Case 3: A 69 year old lady presented with a post menopausal vaginal discharge. Investigations showed a left ovarian mass. Surgical histology revealed malignant struma ovarii and she required total thyroidectomy and radio iodine treatment.
Conclusion
This case series highlight the diagnostic and therapeutic role of thyroid surgeon in the management of benign and malignant form of struma ovarii.

**Multiple myeloma associated with primary hyperparathyroidism**

I. Kun, Z. Szanto & I. Benedek
University of Medicine and Pharmacy, Targu Mures, Romania.

Introduction
The association of multiple myeloma (MM) with primary hyperparathyroidism (pHPT) is very infrequent. In addition pHPT may be overlooked or later diagnosed, because on the one hand certain clinical and laboratory characteristics of MM, such as hypercalcaemia, asthenia, osteoporosis and impaired renal function overlap with the elements of pHPT, on the other hand modern pHPT include non-classical (e.g. normocalcemic or mild clinical) forms. We present the case of a 75-years-old female (P.E.) known with operated recurrent kidney stones (1976, 1997, 2001), multiple fractures (both forearms 2001, clavicle 2004), and hypertension, chronic ischemic heart disease, heart failure NYHA III. In 2006 MM was diagnosed and specific haematological treatment (among others corticosteroids) was applied. In 2008 osteoporosis was discovered and clodronate (800 mg/day) therapy was started. Intermittent hypercalcaemia associated with lumbar pain, asthenia and dizziness were considered related to the hematological disease. In August 2011 arose the suspicion of primary hyperparathyroidism: iPTH: 540.4 pg/ml (normal:15–68.3), se-phosphate (se-P): 0.72 mmol/l ($n$:0.87–1.45), se-Ca: 2.28 mmol/l ($n$:2.15–2.57), Tc-99 m sestamibi scintigraphy suggested diffuse hyperplasia of both superior parathyroid glands. DXA osteodensitometry showed persistent osteoporosis ($-2.49$SD lumbar and $-3.2$SD femoral neck $T$-score). In October 2011 high total se-Ca-level was measured (12.45 mg/dl, $n$:9–11) with iPTH:283 pg/ml ($n$:8.7–79.6), creatinine-clearance: 66.1 ml/min, 25-OH-vitaminD:11 ng/ml ($n>30$), associated with aggravated asthenia. We increased the dose of clodronate to 1.200 g/day, and 40 mg po furosemide was given three times weekly. Within 2 weeks total se-Ca decreased to 11.18 mg/dl, albumine corrected se-Ca:10.74 mg/dl, but iPTH:407.6 pg/ml, so furosemide was reduced to 1 tablet/week. Low-dose calcitriol (0.50 μg/day) was carrefully introduced, taking into account vitamin D deficiency, osteoporosis and reduced kidney function in an aging person. Medical therapy was recommended instead of surgery: cinacalcet in association with bisphosphonate and calcitriol, with monthly control of calcaemia.
Conclusion
A very rare association between two infrequent diseases but with certain clinical/laboratory similarities, as well as the outcome under medical treatment is presented.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Graves' disease with a transient lung mass**

U. Tunc, A. Gedik, A. Akkoclu, F. Bayraktar, T. Demir & A. Comlekci
Dokuz Eylul University Medical Faculty, Izmir, Turkey.

Introduction
Involvement of different tissues and organs may be seen during the course of Graves' disease (GD). We here aimed to present a case with GD and lung mass whose lung lesion disappeared after recieving antithyroid treatment.
Case report
A 60 year old man admitted to our hospital with back pain. His thorax computed tomography (CT) revealed a $1.5\times3$ cm mass in lower right lobe. He was consultated by our clinic preoperatively before thoracotomy for his thyroid function test (TFT) revealing overt hypertyroidism. On laboratory evaluation; TSH:0.004 μIU/ml (0.4–4.0), $fT_3$:9.1 pg/ml (1.57–4.71), $fT_4$:3.23 ng/dl (0.8–1.48), anti-TPO(+) anti-Tg(+) CRP:1.2 mg/l ESR:10 mm/h were recorded. Thyroid ultrasonography revealed hypervascular enlarged thyroid lobes with heterogeneous apperance. Radioactive iodine uptake performed 2 months after iodine exposure from the radiocontrast substance revealed increased uptake. He was started methimazole tretment and his lung surgery was postponed. Two months later his TFT was euthyroid and referred for thoracotomy. He had another thorax CT which showed that the mass in the right lobe of the lung almost totally resolved after which the surgery was cancelled (Fig. 1). He didn't show any sign or symptom of a systemic inflamatory disease that could explain the transient mass lesion in the lung.
Conclusion
Thionamides used in the treatment of hyperthyroidism has also been shown to exhibit immunmodulatory effects, direct anti-inflammatory and immunosupressive properties. This drug group has been associated with protection from chronic inflammation and autoimmune disorders. During the course of antithyroid treatment, remission of some immune-related diseases have been reported. However, there is not enough evidence to associate the disapperance of the lung mass with the antithyroid treatment in our case. This is expected to be coincidental rather than causally related.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Combination of recombinant TSH (rhTSH) and lithium overcomes amiodarone-induced low radioiodine uptake in a thyrotoxic female

N. Laplano & L. Mercado-Asis
University of Santo Tomas Hospital, Manila, Philippines.

Background
Recombinant human TSH (rhTSH) promotes $^{131}$I uptake in selected populations. Lithium increases RAI retention by reducing intra-thyroidal release. In this report, combination of rhTSH and lithium overcame low RAIU in Graves' disease.
Objective
We aim to present the case of a Graves' disease given combination of rhTSH and lithium to overcome amiodarone-induced low $^{131}$I uptake.
Methods and results
A 39-year old female with Graves' disease acquired thionamide-induced agranulocytosis and went into cardiorespiratory arrest. She had ventricular tachyarrhythmias on resuscitation and cardioverted with amiodarone. She was subsequently placed on hydrocortisone (150 mg/day), amiodarone (200 mg/day) and propranolol (60 mg/day). She was referred to our institution for definitive Graves' disease management. On admission, she was normotensive, tachycardic, and afebrile, with fine tremors, hyperreflexia, and diffuse thyromegaly. She had normal complete blood count, hypokalemia, elevated ALT and low TSH (0.03 μIU/l, NV 0.27–3.75). Thyroid ultrasound showed diffuse thyromegaly with uniform echopattern and normal color flow doppler. RAIU was low at 4 and 24 h (6 and 7%, respectively). In preparation for RAI therapy, she was given lithium 900 mg/day and two doses of 0.9 mg i.m. rhTSH. Repeat RAIU after the 2nd dose of rhTSH showed a more than 5-fold increase in 4 h uptake (32 vs baseline 6%). She was given 131-I 25 mCi after the 2nd dose of rhSTH. Clinical and biochemical course continuously improved thereafter.
Conclusion
This is the first case to demonstrate the efficacy of combining rhTSH and lithium to overcome amiodarone-induced low 131-Iodine uptake in Graves' disease.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P448

### Primary hypoparathyroidism presenting as recurrent TIAs with intracranial calcification

M. Reddy, R. Tanday, R. Agha-Jaffar, J. Valabhji & J. Cox
St Mary's Hospital, Imperial College Healthcare NHS Trust, London, UK.

Intracranial calcification seen on CT may be an incidental finding or it can be a direct cause of neurological symptoms depending on which areas of the brain are affected. The differential cause for the formation of intracranial calcium deposits include hypoparathyroidism, congenital infections i.e. toxoplasmosis and Fahr's syndrome.
A 50–year–old woman was referred to the transient ischaemic attack (TIA) clinic in December 2011, with recurrent episodes of dysphasia and right-sided jaw tightening and weakness, each episode lasting 10–20 min. She developed similar symptoms with no other focal neurology during the consultation in the TIA clinic and it was noted that her baseline adjusted calcium done the same morning was very low at 1.13 mmol/l (2.15–2.60). She was immediately admitted to hospital and was treated with 10 ml of i.v. 10% calcium gluconate, followed by infusions of 40 ml of 10% calcium gluconate in 1l of 5% dextrose daily over 3 days. Alphacalcidol 1 microgram twice daily and Adcal D3 two tablets twice daily were started.
The CT findings and blood results (Table 1) were consistent with intracranial calcification caused by primary hypoparathyroidism. Since discharge from hospital she has remained asymptomatic on oral calcium and vitamin D. Addison's, pernicious anaemia and hypothyroidism have been excluded to rule out type 1 polyglandular autoimmune syndrome.
Our case highlights the importance of always checking the calcium when patients present with 'neurological' symptoms as symptomatic hypocalcaemia can mimic various conditions. Secondly, it also brings to attention that hypoparathyroidism, with or without significant hypocalcaemia, must be considered as a cause of intracranial calfication found on imaging of the brain.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Table 1** Baseline investigations and results obtained

| Investigation | Result | Reference range |
|---|---|---|
| Adjusted calcium | 1.13 mmol/l | 2.15–2.60 |
| Parathyroid hormone | $<$0.5 pmol/l $<$0.5 pmol/l(2nd sample) | 1.1–6.8 |
| Phosphate | 2.47 mmol/l | 0.80–1.40 |
| Magnesium | 0.79 mmol/l | 0.70–1.00 |
| 25–OH Vitamin D | $<$10 nmol/l | 70–150 |
| TSH | 0.38 mu/l | 0.30–4.20 |
| ECG | Prolonged QT interval | |
| CT Head | Extensive symmetrical intracerebral calcifications are seen in the basal ganglia, centrum semi ovale, subcortical regions in both occipitallobes and cerebellum. There is some effacement of the cerebral sulci and temporal horns are mildly dilated | |
| Creatinine | 85 umol/l | 60–125 |

## P449

### Ampullary NET presenting as Virchow's node

M. Paja, V. Arosa, A. Lizarraga, E. Ugarte, V. Atín del Campo, N. Arbide del Río, B. Barrios Treviño & N. Iglesias
Hospital de Basurto, Bilbao, Spain.

Troisier's sign names a visible left cervical adenopathy (Virchow's node) as the first sign of a pancreatic tumor, mainly adenocarcinomas, by dissemination through the thoracic duct. Neuroendocrine tumors (NET) of the ampulla of Vater are extremely rare, no more than 2% of ampullary malignancies, and account for $<$0.3% of all gastrointestinal NETs.
A 59–year old woman presented with an enlarging painless left cervical node. Ultrasonographic guided biopsy of a round-shaped and hypervascular lymph node showed a small round cell proliferation with solid pattern positive for chromogranin A (CgA) but negative for calcitonin. Thyroid was normal in sonography. Laboratory results showed normal levels of tumour markers (CgA, gastrin, PP, somatostatin, glucagon and calcitonin), normal bilirrubin and elevated transaminases, mainly γGT(1167 U/l) and alkaline phosphatase. Abdominal CT revealed a dilated bile-duct (15 mm) with prominent papilla. A hypoechoic mass in the ampulla and periportal adenopathies were evident in endoscopic ultrasonography (EUS), both positive for NET when biopsied. She underwent the Whipple resection with extended lymph node dissection and pathological study showed an ampullar NET of 1.7$\times$1.4 cm invading the duodenal mucosa and pancreas with lymphatic permeation in tumour and preaortic and mesenteric nodes, Ki-67$<$2%. One month later, a functional cervical left dissection was performed, showing 9/41 lymphatic nodes affected by the NET, the biggest reaching 4.5 cm (Ki-67$<$2%). At present the patient remains asymptomatic, without evidence of disease neither by CT nor Octreoscan.
Ampullary NETs are very rare tumors, frequently associated with von Recklinghausen's disease. They usually present as obstructive jaundice without carcinoid syndrome. Our case is a new one of this uncommon tumour with a singular first complaint as a cervical node (Troisier's sign), not previously described in ampullary NETs. We remark the vast asymptomatic lymphatic extension in spite of the low Ki-67 and size $<$2 cm of primary tumour.

## P450

**Unusual cause of hypokalemic paralysis**

G.K. Bhat, M. Rajeeb & R. Shetty
A J Hospital & Research Center, Mangalore, India.

Introduction
Thyrotoxic hypokalemic paralysis is a disorder most commonly seen in Asian men. The condition primarily affects the lower extremities. The main characteristic features of this condition are elevated thyroid hormones, hypokalemia and proximal muscle weakness or paralysis.
Cases
Case 1: A 28 year old patient presented to emergency department with 3 day history of progressive weakness of both lower limbs which made him unable to walk. Later the weakness progressed to upper limbs.
Case 2: A 24 year old male presented with a history of recurrent cramps and spasms of the lower limb muscles for a month. He also had a history of acute onset weakness of both lower limbs for 2 days.
Case 3: A 35 year old male presented with repeated episodes of weakness of lower limbs. He was hospitalized thrice for the same complaints and hypokalemia was documented in each episodes.
The laboratory results were notable for a very low potassium level. After excluding other possible causes, thyroid function was done in these cases. $T_3$ and $T_4$ were high and TSH was suppressed in all the three. Technituim scan showed diffuse increased uptake in cases 1 and 2 suggesting Graves' disease. Third case had patchy uptake suggesting MNG. They were started on Carbimazole 30 mg/day and propranolol 60 mg/day. The muscle weakness improved gradually and were discharged on anti-thyroid medications.
Discussion
Thyrotoxic paralysis has a predilection for males of Asian descent. The pathogenesis is not clear but enhanced activity of Na+, K+-ATPase might be the possible etiology. Definitive treatment is correction of the thyrotoxic state along with cautious potassium replacement during the attack.
Conclusion
Hypokalemic paralysis must be included in the differential diagnosis of acute muscle weakness and thyrotoxicosis should be kept in the differential diagnosis especially in Asian men.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P451

**Paraneoplastic severe hyponatremia in a patient with GIST: case report**

V. Bonato[1], M. Lalle[1,2] & G. De Mattia[1]
[1]Villa Mafalda, Roma, Italy; [2]Ospedale Sant'Eugenio, Roma, Italy.

Hyponatremia may manifest with nausea, disorientation, seizures, coma, cerebral edema and even death. The etiology of hyponatremia as paraneoplastic syndrome has been attributed most often to high levels of vasopressin. Correction of hyponatremia is usually successful at moderately low sodium levels, although it must be done slowly to prevent osmotic demyelination. Gastrointestinal stromal tumors (GISTs) rarely present paraneoplastic reactions, a few cases have been reported.
An 81 year-old man presented with anemia (HGB = 8.5 g/dl), mild hyponatremia (Na = 128 mEq/l) and low Plasma Osmolality (273 mmOsm/l). A CT scan showed a large mass originating from the gastric wall, without gastrointestinal obstruction or distant metastases. A tumor, 12 cm in diameter, was completely removed by proximal gastric resection. Histological examination diagnosed a GIST.
During post-operative period, the patient developed arrhythmia, pneumonia, vomit and confusion, requiring recovery in intensive care unit. Blood sample evaluation showed severe hypotonic hyponatremia (Na = 114 mEq/l, Plasma Osmolality = 239 mOsm/l) and worsening anemia. Red blood cell transfusion, antibiotics and supportive care were administered. Treatments to correct hyponatremia (water restriction and hypertonic saline) weren't effective, with persistent and symptomatic hyponatremia. Treatment with tolvaptan 15 mg started 30 days after surgery once daily for five consecutive days. Natremia have gradually reached 130 mEq/l, and plasma osmolality 282 mOsm/l; the treatment was continued weekly for 4 months, and then monthly for 2 months. Tolvaptan treatment was necessary to maintain natremia within normal value. Drug withdrawal occurred six months from the start, with stable normal natremia. PETscan performed 2 months after surgery showed abnormal uptake in the stomach, of uncertain significance. Because of patient's poor performance status a watchful waiting approach was preferred continuing tolvaptan treatment. PETscan performed 4 months after surgery showed a decreased uptake. After 15 months, the patient is well and free from disease.
Vaptans may be useful and safety to treat hypotonic hyponatremia associated with paraneoplatic syndrome.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P452

**Papillary thyroid carcinoma in two patients with primary hyperparathyroidism**

I. Anaforoglu, M. Kose, M. Asik, B. Mollamehmetoglu & E. Algun
Trabzon Numune Education and Research Hospital, Trabzon, Turkey.

Introduction
Co-existence of medullary thyroid carcinoma and primary hyperparathyroidism (PHPT) is well described, however, the association of non-medullary cancer and PHPT is less recognised. Herein, we report two cases of patients with PHPT and papillary thyroid carcinoma (PTC).
Case 1
A 55-year-old woman received a diagnosis of PHPT during investigation of her anemia. (Ca: 11.4 mEq/l, PTH: 256 pg/ml, urinary calcium: 960 mg/day). Thyroid function tests were totally normal. Neck ultrasonography demonstrated multinodular goitre. There were six nodules; one had 20×12 mm diameter and microcalcification. There was a 14×9 mm, hypoechoic, solid lesion compatible with a parathyroid adenoma at the left side. A fine needle aspiration biopsy (FNAB) was performed for the microcalcific nodule. The FNAB was positive for PTC. The patient gone under total thyroidectomy, central lymph node dissection and parathyroidectomy. A parathyroid adenoma and two foci of PTC (2.5 cm and 1.5 cm) with two metastatic lymph nodes were determined.
Case 2
A 60-year-old man presented with back and lombar pain referred for evaluation of PHPT. His laboratory findings confirmed the diagnosis of PHPT: Ca: 15.2 mg/dl, PTH: 1900 pg/ml, urinary calcium: 720 mg/day, serum creatinine: 2.1 mg/dl, alcaline phosphatase: 2142 U/l. Thyroid function tests were normal. Neck ultrasonography showed multinodular goitre. One of 5 nodules was 23×19 mm, hypoechoic, had a satellite nodule and calcification. There was a hypoechoic, solid, 18×17 mm lesion compatible with a parathyroid adenoma at the right side. The FNAB of the nodule was suspicious for PTC. Total thyroidectomy, central lymph node dissection and parathyroidectomy were performed. The pathology report confirmed parathyroid adenoma and a 2 cm of PTC.
Conclusion
These cases represent the probability of concomitant PHPT and PTC. Preoperative evaluation with ultrasonography may be suggested to patients with a diagnosis of PHPT.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P453

**Marked improvement of gastrointestinal pseudo-obstruction after debulking surgery of malignant pheochromocytoma by Intravenous administration of α-blocker phentolamine**

S. Yamaguchi, H. Shibata, K. Miyashita, I. Kurihara, H. Oguchi, K. Futatsuki, A. Murai-Takeda, Y. Mitsuishi, Y. Motosugi, R. Jo, K. Hayashi & H. Itoh
Keio University, School of Medicine, Shinjuku-ku, Japan.

We present a case of severe malignant pheochromocytoma complicated with intestinal pseudo-obstruction, which was refractory to conventional therapies but reacted to intravenous administration of an α-blocker, phentolamine.

Malignant pheochromocytoma typically metastasizes to bones, liver, lungs, and lymph nodes, and average 5-year survival rate in the patient with metastases is approximately 50%. Treatment options for malignant pheochromocytoma include surgical debulking, external irradiation and systemic antineoplastic therapy. The survival rate worsens in proportion to tumor size, so the essential therapeutic goal is tumor reduction by debulking surgery even if the surgery is not curative, and control of symptoms of excessive catecholamine secretion.

We present a case of 65-year-old man who suffered from transient ischemic colitis and persistent paralytic ileus complicated with megacolon due to pseudo-obstruction developing after the surgical manipulation of malignant pheochromocytoma. Even though other symptoms including hypertension were well controlled, the abdominal symptom was fatal. The pseudo-obstruction showed poor response to conventional treatment including oral administration of α- and β-blockers, yet was relieved promptly with chronic intravenous administration of an α-blocker, phentolamine.

In summary, surgical treatment can trigger this kind of ileus in a patient with pheochromocytoma producing higher levels of catecholamines, even though other symptoms are well controlled. We suggest that intravenous administration of an α-blocker, phentolamine, should be initially considered in such gastrointestinal pseudo-obstruction due to overproduction of catecholamines, especially for the patient who is unable to take meals or drugs efficiently, prior to embarking on surgical decompression of severe megacolon.

### Primary and secondary hyperparathyroidism coexisting in patient with liver cirrhosis and coeliac disease: efficiency of preoperative treatment with vitamin D

G. Swider & R. Orlowska-Florek

St. Queen Jadwiga District Hospital No. 2, Rzeszow, Poland.

Introduction

Primary and secondary hyperparathyroidism may coexist unrelated to chronic nephropathy. It can occur more often than expected, especially in elderly population with malabsorption syndrome or /and liver diseases.

Case report

A women 60 years of age was admitted to hospital due to long standing ostealgia. The primary hyperparathyroidism was suspected. The medical history presented recently diagnosed coeliac disease and cryptogenic hepatic cirrhosis.

Lab tests during hospitalization: PTH level was surprisingly high 2200 pg/ml (*n*: 15–65 pg/ml), calcium serum level and calcium urine excretion in 24 h collection in the normal range, phosphates 1.8 mg/dl (*n*: 2.5–4.8 mg/dl), ALP 660 U/l (*n*: 36–123 U/l), 25(OH)D3 extremely below the normal range: 6.7 ng/ml (*n*: 30–80 ng/ml). The level of creatinine was normal. Osteopenia was confirmed. Scintigraphy, USG and CT revealed of single parathyroid adenoma of diameter 3.0 cm.

Gluten-free diet and oral vitamin D (gtt. calcifediol 75 μg each day) was recommended.

Elimination of ostealgia, PTH reduction (540 pg/ml), slight elevation of calcium level: (11.8–12.2 mg/dl), normalization of 25(OH)D3 level (47 ng/ml) were obtained. Surgical removal of parathyroid adenoma was successfully performed five months later. Hungry bone syndrome was not observed post operatively. Vitamin D supplementation was maintained. PTH, calcium, phosphates, ALP, 25(OH)D remains in the normal range.

Conclusions

1. Gastrointestinal diseases especially liver diseases can trigger secondary hyperparathyroidism and enhance primary hyperparathyroidism.
2. High levels of PTH/Ca ratios can be caused by profound deficit of Vitamin D3.
3. Early recognised deficit of D3 followed by preoperative D3 supplementation with strict control of calcium serum levels eliminate post operative severe 'hungry bones syndrome'.
4. Vitamin D3 treatment should lasts at least 3 months considering PTH, D3, Ca receptors regulation.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P455

### Primary hyperparathyroidism and metastatic breast cancer: a simultaneous presentation

H. Tan[1], N. Waheed[1] & M. Butt[2]

[1]Hereford County Hospital, Hereford, UK; [2]Huddersfield Royal Infirmary, Huddersfield, UK.

Introduction

Hypercalcaemia is a frequent complication of breast cancer with bony metastasis. There is also an increase incidence of primary hyperparathyroidism among patients with breast cancer. We report a patient with breast cancer presenting with hypercalcaemia secondary to both parathyroid hormone- related peptide (PTHrP) from liver metastasis and possibly co-existing primary hyperparathyroidism.

Case report

A 53 year old woman, with a history of right sided breast cancer presented as an emergency due to general deterioration and was found to have hypercalcaemia. She had undergone mastectomy, completed six cycles of chemotherapy and 25 fraction of radiotherapy 10 months ago. Blood test revealed an adjusted calcium of 5.54 nmol/l (NR 2.10–2.55 nmol/l), PTHrP of > 60 pmol/l (NR 0.0–1.8 pmol/l), 25-OH Vitamin D of 12 nmol/l (NR 50–200 nmol/l), acute renal failure and deranged liver function tests. Further investigation included a bone scan which excluded any bony metastasis and an abdominal ultrasound revealing liver metastasis.

Despite appropriate treatment with intravenous fluid, bisphosphonate and steroid therapy, patient continued to deteriorate and died.

Conclusion

Hypercalcaemia in malignancy mostly results from bony metastasis and PTHrP. Recent data suggests a strong correlation between breast cancer and primary hyperparathyroidism. Although the exact pathogenesis is unclear, it has been attributed to be the possibility of common etiological pathways shared by the two conditions.

Our patient presented with extreme levels of hypercalcaemia, secondary to PTHrP associated with metastatic breast cancer, without bony involvement. Despite this high level of calcium level, PTH was still measurable, indicating probable primary hyperparathyroidism as well although it could also possibly be because of severe vitamin D deficiency and renal disease.

Hypercalcaemia secondary to PTHrP carries a poor prognosis and co-existing primary hyperparathyrodism in such setting can be an interesting observation but it does not dictate the course of the patients' treatment or outcome.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P456

**Insulinoma presenting as post-prandial hypoglycaemia**

R. Sriraman, R. Said & C. Jagger
United Lincolnshire Hospitals NHS Trust, Lincoln, UK.

A 52 year old lady with hypothyroidism and hypertension was referred by her GP for unexplained low blood glucose on several occasions. There was history of vacant spells with confusion and disorientation over the previous year. When referred for neurological assessment, no abnormality was identified. Her medications included amlodipine 5 mg, ramipril 10 mg, thyroxine 50 mcg, loratidine 10 mg. Her BMI was 44 kg/m$^2$.

Additional investigations arranged by GP included, cortisol (0920 h) 184 nmol/l, short synacthen test (0 min) 331 nmol/l and (30 min) 602 nmol/l, eGFR 62 ml/min.

She reported significant weight gain over the last few years, compared with her twin sister who had a normal BMI. She drinks Lucozade when feeling 'under the weather'.

A prolonged OGTT was performed as an outpatient. She did not complain of any symptoms of hypoglycaemia, no insulin/C-peptide samples were taken.

Analysis of the plasma glucose samples showed hypoglycaemia occurring at 3 h (1.6 mmol/l), rising slowly to 2.3 mmol/l at 4½ h.

An admission was arranged for further assessment. Initially her FBG was 3.6 mmol/l, insulin 197 pmol/l, C-peptide 443 pmol/l. After breakfast she developed postprandial hypoglycaemia (plasma glucose 2.0 mmol/l with a further increase in insulin and C-peptide levels: 682 and 1537 pmol/l respectively. A sulphonylurea screen was negative.

CT scan showed 14 mm hypervascular tumour within tail of pancreas consistent with insulinoma. Cytology from an FNA showed features in keeping with a well differentiated neuroendocrine tumour.

She underwent distal pancreatectomy and splenectomy in June 2011. She was reviewed subsequently in clinic, asymptomatic and successfully losing weight.

Insulinoma presenting as post-prandial hypoglycaemia only is an uncommon presentation of a rare tumour. These patients often have hypoglycaemia unawareness, so close clinical evaluation and monitoring of capillary glucose is vital to avoid unnecessary delays in diagnosis.

**Malignant, ectopic ACTH secreting occult neuroendocrine tumor: a case report**

M. Mannelli[1], F. Lotti[1], C. Pupilli[1], C. Biagini[2], V. Piccini[1] & G. Forti[1]
[1]University of Florence, Florence, Italy; [2]Prato, Italy.

Introduction
Occult neuroendocrine tumors are still a difficult diagnostic/therapeutic challenge.
Case report
In November 2007, a 29-years-old Caucasian woman was admitted to our in-patients clinic with a 2-month history of rapidly progressing signs and symptoms of chronic hypercortisolism, including a bipolar disorder in psychosis. On admission the patient presented with hypokalemia (3.2 mEq/l), high levels of plasma (3164 nmol/l) and urinary free (26 945 nmol/24 h) cortisol and high ACTH levels (354 ng/l), consistent with ACTH-dependent Cushing's syndrome (CS). High-dose-dexamethasone failed to suppress ACTH and cortisol. Magnetic resonance imaging (MRI) of the pituitary was normal and bilateral inferior petrosal venous sampling did not show any central/peripheral or right-to-left gradient. Computed tomography (CT) of the chest and abdomen resulted negative as well as In-111 pentetreotide scintigraphy. No decrease was observed in plasma ACTH after 100 μg s.c. octreotide. Total body bone and MIBI scintigraphy, FDG-PET-CT, Ga-DOTANOC-PET, upper and lower bowel endoscopy, breast and thyroid ultrasound were uninformative. Neuroendocrine oncologic markers such as Cromogranine A (CgA), Ca19.9 and Tpa were only slightly increased. In February 2008 a pelvis MRI showed sacral and iliac osteoblastic lesions; bone biopsy revealed athypical epithelial cells AE1/AE3 citokeratin positive. In June 2008, because of unsuccessful medical therapy, bilateral adrenalectomy was performed, with complete remission of CS. In July 2008, a FDG-PET-CT showed an increased uptake in one left para-aortic and two left supraclavear lymphnodes, which were removed: at histology, an infiltrating neuroendocrine carcinoma AE1/AE3+, CD56+, CgA+, synaptofisine+, ACTH+, was diagnosed. After 14 months of stable disease, a tumor progression was found with bone, chest lymphnodes and hepatic metastases, associated to a hypophosphoremic and hyponatriemic paraneoplastic syndrome. Chemoterapy was started in December 2008, but uneffective. In March 2010, peritoneal tumor dissemination with ascites developed. In June 2010 the patient died, primitive tumor still occult.
Conclusions
Neuroendocrine tumors can manifest with different signs/symptoms/paraneoplastic syndromes. Their management may need change over time.

**Noonan Syndrome in adulthood: two cases reports**

S. Azriel[1], B. Ezquieta[2], V. Martin[1], P. Díaz Guardiola[1] & J. Olivar[1]
[1]Hospital Infanta Sofía, Madrid, Spain; [2]Hospital Infantil Gregorio Marañón, Madrid, Spain.

Introduction
Noonan syndrome (NS) is an autosomal dominant disorder or may occur on a sporadic basis, characterized by short stature, typical face dysmorphology and congenital heart defects. NS is a clinical diagnosis. Establishing the diagnosis can be very difficult, especially in adulthood. There is a great variability in expression and the phenotype become less pronounced with increasing age. The scoring system of Van der Burgt *et al.* has been devised to help the diagnostic process. In 50% of the patients with NS, a missense mutation is found in the PTPN11 gene on chromosome 12. The incidence is reported to be between 1/1000–1/2500 live births.
Subjects
Case 1: A 54-year-old male was studied in the endocrine practice because of subclinical hypothyroidism. He had medical history of mental retardation, bilateral cryptorchidism, hearing loss, cataract and myeloproliferative disorder. Face dysmorphology, pectus excavatum and other characteristic features confirm clinical diagnosis of NS. Karyiotype and molecular study of fragile X premutation were normal. Mutational screening was carried out by direct sequencing of all coding exons of the genes PTPN11, SOS1 and RAF1 and we did not detected heterozygous point mutations or polymorphisms.
Case 2: Fourty-one-year-old woman was refereed for clinical hypothyroidism monitoring. Pulmonary stenosis intervention was performed at the age of eight. Physical examination showed pectus carinatum and face dysmorphology suggesting NS. Clinical diagnosis was confirmed by the finding of pArg552Gly heterozygous mutation in SOS1 gene.
Conclusions
Although NS diagnosis is usually performed in the first childhood, diagnosis in the adulthood should be also suspected because of the implication in genetic advice. NS is genetically heterogeneous and only 50–60% of patients show mutations in the involved genes.

**Unusual course of Amiodarone-induced hypothyroidism: case report**

M. Motyka, M. Kostecka-Matyja, D. Pach & A. Hubalewska-Dydejczyk
Jagiellonian University, Medical College, Kraków, Poland.

Introduction
Amiodarone a potent antiarrhythmic medication induces thyroid dysfunction in about 20% of patients. Amiodarone-induced hypothyroidism (AIH) usually

occurs early in the course of treatment, more often in iodine-sufficient areas, in women, and in the presence of thyroid autoantibodies. Long-term treatment with amiodarone is associated with a reduction in prevalence of AIH, which may reflect adaptation of the thyroid autoregulatory mechanisms to iodine excess.
Case report
A 68-year-old man referred to our outpatient clinic with a history of myocardial infarction, CABG, hypertension, and ventricular extrasystoles (Lown class IVb). He had been treated with amiodarone for the past 8 years. His thyroid hormone status had been checked in regular 6-month intervals showing normal TSH, FT4, FT3 concentrations. However, the last results were as follows: TSH- 33.7 mIU/l, FT4- 13.9 pmol/l (12.4–22.0), FT3- 4.7 pmol/l (2.6–5.7), thyroid autoantibodies assays were negative. He was then started on 50 μg of levothyroxine and amiodarone was discontinued shortly after, as cardiologists considered it safe. For the next one year patient still required substitution with the same dose of levothyoxine and his TSH and FT4 concentrations returned to the middle of reference range. After one year amiodarone was restarted due to deterioration of the arrhythmia, this time permanently. In the time of next 5 years his TSH levels were gradually increasing up to 32 mIU/l, in spite of increasing levothyroxin dose up to 125 μg. FT4 level after initial rise to 27.07 pmol/l was decreasing to high normal values near 22 pmol/l. FT3 concentrations remained close to the lower limit, however recently FT3 concentration fell below normal range to 2.29 pmol/l.
Conclusions
Late onset of AIH in our patient (after 8 years of amiodarone therapy) indicates on a necessity of a life-long monitoring of thyroid function in all patients treated with amiodarone. TSH and FT3 rather than FT4 concentrations should be used to determine levothyroxine dose in AIH patients.

## P460

**Anaplastic thyroid carcinoma: case report**
R. Rangel, A. Martins & V. Leite
IPO Lisboa, Lisboa, Portugal.

Introduction
Anaplastic thyroid carcinoma (ATC) is characterized by an aggressive clinical course and refractoriness to currently available local and systemic modalities of treatment. It is considered the most aggressive solid tumor, with few patients alive more than 1 year following diagnosis.
Bible et al have reported a combined therapy of radiation and radiosensitizing adjuvant chemotherapy, with some positive results.
Case report
The authors report a case of ATC in a 37-year-old woman, with irrelevant past medical history. She referred a left anterior cervical mass, which was detected one year ago. Because of recent fast enlargement, although no compressive symptoms, she was submitted to ultrasound guided biopsy of the dominant node, which revealed ATC.
Total thyroidectomy with central node dissection was performed.
ATC was histologically confirmed. Staged pT4N0MxR1.
Post-operatory US showed no remaining thyroid tissue on the surgical bed, or suspicious nodes.
No pulmonary metastases were found on the CT.
She was submitted to intensity-modulated radiation therapy and radiosensitizing plus adjuvant chemotherapy, intending four cycles of docetaxel plus doxorubicin, with good therapeutic tolerance.
A CT scan performed six months later showed no recurrence of the disease.
Conclusion
This case of an ATC, was atypical because it occurred in a young patient, treated with surgery a combined radiochemotherapy regimen, and the patient is alive 6 months after diagnosis, with unsuspected signs of disease.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P461

**'Collision tumor' of the thyroid: a case report**
M. Yilmaz, A. Gedik, M. Durak, O. Ozdogan, M. Kocdor & F. Bayraktar
Dokuz Eylul University Medical Faculty, Izmir, Turkey.

Introduction
Differentiated thyroid carcinoma (papillary and follicular) being the most common type of thyroid malignancy (80%), originates from the thyroglobuline secreting follicular cells. Medullary thyroid cancer derived from parafollicular C-cells producing calcitonin is relatively rare (5–10%). In this report we aimed to present a case with simultaneous papillary and medullary carcinoma in the same thyroid nodule.
Case report
Sixty nine year old woman admitted with progressive swelling on the right side of the neck. Her past medical history was unremarkable except for well controlled hypertension. She had no radiotherapy exposure to neck and family history was negative for thyroid malignancy. Thyroid function tests were euthyroid. Her neck ultrasonography revealed multinodular goiter and right submandibular solid mass. Fine needle aspiration biopsy of the right dominant 14 mm hipoechoic thyroid nodule and right submandibular mass revealed papillary carcinoma and pleomorphic adenoma respectively. She underwent total thyroidectomy and right suprahyoid neck disection. Pathology was reported as pleomorphic adenoma (submandibular gland), medullary thyroid carcinoma and focal papillary thyroid carcinoma (14×12 mm) (right thyroid nodule). She recieved radioactive iodine ablative therapy. She is currently on follow up in remission state.
Conclusion
The coexistance of different malignancies within the same mass is termed as 'collision tümör'. Appearance of concurrent papillary and medullary pathological features in the same thyroid tumor, so-called 'collision tumor' of the thyroid, is relatively rare being less than 1% of the all thyroid malignancies. There are no pathogenetic mechanisms available so far to explain the concomitant neoplastic transformation of the C-cells and follicular cells in the same thyroid nodule. Further analyses are needed to detect the etiopathogenesis of this condition.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P462

**Unknown reason of continuing hypercalcemia after successful extirpation of parathyroid gland**
Z. Semanová[1], M. Kristianová[1], V. Cápová[2] & E. Zemberová[3]
[1]Private endocrinology surgery, Košice, Slovakia; [2]Institute of Nuclear Medicine, Košice, Slovakia; [3]RIA Laboratory, Košice, Slovakia.

It is to delineate two categories of hypercalcemia: hypercalcemia associated with dysfunction of the parathyroid gland and hypercalcemia that occurs despite appropriate parathyroid suppression.

There is casuistic model of 73 years old woman with several years personal history of hypercalcemia and clinical polyarthritis. After standard examinations there was diagnosed primary hyperparathyroidism. USG screening expected adenoma of parathyroid gland right down, but increased accumulation of radiopharmaceuticals during scitigraphic examination was in area of right submandibular gland. In November 2009 there was executed radionavigated extirpation of parathyroid gland adenoma - adenoma was localized in lower pole of right lobe of thyroid gland.
After operation the level of PTH was normalized, but later the hypercalcemia has continued, temporary with mild increasing of PTH. Based on these laboratory results we assumed the coexistence of another disease, which could participate on hypercalcemia too.
Within differential diagnosis of hypercalcemia there was made complete algorithm of the examinations. At PET/CT expected ectopic hyperplastic parathyroid gland was displayed, but considering of the PTH level we do not assume it is the reason of hypercalcemia.
Considering polyarthritis personal history we executed rheumatologic examination. Within rheumatologic screening the positivity of antibodies ANA, ENA, Ro52, SSA, SSB, SCl 70 was found, but diagnostic criteria of systemic disease were not matched.
Because of polyclonal gammapathy the haematological examination was executed, but the multiple myeloma was not positively proved too. Considering continuing hypercalcemia we add to treatment ex juvantibus the corticosteroids which reduced calcemia under 3 mmol/l.
Hypercalcemia is a common electrolyte abnormality with a wide differential diagnosis. The reason of hypercalcemia is in 90% primary hyperparathyroidism and malignity. In our patient there is no positive reason of hypercalcemia so far. Except above mentioned comes into consideration the autoimmune inflammatory disease, and diagnostic criteria are not matched that time.
Declaration of interest

## P463

**Catastrophic bone deformities associated with primary hyperparathyroidism in a middle-aged man**

K. Agbaht, A. Aytaç & S. Gullu
Ankara University, Ankara, Turkey.

Background
Parathyroid carcinoma is a very rare cause of primary hyperparathyroidism. We aimed to present a case of middle-aged man, who was initially misdiagnosed as parathyroid adenoma, with parathyroid carcinoma and severe bone deformities associated with hyperparathyroidism.
Case
A 36-years old male presented with leg aches and severe hypercalcemia in 2001, when he was diagnosed with primary hyperparathyroidism (corrected serum calcium 18.5 mg/dL (8.4–10.2), parathyroid hormone 400 pg/ml (8–76)). Total spine MRI demonstrated lytic lesions in all thoracal and lumbar vertebra. A parathyroid adenoma (28×20 in diameter, lower right part) was excised. In March 2008, he presented with generalized leg aches and gait disturbances associated with multiple pathological fractures (Figure 1) when his serum calcium was 15.6 mg/dl. Total parathyroidectomy, total thyroidectomy and thymectomy performed. Histopathological examination revealed a parathyroid carcinoma in three different focuses, with an invasion to the adjacent perineural, vascular and lymphatic tissues. He lost his follow-up once again until October 2010, when he presented with malaise, fatigue, gait disturbances and end-stage renal disease. His calcium was 16.5 mg/dl, PTH 1497 pg/ml, serum creatinine 5.5 mg/dL. Radiography of the right femur and hemipelvis demonstrated generalized Brown tumors which are huge and incorporated in distal femur giving it the form of 'woven bone', associated with osteitis fibrosa cystica. Neck ultrasonography showed an irregular shaped parathyroid lesion (17×14 mm), with a surrounding pathological lymph node (14×8 mm). He died of myocardial infarction when he was being prepared for another neck exploration surgery.
Conclusion
In patients presenting with severe hypercalcemia associated with hyperparathroidism, the probability of parathyroid carcinoma must be excluded, in order to avoid a catastrophic bone involvement and mortality associated with hyperparathyroidism severe deformities involving the long bones.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P464

**Severe fetal and neonatal hyperthyroidism following radioiodine therapy in a woman with Graves' disease**

M. Bjørgaas[1,2], H. Farstad[1], S. Christiansen[1] & H. Blaas[1,2]
[1]St. Olavs University Hospital, Trondheim, Norway; [2]Norwegian University of Science and Technology, Trondheim, Norway.

Introduction
Radioiodine (RAI)-therapy for Graves' disease (GD) is often followed by worsening autoimmunity, and the increase in TRAb may persist for several years. In pregnant women TRAb pass the placenta and may stimulate the fetal TSH receptor with a risk of fetal and neonatal hyperthyroidism.
Case report
A 21-year old woman with GD was treated with RAI, and subsequently was euthyroid with L-T4-replacement. Before RAI-therapy, TRAb was 8 U/l (reference $\leq$1.0 U/l). She became pregnant 4 months after RAI-therapy, and simultaneously developed opthalmopathy. Fetal tachycardia (176–180 beats/minute) developed at gestational week (GW) 33, and fetal echocardiography revealed dilated right atrium, right ventricle hypertrophy and tricuspid insufficiency with regurgitation (4–6 m/s). At GW 34+5, she delivered a severely thyreotoxic girl with FT4 >100 (12.0 – 22.0) pmol/l, FT3 > 50 (3.9–6.7) pmol/l and TSH 0.02 (0.99–7.77) mU/l. TRAb in serum of the mother and the neonate were >40 U/l. The neonate had growth acceleration without adequate weight gain (birthweight 2270 g, length 51 cm), goiter, advanced skeletal age (6 months), tachycardia (230–250 beats/minute), needed ventilatory support and developed pneumothorax. Treatment included beta-blockers, iodine, carbimazole, and later L-T4. Her condition improved, the echocardiographic findings were normalized, and she has had a normal development. Later, the mother underwent total thyroidectomy, and TRAb level declined. In a subsequent pregnancy, the fetus showed no sign of hyperthyroidism, and the neonate was euthyroid and healthy, despite elevated TRAb in cord blood (10.9 U/l).
Conclusions
This case report illustrates potential risks of RAI treatment in women with GD and documents passage of TRAb across the placenta in two successive pregnancies, with antibody-associated fetal and neonatal hyperthyroidism in the 1st pregnancy. After thyroidectomy in the mother, TRAb declined. In women who plan pregnancy, total thyroidectomy may be a better treatment option than radioiodine.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P465

**Hypercalcaemia in pregnancy**

V. Stokes[1], N. Whitelaw[1], R. Mihai[2] & A. Ali[1]
[1]Milton Keynes Hospital, Milton Keynes, UK; [2]Oxford University Hospitals, Oxford, UK.

A 28 year old female with no significant medical history, 25 weeks into her second pregnancy was referred to endocrinology with adjusted calcium of 2.99 mmol/l. She had a short history of generalised aches and tiredness. Examination did not reveal any stigmata of MEN1 or the HPT-JT syndromes. There was no known family history of endocrine disorders. Her PTH was 7 pmol/l, confirming primary hyperparathyroidism. As parathyroid Tc-scintigraphy would be contraindicated in pregnancy, an MRI of her neck was reviewed by a radiologist with special expertise in parathyroid imaging. The scan showed evidence of a right sided adenoma. An uncomplicated parathyroidectomy was performed under sedation and bilateral cervical block, without the use of opiates. The histology of the mass was compatible with a benign adenoma. Molecular genetic analysis did not show deletions, duplications or mutations in either MEN1 or RET. She has remained normocalcaemic after 1 year of follow up. Definitive treatment during pregnancy is recommended as hypercalcaemia increases the risk of pregnancy associated complications. Maternal complications such as nephrolithiasis, pancreatitis and bone disease are reported in 67% of mothers. Foetal complications are reported in up to 80%, including preterm labour, neonatal tetany, IUGR and foetal death.

After localising the tumour preoperatively without the use of ionising radiation, surgery should be performed during the second trimester where possible, but may be indicated at any stage of gestation. This case highlights the approach to diagnosing and managing a rare presentation of a common condition. Radiological expertise is required for successful pre operative localisation of parathyroid tumours in pregnancy. In addition to timely surgery, patients should also be investigated for underlying genetic causes as in all young patients with hyperparathyroidism. Although not backed by evidence, long term follow up of these patients with periodic calcium measurement is recommended.

## P466

**Ectopic Cushing's syndrome and thymic hyperplasia**

A. Vieira, I. Paiva, M. Alves, S. Gouveia, J. Saraiva, C. Moreno, F. Carrilho & M. Carvalheiro
Coimbra's University Hospital- EPE, Coimbra, Portugal.

Introduction

Thymic hyperplasia has been described after hypercortisolism resolution. The natural history remains poorly defined: emergence $\geqq$1 month after hypercortisolism resolution, variable duration, usually spontaneous resolution/benign course.

Case Report

♂, 24, referred in 2000 for secondary hypothyroidism: TSH: 0.25 μUI/ml (0.25–5); FT4: 5.55 pmol/l (9–20). Clinical evaluation: insomnia, nocturnal sweating, facial erythema, myalgias, asthenia; acne, abdominal purple striae; BMI: 24.1 kg/m$^2$. Total testosterone-1.8 ng/ml (2.7–11), ACTH-104 pg/ml (9–52), UFC-495 μg/24 h (10–80); Cortisol-17 μg/dl (5–25).

CRH test: ACTH-51, 48, 52 pg/ml (baseline, 15, 30 min respectively); cortisol-110, 188, 211, 176 μg/dl (baseline, 15, 30, 45 min respectively).

Pituitary MRI (07/2000): 'dimensions slightly greater than expected, stalk without deviation; no hypothalamic alterations'. He starts ketoconazole 400 mg/day; dose adjustments (UFC/clinical). Cervico-thoraco-abdominal CT (08/2000):normal. Octreotide scintigraphy (10/2000): 'Focus uptake in the right hemithorax.' Bronchoscopy (01/2001): Normal. In Jan/2001 worsening of hypertension and hypokalemia: KCl + spironolactone were started; at that time UFC 60 μg/24 h, ACTH 159 pg/ml, cortisol 13 μg/dl. Lung surgery (04/2001): '2 lymph nodes without neoplastic aspects removed.' Inferior petrosal sinuses catheterization (05/2001): no gradient. Octreotide scintigraphy (07/2001): 'more evident fixation'. Thoraco-abdominal CT(07/2001): 'Nodular image in the area corresponding to scintigraphy.' Lung surgery(octreotide-labeled probe; 08/2001):'Bronchial carcinoid.' Steroid substitution was done during 9 months, with progressive hypercortisolism stigmata regression. Chest CT (2002): 'anterior mediastinum retrosternal triangular formation; thymus? conglomerate adenopathy?'. Chest CT (2003; 2006): 'mass probably related to thymus…31 × 16 mm'. Chest CT (2011): 'normal appearing mediastinum, centered, no adenopathy'. The patient maintains follow-up.

Conclusions

This case illustrates the frequent difficulty in localizing the source of ACTH production, and the possible association of a thymic hyperplasia occurring after the hypercortisolism resolution. A self-limiting evolution is to consider.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Synchronous papillary thyroid cancer and astrocytoma: case report**

A. Makarov, K. Loskutova, A. Innokentyeva, E. Makarova & L. Korosteleva
National Center for Medicine, Yakutsk, Russian Federation.

Introduction – aim

The incidence of multiple primary cancers is reported to be between 0.3 and 4.3%. The second primary lesion is identified either simultaneously with the primary lesion (synchronous) or after a period of time (metachronous). We report such a rare occurrence of dual malignancy of the thyroid and brain in order to stress the importance of a good preoperative workup to arrive at such a diagnosis preoperatively and also to stress the importance of radical surgery in patients with operable primary tumors.

Case report

A 47-year- old man was admitted to our Medical center on March 18, 2010 with 4-month history of weakness of the right fingers, with a thyroid mass. Magnetic resonance imaging revealed a mass lesion in the right temporal, frontal lobes of brain with diffuse high intensity on T2-weighted and fluid-attenuated inversion images. A few small lesions were enhanced by contrast medium on the T1-weighted images. Ultrasound examination of thyroid: nodules (size 2.6 × 2.1 × 2.0 cm and 5 mm) in the right lobe and 3 nodules (4 mm, 6 mm, 8 mm) in the left lobe. Ultrasonography guided fine-needle aspiration biopsy was performed and the cytological examination revealed cells of papillary thyroid cancer. The absence of familial adenomatous polyposis was determined after a complete colonoscopy. In 24.03.2010 subtotal removal of brain tumor was performed. Histologically the brain neoplasm was astrocytoma grade II. In 5.04.2010 a total thyroidectomy with central and unilateral modified left radical neck dissection was performed. Histology demonstrated a papillary thyroid carcinoma with extrathyroidal extension to parathyroid soft tissue, metastases to the lymph nodes. Postoperatively, he underwent radioactive iodine ablation therapy. In order to explain the molecular basis for such an occurrence, we performed the immunohistochemistry of the operative specimens. The cells thyroid cancer reacted for p53 (reaction +) in 75% sells, Her 2 (+2 in 90% cells), vimentin (+), EMA(+), L-thyroglobulin (+), estrogen receptors – (+), progesterone receptors-(++), pancytokeratin – (++). The astrocytoma was positive only for p53 (+).

Conclusion

In the light of advances in molecular biology we can only conjecture that the mutant p53 which has been found in both papillary thyroid cancers and astrocytomas may be one such putative mutation underlying such an occurrence.

Declaration of interest

## P468

**Exogenous thyrotoxicosis by consumption of pork sausage**

M. Cano Megias, J. Diez, G. Perez López, M. García Villanueva, P. Iglesias & A. Matei
University Hospital Ramon y Cajal, Madrid, Spain.

Background
Exogenous hyperthyroidism is a rare cause of thyrotoxicosis. It is caused by ingestion of excessive amounts of thyroid hormone, which could be intentional or surreptitious (known as factitious thyrotoxicosis). One of the most exceptional cause is the intake of meat or sausage containing thyroid tissue, inadvertently mixed with traces of muscles and other tissues of the animal's neck (hamburger thyrotoxicosis). The clinical symptoms are indistinguishable from other common causes of hyperthyroidism as Graves disease.
Case report
A 82 years-old woman with recurrent self-limiting hyperthyroidism for three years who was admitted in our Endocrinology department. She had weight loss up to 3 kg and abnormal heart beats sensation. The physical examination was irrelevant. The biochemical test showed not detectable stimulating thyroid, thyroglobulin and peroxidases antibodies. The thyroid scintigraphy with Tc99m pertechnetate displayed a heterogeneous uptake pattern and a small normal thyroid. The thyroglobulin levels were low. A further interview with the patient reported a daily consumption of pork sausage. When she stopped consumption of these sausages, she became asymptomatic and thyroid function was normalized. The pathology analysis of a sausage sample detected tissues from the pork's neck, such as thymus, cartilage and salivary glands, but not traces of thyroid glandule.
Conclusions
Thyrotoxicosis induced by food should be suspected in cases of self-limiting and recurrent episodes of hyperthyroidism with suppressed thyroid stimulating hormone (TSH), high levels of triiodothyronine (FT), low levels of thyroglobulin and not detectable thyroid antibodies. The scintigraphy shows usually a low uptake pattern. The levels of FT3 and thyroxine (FT4) could be useful to differentiate the kind of hormone intake. This case illustrates the importance of a thorough and detailed anamnesis to get a accurate differential diagnosis of a repeat silent thyroiditis.

**Ovarian hyperstimulation syndrome and autoimmune primary hypothyroidism in two members of a family**

M. Hedayati Omami, R. Molaei Lngroudi & F. Ghazanfari Amlashi
Guilan University of Medical Sciences, Rasht, Islamic Republic of Iran.

Background
Spontaneous ovarian hyperstimulation syndrome (sOHSS) occurs rarely and has been associated with high level of human chorionic gonadotropin (HCG), mutated FSH receptor (FSHr) gene and hypothyroidism. We report sOHSS in two members of a family with autoimmune hypothyroidism.
Patient Findings
A 15 years old girl presented with abdominal pain and distention and typical features of hypothyroidism.Serum TSH was $>100$ mIU/l and anti-TPO antibody was 290 U/ml. Abdominal ultrasound and CT-scan revealed bilateral multi-lobulated ovarian cysts. FSHr gene sequencing showed no mutation. The second patient, the cousin of the first patient, a 14.5 years old girl was presented with acute abdominal pain and distention after a minor trauma. Hypothyroid feature was remarkable; laboratory test showed TSH: 72.5 mIU/l. Abdominal ultrasound revealed bilateral multilobulated ovarian cysts with one ruptured cyst. Levothyroxine therapy resulted in significant regression of ovarian cysts in both patients.
Conclusion
sOHSS can be simply managed with Levothyroxine in patients with hypothyroidism. However, its association with thyroid autoimmunity and puberty needs more investigation.
Keywords
Ovarian hyperstimulation syndrome, ovarian cyst, Hypothyroidism, Puberty, familial.

**Novel treatment option in the management of SIADH related Hyponatremia: two case reports**

S. Anwar[1] & P. De[2]
[1]University Hospital Birmingham, Birmingham, UK; [2]City Hospital, Birmingham, UK.

Introduction
Current treatment for SIADH related hyponatremia is unsatisfactory. We describe two cases of effective Tolvaptan use in SIADH related to disseminated cancer.
Case 1
Fifty-three year old female with metastatic ovarian carcinoma, vomiting from partial intestinal obstruction, was referred with sodium 121 mmol and normal renal function. She was clinically dry and mildly confused. SIADH was confirmed but urine Na was $<10$ suggestive of hypovolemia.
IV fluid was commenced followed by Demeclocycline – latter caused renal failure and was stopped. Cyclizine pump was started and soon she was able to drink more and renal function normalised. Tolvaptan 15 mg was started (sodium 122 mmol) when adequately hydrated and Urine sodium $>20$. Within 48 h sodium was 127 mmol and 135 mmol/l five days after starting Tolvaptan. Family wanted her home as she was now relatively alert and stable. Unfortunately she passed away 3 days later.
Case 2
Fifty year old lady with ovarian cancer and abdominal metastases – was referred with falling Sodium levels – 138 in April, 134 June, 126 in July (admission). Investigations confirmed SIADH. Fluid restriction was poorly followed and Sodium only improved to 128 mmol/l. Started 15 mg of Tolvaptan. Clinically felt better with progressive rise in Sodium over a week – 134, 139, 140, 142 mmol/l. Tolvaptan was stopped and she was discharged to a Hospice. Day 7 post-discharge sodium was 133 and day 14 it was 134 mmol/l.
Discussion
Tolvaptan (new Vasopressin receptor antagonist) has shown promise in treating hyponatremia due to SIADH. Intermittent vomiting in the 1st patient meant that fluid restriction long-term was impractical and ineffective in the 2nd patient. Demeclocycline caused renal toxicity. Tolvaptan raised and maintained sodium levels without compromising safety, enabled removal of fluid restriction and allowed the patient to spend the last few days at home. It is important to correct dehydration before using Tolvaptan.

**Growth hormone: 'beginning of a new life'**

H. Chahal, E. Casey, A. Hawkins & K. Nikookam
King George Hospital, Barking, Havering and Redbridge University Hospitals NHS Trust, Greater London, UK.

We report three patients who were referred for possible chronic fatigue syndrome and presented with a long standing history of a multitude of symptoms. Comprehensive investigations revealed a low IGF1 and subsequent insulin tolerance test (ITT) demonstrated growth-hormone (GH) deficiency with a normal MRI pituitary in each case. The first patient presented at the age of 34 years with lethargy, aches and difficulty concentrating. Biochemically the only abnormality in th]e basal pituitary tests was a low IGF1 of 9.7 nmol/l (15–39.9). She underwent an ITT where the peak GH-level was low at 0.2 μg/l and the peak cortisol was suboptimal at 414 nmol/l. Her AGHDA score was 20/25 and her symptoms responded dramatically to GH replacement. Her MRI pituitary was normal and currently she takes hydrocortisone at times of stress.

The second patient presented at the age of 36 years with a multitude of symptoms, including lethargy and generalised aches. Biochemistry revealed a low IGF-1 of 12 nmol/l (15–39.9), but no other hormonal deficiencies. He underwent an ITT where all the GH-levels were $<0.1$ μ/l and the peak cortisol was normal at 597 nmol/l. Her AGHDA score was 25/25 and the MRI pituitary was normal. GH replacement was commenced with an improvement in all the symptoms.

The third patient presented at the age of 33 years with difficulty losing weight and tiredness. He had a low IGF-1 at 9.5 nmol/l (15–39.9). After an ITT all the GH-levels were $<0.1$ μg/l and the peak cortisol was suboptimal at 323 nmol/l. Currently after 2 years on GH replacement he has managed to lose weight and is 'much happier with life'.

Patients with multitude of symptoms and/or chronic fatigue syndrome should have endocrinological investigations, in particular looking for GH deficiency, despite normal MRI pituitary. We recommend that all patients with these symptoms should be referred to an endocrinologist for further assessment.

**Severe amiodaron: induced thyrotoxicosis**

A. Dokupilova[1] & J. Payer[2]
[1]Faculty Hospital Nitra, Nitra, Slovakia; [2]University Hospital Bratislava, Bratislava, Slovakia.

Indroduction

Amiodaron is an potent antiarrhythmic drug used for the treatment of ventricular and supraventricular arrhythmias. Long-term amiodaron therapy can cause a thyroid abnormalities in up to 14–18% patients. There are two main forms of AIT: type 1, a form of iodine-induced hyperthyroidism, and type 2, a drug-induced destructive thyroiditis. Differentiation of these 2 types is essential for determining the best management of the disease.

Case report

We present a case of severe amiodaron-induced thyrotoxicosis. 68 years old man with heart failure and severe systolic dysfunction EF – 25%, after implantation of ICD in secondary prevention of sudden cardiac arrest was admitted to our cardiology department after 3 electrical shocks. Patient has been using amiodaron for at least 2 years. We have established the correct function of ICD. Patient had the following laboratory findings: uTSH 0.005 (0.3–4.2 μIU/l), fT4 $>$ 100 (12–22 pmol/l), fT3 18.2 (3.1–6.8 pmol/l), antiTPO 12 (0–60 IU/l), antiTG 18 (0–60 IU/l), TRAK 0.1 (0–1 IU/l). The clinical presentation has included fatigue, weight loss and profound muscle weakness. Color flow Doppler sonography has shown absent hypervascularity, there were a thyroid nodule 10 mm in diameter. There was no improvement in laboratory finding and clinical asesement after discontinuation of amiodaron therapy for more than 2 months. We started a treatment with thionamides in daily dose 60 mg. No effect of these therapy was recorded, so we have to use a combined treatment with thionamides 60 mg daily dose, corticosteroids in daily dose 60 mg and potassium perchlorate in daily dose 800 mg. Improvement has shown 1 week following the start of therapy. Patient has became euthyroid after 2–3 month of the therapy.

Conclusion

Amiodaron is often used in cardiology for the treatment of severe ventricular and supraventricular arrhythmias. In some cases can cause a thyroid dysfunction. Recognition of AIT form is useful for the best treatment of disease.

## P473

**Thyreotoxic periodic paralysis in a Caucasian man after corticosteroid administration**

V. Dimarakis, C. Tsentidis, S. Georgakopoulou, F. Gogali & S. Proikaki
Nicaea Hospital 'Ag. Panteleimon', Piraeus, Greece.

Introduction

Thyreotoxic periodic paralysis (TPP) is a very rare complication of hyperthyroidism in Caucasians. Furthermore there have been reported only a few cases that paralysis was induced by corticosteroids in patients with TPP.

Case presentation

We report the case of a 35-years-old Greek sailorman who had a spider bite in his right hand during a trip in Mexico. He was admitted to local hospital due to the significant swelling of his arm, where he received a single i.m. dose of a corticosteroid. When he woke up next morning he was almost totally paralyzed and able to move only his eyes. He was admitted to hospital again and severe hypokalemia was found. He received a KCl infusion and he recovered completely. A month later he had a second episode of morning paralysis. He had had a heavy carbohydrate meal the previous night. He was admitted to our hospital with severe hypokalemia which was carefully corrected with KCl. The clinical and laboratory examinations revealed hyperthyroidism due to Grave's disease. He took methimazole for several months without thyroxin replacement. Total thyroidectomy was performed and the patient received thyroxin replacement therapy with slow and careful titration. He never got paralyzed again and all potassium measurements are normal.

Conclusion

TPP is a very rare complication of hyperthyroidism in Caucasians, but it has to be considered especially when there's a need for corticosteroid administration.

Declaration of interest

## P474

**Adrenal crisis due to unusual cause: case report**

M. Rathi
King's Mill Hospital, Sutton in Ashfield, UK.

Introduction

A 40-year-old woman, despite previously well controlled Hypothyroidism and Addison's disease, presented with adrenal crisis due to extremely rare cause.

Case Report

In 2002, age 31 years, she presented with symptoms of anorexia, weight loss and postural hypotension. She was subsequently diagnosed to have Addison's disease and primary hypothyroidism (confirmed with positive adrenal and thyroid peroxidase antibody). She was started on Hydrocortisone, Fludrocortisone and 5 days later Levothyroxine was initiated. She was regularly reviewed in endocrinology clinic.

Nine years later, she presented with 2 month history of excessive sweatiness, restlessness, heat intolerance, dizziness, weight loss and increased skin pigmentation despite doubling the dose of Hydrocortisone (20 mg am and 10 mg pm) and taking regular Fludrocortisone and Levothyroxine.

On examination, she had tachycardia (heart rate – 123 bpm), marked postural hypotension, increased tremulousness of outstretched hands and small diffuse goitre.

Investigation confirmed biochemical thyrotoxicosis; Free T4 – 47 (ref 11–23 pmol/l), FT3 – 25.9 (4.1–7.9 pmol/l), TSH $<$ 0.02 (0.3–5.5 mU/l), Cortisol $-$18 nmol/l, Adjusted Calcium 2.50 mmol/l and TPO Antibody $>$ 1300 (ref $<$ 60 IU/ml). Her TSH receptor antibodies were positive.

Levothyroxine was stopped and antithyroid medication was initiated. Gradually her TFT normalised.

Conclusions
This case highlights few important points:
1. When patient with Hashimoto's hypothyroidism present with hyperthyroidism, over-replacement with Levothyroxine is the likely cause, but possibility of endogenous hyperthyroidism should be considered.
2. Transformation of Hashimoto's hypothyroidism to Graves' hyperthyroidism is extremely rare, but does occur. This is due to presence of different types of TSH Receptor Antibodies which recognise different epitopes of TSH receptors and modify the patients' thyroid functions, resulting in hyperthyroidism or hypothyroidism.
3. Development of thyrotoxicosis in a patient with otherwise well controlled Addison's disease can result in hypoadrenal crisis as thyroid hormones accelerate glucocorticoid turnover and increase glucocorticoid requirement.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P475

**Persistently abnormal thyroid function in a 26 year old Afro-Caribbean man: a diagnostically challenging case**

L. De Souza, J. Ormerod & P. De
City Hospital, Birmingham, UK.

Introduction
While most common aetiologies accounting for hyperthyroidism are straightforward and respond predictably to treatment, a subset provides diagnostic or therapeutic challenge. We report such a case.
Case report
A 26-year-old Afro-Caribbean male presented with symptoms of thyrotoxicosis. FT4 was 50 (12–20 pmol/l), FT3 11.5 (3–8 pmol/l) and TSH 5.38 (0.27–4.20 mU/l). He had diffuse non-tender thyromegaly without eye signs. Thyroid antibody was negative. Three months later he felt better on Carbimazole 30 mg but complained of lethargy and weight gain. FT4 was now 15, FT3 12.3, TSH 69.6 mU/l. Carbimazole was therefore discontinued.
10 months later he presented with tremor and palpitations on 20 mg of Carbimazole. He insisted good compliance with medication. FT4 was 36, FT3 was 12.3 and TSH was 11.87 μ/l. Carbimazole was increased to 30 mg.
Short synacthen test and pituitary function was unremarkable. MRI of the pituitary ruled out TSH-secreting adenoma. 1 year after presentation FT4 was 22, FT3 11.7 and TSH 20.58 μ/l. Carbimazole was withdrawn.
Differential diagnoses considered were assay artefact, interfering antibodies to FT4 and Resistance to Thyroid Hormone (RTH). The former two were excluded by testing in multiple laboratories. Genetic testing revealed heterozygosity for a mutation in the thyroid receptor (TR)-β gene (targeted to exons 7, 8, 9 and 10). Patient later disclosed about an aunt in Jamaica with persistent hyperthyroidism on high doses of carbimazole.
Discussion
RTH is a rare, inherited condition of reduced responsiveness of target tissue to thyroid hormone. Incidence is estimated to be 1 case per 40 000 live births and clinical presentation is highly variable. Characteristically FT4 and FT3 are raised with an unsuppressed TSH. Diagnosis can be challenging and other common differentials need to be excluded. It is important to consider this diagnosis in a young person with family history and persistently unsuppressed TSH with raised FT3/FT4.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P476

**Asymptomatic hypocalcemia in elderly**

J. Marti & J. Rodriguez Chinesta
Osakidetza, Zumarraga, Spain.

Introduction
Hypocalcemia varies from asymptomatic biochemical abnormality to life-treating disorder, depending on the duration, severity and rapidity of development.
Case report
A 77-year-old woman was admitted for study of asymptomatic hypocalcemia discovered in routinely laboratory test. Past medical history, left thyroidectomy by goiter 53 year ago without follow-up. She denied any symptoms. Physical examination. Actinic keratosis in right cheek, scar of thyroidectomy. Cardiac and respiratory exam were normal. Neurologic examination discards abnormalities, Chvostek and Trousseau signs were negatives. Laboratory test; calcium 5.72 mg/dl, phosphate 5.67 mg/dl, ionized calcium 3.1 mg/dl, magnesium 1.60 mg/dl, albumin 3.7 g, PTH 2.6 pg/ml, urinary calcium 12.2 mg/24 h, D3, TSH, cortisol, ACTH, hepatic and renal test normal. Thyroid Ab negatives. EKG normal. CT of the neck an brain, normal thyroid remnant, calcifications of basal ganglia and the corona radiata. Skeletal X-ray degenerative lesion age related. Treatments with calcium carbonate 2.5 g. TID and calcitriol 0.25 μg BID were initiated. Follow-up, one month later calcium level 8.5 mg/dl and phosphate 3 mg/dl. Currently patients remain asymptomatic with calcium 2.5 g and calcitriol 0.25 μg daily.
Discussion
The incidence of hypocalcemia varies from 0.4–13.8% after total thyroidectomy to 0.2–1.9% after subtotal thyroidectomy. Chronic or moderate hypocalcemia may be asymptomatic. Clinical signs are observed only with decreases in ionized calcium concentration in our patient despite low level ionized calcium was asymptomatic probably due to duration of hypocalcemia. Chronic hypocalcemia is treated by calcium oral and vitamin D supplementation. The serum calcium level should be targeted to about 8.0 mg/dl. Cerebral calcifications are not reversible.
Conclusion
Periodical routine checks of calcium levels in patients undergoing thyroid surgery would allow early diagnosis of asymptomatic hypocalcemia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P477

**Thyroid nodule: dormant, but lethal**

H. Chahal, A. Pittathankal, E. Casey, A. Ojo, A. Hawkins & K. Nikookam
King George Hospital, Barking, Havering and Redbridge University Hospitals NHS Trust, Greater London, UK.

We report two patients with thyroid nodules where thyroid cancer has unexpectedly been found. The first patient presented at the age of 58 years with a lump in her neck. She was clinically and biochemically euthyroid. Ultrasound revealed a solitary left hypoechoic nodule (23 × 17 mm), with no other suspicious sonographic features. She had two FNA's over a two year period which were reported as showing no malignant cells (THY2). Three annual ultrasounds showed no change in the size of the nodule and no suspicious features. However, despite these investigations, the patient was keen for surgery to provide a definite histological diagnosis. She underwent a left lobectomy and the histology unexpectedly revealed a 21 mm medullary thyroid carcinoma.
The second patient is a 42 year old lady with Graves' disease who presented with a 6 month history of palpitations. Clinically she had a moderate, smooth, non-nodular goitre, audible bruit and biochemically she was hyperthyroid with a free $T_4$ 52.8 pmol/l (10.0–19.8) and TSH $<0.01$ μ/l. A radionucleotide scan revealed features consistent with Graves' disease. She was initially commenced on carbimazole 40 mg daily. However, 14 months later despite being on carbiomazole 60 mg daily, with variable compliance, her free $T_4$ was 31.1 pmol/l. She underwent a total thyroidectomy due to poor compliance and possible resistance to medical therapy. Histology unexpectedly revealed a 4.5 mm papillary carcinoma in the right thyroid lobe; the left lobe was normal.
In summary we report two patients who have undergone thyroid surgery where a malignancy was not suspected on clinical or radiological investigations. The first case illustrates that surgery should be considered in patients with a thyroid nodule, even with a normal FNA. The second case demonstrates that thyroid cancer can still occur in a patient with Graves' disease, and in our patient the variable compliance has 'worked in her favour'.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P478

**Morbid obesity: what can be and should be done?**

M. Lukashova, E. Luchina, T. Meleshkevich, R. Ipatkin, Z. Gabunia & L. Vardaev
Central Clinical Hospital #2 n.a. N.A. Semashko Public Corporation 'Russian Railways', Moscow, Russian Federation.

Patient C Caucasian male, 41 years old was admitted to the inpatient department of endocrinology with newly diagnosed $T_2$ DM, morbid obesity on the 03.03.2011.
Anamnesis: Overweight since childhood, but in the past few years he started to gain weight rapidly (because of smoking cessation). Arterial hypertension since 2003, with maximum increase up to 210/125 and he took antihypertensive drugs regularly. In 2006 painless myocardial ischemia was first diagnosed. He had a history of impaired glucose tolerance since 2009, and was administered diet with metformin 1700 mg/daily, but he soon stopped taking the drug. In 2009 he was endoscopically installed gastric band. His weight decreased up to 30 kilos in 5 month, but not for long. His parents had a history of T2DM.
Objective
Height – 182 cm, Weight – 190 kl, BMI – 57 kl/m$^2$. No signs of Cussing disease. BP 150/90 mm Hg, pulse rate – 80 per min. Medical examination revealed: thyroid hormones, prolactin and cortisol levels were normal, but there was a significant increase in C-peptide – 2.55 nmol/l (0.37–1.47). A1C–8.5%. Glucose levels (04/03/11) 10.3 – 13.6 – 10.4 – 9.7 – 8.9 – 7.7 mmol/l. He was administered metformin 2550 mg/daily and a hypocaloric diet. After his blood sugar became normal (5.2 – 7.0 mmol/l) he was transferred to the Department of Surgery and 30.03.11 he was performed bilio pancreatic bypass in modification of Hess–Marceau. Postoperative period was well. He was recommended calcium supplements, iron and multivitamin complex.
Follow up 09.2011 Weight 141 kl. No complains.
12.2011 Weight – 129 kl, BMI – 42.59 kl/m$^2$, A1C – 5.6%, BP – 120/80 mm Hg. Surgery is a method of choice in treatment of obesity when diet and drugs are no longer effective. It improves quality of life, glycemic control and metabolic disorders and give's patient hope for a better future.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P479

**Sever Grave's disease and diabetes melitus**

E. Luchina, M. Lukashova, T. Meleshkevich & D. Reshetov
Central Clinical Hospital #2 n.a. N.A. Semashko Public Corporation 'Russian Railways', Moscow, Russian Federation.

March 2011. Patient P. Caucasian female, 53 years. Diagnosis: severe Grave's disease (GD), recurrent course. Endocrine ophthalmopathy (EO) NOSPECS – 4, CAS – 7. Thyrotoxic cardiomyopathy. Paroxysmal atrial fibrillation. Thyrotoxic proximal myopathy of the lower limbs. Thyrotoxic hepatitis. Type 2 diabetes mellitus. Chronic obstructive pulmonary disease.
Anamnesis: GD was first diagnosed in 2001, when she started to complain of weight lost (20 kilos in a couple months), tachycardia and general fatigue. Clinical examination revealed thyrotoxicosis. For 10 years she had been taking Thiamazole from 30 to 10 mg/daily depending on the level of hormones, because of fear of thyroidectomy and radioiodine therapy. In 2009 she was admitted to the inpatient Department of Endocrinology with ketoacidosis and blood glucose level – 27 mmol/l. She was administered intensive insulin therapy. 2010 – new complains of double vision, lacrimation and dry eyes appeared.
Clinical examination: TSH – 0.01 ME/ml (0.4 – 4), $fT_3$ – 20 pmol/l (2.3–6.3), $fT_4$ – 25 ng/dl (6.8–15.0), Ab-rTSH – 38 (0–0.99). C-peptide – 3 pmol/l (258–1758), A1C – 11%. Ultrasonography of the orbits (U.S.orbits): the value ofthe retrobulbar tissue (RBT) OD\OS = 18.3/17.5 mm ($n < 16$).
Blood glucose (BG): 17.3–20.0–5.5–18.9–17.6–13.4 mmol/l.
Treatment
Thiamazole 40 mg/daily, oral dexamethasone 0.1 mg/kg on alternate days, dose correction of the insulin, potassium preparations, omeprazole.
After normalization of $fT_3$, $f_4$ levels and BG, the patient was transferred to the surgical department for thyroidectomy.After that she was administered L-thyroxin 125 mkg/daily.
Follow up: November 2011. TSH, $f_4$, $fT_3$ – normal.U.S. orbits reveals no signs of edema. BG: 7.8– 9.0 –8.0 – 7.6 – 8.5 – 9.0 mmol/l, A1c – 7.5%.
After removing the source of the autoimmune aggression we've managed to achieve stable remission of EO, GD's complications and good glycemic control.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P480

**Secondary hypertension: a case presentation**

M. Aboul-Seoud
Faculty of Medicine, Alexandria University, Alexandria, Egypt.

Introduction
Secondary causes of hypertension exist in 10% of hypertensive subjects. Hypertension refractory to antihypertensive treatment must prompt the physician to screen for secondary causes.
Case presentation
A female 53-year old patient from Libya married and has three children. She works in a factory.
Complaints: Headache in attacks 1 year and 4 months, palpitations 4 months. She was discovered to be severely hypertensive and was given captopril 25 mg bid, with poor control of her ABP. No blurring of vision or diminution of visual acuity. No muscle weakness. No polyuria or polydipsia. No dysuria. Normal bowel habits. Normal sleep.
Past history: No past medical or surgical history.
Family history: No family history of hypertension, diabetes mellitus, dyslipidemia or ischemic heart disease.
Menstrual history: Patient is menopausal since 15 years on no HRT.
Social history and special habits
Nonsmoker. No special habits (no licorice intake, no coffee, tea once per day).
Drug history: Captopril 25 mg bid. No diuretics.
Clinical Examination
Radial pulse = 65 beats/min with 10 dropped beats/min, apical pulse = 73 beats/min with 12 dropped beats/min, A.B.P. = 170/100 mmHg, BMI = 30.20 kg/m$^2$, waist circumference = 102.5 cm, hip circumference = 99.5 cm, and WHR = 1.03.
Heart: Except for the frequent dropped beats and increased A2 over the aortic area, no other abnormalities detected.
Lower limbs: Dorsalis pedis felt bilaterally, soft pitting edema bilaterally ++.
The rest of the clinical examination was unremarkable.
Laboratory and radiological investigations were done.
The various causes of secondary hypertension will be reviewed laying particular stress on the patient's laboratory and radiological findings.
Conclusion
Making a diagnosis of a secondary disorder for hypertension is gratifying, because it may lead to significant amelioration or in some instances even cure of the elevated blood pressure like what occurred with the presented case.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Regulation of trophoblast 11β-hydroxysteroid dehydrogenase type 2 expression and role of corticotropin-releasing hormone**

A. Hein, M. Vatish & D. Grammatopoulos
University of Warwick, Coventry, UK.

The formation of the placental syncytiotrophoblast through trophoblast differentiation is a key cellular event, essential for successful embryonic implantation, oxygen/nutrient transport and secretion of placental hormones necessary for fetal development. Trophoblast differentiation alters expression of various molecules with important roles in placental biology, including

11β-hydroxysteroid dehydrogenase type 2 (11β-HSD2), the major component of the placental glucocorticoid (GC) barrier that limits exposure of the fetus and placenta to maternal GC. The endocrine effectors and molecular signaling pathways involved are not fully characterised. To investigate 11β-HSD2 regulation of expression, we employed the BeWo choriocarcinoma cell line, able to differentiate upon forskolin treatment and stimulation of district signaling cascades including the cAMP/PKA and ERK1/2 and P38 MAPKs[1]. Our results showed that BeWo trophoblasts express low levels of 11β-HSD2. Protein expression was significantly enhanced when specific inhibitors were used to inhibit activity of the PI3K-Akt-eNOS pathway that involves molecules recently identified as negative regulators of forskolin-induced BeWo fusion[2]. In contrast, inhibition of ERK1/2 and P38 MAPK attenuated 11β-HSD2 mRNA and protein expression. BeWo trophoblast 11β-HSD2 expression was also regulated by corticotrophin releasing hormone (CRH): interestingly, CRH treatment up-regulated 11β-HSD2 protein without affecting mRNA levels, raising the possibility of non-transcriptional effects of CRH targeting protein stability. Moreover, similar effects of CRH were demonstrated in experiments employing placental explants and appear to involve regulation of the ERK1/2, β38 MAPK and Akt pathways. Thus, this data identified in the BeWo trophoblasts novel signaling regulators of placental 11β-HSD2 expression and placental actions of CRH that might be important in the control of cellular sensitivity to GC with potentially important pathophysiological implications.

### Dimensional profiles of male to female gender identity disorder: an exploratory research

A. Fisher[1], E. Bandini[1,2], V. Ricca[2], N. Ferruccio[2], G. Corona[1], M. Meriggiola[3], E. Jannini[4], C. Manieri[5], G. Forti[1], E. Mannucci[6] & M. Maggi[1]
[1]Sexual Medicine and Andrology Unit, Florence, Italy; [2]Psychiatry Unit, Florence, Italy; [3]S.Orsola Hospital, University of Bologna, Bologna, Italy; [4]Course of Endocrinology and Medical Sexology, L'Aquila, Italy; [5]University of Turin, Turin, Italy; [6]Diabetes Section, Geriatric Unit, Florence, Italy.

Introduction

Male-to-female gender identity disorder (MtF GID) is a complex phenomenon that could be better evaluated by using a dimensional approach.

Aim

To explore the aggregation of clinical manifestations of MtF GID in order to identify meaningful variables describing the heterogeneity of the disorder.

Methods

A consecutive series of 80 MtF GID subjects (mean age $37 \pm 10.3$ years), referred to the interdepartmental Center for Assistance Gender Identity Disorder of Florence and to other Italian centers from July 2008 to June 2009, was studied. Diagnosis was based on formal psychiatric classification criteria. Factor analysis was performed.

Main outcome measures. Several socio-demographic and clinical parameters were investigated. Patients were asked to complete the Bem Sex Role Inventory (BSRI, a self-rating scale to evaluate gender role) and Symptom Checklist-90 Revised (SCL-90-R, a self-rating scale to measure psychological state).

Results

Factor analysis identified two dimensional factors: factor 1 was associated with sexual orientation, and factor 2 related to behavioral and psychological correlates of early GID development. No correlation was observed between the two factors. A positive correlation between factor 2 and feminine BSRI score was found, along with a negative correlation between factor 2 and undifferentiated BSRI score. Moreover, a significant association between SCL-90-R Phobic subscale score and factor 2 was observed. A variety of other socio-demographic parameters and clinical features were associated with both factors.

Conclusions

Behavioral and psychological correlates of Factor 1 (sexual orientation) and Factor 2 (gender identity) do not constitute the framework of two separate clinical entities, but instead represent two dimensions of the complex MtF GID structure, which can be variably intertwined in the same subject. By using factor analysis, we offer a new approach capable of delineating a psychopathological and clinical profile of MtF GID patients.

### GH replacement therapy in patients with primary paediatric brain tumours

E. Seregni, F. Pallotti, V. Biassoni, S. Catania, L. Gandola, F. Spreafico, M. Terenziani, A. Mallia, E. Bombardieri & M. Massimino
National Cancer Institute, Milan, Italy.

Aim

Endocrinopathies are frequent complications in paediatric patients with primary brain tumours (PBT) and among them GH deficiency (GHD) is of particular relevance. In this study we evaluated the incidence of GHD and the impact of GH therapy in a large series of PBT bearing patients or adult patients previously treated for PBT.

Methods

From January 2001 to December 2011 more than 700 PBT patients were screened for endocrine complications. GHD was explored by provocative tests (arginine and clonidine) in a subgroup of patients on the basis of laboratory (IGF1 levels), auxological (growth failure, low height velocity, delayed skeletal maturation) and clinical findings (anti-neoplastic therapies adopted life expectancy). Patients with proven GHD were treated with recombinant GH at initial dosage of 0.22 mg/kg per week for children and 0.3 mg/die for adults. For each patient the GH dose was tailored on the basis of circulating IGF1.

Results

110 PBT patients displayed GHD. Of these patients, 47 had diagnosis of medulloblastoma, 21 germ-cell tumours, eight low-grade gliomas, eight ependymoma, five supratentorial PNET and 21 other histological PBT. They received chemotherapy (conventional and/or high-dose chemotherapy) and/or radiotherapy according to our institutional protocols and to the clinical course. In all but five children (with precocious puberty and cranio-spinal irradiation) growth recovery was observed. Improvement of bone mineral density was attained either in children or in adults. A particularly interesting observation was the improvement in the neuropsychological performances of several patients secondary to GH therapy. A temporary discontinuation of GH therapy was necessary in three patients due to worsening of cerebral radionecrosis. Disease recurrence was found in seven and this relapse rate is lower than in non-GH treated patients.

Conclusions

In our experience GH replacement therapy is safe and effective in the correction of GH deficiency and in improving quality of life of PBT patients.

### The effect of educational program based on BASNEF model on diabetic (type II) control blood sugar

A. Khani Jeihooni
Fasa university of medical science, Fasa, Islamic Republic of Iran.

Introduction

For prevention of diabetic disease complications,educational interventions by using health education models are performance. The purpose of this study was to

determine the effects of educational program based on the BASNEF model on diabetic (type II)) control blood sugar.
Material and methods
This is a perspective and quasi-experimental intervention study,. 100 diabetic patients type II (50 case and 50 control), between the ages of 40 and 65 years, having had diabetes for over 5 years, participated in the study. The instruments for data collecting were a questionnaire established based on the BASNEF model, a check list related to patient practice on the basis of self reporting, a check list for recording the patients' HbA1c and FBS levels report as well. All groups completed the questionnaires and check lists results were documented before and three months after intervention. The patients of the experimental group participated in 6 educational session classes during the one month of intervention and again two months after, with two session meeting classes as the follow up of intervention. The data were collected and analyzed by SPSS computer software.
Results
Our findings indicated that mean scores of BASNEF model variables (beliefs, attitudes, subjective norm, enabling factors) were significantly increased in the experimental group compared to the controls after intervention. Also, behavioral controlling blood sugar, rate of HbA1c (before intervention as 8.65% after three months 7.47%) and FBS levels (before intervention 207.08, after three months 124.2) improved significantly among the experimental group, compared to control group.
Conclusion
Applying the BASNEF model is very effective for developing an educational program for diabetics, in order to control their blood sugar and enhancing behavioral controlling blood sugar. Besides such programs, follow up education on controlling and monitoring is highly recommended.
Keywords: Type 2DM, blood sugar, Educational BASNEF model.

**The timing of the onset of adrenarche in Pakistani boys**

F. Bibi[1], A. Naseem[1], S. Aslam[2], M. Irfan[1], F. Tahir[3], M. Qayyum[1], R. Mansoor[4], S. Murtaza[5] & S. Rizvi[1,6]
[1]PMAS Arid Agriculture University, Rawalpindi, Pakistan; [2]Government College University, Lahore, Pakistan; [3]National Institute of Health, Islamabad, Pakistan; [4]Rawalpindi Medical College, Rawalpindi, Pakistan; [5]Nuclear Oncology and Radiotherapy Institute, Islamabad, Pakistan; [6]Pakistan Science Foundation, Islamabad, Pakistan.

Adrenarche is a normal maturational event that in humans occurs at around 6–8 years of age. During adrenarche, a new zone of the adrenal cortex, the zona reticularis, is developed, resulting in increased production of adrenal androgens, androsteindione, DHEA and DHEAS. The increase in the secretion of adrenal androgens causes the appearance of axilliary and pubic hair, a brief increase in linear growth velocity and bone maturation, and the development of the brain. The premature and/or exaggerated adrenarche results in future onset of diseases and thus has a clinical relevance. The present study was aimed at unraveling the age of the onset of adrenarche in Pakistani boys. The history of the boys of 1–10 years of age with their body weight and height was obtained through a questionnaire. Blood samples were collected from antecubital vein of each boy, plasma was separated and concentrations of androsteindione, DHEAS and testosterone were determined by using specific assay systems. The data were analyzed using Student's *t*-test, ANOVA, and Pearson correlation *r*. The boys gained normal weight and height with the corresponding body mass index. The concentrations of androsteindione started to rise at 3rd year and reached peak levels at 7th year of age. The concentrations of DHEAS started to increase at 4th year and reached first peak at 7th year and continued to increase by 10th year of age. The levels of T remained very low throughout the study period but progressively increased and showed a peak at 6 years and then continued to rise non-significantly from 7th to 10th year of age. We observed strong positive correlations between androsteindione and DHEAS, androsteindione and T, and DHEAS and T at adrenarche. We report here that the age of adrenarche in Pakistani boys is 7 years.

**Post prandial gut hormones: novel activators and regulators of innate immune function**

A. Hogan, J. O'Connell & D. O'Shea
St Vincent's University Hospital, Dublin, Ireland.

Invariant natural killer T (iNKT) cells are key innate immune cells implicated in the pathogenesis of many diseases. Glucagon-like peptide-1 (GLP-1) is an incretin hormone implicated in regulating blood glucose and body weight. We recently demonstrated that GLP-1 is a regulator of iNKT cell function and that inflammatory conditions such as psoriasis, rheumatoid arthritis and ulcerative colitis improve following GLP-1 therapy. GLP-1 is one of several post-prandial gut hormones, including peptide YY (PYY), cholecystokinin (CCK) and ghrelin, each with a distinct metabolic function.
We investigated iNKT cell lines for expression of PYY, CCK and ghrelin receptors by PCR and examined receptor activation impact on cell function by ELISA and flow cytometry.
A PYY receptor (PYY-R) was identified and, as was previously demonstrated with GLP-1, PYY-R activation induced the anti-inflammatory transcription factor CREB and inhibited the pro-inflammatory transcription factor NFκB. This translated into reduced production of the pro-inflammatory cytokine IFN-γ (600–450 pg/ml, $P<0.01$) but not the anti-inflammatory cytokine IL4 (350–349 pg/ml). We also demonstrated increased tumour cell lysis by PYY-treated iNKT cells (6 vs 12% of tumour cells lysed ($P<0.001$).
Stimulation of the CCK receptor resulted in activation of the transcription factor NFκB but had no effect on CREB. This resulted in an increase in cytokine production of both IFN-γ and IL13 (300–400 and 280–370 pg/ml, respectively). We identified a ghrelin receptor on the iNKT cell, but activation had no impact on cell function or the CREB and NFκB transcription factors.
We conclude that post-prandial gut hormones differentially impact and regulate innate immune cell function and may have therapeutic potential as immunomodulatory agents in autoimmunity and malignancy.

**Opposite effect of LXR on myelination process in the central and peripheral nervous systems and interplay with Wnt pathway**

D. Meffre, G. Shackleford, J. Makoukji, J. Grenier, M. Schumacher & C. Massaad
CNRS UMR8194, Paris, France.

Oxysterols are reactive molecules generated from the oxidation of cholesterol. Few data are available about their functions in myelination of nervous system. Our aim was to study the influence of oxysterols on myelin gene expression and myelin sheath formation by oligodendrocytes (central nervous system), and by Schwann cells (peripheral nervous system). We show by gas chromatography/mass spectrometry that oligodendrocytes and Schwann cells contain 24(S)-hydroxycholesterol, 25-hydroxycholesterol and 27-hydroxycholesterol, and that they express their biosynthetic enzymes and receptors (liver X receptors: LXRα and LXRβ). We demonstrate that oxysterols activate the expression of central myelin genes (PLP and MBP) in oligodendrocytes, but inhibit peripheral myelin genes expression (MPZ, PMP22) in a Schwann cells.
In the CNS, we showed that the activating effects of oxysterols were restricted to the cerebellum and dependant of LXR presence as myelin gene expression was drastically reduced in this structure in LXR-KO mice. By, using organotypic cultures of cerebellum slices, we showed that oxysterols were able to stimulate myelin gene expression after lysolecithin-induced demyelination and enhance remyelination process.
In the PNS, the down-regulation of myelin genes is mediated either by LXRα or LXRβ, depending on the promoter context. Importantly, the knockout of LXR in mice results in thinner myelin sheaths surrounding the axons of the nerves. Oxysterols repress peripheral myelin genes via two mechanisms: by binding of LXRs to myelin gene promoters and by inhibiting the Wnt/beta-catenin pathway that is crucial for the expression of myelin genes.
Altogether our results reveal new mechanisms of action of oxysterols and open new perspectives for the treatment of demyelinating diseases by targeting LXR.

**Increased oxidative stress associated with angiogenic growth factors in preeclampsia**

A. Kulkarni[1], S. Mehendale[2], H. Pisal[1], A. Kilari[1] & S. Joshi[1]
[1]Interactive research school for health Affairs, Pune, India; [2]Bharati vidyapeeth medical college, Pune, India.

Hyperperhomocysteine has been implicated in vascular changes and oxidative stress contributing to endothelial dysfunction in preeclampsia. Our earlier studies have shown increased oxidative stress leading to reduced docosahexaenoic acid (DHA) levels in pre-eclamptic women. The present study examines the levels of angiogenic factors (VEGF, PlGF sFlt-1), homocysteine and oxidative stress marker malondialdehyde (MDA) levels, in 90 normotensive (control) and 137 preeclamptic women (90 women delivering at term (term PE) and 48 women delivering preterm (PT–PE)). Maternal homocysteine and MDA levels were higher ($P<0.01$ for both) in preeclampsia groups than control. Maternal plasma VEGF levels were lower ($P<0.05$) in the term-PE group, while it was higher in the PT-PE group ($P<0.05$) than the control group. In contrast, cord plasma VEGF levels were higher ($P<0.05$) in preeclampsia groups than the control group. Maternal plasma PlGF levels were lower ($P<0.05$) in preeclampsia groups as compared to control group. Maternal plasma sFlt-1 levels were higher ($P<0.05$) in preeclampsia groups than control group. Cord sFlt-1 levels were similar in term-PE and control groups while it was lower in the PT-PE group. sFlt-1:PlGF ratio was increased ($P<0.05$) in the preeclampsia groups than the control group. Maternal plasma MDA was positively associated with maternal plasma sFlt-1 levels ($P<0.05$) in the preeclampsia groups. Cord plasma DHA levels were negatively associated with cord plasma sFlt-1 levels ($P<0.05$ for both) in oth preeclampsia groups. Maternal plasma sFlt-1 levels were negatively associated with birth outcome parameters (baby weight, head circumference and chest circumference) in the term-PE group ($P<0.01$ for all). This study for the first time suggests that, levels of angiogenic factors may be differentially regulated in mother and cord. Dysregulation of angiogenic factors may be associated with maternal oxidative stress. Increased oxidative stress may reduce cord DHA levels and increase sFlt-1 levels, leading to poor birth outcomes in preeclampsia.

**Congenital hypothyroidism influences hepatic gene expression of suppressors of cytokine signaling (SOCS) in adulthood**

M. de MIrecki-Garrido[1], R. Santana-Farre[1], A. Flores-Morales[2,3] & L. Fernandez-Perez[1]
[1]University of Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain; [2]Karolinska Institutet, Stockholm, Sweden; [3]University of Copenhagen, Copenhagen, Denmark.

Thyroid hormones (TH) are required for normal postnatal growth development in mammals. The physiological importance of TH becomes evident under the conditions of congenital–neonatal hypothyroidism (CH). If not treated immediately, CH has a profound impact on physiology and can permanently imprint neurological and endocrine systems, which, in turn, led to mental retardation, growth arrest, and metabolic disturbances. A delayed growth development or long-lasting influence of CH on somatotropic-related liver functions could be related with GH resistance. GH resistance has been shown in rat models of sepsis, uremia or in small rats for gestational age. In these models, GH resistance has been associated with increased expression of suppressors of cytokine signalling (SOCS) proteins which contribute to impair GH–JAK–STAT signaling. Here, we studied expression of SOCS genes in liver from rats previously exposed to CH. Pregnant rats were given anti-thyroid drug methimazole (MMI) from Gestational Day 12 until postnatal day (PND) 30 to induce CH in male offspring. Growth defects due to CH were evident as a reduction in body weight and tail length from the second week of life. Once the growth inhibiting condition (MMI) was discontinued on PND30, significant catch-up growth was evident in CH rats. On PND80, significant reduction in body mass, tail length, and circulating IGF1 remained in CH rats. Serum levels of thyroid hormones, cholesterol, and triglycerides showed no significant differences. However, we observed down-regulation of female-predominant (e.g. CYP2C7) together with induction of male-predominant genes (e.g. CYP2C11) which suggested that a male pattern of gene expression was enhanced in CH rat liver. Finally, we observed an impaired somatic growth followed by catch-up growth in rats previously exposed to CH that was associated with increased expression of SOCS (SOCS2 and CIS), a phenomena that requires further research.

**Characterization of a mouse model of paediatric combined hormone deficiency**

K. Prince[1] & S. Rhodes[2]
[1]Indiana University School of Medicine, Indianapolis, Indina, USA; [2]Indiana University – Purdue University Indianapolis, Indianapolis, Indina, USA.

To better understand the molecular and cellular nature of paediatric combined pituitary hormone deficiency diseases, our laboratory has recently generated a novel mouse model of the severe paediatric diseases caused by mutations in the *LHX3* transcription factor gene. Through gene targeting, we have produced an *Lhx3* W227Ter mouse modeling the *LHX3* W224Ter (loss of carboxyl terminus) human disease. Patients with the W224Ter mutation are of short stature and have deficiencies of GH, PRL, TSH, LH, and FSH. The homozygous *Lhx3* W227Ter knock-in mice show symptoms including marked dwarfism, lethargy, reproductive problems, and pituitary hormone deficiencies. To examine the developmental time course of these deficiencies, wild-type and W227Ter knock-in mouse embryos were preserved, cryosectioned and analyzed for pituitary hormone and marker gene expression via immunohistochemistry at embryonic days 13.5, 15.5 and 17.5. Knock-in embryos had a smaller developing anterior pituitary, as well as lower expression levels of ACTH, GH, PRL, TSH, LH, α-GSU, and the pituitary transcription factor PIT1. In addition, structural defects were often noted. To examine the effects of genetic background on the disease, the W227Ter mutation was separately backcrossed six generations into the C57BL/6 and 129/Sv mouse strains. Matings of sixth generation C57BL/6 animals produced viable homozygous knock-in dwarf mice that were able to survive after weaning. By contrast, matings in the 129/Sv background have to date only produced one live knock-in pup, which died before weaning. These differences suggest that genetic background has a significant impact on *LHX3*-associated diseases and that the effects of modifier genes may explain the varied disease outcomes seen in human patients. Supported by NIH HD42024 to SJR and NIH F32HD068113 to KLP.

**DHEA attenuated mature adipocyte proliferation**

I. Mori, K. Kajita, K. Fujioka, T. Hanamoto, T. Ikeda, H. Okada, T. Usui, N. Takahashi, K. Taguchi, Y. Kitada, Y. Uno, H. Morita & T. Ishizuka
Gifu University, Gifu, Japan.

Back ground

Numerous researches indicate that DHEA administration decreases fat mass in human and rodent. We evaluated the effects of DHEA treatment on adiposity. Male Otsuka Long evans fatty (OLETF) rats, hereditary obese type 2 diabetic animals derived from long evans tokushima (LETO) rats. These rats were fed with or without (control) 0.4% DHEA containing food for 52 weeks. Telomere length as a marker of whole cell division in adipose tissue were assessed. Genomic DNA isolated from fat tissue was digested with restriction enzyme, Hinf 1/Rsal, and then Southern analysis was performed to measure telomere length. Treatment with DHEA for 52 weeks in LETO and OLETF decreased fat mass. Furthermore, reduced telomere length in fat tissue isolated from OLETF and LETO rats was restored after treatment with DHEA. These results suggested that accelerated cell division in obese adipose tissue was prevented with DHEA administration.

Aim

We examined whether DHEA administration inhibited mature adipocyte proliferation in this study.

Methods
*In vivo* cell proliferation was estimated with 5′-bromo-2′-deoxyuridine (BrdU), a thymidine analog, uptake in adipose tissue. Male Wistar rats were fed with 0.4% DHEA or 0.005% pioglitazone, a thiazolidinedione, containing food for 4weeks, 200 mg/kg. BrdU was i.p. administered three times before sacrifice, then s.c., epididymal and periintestinal fats were collected. Immunohistochemical study using anti-BrdU antibody revealed that BrdU positive cells were identified both in stromal vascular fraction (SVF) and mature adipocyte.
Results
In visceral fat, BrdU positive cells were detected mainly in mature adipocyte. However they were observed predominantly in SVF area in subcutaneous fat. Treatment with DHEA mainly decreased BrdU positive cells in mature adipocyte. On the other hand, treatment with pioglitazone increased BrdU positive cells in SVF and mature adipocyte.
Conclusion
Considering the fact that DHEA reduce the expression of PPARg in adipocyte as reported previously, these results suggest that DHEA administration inhibited mature adipocyte proliferation, and PPARg may affect on mature adipocyte proliferation.

## P492

**Oestradiol and its biochemical precursor levels decline in men around the age of their late twenties, what may determine the conclusion of bone maturation**

D. Szyska-Skrobot[1,2], J. Slowikowska-Hilczer[1], R. Walczak-Jedrzejowska[1], P. Kula[1], K. Marchlewska[1], E. Oszukowska[1], E. Filipiak[1], R. Mezyk[2], A. Kowalska[2] & K. Kula[1]
[1]Medical University of Lodz, Lodz, Poland; [2]Swietokrzyskie Center of Oncology, Kielce, Poland.

Introduction
Longitudinal bone growth ceases by the end of puberty, and the induction of epiphyseal maturation and closure is thought to be a result in both sexes of the action of increased pubertal oestrogen concentrations. However, bone mass accrual progresses beyond puberty and we related sex steroid hormones and sex hormone binding globulin (SHBG) levels to calcaneal quantitative ultrasound index (QUI) in young adult men.
Methods
Eighty men aged between 18 and 39 years were invited by letter to attend for an interviewer-administered questionnaire, body mass index (BMI) measurement, blood sample and QUI of the calcaneus (Hologic – SAHARA). Blood was assessed for testosterone, oestradiol ($E_2$), DHEAS, SHBG, LH and FSH. The following bioactive fractions of testosterone and $E_2$ were calculated: free (non-bound to SHBG and albumin) and bio-available (non-bound to SHBG).
Results
While total $E_2$, total testosterone, DHEAS, LH and FSH levels were not related, a positive correlations with QUI ($P<0.05$) were found for the levels of free $E_2$, $\beta=6.30$ (CI: 1.14, 11.47), bio-available $E_2$, $\beta=0.21$ (CI: 0.02, 0.41), free testosterone, $\beta=0.04$ (CI: 0.005, 0.08) and bio-available testosterone, $\beta=1.56$ (CI: 0.84, 3.04). SHBG level was related negatively, $\beta=-0.55$ (CI: $-1.00$, $-0.095$). However, after dichotomisation for age, the associations remained significant only for younger subjects (18–28 years $n=41$). Older subjects (29–39 years, $n=39$) revealed in turn lower ($P<0.01$) serum concentrations of total $E_2$ ($-20.1\%$), free $E_2$ ($-25\%$), bio-available $E_2$ ($-25.7\%$), DHEAS ($-17.7\%$) and bio-available testosterone ($-12.8\%$) than the younger. QUI did not change.
Conclusions
In healthy men the levels of all fractions of $E_2$ and their biochemical precursors DHEAS and bio-available testosterone decrease substantially around the age of late twenties. This may determine the conclusion of bone maturation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**The origins and lineages of somatic cells during the formation of the mammalian ovary**

K. Hummitzsch[1], H. Irving-Rodgers[1,2], N. Hatzirodos[1], W. Bonner[1] & R. Rodgers[1]
[1]University of Adelaide, Adelaide, South Australian, Australia; [2]Queensland University of Technology, Kelvin Grove, Queensland, Australia.

