3, Yang Seok Chae4, Gianlorenzo Dionigi5, Stefano Ruasie6, Maria Laura Tanda7, Eliana Piantanida8 & Stefano La Rosa7

1Division of Endocrinology, Department of Internal Medicine, KUMC Thyroid Center, Korea University College of Medicine, Seoul, Republic of Korea; 2Department of Surgery, KUMC Thyroid Center, Korea University College of Medicine, Seoul, Republic of Korea; 3Department of Otolaryngology-Head and Neck Surgery, KUMC Thyroid Center, Korea University College of Medicine, Seoul, Republic of Korea; 4Department of Pathology, KUMC Thyroid Center, Korea University College of Medicine, Seoul, Republic of Korea; 5Endocrine Unit, 1st Division of General Surgery, Department of Medicine and Surgery, Research Center for Endocrine Surgery, University of Insubbria, Varese, Italy; 6Endocrine Unit, Department of Medicine and Surgery, University of Insubbria, Varese, Italy; 7Institute of Pathology, University Hospital of Lausanne (CHUV), Lausanne, Switzerland.

Background

The incidence of thyroid cancer in South Korea has increased rapidly. Increase in medical surveillance and access to health care services have enhanced the detection of asymptomatic tumors. We investigated the differences of tumor characteristics between South Korean patients and Northern Italian patients subject to different healthcare systems.

Methods

The demographic, histopathologic and management features of thyroid cancer operated in two tertiary referral hospitals in Seoul, South Korea (n=4,474) and Varese, Northern Italy (n=2,897) from years 2000 to 2015 were analyzed.

Results

The mean age of diagnosis was similar (49 years) among the Korean and Italian patients. However, the proportion of female was higher among Korean patients (81.3 vs 74.2%, P<0.001). The proportion of papillary subtype was higher (99.2 vs 92.6%, P<0.001) and the size of tumor was smaller (1.03±0.83 vs 1.79±1.01 cm, P<0.001) in the Korean subjects. Interestingly, the prevalence of multifocality (37.8% vs 8.2%), extrathyroidal extension (41.6% vs 13.1%) and lymph node metastasis (34.8 vs 6.7%) was also higher in the Korean patients (P<0.001). Most of the Italian cases received total thyroidectomy (96.0%). In comparison, a lower number of Korean patients received total thyroidectomy (81.3 vs 74.2%, P=0.001). The proportion of the patients who received radioactive iodine therapy was significantly higher among the Korean patients (53.3 vs 29.7%, P<0.001).

Conclusion

We have identified distinct lineaments of thyroid gland cancer between the two different nationalities which could not be explained entirely by early detection from screening. Further prospective studies with controlled treatment strategies are needed to determine long-term prognosis.

**Malignant struma ovarii and synchronous tumour of thyroid gland in the same patient: a single pathway for two different tumours?**

Ricardo Capitão, Catarina Sarava, Francisco Santos, Cátia Férrinio, Catarina Roque, Carlos Bello & Carlos Vasconcelos

Centro Hospitalar Lisboa Ocidental, Lisboa, Portugal.

**Background**

Struma ovarii (SO) is the presence of thyroid tissue as a major cellular component in an ovarian tumour.

**Case report**

A 35-year-old, Caucasian female, asymptomatic and with no malignant physical examination was submitted to left oophorectomy due to ovarian mass (8.2 × 7.0 × 6.0 cm) detected in routine pelvic examination. Her mother also had history of oophorectomy for an ovarian tumour and partial thyroidectomy for benign thyroid nodules. The histological examination of the mass showed a totally intracapsular neoplasm predominantly composed of thyroid tissue (95%) with areas of follicular variant of papillary thyroid carcinoma (FVTPC) which was compatible with malignant SO. She was tested for thyroid function which was normal and thyroid ultrasound revealed a slightly hypoechoic nodule with 1.7 cm in the right lobe. Fine needle cytology of this nodule was performed and was compatible with FVTPC. She underwent total thyroidectomy and histology revealed a well-differentiated thyroid tumour of uncertain malignant potential. No vascular or capsular invasions were recorded. She was treated with 131I and suppressive doses of levothyroxine and remains asymptomatic, without signs of clinical or biochemical recurrence of thyroid and ovarian tumours. The search for BRAF mutations was negative.

**Discussion**

Three other cases of synchronous thyroid and ovarian thyroid tumours have been described so far to the best of our knowledge. In this case, since both tumours were confined and no invasion was documented they were probably synchronous tumours instead of metastasis. These two tumours are embryologically related so we cannot exclude a common mechanism of genomic origin that possibly explains the synchronous tumours and even the familiar history.

**Does Preoperative Serum Neopterin Level Predict Differentiated Thyroid Carcinoma?**

Mazhar Müslüm Tunu, Narin Nasroğlu İmga, Mehtap Naydar Başaran, Berçem Ayıcık Doğan, Canan Topçuğlu, Dilek Berker & Serdar Güler

1Umranıye Training and Research Hospital, Endocrinology and Metabolism Clinic, İstanbul, Turkey; 2Ankara Numune Training and Research Hospital, Endocrinology and Metabolism Clinic, Ankara, Turkey; 3Ankara Numune Training and Research Hospital, Biochemistry Clinic, Ankara, Turkey.

**Introduction**

The frequency of thyroid surgery for suspected malignancy but postoperative results with benign pathology tend to increase in the worldwide. Therefore, additional preoperative markers are needed to prevent excessive surgery. Neopterin is a new molecule secreted by monocytes and macrophages and indicates the activation of cellular immunity. Therefore it can be used as a marker of immune activation. We aimed to evaluate the diagnostic value of serum neopterin levels to differentiated thyroid cancers (DTC).

**Material and method**

This prospective study included 86 patients (67 female and 19 male) who underwent thyroidectomy due to nodular goiter between March 2015 and November 2015. Patients who had overt hyperthyroidism or hypothyroidism, and renal or hepatic dysfunction were excluded from the study. Weight, height and body mass index (BMI) were measured prior the surgery. A fasting blood sample obtained from all study participants prior the surgery to measure serum neopterin levels.

**Results**

Of these patients, 39 were diagnosed with DTC and 47 had benign pathology according to postoperative histologic evaluation. There were no significant differences between the two groups in terms of age, weight, height and body mass index. Demographical data and laboratory results are given in the table. There was a positive correlation with neopterin levels and tumor size (r = 0.776, P < 0.001).

**Discussion**

Our study indicates that there is a strong association between plasma neopterin levels and DTC. Thus, if it is supported with high volume larger studies, neopterin may be a useful marker for predicting the DTC preoperatively.

**Unexpectedly low thyroglobulin levels in differentiated thyroid carcinoma – case report**

Francisco Norton-Brandalı, Teresa Ferreira, Manuel Rio Carvalho, Inês Patrocínio Carvalho, Rita Sousa, Pedro Ratão, Lucilia Salgado, Joana Simões-Pereira & Valeriano Leite

1Nuclear Medicine Department, Portuguese Oncology Institute - Lisbon, Lisbon, Portugal; 2Endocrinology Department, Portuguese Oncology Institute - Lisbon, Lisbon, Portugal.

**Case report**

66 year old male with a neck growing mass performed an ultrasonography and fine-needle aspiration biopsy which was suspicious for papillary carcinoma. The patient was submitted to total thyroidectomy and central and left lateral compartments lymph node dissection. The histological report showed a follicular carcinoma of 9 cm, with multiple lymphovascular invasions and skeletal muscle invasion. There was a focally positive surgical margin and resected lymph nodes had no metastases. Thoracic CT showed multiple lung nodules; PET showed faint uptake in a single nodule in the upper lobe of the right lung. Five months after surgery, 5.5 GBq (150 mCi) of iodine-131 (RAI) were administered. Forty-eight hours after therapy whole-body scintigraphy (WBS) was performed: moderate thyroid remnant and faint uptake in the lower third of the right thoracic area were visible. Non-stimulated serum thyroglobulin (Tg) was undetectable and stimulated levels were 1.5 ng/ml; anti-thyroglobulin antibody (ATg) was negative. Two years after RAI, Tg levels increased to 15.2 and to 43.1 ng/ml six months thereafter. ATg remained negative. Neck and thorax CT showed a new lesion in D3 and no progression of lung nodules. The patient referred light numbness in his left arm and hand. A second RAI was performed under thyroid hormone withdrawal. Stimulated serum Tg was 229.0 ng/ml PET-CT (Default 1) was performed just before RAI administration: uptake in lytic lesions in D3 and D4 was found (SUVmax = 11.3). Post-therapeutic WBS (Default 2) also showed intense uptake in the dorsal spine and faint uptake in pulmonary lesions.

