ENDOCRINOLIGISTS IN SPECIALIST REFERENCE CENTRES

METHOD

EMENA is an alliance of European-based patient groups and clinicians managing families affected by multiple endocrine neoplasia (MEN) disorders. An online, multi-language patient survey regarding Quality of Care was developed and distributed by EMENA via its patient group and health professional members and on a variety of social media channels, including twitter and Facebook. A total of 289 responses were analysed. A single MEN4 response was excluded for lack of comparable responses and 4 duplicated or incorrect disease responses were excluded resulting in a total of 284 responses as detailed below.

RESULTS

Endocrinologists in specialist reference centres were commonly in charge of the care of MEN patients in both the UK and throughout Europe. (See P306 for more information on the differences and similarities in the provision of care in MEN throughout Europe).

We asked patients to rate aspects of their interactions with the medical team in charge of their MEN care. There were no significant differences; however, the generally strong scores were not reflected in the overall rating of care.

CONCLUSIONS

Overall, these results indicate that, in the main, patients believe that endocrinologists in specialist centres are providing high quality care for patients with multiple endocrine neoplasia disorders both in the UK and elsewhere in Europe. Patients commonly feel listened to and involved in care decisions, and consider their team knowledgeable about the care and management of MEN patients. The majority trust and follow the advice of their specialist. However; these ratings are not as convincingly reflected in overall ratings of standard of care, with the majority of patients rating their overall care as “Good”. Further analysis shows that the patients who most highly rate their care are MEN2A patients in the UK. A limitation of this study is the high proportion of patient survey respondents who responded and who may already be more engaged in and therefore happier with their healthcare. However, these results should be viewed as encouraging feedback for endocrinologists who care for MEN patients, and may also be used as evidence to help encourage patients to request referrals to centres of expertise for MEN.