The origins and lineages of somatic cells in mammalian ovaries are poorly understood and not universally agreed upon. By clonally-isolating different phenotypes of bovine fetal stromal cells and conducting microarray analysis, we identified markers of different somatic cells. Antibodies to these markers, markers of other known cell types in fetal ovaries and to extracellular matrix were used to examine bovine ovaries (60–300 days of gestation, $n=51$) by immunohistochemistry. We show that the gonadal ridge is initially formed by replication of surface epithelium of the mesonephros giving rise to a cluster of cells expressing only some epithelial markers (abbreviated to gonadal ridge epithelial like (GREL) cells). Primordial germ cells migrate into the gonadal ridge and form oogonia and replicate. Stroma from the mesonephros also penetrates into the gonadal ridge forming alternating areas of stroma and irregularly shaped ovigerous cords, composed of oogonia and GREL cells. The stroma brings with it capillaries from the mesonephros. Importantly the stroma is always continuously surrounded by a basal lamina, separating it initially from the ovigerous cords. Stromal cells also migrate to just under the outer layers of GREL cells on the surface and spread laterally, establishing a basal lamina under the cells on the ovarian surface and an epithelial/stromal interface and hence a mature ovarian surface epithelium. Stroma continues to partition the ovigerous cords, still with a basal lamina at the interface, to form follicles containing an oogonium/oocyte and GREL cells that form the granulosa cells. This region is the ovarian cortex. The ovarian medulla below is largely residual mesonephric stroma containing some rete ovarii derived from mesonephric nephrons. In summary we have identified the cell lineages and the cell fate decisions needed for maturation of all the different somatic cells in the adult ovary.

**Childhood maltreatment in subjects with male to female gender identity disorder**

A. Fisher[1], E. Bandini[1], V. Ricca[2], M. Meriggiola[3], E. Jannini[4], C. Manieri[5], G. Corona[1], M. Monami[6], G. Forti[1], E. Mannucci[6] & M. Maggi[1]
[1]Sexual Medicine and Andrology Unit, Florence, Italy; [2]University of Florence, Florence, Italy; [3]Center for Reproductive Health, S.Orsola Hospital, University of Bologna, Bologna, Italy; [4]Course of Endocrinology and Medical Sexology, University of L'Aquila, L'Aquila, Italy; [5]University of Turin, Turin, Italy, Torino, Italy; [6]Diabetes Section, Geriatric Unit, Florence, Italy.

Introduction
Childhood maltreatment is quite common and constitutes a non-specific risk factor for a range of different emotional and behavioural problems during lifespan. It has been demonstrated that sexual minorities are at higher risk of maltreatment and abuse, and a high proportion of transsexual subjects reports childhood maltreatment.
Aim
To evaluate the prevalence of reported childhood maltreatment in a clinical sample of patients with male to female gender identity disorder (MtF GID), and to explore the relationship between these early life events, body image, and different psychopathological and clinical variables.
Methods
A consecutive series of 162 patients with male genotype was evaluated for gender dysphoria in different dedicated centers from July 2008 to May 2010. One hundred-nine subjects (mean age $36\pm10$ years) meeting the criteria for MtF GID, were considered.
The occurrence of childhood maltreatment experiences was evaluated through a face-to-face clinical interview. Patients were asked to complete the body uneasiness test (BUT, a self-rating scale exploring different areas of body-related psychopathology) and Symptom Checklist-90 Revised (a self-rating scale to measure psychological state).
Results
More than one fourth of patients reported childhood maltreatment. Maltreated subjects reported a higher body dissatisfaction and display a worse mental health lifetime. They also reported a higher BUT depersonalization score.

Conclusions
An history of childhood maltreatment is associated with body image dissatisfaction, worse psychosocial adjustment during childhood and worse lifetime mental health in subjects with gender identity disorder. The presence of reported childhood maltreatment in these patients has relevant psychopathological implications, and therefore should be carefully investigated.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Post prandial responses of insulin and free fatty acids following consumption malaysian vs mediterranean-like meals among healthy subjects

Y. Yusoff[1], N. Abdul Wahab[1], B. Mohd Yusof[2], S. Shah[1] & N. Kamaruddin[1]
[1]UKMMC Kuala Lumpur, Malaysia; [2]University Putra Malaysia, Kuala Lumpur, Malaysia.

Introduction
Refined carbohydrates which substitute the staple diet in most cultures may exaggerate postprandial responses in term of insulin and free fatty acid levels. These changes may herald the onset of metabolic syndrome and diabetes among those at high risk of these diseases.
Objectives
To determine the postprandial insulin and free fatty acids levels in healthy subjects after the consumption of two different breakfast meals, Mediterranean-like vs Malaysian meal each with different carbohydrate, glycaemic index and glycaemic load content.
Methods
Twenty subjects were made to take two different meals, Mediterranean-like representing low glycaemic index (GI) and low glycaemic load (GL) diets vs Malaysian meals (high GI and high GL) a week apart. Blood parameters including fasting serum lipid, serum insulin, serum non esterified free fatty acid were taken at 0, 30, 60, 90, and 120 min after each meals. Blood glucose was also taken at baseline and 120 min postprandially.
Results
Twenty subjects were randomized to either Mediterranean-like meal or Malaysian meal first, followed by the other meal a week later. Baseline clinical and demographic parameters were comparable for both meals. With both meals there was an increased in serum triglyceride (Mediterranean-like 0.91 vs Malaysian 1.09; $P=0.565$) with a corresponding drop in HDL and LDL levels throughout the 2-h postprandial period (1.47 vs 1.49; $P=0.844$) and (2.86 vs 2.75; $P=0.647$). There is a significant increase in the serum insulin with Malaysian meal compared to Mediterranean-like meal (16.95 vs 1.99; $P=0.001$). However, the non esterified fatty acid levels were significantly lower in Malaysian meal compared to Mediterranean-like meal (0.18 vs 0.28; $P=0.003$)
Conclusion
Malaysian breakfast meal which is characterised by high GI and GL content, resulted in significant increase in insulin responses with concurrent drop in free fatty acid compared to Mediterranean-like meal.
Keywords: Insulin, serum non esterified free fatty acid (NEFA).

### Evaluation of cognitive, affective and relational skills of adolescents treated with testosterone for 47XXY klinefelter syndrome

A. Lubienski[1], K. Guéniche[1,2] & M. Polak[2]
[1]Paris Descartes, Sorbonne Paris Cité, Paris, France; [2]Hôpital Necker Enfants Malades, Paris, France.

The early diagnosis of 47XXY- Klinefelter syndrome (KS) associated with infertility confronts the parents with concerns about their child outcome on cognitive, social skills and sexual identity. Few studies relate the weakness of intelligence, mainly verbal, and relational inhibition. Androgen may be offered to adolescents to normalize anatomic and psychic puberty processes. This has never been evaluated in psychological terms.
Subjects and methods
Eight adolescents aged from 11 to 17 with 47XXY-KS were recruited. The protocol included a semi-directive interview, a Wechsler intelligence scale and projective tests (Rorschach and TAT) offered before (t1) and after 12 months of testosterone treatment (t2).
Results
Interviews underline four themes in the narratives: i) insufficient knowledge of the disorder and medical history ii) problems in socio-educational integration iii) inhibition of psychic conflicts and relational withdrawal iv) shame and secrecy regarding the diagnosis and infertility inside the family. The small cohort only allows for descriptive cognitive results. At t1, the global cognitive abilities are clearly below the standard (average IQ $=75$) with a significant dispersion between verbal and logical/practical skills. At t2, a slight improvement in the global level is observed (average IQ $=79$) with an important homogenization of the scores. Besides, projective tests revealed inhibition in affective life underlined in representations of human relationship (phobic avoidance) and expression of sexual identity. At t2 improvement of relational skills is observed.
Conclusion
Inhibition of cognitive, affective and relational skills is understood as a specific way of expression of the processes of adolescence. The benefits of this research-action are observed at the cognitive and relational levels. More than normalization, it offers to these adolescents the opportunity of a psychic work. This allows the appropriation of their medical history which supports the development of psychic processes of adolescence.

### The development of endocrinologic dysfunction after allogeneic HSCT in children.

I. Ben-Skowronek, K. Drabko, B. Wójcik & J. Kowalczyk
Medical University, Lublin, Poland.

Introduction
Endocrinologic dysfunction is a well-known complication after hematopoietic stem cell transplantation (HSCT) in children. The mechanisms of thyroid damage developing after transplantation remain not completely recognized. Toxicity of the conditioning regimen, especially total body irradiation, is most commonly postulated cause of endocrine abnormalities; immunological mechanisms (e.g. graft vs host disease) may also contribute to thyroid dysfunction.
Patients and methods
We prospectively evaluated the function of thyroid, gonads, pituitary and adrenals in 51 children, aged 1–18 years, who survived more than one year after transplantation. The reasons for bone marrow transplantation were: severe aplastic anemia (SAA), acute lymphoblastic anemia, inborn errors, acute myeloblastic leukemia and others. The conditioning regimen included chemotherapy in 27 children and TBI in eight patients.
In the Endocrinological Dept. the high velocity and sexual maturation of the children were observed. Every year we evaluated TSH, $fT_4$, anti-tyreoglobuline antibodies (a-TG) and anti-peroxidase antibodies (a-TPO), FSH, LH, prolactin, estradiol and testosterone, GH, glycemia, lipidogram, insulin and glucose levels and circadian rhythm of cortisole secretion.
Results
In eight children, autoimmune hypothyroidism was diagnosed; the children needed L-thyroxin replacement therapy. In three patients this feature was transient, while four required thyroxin supplementation. One patient was diagnosed as having Graves' disease. Transient delay of growth velocity was observed in all the children in the first year after HSCT, but only in 2 boys they were permanent; however the growth hormone secretion in sleep was normal. In six children hypogonadism was developed – in four hypergonadotropic hypogonadism and in two hypogonadotropic hypogonadism. Three children were treated for obesity without adrenal and pancreatic disorders.
Conclusions
1. Abnormalities of autoimmunological thyroid function are a most frequent complication in children after HSCT.
2. The frequent complication is hyper- and hypogodotropic gonad disorders.
3. The children after HSCT need permanent observation in the Endocrinological Outpatient Clinic.
The percentage of endocrine disorders after allogeneic HSCT.

**46 XX Male syndrome: is there any relationship with dysembryoplastic neuroepithelioma?**

S. Furqan & N. Haque
Aga Khan University Hospital, Karachi, Pakistan.

Introduction
De la Chapelle syndrome (46XX male syndrome) is a rare anomaly with the characterstics of discordant chromosomal and gonadal sex. Individuals with classical 46XX male sex reversal syndrome have an apparently normal male phenotype and presents with infertility or sub-fertility.
Case report
Twenty five year old male, married 2 years back, came to take opinion regarding his Infertility. He is a healthy looking male with well developed secondary sexual characteristics and normal external male genital phenotype with a normal sized penis and both testis in scrotum and are of normal consistency and volume. Testicular biopsy shows no active spermatogenesis. He was operated at the age of 14 years for an intracranial mass, the histological analysis shows dysembryoplastic neuroepithelioma, a rare benign neoplasm, cytogenetic analysis of which shows mosiac cell line. Sex karyotype in the mosiac and normal cell line was 46XX.
Conclusion
It is a rare disorder of sexual differentiation where the testes and male genitalia develop in the absence of Y chromosome and possibly without the SRY gene. Usually it is caused by unequal crossing over between X and Y chromosomes during meiosis. Is this condition is associated with increased incidence of neoplasm is still a question, needed to be answered. Klinefelter's syndrome, another similar condition causing infertility, is known to have increased incidence of neoplasms.

**Selective suppression of slow wave sleep does not affect insulin sensitivity in patients with type 1 diabetes**

E. Donga[1], M. van Dijk[1], G. Lammers[1], K. van Kralingen[1], G. van Dijk[1], E. Corssmit[1] & J. Romijn[2]
[1]Leiden University Medical Center, Ledien, The Netherlands; [2]Amsterdam Medical Center, Amsterdam, The Netherlands.

Background
Human sleep is composed of different sleep stages, of which slow wave sleep (SWS) is an important modulator of glucose regulation. Curtailment of sleep duration in general and of slow wave sleep (SWS) in particular reduces glucose tolerance in healthy subjects. Previously, we have reported that a single night of partial sleep deprivation reduces insulin sensitivity by 15–20% in patients with type 1 diabetes. We hypothesized that this effect could be a consequence of reduced SWS.
Objective
To determine the effect of selective suppression of SWS on insulin sensitivity in patients with type 1 diabetes.
Methods
We studied insulin sensitivity in seven patients with type 1 diabetes on continuous s.c. insulin infusion therapy without any known sleep disorders after a normal night of sleep and after a night of suppressed SWS. Objective sleep parameters were determined by polysomnography. SWS was suppressed by delivering acoustic tones of varying frequency, to replace SWS with shallow sleep without awakening the patients. The following morning, glucose metabolism was studied by hyperinsulinemic euglycemic clamp studies with infusion of (6.6-2H2) glucose.
Results
The amount of SWS was suppressed by 75% ($P<0.001$) without a reduction in total sleep duration (471 vs 480 min, $P=0.63$). SWS suppression did not affect endogenous glucose production in the basal state nor during clamp conditions compared to normal sleep. During clamp conditions, SWS suppression did not result in differences in glucose infusion rates ($22.6\pm3.1$vs $22.3\pm3.2$ μmol/kg LBM-1 per min, $P=0.95$) or glucose disposal rate ($31.6\pm2.9$ vs $30.0\pm2.7$ μmol/kg LBM-1 per min, $P=0.65$). SWS suppression did not affect plasma free fatty acid levels.
Conclusions
Selective suppression of SWS sleep during a single night does not influence insulin sensitivity in patients with type 1 diabetes. Therefore, the reduction in insulin sensitivity by partial sleep deprivation can not be explained by a reduced amount of SWS.

**Evidence that abscissic acid participates in the response to hyperglycemia in humans**

P. Ameri[1], S. Bruzzone[1], L. Briatore[1], E. Mannino[2], G. Basile[1], M. Ponta[1], A. Grozio[1], M. Magnone[1], L. Guida[1], S. Scarfì[1], A. Salis[1], G. Damonte[1], L. Sturla[1], A. Nencioni[1], D. Fenoglio[1], F. Fiory[2], C. Miele[2], F. Beguinot[2], D. Maggi[1], R. Cordera[1], G. Murialdo[1], A. De Flora[1] & E. Zocchi[1]
[1]University of Genova, Genova, Italy; [2]University of Napoli Federico II, Napoli, Italy.

Abscissic acid (ABA) is a hormone best known for its role in plants. We previously showed that it is released by pancreatic beta-cells upon glucose stimulation, and autocrinally enhances insulin secretion.
Here we additionally report that ABA promotes glucose uptake by rat L6 myoblasts and murine 3T3-L1 cells differentiated to adipocytes, at least partly by inducing GLUT-4 translocation to the plasma membrane.
To determine whether ABA is involved in the response to hyperglycemia *in vivo*, we assessed its plasma concentrations (ABAp) in eight healthy volunteers and eight type 2 diabetes mellitus (T2DM) patients during an oral glucose tolerance test (OGTT). In healthy subjects, ABAp increased two to ninefold over basal values, starting 15–60 min after glucose administration. There was a significant positive correlation between ABA and glucose areas under the curve (AUC) ($r$ 0.905, $P<0.01$). In contrast, ABAp did not increase during OGTT in T2DM patients. An intravenous GTT (IVGTT) was also performed in six of the eight volunteers. Only two showed an increase in ABAp similar to that observed during

OGTT. Overall, median and range ABAp AUC were lower during IVGTT than OGTT.
In rat insulinoma cells INS-1 and human pancreatic islets, GLP-1 potentiated ABA secretion by ~10 and 2 times in low- and high-glucose respectively ($P<0.01$), an effect abrogated by silencing of the GLP-1 receptor.
Beta-cells are likely the major source of circulating ABA, since fasting ABAp was significantly lower in seven type 1 DM patients ($0.17\pm0.10$ nM) than in 25 healthy subjects ($1.51\pm1.29$ nM, $P<0.01$) and in 21 T2DM patients ($1.45\pm1.30$ nM, $P<0.01$). However, human adipose tissue also released ABA when incubated with glucose.
In conclusion, our results suggest that ABA is a new hormone involved in glucose metabolism and particularly in the incretin response to oral glucose in humans.

**Mitochondrial biogenesis is not significantly impaired in non obese asian indians with type 2 diabetes**

M. Chattopadhyay, I. Roy, D. Baitalik, S. Mukhopadhyay & S. Chakrabarti
Institute of Post Graduate Medical Education and Research, Kolkata, India.

Introduction
Deranged mitochondrial biogenesis has been linked to obesity with or without type 2 diabetes but this association has not been reported in non obese type 2 diabetes subjects. This study attempts to identify the various alterations of mitochondrial biogenesis in adipose tissue in obese and non obese type 2 diabetes subjects.
Methods & Design
Since type 2 diabetes is associated with elevated serum leptin and depressed serum adiponectin levels, these parameters were measured in four different groups of subjects- non obese non diabetic (C), non diabetic obese (OB), non obese type 2 diabetes (NOT2D) and obese type 2 diabetes (T2D+OB). Mitochondrial biogenesis was assessed in subcutaneous adipose tissue by estimating the content of several mitochondrial proteins e.g. cytochrome c, ND4L (subunit of complex I), COX 2 (subunit of complex IV etc.) and transcription factors in whole adipose tissue lysate and isolated mitochondria. A cell based model has been designed to examine the role of mitochondria in adipokine secretion and synthesis.
Results
There was a linear increase in serum leptin levels and decrease in serum adiponectin levels from OB to T2D+OB but remained unchanged in NOT2D compared to C. Mitochondrial biogenesis was significantly impaired in adipose tissue of OB and more remarkably in T2D+OB but remains unaffected in NOT2D. This aspect is being investigated in our cell based model.
Conclusion
High serum leptin levels and hypoadiponectinemia were not observed in NOT2D patients. This may account for the relative ineffectiveness of insulin sensitizers in NOT2D subjects as reported previously. Similarly, the absence of impaired mitochondrial biogenesis in NOT2D is an important finding which indicates the critical importance of obesity in mitochondrial pathology of type 2 diabetes. Other pathogenic aspects need to be explored in NOT2D subjects.

**Iron overload induces visceral adipose tissue insulin resistance**

P. Dongiovanni, M. Ruscica, S. La Spina, L. Steffani, V. Borroni, R. Rametta, S. Recalcati, G. Cairo, S. Gatti, P. Magni, S. Fargion & L. Valenti
Università degli Studi di Milano, Milan, Italy.

Excess body iron is associated with the metabolic syndrome, but whether it has a causal role in the pathophysiology of insulin resistance (IR) is not well understood. Aim of this study was to assess (a) the effect of dietary modulation of iron status on IR in Wild-type or ob/ob C57Bl/6 male mice fed a standard iron concentration (8 mg/kg) or an iron enriched diet (30 g/kg; IED), as well as in high-fructose diet (HFD) mice and (b) to investigate the mechanisms whereby. IED determined a progressive increase in glucose levels due to IR, as confirmed by the insulin tolerance test, associated with a reduction in visceral adipose tissue (VAT) mass (perigonadal fat pad: −60%, $P=0.02$), whereas in ob/ob mice IED led to overt diabetes. Moreover, in HFD fed mice increased IR by about 100%, was associated with decreased VAT despite no changes in total body mass, thus suggesting VAT-IR. IED induced iron accumulation in VAT, which was associated with IR, as shown by decreased phospho-AKT/AKT ratio (−80%, $P=0.03$). Gene expression analysis of VAT showed that IED upregulated iron-responsive genes (ferritin and hepcidin) and adipokines associated with IR (resistin and visfatin, both $P=0.005$), whereas downregulated inflammation. This resulted in hyper-resistinemia ($P=0.01$) and in increased levels of SOCS3 ($p<0.05$), a target of resistin and hepcidin implicated in adipose tissue IR. Furthermore, iron treatment induced hepcidin and inhibited the differentiation of human mesenchymal stem cells towards adipocytes. In conclusion, iron overload may induce IR and hyperglycemia by affecting VAT iron metabolism, endocrine function, and differentiation.

**Comprehensive evaluation of type 2 diabetes susceptibility loci in the Japanese population by using 1000 Genomes Project data**

K. Hara[1], H. Fujita[1], M. Horikoshi[1], T. Yamauchi[1], S. Maeda[2] & T. Kadowaki[1]
RIKEN, Yokohama, Japan.

Although over 50 type 2 diabetes (T2D) loci have been identified through genome-wide association studies (GWAS), the vast majority of the genetic predisposition to T2D still remains to be clarified. One explanation is that despite the use of high-throughput genotyping arrays, only a small proportion of genetic variants in the human genome are actually surveyed, especially in non-European populations. We explored the comprehensive catalog of genomic variations provided by the 1000 Genomes Project to identify variations conferring susceptibility to T2D in the Japanese population that were not detected in previous scans. We imputed 10,524,368 variants derived from 194 East Asian subjects (June 2011 release) into 5,976 cases and 20,829 controls genotyped by 610K single-nucleotide polymorphism (SNP) array. Overall concordance was good, although imputed SNPs with minor allele frequency (MAF) below 1% apparently contained poorly imputed SNPs. We then tested associations for T2D before and after adjusting for age, sex, and body mass index. We found that in addition to variants of the previously reported loci there were 16 loci harboring multiple variants with a p value lower than 10–5 at 1q32, 5p13, 6p12, 7p12, 7q32, 8p11, 9q31, 9q34, 10p13, 10q23, 11q13, 11q24, 12p11, 15q26, and 17p13. The MAF range was 0.01 to 0.45, and the odds ratios were between 1.10 and 1.48. We are conducting a replication study to confirm the association in another 7,000 cases and 3,500 controls. We also sought to define the most relevant SNPs for susceptibility to T2D in the previously identified genes. We did not find any stronger association with T2D than the originally reported SNPs in our population. However, there is a tendency that lower frequency variants were enriched in those with large effect size. Our study highlights the benefit of using

data derived from next-generation sequencing of the human genome such as the 1000 Genomes Project to explore T2D loci more comprehensively.

**Glycoalbumin is the best indicator for glycemic variability assessed by continuous glucose monitoring**

S. Suh, J. Joung, S. Park, Y. Cho, S. Jin, S. Kim, H. Kim, J. Bae, S. Kim, J. Chung, Y. Min, M. Lee, M. Lee, K. Kim & J. Kim
Samsung Medical Center, Seoul, Republic of Korea.

Aims
We investigated the interrelationship between HbA1c, fructosamine, glycoalbumin (GA), 1,5-anhydroglucitol (1,5-AG) with glycemic variability data from continuous glucose monitoring system (CGMS).
Methods
Seventy diabetic patients (mean age of 54 years including seven type 1 diabetes mellitus subjects) were enrolled, and all wore a CGMS for 72 hours. For the parameters of glucose excursion, mean glucose, standard deviation (SD) of glucose, the area under the curve for glucose levels >180 mg/dl (AUC-180), and continuous overlapping net glycemic action calculated (CONGA), mean of the daily differences (MODD) and mean post meal maximum glucose (MPMG) were calculated from the CGMS data.
Results
Spearman's correlation coefficients were significant between all glycemic markers and various parameters of glucose excursion. Among them, GA displayed highest correlation ($r$ between 0.581–0.684) with all the parameters (i.e. AUC-180, SD, MAGE, MODD, CONGA-1, CONGA-24, MPMG) except for mean glucose. Mean glucose was best correlated with fructosamine ($r=0.676$, $P< 0.01$). In patients with HbA1c $< 7.5\%$ ($n=36$), 1,5-AG and GA showed better correlation with glycemic parameters for variability than HbA1c and fructosamine. In patients with HbA1c $\geqq 7.5\%$ ($n=34$), GA showed a statistically significant correlation with just AUC-180 and MODD among glycemic variability parameters. Furthermore, GA was significantly correlated to only SD among 3 independent parameters (mean glucose, SD, AUC-180) in multiple regression analysis but the other glycemic markers were significantly correlated with mean glucose.
Conclusion
Our results suggest that GA was the most representative maker for glycemic variability. 1–5 AG was also able to reflect glucose excursions only in well-controlled patients.
Spearman's correlation coefficient between glycemic markers and CGMS data
Table 1

**Table 1** Spearman's correlation coefficient between glycemic markers and CGMS data

| N=70 | HbAlc | Fructosamine | Glycoalbumin | 1,5-AG |

**Nonalcoholic fatty liver disease is associated with atherosclerosis in middle-aged and elderly chinese**

Y. Huang, Y. Bi, M. Xu, X. Li & G. Ning
Shanghai Jiaotong University, Shanghai, China.

Objective: To evaluate the associations between nonalcoholic fatty liver disease (NAFLD) and atherosclerosis.
Methods and Results: A total of 8971 participants aged 40 years and older from Baoshan district, Shanghai were included in the present study. The presence of NAFLD was evaluated by ultrasonography. Carotid intima-media thickness (CIMT) and brachial-ankle pulse wave velocity (ba-PWV) were measured in each participant. The prevalence of NAFLD was 30.0% in the total population, with that of 30.3% in men and 29.8% in women, respectively. Subjects with NAFLD had remarkably higher CIMT and ba-PWV as compared with those without NAFLD ($0.594\pm0.105$ mm vs. $0.578\pm0.109$ mm, $P<0.0001$; $1665\pm425$ cm/sec vs. $1558\pm430$, $P<0.0001$). Subjects with both NAFLD and metabolic syndrome had significantly higher CIMT and ba-PWV as compared with those with neither of or either of these two diseases after adjustment for age and sex ($P$ all $<0.05$). Logistic regressions also revealed that NAFLD conferred 29% and 20% increased odds ratios of elevated CIMT and ba-PWV independent of conventional risk factors and the presence of metabolic syndrome.
Conclusions: NAFLD was associated with elevated CIMT and ba-PWV independent of conventional CVD risk factors and metabolic syndrome. The effects of NAFLD and metabolic syndrome on atherosclerosis might not fully overlap.

## P506

**Altered Mitochondrial Bioenergetics Does Not Explain Increased Ros Production In Non-Obese Asian Indians With Type 2 Diabetes (T2D)**

M. Chattopadhyay, I. Roy, D. Baitalik, S. Mukhopadhyay & S. Chakrabarti
Institute of Post Graduate Medical Education and Research, Kolkata, India.

Introduction
Deranged Mitochondrial bioenergetics is a key feature of type 2 diabetes and obesity but its status in non-obese type 2 diabetes patients is not known. The aim of the present study was to assess the status of mitochondrial oxidative phosphorylation and ROS metabolism in subcutaneous adipose tissue isolated from 4 groups of subjects: non-obese subjects with type 2 diabetes (NOT2D), non-obese non diabetic (C), obese non-diabetic (OB) and obese type 2 diabetes subjects (OB + T2D).
Methods & Design
Mitochondria were isolated from subcutaneous white adipose tissue of four groups of subjects under study: C, NOT2D, OB, and OB + T2D. The activities of respiratory complexes, the trans-membrane potential and the phosphate utilization capacity of adipose tissue mitochondria from these groups were measured. The rate of ROS (reactive oxygen species) formation, the levels of protein and lipid oxidation markers and the activities of SOD and catalase were also measured.
Results
There was a progressive decrease in mitochondrial transmembrane potential, phosphorylation capacity and the activities of respiratory chain complexes from OB to OB + T2D, whereas such parameters remained unaffected in NOT2D, compared to C. However, markers of oxidative stress and damage increased in adipose tissue mitochondria in a progressive manner from NOT2D to OB + T2D.
Conclusion
Mitochondrial bioenergetics was unaffected in NOT2D subjects, whereas a linear increase in ROS production and metabolism were observed from NOT2D to OB + T2D. Therefore, alteration in mitochondrial bioenergetics cannot fully explain the ROS production in all three groups. This raises the possibility of existence of some extra-mitochondrial pathway accounting for increased ROS production in the affected subjects. Our results may also possibly be explained by altered anti-oxidant enzyme status in the patient population under study.
Declaration of interest

### QRFP43 and its fragment 26RFa both promote β-cell survival but differently regulate insulin secretion and glucose uptake in pancreatic β-cells and human pancreatic islets

L. Trovato[1], F. Settanni[1], D. Gallo[1], E. Gargantini[1], L. Bergandi[1], H. Ong[2], E. Ghigo[1] & R. Granata[1]
[1]University of Turin, Turin, Italy; [2]University of Montreal, Montreal, QC, Canada.

RFamides are a family of peptides containing arginine-phenylalanine-amide at their C terminus. A novel 43-amino acid RFamide, named QRFP43, and a shorter endogenous peptide 26RFa, were discovered and identified as ligands of the G protein-coupled receptor GPR103. Different studies have shown that RFamides, such as neuropeptide FF and QRFP43 and 26RFa, play a role in food intake, thermogenesis and energy homeostasis. Here, we investigated the effects of QRFP peptides on survival, proliferation, apoptosis, insulin secretion and glucose uptake of INS-1E pancreatic β-cells and human pancreatic islets. The signaling pathways involved in these actions were also determined. GPR103 expression was evaluated by immunofluorescence and RT-PCR; cell survival by MTT and proliferation by BrdU incorporation; apoptosis was assessed by Hoechst 33258 nuclear staining and caspase-3 activity; insulin secretion by RIA; activation of signaling pathways by Western blot analysis; intracellular cAMP production by ELISA; glucose uptake by [3H]2-deoxyglucose incorporation. The results showed that both INS-1E β-cells and human pancreatic islets express GPR103. Moreover, either QRFP43 or 26RFa promoted survival and proliferation and reduced apoptosis, in both serum-free conditions and under treatment with the cytokines TNF-α, IFN-γ and IL-1β. QRFP43 also stimulated both basal and glucose-induced insulin secretion in β-cells and human islets, enhanced glucose uptake, increased intracellular cAMP levels and ERK1/2 and PI3K/Akt phosphorylation. Conversely, 26RFa reduced insulin secretion and cAMP levels, not exhibited effects on glucose uptake and only increased ERK1/2 phosphorylation. The opposite metabolic effects of QRFP43 and 26RFa involved activation of the G proteins Gαs and Gαi respectively, as demonstrated by the use of specific inhibitors. In all, these findings indicate that both QRFP43 and 26RFa promote β-cell survival; however, they display opposite effects on β-cell function, suggesting a novel and differential role in glucose metabolism.

### Influences of the 2011 Tohoku Earthquake on glycemic control in patients with diabetes mellitus in Tokyo

N. Kumagai, Y. Muroya, M. Shimodaira, K. Tsuzawa & K. Honda
Tokyo Metropolitan Hiroo Hospital, Sibuya, Japan.

Objectives
Huge 9.0 magnitude quake and tsunami attacked eastern areas of Japan, on March 11th 2011. They claimed more than 20,000 lives and destroyed the nuclear power plants. Although the property damage was very little in Tokyo, about 250 miles apart from the epicenter, the people in capital faced a lot of hard situations. For example, unusual food supply, the lack of the daily necessities, the limitation of the electricity supply, and a fear of hundreds of aftershocks and radioactive contamination. Therefore, we evaluated the influence of this disaster on the patients with diabetes in Tokyo.
Methods
We evaluated the changes of glycemic control of 99 diabetic out-patients in our hospital from the results of blood examination before and after the earthquake (PreE / PostE). Furthermore, self-administered questionnaires were applied to assess their changes of the life style, especially about the medical nutrition therapy, the physical activities, and the mental state.
Results
The mean HbA1c levels at one month PostE in 99 patients were significantly higher than those of PreE. However, HbA1c levels at 4 months PostE decreased into the PreE levels. There was further significant decrease at 6 months PostE. Next we divided these 99 patients into two groups. In one group of patients whose HbA1c apparently increased one month PostE, the increase of the food intakes and the decrease of the physical activities were significant. In this group, a fear of the aftershocks and the radioactive contamination must be the main reason for the decrease of the physical activities.
Conclusion
These results show us that the self-management of diabetic patients can be highly disturbed in case of such serious disasters even if they lives apart from disaster areas.

### The impact of pioglitazone administration on circulating endothelial progenitor cells, inflammation and endothelial function of diabetic patients with and without coronary artery disease

A. Kampoli[1], D. Tousoulis[1], Z. Pallantza[2], G. Paterakis[3], N. Papageorgiou[1], A. Miliou[1] & C. Stefanadis[1]
[1]Medical School of Athens, Athens, Greece; [2]Hippokration Hospital, Athens, Greece; [3]General Hospital of Athens "G. Gennimatas", Athens, Greece.

Introduction
Glitazones' admisitration has been proved to affect EPCs in peripheral circulation in endothelial function and inflammatory process. The purpose of this study was to further investigate if the administration of pioglitazone in diabetics can modify the number of EPCs in the peripheral blood and alter the inflammatory state and endothelial function of these patients.
Methods
Twenty five diabetic patients were recruited and pioglitazone was administered to all patients for a one-month period. In parallel 10 non-diabetic control subjects were treated with placebo. Blood samples were drawn on admission and after one month of drug's administration in order to count EPCs and inflammation markers such as CRP, vascular endothelial growth factor (VEGF) and asymmetric dimethylarginine (ADMA) were also measured. Circulating EPCs were defined by the surface markers CD34+ (CD34 expressing cells) and analyzed by flow-cytometry. Moreover the endothelial function was evaluated using the technique of flow mediated dilation (FMD).
Results
In the group of diabetic patients, no significant difference was observed in the number of endothelial progenitor cells before and after the administration of pioglitazone ($3.22 \pm 1.96$ vs $3.55 \pm 1.88$, $P$=NS), either in plasma concentrations of CRP ($2.998 \pm 3.35$ vs $1.962 \pm 1.57$, $P$=NS), ADMA ($0.78 \pm 0.51$ vs $0.67 \pm 0.51$, $P$=NS) or in endothelial function ($0.362 \pm 0.075$ vs $0.38 \pm 0.074$, $P$=NS). The plasma concentrations of VEGF in the group of diabetics showed a significant increase after the administration of pioglitazone ($128.14 \pm 144.85$ vs $177.91 \pm 126.26$, $P<0.05$). The number of circulating EPCs was compared between the groups of diabetic patients and control patients there was a significant difference ($P<0.01$).
Conclusions
Based on the existing data, there is no significant difference in the number of circulating EPCs, CRP and ADMA plasma concentrations and endothelial function before and after the administration of pioglitazone. Nevertheless, the administration of pioglitazone seems to increase plasma levels of VEGF playing a possible role in the stimulation of angiogenesis in diabetes.

### The redution hypothalamic PP2A expression improve peripheral insulin sensitivity

P. Picardi[1], E. Caldeira[1], A. Caricilli[2] & M. Saad[2]
[1]Faculty Medicine of Jundiaí, Jundiaí, Brazil; [2]Unicamp, Campinas, Brazil.

Protein phosphatase 2A (PP2A) is a multimeric serine/threonine phosphatase which has multiple functions. However, the potential involvement of PP2A in insulin's metabolic signaling pathway is presently unknown. Brain insulin resistant state is characterized by disturbances in transducing the signal from IR/IRS/AKT, changing feeding behaviour and body weight. We showed that diet induced obese rats (DIO) have a marked increase in PP2A protein expression in the hypothalamus. Thus, we generated a selective, transient reduction in PP2A by infusion of an antisense oligonucleotide designed to blunt the expression of PP2A

in rat hypothalamic areas surrounding the third ventricle in control and obese rats. The selective decrease in hypothalamic PP2A resulted in decreased food intake, reduced body weight, reduced adiposity after high-fat feeding, improved insulin action and signaling in hypothalamus. Central insulin signaling was increased by phosphorylation of AKT in PP2A ASO treated rats. To assess the impact of hypothalamic PP2A down-regulation on the peripheral action of insulin, we performed hyperinsulinemic-euglycemic clamp studies. The insulin action on peripheral glucose uptake was increased. In conclusion, we have demonstrated an important role of hypothalamic PP2A in the modulation of energy balance, insulin action, and glucose metabolism. Thus, the reduction in hypothalamic PP2A should be sufficient to promote an appreciable weight reduction and access to the brain may also be necessary to optimally improve insulin sensitivity and glucose homeostasis.

### The new combination of risk factors determining a high risk of gestational diabetes mellitus

P. Popova[1,2], E. Kravchuk[1], A. Gerasimov[1], E. Shelepova[1], U. Tsoi[1] & E. Grineva[1,2]

[1]Almazov Federal Heart, Blood and Endocrinology Centre, Saint-Petersburg, Russian Federation; [2]Saint Petersburg Pavlov State Medical University, Saint-Petersburg, Russian Federation.

Introduction

Gestational diabetes mellitus (GDM) is a common complication of pregnancy. Identification of early determinants of GDM is necesary to designate possible preventive strategies. The aim of this study was to reveal the most significant risk factors for GDM.

Design

A total of 209 women with singleton pregnancies were included in the study. Maternal fasting glucose, anthropometric parameters and blood pressure were measured in the first trimester of pregnancy. Pregnant women were screened for GDM between weeks 24 and 28 of gestation, as defined by WHO criteria. Classification Tree Method was used to identify combination of early pregnancy risk factors that predict the highest risk of the development of GDM in later pregnancy.

Results

An age ≧ 35 years in combination with a fasting glucose level ≧ 4.8 mmol/L and a body mass index (BMI) ≧ 28.5 kg/m$^2$ in the first trimester was associated with 89% risk of two-hour glucose ≧7.8 mmol/L following the 75-g oral glucose tolerance test (odds ratio [OR] 15.7, 95% CI 1.8 - 130.6, $P=0.002$). In women aged less that 35 with the combination of a first trimester BMI 28.5 kg/m$^2$ with a level of fasting glycemia 4.8 mmol/L and hypertension (blood pressure ≧140 and/or ≧90 mmHg or use of antihypertensive medications) the absolute risk of the development of GDM was 75% and OR was 6.3, 95% CI 1.9- 20.6, $P=0.001$.

Conclusions

Advanced maternal age, higher BMI, higher fasting glycemia and hypertension in the first trimester predict increased GDM risk. Taking these combinations into consideration may facilitate the identification of women at particular risk for GDM and suggest potential strategies for reducing this risk.

### Glycemic control influences CA19-9, CEA and ferritin levels in type 2 diabetes.

O. Ure[1], N. Ata[1], M. Kucukazman[1], E. Tutal[1], F. Caglar[1], M. Hokkaomeroglu[1], K. Akin[1], K. Dal[1], H. Yilmaz[2], G. Kizilca[1], E. Beyan[1] & D. Ertugrul[1]

[1]Kecioren Research and Training Hospital, Ankara, Turkey; [2]Aydin State Hospital, Aydin, Turkey.

Objective

Diabetes mellitus is associated with various types of cancer. Exocrine pancreas function is also influenced by diabetes.

Materials/Subjects and Methods

In this study we aimed to investigate the effect of glycemic control on tumor and inflammatory markers. Sixty eight type 2 diabetic patients, and 70 healthy controls comprised the study population. We measured fasting blood glucose (FBG), postprandial blood glucose (PPBG), serum total cholesterol (TC), triglyceride (TG), LDL-cholesterol (LDL-C), HDL-cholesterol (HDL-C), γ-glutamyltransferase (GGT), alanine aminotransferase (ALT), aspartate amino-transferase (AST), creatinine, akaline phosphatase (ALP), amylase, lipase, high sensitive C-reactive protein (hsCRP), ferritin, carcinoembryonic antigen (CEA), CA19-9, HbA1c concentrations with an automatic analyzer in diabetic and control subjects.

Results

Diabetic group had significantly higher body mass index (BMI), FBG, PPBG, HbA1c, VLDL, TG, ALT, GGT, ALP, CA19-9, CEA, ferritin, hsCRP and erythrocyte sedimentation rate (ESR) values. AST, HDL-C, LDL-C, amylase and lipase levels were significantly lower in the diabetic group. HbA1c showed significant correlation with ferritin (r: .335, $P$: < .0001), CA19-9 (r: .415, $P$: < .0001), CEA (r: .485, $P$: < .0001), ESR (r: .252, $P$: .003), LDH (r: .369, $P$: < .0001) and amylase (r: -.309, $P$: < .0001) levels. FBG was correlated with both CA19-9 (r: .386, $P$: < .0001) and CEA (r: .465, $P$: < .0001). PPBG was also correlated with both CA19-9 (r: .394, $P$: < .0001) and CEA (r: .560, $P$: < .0001).

Conclusions

We propose to consider the effect of hyperglycemia on CA19-9, CEA, amylase, lipase, ESR and ferritin measurements.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### Effects of perindopril on circulating endothelial progenitor cells, inflammation and endothelial function of diabetic patients with and without coronary artery disease

A. Kampoli[1], D. Tousoulis[1], G. Paterakis[3], Z. Pallantza[2], N. Papageorgiou[1], A. Miliou[1] & C. Stefanadis[1]

[1]Medical School of Athens, Athens, Greece; [2]Hippokration Hospital, Athens, Greece; [3]General Hospital of Athens "G. Gennimatas", Athens, Greece.

Introduction

Endothelial progenitor cells (EPCs) seems to be reduced in patients with diabetes mellitus, however it is unknown whether treatment with ACE-I may modify the number of EPCs. Therefore, the purpose of this study was to investigate if the administration of perindopril in diabetic patients with and without coronary artery disease can modify the number of circulating EPCs and alter their inflammatory state and endothelial function.

Methods

Twenty five diabetic patients were recruited and perindopril was administered to all patients for a one-month period. In parallel, ten non-diabetic control subjects

were treated with placebo. In both groups blood sample were drawn on admission (baseline) and after one month of drug's administration. CRP, vascular endothelial growth factor (VEGF) and asymmetric dimethylarginine (ADMA) were measured by standard techniques. Circulating EPCs were defined by the surface markers CD34+ (CD34 expressing cells) and analyzed by flow-cytometry. Moreover the endothelial function was evaluated both on admission and after treatment using the technique of flow mediated dilation (FMD).
Results
The number of circulating EPCs was compared between the groups of diabetic patients and control patients there was no significant difference in their variation ($P>0.05$). In the group of diabetic patients, no significant difference was observed in the number of endothelial progenitor cells before and after the administration of perindopril ($3.72\pm1.98$ vs $4.02\pm2.03$, $P=$NS), either in plasma concentrations of CRP ($2.472\pm2.74$ vs $1.782\pm1.99$, $P=$NS), VEGF ($126.36\pm99.79$ vs $163.19\pm121.52$, $P=$NS) or in endothelial function ($0.368\pm0.073$ vs $0.388\pm0.073$, $P=$NS). Nevertheless, the plasma concentration of ADMA in the group of diabetics showed a significant increase after the administration of perindopril ($1.473\pm0.899$ vs $0.939\pm0.883$, $P<0.05$).
Conclusions
Administration of perindopril seems to increase plasma levels of ADMA. However, no significant difference in the number of circulating endothelial cells, CRP and VEGF plasma concentrations and endothelial function before and after the administration of perindopril was observed.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Glycemic control in type 1 diabetic patients experience of a university hospital in tunis**

M. Yazidi, M. Chihaoui, F. Lamine, B. Ftouhi, F. Kanoun & H. Slimane
La Rabta Hospital, Tunis, Tunisia.

Recent years have been marked by numerous advances in the quality of type 1 diabetes care. However, glycemic control remains suboptimal for many patients even in developed countries.
The aim of this study was to assess glycemic control in a cohort of Tunisian type 1 diabetic patients and to identify factors associated with poor glycemic control.
Methods
One hundred and eighty-eight type 1 diabetic patients admitted to the Endocrinology - Diabetology department of the university hospital "La Rabta" then followed up in the consultation for at least one year, were studied in a retrospective manner during five years.
Results
Mean age of patients was $28\pm12.3$ years (102 males and 86 females). One hundred and thirty two patients (70.2%) had newly diagnosed diabetes and 56 (29.8%) had previously diagnosed diabetes with a mean duration of $7\pm6.3$ years. Mean HbA1c during the follow-up period was $9.7\pm3\%$. It was less than 7% in 16.8% of cases. There was a reverse correlation between age at diabetes onset and HbA1c value ($P=0.02$). Adolescents had higher HbA1c value than adults ($10.8\pm2.9\%$ vs $9.2\pm2.8\%$, $P=0.02$). No relationship was found between number of daily insulin injections and mean HbA1c value. Mean HbA1c was higher in patients who did not adhere to their insulin treatment ($11.1\pm3.3\%$ vs $8.9\pm2.4\%$, $P<0.0001$), in those with less than 3 clinic visits per year ($10.7\pm3.5\%$ vs $9.0\pm2.2\%$, $P=0.001$), in patients with lipohypertrophy ($10.9\pm2.5\%$ vs $9.2\pm3.4\%$, $P=0.008$) and those with known celiac disease ($14.5\pm5.2\%$ vs $9.6\pm2.9\%$, $P=0.005$).
Conclusion
The overall glycemic control of our type 1 diabetic patients is poor. Several factors are associated with this. We have to target these factors, in particular by intensifying education strategies, to improve the prognosis of these patients.

**Progression to impaired fasting glucose, impaired glucose tolerance and diabetes in urban population during 8 years follow up**

N. Piorowska, B. Piwonska-solska, A. Gilis-Januszewska, A. Hubalewska-Dydejczyk & D. Pach
Jagiellonian University, Krakow, Poland.

Objective
To determine the progression rate to impaired fasting glucose (IFG), impaired glucose tolerance (IGT), and diabetes (DM2) in normal glucose tolerant (NGT) people during 8 years follow up using WHO 1999 criteria and new criteria (IFG-fasting glucose 5.6–6.9 mmol/l).
Research design and methods
This is an eight year prospective study in a randomly selected urban population aged $>=40$ years living in Krakow, Poland. 1752 persons had NGT.based on WHO 1999 criteria, 564 of them (32.2% of invited, (209 men and 355 women, aged 60.7, S.D. $=9.2$) attended the follow-up assessment. Subjects underwent a physical examination including weight/height, waist circumference, biochemical examination including glucose, insulin in 0', 120' OGTT and questionnaire examination concerning CVD health history and family history of type 2 diabetes.
Results
The prevalence of DM2, IFG and IGT according to WHO 1999 criteria in examined population with baseline NGT was 4.43%, 3.37% and 9.93% respectively. The prevalence of IFG using new criteria, was 13.48%. Lowering cutoff point for IFG caused 10.11% increase in the prevalence of IFG.
Among people with diagnosed diabetes, 56% had newly diagnosed diabetes during the control study, in 44% participants diabetes was diagnosed in the period between the baseline and control study.
The prevalence of DM2 and IGT/IFG was increasing with increasing age and BMI categories ($P<0.05$). The lowest obesity prevalence both baseline and after follow up was found in those who remained NGT.
Conclusion
In the studied baseline NGT population after 8 years of follow up high progression rate to impaired glucose metabolism was found. The implementation of new IFG diagnostic criteria increased the prevalence of IFG by 10.1%. The prevalence of impaired glucose metabolism was increasing with age and BMI categories. The lowest obesity prevalence both baseline and after follow up is found in those who remains NGT. Therefore prevention of diabetes initiatives should focus on normal body weight preservation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P516

**The role of sex hormone-binding globulin in the risk of incident metabolic syndrome: further evidence from a longitudinal population-based sample of adult men.**

R. Haring, H. Völzke, C. Spielhagen, M. Nauck & H. Wallaschofski
University of Greifswald, Greifswald, Germany.

Background
In the classic paradigm, the primary function of sex hormone-binding globulin (SHBG) was thought to passively bind and transport steroids and estrogens in the blood to access target tissues and to determine their bioavailable fraction. Now there is increasing evidence that SHBG plays an active role in steroid actions and is an actively contributes to many age-associated comorbidities including type 2 diabetes, obesity, and metabolic syndrome (MetS).
Objective
To further evaluate the suggested independent association of SHBG with incident MetS in men.
Research Design and Methods
We used data from 956 men aged 20–79 years from the population-based Study of Health in Pomerania (SHIP). Cross-sectional and longitudinal logistic regression models with sequential adjustment for 1) age and smoking, 2) SHBG or total testosterone (TT), respectively, 3) body mass index, and 4) glycated hemoglobin were performed.
Results
In model 1) we found lower TT (odds ratio [OR] per SD decrement: 1.48 (95% CI: 1.27–1.73) p-value, $<0.001$) and SHBG (OR: 1.65 (1.36–2.00) p-value, $<0.001$) associated with incident MetS. After additional adjustment for the respective sex hormone, this association was abolished for TT (OR: 1.20 (0.99–1.46) p-value, 0.057), but not for SHBG (OR: 1.47 (1.17–1.86) p-value, 0.001).

Furthermore, p for trend analyses in fully-adjusted models showed a progressive inverse dose-response relationship for quartiles of SHBG ($<0.001$) and risk of incident MetS, but not across TT (0.468) or free T quartiles (0.438).
Conclusions
SHBG is a predictor of incident MetS independent of testosterone in men, but not vice versa.
Multiple logistic regression models for the risk of incident metabolic syndrome.

### Fracture predictors in diabetic postmenopausal women without hyperparathyroidism

A. Gusova[1,2], M. Pavlova[2], G. Melnichenko[2] & G. Kavalersky[2]
[1]Research Institute of Neurosurgery named after N.N. Burdenko, Moscow, Russian Federation; [2]Moscow State Medical University named after I.M. Sechenov, Moscow, Russian Federation.

Introduction
The diabetes mellitus (DM) is the known risk factor of fractures. The aim was to determine predictors of fractures in type 2 diabetic postmenopausal women without hyperparathyroidism.
Design
We analyzed local trauma clinic data for 3 sequential years from 2 662 diabetic persons who were entered The National Register of diabetes mellitus patients (133 subjects with type 1 diabetes mellitus and 1995 ones with type 2 DM). Afterward we examined 62 postmenopausal women with type 2 DM, 32 of them had bone fracture within last month. The control group included 54 non-diabetic women, 25 within a group were recently fractured. Groups were comparable in body mass index, age, duration of menopause and calcium intake. Diabetic subgroups were comparable in glycosylated hemoglobin level. None of them had hyperparathyroidism. Tests involved blood and urine calcium and phosphorus, serum parathyroid hormone (PTH), insulin-like growth factor-1 (IGF-1), 25-hydroxyvitamin D, C-terminal telopeptide of type I collagen (sCTX), osteocalcin levels and data of dual-energy X-ray absorptiometry of lumbar spine and proximal femur. For determining predictors ($P<0.05$) we conducted unidimensional ANOVA.
Results
In epidemiological study main risk factor of fractures was vascular complication of diabetes. Independent risk factors in cohort study were relatively low level of ionized calcium, alkaline phosphatase, phosphorus excretion, vitamin D and osteocalcin, as well as decrease of lumbar spine (L1-4) and femur (trochanter and total hip) bone mineral density.
Conclusion
Fracture risk is elevated in postmenopausal women with type 2 DM but without hyperparathyroidism in whom diabetic influence on bone turnover primary involves bone formation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Characteristics and prevalence of latent autoimmune diabetes in adults (LADA) in a diabetic population

B. Saboo[1], H. Chandarana[1], S. Joshi[2] & S. Shah[1]
[1]Dia Care - A Complete Diabetes Care Center, Ahmedabad, India; [2]Joshi Clinic, Mumbai, India.

Diabetes, one of the most commonly seen metabolic disorders, is affecting a major area of population in many developing as well as most of the developed countries and is becoming an alarming concern for the rising cost of the healthcare system. Latent Autoimmune Diabetes in Adults (LADA) is a form of diabetes which is less recognized and under diagnosed type of diabetes which appears to have characteristics of both type 1 (autoimmune in nature) and type 2 diabetes (adult age at onset and initial response to oral hypoglycemic agents). An epidemiological study was carried out on 500 patients in the western region of India. Various parameters such as age at onset, duration of diabetes, gender, basal metabolic index (BMI), type of diabetes, family history, HbA1c levels, cholesterol levels and current treatment regimen were evaluated and correlated with Type 1 and Type 2 Diabetes. Moreover, diagnostic markers for LADA, viz. GAD auto antibodies and C-peptide levels were determined for 80 patients selected from the epidemiological study. Some of the results obtained were found to be consistent with the literature whereas some results were found to be contradictory to the existing data.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P519

### Non Governmental Organizations [NGO's] & Diabetes- Advocacy for support services in resource-poor nations

S. Pramod
Health Alert Organization of India [NGO], Dhule, India.

Background
Diabetes- support services facilities available only in few city hospitals. Especially diabetics in rural India lack comprehensive diabetes care plan.

NGO's play key role in psychosocial-support/Counseling/rehabilitation in remote towns of india. Our Project aimed to formulate policy for trained personals to give better & cost-effective Diabetes- support services.
Methods
We mobilized training resources from local primary Health-centers. Training in Counseling & diabetes care imparted to nurses. Team consisted 2 social worker, 4 nurse & one physician. Local traditional faith-healers & community leaders involved for more effective diabetes awareness/education programs. Aim was to provide physical-comfort to patient, improve relationship with diabetics family members, gradually we prepared patient/family for long term diabetes care needed by patients. Discomfort/anxiety decreases overall treatment efficacy. 51 Patients enrolled during community out-reach-programs. Data collected on feedback-questionnaire. Most difficult tasks is discussing cost of long term therapy & non availability of newer insulin preparations in rural/tribal areas.
Results
Diabetes Counseling/support services must be made more accessible in rural-areas. Our NGO's approach is also very cost-effective. Due to non-availability of trained-personal in rural areas this approach crucial in resource poor nations. We noted 86% responded favorably to counseling/nursing care programs, 79% showed willingness to motivate fellow patients to facilitate supportive-care-program of NGO-volunteers. Infact 17 patients themselves became regular active facilitators in our NGO's Diabetes-care workshops. Our Holistic approach helped overcome hopelessness/fear depression. supportive care emerged very serious issue affecting QOL in diabetics. NGO's need to Improve access to drugs by collaboration with national diabetes societies.
Conclusion
In no extra cost our NGO's performed good job of Counseling/rehabilitation for diabetics. Restricted resource-limitations didnot permit us to take study large-sample-size, but we can collaborate with other NGO's & diabetic associations like ICE/ECE at 2012 Florence congress venue for larger effort. Our approach most suitable to resource-poor-settings.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding

## P520

**Mesenchymal stem cells-derived microvesicles modulate cellular immune response to islet antigen GAD in type 1 diabetes.**

E. Favaro, M. Deregibus, E. Camussi, R. Granata, E. Ghigo, P. Cavallo Perin, M. Zanone & G. Camussi
Università di Torino, Torino, Italy.

Background and aims
Mesenchymal stem cells (MSCs) exert an immunosuppressive effect on immune system and can abrogate *in vitro* the pro-inflammatory Th1 response to islet antigen GAD in type 1 diabetes by impairing the production of IFN-gamma. The mechanism may involve paracrine factors. Microvesicles (MVs) released from MSCs may account for this paracrine mechanism through a horizontal transfer of mRNA and microRNA. In the present study we evaluated whether MSC-derived-MVs exert immunomodulatory effect similar to that of MSCs on T cell responses against GAD in type 1 diabetes.
Methods
MVs were purified from supernatants of human MSCs and were characterized by cytofluorimetic and gene array analyses. Peripheral blood mononuclear cell (PBMCs) were obtained from 4 type 1 diabetic patients at disease onset with a positive IFN-gamma response to GAD65 stimulation by ELISPOT assay. PBMCs GAD65-pulsed were incubated with or without MV followed by IFN-gamma ELISPOT. Levels of PGE2, TGF-beta, IL-10, IFN-gamma, IL-6 in supernatants were measured by ELISA.
Results
When determined by Nanosizer, the size of MVs has a mean value of 158 nm. MVs showed adhesion molecules expressed on MSC-membrane and contained mRNA and in particular mRNA related to immune regulation. MVs labeled were incorporated by PBMC, as shown by confocal microscopy. Incubation of PMBCs obtained from the GAD-responder patients with MVs, resulted in a significant decrease in the number of IFN-gamma spots. Levels of IFN-gamma, IL-6, in supernatants of GAD65-pulsed PBMCs incubated with MVs were decreased compare to GAD65-pulsed PBMCs alone. Levels of PGE2, TGF-β and IL-10 were significantly increased compare to GAD65-pulsed PBMCs alone.
Conclusions
These results provide evident that MSC-derived-MVs inhibited *in vitro* pro-inflammatory Th1 response to an islet antigenic stimulus, in diabetic patients, possibly mediated by PGE2 and TGF-β. MVs induce IL-10 secretion, suggesting a possible switch to an anti-inflammatory Th2signalling of T cells.

**Prevalence of autoimmune diseases in a Type 1 diabetic population**

M. Marcelino[1,2], S. Castro[2], A. Santos[2], D. Amaral[2], R. Pina[2] & L. Lopes[2]
[1]University Military Hospital, Lisbon, Portugal; [2]Hospital Dona Estefânia, CHLC, Lisbon, Portugal.

Background
Patients with type 1 diabetes (T1DM) are known to have a higher risk of developing other autoimmune diseases. The most common associated disorders are thyroid autoimmunity (Graves' disease or Hashimoto's thyroiditis) and celiac disease.
The aim of this study was to investigate the prevalence of other autoimmune disorders in T1DM patients of our clinic.
Methods
We reviewed 269 files of children and adolescents with T1DM. Autoantibodies to thyroperoxidase (anti-TPO), thyroglobulin (anti-Tg), transglutaminase and endomysial were investigated in all patients. Thyroid function (TSH and fT4) and thyroid receptor antibodies (TRAbs) were determined when appropriated. Statistic study was made in IBM SPSS Statistics, Version 19.
Results
The patient's mean age was 12.1 years, with a similar distribution between sex. The average duration of diabetes was 4.7 years.
Anti-TPO and anti-Tg antibodies were detected in 15.6% of our population, with significant female preponderance. Prevalence of thyroid dysfunction among diabetic patients was 5.3%, with one case of hypothyroidism and 12 subclinical hypothyroidisms. This risk of thyroid dysfunction was higher in cases with both positive antibodies compared with the presence of only one of them. The mean age of positive thyroid autoantibodies onset was 2.4 years after diabetic diagnosis. 10.2% of the population with T1DM had positive transglutaminase or endomysial autoantibodies titers. The prevalence of biopsy-confirmed celiac disease was 4.1%. Positive antibodies for celiac disease were detected after a mean of 2.3 years of diabetic diagnosis.
Graves' disease was present in 3 cases with positive TRAbs. There was 1 case of Addison disease and 4 children presented at least 3 autoimmune diseases simultaneously.
Conclusion
Autoimmune thyroid disease and celiac disease occurs more frequently in children with T1DM than in general population, therefore screening at onset of the disease and repeated measurements of autoantibodies is recommended. Our results are comparable to the published data.

## P522

**Relation of glycemic control to Easter and summer holiday times**

M. Pape, A. Smagadi & I. Haritonidis
AHEPA University Hospital, Thessaloniki, Greece.

Objective
Poor glycemic control in type-2 diabetes mellitus is a risk factor for the development of diabetes complications. The aim of this study was to evaluate the effect of the holiday (Easter time) and the season (summer) on the glycemic control in Greek diabetic subjects.
Methods
50 type-2 diabetic patients participated in the study. Each participant was followed up in primary care settings (Health Centre of Soxos) and underwent a physical exam, including a brief medical history. Of the diabetics, 8 were using insulin, 31 were taking oral hypoglycemics and 11 were using both. Venus blood samples from diabetics were drawn in EDTA tubes and HbA1C was measured using the turbidimetric inhibition immunoassay (Tina-quant HemoglobinA1c, Roche HITACHI 902). These measurements were performed three times, at intervals of 10–12 weeks: pre-Easter holiday period (in the middle of March), at the beginning of summer (in the middle of June) and post-summer period (in the middle of September).

Results
The mean age of the diabetics and controls was 64.5 and 55.9, respectively. Median duration of diabetes was 14.5 years. The first measurement demonstrated a poor glycemic control of the patients, with mean level of HbA1C at 7.16%. The mean HbA1C increased significantly (increase:1.245, $P<0.05$) during Easter holidays and pre-summer period. The patients who were taking oral hypoglycemics demonstrated the poorest control (increase:1.512, $P<0.01$). During summer, the mean HbA1C decreased, but not significantly (decrease:0.404) among diabetics in total and among all patient groups.
Conlusions
Our data indicated a negative influence of the Easter holidays on the glycemic control of type-2 diabetic subjects. This poor glycemic control was not totally reversed during the summer months. More efficient interventions focusing on lifestyle changes and dietary habits during specific holiday (Easter) period are needed in order to improve care for diabetic patients.

### Change in quality of life by multiple education program in type 1 diabetic patients

B. Saboo[1], H. Chandarana[1], S. Joshi[2] & S. Shah[1]
[1]Dia Care - A Complete Diabetes Care Center, Ahmedabad, India; [2]Joshi Clinic, Mumbai, India.

The aim of study was to recurrently follow quality of life in type 1 diabetes patients after multiple educations and counseling. Ninty six patients of the age group of "between" 10 to 25 were initially examined in 2004 and Eighty eight patients of them were reexamined in 2006 after multiple counseling with diabetologist and trained diabetes educator at dia care, Ahmedabad, Gujarat, India. Quality of life was defined as perceived well being and life satisfaction, globally as well as within key domains and functions. Various status and retrospective change ratings were repeatedly performed by patients and significant others. For nine patients quality of life was fairly stable between 2004 and 2006. Further 79 patients had shown very significant and consistent improvement in their quality of life. Delivery of the insulin injection, self monitoring of blood glucose and management of illness, hypoglycemia, hyperglycemia and further topics related to type 1 diabetes were part of education. The study underscores the benefit to other parts of the country that quality of life of type 1 diabetic patients can be improved by continuous and multiple educations.
Declaration of interest

### Cystatin levels in diabetic and prediabetic patients

S. Akin[1], N. Ersoz Gulcelik[3], D. Yazgan Aksoy[2], J. Karakaya[4], M. Bayraktar[1] & A. Usman[1]
[1]Hacettepe University, Ankara, Turkey; [2]Etlik Ihtisas Research and Training Hospital, Ankara, Turkey; [3]Ankara Numune Research and Training Hospital, Ankara, Turkey.

Background and aim
Serum Cystatin C has been shown to be associated with the progression to prediabetes and type 2 diabetes mellitus. High cystatin levels were also found to be associated with body mass index. The aim of this study was to evaluate cystatin C levels in diabetic and prediabetic patients ant its association with anthropometric measurements and insulin resistance.
Methods
Twenty four patients with diabetes, 17 patients with prediabetes and 24 healthy controls were included in the study. Age, weight, body mass index, waist circumference (Wc), fasting plasma glucose (FPG), post pyrandial glucose (PPG), lipid profiles, blood urea nitrogen (BUN) and creatinine levels were measured. None of the patients had any diabetic complications.
Results
Diabetic patients had higher BMI than controls ($P=0.01$). Serum cystatin C levels were not statistically different between the three groups ($P>0.05$) and were similar in men and women. Cystatin C levels were correlated with body mass index and HOMA IR in prediabetic patients ($P=0.039$ and $P=0.05$, repectively)) but not in diabetic patients and controls, when adjusted for age and gender.
Conclusions
Serum cystatin C levels are associated with body mass index and insulin resistance in prediabetic patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Psychoemotional state of diabetic women with fracture

A. Gusova[1,2], M. Pavlova[2], G. Melnichenko[2] & G. Kavalersky[2]
[1]Scientific Research Institute of Neurosurgery named after N.N. Burdenko, Moscow, Russian Federation; [2]First Moscow State Medical University named after I.M. Sechenov, Moscow, Russian Federation.

Background and aims
The aim was to determine psychoemotional state in diabetic and non-diabetic patients with or without fractures and its correlation with bone condition.
Materials and methods
We examined 62 postmenopausal women with type 2 diabetes mellitus (DM), 29 of them had bone fracture within last month. The control group included 56 non-diabetic women, 26 within a group were recently fractured. Groups were comparable in body mass index, age, duration of menopause. Diabetic subgroups were comparable in glycosylated hemoglobin level. We measured depressive symptoms using the Beck depression inventory, Zung Self-Rating Depression and Center for Epidemiological Studies Depression Scales. There were also analyzed correlation with lifestyle factors, data of bone densitometry (lumbar spine and femur) and vitamin D level.
Results
As expected in patients with DM frequency of depression were significantly higher compared to women without DM ($P=0.01$–$0.04$). There were no rising of depression rate in groups with fracture. The direct correlation between Zung Scale total score and diabetes duration ($R=0.513$) was found. Only in non-diabetic group there were inverse correlations of depression score with both bone mineral density ($R=-0.50$ to $-0.62$) and lifetime weight gain ($R=$-0.44). In this (non-diabetic) group there were also found direct relationship of depression symptoms with coffee consumption ($R=0.43$–$0.54$) and smoking intensity ($R=0.46$). No correlation of vitamin D level and depression score was detected.
Conclusion
Depression is more common in diabetic women. Frequency of depression among patients with fracture was the same or even a bit lower. Depression was associated with low bone mineral density only in non-diabetic group.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P526

### Hypoglycemic and hyperglycemic patients in emergency room

N. Yucel, A. Sertkaya & S. Pepele
Inonu University, School of Medicine, Malatya, Turkey.

Aims
To evaluate the process of patients from emergency room (ER) admittance until discharge from the endocrinology service (ES) with hypoglycemia or hyperglycemia.
Methods
Two hundred twenty two patients either with hypoglycemia or hyperglycemia were evaluated. Hyperglycemic patients were divided into three groups: Patients with type 1 diabetes, type 2 diabetes and patients without diabetic history. The complaints, laboratory findings, stay in ER, stay in the ES and mortality rates were documented.
Results
Fatigue like unspecified complaints were the most common finding in whole hyperglycemic patients ($n=206$, age $=59.7\pm16.1$ yrs, glucose $291\pm195.7$ mg/dl). Mean stay in ER was $2.91\pm1.77$ hours, $9.3\pm13.2$ days in ES. Mortality rate was

7.6% in whole hyperglycemics with the highest ratio in the patients without any diabetic history (13%). Hypoglycemic patients ($n=16$, 15 with type 2 DM, age = 66.5 ± 19 yrs, glucose 28.5 ± 7.5 mg/dl) were found to be mostly presented with conscious deterioration (80%). Their mean stay in ER was 2.5 ± 0.7 hours, 2.6 ± 0.7 days in ES. The frequency of type 2 diabetes was 76% and stress hyperglycemia was 17.5%.

Conclusion

1- The short duration for both ER and ES stay (2.5 -3 hours) is the result of our high hospitalization (70%) rates. 2- The guidelines for diabetes lead us to manage these patients with shorter stay. 3- The necessity for diagnose and defining management protocols cause to expend much time on patients without diabetic history regards of hospitalization process. The mortality rates for these patients are higher as well. 4- The high percentage (76%) of type 2 DM -either with hypoglycemia or hyperglycemia- who admitted to ER; reflects the increased frequency of the disease. 5- The increased admittance of critically ill patients to an university hospital seems to account for the increased rate of stress hyperglycemia (17.5%).

## P527

**Diabetes risk in relation to weight loss, weight stability and degree of obesity - The Swedish Obese Subjects (SOS) study**

M. Peltonen[1], L. Sjöström[2] & L. Carlsson[2]

[1]National Institute for Health and Welfare, Helsinki, Finland; [2]University of Gothenburg, Gothenburg, Sweden.

Objective

Among severely obese individuals, surgically induced weight loss reduces the risk for type 2 diabetes. The aim of this study was to analyse the incidence and remission of type 2 diabetes among individuals with different degrees of obesity losing weight, and compare them with obese individuals remaining weight stable during follow-up.

Research design and methods

The ongoing non-randomized prospective controlled Swedish Obese Subjects (SOS) intervention study enrolled 2010 obese persons who received bariatric surgery and 2037 contemporaneously matched obese controls. Health examinations with anthropometric measurements and laboratory analyses were conducted at baseline and at 2- and 10-year follow-up. Diabetes was defined by fasting venous whole blood glucose 6.1 mmol/litre or more, and/or self-reported diabetes medication. Two- and 10-year diabetes risk was assessed by initial BMI and weight changes during follow-up. Incidence and remission rates were calculated for those without and with diabetes at baseline, respectively.

Results

Among weight stable obese individuals with BMI $<35$, 35–40, and 40–45 both at baseline and at 2-year follow-up, type 2 diabetes incidence rates were 6.5%, 7.7% and 9.3%, respectively. Among those with initial BMI of 35–40, 40–45 and $\geqq 45$ attaining five BMI-unit weight reduction, the corresponding rates were 2.4%, 2.0% and 3.4%, respectively. In patients with diabetes at baseline and who attained a 5 BMI-unit reduction at year 2, remission rates were independent of the initial degree of obesity. Similar results were observed with the 10-year follow-up data.

Conclusions

A BMI reduction of 5 units, independent of the initial degree of obesity, is associated with a reduction of diabetes risk compared with weight stability at any obese BMI-level.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P528

**The role of Insulin Receptor in Cancer**

A. Belfiore

University Magna Graecia of Catanzaro, Catanzaro, Italy.

The IGF-I receptor (IGF-IR) and its ligands (IGF-I and IGF-II) play a physiological role in growth and differentiation and are also involved in cancer growth and progression. The insulin receptor (IR), which shares high homology with the IGF-IR, has a predominant role in glucose metabolism. However, several studies have convincingly shown that the IR pathway is more intimately involved in cancer development and progression than previously thought. Recent evidences showing that insulin resistance and hyperinsulinemia are important risk factors for cancer have renewed the interest for these studies. One mechanism explaining the increased sensitivity of malignant cells to hyperinsulinemia is the frequent IR overexpression in cancer cells. Moreover, cancer cells commonly show an altered IR gene splicing, with predominant expression of IR-A, one of the two IR isoforms. IR-A binds not only insulin but also IGF-II and, therefore, it competes with IGF-IR for IGF-II binding. IGF-II, via IR-A, stimulates subtly different signaling than insulin. IR-A overexpression and high IGF-II autocrine production are important factors for both normal and cancer stem cells expansion and are often present in dedifferentiated malignancies. Finally, IR overexpression enhances cell responsiveness to IGF-I and IGF-II by participating to the formation of hybrid IR/IGF-IR receptors, which bind both IGFs.

Until very recently, only IGF-IR, but not IR, has been considered a target in cancer therapy. However, the results of the clinical first trials employing selective anti-IGF-IR drugs have been disappointing, with only a small subset of malignancies showing an objective response. Recent data have indicated that resistance to anti-IGF-IR drugs may include upregulation of IR isoform A and/or increased secretion of autocrine IGF-II. Therefore, cotargeting of IR and IGF-IR may prevent adaptative resistance to selective anti-IGF-IR drugs, especially in malignancies with high IR-A:IGF-IR ratio and autocrine IGF-II production.

**Local effects of cytokine TNF-alpha on glucose, lipid and protein metabolism in the placebo controlled bilaterally perfused human leg**

E. Bosnjak, M. Buhl, R. Nielsen, T. Hafstrøm, M. Vandelbo, E. Tønnesen & N. Møller

Aarhus University Hospital, Aarhus, Denmark.

Introduction

Cytokine TNF-alpha has widespread metabolic actions, including induction of insulin resistance, lipolysis and cachexia. Systemic TNF-alpha administration, however, generates complex hormonal and metabolic scenario. No studies employing regional, placebo controlled TNF-alpha infusion exist. Our study was designed to test the hypothesis that local leg perfusion with TNF-alpha directly induces insulin resistance, lipolysis and protein breakdown.

Methods

We studied eight healthy volunteers with bilateral femoral vein and artery catheters during 3-h basal period and 3-h insulin stimulation (hyperinsulinemic euglycemic clamp). One femoral artery was perfused with saline and the other with TNF-alpha ("Beromun", Boehringer-Ingelheim, 6 ng/kg/h). Amino acid metabolism was quantified with 15N-Phenylalanine tracer, lipid metabolism with 3H-Palmitate tracer and arterio-venous differences of free fatty acids and glucose metabolism was quantified by arterio-venous differences.

Results

TNF-alpha perfusion significantly increased local leg glucose uptake during the clamp. Basal glucose arterio-venous difference was unaltered, but substantially increased during the clamp ($P<0.001$), with 0.925 ± 0.49 mmol/1 in the TNF-alpha leg, and 0.744 ± 0.43 mmol/1 in the placebo leg.

Net phenylalanine release was increased by TNF-alpha perfusion ($P=0.023$). During the basal period there was an increased phenylalanine release ($P=0.003$), with 4466 ± 1390 μg/min in the TNF-alpha leg, and 3794 ± 1122 μg/min in the placebo leg, and an increased phenylalanine uptake ($P=0.023$) with 2951 ± 1134 μg/min in the TNF-alpha leg, and 2464 ± 708 μg/min in the placebo leg.

Free fatty acids and palmitate kinetics were not affected by TNF-alpha.

Conclusion

TNF-alpha directly increased muscle protein breakdown and local muscle insulin sensitivity in terms of increased muscle glucose uptake. The finding of increased muscle loss may contribute to general protein loss during severe illness. The finding of increased insulin sensitivity is unexpected and highlights the necessity of differentiation between direct local cytokine effects as in this study and those secondary to release of stress cascades including hormones such as epinephrine, glucagon and cortisol.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P530

**Increased nuclear translocation of GAPDH in peripheral blood mononuclear cells (PBMCs) of diabetic patients.**

S. Gougoura, M. Filliponi, A. Bargiota, P. Dritsa & G. Koukoulis
Larissa University Hospital, Larissa, Greece.

Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) not only functions as a central glycolytic enzyme but also is implicated in the process of apoptosis and gene transcription moving between the cytosol and nucleus. Oxidative stress modifies the activity of GAPDH.
The aim of the study was to determine whether oxidative stress (OS) in diabetics is associated with induction of the apoptotic process and higher GAPDH translocation to the nucleus in PBMCs.
GAPDH activity and -SH group content were determined in both the cytoplasmic and nuclear fraction of PBMCs collected from 20 diabetic and 20 control subjects. NF-kB p65 subunit and Bcl-2 levels were estimated in the nuclear and cytoplasmic cell fractions respectively. Chromatin integrity was assessed by diphenylamine (DPA) reaction and DNA laddering assay.
Intracellular OS was significantly higher in PBMCs from diabetic patients compared to controls as it is suggested by the -SH groups depletion in both cytoplasmic ($P=0.030$) and nuclear ($P=0.003$) cell fractions. The higher OS in the diabetics was accompanied by a significant increase in the nuclear NF-kB p65 subunit ($P=0.015$) and a three-fold decrease in cytoplasmic Bcl-2 levels ($P=0.001$). DNA damage was more evident in diabetics compared to controls as it is suggested by the DPA reaction ($P=0.002$) and DNA laddering assay. Compared to controls, GAPDH activity in PBMCs was significantly lower in diabetics ($P=0.017$). In spite of this reduction a significantly higher fraction of GAPDH activity was observed in the nuclear compartment of patients ($P=0.001$). In conclusion, diabetic OS activates the pro-apoptotic process in PBMCs and simultaneously the NF-kB, which may acts as anti-apoptotic factor. The higher GAPDH fraction that translocates into the nucleus may facilitates the repair of DNA damage, inserting new insights that link metabolic enzymes with energy production and cell survival.

**Conserved mitochondrial coupling and adaptive substrate control in inuit and caucasians: acclimatization to active life styles in the arctic winter**

R. Boushel[1], B. Saltin[1] & E. Gnaiger[2]
[1]University of Copenhagan, Denmark; [2]Medical University of Innsbruck, Innsbruck, Austria.

Mitochondria oxidize food substrates to generate energy for cellular work and heat is variably generated depending on the degree of coupling of electron transport to oxidative phosphorylation (OXPHOS). It has been hypothesized that climatic pressures exerted selection for mitochondrial haplogroup in arctic populations for a lower coupling of mitochondrial respiration to ATP production in favor of heat production. In this study muscle mitochondrial function was studied in Inuit from northern Greenland and sedentary Caucasian Danes who travelled to Greenland. Muscle biopsies were obtained from the vastus lateralis and deltoid muscles and mitochondrial function was assessed by high-resolution respirometry. OXPHOS capacity in the leg (vastus lateralis) was lower in Inuit compared to Danes ($70\pm4$ vs. $90\pm5$ pmol/mg/sec). Leak respiration was proportionate with OXPHOS such that mitochondrial coupling efficiency was equivalent between groups and across muscles of both arm and leg. The traditional Inuit had a higher OXPHOS capacity with lipid substrate compared to Danes ($27\pm3$ vs. $22\pm3$ pmol/mg/sec). In conclusion, this study refutes the hypothesis that mitochondrial uncoupling and metabolic heat production is higher in arctic haplotype populations, yet reveals acclimatization of mitochondrial substrate control in arctic inhabitants.

## P532

**Association of adiposity trajectories with insulin sensitivity and glycemic deterioration: a longitudinal study of rural chinese twin adults**

R. Liu
Beijing Institute of Heart, Lung and Blood Vessel Diseases, Beijing, China.

Objective
To evaluate associations between adiposity trajectories over time and insulin sensitivity and glucose deterioration in a Chinese twin cohort.
Research Design and Methods
This study focused on 341 males and 292 females who aged 20–50 years old at baseline and had physical, clinical examinations and oral glucose tolerance test(OGTT) at two time points with an average of 6 years apart. Body mass index (BMI), waist circumference (WC), percent body fat (PBF), and percent trunk fat (PTF) trajectories were classified into 5 track groups based on age- and gender-specific tertiles at each visit. We calculated the odds of the insulin sensitivity index(0.120) (ISI(0.120)) or glycemic deterioration at follow-up among 5 defined trajectories (tertile baseline to tertile follow-up) using generalized estimate Default (GEE). Additionally, we applied structural equation models to examine genetic and environmental influences on adiposity, adiposity change over time(ACO), ISI(0.120), and the inter-relationships.
Results
Participants with adiposity (BMI, WC, PBF and PTF) stable in the highest tertile or shifting to the highest tertile tended to have the lowest ISI(0.120) at follow-up or experience glycemic deterioration. Genetic factors exerted the major influence on adiposity, but environmental factors unique to each twin contributed more strongly to ISI and ACO. Correlations between adiposity/ACO and insulin sensitivity were mainly due to environmental influences.
Conclusion
When adiposity stays or becomes high, insulin sensitivity falls and risk of glycemic deterioration rises. Additionally, we found that genetic factors exerted the major influence on adiposity, while environmental factors played the principal role for ACO and insulin sensitivity.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P533

**Direct metabolic effects of locally administered lipopolysaccharide in the placebo controlled bilaterally infused human leg; decreased insulin sensitivity and insulin signaling with unaltered lipid and protein metabolism**

M. Buhl[1], E. Bosnjak[1], J. Gjedsted[1], R. Nielsen[1], N. Jessen[1,2], T. Hafstrøm[1], E. Vestergaard[3], E. Tønnesen[1] & N. Møller[1]
[1]Aarhus University Hospital, Aarhus, Denmark; [2]Aarhus University, Aarhus, Denmark; [3]Regional Hospital Herning, Herning, Denmark.

Introduction
In humans bacterial lipopolysaccharide (LPS/endotoxin) causes chronic low-grade and acute inflammatory responses, which decrease insulin sensitivity and may lead to chronic type 2 diabetes and acute stress diabetes. Systemic LPS invariably generates cytokine release, which triggers release of anti-insulin stress hormones and it is not known whether insulin resistance is secondary to stress hormones or LPS per se. Our study was designed to test whether local placebo controlled leg perfusion with LPS directly induces insulin resistance and affects protein and lipid metabolism.
Methods
We studied eight healthy volunteers with bilateral femoral vein and artery catheters during 3-h basal and 3-h hyperinsulinemic euglycemic clamp conditions. One femoral artery was perfused with saline and the other with LPS (0.025 ng/kg/h). Lipid metabolism was quantified with 3H-Palmitate and arterio-venous differences of FFA. Amino acid metabolism was quantified with 15N-Phenylalanine tracer and lactate and glucose by raw arterio-venous differences.

Results
Overall LPS perfusion significantly decreased leg glucose uptake ($P=0.015$); Basal glucose a-v differences were not significantly reduced ($0.02\pm0.05$ mmol/l vs. $0.06\pm0.06$ mmol/l in the placebo leg, $P=0.19$); during the clamp LPS decreased glucose a-v differences ($0.65\pm0.21$ mmol/l in the LPS leg, and $0.73\pm0.23$ mmol/l in the placebo leg, $P=0.021$). Akt308 phosphorylation was inhibited in the LPS leg both during the basal period ($P=0.021$) and clamp ($P=0.027$). Phosphorylation of AS160 was unaltered by LPS. Regional leg phenylalanine, palmitate, FFA and lactate kinetics were unaffected by LPS.
Conclusion
LPS directly inhibits insulin-stimulated glucose uptake in the perfused human leg without detectable effects on amino acid metabolism, lipolysis or lactate release. The mechanism in all likelihood involves inhibition of insulin mediated Akt308 phosphorylation. These data strongly suggest that a primary metabolic effect of LPS is muscle insulin resistance, which together with secondary insulin resistance caused by stress hormones may trigger diabetes.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding

## P534

**Suppressive effect of hyperinsulinemia on serum interleukin 18 concentration in young healthy subjects**

M. Straczkowski[1,2], M. Karczewska-Kupczewska[1], A. Adamska[1], A. Nikolajuk[2], N. Matulewicz[1], M. Zielinska[1], M. Gorska[1] & I. Kowalska[1]
[1]Medical University of Bialystok, Poland; [2]Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Olsztyn, Poland.

Introduction
Interleukin 18 (IL-18) is a proinflammatory and proatherogenic cytokine which is associated with obesity, insulin resistance and cardiovascular disease. It is supposed that insulin has anti-inflammatory action. The aim of the present study was to estimate serum IL-18 concentration in young healthy population, its regulation by hyperinsulinemia and relationship with insulin sensitivity and glucose and lipid oxidation.
Methods
We studied 36 healthy male subjects (mean age, $24.50\pm2.67$; mean BMI, $25.77\pm3.70$ kg/m$^2$). Serum IL-18 concentration was measured before and after 2 hour euglycemic hyperinsulinemic clamp. In 18 subjects, clamp was prolonged to 6 hours and at the end an additional measurement of serum IL-18 was taken. Respiratory quotient (RQ) and glucose and lipid oxidation (LOx) were assessed with indirect calorimetry in the baseline state and every 2 hours of the clamp.
Results
Hyperinsulinemia decreased serum IL-18, this effect was present both in 2 and 6 hours of the clamp (both $p<0.001$). Additionally, serum IL-18 decreased from 2 to 6 hour ($p=0.044$). Two-hour and 6 hour serum IL-18 values were positively related to plasma free fatty acids in the respective time-points ($r=0.43$, $P=0.033$ and $r=0.52$, $P=0.028$). Two-hour and 6 hour serum IL-18 were also negatively related to RQ ($r=-0.40$, $p=0.018$ and $r=-0.54$, $p=0.02$) and positively to LOx ($r=0.46$, $p=0.006$ and $r=0.66$, $p=0.004$) in the respective time-points. Six-hour IL-18 was negatively related to insulin sensitivity calculated for the 6th hour of the clamp ($r=-0.53$, $p=0.025$). The change in serum IL-18 in response to insulin was inversely related to the white blood cell count ($r=-0.52$, $P=0.027$) and the neutrophil cell count ($r=-0.56$, $P=0.016$), i.e., the higher the cell count, the lower the decrease in IL-18.
Conclusion
Serum IL-18 is negatively regulated by hyperinsulinemia, suggesting anti-inflammatory effect of insulin. IL-18 is related to decreased insulin sensitivity mainly through its association with lipid oxidation.

**The Association of the severity of nonalcoholic fatty liver disease with development of type 2 diabetes: A 4-year longitudinal study**

J. Choi[1], J. Bae[2], S. Park[1], E. Rhee[1], C. Park[1], K. Oh[1], S. Park[1], S. Kim[1] & W. Lee[1]
[1]Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Aims
Nonalcoholic fatty liver disease (NAFLD) is reported to contribute to the development of type 2 diabetes, but it is largely unknown whether such a relationship between NAFLD and incident diabetes relates to the severity of NAFLD or it is independent. We aimed to evaluate the association of the severity of NAFLD with development of type 2 diabetes in a retrospective cohort of Korean subjects.
Methods
This study included 7,849 individuals without diabetes who underwent health check-ups annually for 5 years. Based on the presence or absence of fatty liver on ultrasound and serum alanine aminotransferase (ALT) values at baseline, subjects were classified into controls, an increased ALT group without steatosis, a steatosis group with normal ALT, and a group with presumed nonalcoholic steatohepatitis (NASH) with steatosis and an elevated ALT.
Results
At baseline, there was a significant trend of worsening metabolic variables and index of insulin resistance across the groups from the control group to the increased ALT group, the steatosis group and the NASH group. Over 4 years, the incidence of diabetes was 3.5% in the control group, 4.6% in the increased ALT group, 7.3% in the steatosis group, and 11.8% in the NASH group. The hazard ratio (HR) [(95% confidence interval (CI)] of incident diabetes was increased in the increased ALT group, the steatosis group, and the NASH group in a stepwise fashion. Subjects with NASH had a significantly increased HR of 1.64 (1.27–2.13), even after multivariable adjustment.
Conclusions
The severity of NAFLD as well as the presence of NAFLD has an independent and additive effect on the development of type 2 diabetes. Thus, the evaluation of severity of NAFLD, especially through the clinical diagnosis of NASH, could be included in incident diabetes prediction algorithms.

**Predictive ability of prediabetes defined by fasting plasma glucose and HbA1c for progression to diabetes in Koreans**

C. Kim[1], H. Kim[2], E. Kim[2], S. Bae[2] & J. Park[3]
[1]Soonchunhyang University College of Medicine, Bucheon, Republic of Korea; [2]Asan Medical Center, Seoul, Republic of Korea. [3]University of Ulsan College of Medicine, Seoul, Republic of Korea.

Background
The predictive ability of prediabetes defined by HbA1c (5.7–6.4%) or fasting plasma glucose (FPG) criteria (5.6–6.9 mmol/l) for the development of diabetes may differ according to ethnic groups, but only limited longitudinal data are available in Asians. We examined the progression rate to diabetes in Korean adults diagnosed as prediabetes according to these two criteria.
Methods
We analyzed data of 9432 Korean adults (age 20–79 years) who underwent regular health check-ups in 2005 (baseline) and in 2010 (follow up). After excluding patients with previously diagnosed diabetes ($n=332$) and those with FPG $\geqq7.0$ mmol/l or HbA1c $\geqq6.5\%$ ($n=353$) at baseline, 8747 subjects (5706 men and 3041 women) were included for the analysis.
Results
Among the 8747 participants without diabetes at baseline, 3493 individuals (39.9%) were categorized as prediabetes. Among them, 1318 individuals (15.1%) met HbA1c criteria only (HbA1c only group), 1229 (14.1%) met FPG criteria only (FPG only group), and 946 (10.8%) met both criteria (both group). After 5 years, a total of 356 subjects (4.1% of total participants) converted to diabetes. Only 0.3% (17/5254) of subjects who had normal baseline FPG and HbA1c

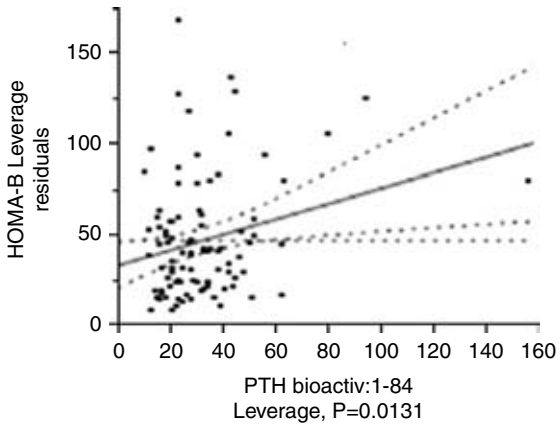
developed diabetes during 5 years. The 5-year incidence of diabetes was 3.5% (43/1229) for the FPG only group, 4.9% (65/1318) for the HbA1c only group, and 24.4% (231/946) for the both group. Multiple logistic regression analysis showed that age, sex-adjusted odds ratios (ORs) for the FPG only, HbA1c only, and both groups were 10.7 (95% CI, 6.0–18.8), 15.8 (9.2–27.1), and 95.0 (57.3–157.4), respectively. After further adjustments for smoking, alcohol drinking, exercise habits, body mass index, waist circumference, systolic blood pressure, hemoglobin, cholesterol, HDL-cholesterol, and triglycerides levels, ORs for the FPG only, HbA1c only, and both groups were 7.7 (95% CI, 4.3–13.9), 12.9 (7.5–22.3), and 69.8 (41.7–116.7), respectively.
Conclusion
Individuals categorized as prediabetes by both of the FPG and HbA1c criteria have substantially high risk for progression to diabetes, while those classified as normal by both criteria have very low risk in Koreans. Those who discordantly met only one criterion have intermediate risk, but HbA1c only group tends to have higher risk than FPG only group.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P537

**Relationship between serum levels of 1-84 parathormone (PTH1-84) and obesity, HOMA insulin-sensitivity or beta-cells function (HOMA-B) in type 2 diabetic patients**

M. Belovici[1] & M. Buysschaert[2]
[1]Universitary Clinics,, Saint Luc'', Bruxelles, Belgium; [2]University of Louvain, Bruxelles, Belgium.

Introduction
PTHrP (Parathyroid hormone-related protein) is known to enhance beta cell function and proliferation. PTH levels predict myocardial and coronary heart disease in non-diabetic patients with normal calcium levels and no kidney failure. We aimed at determining in type 2 diabetes patients without kydney failure the relationship between serum levels of 1-84 parathormone (PTH1-84), obesity, HOMA insulin-sensitivity or beta-cells function (HOMA-B), but also between PTH1-84 and confirmed myocardial arterial disease (MAD).
Research design and methods
106 adult patients with type 2 diabetes were divided into two groups: group A - absent myocardial arterial disease (n=64) and group B- confirmed myocardial arterial disease (n=42). The groups were matched regarding age, HbA1c, body mass index (BMI), glomerular filtration rate, microalbuminuria, vitamin D.
Results
We found a positive correlation between PTH1-84 and abdominal perimeter ($P=$ 0.007), BMI ($P=<0.0001$), fibrinogen ($P=0.008$), beta-cells function ($P=$ 0.01), C-peptid ($P=0.0003$), and a negative correlation between PTH1-84 and HOMA insulin-sensitivity ($P=0.008$) or HbA1C ($P=0.01$). All type 2 diabetic patients had normal levels of PTH 1-84 and calcium, but low levels of 25(OH)D. Serum PTH1-84 were significantly increased in group B (MAD) vs group A (absent MAD) ($P=0.02$). There was a significant correlation between PTH level and systolic left ventricular diameter (p=0.01).



Conclusion
In type 2 diabetic patients, obesity, insulin resistance and poor control of diabetes are positively associated with increased levels of PTH. Parathormone may contribute to the development of systolic dysfunction and myocardial heart disease. In this regard, treating the hypovitaminosis D in type 2 diabetic patients can improve the cardiovascular protection. In the same time, we found a positive correlation between PTH1-84 and beta-cells function suggesting a role for PTH1-84 in insulin secretion.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector

**The burden of disease in elderly people with IFG**

H. Lutgers[1], L. Campbell[1,2], B. Baune[3], H. Brodaty[3], J. Trollor[3], P. Sachdev[3,4] & K. Samaras[1,2]
[1]Garvan Institute of Medical Research, Darlinghurst, Sydney, NSW, Australia; [2]St. Vincent's Hospital, Darlinghurst, Sydney, NSW, Australia; [3]University of New South Wales, Randwick, NSW, Australia; [4]Prince of Wales Hospital, Randwick, NSW, Australia; [5]Prince of Wales Hospital, Randwick, NSW, Australia; University of Adelaide, Adelaide, SA, Australia.

Introduction
The prevalence of impaired fasting glucose (IFG) in the elderly approaches 50% in some community-dwelling cohorts. We examined whether IFG is associated with a higher burden of disease, cardiovascular risk factors and circulating low-grade inflammation than in normoglycemic elderly people.
Methods/Design
Cross-sectional data of 929 participants of the Sydney Memory and Aging Study (MAS) were examined. MAS is a population-derived cohort of community-dwelling adults aged 70–90 years. Normoglycemic (NG) and IFG participants were compared using contingency tables and the Chi-square test. Logistic regression and ANCOVA analyses were performed adjusted for age, sex and Body Mass Index (BMI).
Results
Mean age was 78.6 ($\pm$4.7) years; 47% had IFG, 12% had diagnosed type 2 diabetes and 4% previously undiagnosed type 2 diabetes. There were proportionately more males with IFG compared to NG (49% vs 37% males, $P<0.001$). As expected, BMI was higher in IFG compared to NG subjects (27.4 kg/m$^2$ vs 26.1 kg/m$^2$, $P<0.001$). Hypertension and hyperlipidemia was equally distributed (62% and 60% in IFG vs. 57% and 56% in NG), although lipid-lowering drugs had been more frequently prescribed in IFG (55% vs 42%, $P<0.001$). After adjustment for covariates, rates of stroke, cardiac disease, myocardial infarction, kidney disease or any cancer were similar between participants with IFG and normal fasting glucose. However, PAI-1 (83.7 vs. 79.8 ng/ml, $P<0.05$), IL-8 (21.8 vs. 18.6 pg/ml, $P<0.01$), IL-12p70 (3.64 vs 3.40 pg/ml, $P<0.05$) and products of oxidative metabolism (urate [0.35 vs. 0.32 mmol/l, $P<0.001$] and malondialdehyde [13.4 vs. 12.8 μmol/l, $P<0.001$]), were all significantly higher in IFG.
Conclusion
In this cohort of community-dwelling elderly, IFG was not associated with an increased burden of disease cross-sectionally. Prospective data are required to elucidate whether the moderately increased markers of inflammation accompanying IFG in this population adversely affect health outcomes during residual life span.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### GABA A receptor gene regulatory networks in peripheral blood TCD4+, TCD8+ AND CD14+ cells of recently diagnosed type 1 diabetes mellitus

D. Rassi[1], A. Evangelista[1], D. Brum[1], N. Deghaide[1], M. Foss-Freitas[1], M. Foss[1], E. Sakamoto-Hojo[1], C. Sanjeevi[2], G. Passos[1] & E. Donadi[1]
[1]University of SÐo Paulo, RibeirÐo Preto, Brazil; [2]University of SÐo Paulo, RibeirÐo Preto, Brazil; [2]Karolinska Institutet, Stokholm, Sweden.

Gamma-aminobutyric acid (GABA) is a major inhibitory neurotransmitter primarily produced by neurons and pancreatic beta cells. GABA functional receptors (GABR) are expressed in brain, pancreas and peripheral blood lymphomononuclear cells (PBMC). After evaluating the differential gene expression in PBMC of recently diagnosed type 1 diabetes mellitus patients (T1D), three GABRA networks were observed, modulating the expression dozen of genes. The study was conducted on T (CD4+ and CD8+) and monocyte (CD14+) cells obtained from 20 pre-pubertal patients and 20 age- and sex-matched healthy controls, using cDNA microarrays. Significant and differentially expressed genes, revealed using the SAM program, were studied for gene networks (GeneNetwork 1.2 algorithm). Three different GABR subunit class genes (alpha1, alpha6 and beta1) up-regulated the expression of the genes related to cell cycle (CNNB1-cyclin M1, STOM-stomatin), apoptosis control (FAS-TNF receptor superfamily, BAT3-HLA-B associated transcript 3), cellular receptor (IL1RAP- interleukin 1 receptor accessory protein, BCAP29-B cell receptor, IK cytokine-down-regulator of HLA II), complement control (CD93-C1q receptor), glucose metabolism (PFKFB2-6-phosphofructo-2-kinase/fructose-2,6-biphosphatase 2), insulin receptor (INSR), oncogenes (RHOG-ras homolog gene family, RAB6-member RAS oncogene family), ubiquitins (UBC-ubiquitin C, UBE2Z-ubiquitin-conjugating enzyme E2Z, UBR4-ubiquitin protein ligase E3 component n-recognin 4, and UBAP-ubiquitin associated protein 1), growth factor (COL6A2-collagen, alpha 2, FGF13-fibroblast growth factor 13, FGF9-Fibroblast growth factor 9) among others. Although the role of GABA in the pathogenesis of diabetes has not been established, some studies have shown that GABA down regulates many immune system functions. This study further reports that PBMC may reflect the ongoing diabetes pathogenesis, and further discriminates several other genes with potential interest for T1D.

Declaration of interest

### Diagnosis of Metabolic syndrome in Saudi Arabia: implications for the importance of local criteria

S. Bahijri[1] & R. Al Raddadi[2]
[1]Faculty of Medicine, King Abdulaziz University, Jeddah, Saudi Arabia; [2]Primary Health Care Directorate, Ministry of Health, Jeddah, Saudi Arabia.

Background and Objectives

Different definitions for the metabolic syndrome (MS) exist.Established criteria for diagnosis includes: raised blood pressure, dysglycemia, dyslipidemia, and obesity, but the used thresholds differed. Individual patients with MS need to be identified to reduce future complications. We aimed to determine the characteristics of subjects identified from healthy population to have MS by NCEP-ATP III, IDF and the consensus definition by IDF and AHA/NHLBI, and to investigate the importance of demographic characteristics and other measures of obesity, dysglycemia and dyslipidemia.

Subjects and methods

233 healthy adults aged 18–50 years were recruited randomly from Jeddah. Anthropometric and demographic information were taken. Insulin, glucose, and lipids profile were measured in fasting blood. Individuals were identified using the three definitions of MS, and their characteristics were compared statistically to the rest of the population.

Results

18.9%, 16.7% and 20.6% of population were identified as having MS by IDF, ATPIII, and the consensus definition respectively. Subjects identified by the latter were also identified by either/ or both definitions. The most common feature was central obesity with IDF definition, and low HDL- cholesterol using NCEP-ATP III definition. The least common feature was high blood pressure in all cases. There was no significant difference between subgroups with and without MS with regard to demographic characteristics when any definition was applied.

Using regression analysis the strongest predictors of MS were blood glucose, LDL-C/HDL-C ratio and insulin when NCEP-ATPIII definition or the consensus definition were used, and blood glucose, Waist /Hip ratio and Plasma Atherogenic Index (PAI) when IDF definition was used.

Conclusion

In absence of local thresholds for components of the MS the use of waist: Hip ratio, LDL-C: HDL-C, PAI, and insulin level might help diagnosis. More studies are needed to reach accurate definition of MS in Saudis.

## P541

### Comparison of plasma osteoprotegerin and related factors in two groups of pregnant women

A. Song[1], M. Nie[1], Y. Wang[1,2] & M. Sun[1]
[1]Peking Union Medical College Hospital, Peking Union Medical College, Chinese Academy of Medical Sciences; Key laboratory of Endocrine, Ministry of Health, Beijing, China [2]The Secondly Affiliated Hospital of ShanXi Medical College, Tai Yuan, China.

Objective

The aim of the present study was to determine the plasma osteoprotegerin (OPG) levels in women with gestational diabetes mellitus (GDM) and normal glucose tolerance (NGT) during the last trimester of pregnancy, and to investigate the relationship between OPG and some related factors.

Method

In this study, 65 women with GDM and 65 women with NGT were enrolled. Plasma concentration of OPG was measured by enzyme linked immunosorbent assay (ELISA). The level of fasting plasma glucose (FPG), fasting insulin(FINS), glycated hemoglobin (HbA1c), lipid, high-sensitivity C-reactive protein (hs-CRP), blood cell count was also assayed, and the homeostasis model assessment of beta-cell function (HOMA-B) and insulin resistance (HOMA-IR) was calculated.

Results

The level of plasma OPG was not significantly different between women with GDM and NGT. In the group of NGT, OPG levels were positively correlated with FINS ($r=0.335$, $P=0.012$), HOMA-IR ($r=0.363$, $P=0.006$), platelet count ($r=0.333$, $P=0.009$) and apolipoprotein B ($r=-0.254$, $P=0.043$).

Conclusion

OPG may be involved in insulin resistance and inflammation during the pregnance in women with NGT, the effects were not obvious in the group of GDM. One possible explanation was that OPG tended to have a weaker effect on insulin resistance and inflammation and the role of OPG may be covered by other stronger factors in the pathogenesis of GDM.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This work was supported, however funding details unavailable.

## P542

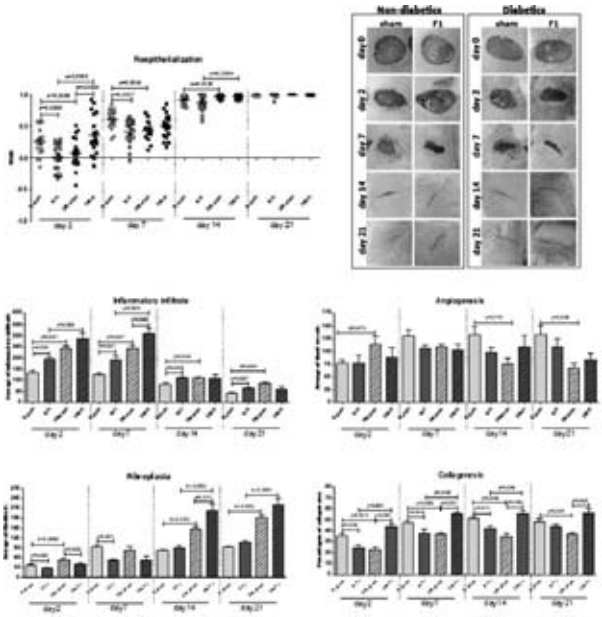
### Protein from Hevea brasiliensis latex rubber tree enhances wound healing in diabetic rats

T. Andrade[1], G. Caetano[2], D. Masson[1], C. Landim[1], J. Coutinho-Netto[1], M. Foss[1] & M. Frade[1]
University of Sao Paulo, Sao Paulo, Brazil.