**Conclusion**

Serum thyroglobulin is usually useful to monitor disease progression. In patients with aggressive differentiated thyroid carcinoma, Tg alone may not reflect...
accurately disease progression, as in this patient with documented bone and pulmonary disease that is both differentiated and aggressive.

EP1455
Papillary thyroid microcarcinoma: is it worth ablating the patients with radioiodine?
Muammer Urban, Eylem Cagiltay & Ferhat Deniz
Sultan Abdulhamid Training Hospital (Former Gata Haydarpasa Training Hospital), Istanbul, Turkey.

Objective
Recently, radioablation has been offered for patients with thyroid microcarcinoma, however some authors favor just follow-up as the prognosis of this disease is excellent. In this study, we compared the long-term follow-up results, for a period of 16 years, in patients with thyroid microcarcinoma in a group of patients with thyroidectomy only and in another both thyroidectomized and radioabluted.

Methods
Two hundred sixty five patients with a proven diagnosis of thyroid cancer <10 mm among 1755 thyroid cancer cases were included in the study. Any patients with unfavorable characteristics such as capsular or perithyroidal invasion, intrathyroidal spread, lymph node invasion or multicentricity were excluded. In group IA, 18 patients (14 female, 4 male; mean age 74), patients were hemi-thyroidectomized only and 64 patients (43 female, 21 male, mean age 66) in group IB had total or near-total thyroidectomy. In group II, 183 patients (123 female, 60 male; mean age; 61) underwent total or near total thyroidectomy and ingested 1-131 (dose range; 30-85 mcI) while they were in abhyothyroid state (TSH >40 uIU/L). In the surveillance period, all patients were monitored with periodical serum Tg/ATg measurement and ultrasound of the neck for a period of two to 16 years.

Results
In group IA and IB, lymph node metastasis was detected in 9 patients (11%) with US-guided fine needle aspiration in the surveillance period. No patient asked for additional treatment including surgical intervention and followed by L-T4 suppression only. Serum Tg levels were less than 2 ng/dl (range; 0.2 to 3.9 ng/dl) in 56 patients an in the remaining 26, ranging from 2.0 to 9.8 ng/dl. Serum Tg levels decreased to lower values than 9.8 ng/dl after no more than one year. In group II, lymph node invasion were detected in 19 patients (10%) and 9 of them had neck dissection for a complete cure. Initial serum Tg levels ranged from 2.1 to 19.8 ng/dl in those patients. In 19 patients with lymph node invasion serum Tg levels ranged between 2.2–19.8 ng/dl.

Conclusion
In both groups, approximately 1/10 of patients presented with recurrent or metastatic disease to regional lymph nodes. As the difference between radioabluted and not ablated groups is statistically not significant, we do not recommend completion thyroidectomy and radioablation for patients with thyroid microcarcinoma (excluding any poor prognostic factor) and follow-up unless the disease becomes clinically apparent.

DOI: 10.1530/endoabs.49.EP1455

EP1456
Anaplastic thyroid carcinoma and multinodular toxic goiter
Oana-Maria Capraru
Saint Constantin Hospital, Brasov, Romania.

A 69 years old female with cervical radiotherapy 25 years ago for an unknown condition, known with multinodular goitre and hyperthyroidism for 6 years, presented with a 6 months history of enlarged right supraclavicular mass, local pain with difficulty in mobilization of the right arm and weight loss. She also reported progressive bilateral exoptalmia especially on the right side, no dysphagia, hoarseness or dyspnoea. Thyroid hormone levels were normal on antithyroid drugs and the thyroid auto-antibodies and parathyroid levels were all normal. Neck CT showed an inhomogeneous large gland with several hypoechoic nodules, compression of the trachea and oesophagus, severe compression of the right internal jugular vein with collateral blood flow and a right supraclavicular adenopathy with no cleavage plan from the thyroid tissue. No significant head, chest and abdominal lesions were described. Fine needle aspiration of the thyroid and the supraclavicular mass revealed anaplastic carcinoma, with no expression of the thyroid transcription factor 1, mamoglobin 1 and positive expression for CK7, CK19 and CK5. The tumour was considered unresectable and the patient was started on chemotherapy with paclitaxel and carboplatin for 4 months. After the first 2 rounds of chemotherapy she had an initial good response, with shrinkage of the supraclavicular mass. The CT after the completion of chemotherapy showed an increased volume of the thyroid gland and the supraclavicular mass, with thrombosis of the internal jugular vein and supraclavicular bone erosion. She is under evaluation for external radiotherapy. The association between a toxic nodular goiter and anaplastic thyroid carcinoma after cervical radiotherapy, with no distant metastases has apparently not been reported so far.

Evaluate the effectiveness of the Bethesda system for reporting thyroid cytopathology in the prediction of thyroid cancer (TBSRTC) on fine needle aspiration (FNA) in Moscow region, Russia
Timur Britvin, Olga Nechaeva, Alexey Kryivosheev, Larisa Bavkyina, Armine Kazaryan & Alexander Dreval
Moscow Regional Research Clinical Institute, Moscow, Russia.

Aim
To evaluate the effectiveness of the Bethesda system for reporting thyroid cytopathology in the prediction of thyroid cancer on fine needle aspiration (FNA).

Materials and methods
This is retrospective study of 70 detected thyroid cancer. Thyroid ultrasound and FNA were performed on all patients. 66 of them with cancer suspicion were communicated to the thyroid surgeon, 4 cases of papillary carcinoma were accidentally diagnosed after histological investigation; 63 patients underwent total thyroidectomy with or without lymph node dissection. One patient refused surgical treatment. 69 intraoperative samples were subjected to histological examination.

Results
In the group with cancer suspicion category VI by TBSRTC was assigned in 51 (73.3%) cases, category V in 13 (19.7%) cases, 1 case (1.5%) with category V and VI with multinodular goitre, and 1 case (1.5%) with category VI and IV with multinodular goitre too. Histochemical examination of 60 (91%) cases confirmed thyroid cancer: papillary carcinoma in 56 (85%) cases; medullary carcinoma in 3 (4.5%) cases; mixed follicular and papillary carcinoma in 1 (1.5%) case. In 6 (9%) cases the cancer wasn’t detected. 2 (3%) of these 6 cases were classified as category VI and 4 cases (6%) as category V. Thyroid cancer was not detected in all cases of categories II-III found after thyroidectomy for other reasons.

Conclusion
Category VI corresponds with 97% of diagnosed thyroid cancer, and category V - 94%. Thyroid cancer was confirmed in only 4 of all cases with category IV. This result indicates the need for additional diagnostic methods in the preoperative period for category IV – for which molecular genetic tests may have potential. To determine the risk of malignancy of thyroid nodules with categories II-III requires long-term monitoring.

Outcomes and imaging results in patients with medullary thyroid cancer
Thein Huy1, Mansour TA Sharabiani2, S Nimalasena2, Kate Newbold2 & Daniel Morganstein1,2
1Diabetes and Endocrinology Department, Chelsea and Westminster Hospital NHS Trust, London, UK; 2Thyroid Unit, Royal Marsden Hospital, London, UK.

Medullary Thyroid Cancer (MTC) is sporadic in approximately 75% whilst 25% of MTC occurs as hereditary forms due to RET mutations. Prognosis is relatively good with 10-year survival rates of 65%. However, many patients develop recurrent disease and imaging is critical to localise the site of recurrence. Eighty-eight MTC patients, attending the Royal Marsden Hospital NHS Trust were...
Thyroid cancer is the most frequent endocrine cancer. Its incidence has been found to increase in recent years. Additionally, environmental factors, which may be implicated in the pathogenesis of thyroid disorders, such as iodine deficiency and salt iodine supplementation are changing and may have an impact on the epidemiology of thyroid cancer. The aim was to study the epidemiology of thyroid within a center of excellence in Athens in the modern world setting. A cohort of 63 patients, aged 46.3 ± 1.77 (mean ± s.e.m), range 16-81 years with thyroid cancer was studied. The histology of the cancer was recorded. The histological subtypes of papillary thyroid cancer were evaluated and recorded. Within a cohort of 63 patients with thyroid cancer 60 were found to have papillary thyroid cancer, three were found to have follicular thyroid cancer, one was found to have a mixed medullary follicular-derived thyroid cancer and one was found to have a B cell lymphoma of the thyroid. Within the group of the patients with papillary thyroid cancer, 39 (67.24%) were found to have papillary, 19 (32.8%) were found to have the follicular variant of papillary thyroid cancer, 1 (1.72%) had encapsulated papillary thyroid carcinoma, and 1 (1.72%) was found to have the tall cell variant of papillary thyroid carcinoma. It appears that in the modern world setting within a center of excellence in Athens papillary thyroid cancer was the commonest type. Although papillary thyroid cancer and the follicular variant of papillary thyroid cancer were the commonest forms of thyroid cancer recorded, more aggressive types of thyroid cancer such as the tall cell variant were also recorded.