The healing effects of Hevea brasiliensis latex biomembrane has been widely cited in the literature, mainly regarding its protein fraction F1 in patients with diabetes. The purpose of this study was to evaluate the wound healing mechanism of F1 in diabetic rats. Eighty Wistar rats were used for the experiments, where: 40 rats were induced to diabetes by streptozotocin 45 mg/kg (DM) and 40 rats were left non-diabetic (N). Two wounds were created on the dorsal of each rat using a skin biopsy punch (1.5 mm diameter). The groups were assigned according to treatments: Carboxymethylcellulose (CMC) Gel 4% [DM sham, N sham ($n=20$)] and CMC +0.01% F1 [(DM F1, N-F1 ($n=20$)]. Wounds were treated daily, over 21 days. On the 2nd, 7th, 14th and 21st days, animals were euthanized and 10 biopsies/group/day were collected. Wounds reepithelialization was assessed and histological parameters (inflammatory cells, blood vessels, fibroblasts and the percentage of collagen area) were analyzed by HE and Gomori's trichrome

staining. DM-F1 group showed higher reepithelialization rates than DM-sham ($p=0.0026$) and all wounds were re-epithelialized on the 14th day, different from N-F1 group. In a similar way, DM-F1 group showed higher collagenesis then DM-sham ($p=0.0001$), different from N-F1; fibroplasia was more evident for DM-F1 ($p=0.0001$) on the 14th and 21st days. Interestingly, these results can be associated with higher reepithelialization of wounds treated with DM-F1. The metabolic status of diabetes induced chemotaxis of inflammatory cells to the skin, that increased with the injury up to the 7th day ($p=0.0026$), mainly when wounds were treated with DM-F1. Angiogenesis was more pronounced for DM-F1 group on the 7th an 14th days. The inflammatory process triggered by the metabolic stress of diabetes mellitus seemed to add and interact with the stimulus induced by F1, accelerating the cutaneous wound healing when compared to non-diabetic groups.

Distribution of variables reepithelialization by Wound Healing Rate (WHR), inflammatory infiltrate, angiogenesis, fibroplasia and collagenesis of wounds treated topically with F1 (F1 groups) and non-treated (sham groups) in non-diabetic (N-F1 ou N-sham) and diabetic (DM-F1 or DM-sham) rats, for 2, 7, 14 and 21 days of follow-up.



Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Prevalence of Microalbuminuria in Galicia (NW Spain) and its association with risk factors: Hypertension, Type 2 diabetes mellitus and Pre-diabetes.**

M. Tomé[1,2,3], M. López-Ratón[2], M. Botana-López[3] & C. Cadarso-Suarez[2]
[1]Hospital Clinico Universitario, Santiago de Compostela, Spain; [2]Facultad de Medicina, Santiago de Compostela, Spain; [3]Hospital Lucus Augusti, Lugo, Spain.

Introduction
Microalbuminuria tends to appear in Type 2 diabetes (T2D) and reflecting underlying cardiovascular disease rather than diabetic nephropathy presented at diagnosis. The objective of this study was to evaluate the prevalence of microalbuminuria and its possible relations with T2D, pre-diabetes and hypertension, in a representative sample ($n=2860$) of the adult population ($>18$ years old) of Galicia (NW Spain).
Material and methods
Subjects were selected through a two-step cluster sampling procedure from the Galician public health service database, which covers more than 95% of the population. The criteria recommended by the Expert Committee on the Diagnosis and Classification of Diabetes Mellitus (2002) were used to establish the existence of T2D or pre-diabetes (presence of impaired fasting glucose (IFG), impaired glucose tolerance (IGT) or both). Chi-square and/or exact Fisher tests and odds ratio association measure were used for assessing the association of categorical covariates. Statistical significance was indicated by $p<0.05$.
Results
The overall prevalence of microalbuminuria in the adult Galician population, defined as persistent albumin excretion between 30–300 mg/day or 20–200 µg/min, was 4.7%, with significant differences by age ($p<0.001$), but without differences by gender ($p=0.095$).
14.9% of the diabetic subjects had microalbuminuria and it increased to 8.1% among hypertensive subjects. This prevalence increased with age, being higher in males than in females (10.2% versus 5.2%). Considering diabetes + hypertension, prevalence increased up to 19.4%. All of these pathologies showed a significant association with microalbuminuria ($p<0.001$ in all cases), Hypertension: OR = 2.393 (1.672–3.426); Diabetes: OR = 4.445 (2.914–6.781); Hypertension + Diabetes: OR = 5.869 (3.663–9.403). However, there wasn't association between pre-diabetes and microalbuminuria ($p=0.423$).
Conclusions
The prevalence of microalbuminuria in Galicia was 4.7%. Significant association was observed between microalbuminuria and T2D and HTA. No significant relation was observed with pre-diabetes, thus it's very important to prevent the transition from pre-diabetes to T2D or to early detection/control of high blood pressure.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

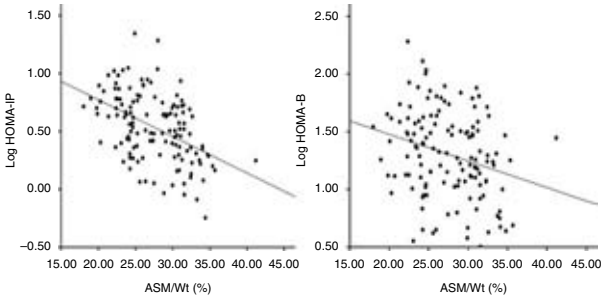
**Sarcopenic phenotype in patients with newly diagnosed type 2 diabetes**

J. Son[1], H. Jeong[1], S. Lee[1], S. Kim[1], D. Kim[2] & S. Yoo[1]
The Hallym University, Seoul, Republic of Korea.

Objective - Sarcopenic phenotype is associated with the increased risk of insulin resistance and type 2 diabetes. We investigated the proportion of sarcopenia and sarcopenic obesity (SO) and their clinical characteristics in patients with newly diagnosed type 2 diabetes.
Research design and methods - We conducted a cross-sectional analysis of 133 (75 men, 58 women) patients with newly diagnosed type 2 diabetes. All patients underwent a 75 g oral glucose tolerance test. Sacopenia was assessed by appendicular skeletal muscle mass(ASM)/weight (%) using dual-energy X-ray absorptiometry and obesity was assessed by a visceral fat area using computed tomography.
Results - The mean age of the subjects was $47\pm12$ years, the mean HbA1c level was $10.59\pm1.94\%$ and the mean body mass index was $25.5\pm3.4$ kg/m$^2$. ASM/weight (%) was inversely associated with the log-transformed homeostasis model assessment of insulin resistance (HOMA-IR) and HOMA-β. The proportion of obesity, sarcopenia and SO was 23.3%, 16.5% and 35.3%, respectively. Sarcopenic phenotype was more prevalent in women than in men (Sarcopenia 29.3% vs. 6.7% and, SO 44.8% vs. 28%, respectively). In comparison to normal phenotype (neither obese nor sarcopenia), SO was significantly associated with higher degree of HOMA-β and the surrogate markers of insulin resistance (HOMA-IR and insulin sensitivity index composite). Notably, SO subjects were more insulin resistant compared to obese without sarcopenia subjects, although there was no significant difference in HbA1c between two groups.
Conclusions - We found the high proportion of sarcopenia and SO in patients with newly diagnosed type 2 diabetes. Among metabolic phenotype, SO was strongly associated with the degree of insulin resistance and compensated hyperinsulinemia in the early phase type 2 diabetes.

**Table 1** The proportion of each metabolic phenotype in patients with newly diagnosed type 2 diabetes

| | Male(%) | Female(%) | Total(%) |
|---|---|---|---|
| Normal | 24(32.0) | 9(15.5) | 33(24.8) |
| Sarcopenia | 5(6.7) | 17(29.3) | 22(16.5) |
| Obesity | 25(33.3) | 6(10.4) | 31(23.3) |
| Sarcopenic Obesity | 21(28.0) | 26(44.8) | 47(35.3) |
| total | 75(100) | 58(100) | 133(100) |



**Relationship of sarcopenic index with log HOMA-IR and log HOMA-B**

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Type 2 diabetes mellitus and Ramadan fasting: a continuous glucose monitoring (CGM) study of glucose excursions in a group of patients with good glycaemic control

N. Lessan[1], H. Hasan[2] & M. Barakat[1]
[1]Imperial College London Diabetes Centre, Abu Dhabi, United Arab Emirates; [2]University of Sharjah, Sharjah, United Arab Emirates.

Introduction
Muslims including many patients with diabetes mellitus practice dawn to sunset fasting during the month of Ramadan. Using CGM recorded data we have investigated glucose excursions with Ramadan fasting in a group of patients with type 2 diabetes mellitus and good glycaemic control.
Methods
Thirty-four patients with type 2 diabetes mellitus (8 female, 26 male, age 46.5±11.1 years, HbA1c 6.9±1.0%, BMI 29.5±6.5 kg/m$^2$) underwent CGM for a minimum of three consecutive days during Ramadan fasting. Comparison with non-fasting CGM was made. Diabetes treatment ranged from none to a mixture of insulin and oral hypoglycaemic agents. Any change in treatment dose/timing during Ramadan followed ADA guidelines. Using CGM sensor values for average (avG), minimum (minG) and maximum (maxG) glucose, duration of time below lower limit (<80 mg/dl-DBL), within limit (80–150 mg/dl-DWL) and above higher limit (>150 mg/dl-DAL) for each patient, mean & SD values were obtained for the group as a whole during and outside Ramadan fasting periods. Comparison was made using paired t-test (SPSS 20).
Results
The group had good glycaemic control as indicated by HbA1c and mean CGM glucose. There were no statistically significant differences in avG, minG, maxG, DBL, DWL or DAL outside and during Ramadan fasting (Table 1). During Ramadan fasting period mean CGM curve showed a characteristic rapid rise in CGM recorded glucose at iftar time.
Conclusion
In this group of patients with good glycaemic control, overall CGM measures of glucose control and excursions show no significant changes with Ramadan fasting. However, timing and pattern of glucose fluctuations were different with a major rise at time of evening meal. Management during Ramadan should specifically address these areas.

**Table 1**

### High GADA titre: a marker of insulin dependence in adult onset autoimmune diabetes

M. Spoletini[1], S. Zampetti[1], M. Capizzi[1], C. Tiberti[1], C. Venditti[1], G. Campagna[1], E. Bosi[2], R. Buzzetti[1] & Nirad Study Group Italian Society of Diabetes[1]
[1]Sapienza University, Rome, Italy; [2]San Raffaele Vita-Salute University, Milan, Italy.

Introduction
In latent autoimmune diabetes of adults (LADA), the progression to insulin-dependent diabetes is usually faster than in type 2 diabetes (T2DM) but the factors influencing this progression are not completely known. The aim of the present study was to determine whether GADA could be used as predictors of insulin dependence and whether GADA titre could define the risk of progression to insulin therapy in LADA patients. We looked for other biochemical and clinical parameters associated with early development of insulin dependence.
Methods
Adult onset GADA positive autoimmune diabetes subjects (n=191) were selected from the Non Insulin Requiring Autoimmune Diabetes (NIRAD) cohort of 4,250 T2DM subjects. GADA titre showed a bimodal distribution which identified two subgroups of patients with high (>32 GADA U) or low GADA titre (≤32 GADA U). One hundred ninety one GADA positive patients were followed for 6 years from diagnosis to evaluate the progression of patients started insulin therapy. Kaplan-Meir curves were plotted and log-rank test was performed to identify possible markers capable to influence the progression to insulin dependence. During the follow up 6/191 GADA positive patients dropped out from the study.
Results
The number of LADA patients who required insulin therapy was 93/191 (48.7%). We observed, that a significant higher number of high GADA titre patients 61/93 (65.6%) progressed to insulin dependence within 6 years of diagnosis compared to low GADA titre patients 32/93 (34.4%) (p=0.003). LADA patients with BMI<25 kg/m$^2$ could have a faster progression towards insulin therapy compared to patients with BMI ≧ 25 kg/m$^2$ (p=0.07).
Conclusion
We observed that neither TPO Ab titre neither gender were predictive markers of progression to insulin dependence. High GADA titre is a marker of progression towards insulin dependence in LADA patients.

**Aerobic and resistance exercise have different short-term effects on glucose levels in type 2 diabetes subjects**

E. Bacchi[1], C. Negri[2], M. Trombetta[1,2], E. Zanolin[1], M. Lanza[1], E. Bonora[1,2] & P. Moghetti[1,2]
[1]University of Verona, Verona, Italy; [2]Azienda Ospedaliera Universitaria Integrata, Verona, Italy.

Introduction
Aerobic (AER) and resistance (RES) exercise similarly improve HbA1c levels in type 2 diabetes subjects. However, it is still unknown whether exercise-induced acute changes in blood glucose differ according to exercise type. Our aim was to compare glucose level changes after a single bout of AER or RES exercise in trained diabetic subjects.
Methods
Twenty-five subjects participating in the RAED2 Study, a RCT designed to compare the effects of AER and RES training in diabetic patients, were submitted to a continuous glucose monitoring during a 60-min exercise and the following 48-h. Glucose concentration areas under the curve (AUC) during exercise, the subsequent night, and the 24-h period following the exercise, as well as the corresponding periods of the non-exercise day, and the low (LBGI) and high (HBGI) blood glucose indices, which summarize duration and extent of hypoglycaemia or hyperglycaemia, respectively, were assessed.
Results
AER and RES groups showed similar HbA1c improvements after training. However, comparison of glucose AUC during the 60-min exercise and the corresponding period of the non-exercise day showed different behaviors between groups (time-by-group interaction, $p=0.04$), glucose being lower during exercise in the AER but not in the RES group. Similar differences between groups were observed in the comparison of nocturnal periods of exercise and non-exercise days ($p=0.02$). Consistently, in the AER group nocturnal LBGI was higher in the exercise day than in the non-exercise day ($p=0.012$), whereas there were no differences in the RES group.
Conclusion
Although AER and RES training show similar long-term metabolic effects in diabetic subjects, the short-term effects of single bouts of these exercise types differ, with a potential increase in risk of late-onset hypoglycaemia after AER exercise. These findings suggest that, in diabetic subjects, medications and diet adjustments to exercise should take into account the scheduled type of physical activity.

**Regulation of somatostatin/cortistatin and ghrelin systems under diet induced obesity conditions at the mouse endocrine pancreas**

A. Martínez-Fuentes[1,2,3], B. Chanclón[1,2,3], R. Luque[1,2,3], J. Córdoba-Chacón[1,2,3], A. Pozo-Salas[1,2,3], L. de Lecea[4], J. Castaño[1,2,3] & F. Gracia-Navarro[1,2,3]
[1]Maimœnides Institute for Biomedical Research (IMIBIC), Cœrdoba, Spain. [2]CIBER FisiopatologÚa de la Obesidad y Nutriciœn, Instituto de Salud Carlos III, Cœrdoba, Spain. [3]Stanford University School of Medicine, Palo Alto, CA, USA.

Somatostatin (SST), Cortistatin (CORT), ghrelin, and their corresponding receptors (ssts and GHS-R) are closely interrelated systems involved in the regulation of essential hormones for metabolic homeostasis, like insulin, whose release is inhibited by SST/CORT and stimulated by ghrelin. To investigate the underlying mechanisms of this insulin regulation, we analyzed the expression of such systems at pancreatic level in wild type (WT) and CORT knock-out mice (CORT-KO) under both normal, low fat (LF) and high fat (HF) diets. Pancreatic tissue was processed for either direct RNA isolation or islet culture, and expression of distinct components of SS/CORT/ghrelin systems was analyzed by quantitative RT-PCR. Results reveal that SST, ghrelin and their receptors are expressed in both whole pancreas and endocrine islets of WT and CORT-KO mice, being their expression levels variable depending upon the peptide and receptor subtype analyzed. CORT expression was not detected in neither whole nor endocrine pancreas of WT-mice. SST levels remain unaltered in obese animals (HF), while ghrelin expression increased exclusively in WT obese mice. When the expression of the systems analyzed was compared between WT and CORT-KO mice, we found that expression levels of ghrelin, GHS-R, ghrelin o-acyl-transferase (GOAT) and insulin (In-2) were significantly reduced in obese mice. Interestingly, blood insulin levels were significantly lower in CORT-KO than those of WT animals. Taken together, our data reveal that key components of the SST/ghrelin/receptors systems are tightly regulated in the pancreas of WT and CORT-KO under normal and obesity conditions, suggesting that both systems may play a relevant role at the endocrine pancreas under normal physiological conditions and/or in response to extreme metabolic conditions (obesity). Moreover, the fact that circulating insulin levels are significantly diminished in CORT-KO mice strongly suggests that endogenous CORT is an important modulator of pancreatic function.

**Influence of iron metabolism indices on HbA1c in non-diabetic pregnant women with and without iron-deficiency anemia: effect of iron supplementation**

D. Rafat, T. Rabbani, J. Ahmad & M. Ansari
Faculty of Medicine, J. N. Medical College Hospital, Aligarh Muslim University, Aligarh, India.

Aims
Condition that influence erythrocyte turnover also affect HbA1c. Although many forms of anemia are associated with lowering of HbA1c, iron-deficiency anemia (IDA) tends to increase HbA1c. In this study, we examined the relationship between HbA1c and erythrocyte indices in non-diabetic pregnancy and assessed the effect of iron supplementation on HbA1c.
Methods
150 women were studied (30 non-diabetic, non-pregnant, non-anemic women in child bearing women with varying parity as controls (Gp 1); 30 non-diabetic, non-anemic pregnant women in first trimester of pregnancy (Gp 2a); 30 non-diabetic, non-anemic pregnant women in second trimester of pregnancy (Gp 2b); 30 non-diabetic, non-anemic pregnant women in third trimester of pregnancy (Gp 2c) and 30 non-diabetic pregnant women with IDA (Gp 2d). HbA1c, OGTT, erythrocyte indices and iron metabolic indices were determined in Gp 2d subjects not supplemented with iron and repeated these indices after 3 months of iron-supplementation.
Results
The mean fasting and postprandial blood glucose levels ($79.9\pm8.0$ mg/dl, $108.1\pm14.1$ mg/dl) in Gp 1 were found to be significantly lower in first trimester among Gp 2a ($74.4\pm5.3$ mg/dl and $97.2\pm11.1$ mg/dl, in second trimester among Gp 2b ($76.2\pm5.2$ mg/dl and $103.4\pm7.9$ mg/dl) followed by increase in IIIrd trimester among Gp 2c ($82.3\pm5.7$ mg/dl and $112.5\pm8.5$ mg/dl) subjects. A significant difference in HbA1c was also observed among the groups (HbA1c $4.7\pm0.3\%$ in Gp 1; $4.6\pm0.4\%$ in Gp 2a; $4.5\pm0.3$ in Gp 2b; $4.7\pm0.3$ in Gp 2c). Among Gp 2d subjects, HbA1c was $5.2\pm0.3\%$ and the level decreased after iron supplementation to $5.1\pm0.3\%$. Significant correlation between erythrocyte indices, iron metabolic indices and HbA1c was also observed. We conclude that consideration should be given for performing glucose testing in patients with IDA to ascertain the reliability of HbA1c in the diagnosis of diabetes. HbA1c concentrations in diabetic patients with IDA should be interpreted with caution

**Both β-cell dysfunction and insulin resistance are primary determinants of diabetes mellitus in patients with liver cirrhosis candidate to organ transplant**

V Grancini[1], E Lunati[1], L Boselli[2], B Masserini[1], D Zimbalatti[1], F Agnelli[3], R Bonadonna[2], P Beck-Peccoz[1] & E Orsi[1]
[1]University of Milan and IRCCS Ca' Granda Foundation, Milan, Italy; [2]University of Verona and Azienda Ospedaliera Universitaria Integrata, Verona, Italy; [3]Azienda Ospedaliera Ospedale Niguarda Ca' Granda, Milan, Italy.

Background
Impaired glucose (G) regulation (IGR) and diabetes mellitus (DM) are common in patients with liver cirrhosis. DM development has been associated to advanced

liver disease (LD) and HCV infection. The relative roles played by insulin secretion and action, advanced LD and HCV infection in DM are somewhat unclear.
Aim of the study
To assess in cirrhotic patients candidate to organ transplantation with no history of G abnormalities: i) prevalence of altered G homeostasis; ii) β-cell function (βF); and iii) insulin resistance.
Materials and methods
104 patients, 33M/71F, age 53±9 years, with liver cirrhosis (HCV +/HCV− = 44/60), with normal fasting G (5.2±0.11 mmol/l) and with HbA1c of 4.9± 0.08%. βF was assessed by state-of-art modeling of G/C-peptide curves during a 180′ sampled OGTT, thereby providing the β-cell responses to the rate of G increase (derivative control: DC) and to G concentration (proportional control: PC). Insulin resistance was estimated by the HOMA index (HOMA-IR).
Results
13 patients had normal G regulation (NGR), 35 had IGR, 56 had DM. HOMA-IR steadily increased with declining G tolerance ($P=0.065$), and it was higher in HCV+ than in HCV- patients (5.7±0.7 vs 4.5±0.5, $P=0.023$). Both DC and PC gradually declined from NGR to IGR to DM ($P<0.01$ for both). Child-Pugh score, HCV infection and alcoholic LD were neither related to alterations in G regulation ($P=0.13$–$0.99$) nor to βF ($P=0.55$–$0.88$). In a multivariate model, HOMA-IR ($P=0.014$) and betaF ($P=0.017$), but no LD related parameter ($P=0.40$–$0.78$), were independent 'predictors' of DM.
Conclusions
In cirrhotic patients, altered G homeostasis, including DM, is due primarily to alterations in both βF and insulin action, neither of which apparently is influenced by alcohol or severity of LD. HCV infection might play a role in deteriorating G homeostasis via insulin resistance.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### The effects of fat distribution and some adipokines on insulin resistance in prediabetic patients

B Ekiz Bilir, S Guldiken, N Tuncbilek, M Demir & A Polat
Trakya University Medical Faculty, Edirne, Turkey.

Introduction
In this study, we aimed to evaluate the effects of fat distribution and some adipokines on insulin resistance (IR) in prediabetic patients.
Materials and Methods
cases were divided into three groups according to 75 gr-oral glucose tolerance test (OGTT) results [27 cases impaired fasting glucose (IFG), 36 cases impaired glucose tolerance (IGT) and 24 healthy control subjects]. Serum fasting insulin levels and lipid parameters were measured. Homeostatic model assessment of insulin resistance (HOMA-IR) was calculated. Body fat mass measurements were assessed by TANITA. Abdominal fat distributions (visceral, subcutaneous, preperitoneal fat thickness) were evaluated by ultrasonography. The fasting serum levels of adipokines [adiponectin, leptin, resistin, vaspin, visfatin, retinol-binding protein 4 (RBP4), tumor necrosis factor-α (TNF-α)] were measured by ELISA method.
Results
There were no differences between groups in terms of the age, sex, body mass index (BMI), mean insulin, lipid parameters, vaspin, RBP4, leptin, resistin, TNF-α, abdominal fat distributions, fat mass measurements. There were significant differences between groups in terms of HOMA-IR values, adiponectin and visfatin (NGT-IFG groups $P>0.05$, $P<0.001$, $P<0.05$; NGT-IGT groups $P<0.05$, $P<0.01$, $P<0.001$ respectively). There was significant correlation between HOMA-IR and BMI values ($r=0.367$, $P<0.01$), waist circumference ($r=0.361$, $P<0,05$), OGTT 2nd hour-glucose ($r=0.282$, $P<0.05$), total fat percentage ($r=0.308$, $P<0,05$), total fat mass ($r=0.411$, $P<0.01$), visceral fat thickness ($r=0.395$, $P=0.01$), adiponectin ($r=-0.322$, $P<0.05$) and resistin ($r=0.245$, $P=0.05$) levels in the prediabetic group. In regression analysis, visceral fat thickness was found to be an independent risk factor for development of insulin resistance ($P<0.001$, B=0.438, 95% CI 0.01–0.039).
Conclusion
In this study, we concluded that adiponectin and resistin affected the insulin resistance in prediabetic patients and especially the increments in visceral fat thickness had negative effects on insulin resistance.

### New fast and reversible leptin antagonist-induced mice model of metabolic syndrome and T2DM

G Solomon[1], E Monsonego-Ornan[1], N Chapnik[1], E Smith[2], O Froy[1], D D'Alessio[2] & A Gertler[1]
[1]The Hebrew University of Jerusalem, Rehovot, Israel; [2]University of Cincinnati, Cincinnati, Ohio , USA.

Obesity and its major consequence, type II diabetes mellitus (T2DM), is epidemic throughout Western society. T2DM accounts for 95% of the diabetes worldwide. One limitation to the development of new diabetes treatments has been a lack of effective animal models to use in research. There are no rodent models that recapitulate the pancreatic β-cell lesions of humans with T2DM. Moreover, animal models of obesity either require overfeeding which is expensive and takes weeks to months to establish, or specific genetic mutations that cause lifelong metabolic dysfunction. Thus the ability to rapidly induce obesity in healthy rat and mouse strains would be a major advance that could enhance research in diabetes and obesity and the development of novel therapies. We have recently developed superactive mouse leptin antagonist (D23L/L39A/D40A/F41A). Mono-pegylated antagonist (PEG-SMLA) is orexigenic, and when given to mice every 24–48 h for 2–3 weeks leads to weight gain of nearly 50% with primarily fat accumulation. PEG-SMLA -induced weight gain is accompanied by elevated fasting glucose and glucose intolerance with hyperinsulinemia, higher plasma cholesterol and TGs, and a dramatic rise of corticosterone. These changes were fully reversible with cessation of PEG-SMLA injections, and disappeared within 10–14 days. 1 month exposure to PEG-SMLA altered the expression of key regulatory genes in adipose tissue, muscle and brain. These findings indicate that leptin antagonism induces systemic dysmetabolism in a rapid, practical manner, and provides a valuable tool for research in obesity and diabetes.

**Table 1** Relative expression of several genes in adipose tissue, brain and muscle.

### High-fructose diet, an animal model of insulin resistance, causes mitochondrial dysfunction by altering the activity of respiratory chain complex I

C Sánchez-Martín[1], M Sanz[1,2], D Detaille[3], J Recio-Córdova[1], F Peralta[4] & G R-Villanueva[1]
[1]University of Salamanca, Salamanca, Spain; [2]Institut Cochin, INSERM U-1016, Paris, France; [3]INSERM U884, Université Joseph Fourier, Grenoble, France; [4]Nuestra Señora de Sonsoles Hospital, Avila, Spain.

Introduction
The current epidemic of Type 2 Diabetes Mellitus (T2DM) and obesity is positively correlated with a rise in consumption of high-fructose syrups and refined carbohydrates. Recent reports have showed that feeding rodent a high-fructose diet leads to insulin resistance, glucose intolerance and dyslipidaemia. Nevertheless, its mitochondrial effects has not been fully studied yet.
Aim
We decided to explore the alterations in mitochondrial bioenergetics induced in high-fructose fed rats, as well as the underlying mechanisms.
Materials and methods
Male Wistar rats were separated in two different groups and received either a standard diet or the high-fructose diet during 6 weeks. Liver mitochondria were isolated from fed animals by standard differential centrifugation. Oxygen consumption rates were measured at 30 °C using a Clark-type oxygen electrode whereas ROS production was assayed by incubating mitochondria in a stirred 2 ml volume with 10 UI horseradish peroxidase and 2 μM Amplex Red. Moreover, the activity of mitochondrial respiratory chain complexes I, II and III were spectrophotometrically determined.
Results
High-fructose diet inhibited oxygen consumption (JO2) when glutamate and malate (GM) or succinate and malate (SM) were used as energetic substrate. This inhibition affected the state three of respiration (in the presence of ADP) and the uncoupled state (after addition of dinitrophenol). On the other hand, after addition of rotenone that stimulates ROS production in presence of GM, mitochondria isolated from fructose-fed rats showed lower ROS production. By using SM as respiratory substrate, high-fructose diet also reduced ROS production. Finally, we found that complex I activity was significantly inhibited by feeding a high-fructose diet.
Conclusions
Our data show that high-fructose diet diminishes respiratory complex I activity leading to a reduction of both ROS production and mitochondrial respiration. This new finding could contribute to the knowledge of the mechanisms involved in mitochondrial dysfunction in type two diabetes.

### Does the presence of thyroid antibodies affect the course and outcome of pregnancy in type1 diabetic women?

V Sarantopoulou, G Philippou, V Vasileiou, P Lymberi, L Sarika, M Alevizaki & E Anastasiou
Alexandra hospital, Athens, Greece.

Introduction
In the literature there are only three papers so far, addressing the impact of thyroid antibodies (Anti-TPO) on pregnancy in Type1 Diabetic Women (DM1) and these present conflicting results. The aim of the study is to evaluate the presence of Anti-TPO in DM1 pregnant women and whether these are related with differences in thyroid function, metabolic control and pregnancy outcome.
Methods
In 78 DM1 women with singleton pregnancies Anti-TPO, Anti-Tg, TSH, FT4I (T4/TBC) were measured each trimester. At each visit (every 1–2 weeks) blood glucose, HbA1c, BMI, units of insulin/kg were recorded, as were complications and pregnancy outcome.
Results
27/78 women (34.6%) presented with positive Anti-TPO Abs. Clinical data of Anti-TPO positive and negative women are as shown in the table.
First trimester TSH levels were statistically different between the two groups.
There were no differences in the prevalence of diabetic complications, gestational hypertension-preclampsia, abortions or preterm deliveries.
Conclusion
One third of DM1 pregnant women presented with positive Anti-TPO Abs. However their presence is not related with worse metabolic control or adverse pregnancy outcome. It seems that early treatment of thyroid dysfunction and stricter metabolic control a plays more important role than the presence of thyroid antibodies with regard to the pregnancy outcome.

### The association between insulin-like-growth-factor I and insulin resistance: a general population study in danish adults

N Friedrich[1], B Thuesen[2], T Jørgensen[2,3], A Juul[4], C Spielhagen[1], H Wallaschofski[1] & A Linneberg[2]
[1]University Medicine Greifswald, Greifswald, Germany; [2]Research Centre for Prevention and Health, Glostrup, Denmark; [3]University of Copenhagen, Copenhagen, Denmark; [4]Rigshospitalet, Copenhagen, Denmark.

Objective
IGF1 has almost 50% amino acid sequence homology with insulin and elicits nearly the same hypoglycaemic response. Studies showed that low and high IGF1 levels are related to impaired glucose tolerance and to a higher risk of type two diabetes. The aim of the present study was to evaluate the association between IGF1 level and insulin resistance in a Danish general population.
Research Design and Methods
From the cross-sectional Health2006 study 3354 adults aged 19 – 72 years were included. The homeostasis model assessment of insulin resistance (HOMA-IR) was used as the index to estimate insulin resistance. Serum IGF1 levels were determined by an immunoassay and grouped into quintiles (Q1–Q5). Linear or multinomial logistic regression analyses were performed.
Results
In the study population 520 subjects (15.5%) had increased HOMA-IR values above 2.5. After adjustment for age, sex, physical activity and waist-to-height ratio, an U shaped association between IGF1 and HOMA-IR was found. Low IGF1 [Q1: OR 1.64 (95% CI 1.15; 2.33), $P<0.01$] as well as high IGF1 [Q5: OR 1.96 (95% CI 1.38; 2.79), $P<0.01$] levels were related to a higher odds of increased HOMA-IR values compared to subjects with intermediate (Q3) IGF1 levels. These associations remained statistically significant after the exclusion of subjects with type two diabetes mellitus and by using the updated computer HOMA2-IR model.
Conclusions
In conclusion, low- as well as high-normal IGF1 levels, are both related to insulin resistance. The biological mechanism of this complex phenomenon has to be elucidated in more detail for future risk stratification.

**Alterations in fecal lactobacillus and bifidobacterium species are associated with differences in cholesterol metabolism in type 2 diabetic patients**

H Hui[1,5], D Cai[1], K Lê[1,3], Y Li[1], X Xu[1], T Liu[1], W Yang[1,2], F He[1,2], X Zhao[1,2], K Su[1,2], S Pandol[1,4,5] & V Go[1,4,5]
[1]Southern Medical University, Guangzhou, China; [2]Dongguan SMU Metabolic Medcine Inc, Dongguan, China; [3]Nestlé Research Center, Lausanne, Switzerland; [4]VA Greater Los Angeles Health Care System, Los Angeles, California, USA; [5]David Geffen School of Medicine at UCLA, Los Angeles, California, USA.

Background
Type 2 diabetic (T2D) patients have alterations in the gut microbiota composition, compared to healthy individuals. Such alterations may play a role in the pathogenesis of T2D and insulin resistance. Bifidobacteria and Lactobacillus are among the most predominant bacteria found in human gut. They can also easily be added in probiotic preparations, thus making them ideal agents for therapeutic interventions. In this study, we aimed to determine if there were alterations in a selected group of fecal Lactobacillus and Bifidobacterium species in T2D patients compared to a control group of patients, and to determine if there were metabolic measures associated with any of bacterial species in the T2D patients.
Methods
Fifty patients with T2D and thirty control individuals of similar BMI were recruited from Southern China. The bacteria species were chosen because of their relevance to probiotic preparations; their fecal amount was measured by real-time quantitative PCR. Insulin sensitivity was measured by an OGTT.
Results
T2D patients had significantly ($P<0.05$) more total Lactobacillus (+17%), L. bugaricus (+13%), L. Rahmnosum (+37%) and L. acidophilus (+17%). In contrast, they had less amounts of total Bifidobacterium (−7%) and B. adolescentis (−12%) ($P<0.05$ both). Cluster analysis showed that gut microbiota pattern of T2D patients is characterized by greater number of *L. Rhamnosus* and *L. Acidophillus*, together with lesser number of B. adolescentis ($P<0.05$). Several of these bacteria were significantly associated with total cholesterol levels ($P<0.05$).
Conclusion
The gut microflora in T2D patients is characterized by greater numbers of Lactobacillus and lesser numbers of Bifidobacterium species. The changes are associated with cholesterol levels suggesting that they play a role in influencing cholesterol metabolism in T2D patients.

## P559

**Low testosterone is associated with decreased expression of glut-4 and hexokinase 2 in muscle of the testicular feminised mouse**

D McLaren[1], D Kelly[1], S Akhtar[1], K Channer[2] & T Jones[1,3]
[1]University of Sheffield, Sheffield, UK; [2]Sheffield Teaching Hospitals, NHS Foundation Trust, Sheffield, UK; [3]Barnsley Hospital NHS Foundation Trust, Sheffield, UK.

Testosterone deficiency is a common in men with type two diabetes (T2D). We have shown testosterone replacement therapy (TRT) improves insulin resistance and glycaemic control. The mechanisms by which testosterone mediates this action are unknown but may be due to a combination of effects on muscle, liver and adipose tissues. This study investigates the expression of Glut4 and HK2, (two key proteins involved in insulin sensitivity) in muscle tissue of the testicular feminised (Tfm) mouse which exhibit non-functional androgen receptors and low circulating testosterone.

Tfm mice were fed a high-cholesterol diet ad libitum for 28 weeks and received either physiological testosterone replacement (mixed testosterone esters, Sustanon100) or placebo (saline) and were compared to wild-type littermates (WT). Striated muscles tissue was collected from the thigh. Expression of Glut 4 and HK2 mRNA and protein expression was analysed by qPCR and Western blotting.

There was a significant decrease in the relative mRNA expression of Glut−4 ($0.59\pm0.14$, $P=0.02$) and HK2 ($0.5\pm0.16$, $P=0.01$) in Tfm mice compared to WT. TRT did not significantly alter mRNA expression of Glut4 or HK2. Western blotting confirmed reduced protein expression of HK2 ($0.33\pm0.09$ vs $0.04\pm0.01$, $P=0.005$) and Glut4 ($1.05\pm0.22$ vs $0.57\pm0.07$, $P=0.037$) in Tfm mice compared to WT. TRT showed no change in HK2 protein expression compared to Tfm placebo ($0.05\pm0.02$ vs $0.04\pm0.01$, $P=0.627$), but an increase in Glut4 was observed ($1.09\pm0.16$ vs $0.57\pm0.07$, $P=0.005$).

Testosterone deficiency is associated with decreased expression of Glut4 and HK2. TRT did not have any effect on HK2 in the Tfm mouse suggesting that testosterone acts via the androgen receptor to stimulate HK2 expression. Although testosterone failed to increase Glut4 mRNA in the Tfm an increase in protein was observed indicating that post-translational mechanisms are involved. This study shows that testosterone has important actions on modulating glucose metabolism in muscle. This may explain part of the mechanism by which testosterone improves insulin sensitivity in T2D.

**Serum visfatin is differentially regulated by insulin and non-esterified fatty acids in healthy men**

I Kowalska, M Karczewska-Kupczewska, A Adamska, A Nikolajuk, N Kaminska, M Zielinska, E Otziomek, M Gorska & M Straczkowski
Medical University of Bialystok, Bialystok, Poland.

Introduction
Visfatin is a protein secreted by adipose tissue which was discovered as a protein with insulin-mimetic properties. Experimental and clinical studies demonstrated that visfatin can be involved in the pathogenesis of insulin resistance. It was demonstrated that plasma visfatin is elevated in insulin resistant states i.e. obesity, type two diabetes mellitus, PCOS. *In vitro* study showed that insulin inhibits visfatin release from adipocytes. The aim of the present study was to evaluate serum visfatin concentration during hyperinsulinemia (6 h hyperinsulinemic euglycemic clamp) and than during insulin resistant conditions caused by an acute elevation of NEFA (6 h hyperinsulinemic clamp combined with Intralipid – heparin infusion).
Materials and methods
The study group consisted of 19 apparently healthy male volunteers (mean age $25.1\pm3.1$ years, BMI-$26.7\pm4.7$ kg/m$^2$). Clinical examination, anthropometric measurements, OGTT, plasma lipids and liver enzymes activity were measured. Subjects underwent 6 h euglycemic hyperinsulinemic clamp and after one week 6 h hyperinsulinemic euglycemic clamp combined with Intralipid – heparin infusion. Measurements of serum visfatin during both clamp studies were performed.
Results
6 h of insulin infusion during clamp resulted in significant decrease in serum visfatin concentration ($P=0.0057$), however after 2 h there was no change in

serum visfatin concentration ($P=0.097$). Concomitant Intralipid-heparin infusion which caused a significant increase in NEFA concentration ($P<0.0001$), resulted in marked increase in serum visfatin ($P=0.00035$) which was already observed after 2 h of Intralipid infusion ($P=0.00028$). Serum visfatin during clamp study after 2 h and 6 h of Intralipid infusion were significantly higher than respective values during clamp study without elevation of NEFA (both $P<0.0001$). The increase of serum visfatin during Intralipid infusion (δ visfatin) was positively related to body weight ($r=0.54$, $P=0.016$), %body fat ($r=0.48$, $P=0.036$) and GGTP ($r=0.56$, $P=0.011$).
Conclusion
Our data show that plasma visfatin is differentially regulated by insulin and NEFA. One might suggest that induction of insulin resistance by NEFA suppress insulin inhibition of visfatin production by adipose tissue, resulting in plasma visfatin increase in insulin resistant conditions.

**Mitochondrial impairment and oxidative stress in leukocytes from type 2 diabetic patients**

V Victor, C Bañuls, L Bellod, S Rovira, R Falcon, M Rocha & A Hernandez-Mijares
Hospital Dr Peset, Valencia, Spain.

Diabetes is associated with oxidative stress. This study evaluated the rates of oxidative stress and mitochondrial impairment in type 2 diabetes patients. The study population consisted of 182 diabetic patients and 50 body-composition- and age-matched controls. We assessed anthropometric and metabolic parameters and mitochondrial function by evaluating mitochondrial oxygen (O2) consumption, reactive oxygen species (ROS) production, glutathione (GSH) levels, GSH/GSSG ratio, mitochondrial membrane potential, and mitochondrial complex I activity in polymorphonuclear cells from diabetes type 2 patients. We found an increase in waist circumference and augmented serum levels of triglycerides, proinflammatory cytokines (IL-6 and TNF-α), homocysteine, glycated hemoglobin, ultrasensitive C-reactive protein, glucose, insulin, and homeostasis model assessment of insulin resistance score in diabetic patients versus controls. There was an impairment of mitochondrial function in diabetic patients, evidenced by a decrease in mitochondrial O2 consumption, an increase in ROS production, decreased GSH/GSSG ratio, a drop in GSH levels, and an undermining of the mitochondrial membrane potential. Furthermore, an impairment of mitochondrial complex I was detected. This study supports the hypothesis of an association of type 2 diabetes and the rate of impaired mitochondrial function. We also propose that one of the targets of oxidative stress responsible for diabetes is mitochondrial complex I.
Declaration of interest

**High prevalence of autoimmunity in adult onset diabetes subjects with high GADA titre**

S Zampetti[1], M Capizzi[1], M Spoletini[1], G Campagna[1], L Cipolloni[1], A Petrone[1], C Tiberti[1], S Di Pietro[2], M Locatelli[3], A Falorni[4], E Bosi[5], R Buzzetti[1] & Nirad Study Group (Italian Society of Diabetes) [1]
[1]Sapienza University, Rome, Italy; [2]INRCA, Rome, Italy; [3]Bambino Gesu' Hospital, Rome, Italy; [4]Università Perugia, Perugia, Italy; [5]San Raffaele, Milano, Italy.

Introduction
LADA is a heterogeneous population of diabetes subjects wherein subgroups can be identified based on their autoimmune status: the titre of autoantibodies to GAD.
The aim of the study was to correlate, in LADA subjects, GADA titre, with the presence of other organ and non organ specific autoantibodies.
Methods
LADA subjects ($n=191$) and type 2 diabetes (T2DM) subjects ($n=382$) were selected from the Non Insulin Requiring Autoimmune Diabetes cohort. GADA titre showed a bimodal distribution (high ($>32$ GADA U) or low GADA titre ($\leq 32$ GADA U). The following autoantibodies were measured: protein tyrosine phosphatase IA-2 (IA–2A), thyroid peroxidase antibodies, (TPO), steroid-21-hydroxylase (21OHAb), anti-parietal cell antibodies (APCA), tissue transglutaminase antibody IgA (tTGA). IA–2A, 21 OHAb, TPO, IgA, tTGA antibodies were measured by a radioimmunoassay and APCA by a ELISA method.
Results
Subjects with high GADA titer compared to low GADA titer showed a significantly higher prevalence of TPOAb (37.2 vs 16.5%; $P=0.002$), IA – 2AIC (25.5 vs 8.2%; $P<0.002$), APCA (23.3 vs 9.3%; $P<0.01$) and ZnT8 (29.7 vs 8.2%; $P<0.0003$). A significant decreasing trend was observed from high GADA titre to low GADA titer and to T2DM for the prevalence of TPO and tTGA ($P<0.001$ for both comparisons). 21OHAb showed a prevalence of 3.2% in high GADA titer and were not present neither in low GADA titer nor in T2DM subjects. The prevalence of tTGA was of 4% in high GADA titer, 1.2% in low GADA and 0.4% in T2DM ($P$ for trend $=0.001$, high GADA vs T2DM $P=0.03$).
Conclusion
High GADA titre, in LADA subjects, is associated with a profile of more severe autoimmunity. Previous studies indicate that the prevalence of multiple autoantibodies is a better index of disease progression than prevalence of antibodies directed at individual antigens. This may indicate intermolecular epitope spreading that can amplifies the autoimmune response.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P563

**Testing of type 2 diabetes risk locus rs7578597 in THADA gene in the czech population**

T Halkova[1,2], O Bradnova[1], M Vankova[1], D Vejrazkova[1], P Lukasova[1], J Vcelak[1], H Kvasnickova[2], S Stanicka[2] & B Bendlova[1]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]Charles University, Prague, Czech Republic.

Introduction
The SNP rs7578597 (Thr1187Ala) of THADA gene was identified in GWA studies as a novel type 2 diabetes risk locus. Nevertheless, subsequent studies of this SNP effect have been inconclusive. In some studies, rs7578597 has been associated with insulin secretion but no significant correlation with type 2 diabetes has been reported. Product of THADA gene is considered to be involved in apoptosis. Whether rs7578597 affects insulin secretion throught the apoptosis of pancreatic β-cells is, however, still unknown. We analyzed the genotype distribution of rs7578597 (TT/CT/CC) in 1084 individuals comprising 247 type 2 diabetes patiens (T2D), 275 women with gestational diabetes mellitus (GDM) and 562 non-diabetics (ND). The association of genetic variants in rs7578597 with anthropometric and biochemical parameters related to type 2 diabetes was examined.
Methods
The SNP rs7578597 was assessed by TaqMan SNP Genotyping Assay. Study cohort was anthropometrically and biochemically characterized, in subgroups GDM and ND 3 h OGTT was performed. For statistical analyses Mann-Whitney test, Chi-square test and ANOVA were used (NCSS 2004).
Results
The allelic frequencies did not differ among subgroups (minor C allele: T2D 23.5%; GDM 19.2%; ND 23.8%). C allele carriership in T2D and GDM subgroups was not associated with any of the studied parameters. Carriers of C allele in non-diabetic subgroup (ND) had decreased insulin levels: AUC insulin CC + CT vs TT $P=0.047$. Insulin secretion was significantly lower particularly in the late phase of OGTT: 90 min $P=0.039$; 120 min $P=0.019$.
Conclusion
We found out that the C allele carriership of rs7578597 is associated with lower insulin secretion in the Czech non-diabetic population.

**Impact of diabetes on length of stay and inpatient mortality for elderly patients presenting with proximal fracture of the femur**

K Nirantharakumar[1,2], H Wijesinghe[1], M Mastan[1], M Srikantharajah[1], S Bhatta[1], D Westwood[2], T Marshall[1] & J Coleman[1,2]
[1]University of Birmingham, Birmingham, UK; [2]University Hospital Birmingham, Birmingham, UK.

Aim
To compare inpatient length of stay (LOS) and mortality of diabetic and non-diabetic patients aged ≧65 years admitted in a single UK hospital with fractured proximal femur.
Methods
Patients with a fractured proximal femur at University Hospital of Birmingham (2007–2010) were identified from administrative data with ICD 10 discharge diagnostic codes S720, S721 and S722 as the primary diagnosis. A discharge diagnostic code for diabetes or a prescription for diabetes medication (excluding prescription for other clinical needs) was defined as diabetes. Univariate analysis (Mann-Whitney-U-test (LOS) and Chi2 (mortality)) and multivariate analysis (linear regression for LOS after log transformation and logistic regression for mortality) to adjust for age, gender, ethnicity, social class and Charlson co-morbidity score (excluding diabetes) were conducted to contrast and assess the impact of diabetes on fracture of proximal femur in elderly patients.
Results
Among 1468 admissions with fracture of proximal femur 197 had diabetes (13.4%). Diabetes patients had a higher median length of stay but this was not significant (20.2 vs 19.1 days; $P=0.17$). After adjustment for covariates diabetes patients had a significant impact on length of stay (regression coefficient β of log transformed data = 0.062; $P=0.05$). Inpatient mortality rates were higher in the diabetes patients (14.2 vs.12%) but it was not significant before ($P=0.37$) or after adjustment for covariates (Odds Ratio 1.11; 0.70–1.77). Increasing age and higher co-morbidity score were independently associated with increasing LOS and mortality ($P<0.001$).
Conclusion
Diabetes patients tend to have slightly longer length of stay compared to non diabetic patients presenting with fracture of proximal femur. Involvement of diabetes specialist team may have had a favourable outcome in reducing the length of stay and improving quality of care. Further study to understand the impact of diabetes on long term mortality (1 year) will be beneficial.

## P565

**Screening of latent autoimmune diabetes in insulin requiring diabetic adults**

R Ben Said, I Kammoun, I Oueslati, Y Htira, C Bouzid, L Ben Salem & C Ben Slama
National institute of nutrition, Tunis, Tunisia.

Introduction
Latent autoimmune diabetes in adults (LADA) is a genetically linked, autoimmune form of type 1 diabetes mellitus (DM) that accounts for 2–12% of all cases of diabetes.
The goal of our study is to detect LADA among patients who were diagnosed as type 2 DM and who became insulin requiring.
Methods
Our study included 45 patients (15 men, 30 women) diagnosed as type 2 DM, who had a poor glycemic control on oral hypoglycemic drugs, and so became on insulin therapy.
These patients had systematically islet auto antibodies testing (anti glutamic acid decarboxylase 65 (antiGAD 65), anti islet cell cytoplasm (ICA) and anti tyrosine phosphatase like protein (IA–2A)).
Results
All our patients were aged more than 30 (mean age: 49 ± 11.3). They have been on oral hypoglycaemic drugs for at least one year (mean duration: 4 ± 2,7 years). They presented with poor glycemic control (mean HbA1c: 11.9 ± 2.36%) and they had an important weight loss (13 kg ± 9.4).
AntiGAD 65 were detected in 32.4% of our patients, ICA in 13% and IA–2A in 4,3%. 44% of patients with positive test presented with ketosis.
Conclusion
Approximately, 10 to 30% of adults diagnosed with type 2 DM are positive for islet auto antibodies, which means that they had in fact a LADA.
Single antibody positivity for GAD is more frequent than ICA and IA–2A, like in our study.
Our results are particularly interesting because they show a relatively high prevalence of LADA in our population. It is important to recognize these patients to prevent complications like ketosis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Epidemiological study of patients attended the pediatric outpatient clinic of national institute of diabetes & endocrinology**

M El Hefnawy
NIDE, Cairo, Egypt.

Background
Diabetes mellitus is the most common endocrine metabolic disorder of childhood. It is widely spread all over Egypt as its prevalence was found to be 1.09 per 1000 among school aged children.
Aim of the work
The aim of this work was to do a retrospective epidemiological study of the records of diabetic children attended the outpatient pediatric clinic in NIDE.
Subjects & Methods
The files 0f 3000 diabetic children were examined retrospectively without any reference to the personal data.
Results
The results showed that there is no statistical differences between male, ($n=1528$) to female, ($n=1472$) distribution. The results of this retrospective study showed that the mean age of onset of diabetes in children attended the outpatient pediatric clinic of National Institute of Diabetes was (mean = 8.37 + 10.96 y). The present study showed also that there was a decrease of age of onset of diabetes among diabetic children as the age of onset between 5–<10 years were the highest percentage (46%). As regards the insulin regimen used by the diabetic children, 17.5% used conventional insulin therapy, 11% used modified insulin therapy as they used regular insulin before lunch, and 71.5% used basal-bolus insulin regimen. The mean percentage of insulin unites per Kg. was 1.00 + 0.38 U/kg./day. The mean BMI was = 24.54 + 6.42, while the BMI distribution was: 56% were with normal weight = < 25, 27% were overweight = 25: <30, 14% were obese = 30: < 40 and only 3% were with severe obesity where BMI = > 40. The results showed also that 34.8% of the diabetic patients were doing continues home blood glucose monitoring with glucose sensors, 25.8% were doing the monitoring only with visual strips, while 39.4% of the diabetic children were not doing home monitoring at all.
Conclusion & recommendations
The discussion of these results documented that it will be essential to follow the international guidelines of management of type 1 diabetes and it was recommended to do proper diagnosis of different types of diabetes among diabetic children and to study the prevalence and incidence of diabetes among Egyptian children as the prevalence and incidence still uncertain till now.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Clinical and histopathology tumor characteristics of patients with invasive breast carcinoma on insulin glargine compared with other types of basal insulin**

N Satej[1], M Mori Lukancic[1] & N Besic[2]
[1]Community Health Centre, Ljubljana, Slovenia; [2]Institute of Oncology, Ljubljana, Slovenia.

Background and aims
*In vitro* studies on breast cancer cell lines showed that the serum of diabetic patients was stronger mitogenic when using glargine as compared to other types of insulin. The aim of this retrospective study was to examine if the patients with diabetes mellitus (DM) using insulin glargine have a higher tumor stage of breast carcinoma in comparison to patients using other types of insulin.
Patients and Methods
Altogether 174 patients were surgically treated because of breast carcinoma in our institution from 2006–2010. A chart review of 174 patients with DM was performed and the object of this study were 55 breast carcinoma female patients (mean age 67.4 years; range 38–86 years), who were on insulin. Insulin glargine was used in 10 patients, while the other 45 patients were on other types of insulin. The data on clinical and histopathology characteristics (age, BMI, TNM tumor stage, number of metastatic lymph nodes, presence of estrogen and progesterone receptors, HER-2 expression) were collected. Clinical and histopathology characteristics of patients on glargine versus other types of insulin were compared by chi-square test and non-parametric statistical analysis.
Results
Mean tumor size was 2.8 cm. TNM tumor stage at diagnosis was not higher among patients on glargine compared to patients on other types of insulin (T1/T2 87 vs 69%, T3/T4 13 vs 31%, $P=0.29$; N1 53 vs 50%, $P=0.85$; M1 2 vs 0% respectively). No significant differences between both study groups were found in age of patients, BMI, tumor histology, grade, number of metastatic lymph nodes, hormone receptors or Her-2 status.
Conclusion
We could not show that the patients with diabetes mellitus using insulin glargine have a higher tumor stage of breast carcinoma in comparison to those using other types of insulin.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Evaluation of clinical care in young type 1 diabetes subjects: a nationwide multicenter study in brazil**

M Gomes[1], A Matheus[1], L Calliari[2], J Luescher[4], T Manna[5], R Cobas[1], B Tschiedel[6], A Ramos[7], R Fonseca[8], N Araujo[9], H Almeida[10], N Melo[11], D Jezini[12] & C Negrato[3]
[1]State University Hospital of Rio de Janeiro, Rio de Janeiro, Brazil; [2]Santa Casa of Misericordia of Sao Paulo, Sao Paulo, Brazil; [3]Bauru's Diabetics Association, Bauru, Brazil; [4]Federal University Hospital of Rio de Janeiro, RIo de Janeiro, Brazil; [5]Clinical Hospital University of Sao Paulo Medical School, Sao Paulo, Brazil; [6]Diabetic Children's Institute of RIo Grande do Sul, Porto Alegre, Brazil; [7]University Hospital of Campina Grande, Campina Grande, Brazil; [8]Diabetes and Metabolism Research Center, Salvador, Brazil; [9]General Federal Hospital of Bonsucesso, Rio de Janeiro, Brazil; [10]State University Hospital of Londrina, Londrina, Brazil; [11]Federal University of Sergipe, Aracaju, Brazil; [12]Federal University Hospital of Amazonas, Manaus, Brazil.

Introduction
The increasing incidence of type 1 diabetes (T1D) is a matter of concern because it negatively impacts both the quality of life and its duration, due to the great morbidity and mortality caused by its chronic complications.
Objective
To evaluate clinical care provided to Brazilian youths with T1D in daily practice, according to the American Diabetes Association's guidelines.
Methods
This was a cross-sectional, multicenter study conducted between December 2008/December 2010 in 28 public clinics, in 20 Brazilian cities. Data were obtained from 1692 patients (55.3% female, 56.4% Caucasian), age 13 (1–18) years, age at diagnosis of $7.1 \pm 4$ years and diabetes duration of $5 \pm 3.7$ years. Overall, 75% of the patients were from a low or very low economic status.
Results
HbA1c goals were reached by 23.2%, LDL cholesterol by 57.9%, systolic blood pressure by 83.9% and diastolic blood pressure by 73.9% of the patients. In total, 20.2% of the patients were overweight and 9.2% were obese. Three or more daily shots of short-acting insulin were reported by 57.9%, and self-monitoring of blood glucose (SMBG) by 73.5% of the patients. A first-degree familial history of type 2 diabetes, obesity, cardiovascular disease or hypertension was reported by 7.6, 12.9, 6.0 and 10.6% of the patients respectively. The rate of annual screening for complications was 66.2% for retinopathy, 69.7% for nephropathy and 62.7% for foot alterations. On multivariate analysis, age, insulin dose, economic status, number of daily SMBG and gender were independently associated with HbA1c levels ($P<0.001$).
Conclusions
Screening for diabetes complications and reaching goals for glucose, lipids and blood pressure are difficult to achieve in Brazilian T1D youths. The low economic status found in the majority of our patients might represent a barrier to reach these goals. Further studies are warranted to address this issue.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**DNA methylation influenced β-arrestin 2 expression in type 2 diabetes patients**

W Zhong
Chinese PLA General Hospital, Beijing, China.

Background
Hyperglycemia and glucose intolerance are perhaps the most common pathophysiologies associated with diabetes. β-Arrestin 2, component of G-protein coupled receptor signaling, has been shown to be down-regulated in insulin resistant and type 2 diabetic mouse models. However, if this down-regulation also existed in diabetic humans, and the possible mechanisms of this differential expression in normal and type 2 diabetes were not clear.
Methods
Venous nucleus cells from normal glucose tolerance subjects and newly-diagnosed type two diabetic patients without any medications were investigated. β-Arrestin 2 mRNA expression were measured by RT-PCR, β-Arrestin 2 DNA promoter methylation was evaluated by MS-PCR. Clinical data of all the subjects were collected.
Results
In diabetic subjects with confirmed insulin resistance, β-Arrestin 2 mRNA was significantly down regulated compared to normal subjects. Tight methylation-regulated CpGs were identified within β-Arrestin 2 promoter area. β-Arrestin 2 promoter methylation were found in diabetic patients but not in the normal subjects.
Conclusion
DNA methylation might be related to the differential expression of β-Arrestin 2 in type 2 diabetes with insulin resistance, and β-Arrestin 2 DNA promotor methylation might contribute to the pathogenesis of type 2 diabetes.

**Innervation and vascularization into islets of langerhans in the presence or absence of proglucagon-derived peptides**

Y Hayashi[1], H Tanaka[1], N Sanzen[2], K Sekiguchi[2] & Y Murata[1]
[1]Nagoya University, Nagoya, Japan; [2]Osaka University, Osaka, Japan.

Introduction
Islets of Langerhans are well innervated and vascularized, however, the regulatory mechanisms for innervation and vascularization are not well clarified. In mice deficient for proglucagon-derived peptides (Gcg–gfp/gfp: GCGKO), islet cells that express green fluorescent protein (GFP) under the control of glucagon promoter ('α"-cells) display hyperplasia and number of islets is increased. The present study was aimed to clarify role of the proglucagon-derived peptides in innervation and vascularization into islets.
Method
Immunohistochemical analyses for pancreata of GCGKO and heterozygous Gcg–gfp/+mice were performed by using antibodies for platelet-endothelial cell adhesion molecule-1 (PECAM1), vascular endothelial growth factor (VEGF), tyrosin hydroxylase (TH), laminin, synapsin I, neuropeptide Y (NPY) and insulin.
Results
Neuronal fibers positive for NPY and/or TH were identified in and around islets of both Gcg-gfp/+ and GCGKO mice. Basement membranes positive for laminin were present around the islets and blood vessels. Synapsin positive spots were mostly identified nearby blood vessels and α-cells. Some of the non-α-cells were positive for TH. NPY was detected in some of α-cells, β-cells and cells negative for both glucagon and insulin. VEGF were expressed in both α-cells and β-cells. In GCGKO islets that contained mostly GFP positive 'α'-cells and β-cells, numbers of blood vessels and nerves, as well as signal intensities of VEGF, NPY, and TH were reduced.
Conclusion
Proglucagon-derived peptides are not an absolute prerequisite for innervation and vascularization into islets. However, reduced innervation and vascularization into malformed GCGKO islets consisted of mostly GFP positive 'α'-cells suggested that non-α populations play regulatory role in establishing networks of nerves and blood vessels in islets of Langerhans.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Expression of ghrelin and its receptor genes is tissue specific in streptozotocin treated piglets**

K Pierzchala-Koziec, J Zubel, E Oclon & M Kuta
University of Agriculture, Krakow, Poland.

Ghrelin is protein hormone originally isolated from the stomach and it is the endogenous ligand for the growth hormone secretagogue receptor (GSH-R 1a). It is well established that ghrelin plays roles in appetite regulation, gut function, metabolic disorders and inflammation. Ghrelin and its receptor is expressed in brain and peripheral tissues sensitive to inflammation such as heart and spleen. As a part of study dealing with the role of ghrelin in the development of inflammation the present study was carried out to assess the effect of streptozotocin (inflammatory agent) on the ghrelin concentration, expression of ghrelin and its receptor genes in piglets heart and spleen. Animal studies were performed on 6 weeks old piglets divided into control and experimental group treated with streptozotocin (STZ) 3 times every two days (75+50+25 mg, i.p.). Ghrelin concentration was estimated by RIA, expression of genes of ghrelin (ghrl) and its receptor (GHS-R1a) was measured by PCR-RT. Expression of ghrelin receptor protein was estimated by Western blot analysis. All tested parameters were higher in the heart than in spleen of control animals. Streptozotocin injections significantly increased the expression of ghrelin and its receptor genes as well as the receptor protein concentration in heart - by 7, 5 and 2 times, respectively. However, the concentration of ghrelin in piglets treated with STZ was lower in the heart and higher in the spleen. Unexpectedly, in spite of higher level of ghrelin receptor protein the expression of ghrelin gene was decreased in the spleen of STZ treated piglets.
The obtained results clearly showed that inflammation and diabetes type I induced by STZ changed the activity of the ghrelin-receptor system in the heart and spleen of piglets. The expression of ghrelin and its functional receptor genes was tissue specific.

**Empowering patients with diabetes: a qualitative study focusing on knowledge of self-care behaviors amongst asians in south florida**

T Imran[1], S Jauhari[1], N Chaudhry[1], S Bengali[1], Z Huq[1], S Uddin[2], D Uddin[2] & A Jaffer[1]
[1]University of Miami Miller School of Medicine, Miami, Florida, USA; [2]University of Miami, Miami, Florida, USA.

Background
South Asians have a higher prevalence of diabetes and increased complications compared to other ethnic minorities, leading to poorer health outcomes. There is a lack of evidence about knowledge of diabetes self-care behaviors amongst this group. Having such knowledge is crucial in preventing complications and providing effective health services.
Objectives
The aim of this study was to identify knowledge of self-care behaviors and factors complicating self-care among South Asians with Type II Diabetes.
Methods
A qualitative focus group analysis was conducted using randomly selected South Asians residing in two counties and receiving care at UHI, a free South Florida clinic. Group discussions were audio-recorded, transcribed, and analyzed using qualitative methodology to identify key themes.
Results
The main barriers to optimal self-care were time constraints, monitoring blood glucose, difficulty in adapting to dietary changes, and lack of understanding of severity and complications. Cultural demands that complicate self-care included the need to honor one's hosts by having otherwise unhealthy dishes and adhering to appropriate social roles, especially among South Asian women. Women reported little time in caring for their own health, in part due to responsibilities to their children and families. In addition to unhealthy dietary habits, they also reported lack of women-only exercise facilities.
Conclusion
Health professionals should strive to provide individually and culturally tailored health education to South Asian diabetics. The needs of women in this community should be addressed. This issue requires more research and should be recognized as a crucial factor in improving the health of communities.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Circulating ghrelin and leptin concentrations in metabolic disorders of obese and lean piglets**

K Pierzchala-Koziec, J Zubel & E Oclon
University of Agriculture, Krakow, Poland.

Ghrelin as well as leptin are involved into regulation of food intake, development of obesity, diabetes (DM I, DM II) and inflammation. However, in spite of many experiments, the correlation between their effects are not fully established. As a part of study dealing with the interaction of ghrelin and leptin in metabolic disorders the present study was carried out to assess the effect of statin, DMI, DMII on the ghrelin and leptin plasma levels in lean and obese piglets. Animal studies were performed on sixty 6 weeks old piglets of two genetically different strains – lean(L) and obese (F), divided into control and four experimental groups. DMI group was treated with streptozotocin 3 times every two days (75 + 50 + 25 mg, i.p.), ATOR group received statin for 5 days, 10 mg/day, per os), third group received streptozotocin and statin (STZ + ATOR) and DMII group was injected i.p. with glucocorticoid for three days in a manner of 30, 20, 10 mg/piglet. Ghrelin and leptin levels were estimated by RIA. The plasma levels of both hormones in control piglets were significantly higher in obese than in lean $-4.66 \pm 0.11$ vs $3.03 \pm 0.08$ nmol/l (ghrelin) and $27.01 \pm 1.1$ vs $23.2 \pm 0.9$ pmol/l, (leptin). Obese piglets were susceptible to streptozotocin, statin and glucocorticoid treatment and reacted by higher significant increase of ghrelin plasma level (by 18–60%) than lean animals. Unexpectedly, the increase of leptin plasma level was much higher in lean piglets treated with streptozotocin and statin than in obese animals. Molar ratio ghrelin/leptin was much higher in obese control and STZ + ATOR groups but was decreased by streptozotocin in lean and obese piglets. The results clearly showed involvement of both hormones into the development of DMI and DMII in piglets but their interaction in lean and obese animals was genetically dependent.

**Effective utilization of anti-GAD measurement**

C. Prosser[1,2], R. Grason[3] & M. Chow[2]
[1]University of Alberta, Edmonton, Alberta, Canada; [2]University of Alberta Hospital, Edmonton, Alberta , Canada; [3]Alberta Health Services, Edmonton, Alberta , Canada.

Introduction

Responsible use of healthcare resources dictates that judicious test ordering be encouraged. Although the appearance of anti-GAD antibodies is known to precede and predict the development of autoimmune diabetes, its use as a screen for risk of developing diabetes is not warranted. Results are useful in determining treatment, however, when it is difficult to distinguish type 1 from type 2 diabetes or when the probability of progression from type 2 to type 1 is high. Method: Anti-GAD measurement was initially made available only to Endocrinologists in the Edmonton Region. The correlation between C-peptide levels and anti-GAD positivity was examined to determine if, as suggested in the literature, there is a C-peptide level above which the probability of the presence of antibody was low. Results: An overall sensitivity of 93% and specificity of 70% was observed using a C-peptide cut-off of 0.80 nmol/l. The anti-GAD positive samples with a C-peptide $>0.80$ nmol/l were from pediatric patients. The laboratory then accepted orders from any physician but implemented criteria for processing requests which included identification of the patient as a diabetic based on HbA1c values or elevated glucose levels and C-peptide levels $<0.80$ nmol/l (normal 0.30–1.32 nmol/l). The Laboratory Information System was programmed to pull the required data and flag those specimens that did not meet the criteria. A positivity rate of 47% was observed when testing was confined to Endocrinologists. With requests accepted from all physicians but restricted using the given criteria the positivity rate was 73%. An audit of pediatric samples continues. Conclusion: Programming the LIS to identify appropriate requests for anti-GAD has been successful in ensuring the test is not used for screening but is available when the result may alter treatment.

## P576

**The relationship between the level of knowledge of physicians on guidelines and the degree of glucometabolic control in type 2 DM patients in Turkey**

I Satman[1], S Imamoglu[2], C Yilmaz[1] & on behalf of ADMIRE Study Group[3]
[1]Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey; [2]Uludag University Faculty of Medicine, Bursa, Turkey; [3]Ege University Faculty of Medicine, Izmir, Turkey.

Introduction

Clinical practice guidelines on diabetes mellitus (DM) was created by The Society of Endocrinology & Metabolism, Turkey (SEMT). The ADMIRE Project is designed to evaluate the effect of implementation activities to increase physicians' awareness on guidelines.

Methods

A total of 180 physicians from national representative diabetes clinics kept medical records of 885 T2DM patients for 6 months, without any interference to their routine practice. Then, following awareness activities they kept medical records of 1616 T2DM patients for 6 months. Adherence to guidelines was scored to reach a total adherence to follow-up procedures (TOTAL_ADH_FU) for medical history (HISTORY), physical examination (PHY_EXAM) and laboratory evaluation (LAB_EVAL). Here, baseline results from pre-activity and post-activity periods (PRE and POST) are compared.

Results

PRE and POST data were similar (age 55 vs 57 years, women 62 vs 59% and DM duration 7.1 vs 7.4 years). Treatment preference in PRE and POST were OAD: 46 vs 55%, insulin: 11% in both, OAD + insulin: 25 vs 26%. In PRE, guidelines had been adhered fully for HISTORY in 41% of patients and increased to 85% in POST. The proportions of patients who had PHY_EXAM in full adherence were 9 vs 34% ($P<0.001$). Patients with LAB_EVAL in full adherence were 30 vs 22% ($P<0.001$). Only 22.9% of patients were at A1C target ($\leq 6.5\%$) in PRE, while this figure increased to 28.3% at POST ($P=0.014$). Proportion of patients at FBG (70–120 mg/dl) and PPBG targets ($<140$ mg/dl) changed from 17.5 and 12.6–20.7 and 12.8% in POST respectively. Mean A1C levels (%) in PRE and POST were $8.7 \pm 2.1$ vs $8.4 \pm 2.1$ ($P=0.002$). FBG (mg/dl) and PPBG levels (mg/dl) were $191 \pm 88$ vs $178 \pm 77$ ($P=0.001$) and $248 \pm 106$ vs $240 \pm 99$ respectively.

Conclusion

Awareness activities significantly increased the proportion of patients at A1C target and decreased both the level of A1C and FBG.

**Previous history of gestational diabetes mellitus and flow mediated dilation of brachial artery**

S Alatab, H Fakhrzadeh, F Sharifi, M Mirarefein, Z Badamchizadeh, M Ghaderpanahi, A Hashemi Taheri & B Larijani
Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Background

Gestational diabetes mellitus (GDM) is a common pregnancy condition which is associated with long term complications. In this study we examined the levels of inflammatory mediators, adiponectin, hemocystein and insulin resistance index in women with and without previous GDM (pGDM). Also association between these factors and early atherosclerosis process was evaluated.

Methods

Serum levels of IL6, hs-CRP, adiponectin, homocystein and other biomedical parameters were measured in 40 women with and without pGDM. The average time passed from the index pregnancy was 4 years (range 1–5 years). Two groups were matched based on age, BMI and years after affected pregnancy. The existence of early atherogenesis process was evaluated by measuring both CIMT and FMD. FMD was measured according to guidelines of American College Cardiology. The Levene's test was used for assessing the equality of variances. Pearson correlation was used to investigate the correlation between quantities variables.

Results

Even not hypertensive, the mean of systolic and diastolic blood pressure in pGDM group was significantly higher ($P<0.04$). Lipid profile, fasting blood sugar, hs-CRP, IL6, adiponectin and homocyteine levels did not significantly different between two groups. However fasting insulin ($6.44 \pm 4.52$ vs $10.19 \pm 5.04$,

$P<0.01$) and insulin resistance index as was measured by the homeostatic model assessment (HOMA; $1.41\pm1$ vs $2.33\pm1.2$, $P<0.01$) were significantly higher in pGDM group. Women with pGDM had slightly, however, not significantly, higher CIMT and significantly lower percent of brachial FMD ($26\pm0.11$ vs $19.32\pm0.05\%$, $P<0.02$). FMD and CIMT, adjusted for age and blood pressure, still showed the same pattern. No correlation between inflammatory markers, adiponectin and homocystein and FMD was found.
Conclusion
Women with pGDM are at increased risk of developing insulin resistance and premature atherosclerosis process despite of any change in lipid profile or being hypertensive. Early follow up with FMD should be considered in this group of women.

## P578

**Frequency and outcome of follow-up testing after a positive gestational diabetes screen**

C Prosser & C Chik
University of Alberta, Edmonton, Alberta, Canada.

Objective
In Edmonton, universal screening of all pregnancies is performed using a 50 g gestational diabetes screen (GDS). Canadian Diabetes Association (CDA) Practice Guidelines recommend a 75 g 2 h oral glucose tolerance test (OGTT) if the GDS glucose result is between 7.8 and 10.2 mmol/l. This study is designed to assess the frequency of OGTT requests in response to a positive GDS and the prevalence of normal OGTT in this population.
Methods
All GDS results reported from April 1 to June 30 2009 and 2010 were collected. The number of OGTT performed within 30 days of a positive GDS was determined. The diagnosis based on the OGTT is compared to that of the GDS.
Results
A total of 8801 GDS were performed, 22% of which produced abnormal results. About 3% met the CDA criteria for diagnosis of GDM (glucose $>10.2$ mmol/l). Although not recommended for these patients, OGTT was requested in 12 and 60% produced normal results. Of the 19% with GDS results between 7.8 and 10.2 mmol/l, 40% did not complete the OGTT within 30 days. Among those who completed the OGTT, 70% were normal.
Conclusions
Confirmatory testing of positive GDS results is not done consistently which may result in misdiagnosis of these patients. The diagnostic cut-off for GDM in the GDS may need further validation.

## P579

**Relationship vitamin D levels and glycemic control in type 2 diabetic patient**

O Oz Gul[1], B Gul[2], S Cander[3], A Eroglu[2], N Keni[2], C Ersoy[2] & S Imamoglu[2]
[1]Bursa Cekirge State Hospital, Bursa, Turkey; [2]Uludag University Medical School, Bursa, Turkey; [3]Bursa Sevket Yilmaz State Hospital, Bursa, Turkey.

Objective
Vitamin D deficiency has been shown to alter insulin synthesis and secretion in both humans and animal models. However, less is known on the association between vitamin D and type 2 diabetes mellitus. In the current study we aimed to analyze the relationship between vitamin D levels with glycemic control in type 2 diabetic patients.
Material and methods
Three hundred and twenty diabetic patients who are follow up at least 6 months for diabetes and one hundred fifty five healthy volunteers were included in this study. Physical examination and anthropometric measurement were performed in all the patients. Metabolic and glycemic indicators such as fasting glucose, hemoglobin A1c (A1c), homeostasis model assessment-insulin resistance (HOMA-IR), high-density lipoprotein cholesterol, triglyceride and insulin levels were measured. Also vitamin D and parathyroid hormone (PTH) levels were evaluated in all patients.
Results
Plasma vitamin D levels were significantly lower in diabetic patients than in control group ($P=0.025$). PTH levels were significantly higher in diabetic patients ($P=0.001$). Serum calcium, phosphorus and alkaline phosphatase levels were similar between diabetic and control groups. No correlation was observed among plasma vitamin D levels, PTH levels and glycemic parameters. Compared with non-diabetic patients, diabetic patients had high plasma glucose, A1c, HOMA-IR, triglyceride levels as expected.
Conclusion
These results indicate that diabetic patients have low levels of vitamin D. Decreased vitamin D levels could influence the prevalence of diabetes mellitus in a population. To clarify these important points, future prospective studies conducted in larger patient groups.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Association between educational level with glycemic and risk factor control in type 1 diabetes: results from DIACAM 1 study**

J Sastre[1], P Pines[2], J Moreno[3], I Quiroga[4], M Delagado[5], D Calderon[6], S Herranz[7], J Lozano[2] & J Lopez[1]
[1]Complejo Hospitalario de Toledo, Toledo, Spain; [2]Complejo Hospitalario de Albacete, Albacete, Spain; [3]Complejo Hospitalario Mancha Centro, Alcazar de San Juan, Spain; [4]Hospital Nuestra Señora del Prado, Talavera de la Reina, Spain; [5]Hospital General de Ciudad Real, Ciudad Real, Spain; [6]Hospital Virgen de la Luz, Cuenca, Spain; [7]Hospital Universitario de Guadalajara, Guadalajara, Spain.

Objective and aims
This study was designed to investigate the clinical characteristics of a representative group of type 1 diabetic (T1D) population in Castilla La Mancha, a region in central Spain. The aim of this report is to evaluate the relationship between the educational level and cardiometabolic risk in adult patients with T1D.
Patients and methods
This is an observational, cross-sectional, prospective and multicentre study of 1465 patients who received attention along 2010. From this cohort patients aged $>25$ years were analyzed ($n$:1130, 48% women, mean age $42.9\pm11.6$ years and mean diabetes duration: $20.9\pm0.9$ years). Educational levels were classified as low (no studies or primary school, $n$:541 (47.9%)), middle (high school, $n$:347 (30.7%)) or high (university, $n$:242 (21.4%)). Diabetic patients underwent clinical and laboratory evaluation. A multivariate logistic regression analysis was used to asses the influence of educational status in good glycemic control (HbA1c $\geq7\%$).
Results
There was no difference between groups regarding gender, but patients with low educational level (LEL) were older and had longer duration of diabetes ($P<0.001$). The prevalence of cardiovascular risk factors was higher in patients with LEL (Table). The prevalence of metabolic syndrome (IDF criteria) was higher in patients with LEL versus high (39.7 vs 21.5%, $P<0.001$). Glycemic control was worse in patients with LEL (HbA1c $8.1\pm1.2$ vs $7.3\pm1.0\%$, $P<0.001$). There were no differences in lipid and pressure control between groups (except for HDLc and systolic blood pressure) but antihypertensive and lipid-lowering treatments were more prevalent in LEL group. After adjusting for diabetes duration, LEL was inversely associated with good glycemic control (OR 0.7 95% CI: 0.5–0.9, $P<0.01$).
Conclusions
In this cohort of adult TID patients, LEL is associated poor glycemic control and higher prevalence of cardiovascular risk factors, these patients should receive adecuate follow-up to reduce their risk of complications.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Table 1** Prevalence of classic cardiovascular risk factors according to educational level

| | Low | Middle | High | *P* |
|---|---|---|---|---|
| Hypertension (%) | 32.5 | 24.2 | 14.0 | <0.001 |
| Dyslipidemia (%) | 46.2 | 38.2 | 28.5 | <0.001 |
| Obesity (%) | 20.9 | 13.4 | 13.6 | <0.01 |
| Smoking (%) | 29.6 | 28.2 | 19.0 | <0.01 |

**Basal and postprandial free fatty acid kinetics in normal and type 2 diabetic subjects: effects of various treatments**

O Celer & B Efe
Eskisehir Osmangazi University, Faculty of Medicine, Eskisehir, Turkey.

The pathophysiology of type 2 DM is complex and involves insulin resistance, pancreatic beta cell dysfunction and visceral adiposity. The levels of free fatty acids (FFA) increases in obese persons and diabetic patients. Elevated levels of FFAs may cause resistance and deficient insulin secretion. Our aim in this study was to investigate the change of FFA levels, glucose, insulin and triglyceride in fasting and postprandial state in 15 healthy controls and 45 diabetic patients under treatment of various agents.

Our study included four groups; 15 patients on diet or plus metformine, 15 patients using rapid acting insulin analogues, 15 patients having glinides, 15 healthy controls. Blood samples were withdrawn at fasting and following breakfast composed of foods proper for each person, at 60th, 90th and 120th min. In control group glycemia peak occured at 90th min and insulin peaked at 60th min, when the levels of FFA was lowest. In the group of patients using glinide, glycemia and insulin levels peaked at 90th min. In the group of patients on diet and metformin, glycemia and insulin levels peaked at 60th min, whereas glycemia has peaked at 60th and 90th min at insulin group. FFA levels were lowest at 120th min in both groups. In the group of patients using insulin analogues glycemia levels peaked at 60th min, FFA levels were lowest at 120th min. FFAs were decreasing postprandially in all groups.

Basal FFA and TG levels were higher in diabetic patients than controls but the difference was not statistically significant. At postprandial phase: 1-FFAs suppression was late in diabetic patients independent from the treatment modality comparing with the healthy individuals. 2-FFA level was inversly associated with insulin and positively associated with HbA1c and fructosamine.

Conclusion

A reduction in elevated plasma FFA should be an important therapeutic target in type 2 diabetes.

**Measles and new onset type 1 diabetes presented with bilateral facial paralysis: report of a case**

E Demir Onal, B Polat, F Balkan, G Kaya, O Deniz, R Ersoy & B Cakir
Yildirim Beyazit University Medical School Ataturk Teaching and Research Hospital, Bilkent, Ankara, Turkey.

Introduction

Measles virus infections generally occur in childhood, but infections in adolescence and adulthood can lead to complications.

Case report

A previously well 28-year-old woman had suffered from nausea, vomiting and generalized fatique for one day before being transferred to our emergency department in a confused state. A diagnosis of type 1 diabetes mellitus (T1D) complicated by ketoacidosis was made based on markedly decreased serum C-peptide level, antiGAD positivity, ketonuria and metabolic acidosis. She was treated by intravenous infusion of saline and insulin and eventually switched to intensive insulin therapy four times a day. On the second day of hospitalisation she developed bilateral facial paralysis. Serological testing for several viral antibodies revealed significant elevation of the measles IgM and IgG titers. One week later, the patient's facial weakness had improved spontaneously with no residual weakness.

Conclusion

Our case is interesting due to coexistence of bilateral facial paralysis, new onset T1D and measles. And there is not a similar case in the literature. Although there are limitations with respect to the true relation between measles and these two manifestations, this clinical picture should be kept in mind as a possible atypical presentation of measles infection in adults.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P583

**Identification of dipeptidyl peptidase-4 inhibitors among boioactive peptides derived from whey proteins**

G Tulipano, L Faggi, A Caroli & D Cocchi
University of Brescia, Brescia, Italy

Preclinical and clinical studies suggest that whey protein intake can ameliorate postprandial glucose control and potentiate insulin release in both type-2 diabetic patients and healthy subjects.

Most likely, the insulinotropic effect of whey occurs by multiple pathways, including the potentiation of incretin activity through inhibition of DPP-4 in the proximal bowel, with the outcome of increasing intact incretin levels.

During last decades, it has been clearly shown that milk proteins, both caseins and whey proteins, are a source of short peptides with distinct biological activities which are generated by enzymatic hydrolysis during gastrointestinal digestion or during food processing.

Our aim was to identify DPP-4 inhibitors among short peptides occurring in hydrolysates of β-lactoglobulin, the major whey protein found in the milk of ruminants, by *in silico* and *in vitro* analysis.

The peptide Ile-Pro-Ala (IPA), called β-lactosin A have been previously identified in β-lactoglobulin hydrolysates prepared using proteinase K. We tested IPA in vitro for DPP-4 inhibitory activity, due to its structure similarity to the well-known inhibitor Ile-Pro-Ile. Although the substitution at position 3 resulted in a weakening of the inhibitory effect vs the reference compound Ile-Pro-Ile ($IC_{50}$ value of 59 vs 7 μM), our results showed that the β-lactoglobulin-derived peptide IPA can be regarded as a moderate DPP-4 inhibitor.

Two more peptides (Leu-Leu and Leu-Ala) proved to act as DPP-4 inhibitors but their potency was tenfold lower as compared with IPA.

Based on *in silico* analysis of published β-lactoglobulin amino acid sequences, the peptide IPA is conserved across bovine, ovine and caprine species and within bovine variants but it is absent in β-lactoglobulin from donkey. More interestingly, our results suggest that the differential level of expression of β-lactoglobulin across and within species could significantly affect DPP-4 inhibitor content of whey.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P584

**Decreased sucrose preference in humans and rodents with diabetes**

J Yu & M Kim
Asan Medical Center, Seoul, Republic of Korea.

Objective

Craving of sweet foods and sucrose may be a big obstacle for glycemic control of diabetic patients. It is generally believed that diabetic patients may prefer sweet taste. However, few studies have examined sucrose preference in diabetic patients. Therefore, we investigated changes in sucrose preference in diabetic condition.

Research design and methods
We performed two-alternative staircase methods and forced-choice tracking procedures to assess sucrose thresholds and preferences, respectively in 172 type 2 diabetic patients and 104 age and sex-matched controls. To examine if glycemic control state may affect sucrose preference and sensitivity, 88 diabetic patients underwent follow-up test in 3 months later. To test the emotional effect of sweet taste in diabetic patients, we also performed sucrose preference test in streptozocin-induced diabetic rats.
Results
Unexpectedly, diabetic patients liked a lower concentration for sucrose compared to non-diabetic subjects (most palatable sucrose concentration: diabetic $0.32 \pm 0.02$ M vs non-diabetic $0.40 \pm 0.02$ M, $P=0.001$). Similarly, streptozocin-induced diabetic rats had reduced preference for sucrose compared to normal rats, suggesting that diabetes itself may reduce sucrose preference. Meanwhile, sucrose detection threshold was elevated in diabetic patients (sucrose concentrations detectible sweet taste: diabetic $21.2 \pm 1.0$ vs non-diabetic $16.2 \pm 1.0$, $P<0.001$), indicating that diabetic patients taste sweet less effectively. Both the preference and sensitivity for sucrose were not affected by glycemic control status in follow-up tests.
Conclusions
Diabetic patients and rodents showed lower sucrose preference. The preference and sensitivity for sucrose were independent of changes in blood glucose levels.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P585

**Regulatory T cells number and function in patients with LADA**

T Nikonova[1], E Pekareva[1], V Gorelysheva[1], P Apanovich[2], A Karpuhin[2] & I Dedov[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Medical Genetics Research Centre, Moscow, Russian Federation.

CD4+CD25+lymphocytes (Tregs) play a crucial role in self-tolerance and autoimmunity. LADA is associated with the loss of immune tolerance to β-cell autoantigens similar to classic type 1 diabetes mellitus. The aim of the study was to evaluate changes in terms of Tregs number and function (FOXP3 expression) in LADA patients.
Material and methods
We examined 74 patients with LADA at different stages of the disease. Fifty-six healthy subjects (control group) were included. The HLA-DR and DQ alleles were detected by using PCR method. CD4+, CD8+, CD25+, CD4+25+, CD95+, CD95L+ cells were analyzed by flow cytometry. FOXP3 expression was determined by real time PCR. All subjects were tested for ICA, GADA, IA-2A, C-peptide, HbA1c.
Results
In recent-onset LADA FOXP3 expression was similar to that in control subjects. However, the percentage of Tregs was significantly higher: 2.1 (0.3; 2.3) vs 0.8 (0.6; 0.8). During the period from 6 to 12 months upon the onset of the disease a reduced FOXP3 expression 0.43 rq (0.11; 0.75) was observed in LADA patients if compared with control subjects with 1.11 rq (0.66; 2.26; $P<0.05$). There was no significant difference in the percentage of Tregs in this period ($P>0.05$). FOXP3 expression became normal again after the first and until the 5th year of the disease. Correlation between FOXP3 and Tregs amount was found only in control group. No correlation was established between C-peptide level and autoantibodies titers in LADA patients. In all LADA patients expression of apoptosis markers (CD95 and CD95L) was comparable with the control group ($P>0.05$). Correlation analysis showed strong positive association between GADA and CD95L expression ($r=0.94$, $P=0.05$).
Conclusions
Tregs functional deficiency is delayed in LADA patients. It appears to be compensated by a rise of Tregs number in the first 6 months. This may contribute to slowing β-cells autoimmune destruction.

**Depression as a predictive factor for glycemic control and family functioning in Japanese patients Swith type 2 diabetes: a 6-month follow-up study**

T Saeki[1], M Takaishi[2], K Ishida[3], T Komo[4], S Tazuma[1] & S Yamawaki[2]
[1]Hiroshima University Hospital, Hiroshima, Japan; [2]Graduate School of Biomedical Sciences, Hiroshima University, Hiroshima, Japan; [3]Hiroshima General Hospital, Hatsukaichi, Japan; [4]Miyoshi Central Hospital, Miyoshi, Japan.

Purpose
To investigate the impact of depression for diabetes-related quality of life and glycemic control among Japanese patients with type 2 diabetes and their family members.
Methods
Ambulatory patients with type 2 diabetes were drawn consecutively from the inpatient population participated in a 2-week educational intervention program at two general hospitals affiliated with Hiroshima University. Written informed consent for the study was obtained from 123 patients and 75 family members. Before and after the intervention program, the subjects and their family members completed the Zung self-rating depression scale, the Zung self-rating anxiety scale (SAS), and the subjects also completed the diabetes quality of life (DQOL) and the problem areas in diabetes scale. Family functioning was assessed by the family assessment device (FAD) before the program. This study was approved by the Institutional Review Boards and the Ethics Committees of those two hospitals and Hiroshima University.
Results
'Depressed patients' ($n=69$; SDS at baseline $\geq 40$) perceived significantly worse diabetes-related quality of life including family functioning than 'non-depressed patients' ($n=54$; SDS at baseline $<40$) before the intervention. At the 6-month follow-up after the intervention. Depressed patients apparently improved in their mood, but still reported significantly worse diabetes-related quality of life including family functioning and tended to show higher HbA1c values than non-depressed patients. Furthermore, at the 6-month follow-up, family members of depressed patients perceived significantly higher level of conflict in their families than those of non-depressed patients.
Conclusion
The findings of the study suggested that, as for patients with diabetes, depression at baseline might predict worse quality of life, less effective family functioning, and worse glycemic control afterward. Consequently, diabetes care professionals should devote attention to taking care of mood status of patients, and intervene to promote appropriate affective interaction among patients and their family members.

**What arises from the decrease of visceral adiposity in Japanese diabetic patients with visceral fat accumulation?**

T Ohoshi[1], Y Hiromine[2], T Yamauchi[2], Y Kishitani[3], K Ogawa[4], T Akamizu[5] & K Nanjo[6]
[1]Hashimoto Municipal Hospital, Hashimoto, Japan; [2]Kinki University School of Medicine, Osaka-Sayama, Japan; [3]Nara Hospital Kinki University School of Medicine, Ikoma, Japan; [4]Kihoku Hospital Wakayama Medical University, Ito-gun, Japan; [5]Wakayama Medical University, Wakayama, Japan; [6]Wakayama Rosai Hospital, Wakayama, Japan.

Aim
To clarify what arises from the decease of visceral adiposity in Japanese diabetic patients with visceral fat accumulation.
Patients
Diabetic patients ($n=30$) whose visceral fat areas (V), determined with abdominal CT, were larger than 100 $cm^2$.
Methods
$V$ was followed at every 6 month, and clinical profiles and course were compared of eight patients (group D), whose changes of $V(\Delta V=(V$ at the second exam or

more) − (*V* at the first exam)) were under the (mean - S.D.) of Δ*V*, with of the other patients (group C).

Results

In group D, at the beginning *V* was larger, frequency of fatty liver and serum concentrations of TG and LDL-C were higher, insulin therapy was fewer, and fibrates were used more than in group C, during the following BMI was decreased, frequency of more than 5000 steps/day was increased, A1C (NGSP %) was decreased, and use of ACEI/ARB was increased, though diastolic pressure was decreased in group C, and at the ending serum TG was yet higher than in group C.

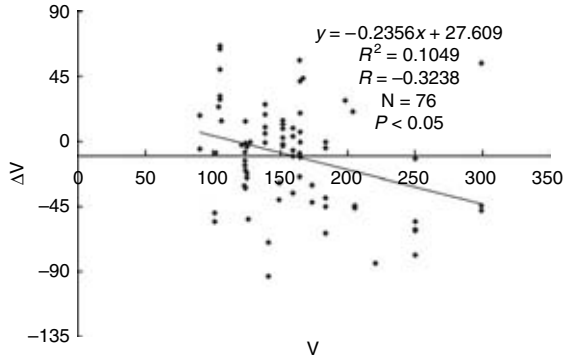
Discussion

As *V* was decreased, body weight was decreased and the metabolism of glucose and lipids were improved. Increase of ADL was important for decrease of visceral adiposity.

**Table 1** Comparison of clinical profiles and course between the groups

| Clinical parameter | Group | At the begining | At the ending | *P* 1 |
|---|---|---|---|---|
| *V* ($cm^2$) | D (*n*=8) | 191±66 * | 128±70 | 0.000 |
| | C (*n*=22) | 140±29 | 134±39 | 0.277 |
| BMI | D | 27.3±4.2 | 26.2±4.2 | 0.015 |
| | C | 27.9±3.4 | 27.8±3.5 | 0.696 |
| A1C (NGSP%) | D | 8.2±2.2 | 6.6±0.6 | 0.039 |
| | C | 7.2±1.3 | 7.2±1.4 | 0.818 |
| Fatty liver | D | 6/8 * | 3/8 | 0.131 |
| | C | 7/22 | 7/22 | 1.000 |
| TG (mg/dl) | D | 427±456(8) * | 227±186(7) * | 0.140 |
| | C | 146±107(20) | 128±64(22) | 0.416 |
| LDL-C (mg/dl) | D | 144±15(8) * | 135±38(7) | 0.514 |
| | C | 108±42(17) | 106±41(22) | 0.231 |
| Times of counseling | D | 0.6±1.1 | 1.8±1.3 | 0.174 |
| by dietitian 2) | C | 0.9±0.9 | 2.4±3.6 | 0.056 |
| More than 5000 | D | 3/8 | 7/8 | 0.039 |
| steps/day | C | 11/18 | 13/20 | 0.804 |

Mean±S.D.(*n*)/ratio 1) (at the beginning) vs (at the ending), statistically analysed with paired *t*-test/$\chi^2$ test 2) compared at the ending(during the following) with at the beginning(during the same length of period before following) *$P<0.05$ (D vs C), analysed with unpaired *t*-test/$\chi^2$.



Relationship between visceral fat area (V) and the change of *V* (Δ*V*). In *y* axis, the crossing level with *x* axis shows the mean of Δ*V*, and the level of −45 is the (mean-S.D.) of Δ*V*.

### Outcome of a young adolescent diabetes transition clinic in an inner city ethnic population in Birmingham: an audit

J Cutler, B Munir, L Hudson, J Ashton, S Holmes, M Plunkett & P De

City Hospital, Birmingham, UK.

Introduction

Management of adolescent diabetes is challenging due to a complex interplay of physiological and psychological factors.

Aims

To audit the outcome of our local hospital adolescent diabetes clinic.

Method

Adolescents aged 16–24 years are seen by our multi-disciplinary team (adult and paediatric diabetes consultant, diabetes specialist nurses and a dietician) every 4 months after transfer from paediatric service. We looked at the clinic records and electronic data of 56 patients over 5 years (2006–2010).

Results

Forty-seven had TIDM, eight T2DM and one possible MODY (31 males, 25 females). Mean age 20 (range 17–26) years and average diabetes duration 9.5 years (Asian – 28, Afro-Caribbean – 9, Caucasian – 16, African – 3).

Seventeen patients had undergone structured education (DAFNE) and four are on waiting list. Four had 1:1 carbohydrate counting sessions.

Two patients had coeliac disease, two used recreational drugs and eight took alcohol. Four patients developed retinopathy and five microalbuminuria over these 5 years. Mean HbA1c in 2006 was 9.2% and in 2010 was 9.6%. HbA1c improved in 15/56 (27%) patients and was static in eight patients. There were 40 patients in 2006 on multi-dose insulin injection, increasing to 52 by 2010. There was a 44% (nine in 2008, five in 2010) and 35% (35 in 2007, 23 in 2010) reduction in DKA and hypoglycemia related hospital admissions respectively. Clinic attendance rates improved from 68 to 79%. User questionnaire results show significant patient satisfaction.

Conclusions

Our ethnically mixed adolescent diabetes clinic remains a big challenge. We have started to convert more patients to multi-dose insulin injections and enrol into structured education (DAFNE). Empowerment and clinic attendance is getting better, DKA and hypoglycaemia admissions have fallen through more frequent diabetes specialist nurse contact and support (by e-mails, mobile text messaging, drop-in clinics) – hopefully, we shall see concomitant improvements in HbA1c in future.

### Microcirculatory disorders in adolescents with type 1 diabetes mellitus

N Nikolaeva, N Bolotova, N Filina & O Kompaniets

State Medical University, Saratov, Russian Federation.

Aim

To study microcirculatory disorders in adolescents with type 1 diabetes mellitus (T1DM).

Patients and methods

Eighty-five adolescents 12–17 years with T1DM were examined. The duration of T1DM was: <1 year – in 29 (HbAc1 7.1±0.4%) – group 1, from 1 to 5 years – in 26 (HbAc1 9.2±1.1%) – group 2, more then 5 years – in 30 patients (HbAc1 10.7±1.1%) – group 3. The indexes of tromboresistance of vessel wall measured by manjetic method. The indexes of trombocyte aggregation by laser method and intravascular aggregation were evaluated.

Results

Tromboresistance of vessel wall was normal in group 1 ($P<0.05$). Levels of adrenalin-stimulating and intravascular aggregation of thrombocytes were increased ($P<0.05$). Tromboresistance of vessel wall was decreased in group 2 ($P<0.05$). Levels of ADP-, kollagen-stimulating and intravascular aggregation ($P<0.05$) were increased in group 2. Decrease of tromboresistance of vessel wall ($P<0.001$), increase of activity of thrombocytes ($P<0.05$) and intravascular aggregation ($P<0.001$) were found in patients of group 3.

Conclusions

Microcirculatory disorders in adolescents with T1DM correlated with duration of the disease and may demand treatment.

**Screening for unknown diabetes mellitus or IFG in a population of South Italy**

A. Caretto[1], F. Cannalire[2], P. Piscitelli[3], A. Argentiero[3], A. Sturdà[1], C. Menga[3] & V. Lagattolla[1]
[1]Hospital 'Perrino', Brindisi, Italy; [2]Federfarma, Brindisi, Italy; [3]Euro-Mediterranean BioMedical Scientific Institute, Brindisi, Italy.

The importance of early detection of diabetes mellitus helps to prevent the development of related chronic complications.
Screening, which lasted a week, has been implemented in 31 pharmacies in the territory of the Province of Brindisi (Apulia–Italy) on a random sample of 1048 people. Blood glucose was measured by glucometer; a questionnaire was administered with anthropometric data and medical history and evaluation of the lifestyle of exercise and different dietary habits.
In total, 964 people did not know they have diabetes mellitus or impaired glucose. In 44 of these (equivalent to 4.6%; 23 males M and 21 females F) there was a fasting glucose greater than 125 mg/dl (mean blood glucose 149 mg/dl with S.D. 30.3), and 178 (18.5%; 89 M and 89 F) had blood glucose between 101 and 125 mg/dl.
About 77% of the 44 newly diagnosed with diabetes mellitus and 83% of subjects with fasting glucose between 101 and 125 mg/dl did not exercise more than two times a week. Of the 44 subjects with fasting blood glucose greater than 125 mg/dl, 27% had a normal BMI, 34% overweight, 30% obesity class I, 7% obesity class II and 2% class III. Of the subjects with fasting blood glucose levels between 101 and 125 mg/dl, 1% were underweight, 32% normal weight, 42% overweight, 18% obesity class I and 7% class II. Finally, there was a significant positive correlation between the presence of a known pre-existing hypertryglyceridemia and/or hypertension and the detection of fasting hyperglycemia.
This study demonstrates the importance of screening for the blood glucose determination in the population, especially in the presence of one or more components of metabolic syndrome, to allow, as early as possible, to investigate the diagnosis of an unknown overt or preclinical diabetes mellitus.

**Adiponectin among markers of low grade inflammation in gestational diabetes mellitus**

B. Matuszek, A. Burska, A. Malecha-Jedraszek, M.. Lenart-Lipinska, A. Nowakowski & H. Donica
Medical University, Lublin, Poland.

Background and aims
The subclinical inflammation connected with hypoadiponectinaemia and inflammatory pattern may favor the development of gestational diabetes mellitus (GDM).
Methods
In total, 66 pregnant women were enrolled in the study during systematic testing for GDM between 24 and 28 weeks of gestation. GDM was diagnosed in 42 cases, 24 were normal glucose tolerant control group (NGT). In blood serum concentration of glucose, insulin, adiponectin (AdipoQ), hyaluronic acid (HA), CRP were assessed during pregnancy and 12 weeks after delivery.
Results
Fasting and 2 h glucose, insulin concentration, HOMA IR, HOMA B were significantly higher, Quicki lower in women with GDM than in NGT. AdipoQ (12.5 vs 20.6 ng/ml; $P<0.001$) and HA (7.3 vs 24.1 μg/ml; $P<0.001$) concentrations were significantly lower in women with GDM than in NGT. CRP levels did not differ between groups (3.3 vs 2.7 mg/l; $P=0.54$). AdipoQ significantly correlated with basal insulin ($r=-0.477$), HOMA IR ($r=-0.394$), HOMA B ($r=-0.428$), Quicki ($r=0.394$), CRP ($r=-0.399$). HA concentrations correlated with glucose at baseline ($r=0.448$) and 2 h ($r=0.509$). Postpartum levels of AdipoQ negatively correlated with CRP ($r=-0.526$) and glucose at baseline ($r=-0.546$). HA was considerably higher (8.8 μg/ml vs 13.3 μg/ml; $P=0.031$), and CRP lower (3.8 vs 2.2 mg/l; $P=0.012$) at postpartum than in pregnancy.
Conclusions
The course of gestational diabetes is connected with low levels of AdipoQ and HA. After delivery most of women with GDM returned to NGT, which was linked with rise in HA and AdipoQ concentrations. The way of delivery itself had no effect on serum HA levels whatsoever.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P592

**Comparative analysis of adiponectin isoforms distribution in pregnant women with gestational diabetes mellitus and after delivery**

B. Matuszek, A. Burska, B. Leszczynska-Gorzelak, H. Donica & A. Nowakowski
Medical University, Lublin, Poland.

Objective
The aim of the study was to evaluate distribution of circulating adiponectin (AdipoQ) isoforms at pregnant women with gestational diabetes mellitus (GDM) and comparison analysis of isoform distribution changes 12 months after delivery.
Design
The study was conducted on 64 pregnant women who underwent routine pre-natal tests for GDM between 24 and 28 week of gestation and 30 of them 12 months after delivery. The study group included 36 women diagnosed with GDM based on the results of 75 g OGTT and the control group of 28 healthy pregnant women with a normal screening test and no risk factors for GDM.
Methods
Quantitative determination of total AdipoQ and its isoforms in serum was performed with the multimeric adiponectin ELISA (Alpco Diagnostics, Salem, NH, USA). The assays were run according to the manufacturer recommendations.
Results
Total AdipoQ concentration in women with GDM was significantly lower than in women without GDM. Among adiponectin isoforms significantly lower concentrations of HMW multimers and LMW trimers in women with GDM were found in comparison to the control group during pregnancy, while the concentration of MMW hexamers did not differ between the groups. After delivery a significant increase in total AdipoQ as well as in the concentration of HMW and LMW was found in women with the history of GDM. While searching for correlations between different forms of AdipoQ we found that HMW and MMW negatively correlated with BMI before and during gestation as well as after delivery.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Three novel mutations in maturity-onset diabetes of the young genes in Spain**

R. Palmeiro, R. Luna, I. Seoane, C. Trigo, P. Sanchez, Y. Lopez, M. Penin, C. Paramo & R. García-Mayor
Complexo Hospitalario Universitario de Vigo, Vigo, Spain.

Introduction
Maturity-onset diabetes of the young (MODY) is a genetically, metabolically and clinically heterogeneous subtype of diabetes mellitus characterized by an early onset, an autosomal dominant inheritance, and a primary defect in insulin secretion. They are caused by mutations in a reduced number of β-cell genes. Mutations in glucokinase gen (MODY 2) and hepatic nuclear factor 1α (HNF 1α) (MODY 3) are the most common.
Materials and methods
We present the cases of monogenic diabetes diagnosed in our environment between 2006 and 2010. This study involves 13 families with 23 patients (13 index cases and 10 relatives). The clinical features are listened in Table 1.
Mutations in the glucokinase gene were detected in 82.5% of the families studied, two of them have not been previously described (c984delA and C380C > A). Only one patient presented mutation in HNF 1α, neather previosly described (T156M). In the other three families no mutation where detected.
Conclusions
– Most of our patients were MODY2, since its clinical presentation makes it suspect the probability of monogenic diabetes.

– It is important to improve in the genetic study of MODY patient's relatives to enlarge de map of mutations involved.

### Proteomic identification of plasma biomarkers in type 1 diabetes mellitus: an implication of hemopexin overexpression in diabetes mellitus

Y. Lee[1], C. Chen[1], Y. Chen[2], Y. Lu[2], W. Lee[1], C. Lu[1], Y. Chen[2], H. Chou[3], J. Timms[4] & H. Chan[2]

[1]Chiayi Christian Hospital, Chiayi, Taiwan; [2]National Tsing Hua University, Hsinchu, Taiwan; [3]National Hsinchu University of Education, Hsinchu, Taiwan; [4]University College London, London, UK.

Type 1 diabetes mellitus (T1DM) not only is congenital disease that known as insulin-dependent diabetes, often occurs in children and adolescents. Recent advances in quantitative proteomics including fluorescence two-dimensional differential gel electrophoresis (2D-DIGE) and matrix assisted laser desorption ionization-time of flight mass spectrometry (MALDI-TOF MS) have offered opportunities to discover plasma proteins as biomarkers for tracking the progression and for understanding the molecular mechanisms of diabetes. Proteomic analysis of the plasma proteome in T1DM and healthy donors indicated that 41 proteins representing 36 unique proteins are T1DM associated biomarkers including heme-associated protein, hemopexin. Further investigation of glucose mediated hemopexin induction was determined *in vitro*. Our data indicated that hemopexin can be induced in numerous cell lines (ARPE19, chang's liver cells, HT29 and Hela) by increasing the glucose concentration in the medium. Interestingly, the glucose-induced hemopexin overexpression can be reduced by ROS scanvenger such as glutathion implying hemopexin expression is linked to glucose-induced oxidative stress. To sum up, the current work has identified numerous T1DM specific biomarkers by proteomic strategy. In addition, to our knowledge, this is the first report showing the expression of hemopexin can be modulated by glucose concentration which is mediated by ROS.

### Comparative incidence of type 1 diabetes mellitus in school-aged children between immigrated families and the background population living in Piedmont or in Morocco, 2005–2009: a role for vitamin D?

S. Savastio[1], F. Prodam[1], A. Perino[1], A. Balafrej[2], A. Monzani[1], R. Lera[3], F. Fontana[4], F. Cerutti[1,5], G. Bona[1] & F. Cadario[1]

[1]University of Piemonte Orientale, Novara, Italy; [2]Children's Hospital, Rabat, Morocco; [3]Ospedale Infantile Cesare Arrigo, Alessandria, Italy; [4]Ospedale Civile SS Antonio e Margherita, Tortona, Italy; [5]University of Turin, Torino, Italy.

Introduction

The aim was to compare the incidence of type 1 diabetes between immigrant Moroccan and Romanian children and background population in Piedmont, Italy, and between Moroccan children living in Italy and their counterpart in Morocco.

Patients and methods

All new cases of type 1 diabetes aged 6–13 years in Piedmont and Morocco in 2005–2009 were retrieved by regional registries. Numbers of children regularly registered to primary and middle school were chosen as reference population to bypass the demographic impasse of irregular immigration. Skin phenotype and vitamin D levels were evaluated in diabetic and healthy, Moroccan and Italian children, living in Piedmont or in Morocco. Incidence rates and their ratios were calculated.

Results

Increased incidence rates in brown skinned Moroccan children living in Piedmont (44.8, 95% CI 25.6–71.6) were recorded respect to white skinned Italian and Romanian children in Piedmont (16.8, 95% CI 14.7–19.1 and 9.1, 95% CI 2.4–22.5) and Moroccan children in Morocco (10.2, 95% CI 9.0–11.6). Moroccan children living in Piedmont had a higher risk to develop type 1 diabetes respect to the Italian population (incidence rate ratios, 2.663, 95% CI 1.858–4.897). Lower vitamin D levels were associated with type 1 diabetes in children living in Piedmont, but not in those living in Morocco.

Conclusions

The Moroccan origin is a strong determinant of type 1 diabetes in immigrant children living in Piedmont, with brown skin as one of the major risk factors for the disease. Vitamin D status could play a role in type 1 diabetes onset in immigrant brown skinned population living in the Northern part of the Mediterranean area.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P596

### HbA1c as a tool for the diagnosis of type 2 diabetes in 208 premenopausal women with polycystic ovary syndrome

L. Velling Magnussen, H. Mumm, M. Andersen & D. Glintborg

Odense University Hospital, Odense, Denmark.

Objective

To study HbA1c as a tool for diagnosing diabetes and to study HbA1c as a cardiovascular risk marker in patients with polycystic ovary syndrome (PCOS).

Methods

A retrospective observational study at an academic tertiary-care medical center. In total, 208 premenopausal women with PCOS participated. Patients underwent clinical evaluation (Ferriman–Gallwey score, body mass index, waist, blood pressure), hormone analyses (testosterone, sex hormone-binding globulin, fasting lipids, insulin, glucose, HbA1c), transvaginal ultrasound, and 2-h oral glucose tolerance tests (OGTT) measuring capillary blood glucose (BG) at 0 (BG 0) and 120 (BG 120) min, insulin, and C-peptide.

Results

In total, 20 patients were diagnosed with type 2 diabetes during OGTT. The sensitivity and specificity of HbA1c $\geq$ 6.5% for the diagnosis of diabetes were 35 and 99%, respectively, compared with the diagnosis established by OGTT. HbA1c showed closer correlation with waist, body mass index, and lipid profile than BG 120, suggesting that HbA1c could be a cardiovascular risk marker.

Conclusion

The clinical utility of HbA1c for diagnosing impaired glucose tolerance and type 2 diabetes in PCOS in daily practice is low. Long-term prospective studies are needed to determine whether HbA1c is superior to glucose levels as a cardiovascular risk marker in patients with PCOS.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P597

**Non-HDL and LDL cholesterol in type 2 diabetes mellitus patients at tertiary care hospital of Pakistan**

N. Ram & J. Abdul
Aga Khan University Hospital, Karachi, Pakistan.

Objective
The objective of this study was to determine level of non-HDL and LDL cholesterol in type 2 diabetic patients with or without coronary artery disease irrespective on lipid lowering therapy and the common factors associated with elevated non-HDL cholesterol.
Study design: cross-sectional study
Place and duration of study: diabetic clinic, Aga Khan University Hospital, Karachi. Data of Type 2 diabetes mellitus patients attended clinics during 2007 and 2011 were reviewed.
Patients and methods
All type 2 diabetic patients of either gender with fasting lipid profile irrespective of on lipid lowering therapy were included. T1DM, gestational diabetes, type 2 diabetes patients with pregnancy and those T2DM patients with incomplete data were excluded. Multivariable regression was done to identify common factors associated with elevated non-HDL cholesterol.
Results
A total of 5000 patients visited diabetes clinics during 2007–2011. Out of these 1352 patients fulfill the eligibility criteria. Among them 169 (13%) had coronary artery disease. Mean age of patients was $48 \pm 6.3$ years, 57% were males, more than 80% were obese with equal proportion had HBA $1C > 6.5$. Mean non-HDL cholesterol was 132 mg/dl S.D. $\pm 43$. Mean LDL cholesterol was103 mg/dl S.D. $\pm$ 37. Both LDL $\leq 100$ and non-HDL $\leq 130$ was achieved in 645(48%) patients. In total, 728 (61.5%) patients achieved target LDL of $\leq 100$ mg/dl among them 83 (11.4%) have non-HDL cholesterol $> 130$ mg/dl ($P < 0.05$). In patients with CAD, combined goal achievement of LDL $\leq 70$ and non-HDL $\leq 100$ was seen in 59 (35%). Among patients with LDL $\leq 100$ mg/dl, 8 (11.9%) patients have non-HDL $> 100$ mg/dl ($P < 0.05$). Multivariable analysis shows that age $\leq 60$ years and BMI $> 25$ are independently associated with NHDL $> 130$ (Adj. OR 1.5, 95% CI 1–2.2) and (Adj. OR 3.8, 95% CI 1.6–8.6), respectively. Similarly, HBA1C $>$ 6.5 was 40% more associated with NHDL $> 130$ (Adj. OR 1.4, 95% CI 0.9–2.3).
Conclusion
T2DM patients need aggressive lipid lowering therapy to achieve non-HDL cholesterol for residual risk reduction.

**Prevalence of diabetes-associated antibodies and impaired insulin response to glucose in first degree relatives of diabetic patients Ebtissam M. Salah*, Hesham El-Hafnawy**, Mona Anwar*, Samar M. E. Salem*, Mai M. Youssef*, Atef Bassyoni** and Marry Aziz****

M. El Hefnawy
NIDE, Cairo, Egypt.

Type 1 diabetes is a chronic autoimmune disease with a subclinical prodromal period characterized by the presence of circulating antibodies to various islet cell proteins. Our main objective is to estimate the prevalence of diabetes-associated autoantibodies in a group of 1st degree relatives, compared to healthy control subjects. Also, we tried to assess the insulin secretory capacity in subjects having multiple antibodies using first phase insulin response (FPIR) to intravenous glucose.
Eighty children and adolescents of the 1st degree relatives of diabetic patients attending the out patient clinic in the diabetic institute participated in our study. They were (34 boys and 46 girls, 50 siblings and 30 offspring of diabetic parents, aged 8–20 years with mean age $13.23 + 3.6$). 20 age and sex matched control subjects with negative family history of diabetes were enrolled from the child health clinic in the NRC. Sera of all subjects and controls were monitored for: islet cell antibodies (ICA), anti-insulin autoantibodies (IAA) and glutamic acid decarboxylase antibodies (GAD) using ELIZA technique, and (IA-2) antibodies using radioligand binding assay. It was found that: according to the considered cut off point for positivity, 23 out of the 80 relatives (28.75%) showed positive ICA. 21 out of 80 relatives (26.25%) showed positive IAA. 17 out of 80 relatives (21.25%) showed positive GAD antibodies. 5/80 relatives (6.25%) showed positive IA-2 antibodies. As regard the control group only one subject tested positive for ICA and another one tested positive for IAA. None of the control group tested positive for GAD or IA-2 antibodies. On studying different combinations of positive antibodies, it was found that only two subjects of the study group (2.5%) had three positive antibodies, 10% had positive ICA and IAA, 3.75% had positive ICA and anti-GAD. The same percent of the study group had positive IAA and anti-GAD. Those subjects showing more than one positive antibody underwent IVGTT to determine FPIR to predict subjects at high risk for developing type 1 diabetes. One subject was found to be at risk and four subjects were found to be at high risk for developing type 1 diabetes.

## P599

**Is there a seasonal variation in the incidence of gestational diabetes mellitus?**

V. Vasileiou, E. Kyratzoglou, A. Athanasiadou, A. Giakoumi, S. Mouzakioti, M. Alevizaki & E. Anastasiou
Alexandra Hospital, Athens, Greece.

Introduction
GDM seasonability has been rarely addressed, with conflicting results. The aim of the study is to evaluate monthly GDM incidence in a large group of Greek women.
Methods
7618 pregnant women underwent 100g OGTT during the third trimester (GDM: ADA 2000 criteria). Seasonal, monthly GDM incidences and mean seasonal glucose levels during OGTT were calculated. Mean month temperature data were obtained from the Greek Meteorological Service.
Results
GDM incidence, relative prevalence (RP), odds ratio (OR–95% CI) and mean temperature per month as in Table 1.
Seasonal GDM incidence was significantly different: Winter (W) = 28.1%, Summer (S) = 39.2%, Spring (Spr) = 32.4% and Autumn (A) = 32.4% ($\times 2 =$ 51.0, $P < 0.0001$). Glucose levels (Glu) during OGTT were calculated. There was no statistical difference in fasting glucose blood levels. On the contrary, significantly increased blood glucose values were observed at 60, 120 and 180 in S vs W, while Spr and A values were intermediate (ANOVA: $P < 0.0001$). Glu60 (mg/dl): $W = 163 \pm 42$, $Spr = 166 \pm 42$, $A = 167 \pm 39$, $S = 173 \pm 40$, Glu120: $W = 137 \pm 41$, $Spr = 138 \pm 41$, $A = 139 \pm 38$, $S = 146 \pm 40$, Glu180:$W = 109 \pm 33$, $Spr = 110 \pm 33$, $A = 111 \pm 32$ $S = 116 \pm 34$.
The effect of season on postload glucose levels remained an independent significant factor after adjustment for age, gestational age, BMI, weight gain and blood pressure (MANOVA model, $P < 0.0001$).
Conclusions
GDM incidence in Greece presents seasonal variation. GDM risk diagnosis in summer is significantly increased ($\sim 70\%$) compared to winter. Diifferences in seasonal incidence are due to post glucose load levels. Whether the observed variations could be attributed to differences in ambient temperature or other environmental factors, remains to be clarified.

## P600

**We can do better: activity report of ambulatory educative sessions for the patients treated with external pumps**

S. Baillot-Rudoni, C. Brunner, E. Crevisy, G. Vaillant & B. Vergès
CHU, Dijon, France.

Since the end of 2006 in France we have the obligation to evaluate yearly the educational level in diabetic patients treated with pumps. In 2007 we created bimonthly ambulatory group sessions for these patients (six persons per group). After receiving an explanation letter, the patients have to register by calling the service. The aim of the study was to evaluate quality and quantity of the sessions we have been performed.
Methods
We conducted analyses between March 2007 and October 2010. The program of evaluation was conformed to French medical diabetologic recommendations for knowledge in patients treated with pumps. During this period, several members of the team passed an official exam (education to diabetic patients) to improve efficacy of the sessions. For the quantity evaluation we counted the number of patients who attended the session and for the quality evaluation we used satisfaction surveys.
Results
During 43 months we evaluated 179 patients through 40 ambulatory group sessions. For these patients, the pump was first initiated between 2006 and July 2009. Some of them have participated twice or more. The theoretical number of patients should have been about 240 if we consider the number of new patients treated by pump during year 2006 and until the end of 2009. This total amount represents 25% of non-evaluated subjects. We analyzed 173 satisfactory questionnaires. On one hand, 98% of the patients were satisfied from the cordial welcome, 95% appreciated the technique sessions (in particular 'catheter replacement') and the talks between each other or the exchanges with the team. On another hand 31% disagreed with the session called 'check your material' (new devices for glycemic control, replacement insulin pens) and 16% did not like the session called 'real life clinical situations'.
Conclusion
We need to increase the number of the patient's registration to this educative program and we need to improve the methods for practical session, although we previously demonstrated the feasibility of this specific ambulatory training for the evaluation of patients treated with pumps. We have to create a tool to evaluate the number of 'lost of follow-up', patients who never call the service to register.

**Diagnostic value of cytogram analysis of different types of oral cavity mucous epithelium in type 2 diabetes mellitus elderly patients**

R. Yuy Tsun-Shu, A. Mansharipova, S. Mulkibaeva, S. Semchenkova, T. Kruglikovskaya & N. Tusupova
Kazakh National Medical University, Almaty, Kazakhstan.

Objective
To define diagnostic value of cytogram analysis of different types of oral cavity mucous epithelium in type 2 diabetes mellitus patients using cytological methods.
Material and methods
Material for cytological analysis was oral cavity mucous swab in 22 healthy people and 41 sick ones with type 2 diabetes mellitus at subcompensational stage. The group under study was homogenous in age, sex and biorhythmic type. Oral swabs were fixed in spirit–acetone and were May-Grunvald's and Romanovsky-Himsa's dyed. In swabs at the rate of 1000 cells the epithelical cells at various stages of differentiation were determined. Differentiation and cornification indexes of epithelial cells (DI and CI) were calculated in the swabs according to cytograms. Moreover, blood glucose level was determined. Correlation analysis and student's criteria were used.
Results
Research in lining type mucous (lips and cheeks) showed that in type 2 diabetes mellitus patients on the second day in hospital the DI and CI significantly increased ($P<0.01$). In specialized type mucous epithelium cytogram (tongue) DI and CI increased but in a less degree ($P<0.05$). According to the data obtained from the cytogram analysis of chewing type mucous epithelium (gingivia and hard palate) figures of DI and CI did not differ from the norm. Strong correlation between high DI and CI in the lip and cheek cytogram and increased blood glucose level in diabetes mellitus were observed.
Conclusion
The present study shows that cytological indexes of lining type mucous are the most informative for type 2 diabetes mellitus diagnostic. Obvious increase of DI and CI of lining type mucous cytogram against increased content of blood plasma glucose level indicate hyperglycemia during two previous weeks.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P602

**Socio-demographic factors associated with pediatric diabetic ketoacidosis admissions in Southern West Virginia**

K. Lewis[1], S. Bendre[1], C. Clark[3] & D. Wiley[2]
[1]West Virginia University, Charleston, West Virginia, USA; [2]Charleston Area Medical Center, Charleston, West Virginia, USA; [3]Mountain State Univeristy, Beckley, West Virginia, USA.

Background
Diabetic ketoacidosis (DKA) is a well-known complication in children with type 1 diabetes (T1DM) with a mortality rate estimated at 2%. Sparse data are available from the literature describing socio-demographic factors associated with DKA admissions in children. A previous study identified that children of non-Caucasian race and Medicaid, with T1DM, had increased incidence of DKA admissions.
Aims
To identify the socio-demographic factors associated with DKA admissions including type of insurance coverage, income by county, race, gender and HbA1c in West Virginia, a rural part of Appalachia.
Methods
A retrospective chart review of patients with known type 1 diabetes ages 1–18 years admitted to the Pediatric ICU with DKA in Charleston WV from January 2007 to December 2010 in comparison to our general type 1 diabetes population. The data collection tool included multiple socio-demographic factors and HbA1c.
Results
We reviewed a total of 167 patients with an admitting diagnosis of DKA; 63 charts were excluded because they did not meet either DKA criteria, age criteria, had new onset diabetes or lived outside of WV. About 57% were female, 43% male. Average age was 13.6 years (S.D. $\pm$2.81) 56% were covered by Medicaid or Chips insurance and 44% by commercial payers. About 11.5% were African American and 88.5% were Caucasian. The average HbA1c was 10.85% (S.D. $\pm$ 2.364).
Conclusions
Salient findings include higher HbA1c, higher rates in African American patients and in those covered by Medicaid.
Clinical implications
This study identifies socio-demographic factors associated with children admitted for DKA in WV. Patients identified at higher risk for DKA include those with elevated HbA1c, African American race and those covered by Medicaid/CHIPS. Findings can be utilized to identify patients at higher risks for DKA and implementation of prevention strategies.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P603

**Hypersomatotropism and glucose metabolism disorders**

F. Belhimer, S. Namani, A. Lyazidi & F. Chentli
Bab El Oued Hospital, Algiers, Algeria.

Introduction
Glucose metabolism disorder (GMD) is a classic complication of acromegaly, but its frequency varies from study to study.
Aim
We aimed to analyze GMD frequency in our population, and predictive factors such as: family history of diabetes mellitus (DM), age, gender, and GH rates.
Subjects and methods
It is a prospective study where 75 hypersomatotropic subjects were analyzed. They all had fasting and postprandial blood glucose evaluation. When the last

ones were normal glucose tolerance test was done and analyzed according to the WHO recommendations.
Results
In our group GMD were observed in 41 patients (22M/19F) = 55%. Diabetes mellitus was found in 27 subjects (65%), and impaired glucose tolerance (IGT) in 14 (35%). The diagnosis of DM was made before the hypersomatotropism's one in 37%, the delay was 5 years. Mean age at diagnosis for diabetic patients was $40 \pm 11$years, and $38 \pm 13$ years for non-diabetic subjects. Glucose metabolism disorders were more frequent in women: 54 vs 46% for men, but the difference was not statistically significant. Mean plasma GH was = 75.25 ng/ml in DM subjects vs 46.1 ng/ml for non-diabetic patients ($P < 0.05$). For family history of diabetes mellitus there was no difference between both groups.
Conclusion
In this study 55% hypersomatotopic subjects suffer from GMD. DM is more frequent than IGT (65 vs 35%). On the statistical side, there is a positive correlation between GMD and GH concentrations, but not with gender, age and family history of DM.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P604

**Questionnaire survey about a hospital adolescent transition diabetic clinic**

J. Cutler, M. Plunkett & P. De
City Hospital, Birmingham, UK.

Introduction
Our adolescent transition diabetes clinic (16–24 years) is run by a multi-disciplinary team (adult and paediatric diabetes consultant, diabetes specialist nurses and a dietician) every 4 months.
Aim
Questionnaire survey of patients understanding of their diabetes and satisfaction about the running and set-up of this unique transition clinic.
Method
A two-page questionnaire given to patients attending clinic or posted out.
Results
In total, 34 out of 56 questionnaires were returned. About 70% were aware of their most recent HbA1c. About 77% felt that their diabetes knowledge was good to excellent. About 23 and 21% patients experienced between 1–2 and 2–5 minor hypoglycaemia per week respectively. About 42% had attended the DAFNE course.
With regards to clinic environment, 88% rated clinic staff to be friendly and helpful, 84% thought that privacy level was good to excellent and 86% felt that enough time was devoted to appointments with minimal waiting times.
Timely notification of appointment letter was appreciated by 93%. About 73% felt adequate information was provided in the clinical correspondence. About 86% of patients were very satisfied with the accessibility and on-going support from diabetes specialist nurse (drop-in clinics, e-mail and mobile contact).
About 91% felt that the quality of care received in this clinic was good to excellent. About 94% wanted this transition clinic in the hospital setting rather than in the community. About 89 and 97% felt very satisfied with the consultations received from the doctors and nurses respectively. About 97% believed that this transition clinic helped them deal more effectively with their diabetes.
Conclusion
Although majority of our adolescents were satisfied with clinic environment and overall care received in the transition clinic, we need to focus more on specific aspects to further improve patient empowerment, mainly, patients own knowledge of their HbA1c, uptake of DAFNE and written clinical information given to our patients. We plan to re-audit this in future.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P605

**Celiac disease, autoimmune thyroiditis, vitamin B12 deficiency and adrenal failure among adult Turkish patients with type 1 diabetes mellitus**

I. Anaforoglu, S. Pulak, A. Livaoglu, S. Karagol, M. Asik, M. Ustaoglu & E. Algun
Trabzon Numune Education and Research Hospital, Trabzon, Turkey.

Introduction
Autoimmune polyglandular syndromes are characterized by the coexistence of at least two autoimmune endocrinopathies. Organ-specific autoimmunity is frequent in patients with type 1 diabetes mellitus (T1DM). The aim of this study was to estimate the prevalence of celiac disease and other autoimmune diseases like thyroiditis, pernicious anemia and adrenal failure among adult patients with T1DM.
Methods/design
Sixty-nine, asymptomatic patients with T1DM (32 females, 37 males), aged between 16 and 51 years were screened for celiac disease using antigliadin Ig A-G (AGA), endomisyal antibodies (EMA), anti-tissue transglutaminase (tTG). Endoscopic biopsies were performed for patients with positive antibody results. HLA-DQA1, HLA-DQB1 and HLA-DRB1 were available for 37 patients. Thyroid function tests, antithyroglobulin, antiperoxidase antibodies, level of vitamin B12, basal cortisol were measured for each patient.
Results
AGA was positive for 15 patients, EMA for two patients and tTG was positive for three patients; EMA and tTG positive patients were also positive for AGA. Endoscopic biopsies were performed in 10 patients, five patient did not accept to go undergo endoscopy. Two cases (2.9%) took a diagnosis of celiac disease with positive endoscopic biopsies revealing total mucosal atrophy. Increased intraepithelial lymphocyte count was present in four patients and gastritis was detected for remaining three patients. All patients were screened for autoimmune thyroid disease, adrenal disease and deficiency of vitamin B12. There were four (5.8%) cases of subclinical hypothyroid and three (4,3%) cases of overt hypothyroid patients. All were antibody positive. Thyroid antibodies were detected in 16 (23%) patients with normal thyroid function. Insulin tolerance test was performed for two patients whom basal cortisol levels were low. One took a diagnosis of Addison (1.4%). There were seven (10.1%) patients with vitamin B12 deficiency. Of 37 patients, HLA-DQA1 was positive for 25 patients, HLA-DQB1 for 24 patients and HLA-DRB1 for 18 patients. Although six patients were negative for HLA, one had high levels of thyroid antibodies and one had deficiency of vitamin B12.
Conclusion
Clinicians should be aware of possible autoimmune disease among patients with T1DM.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P606

**Correlation of fasting blood glucose with menopausal status in middle aged women with their obesity status**

P. Ashok & A. Joshi
BVDUMC, Pune, India.

Introduction
The association between type 2 diabetes mellitus and obesity is very close. Obesity is common in women aged between 45 and 49 years. Prevalence of prediabetes, i.e. impaired fasting glucose also seems to be higher in women than men in the Indian population. The present work is planned to study the prediabetic status in preobese and obese in pre- and post-menopausal women with the help of estimation of fasting blood glucose (FBG) levels.
Materials and method
Fasting blood glucose levels and BMI were estimated in 300 asymptomatic women with no family history of type 2 diabetes mellitus (DM) using GOD–POD

method. Pre- and post-menopausal subjects are divided in control (I), preobese (IIa) and obese group (IIb). The results is analyzed statistically ANOVA test.
Result and conclusion
Mean FBG levels in preobese and obese group are higher than control group in both pre- and post-menopausal women. There is significant difference between BMI and fasting blood glucose levels in pre- and post-menopausal women. In a nutshell obesity with & without menopause both act as a important predictor for type 2 DM. Thus in premenopausal women lifestyle modifications may prove as important means for prevention of obesity and type 2 DM to minimize the complication in post-menopausal status.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding

## P607

**Insulin resistance and C reactive protein level**

D. Dimic, M. Velojic Golubovic, S. Radenkovic, D. Stojic & S. Antic
Clinical Center Nis, Nis, Serbia.

C reactive protein is a sensitive marker of subclinical inflammation. C-reactive protein is associated with obesity, diabetes mellitus and increased cardiovascular risk. The mechanism of elevated CRP levels could have connections with insulin resistance. Inflammation seems to have significant role in pathogenesis of diabetes and cardiovascular disease. The aim of this study is to show that the subjects with greater insulin resistance, measured by HOMA-IR have higher levels of CRP.
Material and method
We included in the study 154 subjects with BMI below 25 kg/m$^2$, with no history of diabetes mellitus, conditions and medications that influence glucose control. We excluded patients with diabetes mellitus and CRP higher than 10 mg/l. In all subjects we measure body weight and height, BMI, CRP, FBG and insulin and calculated HOMA-IR.
Results
Regarding HOMA-IR values we divided all subjects in Group A with HOMA-IR less than 2 and Group B HOMA-IR higher than 2. In Group A CRP level was $1.76 \pm 0.72$ mg/l. In Group B CRP level was $3.84 \pm 1.45$ mg/l. There is statistically significant higher value of CRP in group B comparing to Group A, $P < 0.001$.
Conclusion
Our results show that greater HOMA-IR is associated with higher levels of CRP and that low-grade inflammation is associated with insulin resistance. Sublicinal inflammation leads to endothelial dysfunction and increased peripheral resistance that promotes insulin resistance further. Levels of CRP higher than 3 mg/l seems too be associated with increased risk for cardiovascular disease and diabetes mellitus. Our observation maybe can be used like adjunctive method for early detection of type 2 diabetes mellitus.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**The antropometric characteristic of type 1 diabetic patients in Kragujevac**

V. Mladenovic, A. Djukic, J. Petrovic & S. Sipetic
CC Kragujevac, Kragujevac, Serbia.

Background
Diabetes mellitus is a condition of chronic hyperglicemia (as well as metabolic disorders of the other carbohydrates, lipids and proteins), as a result of absolute and/or relative lack of insulin or lack of insulin effects. The aim of the research presented in this study is examination of antropometric characteristics of patients suffering from type 1 diabetes in Kragujevac depending on gender.
Material and method
We examined 206 patients with type 1 diabetes in Kragujevac, and compare according to gender (107 men and 99 women). All these patients were treated with insulin therapy.
Results
The average duration of DM1 was $12.1 \pm 5.2$ years. The prevalence of overweight was 11.3%. The average height was $173.14 \pm 9.4$ vs $164.16 \pm 7.27$ cm (man vs women, $P < 0.001$), the average weight was $74.22 \pm 14.04$ vs $67.58 \pm 11.28$ kg, $P < 0.001$), the average value of BMI was $26.01 \pm 8.19$ vs $28.55 \pm 5.25$ kg/m$^2$, man vs women, $P < 0.001$), the average value of waist $95.6 \pm 12.01$ vs $79.5 \pm 10.35$ cm, man vs women, $P < 0.001$), the average value of hip $97.89 \pm 7.7$ vs $104.61 \pm 8.67$ cm, man vs women, $P < 0.001$).
Conclusion
There is significant difference in height, weight, BMI, waist and hip between man and woman in type 1 diabetic patients.

## P609

**Resolution of type 2 diabetes following IFN-α therapy for chronic hepatitis C**

D. Kim & J. Park
Hallym University College of Medicine, Seoul, Republic of Korea.

We report on a patient whose type 2 diabetes resolved following interferon-α (IFN-α) therapy for hepatitis C virus (HCV). A 57-years-old man, presented with fatigue, polyuria and polydipsia. He was newly diagnosed with type 2 diabetes. During the hospital day, he was also diagnosed with chronic hepatitis. Serological studies for chronic hepatitis demonstrated presence of hepatitis C, type 2a/2c genotype. He was started on subcutaneous insulin and IFN-α. After 24 weeks of treatment of IFN-α, HCV polymerase chain reaction was negative. And diabetes resolved despite an increase in his body weight. A number of papers have described associations between IFN-α therapy and the precipitation of diabetic ketoacidosis as the presenting feature of new-onset diabetes. Our case shows a resolution of diabetes after IFN-α therapy for chronic hepatitis C. HCV mainly affects the liver, but also several tissues outside the liver have been reported to be involved, resulting in a wide spectrum of extrahepatic manifestations. It has been hypothesized that diabetes also could be one of these extrahepatic conditions attributable to HCV infection. Previous HCV infection markedly increased the prevalence of type 2 diabetes, regardless of the presence of liver cirrhosis. Non-diabetic HCV patients have insulin resistance and specific defects in the insulin-signaling pathway. The specific mechanisms by which HCV lead to type 2 diabetes are not fully understood, but it seems that an increase of insulin resistance associated with both steatosis and the overproduction of pro-inflammatory cytokine could play a crucial role. Although it is unclear whether the resolution of diabetes in this case occurred as an effect of IFN-α or as a result of becoming HCV RNA negative, it has suggested a great deal about the role of IFN-α and HCV infection in the pathogenesis of diabetes.

## P610

**Art and its role in therapeutic patient education**

R. Kurashvili, E. Shelestova, L. Kurtsikashvili & L. Tsutskiridze
National Center for Diabetes Research, Tbilisi, Georgia.

Art-painting, poetry, music, is an inexhaustible source of inspiration and motivation. Patient education (TPE) in chronic diseases is a long and tedious process. To achieve high motivation one must use all existing possibilities. Art is the most potent tool to influence the conscious and subconscious of a person to motivate him/her to adhere to treatment and healthy lifestyle. Literature, and mainly W. Shakespeare, could be used for TPE, as deep understanding of existing health problems are reflected in his works. Shakespeare's worlds are the mirror of the various aspects of medicine during the renaissance. Most of the problems, such as obesity/overweight, excessive appetite, and alcohol intake, hereditary factors, depression, influence of every day's life on person's wellbeing are described in Othello, Hamlet, Richard III, Henry VI, Love's Labor's Lost, Comedy of Errors and others. Longville's words (Love's Labor's Lost) 'fat paunches have lean pates; and dainty bits make rich the ribs, but bankers out the wits', may be used as strong motivational element when eating habits and weight control are aimed at. We are widely using painting, literature, music in patient education process. The questionnaires used to assess the effect of art showed that almost all patients give positive evaluation to such approach. Patients we are working with express their impression of the art as follows 'it penetrates deeply into the subconscious and helps to change the habitual world'. Case reports, presented by W. Shakespeare can be widely used to stimulate educational process.

**The antropometric characteristic of type 2 diabetic patients in Kragujevac**

J. Petrovic, V. Mladenovic, A. Djukic & S. Sipetic
CC Kragujevac, Kragujevac, Serbia.

Introduction

Diabetes mellitus is a condition of chronic hyperglicemia (as well as metabolic disorders of the other carbohydrates, lipids and proteins), as a result of absolute and/or relative lack of insulin or lack of insulin effects.

The aim of the research presented in this study is examination of antropometric characteristics of people suffering from type 2 diabetes in Kragujevac.

Material and method

We examined 3108 patients with type 2 diabetes in Kragujevac, and divide patients in two groups: 2470 patients (73.8%) with oral antidiabetic therapy (DM2) and 638 patients (19.1%) with insulin therapy (DM2I).

Results

The average duration of DM2 was $6.37 \pm 5.8$ years, and for DM2I $12.87 \pm 7.39$ years. The average height was $165.8 \pm 9.68$ vs $167.2 \pm 9.69$ cm (DM2 vs DM2I, $P = 0.041$), the average weight was $79.37 \pm 14.19$ vs $74.19 \pm 13.73$ (DM2 vs DM2I, $P < 0.001$), the average value of BMI was $28.82 \pm 4.72$ vs $26.56 \pm 4.59$ kg/m$^2$ (DM2 vs DM2I $P < 0.001$), the average value of waist $98.09 \pm 11.13$ vs $92.59 \pm 11.72$ cm (DM2 vs DM2I $P < 0.001$), the average value of hip $108.67 \pm 9.88$ vs $104.61 \pm 8.67$ cm (DM2 vs DM2I $P < 0.001$). We also compared patients according to sex: the average height was $174.14 \pm 9.4$ vs $161.16 \pm 7.27$ cm (man vs women, $P < 0.001$), $81.99 \pm 15.11$ vs $74.22 \pm 14.04$ (man vs women, $P < 0.001$), the average value of BMI was $26.86 \pm 4.43$ vs $28.55 \pm 5.25$ kg/m$^2$ (man vs women, $P < 0.001$), the average value of waist $98.92 \pm 10.75$ vs $95.6 \pm 12.01$ cm (man vs women, $P < 0.001$), and the average value of hip $107.7 \pm 7.49$ vs $109.39 \pm 10.6$ cm (man vs women, $P < 0.001$). There is significant difference in height, weight, BMI, waist and hip between man and woman.

Keywords: diabetes mellitus type 2, antropometric characteristic.

## P612

**Prevalence of microvascular complications in youth with type 2 diabetes: systematic review and meta-analysis**

C. McLennan[1], Y. Cho[2,3], K. Donaghue[2,3] & M. Craig[1,2,3]
[1]University of New South Wales, Sydney, NSW, Australia; [2]The Children's Hospital at Westmead, Sydney, New South Wales, Australia; [3]University of Sydney, Sydney, New South Wales, Australia.

Introduction

Type 2 diabetes (T2D) has increased in youth and complications rates may be higher than type 1 diabetes (T1D).

Aims

To estimate the prevalence of complications and hypertension in youth with type 2 diabetes and compare complication rates between T2D and T1D.

Design and methods

Systematic review and meta-analysis of observational studies, analysed with random effects models.

Data sources

Medline and Embase (until Oct-2011), article bibliographies and contact with experts.

Eligibility criteria

Longitudinal or cross-sectional observational studies measuring incidence or prevalence of nephropathy, hypertension, retinopathy, peripheral neuropathy and/or autonomic neuropathy in youth or young adults ($\leq$28 years) with T2D. Studies of youth with both T2D and T1D were included; where possible meta-analysis was conducted to compare complication rates. Evidence levels were assigned using the Oxford CEMB and quality assessed using the Newcastle–Ottawa scale.

Results

The final search yielded 25 studies involving 3321 youth. Overall, methodological quality was poor. Among those with T2D, median age was 14.5 years, duration 1.7 years and HbA1c 7.7%. Pooled prevalence (95% CI) for T2D was: microalbuminuria 18% (17–20%); macroalbuminuria 5% (3–7%); hypertension 28% (26–29%); retinopathy 2% (1–3%); peripheral neuropathy 2% (1–4%); and autonomic neuropathy 43% (25–63%). Compared with T1D, microalbuminuria was more common in T2D: odds ratio (OR) 3.5, 95% CI 1.6–7.8, and hypertension: OR 3.4, 95% CI 2.4–4.8. There was significant heterogeneity across studies for microalbuminuria, hypertension and nephropathy ($P < 0.01$).

Conclusions

This is the first systematic review of complications in youth with T2D; they have higher rates of microalbuminuria and hypertension compared with T1D, despite shorter diabetes duration. There is a paucity of quality data on complications in youth with T2D. Large-scale prospective cohort studies are required to better understand their specific risk factors for microvascular complications, and to guide complications screening and treatment.

Figure 1 – Odds ratio for nephropathy prevalence in youth with type 2 vs type 1 diabetes.

**The intake of fiber suppresses the high fat high carbohydrate meal induced endotoxemia, oxidative stress and inflammation**

H. Ghanim, M. Batra, S. Dhindsa, K. Green, S. Abuaysheh, A. Chaudhuri & P. Dandona
State University of NY at Buffalo, Buffalo, New York, USA.

Our previous work has shown that the intake of a high fat high carbohydrate (HFHC) meal results in an increase in endotoxin (LPS) and LPS binding protein (LBP) concentrations concomitant with an increase in the expression of TLR-4, the receptor for LPS, and CD-14, which facilitates the binding of LPS to its receptor. In addition, there is an increase in ROS generation, NFkB binding and the expression of TNF-$\alpha$ and IL-1$\beta$. Our work has also demonstrated that an equicaloric meal rich in fiber and fruit (American Heart Association (AHA) recommended meal) does not induce these changes. We hypothesized, therefore, that the addition of fiber to a HFHC meal will prevent the changes induced by HFHC meal. Eight fasting normal subjects (BMI $<25$ kg/m$^2$) were given 900 Calorie meals of either HFHC or AHA or HFHC with additional fiber (30 g) (Fiber One Original) on three sequential visits one week apart in a randomized crossover design. As expected, the HFHC meal induced an increase in LPS concentrations (by $69\pm14\%$) with an increase in ROS generation (by $120\pm24\%$) and the expression of TLR-4, CD14 and IL-1$\beta$ (by $71\pm14$, $86\pm14$ and $127\pm14\%$, respectively; $P<0.05$ for all) in MNC. The AHA meal did not induce any of these changes. The addition of fiber to HFHC meal significantly reduced the increase in LPS concentrations (by $58\pm10\%$; $P<0.05$), ROS generation (by $47\pm14\%$; $P<0.05$) and the expression of TLR-4, CD14 and IL-1$\beta$ (by $37\pm11$, $46\pm12$ and $52\pm15\%$, respectively; $P<0.05$ for all) observed with the HFHC meal alone. Additionally, the intake of fiber with the HFHC meal reduced postprandial glucose excursion and increased insulin concentrations compared to HFHC meal alone. We conclude that the addition of fiber to a pro-inflammatory HFHC meal has a beneficial anti-inflammatory and metabolic effect. Thus, the fiber content of the AHA meal may account for its non-inflammatory nature. Since ROS, TLR-4 and IL-1 $\beta$ potentially interfere with insulin signal transduction and are known to be pro-inflammatory in the arterial wall, this action of dietary fiber may contribute to its benefits in the prevention of insulin resistance, type 2 diabetes and atherogenesis.

**Blocking Notch pathway improves wound healing in diabetic mice**

V. Sunkari, I. Botusan, J. Grunler, K. Brismar & S. Catrina
Karolinska Institute, Stockholm, Sweden.

Aim

We have proposed to study the modulation of the Notch pathway in diabetes having in mind the essential role played by the Notch system in the regulation of cell differentiation and angiogenesis.

Methods

The effect of hyperglycemia on Notch system was studied *in vitro* and *in vivo* using western blot, reporter gene assay or evaluation of target genes (qRT-PCR). The functional consequences of the Notch system modulation were studied by the assessment of the migration and angiogenesis potential. Notch pathway inhibition was induced either chemically with gamma secretase inhibitors (DAPT, L-685,458). The effect of the Notch inhibition on wound healing was evaluated in db/db mice.

Results

Hyperglycemia activates Notch pathway at several levels as shown by increased NICD level, increased reporter gene activity and enhanced expression of several essential target genes as evaluated both *in vitro* and *in vivo*. The inhibitory effect of high glucose on migration of HDF and angiogenesis was cancelled by blocking the Notch signaling with different gamma-secretase inhibitors (DAPT or L-685,458). Specific inhibition of different Notch receptors (1–4) by siRNA pointed out to a crucial role of Notch1 in migration and angiogenesis. Local treatment with gamma-secretase inhibitors (DAPT or L-685,458) improved the wound healing in db/db mice (percentage of wound closure on day 12 was $60\pm2\%$ (DAPT), $70\pm4\%$ (L-685,458) and $43\pm5\%$ (placebo) respectively ($P<0.01$). Blocking Notch pathway in diabetic wounds was followed by increase in granulation and epidermal formation, increase in blood vessel formation and increase in expression of chemokine (SDF-1 alpha) responsible for better recruitment of EPCs.

Conclusions

Hyperglycemia activated Notch signaling with deleterious effects on cell migration and angiogenesis. Blocking the overactive Notch pathway by local treatment with gamma-secretase inhibitors improves wound healing rate in diabetic animal model.

**The role of AMP-activated protein kinase in myocardial tolerance to ischemia in rats with diabetes mellitus type 2 and its relation to metformin therapy**

E. Kravchuk, E. Grineva, M. Galagudza & A. Kostareva
Almazov Federal Heart, Blood and Endocrinology Centre, Saint Petersburg, Russian Federation.

Introduction

The aim of our experimental study was to investigate the effect of both T2DM and metformin treatment on myocardial tolerance to ischemia-reperfusion injury and cardiac AMP-activated protein kinase (AMPK) activity.

Methods

The protocol included four groups: i) controls ($n=13$) – non-diabetic rats treated with i.p. vehicle injections for 3 days prior to the heart perfusion, ii) controls + metformin (CM; $n=12$) – non-diabetic rats treated with metformin (200 mg/kg) i.p. for 3 days prior to the perfusion, iii) T2DM ($n=12$) – diabetic animals receiving vehicle, iv) T2DM + metformin (T2DMM; $n=7$) – diabetic rats treated with metformin. In all groups, the hearts were subjected to 30-min global ischemia and 120-min reperfusion according to Langendorff followed by histochemical determination of infarct size. Phosphorylated $\alpha$-AMPK was evaluated with western blot analysis.

Results

Infarct size and postischemic recovery of left ventricular function were not different between controls and CM-group. Infarct size in T2DM was significantly lower than in controls ($24.4\pm7.6$ vs $45.0\pm10.4\%$, respectively, $P<0.01$), which is indicative of the phenomenon of metabolic preconditioning in T2DM. At the same time in T2DMM group there was no appreciable effect on infarct size ($37.7\pm8.3\%$). In comparison to controls, $\alpha$-AMPK phosphorylation was significantly increased in T2DM and, to a lesser extent, in CM-animals. However, AMPK activity was not different between T2DM and T2DMM groups.

Conclusion

AMPK phosphorylation was increased in both T2DM and CM, but it did not provide a significant cardioprotection in CM group. Moreover, combination of T2DM and metformin treatment had not potentiated infarct-limiting effect of T2DM, meaning that AMPK activation by metabolic preconditioning is not additive to that seen with metformin treatment. As the diabetes may act through many different pathways in the cell the effect of diabetes was more manifested in ischemia tolerance improvement.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P616

**A novel case of diabetes mellitus and aniridia in a Caucasian family**

D. Chen[1,2], A. Jenkins[2,3] & L. Campbell[1,2]
[1]St Vincent's Hospital, Sydney, New South Wales, Australia; [2]Garvan Institute of Medical Research, Sydney, New South Wales, Australia; [3]University of Wollongong, Wollongong, New South Wales, Australia.

Introduction

We describe a novel case of familial congenital aniridia in a Caucasian woman with associated insulin requiring diabetes mellitus. This human combination has been described in Asian families in association with a heterozygous Paired Box 6 (PAX6) mutation (1) with subsequent evidence supporting that the mutation in

this transcription factor causes decreased Proconvertase 1/3 function in the pancreas and a high proinsulin to insulin ratio (2). Our case does not have a PAX6 mutation and study ratios of proinsulin to insulin were not consistent with impaired conversion.

Clinical case:

A 54-years-old woman of Caucasian descent was diagnosed with diabetes mellitus aged 28. She commenced a basal-bolus regimen soon after diagnosis, currently taking $<20$ units insulin per day. She has a HbA1C of 7.5% without microvascular complications. Her body mass index is 21 kg/m$^2$. Recent glutamic acid antibody and islet cell antibody tests were negative.

The patient has congenital bilateral aniridia with subsequent bilateral cataracts. She has an intraocular lens implant in her left, and a contact lens in her right eye. There is a significant family history with her father having aniridia without diabetes, her sister having aniridia with poorly controlled diabetes, renal failure, and severe retinopathy, her nephew having aniridia alone.

Conclusions

Up to 10% of congenital aniridia cases do not have identifiable PAX6 mutation (3). This could be due to genomic alterations in regulatory elements of PAX6 or a mutation in another gene known to cause congenital iris abnormality (4). An ocular developmental gene forkhead box C1 (FOXC1) heterozygous mutation (W152G) has been suggested to produce aniridia in man by resulting in failed autophagy of poorly folded proteins (5).

We postulate that this mechanism could offer another means by which the beta cell may be vulnerable in man and should be sought in PAX6 negative aniridia cases with diabetes.

**Experience of diabetic dyslipidemia correction in patients with ischemic heart disease and type 2 diabetes mellitus using α-lipoic acid in combination therapy**

N. Lopina & L. Zhuravlyova

Kharkov National Medical University, Kharkov, Ukraine.

Purposes

To investigate the effects of α-lipoic acid (ALA) on diabetic dyslipidemia, endothelial dysfunction, levels of adiponectin and proinflammatory mediators in combination therapy of patients with ischemic heart disease (IHD) and type 2 diabetes mellitus (T2DM).

Methods

We examined 40 patients with IHD and T2DM (19 males, age $60.5\pm4.7$ years). Baseline characteristics of patients included history of IHD ($7.2\pm2.3$ years), T2DM ($4.7\pm0.5$ years). The level of HbA1c was $<7.5\%$. All patients were divided into two groups: the 1st ($n=20$) – received the standard therapy, the 2nd ($n=20$) in the standard therapy received ALA 600 mg once daily. In all patients were determined the levels of total cholesterol (TC), low-density lipoprotein cholesterol (LDL), triglycerides (TG), high-density lipoprotein cholesterol (HDL) by enzymatic colorymetric method, proinflammatory mediators (TNF-α, hsCRP), vascular endothelial growth factor (VEGF) and adiponectin by ELISA method at baseline and in 6 months.

Results

Using in combination therapy ALA increased plasma levels of HDL on 5% (0.4 mmol/l), decreased TC, LDL and TG levels on 4, 5.2 and 6.3% respectively (all $P<0.001$), substantially lowered plasma levels of TNF-α by $6\pm1.5\%$ ($P<0.05$) and hsCRP from $1.53\pm0.13$ to $0.98\pm0.11$ pg/ml ($P<0.05$), increased plasma levels of adiponectin by $18\pm2\%$ ($P=0.001$) compared with the 1st group. The serum VEGF concentrations in patients who received in the standard therapy ALA were significantly reduced from $320\pm26$ pg/ml at baseline to $212\pm22$ pg/ml in 6 months ($P=0.022$). There were correlations between changes in adiponectin levels and the VEGF concentrations ($r=-0.31$, $P=0.043$).

Conclusions

Combination therapy with ALA significantly reduced TC, LDL, TG and proinflammatory mediators, VEGF, increased HDL in patients with IHD and T2DM.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P618

**Changes of NO concentration in the cause of streptozotocin diabetes mellitus and under action of different NOS inhibitors in streptozotocin rats**

J. Sokolovska[1,2], J. Sharipova[1], L. Lauberte[1], L. Baumane[1], I. Kalvins[1] & N. Sjakste[1,2]

[1]Latvian Institute of Organic Synthesis, Riga, Latvia; [2]University of Latvia, Riga, Latvia.

Background

Diabetes mellitus (DM) and its complications cause numerous health and social problems throughout the world. Pathogenic action of nitric oxide (NO) is responsible to a large extent for development of complications of the disease. Thus modification of NO production in DM patients appears to be an option for treatment of DM complications.

Objective

To study changes in NO concentration in diabetic rats after administration of different compounds with potential influence of NO production: iNOS inhibitors

aminoguanidine and 1400 W, specific inhibitor of Kupffer cells GdCl3 and xantine oxidase inhibitor allopurinole.
Methods
Severe diabetes mellitus in rats was induced by single injection of streptozotocin (STZ) 50 mg/kg, i.v., after 1 week of diabetic state compounds of interest were administered. Production of NO was monitored by means of ESP spectroscopy of Fe–DETC–NO complex in brain cortex, cerebellum, liver, kidneys, whole blood, skeletal muscle, subcutaneous fat and aorta.
Results
Development of STZ DM was followed by increase of NO production in the liver from 45.39±5.93 to 101.81±12.12 ng/g tissue, kidneys (from 2.64±0.97 to 15.04±2.04 ng/g tissue), blood (from 29.36±2.15 to 41.62±3.93 ng/g tissue), muscles (from 7.82±1.87 to 12.65±0.87 ng/g tissue), aorta (from 14.4±0.2 to 42.2±4.2 ng/g). In adipose tissue NO production decreased from 34.00±3.68 to 18.56±1.81 ng/g tissue. In diabetic rats, 1400 W decreased NO concentration in liver, kidney, muscle, whole blood, fat and aorta, aminoguanidine – in all studies organs except brain cortex, allopurinol – in kidneys, muscle, aorta and fat.
Conclusions
Diabetic state provokes increase of NO production in rats. iNOS inhibitors aminoguanidine and 1400 W, as well as allopurinole attenuated increase of NO concentration in most organs studied. Modification of NO production could be useful in prevention of some diabetic complications.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding

## P619

**Cardiac dyssynchrony as a pathophysiological mechanism of heart failure development and progression in type 2 diabetic patients**

D. Lopin[1], N. Lopina[2], J. Rodionova[1], M. Vlasenco[1] & D. Volkov[3]
[1]Kharkov Medical Academy of Postgraduate Education, Kharkov, Ukraine; [2]Kharkov National Medical University, Kharkov, Ukraine; [3]Institute of General and Urgent Surgery of NAMS of Ukraine, Kharkov, Ukraine.

Objectives
Diabetes mellitus (DM) is an independent predictor of new onset heart failure (HF) and adverse outcomes among patients with already existing HF. However mechanisms leading to impaired cardiac performance due to DM are still unclear. The purpose of investigation was to assess the influence of cardiac dyssynchrony (DYS) on systolic and diastolic function in patient with type 2 diabetes mellitus (T2DM) with concomitant stable coronary artery disease (CAD) and without arterial hypertension (AH).
Methods
In total, 42 patients (67±12 years, 20 males) with stable CAD, without AH in HF II–III NYHA class were divided into two age-matched groups: 1st group ($n=22$) – patients with T2DM (average duration 5.6±2.1 years) and 2nd group ($n=20$) – patients without DM. In all patients were determined body mass index (BMI), HbA1c level, HOMA-IR and specific echocardiographic tissue Doppler imaging (TDI) parameters as myocardial mitral annular (Sa) and basal segmental (Sm) systolic and early diastolic (Ea and Em) velocities, transmitral to TDI Ea ratio (E/Ea) and time to peak and onset of Sm from four basal and four mid left ventricular (LV) segments. Maximal difference in time between Sm-Ts-diff > 90 ms and standard deviation-Ts-SD > 37 ms were considered DYS.
Results
In the 1st group DYS and diastolic dysfunction were significantly more frequent than in the 2nd one (45.5 vs 35.0% and 68.2 vs 60.0% respectively, both $P<0.05$). Subanalysis of 1st group has shown correlation between Ts-SD and HbA1c level ($r=+0.48$, $P<0.05$), BMI ($r=+0.51$, $P<0.05$) and HOMA-IR ($r=+0.57$, $P=0.048$). The highest values of Ts-SD and Ts-diff were obtained in patients with Ea = 2.2 m/s and E/Ea = 42.
Conclusions
It was found that in patients with T2DM DYS is one of the factors which have negative impact on cardiac performance and thus the prognosis. The degree of mentioned disturbances correlates with glycemic control and insulin resistance.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P620

**Possible risk factors of type 2 diabetes and role of long term oral hypoglycemic agent, metformin**

A. Chakraborty[1], S. Chaudhury[2] & M. Bhattacharyya[1]
[1]CU Kolkata, India; [2]IPGMER, Kolkata, India.

Introduction
Over the past decades diabetes emerged as epidemic dimension due to person's genetic pre disposition and environmental condition. Despite significant advancement in the development of oral hypoglycemic agents, an ideal drug for treating T2DM and its complication is still a distant reality. Hyperglycemia has a variety of toxic effects, including elevated generation of ROS nitrosative stress and inflammation. This work attempts to explore the role of oxidative and nitrosative stress for the electron leakage in the mitochondria initiating cardiovascular disease pathogenesis. Apart from classical risk factors, elevated serum concentration of Hcy is closely associated with the increased risk of atherosclerosis. Here we report, how Hcy upregulation may be controlled in diabetic patients administered with hypoglycemic agent, metformin.
Methods
Metformin administered and placebo T2DM subjects participated in the study.
Results
Metformin treatment diminished ROS production, MMP, inflammation and restore nitric oxide production in diabetic subjects. Homocysteine level is higher in metformin administered patients (16.2+3.5 vs 14.5+2.9 μmol/l). Vitamin B12 level is greatly reduced in metformin treated patients compared to placebo ($P=0.001$). The mean values of Hcy level for genotypes (677C > T MTHFR)11, 12 and 22 are 14.76, 23.37 and 29.12 μmol/l respectively.
Conclusion
Greater reduction of ROS, AOPP, CRP and pentosidine level and restoration of NO from baseline were achieved in metformin administered patients, elucidating that metformin extends added protection to combat the disease pathogenesis. Metformin treatment balance mitochondrial homeostasis by normalizing the ion transport. Enhanced Hcy production is not related with metformin treatment rather it is a drug independent phenomena and depend greatly on polymorphism in MTHFR 677 C > T phenotype. These information will be beneficial for the emergence of new pharmacogenomic initiatives.
ROS generation (1a,1c-baseline,1b-metformin administered,1d-placebo) and hyperpolarisation of mitochondrial membrane (3a,3b,3e,3f-baseline,3c,3d-metformin administered 3g,3h-placebo) reduced in metformin administered subjects in comparison to placebo. Nitric oxide production (2a,2c-baseline,2b-metformin administered,2d-placebo) is restored in metformin treated subjects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P621

**Complex ventricular arrhythmias with early repolarization in type 2 diabetes mellitus**

A. Kopaleishvili, T. Akhobadze, R. Kurashvili, M. Dundua & E. Inashvili
National Center for Diabetes Research, Tbilisi, Georgia.

Background and aims
Mortality rate from cardiovascular disease (CV) including sudden death (SD) is pronounced in type 2 diabetic (T2DM) patients with cardiac autonomic neuropathy (CAN) and/or complex ventricular arrhythmias (CVA). Early repolarization (ER) is also considered to be a significant risk factor for SD. The aim of the study was to evaluation the relation between CAN, CVA and ER in T2DM patients.
Materials and methods
Participants were 44 T2DM patients (24m/20f, mean age 56.9 $\pm$ 7.3 years) with ER pattern (Gr.1) at the surface ECG defined as a J-point elevation of at least 0.1 mV in at least two leads I,II,III,avF,avL,V4,V5 or V6, when slurring of the terminal part of QRS was associated with an elevation of ST segment. As controls (Gr.2) 35 sex, age and diabetes duration matched patients were selected. In all patients 24 h Holter ECG was performed.
Results
CVA, such as paired ventricular extrasystoles, episodes of ventricular tachycardia (VT) were more frequently registered in Gr.1 (43.2 vs 34.3%), while frequent supraventricular extrasystoles were more often observed in Gr. 2 (37.1 vs 34%), though this difference was not significant. Heart rate variability (HRV) parameters SDNN (0.091 $\pm$ 0.023 vs 0.118 $\pm$ 0.029, $P = 0.000$) and triangular index (25.4 $\pm$ 6.3 vs 33.6 $\pm$ 8.1 $P = 0.000$) were significantly lower in Gr 1.
Conclusion
CVA were more frequently observed in T2DM patients with ER. HRV parameters were lower in patients with ER. Increased risk of sudden cardiac death in T2DM patients may be associated with repolarization abnormalities due to cardiac autonomy neuropathy that predisposes to fatal ventricular arrhythmias. Further studies are required in order to assess the role of cardiac autonomy neuropathy in the development of repolarization abnormalities in T2DM patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P622

**Diabetic nephropathy in pregnant women with type 1 diabetes mellitus**

Y. Themeli[1], V. Bajrami[1], A. Idrizi[2], K. Zaimi[1], K. Mustafaraj[1], A. Shtylla[3], E. Peci[5] & J. Gjoshe[4]
[1]DC 'Ikeda-Euromedica', Tirana, Albania; [2]UHC 'Mother Teresa', Tirana, Albania; [3]UHC 'Koco Glozheni', Tirana, Albania; [4]'Hygeia' Hospital, Tirana, Albania; [5]American Hospital, Tirana, Albania.

Background
Diabetic nephropathy represents one of the most common causes of end-stage renal disease. During pregnancy it is associated with an increased perinatal morbidity as a striking result of the consistently high rate of preterm deliveries, mainly due to the frequent development of pre-eclampsia.
Aim
To describe pregnancy outcome in type 1 diabetic women with normoalbuminuria, microalbuminuria, or diabetic nephropathy after implementation of an intensified antihypertensive therapeutic strategy.
Design and methods
In our prospective study were enrolled 80 pregnant women with type 1 diabetes. Antihypertensive therapy, mainly methyldopa, was given to obtain blood pressure $<$135/85 mmHg and urinary albumin excretion $<$300 mg/24 h. Blood pressure and HbA1C were recorded during pregnancy. The pregnancy outcome was compared with recently published studies of pregnant women with microalbuminuria or diabetic nephropathy.
Results
Antihypertensive therapy was given in 9 of 54 women with normoalbuminuria, 8 of 18 women with microalbuminuria, and all eight women with diabetic nephropathy. Mean systolic blood pressure during pregnancy was 124 mmHg (range 105–151), 125 mmHg (119–138), and 138 mmHg (113–147) in women with normoalbuminuria, microalbuminuria, and diabetic nephropathy, respectively ($P = 0.0095$). No differences in mean diastolic blood pressure or HbA1C were detected between the groups. No women with microalbuminuria developed preeclampsia. The frequency of preterm delivery was 22% in women with normoalbuminuria and microalbuminuria, in contrast to 75% in women with diabetic nephropathy ($P < 0.01$) where the median gestational age was 254 days.
Conclusions
With intensified antihypertensive therapy and strict metabolic control, comparable pregnancy outcome was seen in type 1 diabetic women with microalbuminuria and normoalbuminuria. Diabetic nephropathy was associated with more adverse pregnancy outcome, compared to other studies.

**Effects of chronic administration of Vardenafil on endothelial function in patients with type 2 diabetes mellitus. A longitudinal, randomized, placebo-controlled, double blind, non-sponsored clinical trial**

D. Santi, A. Guidi, A. Granata, M. Simoni & C. Carani
University of Modena & Reggio Emilia, Azienda Unità Sanitaria Locale, Modena, Italy.

Introduction
The endothelium produces molecules regulating vascular function, such as nitric oxide (NO). NO protects blood vessels from endogenous injury and causes vasodilation through activation of second messengers. In diabetes mellitus (DM), hyperglycemia provokes oxidative stress, reduction of NO and increased synthesis of vasoconstrictors (e.g. endothelin). Cyclic nucleotide phosphodiesterases (PDEs) are enzymes, controlling the rate of degradation of second messengers. In short-term studies PDE-5 inhibitors showed promising results on endothelial function parameters. No data about chronic treatment in diabetic subjects are available.
Aim
To investigate if chronic treatment with Vardenafil for six months can prevent or delay the deterioration of systemic endothelial function in patients with type 2 DM.
Methods
Longitudinal, randomized, placebo-controlled, double-blind clinical trial involving men with type 2 DM. Study duration: 52 weeks including enrollment (4 weeks), treatment (24 weeks), follow-up (24 weeks). Treatment: 2 $\times$ 10 mg/day of Vardenafil/placebo. Parameters: andrological and instrumental examination and blood sampling performed at each visit. Primary end-point: serum endothelin-1. Sample size: 53 patients per arm.
Results
Interim analysis of blinded data: of 35 patients enrolled so far, 18 (51.43%) completed the treatment phase, 12 (34.29%) ended the study. Five patients dropped-out (14.29%). All patients, had a good adherence to treatment (mean of tablets taken: 92.2%). Glycated hemoglobin, considering 18 patients who ended the treatment phase, improved in seven (38.9%), worsened in 2 (11.1%) and remained elevated in five (27.8%) patients. Flow-mediated dilation (FMD, 13 patients) improved in 1 (7.7%), worsened in three (23.1%) and persisted elevated in three (23.1%) patients. Intima-media thickness (IMT) and IIEF-15 improved in 1 patient. Endothelin-1 and other serum parameters will be measured at the end of the study.
Conclusion
Intervention per se results in variations of glycated hemoglobin and FMD values (improvement/impairment) in 50% and 30.8% of patients, respectively but does not seem to influence IMT and IIEF-15 values.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Pattern of chronic complications among Nigerian patients with DM: the need for focused prevention initiatives**

O. Kayode[1], O. Odukoya[2], I. Odeniyi[2], O. Fasanmade[1,2] & A. Ohwovoriole[1,2]
[1]Lagos University Teaching Hospital, Lagos, Nigeria; [2]College of Medicine, University of Lagos, Idi-Araba, Lagos, Nigeria.

Introduction
The prevalence of diabetes mellitus among Nigerian adults has been increasing over time. A considerable number of chronic complications of DM can be

adequately prevented, however, the proportion of patients presenting with chronic complications of DM in our setting is still relatively high.
Objectives
This study was carried out to assess the pattern of chronic diabetic complications among patients attending the diabetic clinic of Lagos University Teaching Hospital and to identify the factors associated with these complications.
It is hoped that this data will provide information to physicians and public health workers for focused prevention initiatives for these patients.
Methodology
A cross-sectional descriptive survey was carried out among patients attending the diabetic clinic from January to March 2011 using a systematic random sampling method. In total, 419 patients were selected and interviewed using a pre tested interviewer administered questionnaire after written informed consent.
Results
The age of the patients ranged from 25 to 84 years with a mean of $55.2 \pm 12.5$ years. There were more females (62%) than males (38%). Most of them were married (65%) with a mean duration of DM of $8.4 \pm 6.5$ years. Up to 16.9% of the patients had at least one complication of DM at the time of the survey. Eye problems were by far the commonest type accounting for 65% of these. This was followed by neurological complications (16.7%). Cardiovascular problems accounted for 11.6% while foot complications and renal problems were 3.3 and 1.7%, respectively. A bi-variate analysis revealed that increasing age, lower educational status, increasing duration of DM, the presence of co-existing hypertension and a higher waist circumference were significantly associated with the presence of chronic complications among these patients. A logistic regression revealed that increasing age and co-existing hypertension were the strongest predictors of chronic complications among these patients.
Conclusion
There is therefore a need to focus on routine preventive eye screening especially among the elderly diabetics attending this clinic. The prevention and appropriate management of hypertension among known diabetics will also play an important role in the prevention of chronic complications among these diabetic patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### The correlation between metabolic syndrome and albuminuria in type 2 diabetes mellitus

Y. Themeli[1,3], V. Bajrami[1], M. Barbullushi[2,3], A. Idrizi[2], D. Teferici[2,3], L. Muka[1] & E. Ktona[3]
[1]DC'Ikeda-Euromedica', Tirana, Albania; [2]UHC'Mother Teresa', Tirana, Albania; [3]DC'Med.al', Tirana, Albania.

Background
Diabetic nephropathy (DN) represents the leading cause of end-stage renal disease (ESRD). It is known that patients with ESRD have the highest risk of cardiac morbidity and mortality. Thus, identifying and treating risk factors associated with cardio-vascular disease in diabetes may offer the best approach for preventing and delaying adverse renal and cardiovascular outcomes.
Aim
To determine the relationships between metabolic syndrome (MS), diabetic nephropathy (DN) and renal function in type 2 diabetes mellitus (DM).
Methods
In our clinic-based cohort study were enrolled 374 type 2 diabetic patients, from which 52% males and 48% females, with a mean age $58 \pm 10$ years. We analysed MS, detected DN and estimated glomerular filtration rate (eGFR) during a 4 years period.
Results
Prevalence of both microalbuminuria and macroalbuminuria were higher in subjects with MS, increasing proportionally with the number of MS components. eGFR was lower in subjects with MS than in those without ($89 \pm 18$ vs $91 \pm 20$ ml/min per 1.73 $m^2$; $P < 0.001$). The lowest eGFR values were found in those with four or more components of MS. Prevalence of low eGFR increased with the stage of DN and was affected by MS only in normoalbuminuric patients. The most important result was that MS was independently associated with DN, but not with low eGFR, after adjustment for all of the individual components of the MS.
Conclusions
In this study we have noted an independent association between MS and DN. This is a strong argument for treating the MS by an intensive multifactorial therapy, in order to prevent the progression of DN to the renal failure.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P626

### Diabetic nephropathy and risk factors associated with DM in newly diagnosed type 2 diabetics

Y. Themeli[1,3], V. Bajrami[1], M. Barbullushi[2,3], A. Idrizi[2], D. Teferici[3], L. Muka[1] & E. Ktona[3]
[1]DC'Ikeda-Euromedica', Tirana, Albania; [2]UHC'Mother Teresa', Tirana, Albania; [3]DC'Med.al', Tirana, Albania.

Objective
Nephropathy is a common complication in diabetes mellitus (DM), with significant morbidity and mortality. Diabetic nephropathy (DN) is more likely to develop in the presence of some risk factors associated with type 2 diabetes mellitus, even in newly diagnosed diabetics.
Aim
To study the incidence of diabetic nephropathy in newly diagnosed type 2 diabetics and to study the relationship of development of nephropathy with various risk factors associated with DM, like age, sex, blood pressure, blood sugar and body mass index (BMI).
Material and methods
We analysed 100 newly diagnosed type 2 diabetics (diagnosed within 2 years), between September 2008 to October 2010. Presence of urinary microalbuminuria in two samples in a period of 6 months was taken as criteria for detecting nephropathy.
Results
Incidence of DN in newly diagnosed type 2 diabetics was 15% (15/100). This incidence had significant correlation with age, increasing significantly with increase in age (33% in age group $>60$ years). Also, DN resulted more frequent in male sex and high blood pressure, with incidence of nephropathy being as high as 8% at BP $>160/100$ mmHg ($P = 0.001$). The incidence of DN also increased with increase in BMI as well as HbA1c. Dyslipidemia also significant effect, especially hypertrigliceridemy ($P = 0.01$). The familly history of DM didn't result significantly important in development of DN.
Conclusion
Incidence of DN in newly diagnosed type 2 diabetics is as high as 15%. Hypertension is the most important associated factor contributing to development of nephropathy in these patients. Age over 60 years old, male sex, poor glycemic control, high BMI and dyslipidemia play significant role.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P627

### Clinical experience of gel testosterone in men with diabetes type 2 and late-onset hypogonadism

O. Vasilkova[1] & T. Mokhort[2]
[1]Gomel State Medical University, Gomel, Belarus; [2]Belarussion State Medical University, Minsk, Belarus.

Aim
To study the effect of testosterone replacement treatment in the aging male with T2DM.
Material and methods
Twenty-six hypogonadal men with T2DM and late-onset hypogonadism between the age 50–65 years (55.00 (50.00; 58.00)) were treated with a 1% testosterone gel within 12 months.
Results
Testosterone levels increased from 4.65 (2.70; 6.10) nmol/l at baseline to 13.65 (12.60; 15.20) nmol/l after 48 weeks of treatment ($P < 0.001$). Free testosterone increased from 0.106 (0.062; 0.152) nmol/l to 0.426 (0.345; 0.553) nmol/l ($P < 0.001$). SHBG decreased from 43.75 (31.83; 48.48) nmol/l to 30.40 (26.28; 32.03) nmol/l ($P < 0.001$). We showed reduction of levels of TG from 2.09 (1.37; 3.42) mmol/l to 1.33 (1.12; 1.62) mmol/l ($P = 0.002$), HbA1C from 8 (6.93; 10.68) to 6.8 (5.90; 8.15)% ($P < 0.05$), leptin from 10.0 (4.0; 22.7) μg/l to

5.25 (4.03; 8.23) μg/l, HOMA-IR from 4.37 (1.98; 5.76) to 2.46 (1.98; 3.04). PSA levels fluctuated minimally within in the normal range. All patients reported improved mood, sexual function and QoL.
Conclusions
Treatment with the 1% testosterone gel was associated with significant improvements in the testosterone, triglyceride, HbA1C, leptin, HOMA-IR levels in men with late-onset hypogonadism and T2DM.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P628

**Influence of planning pregnancy in pregestational diabetes**

S. Gonzalez Romero, R. Vallejo Mora, I. González Molero, F. García-Torres, M. Palomo & F. Soriguer
Carlos Haya Hospital, Malaga, Spain.

Introduction and objective
The pregnancies in women with pregestational diabetes are associated with increased risk of abortion, birth defects, complications of pregnancy and perinatal morbidity and mortality. Pregnancy planning would be associated with better metabolic control, and therefore better obstetric and perinatal outcomes. The objetive of this study has been to evaluate the obstetric results of women with pregestacional type 1 diabetes and compare planned with not planned pregnancies.
Material and methods
Retrospective cross-sectional study including pregnancies followed in our Endocrinology and Pregnancy Unit (1996–2010). We compare the results between planned and unplanned pregnancies and present descriptive data (frequencies, means and S.D.). The frequencies are compared with the $\chi^2$ test, the means by parametric tests (Student' *t*-test) or nonparametric (Mann–Whitney). It was considered significant a $P<0.05$.
The results in planned (122 pregnancies) vs non planned (136 pregnancies) were: we found differences in: age (years): 30.7 vs 28.8, *P* 0.007; evolution DM (years): 16.8 vs 14.1, *P* 0.014; first visit (week): 6.8 vs 10, *P* 0.000; CSII treated: 34.7 vs 5.9%, *P* 0.000; HbA1c pregestational: 6.6 vs 8.2, *P* 0.000; HbA1c first trimester: 6.4 vs 7.5%, *P* 0.000; HbA1c second trimester: 6.07 vs 6.48, *P* 0.000; respiratory distress: 3.2 vs 12.2%, *P* 0.021; birth trauma: 0 vs 10%, *P* 0.002 and Jaundice (phototherapy): 14.4 vs 29.5%, *P* 0.015. There were no differences in HbA1c third trimester: 6.1 vs 6.2; retinopathy worsening: 6.4 vs 7.5%; nephropathy worsening: 2.9 vs 1%; abortion: 14.4 vs 16.5%; preterm (<37w): 20.8 vs 27.4%; cesarean: 56.8 vs 56.6% and other perinatal complications.
Conclusions
Planning pregnancy is associated with better glycemic control before conception, in first and second trimesters and better perinatal outcomes (reduced presence of respiratory distress, birth trauma and jaundice requiring phototherapy).
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Diabetic nephropathy and retinopathy: complications in pregnancy and labor**

Y. Themeli[1,5], V. Bajrami[1], M. Barbullushi[2,5], A. Idrizi[2], K. Zaimi[1], K. Mustafaraj[1,5], J. Lulo[1], A. Shtylla[3], J. Gjoshe[4] & E. Peci[6]
[1]DC 'Ikeda-Euromedica', Tirana, Albania; [2]UHC 'Mother Teresa', Tirana, Albania; [3]UHC 'Koco Glozheni', Tirana, Albania; [4]'Hygeia' Hospital, Tirana, Albania; [5]DC 'Med.al', Tirana, Albania; [6]American Hospital, Tirana, Albania.

Background
Diabetes microangiopathy is an important negative factor, that affects directly the maternal and neonatal morbidity.
The objective
To determine the risk factors for the morbidity of the mothers and their fetus in patients with diabetic retinopathy and/or nephropathy.
Methods and design
We followed the course of 50 pregnancies in diabetic woman with nephropathy and/or retinopathy and 50 other pregnancies in diabetic woman without severe microangiopathy. We compered the two groups for the diabetic complications and the maternal and neonatal morbidity.
Results
We found a correlation between retinopathy progression and hyperglycaemia during the first trimester ($P<0.05$). There was an increase in the deterioration of visual acuity up to blindness due to the progression of microangiopathy in cases of proliferative retinopathy. There was a significant increase of the mean diastolic blood pressure and preeclamptic symptoms occurred in of 67% of the cases with severe microangiopathy ($P<0.05$). Deterioration of the diabetic nephropathy with excessive proteinuria (>10 g/day) and unmanageable hypertension or a progression of the retinopathy led to an earlier delivery in 83% of the patients ($P<0.05$). A high rate of preterm deliveries (39%) and a frequent occurrence of intrauterine growth retardation's (13%) characterised the fetal outcome.
Conclusions
All womans diagnosed with diabetes mellitus during childhood or if the course of the disease is between 10 and 15 years, should have periodic ophthalmological evaluations, control of the renal function, contraceptive advice and an improvement of the metabolic situation. In case of a diabetic nephropathy in combination with hypertension the patients shoud be warned against pregnancy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Quality of life of people with diabetes living in rural area**

S. Abdoli[1], S. Abdoli[2] & M. Mirzayi[3]
[1]Health Care Centre, Malayer, Islamic Republic of Iran; [2]Nursing and Midwifery Faculty, Isfahan University of Medical Sciences, Isfahan, Islamic Republic of Iran; [3]Parsian Hospital, Tehran, Islamic Republic of Iran.

Introduction
Diabetes with a high prevalence in Iran could affect all aspects of the individual life. Iranian people with diabetes living in rural area have access to health care system and family physician through the health care homes which offer health related care and education to the population. The services are provided by family physician and assistant health provider for remote rural area by weekly visiting tour to provide the opportunity to use health care system's services. All the activities aim to improve QOL of people living in rural area special those living with diabetes. The information about the QOL in the population can be considered as baseline information.
Objective
The aim of the study was to access the QOL in the remote rural population of Malayer (a small town in the west of Iran) who live with diabetes.
Methods
In this descriptive study 39 people with type 2 diabetes participated who were visited by the family physician during weekly tour. The physician filled out the Iranian version of WHOQOL-BREEF for all.
Results
The participants were both male (46.2%) and female (53.8%) with the rage of 39–80 years old. Mean (S.D.) of domain scores of the aforementioned questionnaire in the population under study were 10.76 (S.D. = 1.38) for physical health, 10.43 (S.D. = 1.19) for psychological health, 10.28 (S.D. = 1.64) for social relationships, and 10.51(S.D. = 1.19) for environment. In analysis of different sex bands, scores of the environmental and physical health for female were significantly lower than male. In addition, people with higher education level had higher scores in the environmental and physical health. Moreover, there was no difference between marriage status and job of the population.
Conclusion
However the QOL of Iranian people with diabetes living in remote rural area were lower than the population studied by WHO in overall; the score of QOL in domains such as psychological and environmental was very close to the result in Argentina, India and USA.
Keywords: Quality of life, WHOQOL-BREEF, remote rural area, people with diabetes, Iran.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P631

**Insulin resistance: policy plan to address burning issue by NGO from rural India**

S Pramod
Health Alert Organization of India (NGO), Dhule, India.

Issues
Newer anti-diabetic therapies out of reach of >84% populations of Asia. Pharmaceuticals donot provide price discounts in resource-constrained-countries. incidence of insulin resistance neglected issue in resource-poor nations. Diabetes forums failed to address this concern. Hence we formed liaison study group of four clinics to analyse this issue and make policy paper. Resource poor nations have little technical expertise/manpower to study insulin resistance. Lack of resources for such research had demotivates young researchers.
Description
In developing countries cost-economics of diabetes treatment in rural/tribal India leads to poor-therapeutic-compliance. National/international programs donot offer discounted drugs, or diagnostics/technical assistance in diabetes-care. Insulin-resistance must be evaluated and corrective steps to minimise it. Health-care NGO's pivotal to facilitate development of sound/sustainable diabetes-care-programs. Its need of hour to organise specialised sessions on Insulin-resistance at ICE/ECE-congress for participants like us from Asian-countries.
Results/observations
There is need to provide technical/research skills from Industrialised-nations researchers to filter it to lesser privileged from developing nations like India. Currently no facility to learn/train on insulin-resistance. Major Lacunae is absence of system linking diabetes-caregivers from rural/tribal zones. Forums needed to implement/expand this suggestion/policy. Most of conferences address issues of cost/availability/ADR's BUT issues of drug-resistance neglected.
Recommendations
Development of tolls to tackle insulin-resistance is in infantile stage in developing-nations. Dialogue with western/European-researchers will accelerate policy implementation, increases resource and access to technical expertise. We need to break north-south barriers to counter resistance-issues. patient-advocates at ICE/ECE-2012 need to collaborate in future research-projects on this issue. We NGO-representatives from developing-nations need exposure to research technicalities/methodologies used by European/American experts. This is possible by our participation at Trondheim-meeting.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P632

**Seeking a new identity: the empowerment process in Iranian people with diabetes**

S Abdoli[1], T Ashktorab[2], F Ahmadi[3] & S Parvizi[4]
[1]Isfahan University of Medical Sciences, Isfahan, Islamic Republic of Iran; [2]Shahid Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran; [3]Tarbiat Modaress University, Tehran, Islamic Republic of Iran; [4]Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Facilitating empowerment among people with diabetes is the responsibility of all health care providers. However, research suggests that the health care providers do not have the knowledge and skills to facilitate empowerment. As a result, many Iranian people with diabetes experience low levels of empowerment. The aim of the study was to explore and understand how empowerment occurs in people with diabetes in Iran. Grounded theory method using in-depth interviews, field notes, and memos, were used to collect data from 25 people with diabetes, their families, and health care providers. Constant comparative analysis was used to analyze the data. Findings showed that empowerment is a transitional, perceptual and continuous process in people with diabetes and includes threatened identity, reconstructing pre-diabetes identity and gaining a new identity, which is influenced by a combination of knowledge, social support, values and beliefs, psychosocial issues, and the nature of diabetes. Facilitating empowerment can help people with diabetes integrate diabetes into their self-identity; however, achieving empowerment is complex and occurs over time.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Prevalence of Charchot arthropathy after the introduction of electronic foot ulcer patient record**

I Marolt, V Kosmina Novak & S Mankoc
Zdravstveni dom Koper, Koper, Slovenia.

Introduction
Loss of protective sensation, inflammation and trauma may lead in predisposed diabetics with peripheral neuropathy to Charcot foot.
Methods
Regular foot screening enables identification of those individuals who are at highest risk for foot ulceration. Special attention must be paid to infection. Differentiation between osteomyelitis and Charcot arthropathy is mandatory, the two conditions may coexist. Basic conservative treatment for Charcot arthropathy is offloading with bed rest or total contact cast with healing shoe. The active acute form should be detected promptly in order to apply bisphosphonate or calcitonin therapy which may improve healing and stabilisation of the disease and postpone deformities. Few data on this treatment are available. In our clinic we keep an electronic diabetic foot patient record since 2009. Among 6000 diabetics, 185 have electronic record, 89 an active foot ulcer. Seven with Charcot arthropathy were detected, all having peripheral neuropathy, one due to alcohol, two women and five men. One patient died in 2009. One has chronic bilateral form of the disease, other presented with an acute form. All have been referred to orthopaedic surgeon with a native X-ray, one with scintigram, one MRI was done. All were complicated with infection and healed in 8–24 months. One had transmetatarsal amputation. Two have ischemia, others mediocalcinosis. In the observational period no one received drug treatment, one received bisphosphonates in 2006 when the disease was active on his left foot.
Results and conclusions
We conclude that in this short period the incidence of the acute form of Charcot arthropaty was higher. The acute active form of Charcot arthropathy can be found if it is searched for. Early detection of patients with acute Charcot foot and appropriate treatment are cornerstones of foot ulcer and deformity prevention.

**Development of a high-sensitive urinary albumin immunosensor based on MCM-41-PVA nanocomposite and AuNPs**

K Omidfar & F Gholizadeh
Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Accurate and sensitive detection of the biomarkers is important both for preclinical research fields such as biochemistry, biomedicine, and clinical diagnostics. Immunosensors are the miniaturized analytical devices that combine high specificity of immunological reaction with sensitivity of detection techniques.
In this study, we developed a new competitive immunosensor with employing antibody (Ab) labeled AuNP (Ab-AuNP) and mobile crystalline material-41 (MCM-41)-polyvinyl alcohol (PVA) mesoporous nanocomposite modified screen-printed carbon electrode (SPCE) surface to detect the urine albumin. Field emission scanning electron microscopy (FE-SEM) of modified electrode showed a suitable and stable attachment between HSA antigen – mAb and AuNP. Cyclic voltammetric (CV) method demonstrated that modification process was well performed.
Differential pulse voltammetry (DPV) was employed for quantitative determination of antigen in biological samples. The electrochemical measurements performed with other proteins mixed with samples demonstrated a high specificity and selectivity for this biosensor in detecting the HSA. In optimal conditions, this immunosensor could detect HSA in a high linear range (0.5–200 μg/ml) with a low detection limit of 1 ng/ml. The proposed method showed acceptable reproducibility, stability, and reliability and could also be applied to detect the other antigens.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P635

### Metformin-associated lactic acidosis: prevention is the real challenge!

M Safraou[1] & J Altman[1,2]
[1]Européen Georges Pompidou, Paris, France; [2]Descartes Paris V University, Paris, France.

Introduction
More than 50 years after its introducing in 1957 (1996 in USA), metformin is used today in more than 90 countries. It is the most efficient, safe and costless anti-hyperglycemic agent in the treatment of type 2 diabetes mellitus. Its principal risk remains metformin-associated lactic acidosis (MALA), subject of controversies as reported in a recent Cochrane database review in 2010.
Patients and methods
We present personal series of all cases of MALA diagnosed in an 8 year-period in an Emergency department admitting 16 000 patients yearly.
Serum lactic acid over than 5 mmol/l at admission (normal value $<2$ mmol/l) in a context of metabolic acidosis is the key of the diagnosis.
Results
Four cases of MALA are diagnosed in this 8 year-period. The incidence is three for 100 000 patients admitted in emergency.
The indication of the metformin was not relevant in 1 case (mitochondrial disease) and subject of discussion in two others (with chronic alcoholism in on case and chronic use of anti-inflammatory drugs in the other). The case 4 treated with 3000 mg of metformin, presents also a mild asthma.
The clinical presentation is misleading in the four cases. The evolution was favorable in 50% of the cases, fatal in two cases (severe impaired renal function, hepatic insufficiency).
Discussions and conclusions
MALA incidence is probably underestimated. The frequency of co-morbidity makes its diagnosis difficult. Checking serum lactic acid for all diabetic patients treated with metformin when admitted for any acute problem in emergency is the main 'take home message' of this report.
Diagnosed and treated without delay, the evolution of MALA can be quickly favorable.
In UKPDS, Metformin given not more than 2550 mg daily has shown to reduce total mortality but no clinical evidence for the superiority of higher doses in studies.
We suggest, in addition to the strict respect of contraindications, the integration of the benefit-risk balance when prescribing higher doses.
Finally, the expertise of Diabetologists in Emergency rooms could improve the quality of care for diabetic patients. Helpful in the management and prevention of complications, it is enhancing educational messages of safety for patients and physicians.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Oxidative stress and histopathological differences on the skin of diabetes mellitus compromised rats

T Andrade[1], V Malachias[2], G Caetano[3], D Masson[1], A Jordão[1], C Landim[1] & M Frade[1]
[1]University of Sao Paulo, Ribeirao Preto, Brazil; [2]Londrina State University, Londrina, Brazil; [3]University of Sao Paulo, Sao Paulo, Brazil.

Background
Several studies on diabetes mellitus and cutaneous wounds have been reported. However, only few studies show the influence of diabetes on the skin regarding its oxidative stress, antioxidants mechanisms and histopathological aspects.
Objectives
The aim of this study was to evaluate these parameters by comparing them to non-diabetic rats skin.
Methods
Ten Wistar rats were assigned to groups: diabetic rats (induced by streptozotocin 45 mg/kg; DM; $n=5$) and non-diabetic rats (N-DM; $n=5$). After verifying the diabetes status (hyperglycemia), animals were euthanized and biopsies were taken from the dorsal surface using a skin biopsy punch (1.5 mm diameter). Biochemical analysis was carried out to measure markers of oxidative stress (MDA, malondyaldeide; NO, nitric oxide; FOX, $H_2O_2$) and antioxidant activity (GSH, glutathione). Histological analysis (HE and Gomori's trichrome staining) was performed to assess inflammatory cells, blood vessels, fibroblasts and the percentage of collagen area.
Results
Hyperglycemia was confirmed for DM group, reaching statistical difference compared to N-DM group ($P=0.0001$). Diabetes pathology increased the number of inflammatory cells ($P=0.0001$) and NO production ($P=0.0473$) on the skin, however, it decreased MDA ($P=0.0001$), FOX ($P=0.0001$) and GSH ($P=0.0035$). The number of blood vessels was lower for the DM group compared to the N-DM group ($P=0.0001$), suggesting that there is an influence of diabetes pathology on the quantity of skin blood vessels. The number of fibroblasts an collagen content were similar for both groups ($P>0.05$).
Conclusion
The pathophysiology of diabetes changed the skin by increasing the influx of inflammatory cells and NO production, decreasing the antioxidant defense and the number of blood cells.
Glycaemia (mg/dl) of diabetic (DM) and non-diabetic (N-DM) rats. Distribution of variables inflammatory cells, NO, MDA, FOX, GSH, blood vessels, fibroblast and collagen of dorsal skin in diabetic (DM) and non-diabetic (N-DM) rats.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Relationships between hyperglycemia and the oxidative stress in type 2 diabetes

M Itoh[1], I Hiratsuka[1], J Hanashita[2], M Kimura[1], M Kondo[1], K Yoshida[2], Y Kuroyanagi[2], T Takayanagi[1], H Hirai[1] & M Makino[1]
[1]School of Medicine, Fujita Health University, Toyoake, Japan; [2]Fujita Health University Hospital, Toyoake, Japan.

A continuous glucose monitoring (CGM) provides a good tool to investigate the influence of glucose fluctuation on oxidative stress regarding as the pathogenesis of arteriosclerosis in type 2 diabetes (T2DM). The CGM can detect min-to-min glucose fluctuation under the daily activity and eating habit. We measured various indexes for oxidative stress and compared with the glycemic factors detected by the CGM.

Methods
T2DM ($n=25$) and healthy controls ($n=14$) were subjected to the CGM for 72 h and they were simultaneously measured blood levels of HbA1c, LDL, HDL, triglyceride, small dense (sd)- and oxidative (ox)- LDL, remnant-like particle lipoprotein (RLP), high-sensitivity (hs)-CRP, leptin, adiponectin, total free radical derived from reactive oxygen species (ROS), urinary output of 8-hydroxy-2′-deoxyguanosine (8-OHdG) and 15-isoprostane F2t (isoprostane).
Results
The mean and 2s.d. of the glucose in the control group were ranged from 73.2 to 148.3 mg/dl. Therefore, the hyperglycemic excursion was defined as the AUC above 140 mg/dl of glucose. The total ROS and urinary output of 8-OHdG and isoprostane were not different between the T2DM and control groups. However, the mean glucose and hyperglycemic excursion measured by CGM were correlated with total ROS ($r^2=0.191$, $r^2=0.230$, $P<0.05$) and urinary isoprostane ($r^2=0.187$, $r^2=0.200$, $P<0.05$). The glycemic indexes were not correlated with LDL, HDL, TG, RLP, sd-LDL, or ox-LDL. The glucose instability expressed as s.d. of the mean glucose and the combined percentages of hyper-plus hypoglycemia were not correlated with the oxidative stress indexes.
Discussion and conclusion
Hyperglycemia *per se* increased the production of oxidative stress detected by total ROS and urinary output of isoprostane and may accelerate the arteriosclerosis. The markers for oxidative stress might depend on its half-life and the exposed time for the hyperglycemia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Somatostatin eye drops prevent retinal neurodegeneration in experimental diabetes**

R Simó[1], L Corraliza[1], M Garcia-Ramirez[1], B Ponsati[2] & C Hernández[1]
[1]Vall d'Hebron Research Institute, Barcelona, Spain; [2]BCN Peptides, Barcelona, Spain.

Introduction/aim
There is growing evidence to suggest that retinal neurodegeneration is an early event in the pathogenesis of diabetic retinopathy (DR). Somatostatin (SST) has a neuroprotective action and we previously found a downregulation of SST associated with the hallmarks of retinal neurodegeneration (glial activation and apoptosis) in human retinas. The aim of the study was to test the hypothesis that SST is useful in preventing retinal neurodegeneration.
Methods
Male Sprague–Dawley rats in which diabetes was induced by streptozotocin were treated with either eye-drops of SST (10 mg/ml; 20 µl/eye; $n=8$) or vehicle ($n=8$) for 15 days. Non-diabetic Sprague–Dawley rats ($n=8$) treated with vehicle served as control group. Electroretinography (ERG) studies were performed before starting treatment and one day prior death. Glial activation was evaluated by measuring glial fibrillar acidic protein (GFAP) by immunofluorescence. Apoptosis was assessed by TUNEL assay.
Results
Treatment with SST eye drops prevented ERG abnormalities (reduction in b-wave amplitude and increase in b-wave implicit time), as well as the characteristic features of neurodegeneration (glial activation and apoptosis) caused by diabetes. In fact, glial activation and apoptosis in diabetic rats treated with SST were similar than in non-diabetic rats.
Conclusion
SST eye drops prevented both functional and morphologic abnormalities in the diabetic retina. Based on these promising results in rats we have designed and initiated a multicentric clinical trial (EUROCONDOR. FP7-Health-2011-278040) in order to demonstrate the potential beneficial effects of SST topical administration in preventing or arresting DR development.

**Serum high sensitivity c-reactive protein as predictor of metabolic syndrome and its relationship with albuminuria in type 2 diabetes mellitus**

F del Cañizo-Gómez, I Moreno-Ruiz, B Silveira-Rodriguez, C De Gorospe, T Gonzalez-Losada & A Segura-Galindo
Hospital Universitario Infanta Leonor, Madrid, Spain.

The high sensitivity C-reactive protein (hs-CRP), mediator of atherosclerotic disease, is known to be a sensitive predictor of coronary heart disease in type 2 diabetes mellitus (T2DM).
Aims
To evaluate the relationship of hs-CRP levels to metabolic syndrome (MS) and albuminuria in T2DM.
Methods
Four hundred and eighty-eight T2DM subjects were recruited. Patients with hs-CRP $\geq 10$ mg/l, creatinine $\geq 1.4$ mg/dl, chronic inflammatory and cardiovascular diseases, smokers or on antiplatelet therapy were excluded. In all the 178 subjects ($65.2 \pm 10.7$ years, 71 men and 107 women) enrolled, we measured hs-CRP, waist circumference (WC), fasting plasma glucose (FPG), systolic and diastolic blood pressure, high density lipoprotein-cholesterol (HDL-Ch), triglycerides (TGs), and 24 h. Albumin excretion (ALB-e). The MS was defined according to the IDF criteria. Student's *t*-test was used to compare the means, and the Mann–Whitney *U* test to analyze the relationship between hs-CRP levels and the presence of MS. Spearman partial correlation coefficients were calculated to assess the correlations of log hs-CRP with all variables. A *P* value $<0.05$ was considered significant (SPSS).
Results
The hs-CRP level was higher in those subjects with WC $>94$ cm in men and $>80$ cm in women ($P=0.000$), TGs $>150$ mg/dl ($P=0.01$), HDL-Ch $<40$ mg/dl for men and $<50$ mg/dl for women ($P=0.012$), in subjects with MS ($P=0.025$), and with macroalbuminuria ($P=0.045$). After adjusting for age and sex, the log hs-CRP correlated significantly with WC ($r=0.368$), BMI ($r=0.297$), log TGs ($r=0.382$), FPG ($r=0.172$), HbA1c ($r=0.162$), and log ALB-e ($r=0.233$).
Conclusions
The serum hs-CRP level may be used to predict MS in T2DM patients. The correlation between hs-CRP level and albuminuria, suggests that the inflammatory process plays a role in nephropathy in T2DM.

**Relationship between hyponatremia and diabetes mellitus**

A Duran, M Cuesta, I Runkle, P de Miguel, G Sotres & J Marco
Hospital Clinico San Carlos, Madrid, Spain.

Aims
Our aim is to retrospectively analyze the diagnosis of hyponatremia in the discharge sheets of a tertiary hospital during 5 years and its relationship with type 1 and 2 diabetes mellitus.
Methods
Data from the MBDS (Minimum Basic Data Set) of the discharged patients from the Hospital Clínico San Carlos (Madrid) between the years 2005 to 2009 was analysed. The 5th Edition of the ICD-9-CM was used for the codification of the diagnoses and procedures. The system of patient classification of Diagnosis Related Groups – AP-DRG (version 21.0) was used for the grouping of discharge processes. The Charlson index was use as a measure of comorbidity. Patients with a main or secondary diagnosis of hyponatremia suffering also from type 1 or type 2 diabetes were selected and analyzed. Age, sex, length of stay, comorbidity, procedures and mortality were taken into account.
Results
Reported hyponatremia was 1.7% in type 1 diabetes and 2.3% in type 2. Mean age was 33.6 years for type 1 and 68.3 years for type 2. In type 1 diabetes, 48.7% were males vs 43.1% in type 2 diabetes. Mean stay was 7.2 days for type 1 vs 9.9 days for type 2. A Charlson index $>2$ was present in 17% of type 1 diabetic patients and in 22% of those with type 2. Mortality reached 14% in type 1 and 7% in type 2.
Discussion
The low prevalence of the notification of hyponatremia, very far from the real prevalence of this disturbance is our first observation. In our series, two

populations are distinguished: patients with type 1 diabetes are younger, with a shorter stay, less comorbidity and higher mortality. On the other side, type diabetics are older, predominantly female, with higher comorbidity and longer hospitalizations but lower mortality.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P641

### The relationship between daytime, nighttime and total heart rate with albumin and protein excretion in newly diagnosed type 2 diabetic patients

B Afsar
Konya Numune State Hospital, Konya, Turkey.

Introduction
Autonomic nervous system dysfunction has been widely observed in patients with type 2 diabetes. Twenty-four hour ambulatory heart rate measurements (AHRM) have been found to associate with autonomic dysfunction in patient with type 2 diabetes. Since albumin excretion is also related with autonomic dysfunction; in the current study, we analyzed whether 24-h AHRM were related with 24 h urinary albumin excretion (UAE) and urinary protein excretion (UPE) in newly diagnosed patients with type 2 diabetes.
Methods
All patients underwent following procedures: history taking, physical examination, blood pressure measurement, 12 lead electocardiographic evaluation, routine urine analysis, biochemical analysis, 24-h urine collection to measure urinary sodium and protein excretion and creatinine clearance calculation. Twenty-four hour ambulatory blood pressure and heart rate monitoring were performed for all patients. Diagnosis of diabetes was based on at least two fasting blood glucose.
Results
In total 80 patients (34 male, 46 female aged $50.4 \pm 9.2$ years) with newly diagnosed type 2 diabetic patients were included. Stepwise linear regression of factors including age, gender, body mass index, smoking status, presence of coronary artery disease, dipping status, averaged fasting blood glucose, 24-h creatinine clearance, 24-h average ambulatory systolic blood pressure (AASBP), 24-h average ambulatory diastolic blood pressure (AADBP), daytime AHRM, nighttime AHRM and 24-h AHRM revealed that logarithmically converted 24-h UAE were independently related with 24-h AASBP (*b*: 0.02, CI: 0.09–0.031, *P*: 0.001) and nighttime AHRM (*b*: 0.05, CI: 0.03–0.069, $P<0.0001$). Using the same independent variables logarithmically converted 24-h UPE were independently related with age (*b*: $-0.014$, CI: $-0.027$ (to) $-0.001$, *P*: 0.032), with averaged fasting blood glucose (*b*: 0.011, CI: 0.002–0.021, *P* 0.023), 24-h AASBP (*b*: 0.013, CI: 0.005–0.020, *P* 0.002), nighttime AHRM (*b* 0.021, CI: 0.009–0.033, *P* 0.001).
Conclusion
Nighttime AHRM but not daytime and 24-h AHRM were related with both 24-h UAE and UPE in patients with type 2 diabetes. Whether augmentation of autonomic dysfunction specifically during nighttime should be evaluated in patients with type 2 diabetes.

## P642

### Cystatin C and TGF-β as a biomarker of diabetic nephropathy in normo and microalbuminuric patients

A Dogruk Unal, M Takir, P Hulya, O Tarcin, N Bayraktar, E Erdogan & N Guvener Demirag
Baskent University Hospital, Istanbul, Turkey.

Background and aims
This study was done to predict renal impairment in type 2 diabetic patients with normo or microalbuminuria by detection of serum cystatin C, serum and urinary TGF-β levels.
Material and methods
Seventy-eight patients were categorized into four groups depending on urinary albumin excretion and eGFR: eGFR $<60$ ml/min per 1.73 $m^2$ with normoalbuminuria in group 1; eGFR was $<60$ or $>60$ ml/min per 1.73 $m^2$ with microalbuminuria in group 2; normoalbuminuria in group 3 and 4 patients with eGFR $>120$ and eGFR between 90–120 ml/min per 1.73 $m^2$ respectively.
Results
Baseline characteristics of subjects are shown in Table 1. Although blood glucose regulation was best, blood urea, serum creatinine were higher and eGFR was significantly lower in group 1. While serum cystatin C level was significantly high in group 1, serum and urinary TGF-β levels were high in group 2.
Conclusion
Although urinary albumin excretion is suggested for detection of type 2 diabetic nephropathy, there is subgroup of patients with impaired renal function without increased urinary albumin excretion. This study showed that serum cystatin C level could be used as an early biomarker of diabetic nephropathy in normoalbuminuric patients.

### The impact of hyperinsulinemia on the serum IL12p40 subunit concentration

A Nikolajuk[1,2], A Adamska[1], M Karczewska-Kupczewska[1], N Matulewicz[1], M Zielinska[1], M Górska[1], I Kowalska[1] & M Straczkowski[1,2]
[1]Medical University, Bialystok, Poland; [2]Polish Academy of Sciences, Bialystok, Poland.

Introduction
Numerous studies indicate an association between low-grade chronic inflammation and predisposition to type 2 diabetes and atherosclerosis. IL12 is a proinflammatory cytokine with proatherogenic properties. IL12 is a disulfide-linked, 70 kDa (p70) heterodimeric glycoprotein composed of a 40 kDa (p40) subunit and a 35 kDa (p35) subunit. Many data reported higher levels of p40 subunit than total IL12. The aim of the present study was to investigate the influence of hyperinsulinemia on serum p40 subunit.
Methods
Our study involved 35 young (age: $24.31 \pm 2.81$ years), apparently healthy men with normal glucose tolerance. Anthropometric measurements, blood

biochemical analysis and euglycemic hyperinsulinemic clamp were performed in the studied group.
Results
The serum concentrations of p40 was significantly lower after the clamp than the baseline state ($P<0.05$). The change in IL12p40 during the clamp was already to the steady-state insulin (SSI) concentrations ($r=0.35$, $P=0.037$) – the higher SSI the greater decrease in serum IL12/p40. We found inverse correlations between post-clamp serum p40 and total cholesterol and LDL-cholesterol ($r=-0.34$, $P=0.049$ and $r=-0.46$, $P=0.006$ respectively). A significant association between basal and post-clamp p40 subunit and lymphocyte cell count ($r=0.35$, $P=0.037$ and $r=0.45$, $P=0.006$ respectively) and significant negative correlations with neutrophile cell count ($r=-0.41$, $P=0.014$ and $r=-0.51$, $P=0.002$ respectively) was observed in the studied group.
Conclusion
Our data indicated that hyperinsulinemia decreased serum IL12/p40 concentration.

**Association of cardio-ankle vascular index with diabetes mellitus-related peripheral arterial disease in chronic hemodialysis patients**

A Okamura[1], F Furuya[1], D Akiyama[1], H Shimura[1], A Motosugi[2], K Haraguchi[2] & T Kobayashi[1]
[1]University of Yamanashi, Chuo, Japan; [2]Haraguchi Clinic, Kai, Japan.