Prevalence of thyroid cancer in malaga and province

Hospital Clinico Universitario Virgen de la Victoria, Málaga, Spain.

Introduction
Thyroid cancer is the most common endocrine neoplasia, being its papillary version the most frequent. (90% of all differentiated thyroid neoplasms). It is usually multifocal and metastasizes normally to regional lymph nodes.

Objectives
To describe the prevalence of thyroid cancer and its histopathological variants in the different regions of the province of Málaga.

Material and methods
We performed a retrospective descriptive study. We collected the thyroid cancer diagnoses in the databases of pathological Anatomy of the different hospital centers of the province between 2010 and 2015.

Results
545 cases were collected, it is more frequent in women (79.63%) than in men (20.37%); the average age at diagnosis was 50±15 years. Analyzing in different areas: 30.1% East Málaga; 12.5% West Málaga; 30.1% Costa del Sol, 1.3% Guadalhorce Valley, 1.5% Serranía de Ronda/Sierra de las Nieves, 7.3% Axarquia, 3.1% Antequera, 2.4%, 2.7% Melilla. The most frequent histological variant was papillary (69.72%) and in the different areas: East Málaga: 76.22% papillary, 9.15% follicular, 6.71% micropapillary, 3.65% medullary, 1.83% anaplastic, 1.22% Hurtele cell, 1.22% oncocytic. West Málaga: 63.25% were papillary, 11.76% were follicular, 13.23% were micropapillary, 4.41% were medullary, 4.41% were oncotic, 2.94% were Hurtele; Or anaplastic. Axarquia 73.17% papillary, 4.88% follicular, 9.76% micropapillary, 9.76% medullary, 2.44% anaplastic. Guadalhorce Valley 77.59% were papillary, 6.89% follicular, 10.34% micropapillary, 1.72% medullary, 3.45% no data. Antequera, 64.71% papillary; 17.65% follicular, 11.76% micropapillary, 5.88% medullary. Serranía Ronda/Sierra Nevus: 75% papillary, 12.5% follicular, 12.5% micropapillary. In Costa del Sol 59.76% papillary, 12.20% follicular, 8.54% micropapillary, 1.22% medullary, 0.61% anaplastic, 4.27% Hurtele cell, 3.41% no data. Melilla: 80.02% papillary, 6.66% follicular, 6.66% micropapillary, 6.66% anaplastic In other provinces: 84.62% papillary, 7.14% follicular, 7.14% medullary. Tumor tissue was noticed to surpass the resection capsule in 19.08% (without data 11.93%). In 33%, no ganglia were removed, 21.6% of affected nodes and distant metastasis> 1%.

Conclusions
The prevalence of thyroid cancer in our population was similar to those described in Spain. In the analysis of different types, papillary was the most frequent, followed by follicular and micropapillaries. The overall prognosis is good.

DOI: 10.1530/endoabs.49.EP1462

Lymph node metastases location (central vs lateral neck) in well-differentiated thyroid carcinoma: Is it important?

Bernardo Marques, Raquel Martins, Joana Couto, Jacinta Santos, Teresa Martins & Fernando Rodrigues
Instituto Português de Oncologia de Coimbra FG, EPE, Coimbra, Portugal.

Introduction
Regional lymph node (LN) metastases have prognostic significance in differentiated thyroid cancer (DTC). Several studies demonstrated that lateral neck LN metastasis, classified as N1b, have a greater impact on overall survival than central LN metastasis. Our study aimed to assess the risk of N1a vs N1b involvement on outcome in patients with differentiated thyroid cancer (DTC), according to the 7th edition of the TNM staging system.

Methods/design
This was a retrospective study of 276 patients identified from our institutional database, who underwent surgery for DTC between 2000 and 2013. All patients had: lymph node metastasis, apparent complete tumour resection, without distant metastasis at diagnosis and nonaggressive histologic variant. The association between variables was assessed using chi-square and Student’s t-tests.

Results
All patients were followed for a minimum of 3 years postoperatively (146.3±87.1 months). Most patients had papillary thyroid cancer (99%). One hundred and twenty seven patients (46%) were classified as N1a and mean age was similar in both groups (46.6 years in N1b patients vs 47.5 in N1a; P = 0.560). There was no significant association between N1b classification and extra-thyroid extension (44.9% of N1b patients vs 46.3% of N1a patients; P = 0.812), tumour size (mean size was 23.3 vs 23.2 mm; P = 0.958), persistence of disease (29.4% vs 21.1%; P = 0.163), recurrence of disease (14.5% vs 9.1%; P = 0.182) and disease specificity (5% vs 1.5%; P = 0.1). Conclusion
Our results suggest that there is no difference in patients’ outcome with LN metastasis in the central neck compared to LN metastasis in the lateral neck or metastatic, namely disease specific mortality, recurrence and persistence of disease. These data support the recently updated TNM classification in which lymph node metastases location is not considered for staging purposes.

Two cases with metastatic thyroid cancer

Murat Dagdeviren1, Mustafa Altay1, Ozge Safak2 & Tolga Akkan3
1Endocrinology and Metabolism, Kecerioren Education and Research Hospital, Ankara, Turkey; 2Sanatoryium Education and Research Hospital, Ankara, Turkey; 3Internal Medicine, Kecioren Education and Research Hospital, Ankara, Turkey.

Although the thyroid gland has an abundant blood supply, metastasis to the thyroid gland is a rare condition. Its incidence varies from 0.1% and 3% in clinical series. First case: A 56-year-old man presented to emergency services with neurological symptoms. CT of brain revealed multiple hyperdens lesions. Posteroanterior chest X-ray showed increased opacity in the left lung. Metastatic lung cancer was considered as a preliminary diagnosis and PET/CT was performed. PET/CT showed a mass lesion of 15.8×7.6×8.5 cm in the upper lobe of the left lung and multiple pathologic involvements with metastatic appearance were present in many organs, especially thyroid gland. A biopsy was performed from the mass lesion and biopsy revealed squamous cell lung cancer. FNA was performed from a nodule located in the right thyroid lobe and cytopathological analysis of aspiration material showed metastatic epithelial carcinoma. Second case: A 42-year-old man presented with fatigue, dyspnea and cough. Thorax CT revealed a nodular lesion of 27×17 mm in posterior segment of the right upper lobe. PET/CT showed increased FDG uptake in the lung, mediastinum and abdominal multiple lymph node regions, thyroid gland and skeletal system. Biopsy was performed with fiberoptic bronchoscopy and the result was consistent with primary adenocarcinoma of the lung. FNA was performed from a nodule located in the right thyroid lobe and from a suspicious right cervical lymph node in level III. Cytopathological analysis of both aspiration materials revealed metastasis of malignant epithelial carcinoma. It was thought that medical palliative approach would be more appropriate treatment option for two cases when presence of multiple synchronous metastases, absence of local symptoms, characterization of primary diseases, general condition and life expectancy of the patients considered. Discussion. It should be known that the treatment approach in patients with metastatic thyroid cancer affects survival and treatment should be individualized.

Isolated bone metastases: a rare form of presentation of papillary thyroid carcinoma

Mariana Peyroteo, Cátia Ribeiro, Pedro C Martins, Ana Ferreira, Laurinda Giesteira, Rui Barbosa, Machado Carvalho, António Ramalho, Augusto Moreira & Abreu de Sousa
IPO Porto, Porto, Portugal.