Introduction
Peripheral arterial disease (PAD) is increased associated with an accumulation of patients with end stage kidney disease and diabetes. Recently, the cardio-ankle vascular index (CAVI) has been developed as an index reflecting the stiffness of the aorta independently of blood pressure. The aim of this study was to assess the prevalence of PAD in hemodialysis patients with diabetes.
Methods
To examine the usefulness of CAVI to screen for the presence of PAD, cross-sectional studies were performed on 94 patients undergoing chronic hemodialysis. Patients were referred to echocardiography or analyzed HbA1c and a blood inflammatory marker, high-sensitivity C-reactive protein (hs CRP). We also analyzed the ankle brachial index (ABI) and values of skin perfusion pressure (SPP) in all patients.
Results
CAVI significantly correlated to age but not blood pressure. CAVI in diabetics was significantly higher than that in non-diabetics. In contrast, ABI or SPP was no differences between diabetics and non-diabetics. Furthermore, CAVI was markedly elevated in patients with a history of PAD or cardiovascular disease. When diabetic patients were classified on the basis of CAVI quartiles, the odds ratio for the prevalance of PAD was increased. Increased CAVI was also associated with other risk factors for PAD (HbA1c, hs CRP, body mass index or history of PAD). However, the association with HbA1c was not observed in ABI.
Conclusion
The prevalence of PAD is high in diabetic elderly patients with hemodialysis. The present findings suggest that CAVI can be useful index that predicts the occurrence of microvascular complications in dialysis patients with diabetes.

**Pituitary function in patients with autoimmune type 1 diabetes evaluated by CRH test**

K Simunkova[1,2], M Duskova[2], L Starka[2], M Hill[2], J Kubatova[2] & K Vondra[2]
[1]General Faculty Hospital, Prague, Czech Republic; [2]Institute of Endocrinology, Prague, Czech Republic.

This work aimed at acquiring data on pituitary response to CRH test in autoimmune type 1 diabetics with adult onset with/without thyroid autoimmunity. Our previous study showed 25% of such diabetic patients without clinical and immunological signs of adrenal insufficiency had lower response to the Synacthen test with normal basal levels of ACTH and cortisol.
Twenty-seven diabetics were investigated; age $44\pm10$ years (mean $\pm$ S.D.), age at diagnosis $28.5\pm10$ years, disease duration $15\pm8$ years, BMI $24.5\pm2.7$ kg/m$^2$, HbA1c $7.2\pm1.2$%. The group of patients consisted of 13 diabetics without and 14 diabetics with thyroid autoimmunity. The study was approved by the ethical committee.
The pituitary function was tested by CRH test. We evaluated serum ACTH and cortisol, salivary cortisol, thyroid function and metabolic paramerts of diabetics. The group of patients with subnormal cortisol response to Synacthen showed a significantly lower cortisol response but a significantly higher ACTH response to CRH test. We divided this group to diabetics with and without thyroid autoimmunity. We found significantly lower cortisol response to CRH in diabetics without thyroid autoimmunity but significantly higher ACTH response to CRH, in comparison with diabetics with thyroid autoimmunity.
The results indicate that both groups of patients with subnormal response to Synacthen required the higher levels of ACTH to achieve normal cortisol response to CRH in contrast to group of patients with normal cortisol response to Synacthen. This higher activity on the pituitary level may be the first step of latent adrenocortical hypofunction to offset the stressful event. These results obtained may contribute to better understanding latent adrenal insuficiency adaptation in type 1 diabetics. The study was supported by grant no. NT 11 277 and NT 12340-5 of the IGA MZCR.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Microvascular complications in type 1 diabetes mellitus: prevalence and associated risk factors in DIACAM 1 study**

J Lopez[1], M Aguirre[2], L Lopez[3], C Roa[4], I Gomez[5], S Aranda[6], C Lamas[3], A Vicente[1] & J Sastre[1]
[1]Hospitalario de Toledo, Toledo, Spain; [2]Hospital General de Ciudad Real, Ciudad Real, Spain; [3]Complejo Hospitalario de Albacete, Albacete, Spain; [4]Hospital de Puertollano, Puertollano, Spain; [5]Complejo Hospitalario Mancha Centro, Alcazar de San Juan, Spain; [6]Hospital Virgen de la Luz, Cuenca, Spain.

Background and aims
DIACAM1 study was designed to investigate the clinical characteristics of a representative group of type 1 diabetic (T1D) population in Castilla-La Mancha (Spain). The aim of this report is to describe the prevalence of microvascular complications and the factors associated with such complications.
Materials and methods
This is an observational, cross-sectional, prospective and multicentre study of 1465 patients who received assistance during 2010. All reported patients were aged $>16$ years at the time of the study and duration of diabetes was $>5$ years. There were 48.5% women, mean age $39.4\pm13.5$ years, and mean diabetes duration $19.4\pm10.6$ years. Patients underwent clinical and laboratory evaluation. A multivariate logistic regression analysis was used to assess variables independently associated with microvascular complications.
Results
The prevalence of retinopathy was 32.5%. Non proliferative retinopathy was found in 20% and severe retinopathy in 12.5% (proliferative 8.9%). The prevalence of nephropathy was 18%. Without renal function impairment in 12.9% and with evident renal injury in 5.1% (NFK stages 3–4 in 3.5% and ESRD in 1.6%). There is significative increase ($P<0.001$) of microvascular complications with time evolution (Table 1). Independent variables for the presence of retinopathy were duration of diabetes ($\geq10$ years. OR 19.9 and $\geq30$ years. OR 6.8, $P<0.001$), hypertension (OR 3.1, $P<0.001$) and current HbA1c $>8$% (OR 1.4, $P<0.05$). Independent factors associated with nephropathy were: hypertension (OR 7.04, $P<0.001$), diabetes duration $\geq30$ years (OR 2.8, $P<0.001$) and current HbA1c $>8$% (OR 1.84, $P<0.05$).
Conclusions
Retinopathy and nephropathy are less prevalent than expected. Microvascular complications are strongly influenced by the time of evolution of the disease, higher glycosilated hemoglobin and the presence of hypertension. These results are consistent with the trends of reduction of diabetes complications in other studies, due to intervention therapies and improvement of diabetes care.

### Urinary pentosidine concentration in patients with type 2 diabetes and risk of vascular complications

M Tanaka, S Takeda, T Kawai, S Meguro, J Irie, Y Saisho & H Itoh
School of Medicine, Keio University, Shinjuku-ku, Japan.

Aims
We investigated the association between urinary pentosidine concentration (UPC) and vascular complications.
Methods
UPC was measured in 66 patients (31 men and 35 women) with type 2 diabetes. We compared UPC between patients with and without diabetic microangiopathy, and between patients with and without macroangiopathy (cerebral infarction (CI), coronary artery disease, and peripheral arterial disease). Stepwise regression analysis was performed to examine the effects of various factors on UPC, and the following factors were considered as independent variables: age, duration of diabetes, microangiopathy, CI, and systolic blood pressure (SBP). Logistic regression analysis was performed to examine the effects of various factors on vascular complications, and the following factors were considered as independent variables: UPC, eGFR, age, duration of diabetes, HbA1c, SBP, and smoking habit.
Results
UPC was significantly higher in patients with retinopathy ($71.3 \pm 32.7$ vs $54.5 \pm 25.5$ pmol/mgCr, $P=0.026$), nephropathy ($72.9 \pm 36.9$ vs $54.2 \pm 19.9$ pmol/mgCr, $P=0.022$), and neuropathy ($68.7 \pm 32.5$ vs $53.5 \pm 24.2$ pmol/mgCr, $P=0.045$) compared with that in patients without complications. UPC in patients with CI ($87.3 \pm 36.5$ vs $59.1 \pm 28.0$ pmol/mgCr, $P=0.026$) was significantly higher than that in patients without CI. Stepwise regression analysis demonstrated that retinopathy ($\beta=0.31$, $F=4.15$, $P=0.049$) and CI ($\beta=0.37$, $F=7.25$, $P=0.011$) were independent factors for UPC. Logistic regression analysis demonstrated that UPC (OR 1.03, 95% CI 1.00–1.06, $P=0.048$) and duration of diabetes (OR 1.17, 95% CI 1.07–1.28, $P=0.0007$) were independent factors for retinopathy.
Conclusions
High UPC could be an important factor for the incidence of vascular complications, especially retinopathy, in type 2 diabetic patients.

### The mechanisms of anemia development in patients with early stages of diabetic nephropathy

I Pchelin & A Shishkin
St Petersburg University, St Petersburg, Russian Federation.

Anemia occurs early and predicts high risk of cardiovascular events and death in patients with diabetic nephropathy (DN). It may result from various factors including erythropoietin (EPO) deficiency, iron and vitamin deficiencies, systemic inflammation, adverse effects of some drugs and others. However, the clinical significance of each factor is not fully known. The aim of this study was to assess the relative contribution of EPO deficiency, iron deficiency and systemic inflammation as pathogenetic factors of anemia development in patients with early stages of DN.
We investigated 72 anemic patients with type 2 diabetes mellitus and chronic kidney disease (CKD) stages 1–3. GFR was calculated by Cockcroft-Gault formula. Anemia was defined according to World Health Organization criteria (2008). Serum levels of EPO, ferritin, vitamin B12, interleukin 1β (IL1β), IL6 and tumor necrosis factor-α (TNF-α) were measured by immunoassay (Labsystems MR 600 analyser).
EPO deficiency was in found in 48.6%, low serum ferritin levels – in 11.1%, low vitamin B12 levels – in 2.8% of patients. Most individuals had elevated levels of at least one of the proinflammatory cytokines (IL1β, 73.6%; IL6, 54.2%; TNF-α, 33.3%). The contribution of these factors varied depending on the degree of renal impairment. EPO deficiency was found in 20.8, 45.8 and 79.2% patients with CKD stages 1, 2 and 3 respectively. The prevalence of iron deficiency was 16.6, 12.5 and 4.2% in patients with CKD stages 1, 2 and 3 respectively.
The results of the study suggest that pathogenesis of anemia in patients with early stages of DN is multifactorial. The most prevalent pathogenetic factors are EPO deficiency and systemic inflammation. The role of EPO deficiency increases and the role of iron deficiency decreases with progression of DN.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P649

### Non-alcoholic fatty liver disease and cardiovascular disease in type 2 diabetic patients with metabolic syndrome

E Nelaj, E Sadiku, M Gjata & M Tase
University Hospital Center, Tirane, Albania.

Background
Type 2 diabetes is often associated with non-alcoholic fatty liver disease (NAFLD). Patients with NAFLD may be at greater risk for CVD than those without. The relationship between NAFLD and metabolic syndrome (MS) is very well recognized. The aim is to determine the association of NAFLD and the CVD between type 2 diabetic patients with and without MS.
Materials and methods
One hundred and thirty type 2 diabetic patients (M: 71, F: 59, mean age 59, 32 +11, 94), were studied. All subjects were assessed for diabetes duration, the degree of obesity, CV risk factors, HbA1c, C reactive protein and lipid profile. NAFLD was assessed by patient history and ultrasound. MS was defined based on NCEP-ATP 3 criteria. The previous and current CVD (myocardial infarction, angina or revascularization) was assessed. The patients were categorized as four groups: MS (−) and NAFLD (+), MS (−) and NAFLD (−), MS (+) and NAFLD (+), MS (+) and NAFLD (−).
Results
The prevalence of CVD in type 2 diabetic patients with NAFLD was higher than in those without NAFLD (44.2 vs 38.1%). The prevalence of CVD in type 2 diabetic patients with MS was higher than in those without (40.1 vs 35.8%). The risk of CVD in patients with MS was significantly increased by the presence of NAFLD (53.4 vs 32.3%). In type 2 diabetic patients with MS (+) and NAFLD (+) the number of components of MS, BMI, and systolic BP were positively associated with CVD.
Conclusions
What this study suggests to us is that the presence of NAFLD increases the risk of CVD in type 2 diabetic patients with MS.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Microalbuminuria and blood pressure in normotensive subjects with type 2 diabetes mellitus**

E. Nelaj, M. Gjata & M. Tase
University Hospital Center, Tirane, Albania.

Objective
Albuminuria has been shown to predict cardiovascular disease in populations with diabetes mellitus. The aim of this study was to assess the mean pressure values and the circadian rhythm of blood pressure during its ambulatory monitoring in normotensive diabetic patients, dividing them according to the presence of microalbuminuria.
Methods
The study group comprised of 77 type 2 diabetic patients. Their mean age was 56.5±6.7 years, and the mean duration of their disease was 8 years. For microalbuminuria, spot urine samples were collected in the early morning and microalbuminuria was defined as, a urinary albumin excretion between 30 and 300 mg/g. These patients, also underwent determination of ambulatory blood pressure monitoring.
Results
9 (24.6%) patients were microalbuminuric. Ambulatory blood pressure monitoring in the microalbuminuric patients had higher mean pressure values, mainly the systolic pressure, during sleep as compared with that in the normoalbuminuric patients (120.1±8.3 vs 110.8±7.1 mmHg; $P=0.007$). The pressure load was higher in the microalbuminuric individuals, mainly the systolic pressure load during wakefulness (6.3 (2.9–45.9) vs 1.6 (0–16%); $P=0.001$). This was the variable that better correlated with the urinary excretion of albumin ($r_S=0.61$; $P<0.001$). Systolic pressure load >50% and diastolic pressure load >30% during sleep was associated with microalbuminuria ($P=0.008$). The pressure drop during sleep did not differ between the groups.
Conclusion
Microalbuminuric normotensive type 2 diabetic patients show greater mean pressure value and pressure load during ambulatory blood pressure monitoring, and these variables correlate with urinary excretion of albumin.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P651

**The relationship Between Self-Reported Nocturnal Sleep Duration, Daytime Sleepiness and 24-hour urinary Albumin and Protein Excretion in Newly Diagnosed Type 2 Diabetic Patients**

B Afsar
Konya Numune State Hospital, Konya, Turkey.

Aim
Few studies demonstrated that self-reported nocturnal sleep duration (NSD) were related with urinary protein excretion. However no previous study has specifically addressed the relationship between 24-hour urinary albumin excretion (UAE) and 24-hour urinary protein excretion (UPE) in newly diagnosed type 2 diabetic patients.
Methods
All patients underwent history taking, physical examination, blood pressure (BP) measurement, 12 lead electrocardiographic evaluation, routine urine analysis, biochemical analysis, 24-hour urine collection to measure UAE, UPE and creatinine clearance. Self reported NSD and daytime sleepiness (using Epworth Sleepiness Scale (ESS)) were recorded for all patients.
Results
In total 110 patients (56 male, 54 female) were included. The average 24-hour UPE, and UAE were 370.4±571.6 mg/day and 162.8±250.5 mg/day respectively. The self reported sleep duration was 7.17±1.07 hours. The mean ESS score was 5.59±2.48. Stepwise linear regression of independent factors including age, gender, smoking status, body mass index, clinical SB and diastolic BP fasting blood glucose, Hba1c, creatinine clearance, insulin resistance as evaluated by HOMA-Index, self reported NSD and ESS score revealed that logarithmically converted 24-hour UAE was related with clinical systolic BP (b:0.012, CI:0.004–0.021, *P*: 0.005), Hba1c (b:0.097, CI:0.011–0.183, *P*: 0.027), self reported NSD (b:-0.114, CI:-0.0253 (-)-0.036, *P*:0.009) and ESS score (b:0.049, CI:0.001–0.096, *P*: 0.044). Using the same independent parameters 24-hour UPE was related with clinical systolic BP (b:0.01, CI:0.002–0.018, *P*: 0.011) and self reported nocturnal sleep duration (b:-0.167, CI:-0.0267 (-)-0.067, *P*: 0.001).
Conclusion
Self reported NSD and daytime sleepiness were related with both UAE and UPE in newly diagnosed type 2 diabetic patients.
Declaration of interest

## P652

**Office hypertension and masked hypertension and their association with left ventricular hypertrophy and diastolic dysfunction in patients with type 2 diabetes and hypertension**

L. Leiria, P. Ledur, M. Severo, A. Becker, F. Aguiar, D. Massierer, V. Freitas, M. Gus & B. Schaan
Hospital de Clínicas De Porto Alegre, Porto Alegre, Brazil.

Background
The association between isolated office hypertension (IOH) and masked hypertension (MH) with left ventricular hypertrophy (LVH) and diastolic dysfunction cannot be the same, determining different increased cardiovascular risk.
Aims
To evaluate the prevalence of MH and IOH in treated hypertensive patients with type 2 diabetes and their association with LVH and diastolic dysfunction.
Methods
A cross-sectional study was conducted in 193 consecutively selected hypertensive patients with type 2 diabetes, at the outpatient clinic of a hospital in Southern Brazil. Patients performed an evaluation with office blood pressure (BP), 24-h ambulatory BP monitoring (ABPM) and echocardiography. They were classified according to their BP control (office: <140/90 or ≥140/90 mmHg; daytime ABPM: ≤130/85 or >130/85 mmHg) in controlled hypertension (CH: low office BP, low ABPM), IOH (high office BP, low ABPM), MH (low office BP, high ABPM), and truly uncontrolled hypertension (TUH: high office BP, high ABPM).
Results
Seventy patients were men, mean age 56.8±6 years, HbA1c 8.1±1.9%, diabetes duration 11.9±8.8 years, of which 19.7%, 15.5%, 24.4%, and 40.4% were identified as having CH, IOH, MH and TUH, respectively. Interventricular septum was 0.98±0.21, 0.95±0.15, 1.04±0.17 and 1.03±0.16 mm in CH, IOH, MH and TUH, respectively, $P=0.05$. The posterior wall thickness was 0.91±0.14, 0.90±0.13, 0.98±0.13 and 0.99±0.15 mm in CH, IOH, MH and TUH, respectively, $P=0.004$. In a logistic regression model using body mass index and age as covariates, LVH (septum>1 mm) was not associated with IOH (OR 0.53, CI 0.19–1.51, $P=0.241$) or MH (OR 1.70, CI 0.683–4.23, $P=0.254$). Diastolic dysfunction did not differ among groups.
Conclusions
The prevalence of MH and IOH was lower than estimated in the literature in diabetic patients. Masked hypertension and TUH seem to be similar entities with respect to their effects on hypertrophy parameters, while IOH would be a more benign condition.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Dynamics of insulin-like growth factor-1 concentrations during diabetic ketoacidosis**

R. Danciulescu, D. Margina, C. Poiana & M. Musat
Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Background and Aim
Clinical and experimental studies demonstrated that total insulin-like growth factor 1 (IGF-1) levels are reduced in the patients with poorly controlled diabetes. The aim of the present study was to investigate the levels of IGF-1 in patients with acute metabolic acidosis.
Materials and Methods
17 patients with thype 1 diabetes and moderate or severe metabolic acidosis were recruited for this study. Serum levels of IGF-1 were determined by radioimmunoassay. Results were compared with 12 diabetic controls without metabolic acidosis.

Results. The subjects of study group: 8 women (47.05%) and 9 men (52.94%) were 26 to 38 years (30.20±3.22 years). 13 patients (76.47%) exhibit moderate metabolic acidosis (according to American Diabetes Association, moderate acidosis is characterized by pH 7.00–7.25, bicarbonate 10–15 mmol/l), and 4 patients (23.52%) severe ketoacidosis (according American Diabetes Association severe acidosis is characterized by pH below 7.00, bicarbonate below 10 mmol/l) Diabetic ketoacidosis occurs due to intercurrent illness and poor compliance with insulin therapy. The levels of IGF-1 were significantly decreased in patients with thype 1 diabetes with metabolic acidosis compared to those without metabolic acidosis (122 ng/dl vs 286 ng/dl, $p<0.005$). The normal IGF1range for age 25–39 years 114 to 492 ng/dl

Conclusion. In this study we found significant differences for the IGF-1 levels between patients with diabetic ketoacidosis and patients with thype 1 diabetes without ketoacidosis. Our results are consistent with several studies that have reported that in diabetic ketoacidosis IGF-1 is impaired.

metabolic acidosis, insulin-like growth factor 1 levels, thype 1 diabetes

### Diabetic peripheral arterial occlusive disease is associated with microvascular complications but coronary atherosclerosis might not be associated with them

D. Tesic, B. Kovacev-Zavisic, M. Mitrovic, V. Popovic, B. Vukovic & J. Novakovic-Paro

Clinical Centre of Vojvodina, Novi Sad, Serbia.

Background and aims

The distribution of arterial occlusive disease is not fully explained in diabetes. The aim of this study was to examine the prevalence of CHD and PAD in diabetic patients complicated by abnormal test of distal autonomic function (Neuropad®) and large fibre neuropathy.

Materials and Methods

237 patients were analysed, M/F 111/126, age (mean±SD) 61.3±9.5years (ys), diabetes duration 16.4±10.6ys., type 1 n=22 (9.3%), HbA1c 9±1.98%, 66.5% on insulin therapy, BMI 25.5±4.8 kg/m2, W 97±12.4 cm, high BMI 28.8 ±5.96. Sudomotor neuropathy was determined on the sole of the foot using the Neuropad® response. 32 patients (pts) with small fibre neuropathy (DN), (group 1; G1); 42pts with small and large fibre DN (group 2; G2); 60pts with large fibre neuropathy, VPT<6, AR>3 (group 3; G3); and 103pts without DN (G4).

Results

ANOVA: age (G1 58.3±11.3, G2 64.5±7.8yrs; p 0.01), DM duration (G1 13.5±8.6, G2 20.5±9.6, G3 19.3±11.9, G4 14±9.8yrs; $p<0.01$), proteinuria (G1 147.2±131.8, G2 350.9±485.2, G3 615.4±1174.2, G4 446 ±1197 mg/dU; $P<0.05$), W (G1 92.1±14.8, G2 99.7±10.8, G3 99.3±10.6, G4 96.1±12.7; $P$ 0.02;). The contingency tables (X2) were used: maculopathy (G1 15.6%, G2 46.6%, G3 40%, G4 17.5%; $p<0.01$), prolipherative retinopathy (G1 0%, G2 14.3%, G3 16.6, G4 2.9%; p 0.01), CHD (G1 15.6%, G2 40.5%, G3 33.3%, G4 29.1%; $P$ 0.02), PAD (G1 14.8%, 30.95%, 26.7%, 8.3%; $P$ 0.05), major amputation (G1 0%, G2 11.9%, G3 0%, G4 0%; $P$ 0.04).

Conclusion

Small fibre neuropathy on feet together with large fibre neuropathy is strongly associated with both micro- and macro- vascular diabetic complications. In patients without neuropathy (G4) there is still increase in prevalence of coronary artery disease but not peripheral artery disease. It is possible that endogenous insulin may exert an adverse effect on the incidence of coronary atherosclerosis and protective on microvascular in this group of patients.

## P655

### Predictors of Cardiovascular Risk: Metabolic Syndrome vs. Diabetes Mellitus and Hypertension

T. Isailovic, M. Petakov, S. Ognjanovic, V. Elezovic, D. Macut, B. Popovic, I. Bozic, T. Bogavac & S. Damjanovic

Clinic for Endocrinology, Diabetes and Metabolic Diseases, Belgrade, Serbia.

Introduction

Metabolic syndrome (MS) is an independent risk factor of coronary artery disease (CAD). We investigated how influenced this risk is by the definition of MS, and whether the risk is greater than that conferred by its components.

Methods

We analyzed 200 consecutive patients (35–79 years, mean 59.23±8.6, men 132, women 68) who underwent coronary angiography due to suspected myocardial ischemia. MS was obtained by several definitions: ATPIII, IDF, and JIS from 2009. CAD was defined by the presence of stenosis of any severity. CAD severity was determined by Gensini, and extent of disease scores. The effects of predictors on the presence of CAD and its severity were analyzed using binary logistic regression, and multiple linear regression analysis.

Results

MS was present in 151(75.5%), 167(83.5%), and 172(86%) patients, using ATPIII, IDF, and JIS criteria, respectively. Regardless of used criteria, MS was associated with increased risk of CAD (OR=3.30, CI95%: 1.64–6.63, OR=4.48, CI95%: 2.05–9.82, OR=5.62, CI95%: 2.43–13.0, for ATPIII, IDF and JIS criteria, respectively). Overall risk was significantly higher in women with MS than in men with MS, using all three criteria. Patients with ≥3 clustered components were in greatest risk of CAD (OR=4.19, CI95%: 2.03–8.67). However, diabetes and hypertension, each or together, had similar strength in predicting CAD. Waist circumference did not have effect on CAD risk. The higher the number of components of MS included, the higher the value of Gensini and extent of disease score was obtained ($r=0.36$, $P=0.0001$, and $\tau=0.4$, $P=0.001$, respectively). However, the strongest independent risk factor of severity of disease defined by Gensini score was diabetes, while hypertension was the strongest predictor of extent of disease score.

Conclusion

Irrespectively of diagnostic criteria, MS has similar clinical significance as diabetes and hypertension individually.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P656

### Risk Factors and Therapeutic Management of type 2 Diabetes in Georgia

T. Akhobadze, R. Kurashvili, K. Paghava & M. Avazashvili

National Center of Diabetes Research, tbilisi, Georgia.

Background and aims

Cardiovascular disease (CVD) is a leading causes of death in type 2 diabetes mellitus (T2DM), thus prevention of CVD is of utmost importance. Our aim was to determine whether the ESC/EASD guidelines on CVD prevention in T2DM patients are followed in clinical practice in Georgia.

Materials and methods

In total, 824 T2DM patients (age <80 yrs) with no history of coronary or other atherosclerotic disease, who entered Georgian Diabetes Center in 2009–2010 were included in a retrospective study. Data collection was based on a review of Patients' Medical Notes, and interviews and examinations during at least six months post drug therapy initiation.

Results

Only 46.9% of patients had HbA1c <6.5%; 67.3% had average blood pressure (BP) ≥ 130/80 mmHg. Only 27.8% of patients on antihypertensive medications achieved BP goals; 74.7% had total cholesterol (TC) ≧4.5 mmol/l; out of all patients on lipid lowering therapy 67.7% achieved TC, 38.8% - triglycerides and 37.9% HDL-C goals. Following cardioprotective medications were used: aspirin or other anti-platelets - in 37.3% of patients, ACE inhibitors/ARB - in 61.5%, beta-blockers - in 27.1%, calcium channel blockers - in 33.5% and statins in 37.4% of patients.

Conclusion

Our study shows that glucose, blood pressure and lipid control are completely inadequate in a large majority of T2DM patients in Georgia; targets defined in the prevention ESC/EASD guidelines are not achieved. To some extent it is due to the

fact that part of the patients quits or changes prescribed antihypertensive and/or lipid-lowering therapy. The fact that in patients on statin therapy triglycerides and HDL-C levels, when compared to TC ones, were mostly poorly controlled indicates to the necessity of administering additional agents to achieve target levels of lipids. Primary prevention needs systematic approach to therapeutic management that addresses various risk factors, and health care system that invests in prevention.

## P657

**Effects of Hyperglycemia on Oxidative Stress and Antioxidant Potential in Patients with Type 2 Diabetes**

M. Ikebuchi[1], Y. Nishio[2], H. Maegawa[3] & A. Kashiwagi[3]
[1]Ikebuchi Clinic, Osaka, Japan; [2]Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan; [3]Shiga University of Medical science, Ohtsu, Japan.

Background
Many *in vitro* studies have suggested that oxidative stress induced by hyperglycemic condition has pivotal role for pathogenesis of vascular complications in diabetics. This study intended to evaluate oxidative stress and antioxidant potential in patients with type 2 diabetes mellitus (DM), and to clarify the relation between oxidative stress and metabolic derangements including chronic hyperglycemia.
Materials and methods
We measured the levels of derivatives of reactive oxidative metabolites (ROM) and biological antioxidant potential (BAP) in 59 patients with type 2 DM and 10 healthy controls. Values for ROM and BAP were assessed using Free Radical Analytical System 4 (FRAS4; H&D srl, Parma, Italy). The adjusted BAP/ROM ratio was calculated by dividing the BAP/ROM ratio by 7.510, which was the average value obtained from healthy Japanese adults, and thus the data were standardized to a level 1.00.
Results
ROM levels in patients with type 2 DM increased significantly compared with those in controls ($370 \pm 69$ vs. $299 \pm 23$ CARR U, respectively; $p < 0.01$). There were no differences in BAP levels between the two groups. On the other hand, adjusted BAP/ROM ratios were significantly decreased in patients with type 2 DM compared with those in controls ($0.84 \pm 0.20$ vs. $0.98 \pm 0.17$ μM/CARR U, $p < 0.05$). It was found that ROM levels positively correlated with HbA1c, plasma glucose, and waist size, and adjusted BAP/ROM ratios negatively correlated with HbA1c, plasma glucose, waist size, and serum triglycerides. Stepwise multiple regression analysis indicated that HbA1c and waist size were independent factors contributing to the elevated ROM levels. The ROM level in type 2 DM patients complicated with metabolic syndrome was significantly 10% higher than that in DM patients without metabolic syndrome ($p < 0.05$). Treatment with either glimepiride($n = 10$), miglitol ($n = 5$)or vildagliptin($n = 13$) for 3 months improved HbA1c level from 11.1% to 7.4%, 6.8% to 6.4%, 7.6% to 6.9% and reduced ROM levels significantly by 13%*, 4%*, 7%*(from $330 \pm 46$ to $290 \pm 45$, from $337 \pm 66$ to $322 \pm 61$, from $289 \pm 40$ to $269 \pm 49$ CARR U, $*P < 0.05$), respectively.
Conclusions
These results clearly demonstrate that glycemic control and visceral obesity are independently associated with an increasing oxidative stress in patients with type 2 DM.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P658

**Serum vitamin D and parathormone (PTH) concentrations as predictors of the development and severity of diabetic retinopathy.**

R. Naguib[1] & M. Abdel Fattah[2]
[1]Faculty of Medicine,Alexandria University, Alexandria, Egypt; [2]Faculty of Medicine,Cairo University, Cairo, Egypt.

Introduction
Vitamin D is suggested to be an inhibitor of angiogenesis. The degree of severity of Diabetic retinopathy (DR) may be related to serum Vitamin D concentration so this study aims at investigating vitamin D and parathormone (PTH) concentrations as predictors of the development and severity of diabetic retinopathy.
Material and methods
Levels of vitamin D [25(OH) D3 and Calcitriol] and PTH were measured in 200 diabetic patients presenting with suspected diabetic retinopathy. Diabetic retinopathy was assessed using 7-field stereoscopic Fundus photography.
Results
Mean serum concentration of 1, 25 dihydroxy vitamin D 3 (1, 25(OH)2 D3) was significantly lower in diabetic subjects with retinopathy than in diabetic subjects with no retinopathy and There is a significant negative correlation between the mean level of 1, 25 (OH) 2 D3 and the degree of severity of retinopathy. Level of PTH was significantly higher in severe NPDR and PDR compared to patients with no retinopathy.
Conclusions
low levels of vitamin D might be a risk marker of development or progression of diabetic retinopathy. It might be advisable that detailed ophthalmologic examination is needed for diabetics whose serum 1, 25(OH) 2D3 concentrations are gradually decreases. The measurement of serum 1, 25(OH) 2D3 concentrations could become a useful biochemical means to predict the severity of DR in patients with diabetes mellitus.

**Epidemiology of Diabetic Ketoacidosis in National Institute of Diabetes and Endocrinology (NIDE) by:Bassyouni, A.; El Ebrashy, I.; El Hefnawy, H**

M. El Hefnawy
NIDE, Cairo, Egypt.

Background
Diabetic ketoacidosis (DKA) is the most serious acute metabolic complications of diabetes. Unfortunately, there is a dearth of published data on this entity from Egypt. The aim of our work was to determine the clinical characteristics, precipitating causes and mortality rate of patients with diabetic ketoacidosis in National Institute of Diabetes and Endocrinology.
Methods
Our work is a retrospective study in which we reviewed and analyzed the data of all patients (1297 diabetics: 85.8% type1 and 14.2% type2 diabetics, 59.6% females and 40.4% males) who admitted to NIDE in Cairo, Egypt with diagnosis of DKA over the last three years. The mean age of the patients was $22.9 \pm 15.6$ year and the mean duration of DM was $5.5 \pm 5.7$ year.
Results
DKA among our study diabetics was attributed to non-compliance (45.5%), infection (27.2%),myocardial infraction (6.4%), and new-onset type 1 diabetes (20.9%).Respiratory infection (46.9%), urinary tract infection (36.3%), gastoentritis (9.7%),diabetic foot (2.5%) and abscess (4.6%) were the most frequent infection in the our patients. The patient's age,weight, blood pressure, pulse, serum creatinin, duration for recovery from DKA, type of DM and presence of coma were associated with mortality in these patients. Logestic regression revealed that duration for recovery from DKA was the only independent risk factor for mortality among diabeticswithDKA.
Conclusion
Most of diabetics with DKA are young, females and have type1 DM. Noncompliance and infection were the leading precipitating causes for DKA among type1 and type2 respectively. Recurrent admission for DKA and delayed diagnosis of new onset type1 DM are frequent and may indicate inadequate education. Respiratory and urinary tract infections accounted for the majority of infections in these patients. Mortality was infrequent finding among our diabetics with DKA. Although young age, underweight, tachycardia, hypotension, high serum creatinin, type 2 DM, rapid recovery from DKA and coma were associated with higher mortality rate among patients with DKA, rapid recovery from DKA was the only independent risk factor (predictor) for mortality in these patients.

**Evaluation of capillary Beta-hydroxybutyrate measurement In diabetic ketoacidosis By: Hesham El Hefnawy By:El Hefnawy, H.*; Bassyouni, A.** and Emara, I.*** From: *Pediatric, **Internal Medicine and ***Biochemistry departments, National Institute of Diabetes & Endocrinology (NIDE)**

M. El Hefnawy
NIDE, cAIRO, Egypt.

Background
Current criteria for the diagnosis of diabetic ketoacidosis (DKA) are limited by their nonspecificity (serum bicarbonate [HCO3] and pH) and qualitative nature (the presence of ketonemia/ketonuria). A new method is now available to measure capillary levels of beta-hydroxybutyrate (beta -0HB), It is a quantitative and enzymatic test that uses the same equipment as for home capillary blood glucose determination but with specific strips. Aim of the work: The aim of this study was to evaluate the use of measurement of capillary B-hydroxybutyrate (beta-OHB) during the diagnosis and follow up of type 1 diabetic patients with DKA.
Subjects and Methods
This study was conducted on 40 type 1 diabetic patients presented to (NIDE) with DKA and who were aged 4–20 years and half of them was males. 140 capillary blood samples were tested for beta-hydroxybutyrate using blood beta-OHB test strips. Measurement of serum bicarbonatre (HCO3), blood glucose and urine acetone and estimation of venous blood pH and anion gap had been done for all patients.
Results
Linear regression revealed highly significant correlation between capillary β-OHB levels and all indices of acidosis but no significant correlation between acetone in urine and serum bicarbonate. Using regression to predict values of HCO3, pH and anion gap from β-OHB levels revealed that levels of β-OHB of 1.4, 1.9, 2.7,3.5 and 4.0 mmol/l corresponded to HCO3 levels of $>18$, 15–18, 10-$<15$, 5-$<10$ mEq/l.
Conclusions
The measurement of capillary β-OHB levels is easy and give rapid and objective results. Capillary β-OHB levels are more predictable than urinary acetone for degrees of acidosis and severity of DKA and can be used at diagnose and follow up of type1 diabetic patients with DKA to improve their management.
Key words: Acetoacetic acid (ACAC) B-hydroxybutyrate (β-OHB) Diabetic Ketoacidosis (DKA) bicarbonate (HCO3) and National Institute of Diabetes & Endocrinology, (NIDE).

**Clinical characteristics of diabetic peripheral neuropathy in past and present in Korea**

C. Kim[1] & S. Kim[2]
[1]Sejong General Hospital, Bucheon city, Republic of Korea; [2]Bucheon St. Mary Hospital, The Catholic University of Korea, Bucheon city, Republic of Korea.

Diabetic peripheral neuropathy (DPN) is a most common complication of diabetes mellitus. Patients with DPN have chronic, painful symptoms that disrupt sleep, depressed mood and can lead to diminish quality of life. We evaluated clinical characteristics of diabetic peripheral neuropathy in past and present in Korea
We performed the study to determine the prevalence and to understand the clinical characteristics of diabetic peripheral neuropathy in Koreans on 2005 and 2010.
A cross-sectional study was carried out on type 2 diabetic patients from the diabetic clinics of 33 medical centers throughout Korea on 2005. The study pool consisted of 875 randomly selected type 2 diabetic patients (45% men and 55% women, mean age: $59\pm10$ years). Of the 875 patients, 54% (51% men and 49% women) had DPN. There was significant differences in prevalence between the genders (40.7% men and 59.3% women, $P<0.002$) and the different age groups ($60.7\pm10.6\%$ vs $56.6\pm11.7\%$, $P<0.001$). The prevalence increased steadily with the duration of diabetes since the time of diagnosis. The DPN patients had higher HbA1c values than did the diabetic patients without DPN (8.0% vs 7.2% respectively $P<0.001$). The mean number of DPN symptoms was $3.2\pm1.7$. Among them, 'severe pain on the leg or feet at night', 'a sudden cramp on the leg or feet', and 'feeling a pin-prick on the leg or feet' were common, and the incidences of those symptoms were 31%, 29% and 29% respectively.
A cross-sectional study was carried out on 4,000 type 2 diabetic patients from the diabetic clinics of 40 medical centers throughout Korea on 2010. Of the 4000 patients, 33% (51% men and 49% women) had DPN. There was significant differences in prevalence between the genders (40.7% men and 59.3% women, $p<0.002$) and the different age groups ($60.7\pm10.6\%$ vs $56.6\pm11.7\%$, $P<0.001$). The prevalence increased steadily with the duration of diabetes since the time of diagnosis. The mean number of DPN symptoms for the patients was $3.1\pm1.7$. The mean number of DPN symptoms was $3.1\pm1.7$. Among them, 'a numbness on the legs or feet', 'feeling a pin-prick on the legs or feet' and 'severe pain on the legs or feet at night' were common, and the incidences of those symptoms were 65%, 46% and 36% respectively. DPN is a common complication of diabetes affecting 33–54% of patients with diabetes in Korea.

**The effects of metoprolol,diltiazem and pilocarpine in Prolonged QTc interval caused by insulin induced hypoglycemia in rats**

O. Erbas
Ege University Faculty of Medicine, Izmir, Turkey.

Introduction
Insulin induced Prolonged QTc interval cause severe ventricular arrhythmias and sudden cardiac death.
The purpose of this study is to reveal the effects of metoprolol,diltiazem and pilocarpine on insulin induced prolonged QTc interval(Bazett)
Material-Method
In this study 24 Sprague-Dawley adult male rats were used.Before application under anesthesia ECG were taken in derivation(D)I and normal QTc interval was determined in normoglycemic rats.
For the induction of hypoglycemia 40 U/kg crystalline insulin were injected to the 24 rats.Rats were divided into 4 groups ($n=6$). After 2.5 hours insulin injection, For first group saline(S), for second 1 mg/kg metoprolol, for the third group 0.8 mg/kg pilocarpine and fort he forth group 1 mg/kg diltiazem were applicated intraperitoneally.
3 hours after insulin injection, blood sugar was measured from all four groups rats tail with stick. 40 mg/dl defined as the limit of hypoglycemia. The all hypoglycemic rats below this value, under anesthesia,QTc was calculated and interpreted by taking ECG in DI
Results
In the first group hypoglycemic (HG) rats which is taken saline QTc interval ($0.143\pm0.01$s)is significantly ($P<0.05$)prolonged than normoglycemic rats QTc ($0.123\pm0.009$s)
In the second group HG rats which is taken metoprolol QTc ($0.121\pm0.004$s), in the third group HG rats which is taken pilocarpine QTc ($0.116\pm0.002$s), in the forth group HG rats which is taken diltiazem QTc ($0.129\pm0.001$s) were founded. QTc intervals in second,third, forth groups HG rats which is taken metoprolol, pilocarpine and diltiazem QTc intervals were significantly ($P<0.05$)shorten than HG rats which is taken saline QTc ($0.143\pm0.01$s).
Conclusion
Pilocarpine,metoprolol and diltiazem prevented elongation in QTc intervals in HG rats.The prophylactic use of this drugs may be an hope by reducing sudden cardiac death in patients taking insulin.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Proximal upper and lower extremities severe pain, muscle weakness in a young diabetic male with multiple chronic complications. A rare and unusual clinical presentation

O. Torres, C. Palermo, M. Padilla, J. Martinez, K. Davila, M. Miranda, E. Gonzalez, M. Mangual, I. Laboy, R. Tirado, I. Chinea & M. Miranda
San Juan City Hospital, San Juan, Puerto Rico.

A 49 years old male patient with 12 years history of poorly controlled type 2 diabetes mellitus on insulin therapy, complicated with neuropathy, nephropathy, retinopathy, peripheral arterial disease (right toe amputation), hypertension and dyslipidemia. He presented with upper extremities proximal muscle and upper back moderate pain that progressed to excruciating pain with restriction of motion, weakness, and stiffness of 3 days of evolution. He denied trauma, abnormal exercise, arthralgia, fever, nausea or vomiting. Physical examination was remarkable for bilateral upper extremities edema, local tenderness and indurations without palpable crepitus. Laboratory results showed normocytic normochromic anemia, hyperkalemia, creatinine of 1.9 mg/dl, high anion gap metabolic acidosis, erythrocyte sedimentation rate of 76 mm/hr and increased creatine kinase of 225 U/L. Electrocardiogram demonstrated a sinus tachycardia and peaked T waves. Blood cultures were negative. Upper extremities Venous Doppler was negative for DVT. Echocardiogram revealed moderate LVH, non thrombus or vegetation. MRI of the left arm showed diffused soft tissue swelling and T2 hyper intensity of the deep biceps, brachialis, and brachioradialis muscles in the anterior muscle compartment with heterogeneous patchy contrast enhancement consistent with diabetic myonecrosis. Similar findings noted in latissimus dorsi muscle. After two week he started with the same symptomatology in both thighs, with gradual relief of upper extremities affection, but with residual muscle wasting. A muscle biopsy with electronic microscopy allowed us to rule out other conditions. Currently he has symptomatic improvement.
Diabetic muscle infarction is a rare complication of longstanding diabetes referring to spontaneous ischemic necrosis of skeletal muscle, unrelated to atheroembolism or occlusion of major arteries. This condition cause acute or subacute pain, swelling and tenderness, typically in the thigh or calf. Rarely, the upper limb may be involved and only one case has been reported. Diabetic myonecrosis is an indicator of poor prognosis, tends to resolve spontaneously but with frequent relapses. A review of the literature, identified at total of 116 patients.

### Risk factors for cardiovascular diseases in T1DM

T. Mokhort[3], M. Rusalenko[1,4], I. Davydova[2], N. Shilova[1], T. Sharshakova[4] & A. Rozhko[1]
[1]The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus; [2]Gomel State University of F. Skorina, Gomel, Belarus; [3]Gomel State Medical University, Gomel, Belarus; [4]Belarusian State Medical University, Minsk, Belarus.

Rationality
T2DM is a component of the metabolic syndrome, the occurrence of overweight, arterial hypertension (AH), and dyslipidemia in T1DM is variable according to the literature.
Objective
Study of the occurrence of overweight, AH and dislipidemy in T1DM
Materials and methods
Total 726 patients with T1DM (348m, 378f), mean age ($M \pm \sigma$) $34.71 \pm 0.58$ yrs (1–78), age of T1DM manifestation $12.41 \pm 0.36$ yrs and special form including questions about T1DM. Levels of triglycerides (TRIG), total cholesterol (CHOL), high density lipoprotein (HDL), low density lipoprotein (LDL), very low density lipoprotein (VLDL) and HbA1C (%) were measured by biochemical analyzer 'ARCHITECT C8000' (Abbott, USA). Body mass index (BMI), systolic blood pressure (sBP), diastolic blood pressure (dBP) were analysed. Control includes 206 healthy volunteers of similar age and sex.
Results
The levels of sBP, dBP, HbA1C, TRIG and LDL were significantly higher in T1DM, than in the control (*$P<0.001$). Differences of rates are fixed in patients in their division into age categories: under 18, 18 and over (table -^$P<0.001$).
BMI of 25–29.9 kg/m2 was recorded in 188 patients (31%) and 41 subjects of control (28%), BMI of 30–34.9 kg/m2 in 89 patients (14%) and 16 subjects of control (11%), BMI of 35–39.9 kg/m2 in 25 patients (4%) and 5 subjects of control (4%), BMI of 40 kg/m2 and more (obesity of the third degree) in 5 patients (1%) and 6 subjects of control (4%). The levels of sBP, dBP, CHOL, TRIG and LDL ($P=0.001$) were higher and the level of HDL was lower ($P=0.015$) in the presence of T1DM and overweight, such differences occurred in men and women.
Conclusion
The patients over 18 with T1DM have often AH, dislipidemy, overweight and obesity. The patients with overweight and T1DM had high BP (>130/80 mm Hg) and metabolic changes in the form of atherogenic shifts in blood lipid spectrum. That indicates the risk increase of cardiovascular diseases.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### Relationship Between HbA1c and Asymptomatic Coronary Artery Disease in Type 2 Diabetes Patients

M. Dundua, T. Akhobadze, R. Kurashvili & A. Kopaleishvili
National Center for Diabetes Research, Tbilisi, Georgia.

Background
Patients with type 2 diabetes mellitus (T2DM) have elevated risk of coronary artery disease (CAD) development. In this population CAD often proceedsa-symptomatically, especially if cardiac autonomic neuropathy (CAN) is present. Our aim was to assess relation between glycemia control and asymptomatic CAD inT2DM pts. Materials and methods: Participants were 160 T2DM patients without documented CAD divided into four groups (Gr.) according to HbA1c levels: Gr. 1 -HbA1c6.0–7.0%($n=42$; mean age (MA)- 48.3+9.1yrs; 27m/15f); Gr. 2 - HbA1c 6.0–8.0% ($n=46$; MA 51.4+6.7yrs; 26m/20f); Gr. 3 - HbA1c8.0–10.0% ($n=40$; MA 49.9+7.1yrs; 22m/18f); Gr. 4 - HbA1c>10.0% ($n=32$;MA 51.9+9.7yrs; 17m/15f). In Gr. 1 target HbA1c (6.0–7.0%) were selected individually. In all pts 12 - lead rest ECG,exercisestress-tests (veloergometry) or 24-hr. Holter ECG were performed. To put final CAD diagnosis coronary angiography was performed in subjects with positive stress-test or ischemic episodes on Holter ECG. Results: Abnormal ECG atrest was observed in 7.1% of Gr. 1, 6.5% - Gr. 2, 12.5% - Gr. 3 and 15.6% of Gr. 4 patients. Positive stress test or ischemic episodes on Holter ECG were found in 38 out of 160 (23.8%) patients, and were more frequently observed, when HbA1c levels were high - 11.9% - Gr. 1; 19.6%-Gr. 2; 30%-Gr. 3 and 37.5%ofGr. 4 patients. Among 38 pts with positive stress-test or ischemic episodes on Holter ECG, 23 subjects received CAG, CAD was diagnosed in 14(60.9%) patients. Conclusion: Hyperglycemia, reflected by significantly elevated HbA1c levels, is associated with increased risk of CAD development that often proceeds asymptomatic. This may be due to CAN, caused by elevated glycemia levels. In uncontrolled T2DM more attention should be paid to glycemia normalization and early CAD revealing. This will permit to timely take necessary measures to improve the outcomes.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Treating depression in type 2 diabetic patients improves depressive symptoms and quality of life but not metabolic control

J. Nicolau Ramis, C. Francés Artigas, R. Rivera Irigoin, J. Olivares Alcolea, A. Gil Palmer, L. Gómez Gómez, I. Rodriguez Rodriguez, B. Chacártegui Quetglas, J. Quevedo Juanals & L. Masmiquel Comas
Hospital Son Llàtzer, Palma de Mallorca, Spain.

Introduction:Type 2 Diabetes (T2DM) almost doubles the risk of comorbid depression, with lifetime prevalence up to 29%. It is important to recognize and treat depression in T2DM because its association with hyperglycemia, increased diabetic complications and poor quality of life (QoL) is well established. However, currently available medical therapy for depression is effective in reducing depressive symptoms, but does not consistently improves HbA1c levels. Aims:Determine the effects of antidepressant therapy on depressive symptoms, health-related QoL and metabolic control in T2DM. Material and methods:33 T2DM (47.8%♂, age 59.8±11.1, progression period of DM 9.5±6.5 years) who had a Beck Depression Inventory (BDI) test greater than 16 were prescribed citalopram 20 mg once daily; 10 out of 33 refused it. BDI score, BMI, HbA1c and the Spanish version of the SF-36 Health Survey were recorded baseline and after 6 months of treatment. Sociodemographic characteristics (marital status, educational level, labor situation), complications related to T2DM and comorbidities were also registered. Results:No differences in baseline characteristics were observed between the two groups. When compared with the untreated group ($n=10$), patients treated with citalopram ($n=23$) showed significant improvements in BDI score and in almost all areas of quality of life. No differences in HbA1c, waist circumference or BMI were seen (Table 1). Conclusions:Treating depressive symptoms with medical therapy in T2DM is associated with improvements in QoL and depression with lack of efficacy in metabolic control or weight.

**Table 1** BMI: body mass index. BDI: Beck Depression Inventory

| | Baseline | 6 month-treatment | p |
|---|---|---|---|
| BMI | 30.79±4.83 | 31±4.54 | $p=$ 0.56 |
| Waist circumference(cm) | 104±13 | 106±13 | $p=$ 0.091 |

### Cardiorespiratory fitness is decreased and not correlated with C-Reactive Protein levels in adults with Diabetes Mellitus

C. Francisco, A. Catai, S. Moura, S. Lopes, A. Del Vale & A. Leal
Federal University of São Carlos, São Carlos, Brazil.

Diabetes Mellitus (DM) has been associated with lung dysfunction and impairment of cardiorespiratory fitness and increasing evidences have suggested that comorbidities and systemic inflammation may be involved in these derangements. However, the results regarding cardiopulmonary dysfunction and its underlying mechanisms in DM are still controversial. In this study, we evaluated the relationship between metabolic variables and inflammation marker, including hemoglobin A1C (HbA1C), lipid profile and C-reactive protein (CRP) levels, and cardiorespiratory fitness in adult patients with DM. Nineteen men with diabetes (aged 51±6 years; mean ± SD) and nineteen age and sex-matched control subjects (aged 49±7 years) were studied. The average duration of diabetes was 11 years (range, 2–25 years) and the HbA1C mean levels were 8.4% (range, 6–12.9%). All individuals were subjected to incremental cardiopulmonary exercise test and spirometry. Blood pressure, triglycerides, HDL, LDL, total cholesterol and CRP were not different in control subjects and individuals with DM. Body mass index (28.7±1 vs 25.6±0.4 kg/m2, mean ± SD, $P<0.01$) and resting heart rate (78.3±2.2 vs 71.3±2.1 beats/min, mean ± SD, $P=0.03$) were significantly higher in individuals with DM than in control subjects, respectively. No significant difference was noted in spirometric variables, including forced vital capacity (FVC), forced expiratory volume in 1s (FEV1), forced expiratory flow midexpiratory phase (FEV25–75%) and peak expiratory flow (PEF). In the exercise test, maximal overload (W), peak heart rate (HRpeak), peak oxygen consumption (VO2peak) at anaerobic threshold (VO2AT) and respiratory exchange ratio (RER) were significantly lower in patients with diabetes than in control subjects. No correlations were observed between HbA1C and CRP plasma levels and cardiorespiratory variables. These data indicate that cardiorespiratory fitness is reduced and spirometric values are preserved in patients with diabetes. However, decreased cardiorespiratory fitness is not correlated with CRP levels or HbA1C.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Evaluation of Brainstem Auditory Evoked Potential in Diabetics

S. Chaudhary
Edmond City Hospital, Butwal, Nepal.

Background
Brainstem auditory evoked potentials (BAEP) have been used for electrophysiological assessment of central neuropathy in diabetes. However, the role of this test in documenting the abnormality, the site of abnormality and relation of these abnormalities with metabolic control of diabetes are not clear as yet. The present study was done to explore the presence of abnormalities, if any, in the test parameters and relation of these with diabetic status.
Methods
It was a cross sectional study with controls. Thirty patients of diabetes mellitus (group 1) and thirty healthy controls (group 2) were included in the study. All the patients were subjected to laboratory examination including haemogram, fasting and postprandial plasma sugar (2 hours), HbA1c, urine R/E, 24 hour urine for proteins, ECG, RFT, LFT and lipid profile. BAEP was done in all the subjects
Results
Mean peak latency of waves I, III, V and interpeak latency of I-III, III-V, I-V were prolonged in group 1, but were not statistically significant. Abnormal BAEP response was found in 8 patients (27%) in group 1. Abnormal BAEP response reflex response was significantly correlating with postural drop in blood pressure ($P$-value 0.013 and 0.046). There was no significant relation between abnormal BAEP response with age, sex, type of diabetes, duration of diabetes since detection, fasting plasma sugar level, postprandial plasma sugar level, glycosylated haemoglobin, presence of retinopathy, nephropathy and peripheral neuropathy.
Conclusions
BAEP is a useful method for obtaining an early diagnosis of central and cranial nerve abnormalities in diabetic patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### The Loss of Work Productivity in Type 2 Diabetes Mellitus in Turkey

I. Satman[1] & S. Akalin on behalf of Cost of Diabetes Study Group[2]
Marmara University Medical Foundation, Istanbul, Turkey.

Introduction: An update of health economics analysis of diabetes mellitus (DM) in Turkey was performed. The primary objective was to collect and calculate the healthcare resources utilized for the management of DM.
Methods: Thirty-one out of 40 randomly chosen centers completed the study. Medical files were reviewed for the data recorded for at least two years prior to the study. Collected data included laboratory tests, treatments, inpatient/outpatient follow-up visits, consultations and patient education. Data on work loss collected via validated "Work Productivity and Activity Impairment Questionnaire: General Health V2.0 (WPAI:GH)".

Results: A total of 942 patients' data were included in the analysis. Mean age was 57.7 ± 11.4 years; 58% were female, median DM duration was 8 years. Metabolic (28%), ocular (21%), cardiovascular complications (12%), neurologic (11%) and renal (4%) were the first five causes for seeking care. A total of 657 (69.7%) patients answered the WPAI:GH questionnaire. The percentage of patients, who had a job, at the time of the study conducted, was 14%. The proportion of the working patients who stated that health problems had caused 50% or more productivity loss while working in last 7 days was 21%. This figure for regular daily activities other than the ones at the job was 30% of all patients. Scores of work impairment and activity impairment were 23% and 31% over 100%. Nearly 1/5 of the patients were getting help (professional, volunteered or from a family member) for daily health care, due to health problems. Mean percentages for absenteeism and presenteeism were 24% and 15%, respectively. General work productivity loss (absenteeism plus presenteeism) was found as 39%.
Conclusion: DM is a disease that affects work and daily productivity of both the patients and their companions, negatively. Productivity loss of patients' and their companions can be prevented with better management of DM.

### The Relationship between Cognitive Function and Microalbuminuria in Elderly Type 2 Diabetic Patients

O. Oz Gul[1], C. Gul[2], M. Hartavi[2], A. Bayindir[2], S. Cander[3], C. Ersoy[2] & S. Imamoglu[2]
[1]Bursa Cekirge State Hospital, Bursa, Turkey; [2]Uludag University Medical School, Bursa, Turkey; [3]Bursa Sevket Yilmaz State Hospital, Bursa, Turkey.

Objective: The prevalence and incidence of diabetes mellitus (DM) are increasing at all ages, including older populations. Several studies have shown that elderly diabetics have impaired cognitive function compared to age-matched non-diabetics, as well as a higher risk of dementia. In the current study we aimed to analyze relationship between microalbuminuria and cognitive dysfunction in elderly patients with type 2 diabetes.
Material and Methods: One hundred four diabetic patients who are over 60 years and diagnosed at least 6 months ago and forty four healthy volunteers who are over 60 years were included in this study. Medical history taking, physical examination, biochemical analysis and collection of urine specimens to determine microalbumin-creatinine ratio were performed. Cognitive function was evaluated by the Standardized Mini Mental State Examination (SMMSE). The patients were evaluated in three groups: type 2 diabetic patients without microalbuminuria (group 1), type 2 diabetic patients with microalbuminuria (group 2) and the control (group 3).
Results: One hundred four diabetic patients (42 males, 62 females; mean age: 65.8 ± 5.1 years) and 44 healthy volunteers (17 males, 27 females; mean age: 65.4 ± 5.0 years) were enrolled in the study. SMMSE scores significantly lower in diabetic patients compared with the control group ($P < 0.05$). The mean SMMSE scores of normoalbuminuric (60 patients) and microalbuminuric (44 patients) patients were 22.3 ± 4.6 and 22.6 ± 4.9 respectively. Hemoglobin level ($P = 0.044$) and educational status ($P < 0.01$) were positive, systolic blood pressure ($P = 0.032$), diastolic blood pressure ($P < 0.01$) and hemoglobin A1c ($P = 0.01$) were negative correlated with SMMSE scores. However, there was no statistically significant relationship between microalbuminuria and SMMSE scores. Decreased cognitive functions related with diabetic neuropathy.
Conclusion: Cognitive functions are lower in diabetic elderly patients when compared with healthy elderly volunteers. There were no significant relationship was found between cognitive function and microalbuminuria.

### Is skin tag associated with diabetic macro and microangiopatyh? Preliminary Report

B. Koyuncu, M. Karaca & R. Sari
Akdeniz University, School of Medicine, Antalya, Turkey.

Introduction
Although skin tag is associated with diabetes mellitus, no data in the literature show that the presence of skin tag is associated with diabetic macro and microangiopathy. The purpose of this study was to investigate frequency of hypertension, dyslipidemia, obesity, macro and micro angiopathy in type 2 diabetic patients with and without skin tag.
Methods/Design
We evaluated 99 (40 female and 59 male) type 2 diabetic patients. All patients were evaluated for blood pressure, body mass index, lipids, HbA1c, macroangiopathy (peripheral vascular disease, cerebrovascular disease and coronary hearth disease), microangiopathy (neuropathy, nephropathy, retinopathy) and skin tag.
Results
Mean HbA1c was 8.1 ± 2.0% and body mass index was 30.5 ± 6.4 kg/m2. The frequency of skin tags 53.5%, dyslipidemia 68.7%, hypertension 69.7%, obesity 39.4%, macroangiopathy 61.6% (peripheral vascular disease 12.1%, cerebrovascular disease 16.2%, and coronary heart disease 49.5%), microangiopathy 63.6% (neuropathy 21.2%, nephropathy 38.4%, retinopathy 38.4%) were detected. Higher body mass index (p: 0.04) and frequency of obesity (p: 0.03) were detected in patients with skin tag than without skin tag. HbA1c (p:0.4) and the presence of dyslipidemia ($P = 0.4$), hypertension (p: 0.6), macroangiopathy (p: 0.2), and microangiopathy (p: 0.9) were not different in patients with and without skin tag.
Conclusion
We conclude that presence of skin tag is merely related to obesity and may not be strongly associated with macro- and microangiopathy in type 2 diabetic individuals. Further studies with large patient population are required to elucidate the association between the presence of skin tag and diabetic angiopathy.

### Incidence and mortality of diabetic ketoacidosis in Benghazi-Libya

R. El Mehdawi[1], M. Ehmida[2], H. Elmagrehi[3] & A. Alaysh[1]
[1]Garyounis university, Benghazi, Libyan Arab Jamahiriya; [2]Al Jamhuria hospital, Benghazi, Libyan Arab Jamahiriya; [3]7th of october hospital, Benghazi, Libyan Arab Jamahiriya.

Background: Diabetic ketoacidosis is a frequent cause of morbidity and mortality among diabetics. The annual incidence and the mortality from this condition in Libyan diabetics have not been studied before. Aim and objectives: The aim of this study was to estimate the incidence of diabetic ketoacidosis and the its mortality rate at Benghazi city. Patients and methods: a descriptive retrospective analysis of the records of all patients admitted with diabetic ketoacidosis to all Benghazi hospitals (governmental and private) between 1st of January and 31st of December 2007. Results: the annual incidence of diabetic ketoacidosis was 41.7 episode/100 000 populations with a mean age of 33 ± 20.1 years (2–93). Around 52% of all the episodes occurred in males and 2.6% of adult DKA occurred in pregnant females. Type-2 diabetics were responsible for 27.7% of all episodes. The commonest precipitating factor in the whole study group was dose disruption (35%) followed by infection (20%). The commonest presenting symptoms were the gastrointestinal, whilst 3.5% of the patients were comatose at presentation. The overall mortality was 11.7% and there was no significant difference in mortality between males and females (11% vs. 12.6%, $P = 0.6$) however type-2 diabetics showed a significantly higher mortality rate (29.3% vs. 4.9%, $P = 0.000$). The died patients were significantly older with longer duration of diabetes and higher rate of co-morbidities and they had significantly faster respiratory rate, lower blood pressure, higher urea and platelet count at presentation. Conclusion: diabetic ketoacidosis is a common condition in Libya with a high mortality rate and type-2 diabetics constitute a considerable number of the cases.

## P673

**Drugs or insulin used in diabetics not associated with increased risk of malignancy**

Y. Aydin[1], M. Erden[1], A. Kutlucan[1], E. Önder[1], G. Celbek[1], S. Kir[1], H. Coskun[1] & L. Aydin[2]
[1]Endocrinology and Metabolism Department, Duzce, Turkey;
[2]Chest Disease Department, Duzce, Turkey.

Aim
The aim of the present study is to determine the effects of the diabetes mellitus (DM) treatment regimens on malignancy retrospectively.
Material-Method
655 DM patients were enrolled in this study. Patients receiving diabetes therapies for at least one year were assessed with physical examination, detailed medical and family history, habits, demographic characteristics and laboratory tests and divided into two groups according to the diabetes treatment type (using oral agent or insulin and using metformin or not). Insulin users were grouped according to insulin regimens (intensive, basal and mixed) and the insulin type (glargine, detemir, human insulin, biphasic analogue). Cancer cases were identified at the first visit. And if there was a cancer suspicion, clinical examination was made for clearing the diagnose. Patients who have not administrative data of cancer or benign tumor and diagnosis of cancer before date of diagnosis of diabetes mellitus, were excluded from the study.
Results
655 DM patients with 13 (%2) Type 1 DM, 642 (%98) Type 2 DM, 379 (%58) female, 276 (%42) male were enrolled. 36 cancers (4 colorectal, 1 lung, 4 larinx, 1 biliary duct, 5 breast, 4 prostate, 4 bladder, 3 leukemia/lymphoma, 1 urogenital, 2 hepatic, 5 thyroid, 1 renal, and 1 unknown origin) and 76 benign tumors were observed. Patients with and without a cancer were compared for diabetes treatment regimens and types of agents. No significant differences was observed between groups using oral agent or insulin (p:0.429) and using metformin or not (p:0.119). Also no significant differences was observed between groups according to insulin regimens (p:0.059) and the insulin type (p:0.418).
Conclusion
Between the types of pharmacological treatments of diabetes, there was not any significant differences in regard to cancer risk. But in subgroup analysis, patients using metformin had lower rates of benign tumor compared to metformin non-users.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding

## P674

**Polyneuropathy in diabetic patients based on the clinical and paraclinical findings**

M. Afkhamizadeh[1] & B. Reza[2]
quaem hospital, Mashhad, Islamic Republic of Iran.

Introduction
Prevalence of diabetic neuropathy is between 10 to 90% in different studies base on the method of it evaluation(clinical or paraclinical).
Objective
Evaluation of frequency of diabetic polyneuropathy indiabetic persons in endocrinology clinic of mashad endocrinand metabolic research center based on symptoms,signs and electrodiagnostic study.
Method
The study was cross-sectional; 110 diabetic patients were enrolled.patients with other causes of polyneuropathy such as hypothyroidism, collagen-vasculardiseases,renal failure were excluded. Neuropathic symptoms (paresthesia, hyperesthesia,neurotic pain,…) were recorded in questionnaire. Physical exam included evaluation of superficial sensation (by 10 gram monofilament), vibration(by 128Hz fork), position, pain, temperature and deep tendon reflexes. Electrodiagnostic tests conducted in proneal, sural and sensory branch of radial nerve.
Results
Frequency of neuropathy based on symptoms, signs and electrodiagnostic tests were 55.4%, 59.09% and 70% respectively. Most frequent symptom was paresthesia, most frequent sign was abnormal DTR and most frequent finding of electrodiagnostic tests was decreased amplitude of proneal and sural nerves. only 16 of 77 patients with abnormal electrodiagnostic findings didn't have any symptom and sign.
Discussion
Frequency of symptoms, signs and abnormal electrodiagnostic findings were consistent with several other studies. The percentage of abnormal electrodiagnostic findings were low in patients without both signs and symptoms.
Conclusion
It seems history and physical examination has an important role compared to expensive electrodiagnostic tests.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Not all neuropathies in people with diabetes are due to diabetic neuropathy - a case of chronic inflammatory demyelinating polyneuropathy(CIDP) in a type 1 diabetic**

C. Eboh
Great Western Hospital, Swindon, United Kingdom.

46yr old gentleman. Recently diagnosed with late-onset type 1 diabetes.HBA1C of 12% (108 mmol/molHb) at diagnosis. Also Vit B12 deficient. Normal TSH, Normal 9am cortisol, Normal TTG antibodies. On Novomix 30 Insulin.
No diabetic end-organ complication. Smokes 8g tobacco/day. Moderate alcohol intake
Presented with a year history of painful neuropathy,started with his left toes and progressed in an ascending manner to involve the whole foot ant the lower leg. Shortly afterwards, his right leg became involved in exactly the same manner. At a later stage, both hands became involved spreading to the forearms.
Associated with these was marked wasting of his Quadriceps,calves, tricep and bicep muscles.
Neurological examination showed normal strength but quite significant wasting especially in both quadriceps. There were patchy areas of decreased sensation all over his body with impaired proprioception distally in his right leg. Lower limb reflexes were absent.
Rest of systems examination were normal.
Results
Polyneuropathy Screen -
Normal U & E, folate and ferritin levels
Normal FBC
TSH Normal
Purkinje Cell Antibodies NEGATIVE
Cryoglobulins Not detected
Serum ACE 45 (Ref: 8–70 U/L)
Myeloma screen - Negative
EMG - Evidence of mild neurogenic change in the right lower limb
Nerve Conduction Report - Reduced CMAP(compound muscle action potential) amplitude and conduction velocity compatible with a primarily demyelinating polyradiculoneuropathy - Likely CIDP
Treatment
Currently has had IV Immunoglobulin treatment with good response i.e marked improvement in muscle strength and pain
Discussion
CIDP is suspected in patients who develop a sub-acute and progressive predominantly motor neuropathy with proximal weakness, which is distinguished from the "typical" diabetic neuropathy that is predominantly sensory and length-dependent. Incidence of diabetes in CIDP and vice versa may be higher than in the general population. Diagnostic criteria for CIDP in diabetes is similar to CIDP in general. However, making a diagnosis of CIDP in diabetics can be rather difficult as nerve conduction abnormalities are common in diabetes along with axon loss and demyelination. This distinction is of importance, as these patients can respond to immune therapies similar to patients with CIDP without diabetes
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**High burden of comorbid disease and complications in underprivileged type 1 diabetes children**

S. Kalra[1], N. Agrawal[2], G. Chatley[3] & B. Kalra[1]
[1]BRIDE, Karnal, India; [2]DOTC, Gwalior, India; [3]Uttam Clinic, Karnal, India.

This multicentric cross sectional study, conducted in northern India, aimed to assess the clinical profile of socioeconomically underprivileged children and adolescents, aged below 18 years, with type 1 diabetes. A structured questionnaire was distributed to OPD patients, after taking informed written consent. These patients hailed from six states of India, thus providing a comprehensive picture of the burden of disease. Data was collected regarding their clinical history and laboratory investigations.

Of the 70 patients studied, 47 were male. This skewed gender ratio is typical of this region of India. Age ranged from 2.5 to 17 years, with a duration of diabetes ranging from 1 month to 9 years. Six patients had experienced an episode of DKA in the past 3 months, while none had experienced severe hypoglycemia. Only one patient was overweight, and she had severe acanthosis nigricans. Surprisingly, one boy (aged 7) had acute balanoposthitis, while two premenarcheal girls had pruritis vulvae. Three children complained of painful neuropathy. Four children were found to have short stature, as per Indian standards. Seven girls were hypothyroid, and two boys had subclinical hypothyroidism. Two patients exhibited syndrome of limited joint mobility, two girls had coeliac disease, while four boys had delayed puberty.

HbA1c varied from 6.6% to 16.7%, with 53 patients having an A1c $>9.0\%$. While 56 patients were on a traditional basal-bolus regime, 7 were on a three dose regime (premixed- regular-premixed: 4, or regular-regular-premixed: 3), and 7 were on premixed biphasic insulin twice daily. None of the patients were found to have microalbuminuria or retinopathy.

This abstract highlights the unique clinical features of type 1 diabetes in an underprivileged cohort of children and adolescents in northern India. It quantifies the burden of acute and chronic complications of diabetes in this group of patients. There is a high prevalence of hypothyroidism, diabetic ketoacidosis, genitourinary infections and chronic complications.

## P677

**Effects of acute hyperglycaemia on ANP levels in diabetic patients**

R. Villar[1], A. Becerra[2], C. Alameda[3], N. Gonzalez P de Villar[1], G. Canovas[1], E. Cancer[1], A. Rodriguez[1], G. Pérez-López[2] & M. Menacho[4]
[1]Hospital Universitario de Fuenlabrada, Madrid, Spain; [2]Hospital Universitario Ramón y Cajal, Madrid, Spain; [3]Hospital Infanta Sofía, Madrid, Spain; [4]Hospital Ramón y Cajal, Madrid, Spain.

Introduction

Mechanism underlying glucose-mediated development and progression of diabetic complication are incompletely understood. Atrial natriuretic peptide (ANP) is a hormone released by atrial myocytes in response to acute and chronic extracellular volume expansion. Moderate hyperglycaemia ($>400$ mg/dl) in diabetic rats is associated with an elevation in circulating ANP levels and in GFR (glomerular filtration rate), (1) and play a role in the development of microalbuminuria (2).

Elevated plasma ANP concentrations have been reported in human diabetic subjects with poor glycaemic control although these findings have not been confirmed by other studies (3).

Materials and methods

We included 21 diabetic patients, with ages (X $\pm$ DS) 61.3 $\pm$ 12.6 years and 8.4 $\pm$ 9 years of diabetes progression. They were 2 type 1 diabetes and 19 were type 2. We analyzed levels of ANP levels by RIA.

Results

-There was no change in the levels of ANP in hyper-or normoglycaemia (90.52 $\pm$ 47.48 pg/ml vs. 86.98 $\pm$ 37.74 pg/ml). $P=0.56$.

-The average levels of glucose in hyperglycaemia were 294.85 $\pm$ 75.19 mg/dl and 134 $\pm$ 34.16 mg/dl in normoglycaemia.

Conclusion

-Hyperglycaemia did no induce changes in the ANF levels in our study.

-This result could be influenced by the higher prevalence of type 2 diabetics in our group with higher basal levels of ANF.

-Furthermore, the level of hyperglycemia was not too high in our work and this can be a stimulus course shorter than in other published studies with more marked hyperglycaemia.

**Hyperhomocysteinemia as Risk's Factor of Diabetic Nephropathy in the Patients with Diabetes Mellitus Type 1 and Depression**

Y. Navmenova[1], I. Savasteyeva[3], M. Kapliyeva[1] & T. Mokhort[2]
[1]Gomel State Medical University, Gomel, Belarus; [2]Belorussian State Medical University, Minsk, Belarus; [3]Republican Scientific Practical Center of Radiation Medicine and Human Ecology, Gomel, Belarus.

The aim was to evaluate the space of hyperhomocysteinemia presence with depression and diabetic nephropathy (DN) in diabetic mellitus type 1 (DMT1) patients.

Materials and methods

it was examined 147 patients with DMT1 (57.1% of males, 42.9% - females) and duration of disease was 11.17 [9.07;12.26] years. Moderate age was 40.08 [30.44; 48.79] years. DN of 3–5 stages was diagnosed in 43 patients (29.3%). To provide analysis it used blood serum creatinine level, total cholesterol (TC) and homocysteine (HC) determining. The hospital scale of anxiety and depression was used for detection of depression.

Results

HC level in DMT1 patients with depression was 10.50 mmol/l vs 9.95 mmol/l in the the patients without depression ($U=1066.0$; $P=0.085$). HC level correlated with duration of disease in DMT1 patients ($r=0.44$; $P=0.02$).

HC level was 11.20 [8.80;11.65] mmol/l at the presence of DN vs 9.41 [7.96;11.30] mmol/l at the patients without DN ($U=605.00$; $P=0.034$). Creatinine concentration was higher at DN presence 81.50 [72.50;86.5] mmol/l vs 76.00 [69.00;83.00] mmol/l at the patients without DN ($U=614.50$; $P=0.004$). TC level was 5.60 [4.40;6.60]mmol/l at the patients with DN vs 4.70 [4.00;5.60] mmol/l at the patients without it ($U=582.00$;$P=0.002$).

Using quartile value of HC level it was pointed, that creatinine blood level was decreased at the patients with HC level less than 8.35 mmol/l. Analyzing the frequency of DMT1 complications we estimated higher frequency of DN complicated by arterial hypertension ($\chi 2=3.78$; $P<0.05$) in group of patients with HC level more than 12.55 mmol/l to compare the patients with HC level presented less than 8.35 mmol/l.

Conclusion

Increasing DMT1 duration leads to increasing of blood HC level. HC level got the tendency to growing in the patients with D1TM and depression.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P679

**No influence of the chronic poor clycaemic control on ANP levels in diabetics with microvascular illness**

M. Villar[1], C. Alameda[2], A. Becerra[3], M. Menacho[3] & G. López-Pérez[3]
[1]Hospital Universitario de Fuenlabrada, Madrid, Spain; [2]Hospital Infanta Sofía, Madrid, Spain; [3]Hospital Ramón y Cajal, Madrid, Spain.

Introduction

Atrial natriuretic peptide (ANP), a member of the natriuretic peptide family, regulates several physiologic parameters including diuresis and natriuresis, and lowers arterial, blood pressure.

It has been reported that plasma concentrations of ANP rise in response to acute hyperglycaemia in diabetes (1) (2) and this may indicate a neurohormonal response to limit target organ damage (3).
We investigate if in situation chronic poor glycaemic control, determined by measuring Hba1c levels, there might be changes in concentrations of plasmatic ANP as regards a metabolic state of aggression y patients with microvascular disease.
Materials and methods
The study analyzes a group of 7 diabetic patients affected by microvascular disease compared with a control group of 34 patients. The control group were 21 women and 13 healthy men, aged 46±21.1 years (range 24–78 years). In the diabetic group had 4 females and 3 males, aged 37±16 years (range 17–61), 5 with type 1 diabetes and 3 type 2. Poor glycemic control groups were those with chronic HbA1c >9%. Microangiopathy was defined as the presence of renal, ocular or neuropathic disease. Statistical analysis was carried out by the statistics department of the Centre, through SPSS. The determination of ANP levels was performed by RIA.
Results
No differences were found between the levels of ANP from the group of diabetic microangiopathy with HbA1c >9% compared to HbA1c <9%.
However we could demonstrate significantly higher levels of ANP in the diabetic group than the control group.
Conclusion
-No evidence of elevated ANP levels in relation to chronic poor glycemic control in diabetic patients suffering from microvascular disease.
-ANP levels are higher in diabetics with microvascular disease than in healthy controls without diabetes.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Table 1** ANP levels in diabetics according to the metabolic control

| | Control group ($n=34$) | Diabetics with microangiopathy ($n=4$) HbA1c<9% | Diabetics with microangiopathy ($n=3$) HbA1c>9% |
|---|---|---|---|
| ANP levels (pg/ml) | 5.84±3.96** $p<0,05$ | 20.12±18.68 | 13.08±11.82 |

## P680

### Nephropathy could be a main factor in the increased levels of ANP in diabetes

M. Villar[1], A. Becerra[2], C. Alameda[3], G. López-Pérez[2] & M. Menacho[2]
[1]Hospital Fuenlabrada, Madrid, Spain; [2]Hospital Ramon y Cajal, Madrid, Spain; [3]Hospital Infanta Sofia, Madrid, Spain.

Introduction
Its has been suggested that atrial natriuretic peptide (ANP) may contribuye to the development of microalbuminuria in diabetes mellitus.
Plasma ANP concentration have been reported to be elevated in association with microalbuminuria, all of wich predict the future development of overt nephropathy in diabetes (1).
Key players in neurohormonal activation include neuropeptides and their receptors wich include the ANP (2).
Targeting neuropeptides and their signalling pathways might thus serve as new therapeutic interventions in the treatment of complication associated with diabetes.
In addition, the magnitude of the albuminuric response to ANP is greater in diabetic subjects than in healthy volunteers, suggesting increased renal sensivity to the albuminuric action of ANP (3).
Materials and methods
We performed a study of 16 diabetic patients, 10 women and 6 men, aged 37.4± 16.2 years (range 17 to 61) and an evolution of diabetes of 13.6±7.7 years. Of the total group 11 were diabetic type 1 and 5 were type 2 diabetics. In the group only 12% of patients had with any degree of renal lesion and 56% did not had any vascular complication. Microangiopathy was defined as the presence of renal, ocular or neuropathic disease- The determination of ANP levels was performed by RIA.
Results
In our group, with a low incidence of nephropathy, we found no differences in the levels of ANP between patients with and without microvascular disease (anp 20.12±18.69 pg/ml vs 9.24±5.29, $P=0.12$ (ns).
Conclusion
-The presence of renal hyperfiltration, increased albumin permeability and target organ damage may determine the elevation of ANP in diabetes, therefore in our group, with low incidence of nephropathy, did not show a clear increase in the levels of this neuropeptide.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P681

### Quality of life and its dimensions among the type2 diabetes patients referred to the diabetes center of Zanjan University of medical science (Vali-e-Asr Hospital)-2010

M. Moraveji
Azad University of Zanjan, Zanjan, Islamic Republic of Iran.

Introduction
One of the most important methods for evaluation of treatment and care of diabetic patients is to assess the quality of life (QOL). The aim of this study is assess QOL and this dimensions and relational pattern between demographic characteristic.
Method
This study is cross-sectional study wit convenience random sampling. The sample consisted 161 patients with type2 diabetic who refferd to diabetes center of Zanjan. Research instruments was standard instrument of QOL related to health included: physical, psychological, social and demographic Aspect of diabetic patients. Data were analyzed with SPSS software.
Finding
The finding indicated that physical dimension (%49.1) and psychological dimension (%50.3) and social dimension (%9.9) and specific dimoinsion (%17.4) were desirable. The finding showed that independent variables (age, marriage, family income, sex, educational level) were meaningful relationship with QOL.
Conclusion
Personal, social and economic factors can affect QOL in diabetic patients. It is suqqested that managers should take care of bio-psycho-social support in such groups for improving quality of life in diabetic pationts.
Keywords: diabetes, quality of life.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Sexual weakness: Different demographic and clinical features & cost-effective management

S. Ashraf & Z. Latif
BIRDEM, Dhaka, Bangladesh.

Introduction
The inability to achieve and maintain an erection sufficient for satisfactory sexual intercourse is a distressing and common symptom in Bangladeshi Diabetic subjects.
Aims and Objectives
The purpose of this study is to present a framework for cost effective evaluation & treatment. Because many of the diabetic subjects usually suffers from psychological stress since he is detected as diabetic and many of them believe in Myths that diabetes makes a person impotent.

Materials and Methods
Diagnosis of erectile dysfunction was based on patient self-reporting. Clinical information was collected by participating physicians. The depressive symptoms was assessed using visual analogue scale. Minimal lab investigations are suggested.
Results
255 diabetic, male were interviewed and Investigated. Age 43.88±11.38. BMI 24.5±3.3 and duration of diabetes 5.69±5.01 years. 31% smoker and 36% subjects having moderate to severe stress. Age of spouse(wife) ranges 35.32 ±10.88 years. Their age differences are <5 years 23.8%, and >10 years 21%. Among them libido was normal only in 50%. 66.7% cases have premature ejaculation. More than 50% have extramarital affairs. 70.7% subjects were HbA1c > 8% (Mean 10.54±3.32 SD). 33.3% haves. Testosterone < 3.4 ng/l. Serum PRL was higher in 6.7% cases. Associated IHD was detected (by ECG change) in 7.2% and Enlarged Prostate in 3.4% subjects.
Conclusion
Interplay of clinical and psychological factors determines the risk of erectile dysfunction in type 2 diabetics. Greater attention is needed to detect demand of the patient. All are not having Erectile problems. Cost of hormonal investigations may be lessen by clinical judgment.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Role of education in prevention and delay of complications in type 2 diabetic patients**

I. Ahmeti[1], G. Petrovski[1], I. Bitoska[1], T. Milenkovic[1] & S. Lumani[2]
[1]UKC clinic of endocrinology, Skopje, The Former Yugoslav Republic of Macedonia; [2]Lincest clinic, Skopje, The Former Yugoslav Republic of Macedonia.

Aim: To assess the impact of education of people with T2DM and complications. Patients and methods. Observational study, 100 T2DM patients of age 35–75 years, both sex, duration of DM >1 year.Results. From 100 T2DM 47% were male sex and 53% female. Mean age 60.45±8y, duration of DM 10.45y±3 y. Average A1c 8%±0.6, BMI 27%, systolic BP 140±6 mmHg, TG 2.2± 0.3 mmol/L, LDL 4.0±0.6 mmol/L. Education (diet, physical activities, drug compliance) for DM was 67% for male and 54% for female. Education for diabetic foot care (inspection, foot hygiene, appropriate shoes) 51% for male and 49% for female.
Conclusion
Metabolic risk factors are poorer in no educated than in educated T2DM, People who had not satisfactory education for foot care have higher risk for foot ulceration.
Education, diabetes, complications, foot care

## P684

**Structured outpatient education and treatment program in type 1 diabetes patients during preconception care and pregnancy**

E. Inashvili, N. Asatiani, R. Kurashvili, E. Shelestova, M. Dundua & A. Kopaleishvili
National Center for Diabetes Research, Tbilisi, Georgia.

Our aim was to evaluate the efficacy of a structured outpatient education and treatment program (SOETP) in type 1 diabetes patients (T1DM) patients during preconception care (PC) and pregnancy, and its effect on pregnancy outcomes. Study Methods: In total 173 women with T1DM were supervised. Maternal age was 28±8 yrs and diabetes duration - 12±7yrs. SOETP combined group and individual training. Stage 1 - preconception care (group and individual training). Stage 2 - individual education once per week throughout the pregnancy; group discussion once per month. SOETP included: diabetes physiology in pregnancy, managing hypoglycemia, diet, insulin therapy, glucose self-monitoring, relaxation, exercise, non-stress tests and diabetes complications. Specific Knowledge Assessment Questionnaire (65 questions) was completed by all patients pre- and post-program.
Gr. 1 - 88 women went through Stage 1 and 2; Gr. 2 - 85 women - only through Stage 2. Results. At conception women from Gr. 1 were well-controlled (HbA1c - 6.0 (0.31)%, postprandial glycemia - 142.2 (10.6)mg/dl), though HbA1c and PPG levels in women from Gr. 2 were statistically higher (8.4 (0.51)%, P=0.000; 184.8 (13.3) mg/dl, $P=0.000$ respectively). By the end of the 1st trimester those indices dropped. All patients were tested to evaluate knowledge. At entry number of correct answers was very low (28%); post-program scores were significantly higher (96%). Spontaneus abortions were revealed in 2.2% (Gr. 1) vs 5.8% (Gr. 2); preeclampsia- in 6.8% (Gr. 1) vs 14.1% (Gr. 2); perinatal mortality - in 1.1%(Gr. 1) vs 3.5% (Gr. 2).
Conclusion
SOETP may be effectively used for T1DM patient education during PC and pregnancy; it significantly reduced rates of spontaneous abortion rates, mortality and morbidity.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P685

**A Randomized controlled trial of the effect of internet based mentoring program for type 1 diabetes patients with inadequate glycemic control**

S. Suh, S. Park, Y. Cho, J. Joung, S. Jin, S. Kim, H. Kim, J. Bae, S. Kim, J. Chung, Y. Min, M. Lee, M. Lee, K. Kim & J. Kim
Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Introduction
Widespread availability of internet makes it an attractive communication tool among patients and providers. However, the clinical benefit of telemedical support on diabetes care remains inconclusive. This study is to determine whether an internet based mentoring program can improve glycemic control in type 1 diabetes (T1DM) patients with inadequate glycemic control.
Methods
Patients with T1DM on intensive insulin therapy and with HbA1c ≧ 8.0% were randomized to mentoring (glucometer transmission with feedback from mentors) or control (glucometer transmission without feedback) for 12 weeks. Five mentors (3 male and 2 female) were interviewed and selected from an internet community for Korean T1DM people (i.e. JahkEunSon(small hands)'s Type 1 Diabetes Cafe; http://cafe.naver.com/dmtype1.cafe). Two of them were T1DM patient themselves and three of them were parents of at least 1 child diagnosed with T1DM for at least 5 years. They were all university graduates except for one with 2 years of college education.
Results
A total of 57 T1DM patients with mean diabetes duration 7.4 years were recruited from Samsung Medical Center in Seoul, Republic of Korea. In total, the mentoring group and control groups login to the website 764 and 203 times, respectively. There was a reduction in fasting plasma glucose from 231.03± 79.39 mg/dL to 191.63±81.38 mg/dL in the mentoring group after 12 weeks. In addition, treatment satisfaction score (from 28.94±7.26 to 33.21±4.89) and number of self blood glucose monitoring (from 3.96±1.91 to 5.02±2.36) improved in the mentoring group. There was no significant reduction in fructosamine and HbA1c in the mentoring after completion of the study. However, these differences in changes in metabolic parameters and questionnaire scores between groups were not statistically significant.
Conclusions
Internet based mentoring program for T1DM patients with inadequate glycemic control has not proved to be superior to the usual follow-up.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Type 1 diabetic women treated with insulin pumps or multiple daily injections of insulin: pregnancy outcome and glycemic control**

S. Gonzalez Romero, I. González-Molero, R. Vallejo Mora, M. Ruiz de Adana, M. Domínguez López, I. Sanchez Reyes, M. Palomo & F. Soriguer
Carlos Haya Hospital, Málaga, Spain.

Introduction
Pregestational diabetes is a threatening condition for pregnancy; a strict glycemic control can decrease some pregnancy complications. That control can be achieved while on multiple daily insulin injections (MDI) treatment or with subcutaneous insulin infusion systems (CSII). Up to now no benefits of CSII treatment over MDI on pregnancy outcomes have been proved.
Design
Case control retrospective study, comparing glycemic control and pregnancy outcomes between type 1 diabetic pregnancies CSII or MDI treated (1996–2010). Selected variables were compared with X2 or Student-T or Mann-Withney tests. A $P<0.05$ was considered significant.
Results
Women treated with MDI were older; to get comparable groups, we excluded some women (disease for <7 years), then obtaining 206 pregnancies (138 women): 50 pregnancies treated with CSII and 156 with MDI. Age, duration of diabetes, retinopathy and nephropathy were not significantly different. Insulin pumps were mostly installed while on pregnancy planning; thus, planned pregnancies were much more common in the CSII group (84% vs 40.4%, p <0.000). Preconception HbA1c was significantly lower for CSII group (6.78±0.68 vs 7.32±1.36, p 0.015); for the 1st and 2nd terms no differencies were found, and for the 3rd term HbA1c was even better for MDI group (6.50±0.64 vs 6.16±0.74, p 0.015). Severe hypoglycemic events and ketoacidosis, miscarriages, gestational hypertension, preterm birth, cesarean sections, congenital anomalies, big babies, respiratory distress, hypoglycemia or jaundice did not show significant differences between groups, either.
Conclusions
As other authors, we were not able to show that CSII treatment improved metabolic control or pregnancy outcomes.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P687

**DPP-4 inhibitor vildagliptin reduces urinary albumin excretion in type 2 diabetic patients with microalbuminuria**

M. Watanabe, F. Furuya & T. Kobayashi
University of Yamanashi, Chuo, Japan.

Introduction
A potent and selective DPP-4 inhibitor improves islet function by enhancing α- and β-cell responsiveness to glucose in the diabetic patients. Renal impairment is a common complication of type 2 diabetes mellitus (T2DM). Vildagliptin is used to treat T2DM as monotherapy or in combination with other antidiabetic drugs, since that it efficiently decreases glycated hemoglobin (HbA1c) values. Additionally, vildagliptin has been shown to be safe in patients with moderately impaired kidney function.
Designs
We studied 107 T2DM patients with diabetic nephropathy, the mean ages are 62.2± 10.4 y; early nephropathy stage with microalbuminuria ($n=37$), apparent nephropathy stage with daily urinary albumin excretion more than 300 mg/g of albumin-creatinine ratio or eGFR less than 60 ml/min ($n=50$), renal failure stage with increased serum creatinine concentration ($n=16$) or dialysis stage ($n=7$). All patients were treated with vildagliptine at least 3 months before entry of this study. We monitored body weight, urine albumin excretion or eGFR of the patients during 6 months.
Results
Vildagliptin-treatment had no influence on the body weight or eGFR in all stages of diabetic nephropathy. In the patients in early nephropathy stage, vildagliptin therapy significantly decreased the concentrations of albumin. Patients in other stages exhibited no differences in concentration of urinary albumin between before and after administration of vildagliptin. There were no severe side-effects of vildagliptin in these patients. Four patients in renal failure stage and 5 dialysis patients were able to convert to monotherapy with vildagliptin from insulin therapy.
Conclusion
Vildagliptin 50 mg qd is well tolerated and efficacious in T2DM patients with severe renal impairment. Otherwise vildagliptin therapy is effective to reduce microalbuminuria in the patients with early diabetic nephropathy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P688

**Insulin protocol for hospital management of diabetes: a retrospective evaluation one year after the implementation**

F. García Torres, S. Valdes, I. González-Molero, M. Gonzalo Marín, I. Rubio, J. García Arnes, A. Muñoz, G. Olveira, M. Ruiz de Adana & F. Soriguer
Carlos Haya Hospital, Málaga, Spain.

Introduction
Protocols for identifing and managing hyperglycemia and diabetes in hospital are necessary. Glycemic goals in non critical inpatients are:140 mg/ml(preprandial) and 180(posprandial),oral antidiabetic drug(OADs) withdrawn, avoid hypoglycemias, basal/bolus insulin (nor sliding scale) and request glycosylated haemoglobin.
Aims
To evaluate the implementation of a protocol for management of diabetes(PHD) during the years 2009 and 2010 in our Hospital.
Methods
In January2009 we presented a PHD for non critical patients. Educational meetings were given the first 6 months of the year2009. A nurse supervised the protocol fulfillment. We evaluated HbA1c requested, used treatment and variables of results (glucemias for 3–6 correlative days) in a sample of 1367 patients.
Results
PHD was implanted in 70. 5% of the patients evaluated in 2009: 17.7% had sliding scale,5.4% other insulin treatments and 6.4%OADs. In 2010 the proportions were 61.8%, 19.2%, 11.3% and 7.7% respectively. The average glycemias in the first and last day of registered treatment were 182.0±69.1 mg/dL and 162.4±67.8 mg/dL in the group PHD, 164.5±51.4 mg/dL and 161.5±55.2 in the group Insulin in scale, 185.1±64.8 and 169.6±81.6 mg/dl in the group of other insulin treatments, 133.8±35.2 mg/dL and 133.2±38.6 mg/dl in the group OADs, being the difference between glucemias −19.6±64.6 mg/dl, −3.0±48.1, −15.5±85.6 and -0.6±42.7 mg/dL respectively($P<0.01$). HbA1c was determined in 37% of patients in 2009 and 47.6% in 2010.
Conclusions
Protocol implementation was better in the first year of evaluation. Less than 50% of diabetic patients had HbA1c during the hospitalization. PHD patients had better control than the others. The results show that it is not enough to design a PHD, it is necessary to supervise and evaluate it constantly.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P689

**Analysis of fasting glycemia variability in patients with type 1 diabetes mellitus undergoing different types of basal insulin therapy: glargine vs. NPH**

M. Mashkova
Belorussian State Medical University, Minsk, Belarus.

The goal of this research was to analyze fasting glycemic variability in patients with DM1 depending on the type of basal insulin therapy - insulin NPH versus Glargine.
Material and methods
The glucose levels 24-hour monitoring was performed applying the CGMS. Glargine group - 19 and NPH group - 24 patients.
Results
In the glargine group there have been no episodes of severe fasting hypoglycemia (<2.8 mmol/L), LBGI=2.42±1.26; in the NPH group the relative duration of period of severe nocturnal hypoglycemia was 15.41±23.12%, LBGI=9.18± 8.21. Intra-day variability indices: SD - 1.98±1.01 and 2.71±1.39 mmol\l; VC −24.32±15.49 and 31.51±16.21%; IQR −3.21±1.74 and 5.16±2.75 mmol\l;

amplitude of glycemic excursions -7.31±3.42 and 11.24±5.58 mmol\l, CONGA1 - 1.60±0.72 and 2.71±1.62 mmol/l×h-1, $P<0.05$; for the glargine and NPH groups respectively. The predictors of high fasting glucose variability are frequent short-time (<1h) severe hypoglycemic episodes.
Both groups revealed a strong positive correlation between MODDf (analogous to MODD, but calculated for fasting period only) and difference of mean fasting blood glucose values: in the glargine group - rs=0.78; in the NPH - rs=0.895; $P<0.001$. Glargine group - MODDf=2.30±1.12; NPH group - MODDf=5.01±2.62, $P<0.001$.
In the NPH group only, high inter-day variability of blood glucose levels at 3 AM is a reliable predictor of high values of the difference of mean fasting blood glucose values (B=0.662; $P<0.001$). According to the equation of the linear regression with an increase of the difference of blood glucose values at 3 AM on 1 mmol/L, the difference of mean fasting blood glucose values increases by 0.662 mmol/L. In the Glargine group day-to-day blood glucose values at the control points - 3, 5 and 7 AM - were much more stable.
Conclusion
The use of glargine leads to a significant reduction in daily variability of fasting glycemia, minimizes the risk of hypoglycemia and provides a greater reserve in dosage increase in comparison with NPH insulin.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P690

**To evaluate and compare the outcome of pregnancies in women with type 1 diabetes treated with continuous subcutaneous insulin pump or multiple insulin injections**

B. Saboo[1], H. Chandarana[1], S. Joshi[2] & S. Shah[1]
[1]Dia Care - A Complete Diabetes Care Center, Ahmedabad, India;
[2]Joshi Clinic, Mumbai, India.

The study was aimed to compare the outcome of pregnancies in women with type 1 diabetes treated with continuous subcutaneous insulin infusion pump (CSII) or multiple insulin injections (MDI). Total 14 patients were treated with insulin pump and 20 patients were treated with multiple injections; were mainly investigated for HbA1c, incidence of hypoglycemia, fetal outcome, rates of pregnancy induced hypertension and cesarean section. HbA1c with insulin pump was significantly better from that obtained with multiple injections. Hypoglycemic events were significantly less in CSII group as compared to MDI group. Moreover, severe hypoglycemia was not seen in CSII group, whereas there were numerous episodes of severe hypoglycemia in MDI group, few of them required hospitalization. Rate of early or mid pregnancy abortion was 10% treated with multiple insulin injections, while no abortion was seen in CSII group. Fetal prognosis was also better in pump treated patients, macrosomia was seen in 4 new borns in pump group whereas 12 in MDI group. The occurrence of pregnancy induced hypertension was similar in both groups. The rate of cesarean section was not influenced by therapeutic device, similar in both groups.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P691

**Antihyperglycemic effects of sodium orthovanadate and Trigonella foenum graecum in diabetic rats**

P. Kumar, R. Kale & N. Baquer
Jawaharlal Nehru University, New Delhi, India.

Objectives
Oral administration of vanadate to diabetic animals have been shown to stabilize the glucose homeostasis and restore altered metabolic pathways. The present study explored the prospect of using low doses of vanadate with Trigonella foenum graecum, seed powder (TSP), another antidiabetic agent, and to evaluate their antidiabetic effect in diabetic rats. The effect of these antidiabetic compounds was examined on general physiological parameters, monoamine oxidase activity, calcium homeostasis, membrane fluidity and distribution of lipofuscin accumulation in liver, brain and heart tissues. Expression of glucose transporter (GLUT4) protein was also examined by immunoblotting method in experimental rat heart after three weeks of diabetes induction.
Methods
Diabetes was induced by administration of alloxan monohydrate (15 mg/100g b.wt.) and rats were treated with 2IU insulin, 0.6 mg/ml SOV, 5%Trigonella in the diet and a combination of 0.2 mg/ml SOV with 5% Trigonella separately for 21 days.
Results
Diabetic rats showed high blood glucose levels. Activity of monoamine oxidase increased in diabetic brain, liver and heart. Diabetic rats exhibited an increased level of calcium with lipofuscin accumulations and decreased membrane fluidity. GLUT4 distribution was also significantly lowered in heart of alloxan diabetic rats. Treatment of diabetic rats with insulin, TSP, vanadate and a combined therapy of lower dose of vanadate with TSP revived normoglycemia and restored the altered level of monoamine oxidase, calcium homeostasis, lipofuscin and membrane fluidity and also induced the redistribution of GLUT4 transporter. TSP treatment alone is partially effective in restoring the above diabetes-induced alterations.
Conclusion
Combined therapy of vanadate and TSP was the most effective in normalization of altered metabolic parameters and GLUT4 distribution without any harmful side effect.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P692

**Therapy with analogous of glp 1 and basal insulin in patients with diabetes mellitus type 2. Our experience.**

J. Pérez Rodríguez, C. Morales Portillo, C. García García, I. Fernández Peña, V. Hernando Jiménez, I. Serrano Olmedo, C. De la Cuesta Mayor & Sendón Pérez
University Hospital Virgen Macarena, Seville, Spain.

Objectives
Evaluate the impact of the therapy with GLP-1 analogues (exenatide) toguether with basal insulin in glycemic control and weight of patients with type 2 diabetes mellitus poorly controlled.
Materials and methods
We analyzed 37 patients with type 2 diabetes with poor glycemic control and obesity, treatment with exenatide and basal insulin. As pre-treatment 56.7% of our patients were with basal insulin, 10.8% with insulin mixtures and 32.4% with basal-bolus regimen. The patients with basal insulin exenatide were added exenatide. The patients with insulin mixtures were passed to basal insuline more exenatide. Finally to the patients with basal bolus insulin we replaced rapid insulin by exenatide, always maintaining the metformin unless contraidicated. At the start we reinforce the diabetes education and we analyze the variables: HbA1c, weight and the insulin requeriment in 3 months. We did statistical analysis with SPSSv18 throught t-student for paired data.
Results
Our series had a mean age of 51.8±11.5 years, 26 men (70.3%) and 11 women (29.7%).They had about 8.0±7.5 years of disease progression and poor metabolic control expressed as HbA1c of 8.27±1.71% and BMI of 40.3±6.0 kg/m2. In our series 22 patients (59.5%) were on glargine and 15 patients (40.5%) with detemir. We observed a decrease clinically relevant and statistically significant in the average HbA1c at 3 months of 8.27% to 6.95% (1.33%) ($P<0.001$). At the same time there is a average weight loss of 5.3 kg at 3 months ($P<0.001$). We also analyzed the insulin needs to appreciate an average reduction in dose of 0.38 IU/kg to 0.31 IU / kg (−0.07 IU / kg) at 3 months ($P<0.05$). As Adverse effects of interest were reported gastrointestinal disturbances (nausea, vomiting) in 6 patients causing 2 retired. We did not observed episodes of hypoglycemia.
Conclusions
The association of GLP-1 analogues with basal insulin in patients with type 2 diabetes, who need insulin therapy for their poor control, is an interesting therapeutic option and to consider for the improvement in glycemic control and weight loss. This also contributes to the decrease of the insulin requirements in their treatment.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P693

**Variations in insulin daily dose and weight with continuous subcutaneous insulin infusion therapy**

S. Belo[1,2], C. Esteves[1,2], M. Pereira[1], C. Neves[1,2] & D. Carvalho[1,2]
[1]Centro Hospitlar S.João, Porto, Portugal; [2]Universidade do Porto, Porto, Portugal.