Background
Papillary thyroid cancer (PTC) is the most frequent type of well-differentiated thyroid cancer (WDTC) and frequently poses a management dilemma. Its indolent behavior associated with high long term survival support the trend towards a more conservative management approach. The authors present a case of isolated bone metastases as the form of presentation of papillary thyroid carcinoma. A 61-year-old man was admitted with complaints of lower back pain for the previous 3 months. A longsabral spine CT and sacral MRI were performed, showing a 9×9×7.5 cm mass centered on the sacrum infiltrating the sacral canal, with soft tissue density associated with extensive lytic lesions of the sacral vertebra, suggestive of chordoma. The patient was submitted to a sacrectomy with reconstruction. The histology of the removed specimen revealed involvement of the sacrum by thyroid cancer, namely papillary type (follicular variant), with positivity for thyroglobulin and TTF-1 on the
immunohistochemistry study. The thyroid ultrasound showed multiple nodes bilaterally and the FDG-PET scan showed increased uptake in the left thyroid lobe and in the area of the sacral surgery, without other areas of high uptake. The patient was submitted to a total thyroidectomy, with the histologic study of the thyroid revealing a multifocal papillary thyroid cancer (follicular and oxyphilic variants). Ablative treatment with radioactive iodine was administered after the surgery.

Conclusion
Distant metastatic disease at presentation is rare in WDTC, with these patients having less favorable outcomes. For this reason, many risk stratification algorithms include metastatic disease as a high risk factor. This clinical case reports a rare form of presentation, showing us that, although most FTC are indolent, there are still factors about this type of tumor we need to study in order to be able to single out these specific cases for more aggressive treatment.

Association between preoperative serum MMP-9 and histopathological features of thyroid tumors
Ruxandra Dobrescu1, Catalina Piciu1, Sorina Schipor1, Adriana Padure1, Liliana Parvu1, Dana Mandai1, Dumitru Ioachim1, Corin Badiu1,2 & Andra Carageahegeopol1
1 CI Parhon National Institute of Endocrinology, Bucharest, Romania; 2 Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Matrix metalloproteinase-9 (MMP-9) is a zinc dependent proteolytic enzyme used by cells for degradation of the extracellular matrix during invasion and migration. There are only a few reports regarding the role played by MMP-9 in papillary thyroid carcinoma (PTC).

Aim
To evaluate the association between MMP-9 secretion, reflected by preoperative serum levels and the histopathological features of thyroid tumors.

Materials and methods
We assessed serum MMP-9 in 329 subjects: 309 patients with thyroid tumors and 20 healthy controls (C). Patients were divided into 2 groups, following the pathology report: benign disease group (BD) (n=176, aged 50.5±12.88 years) and PTC group (n=133, aged 48.6±14.92 years). In the PTC group histopathological features of thyroid tumors were analyzed according to pathological stage, histological subtype, multifocality and invasion. The histology showed classic PTC (cPTC) in 49 patients, follicular variant (fvPTC) in 52 and aggressive forms (AGR) in 32 patients. Sera were collected before patients underwent surgery.

Results
We found a significant difference in serum MMP-9 levels between controls and thyroid tumors (BD+PTC) (mean±SEM: 561.45±49.37 ng/ml vs 787.47±31.24 ng/ml; P<0.001). According to the pathology tumor (T1-T4), we found higher MMP-9 levels in T3 (869.77±79.48 ng/ml) compared to more incipient stages (T1 vs T3 P<0.01, T2 vs T3 P<0.03 respectively). fvPTC showed lower MMP-9 levels vs cPTC or AGR (596.38±34.76 ng/ml vs 760.35±70.54 ng/ml or vs 835.75±109.9 ng/ml, respectively, P<0.05). There was no significance between cPTC and AGR. There was no difference in MMP-9 in terms of multifocality, but patients with invasive tumors had significantly higher serum MMP-9 than non-invasive ones (838.14±80.3 ng/ml vs 618.68±30.9 ng/ml, P<0.02).

Conclusions
Preoperative serum MMP-9 might differentiate patients at risk for invasive and more aggressive tumor behavior, with implications in post-surgical radioiodine treatment and follow-up.

Follicular thyroid carcinoma and follicular variant papillary thyroid carcinoma: Clinical and histological features depending on the size
Fernando García Pérez1, Guillermo Martínez de Pinillos Gordillo2, Mariana Tomé Fernández-Ladreda3, Eyyve Arturo Cuéllar Lloclla4, José Alvaro Romero Porcel4, Carmen Carretero Marin5 & María Victoria Cósar León6
1 Hospital Universitario de Valme, Sevilla, Spain; 2 Hospital Punta de Europa, Gibraltar, Spain.

Introduction
Follicular Thyroid Carcinomas (FTCs) and Follicular Variant Papillary Thyroid Carcinomas (FVPTCs) may present absence of suspicious ultrasonography features more frequently than classic papillary carcinomas. Thus, some cases may be identified with the pattern of ‘low suspicion’ rather than intermediate or high suspicion defined in the American Thyroid Association (ATA) guidelines of 2015. These guidelines establish a size cutoff of 1.5 cm to recommend fine-needle aspiration in nodules belonging to this category of low suspicion, justified because the possibility of distant metastasis in FTCs <2 cm is rare. The aim of this study is to analyze the peri-thyroidal extension and the presence of variables associated with greater aggressiveness in cases of FTC and FVPTC as a function of the initial size.

Description of methods
A retrospective study of 76 patients with diagnosis of FTC or FVPTC was conducted. The presence of the followings clinical and histological parameters were evaluated: initial perithyroidal extension; aggressive histologic variants (extensive capsular invasion, oncocytype features, undifferentiated foci); presence of vascular invasion, presence of lymph node metastases and distant metastases at diagnosis and during follow-up. The differences between the 2 groups were analysed according to nodular size: <1.5 cm (group A) and ≥ 1.5 cm (group B).

Results
76 cases with a mean age of 53.16 years, 75% women. Group A: 40 cases, size 0.72±0.34 cm, 8% FTC and 92% FVPTC. Group B: 36 cases, size 2.76±1.04 cm, 33% FTC and 67% FVPTC. Extraplatyzod extension 5% vs 19.4% (P=0.052); aggressive histologic variants 0% vs 22.2% (P=0.002); vascular invasion 0% vs 19.4% (P=0.003); lymph node metastases 10% vs 13.9% (P=0.6); distant metastasis 0% vs 2.3% (P=0.28).

Conclusion
The presence of aggressive histologic variants and vascular invasion was significantly greater in the carcinomas ≥1.5 cm. None of the carcinomas <1.5 cm presented aggressive histological, vascular invasion or distant metastases at diagnosis or during follow-up. Our data agree with the recommendation established by the ATA to choose a size cutoff of 1.5 cm for low suspicion pattern nodules.

**Metastatic papillary thyroid carcinoma with intraglandular dissemination in remission of Graves’ disease**

Dubravka Brdar, Davor Eterović, Gordana Sošo, Tina Majstorović & Ante Punda

University Hospital Center Split and Split University School of Medicine, Split, Croatia.

A 26-year-old woman was referred to our outpatient clinic, presenting with growing left sided neck mass. She was in remission of Graves’ disease for the last two years. Ultrasound examination revealed isoechogenic nodule with microcalcifications in the upper third of the left thyroid lobe measuring 9.5 × 6.6 mm and conglomerate of lymph nodes on the left side of the neck, the largest node measuring 37 × 21 × 13 mm. Behind the lower pole of the left thyroid lobe we found lymph node. Fine needle aspiration of the isoechogenic nodule in the left thyroid lobe, conglomerate of lymph nodes on the left side of the neck and lymph node behind the lower pole of the left thyroid lobe revealed papillary carcinoma. Total thyroidectomy with left modified radical neck dissection was performed. Histopathological examination confirmed papillary thyroid carcinoma with intraglandular dissemination and metastases to 18 out of 26 lymph nodes. Patient received ablative-therapeutic dose of 3.83 GBq of 131I. Now, 6 years later, the patient is disease free.

**Thyroid nodule size and the risk of malignancy**

Entela Puca1, Ema Lumii2, Blerta Oldilash2, Sonila Bitri1, Dorina Yli1, Agron Yli1 & Edmond Puca2

1American Hospital 2, Tirana, Albania; 2Neo-Style Clinic, Tirana, Albania; 3UHC Mother Teresa, Tirana, Albania; 4Regional Hospital Temi Konomi, Korce, Albania.

**Introduction**

Thyroid nodule size is routinely assessed and has been a cause for concern, if it is a carcinoma or not.

**Aim**

Our aim was to evaluate the relationship between thyroid nodule size and cancer risk. It was a retrospective analysis of 386 patients with thyroid nodules who referred to surgery in our hospital from January 2011 to March 2016. Patient’s demographic data, nodules size, and final pathology were recorded. All data were analyses using SPSS18.

**Results**

From the total of 386 patients, female were 86% and male 14%, with mean age of 46.75 years old ± 14.24 DS were included for this study. Based on final pathology 179 patients (46.5%) had malignant nodules. The mean size of malignant and benign nodules were 3.07 ± 1.52 cm and 3.6 ± 1.59 cm respectively (P < 0.003). For the purposes of this investigation, thyroid nodules < 1 cm in diameter provided baseline cancer risk for comparison (5.6% risk of cancer). The overall prevalence of cancer in nodules 1.0–1.9 cm was 20.1%; 2–3.9 cm was 30.8%; in nodules 3.0–3.9 cm, 23.4%; and in nodules ≥ 4.0 cm, 20.1%. The primary influence of this association was the low malignancy rate in nodules under 1.0 cm. When comparing nodules 1.0–1.9 cm, 2.0–2.9 cm, 3.0–3.9 cm, no difference in malignancy rate was demonstrated (P = 0.5). For nodules > 4 cm the differences was statistically significant (OD: 3.17; CI95%: 1.01–10.02; P < 0.04).

**Conclusion**

These data provide strong evidence that thyroid nodule size > 4 cm is associated with an increased risk (three fold) of well-differentiated thyroid cancer and can be applied in medical decision for thyroid surgery.

**Lateral cervical lymph node metastasis from papillary thyroid cancer of undetected primary: a case report**

Athanasios Panagiotoud1, Fotini Adamidou1, Panagiotis Anagnostis1, Mattheos Bobos1, Dimitris Hatzibougias1, Keraso Tzelpe1 & Marina Kita1

1Ipipokration General Hospital of Thessaloniki, Thessaloniki, Greece; 2Microdiagnostics Ltd, Thessaloniki, Greece; 3St Luke’s Hospital, Thessaloniki, Greece.

**Background**

Lymph node metastasis from papillary thyroid cancer without detectable primary within the thyroid gland is extremely rare. We describe a case of a young woman with a cervical metastasis, without detectable orthotopic or ectopic thyroid focus.

**Case report**

A 30-year-old woman with a history of adenocarcinoma of the ascending colon six years previously, presented at the 15th week of a normal second pregnancy, for management of subclinical Hashimoto’s thyroiditis. She had received thyroxine replacement during her first pregnancy 2 years earlier. She had a family history of colon cancer in her maternal grandmother and her mother’s two cousins. On examination she had a palpable node at the right lateral compartment and her thyroid was not palpable. Ultrasound examination of the neck showed a small, mildly hypoechoic, heterogeneous gland and a well-defined, hypoechoic mass 30 × 15 × 13 mm, lateral to the right carotid artery at level IV. The mass was finally excised one year postpartum and was found to be a lymph node occupied extensively by follicular variant of papillary thyroid cancer. She subsequently underwent total thyroidectomy with central and right lateral node dissection without complications. Thoracic histologic examination of the thyroid failed to reveal cancer, central compartment nodules were negative (0/17) and one more node harbored microscopic metastasis (1/18) on the right side. The contralateral nodes dissected were negative (0/9). MRI of the oropharynx, mediastinum, abdomen and pelvis and non-contrast CT of the lungs (scheduled for follow up of the bowel carcinoma) were normal. The patient has been referred for radioactive iodine treatment.

**Conclusions**

Papillary thyroid cancer presenting as a cervical mass in the absence of a thyroid primary, needs to be differentiated from ectopic thyroid cancer in the neck or elsewhere. A picocarcinoma or one that has spontaneously regressed cannot be excluded.

**Birt–Hogg–Dubé and papillary thyroid carcinoma: a case report**

Ines Barka1, Katherina Krompa2, Camille Baudry1, Frédéric Caux1 & Hélène Bihan3

1Endocrinology, Diabetology and Metabolic Disease, Hôpital Avicenne – Hôpitaux Universitaires Paris, Seine-Saint-Denis, France; 2Dermatology, Hôpital Avicenne – Hôpitaux Universitaires Paris, Seine-Saint-Denis, France.

**Background**

Birt–Hogg–Dubé (BHD) syndrome has been reported to be associated with neoplastic conditions. Its association with thyroid carcinoma has been reported but remains controversial. Here we report the case of a BHD patient with a thyroid papillary carcinoma.

**Case report**

A 47-year-old man presented with asymptomatic facial papules, which had been gradually increasing in number for 6 years. A biopsy was taken from a papule on the nose and histology examination showed epithelial proliferation. Mutation in exons of FLCN was identified which confirmed the diagnosis of BHDs. A systematic ultrasound examination of his neck showed a 2 cm solid isoechic nodule of the right thyroid lobe. The left thyroid lobe and the isthmus appeared to be normal. Serum levels of free thyroxine, and thyrotropin were within normal ranges. Fine needle aspiration of the nodule revealed papillary clusters that had atypical nuclei and intranuclear inclusions and that appeared to be a papillary carcinoma. Our patient underwent a total thyroidectomy with neck exploration. The pathologic examination confirmed the diagnosis of papillary carcinoma classified T1/N0/MX. The patient was put on L-thyroxine and a radioiodine therapy will be considered.

**Discussion**

Birt–Hogg–Dubé syndrome consists of multiple fibrofolliculomas traditionally associated with trichodiscomas and acrochordons. Medullary carcinoma of the thyroid was the most reported type of cancers. Even though, other types of carcinoma as papillary carcinoma et carcinoma were not the common form of BHD syndrome could also occur. Our report is of high scientific interest because it will increase awareness of BHD in the medical community, as this syndrome is too often overlooked even when obvious clinical manifestations are present. So the neck ultrasound is recommended for BHD patients and family members.
Among other BHD patients followed in our hospital, we will look for the frequency and results of ultrasounds.

Diagnosis of papillary thyroid carcinoma: Is it time to reconsider?
Panagiotis Panousis, Stella Vasileiadou, Michael Katsamakas, Maria Boudina, Anastasia Nikolaoud, Alexandra Chrysoyidou, Kalliopi Pazaitou-Panayiotou & George Zafeiriou
Theagenio Cancer Hospital, Thessaloniki, Greece.

Aim
The aim of this retrospective study was to evaluate the diagnostic significance of presurgical thyroid ultrasound in comparison with FNAC of thyroid nodules and their contribution in detecting thyroid cancer.

Patients and methods
We retrospectively studied the files of 118 thyroid cancer patients, 18 men (15.2%) and 100 women (84.8%), who underwent thyroidectomy from January 2013 until December 2016, in the Department of Surgical Oncology of Theagenio Cancer Hospital, Thessaloniki, Greece. All patients were diagnosed and followed up by the Section of Endocrinology and were operated upon by the same surgical team. The mean patient age was 55 years (+12.6). We evaluated the suspicious ultrasound findings according to the ATA Guidelines of 2015 (hypoechoicity, microcalcifications, taller than wide shape, irregular margins, extrathyroid extension) and the results of FNAC (in accordance to Bethesda Score), in association with the pathology report. All ultrasounds were scored based on the suspicious characteristics.

Results
Mean tumor size was 7.1 mm (±8.73 mm), multifocality was found in 69 patients (58.5%). The Bethesda score was positive for malignancy in 45% of the patients whose age at diagnosis was 45 years more frequently had WI-FTC (27.3% Vs 4.0%, P<0.010). A higher cancer stage (III–IV) was also confirmed. In subsequent follow-ups there were no signs and symptoms of the disease recurrence. Thyroid CASTLE might be easy overlooked because of its rarity and similarity to some thyroid cancers like squamous cell carcinoma or anaplastic carcinoma. Complete thyroid resection and lymphadenectomy are important to improve the long-term survival and the locoregional recurrence rate, although CASTLE course is usually clinically indolent. The short review of the already published data regarding CASTLE was done.

DOI: 10.1530/endoabs.49.EP1474

EP1475

Minimally and widely invasive follicular thyroid carcinomas: are there significant differences in clinical behaviour and prognosis?
Diana Martins1, Cristina Ribeiro1, Miguel Melo1, Joana Saraiva1, Maria Joa˜o Martins2, Carla Baptista1, Diana Oliveira1, Mara Ventura1, Adriana Lages1, Nelson Cunha1, Diana Catarino1, Luısca Fadiga1, Gracinda Costa2 & Francisco Carrilho1
1Endocrinology, Diabetes and Metabolism Department of Coimbra Hospital and University Centre, Coimbra, Portugal; 2Anatomic Pathology Department of Coimbra Hospital and University Centre, Coimbra, Portugal; 3Nuclear Medicine Department of Endocrinology, Diabetes and Metabolism Department of Coimbra Hospital and University Centre, Coimbra, Portugal.