Introduction
Intensive diabetes type 1 management can be achieved either with multiple daily insulin injection therapy or with continuous subcutaneous insulin infusion (CSII). The former is becoming increasingly popular do to its positive effects on glycemic control.
Objectives
Evaluate the evolution of total daily insulin dose (TDID) and weight on patients with CSII.
Methods
Patients with CSII of our department were included. Data regarding glycemic control, anthropometric parameters and TDID was collected before beginning of CSII, and 6 and 12 months after. Paired sample T-test was used to compare means and Pearson correlation coefficients were calculated, a value of $P<0.05$ was considered significant.
Results
We studied 64 patients (24 men; 39 women) with a mean HbA1c before CSII initiation of 8.2%±1.4, mean diabetes duration of 24.1±12.7 years and mean age in the moment CSII initiation of 33.6±11.2 years. We found a significant reduction in weight 12 months after the beginning of CSII (69.9 kg ±10.3 vs 68.3 kg ±11.1; $P<0.001$) and in HbA1c (8.2%±1.4 vs 7.4%±1.1; $P=0.002$). A reduction of TDID was also found but without statistical significance (52.6±14.9 vs 49.0±11.3; $P=0.058$). There was a moderate correlation between the variation of TDID with the duration of diabetes ($r=0.56$; $P=0.007$). No correlation was found between diabetes duration and weight variation or between weight and DTID.
Conclusions
Continuous subcutaneous insulin infusion therapy seems to be associated not only with the improvement of glycemic control, but also with reduction in body weight and in TDID. Diabetes duration seems to play a role in the individual response to CSII.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P694

**Insulin therapy requirement in ESRD patients (Our experience)**

A. Eltobgi & A. Abuharba
Zahra Nephrology Center, Zahra, Libyan Arab Jamahiriya.

Diabetes (DM) is the leading cause of end-stage-renal disease (ESRD). Majority of T2DM patients (Pts) with ESRD need insulin. Kidneys play significant role in exogenous insulin metabolism. Chronic renal disease is associated with alterations in insulin metabolism and glycemic control. As renal function starts to decline, insulin requirement needs to be adjusted to reach euglycemia.
A good metabolic control is not only important in the early phase of diabetic nephropathy but also in diabetic Pts with ESRD. Glycemic control can reduce the progression of atherosclerosis and improve the survival in Pts treated with hemodialysis (HD).
Zahra nephrology center is located close to Tripoli (40 Km) with 180 Pts on HD (~8% of total HD Pts).
Aim
Evaluate the effect of HD on pre to post dialysis in insulin requirements to achieve euglycemia.
Method
11 Pts (6 male) were included. Average age 59.7 years, mean duration of DM 20 years, 75% were on insulin (pre mixed) prior to HD. Mean duration of HD was 4.5 years, 3 sessions a week.
Pts were admitted to our hospital, insulin physiological regimen (basal & bolus) was applied to maintain euglycemia (BS=100–140 mg/dl). Insulin is adjusted hourly pre,during and post-HD, and investigation compared day-to-day insulin requirements.
Result
Early results should that ESRD due to diabetic nephropathy is counted for 15% in our center. Since HD was started, insulin requirements were reduced in 91%. 3 Pts are off treatment since HD (2 pts were in oral therapy). Insulin was reduced by 75 to 50% in 5 Pt and by 40 to 25% in the rest of the Pts. Only one Pt kept in the same dose.
All Pts are off insulin on HD day, and all of them were experienced hypoglycemic attacks.
Rest of results well be published by the meeting time when are completed.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Comprehensive approach to Paediatric diabetes management: NGO initiatives in developing country India.**

S. Pramod
Health Alert Organization of India [NGO], Dhule, India.

Issues
In developing nations diagnosis of diabetes brings mental-trauma/depression in family. Focused treatment for pediatric age-group is unavailable in developing-countries. 26% of diagnosed diabetics are children's. Adequately trained physicians/Nurses in issues of pediatric-diabetes provide continuity of care, relief from depression and smooth transition from diagnosis to treatment. Qualitative collaborative relationship between these makes diabetics life bearable. Our NGO-project highlights significance of relationship between nurses and diabetic-children in community clinic setup of rural India.
For Diabetes, its assumed that depression is inevitable sequel to diagnosis. Retrospective analysis of past studies shows—counselling improves QOL & attitude towards diabetes-treatment.
Aims
To describe care issues in diabetic-children's. Observe/modify nature of relationship between nurse and child. To evolve comprehensive treatment plan for patients and families.
Methods
A retrospective analysis of data base from 7 rural health-clinics. Specialized therapy/support to pediatric-age-group not available at any centre. Total 117 children's [4–13 years] diagnosed with diabetes. 23 had additional endocrine/metabolic problems. Nursing/medical care plan analyzed. No specialized trained personal in rural/tribal India. Opinion/needs from patients families collected on feedback questionnaire. Then we trained 10 nurses & 2 physicians for handling pediatric cases [4 weeks training].
Results
Out of 117, 41 discontinued Rx due to improper counseling/guidance. 3 died. Patient/family's feedback highlights: Better access to newer drugs-delivery-systems, psychosocial support, follow-up-plan. Nurses/physician be sensitized in pediatric care-issues. Main issues of concern were: [1] illness and coping with their feelings. [2] Initial impact of diagnosis and a search for solution? Expectations for future life & its quality? [3] Concerns of cost of RX [4] Availability of proper follow-up centers in rural areas of developing nations.
Conclusion
Multifaceted Relationship between physician/nurse and Diabetics childrens is crucial. This relationship provides better continuity of treatment. We show concerns/difficulties while working in Asian set-up to experts/seniors at ECE-2012-congress.

**Renal sodium dependent glucose co-transporter 2 (SGLT2): A neoteric target for treatment of type2 diabetes mellitus**

D. Ahmed
Sam Higginbottom Institute of Agriculture, Technology & Sciences (SHIATS)-Deemed University (Formerly Allahabad Agricultural Institute-Deemed University), Allahabad, India.

Contemporary therapies to rationalize the hyperglycaemia in type 2 diabetes mellitus (T2DM) generally involve insulin-dependent mechanisms and lose their effectiveness as pancreatic b-cell function decreases to a greater extent. Kidney emerges out as a novel and potential target to trim down the T2DM. The filtered glucose is reabsorbed principally through the sodium glucose co-transporter-2 (SGLT2), a low affinity transport system, which are present at the luminal surface

cells that covers the first segment of proximal tubules. Competitive inhibition of SGLT2 therefore represents an innovative therapeutic strategy for the treatment of hyperglycaemia and/or obesity in patients with type 1 or type 2 diabetes by enhancing glucose and energy loss through the urine. Selective inhibitors of SGLT2 reduce glucose reabsorption, causing excess glucose to be eliminated in the urine; this decreases plasma glucose. SGLT2 inhibitors are coupled with osmotic dieresis and loss of weight which aid in reducing the blood pressure. The observation that individuals with familial renal glycosuria maintain normal long-term kidney function provides some encouragement that this mode of action will not adversely affect renal function. This novel mechanism of targeting kidney for the treatment of T2DM is reasonably valuable and is independent of insulin and clutch with the low risk of hypoglycemia.

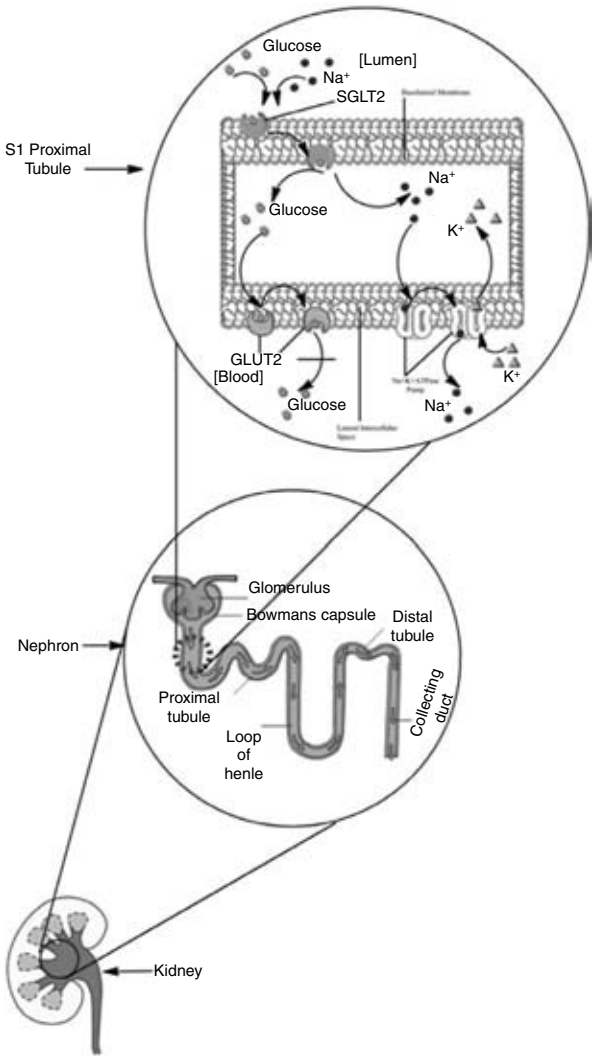

**Fig.** Reabsorption of glucose from the renal proximal tubules by the sodium glucose cotransporters SGLT2. Almost all of the glucose entering glomeruli in the afferent glomerular arterioles is filtered into the nephron fluid of the promimal renal tubules. Most (upto 90%) of this filtered glucose is reabsorbed in the initial proximal convoluted segment (SI) by SGLT2 located at the luminal surface of proximal tubular cells. Remaining glucose is reabsorbed from the filtrate in themore distal convoluted and straight segments by SGLTI. Glucose within the proximal tubular cells is then transported back to the interstitial compartment and thence to the plasma by the facilitative glucose transporters GLUT2 in the SI segment, respectively. In normal individuals with an average plasma glucose concentration of 5–5.5 mmol/L (90–100mg/dL), approximately 160–180 g of glucose is filtered daily, with less than 0.5 g/day of glucose appearing in the urine. Based on Bakris et al. and Bays

**Management of Diabetes in Hospital**

M. Mirzayi[1], F. Esfahanian[1] & S. Abdoli[1]
Primary Health Care Centre, Malayer, Islamic Republic of Iran.

Introduction
People with type 1 or type 2 diabetes mellitus are frequently admitted to a hospital, usually for treatment of conditions other than the diabetes. Whether in hospital or not, glycemic control is likely to become unstable in these patients because of the stress of the illness or procedure, the concomitant changes in dietary intake and physical activity, and the frequent interruption of the patient's usual antihyperglycemic regimen. Once in the hospital, the length of stay and cost are greater for people with diabetes than for those without it. Efficient treatment of diabetes in hospital may be an important factor in limiting the costs of care.
Aim
To assess diabetes management in general wards of hospital.
Methods
This study was a retrospective cross sectional descriptive one which accessed diabetes management criteria in 120 hospitalized people with diabetes in a private hospital in Tehran during 6 months in 2011. The data gathered from patients' recorders including Hb A1C, FBS, BS, TG, Chol, and Cr.
Results
The finding showed 60% of the samples were women and 40% were men. The mean duration of hospitalization was 6 days. In addition the mean amounts of different diabetes management criteria were HBA1C: 8/14%, FBS: 165, BS: 181, TG: 145, and CHOL: 170.
Conclusion
However the results special mean of FBS and BS were reasonable for hospitalized people with diabetes; better outcomes for people with diabetes following admission to hospital can be improved in the hospital as well.

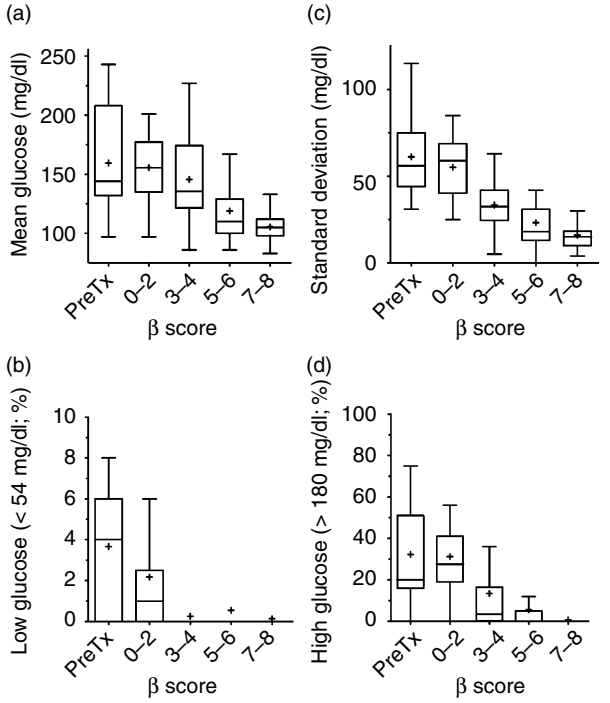
**Relation between glucose daily profile (CGMS) and graft function after islet transplantation for type 1 diabetes mellitus**

M. Vantyghem, V. Raverdy, A. Balavoine, F. Defrance, R. Caiazzo, J. Kerr-Conte, M. Hazzan & F. Pattou
Lille University Hospital, Lille, France.

Context
The influence of beta cell replacement on daily glucose profile in Type 1 diabetes mellitus (T1DM) is not firmly established.
Objective
To examine the influence of islet transplantation (IT) on the various component of dysglycemia in T1DM patients.
Design, setting and patients
Single arm open labeled study. Twenty-three consecutive patients with T1DM, 11 males and 12 females, 14 non uremic and 9 uremic with a previous kidney graft, receiving IT at a referral center from 2003 to 2007. All participants completed a 3-year follow-up.
Intervention
IT consisting of 2 or 3 intra-portal allogenic islet infusions over 3 months with the Edmonton immuno-suppression protocol.
Outcomes
Glucose daily profile was assessed during 72 hours by continuous glucose monitoring system (CGMS) prior to transplantation, at 6 months and yearly during 3 years after transplantation. Outcomes were mean glucose (MG), glucose standard deviation (GSD), the percentage of time spent in hyperglycemia

>180 mg/dL (HYPER), and the percentage of time spent in hypoglycemia < 54 mg/dL (HYPO). Graft function was estimated with beta score, a previously validated index (range 0–8) based on insulin or oral treatment requirements, plasma C-peptide, blood glucose, and A1C. Analysis was per intention to treat.
Results
At 3 years, 19 patients had a functional graft and 10 remained insulin independent with A1c ≤6.5%. Median A1c in the whole cohort was 6.7% (interquartile range[IQR], 5.9%-7.7%) vs. 8.3% (IQR, 7.3%-9.0%) at baseline ($P<0.01$). The four CGMS outcomes were significantly improved vs. baseline ($P<0.01$), in a close relation with graft function ($P<0.001$). Partial function (beta score 3) was sufficient to abrogate HYPO but optimal function (beta score 8) was necessary to normalize MG, SD, and HYPER.
Conclusion
Glucose daily profile significantly improved during the 3-year period post-IT and reached normal values when optimal graft function was achieved.



Relation between graft function and the various outcomes of continuous glucose measurement during follow-up (a, mean glucose; b, glucose standard deviation; c, percentage of time with glucose >180 mg/dL; d, percentage of time with glucose <54 mg/dL). Tukey box plots indicates median interquartile range and upper and lower range. ($P<0.0001$; test for linear trend).

**Evolution of macro-angiopathy 5-years after islet transplantation (IT) in type 1 diabetes**

M. Vantyghem, A. Balavoine, F. Defrance, C. Douillard, E. Van Belle, C. Foucher, C. Gautier, J. Kerr-conte, C. Noel & F. Pattou
Lille University Hospital, Lille, France.

Long-term benefit-risk ratio of IT remains poorly evaluated. The aim of this work was to determine the evolution of macroangiopathic complications 5 years after IT.
21 out of the 36 prospectively followed islet-transplanted patients in a single center, had at least 5 years of follow-up and were included. Their initial features were: duration of C-peptide negative diabetes: 28±9years; age: 43±7years; BMI: 24±0.2 kg/m2; 8/21 kidney-transplanted patients for 23±10 months; immunosuppression: Edmonton. These 21 patients had a systematic screening for macroangiopathy before transplantation, and then yearly for 5 years. Three «islet-alone » and 2 « islet-after-kidney» patients had lost their islet function at 5 years. Nine patients were insulin-independent, 8/9 with HbA1c ≤ 6.5% (38% with both criteria). The mean HbA1c level was 8.1±1.0% before vs. 7.1±1.0% 5 years after IT ($P<0.01$). Analyses were performed in intention-to-treat. There was no loss of follow-up.
The mean level of cholesterol total (1.86±0.37vs.1.76±0.36g/l), HDL (0.71 ±0.18vs. 0.73±0.27g/l), LDL (0.98±0.32vs.0.88±0.30g/l), triglycerides (0.79±0.33vs.0.83±0.34g/l) and mean blood pressure (124±17/72±7 vs. 127±13/72±8 mmHg) did not differ before vs. after transplantation (patients treated with statins: 28% vs. 65% and with ≧ 1 antihypertensive drug: 38% vs. 75%). Three patients among whom 2 « islet-after-kidney» had macroangiopathic complications before transplantation (2 femoral by-passes among which 1 with amputation, 1 coronary stent). There were no clinical acute cardiovascular events during these 5 years., Macroangiopathic screening was abnormal before vs. after transplantation for: carotid ultrasound: 37%vs.52%; lower limb ultrasound: 36%vs.85% (22 vs 25% if mediacalcosis was excluded), non-invasive test for cardiac ischemia: 19% (with 3 normal coronarographies except for 1 calcification) vs. 24% (among which 4 stented). Conclusion: IT was not associated with acute clinical cardiovascular event in these 21 patients with long-lasting diabetes, among whom 8 kidney-transplanted at the expense of systematic screening and treatment of macroangiopathic complications.

**Sustained Exendin-4 secretion through gene therapy targeting salivary glands in Zucker fa/fa rats and high fat diet fed mice.**

I. Dicembrini[1], G. Di Pasquale[4], L. Raimondi[2], C. Pagano[3], J. Egan[4], A. Cozzi[2], L. Cinci[2], E. Manni[2], A. Loreto[2,3], S. Berretti[2], A. Morelli[2], B. Baum[4], M. Maggi[2], R. Vettor[3], J. Chiorini[4], C. Rotella[1] & E. Mannucci[1]
[1]Careggi Teaching Hospital, Florence, Italy; [2]University of Florence, Florence, Italy; [3]University of Padua, Padua, Italy; [4]National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD, USA.

Background
Exendin-4 (Ex-4) is a GLP-1 receptor agonist approved for the treatment of Type 2 Diabetes (T2DM). Aim of this study was to characterize the effects of Ex-4 expressed continuously from salivary glands (SG), following adeno-associated virus-mediated (AAV) gene therapy in two different model of obesity and T2DM. Several trials support an AAV good safety and little toxicity profile. Serotype 5 (AAV5) presented enhanced gene transfer activity in SG and an efficient protein secretion into the bloodstream. Materials and methods: a recombinant AAV vector was produced using a four-plasmid procedure. Following 5x1012 DRP/ml vector (encoding Ex-4 or empty) administration, efficacy and metabolic effects in high fat diet (HFD) fed mice ($n=20$) and Zucker fa/fa rats ($n=10$) were evaluated.
Results
Ex-4 levels averaged 138.9±42.3 pmol/L at day 42 in treated mice and 238.2± 72 pmol/L at day 30 increasing to 3 nmol/L at day 60 in treated rats. Transduction specificity was confirmed through a qPCR amplification using specific primer in SG, liver, spleen and pancreas. Treated animals reached a significantly lower weight gain in comparison to controls at day 42 in mice (16.5±2.7 vs 19.5±1.9 g; $P<0.05$) and by day 35 in rats (156.8±17.5 vs 186.2±18.6 g, $P<0.05$) throught the study. Transient reduction on food intake was reported. Furthermore, treated mice presented: significant lower leptin circulating levels (2.24±0.39 vs 5.89±1.07 ng/ml; $P<0.01$) and visceral adipose mRNA expression (3.43±0.48 vs 8.28±0.72 Arbitrary Unit; $P<0.01$) and at day 41, a greater insulin-induced reduction in glycaemia during an intraperitoneal insulin tolerance test. A significant reduction in HbA1c (4.7±0.1 vs 4.9±0.1%; $P<0.05$) and glycosuria (4 cases vs 0) was reported in treated rats.
Conclusion
This study suggests an alternative approach delivering Ex-4 in the treatment of T2DM.

**A Hydrophilic Derivative of Probucol, Probucol-(glutaric branched-triglycerol)$_2$ (ProBGL$_2$) Ameliorates Glucose Tolerance and Insulin Sensitivity by Independent Mechanism of the Canonical Potency of Probucol in HFD-fed mice.**

L. Miyamoto, M. Kono, T. Nakagawa, H. Hattori, K. Ishizawa, Y. Yoshimura, H. Nemoto & K. Tsuchiya
The University of Tokushima Graduate School, Tokushima, Japan.

Probucol is a traditional anti-hyperlipidemic agent harboring marked antioxidant activity. While probucol is highly hydrophobic, its succinic acid ester, succinobucol, was reported as a water-soluble derivative and was in clinical trials. Succinobucol was shown to be more potent in lipid-lowering, anti-inflammatory and anti-atherogenic effects than probucol in animal models. In addition, succinobucol reduced HbA1c in diabetic patients. Although the clinical trials finally ended in failure, it appears a promising strategy for drug discovery to modulate water-solubility of established active compounds. Meanwhile, we have reported chemical modification of lipophilic agents with branched origo-glycerol as a suitable approach to intensify hydrophilicity. Thus we synthesized highly hydrophilic derivative of probucol, ProBGL$_2$ and evaluated its effects on glucose and lipid metabolism in HFD-fed mice. 1 g/kg/day of probucol or ProBGL$_2$ were orally administered for a week to male ddY mice fed HFD (24 wk), and then ipGTT was performed. Plasma insulin and lipid parameters were also determined. While body weight and food intake were not affected, glucose tolerance was much improved in probucol and ProBGL$_2$ groups (AUC; -50%). Fasting plasma insulin levels and HOMA-IR in the both groups were 70% decreased, suggesting increase in insulin sensitivity. However, ProBGL$_2$ did not change plasma total cholesterol concentration though probucol lowered it more than 50%. Furthermore, TBARS assay revealed ProBGL$_2$ did not possess antioxidant activities in contrast to probucol. Plasma TG and NEFA levels were not altered. Our data demonstrate that probucol and its hydrophilic derivative, ProBGL$_2$ ameliorate glucose intolerance and insulin resistance in HFD-fed mice and those are independent of the canonical potency of probucol such as lipid-lowering or antioxidant activities. ProBGL$_2$ should be a novel potent anti-diabetic agent.

**Simultaneous Pancreatic Kidney Transplant Experience in The South West of Ireland between 2001–2011**

D. Slattery, T. Hussain, M. O'Cathail, A. Tuthill, W. Plant & D. O'Halloran
Cork University Hospital, Cork, Ireland.

Introduction

Simultaneous pancreatic kidney transplantation (SPK) has become the therapy of choice in patients with type 1 diabetes mellitus (DM) and end stage diabetic nephropathy.

Methods

An analysis was performed of type 1 diabetic patients with end stage diabetic nephropathy who received treatment with SPK between 2001–2011 in the South West of Ireland, population 663,176 with a prevalence of type 1 DM in this region estimated to be 0.3%. Data was obtained from the South West of Ireland nephrology database.

Results

Between 2001 and 2011, 35 type 1 diabetics with end stage diabetic nephropathy were treated in the South West of Ireland. 14 have undergone SPK and 8 have undergone kidney transplant alone. 3 patients are currently awaiting SPK and 3 awaiting kidney transplant alone. Seven out of 35 died while receiving dialysis. The mean age of the SPK group was 41 years $\pm$9.80. The mean duration of disease at time of SPK was 29.58 years $\pm$9.48. The average waiting time from being placed on the transplant pool to transplantation was 19 months $\pm$12.38. No mortality was reported post SPK. There was loss of pancreatic allograft in 4 patients: 2 in the immediate post-operative period ($<$ 10 days post op), 1 at 9 years post-transplant and 1 at ten years post-transplant. The mean pre-operative HbA1C was 9.6% and 12 months post-operatively was 6.2% in the 12 functioning pancreatic allografts. Twelve month mean post-operative GFR in the 14 patients was 55mL/min/1.73m2.

Conclusion

SPK is the treatment of choice in type 1 diabetics with end stage diabetic nephropathy. SPK is performed in a single centre in Ireland, with 12 month pancreas allograft survival rates in our cohort of 79% which is comparable to international centres of excellence.

**Implementation of the principles of the personalized medicine in the clinical practice: a pilot study for type 2 diabetes**

L. Zarina[1], L. Tarasova[4], L. Nikitina-Zake[4], I. Kempa[4], M. Cirse[4], J. Klovins[4], K. Geldnere[1,2], I. Konrade[3], A. Lejnieks[3] & V. Pirags[1,2]
[1]Pauls Stradins Clinical University Hospital, Riga, Latvia; [2]University of Latvia, Riga, Latvia; [3]Riga Stradins University, Riga, Latvia; [4]Latvian Biomedical Research and Study Center, Riga, Latvia.

Background

Many patients with type 2 diabetes (T2D) are not reaching glycemic targets even by using different combinations of antidiabetic drugs, including insulin. On the other hand, intensified multidrug therapy is associated with increased risk of severe side effects and individualized selection of medication is essential. The aim of our study is to evaluate efficiency of personalized pharmacotherapy according to the genotype and phenotype of T2D patients.

Methods/design

95 treatment naive T2D patients were involved in prospective clinical trial. Genotyping by GoldenGate Genotyping Assay with VeraCode technology (Illumina, Inc.) of 192 SNP in previously reported genes influencing T2D treatment efficiency and tolerability (OCT1,2,3, MATE1,2, PMAT and others) was performed in all patients.

Results

First results of treatment efficiency and tolerability are currently available in 61 patients. Decrease of the mean HbA1c from 7.7$\pm$2.0% to 6.7$\pm$0.8% and the mean BMI from 34.6$\pm$5.9 kg/m$^2$ to 34.1$\pm$5.6 kg/m$^2$ was measured. SNP located in region between genes SLC22A2 – SLC22A3 was associated with HbA1c decrease after 3 month metformin therapy and the commonly carried A allele was more often detected in patients who responded to metformin therapy. Unadjusted association test ($P$=9.29e$-$005, OR (CI 0.95)=4.971[2.163–11.43]) identified association between genetic polymorphisms and response to metformin therapy. Association maintained statistical significance after Bonferroni correction ($P$=0.01793).

Conclusions

Genotyping of large number of known polymorphisms in genes responsible for efficiency of T2D therapy may help to individualize treatment schemes. Genetic polymorphisms in SLC22A2 – SLC22A3 gene region are associated with efficiency of short-term metformin treatment.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Pathway Integration of Pro-Inflammatory Cytokines, 12-Lipoxygenase and NADPH Oxidase in Beta Cell Dysfunction; Protection by Novel Selective 12-Lipoxygenase Inhibitors.**

D. Taylor-Fishwick[1], J. Weaver[1], B. Ganesha[2], T. Holman[3], A. Jadhav[2], D. Maloney[2], J. Nadler[1] & A. Simeonov[2]
[1]Eastern VA Medical School, Norfolk, VA, USA; [2]Center Translational Therapeutics, Rockville, MD, USA; [3]UCSC, Santa Cruz, CA, USA.

In this study we explore and integrate a pathway for loss of functional beta cell mass in diabetes. Inflammatory cytokines induce human islet dysfunction, elevate expression of 12-lipoxygenase, increase cellular reactive species and induce NADPH oxidase. These pathways are elevated in islets from diabetic donors. NADPH oxidase-1 (NOX-1) is significantly induced in either human donor islets, primary mouse islets or homogeneous beta cell lines following stimulation with a cocktail of inflammatory cytokines (TNF$\alpha$, IL-1$\beta$, INF$\gamma$) ($P<0.05$). Beta cell dysfunction was concomitantly induced by the pro-inflammatory cytokine (PIC) stimulation as measured by the loss of glucose stimulated insulin response ($P<0.05$), elevated expression of MCP-1 ($P<0.01$), increase in cellular reactive oxygen species (ROS) ($p<0.05$) and induced cell death. Inhibitors of NADPH oxidase, apocynin, diphenylene iodonium or selective NOX1/4 inhibitors, block ROS generation ($P<0.01$) and inhibit expression of MCP-1 ($P<0.05$) induced by PICs. In islets from diabetic donors, expression of NOX-1 is elevated ($P<0.05$, $n=5$).

12-lipoxygenase (12-LO) has been shown to regulate NADPH oxidase in non-islet models. Does this linkage occur in islets? Stimulation with PICs increases the expression of 12-LO in human islets, and 12-HETE (12-hydroxyeicosatetraenoic acid), a product of 12-LO activity, stimulates NOX-1 expression 12±4 fold ($P<0.05$) in human islets. Validating an association between 12-LO and NOX-1 in islets, we show that a selective inhibitor of 12-LO (NCTT-956) blocks 80% of NOX-1 expression ($P<0.01$) and inhibits procaspase 3 cleavage ($P<0.05$) induced by PICs in homogeneous beta cells. An inactive structural analog (NCTT-695) did not exert these effects.
This report unifies 12-LO and NOX-1 in beta cell dysfunction induced by PICs, a pathway not previously described in islet beta cells. Inhibition of this pathway is a candidate target to preserve and protect beta cell mass in diabetes.

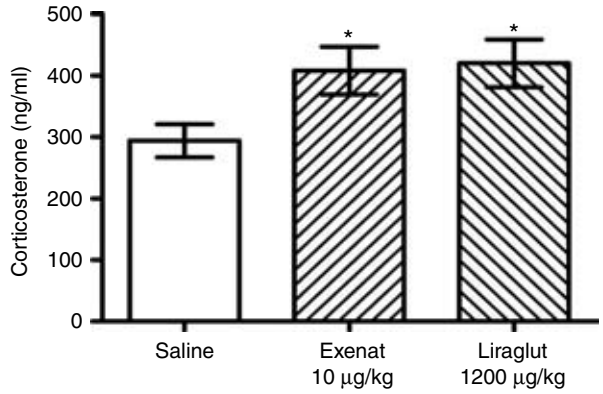
**GLP-1 agonists enhance stress-induced corticosterone release**

V. Volke[1,2], K. Rünkorg[2] & M. Krass[2]
University of Tartu, Tartu, Estonia.

Introduction
Currently, there are two glucagon-like peptide 1 (GLP-1) receptor agonists approved for the treatment of type 2 diabetes.
While the primary pharmacological actions of GLP-1 agonists are antihyperglycaemic effect and weight reduction, these drugs may influence other neural and hormonal processes. Animal studies have indicated that GLP-1 receptors are involved in the regulation of stress, anxiety, learning and memory as well as regulation of corticosterone and aldosterone release.
Objective
The aim of the current study was to compare the behavioural and hormonal effects of glucaemically equipotent doses of exenatide and liraglutide in mice after acute and chronic treatment.
Methods
The effects of GLP-1 receptor agonists were determined on anxiety level in the light-dark compartment test, the motor activity in automated activity cages and finally, the forced swimming test (used to detect antidepressant-like effects) was performed. The plasma levels of corticosterone and aldosterone were also measured.
Results
Both exenatide (1–20 μg/kg s.c.) and liraglutide (200-1200 μg/kg s.c.) induced very similar behavioural and hormonal effects after acute administration: there was no change on anxiety level or immobility time, however, both drugs dose dependently suppressed motor activity. Remarkably, GLP-1 agonists stimulated corticosterone release even when combined with the swimming stress. After chronic dosing of GLP-1 agonists (exenatide 10 μg/kg bid; liraglutide 1200 μg/kg qd for 2 weeks) both drugs still enhanced stress-induced corticosterone release but did not change the locomotion of animals. The effects on aldosterone levels are also reported.
Conclusion
We conclude that exenatide and liraglutide induce very similar suppression of motor activity and stimulation of corticosterone release in mice. Interestingly, tolerance developed to hypolocomotory effect but not to corticosterone stimulating effect of GLP-1 agonists during 2 weeks of treatment.



Effect of chronic treatment with exenatide and liraglutide on plasma corticosterone Results are expressed as mean ±S.E.M. $n=9$–10. *$P<0.05$ vs. saline (Newman-Keuls test)

**Bile acid binding resins affect diverse molecules to improve metabolic control.**

K. Morimoto[1], M. Watanabe[1], S. Houten[2], N. Kaneko-Iwasaki[1], T. Sugizaki[1], Y. Horai[1], C. Mataki[3], E. Arita[1], K. Schoonjans[3], J. Auwerx[3] & H. Itoh[1]
Ecole Polytechnique Federale de Lausanne, Lausanne, Switzerland.

Introduction: Bile acid binding resins (BABRs), anion exchange resins developed as medication for hypercholesterolemia, have been reported to improve glycemic control in patients and animal models with type 2 diabetes mellitus. Although the mechanism has not been clarified yet, we suspect that diverse factors including peripheral bile acid composition and incretins play significant roles in the effect. Besides BABRs, bile acids (BAs) administration has been recently reported to ameliorate metabolic status. In our study, we also administered BAs to metabolic syndrome model mice, to show similarities and differences of BABRs and BAs, to elucidate the mechanism of their anti-metabolic syndrome effects. Methods: We evaluated the metabolic effects of BABR and BA by administering colestimide and cholic acid to male C57BL/6J and KK-Ay mice, at 6 weeks of age, fed normal or high-fat diet supplemented with / without colestimide or cholic acid. A dipeptide peptidase-4 (DPP-4) inhibitor had been also administered alone or combined with colestimide or cholic acid. We performed animal studies including body weight gain, food intake, OGTT, IPGTT, IPITT, serum GLP-1 and insulin concentrations. Morphological study of major tissues, bile acid composition analysis, and gene expression analysis were conducted with samples from the model mice. Results: BABR administration increased energy expenditure to induce weight reduction and insulin sensitization. The effect was similar to that of BA administration on BA composition and thermogenesis. BABR and BA also stimulated GLP-1 secretion, and additional administration of DPP-4 inhibitor augmented antidiabetic effect of BABR and BA. Conclusion: Our data suggest that BABRs could be useful for the management of not only hypercholesterolemia but metabolic syndrome. Futhermore, Combination uses of DPP-4 inhibitor with BABRs or BAs could exhibit great efficacy, providing clues to elucidate the effect of BABRs, and proposing new combination of established medications.

## P707

**A novel beneficial effect of liraglutide: the reduction in subclinical atherosclerosis in patients with type-2 diabetes**

M. Rizzo[1], A. Patti[1], V. Di Bartolo[1], R. Giglio[1], G. Montalto[1] & A. Rizvi[2]
University of South Carolina School of Medicine, Columbia, SC.

Introduction
There is currently high interest in the non-glycemic effects of incretin-based therapies, specifically glucagon-like peptide 1 (GLP-1) analogues, such as those on cardiovascular system. Liraglutide has been approved in Italy since one year to be prescribed in combination with oral hypoglycemic agents; it has several non-glycemic properties, but its effect on carotid intima-media thickness (IMT), a recognized marker of subclinical atherosclerosis, is still unknown.
Methods
We evaluated in our Italian center the effect of liraglutide on carotid IMT as assessed by B-mode real-time ultrasound, in a prospective study of 33 patients with type 2 diabetes (58% males, age: 59±9 years), when added to metformin at a fixed dose of 1500/daily. Patients were newly diagnosed or previously treated subjects with oral hypoglycemic agents. The dose of liraglutide was 0.6mg/daily for the first 2 weeks, followed by a dose of 1.2 mg/daily. Statistical analysis was done using paired t-test and the Spearman correlation method.

Results
At baseline patients weighted 82±9 Kg, with average fasting glucose 9.5± 1.4 mmol/L and HbA1c 8.3±0.6%. The following significant changes in these parameters were recorded after 4 months of therapy: weight decreased by 3.1 kg, fasting glucose by 2.3mmol/l, and HbA1c by 1.8% ($p<0.0001$ for all). In addition, carotid IMT decreased from 1.55±0.45 mm to 1.36±0.31 mm ($P=0.0003$) after 4 months of treatment. Changes in carotid IMT did not correlate with changes in body weight, fasting glucose, or HbA1c; yet, we cannot exclude that this maybe due to the small sample size.
Conclusions
Liraglutide has desirable actions on carotid IMT, a surrogate marker of subclinical atherosclerosis, in type 2 diabetes after only a few months of therapy. This result may be at least partially independent of the effect of liraglutide on glucose metabolism. Future studies are needed to further explore this topic.

**The Sodium Glucose Cotransporter-2 Inhibitor Empagliflozin Does Not Alter ECG Endpoints in a Thorough QT (TQT) Study**

A. Ring[1,2], T. Brand[1], S. Macha[3], K. Breithaupt-Groegler[4], G. Simons[1], B. Walter[5], H. Woerle[6] & U. Broedl[6]

Empagliflozin is a potent, highly selective sodium glucose cotransporter-2 inhibitor in development for treatment of type 2 diabetes mellitus. This randomized, placebo-controlled, double-blind study assessed the effects of empagliflozin on the QT interval. Thirty healthy subjects (14/16 female/male; mean [range] age 34.5 [18–52] years) received single doses of 25 mg (within therapeutic range) and 200 mg (supratherapeutic) empagliflozin and 400 mg moxifloxacin as positive control. A new 5-period crossover, 'double-placebo period' design was utilized that reduced the sample size (from 40 to 30 subjects) and the total number of treatment periods compared with the classical 4-period TQT-design. Triplicate 12-lead 10-s-ECGs were recorded at baseline and selected time points over 24 h after dosing. Placebo-corrected mean change from baseline (MCfB) in population heart rate (HR)-corrected QT interval (QTcN) 1–4 h after dosing (primary endpoint) was 0.6 (90% CI: −0.7, 1.9) ms and −0.2 (−1.4, 0.9) ms for 25 and 200 mg empagliflozin, respectively – below the ICH E14 non-inferiority margin of 10 ms. Maximum placebo-corrected MCfB in QTcN between 0.5–24 hours after dosing were 2.2 (−0.3, 4.7) ms and 1.6 (−0.4, 3.5) ms for 25 and 200 mg empagliflozin, respectively. 90% CIs for placebo-corrected MCfB in HR 1–4 h after dosing were within −1.8 and 0.8 beats per min for both doses, indicating no relevant empagliflozin-related changes. Assay sensitivity was confirmed by placebo-corrected MCfB in QTcN 2–4 h post dose of 12.4 (10.7, 14.1) ms with moxifloxacin. Empagliflozin tolerability was rated 'good' for all subjects. Adverse events (AEs) were reported for 23.3% of subjects receiving empagliflozin and 27.6% receiving placebo. The most frequent AE was nasopharyngitis (4 subjects on empagliflozin, 5 on placebo). In conclusion, single doses of empagliflozin 25 and 200 mg were not associated with QTcN prolongation or changes in HR, and were well tolerated.

**Safety and efficacy of linagliptin in type 2 diabetes (T2D) patients (pts) with common renal and cardiovascular risk factors**

M. von Eynatten, Y. Gong, A. Emser & H. Woerle
Boehringer Ingelheim, Ingelheim, Germany.

Introduction
Vascular complications are the leading cause of morbidity and mortality in T2D. Hypertension and/or microalbuminuria predict renal and cardiovascular outcome. This large pooled analysis from a global development program aimed to evaluate the safety and efficacy of linagliptin in this particularly high-risk population.
Methods
Data of 1982 pts from 3 randomized, double-blind, placebo(PBO)-controlled phase 3 trials were analyzed. Pts with microalbuminuria (urine albumin-to-creatinine ratio [UACR] 30-300 mg/g) and hypertension (systolic BP ≧140 and/or diastolic BP ≧90 mmHg; and/or taking antihypertensive drug; and/or history of hypertension) at baseline were eligible for this analysis. Pts were treated with linagliptin 5 mg qd or PBO as monotherapy (18 wks), add-on to metformin (MET) or MET + sulphonylurea (SU) (24 wks). Efficacy endpoints were change from baseline in HbA1c and fasting plasma glucose (FPG) after 18 or 24 wks. Descriptive analysis for safety was performed, including adverse events (AE), serious AE, and hypoglycaemia episodes.
Results
340/1982 pts met screening criteria; 251 linagliptin, 89 PBO. Baseline demographics and characteristics were similar between groups (mean [SD] HbA1c, 8.3 [0.9]%; FPG, 171 [46] mg/dL; age, 59.9 [10.2] yrs; eGFR (MDRD) ≧90/60–<90/30–<60 mL/min, 53.2%/38.5%/8.2%). Linagliptin significantly lowered HbA1c and FPG vs PBO (Table). Overall, the incidence of AE and serious AE with linagliptin were similar to PBO (AE 65.7% vs 66.3%; serious AE 3.2% vs 6.7%, respectively). Hypoglycaemic event rates were increased only when linagliptin was administered with SU (linagliptin 13.5% vs PBO 2.2%). The hypoglycaemic event rate with linagliptin was <1% as monotherapy or add-on to MET.
Conclusion
In T2D pts with hypertension and microalbuminuria, linagliptin was well tolerated and achieved significant, clinically meaningful improvements in glycaemic control. Linagliptin may support long-term preventive strategies to reduce risk of cardiovascular events and declining renal function.

**Table 1** Red blood cell fatty acid composition in volunteers (% of total FA)

**Effects of flaxseed oil on anti-oxidative system and membrane deformation of human erythrocytes in high glucose level**

W. Yang
Public health, Wuhan, China.

Aim
The erythrocyte membrane lesion is a serious diabetic complication. Although most available data demonstrated by earlier studies that n-3 fatty acid was a potent agent in this complication of diabetes. Realization about protection effects of flaxseed oil on antioxidative capacity and against to membrane deformation of human peripheral blood erythrocytes in high glucose model is limited.
Main methods
In this study, erythrocytes were treated with 50 mM glucose to mimic hyperglycemia in the presence or absence of three doses of flaxseed oil (50, 100 and 200 μM) in the medium at 37 °C for 24 h. The malondialdehyde and L-glutathione were checked by HPLC and LC/MS respectively. The phospholipids symmetry and membrane fatty acid composition of erythrocytes were demonstrated by flow cytometer and gas chromatograph (GC). The morphology of erythrocyte was illuminated by ultra scanning electron microscopy.
Key findings
Our results illustrated that the flaxseed oil could prevent lipid peroxidation and delay the antioxidant capacity decreasing in erythrocytes. Also, the results of GC demonstrated that flaxseed oil groups contained higher C22:5 and C22:6 than 50 mM glucose group. These data indicated that flaxseed oil could reduce lipid asymmetric distribution and membrane perturbation.
Significance
This study provides new insights that the flaxseed oil supplementation may prevent the lipid peroxidation and membrane dysfunction of erythrocytes in diabetes.

**Table 1** Red blood cell fatty acid composition in volunteers (% of total FA)

| | 50 μM flaxseed oil +50 mM glucose | 100 μM flaxseed oil +50 mM glucose | 200 μM flaxseed oil +50 mM glucose | glucose group (50 mM) | PBS (0.01 M) |

### Rapidly and strong suppression of human acylated ghrelin serum concentrations during infusion of des-acyl ghrelin in obese diabetic subjects.

B. Ozcan[1], S. Neggers[1], A. Reifel Miller [3], H. Yang[3], P. Delhanty[1], S. Allas[2], T. Abribat[2] & A. van der Lelij[1]

Aim
To assess the effects of a continuous overnight infusion of two doses of UAG (3&10 μg UAG/kg.hr-1) versus placebo in a double blind cross-over study on AG levels, as well on glucose and insulin response to a standard breakfast meal (SBM) in 8 overweight patients with type 2 diabetes (HbA1c 6.5-7.5%).
Methods
During these 3 admissions, in randomized order, all subjects received either placebo, or UAG 3 μg/kg.hr-1 or UAG 10 μg/kg.hr as a continuous venous infusion. The admission were divided by a wash-out period of >7 days. Serum glucose were assessed at regular intervals and via a continuous glucose monitor. Continuous infusion of either placebo or UAG started at 22.00 until 13.00 hr the next day. At 08.00–08.15 hr a standard breakfast meal (SBM) was used. SBM consisted out of 714 kcal (17% proteins; 46% fat; 37% carbohydrates).
Results
Morning AG levels (before SBM) dropped significantly from 21.01±8.9 (mean±SD) to 3.0±6.7, to 1.4±3.2 pg/ml after placebo, 3 and 10 mcg/kg.hr UAG infusion, respectively. After breakfast AG levels drop from 14.03±9.4, 0.8±1.8, to 0.8±1.8 pg/ml after placebo, 3 and 10 mcg/kg.hr-1 UAG infusion, respectively.
UAG levels, increased from 105.9±31.4, 10,998±2,623, 12,085±1,616 pg/ml after placebo, 3 and 10 mcg/kg.hr UAG infusion, respectively.
During continuous glucose monitoring, post-SBM, overnight infusion of 10 mcg/kg.hr UAG significantly decreased glucose levels. The AUC decreased from 1618, 1601, to 1540 mmol/3 hrs of placebo, 3 and 10 mcg UAG infusion.
A significant decrease in peak serum glucose levels after SBM during 10 mcg UAG infusion was observed.
Conclusion
UAG is a potent inhibitor of ghrelin levels in obese mild diabetics. Additionaly, UAG improves postprandial glycemia, especially in whom preprandial AG levels are high, which makes UAG (analogs) strong potential candidates for the development of drugs in the treatment of metabolic disorders or other conditions in which a disturbed AG/UAG ratio has been found.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Educating educators - the way to improve health outcomes of people with diabetes

E. Shelestova, R. Kurashvili & L. Tsutskiridze
National Center for Diabetes Research, Tbilisi, Georgia.

Background and Aims
Diabetes causes immeasurable personal suffering and costs to the society, though diabetes and its complications are largely preventable. There are proven, affordable preventions available, that can stop or delay diabetes/complication development. Political Declaration adopted by UNO stresses importance of educational measures to promote health education and literacy. IMAGE Project/Toolkit on Type 2 Diabetes Prevention in Europe outlines education as cornerstone of motivation creation. To provide high quality Therapeutic Patient Education (TPE) /motivation, education/training of educators (ETE) is essential. TPE is voluntarily practiced in Easter-European countries (EECs) for around 20yrs, though systematic ETE is rarely performed, besides, lack in education materials (EM) is experienced. Our aim was to train healthcare providers (HCPs) using Conversation Map Education Tools (CMapT) and provide them with EM.
Materials and Methods
Totally, 21 HCPs from 7 EECs participated in 2-day education course using CMapT. Training was carried out under the aegis of IDF-Global and IDF-Europe. CMapT are developed by HealthyInternational, Canada. HCPs were endocrinologists, pediatrician-endocrinologists, cardiologists/endocrinologists, psychologists, GPs, family medicine/nursing trainers. Agenda included 4 lectures and 7 Small Group Activities (SGA).
Results
Participants highly appreciated possibility to discuss problems and share views, they showed interest in CMapT and their implementation, ranging from HCPs education to school staffs and various civil services training/awareness-raising campaigns. Participants stated that CMapT make education flexible; interesting both for HCPs and people with diabetes; help to avoid professional burnout; create strong motivation; solve problems with EM.
Conclusion
IDF Global Diabetes Plan includes continuous self-management education and support in its core components. This training was important from standpoint of Political Declaration and interest paid by EEC Governments to TPE. Our challenge is to reduce human and financial costs of diabetes; TPE/ETE is an important tool in achieving this goal. Education of educators needs further development to make progress sustainable.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P713

**Reducing Residual Vascular Risk Through combination Therapy with Fenofibrate and Alpha-Lipoic Acid in Patients with Ischemic Heart Disease and Type 2 Diabetes Mellitus**

L. Zhuravlyova & N. Lopina
Kharkov National Medical University, Kharkov, Ukraine.

Purposes
To investigate effects of combination therapy with fenofibrate and α-lipoic acid (ALA) on atherogenic dyslipidemia, which determines the residual vascular risk and endothelial dysfunction, levels of proinflammatory mediators in patients with ischemic heart disease (IHD) and type 2 diabetes mellitus (T2DM).
Methods
We examined 42 patients with IHD and T2DM (19 males, age 60.5±4.7 years). Baseline characteristics of patients included history of IHD (7.2±2.3 years), T2DM (4.7±0.5 years). The level of HbA1c was less than 7.5%. All patients were divided into 2 groups: the 1st ($n=22$) - received the standard therapy, the 2nd ($n=20$) in the standard therapy received combination of fenofibrate 145 mg once daily with ALA 600 mg once daily. In all patients were determined the levels of total cholesterol, low-density lipoprotein cholesterol (LDL), triglycerides (TG), high-density lipoprotein cholesterol (HDL) by enzymatic colorymetric method, and proinflammatory mediators (TNF-α, hsCRP) by ELISA method at baseline and in 6 months.
Results
As compared with baseline, combination therapy with fenofibrate and ALA substantially lowered plasma levels of TNF-α by 7±2% ($P<0.05$) and hsCRP from 1.58±0.19 to 0.98±0.17 pg/ml ($P<0.05$) compared to the 1st group. Furthermore, combination therapy increased plasma levels of HDL on 12% (0.13 mmol/L), decreased total cholesterol, LDL and TG levels on 7%, 9% and 12% respectively (all $P<0.001$).
Conclusions
Combination therapy with fenofibrate and α-lipoic acid significantly reduced total cholesterol, LDL, and TG, proinflammatory mediators, increased HDL and as a result reducing residual vascular risk in patients with IHD and T2DM.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P714

**Antidiabetic therapies and malignancy: a retrospective study in oncological cases.**

C. Anil[1], C. Demir[1], B. Erismis[1], S. Can[1], S. Yalcin[1], O. Altundag[1], G. Gunes[2] & N. Bascil Tutuncu[1]

Introduction
Despite the relation between Type 2 Diabetes Mellitus (DM) and development of malignancy is well known, data on antidiabetic drugs and cancer risk is contradictory. Thesis which have suggested that analogue insulins, especially glargine, increase cancer risk, has not been validated. The present study aimed to evaluate the possible contributions of diabetes durations and medications to the type and course of malignancy in patients with both diabetes and malignancy.
Methods
Among patients registered in the Oncology department of Baskent University Hospital, those who had DM before the oncological diagnoses were enrolled. The course of diabetes, antidiabetic medications and their relevance to the oncological diagnoses were examined.
Results
Totally, 246 patients were enrolled. Some characteristics of the group were summarized in Table 1. Among 69 patients receiving insulin, no relation was determined between duration of DM, basal glycohemoglobin values and stage of malignancy at diagnosis and the course of malignancy. There was no relation between the type and duration of antidiabetic therapy used (including metformin, glargine insulin) and the type of malignancy, stage at diagnosis and the final state of malignancy.
Conclusion
Despite this retrospective study may not give idea about possible cancer initiating or promoting potential of antidiabetic medications, it may suggest that therapies put forward to be protective (such as metformin) or risk increasing (such as glargine) might not have any influence on the type and biological behavior of the developing malignancy. Prospectively designed research is required to exhibit these relations clearly.
Some features and results of the study

**Table 1**

| | |
|---|---|
| N (female / male) | 246 (132/114) |
| Age (years, mean±S.D.) | 70.3±11.3 |

**Adding Liraglutide to insulin treated obese type 2 diabetics improves glycaemic control with sustained weight reduction and low hypoglycaemia rate**

R. Jindal, N. Gupta, M. Gupta, M. Siddiqui & S. Wangnoo
Indraprastha Apollo Hospital, New Delhi, India.

Aims
To evaluate the effect of Liraglutide on clinical parameters in obese Type 2 diabetic patients with inadequate glycemic control despite treatment with oral hypoglycaemic agents (OHAs) and insulin.
Methods
Three hundred and fifty three (M:232, F:121) obese (according to Asian-Indian criteria) type 2 diabetic patients with inadequate glycemic control (HbA1c>7% & <10%) attending outpatients clinic on insulin and OHAs were initiated on liraglutide. Weight, Blood pressure, BMI, HbA1c, fasting lipids, high sensitivity C-reactive protein (hsCRP), and insulin doses (basal, prandial & total) were recorded at baseline, 3, 6 and 12 months. Side effect profiles were recorded.
Results
Ten patients discontinued therapy because of nausea. The remaining patients demonstrated a reduction in mean HbA1c by 0.9±0.21% ($P<0.001$), weight reduced by 10.7±0.7 kg ($P<0.001$) and insulin doses were reduced from 83.1+3.9 U to 52.2+5.3 U ($P<0.001$). There was a reduction in serum total cholesterol by 12.4±4.1% ($P=0.03$), triglycerides by 30±4.6% ($P=0.01$), systolic blood pressure by 10.2±2.5 mm Hg ($P=0.01$), and hsCRP by 29±11.3% ($P=0.02$). There was also a reduction in glycemic excursions at the end of study period. Hypoglycemia was seen in 4 patients. Nausea, diarrhoea, vomiting, headache, and constipation were main adverse events noticed in patients.
Conclusions
The addition of Liraglutide effectively treats obese type 2 diabetics on insulin, leading to weight loss and reduction in levels of HbA1c, systolic blood pressure, tri¬glycerides, hsCRP & a significant reduction in insulin dosages. Liraglutide could be considered in a subset of obese type 2 diabetics with poor glycemic control who might gain more weight and be exposed to hypoglycaemia with increasing doses of insulin in striving to achieve adequate glycemia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P716

**Clinical and Patient Reported Outcomes over the 24 Months of Insulin Therapy in Patients with Type 2 Diabetes in Greece: Data from The Instigate Study**

K. Aloumanis[1], M. Benroubi[2], S. Sourmeli[1] & V. Drossinos[1]
General Hospital, Athens, Greece.

Aims
We present final Hellenic data from the INSTIGATE study which assessed direct costs, resource utilisation, and clinical outcomes in the first 24 months of insulin therapy in type 2 diabetic (T2D) patients.
Methods
INSTIGATE was a prospective European observational study of patients with type 2 diabetes who had initiated insulin during usual care. Data were collected at baseline, when subjects initiated insulin (visit T1), then 3 (T2), 6 (T3), 12 (T4), 18 (T5) and 24 months (T6) later.
Results
The data presented here is for the 237 patients with Baseline, 6 and 12 month visits; at 18 and 24 months data were available from 229 and 227 patients respectively.
Following insulin initiation mean HbA1c improved from (SD) 9.65(1.63)% at baseline to 7.44(1.06)%, 7.39(1.15)%, 7.28(0.96)% and 7.14(0.85)% at 6, 12, 18 and 24 months respectively. Mean fasting blood glucose (FBG) improved from (SD) 12.8(3.9) mmol/l to 7.8(2.2) mmol/l, 7.8(2.4) mmol/l, 7.5(2.1) mmol/l and 7.3(2.1) mmol/l over the same period. Mean BMI (SD) was 28.2(4.7) kg/m2 at baseline up to 29.4(4.6) kg/m2 at 24 months. Patients reporting at least one hypoglycaemic episode were 3.0% (in the three months prior to insulin initiation) 29.1% (in the six months after initiation) and above 20% thereafter. Health status, measured by EQ-5D visual analogue scale score, improved from baseline to 6, 12, 18 and 24 months, the highest improvement being from baseline up to 6 months after insulin initiation.
Conclusions
Greek patients initiated insulin when HbA1c is by much higher than recommended by international guidelines; yet their glycaemic control improved in the 6 months following initiation, the best improvement being observed from baseline to 6 months. Mean health-related quality-of-life scores also improved, however there was an increase in the number of patients reporting hypoglycaemia.

## P717

**The outcome of Beta cell function after early insulin therapy in the recently diagnosed type 2 diabetes (in Egyptian population) our experience in EL-Minia university hospital**

Y. Mousa, A. Mohamed & M. Kamel
Minia University, Minia, Egypt.

The purpose of this prospective cohort study was to evaluate whether early insulin therapy is more advantageous in achieving long-term optimal glycemic control with improved B cell function than oral drugs in the recently diagnosed type 2 diabetes mellitus. Methods: Sixty consecutive patients with recently diagnosed type 2 diabetes mellitus were divided into 3 groups.The 1st group received 2 SC injections of premixed insulin. The 2nd group received bed time NPH and 3 injections of regular insulin before meals. The 3rd group received metformin and/or sulphonylureas. The treatment continued for 3 months till euglycemia was reached. Then, all medications were stopped and the patients were followed up till the end of the year. BMI, FBG, PPG, HbA1C, fasting level of insulin, proinsulin, C-peptide, HOMA-IR, HOMA-B, serum cholesterol, triglycerides were estimated. Results: Six patients from group I (30%), nine from group II (45%), and only one from group III (5%) succeeded to maintain euglycemia without further therapy for 9 months after stoppage of treatment. The mean HbA1C level was 6.5% in group I, 6.1% in group-2, and $>7$% in the group-3. Level of HbA1C in the succeeded patients declined significantly in comparison to the failed patients. Markers of β-cell function of the succeeded patients showed a statistical significant increase regarding the C-peptide, insulin and HOMA-B. Meanwhile, proinsulin level and proinsulin / insulin ratio declined ($P=0.0001$). The total serum cholesterol and triglycerides of insulin treated groups reduced significantly ($P=0.001$). Conclusions: Short-term insulin therapy in a newly diagnosed type 2 diabetes naive patients can preserve β-cell function and insulin secretion, allowing long-term glycemic control without medication and may improve glycemic responses to supplemental oral treatment if needed.

Keywords: Type 2 DM, early insulin therapy, B cell function
Abbreviations: BMI: Body mass index, FBG: fasting blood glucose; PPG: postprandial glucose, HbA1C: Glycosylated haemoglobin, OADs: oral antidiabetic drugs; HOMA-B: homeostasis model assessment of B-cell function; HOMA-IR: homeostasis model assessment of insulin resistance.

## P718

**Gender differences in metabolic outcomes of continuous subcutaneous insulin infusion therapy**

C. Esteves[1,2], M. Neves[1,2], S. Belo[1,2], M. Pereira[1], Z. Sousa[1] & D. Carvalho[1,2]
University of Oporto, Oporto, Portugal.

Introduction
The continuous subcutaneous insulin infusion (CSII) is an alternative to multiple daily injection therapy in type 1 diabetes and its use is increasingly common due to the beneficial effects on the glycemic control of the patient.
Aims
To find differences on outcomes of CSII therapy between genders. Patients and methods: Patients on CSII therapy in our department were included in the study and we recorded outcomes regarding the following set points: immediately before beginning of CSII therapy, 12 months after inclusion and in the last appointment. For statistical analysis, we used the Student's t-test and Pearson correlation, and considered significant a value of $P \leq 0.05$.
Results
We studied 64 patients (24 men; 39 women) with a mean HbA1c before initiation of $8.2\% \pm 1.4$; mean age at the time of placement of $33.6 \pm 11.2$ years; and mean time of follow up after placement of $2.1 \pm 1.9$ years. Men had significantly lower levels of HbA1c than women ($7.8 \pm 0.8\%$ vs $8.4 \pm 1.7\%$, $P<0.05$). The reduction of HbA1c on the last consultation was not sustained in the group of men, whereas in women there was a persistent tendency to reduction of HbA1c ($\Delta$HbA1c $0.1 \pm 1.2\%$ vs $\Delta$HbA1c $-1.3 \pm 1.6\%$, $P=0.01$). There was no significant correlation between duration of diabetes, age, gender and weight change. When adjusted to gender, there was a negative correlation between previous HbA1c and its reduction by the end of follow-up ($R=-0.555$, $P=0.021$) and a positive correlation between weight gain and HbA1c reduction at 12 months ($R=0.505$, $P=0.04$). There was a significant correlation between duration of diabetes and reduction of HbA1c at 12 months ($R=0.600$, $P=0.01$).
Conclusions
In our study we found better results of CSII therapy in women than men, probably reflecting the fact that patients with higher baseline HbA1c benefit most of this diabetes therapeutic modality.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P719

**Continuous subcutaneous insulin infusion systems: experience in 92 patients with type 1 diabetes**

J. Saraiva, F. Carrilho, L. Barros, C. Batista, M. Melo, L. Gomes, A. Vieira, M. Alves, S. Gouveia, C. Moreno & M. Carvalheiro
Coimbra University Hospital, Coimbra, Portugal.

Background
Continuous subcutaneous insulin infusion (CSII) using an external pump is an alternative intensive diabetes therapy recognized to improve metabolic control and glycemic instability in selected type 1 diabetic (T1DM) subjects. The aim of this study was to examine the clinical effectiveness and safety of CSII systems over a 5-year follow-up period in T1DM patients.
Materials and methods
We performed a retrospective observational study of T1DM patients previously treated with multiple daily insulin therapy who initiated CSII until December

2010. We analyzed A1C, weight and total daily insulin dose (TDD) at the start of therapy, 6 months after and then annually for 5 years. We examined the occurrence of hypoglycemic and diabetic ketoacidosis (DKA) episodes and local problems at infusion site.
Results
We followed 92 patients treated with CSII during 4.08±3.01years, 62% female, mean age 28.73±11.7years-old, diabetes duration 15.63±8.97 years. The main reasons for starting CSII were: poor glycemic control in 47.7%, glycemic instability 31.1%, frequent and unnoticed hypoglycemia 12.1% and dawn phenomenon in 4.5%. Baseline A1C was 8.79±1.62% and decreased to a minimum of 7.58±1.0% at 6 months ($P<0.05$). Compared to baseline, A1C remained lower in all follow-up period ($P<0.05$). Patients followed during 5 years maintained lower A1C (8.95±1.6% vs 7.60±0.94%, $P<0.05$), although we verified a slight increase between 1 and 4 years (7.35±1.08% vs 7.75±0.91%, $P<0.05$). Insulin requirements reduced from 57.7UI/day to 41.3UI/day ($P<0.05$) at 6 months and we found no statistically weight difference (59.5 vs 58.3 kg). We registed 18 severe hypoglycemia (incidence 0.057/patient/year), 12 DKA (0.038/patient/year) and 11 recurrent infections at the infusion site. Eight (8.7%) patients quit pump therapy mainly because of maladaptation.
Conclusion
In this study CSII improved glycemic control during long term follow-up and reduced total daily insulin requirements. The rate of major complications was low and similar to those reported in other studies.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P720

**A 52-week efficacy and safety profile of sitagliptin in Japanese type 2 diabetic patients in clinical settings**

A. Matsuda[1,2], K. Hamada[1], A. Misaka[1] & M. Matsuda[2]
Medical Center, Saitama Medical University, Kawagoe, Japan.

Background of Study
Some medications for the treatment of type 2 diabetes mellitus fail to achieve a continuous favorable glucose control in the long run during clinical use. Therefore we examined the durability of dipeptidyl peptidase-4 (DPP-4) inhibitor, sitagliptin which is relatively new to Japanese type 2 diabetic patients in clinical settings.
Objectives and Methods
117 subjects (M/F=65/52, Age: 66±10 y.o., duration of diabetes 12±8 y. body weight 62 kg) received sitagliptin 50 mg q.d. and were followed up for 52 weeks. We observed HbA1c, body weight, blood pressure, and lipid profile. The percentage of concomitant use of sulfonylureas, biguanides, tiazolidinediones, alpha glucosidase inhibitors, and glinides are 63%, 45%, 28%, 20%, and 6% individually.
Results
Five subjects terminated medication due to loss of hypoglycemic potency and worsening patients' condition. In the rest of 112 subjects, HbA1c was decreased from 7.89 to 7.00% ($P<0.001$), while there were no significant changes in body weight (62.2 to 62.2 kg), systolic blood pressure (133 to 131 mmHg) and lipid profiles (LDL-C: 111 to 108 mg/dl, HDL-C 55 to 56 mg/dl). The rate of achievement of HbA1c less than 6.9% was increased from 5 to 41%,and the frequency of decrement more than 0.4% was 66%. Contribution of HbA1c before the treatment was significant to the decrement of HbA1c, while there were no contributory effect of sex, age, the duration of diabetes, weight, combination medications and existence of complications. There were no serious adverse events.
Conclusions
Sitagliptin is a good therapeutic additive option to improve glycemic controls continuously in Japanese type 2 diabetic patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P721

**Short-term liraglutide therapy as compared with basal insulin therapy on restoration effect of insulin secretion in Japanese patients with type 2 diabetes**

S. Kaneko[1], K. Yoshimi[1], Y. Tahara[1,2], Y. Sato[1,2] & M. Tashima[1]
School of Medicine Kyoto University, Kyoto, Japan.

Objective
To investigate whether restoration of insulin secretion and long-term optimal glycemic control can be achieved by short-term liraglutide (a glucagon-like peptide-1 receptor agonist) therapy compared with basal insulin therapy in Japanese patients with type 2 diabetes.
Research Design and Methods
Japanese subjects with type 2 diabetes had a short-term, 3 week course of basal insulin therapy ($n=114$) or liraglutide therapy ($n=29$) to achieve a target two hours postprandial glucose of less than 140 mg/dL, then they were discontinued. Efficacy and safety of short-term liraglutide and basal insulin were retrospectively compared in terms of restoration effect of insulin secretion evaluated by fasting C-peptide immunoreactivity (CPR) (ng/mL) / fasting blood glucose (FBS) (mg/dL), two hours postprandial CPR / two hours postprandial blood glucose, insulinogenic index and urinary CPR.
Results
Fasting CPR / FBS was improved from 0.014±0.007 to 0.021±0.008 in liraglutide group, favorably compared to the improvement in basal insulin group (from 0.011±0.006 to 0.020±0.006). Moreover, liraglutide also improved two hours postprandial CPR / two hours postprandial blood glucose from 0.027±0.024 to 0.052±0.028, insulinogenic index from 0.18±0.16 to 0.50±0.39, and urinary CPR from 103.3±69.4 to 66.8±39.5 μg/day. Blood glucose levels of liraglutide-withdrawn patients were kept in long-term good control without medication or with only oral antidiabetic drugs. Gastrointestinal side effects were occasional but tolerable, and hypoglycemic episode was never observed in liraglutide group.
Conclusion
Short-term liraglutide and basal insulin therapy induced the same degree of improvement on insulin secretion in Japanese type 2 diabetic patients. A long-lasting protective effect on pancreatic beta-cell function can be expected by short-term liraglutide therapy.

**Vitamin B-12 deficiency associated with metformin treatment of type 2 diabetes mellitus in daily practice: Clinical consequences**

E. Jungmann, J. Bolle, C. Schmitz & G. Jungmann
St. Vincent's Hospital Rheda-Wiedenbrück, Rheda-Wiedenbrück, Germany.

In a recent study, vitamin B-12 deficiency was observed in 10% of metformin-treated type 2 diabetic patients, but neurological status of the patients was not defined. Thus, potential consequences of this observation remained subject to controversy. Therefore, we decided to examine to which extent a vitamin B-12 deficiency can be detected in metformin-treated diabetic patients in daily practice and which impact vitamin B-12 deficiency – if present – could have on the development of diabetic neuropathy in these patients.
88 consecutive type 2 diabetic patients with metformin treatment for >1 year (37 females, 51 males, age, 66±2 years [SEM], duration of diabetes, 10±2 years, metformin, 1450±120 mg/day for 6±2 years) were included in this cross-sectional study. We measured vitamin B-12 levels, folate, 25-OH-vitamin D and PTH by enzyme immunoassay, additionally we performed a routine screening of all patients for signs or symptoms of diabetic neuropathy.
10% of the patients had vitamin B-12 deficiency, a total of 29% of the patients had vitamin B-12 levels<200 pmol/l. Patients with decreased vitamin B-12 levels received higher doses of metformin for longer duration than patients with vitamin B-12 levels >200 pmol/l ($P<0.05$). Moreover, they exhibited an increased prevalence of diabetic neuropathy, had decreased folate levels and decreased vitamin D levels ($P<0.05$). In patients with decreased vitamin B-12, diabetic neuropathy developed after shorter duration of diabetes and despite better HbA1c levels than in patients with normal vitamin B-12 ($P<0.05$).
In this cross-sectional study in daily practice, there is evidence for neurological consequences of metformin-associated vitamin B-12 deficiency, which therefore

must be considered as eventually harmful for metformin-treated patients. Thus, patients should be regularly screened and vitamin B-12 replacement started as early as necessary, together with the replacement therapy of mostly associated vitamin D-deficiency.

**A comparison of pharmacokinetics and pharmacodynamics of insulin aspart, biphasic insulin aspart 70, biphasic insulin aspart 50 and human insulin: a randomized, quadruple crossover study**

Z. Ma[1], T. Parkner[1], J. Frystyk[1,2], T. Laursen[2], T. Lauritzen[2] & J. Christiansen[1]
Aarhus University, Aarhus, Denmark.

Aims
To compare the pharmacokinetic and pharmacodynamic profiles of insulin aspart, biphasic insulin aspart 70 (BIAsp70), biphasic insulin aspart 50 (BIAsp50) and soluble human insulin under experimental conditions.
Methods
In this randomised, four-period crossover study, 19 type 1 diabetic patients received subcutaneous injections of identical doses (0.2 U/kg) of either insulin aspart, BIAsp70, or BIAsp50 immediately before a standardized meal, or human insulin 30 min before meal. Plasma glucose and serum insulin were measured for 12 h postprandially.
Results
The pharmacokinetic and pharmacodynamic profiles of human insulin differed from insulin aspart, BIAsp70 and BIAsp50. The 3 different aspart preparations had easily distinguishable features as regards onset and duration of action. Insulin aspart preparations were, on average, absorbed twice as fast as human insulin. In the initial phases (0–4 h and 0–6 h), AUCins was significantly higher during insulin aspart treatment as compared to the others, whereas insulin aspart had a significantly lower AUCins over the last 6 h ($P<0.05$). BIAsp70 and BIAsp50 provided comparable insulin coverage to that of human insulin over the last 6 h. Insulin aspart had the most pronounced onset of action and the shortest duration. Comparing with insulin aspart and BIASp70, BIAsp50 revealed a closer treatment ratio to human insulin on pharmacodynamic endpoints.
Conclusions
BIAsp70 and BIAsp50 injected immediately before a meal are at least as effective as human insulin injected 30 minutes earlier in controlling postprandial glycaemic excursions. BIAsp50 showed the greatest similarity to human insulin as regards pharmacokinetic and pharmacodynamic profiles.

**Resource utilization and patient satisfaction associated with switching insulin in Greece (Subanalysis of the SWING study).**

K. Aloumanis[1], N. Tentolouris[2], M. Reaney[3], C. Dafni[1] & V. Drossinos[1]
Eli Lilly & Co Ltd, Surrey, United Kingdom.

Purpose
Diabetic patients (T2D) switch from short-acting insulin to rapid-acting analogue (H-A) and less commonly from A-H. The SWING study was designed to assess treatment costs, glucose control, satisfaction, and quality of life in T2D following H-A or A-H switches.
Methods
SWING was a multinational, prospective, observational study of previously mentioned parameters associated with switching in either direction between any rapid-acting analogue insulin therapy and short-acting human insulin therapy over 12 months following the switch. Data were collected at baseline (switch) and at approximately 3, 6 and 12 months post-switch. Descriptive analysis of the Hellenic subgroup data is presented.
Results
309 Greek patients switched H-A [N = 270, mean(SD) age 65.3(11.9), Body Mass Index (BMI) 28.8(4.5) kg/m2, diabetes duration 15.6(9.0) years] or A-H [N = 39, age 64.4(12.6), BMI 28.8(5.4) kg/m2, diabetes duration 13.7(7.9) years] insulin. Mean (SD) HbA1c at baseline was 8.4(1.3) % (H-A) and 8.4(1.4)% (A-H) respectively and decreased over 12 months: −1.2(1.1) units H-A, −1.3(1.3) units A-H.
Reported hypoglycaemia incidence (recalled over the 6 months preceding baseline) was 45.9% for H-A and 28.2% for A-H.
Mean (SD) direct diabetes-related costs for standardized 6 month periods prior to switch, 0–6 months and 6–12 months following switch were €692.2(293.1), €755.3(235.7) and €734.6 (231.9) for H-A, and €788.9(402.0), €670.5(170.0) and €646.8(171.5) for A-H respectively. Compared to baseline, intra-patient standardised costs at 0–12 months post switch were mean (SD) €31.0(257.9) higher in H-A ($n=246$) and €168.6(342.2) lower in A-H ($n=36$).
Conclusions
In a cohort of Greek diabetic patients switching short-acting insulin A-H, total mean direct costs were lower in the 6–12 month period post-switch than in the 6 month period prior to the switch, although standard deviations are wide. Mean HbA1c decreased following switch in both groups. Substantially more patients were switched to analogues. Results should be interpreted in the context of an observational study.

**Inpatient Hypoglycaemia Management**

C. Sobajo & P. Rao-Balakrishna
Central Manchester University Trust, Manchester, United Kingdom.

Introduction
Inpatient hypoglycaemia management remains a significant challenge. An audit in 2009 revealed poor understanding ("recognition" by frontline staff) of the need to treat and manage hypoglycaemia. Consequently a management protocol, documentation sheet and hypoboxes with standardized quantities (15 g) of dextrose in various forms were introduced throughout the hospital.
Aims
We re-audited inpatient hypoglycaemia management and the impact of the standardized hypo-boxes and guidelines.
Methods
For the purposes of these audits, hypoglycaemia, was defined as capillary blood glucose (CBG) $\leq 4$ mmol/l and "Recognition" by staff as identifying the low CBG and initiating treatment. On a single day, 126 diabetes inpatients were identified, of whom $n=33$ had $\geqq 1$ episode(s) of hypoglycaemia totaling 62 events, as evidenced by their CBG. Data relating to 'recognition' and

management of the event(s) by the staff was collected and compared with the 2009 audit.
Results
Similar numbers of inpatients with diabetes experienced hypoglycaemia in 2009 ($n=32/120$) and 2011 ($n=33/126$), but the total episodes decreased from 79 to 62. Frontline staff failed to "recognize" hypoglycaemia in $n=12$ (36% of 33). Only 64% of the initial and 27% of the subsequent management was appropriate despite the new management tools. Recognition and management was better when events were recurrent (100% at $>4$ recurrences). Recovery from hypoglycaemia was confirmed in 24% in 2011 vs only 6% in 2009. Documentation in notes; ranged from 12% with one event and 55% with $\geqq 4$ events compared to 3% and 13% in 2009. Medication-review and diabetes-team referral improved by 6% and 15% respectively. Introduction of the hypo-box was considered beneficial by 73% of frontline staff.
Conclusions
Introduction of hypoboxes and guidelines have led to improved reassessment and documentation after treatment and the benefit reflected by the fewer number of recurrent hypos. Further guidelines to proactively decrease the incidence of hypoglycaemia are planned.

**Study of the outcomes of application of ISPAS versus ADA guidelines of diabetic Ketoacidosis in type 1 diabetic children**

M. El Hefnawy
NIDE, Cairo, Egypt.

Diabetic ketoacodosis (DKA) is a serious complication of diabetes mellitus, especially type 1, and its secondary consequences account for a large proportion of diabetes-related hospitalizations and mortality in children with type 1 diabetes. Aim of the work: The aim of this study was to compare between the outcomes of application of ISPAD (International Society of Pediatric & Adolescence Diabetes) versus ADA, (American Diabetes Association) guidelines for management of diabetic ketoacodosis in type 1 diabetic children attending the National Institute oof Diabetes & endocrinology in Cairo, Egypt (NIDE). Each protocol had been applied on 100 dibetic children with DKA with no significant difference between both groups as regarding, age, sex, acidity represented by ph. and serum bicarbonate and anion gap or coma score. The results showed that there was no statistical difference as regarding all outcome results as duration of recovery of acidosis or dehydration or the morbidity or mortality results. While the results of the change in potassium was better in ISPAD protocol. The Net results showed that there is no great difference between both groups. It could be recommended to apply any of the ISPAD or ADA protocols for managment of DKA in type 1 diabetic children but it will be more benificial to delay the insulin therapy for 1 hour after giving the intravenous fluid therapy as had been recommended by the ISPAD guidelines.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P727

**Subcutaneous use of rapid insulin analog: an alternative treatment for patients with mild to moderate diabetic ketoacidosis**

M. El Hefnawy
NIDE, Cairo, Egypt.

Background
Diabetic ketoacidosis (DKA) is a life-threatening condition that requires hospitalization in children with type 1 diabetes. Many reports have indicated that low-dose insulin therapy is quite effective regardless of the route of administration, whether, intramuscular, or subcutaneous.
Aim of the work
The aim of this study was to look for technical simplification and economic efficiency in the treatment of diabetic ketoacidosis (DKA) with subcutaneous use of the rapid-acting insulin analog and compare its use with regular intravenous insulin treatment.
Subjects & methods
A total of 80 consecutive patients admitted with DKA were randomly classified into 4 groups: Group 1: Patients with DKA on regular insulin by infusion pump, (infusion pump, $n=20$), group 2: Patients with DKA on subcutaneous rapid onset of action-aspart insulin analog (Novolog; Novo Nordisk) / 2 hrs, sc-2 hr, $n=20$), group 3: Patients with DKA on subcutaneous rapid onset of action-aspart insulin analog (Novolog; Novo Nordisk) / 1 hrs, (sc-1 hr, $n=20$), and group 4: Patients with DKA on rapid insulin analog by continues subcutaneous insulin pump (CSII, $n=20$).
Results
The results of this study showed that there was no statistical difference between the 4 groups as regarding age in years, blood glucose in mg/dl before the starting of management of DKA, pH, serum HCO3, serum K, anion gap, urine acetone and time needed for resolution of DKA by hours.
Conclusion
It could be concluded that management of any patient with mild to moderate DKA with good tissue perfusion can be treated with subcutaneous rapid insulin analog every 1 or 2 hours or to be treated by continuous insulin infusion pumps, if available with same results as giving regular insulin by intravenous infusion pumps.
Diabetic ketoacidosis (DKA), Insulin analog and continues subcutaneous insulin infusion (CSII).

## P728

**Planning Treatment of Diabetic Patients with Chronic Renal Disease Using Pre-mixed Insulins Having Higher Proportion of Soluble Insulin**

V. Nikhra
Hindu Rao Hospital, New Delhi, India.

Diabetes mellitus is a leading cause of chronic renal insufficiency and later end-stage renal failure; on the other hand, chronic renal disease has been linked with alterations in carbohydrate and insulin metabolism. The pharmacokinetics of various insulin preparations has not been well studied in patients with varying degrees of renal dysfunction. There exist sparse guidelines regarding appropriate dosing adjustment of insulin. Further, chronic renal insufficiency is associated with variably impaired insulin sensitivity. These patients may show about 2.5-fold increase of insulin elimination half-life. There are erratic insulin secretory patterns, as well. In summary, CRF is associated with a complex disruption of the processes of insulin release and resistance; its metabolism and elimination.
These facts are important while treating the diabetic patients suffering from a variable chronic renal deficiency, because they will entail adequate therapy adjustments in a patient with declining renal function decline. The rational insulin therapy will improve glycaemic control, a reduced incidence of hypoglycaemia and a retarded progression to end-stage renal disease. The adequate glycaemic control has also been associated with a reduced cardiovascular morbidity and mortality in these patients.
There exists opinion that in patients with end-stage renal disease, long-acting insulin preparations should be avoided because of increased hypoglycaemic events. A rapid acting insulin preparation on the other hand may entail less than desirable uniform blood sugar control. In this background, treating the diabetic patients with chronic renal disease using premixed insulin preparations having a higher proportion of soluble (rapid acting) insulin may be most plausible option.

### Study on cases with hypoglycemia carried to the emergency room in the last two years

T. Kudo & N. Kasai
Hachinohe City Hospital, Hachinohe, Japan.

Recently, many cases with hypoglycemia who take oral hypoglycemic agents and/or insulin therapy are carried to the emergency room in our hospital due to hypoglycemia. Pharmacotherapy for patients with diabetes mellitus occasionally can causes severe hypoglycemic attack. In this study, we investigated 69 type 2 diabetics on clinical features (26 outpatients of our hospital, 43 outpatients of other clinics) among 100 patients who were carried to the emergency room due to hypoglycemia from October, 2009 to September, 2011 to reveal the cause of hypoglycemia that required the treatment in medical facilities. Age (79.2±8.8 vs 70.4±12.6 years old) and the prevalence of pharmacotherapy with sulfonyl urea (SU, 65.8 vs 26.7%) are significantly higher in cases of HbA1c<7.0% than in cases of HbA1c≧7.0%. Patients needed to be hospitalized have significantly higher than those needed not to be hospitalized in age (78.1±9.8 vs 71.9±12.8 years old), and in the prevalence of pharmacotherapy with SU (64.7 vs 31.4%). Outpatients of other clinics have significantly lower HbA1c value than outpatients of our hospital (6.64± 0.93 vs 7.55±1.33%), and rate of the prevalence of pharmacotherapy with SU significantly higher than outpatients of our hospital(69.8 vs 11.5%).
Pharmacotherapy with SU is widely practiced for the treatment with type 2 diabetics. However, in elder patients strict glycemic control by SU may increase the risk of hypoglycemia. It is suggested that we should pay attention to the risk of hypoglycemia due to pharmacotherapy, especially with SU, and effort to direct the patient's attention to the risk of hypoglycemia and guide how to take measure to hypoglycemia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P730

### Treatment of obese type 2 Diabetes Mellitus patients with CSII Humulin U-500 Regular Insulin infusion vs. CSII Aspart insulin infusion coupled with basal insulin and metformin

S. Herscovici
Manchester VAMC, Manchester, UK.

We describe 10 obese patients with longstanding type 2 diabetes mellitus treated with a combination of basal insulin coupled with insulin Aspart and oral metformin. Average age was 59.5 years. Average BMI was 31.82 and Hemoglobin A1c 8.71%. Average Total Daily insulin dose (TDD) was 157.1 IU. EGFR was >60 in all patients. No patient underwent weight reduction surgery.Patients were randomized into 2 groups of 5 patients each. One group(1) received only Humulin U-500 Regular insulin by (CSII) via Animas pump. The other group(2) was randomized to receive 2/3 of the basal insulin dose coupled with CSII insulin Aspart via Animas pump and continuation of metformin. The patients in group1 also received the CGMS Dexcom sensor. Duration of the study was 15 months. At the end of the study, the average BMI was 33.47, average A1c hemoglobin 7.14% and TDD was 145 IU in group 1 vs. 35.28 BMI, 7.26% A1c hemoglobin and 149.2 TDD in group 2. (table 1). Average incidence of hypoglycemia was 8% in group1 vs. 4% in group 2.
Conclusion: Treatment of significantly obese type 2 diabetes mellitus patients with Humulin U-500 Regular insulin via insulin pump can lead to signicant improvement in glycemic control and at a statisticallly significant weight advantage over a combination of continous insulin Aspart coupled with adjuvant basal insulin and metformin. The additional hypoglycemia could be prevented by adding a CGMS to the treatment algorithm.
TDD is expressed in 100 unt/ml (for U-500 units divide by 5) A+L+M=Aspart CSII +Lantus or Levemir+Metformin WCM=White Caucasian Male AAM= African American Male Lantus, Levemir, Humulin U-500, Animas, Dexcom are all Registered Trademarks.

**Table 1** Trial Data U-500 Insulin CSII VS. Aspart CSII+Basal Insulin+Metformin

| Patient | Race/ sex | Initial BMI | Initial a1C | Initial TDD (IU/) | BMI Post Treat-ment | A1c post treat-ment | TDD post treat-ment | Treatment type |

### Effects of DPP-IV inhibitors on the changes of glycemic and lipid control of type 2 diabetes patients at the great east Japan earthquake

T. Yamagishi
Tohoku Kosai Hospital, Sendai, Japan.

Purpose
The effects of the Great East Japan Earthquake, a life-threatening event, on glycemic and lipid control in type 2 diabetic patients were examined. The influence of the DPP-IV inhibitors on glycemic and lipid levels was studied.
Method
Three hundred fifty type 2 diabetes outpatients (age 63 years old) who followed careful diet regimen on a normal condition were divided into the two groups: the administrated group (A group), 175 patients who were given DPP-IV inhibitors (Sitagliptin, Vildagliptin, Alogliptin) at least three months before the earthquake and the non-administrated group (NA group), 175 patients were given not given. Sulfonylurea and/or α-glucosidase inhibitor were used in some patients in both groups. All patients were able to have meals and visit our hospital before and after the earthquake. Their meal contents were confirmed by hearing and glycemic and lipid levels were examined.
Results
Before the earthquake, there were no differences in levels of fasting plasma glucose (FPG), HbA1c, triglyceride (TG), HDL-C, LDL-C in the two groups. One month after the earthquake, in both groups, the 77% patients increased intake of carbohydrates compared with the normal condition due to emergency food and stress. The transient increases of FPG and TG occurred after one month of the earthquake. However, the increases of the values were significantly lower in A group than those in NA group (0% vs. 3%, 6% vs. 17%, $P<0.05$), and the HDL-C significantly increased in A group. The LDL-C, HbA1c and body weight revealed tendencies of decline in the two groups.
Conclusion
These results suggest an association between life-threatening stress and the worsening of metabolic control in the type 2 diabetes patients. The DPP-IV inhibitors may possess ability to improve the unfavorable changes of FPG and TG to some extent.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Exenatide versus insulin glargine in type 2 diabetes inadequately treated with metformin

P. Karagianni, S. Polyzos, N. Kartali, I. Zografou & C. Sambanis
Aristotelian University, Thessaloniki, Greece.

Introduction
The recent ADA and EASD algorithm for the treatment of type 2 DM suggests addition of basal insulin or GLP-1 agonist to pre-existing treatment when glycemic control is not achieved.
Aim
Compare efficacy and safety of exenatide (E) versus insulin Glargine (G) added after metformin monotherapy.
Patients and method
Our study was open labeled, non- randomized, retrospective and included 48 patients, 17 men/ 31 women, mean age 61.98±8.8 years, mean duration of DM 11.8±7.25 years, and mean HbA1c 8.34±1.63 at baseline. All patients were on

metformin (1700 mg/day) for at least 3 months when E or G was added. Body mass index (BMI), systolic (SBP) and diastolic (DBP) pressure, frequency and severity of hypoglycemic episodes, gastrointestinal side effects, HbA1c and lipid profile were determined at baseline and after 24 weeks.
Results
HbA1c reduction was similar in both groups (E: $P=0.006$ vs G: $P=0.010$). G group had more hypoglycemias ($P=0.039$). E group had greater BMI reduction than G ($-2.5\pm1.8$ vs $0.1\pm1.4$; $P=0.002$). GI side effects and changes in SBP/DBP were insignificant in both groups. Total cholesterol was reduced (E: $P=0.010$ vs G: $P=0.014$). E group had higher HDL $P=0.021$, lower LDL ($P=0.012$) and triglycerides ($P=0.016$) at the end of the study.
Conclusion
Exenatide equals Glargine in glycemic control with fewer hypoglycemias and better metabolic parameters. In order to form selection criteria between the two strategies further testing is needed with randomized studies, longer observation period and greater numbers of patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P733

**Vitamin D3 deficiency effect on the HbA1c in type 2 diabetic Population**

H. Coskun, Y. Aydin, A. Kutlucan, H. Yildirim, O. Kudas, S. Kir, G. Celbek & M. Turgut
Duzce University, Faculty of Medicine, Duzce, Turkey.

Introduction
Aim is to determine vitamin D level in patients with Type 2 DM and to evaluate the relationship between vitamin D level and glycemic control.
Methods
We evaluated 107 women and 63 male patients with Type 2 DM whose mean age was $55\pm0.81$. Patients fasting blood glucose (FBG), postprandial blood glucose (PPBG), HbA1c and 25(OH)D3 level were measured. The cases were divided into three groups according to measured 25(OH)D3 level (Vitamin D value $\leq$20 ng/ml, between 20–30 ng/ml, $\geqq$30 ng/ml). DM less than 6 months duration, hypercalcemia or hypocalcemia, existing diagnoses of hyperparathyroidism or hypoparathyroidism, receving vitamin D treatment were excluded.
Results
Vitamin D level was found $\leq$20 ng/ml in 41 cases, between 20–30 ng/ml in 50 cases and $\geqq$30 ng/ml in 79 cases. Mean 25(OH)D3 level was found as 38.10 ng/ml (11 to 68.7 ng/ml) in men and 24.20 ng/ml (5.8 to 70.7 ng/ml) in female ($P$:0.001). Between the vitamin D groups, no significant difference was founding in terms of the FBG, PPBG and HbA1c levels ($P$:0.97, 0.96, 0.44). Between the vitamin D groups, in regard to age, BMI and waist circumference, significant differences were detected ($P<0.001$). There was a significant difference between calcium (Ca) levels between these 3 groups ($P$: 0.02). Vitamin D level was higher in the group with HbA1c $\leq7$ than the group with HbA1c$>$ 7 ($P$: 0.115).
Conclusion
A53% of the patients with Type 2 DM was found to have vitamin D deficiency and insufficiency. Vitamin D deficiency was more evident in women than in men. Although there was not any difference in terms of blood glucose regulations between the patients with Vitamin D deficiency or insufficiency and without deficiency, vitamin D level was found to be higher in patients with HbA1c$\leq$7.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P734

**Salsalate effect on BRACHIAL FLOW-MEDIATED DILATION in early diagnosed Diabetes mellitus**

N. Khalili & E. Faghih Imani
Isfahan University of Medical Science, Isfahan, Islamic Republic of Iran.

Objective
Obesity and fat deposition in tissues along with inflammatory response may induce insulin resistance and finally type 2 diabetes mellitus Salsalate, a prodrug form of salicylate can inhibit IKKβ and NF-kappaB inflammatory pathway as a potential pharmacologic target in diabetes. The aim of this study was to determine the efficacy of salsalate as an anti-inflammatory drug to resolve endothelial dysfunction in diabetic patients.
Methods
This was a double blind controlled trial study. Forty newly diagnosed type 2 diabetic patients (30 to 45 years of age) were randomized in the drug and placebo groups. The drug group received 3 g Salsalate per day(two 750 mg tablets every 12 hours orally) for one month. The placebo group received identical placebo. Fasting plasma glucose level was assessed in two groups before and after treatment period. Endothelial function was assessed via flow mediated dilation (FMD) of the brachial artery following reactive hyperemia before and after treatment period in two groups.
Results
Thirteen patients in the drug group and 15 ones in the placebo group finished the study. At baseline, there was no significant difference in mean fasting plasma glucose level (120 vs. 122 mg/dl, $P=0.621$) and FMD ($10.5\pm5.2$ vs. $10.2\pm5.4\%$, $P=0.19$) between drug and placebo groups, respectively. Salsalate reduced the fasting glucose level in the drug group (18 mg/dl) significantly, in comparison with the placebo group ($P<0.05$). At the end of the trial, FMD in the salsalate and placebo group was $11.5\pm5.6$ vs. $10.1\pm5.3\%$, respectively ($P=0.09$).
Discussion
This study showed that daily use of 3 grams salsalate for one month reduced 15.5% of baseline blood glucose level in diabetic cases. However, endothelial dysfunction did not change significantly. It might be because of the short duration of the study. We suggest further studies with longer treatment duration and controlling other factors of insulin resistance, should be done to investigate the role of salsalate in resolving the endothelial dysfunction in diabetic patients.
Conclusion
These data demonstrate that salsalate improves glucose homeostasis, but endothelial dysfunction did not change.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P735

**Differences in health related resource use and costs before and in 24 months after insulin initiation in patients with type 2 diabetes: final data from instigate study**

K. Aloumanis[1], M. Benroubi[2], V. Drossinos[1] & A. Polydorakis[1]
"Polikliniki" General Hospital, Athens, Greece.

Aims
We present final Hellenic data from the INSTIGATE study on direct costs of care and resource use, over the 24 months after insulin initiation, in type 2 diabetic (T2D) patients.
Methods
INSTIGATE, a prospective European observational study involving T2D patients who initiated insulin during usual care, assessed direct costs of care over the 6 months prior to and for the intervals from baseline to 6 months, 6–12, 12–18 and 18–24 months after insulin initiation.
Costs of health related resource uses, ancillaries, oral anti-diabetic medication-s/insulin and the cost of hospitalization were analyzed after collecting data on individual resource use and assigning local unit costs (from 2006).
Results
237 patients at baseline, 6 and 12 month visits and 229 and 227 patients at 18 and 24 months respectively were followed.
Mean total contacts with Health Care Professionals were 7.5 per patient during the 6 months prior to insulin initiation and 9.8, 5.4, 4.8 and 4.4 during the baseline to 6, 6–12, 12–18 and 18–24 month periods respectively. Although mean total contacts decreased from baseline to 24 months, increase in visits to specialists was shown (mean from 1.9 to 3.2 visits).
Numerical increase in median total costs per patient was observed at the first six months following insulin initiation. Cost of insulin was 199–224€. In the first 6 months median costs of oral anti-diabetic treatment reduced from baseline to 6 months (from 197 to 17€) and remained low while costs for Blood Glucose Monitoring increased sharply (from 60 to 146€) but somewhat lower at 24 months (121€).
Conclusions
In the first 6 months following insulin initiation, we observed more frequent use of specialist care and increase of diabetes related costs. After the first 6 months health care resource use as well as total cost of diabetes care slightly decreased.

**Clinical Findings on the Effect of Early Insulin Therapy in Newly Diagnosed Type 2 Diabetes**

Ming-Chin Wu & Ya-Hui Hu
Buddhist Tzu Chi General Hospital, New Taipei City, Taiwan.

Several recent studies have shown that early intensive insulin therapy can improve β-cell function in newly diagnosed type 2 diabetes. However, in clinical practice, insulin therapy has not been widely used in out-patients due to the fact that insulin therapy is perceived by the patients as the strongest and the last remedy and patients fear that, once on that therapy, they will have to remain on it for life. In fact, based on our clinical data, out-patients, who were newly diagnosed type 2 diabetes with HbA1c > 9% or fasting plasma glucose > 250 mg/dl and agreed to insulin therapy, could successfully shift to oral antidiabetic drugs within 6 months' of insulin therapy. After the termination of insulin therapy, almost all of those patients can maintain optimal glycemic control (HbA1c < 7.0) for many years with metformin only and some with combination use of metformin and sitagliptin.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P737

**The effect of nighttime glargine with morning NPH in type 2 DM.**

Y. Kim & D. Shin
Jesaeng Hospital, Seongnam, Republic of Korea.

Recently basal insulin is the first recommended step when failed with oral medication, and adding morning NPH is one of step 1 intensive insulin treatment regimen when failed with basal insulin alone and post-lunch glucose level is high. But morning NPH or premixed insulin alone was the usual first step before basal insulin was available. When once a day morning insulin failed to reach target, next option was splitting twice a day injection. But many patients don't agree to pre-supper insulin because they frequently eat out due to their social environment. Also frequent nighttime hypoglycemia was troublesome when pre-supper insulin was added. Long acting basal insulin is very efficient in controlling fasting glucose and safe in terms of hypoglycemia because fasting glucose is not variable when same amount of it was given at same time compared to NPH or premixed insulin. So we tried to evaluate the effectiveness and compliance of morning NPH with night-time basal insulin in type 2 DM.
We recruited 2 groups of morning NPH and nighttime glargine therary.
The group 1 was 45 type 2 DM who failed target with NPH alone and their HbA1c was above 7.5%. They were asked to add nighttime glargine with morning NPH. The dose of glargine was adjusted by fasting glucose below 120 mg/dL.
The group 2 was 63 who failed target with glargine alone and HbA1c level above 7.5%. They were directed to add morning NPH to control postprandial glucose and NPH dose was changed to control post lunch glucose level below 180 mg/dL. Their HgA1c level 6 months after changing was compared with HgA1c level just before changing and incidence of hypoglycemic event was also compared.
In 44 out of 45 group 1, HgA1c was improved by between 0.3% and 3.5%. The minor hypoglycemia was increased in some patients (30% of all), especially when their previous fasting glucose was not so high. Their compliance to twice a day insulin injection was very good and they rarely skip nighttime insulin injection. In 61 out of 63 group 2, HgA1c was improved by between 0.2% and 2.1%. The frequency of daytime hypoglycemia was increased in most patients after adding morning NPH, but major hypoglycemia was rare.
In conclusion, morning NPH and nighttime glargine therapy is very efficient in improving glucose control and safe in major hypoglycemic events.
Declaration of interest

**Telemedicine and Type 1 diabetes: A pilot project**

R. Arrais, J. Diniz & R. Valentim
UFRN - Federal University of Rio Grande do Norte, Natal, Brazil.

Type 1 diabetes is among the top rising problems in public health, since its incidence is growing in almost all series studied, all over the world. The gold standard for its control is based on achieving good metabolic control, through insulin, diet and regular physical activities, and it is delivered by a multi-professional team in tertiary centers, which have enough resources (material and personnel). Scheduled visits are ideally programmed three to four times annually, but many patients, especially in a country like Brazil, with great distances between small villages and towns without specialists and tertiary centers make the task very hard to accomplish, with direct effect on the metabolic control of these patients. The availability of a structure for videoconferences between a tertiary center and health centers in geographically distant regional relevant cities allowed the project to be designed. It is based in training small teams with updated protocols of assistance to diabetic children and adolescents, and monitoring its assistance by following its register in computerized registers, that will be shared electronically with the tertiary center. There will be also weekly live videoconferences between the tertiary center and the health provider, in order to discuss specific issues, difficult cases and even update protocols. This project is about to start its activities, since the chosen city (Caicó), which is about 280 km away from Natal (our tertiary center), has already received all the hardware, while the local teams' training is scheduled to early 2012. We firmly believe that this project has a strong potential to change the reality of many diabetic patients that are even without basic follow-up. After the implementation of this program, other pathologies (from endocrinology or other pediatric areas) can also benefit from this project in the near future.

**The State of Therapeutic Patient Education in Diabetes**

L. Tsutskiridze, E. Shelestova, R. Kurashvili & N. Asatiani
National Center for Diabetes Research, Tbilisi, Georgia.

Background: It is impossible to provide qualified diabetes care without patient education (TPE). Effect of education on treatment outcomes was demonstrated in 1972. Unfortunately in 1970-ies we lived in society, where many progressive ideas were not acceptable. Though progress at the end of 1980-ies leading Centers started to implement TPE. Methods: In Georgia first "5-day in-patient education course" was initiated. It was carried out at our Center. The Course was based on Berger/Jorgens program. Books for type 1 and 2 DM (T1/T2 DM) were first translated into Georgian. Past 20-yrs were hard period for Georgia - economic, energy, political crises, healthcare system reorganization; no insurance system slowed integration into global processes. Due to objective reasons, regular, obligatory TPE in T2DM is not carried out, though individual training is performed. Since 2000 we realized that only TPE could not improve treatment outcomes; professional education (medical students, Society) also need attention. Results: In 2009–2010 Ministry of Health of Abkhazia carried out a 2-yr. Screening/Management Program for T1/T2DM. Around 100 people were enrolled in total. Education was an integral part of the program. Conversation Maps (CM) were used during a 4-day education course. To accelerate the process of establishing TPE and training educators, an Expert Training for healthcare providers from Georgia and other Eastern European countries is initiated this year together with IDF-Global and IDF-Europe. Number of Expert Trainers will be trained for each country. It will permit to create a basis for professional diabetes education in our country and in the region. Conclusion: Diabetes education is a complex system, where all elements are equally important. If only TPE is addressed - we will face reality where "educated patient is too expensive". Thus, main goal is to change mentality of the whole society. This needs time and effort.

**Diabetes mellitus management in elderly over 80 years old.**

T. Crea, S. Rosati, S. Malvaux & P. Cuny
chr metz thionville, Thionville, France.

Introduction
The prevalence of diabetes mellitus increases with age in all population. With the demographic transition and population aging, diabetes mellitus will be a major public health problem in all countries.
Aims: to study the specific management of diabetes in very old subjects with multiple co morbidities and functional disabilities.
Patients and Methods
We described a population of 199 diabetic patients aged 80 years and over consecutively admitted in the department of endocrinology from August 2007 to August 2011.
Results
patients are hospitalized in emergency and particularly with diabetic ketoacidosis or hyperglycemic hyperosmolar state. 12 patients were newly diagnosed with type 1 diabetes mellitus On 104 patients who were hospitalized for chronic complications of diabetes mellitus 75 subjects had diabetic foot ulcers.
We described the characteristics of diabetes and its management and therapeutic goals in the elderly over 80 years old...
The management of very elderly patients with any type of diabetes requires careful consideration. Advancing age and changes in health status can have on the competing risks and benefits of therapeutic interventions.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P741

**Improving health numeracy: utilizing objective parameters to improve shared decision making for insulin initiation**

S. Kalra[1], N. Agrawal[2] & B. Kalra[1]
DOTC, Gwalior, India.

Background
Health numeracy is the ability to understand, and act upon quantitative data, in an appropriate and effective manner. Health numeracy is distinct from health literacy. Health numeracy is associated with better self-management.
Aims and objectives
This study was performed at two endocrine centres in north India, to assess and improve the health numeracy of patients with type 2 diabetes, with an aim to improving the quality of shared decision making (SDM).
Material and methods
A three months long campaign was begun to explain the meaning of HbA1c, vibration perception threshold and mean plasma glucose to 1000 patients presenting with T2DM in the OPD. This study was carried out by laboratory technologists, by means of semi-structured training, at each OPD visit.
Results
At baseline, 24.5, 11.8 and 45.0% of patients understood the meaning of HbA1c, mean vibration perception threshold (VPT) and mean plasma glucose (MPG) respectively. At three months, these proportions had increased to 56.6, 90.0 and 67.3% respectively.
During these three months, 351 patients were initiated on various regimes of insulin, of which 250 consented to fill a pre structured questionnaire. 60.0% of them felt that understanding their HbA1c value had played a major role in motivating them to begin insulin. Similar response was given by 80.0% for mean VPT and 100% for MPG.
Conclusion
This paper highlights the efficacy of improving health numeracy as a means of enhancing shared decision making, and facilitating insulin initiation in type 2 diabetes. It reveals the higher importance of mean plasma glucose values, rather than HbA1C and mean VPT in motivating patients to accept insulin.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Challenges and problems in the management of glycemia in patients with co-existing diabetes mellitus and a malignant disease in the Gerontology Institute - Hospice "Sue Ryder"-Skopje in the period of 2009–2011**

A. Mitevska & J. Jakimovska
Gerontology Institute 13 November Skopje, Skopje, The Former Yugoslav Republic of Macedonia.

Objectives
Pointing out all the problems and challenges that the medical staff encounters in the management of the patients with a terminal malignant disease with co-existing diabetes mellitus.
Methods
Medical documentation, laboratory results, US (Ultra Sound) etc.
Results
The study included patients hospitalized in the Gerontology Institute - Hospice "Sue Ryder"-Skopje, with a capacity of 75 beds, in the period of 2009–2011. During that period the institute hospitalized 212 patients, 35 of which had co-existing diabetes mellitus and a malignancy. All of the 35 patients were on an insulin therapy (Novomix, Mixtard 30, Insulatard, Levemir etc.) and a diabetic food regime. Most of the patients were with disseminated metastatic deposits in the lungs, liver, brain and bones.
Conclusions
Despite the insulin therapy and the diet regime it was not possible to regulate the glycemia in these patients with a severe illness. The glycemia reached a score of 29,0 mmol/L in some patients. There were no sings of hyperglycemia, which is unlike to happen in patients with Diabetes mellitus without co-existing malignancy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P743

**Efficacy and Safety of Insulin Glargine in Type-2 Diabetes Mellitus Patients with Moderate Renal Failure**

M. Niafar[1], M. Nakhjavani[2], A. Esteghamati[2], A. Ziaie[3], J. Azmandian[4], A. Jahed[5], M. Khamseh[2], G. Yousefzadeh[4], M. Gozashti[4] & M. Malek[2]
Tehran Islamic Azad University of Medical Sciences, Tehran, Islamic Republic of Iran.