Introduction
The existence of clear differences between the biological course and clinical behaviour of minimally invasive (MI) and widely invasive (WI) follicular thyroid carcinomas (FTC) is still debatable. The present study was conducted to outline the clinical differences between MI and WI-FTC and evaluate outcomes in both tumors.

Methods
We conducted a retrospective cohort study involving 80 cases of FTC. The comparison between MI-FTC and WI-FTC included an evaluation of clinicopathologic characteristics, including tumor staging, and outcome assessment.

Results
The cohort included 65 patients with MI-FTC and 15 patients with WI-FTC. Patients whose age at diagnosis was ≥45 years more frequently had WI-FTC (27.3% Vs 4.0%, P=0.023). Mean tumor size was significantly greater in WI-FTC patients than in the MI-FTC (43.07 vs 30.94 mm, P=0.007). At univariate analysis, vascular invasion, infiltrative margins and invasion of thyroid capsule were significantly related to the presence of WI-FTC (P<0.001, P<0.001 and P=0.010, respectively). A higher cancer stage (III–IV) was also associated with the occurrence of WI-FTC (50% vs 8.6%, P<0.001). After a mean follow-up of 52.6 and 76.4 months in MI and WI-FTC, respectively, one patient of the first group and two patients of the second died of FTC. Patients with MI and WI tumors respectively presented a disease-free survival of 100% and 84% at 10 years.

Conclusions
The study reported a good outcome in both MI and WI patients, probably related to an aggressive therapeutic strategy and strict follow-up. Our data confirm previous studies which showed that WI-FTC are typically larger tumors with higher stage, more frequent vascular invasion and invasion of the thyroid capsule. Accordingly, we believe that the tumor grade of invasiveness must be taken into account on the staging process of disease.

EP1476

Cystic masses of neck: a case report
M Teresa Gallego, Lucía Vera, Amparo Meoro, Cristina Del Peso & Manuel Martín
Hospital General Universitario Reina Sofia, Murcia, Spain.

Thyroid carcinoma showing thymus-like differentiation (CASTLE) is an extremely rare thyroid neoplasm. This type of tumour may arise from branch pouch remnants or ectopic thymus and is considered as independent clinicopathological entity of thyroid neoplasms. There have been only about 100 cases described in the literature, so far. Here, we have retrospectively analyzed the data from histopathology and clinics of a 70 year old female patient with thyroid CASTLE who underwent total thyroidectomy in 2009 due to thyroid nodule in the right lobe (25×25×30 mm) and suspicion of papillary thyroid carcinoma in the fine needle aspiration biopsy. At that time histopathological examination suggested presence of metastasis to the thyroid likely from the ovary or thymus however, the detailed clinical and imaging study did not confirm that these organs could be the source of this lesion. In February 2011 patient underwent neck lymphadenectomy that revealed metastases to the lymph nodes with unknown origin but thyroid carcinoma was ruled out. Patient was all time under control of endocrinologist and oncologist. In May 2014 patient was again hospitalized and next lymphadenectomy was done. At that moment histopathology of the lymph nodes indicated CASTLE (HMWCK +, p63 +, CD5 +, bcl2 +, CEA +, synaptophysin +, Calc +, THY +, TTF1 +). Therefore, the thyroid specimens were reevaluated again, and the presence of CASTLE in the gland was also confirmed. In subsequent follow-ups there were no signs and symptoms of the disease recurrence. Thyroid CASTLE might be easy overlooked because of its rarity and similarity to some thyroid cancers like squamous cell carcinoma or anaplastic carcinoma. Complete thyroid resection and lymphadenectomy are important to improve the long-term survival and the locoregional recurrence rate, although CASTLE course is usually clinically indolent. The short review of the already published data regarding CASTLE was done.

DOI: 10.1530/endoabs.49.EP1476

Endocrine Abstracts (2017) Vol 49
Introduction

Cystic masses of neck consist of a variety of pathologic entities. The age of presentation and clinical examination narrow down the differential diagnosis. In adults are considered to be malignancies until proven otherwise (thyroid lesions, salivary gland neoplasms, metastatic squamous cell carcinoma and lymphatic malformations such as the cystic lymphangioma. Ultrasound (US) is often used for initial evaluation. Computed tomography (CT) and MRI provides additional information. FNAC has a supplementary role for confirmation of diagnosis but its accuracy may depend on the experience of the cytopathologist.

Case report

A 41 years old woman presented with a left-side neck mass that had slowly enlarged over the past 6 months with a serious burn. MRI showed a 72*57*47 mm septate mass, with solid and cystic components with contralateral airway displacement and posterior displacement of the carotid. Thyroid US had revealed a normal gland. FNAC was nondiagnostic but the initial diagnosis was a cystic lymphangioma and the patient was treated with Plicibanil (OK-432) without any result. Six months later she underwent surgical excision. The histopathology report came out as Cystic metastatic lymph node from Papillary carcinoma of the thyroid. US demonstrated a poorly defined nodule with micro-calciﬁcation in the left lobe of the thyroid. One week later she underwent a total thyroidectomy and bilateral cervical lymphadenectomy. The final diagnosis was a 12 mm Papillary Carcinoma with bilateral metastatic lymph nodes.

Discussion

Metastatic nodes from head-and-neck malignancy, especially papillary carcinoma of the thyroid, are the most common types of nodal metastases presenting as cystic masses in the neck. Eighty percent of the cystic masses in patients over 40 years of age are due to necrotic lymph nodes. On US presence of punctate calcification within the solid component of the cystic node warrants careful search for primary papillary carcinoma in the thyroid gland. In our patient the diagnosis unfortunately was a challenge.

Conclusions

Cystic lesions of the neck are commonly encountered on imaging studies. Clinical presentation along with imaging features as assessed by Doppler US or CT help in accurate diagnosis. These imaging modalities also aid in optimal pre-operative planning. Imaging is essential for accurate diagnosis and pretreatment planning.

EP1478

Cystic node and carcinoma of thyroid gland, diagnosis and treatment of cistic nodule

Snezana Mihajlovska & Marija Mihajlovska
1Department of Nuclear Medicine, Clinical Center ‘St. Trifun Panovski’, Bitola, Macedonia; 2Department of Endocrinology, General Hospital ‘8-mi Septemvri’, Skopje, Macedonia.

The cystic nodule is by its origin a real or pseudo cyst. According to the date of literature the papillary thyroid carcinoma is being detected in the cystic nodule in up to 27% of the cases. Ultrasound is the best diagnostic method of the cystic nodule and fine needle aspiration under ultrasound examination is a diagnostic method for cytological diagnosis.

Results

Seventy patients with detected cystic node underwent fine needle aspiration and the aspirational content was cytopathologically examined. In 31/70 (44.3%) of patients there was a complete discharge of the cyst. In 4/70 (5.7%) there was partial discharge but without recidivans and in 35/70 (50%) of patients there were recidivants of cystic contents. According to the fine needle pathohystological findings in nine patients was detected a malignancy (eight patients had papillary and one follicular carcinoma).

Conclusion

Cystic nodule in thyroid gland is diagnosed by using ultrasound. Fine needle aspiration is used for discharging of the cyst. Cysts which recidivate after few needle aspiration should be operated surgically, and the patient with proved carcinoma are cured according to the protocol for the treatment of thyroid malignant disease.

EP1479

Incidence of thyroid cancer in the gray bethesda categories

Berta Barbosa, Moreira da Costa, Vítor Valente, Fatima Borges & André Carvalho
Centro Hospitalar Porto, Porto, Portugal.

Objective

The recommendations for action in a Bethesda category III are to repeat the cytology or to perform molecular tests, and if these are inconclusive, surveillance or surgical indication may be maintained, depending on the risk factors, ultrasound characteristics of the nodule and patient preference. In case of category IV of Bethesda, the recommendation is the surgery. The objective of this study was to evaluate the impact of age, gender and nodule size on the incidence of malignant lesions in patients with thyroid nodules with Bethesda III and IV classification.

Material and methods

Retrospective observational study of patients undergoing Total Thyroidectomy between July 2014 and June 2016. Totalizations were excluded. Descriptive analysis and statistical test with SPSS 20.

Results

Four hundred ninety two patients were submitted to Total Thyroidectomy after their presentation at the Multidisciplinary Thyroid Group consultation. The mean age of the patients was 54.6 years, being 82.7% female. Bethesda III was indicated in 52 patients, and Bethesda IV in 125 patients. In category III, in seven patients (13.5%) the histology revealed to be a malignant lesion, 71.4% female, mainly in the 5th decade of life; the majority of patients were T1b. In category IV, in 20 patients (16%) the histology revealed a malignant lesion, 65% female, mainly in the 6th decade of life; the majority of patients were T1b.

Conclusions

In our series, 13.5 and 16% of patients with a category III and IV Bethesda surgical indications were found to be malignant lesions, respectively, according to the literature (5–15% for Bethesda III, 15–30% for Bethesda IV). It was not possible to find a statistically significant difference between the variables tumor size, age group of patients and gender.

EP1477

Staging of thyroid cancer at the time of its diagnosis in a single clinical centre

Agata Baldis-Waligorska1, Maciej Kolodziej1, Monika Buziak-Bereza1, Michal Koziara1 & Andrzej Sokolowski2
1Jagiellonian University College of Medicine, Krakow, Poland; 2University of Economics, Krakow, Poland.

Medical documentation of 976 patients treated and followed-up over the years 2000–2006 at our 131-I–radioisotopes treatment centre was analysed with respect to their thyroid cancer staging. The mean age at their time of diagnosis was 59 ± 15.1 years. From histopathology, papillary, follicular or poorly differentiated cancer was diagnosed in 87.6, 11.7, and 0.7% of these patients, respectively. The mean ages of patients with papillary, follicular or poorly differentiated cancer were 58.4 ± 15.0, 62.9 ± 15.7 and 70.6 ± 14.6 years, respectively, the age differences between these patient groups being statistically significant (P = 0.0014). On their admission, patients were TNM-staged. Patients with microcarcinoma pT1a formed the largest group – 38.9%, followed by T1b – 32.3%, T2 – 10.0%, T3 – 12.3%, T4 – 3.0%, and T4s – 3.5%. In the last case the tumour diameter was not established by the surgeon or pathologist. Most patients were staged at N0 – 88.9%, followed by N1a – 9.7%, and N1a + b – 1.4%. At the time of diagnosis, distant metastases to lungs or bones was staged as M1 only 0.6% of patients. On chi-square analysis of percentage distribution of tumour size (T) in papillary cancer patients, pT1a was most frequent (42.8%), while T2 dominated in the follicular cancer group (32.5%). This difference was statistically significant (P = 0.0000). No differences were found with respect to N or M classes. In the follow-up of this patient group, 77 patients were re-operated due to lymph node or lung metastases, and 23 patients were operated three times. Multiple 1-131 treatment (2–6 times) was applied in this last group. Three patients died due to thyroid cancer progression.

Conclusion

On their diagnosis, patients with papillary cancer and follicular cancer significantly differed with respect to age and stage of disease.

Sentinel lymph node biopsy in medullary thyroid microcarcinoma after methylene blue dye mapping – a pilot study

Radan Dzodic1,2, Nada Santrac1, Marko Buta1,2, Merima Goran1, Igor Djurisic1 & Ivan Markovic1,2

1Department of Nuclear Medicine, Clinical Center '8-mi Septemvri', Skopje, Macedonia.

Endocrine Abstracts (2017) Vol 49
Introduction

The aim was to analyse usefulness of sentinel lymph node (LN) biopsy of jugulo-carotid regions after methylene blue dye mapping for selection of clinically N0 patients with medullary thyroid microcarcinomas (MTMC) and lateral LN metastases for one-time modified radical neck dissection (MRND).

Materials and methods

From 2007 to 2016, 15 patients were operated in our institution due to MTMCs with serum calcitonin levels lower than 1000 pg/ml, tumors under or 10 mm in size and clinically negative regional LNs. Total thyroidectomy with central neck dissection was done in all patients. Sentinel LN mapping was performed by injecting 0.2–0.5 ml of 1%-methylyene blue dye in the thyroid lobes. Blue stained sentinel LNs were removed from II/III levels and examined by frozen section. In case sentinel LNs were benign, additional non-colored LNs were removed for standard pathological analysis. If sentinel LNs were positive on frozen section, one-time MRND was performed.

Results

One patient had hereditary form of medullary thyroid carcinoma, with bilateral subcentimeter tumors, while others had sporadic, unilateral MTMC. Sporadic MTMCs showed neither central nor lateral LN metastases on bilateral sentinel LN biopsy, with no indication for MRND. Hereditary MTMC had central LN metastases, with positive sentinel LNs on both sides, thus one-time bilateral MRND was performed. This patient had metastases in other dissected LNs, as well, and serum calcitonin level of 221 pg/ml. Frozen section and definite pathological analysis were 100% match.

Conclusion

Sentinel LN biopsy after methylene blue dye mapping can be precisely used for intraoperative assessment of lateral neck LNs. It optimizes surgery of MTMCs, selecting clinically N0 patients with metastases on frozen section for one-time MRND. This pilot study is the first reported experience with sentinel LN biopsy of jugulo-carotid regions in medullary thyroid carcinomas using methylene blue dye, focusing on the subgroup of microcarcinomas.

reached remission was 0% (0/5) with extracapsular involvement vs 50% (5/10) without extracapsular involvement (P 0.053). Among 15 patients with N1 category, only three were cured (all had < 5 LN and a size LN < 2 cm).

In our case series we observed that N category and number of LN is associated with PD in the long term. Furthermore, there was a linear trend between the size of the greatest LN and the extracapsular involvement with the PD. This reinforces the importance of a correct characterization of LN involvement.

EP1482

A case of bilateral metastatic renal tumor of thyroid carcinoma

Lila Brakni
Endocrinology, Algiers, Algeria.

Introduction

Distant metastasis caused by thyroid carcinoma is common and usually found in lung or bone. Clinically detectable, welldifferentiated metastatic thyroid carcinoma to the kidney is rare. Only 16 cases have been reported in the literature. We describe a case of metastatic vesicular thyroid carcinoma to the bilateral kidneys in a 61 years women, with bone, pulmonary lever and lymph nodes metastasis.

Case report

A 61 old women with a past history of thyroid tumor that had been surgically treated 19 years earlier She underwent a total thyroidectomy, radiotherapy, s ablation treatment with iodine 131 and thyroxin suppression therapy (200 μg/day) and has been diagnosed as vesicular thyroid cancer developed a left renal metastasis with chest pain. The lesion was detected with iodine 131 scintigraphy which measured in the CT Scan 68/60/13 mm. Biological tests showed: The thyroglobulin 3000 ng/ml (0.8–5.5) and 0.02 μU/ml. Subsequent surgery and histopathology analysis of the renal lesion confirmed the diagnosis of vesicular thyroid metastatic carcinoma. Four years later a second metastasis of the right kidney appeared with pulmonary, bone, leaver and lymph nodes metastasis. She underwent surgery where metastatic carcinoma was confirmed (3 cm of diameter).

Discussion - Conclusion

Only few cases of metastatic spread to the kidneys are described in the literature. 16 cases have been reported. They are mostly unique and rarely bilateral. The common use of the ultrasound and the CT Scan in assessment of monitoring of a cancer, patient allowed bringing to light more frequently this kind of lesion. The concomitant existence of metastasis in the other sites is variously appreciated in the literature. They varies from 50 to 100% observed cases and pejorative from the point of view of the prognosis. The most frequent locations are pulmonary, mediastinal and bone. The patient has benefited a dialysis treatment and deceased a year later.

EP1483

Is prophylactic central cervical dissection in papillary carcinoma of the thyroid justified?

Berta Barbosa, Moreira da Costa, Vitor Valente, Fátima Borges & André Carvalho
Centro Hospitalar do Porto, Porto, Portugal.

Objective

Thyroid cancer is the most common of the endocrine tumors, with papillary being the most frequent. There is no consensus about prophylactic central cervical dissection in patients with papillary carcinoma of the thyroid. The aim of this

Endocrine Abstracts (2017) Vol 49
study is to analyze surgical complications and the rate of recurrence of papillary carcinoma in patients undergoing total thyroidectomy and prophylactic central cervical dissection, and patients submitted to total thyroidectomy alone.