Background and aims
Due to increasing risk of hypoglycemia, tight control of glycemia is difficult to achieve in the diabetic patients with diabetic nephropathy. Also, there are no absolute guidelines defining appropriate dosing adjustments of insulin in such patients. This study was aimed to determine the safety and efficacy of insulin glargine in type 2 diabetic patients with diabetic nephropathy.
Methods
A total of 89 subjects with type 2 diabetes (mean age $62.9 \pm 10.7$ and diabetes duration $13.9 \pm 7.6$ years) who had moderate renal failure (mean GFR $34.4 \pm 11.6$ ml/min) were included in the study. All the patients had been receiving insulin glargine at bedtime after discontinuing all oral hypoglycemic agents and other types of human insulin. Doses were begun with 0.1 U/kg and adjusted to obtain target fasting glucose (5–7.2 mmol/l). The medical records obtained before and 2 and 4 months after beginning insulin glargine.
Results
At the end of 4 months of treatment, significant reduction in HbA1c was observed (from $8.4\% \pm 1.6$ to $7.7\% \pm 1.2$) ($P < 0.001$). The treatments were associated with significant reductions in fasting glucose levels (from $159.7 \pm 67$ to $119.4 \pm 28.4$ mg/dl) ($P < 0.001$). No increment in body mass index (BMI) was seen at the end of 4 months of therapy ($26.2 \pm 3.9$ and $26.2 \pm 3.8$ kg/m2) ($P = 0.966$). Mild symptomatic hypoglycemia was seen in 12.5% of subjects. No other side effects were noted throughout the study.
Conclusion
Insulin glargine improved HbA1c at short-term and proved to be safe and well tolerated in type 2 diabetic patients with diabetic nephropathy.
Keywords: Insulin glargine, diabetic nephropathy, hypoglycemia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P744

**The weight reduction could be achieved on DPP-IV inhibitors in very obese T2D patients**

I. Smirnov & L. Zhuravlyova
Kharkov National Medical University, Kharkov, Ukraine.

Incretin-based therapy can improve glucose control in type 2 diabetes (T2D) with no weight gain. Usually dipeptidyl peptidase-IV (DPP-IV) inhibitors considered as weight neutral and glucagon-like peptide-1 receptor agonists are associated with weight loss. Some trials showed non-remarkable weight-lowering effect on DPP-IV inhibitors. We aimed to identify patients on DPP-IV inhibitors which are likely to achieve both outcomes either good glycaemic control or weight loss.
We studied 89 (58F/31M) T2D drug-naïve patients treated with metformin 1000–2000 mg/24 plus sitagliptin 100 mg/24 for 26 weeks. The age was 57.1 + 6.5 y (M + SD), A1c − 8.4 + 1.0%. 44 patients with weight more then 100 kg (Group 1) were compared with 45 controls from Group 2 (weight less then 100 kg). Groups were matched for gender and age.
At the beginning patients from Group 1 on average were approximately 25 kg heavier: 113.3 + 6.49 kg vs. 88.2 + 6.13 kg in Group 2 (BMI 39.1 + 3.25 kg/m2 vs. 30.4 + 3.28 kg/$m^2$ respectively). After 26 weeks of treatment A1c not differed between groups (7.20 + 0.18% vs. 7.15 + 0.20%). At the same time change in weight in Group 1 reached (−)3.2 kg (from 113.27 + 6.49 kg to 110.05 + 6.96 kg) and was significant. In Group 2 twice less weight lowering effect was observed (from 88.22 + 6.13 kg to 86.56 + 6.23 kg) and there was no significant difference. Moreover, weight reduction more then 3% (from 4 up to 14 kg) was seen in 18 from 44 patients (40.9%) in Group 1 and only in 10 (from 3 to 6 kg) from 45 patients (22.2%) in Group 2 ($P < 0.05$).
We concluded the glycaemic control in T2D patients on DPP-IV inhibitors could be associated with remarkable weight loss. The composite outcome is more likely to be achieved in very obese persons.

**Diabetes Mellitus Control Status of Turkish Diabetic Patients**

O. Kudas, Y. Aydin, A. Kutlucan, E. Önder, C. Gokhan, H. Coskun, S. Kir & E. Yildizhan
Duzce University, Faculty of Medicine, Duzce, Turkey.

Introduction
Our aim was to collect demographic data of diabetes mellitus (DM) patients to determine the patients education, follow-up and treatment priorities.
Material-Method
500 patients with diagnosis of DM followed up at least 6 months were included the study. Datas containing patients demographic characteristics, treatment modalities, biochemical parameters were retrospectively reviewed. On the day of admission patients; fasting blood glucose (FBG), postprandial blood glucose (PPBG), and glycated hemoglobin (HbA1c), creatinine, albumin/creatinine ratio electrolytes (Na, K), and lipid parameters were recorded
Results
Mean age and BMI was 56.6 ± 11.8 years, and 31.7 ± 6.9 kg/m respectively. 97% of cohort had Type 2 DM. DM duration was 9.3 ± 7.3 years in Type 1 and 8.1 ± 7.2 years in Type 2. 20% of them were being treated with insulin, 26.5% with insulin and oral antidiabetics (OAD) and 53.5% with OAD. There was a significant relationship between the form of treatment and duration of diabetes ($P < 0.001$). Insulin usage increases with increased DM duration. 31.9% retinopathy, 50.6% neuropathy, 37.1% nephropathy, 70.8% hypertension (HT), 69.8% hypercholesterolemia was detected. Chronic complications of DM were seen lesser in patients receiving OAD (63.4%) than receiving insulin or insulin and OAD (%85). Complication rates were increasing with aging ($P < 0,001$) and longer duration of DM ($P < 0,001$). The mean HbA1c was 8.1 ± 2. Only 32% of patients had HbA1c < 7%. As duration of DM prolonged, the ratio of well metabolic control were decreased ($P < 0.001$). Metabolic control of the insulin users was worse than others ($P < 0.001$).
Conclusion
These findings shows that metabolic control levels and follows-up of diabetics are generally poor. There is numerous medical and social factors that affect metabolic control so both of the patients and health personel should give adequate consideration to this matter.
Declaration of interest

**Insulin analogues in the treatment of diabetes**

O. Lozanovska & O. Lozanovska
Clinical Hospital Bitola, Bitola, The Former Yugoslav Republic of Macedonia.

Nowadays the human insulines and insuline analogues are used in the treatment of diabetes.
The Advantages of modern insulines
Better glycemic control;
Reduction of hypoglycemia
The reduction of the weight;
Low variability of developing of the complication.
The objective of the survey is to come up to the specific functional benefits about modern insulines through the data analysis, and through researching of
Hemoglobine A1C
The presence og hypoglycemia
Fasting blood glucose.
There were analyzed 40 patients aged 50–80 years in the period of 5 months, who were transferred from a human to modern insulin analogues. Of these, 22 were men and 18 were women.
Conclusion
- The research was done on 40 patients (22 males, 18 females).
- The transfer from human to modern insuline was done on 37 patients although on 3 patients that transfer was done to insuline glargine.
The reason of this transfer was the enormous increasing of their weight.
- According to the hypoglycemias there was reduction of their number despite their glycemic control.
Besides this only two patient complained on the major hypoglycemia and the main reason for this was not taking their meal during the day.
The measurement and the values of AB A1C showed that only 5 patients had hemoglobine A1C higher then 9.
Fasting blood glucose refered from 6.5 mmol/l to 7.9 mmol/l.
Keywords: insuline analogues, Hemoglobine A1C, hypoglycemia, hyperglycemia.

**Effects of octylphenol and bisphenol A on the expressions of calcium transport genes during pregnancy in mice**

S. Kim, H. Yang & E. Jeung
Chungbuk National University, Cheongju, Republic of Korea.

Introduction
Octylphenol (OP) is a degradation product of alkylphenol ethoxylates that are widely used to in rubber, pesticides and paints. Bisphenol A (BPA) is an organic compound with two functional phenol groups and used to make polycarbonate plastic and epoxy resins, along with other applications. OP and BPA are known as endocrine disruptors that can induce inappropriate estrogenic action, and may disturb natural calcium metabolism. In the present study, the effects of OP and BPA on the calcium levels of serum and urine, and calcium transport genes were investigated in the duodenum, kidney and placenta of the pregnant mice.
Methods
From 6.5 to 16.5 days after post coitus (dpc), pregnant mice were orally given with ethylestradiol (EE, 0.2 mg/kg/day), OP (15, 45, or 135 mg/kg/day) or BPA (5 or 50 mg/kg/day) dissolved in corn oil. The duodenum, kidney, placenta, blood and urine were obtained from mice at day 18.5 of pregnancy.
Results
As a result, serum and urinary calcium levels were decreased by OP and BPA in a dose dependent manner. The expression levels of calcium transport genes, TRPV6, TRPV5 and CaBP-9k were decreased in the kidney after treatment with OP and BPA, while duodenal expression of TRPV6 was reduced by high a dose of BPA. In the placenta, the gene expressions of TRPV6 and CaBP-9k were induced in the mice treated with OP, whereas it was not altered by BPA.
Conclusion
OP and BPA altered gene expressions of calcium transport in the pregnant mice, which may cause reduced serum and urine calcium levels. These results suggest that estrogenic actions of OP and BPA may lead to influence the calcium levels during pregnancy in the mice.
Declaration of interest

**Effects of Quercetin on mRNA expression of Steroidogenesis genes in Primary Cultures of Interstitial Leydig cells treated with Atrazine**

S. Abarikwu[1], A. Pant[3] & E. Farombi[2]
Indian Institute of Toxicology Research, Lucknow, India.

The mechanisms of reproductive malfunction of male mammals caused by atrazine (ATZ) remain unknown. To explore the effects of ATZ on the expressions of StAR (steroidogenic acute regulatory protein), CYP (cytochrome-P450) 11A1, CYP17A1, 3β-HSD (3β-hydroxysteroid dehydrogenase), INSL-3 (insulin-like factor 3), AR (androgen receptor), ER (estrogen receptor), LHR (luteinising hormone receptor) and INH-α (inhibin-alpha), we isolated Leydig cells from healthy immature rats (18–20 days Wistar rats), set up Leydig cell cultures, evaluated the toxicity, and measured the expression levels of mRNA of tested genes by real-time polymerase chain reaction method after cultured Leydig cells were exposed *in vitro* to ATZ (232 μM) for 6 h. The results showed that the survival rate of Leydig cells decreased sharply with ATZ which could be blocked by a phytochemical agent, quercetin (50 μM). The mRNA expression of the tested genes increased with ATZ treatment which could be block by quercetin except AR and ER expressions. Furthermore, the phytochemical agent (15–50 μM) caused a dose-dependent increase in both AR and ER mRNA expressions, suggesting stimulatory effects of QT on AR and ER-responsive signaling. The expressions of these genes were unaffected by cyclic-AMP when the stimulatory effects of ATZ on the tested genes were sustained. These findings suggest that ATZ may stimulate the expression of the tested steroidogenesis genes via a mechanism independent of cyclic-AMP signalling which could be blocked by QT. In addition, QT might promote the survival of interstitial Leydig cells exposed to ATZ.

**Octylphenol and triclosan induced proliferation of human breast cancer cells via an estrogen receptor-mediated signaling *in vitro***

H. Lee, M. Park, B. Yi & K. Choi
Chungbuk National University, Cheongju, Republic of Korea.

The class of endocrine disrupting chemicals (EDCs) is comprised of both naturally occurring and man-made compounds which are structurally similar or distinct to estrogen, and can interfere with the actions of an endogenous steroid hormone via estrogen receptors (ERs). Octylphenol (OP) is alkyl phenol chemical, which is considered to be a low-level endocrine disruptor owing to its tendency to mimic estrogen. It has been reported that triclosan can cause endocrine disruption and has weak estrogenic properties with binding to ERs. In this study, we examined that these EDCs, which have an estrogenic activity, can induce cell growth of human breast cancer cells via an ER-dependent signaling pathway by using the cell proliferation assay, semi-quantitative RT-PCR and Western blot analysis. Treatments of MCF-7 breast cancer cells with OP and triclosan resulted in the stimulation of their cell gorwth and induced the alteration of transcriptional and translational levels of cell cycle-related genes. These OP and triclosan increased the proliferation of MCF-7 breast cancer cells in a dose-dependent manner, similar to 17-beta estradiol (E2). We also found that they caused the induction of cyclin D1 gene and reduction of p21 gene at tranlational levels. It can be assummed that the alterations of genes associated with G1/S transition in MCF-7 cells by OP and triclosan may result in the increase of cell growth. However, cell growth and alteration of genes caused by OP and tricalosan can be reversed by an ER antagonist, ICI 182,780, in these cells. An activation of an ERa signaling pathway by propyl pyrazoletriol (PPT) can promote the stimulatory effect of OP and triclosan on the alteration of transcriptional regulation in cell cycle. To ensure the effect of these EDCs on ERa, we knowdowned ERa by siRNA in MCF-7 cells. When ERa level was knockdowned in these cells, the effects of these EDCs on the upregulation of cyclin D1 and downregulation of p21 disappeared. Taken together, OP and triclosan can lead to stimulate breast cancer cell growth via the alterations of cyclin D1 and p21 genes in human breast cancer cells through an ER-mediated signaling pathway. A further study is required to determine the effects of EDCs on breast cancer carcinogenesis *in vivo*.

**Endocrine disrupting chemicals induced alteration of cell cycle related genes resulting in proliferation of human breast cancer cells via an estrogen receptor-mediated signaling pathway *in vitro***

H. Lee, B. Yi, E. Jeung & K. Choi
Chungbuk National University, Cheongju, Republic of Korea.

Endocrine disrupting chemicals (EDCs) have brougt the growing concern about the potential to interfere with the endocrine system and to cause health problems. Among EDCs, bisphenol A (BPA) and 1,1,1-trichloro-2,2-bis(4-methoxyphenol)-ethane (methoxychlor, MXC) can bind to estrogen receptors (ERs) and lead abnormality of ER depenent signaling pathways, resulting in human health problems such as dysfuction of reproduction and carcinogenesis. In this study, we investigated whether BPA and MXC promote transition of cell cycle and the cell growth by ER binding in human breast cancer cells, MCF-7 cells. We further examined the alterations of the cell cycle -related genes in MCF-7 cells following treatments with BPA or MXC, compared to a vehicle (EtOH). Both BPA and MXC induced up-regulation of cyclin D1 and down-regulation of p21. To determine whether BPA and MXC increase the growth of MCF-7 cells though an ER signaling pathway, we co-treated MCF-7 with agonists of ER signaling pathways (propyl pyrazoletriol, PPT, and diarylpropionitrile, DPN) or an antagonist of ER (ICI 182,780) in the presence of BPA or MXC. The effect of BPA and MXC on the breast cancer cell growth was enhanced in the presence of PPT in MCF-7 cells. The expressions of cyclin D1 and p21 were altered by BPA or MXC in the presence of PPT, but it was less altered by them in the presence of DPN. We knockdowned ERa gene expression via siRNA in MCF-7 cells before EDCs treatment. When the expression level of ERa was knockdowned in MCF-7 cells, effects of BPA and MXC were lost on the expression levels of cyclin D1 and p21 genes. Taken together, these results indicate that BPA and MXC altered the

gene expressions associated with cell cycle, especially in G1/S transition, and resulted in the stimulation of breast cancer cell growth via an ERa signaling pathway. These collective results confirm that these EDCs may have the carcinogenicity via an ER-mediated signaling pathway in vitro. A futher study is required to determine whether EDCs may have a potency to be carcinogenic in human breast cancer cells.

**Bisphenol A and phthalate stimulated the growth of human prostate cancer cells and altered downstream target genes of ras signaling pathway**

K. Kim, H. Lee & K. Choi

Chungbuk National University, Cheongju, Republic of Korea.

Prostate cancer have been most cause of cancer death to men in recent, but there are not effective treatments for this cancer. In growth of prostate cancer, steroid hormones such as androgen play a role in their growth and survival. However, endocrine disrupting chemicals (EDCs) intend to bind the hormone receptor and induce the abnormal hormone response. EDCs have potency to activate estrogen receptor (ER) and androgen receptor (AR) mediated signaling pathways, and they cause the human health problem including hormone-dependent carcinogenesis. Bisphenol A (BPA) has the phenolic structure with the effect on the endocrine system and promotes human breast cancer. Recent studies have reported that phthalates have a potency to disrupt reproductive system in male rodents. Thus, we identified in this study whether BPA and dibutyl phthalate (DBP) stimulate the cell growth of prostate cancer cells, LNCaP cells, which have both ERs and ARs. We evaluated proliferation of LNCaP cells following BPA and DBP treatment using a cell viability assay. Both BPA and DBP promoted LNCaP cells proliferation over two-fold at $10^{-7}$ M to $10^{-5}$ M compared to a vehicle. Further, we examined the alteration of the downstream target genes of ras signaling pathways by using the semi-quantitative RT-PCR. Like 17b-estradiol (E2) and dihydrotestosterone (DHP), the treatments with BPA and DBP resulted in a significant increase in the transcriptional levels of c-myc and c-fos in LNCaP cells at 30 min to 6 h, compared to a vehicle. In addition, these EDCs induced cyclin D1, a cell cycle related gene, at 6 h after treatment. Taken together, these results suggest that BPA and phthalate can alter gene expressions of downstream targets associated with ras signaling and cell cycle related pathways in prostate cancer cells. A novel effect of EDCs may result in the cell growth of human prostate cancer cells. A further study warranties to determine the potential of EDCs in the carcinogenesis of prostate cancer. **Treatment with resveratrol resulted in an inhibition of cell proliferation induced by 17 β-estradiol or various endocrine disrupting chemicals via down-regulating the cell cycle progression in BG-1 ovarian cancer cells**

N. Kang, K. Hwang & K. Choi

Chungbuk National University, Cheongju, Republic of Korea.

Resveratrol (trans-3,4,5-trihydroxystilbene, RES), a phytoestrogen, exists in grape skin and red wine. Endocrine disrupting chemicals (EDCs) appear to promote the development and progression of the estrogen dependant cancers. In this study, we evaluated the inhibitory effect of RES on the cell growth and progression induced by various EDCs in BG-1 ovarian cancer cells expressing estrogen receptors (ERs). The various EDCs, i.e., bisphenol A (BPA), nonylphenol (NP), octylphenol (OP), methoxychlor (MXC), and hexabromocyclododecane (HBCD) were employed in this study. In the *in vitro* experiments, treatments of BG-1 cells with E2, BPA, NP, OP, MXC, or HBCD resulted in an increase of their growth. The treatment of BG-1 cells with ICI 182,780, a well known antagonist of ERs, reversed EDCs-induced cell growth in these cells, indicating that their growth-stimulatory effect is mediated through ERs. In addition, we evaluated the effect of RES in the presence of other EDCs by MTT assay. As a result, increased cell viability induced by these EDCs was reversed when co-cultured with RES. In addition, we further examined the regulation of cell cycle-dependent genes by RT-PCR. Concretely, the treatment with each EDC only decreased the gene expression of p21 and increased the expression of cell cycle-dependent kinase 2 (CDK2). However, co-treatment with RES and one of EDCs resulted in the increased gene expressions of p21 and the decreased expression of CDK2. Cyclin D1 was increased by down regulating p21 when only treated with each EDC in the absence of RES, while co-treatment with RES and each EDC decreased the gene expression of cyclin D1 by upregulating p21. Taken together, these results indicate that RES appears to be an inhibitor of Cyclin D1 and CDK2 and is responsible for the cell cycle arrest at G1 phase. In addition, when co-treated with each EDC, RES increased the expressions of p21 and resulted in the growth inhibition of BG-1 ovarian cancer cells. As a result, we confirmed the cell growth inhibitory effect of RES, a dietary phytoestrogen, on the estrogen-dependant ovarian cancer cells prompted by EDCs.

**Perinatal exposure to a commercial formulation of glyphosate reduces the mRNA expression and increases the protein content of beta TSH in the pituitary of male offspring.**

R. Romano[1], P. Souza[1], M. Nunes[1] & M. Romano[2,3]

University of Centro-Oeste, Guarapuava, Brazil.

Glyphosate is a broad spectrum herbicide that is effective against weeds, especially in association with transgenic glyphosate resistant crop systems, and represents approximately 30% of all herbicides used in agriculture. It was demonstrated that glyphosate has an activity of endocrine-chemical disruptor (ECD) in the reproductive axis, altering the production of testosterone and causing disturbances on the reproductive development of male offspring from dams treated during the gestational period. The hypothalamic-pituitary-thyroid axis is quite sensitive to be a target of many ECDs, but it is not known if glyphosate may affect it. To evaluate this possibility 90-day-old female Wistar rats were mated in a monogamous couples and the beginning of gestation (GD1 – gestational day) was confirmed by vaginal smear containing spermatozoa. Glyphosate Roundup Transorb was diluted in a watery suspension and administered to the mothers once a day, p.o. from GD18 to PND5 (post natal day) (50 mg/kg or 0 mg/kg for control group). The male offspring were decapitated at PND60 and the pituitaries submitted to analysis of beta TSH and alpha subunit mRNA by RT/qPCR and to protein content by Western Blotting. The genes RPL19 and GAPDH were used as internal control and the results were analyzed by Student's *t*-test ($P<0.05$). Perinatal exposure to glyphosate decreased the content of beta TSH mRNA and increased its protein content in the pituitary, without altering the expression of alpha subunit. These results show for the first time the effects of glyphosate in the pituitary-thyroid axis and demonstrated that the EDC effect of glyphosate is not restricted to the reproductive axis. It is not known whether the dose used in this study is in fact the levels of exposure of population to the glyphosate herbicide. However, it was shown that women occupationally exposed to this herbicide have reproductive disorders and may also need necessary to consider in the future the possibility of disturbances in the thyroid function.

**Synergistic effects of bisphenol A and paraben on the induction of calbindin-D9k and progesterone receptors via an estrogen receptor pathway in rat pituitary GH3 cells**

E. Jung, K. Choi & E. Jeung
Chungbuk National University, Cheongju, Republic of Korea.

Introduction
There are concerns about the combined estrogenic effects of endocrine disrupting chemicals (EDCs), since mixtures of these chemicals exist in our environment. This study investigated potential synergistic interactions between bisphenol A (BPA) and isobutylparaben (IBP), which are major xenoestrogens used in the manufacture of plastics, cosmetics, drugs, and other products. The combined effects of these two chemicals were analyzed by measuring expression of calbindin-D9k (CaBP-9k) in the rat pituitary GH3 cells.
Methods
GH3 cells were treated with single and combination doses of both chemicals (BPA single doses: $10^{-7}$, $10^{-6}$ and $10^{-5}$ M; IBP single doses: $10^{-7}$, $10^{-6}$ and $10^{-5}$ M, and each of BPA and IBP doses combined). Prior to treatment, the cells were temporarily transfected with a plasmid containing an estrogen response element (ERE). A luciferase activity was measured as an indicator of ERE activation by 17β-estradiol (E2), BPA, and IBP.
Results
In addition to E2, EDC induced a significant increase in luciferase activity. Twenty-four hours after treatment, dose-dependent effects were observed in both single and combined groups, and several combined doses induced a synergistic increase in the expression of CaBP-9k and progesterone receptor (PR) at both transcriptional and translational levels. Pre-treatment with fulvestrant, a pure estrogen antagonist, significantly reversed EDC-induced CaBP-9k and PR upregulation in GH3 cells.
Conclusions
Our results indicate that BPA and IBP may have synergistically increased estrogenic potency via an estrogen receptor-mediated pathway.
Declaration of interest

## P755

**Benzophenone-1 promoted cell growth of BG-1 ovarian cancer cells with estrogen receptors via progression of cell cycle**

M. Park, H. Lee, E. Jeung & K. Choi
Chungbuk National University, Cheongju, Republic of Korea.

Benzophenones are organic chemicals widely used as stabilizers to UV light irradiation in plastic surface coatings and food packaging. They have been known that their derivatives appear to have cytotoxic effects. 2-Hydroxy-4-methoxybenzophenone (Benzophenone-3, BP-3) and its metabolite, 2,4-dihydroxybenzophenone (Benzophenone-1, BP-1), are used mostly in the formulation of nail polishes, enamels, bath products, sunscreens and skin care products. In this study, the estrogenic effects of BP-1 were examined in an ovarian cancer BG-1 cells expressing high levels of estrogen receptors (ERs) by an cell viability assay, semi-quantitative reverse-transcription PCR (semi-quantitative RT-PCR) and Western blot analysis. The treatment of BG-1 cells with BP-1 ($10^{-8} \sim 10^{-5}$ M) resulted in an increase in their cell proliferation as 17-beta estradiol (E2) did. But, the cell growth stimulation by BP-1 was reversed by cotreatment with ICI 182,780, an ERs antagonist, suggesting that the proliferation of BG-1 cells is mediated by an ER-dependent pathway. In addition, BP-1 upregulated the expression levels of cell-cycle regulating genes, i.e., cyclin D1, which is a downstream target of ER, at 6 h after treatment. But, the expression of p21 gene was not altered by BP-1 at any time points. In translational levels, BP-1 also upregulated the expression level of cyclin D1 at 24 h after its treatment. Taken together, these results suggest that BP-1 is one of EDCs with have apparent estrogenic activities by stimulating cell proliferation of BG-1 cells and by inducing the expression of cyclin D1. Our results can support that BP-1 may have a potency to disrupt endocrine system and to stimulate cell growth in ER-positive cancer cells. ## P756

**A phytoestrogen, genistein, reversed 17 β-estradiol or bisphenol A-induced cell growth via downregulation of the cell cycle progression in BG-1 ovarian cancer cells**

K. Hwang, N. Kang & K. Choi
Chungbuk National University, Cheongju, Republic of Korea.

One of estrogens, 17b-estradiol (E2), is a pleiotropic hormone that regulates the growth and differentiation of many tissues and also acts as a mitogen that promotes the development and proliferation of hormone-responsive cancers. Bisphenol A (BPA) is a widely used industrial compound and classified as one of endocrine disrupting chemicals (EDCs) and especially a xenoestrogen that imitates estrogen in living organisms. In this study, we examined the effect of a phytoestrogen, genistein, on the cell growth of BG-1 ovarian cancer cells expressing estrogen receptors (ERs) caused by E2 and BPA. In the cell proliferation test in vitro, E2 or BPA increased the growth of the BG-1 ovarian cancer cells expressing ERs. Their proliferation activity was reversed by the treatment of ICI 182,780, a well-known antagonist of ERs, which demonstrates that the cell proliferation by E2 or BPA is mediated by ERs and BPA certainly acts as a xenoestrogen in the BG-1 ovarian cancer cells. Genistein, an isoflavone, is one of phytoestrogens that are plant-derived, naturally occurring, and dietary xenoestrogens and influences multiple biochemical functions. In this study, genistein effectively suppressed the BG-1 cell proliferation induced by E2 or BPA by adversely down regulating the cell cycle progression that was upregulated by E2 or BPA. Concretely, E2 or BPA decreased the gene expression of p21, which is a potent cyclin-dependent kinase (Cdk) inhibitor and responsible for the cell cycle arrest at G1 phase, to proliferate the BG-1 cells. On the other hand, genistein upregulated the expression of p21 gene cultured in the presence of E2 or BPA, leading to the growth inhibition of the BG-1 cells. Also, the alteration of p21 gene expression by E2, BPA, or genistein affected the expression of its downstream genes of cell cycle, cyclin D1 and Cdk-4. Taken together from these results, we may suggest an anticancer effect of genistein, a dietary phytoestrogen, on the estrogen-dependant cancers like ovarian cancer prompted by E2 or BPA. **Proliferative and apoptotic effects of bisphenol A and its combination with estradiol in human breast carcinoma cells**

T. Havranek, L. Macho & M. Fickova
Institution of Experimental Endocrinology SAS, Bratislava, Slovakia.

Bisphenol A (BPA) is an endocrine disruptor (ED) used as plasticiser present in plastic products of daily use. The leakage of BPA monomer into food, drinks represents the ubiquitous exposure to the general population. BPA stimulatory effect on breast cancer cells growth *in vitro* and increased incidence of hormone dependent malignancies suspected BPA from carcinogenic effect.
The aim of this study was to investigate the effects of BPA alone and in the combination with estradiol (E2, 110-12M, COM) on cell proliferation, DNA synthesis and proteins of apoptosis. The time (24, 48, 72h) and dose ($1\times10^{-15}$–$1\times10^{-6}$ M) dependent effects were compared to E2 in breast carcinoma cells MCF7. Cells were maintained in RPMI 1640 medium containing 5% dextran-charcoal-treated FBS. MTT test was used in proliferation experiments, BrdU incorporation into newly synthesized DNA was analyzed. The expressions of proapoptotic Bax, p53 and antiapoptotic Bcl-2 proteins were determined by Western blot.

Higher BPA concentrations moderately (~130%), but significantly increased proliferation (vs COM) after 48h as the consequence of previous (24 h) huge (180–220%) increase of de novo DNA synthesis (vs E2, COM). The mixture E2 (10–12 M)+BPA induced 140–160% increase of DNA synthesis (vs BPA, E2) after 48 h, followed by enhanced proliferation (~140%, vs BPA, E2) after 72 h thus exceeding effects of individual compounds. The mixture had neither additive, nor synergic effect.
E2 (48 h) reduced p53 (by 20%) while BPA displayed a slight stimulation; E2+BPA inhibited p53 as E2. Similar tendencies of changes were observed in Bax protein. No modifications in Bcl-2 was present except moderate increase by BPA (vs E2 and COM) after 48 h.
BPA and mixture BPA+E2 stimulate MCF7 cells proliferation after preceding elevated DNA synthesis and by protein modification(s) of apoptosis.

**Parabens inhibit ovarian follicle development of neonatal female rats**
H. Ahn, H. Yang & E. Jeung
Chungbuk National University, Cheongju, Republic of Korea.

Introduction
Parabens, esters of para-hydroxybenzoic acid, are widely used as an antimicrobial agent in the cosmetic products and pharmaceutical industries. Recently, it has been reported that parabens including methyl-, ethyl-, propyl-, butyl-, isopropyl-, and isobutylparaben act as xenoestrogens, a class of endocrine disruptors. In this study, we hypothesized that parabens may disrupt ovarian follicle maturation in female rats during the neonatal period.
Methods
Fifty-five female neonatal rats were divided into eleven groups, and were given daily subcutaneous injection, with methyl-, propyl- and butylparaben (62.5, 250, or 1000 mg/kg/day) at neonatal 1–7 days. The total mRNA and protein were extracted from the ovaries excised at the postnatal day 8 of female rats, and the levels of AMH mRNA and protein were analyzed by real-time PCR and Western blot analysis. The ovaries were also fixed and stained with H&E for histological analysis.
Results
The regulation of AMH gene expression was modulated by propyl-, butyl-parabens and methyl-paraben. The mRNA and protein levels of AMH significantly were increased by treatment of butylparaben while they were decreased by methyl-paraben. The number of follicles was counted and classified into primordial, primary, or secondary stages after serial sections of the ovary. The histological results showed that total number of follicles and primordial follicles was increased by butylparaben compared to a negative control.
Conclusion
Butylparaben may have an estrogenic effect to disrupt ovarian follicle development in the neonatal female rat.

**Bisphenol-A exposure from electronic gadgets: A risk assessment**
N. Kumar[1,2], R. Khan[1], P. Kumar[3] & V. Sharma[2]
Jawaharlal Nehru University (A Central University), New Delhi, India.

We are living in the electronic era and day to day exposed by estrogenic disruptors such as Bisphenol-A (BPA). Electronic gadgets such as cellular phones, CDs, DVDs, RFIDs even baby feeding bottles are made with composition of BPA and their huge application are matter of debate in present. The chronic exposures of BPA have become a major health concern. In this study we assessed the neurobehavioral alterations caused by BPA in the rats. We examined the neurobehavioral changes in Albino Wister rats of (190±20) g body weight. Two groups of rats, control and BPA treated (4 mg/kg body weight in corn oil), were used to find the effects of BPA. Neuro-behavioural studies were carried out as per plan after the last dose of treatment. A set of five rats randomly selected from each treatment group was used to assess spontaneous locomotor activity 24 h after the last dose of treatment. The same set of rats was used to measure grip strength, 1 h after the spontaneous locomotor activity test. Locomotor activity parameters were assessed in control and BPA treated rats at age of 90 and 120 days. Exposure to BPA in rats caused a decrease in total distance travelled (42%), stereotypic time (52%), time moving (38%), rearing (44%) and an increase in resting time (17%) as compared to rats in the control group. Finally we observed that BPA exposure (4 mg/kg b.wt.) cause neurobehaviour alterations in rats. The chronic exposure of BPA may cause neurotoxicity and that can result mental problems like weakness, memory, cognitive and locomotor dysfunction etc.

**Unconjugated bisphenol A cord blood levels in boys with descended or undescended testes**
P. Fénichel[1], H. Déchaux[2,3], C. Harthe[3], P. Ferrari[1], P. Pacini[1], K. Wagner-Mahler[1], M. Pugeat[2,3] & F. Brucker-davis[1]
Hospicesw civils d eLyon, Lyon, France.

Background
Human toxicity of bisphenol-A (BPA), a weak estrogenic environmental endocrine disruptor widely used in plastics, babybottles, cans and dental sealants, is under investigation. Human pharmacokinetics involves a rapid inactivation by hepatic glucuronyl- or sulfoconjugation and renal clearance. Fetal or perinatal exposure in rodents is associated with programmed adult reproductive diseases. Human epidemiological studies remain scarce especially concerning testicular development.
Methods
Using a radioimmunoassay performed after extraction, validated by HPLC and mass spectrometry, active, unconjugated BPA (uBPA) cord blood (CB) levels were measured in 152 boys born after 34 weeks of amenorrhea with or without descended testes.
Results
Active uBPA was detectable in all CB samples with values in the control group (N=106) between 0.14 and 4.76 ng/ml, median: 0.9 ng/ml; mean±SD: 1.12 ng/ml±0.86 ng/ml. uBPA in controls correlated with CB inhibin B ($P<0.01$) and total testosterone ($P<0.05$) and maternal milk polychlorinated bisphenyl (PCB) 138 ($P<0.03$). uBPA did not correlate with clinical maternal or fetal parameters nor with other steroid or polypeptidic CB hormones assessed. uBPA levels were not significantly different in cryptorchid boys (N=46): 1.26±1.13 ng/ml ($P=0.38$).
Conclusions
uBPA was present in all cord blood samples assessed, illustrating placenta transfer and foetal exposure due to either placental hydrolysis of maternal conjugated BPA and/or immaturity of fetal detoxification capacity. uBPA correlation with testosterone CB levels could be in relation to androgen dependent regulation of glucuronyltransferase gene expression. Lack of difference of cord blood uBPA levels between control and cryptorchid groups in this prospective study, makes unlikely the participation of fetal exposure to uBPA in the physiopathology of undescended testes. However the observed uBPA concentrations (nM) similar to those able to induce relevant effects in vivo in rodents or *in vitro* in human cancer cell lines, invite to further assess epidemiological relationship between cord blood uBPA and other human reproductive or not reproductive diseases.

**Measurement of estrogen receptor alpha homodimerization caused by xenoestrogens using bimolecular fluorescence complementation**

P. Tarnow, D. Hunecke & A. Luch
Federal Institute for Risk Assessment, Berlin, Germany.

Introduction
After binding its ligand, a conformational change in estrogen receptor alpha (ERα) occurs, leading to subsequent homodimerization of two monomeric ERs. The dimer then binds to specific DNA-elements or to other transcription factors already bound on gene promoters to regulate target gene expression. Protein-fragment complementation assays in general are simple tools to monitor protein–protein interactions and are useful to visualize the subcellular sites of interactions in living cells. In case of bimolecular fluorescence complementation (BiFC), two fragments of a fluorescent protein (e.g. YFP) are genetically fused to proteins of interest. The single fragments show no fluorescence, but when the proteins mutually interact, the fluorescent protein refolds and gives a fluorescence signal. Here we aimed to use BiFC to monitor ERα homodimerization after stimulation with several estrogenic substances present in human environment.
Methods
To monitor ERα dimerization we fused full length ERα to the carboxyterminal and aminoterminal fragments of the citrine variant of YFP and cotransfected these constructs transiently into COS-7 cells. After stimulation with estrogens, fluorescence was measured in a photometer or visualized by confocal microscopy.
Results and Conclusions
Compared to mock transfected cells cotransfection caused a visible fluorescence signal in the nuclei of transfected cells. Stimulation of the cells with the ERα agonists 17β-estradiol (E2), bisphenol A, genistein and butylparabene but also with the antagonist fulvestrant (ICI) and the selective estrogen receptor modulator 4-hydroxytamoxifen (4-OHT) dose dependently increased fluorescence signals. Interestingly, ICI and 4-OHT stimulation caused higher fluorescence signals than E2. If this is caused by a higher amount of dimers or by conformational differences remains to be shown. Except stimulation with ICI, which translocated ERα-dimers into cytoplasma, fluorescence signals were only seen in the nuclei. The partial ERα agonist 4-bethylbenzylidene camphor as well as the heavy metal cadmium caused no increase of the fluorescence signal.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**The effects of BPA exposure on fat mass and serum leptin concentrations have no impact on bone mineral densities in non-obese premenopausal women.**

J. Liu, H. Zhao, Y. Bi, L. Ma, L. Zhang, L. Zhao, B. Tao, L. Sun, T. Wang, Y. Zhao, W. Wang, M. Xu, J. Chen & G. Ning
Rui-jin Hospital, Shanghai Jiao-tong University School of Medicine, Shanghai, China.

Objective
Bisphenol A (BPA) exposure may promote obesity, but its effect on bone mineral density (BMD) has not been reported in humans. In the present study, we aimed to examine the complex interplay between BPA exposure, fat mass, fat-free mass, serum estradiol, leptin, osteocalcin levels and BMDs in a group of premenopausal women.
Methods
A total of 246 Chinese premenopausal women aged 20 years and older with regular menstrual cycles were investigated. Body mass index (BMI), fat mass, fat-free mass and BMDs were measured by DXA. Serum estradiol, leptin, osteocalcin, urinary BPA and NTx levels were also tested.
Results
Urinary BPA levels were positively associated with fat mass ($r=0.193$, $P=0.006$) and leptin ($r=0.236$, $P=0.001$) but not with fat-free mass after adjusting for age and BMI. A multivariate stepwise regression analysis confirmed the positive association between BPA and leptin ($\beta=0.31$, $P<0.001$). Serum leptin levels were positively influenced by fat mass ($\beta=0.746$, $P<0.001$) and BPA ($\beta=0.127$, $P=0.01$) but negatively correlated with fat-free mass ($\beta=-0.196$, $P<0.001$). The changes of BMDs at the lumbar-spine ($\beta=0.298$, $P<0.001$) and femoral neck ($\beta=0.305$, $P<0.001$) were primarily explained by fat-free mass. BPA was not associated with either serum estradiol levels or BMDs. BPA was unrelated to the bone resorption marker, NTx, or the bone formation marker, osteocalcin.
Conclusions
BPA's effect on fat mass was mediated by leptin. The neutral effect of BPA on BMDs in premenopausal women is due to the exclusive role of fat-free mass, which is unrelated to BPA, rather than of fat mass or leptin in determining BMDs.
Declaration of interest

## P763

**The effects of endocrine disruptor compounds on the hormone release of rat pituitary *in vitro***

M. Radacs, Z. Valkusz, T. Ocsko, Z. Molnar, P. Varga, E. Marsi & M. Galfi
University of Szeged, Szeged, Hungary.

The endocrine disruptor compounds (EDC) (e.g. chlorobenzenes (ClB), phenurone (PU), monurone (MU), diurone (DU)) are accumulative, lipophilic, chemical pollutants that can disturb the homeostatic balance and exert tumorigenic effects. The aim of the present study was to investigate the effects of EDCs on the adrenocorticotropic hormone (ACTH) and prolactin (Prl) release in primary cell cultures derived from rat normal adenohypophysis and prolactinoma.
The prolactinoma formation was induced by estrone-acetate (2 mg/bw kg/day; subcutan for 6 months). The ten-day-old cell cultures, obtained from rat normal adenohypophysis and prolactinoma, were treated as follows: I. 0.1 μg/ml EDCs (ClB, MU, DU, PU) for 1 hour; II. 10 μg/ml arginine-vasopressine (AVP) for 1 hour in itself and subsequently 10 μg/ml corticosterone was also added; III. EDCs in combinations with AVP and corticosterone. ACTH and Prl levels were detected in supernatant media by radioimmunoassay. The protein content was measured by Protein Assay system.
The basal ACTH (1500 pg ACTH/mg protein) and Prl (7 ng Prl/mg protein) levels did not change significantly after the EDC treatment in the supernatant media of the adenohypophysis cell culture. The EDCs (ClB:14500; PU:11900; MU:13100; DU:13800 pg ACTH/mg protein) significantly increased the AVP induced ACTH release of normal adenohypophyseal cells (10200 pg ACTH/mg protein) but did not influence the effects of corticosterone. The prolactinoma cells showed increased secretions of ACTH (2200 pg ACTH/mg protein) and Prl (17,2 ng Prl/mg protein) compared with the normal adenohypophyseal cells. The basal ACTH and Prl levels in the supernatant media of the prolactinoma cells were significantly increased by the EDC treatments (ClB:2973; PU:2417; MU:2539; DU:2701 pg ACTH/mg protein; ClB:23.1; PU: 19.7; MU:21.5; DU:22.4 ng Prl/mg protein).
The ACTH and Prl synthesis and release capacity of normal adenohypophyseal and prolactinoma cells were altered by EDCs. This work was supported by: TAMOP 4.2.1/B-09/1/KONV-2010-0005; HURO/0901/037/2.2.2.

**Activation of the enzymes of phase I (CYP1A1 and CYP2B1/2) and phase II (SULT1A and COMT) metabolism by BDE-47 in the ovary.**

A. Karpeta, J. Jerzak, A. Ptak & E. Gregoraszczuk
Jagiellonian Univeristy in Krakow, Krakow, Poland.

The aim of the current study was to determine whether the porcine ovary was capable of metabolizing polybrominated diphenyl ether – BDE-47, which is the most abundant congener found in wildlife and in humans. It have been showed by us that this congener disrupt ovarian function by direct action on steroidogenesis. In the current study we analyzed the activity and expression of enzymes involved in phase I (CYP1A1 and CYP2B1/2) and phase II (SULT1A and COMT) of BDE-47 metabolism. CYP1A1 and CYP2B1/2 activity was determinated by conversion of ethoxy- and pentoxyresorufin in resorufin respectively, using fluorescent method. Enzymes of II phase of metabolism were evaluated by colorimetric methods: SULT1A activity was based on sulfotransferase ability to release p-nitrophenol with the PAPS, and the activity of COMT, based on the ability of

catechol-O-methyltransferase to convert nitrocatechol (NC) for 3-metylnitrocatechol (2-methoxy-4-nitrophenol) with S-adenosylmethionine (SAM). Additionally, protein level was determined by immunoblot and ELISA. Basal CYP1A1 and CYP2B1/2 activity increased during culture. BDE-47 had no effect on CYP1A1 activity, however CYP2B1/2 activity increased after exposure for 1 and 6 h. Basal SULT1A activity was 2.5 fold lower than that of COMT, and both proteins were stable during culture. BDE-47 increased SULT1A activity after exposure for 6 and 12 h, and COMT activity increased after exposure for 24 and 48 h. For the first time we demonstrated SULT1A protein levels in pig ovary measured by immunoblot and ELISA analyses. BDE-47 had no effect on the expression of all investigated enzymes.
In conclusion, fast activation of CYP2B1/2 and late activation of COMT (with a very low basal SULT1A activity) indicates a possible action of locally produced hydroxylated metabolites prior to their detoxification.

**Changes of hemostatic variables during cross-sex hormone treatment in transsexual people.**

M. Sánchez-Pacheco, M. Mijares-Zamuner, G. Negueruela-Avellán, L. Segura, P. Marco, A. Picó-Alfonso & O. Moreno-Pérez
Hospital de Alicante, Alicante, Spain.

Introduction
Cross-sex hormone treatment (CHT) in male-to-female (M2F) transsexuals affects the hemostatic balance, with the emergence of a prothrombotic state with the use of certain estrogen (oral ethinyl estradiol vs 17β estradiol). Testosterone administration to F2M transsexuals had an antithrombotic effect. In female-to-male in (F2M) transsexuals administration of testosterone seems to carry a mild antithrombotic effect.
Objective
To quantify prevalence of alterations in the coagulation parameters in naive transsexuals people for CHT. To quantify changes of hemostatic variables after 12 months of physiology doses treatment: M2F (17βestradiol with cyproterone acetate/espyronolactone) and F2M (testosterone td, im).
Subjects and Methods
A prospective, observational study of 47 CHT-naive patients; available data of hemostatic balance in 15 patients (8 M2F, 7 F2M) baseline and after 12 months of treatment. Statistical analysis: descriptive statistics and prevalence; Wilcoxon test for paired data for changes in hemostatic state (SPSS 11.0 for windows).
Results
Prevalence of coagulation alterations 21%(IC95%12–35): 3 patients antiphospholipid antibody; 6 prothrombin gene G20210A mutations, 1 increased beta 2 glycoprotein. Antiplatelet treatment was initiated in two M2F (acetylsalicylic acid). Significant differences of hemostatic variables were demonstrated in M2F people on Trombin Time. There were not differences on F2M.
Conclusions
The prevalence of coagulopaties in transsexual people is moderated and similar to general population. The administration of 17βestradiol in combination with cyproterone acetate on M2F or testosterone on F2M it was not associated with changes of hemostatic balance.

**The relation for normal fasting plasma glucose levels and metabolic syndrome in normoglycemic adults.**

Y. Cho
Pusan National University Yangsan Hospital, Yangsan, Republic of Korea.

Background
Metabolic syndrome has been introduced to increase the incidence of cardiovascular diseases and type 2 diabetes mellitus. Our aim of this study was to investigate the relation for normal fasting plasma glucose levels and metabolic syndrome in normoglycemic adults.
Methods
The study subjects consisted of 636 individuals who visited the Center for Health Promotion in Pusan National University Hospital for a medical checkup in 2002 to 2005. Among 636 subjects, 469 subject who don't have metabolic syndrome and had normal fasting plasma glucose, were included and followed up for 3years. We measured fasting glucose, lipid profiles blood pressure and their metabolic components.
Results
As the quartile of plasma glucose, 3 year follow-up incidence of the metabolic syndrome was increased. Logistic regression analysis adjusting for sex, age, alcohol drinking status, smoking status, and physical activity showed that the odds ratio(95% confidence Interval, P-value) of each plasma glucose quartile was 1.127(0.549∼2.314, $P=0.744$), 2.131(1.121∼4.051, $P=0.021$), 3.235(1.682∼6.224, $P=0.000$), respectively
Conclusion
As shown above, These results showed that normal fasting plasma glucose level was closely related to the incidence of the metabolic syndrome.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Effects of neonatal exposure to thyroid hormones on gene expression profile of the pituitary-thyroid-liver axis in rats**

N. Fujimoto[1], K. Matsubara[2], S. Sanoh[2], S. Ohta[2], S. Kitamura[3] & K. Sugihara[4]
Hiroshima International University, Kure, Japan.

Purpose
Disruption in thyroid hormone homeostasis by environmental chemicals during the prenatal and/or neonatal period might lead to developmental disorders since thyroid hormones (T3/T4) play a critical role in growth and the differentiation of many tissues including the central nervous system. Neonatally given T3 or T4 disrupts the thyroid hormone system resulting in decreased serum T4 level in the adulthood in rats. In the present study, changes in gene expression profile in the pituitary-thyroid-liver axis by neonatal hyperthyroidism were examined to identify possible neonatal effects of thyroid hormone disrupting chemicals.
Materials and Methods
Male F344 rats were exposed to T3, T4 or amiodarone (0.04, 4 and 0.4 mg/kg bw, respectively) at PND 1, 3 and 5. Animals were sacrificed at 8 weeks old and total RNAs were extracted from the pituitary, thyroid and liver. Expression of the genes related to the thyroid hormone homeostasis was measured by the quantitative RT-PCR method. Serum T3 and T4 were determined by ELISA.
Results and Conclusions
1) Neonatal hyperthyroidism resulted in lower serum T4 level in rats at 8 weeks old. 2) Expressions in thyroid hormone receptor alpha, T3 responsive genes (RLT3-2 and RLT3-24) and an enzyme related to T3/T4 metabolism, Sult1C3, increased in the thyroid and liver tissues in T3/T4 treated groups. 3) Amiodarone showed the similar effects on the gene expression profile with T3 albeit in a lesser extent. The present study demonstrated that neonatal exposure to thyroid hormones irreversibly altered the expression profile of the genes related to the thyroid hormone homeostasis. In addition, amiodarone, a chemical exhibiting thyroid hormone-like activity, showed the similar neonatal effects. The changes in gene expression profile in the pituitary-thyroid-liver axis could be markers for the neonatal effects by thyroid hormone disrupting chemicals.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Apoptosis induced by arsenic is partially reverted by antioxidants in anterior pituitary cells.**

S. Ronchetti[1], S. Nudler[1], J. Cabilla[1], M. Gonsebatt[2] & B. Duvilanski[1]
Universidad Autónoma de México, México DF, Mexico.

Exposure to arsenic (As) through consumption of contaminated water is considered one of the top environmental health threats worldwide. Human exposure to As has been associated with cancer of several organs, neurological disorders and reproductive problems. Nevertheless, there are no reports on the effect of As on anterior pituitary gland and little is known about the effect of As on hormone release. We have previously shown that 25 μM As (as sodium arsenite) reduces prolactin release and pituitary cell viability after 24 h. The aim of the present work was to study the mechanisms of arsenic citotoxicity in primary anterior pituitary cultures from male Wistar rats. Arsenic decreased cell viability from 9 h of treatment (MTT assay, Abs. 600 nm, % of control (C); 9 h: 83.6 2.8*, 18h: 82.2 5.4*, 24h: 70.3 2.6***; $*P<0.05$; $***P<0.001$ vs. C). Apoptotic morphology became evident after 18 and 24 h of As exposure (% apoptotic nuclei/total nuclei; C: 3.3 0.5, 9h: 4.9 1.2; 18h: 10.3 1.4**; 24h: 11.8 1.3**; $**P<0.01$ vs. C). Mitochondrial membrane potential (DiOC6 by flow citometry) was significantly reduced after 6 h of As exposure. In parallel, there was an early increase in reactive oxygen species levels during the first hour of As exposure (DHR 123 by flow citometry). Arsenic modified mRNA expression of stress response genes [relative units as % of C, heme oxygenase-1 (3h: 172; 6h: 128; 9h: 174); metallothionein-1 (3h: 174; 6h: 121; 9h: 160); nitric oxide synthase-1 (3h: 82; 6h: 71; 9h: 96)]. Antioxidant treatment with N-acetyl-cysteine (NAC) was able to partially reverse As-induced apoptosis (annexin V- propidium iodide staining, % of C, As: 243.6; As + NAC: 180.5). These results suggest that As citotoxic action on anterior pituitary cells is produced by an apoptotic process which can begin with an imbalance on cell redox status.

**Nigella Sativa oil alleviating the reproductive toxicity of chlorpyrifos in male rat**

R. Mosbah[1], S. Azzoug[2], N. Haroun[1] & M. Boulakoud[3]
University of Badji Mokhtar, Annaba, Algeria.

Chlorpyrifos (CPF) is a worldwide used organophosphate insecticide for controlling many types of pests in the household, farm and residential settings. It has the potential to negatively affect the reproductive system and fertility. Nigella sativa has been used both as seeds or oil to promote health and fight disease. Hence, the present work was undertaken to evaluate the possible protective role of Nigella sativa oil (NSO) against chlorpyrifos induced reproductive toxicity in male rats. Thirty two adult male Wistar rats were randomly divided into 4 groups/8 of each and were daily treated for 30 consecutive days as follow: group I served as control, group II was orally administered Nigella sativa oil (NSO) (1 ml/kg/day); group III was orally given an emulsion solution of chlorpyrifos (CPF) at dose of 20 mg/kg/day, while group IV was pretreated with NSO (1 ml/kg/day) and after 30 min received CPF (20 mg/kg/day). In this experiment, body weight gain and relative weights of vital and reproductive organs, sperm characteristics, testosterone and free thyroxin (FT4) levels and histopathological changes in the testes were investigated. Results elicit that CPF induces a significant decrease in body weight gain (BWG), feed intake (FI), and the relative weight of testes (RTW) and epididymes (REW) whereas, an increase in the relative weight of liver (RLW), kidney (RKW) and adrenal gland (RAW) was noted. Besides, treatment with CPF affects markedly the semen characteristics that pronounced by a reduction in sperm count (SC) and spermatids number (SN), daily sperm production (DSP), sperm motility and viability, however abnormal sperm morphology was augmented. Serum testosterone and FT4 levels were significantly lowered in CPF-group. Histopathological examination of testes showed a decrease in the number of seminiferous tubules along by their shrinkage, enlargement of the connective tissue and gametogenic changes in germ cells. NSO co-administration with CPF reverses partly or completely the changes in the relative reproductive and vital organs weights, semen characteristics, hormones levels and the histopathological injuries of testes to the normal status and thereby improved semen quality. By the term of this research, we concluded that NSO can improve semen picture and moderate CPF-induced reproductive toxicity.

**The Interference Endocrinous – Metabolic in Thyro-gonadal Failure**

M. Bistriceanu[1], M. Popescu[1], I. Bistriceanu[2], S. Preda[1], S. Bondari[1], D. Bondari[3], A. Covei[3] & M. Preda[2]
Hospital Philanthropy, Craiova, Romania.

It is known that the genetic similarity, embryonic and functional hypothalamic-pituitary-gonadal system has close correlation with hypothalamic-pituitary-thyroid axis. Recent research has suggested the existence of interactions between the gonad and the functional capacity of the thyroid.

The study was performed on 93 cases admitted to the Endocrinology Clinic during 2005–2011, whose age ranged from 16–44 years. Correlate with clinical features Thyro-gonadal function exploration objectified by hormonal and metabolic laboratory investigations performed in the context of specific clinical case. Note that all cases included in the study had an extra weight in varying degrees.

Hormonal assays results obtained by us show that overweight patients studied, ovary and thyroid functional capacity are significantly reduced. Reduced urinary excretion of estrogen, along with decreases in serum thyroid hormones, explaining increased serum cholesterol and β-lipoproteins and decreased progesterone involves a gradual increase serum lipids.

Conclusion

In view of relations between endocrinology and gynecology, comprehensive approach is required to study endocrino-metabolic correlation in thyro-ovarian failure, to adopt a differentiated therapeutic attitudes pathogens.

In the thyroid gland pathology, thyroadenitis prominently in their scope, whose etiologic diagnosis is often difficult to objectified and therapeutic attitudes are not yet codified today. mechanisms production in the thyroid thyroid lesions are still far from being elucidated, and concepts are still ongoing reshuffle. There is another explanation that can withstand a critical analysis of how the thyroid's self tolerance is repealed and the breaking of tolerance in a row followed by antithyroid antibodies and thyroid lesion.

Personal research were performed on 89 cases admitted to the Endocrinology Clinic in the period 2000–2009, whose age ranged from 15–68 years. The diagnosis was suggested by historical data and clinical and laboratory investigations confirmed the etiology of each case. Therapeutic attitudes were conditioned by the results of laboratory assays. He turned to antibiotics, corticosteroids, NSAIDs, antithyroid synthetic thyroid hormones or thyroidotomy.

The results show that the treatment of choice is thyroadenitis administration of glucocorticoid hormones. In subacute thyroiditis phase required a stunning combination of low doses of antithyroid synthetic beta-blockers. To prevent thyroid nodularisation phenomenon, it is desirable thyroid hormone replacement therapy when natural evolution of the disease remit to hypothyroidism. Surgical indication is considered appropriate only for cases resistant to other modes of therapeutic approach to cases abcedate.

Hypertension is the most common cardiovascular disease in the mass population and one of the most important public health problems. Is recognized as a major risk factor for atherosclerosis, particularly coronary localized, brain, kidney and leading cause of cardiovascular morbidity and mortality in most industrialized countries and overall.
Our study was performed in 121 patients with endocrine disorders (hypercortisolism, acromegaly, hyperthyroidism, hypothyroidism), hospitalized in the Clinic of Endocrinology, which was assessed at the time of onset of hypertension and hypertension to monitor developments in relation to the evolutionary stage of endocrine disease. Objectivity endocrine disease diagnosis was based on correlative investigation: hormonal, imaging, electrophysiological and metabolic. It emerged following conclusion with practical implications: early diagnosis of endocrine disease and the establishment of adequate etiological therapy, is the prerequisite for prevention and monitoring of cardiovascular complications.

**New insights into the molecular and cellular pathogenesis of human craniopharyngioma: do pituitary stem cells underlie the origin of these tumours?**

C. Andoniadou, C. Gaston-Massuet, R. Reddy, T. Jacques, M. Dattani & J. Martinez-Barbera
UCL Institute of Child Health, London, United Kingdom.

Activating mutations in the gene encoding β-catenin have been identified in the paediatric form of human craniopharyngioma (adamantinomatous craniopharyngioma, ACP), an aggressive pituitary tumour accounting for up to 10% of paediatric intracranial tumours. Recently, we generated an ACP mouse model and revealed that, as in human ACP, nucleocytoplasmic accumulation of β-catenin (βcat-nc) and over-activation of the Wnt/β-catenin pathway occurs only in very few cells that form clusters. Here, combining mouse genetics, fluorescence labeling and flow-sorting techniques, we have isolated these cells from tumorigenic mouse pituitaries and show that the βcat-nc cells contain higher numbers of colony-forming cells when cultured in stem cell-promoting media, and longer telomeres, indicating shared properties with normal pituitary progenitors/stem cells (PSCs). Global gene profiling analysis has revealed that these βcat-nc cells express high levels of factors encoding secreted mitogenic signals, such as members of the SHH, BMP and FGF family, in addition to several chemokines and their receptors, suggesting an important non-cell autonomous role of these cells in the pathogenesis of ACP and a reciprocal communication with their environment. Through genetic approaches utilising inducible Cre mouse lines, we are targeting PSCs to exclusively sustain the activating mutation in β-catenin and assess if this leads to a pre-tumoral lesion. Alongside providing further support to the concept that PSCs may play an important role in the aetiology and/or pathogenesis of human ACP, our data reveal novel disease biomarkers and potential pharmacological targets for the treatment of these devastating childhood tumours.

**Diagnostic and Prognostic Role of 68GA-Dotatate in Patients with Neuroendocrine Tumors**

F. Marciello[1], A. Faggiano[2], L. Aloj[2], C. Caraco[2], V. Ramundo[1], V. Marotta[1], M. Del Prete[1], A. Carratù[1], A. Colao[1] & S. La Storia[2]
National Cancer Institute "Fondazione G. Pascale", Naples, Italy.

Octreoscan is currently the gold standard for diagnosis of somatostatin receptor positive NET but it is limited by a lower spatial resolution and physiological uptake noises. DOTATATE is a somatostatin analogue, radiolabelled with 68Ga and adapted for PET imaging.
Aim of this study was to evaluate the diagnostic performance of 68Ga-DOTATATE PET compared to Octreoscan in NET.
Fifty-one patients with NET (40 sporadic, 17 MEN1) of different origin were enrolled. 68Ga-DOTATATE PET was performed in all cases by acquiring whole body studies 40–60 min after the radioligand i.v. injection (74–111 MBq). Octreoscan was also performed in 27/51 patients using injection of Indium-111-DTPA-Phe1-Octreoscanreotide (120–200 MBq). Examinations results were rated considering histology, CT/MR examination and clinical follow-up.
The patient based sensitivity and specificity of PET was 77% and 100%,respectively; the lesion based sensitivity was 64% with a specificity of 85%. Positive and negative predictive values were 100% and 65%, respectively. The sensitivity was $\sim$100% in pancreas and gut, $\sim$75% in lung and thyroid, $<$50% in stomach. In the subgroup undergone both PET and Octreoscan, the result was concordant in 21 and discordant in 6 cases. The discordant cases were 5 PET positive/Octreoscan negative (3 pancreatic NET, 2 medullary thyroid cancer) and 1 PET negative/Octreoscan positive (atypical lung carcinoid). In PET-positive patients, a significant inverse correlation between SUVmax and Ki67 was recordered ($P<0.01$). At ROC analysis, SUVmax in patients with progressive disease was $\leq$17 while it was $>$17 in patients with stable or responsive disease ($P<0.01$). In patients with NET 68Ga-DOTATATE PET shows higher diagnostic performance than Octreoscan and is suggested to predict clinical behaviour of the tumor.

**Meta-analysis of mRNA, microRNA expression and chromosome aberrations in phaeochromocytoma and neuroblastoma**

P. Szabo[1], M. Pinter[2], D. Szabo[1], A. Zsippai[1], A. Patocs[3], A. Falus[1], K. Racz[1] & P. Igaz[1]
Hungarian Academy of Sciences, Budapest, Hungary.

Background
The pathogenesis of neural crest-derived tumours (phaeochromocytoma and neuroblastoma) is complex, and several studies applying functional genomics approaches have been performed in these tumours to date. However, the comparison of their genomic features has not been performed yet.
Objective
We have carried out an in silico meta-analysis of altogether 1784 neuroblastoma and 351 phaeochromocytoma samples to establish similarities and differences using analysis of mRNA and microRNA expression, chromosome aberrations and a novel bioinformatical analysis based on cooperative game theory.
Methods
Datasets obtained from Gene Expression Omnibus and Array Express have been subjected to a complex bioinformatics analysis using Gene Spring, Gene Set Enrichment Analysis, Ingenuity Pathway Analysis and own algorithms.
Results
Comparison of neuroblastoma and phaeochromocytoma with other tumours revealed the over expression of genes involved in development of noradrenergic cells. Among these, the significance of paired-like homeobox 2b (PHOX2B) in phaeochromocytoma has not been reported previously. The analysis of similar expression patterns in neuroblastoma and phaeochromocytoma revealed the same anti-apoptotic strategies in these tumours. Cancer regulation by stathmin turned out to be the major difference between phaeochromocytoma and neuroblastoma. Underexpression of genes involved in neuronal cell-cell interactions was observed in unfavourable neuroblastoma. By the comparison of hypoxia- and Ras-associated phaeochromocytoma, we have found that enhanced insulin like growth factor 1 signalling may be responsible for the activation of Src homology 2 domain containing transforming protein 1 (SHC1), the main co-factor of RET.

Hypoxia induced factor 1α (HIF1α) and vascular endothelial growth factor signalling included the most prominent gene expression changes between von Hippel-Lindau and multiple endocrine neoplasia type 2A-associated phaeochromocytoma and we have supplemented these previously described pathways with several new members.
Conclusions
These pathways include previously undescribed pathomechanisms of neuroblastoma and phaeochromocytoma and associated gene products may serve as diagnostic markers and therapeutic targets.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Metformin inhibits the androgen mediated up-regulation of Insulin Growth Factor-I Receptor in prostate cancer cells**
R. Malaguarnera, A. Sacco, C. Voci & A. Belfiore
University Magna Graecia of Catanzaro, Catanzaro, Italy.

Introduction
The insulin-like growth factor-I receptor (IGF-IR) plays a key role in regulating growth, survival and invasion of several human malignancies including prostate cancer. In prostate cancer cells, the IGF-IR expression is upregulated by androgens through a nongenotropic signaling unresponsive to antiandrogens and requiring AMP-response element-binding protein (CREB) activation. This mechanism sensitizes cells to the proliferative and protumor effects of IGF-I. Metformin, a widely used antidiabetic drug with pleiotropic activity, has been shown to be anti-mitogenic in several cancer cells, partially through the activation of AMP-activated protein kinase (AMPK).
Aim
We investigated whether metformin could affect androgen-induced IGF-IR upregulation in prostate cancer cells.
Methods and results
Using the androgen-sensitive LNCaP prostate cancer cells, we found that metformin specifically inhibits the androgen-mediated upregulation of IGF-IR mRNA and protein levels by blocking the mTOR/p70S6K pathway. These effects were only partially dependent on AMPK activation. Indeed, in the same cells, after knocking-down AMPK, metformin was still able to inhibit the IGF-IR upregulation induced by androgens. Furthermore, in 293HEK cells cotrasfected with constructs encoding for the androgen receptor and the full length IGF-IR promoter, metformin markedly reduced the androgen-stimulated IGF-IR promoter activity by inhibiting CRE activity and CREB phosphorylation at Ser133.
Conclusion
Metformin inhibits androgen-induced nongenotropic IGF-IR upregulation by acting through the inhibition of mTOR/p70S6K pathway, in a manner partially dependent on AMPK activation. These data open promising perspectives for prostate cancer treatment as they suggest that metformin may be a useful adjunct to the classic therapy with antiandrogens.

**Investigations into the epigenetic mechanisms regulating the prostanoid receptor EP2 in estrogen dependent breast cancer**
S. To[1,3], K. Takagi[2], Y. Miki[2], H. Sasano[2], E. Simpson[1,3], K. Knower[1] & C. Clyne[1,3]
Monash University, Melbourne, VIC, Australia.

Estrogen excess is a major contributing factor to the development and progression of post-menopausal Estrogen Receptor positive (ER+) breast cancers. Increased activity of aromatase, the enzyme that converts androgens to estrogens, and upregulation of its encoding gene CYP19A1 is often observed in breast adipose fibroblasts (BAFs) surrounding ER+ tumours. Understanding the process by which CYP19A1 is regulated between normal and diseased breast stroma may help to improve outcomes for breast cancer sufferers.
Prostaglandin E2 (PGE2), secreted by breast tumours, stimulates CYP19A1 expression and estrogen production in surrounding BAFs. Whilst hormonal regulation of this process has been examined, there is increasing evidence suggesting that epigenetic mechanisms, such as DNA methylation, serve to influence the PGE2 pathway. These mechanisms are thought to lead to CYP19A1 transcription by silencing or activating upstream factors. The present study aims to determine whether an inverse correlation existed between expression of the prostanoid receptor EP2 and their promoter DNA methylation status in the context of breast cancer derived cell lines and clinical samples of cancer-associated stroma and matching normal stroma.
Sodium bisulfite sequencing of CpG methylation within the EP2 promoter revealed differential methylation showing inverse correlation with respective mRNA levels in cell lines MDA-MB-231 (ER-), MCF7 (ER+) and MCF10A (normal epithelial). Results were confirmed with inhibition of DNA methylation using 5-aza-2-deoxycytidine (5aza), which showed that expression of EP2 in MDA-MB-231 cells could be increased upon demethylation. Analysis of 9 clinical samples comprising ductal carcinoma in situ, invasive ductal carcinoma and triple negative tumours showed that differences in expression levels of EP2 between normal and cancer-associated stroma could not be attributed to differences in promoter methylation status. This suggests that upstream factors are responsible for the epigenetic regulation of CYP19A1 and EP2. Identification of these factors will further our understanding of epigenetic gene regulation in ER+ breast cancer.

**GPR30, the non classical membrane G protein related estrogen receptor (GPER), is overexpressed in human seminoma and promotes seminoma cell proliferation.**
N. Chevalier[1,2], R. Paul-Bellon[2], A. Vega[2], A. Bouskine[2] & P. Fénichel[1,2]
UMR INSERM U1065 / UNS - C3M, Nice, France.

Background
Testicular germ cell tumours are the most frequent cancer of young men. While pathogenesis and reasons of an increasing incidence all over the world remain unknown, epidemiological and clinical data have suggested that fetal exposure to environmental endocrine disruptors (EEDs), especially with estrogenic effects, could participate to testicular germ cell carcinogenesis. However, EEDs (like bisphenol A) are often weak ligands for classical nuclear estrogen receptors. In fact, this promoting effect could act through the non classical membrane G-protein coupled estrogen receptor (GPER/GPR30), which has been recently shown to mediate the effects of several xenoestrogens and also overexpressed in various estrogen dependent cancer cells (breast, ovary, endometrium).
Methods
The aim of this study was to demonstrate that GPER was also overexpressed in testicular tumours ($n=15$) compared to normal peritumoral testicular tissue and was able to trigger JKT-1 seminoma cell proliferation *in vitro*.
Results
In normal adult human testes, GPER was expressed by somatic (Sertoli cells) and germ cells (spermatogonia and spermatocytes). GPER was exclusively and significantly ($P < 0.05$) overexpressed in seminomas, the most frequent testicular germ cell cancer. In JKT-1 seminoma cells, GPER was localized at the cell membrane and triggered *in vitro* the proliferative effect induced by G1 (a GPER selective agonist) and by an impermeable E2-conjugate (E2-BSA). This effect was completely abolished by G15 (a GPER selective antagonist) and by GPER siRNA invalidation.
Conclusion
Our results confirm that human seminomas overexpressed functional GPER; moreover, agonist and antagonists demonstrate its ability to induce proliferative effect in seminoma cells. Thus, this non classical membrane G protein related estrogen receptor may represent a molecular basis for a possible effect of xenoestrogens during testicular carcinogenesis.

**Sorafenib stops disease progression in the majority of patients with advanced differentiated thyroid cancer refractory to radioactive iodine.**

V. Marotta[1], V. Ramundo[1], M. Del Prete[1], F. Marciello[1], G. Palmieri[1], L. Camera[1], M. Vitale[2], A. Colao[1] & A. Faggiano[1,3]
National Cancer Institute, "Fondazione G. Pascale", Naples, Italy.

Differentiated thyroid cancers (DTC) have an excellent prognosis with a 10 year disease-related survival of 85%. However, about 5% of DTC patients develop an aggressive disease with distant metastasis and loss of radioactive iodine (RAI) avidity. An effective treatment is not available for these patients and survival rates are less than 15%. The MAP-kinase pathway is strikingly involved in the pathogenesis of DTC. This is why compounds striking the MAP-Kinase pathway may be useful for treatment of advanced DTC refractory to RAI.
A phase II clinical trial was designed to assess efficacy and safety of the Tyrosine-Kinase inhibitor Sorafenib in 9 patients with progressive RAI-refractory DTC. Median follow-up period was 10 months. Sorafenib was administered at a starting dose of 400 mg b.d. Computed tomography scans were performed at baseline and at 12-weeks intervals to assess radiologic responses. Determination of Tg was performed at 4 weeks intervals to assess biochemical response. Patients were subjected to clinical and biochemical examinations at 4-weeks intervals to assess the occurrence of adverse events (AE).
In eight patients (89%) disease progression was arrested. According to RECIST criteria, 5 of them achieved a stable disease (56%) and 3 a parzial response (33%). Five out of 8 responding patients (62%) had a durable response. In all responding patients a dramatic drop in Tg levels was observed with a median time of nadir of 60 days. The most prevalent AE were hand-foot syndrome (87%), TSH increase (75%), asthenia and arthralgia (75%), hypertension (50%), anemia (37,5%), alopecia (25%). Only one patients stopped treatment because of toxicity. Toxicities were fully controlled by halving the dosage in 7 patients (77,7%).
Sorafenib is effective in controlling disease progression in the majority of patients with advanced DTC refractory to RAI, also resulting in objective response in one third of them.

## P780

**The pilot study on clinical presentation of pituitary adenomas (Pa) in patients with multiple endocrine neoplasia type 1 (Men1) phenotype with and without *Men1* mutation**

L. Rostomyan[1,2], M. Tichomirowa[1,3], N. Kirdyankina[2], N. Mokrysheva[2], N. Molitvoslovova[2], L. Dzeranova[2], A. Tiulpakov[2], L. Rozhinskaya[2] & A. Beckers[1]
University of Mainz, Mainz, Germany.

*MEN1* germline mutations are identified in 70% of the familial forms of MEN1 and about 10%of the sporadic cases. Little is known about clinical differences between MEN1 with and without identification of *MEN1* germline mutation particularly in terms of PA characteristics.
Aim
To compare the clinical features of PA in MEN1 cases with and without germline *MEN1* mutation and sporadic cases of PA. Patients and methods: Data were obtained in 39 patients: 22 with *MEN1* mutation (Group-I) and 17 sharing MEN1 phenotype but tested negatively for *MEN1* mutation (Group-II). All patients presented with PA and primary hyperparathyroidism (PHPT). The genetic diagnosis was performed by direct sequencing of *MEN1* exons and intronic boundaries. In 17 *MEN1*-negative patients large deletions of *MEN1* were excluded by MLPA and direct sequencing of *CDKN1B* gene did not reveal the presence of genetic mutations. Control group (Group-III) included 17 patients with sporadic PA and no evidence of other endocrine tumors (matched by type of secretion and follow-up period to those in Group-II).
Results
In Group-II PA as primary tumor site were more frequent than in Group-I (70% vs 51%, $P=0.04$). The distribution of the PA type was significantly different between Group-I and Group-II. In Group-II 52% had somatotropinomas, 17% prolactinomas, 17% nonfunctioning adenomas, 11% corticotropinomas. In contrast, in the Group-I 53% consisted prolactinomas and only one patient had acromegaly. The frequency of macroadenomas was not different in Group-I and Group-II (55% vs 59%; $P=0.8$), but was higher in Group-II patients than in Group-III (59% vs 44%, $P=0.041$). In secreting PA normalization of pituitary hypersecretion was not significantly different in Group-I and Group-II (50% vs 52%, $P=0.48$), whereas it was more frequent in Group-III than in Group-II (76% vs 52%, $P=0.001$). During the whole follow-up 81% patients in Group-I developed gastroenteropancreatic neuroendocrine tumors, whereas in the Group-II such tumors were identified in only 2 patients.
Conclusion
PA in MEN1-phenocopies have different clinical characteristics than those with germline *MEN1* mutations. The pituitary tumorogenesis in these patients, especially in those with GH-producing PA and PHPT, might involve mechanisms others than either *MEN1* or *CDKN1B* mutations.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P781

**Hepatocellular carcinoma (HCC) as a neuroendocrine tumor: a preliminar molecular study.**

C. Pivonello[1], G. Vitale[3], F. Izzo[4], A. Di Sarno[5], A. Giorgio[5], L. Hofland[2], A. Colao[1] & R. Pivonello[1]
Cotugno Hospital, Napoli, Italy.

Hepatocellular carcinoma (HCC) is often diagnosed at late stage or metastatic condition. Surgical resection is considered treatment of choice and other treatment options include chemoembolization, radiofrequency ablation and photodynamic therapy. We evaluated the expression levels of the 5 somatostatin receptors (SSTRs) in 23 biopsies of HCC patients and also mTOR, p70S6K and 4eBP1 in HuH-7 and HepG2 and investigated the *in vitro* effect of somatostatin analogs (SA) and mTOR inhibitors on cell proliferation. The receptor expression was assessed by RT-qPCR and sstr2 and 5 localization by ICC. The proliferation was tested using DNA assay. Sstr2 > sstr1 > sstr5 were expressed in the patients. Cell lines showed the presence dell'sstr1, 2, and 5 as well as mTOR, p70S6K, 4eBP1. ICC showed a heterogeneous localization of sstr5 and sstr2 in Hep-G2 and Huh-7. Octreotide showed a no significant dose-dependent inhibitory effect in both cell lines. Bim23244 induced a significant inhibitory effect (18.2%, $P=0.02$) in HepG2 at $10^{-7}$ M and Bim23926 16.4% ($P=0.00$) at $10^{-7}$ M in Huh-7. Incubation with mTOR inhibitors resulted in a dose-dependent growth inhibition in both cell lines. Octreotide has not synergistic or additive effect with rapamycin at high concentration, but when it was used in combination with rapamycin at low concentration was able to revert the antiproliferative effect of rapamycin in HepG2 and HuH-7. This effect was also associated to an hyperexpression of sstr2 and 5 and upregulation of pERK1/2. Our data provide evidence of sstrs expression in HCC but other studies will be required to justify the clinical use of these compounds in the treatment of advanced HCC. mTOR inhibitors have an essential growth inhibitory effect in HCC cell line, even though *in vitro* the rapamycin effect can be reverted by octreotide, showing that HCCs do not act as a typical neuroendocrine tumor.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P782

**Urinary steroid profiling demonstrates induction of CYP3A4 and inhibition of 5alpha-reductase by mitotane treatment for adrenocortical carcinoma**

A. Taylor[1], V. Chortis[1], P. Schneider[1], J. Tomlinson[1], B. Hughes[1], D. Smith[1], R. Libe[2], B. Allolio[3], X. Bertagna[2], J. Bertherat[2], F. Beuschlein[7], M. Fassnacht[3], M. Mannelli[4], F. Mantero[5], G. Opocher[5], E. Porfiri[1], M. Quinkler[3], M. Terzolo[6], C. Shackelton[1], P. Stewart[1], S. Hanher[3] & W. Arlt[1]
Ludwig-Maximilians University, Florence, Italy.

Mitotane (o,p'DDD) is commonly used for the treatment of adrenocortical carcinoma (ACC), both for advanced disease and in the adjuvant setting. Mitotane induces adrenal insufficiency but specific effects on steroidogenic enzymes are unknown.

We investigated 24-h urinary steroid metabolite excretion in ACC patients on adjuvant mitotane (AD) or mitotane for metastatic disease (MET). We compared samples collected before mitotane treatment (BEFORE; MET $n=57$; AD $n=12$) to samples collected after 3–4 months of treatment when therapeutic range plasma mitotane levels had been achieved (AFTER; MET $n=47$; AD $n=11$). Steroid metabolite excretion was analysed by gas chromatography mass-spectrometry, facilitating the selective identification and quantification of 32 steroid metabolites. We also calculated steroid substrate over product ratios to diagnose impairment of distinct steroid converting enzymes including 5alpha-reductase (5alpha-tetrahydrocortisol/tetrahydrocortisol; 5αTHF/THF) and CYP3A4 (6beta-hydroxycortisol/cortisol; 6βOHF/F).

We found a strong inhibition of 5alpha-reductase activity by mitotane (5αTHF/THF: MET-before $3.6\pm6.3$ vs. MET-after $0.05\pm0.07$; AD-before $0.5\pm0.4$ vs. AD-after $0.02\pm0.01$; all $P<0.001$). The extent of this inhibition was comparable to patients treated with the known 5alpha-reductase type 2 inhibitor finasteride (5αTHF/THF $0.02\pm0.006$; $n=5$) and patients with inactivating 5alpha-reductase type 2 mutations (5αTHF/THF $0.04\pm0.03$ $n=23$). We also found evidence of a strong induction of the major drug and steroid-metabolising enzyme CYP3A4 (6βOHF/F: MET-before $2.1\pm3.6$ vs. MET-after $20.5\pm9.7$; AD-before $2.4\pm0.8$ vs. AD-after $30.2\pm5.1$; all $P<0.001$). 6βOHF represented only 3.4% (1–4%) of total cortisol metabolite excretion before mitotane, which increased hugely to 54% (39–70%) on mitotane ($P<0.001$) irrespective of tumour load.

Longitudinal data from patients receiving adjuvant mitotane ($n=4$) demonstrated lasting effects on CYP3A4 and 5alpha-reductase activities, with restoration to normal only after 12 months off treatment. CYP3A4 induction results in rapid inactivation of hydrocortisone replacement, explaining the increased hydrocortisone dose requirements in mitotane-induced adrenal insufficiency.

## P783

**Bronchial carcinoid response to mTOR inhibitors depends on mTOR expression levels**

T. Gagliano, R. Rossi, D. Molè, E. Gentilin, M. Minoia, F. Tagliati, E. degli Uberti & M. Zatelli
University of Ferrara, Ferrara, Italy.

Introduction

Bronchial carcinoids (BCs), originating from endocrine cells dispersed in the respiratory epithelium, can be divided into typical (TBC) and atypical (ABC). TBC are less aggressive, smaller, and much less likely to metastasize, while ABC are more aggressive and metastasize. mTOR has a central role in regulating cell growth, metabolism, and apoptosis. A differential mTOR activation in BCs has been previously demonstrated, suggesting that mTOR pathway might play a predictive role in patients eligible for mTOR-targeted therapies.

Aim

To evaluate the effects of mTOR inhibitors on human BCs cells lines.

Materials and methods

NCIH720 (ABC) and NCIH727 (TBC) cells were treated with Everolimus or with NVP-BEZ 235, a dual PI3K/mTOR inhibitor. Cell viability, caspase activity and cell cycle progression were evaluated after 72 h.

Results

Everolimus inhibits cell viability in both cell lines with a more pronounced effects on NCIH720, does not activate apoptosis but determined G1/G0 accumulation. NVP-BEZ235 had similar effects to Everolimus in terms of cell viability in NCIH727, but was more potent in NCIH720 cells. Caspase activity was not induced by NVP-BEZ 235 in NCIH727, but was enhanced in NCIH720. Western blot and Q-PCR were performed to assess whether this differential effect is due to variations in mTOR expression in BCs cell lines. mTOR expression is 1.5-fold higher in NCIH720 as compared with NCIH727.

Conclusion

These data demonstrate that mTOR inhibitors affect BCs cell lines differently depending on mTOR expression.

Declaration of interest

**TNFα induced aromatase expression is mediated by the Early Growth Response transcription factors in breast adipose**

S. To[1,2], E. Simpson[1,2], K. Knower[1] & C. Clyne[1,2]
Monash University, Melbourne, VIC, Australia.

Breast cancer remains the leading cause of cancer-related death in Australian women. Up to 70% of post-menopausal tumours are estrogen-receptor positive (ER+), dependent on estrogen for continued growth and proliferative advantage. Adjuvant anti-estrogen therapies are considered the cornerstone approach to the treatment of such tumours, and research is ongoing to maximize its effectiveness. The major source of estrogens for ER+ breast cancers is local conversion of androgen precursors by the enzyme P450 aromatase. Inflammatory factors such as Tumour Necrosis Factor-α (TNFα) stimulate transcription of CYP19A1, the gene that encodes aromatase, via its adipose-specific promoter I.4 (PI.4). The pathways by which this is achieved are not fully understood. We aim to identify the mechanisms underlying TNFα-dependent aromatase induction in the context of ER+ breast cancer.

TNFα treatment of human breast adipose fibroblasts (BAFs) increased mRNA levels of all four early growth response transcription factors, with a 7-fold EGR2 induction being the highest. Overexpression of EGR2 caused an increase in endogenous CYP19A1 expression in the human pre-adipocyte cell line SGBS, driven by increased PI.4-specific transcripts. PI.4 luciferase reporter activity is dose-dependently increased by EGR2, EGR3 and EGR4, with EGR2 causing a 70-fold luciferase response. Deletion analysis indicates this promoter activity was indirectly mediated by a short region of the promoter not containing any previously characterised binding sites, and we further show that EGR2 cannot bind directly to this promoter region. This suggests involvement of a secondary factor.

Our studies demonstrate that the Early Growth Response (Egr) transcription factors play an important role in the TNFα-induced signalling pathway resulting in elevated PI.4 transcription. This unveils a novel component of the aromatase gene regulatory network, and further enhances our understanding of estrogen production in the breast.

**Mitochondrial respiratory chain defects: a novel molecular mechanism of Mitotane for treatment of Adrenocortical Carcinoma**

S. Hescot[1], A. Slama[2], A. Paci[3], H. Remy[3], R. Chadarevian[4], S. Trabado[1,2], A. Lombès[5], J. Young[1,2], E. Baudin[1,3] & M. Lombès[1,2]
Institut Cochin, Paris, France.

Mitotane (o,p'DDD) represents the most effective treatment of adrenocortical carcinoma (ACC). However, molecular mechanisms of mitotane action remain poorly understood. Mitochondrial (mt) impact of mitotane has previously been suggested but not yet fully validated. We investigated functional consequences of mitotane exposure on mitochondrial steroidogenesis, respiratory chain activity and biogenesis, using human adrenocortical secreting H295R and non-secreting SW13 cells. We first confirmed that mitotane exposure inhibits cell proliferation in a dose- and time-dependent manner. We were however unable to detect mitotane metabolites, o,p'DDA and o'p'DDE, in cultured cells supernatant. We

demonstrated that mitotane drastically reduces cortisol and 17-hydroxyprogesterone secretions by 70%, at a 50 μM (14 mg/L) concentration, considered as the therapeutic plasma level threshold. This was accompanied by significantly decreased expression of genes encoding mitochondrial proteins involved in steroidogenesis (STAR, CYP11B1, CYP11B2). In both H295R and SW13 cells, 50 μM mitotane induced a significant and reproducible 50% decrease of the maximum velocity of the respiratory chain complex IV (cytochrome c oxidase, COX) activity. This was associated with significantly decreased expression of both the mtDNA-encoded COX2 and the nuclear DNA encoded COX4 COX subunits, and with an important reduction of the whole COX steady state expression, as revealed by Blue Native PAGE. Enhanced mitochondrial biogenesis was shown by an increased mt DNA content and enhanced expression of the transcriptional regulator PGC1α, consistent with an adaptive and compensatory mechanism against mitochondrial defect. Mitotane exposure also triggered a morphologic shift from filamentous to punctuate aspects of mitochondrial network, providing additional support for alteration in the mitochondrial compartment dynamics.

Collectively, our results provided first evidence that mitotane induces mitochondrial respiratory chain defect. Better understanding of mitotane pharmacology should enable us to identify predictive factors of efficacy and toxicity.

### Screening of AIP mutations in young Romanian patients with sporadic pituitary adenomas

I. Baciu[1], C. Capatina[1,2], D. Aflorei[2], I. Botusan[1], M. Coculescu[1,2] & S. Radian[1,2]

C I Parhon Institute of Endocrinology, Bucharest, Romania.

Introduction

The pathogenesis of pituitary adenomas is incompletely understood. It was recently demonstrated that mutations in AIP, a novel tumor suppressor gene, are causing the familial isolated pituitary adenoma syndrome. Although initial data suggested that AIP mutations are rare in non-familial cases, a recent study demonstrated an increased prevalence in young sporadic macroadenoma patients.

Aim

To perform a systematic screening of AIP mutations in young Romanian sporadic pituitary adenoma patients.

Patients and methods

We studied 40 pituitary adenoma patients from a tertiary referral endocrinology center. Patients were evaluated clinically, biochemically and by pituitary imaging. After informed consent, blood DNA was extracted and all six AIP exons were PCR-amplified and sequenced (Beckman CEQ8000).

Results

The 40 patients included presented the following adenoma types: 9 prolactinomas, 24 GH-secreting, 2 mixed GH-PRL, 1 ACTH-secreting, 4 non-functioning pituitary adenomas (NFPA).

We found several AIP nucleotide single-base substitutions. Bioinformatic analysis was employed to distinguish mutations from known SNPs. One NFPA male patient associating mental retardation (38 yrs. old) presented a heterozygous R16H AIP exon 1 mutation. This has been previously described in familial and sporadic pituitary adenomas, 2 colon cancer patients and 1 control. One male acromegalic patient (18yrs. old at onset), with a large invasive macroadenoma resistant to somatostatin analog therapy, harboured a novel heterozygous exon 6 mutation – R314W. Another acromegalic male patient (29 yrs. old), presenting a macroadenoma resistant to chimeric dopamin-somatostatin analog therapy, harboured a novel heterozygous exon 2 mutation – W73R. Both substitutions affect conserved aminoacids.

Conclusion

We describe two novel putative AIP mutations. In vitro confirmation of their pathogenicity will be needed. Screening of a larger control sample will help exclude that these are rare polymorphisms. Our results suggest that current AIP mutation screening criteria may need to be extended, as evidence is accumulating for their significant prevalence in sporadic adenomas.

### Expression of a novel isoform of thyroid peroxidase (TPO) gene in breast cancer (BC)

I. Muller[1], C. Giani[1], E. Fiore[1], V. Belardi[1], S. Sabatini[1], V. Rosellini[1], N. Funel[1], D. Campani[1], F. Grennan-Jones[2], L. Zhang[2], M. Lewis[2], A. Bakhsh[2], M. Roncella[1], M. Ghilli[1], A. Pinchera[1], P. Vitti[1], C. Dayan[2] & M. Ludgate[2]

School of Medicine, Cardiff University, Cardiff, United Kingdom.

Introduction

BC patients have a high prevalence of anti-TPO-autoantibodies (TPOAb), which seem to be protective in BC patients. We hypothesized the presence of T-lymphocytes citotoxicity against a common antigen between thyroid and BC cells.

Aim

To evaluate the possible expression of TPO gene in BC.

Materials

Frozen tissue specimens: 8 BC, 5 peri-tumoral breast tissues (PT), 3 pancreatic adenocarcinoma (P), 2 kidney cancers (K) and thyroid (T) as positive control. 3 BC cell-lines (C), MCF-7, T47-D and MDAMB-231, grown with and without β-estradiol and/or insulin-growth-factor-II (IGF-II).

Methods

TPO mRNA expression was evaluated by Reverse-Transcriptase-PCR using different primers pairs distinguishing among different known TPO isoforms. TPO protein expression was studied with Western Blot using monoclonal mouse antibody ab76935.

Results

Known TPO variants mRNA was expressed in all BC and PT, weakly in C independently from β-estradiol and/or IGF-II exposition, at the limit of detection in P and K and highly in T. In particular BC, PT and C presented a new TPO isoform without exons 14 and 16, weakly expressed in T and absent in P and K. TPO protein was found at the expected level (100–110 kDa) in T, C and many BC, PT, P, K; the signal was reduced or disappeared after ab76935 pre-absorption with recombinant TPO fragments, indicating a specific binding. All samples presented also other signals corresponding to lower molecular weight (MW) proteins, present also in T: they could represent corresponding proteins of smaller TPO isoforms.

Conclusions

TPO main isoforms mRNA and protein are weakly but clearly expressed in almost all samples. BC, PT and C present also a new variant without exons 14 and 16, absent in P and K. Further experiments are necessary to quantify TPO expression and to search for a lower MW protein corresponding to the new TPO isoform found.

### Is combined radionuclide therapy with 90y-Dotatate and 177lu-Dotatate an effective treatment option for patients with metastasised neuroendocrine tumours? An ongoing study

E. Seregni, M. Vincenzo, F. De , Braud , , R. Buzzoni, M. Marco, A. Coliva, C. Pascali, A. Mallia & E. Bombardieri

Fondazione IRCCS "Istituto Nazionale dei Tumori", Milan, Italy.

Introduction

Neuroendocrine tumors (NETs) over-express somatostatin receptors (SRs) and the efficacy of peptide receptor radionuclide therapy (PRRT) with somatostatin analogues labeled with high activities of β-emitting radioisotopes has been reported.

Aim

Ongoing study to evaluate efficacy and toxicity of combination treatment with 4 cycles of radiolabeled DOTATATE, alternating 177Lu and 90Yin patients with metastasised NETs expressing SRs refractory to conventional therapies.

Method
Since 2008 forty-four patients with disseminated NETs were included in the study prospectively to be treated with 4 cycles of PRRT, alternating 177Lu-DOTATATE (5.55 GBq) and 90Y-DOTATATE (2.6 GBq).Dosimetric evaluation on each patient was performed following administration of 177Lu-DOTATATE. Hematological and renal toxicities are graded according to WHO toxicity grading scales and treatment efficacy evaluated using RECIST criteria. Quality of life is assessed following each treatment cycle.
Results
So far twenty-six patients have completed all 4 cycles together with a 6 month treatment evaluation (SD = 38.5%, PR = 38.5%, CR = 8% and PD = 15%). A symptomatic improvement was reported by 90% of patients with pre-treatment carcinoid syndrome. The remaining eighteen patients are currently undergoing treatment. Side effects and blood toxicities were rare, mild and transient. To date no renal or hepatic toxicities have been observed. Average tumor absorbed doses were 13–63 Gy for 177-Lu and 20–93 Gy for 90Y.
Conclusions
Combined PRRT therapy represents an innovative treatment strategy for patients with metastatic NETs with the aim of improving therapy efficacy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P789

**The pathogenesis of non functioning pituitary adenoma with positive staining for glycoproteins is associated with MEG3/DLK1 under-expression/GSTP1 overexpression and modulated by microRNAs (miRNAs)**

B. Paixao, D. Lima, P. Peitl, A. Dinarte, F. Saggioro, A. Moreira, W. Silva, H. Machado & M. Castro
School of Medicine of Ribeirao Preto, Ribeirao Preto, Brazil.

Context
Pathogenesis underlying non functioning pituitary adenoma (NFPA) formation and progression has not been well established. MEG3 is strongly expressed in the normal pituitary (NP) but not in NFPA derived from gonadotroph cells. High GSTP1 gene expression also seems to contribute to gonadotroph adenoma development. Recent reports indicate a role of miRNAs in the pituitary adenoma pathogenesis.
Objective
To evaluate the expression of MEG3, DLK1, GSTP1 genes and a panel of miRNAs and verify whether they correlate with clinical findings in NFPAs.
Material and Methods
MEG3, DLK1, GSTP1 genes and miRNAs were validated by real time PCR in 29NFPA and 15NP. GSTP1 protein was also evaluated by Western Blotting in 11NFPA with positive- (NFPA+), 11NFPA negative- (NFPA-) staining for glycoproteins, and 9NP.
Results
We observed underexpression of MEG3 ($-13.5$ fold; $P=0.0004$) and DLK1 ($-100$ fold; $P<0.0001$) genes and overexpression of GSTP1gene (4.8 fold; $P=0.01$) and its protein ($P=0.04$) in NFPAs. No expression of miR–21 and 145 and underexpression of miR-141, 16, let-7a, 133a, 150, 143 (ranging from $-14.3$ to $-4.0$–fold; $P<0.002$) were found in NFPAs. MEG3 underexpression and GSTP1 overexpression were associated with NFPA+ ($P=0.004$ and 0.05, respectively), which were also associated with bigger tumors ($P=0.02$). In addition, lower expression of miR–16 was associated with bigger tumors ($P=0.01$) and NFPA+ ($P=0.03$).
Conclusion
Our studies confirm that the loss of expression of DLK1 and MEG3 genes and overexpression of GSTP1 gene/protein are specifically important to the pathogenesis of NFPA+. Besides these genes, our data also show that miR143 underexpression seems to be involved in pathogenesis of NFPA+, while miR16 seems to regulate genes involved in controlling tumor size. In addition, we demonstrate that NFPA+ are bigger and have worse chance to achieve clinical control. These data shed lights on NFPA cytodifferentiation processes, which might improve future classification of its histotypes.

**The influence of surgery in the management of recurrent adrenocortical carcinoma.**

T. Deutschbein[1], I. Erdogan[1], C. Jurowich[1], M. Kroiss[1], M. Quinkler[2], P. Langer[3], H. Willenberg[4], F. Beuschlein[5], C. Fottner[6], S. Klose[7], A. Heidemeier[1], D. Brix[1], W. Fenske[1], S. Hahner[1], J. Reibetanz[1], B. Allolio[1] & M. Fassnacht[1]
University of Magdeburg, Magdeburg, Germany.

Objective
The role of surgery for recurrent adrenocortical carcinomas (ACC) is not well defined. Therefore, we evaluated the outcome after surgery for tumor recurrence in patients from the German ACC Registry.
Methods
Only patients with first recurrence after initial R0 resection were investigated. Progression–free and overall survival (PFS, OS) after first recurrence were analyzed by Kaplan–Meier method. Cox proportional hazards regression models were used to identify prognostic factors.
Result
Of 154 patients with first recurrence, 101 underwent repeated surgery (R0 resection, $n=78$) and 99 received (additional) nonsurgical therapy. After a median interval of 6 (range 1–221) months, 144 patients (94%) experienced progressive disease. Multivariate analysis adjusted for age, sex, tumor burden, time to first recurrence (TTFR), resection status after surgery for recurrence and additional therapy indicated that only two factors were significantly associated with shorter PFS (hazard ratio for progression: TTFR $>12$ months 1.8 [95% CI 1.2–2.5] in comparison to TTFR $\leq 12$ months; R2 resection 3.4 [1.5–8.0] and no surgery 3.4 [1.7–7.1] in comparison to R0 resection) and OS (hazard ratio for death: TTFR $>12$ months 3.0 [2.0–4.6] in comparison to TTFR $\leq 12$ months; R2 resection 2.6 [1.0–6.7] and no surgery 4.2 [1.8–9.8] in comparison to R0 resection). Patients who had both TTFR $>12$ months and R0 resection of recurrent tumors ($n=22$) had the best prognosis (median PFS 24 months, median OS 58 months).
Conclusions
The best predictors of prolonged survival after first recurrence of ACC are TTFR $>12$ months and R0 resection. Patients with longer TTFR and tumors amenable to radical resection should therefore be operated, whereas patients with shorter TTFR or tumors not amenable to radical resection do most likely not benefit from incomplete surgery.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Over-expression of AIP protein in GH3 cells reduces cAMP signalling and Growth hormone secretion**

R. Formosa[1], A. Xuereb-Anastasi[1] & J. Vassallo[1,2]
Mater Dei Hospital, Msida, Malta.

Mutations in the AIP gene have been linked to familial cases of pituitary adenomas (Vierimaa et al, 2006). Analysis of the protein support its role as a tumour suppressor since mutations cause a loss-of-function with reduced protein interactions and over-expression of wild-type (WT) AIP reduces cell proliferation (Leontiou et al, 2008). AIP interacts with a number of interesting proteins, among them are the phosphodiesterases, PDE4A5 and PDE2A, the G proteins, Gαq and Gα13, survivin, RET, nuclear receptors and others (Trivellin & Korbonits, 2011). However, the mechanism by which AIP dysfunction causes increased susceptibility to pituitary adenomas remains unknown. Owing to AIP's interaction with the phosphodiesterases and G proteins, we investigated the effect of WT and mutant AIP proteins on cAMP signalling and its downstream effectors in cell cultures.
WT AIP, R304X-AIP mutant and empty vector (EV) were transfected into GH3 cells. Basal and forskolin – induced cAMP signalling was analyzed using cAMP assays, CRE-promoter luciferase assays, real-time PCR and finally growth hormone (GH) assays.
WT AIP was able to reduce forskolin-induced, but not basal, cAMP signaling. Total cAMP, the luciferase activity of cAMP-driven promoter and target gene expression were reduced when compared to EV and R304X mutant. Additionally,

analysis of GH secretion which occurs after cAMP cascade activation, was slightly but significantly reduced in WT over-expressing GH3 cells treated with forskolin. Addition of IBMX, a phosphodiesterase inhibitor, did not reverse the effect of AIP on cAMP signalling or GH secretion, indicating that this effect occurs independently of AIP-phosphodiesterase interaction.
AIP protein appears inhibit pituitary cells from proliferation by suppressing cAMP production, activation of which is known to cause tumour formation (Lania et al, 2003) and thereby also influencing GH secretion. However, this effect appears not to be mediated by the AIP-phosphodiesterase interaction, suggesting G protein involvement in mediating this outcome.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P792

**Novel 45A > G & 46D > G mutation of SDHB Exon-1 in a Patient with Urinary Bladder & Posterior Mediastinum Paraganglioma.**

P. Gupta, M. Khurana, A. Ammini, P. Singh, R. Kumar & D. Khandelwal
AIIMS, New Delhi, India.

Introduction
Extra adrenal paraganglioma (PGL) account for approximately 15% of all pheochromocytoma. Urinary bladder & mediastinum are rarest form of PGL. We present a case of bladder &Mediastinal PGL with a novel mutation in exon 1 of SDHB gene.
Case Report
18 years old male patient was admitted with five years episodic symptoms of headache, sweating, and palpitations, especially after urination. He also complained of postural dizziness for last 6 months. He was admitted in some other hospital and was found to have labile blood pressure. His blood pressure readings varied from 210/120 mmHg to 80/50 mmHg. He was referred to our clinic for further investigations. His biochemical investigations showed elevated urinary 24 hour norepinephrine & metanephrines. MRI showed heterogeneously enhancing T2 hyperintense lesions of 7×4 cm in posterior mediastinum and 4.1×4.2 cm in urinary bladder, both of these lesions were confirmed in Ga68-DOTANOC imaging. He was operated with a collaborating team of urologist and thoracic surgeons. Post operatively, he developed hypotension and required ionotropic support for few days. Histopathological features were consistent with paraganglioma of both locations. Tumor cells were positive for synaptophysin & chromogranin & negative for cytokeratin. Patient is currently normotensive and asymptomatic after follow up of 10 months. The genetic analysis of the patient showed a novel 45A > G& 46D > G heterozygous germline mutation in SDHB exon-1.
Conclusion
Concurrence of urinary bladder PGL with mediastinum PGL has not been reported earlier to the best of our knowledge. We observed a novel 45A > G& 46D > G heterozygous germline mutation in SDHB gene in exon-1.