Material and methods
Prospective study of consecutive patients submitted to total thyroidectomy and prophylactic central cervical dissection between January 1993 and December 1999, and consecutive patients submitted to total thyroidectomy alone, in the same period of 7 years, for papillary carcinoma of the thyroid. The groups were compared in relation to surgical complications and the rate of disease recurrence.

Totalizations of thyroidectomy were excluded. Statistical analysis with SPSS 20

Results
Fifty-nine patients underwent total thyroidectomy and prophylactic central cervical dissection (mean age 46.3 years, 86.4% female), 43 patients underwent total thyroidectomy alone (mean age 46.2 years, 95.3% female). Recurrent laryngeal nerve injury occurred in 10 patients after CCD and in two patients after TT. Hypoparathyroidism occurred in 24 patients (20.8% definitive) after CCD and in 15 patients (14.3% definitive) after TT. Disease-free survival rates were of 84.3% of patients 10 years after CCD, and 88.6% after TT alone.

Conclusions
In our series, it was not possible to establish a statistically significant difference between groups regarding recurrence of the disease, but a statistically significant difference regarding surgical complications. According to our results, we consider prophylactic central cervical dissection in papillary carcinomas of the thyroid not justified.

DOI: 10.1530/endoabs.49.EP1483

EP1484
Thyroid cancer frequency over three decades
Cecilia Sanchez-Ragnarsson, Silvia Gonzalez & Edelmiro Menendez-Torre
HUCA, Oviedo, Spain.

Aim
To investigate the frequency of thyroid carcinoma and its subtypes in one region over three decades.

Material and methods
Data retrospectively collected from a tissue bank where all hospitals in a region with a little above 1 million inhabitants should send samples from all operated tumors, from 1981 to 2010.

Results
From 1981 to 1990 there were 156 thyroid cancers; 206 from 1991 through 2000 and 362 from 2001 through 2010, with a 132% rise from the first decade to the last one. Papillary cancer accounted for just 42% in the first decade, rising to 65% in the 2000s. There was also an absolute 50% rise in follicular cancer incidence, although the relative percentage fell from 40% in the first decade to 26% in the last one. Medullary cancer incidence increased by 150%, but relative percentage remained stable between 3 and 4%. Frequency of other rare types of thyroid neoplasms such as anaplastic, lymphoma or squamous carcinoma remained stable.

Conclusions
Thyroid carcinoma incidence is rising, mainly due to a rise in papillary carcinoma, as previously reported, but we also observed an increased incidence in follicular carcinoma.

Thyroid nodules: a huge dilemma!
Bonnie Grant1, Bethan Goulden1, Raj Tanday1, Edel Casey1, Antony Pittathankal2, Akin Ojo1, Imran Syed1 & Khash Nikookami1
1Diabetes and Endocrinology Department, Barking Havering and Redbridge University Trust, Greater London, UK; 2Surgery Department, Barking Havering and Redbridge University Trust, Greater London, UK.

Current UK guidelines for thyroid nodules advise a thyroid ultrasound (ThyUSS) with U-Classification with or without Fine Needle Aspiration (FNA) with Thy-Classification to determine malignancy risk. We report four cases where thyroid carcinoma was diagnosed histologically following reassuring cytology and radiological examination. This is a case of 28-year-old female who presented with neck swelling. ThyUSS showed an enlarged left thyroid with cystic and solid components; FNA was Thy2. Surveillance ThyUSS showed additional right-sided nodules without pathological features; FNA was Thy1. The patient opted for thyroidectomy; histology showed two small foci of papillary carcinoma. 53-year-old female referred with a right dominant nodule following ThyUSS; FNA was Thy2. Subsequent ThyUSS showed a mildly hypoechogenic, vascularised nodule with peripheral halo; FNA was Thy1. The patient opted for right thyroid lobectomy; histology showed benign follicular nodules with the dominant nodule containing an incidental papillary microcarcinoma. 60-year-old female had an incidental finding of a left thyroid nodule on CT neck on a background of autoimmune hypothyroidism and a family history of thyroid cancer. ThyUSS showed a left dominant nodule with increased peripheral vascularity and smaller right-sided nodules; FNA was Thy2. The patient opted for a left thyroid lobectomy; histology showed papillary thyroid carcinoma and subsequent right thyroidectomy. Histology also showed papillary micro- carcinoma. 41-year-old female presented with T3-thyrotoxicosis with positive thyroglobulin antibodies and swelling corresponding to the thyroid. ThyUSS showed a right-sided, solid homogenous nodule and two small left-sided nodules. Repeated ThyUSS over nine months were stable; FNA was Thy2 and Thy1c. Technetium scan showed a right-sided toxic nodule and co-existent cold nodule. Following right hemithyroidectomy histology showed benign follicular adenoma and an incidental papillary microadenoma.

Conclusion
These cases demonstrate that whilst the U- and Thy-Classifications are reassuring they do not exclude malignancy. This uncertainty should be highlighted to patients when discussing management of thyroid nodules.

Timing to repeat thyroid fine-needle aspiration after a follicular lesion of undetermined significance result - does it matter?
Francisco Sousa Santos1, Carla Ferrinho1, Ricardo Capitão1, João Sequeira Duarte1, Martinha Chorão1, Clotilde Limben1 & Carlos Vasconcelos1
1Centro Hospitalar Lisboa Ocidental - Serviço de Endocrinologia, Lisboa, Portugal; 2Centro Hospitalar Lisboa Ocidental - Serviço de Anatomia Patológica, Lisboa, Portugal.

Introduction
Regarding thyroid nodules, in case of follicular lesion of undetermined significance (FLUS), performing repeat fine-needle aspiration (FNA) is a common follow-up strategy. It has been suggested that a waiting period of at least 3 months between FNAs would increase the diagnostic yield. Our study aims to clarify the optimal time for repeat FNA in case of an initial FLUS result.

Methods
We identified retrospectively all thyroid FNA FLUS results that occurred in our institution in 2016 and analysed only the patients who were submitted to repeat FNA. We recorded cytologic diagnosis, time between FNA and histologic results. We compared in relation to surgical complications and the rate of disease recurrence.

Results
A total of 79 patients were included, with ages between 34 and 86 years. Mean nodule diameter was 26.7 ± 11.7 mm. After the second FNA, 8 (10.18%) patients also underwent a third one. A total of 6 (7.6%) had surgery performed at some time during follow-up – 2 cases with malignant histology results. The result of the second FNA was non-diagnostic in 27.8% of cases and remained FLUS in 26.6%. Mean time interval between the first and second FNA was 3.8 ± 1.4 months. We did not find a statistically significant difference in diagnostic yields (P = 0.267) or diagnostic non-FLUS results (P = 0.523) between second FNA’s performed 3 months or earlier (36 patients) compared to those performed later (43 patients). Timing (as well as sex, age and nodule diameter) remained not correlated with diagnostic yield or diagnostic non-FLUS results after regression analysis using time between FNAs as a continuous variable.

Conclusion
Although our study had limited numbers, its results suggest that in case of a first FLUS FNA result, and if the decision to repeat is considered by the clinician, the timing of the second FNA does not seem to affect its diagnostic yield or the likelihood of another FLUS result.

Endocrine Abstracts (2017) Vol 49
Development of hypoparathyroidism due to targeted therapies
Asena Gökçay Canpolat¹, Berna İmge Aydoğan², Sevim Gullu¹ & Murat Faik Erdogan¹
¹Department of Endocrinology and Metabolism, Ankara University Faculty of Medicine, Ankara, Turkey; ²Batman State Hospital, Batman, Turkey.

Due to inhibition affect on proliferation, motility, resistance to apoptosis and growth of metastasis, the epidermal growth factor receptor (EGFR) inhibitor erlotinib and vascular endothelial growth factor receptor (VEGF) and EGFR inhibitor vandetanib are viable treatment options for treatment of advanced non-small cell lung cancer and thyroid cancer respectively. Advanced non-small cell lung carcinomas (NSCLC) or medullary and differentiated thyroid carcinomas (MTC and DTC) may present with bone metastasis in the presence of bone pain, elevated serum calcium or elevated alkaline phosphatase levels. We, hereby represent two patients who had diagnosis of NSCLC and MTC with bone metastasis, both treated with EGFR inhibitors and presented surprisingly with hypocalcemia in our outpatient clinic as a result of hypoparathyroidism. Sudden declines in calcium levels after initiating EGFR inhibitors contrary to the evidence of bone metastasis in these cases preoccupied that these agents may prevent parathyroid cell growth and decreased PTH levels lead to hypocalcemia.