## P793

**Refractory Seizures as a Presenting Feature of Insulinoma**

T. Varma, R. Panchani, A. Saini, P. Correia & G. Nath
Sir Ganga Ram Hospital, New Delhi, India.

Introduction
Insulinomas are the commonest hormone-secreting tumor of gastrointestinal tract. Presentation is usually insidious with neuroglycopenia and fasting hypoglycemia. Many patients do not report adrenergic symptoms of hypoglycemia and present with neurological or psychiatric manifestations that often lead to misdiagnosis. The symptoms of insulinoma lack specificity, including various seizure disorders, personality change, bizarre behavior, amnesia, convulsions, and incidentally dystonia and polyneuropathy and cause delay in diagnosis. This case highlights the importance of considering hypoglycemia in atypical neurological or psychiatric episodes.
Case Report
A 29 yr man had 1yr history of multiple seizure episodes despite being on regular 3 antiepileptic drugs. Episodes occurred on awakening in early morning. The attacks were episodic stereotyped confusional spells characterized by abnormal posturing, perioral and eyelid twitching and unresponsiveness. Compliance was checked and metabolic causes ruled out. MRI Brain was normal. No interracial epileptic activity observed on video EEG monitoring. He presented with unconsciousness and hypoglycemia (48 mg/dl) which recovered immediately after treatment. It was apparent that his previous seizures tended to occur in early morning or several hours after the meal and post seizure confusion state could be shortened if he ate something. The patient gained 10 kg weight in last 6 months. Endocrine evaluation suggested insulinoma. CT revealed a solitary insulinoma in the head of pancreas. The patient had surgical removal and benign insulinoma was confirmed on histopathology.
Conclusion
1) Many patients with an insulinoma do not report the adrenergic symptoms of hypoglycemia and present with neurological or psychiatric manifestations that often lead to misdiagnosis. 2) Seizure disorder has been described in few contemporary cases of persistent hypoglycemia later on diagnosed as insulinoma and insulinoma presenting first time with refractory seizures is rare. 3) Benign insulin secreting adenomas are a potentially curable cause of seizures but may be fatal if unrecognized. 4) Our case reiterates the importance of evaluating the metabolic cause of refractory seizure disorders. 5) Early diagnosis and treatment can free many patients from burdensome multiple antiepileptic treatments.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P794

**Rare Case of Atypical Pituitary Adenoma: Intermediate form of Adenoma between the common Benign Adenoma & exceedingly rare Pituitary Carcinoma**

C. Vaz & A. Chaudhuri
State University of New York, Buffalo, NY, USA.

We describe a case of aggressive pituitary adenoma with atypical biological behavior treated with surgery radiation & chemotherapy. A 46 y/o F presented with nausea & acute vision loss R > L,with no symptoms of amenorrhea, hypothyroidism or hypoadrenalism. Brain MRI showed 4.7×3.6×3.6 cm pituitary macroadenoma with mass effect on optic chiasm, cavernous sinus extension, internal carotid artery encasement, extension into R foramen ovale, orbital apex, sphenoid & ethmoid sinus, prepontine cistern resulting in mass effect on midbrain & pons. Pituitary hormone profile was TSH 1.41 mcU/ml (0.4–5) FT4 0.53 ng/ml (0.8–1.8) ACTH 20pg/ml (6–46) Prolactin 20.6 ng/ml ( < 0.5–25) FSH 1.4 mU/ml (1–25) LH 0.2 mU/ml (0.1–77) GH 7.9 ng/ml cortisol 2.9 mcg/dl(5–25). She had tumor debulking & optic nerve decompression. Postop MRI showed residual tumor with extension into medial brain structures. Tumor pathology showed sparsely granular chromophobe staining pattern, chromogrannin immunohistochemistry +, CAM 5.2 & cytokeratin + fibrous bodies. Ki67 labelling index 10%. Pathological classification was nonfunctional chromophobe adenoma. Symptoms & vision improved but she had residual R visual loss. Postop pituitary hormone profile revealed TSH 0.088 mcU/ml, FT4 0.54 ng/dl, IGF 532 ng/ml (288–736), ACTH 13 pg.ml (5–27), am cortisol 10.6 ng/ml (4–22). She received DDAVP for transient diabetes insipidus, thyroxine for secondary hypothyroidism & hydrocortisone taper. 1 month CT showed marked increase in residual tumor, near doubling of tumor volume, complete encasement of optic

nerve, extension into orbit & cranial base pathways down to hypoglossal canal. She underwent gammaknife therapy, temozolamide chemotherapy & radiological surveillance. While there are no endocrinological, neuroradiological & histological criteria to distinguish pituitary adenoma & carcinoma MIB-1 index of 10%, invasive growth pattern & mitotic activity predicted aggressive biologic behavior of this atypical adenoma(1). As pituitary carcinomas are thought to arise from transformation of benign invasive macroadenomas, given the potential for malignant transformation of this invasive adenoma & due to higher risk of immediate revision surgery, temozolamide & radiation was initiated. We are monitoring response to radiation & chemotherapy with imaging.

**A novel mutation of the MEN1 gene in an Italian family with Multiple endocrine Neoplasia type 1**

G. Sciortino[1,2,3], G. Vitale[1,2,3], F. Guizzardi[3] & L. Persani[1,2,3]
Istituto Auxologico Italiano IRCCS, Cusano Milanino, Italy.

Introduction
MEN-1 is a rare autosomal dominant familial cancer syndrome characterized by involvement of parathyroid glands, enteropancreatic endocrine tissues and anterior pituitary gland. This disease is linked to germline mutations in the MEN1 gene (more than 460 described), whose identification allows the familial genetic counselling. Here we describe a novel germinal mutation in exon 10 of the MEN1 gene identified in an Italian family.
Case Report
A 61-yr-old woman presented with recurrent kidney stones (first manifestation at 25 years of age), osteoporosis, upper abdominal pain. She reported hysterectomy for uterus leyomiomas at 21 years of age, hyperprolactinemia since 30 years, surgical removal of multiple lipomas. Her sister had a diagnosis of prolactinoma at 20 years of age, primary hyperparathyroidism (PHPT), gastric tumor. She had a positive familial history for neoplastic diseases on both maternal (gastro-enteric tumors) and patern(pancreatic tumors and PHPT) sides of her pedigree.
Proband's laboratory examinations showed high values of PRL, gastrin and PHPT (high calcium and PTH with low phosphate). Neck US showed a voluminous parathyroid enlargement. MRI with gadolinium disclosed a pituitary micro-adenoma.
The proband's 40-yr-old son reported a history of recurrent kidney stones already treated by laser lithotripsy, sexual dysfunction, pseudo-gynecomastia, multiple lipomas. Laboratory data revealed severe hyperprolactinemia, hypogonadotropic hypogonadism, PHPT. The MRI showed a pituitary macroadenoma invading the right cavernous sinus. Neck US disclosed two enlarged parathyroid glands.
In all affected family members the genetic testing identified a novel MEN1 germline heterozygous deletion in exon 10, p.K564RfsX3(c.1691delA), resulting in a frameshift generating a premature termination codon consistent with a pathogenic effect.
Conclusion
We describe a new mutation of MEN1 gene with an apparent high degree of penetrance.

## P796

**Pheochromocytoma releasing ACTH: two in one.**

A. Adamska, J. Mysliwiec & M. Gorska
Medical University, Bialystok, Poland.

Introduction
Ectopic release of ACTH caused by pheochromocytoma is extremely rare. The clinical picture of hypercortisolism is overlapped by catecholamine excess that makes diagnosis more difficult.
Case report
A 74-year-old women was admitted to the hospital because of hypertension, recently diagnosed diabetes and weight loss (10 kg per six months). In physical examination: cachexia, dehydratation, pallor, hirsutism, proximal muscle weakness, elevated blood pressure, tachycardia and increased sweating. Laboratory studies revealed severe, resistant for treatment hypokalemia, elevated testosterone and 17-OH progesterone concentrations, severe hypercortisolism without circadian rhythm and not suppressed with 8 mg of dexamethasone; increased plasma ACTH concentration and elevated urinary cortisol and catecholamines levels. In CT tumoral mass in the right adrenal gland was found. The immunohistochemistry of the adrenal tumor confirmed diagnosis of both pheochromocytoma and ACTH.
Summary
Simultaneous secretion of catecholamines and ACTH by the same tumor is a very rare finding. Clinical implications of this co-secretion made diagnostics process more complicated and final diagnosis quite surprising.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P797

**Hypergastrinemia in a Patient with Lymphocytic Colitis and Chronic Gastritis**

E. Melcescu[1], R. Hogan[2], K. Brown[2], S. Boyd[1], T. Abell[1] & C. Koch[1]
Jackson Private Clinic, Jackson, MS, USA.

Serum gastrin (G) levels $>1000$ pg usually raise the suspicion for a neuroendocrine tumor (NET) secreting G. Rarely, such elevated G levels are seen in pts with pernicious anemia (PA) which most commonly is associated with autoimmune gastritis (AG) (1). AG can occur concomitantly with other autoimmune d/o incl. lymphocytic colitis (LC) (2). G stimulates enterochromaffin-like cells which increase histamine (H) secretion. H excess can cause diarrhea (D) as can bacterial overgrowth (BO) or LC.
A 57 yo WF presented with D, sporadic epigastric pain, and bloating. She also had a h/o interstitial cystitis and took pentosan, cetirizine, (pantoprazole in past). She had no h/o ulcers, renal impairment or carcinoid syndrome. PE was unremarkable. Serum G was 1846 pg. EGD revealed gastritis, a pH of 7 with low stomach acid. Bx of the antrum, body of the stomach, and CLO urease testing r/o H. pylori infection. Pathology: chronic gastritis without H. pylori. Serum G and plasma CgA were suggestive of a gastrinoma or NET (table). PA was unlikely b/o nl B12 (748 pg), methylmalonic acid, homocysteine, Hb and MCV.
CT abdomen/pelvis were noncontributory. Pancreatic protocol MRI with arterial, venous, and delayed phase imaging did not reveal a pancreatic lesion.

Random colon bx performed to assess for LC was compatible with LC which may explain her diarrhea, although we also considered excessive H from elevated G, BO, and pentoasan polysulfate which can cause D and be misleading in this setting, pointing to the dx of gastrinoma. She could not stop pentosan but started a PPI and rifaximin for 10 days which decreased bloating and D. Serum G levels decreased but remained elevated (686 pg on prednisone 20 mg and a PPI).
This case illustrates that D may be associated with very high serum G levels in the setting of chronic gastritis (possible BO), LC, and interstitial cystitis (pentosan use), without clear evidence for a gastrinoma or NET. If no h/o ulcers or liver metastases is present in such cases, watchful observation rather than an extensive/invasive and costly search for a NET may be justified.

**Primary hyperparathyroidism due to a parathyroid adenoma, a parathyroid carcinoma and a subsequent adenoma: A case report**
M. Naranjo & E. Tan
St. Luke's Medical Center, Quezon City, Philippines.

Objective
To describe a patient with an unusual course of primary hyperparathyroidism (PHPT) due to parathyroid adenoma in 2004, who developed recurrent hyperparathyroidism due to parathyroid carcinoma in 2010, and a subsequent adenoma in 2011.To our knowledge, this sequential occurrence has not been previously reported in literature.
Case
A 57-year old male was operated on for a parathyroid adenoma in the right inferior gland in 2004. He was asymptomatic until six years later (2010), he was hospitalized due to hypercalcemia with markedly elevated parathyroid hormone level (intact PTH 520 pmol/L). Parathyroid scan showed increased uptake in the inferior right thyroidal bed. Radio-guided parathyroidectomy with intra-operative PTH assay was performed (pre-excision PTH 520,10 min post-excision 8.7, 6 in post-excision 3.77). A 2.3 cm parathyroid carcinoma of the right inferior and superior glands was found. Post-operatively, he developed hungry bone syndrome and was managed with calcium and vitamin D supplements. Upon discharge, ionized calcium level normalized.
In 2011, he developed recurrent hypercalcemia with low phosphorus and elevated intact PTH levels. Repeat parathyroid imaging showed a new lesion in the suprasternal notch. Recurrent and/or metastatic parathyroid carcinoma was primarily considered. However, re-exploration of the neck revealed a 1.5 cm parathyroid adenoma with lymph node negative for metastasis. (Pre-excision PTH 22.7, 10 min post-excision 7.26, 30 min post-excision 5.12). Post-operative ionized calcium was normal.
Conclusion
It is very rare for three independent episodes of PHP to be caused by different pathology in the same patient within a 7-year time frame. Recurrent PHP after resection of a parathyroid carcinoma does not necessarily indicate persistent or recurrent parathyroid carcinoma but can also be caused by a parathyroid adenoma. This underscores the necessity of adequate long-term follow-up to ensure early detection and management of parathyroid tumors.

**Neuroendocrine Tumor with Clinical Characteristics of Insulinoma**
J. Menezes, E. Rodrigues, C. Nogueira, C. Esteves, G. Jorge, M. Matos, L. Graça, J. Pinheiro, Loureiro, J. Lopes, J. Costa , Maia & D. Carvalho
Hospital São João, Porto, Portugal.

Introduction
Insulinomas are almost always located in the pancreas and are usually small. The peak incidence is from the third to fifth decade of life, with females being slightly more frequently affected. The average duration of neuroglycopenic symptoms prior to diagnosis is often prolonged, being more than 5 years in 20% of patients.
Case presentation
Female, 52 years old, medical history notable for hypertension, dislipidemia and Graves disease. She presented with a 4-month history of hypoglycemia with associated symptoms of weakness and tremor. The patient was admitted in the emergency room with garbled speech and disorientation. At that time, her finger-stick blood glucose level was 26 mg/dL. Because of the suspicion of insulinoma, a complete endocrine evaluation was performed specifically, the patient was observed while fasting. At 26 hours of fasting the blood glucose level was of 43 mg/dL, with response to glucagon injection, and the patient was found to have insulin level s $>3$ UI/mL and C-Peptide value $>=0.6$ ng/mL, with glycemia $<55$ mg/dL. Parathyroid hormone and calcium were normal. A high-resolution CT demonstrated a heterogeneous enhancing mass 2.9 cm. The patient was submitted to laparoscopic distal pancreatectomy. A a neuroendocrine well differentiated tumor ($2.8\times1.7\times0.9$ cm) – G1 (ENET) – pT2N0R0 was found in the tail of the pancreas. Immunohistochemical stains for chromogranin and synaptofisin were positive, however for insulin was negative. Less than 2% of the tumor cells were ki67+. Postoperativelty, the patient's symptoms resolved with no further hypoglycemic events.
Conclusion
We report this case because it took just 4 months for diagnosis, because of the dimensions of the tumor and also because, although the biochemical diagnosis of

insulinoma was established, there was no immunohistochemical evidence of insulin production. The patient glycemia however returned to normality with no further symptoms.

**Effects of mTOR inhibitors in the control of non functioning pituitary adenomas cell growth**

M. Minoia, E. Gentilin, M. Rossi, F. Tagliati, E. degli Uberti & M. Zatelli
University of Ferrara, Ferrara, Italy.

Introduction
The main therapeutic approach for non functioning pituitary adenomas (NFA) is surgery, since radiotherapy has several important side effects and medical therapy is rarely effective. Therefore, understanding the molecular pathways regulating NFA cell proliferation is crucial for future drug development. We here explore the possible role of mTOR inhibitors, Everolimus and BEZ235 (which also inhibits the PI3 K pathway) on the effects of Insulin-like Growth Factor-1 (IGF-1) in regulating NFA cell growth in primary culture.
Aims
To this aim 20 NFA primary cultures were incubated with or without IGF-1 in the presence or in the absence of Everolimus and BEZ235, which down-regulate IGF-1 signalling through the PI3 K/Akt pathway.
Materials and methods
Cell viability and apoptosis were evaluated after 48 h. AKT phosphorylation was evaluated by alpha-screen.
Results
Everolimus and BEZ235 significantly reduced NFA cell viability, by 30 and 40% respectively., while IGF-1 enhanced cell viability, an effect completely blocked by the presence of mTOR inhibitors. Co-incubation with an IGF-1 receptor blocking antibody enhanced the antiproliferative effects of Everolimus and BEZ235. Phosphorylation of p70S6K, a down-stream effector of mTOR in the PI3K/Akt pathway, was as well enhanced by IGF-1 and reduced by Everolimus and BEZ235, indicating that IGF-1 exerts its proliferative effects by inducing this pathway, which, in turn, can be effectively blocked by mTOR inhibitors.
We also observed that AKT phosphorylation is enhanced by IGF-1 treatment and significantly reduced by treatment with BEZ235.
Conclusion
In conclusion, our results indicate that IGF-I directly stimulates NFA cell viability through its own receptor. This effect is blocked by Everolimus and BEZ235 which may represent a new medical therapeutic approach for NFA.

## P801

**mTOR inhibitors hamper cell viability in selected human medullary thyroid carcinoma primary cultures**

M. Minoia, M. Rossi, E. Gentilin, D. Molè, E. degli Uberti & M. Zatelli
University of Ferrara, Ferrrara, Italy.

Introduction
It has been demonstrated that mTOR inhibitors have potent anti-proliferative effects in a human Medullary Thyroid Carcinoma (MTC) cell lines. We here explore the possible role of mTOR inhibitors, Everolimus and BEZ235 (which also inhibits the PI3K pathway) on the effects of Insulin-like Growth Factor-1 (IGF-1) in human MTC primary cultures.
Aims
To this purpose, 20 MTCs primary cultures, were treated without or with 1 uM Everolimus, 10 nM BEZ235, and/or 50 nM IGF-1.
Materials and methods
Cell viability and apoptosis were evaluated after 48 h. p70S6K phosphorylation was evaluated by ELISA.
Results
we observed that Everolimus and BEZ235 significantly reduced MTC cell viability, by 20 and 35% respectively, while IGF-1 enhanced cell viability, an effect completely blocked by mTOR inhibitors. Co-incubation with an IGF-1R blocking antibody enhanced the antiproliferative effects of. Everolimus and BEZ235. Caspase activity was enhanced by BEZ235 and reduced by IGF-1, an effect that was attenuated by co-treatment with mTOR inhibitors. Phosphorylation of p70S6K, a down-stream mTOR effector in the PI3K/Akt pathway, was evaluated to assess whether this effect is due to variations in mTOR activity. We observed that IGF-1 enhanced p70S6K phosphorylation, that is reduced by mTOR inhibitors, indicating that IGF-1 exerts its proliferative effects by inducing this pathway.
Conclusion
In conclusion, mTOR inhibitors reduced MTCs cell viability by inducing apoptosis, with a mechanism likely involving IGF-1 signalling, suggesting that these drugs might represent a possible medical treatment for persistent/recurrent MTCs.

## P802

**Disturbed alternative splicing of growth hormone is associated with increased expression of SF2/ASF oncogene in pituitary adenoma**

A. Piekielko-Witkowska[1], H. Kedzierska[1], B. Rybicka[1], P. Nauman[2], Z. Bonicki[3] & A. Nauman[1]
M. Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Warsaw, Poland.

Introduction
Pituitary adenomas account for 10–25% of all intracranial tumours. Although rarely malignant, they are associated with high morbidity due to severe endocrine effects and difficult surgical access. Alternative splicing (AS) consists in selective removal of non-coding regions from pre-mRNA and joining of coding regions to produce mRNA variants that may be further translated. AS is regulated by splicing factors and is often disturbed in cancer. AS of growth hormone (GH) leads to synthesis of five transcript variants. Variant 3 encodes a 17.5 kDa protein which is a dominant negative and blocks secretion of biologically active GH proteins encoded by variants 1 and 2. AS of GH is regulated by splicing factors SF2/ASF and SC35. SF2/ASF is an oncogenic protein. In this study we hypothesized that AS of GH may be disturbed in pituitary tumours.
Methods
The study involved 28 human pituitary adenomas (21 gonadotroph adenomas and 7 other types adenomas) and five non-neoplastic pituitary tissue specimens obtained with the permission of local Bioethics Committee. The used methods were: RNA isolation, reverse transcription, PCR using primers designed to detect GH splice variants, cloning using pGEM-Teasy vector, sequencing, and real-time PCR.
Results
Using GH-specific PCR we found that while in control samples only transcript variant 1 was expressed, in adenoma samples variants 1, 2, and 3 were present. This was confirmed by cloning and sequencing of all three variants. Variant 3 was expressed in 20 (71%) of analyzed adenoma specimens. This was associated with statistically significantly increased expression of SF2/ASF and SC35 mRNAs in gonadotroph adenomas when compared with control samples.
Conclusion
Alternative splicing of GH is disturbed in pituitary adenomas, possibly due to impaired expression of splicing factors SF2/ASF and SC35. Altered splicing of GH may possibly serve as a neoplastic marker in pituitary adenomas.

**Estradiol Potentiates the Inhibitory Effects of SOM230 on Prostate Cells *in vitro* Up-regulating Ligand Binding Domain Expression of SSTR2 and 5**

V. Rossi, D. Visconti, G. Bellastella, V. Palumbo, C. Abbondanza, C. De Rosa, A. Bellastella & A. Sinisi
Seconda Università di Napoli, Napoli, Italy.

The effects *in vitro* and *in vivo* of somatostatin (SS) analogues are linked to the presence of specific binding sites on target cells. Estradiol (E2) may modulate the expression of SS receptors (SSTR) in some cell models, including breast cancer and pituitary cells. Aim of this study was to evaluate the effects of E2 on SSTR1-5 ligand binding domains (LBD) expression levels in prostate epithelial cells (PEC).

Methods

We investigated the effects of E2 on the expression of SSTRs and its influences on SST-analogue SOM230 treatment on a PEC line (EPN) expressing both estrogen receptors (ER) alfa and beta. SSTR proteins were evaluated by Western-blot using specific MoAb recognizing their LBD epitopes (Y-SSTRs MoAb). Starved cells were treated with 20 mM E2 or $10^{-6}$ or $10^{-8}$ SOM230 or 20 mM E2+ SOM230 ($10^{-8}$ or $+10^{-6}$) for 48h. Cells were differently harvested for real time RT-PCR, Western blot or FACS assays.

Results

E2 up-regulated SSTR 1, 2 and 5 mRNAs and proteins. E2 or SOM $10^{-6}$ alone induced apoptosis and decreased slightly proliferation; 20 mM E2+ SOM230 ($10^{-8}$ or $10^{-6}$) combined treatment induced a stronger rate of apoptosis and a greater decrease of proliferation. The synergistic action was correlated to: a reduction in S-phase proliferation with an arrest in G0/G1 phase induced by SOM230 and increased by E2+SOM 230 co-treatment; a caspase-dependent apoptosis induced by SOM230; a reduction of bcl-2 levels induced after addition of E2 that amplified SOM230 effects at lower doses.

Conclusions

E2 induces an up-regulation of LBD of SSTR 1, 2 and 5 and potentiates the inhibitory effects of SOM230 in PEC *in vitro*. Thus estrogens may negatively control prostate tumorigenesis acting directly on cell growth and death and indirectly by up-regulating SSTRs.

**β-Catenin signaling controls tumorigenesis in menin-deficient insulinoma**

G. Ning, Y. Cao, X. Jiang, F. Li, J. Lu, X. Li & W. Wang
Ruijin Hospital, Shanghai, China.

Multiple endocrine neoplasia type 1 (MEN1) is an inherited tumour syndrome characterized by the development of tumours of the parathyroid, anterior pituitary and pancreatic islets, etc. Heterozygous germ line mutations of MEN1 gene are responsible for the onset of MEN1. Here We reported totally 87 patients from 24 unrelated Chinese families associated with MEN1 and identified five novel mutations and several previously reported mutations. Furthermore, we detected a loss of heterozygosity (LOH) at chromosome11q in the removed tumours, including gastrinoma, insulinoma and parathyroid adenoma. After that, we try to explain how the mutated MEN1 genes induced the tumours in multiple endocrine neoplasia type 1 syndrome. Menin is able to interact with β-catenin, and regulates translocation and transcriptional activity of β-catenin via nuclear-cytoplasmic shuttling. To determine the role of β-catenin signaling in β-cells and menin-deficient insulinoma, we established pancreatic β-cell specific ctnnb1 knockout mice (BBKO) and Men1/ctnnb1 double-knockout mice (DBKO). BBKO mice were phenotypically normal compared to WT mice under a chow diet or challenged with a high fat diet, indicated that β-catenin is not crucial for β-cell development and physiological proliferation. Double-knockout of menin and β-catenin rescued the hypoglycemia phenotype and exhibit elevated survival rate compared with Men1 conditional knockout mice. Loss of β-catenin reduced the expression of a series of proproliferative genes, which were up-regulated in menin-deficient islets, including ccna2, pbk, mcm5, mcm6 and Mki67. These results indicate that β-catenin signaling is critical for tumorigenesis of menin-deficient β-cells.

**Hypermethylated in cancer 1 (HIC1), a tumour suppressor gene epigenetically deregulated in hyperparathyroid tumours by histone modification**

J. Svedlund[1], S. Koskinen Edblom[1], V. Marquez[2], G. Åkerström[1], P. Björklund[1] & G. Westin[1]
NCI-Frederick, Frederick, MD, USA.

Primary hyperparathyroidism (pHPT) resulting from parathyroid tumours is a common endocrine disorder with incompletely understood etiology. In renal failure, secondary hyperparathyroidism (sHPT) occurs with multiple tumour development as a result of calcium and vitamin D regulatory disturbance.

The aim of the study was to investigate whether HIC1 may act as a tumour suppressor in the parathyroid glands and whether deregulated expression involves epigenetic mechanisms.

Parathyroid tumours from patients with pHPT included single adenomas, multiple tumours from the same patient, and cancer. Hyperplastic parathyroid glands from patients with sHPT and hypercalcemia, and normal parathyroid tissue specimens were included in the study. Quantitative RT-PCR, bisulfite pyrosequencing, colony formation assay, ChIP, and RNAi was used.

HIC1 was generally underexpressed regardless of the hyperparathyroid disease state including multiple parathyroid tumours from the same patient, and overexpression of HIC1 lead to a decrease in clonogenic survival of parathyroid tumour cells. Only the carcinomas showed high methylation level and reduced HIC1 expression. Cell culture experiments, including use of primary parathyroid tumour cells prepared directly after operation, the general histone methyltransferase inhibitor DZNep, ChIP, and RNAi, supported a role of repressive histone H3 modification rather than DNA methylation in repression of HIC1.

The results strongly support a tumour suppressor role of HIC1 in the parathyroid glands and suggest that perturbed expression of HIC1 may represent an early event during tumour development. Repressive histone modifications are involved in repression of HIC1 expression in hyperparathyroid tumours.

**Stem cell genes are deregulated in parathyroid tumours**

V. Vaira[1], C. Verdelli[2], I. Forno[1], F. Elli[1], V. Guarnieri[3], S. Ferrero[1], A. Scillitani[3], E. Costa[2], L. Vicentini[1], G. Steffano[4], F. Cetani[5], A. Spada[1], S. Bosari[1] & S. Corbetta[6]
IRCCS Policlinico San Donato, Milan, Italy.

In our previous investigation on microRNAs expression pattern in parathyroid carcinomas (Ca), we detected the over-expression of microRNAs belonging to C19MC, the largest human cluster on chromosome 19q13.41. In the present study, the analysis of the expression of selected C19MC and the closely distal MIR371-3 clusters microRNAs (MIR512-3p, MIR517C, MIR520H and MIR372) was extended to 11 Ca, 24 adenomas (Ad) and 6 normal glands. The four microRNAs was expressed in 11% of parathyroid neoplasia. Almost all Ca showed elevated MIR517C levels compared to normal glands, while MIR517C over-expression occurred only in two Ad. MIR372 was detected in 45.5% of Ca and in 37.5% of Ad. By copy number variation analysis, C19MC amplification was identified in most Ca extending distal to the MIR371-3 cluster in almost all amplified samples. Conversely, C19MC amplicon was detected in a small subset of Ad extending distal to MIR371-3 in one sample. C19MC promoter was hypomethylated in 38% of the samples with no difference in frequency between Ad and Ca. Few tumours did not show C19MC amplicon nor hypomethylation. Since the C19MC as well as the MIR371-3 clusters have been linked with the signature characteristic for human embryonic stem cells, we investigated genes of the transcriptional regulatory network governing stem cells pluripotency and self-renewal. By immunohistochemistry, cells with a positive nuclear staining for NANOG were more abundant in Ca (50–70%) compared to normal glands (<10%) and to Ads (5–20%). In parathyroid tumours, NANOG expression was associated with the expression of OCT4 and the loss of the OCT4-inhibited gene DKK1, while SOX2 was undetectable evidencing an impairment of the core

regulatory circuit. Moreover, zfp42/REX1 gene expression was lost in some tumours, as described in other human cancers. These data identified a genetic stem cell signature in parathyroid tumours that seems to correlate with more aggressive tumoral features.
Declaration of interest

## P807

**Long-acting somatostatin analogues are highly effective in men1 patients with early stage duodeno-pancreatic neuroendocrine tumors**

A. Faggiano[1,4], V. Ramundo[1], M. Del Prete[1], V. Marotta[1], F. Marciello[1], L. Camera[1], V. Napolitano[2], L. De[3], G. Lombardi[1] & A. Colao[1]
National Cancer Institute, Fondazione G. Pascale, Naples, Italy.

Somatostatin analogues (SSA) represent a recognized therapeutic option in patients affected with functioning neuroendocrine tumors (NET). In non-functioning NET, SSA are reported to induce tumor stabilization in most of cases and objective response in $<5\%$. NET associated to Multiple Endocrine Neoplasia type 1 (MEN1) are inherited tumors, generally located in the duodeno-pancreatic trait, characterized by well differentiated histotype, high expression of somatostatin receptors and diagnosed at an early stage because of the genetic screening in all first-degree relatives of MEN1 patients. All these features make MEN1 NET susceptible to respond to SSA, however, this has never been specifically investigated.
To evaluate the efficacy of long-acting SSA in MEN1 patients affected with duodeno-pancreatic NET.
All first-degree relatives of MEN1 subjects who genetically diagnosed for MEN1 before the clinical diagnosis of NET and with evidence of one or more duodeno-pancreatic NET $<15$ mm in size were enrolled. Twenty-four patients with MEN1-related duodeno-pancreatic NET (age range 21–42 yrs) were treated with octreotide LAR or lanreotide autogel at standard doses. Treatment duration ranged 6–76 months. At the radiological evaluation (performed by multidetector-row computed tomography and endoscopic ultrasound), multiple duodeno-pancreatic NET (range 1–9), sized 3–14 mm, were detected.
An objective tumor response was observed in 17%, stable disease in 75% and progression of disease in 8% of cases. Due to the low number of progressions, the median time-to-progression could not be estimated. In seven patients with abnormally increased gastrin, insulin and/or chromogranin-A serum concentrations, a complete hormonal response was observed in 100% cases and was stable along the follow-up.
In conclusions, therapy with SSA is highly effective in patients with early stage MEN1 duodeno-pancreatic NET, resulting in long-time suppression of tumor and hormonal activity. Objective response is 17%, suggesting that MEN1 NET is a subgroup more sensitive to SSA than sporadic NET.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P808

**Insulin, IGF-II and a low-affinity insulin analog differentially regulate insulin receptor isoform A trafficking and induce a different balance of metabolic and mitogenic effects**

A. Morcavallo[1], M. Genua[1], A. Palummo[1], E. Kletvikova[3], J. Jiracek[3], A. Brzozowski[4], R. Iozzo[2], A. Belfiore[1] & A. Morrione[2]
University of York, York, United Kingdom.

Introduction
The isoform A of the human insulin receptor (IR-A) binds insulin with high affinity, and binds IGF-II with a 3–10 folds lower affinity. Cells lacking the insulin-like Growth Factor-I receptor (IGF-IR) and overexpressing the human IR-A (R-/IR-A cells) respond to IGF-II with reduced metabolic effects but unaltered or increased mitogenesis as compared to insulin stimulation. We hypothesized that this altered ratio of metabolic-to-mitogenic effects of IGF-II in R-/IR-A cells may depend on the differential regulation of IR-A trafficking. Moreover, we hypothesized that similar different biological effects are features of other low-affinity IR-A ligands.
Methods
We used R-/IR-A cells and evaluated IR-A phosphorylation and trafficking after stimulation with insulin, IGF-II and a synthetic insulin analog (NMeTyrB26-insulin) that binds IR-A with a similar affinity to IGF-II.
Results
We found that NMeTyrB26-insulin has a similar mitogenic activity than IGF-II. Insulin induced strong IR-A phosphorylation, which was instead reduced after IGF-II and NMeTyrB26-insulin stimulation. A clear reduction in cell surface IR-A was strongly induced by insulin, while IGF-II and NMeTyrB26-insulin promoted only modest IR-A internalization. Prolonged cell stimulation with insulin, but not with IGF-II or NMeTyrB26-insulin, targeted the IR-A for proteosomal and lysosomal degradation despite similar levels of IR-A ubiquitination. IRS-1 was also down-regulated by insulin but not by IGF-II or NMeTyrB26-insulin. Clathrin-dependent endocytosis was critical for IR-A-dependent Akt activation, while clathrin-independent IR-A endocytosis regulated ERKs activation. p70S6K activation was instead slightly increased by inhibiting IR-A internalization.
Conclusions
The lower IR-A phosphorylation elicited by IGF-II or NMeTyrB26-insulin, as compared to insulin, may protect IR-A and IRS-1 from negative feed-back down-regulation mechanisms, thus sustaining potent mitogenic stimuli in spite of decreased metabolic activity. These data may have profound implications in the design of insulin analogs and in our understanding of the role of IGF-II in cancer.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P809

**Immunohistochemical, ChIP, and microarray analysis reveals how stromal AR controls prostate cancer outcome through fibroblast specific action of androgen signalling on ECM production and DNA licensing**

D. Leach[1], E. Need[1], D. DeFranco[2], C. Pinnock[3], S. Chopra[3,4], R. Taylor[5], G. Risbridger[5] & G. Buchanan[1]
Monash University, Melbourne, VIC, Australia.

A breakdown in stromal-epithelial interactions mediated by androgens is emerging as a key factor in prostate cancer (PCa) aetiology and progression. Currently however, we have limited knowledge of the mechanics of androgen and androgen receptor (AR) action in prostate stroma, or how dysfunction in that compartment contributes to the disease process.
In this study, immunohistochemical analysis of 64 PCa samples revealed an inverse relationship between stromal AR content and both primary tumour burden and PCa-related death ($P<0.05$). In contrast, epithelial AR content was positively related to Gleson stage and tumour burden but not outcome ($P<0.03$). These relationships were not evident in patient-matched BPH samples. In order to understand how stromal AR might inhibit progression, we investigated androgen action in the AR positive prostate myofibroblast cell line, pshTERT-AR. By chromatin immunoprecipitation, we find lineage-specific chromatin occupancy of regulatory elements by the AR. These differences in DNA interactions leads to divergent enhancement of functional pathways and physiological response. Microarray profiling revealed that only 10% of the genes regulated by androgen in myofibroblasts were also regulated in PCa epithelial cells. This distinct set of genes regulated by androgens lead to regulation of adhesion and ECM production pathways specifically in fibroblasts, as well as opposing effects on apoptosis and cell cycle pathways in comparison to epithelial cells. A key outcome is divergent growth responses, with androgens inhibiting fibroblast proliferation (66% control at 5 days; $P=0.002$) potentially via DNA licensing protein, FBXO32, but stimulating epithelium (50%, $P=0.001$). Importantly, androgens were also found to alter the constituents of fibroblast-deposited extracellular matrix (ECM), resulting enhanced anchorage of both fibroblasts (40%; $P<0.05$) and PCa epithelia (35%, $P<0.05$). In summary, the loss of fibroblast/stromal AR is predicted to stimulate fibroblast proliferation, dysregulate stromal-epithelial interactions in the prostate microenvironment, decrease ECM adhesive characteristics and create an environment that predisposes to epithelial metastasis.

**Looking for the molecular bridge between sex hormone-binding globulin (SHBG) and breast cancer cells**

F. Marano[2], M. Catalano[1,2], R. Frairia[2], G. Boccuzzi[1,2] & N. Fortunati[1]
University of Torino, Torino, Italy.

Sex Hormone-Binding Globulin (SHBG), the specific plasma carrier for sex steroids, interacts with cell membranes. In breast cancer cells, SHBG-cell interaction is closely related to estrogen-sensitivity and it is followed by a well-defined cascade of events. Soon after SHBG binding to cell membranes, cAMP accumulates in the breast cancer cells, activates PKA that in turn suppresses estradiol-induced ERK activation. ERK inhibition abolishes the anti-apoptotic effects of estradiol and reduces ERα transcriptional activity. The final result is a significant inhibition of estradiol-induced proliferation. The cell membrane molecule SHBG interacts with has never been certainly identified. A number of candidates, generally being part of the matrix-associated proteins, have been suggested, such as megalin and fibulin. The aim of the present study was to investigate the expression and potential function in SHBG-cell interaction of megalin and fibulin1 and 2, in estrogen-sensitive breast cancer cells (MCF-7 and T47D) where SHBG interaction and anti-estrogenic effect had been widely described. Megalin, fibulin 1 and 2 gene expression was evaluated in both cell lines in basal condition and after estradiol treatment with Real time PCR. Megalin and fibulin 2 were not expressed. Fibulin 1 expression, already detectable in basal condition, was increased by estradiol. The results were confirmed by Western blot, that allowed us to observe also the correct expression of the protein in cell membranes. Finally, immunofluorescence experiments in MCF-7 cells showed a colocalization of fibulin 1 and SHBG on membranes. We, therefore, suggest that fibulin 1 is likely to be the bridge between SHBG and breast cancer cells. SHBG, interacting with fibulin 1 communicates with breast cancer cell, triggers its molecular mediators, and, at the end, blocks estradiol-induced cell growth.

**Parathyroid atypical adenomas: mutational screening of CDC73/HRPT2 gene**

E. Pardi, S. Borsari, C. Banti, F. Saponaro, L. Torregrossa, C. Marcocci & F. Cetani
University of Pisa, Pisa, Italy.

Atypical parathyroid adenomas represent a subset of tumors with histological features worrisome for carcinoma (PC), such as trabecular growth, fibrous bands and increased mitotic activity without unequivocal criteria of malignancy (local recurrence and/or metastasis). The question of whether these lesions might represent an anticipation of an aggressive clinical behavior that overtime may acquire the full blown features of malignancy remains to be established.

CDC73/HRPT2 tumor suppressor gene mutations have been reported in up to 80% of sporadic PC, mainly associated with reduced expression or loss of its encoded protein, parafibromin. With the exceptions of some studies on parafibromin expression, there are no genetic studies of HRPT2 gene on atypical adenomas.

We collected 15 parathyroid atypical adenomas from patients with sporadic primary hyperparathyroidism (PHPT), obtained at the time of surgery or retrieved from paraffin embedded sections. All but one patients, 8 males and 7 females, with a mean age at diagnosis of 47 years (range 16–68 yrs), were submitted to a single parathyroidectomy. Familial history of PHPT was negative in all patients. Follow-up after surgery ranged from 6 months to 9 years.Thirteen patients were cured by surgery, and two had persistent PHPT.

All specimens were screened for HRPT2 mutations. The entire coding region of the gene and splice sites were sequenced with a BigDye chemistry.

A heterozygous mutation in the donor splice site of intron 1 (c.131G>T) was identified in one adenoma. Unexpectedly, this mutation was a germline mutation, carried by the younger patient of our series. The mutation was also found in the patient's healthy father. The remaining tumors were negative.

Our results suggest that the involvement of HRPT2 gene in parathyroid atypical adenoma is rare. However, HRPT2 gene screening can be suggested in young patients with single atypical parathyroid adenoma.

**Is biochemical screening for pheochromocytoma in adrenal incidentalomas expressing low unenhanced attenuation on computed tomography necessary?**

T. Sane, C. Schalin-Jäntti & M. Raade
Helsinki University Central Hospital, Helsinki, Finland.

Introduction

Pheochromocytomas are characterized by a high attenuation value on unenhanced computed tomography (CT). It is not known whether pheochromocytoma can be outruled as a cause of adrenal incidentalomas based on unenhanced attenuation values only. We evaluated the outcome of routine biochemical screening for pheochromocytoma in a series of patients with adrenal incidentalomas in relationship to the unenhanced attenuation values on CT.

Design and methods

An unenhanced CT was available in 174 of 184 patients with altogether 214 adrenal incidentalomas. All patients were screened for pheochromocytoma with 24hr urinary metanephrines and normetanephrines and for hypercortisolism (1 mg DXM-test and ACTH). Patients with hypertension were screened for aldosterone overproduction (aldosterone/renin ratio and 24hr urinary aldosterone).

Results

One hundred and forty-six incidentalomas in 115 patients had an unenhanced attenuation value $<$ 10 Hounsfield units (HU), but none of these patients had increased 24hr fractionated urinary metanephrines or normetanephrines indicating pheochromocytoma. Sixty-eight incidentalomas in 59 patients had an unenhanced attenuation value $\geqq$10 HU and nine (15.2%) of these patients had surgi-cally and histologically verified pheochromocytoma. Incidentalomas with a HU $\geqq$ 10 were characterized by significantly larger size (2.6$\pm$1.5 vs. 2.3$\pm$1.2 cm; $P<0.001$), were more often functional (27.9% vs. 8.9%, $P<0.001$) and more often operated (44.1% vs. 10.2%; $P<0.001$) than those with a HU $<$ 10.

Conclusion

Pheochromocytoma was outruled as a cause of adrenal incidentaloma if the attenuation value on unenhanced CT was $<$ 10 HU. The results challenge the need for routine biochemical screening of pheochromocytoma in adrenal incidentalomas discovered on unenhanced CT and characterized by a HU $<$10. However, if the incidentaloma is first discovered on contrast enhanced CT imaging, measurements of urinary or plasma fractionated metanephrines is mandatory in order to rapidly exclude the possibility of pheochromocytoma.

## P813

**Clinical and biochemical characteristics of succinate dehydrogenase (SDH) mutation carriers**

H. Venkataraman, M. Debono, J. Cook & J. Newell-Price
Sheffield Teaching Hospitals NHS trust, Sheffield, United Kingdom.

Background

Germline mutations in SDHB, SDHC, and SDHD cause hereditary phaeochromocytoma and paraganglioma (PGL) syndromes. The genotype-phenotype correlation of these mutations and relationship to penetrance is poor. Our objective was to assess characteristics of patients with SDH mutations seen in our dedicated multidisciplinary clinic.

Methods

A retrospective observational study of patients attending from May 2005 to May 2010, approved as an institutional case notes review. Clinical, genetic, biochemical and radiological characteristics were recorded. All patients underwent yearly biochemical screening with urinary catecholamines/metanephrines, and plasma metanephrines, and 2–3 yearly MRI of the sympathetic and parasympathetic chain using axial and coronal T1/T2 spin-echo sequences, with 18FDG-PET if needed for clinical decision making if abnormalities found

Results
From a total of forty-five mutation carriers, tumours were detected by MRI in eighteen patients (median age): 11/34 (26) SDHB (8 secreting), 2/4 SDHC (36) (1 secreting), 5/7 (48) SDHD (all non secreting). 4/11 SDHB patients belonged to one large family of 17 with frame-shift mutation c.379dupA(p.LLe127AsnfsX28) in exon 4 of SDHB Gene. Only one patient had a metastatic phaeochromocytoma at presentation. One patient with an aggressive glomus tumour (SDHC) secreted high levels of dopamine in isolation, treated effectively with Gamma knife. The SDHD associated glomus tumour was nonsecreting and SDHB glomus tumour secreted noradrenaline. Six SDHB patients had false positive biochemistry, most commonly urine metanephrine and normetanephrine, which subsequently normalized. Two new tumours were detected on screening (SDHB,SDHD).
Conclusion
MRI is effective to monitor these patients. False positive biochemistry is common in SDHB, but normal in SDHD despite the presence of tumours. SDHB present at a younger age with abdominal PGL. Dopamine can be the only biochemical abnormality in some aggressive tumors. Gamma knife radiosurgery can be considered for glomus tumours. No new tumours were missed by an interval of MRI imaging every 2–3 years.

## P814

**Efficacy of Everolimus to prevent hypoglycemia in patients with metastatic insulinomas: for the French group of endocrine tumors (GTE-Renaten)**

V. Bernard[1], C. Lombard-Bohas[2], B. Goichot[3], V. Rohmer[4], R. Guimbaud[5], P. Niccoli[5], C. Chougnet[1], P. Ruszniewski[7] & E. Baudin[1]
Hôpital Beaujon, Clichy, France.

Background
Refractory hypoglycemia in patients with metastatic insulinomas (RHMI) is an important cause of morbidity and mortality and everolimus could be a new therapeutic option.
Methods
We conducted a restrospective multicentric study within the French group of endocrine tumors to evaluate the time to first symptomatic recurrence (TSR) in patients with RHMI after everolimus initiation. Ongoing hyperglycemic medical options and safety were recorded.
Results
Twelve patients with RHMI treated with everolimus (dose initiation: 10mg/d except one patient 5mg/d) between May 2007 and June 2011 were reviewed. Everolimus was given after a median of four previous therapeutic lines and median duration was 6.5 months (range, 1.5–32+ = ongoing months). Clinical benefits were observed in eleven patients. Median TSR was 6.5 months (range, 0–32+ months): 7 and 5 patients remained symptom free for more than 3 and 6 months respectively. 5 patients were still treated at 6, 7, 10, 12 and 32+months. Six patients discontinued additional hyperglycemic therapies including three glucose infusions. Three patients discontinued everolimus because of pulmonary side effects at 1.5, 3 and 7 months of initiation: two deaths occurred (one non-infectious pneumonitis and one pneumocistis pneumonia). Three patients discontinued everolimus because of disease progression at 2, 3 and 10 months of initiation, without hypoglycemia recurrence.
Conclusion
Everolimus appears as a new effective treatment modality for metastatic insulinomas complaining of refractory hypoglycemia. Pulmonary tolerance should be carefully monitored.

**Differential TNFα -synthesis and signaling in endocrine tumors after treatment with the Tumor-Vascular-Disrupting Agent ASA404 (vadimezan)**

C. Hantel, A. Ozimek, R. Frantsev, F. Scheller, M. Reincke, T. Mussack & F. Beuschlein
Ludwig-Maximilians-University, Munich, Germany.

Recently, we investigated effects of the Tumor-VDA ASA404 in tumor models for neuroendocrine tumors of the gastroenteropancreatic system and adrenocortical carcinoma 24 hours after treatment of BON and NCIh295 tumor bearing mice with ASA404 (A), paclitaxel (P) or the combination (A+P). We detected for BON tumors extensive necrotic areas as well as a significant decrease in cell proliferation, increase of apoptotic cells and reduction of microvessels after A or A+P treatment while no comparable effects were detectable in NCIh295 tumors. As TNFα -signaling is assumed to mediate parts of A induced effects we thenceforth utilized these models with their different responsiveness for characterization regarding TNFα stimulation and signaling. We detected in both groups a significant increase of TNFα serum levels compared with controls ($P<0.05$), but no significant differences between both tumor entities upon A treatment (BON: 2818±999%; NCIh295: 1165±422%, $P=0.18$). However, intra-tumoral TNFα content was significantly increased for BON tumors after A treatment while no differences were detectable for NCIh295 (basal: 100%; BON: 1178±263%, $P=0.007$; NCIh295: 220±86%, $P=0.23$). *In vitro* we detected a TNFα dependent 4-fold higher induction of apoptosis (basal: 100%; BON: 823± 35% vs. NCIh295: 244±12%; $P=0.007$) and increase in IKK beta activity for BON but not for NCIh295 cells (basal: 100%; BON: 140±4%. $P<0.001$; NCIh295: 108±5%; $P=0.32$). Basal TNF receptor 1 expression was not significantly different, but we detected high levels of Toll-like-receptor (TLR)-4 in the BON tumor model *in vitro* and *in vivo* while receptor expression appeared to be abrogated for NCIh295. TLRs are widely expressed in cytokine producing cells and TNF alpha is an important downstream mediator of TLR-4 signaling. Thus, ASA404 treatment holds promise in the treatment of GEP-NETs. Furthermore, the utilized tumor models might help to delineate resistance mechanisms involved in VDA induced anti-tumor activity.

**Anti-proliferative effect of GHRH antagonist JMR-132 on ovarian cancer cell via EGFR-Akt pathway**

J. Guo[1], A. Schally[2] & P. Leung[3]
University of British Columbia, Vancour, BC, Canada.

Antagonists of growth hormone-releasing hormone (GHRH) are being developed for the treatment of various human cancers. In this study, we investigated the effectiveness of GHRH antagonist JMR-132 treatment in ovarian cancer cell lines (SKOV-3, CaOV-3 and OVCAR-3). Using MTT assay, we found that JMR-132 has a strong anti-proliferation effects on SKOV-3 and CaOV-3 cells in a time (0, 24 h, 48 h, 72 h, 96 h) and dose (0, 25 nM, 50 nM, 100 nM and 200 nM) dependent manner. Also, JMR132-induced the activation and increases cleaved caspase-3 in a time-dependent manner in both cell lines. In addition, flow cytometry assay showed that there is a G1 phase cell circle arrest after treatment of JMR-132 in these two cell lines. With 100 nM JMR-132 per day for 4 days, the phosphorylation of Akt (p-Akt) decreased significantly, suggesting that JMR-132 inhibit the PI3K-AKT pathways in ovarian cancer cells. Treatment of the SKOV-3 and CaOV-3 cell with specific PI3K inhibitor LY294002 (10 nM) in combination with the presence or absence of EGF (10 ug/ml) abolished JMR-132 attenuated EGF-induced proliferation in both cell lines. More importantly, continuous treatment with JMR-132 reduced the expression of total EGF receptor (EGFR) in a time dependent manner. Knockdown of the endogenous expression of EGFR by siRNA attenuated JMR-132 inhibited proliferation of SKOV-3 and CaOV-3 cells by EGF. In summary, the present study demonstrates that the antiproliferation effect exerted by GHRH antagonist JMR-132 is due in part by interference of the EGF receptor-Akt pathway in ovarian cancer cell.

**Characterization of circulating tumor cells in prostate cancer patients**

S. Maheswaran, S. Stott, S. Nagrath, R. Lee, M. Toner & D. Haber
Massachusetts General Hospital, Boston, MA, USA.

This work focuses on the characterization of circulating tumor cells(CTCs) captured from the blood of cancer patients using a microfluidic chip functionalized with an antibody against the epithelial cell adhesion molecule (EPCAM). We visualize CTCs captured from the blood of prostate cancer patients taking advantage of the unique tumor-associated marker, prostate specific antigen (PSA). Our data demonstrate that CTCs are detectable preoperatively in patients with early stage, resectable prostate cancer with an immediate dramatic postoperative decline ( < 24hrs). However, some patients had persistent CTCs for up to 3 months following prostate resection, suggestive of transient extraprostatic tumor deposits. Moreover, CTC counts in patients with metastatic disease declined following the initiation of androgen deprivation therapy or other effective treatments. Remarkably, dual staining of captured CTCs for PSA and Ki67 indicated a broad range in proliferative index of CTCs, reflective of the evolution of prostate cancer growth traits under castrate conditions. Thus, we believe that isolation and analysis of CTCs in both localized and metastatic prostate cancer will provide novel insight into early hematogenous dissemination of prostate cancer and enable molecular analyses of treatment-responsive and -resistant disease, supporting their application in long-term clinical studies.

**Mitotane Inhibits Cell Growth Proliferation and Modulates MRP1 Protein Expression In Different Human Cancer Cell Lines**

A. Stigliano[1,2], L. Cerquetti[1,2], C. Sampaoli[1,2], B. Bucci[2], D. Amendola[2], M. Rosato[1,2], R. Marchese[2], G. Novelli[2] & V. Toscano[1]
San Pietro Hospital, Rome, Italy.

Background

Actually mitotane is an adrenal-specific agent employed in the treatment of adrenocortical carcinoma (ACC), and although it has been used for several decades, its exact mechanism of action, remain to be fully elucidated. Some authors reported that mitotane affected *in vitro* the multidrug resistance gene mdr-1/P-glycoprotein. MRP1, belonging a multidrug resistance protein family, exerts a chemo-resistance activity in many type of cancer leading to the failure of chemotherapy. Interestingly many aggressive tumours are often associated to MRP1 over-expression.

Aim

In this study we investigated the effect of mitotane in different human cancer cell lines. The aim of the present study was to investigate the hypothetical link between MRP1 protein expression level and response to mitotane treatment.

Materials and methods

Adrenocortical cancer, glioblastoma, medulloblastoma, ovarian cancer and breast cancer cell lines were grown in appropriate culture medium and treated with mitotane at different concentration. Cell cycle analysis was analyzed by flow cytometry (FCM). Cell cycle related protein and apoptotic molecules expression levels were detected by Western Blot analysis. Instead MRP1 protein was evaluated by immunofluorescence flow cytometric analysis.

Results

Mitotane treatment induced in all cell lines examined a cell growth inhibition characterized by an alteration of cell cycle. The expression level of MRP1 protein was modulated after mitotane exposure, indicating its possible role in response to treatment. In addition, we also observed a different expression of cell cycle molecules (cyclin B1 and E, cdk1) and apoptotic cell death protein (caspase 3) affected by mitotane treatment in human cancer cell lines examined.

Conclusions

Mitotane exposure shows an antiproliferative effect in several cancer cell lines, interfering with MRP1 expression. It could explain the pharmacological effect of the drug. These findings support the hypothetical role of mitotane in therapeutic approach in different type of human cancers.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Hormone combinations produce unique steroid receptor binding and regulatory profiles in breast cancer cells**

E. Need, E. Swinstead & G. Buchanan
The University of Adelaide, Adelaide, SA, Australia.

Studies into estrogen receptor alpha (ERα), progesterone receptor (PGR) and the androgen receptor (AR) involvement in breast, uterine and prostate cancers has provided considerable insight into the molecular actions these receptors, but have thus far focused on each receptor individually and alone in different cell types. Here, whole genome expression microarray analysis and ChIP-sequencing in ZR-75-1 breast cancer cells, in response to combinations of 17β-estradiol (E2), progesterone (PROG) and 5α-dihydrotestosterone (DHT), was used to provide new information on action of steroid combinations. For each steroid/receptor alone, a remarkably small subset of high affinity binding sites and expression responses were found to be common amongst different cells and disease states ( < 10%). The larger proportion of lower affinity sites and responses were found to predominate, and likely govern cell specificity of hormone responses. Importantly, when we add more than one hormone, we identify distinct DNA binding patterns for each receptor, as well as unique gene expression profiles and important gene families critical in cellular function. For example, long term E2 treatment in combination with PROG results in a dramatic 10-fold increase in the number of PGR binding sites detected at an equivalent peak threshold in comparison to PROG alone. Furthermore, only E2 and PROG combination treatment resulted in PGR binding sequences enriched for hormone response elements and important coregulator binding sequences, such as FOXA1. These data suggest that the actions of steroid receptors in breast cancer cells are not additive or independent, but combine in a different way to produce a unique cellular response that is not evident by investigation of each receptor in isolation.

### Medical and Peptide Receptor Radionuclide Therapy with Somatostatin Analogues in Well and Moderately Differentiated Neuroendocrine Tumours

A. Bianchi, D. Iacovazzo, F. Lugli, A. Fusco, S. Chiloiro, M. Mormando, L. Tartaglione, G. Grande, A. Larghi, G. Schinzari, G. Doglietto, S. Margaritora, G. Perotti, G. Rindi, A. Pontecorvi & L. De Marinis
Policlinico "A. Gemelli" - Catholic University, Rome, Italy.

Introduction
Peptide receptor radionuclide therapy (PRRT) is a treatment choice for inoperable or metastasized neuroendocrine tumours and this therapy seems more effective in the biochemical and volume control of disease than somatostatin analogues (SSA).
Aims
To demonstrate the efficacy of medical therapy with SSA and PRRT in patients with well and moderately differentiated neuroendocrine tumours.
Materials and methods
We evaluated 60 patients (29 males, 31 females; mean age at diagnosis $53 \pm 17$ years) affected by well and moderately differentiated neuroendocrine tumours. 26 patients (43%) were affected by bronchial carcinoids, 16 patients (27%) by intestinal neuroendocrine tumours, 15 patients (25%) by pancreatic neuroendocrine tumours, 3 patients (5%) by metastases from neuroendocrine carcinoma of unknown origin. 25 patients (42%) with either metastatic or recurrent disease, unresectable primary tumours or symptoms of hormone excess were treated with SSA. Among these, 10 patients (17%) with metastatic disease or unresectable primary tumours with intense hyperuptake at the Octreoscan underwent 2 to 7 cycles of PRRT with 90Y-DOTATOC or 177Lu-DOTATATE. Mean follow up was $41 \pm 10$ months.
Results
Medical treatment with SSA allowed control of symptoms related to hormone excess in all patients but 1 with refractory carcinoid syndrome. Among the patients that underwent PRRT, 6 (60%) had minor or partial response, 3 (30%) had stable disease while 1 patient had progression of disease. Interestingly, 3 of the 6 patients with minor or partial response to PRRT had further progression with a mean PFS of 12.7 months.
Conclusions
Medical treatment with SSA allowed control of hormone secretion in the majority of patients. PRRT allowed minor or partial response of disease in a high proportion of treated patients. However, among these, a relatively high proportion of patients had further progression of disease.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### Expression of ErbB2 in craniopharyngiomas: Possible therapeutic implications

Sayid Shafi Zuhur[1], Canan Tanik[2], Selvinaz Velet[1], Ahmet Murat Musluman[3], Fevziye Kabukcuoglu[2] & Yuksel Altuntas[1]
[1]Sisli Etfal Training and Research Hospital, Endocrinology and Metabolism Department, Istanbul, Turkey; [2]Sisli Etfal Training and Research Hospital, Pathology Department, Istanbul, Turkey; [3]Sisli Etfal Training and Research Hospital, Neurosurgery Department, Istanbul, Turkey.

Background
Currently, there is no satisfying treatment option other than gross total or subtotal resection in combination with adjuvant radiotherapy for the treatment of craniopharyngiomas. However, recurrence could occur in a substantial proportion of craniopharyngiomas despite gross total resection and radiotherapy. Human epidermal growth factor receptor 2 (HER-2/ErbB2) overexpression was determined in various human carcinomas and is associated with aggressive clinical behavior. Therefore, ErbB2 has been the target for immunotherapy. To date, ErbB2 immunoexpression has not been determined in craniopharyngiomas.
Purpose
To determine the expression of ErbB2 in craniopharyngiomas to assess the rationale for targeting this receptor for the treatment of craniopharyngiomas.
Methods
The ErbB2 immunostaining was performed on 20 adamantinomatous craniofaryngiomas using avidin-biotin-peroxidase complex method. ErbB2 immunoexpression was evaluated using a light microscope and was interpretted according to the American Society of Clinical Oncology/College of American Pathologists criterions (score 0, no staining or membrane staining is observed in $<10\%$ of the tumor cells; score 1+, faint/barely perceivable membrane staining is detected in $>10\%$ of the tumor cells, and only part of the membrane is stained; score 2+, weak to moderate complete membrane staining is observed in $>10\%$ of the tumor cells; score 3+, strong complete membrane staining is observed in $>30\%$ of the tumor cells).
Results
Of the 20 cases evaluated, 2 (10%) were score 3+ for ErbB2. One of these patients was a 12 years old female child who was died soon after the first surgery and the other was a 30 years old male patient who underwent 3 surgeries and radiotherapy due to the repeated recurrences.
Conclusion
Results from this study suggests ErbB2 overexpression in a considerable number of craniopharyngiomas. Further studies are required to assess the efficacy of ErbB2 inhibitors in the treatment of conventional treatment resistant craniopharyngiomas with high ErbB2 expression.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

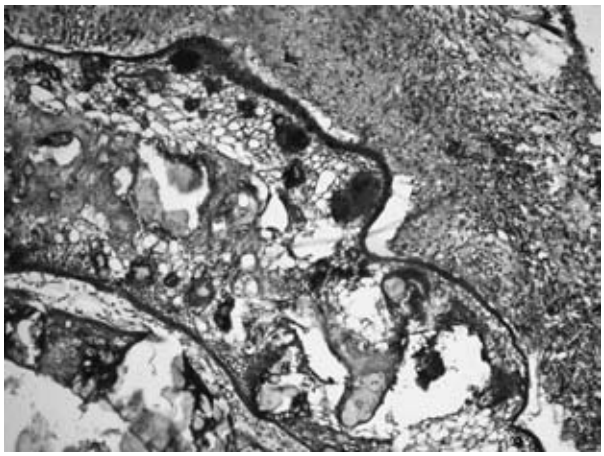

**Figure 1.** Score 3+ ErbB2 immunoexpression in adamantinomatous craniopharyngioma (case 1) (magnification × 40)

## P822

### Wnt-signalling in human insulinomas

A. Pohle, M. Anlauf, A. Raffel, M. Krausch, W. Knoefel, M. Schott, W. Scherbaum & S. Schinner
University Hospital, Düsseldorf, Germany.

Objectives
The Wnt-signalling pathway is involved in tumor development in various tissues. Wnt-signalling molecules are expressed in pancreatic beta-cells. In addition, Wnt-signalling regulates insulin secretion and the proliferation of pancreatic beta-cells *in vitro* and in animal models. However, it is not clear whether Wnts play a role for the development of human insulinomas. Therefore, we investigated the expression pattern of Wnt-signalling molecules in benign and malign human insulinomas.
Methods
human insulinomas were analysed using tissues arrays. The insulinomas were classified as benign ($n=49$) or malign ($n=10$). Immunohistochemistry (IHC) for Wnt3a, Wnt4 and frizzled was performed. The expression of these molecules was assessed with a score model (expression level multiplied by number of positive cells, maximum score: 12). Healthy pancreas sections served as controls. Proliferation assays ([3H]-thymidine uptake) of INS-1 insulinoma cells were performed after stimulation with Wnt3a protein.

Results
1 Wnt3a, Wnt4 and frizzled are expressed in the normal human endocrine pancreas (control group). 2. The extracellular ligand Wnt3a is strongly over-expressed in human insulinomas (benign: $7.59 \pm 3.20$, $P < 0.05$; malign: $3.39 \pm 2.51$, *n.s.*) compared to controls ($2.50 \pm 0.50$). 3. The Wnt-receptor frizzled is over-expressed in insulinomas (benign: $6.21 \pm 3.44$, $P < 0.05$; malign: $5.47 \pm 3.34$, $P < 0.05$) compared to healthy control pancreas ($1.5 \pm 0.50$). Using *in vitro* assays we found Wnt3a to induce the proliferation of INS-1 insulinoma cells to 151.2% of untreated controls.
Conclusions
These data demonstrate that the expression of Wnt3a and frizzled is increased in human insulinomas compared to normal endocrine pancreatic tissue. On the functional level, Wnt3a stimulates the proliferation of insulinoma cells *in vitro*. This suggests that dysregulated Wnt-signalling is involved in the development of insulinomas. Wnt-signalling molecules are not useful as markers for malignancy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P823

**How clinical presentation of insulinoma is changing**

M. Toaiari, M. Davì, L. Boninsegna, M. Falconi & G. Francia
University of Verona, Verona, Italy.

Introduction
In 2009 the Endocrine Society's clinical practice guidelines for management of hypoglycemic disorders, confirming previous suggestions, have stated that the new cut-off of insulin for the diagnosis of insulinoma should be lowed to 3 μU/mL in presence of hypoglycemia (serum glucose $\leq$55 mg/dL). Moreover hypoglycemia in post-prandial status has been reported in insulinoma, alone or associated with fasting hypoglycemia. Finally preexisting diabetes mellitus is increasingly recognized in these patients.
Aim
To evaluate clinical features and diagnostic criteria in a monocentric series of insulinomas including sporadic and multiple endocrine neoplasia type 1 (MEN-1) patients. In addition anamnestic glucose metabolic profile was investigated.
Patients and methods:
Clinical and biochemical data regarding 33 patients including 27 sporadic and 6 MEN1 were retrospectively analyzed.
Results
The 72 hour fasting test was positive in all cases. However in one case it was initially negative since hypoglycemia did not occur, but became positive after 2 year follow-up. Three patients showed a nadir insulin level $>3$ μU/ml but $<6$ μU/ml. In the remaining 30 cases lowest insulin level was $>6$ μU/ml. At presentation 27 patients (82%) reported only fasting symptoms, 3 (9%) only post-prandial symptoms and 3 (9%) both. Four cases (12%) had been previously affected by type 2 diabetes mellitus and 4 cases by impaired fasting glucose
Conclusion
The new cut-off of insulin has further increased the sensitivity of 72 h fasting test for the diagnosis of insulinoma from 87 to 100% in patients. However the absence of hypoglycemia during test does not rule out in definitive manner the diagnosis and the test should be repeated in any high suspicion case. Surprisingly previous glucose metabolism alterations are not infrequent and require further evaluation in wider series.

**Effects of mitotane on gene expression in the NCI-H295R cell line**

A. Zsippai[1], D. Szabo[1], Z. Tombol[1], P. Szabo[1], K. Eder[1], A. Patocs[2], S. Toth[1], A. Falus[1], K. Racz[1] & P. Igaz[1]
Hungarian Academy of Sciences and Semmelweis University, Budapest, Hungary.

Background
The adrenolytic agent mitotane is widely used in the adjuvant treatment of adrenocortical cancer, but its mechanism of action including potential effects on mRNA expression is poorly elucidated.
Objective
To examine mitotane-induced mRNA expression changes in the H295R adrenocortical cancer cell line.
Methods
Various concentrations of mitotane in different treatment periods (24–120 h) have been tested in cell viability assays (MTT colorimetric assay and propidium iodide flow cytometry) and for hormone measurements (cortisol and androstenedione) to select the optimal mitotane concentration effectively inhibiting hormone secretion without affecting cell viability. Total RNA isolated from cultures treated for 48 and 72 hours have been subjected to Agilent $4 \times 44$ K microarray platforms. Significantly differentially expressed mRNAs have been validated by quantitative real-time polymerase chain reaction (qRT-PCR).
Results
The mitotane concentration $5 \times 10^{-6}$ M has been selected based on analysis of hormone secretion and cell viability. Altogether 227 genes with significant differences in expression have been found, and the underexpression of 3 genes involved in steroid hormone biosynthesis (3-beta-hydroxysteroid dehydrogenase types 1 and 2 (HSD3B1 and HSD3B2), 21-hydroxylase (CYP21A2)) and 3 significantly overexpressed genes (aldehyde dehydrogenase 1 (ALDH1L2), growth differentiation factor 15 (GDF15) and serpin peptidase inhibitor (SERPINE2)) have been validated relative to the ZNF625 housekeeping gene.
Conclusions
These results demonstrate that the mitotane-induced decrease in adrenocortical hormone secretion is in part mediated at the mRNA level, and mRNA expression changes might be involved in the adrenolytic action of mitotane.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Ouabain as an antiproliferative agent on adrenocortical cell models and on primary adrenocortical tumor cells**

R. Pezzani, B. Rubin, S. Barollo, M. Redaelli, C. Mucignat-Caretta & F. Mantero
University of Padova, Padova, Italy.

Ouabain is a cardiotonic steroid belonging to Strophanthus species. Recently its role in the treatment of tumors has been investigated, as ouabain seems to exert antiproliferative effects. Adrenocortical carcinoma (ACC) is a rare cancer, with poor prognosis, of which SW13 and H295R cells could be considered a cellular model.
Our aim was to evaluate if ouabain exerts anticancer property.
The effects of ouabain were assessed by MTT assay, by [3H] thymidine assay, by Wright's staining method, by flow cytometry analysis, by homogeneous caspase assay and by western blot.
Ouabain induced a reduction in cell viability at 24h and 72h in SW13, in H295R and 4 primary adrenocortical tumor cells. Proliferation rate decreased effectively in SW13 and H295R at higher doses. Marked morphological changes were observed both for SW13 and H295R, with an increase in necrotic process. Cell cycle distribution was altered by ouabain in SW13. Apoptosis analysis demonstrated an increase in caspase activity, clearly evident for SW13 at 72h. FACS analysis by Annexin V-FITC and propidium iodide confirmed an increase in necrotic process especially at higher concentrations. Western blot analysis showed Erk, Akt, p-Akt, P70s6k and p-P70s6k decreased in the treatments of SW13.
Our study demonstrated the antiproliferative effects of ouabain on SW13 and H295R cell models and on primary adrenocortical tumor cells. The results we obtained are promising, but more data are needed to better clarify the role of ouabain in these cellular models, before attempting any approach to animal models.

**Profile of Patients with Pheochromocytoma & Paraganglioma**

P. Gupta, M. Khurana, A. Ammini & S. Sharma
AIIMS, New Delhi, India.

Introduction
There is scarcity of information regarding the profile of patients with Pheochromocytoma and paraganglioma from India.
Aim
To study clinical profile of patients with Pheochromocytoma (PHEO)/ Paraganglioma (PGL) attending the AIIMS hospital.
Methodology:
Study protocol was approved by the AIIMS ethics committee. Written informed consent was taken from patients (parents in case of children). Patients of PHEO & PGL attending the AIIMS hospital from March 2009 were enrolled for this study. The patients with the features of VHL & MEN-1 &2 syndromes were excluded from the study.
PHEO/PGL were diagnosed on the basis of clinical profile, elevation of metabolites Epinephrine, Norepinephrine, Dopamine, Vinylmandelic acid, Normetanephrine, Metanephrine, MRI, MIBG uptake, Ga-DOTANOC uptake etc. Diagnosis was confirmed with histopathologically.
Results
Forty three new patients were diagnosed to have PHEO/PGL during 22 month period starting from March 2009. Age range from 14–62 years (mean 35.09 y $\pm$ 14.07), 18M & 25F.Twenty two (51.1%) *P* were PHEO, 2(4.6%) had PHEO along with extra-adrenal PGL, 1 (2.3%) had PHEO along with parathyroid adenoma. 18 (41.6%) patients had PGL. Out of these 18 patients, 2(11%) had 2 PGL, (one with chest & urinary bladder (UB) PGL & one with Carotid body & thyroid), 1 (5.5%) with UB PGL, 2(11%) with chest PGL, 1(5.5%) with pulmonary, and 1 (5.5%) with abdominal PGL. 11 (61.1%) had head & neck PGL. 10 (23.2%) patients with PHEO/PGL had positive family history. 9 (90%) of these patients with positive family history were below 45 years of age, whereas only 1 (10%) patient with age above 45 year had positive family history. One patient had malignant PHEO. Twenty three (53%) patients had elevated blood glucose. Tumor size range from 2$\times$2$\times$2.1 cm to16.2$\times$9$\times$9 cm.
Conclusion
Patients with PHEO/ PGL with positive family history are diagnosed at early age.

## P827

**The role of circulating and tumor infiltrating T-cells on clinical outcome in adrenocortical carcinoma**

S. Sbiera[1], T. Dexneit[1], S. Schmull[1], H. Voelker[2], L. Kraus[1], S. Steinhauer[1], B. Allolio[1] & M. Fassnacht[1]
University of Würzburg, Würzburg, Germany.

In recent years, it was demonstrated that tumor infiltrating and circulating regulatory and cytotoxic T-cells are associated with clinical outcome in several solid tumors. However, their role in adrenocortical carcinoma (ACC) was never studied, although 60% of these tumors secrete autonomously cortisol, a well-established potent immunosuppressant that most likely influences the balance between different T-cells.
Firstly, we analyzed the circulating regulatory T cells (T(reg); CD4+ CD25highFOXP3+) in 173 blood samples of ACC patients (44 tumor-free, 86 with tumor but no endogenous cortisol excess and 43 with present cortisol excess) compared to 20 healthy blood donors. Secondly, we performed immunofluorescence analyses on paraffin embedded primary tumor tissue from 58 ACC patients for T(reg)(CD3+FOXP3+), cytotoxic T lymphocytes (CTL; CD3+CD8+) and T-helper cells (CD3+CD4+). Furthermore, we performed uni- and multivariate survival analyses.
The percentage of circulating T(reg) in ACC patients with cortisol oversecretion was significantly higher than in the other ACC groups (7.7$\pm$4.5 vs. 5.7$\pm$3 and 5.5$\pm$2.5%; $P<0.05$) and much higher than in healthy donors (3.6$\pm$0.9%; $P<0.001$). While univariate analysis showed a significantly negative association of T(reg) with survival (HR=1.78; $P=0.02$), this influence disappeared in a multivariate analysis adjusting for tumor burden and cortisol excess.
In 41(70%) of ACC samples CTL tumor infiltrates were present (mean 17.8$\pm$ 46.1 cells/HPF) and 31 samples (64.5%) showed T(reg) infiltrates. However, no significant correlation with survival could be demonstrated in a multivariate analysis. Surprisingly, infiltrating CD4+T-cells, present in 17(35.4%) of cases, were independently associated with a better survival (HR=0.39(95%CI 0.16–0.91); $P=0.03$).
In conclusion, neither circulating T(reg) cells nor tumor infiltrating T(reg) nor CTL are associated with clinical outcome in patients with ACC after adjusting for tumor burden and cortisol secretion. Interestingly, CD4+T-cell infiltrates were significantly associated with a better prognosis suggesting a potentially relevant role of these cells in ACC.

**Surgical management of primary hyperparathyroidism in a unit where Intra-operative PTH (IOPTH) monitoring is not routinely performed**

N. Rughooputh, R. Vinayagam & S. Pain
Norfolk and Norwich University Hospital, Norwich, United Kingdom.

Introduction
Parathyroidectomy is performed in primary hyperparathyroidism using either focussed approach or bilateral neck exploration depending upon the pre-operative localisation results. The type of localising investigations and utility of intra-operative adjuncts like IOPTH vary in individual units. In our unit, parathyroid sestamibi scan and neck ultrasound (USS) are done routinely for all cases, and SPECT/CT and CT or MRI are reserved for selective patients. This study looks into our practice to evaluate our first-time success rate and eventual cure rate.
Methods
All consecutive patients who underwent parathyroidectomy for primary hyperparathyroidism between January 2009 and October 2011 were reviewed. 10 patients who had intra-operative sestamibi injection with gamma probe guidance and IOPTH were excluded.
Results
Out of 150 (Male/Female: 42/108) patients, 67 had focussed parathyroidectomy and 83 had bilateral neck exploration. Median age was 64 years (range 22–86). All 150 had sestamibi scan and 147 had USS (one had CT neck, one had SPECT/CT and one had none) with concordance in 69 cases (46%). The median duration of operation was 34 minutes (range 8–126).
The serum calcium level was normal in 142 patients at follow-up (first time success rate 94.7%). Out of the remaining 8 patients (2 focussed and 6 bilateral exploration), 5 had re-exploration and were cured, 3 did not have further operation (2 are awaiting further investigations for MEN1, 1 patient has normal calcium and is being actively monitored). Histology showed single adenoma in 137 cases, 2 double adenomas, 6 multi-glandular hyperplasia, 3 normal parathyroid gland, 1 thyroid colloid nodule and 1 thymic tissue. The eventual cure rate was 98% pending three patients who have not had re-operation yet.
Conclusion
Parathyroidectomy for primary hyperparathyroidism can be safely performed with acceptable cure rates reserving the costly and time-consuming intra-operative adjuncts for cases with difficult preoperative localisation.

**Enhanced antitumor efficacy of fructose conjugated-gefitinib on lung cancer cell lines *in vitro* and *in vivo***

H. Hui[1,2,4], S. Zhang[3], W. Ding[1,2], J. Li[2], X. Zhao[1,2], M. Zuo[3], X. Wang[3], W. Gu[4], S. Pandol[2,4] & V. Go[2,4]
David Geffen School of Medicine at UCLA, Los Angeles, CA, USA.

Cancer cells have shown an overexpressed fructose transporter GLUT5 and preferential utilization of fructose as compared to glucose, implicating that a

fructose-based analogue would be a useful target for diagnosis and treatment of cancer. We have successfully synthesized the fructose conjugated-gefitinib compounds {N-[4-(3-chloro-4-(3-fluorobenzyloxy)phenylamino)-7-methoxy-quinazolin-6-yl]-4- [N-methyl-N-(1-deoxy-1-fructosyl)]aminobutanamide}, and examined its antitumor efficacy on cancer cell lines *in vitro* and *in vivo*. Conjugation of fuctose with gefitinib, a sparingly water-soluble drug, dramatically improved its aqueous solubility. Dose-and time-dependently anti-proliferation and apoptosis effect of fructose-gefitinib compound 1 have been observed with MTT assay and FACS in both human colon adenocarcinoma cell line SW480 and human lung adenocarcinoma epithelial cell line A549, the median IC50 values of compound 1 for SW480 and A549 cell lines at exposure durations of 72 h were 2.96 μM and 10.69μM, considerably lower than 8.26 μM and 21.4 μM of gefitinib on SW480 and A549 cell lines, respectively. Furthermore, its attenuated efficacy have been observed in cells trasfected with Glut5 SiRNA. In addition, the enhanced antitumor effects of the compound I was confirmed in A549 tumor xenograft models. Our data demonstrate, for the first time, that conjugation of fuctose and gefitinib imporved the solobility and ehnhanced antitumor effect of gefitinib on lung cancer *in vitro* and *in vivo*, at least, via increased fructose-medicated gefitinib uptake, and suggest that metabolic characterization of cancer could be a potential target for diagnosis and treatment.

### Specific transcriptional response of four blockers of estrogen receptors on estradiol-modulated genes in the mouse mammary gland

E. Calvo, V. Luu-The, C. Martel & F. Labrie

Laval University and Laval University Hospital Research Center, Quebec City, QC, Canada.

Introduction

The efficacy and exceptionally good tolerance of estrogen blockade in the treatment of breast cancer is well recognized. Acolbifene (ACOL) is a novel and unique completely free of estrogen-like activity in both the mammary gland and uterus. In theory, this new antiestrogen represents a unique opportunity for a highly potent and specific blockade of estrogen action in the mammary gland and uterus while exerting estrogen-like beneficial effects in other tissues (selective estrogen receptor modulator or SERM activity).

Description of methods/design

In order to better understand the specificity of action of acolbifene, we have used Affymetrix GeneChips containing 45,000 probe sets to analyze 34,000 genes to determine the specificity of this compound compared to the pure antiestrogen fulvestrant, as well as the mixed antagonists/agonists tamoxifen and raloxifene, in their ability to block the effect of estradiol (E2) and to induce effects of their own on gene expression in the mouse mammary gland. The genes modulated by E2 were those identified in two separate experiments and validated by quantitative real-time PCR (Q_RT-PCR).

Results

Three hours after the single subcutaneous injection of E2 (0.05 μg), the simultaneous administration of acolbifene, fulvestrant, tamoxifen and raloxifene blocked by 98%, 62%, 43% and 92% the number of E2 upregulated genes, respectively. On the other hand, 70%, 10%, 25% and 55% of the genes down-regulated by E2 were blocked by the same compounds. Acolbifene was also the compound which, when used alone, modulated the smallest number of genes also influenced by E2, namely 4%.

Conclusion

The present data offer a possible explanation for the potent tumoricidal action of acolbifene in human breast cancer xenografts where 61% of tumors disappeared, thus bringing a new paradigm in the hormonal therapy of breast cancer.

### Non pituitary effects of GnRH analogues in prostate cancer cells: revertion of maligant phenotype and synergism with bicalutamide and radiotherapy

C. Festuccia[1], G. Gravina[1,2], F. Marampon[1], M. Piccolella[3], M. Motta[3], A. Lenzi[2], V. Tobolini[2] & E. Jannini[1]

University la Sapienza di Roma, Roma, Italy.

Background

Gonadotropin-releasing hormone (GnRH) receptor is a G protein-coupled receptor involved in the synthesis and release of pituitary gonadotropins. GnRH analogs constitute the most widely employed medical treatment for prostatic cancer. The predominant mechanism of action is presumed to be via the inhibition of gonadotropins and resultant decrease in androgen. Although pituitary and extra-pituitary GnRH-R transcripts appear identical, their functional characteristics may differ and most extra-pituitary GnRH-Rs may not discriminate between agonists and antagonists in the same way as do pituitary GnRH-Rs. However, GnRH analogs have also been shown to directly inhibit prostate cancer cells both *in vitro* and *in vivo*. GnRH analogues influence the *in vitro* proliferation of cultured human cells by complex interactions that are still partially understood.

Aims

Our hypothesis is that GnRH analogues modulate prostate cancer progression acting on invasive capacity and androgen responsiveness of tumor cells. So, GnRH triggering may revert maligancy of advanced castrated refractory prostate cancer models.

Results

We demonstrated that: GnRH analogues show non pituitary effects both in hormone sensitive and castrated refractory prostate cancer cell models. GnRH analogues induce antiproliferative and pro-apoptotic effects altering the p75NTR:TrkA and p75NTR/TrkB ratios, activating extrinsic apoptotic pathways and partecipating to reduce anoikis and survival in the blood stream and in metastatic sites. In particular, GnRH analogues induce PTEN expression and reduce Akt actity in PTEN+/AR+ 22rv1 cells and induce extrinsic apoptosis pathways triggering TRAIL-Receptor signaling. GnRH analogues revert malignant phenotype by induction of p75 NTR and AR expression both in AR positive (22rv1 and LAPC-4) and negative (PC3) cell models resulting synergistic with bicalutamide and Radiotherapy both *in vitro* and *in vivo*.

Conclusions

Our results support a potential use of these agents for the treatment of locally aggressive as well as advanced prostate cancer.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P832

### Histone deacetylase inhibitor belinostat (PXD-101) represses androgen receptor expression and acts synergistically with castration and bicalutamide treatment to inhibit prostate cancer growth in hormone refractory models

C. Festuccia[1], G. Gravina[1,2], F. Marampon[1], P. Muzi[1], A. Mancini[1], M. Piccolella[3], P. Negri-Cesi[3], M. Motta[3], V. Tobolini[2], A. Lenzi[1] & E. Jannini[2]

University of Milano, Milano, Italy.

Rationale and aims

Aberrant activation or "reactivation" of androgen receptor in the course of androgen-ablation therapy shows a potential cause for the development of castration-resistant prostate cancer. This study tested the hypothesis that belinostat (PXD101), a potent pan histone deacetylase inhibitor, may potentiate hormonal therapy and prevent onset of castration resistant phenotype Material and Methods. A panel of human prostate cancer (Pca) cells with graded castration resistant phenotype and *in vivo* models were used to verify this hypothesis.

Results

In this report we demonstrated that hormonal manipulation favors the onset of castration-resistant phenotype by the increase of HDAC expression and activity as well as by the increased expression and activity of AR, EGFR, HER2 and Akt. Consistent with these observations, the functional knockdown of HDACs by Belinostat prevented the onset of castration resistant phenotype with a significant down-regulation of AR, EGFR, HER2 and Akt expression/activity. The deregulation of functional cooperation between HDAC-6 with hsp90, on one hand, and between GSK-3beta with CRM1, on the other hand, may explain the biological effects of Belinostat. In this regard, the HDAC-6 silencing or the

functional knockdown of hsp90 by 17AAG resulted in the selective down-regulation of AR, EGFR, HER2 and Akt expression/activity, while the decreased p-GSK-3beta expression after Belinostat treatment increased the nuclear expression of CRM1 which in turn modified the AR and survivin recycling with increased caspase-3 activity.
Conclusions
HDAC inhibitors retain the ability to prevent the onset of castration resistant phenotype and, therefore, merit clinical investigation in this setting. However, further information are necessary to develop clinical treatment strategies for this disease stages.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Confirmation of pathogenicity of the MEN1 missense mutations by analysis of protein instability and aberrant splicing**

Y. Nagamura[1], M. Yamazaki[2], S. Shimazu[1], K. Sano[2], T. Tsukada[1] & A. Sakurai[2]
Shinshu Univeristy School of Medicine, Matsumoto, Japan.

Multiple endocrine neoplasia type 1 (MEN1) is a relatively rare autosomal dominantly inherited condition characterized by hyperplastic and neoplastic disorders of endocrine organs such as the parathyroid, anterior pituitary and gastroenteropancreatic endocrine tissues. Germline mutation of the causative gene, MEN1, which localizes to human chromosome 11q13 and encodes the 610 amino-acid nuclear protein menin, can be identified in most affected subjects. MEN1 gene mutation analysis is a powerful tool for the early diagnosis of MEN1, but the clinical significance of MEN1 gene mutations is not always obvious. In the case of frameshift mutations, nonsense mutations or large deletions, it is relatively straightforward to consider those lesions as pathogenic. However, when identified mutations are missense mutation or in-frame deletions, molecular diagnosis of MEN1 is not so simple, since the pathogenicity of these mutations is not clear per se. We recently identified previously unreported missense MEN1 gene mutations, c.824G>T and c.1118C>T, from patients with primary hyperparathyroidism, and evaluated for their pathogenicity.
These mutations were predicted to generate putative missense menin proteins, R275M and P373L, respectively. A stability test using a quantitative fluorescent immunohistochemical method (Yaguchi 2004, Shimazu 2011) demonstrated that the P373L mutant is highly unstable, suggesting that this mutation is likely causative for typical MEN1, whereas the stability of the R275M mutant was reduced only slightly. Given that the c.824G>T mutation occurred at an exon-intron junction, this mutation was suspected to act as a splicing mutation rather than a simple missense mutation. Analysis of leukocyte mRNA and minigene experiments indicated that the mutant c.824G>T allele gives rise to abnormally spliced menin mRNA.
We conclude that both mutations are likely causative for typical MEN1. The menin stability test and leukocyte mRNA analysis may be valuable for the initial molecular diagnosis and subsequent management of patients with germline MEN1 mutations, especially in the case of putative missense mutations of ambiguous pathogenicity.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P834

**Expression of MAPK7 and CCNL1 in corticotrophinomas and functional analysis of miR-143 and miR-145 in corticotrophic tumoral lineage AtT20**

R. Camargo, B. Paixão, L. Colli, W. Varanda, J. Rodrigues, L. Elias & M. Castro
School of Medicine of Ribeirão Preto - University of São Paulo, Ribeirão Preto, Brazil.

Introduction
miR143 and 145 seem to be involved in the pathogenesis of cortitotrophinomas by modulating the expression of MAPK7 and CCNL1 genes, which protein products are involved in cell proliferation, differentiation, and cell cycle progression. Objective: To analyze the modulation of miR-143 and -145 in the expression of MAPK7 and CCNL1 genes in corticotrophinomas and corticotrophic tumoral lineage (AtT20).
Material and Methods
The expression of MAPK7 and CCNL1 was evaluated by Real Time PCR in 25 corticotrophinomas obtained from patients with Cushing's disease and 6 normal anterior pituitaries and in primary culture of anterior pituitary cells and in AtT20 culture cells from mouse. Functional analyses of the interaction of miR-mRNAs were performed by the transfeccion of miR precursors in AtT20 cell lineage (siPORT, Applied Biosystems).
Results
We observed no differential expression of MAPK7 ($0.94\pm0.36$ vs $1.16\pm1.30$) and CCNL1 ($0.90\pm0.29$ vs $0.64\pm0.51$) genes between normal pituitaries and corticotrophinomas. We observed an overexpression of MAPK7 ($3.61\pm1.84$ vs $0.93\pm0.17$, $P=0.002$) and CCNL1 ($2.6\pm0.7$ vs $0.99\pm0.08$, $P=0.002$) in AtT20 cells compared to primary pituitary culture cells. The transfections were confirmed by overexpression of miR143 ($1.25\pm0.79$ vs $1552\pm730$, $P<0.0001$) and miR145 ($1.43\pm1.42$ vs $4567.6\pm1235$, $P=0.0003$). We observed no differential expression of MAPK7/ERK5 gene neither with miR-143 ($1.04\pm0.2$ vs $1.07\pm0.02$) nor with miR-145 ($1.04\pm0.2$ vs $1.13\pm0.2$) in AtT20 transfected cells. There was also no differential expression in CCNL1gene in AtT20 cell transfected with miR143 ($1.05\pm0.3$ vs $1.05\pm0.3$); however, there was CCNL1 overexpression ($1.05\pm0.3$ vs $1.17\pm0.2$;$P=0.003$) in AtT-20 transfected cells with miR145.
Conclusion
The differential expression between corticotrophinomas and AtT-20 tumoral culture cells may be due to culture immortalization. The interaction of miR-143 and MAPK7 gene does not occur by mRNA degradation, suggesting a posttranscriptional event. miR-145 may up regulate CCNL1 gene, which might lead to deregulation of the cell cycle and contribute to the pathogenesis of corticotrophinomas.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Tc- 99m Sestamibi parathyroid scan in primary hyperparathyroidism and surgical outcomes**

J. Shah & T. Walsh
Southern AZ VA Healthcare System and University of Arizona, Tucson, AZ, USA.

Tc- 99m Sestamibi parathyroid scan (SP scan) is performed to identify location of either hyperplastic or adenomatous gland(s) in primary hyperparathyroidism (HPT). In this study we evaluated diagnostic outcome in 55 consecutive patients with clinical diagnosis of HPT who were referred for SP scans and subsequently had parathyroid surgery. These patients with HPT were of $66.9+12.46$ (mean + SD) age, and had serum calcium $10.9+0.93$ mg/dl, phosphorus $3.0+0.51$ mg/dl, chloride $107+3$ mEq/L, chloride/phosphate ratio $36.9+5.4$, creatinine $1.16+0.32$ mg/dl, and intact parathyroid hormone level $132+83$ pg/ml. SP scans were performed early (at 0 to 30 min) or delayed (90 to 210 min) following injection of 20 mCi of Tc- 99m Sestamibi. Of 55 patients, SP scan finding were concordant with surgical findings in 36 (66%) patients. In 19 patients (34%) SP scan findings were discordant with surgical finding. All 19 discordant scans were reevaluated. Of 19 discordant SP scans, four were read as adenoma. An adenoma and one large hyperplastic parathyroid gland were found in one of these four, and in the other three the adenoma was actually found contralateral to the side indicated on the scan. The scan findings were confirmed at reevaluation. In the reevaluation of remaining 15 discordant SP scans read as hyperplasia, the previous SP scans reading was confirmed in three patients. However, in 12 patients a focally increased radioisotopic uptake was present during the early images of SP scan but not in the delayed images. The early increased focal radioisotopic uptake in these SP scans coincided with surgical findings of parathyroid adenomas in all 12 patients thus increasing SP scan concordance to surgical outcomes to 87% (48 of 55 SP scans). These findings suggest that in HPT careful evaluation of early increased radioisotopic uptake during SP scan can be important in identifying parathyroid adenomas when delayed images show no focal retention of radiotracer.

**Vitamin D from genetics to the clinical in prostate cancer**

F. Cariati, A. Negri, C. Pivonello, M. Ferro, M. Sarnataro, D. Terracciano, M. Galdiero, P. Vitale, V. Altieri, A. Colao & R. Pivonello
University Federico II, Naples, Italy.

Background
The prostate cancer (CaP) is among the most commonly diagnosed cancers, accounting for about 20% of all newly diagnosed cancers. Subject of recent studies is the role of vitamin D in the pathogenesis of CaP. Literature data speculated about the role of vitamin D in the progression of Cap. In addition, several studies have shown an association between VDR gene polymorphism FokI and CaP especially in the Asian population.
Objective
The aim of this study is to compare two populations: CaP vs benign prostatic hyperplasia (BPH), to study both the potential role of serum 25-OH vitamin D (25 (OH) D3) and assess the relationship between serum 25 (OH) D3 and VDR gene polymorphisms FokI and TaqI and between polymorphic sites and the risk of developing cancer.
Material and method
Two hundred patients (aged 41 to 83 years) in whom biopsies revealed CaP or BHP were enrolled in the present study. The concentration of 25 (OH) D3 was measured by chemiluminescence immunoassay and polymorphisms were detected by PCR-restriction fragment length polymorphism (RFLP).
Results and conclusion
The results showed a significant association ($P=0.002$) between the genotype FF FokI polymorphism, responsible for the translation of a shorter protein and therefore more functional than that normal one, in the BPH population compared to CaP, as well as the genotypes of the TaqI polymorphism ($P=0.009$). Serum 25 (OH) D3 did not showed significant correlation respect to polymorphisms and compared to disease, although the concentration was low ($<30$ ng/mL) in 97% of the analyzed samples of the two populations. Concluding the CaP is associated with a less functional VDR variation due to a lower frequency of the genotype FF and for the first time there was evidence that the tt genotype of TaqI polymorphism (synonymous polymorphism) is associated negatively to the disease.

**Progesterone receptor B induces autophagy antagonizing the phosphatidylinositol-3 kinase PI3K/AKT pathway in breast cancer cell lines**

F. De Amicis, C. Guido, M. Santoro, P. Avena, I. Perrotta, M. Panno, S. Panza, R. Bruno & S. Aquila
University of Calabria, Rende, Italy.

Progesterone (PRG) deficiency has been linked to an increased risk of cancer, while normal levels of PRG in the body actually help protect you against some forms of cancer. The tumor suppressor role of this steroid was envisaged, however the mechanism through which this occurs was not clearly established. The effects of progesterone act via the progesterone receptor (PR) of which two isoforms, called A (PR-A) and B (PR-B) were discovered. Herein, we present a novel finding since PRG through PR-B induces of cell death by autophagy in breast cancer cells. The link between autophagy and cancer appears to be complex and multifaceted. Of importance is the understanding of the circumstances under which autophagy promotes either cell death or cell survival in the context of tumorigenesis, as this may have implications in cancer therapy. Analysis of different autophagy-related markers such as AMPK, AKT, mTOR, PI3III, Beclin 1, AMBRA and UVRAG indicated for the first time the ability of OHPg/PR-B to induce their expression. The monitoring of autophagic process, assessed by either biochemical (MDC) and ultrastructural methods (TEM), confirmed the molecular data. In the present study we report that PRG, through the PR-B isoform, produces a significant inhibition of MCF-7 breast cancer cell survival by autophagy. These data underscore a novel mechanism through which PRG/PR-B exerts its beneficial effects on breast cancer, sustaining that PRG/PR signaling may be considered as useful pharmacological tool to be exploited for innovative adjuvant strategies in breast cancer treatment.

**Insulinoma in patients with multiple endocrine neoplasia type 1**

A. Sakurai[1], T. Imai[2], T. Kikumori[2], K. Horiuchi[3], T. Okamoto[3], S. Kosugi[4], S. Suzuki[5], S. Uchino[6], M. Yamada[7], T. Katabami[8], T. Igarashi[9], T. Iwatani[10], A. Miya[11], I. Komoto[12], A. Miyauchi[11] & M. Imamura[12]
Kansai Electric Power Company Hospital, Osaka, Japan.

More than half of patients with multiple endocrine neoplasia type 1 (MEN1) develop gastroenteropancreatic neuroendocrine tumors (GEPNETs). Among GEPNETs in MEN1, insulinoma is the second common functioning tumor and often diagnosed by its pathognomonic clinical feature, i.e. hypoglycemia. Compared to other functioning and nonfunctioning GEPNETs in MEN1, insulinoma is known to develop in younger age. We have recently constructed a database of Japanese patients with MEN1 and here report clinical features of patients with MEN1 who developed insulinoma. Among 582 registered patients, 560 cases were considered to be eligible for analysis. GEPNETs were seen in 314 patients and 69 patients had insulinoma. Tumors predominantly occurred in body and tail of pancreas. Among 54 patients whose age at diagnosis of insulinoma was recorded, only 11 patients (20.4%) had a single tumor at the diagnosis; that complicates surgical decision making. Surgery was performed for 51 patients and 6 patients needed multiple surgery. Age at diagnosis of insulinoma was $38.9\pm18.1$ yrs for proband (including sporadic cases) and $30.9\pm13.9$ yrs for family members. It is to be noted that 13 patients (24.1%) were diagnosed of insulinoma before 20 yrs of age. Five were probands and their parents were diagnosed as having MEN1 after diagnosis of their offsprings. Such young onset was not seen in other GEPNETs. According to recent epidemiological study which analyzed more than 3,000 cases with pancreas NET in Japan, only 1% of patients developed pancreas NETs at younger than 20 yrs. It also revealed that 10% of patients with pancreas NETs had MEN1. These results indicate that insulinoma diagnosed before 20 yrs strongly suggests the presence of MEN1 and warrants further investigation including MEN1 genetic testing.

**Multiple endocrine neoplasia syndrome type 1 (MEN-1) in Sardinian population: low prevalence of Men-1 mutations and detection of a new inactivating mutation of the CDKI gene p27**

M. Mastinu[1], F. Cetani[2], C. Marcocci[2], E. Pardi[2], A. Cappai[1], C. Satta[1], F. Badessi[3], A. Delitala[3], R. Lai[3], G. Fanciulli[3] & S. Mariotti[1]
University of Sassari, Sassari, Italy.

Introduction
The genetic basis of multiple endocrine neoplasia type 1 (MEN-1) syndrome is often represented by inactivating mutations of Men-1 gene, found in 50–80% of different series. Recently, other mutations of genes encoding for the CDKI complex (p15, p18, p21, and p27) and of the AIP gene have been described in a small number of Men-1-negative patients.
Methods and results
Since 2002 we tested for Men-1 mutations 16 patients born and living in Sardinia, an island with approximately 1,500,000 inhabitants and peculiar genetic background due to long-lasting isolation. The series included 13 patients with a clear MEN-1 phenotype (7 with familial history, for a total of 5 families, and 6 apparently sporadic) and 3 with apparent MEN-1 phenotype (1 familial and 2 apparently sporadic). Men-1 mutations were detected in only 3 cases (2 familial, 1 sporadic), corresponding to 27.2% of patients with clear MEN-1 phenotype. Identified mutations were Arg229His in exon 4 and splicing 894-9 G > A (familial cases) and frameshift 1284-of G in the exon 8 (sporadic case). We then started to look for the presence of other mutations in Men-1-negative patients and to date

we completed the analysis for p27. A new p27 mutation (c.372_373delCT in exon 1) was found in a patient with an apparently sporadic typical MEN-1 syndrome (neuroendocrine tumors of the pancreas and distal duodenum and primary hyperparathyroidism due to multiple parathyroid adenomas).
Conclusion
These results suggest that in the particular context of the Sardinian population, the genetic basis of MEN-1 could be different from that commonly observed, with a relatively low prevalence of Men-1 as compared to non-Men-1 mutations. The detection in this small series of a new p27 mutation confirms that a complete screening for rare mutations is advisable in all Men-1 negative patients with clear MEN-1 phenotype, irrespective of positive family history.

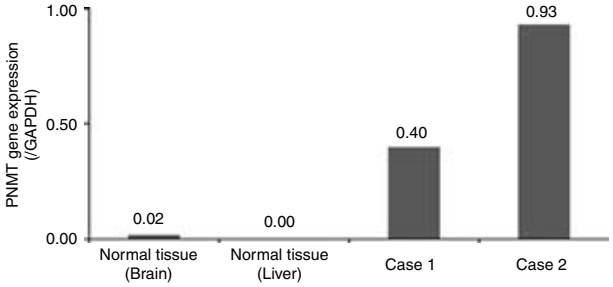
**Atypical paragangliomas responsible for adrenaline-dominant catecholamine secretion due to ectopic expression of phenylethanolamine-N-methyltransferase**

K. Morimoto[1], H. Shibata[1], K. Miyashita[1], I. Kurihara[1], K. Bokuda[1], A. Murai-Takeda[1], Y. Mitsuishi[1], Y. Motosugi[1], R. Jo[1], K. Isobe[2], K. Takekoshi[2] & H. Itoh[1]
University of Tsukuba, Tsukuba, Japan.

Introduction
Pheochromocytoma (PHEO) is a rare tumor of chromaffin cells with variable clinical presentation. Adrenal PHEOs secrete excessive amounts of noradrenaline or of noradrenaline plus adrenaline, whereas extra-adrenal PHEOs (paragangliomas) mostly secrete noradrenaline alone due to lack of expression of phenylethanolamine-N-methyltransferase (PNMT), the key enzyme converting noradrenaline into adrenaline. We report two exceptional cases of paragangliomas responsible for adrenaline-dominant catecholamine secretion.
Case Report
[Case 1] A 58-year-old man presented hypertension, hot flush, and dizziness. Computed tomography (CT) of the abdomen revealed right retroperitoneal tumor (25 mm in diameter) 1 year ago. He had been treated with nifedipine. CT also revealed gradual enlargement of the tumor (41 mm in diameter) during 2-year follow up. Endocrinological evaluation showed PHEO due to very high levels of 24-hour urine adrenaline (877.5 μg/day), noradrenaline (307.5 μg/day), metanephrine (4.6 mg/day), and normetanephrine (1.0 mg/day). [Case 2] A 74-year-old woman had presented resistant hypertension for 2 years and nocturnal transient hypertension attack for a few weeks. Endocrinological evaluation showed PHEO due to high levels of 24-hour urine adrenaline (109.6 μg/day), noradrenaline (214.7 μg/day), metanephrine (0.92 mg/day), and normetanephrine (0.56 mg/day). Magnetic resonance imaging (MRI) revealed right retroperitoneal mass (19 mm in diameter) beside inferior vena cava. The tumors were confirmed by 131I-MIBG scintigraphy in both cases. Laparoscopic tumorectomy was performed, and pathological findings indicated paragangliomas in both cases. The symptoms and the catecholamine excess diminished after surgery. Interestingly, quantitative RT-PCR analysis showed significant PNMT gene expression in both tumors.
Discussion
Atypical phenotypes of adrenaline-dominant catecholamine excess in two paraganglioma cases may be due to aberrant PNMT gene expression supposed to be induced by high local glucocorticoids levels adjacent to the adrenal glands and by other transcription factors.

**Aberrant PNMT gene expression in paragangliomas compared with normal tissues.**



Conclusion
We present 2 atypical cases of paragangliomas responsible for adrenaline-dominant catecholamine secretion.

**Evaluation of patients with adrenal diseases operated laparoscopically between 1997 and 2011**

M. Otto, J. Dzwonkowski, M. Jedrasik, M. Juszyñski & J. Szmidt
Medical University of Warsaw, Warsaw, Poland.

Aim of the study
Presenting the changes in surgical management and patients' characteristics based on a single-center data.
Material and method
From 29/10/1997 to 31/04/2011 824 adrenalectomies were carried out, 641 (78%) laparoroscopic and 183 (22%) open. In all cases of laparoscopic adrenalectomy (LA) lateral transabdominal approach was used. Bilateral simultaneous adrenalectomy with the changing patient position was performed for bilateral pheochromocytoma, while in hypercortisolemia two-stage adrenalectomy with time interval was preffered. Indication for LA in 349 (54%) were hormonal active lesions, in 292 (46%) non-active lesions. In this study the characteristics of patients, size of the tumor and technical aspects of laparoscopy were compared between two periods: 1997–2005 and 2006–2011.
Results
The number of patients operated due to hormonal active lesions increased (53.4 vs 55.2%), mainly due to hypercortisolemia (34.6 vs 39.5%) and pheochromocytoma (33.6 vs 39.5%). The higher incidence of patients with hypercortisolemia is a result of rise of cases of Cushing's disease (2.5 vs 4.5%) and pre-Cushing's syndrome (16.1 vs 18%). The amount of cases with Cushing's syndrome didn't change significantly (16.8 vs 17%). In the same time the number of patients with Conn's syndrome has decreased (30.9 vs 19%). Among non-active tumors: the amount of adenomas inreased (63.8 vs 72.2%), while the remaining number of cases lowered (46.6 vs 44.8%). Distribution of tumors size was comparable. The number of tumors with diameter: $< 4$ cm was 46%, $\geqq 4 < 6$ cm - 33%, $\geqq 6 <$ 8 cm - 16% and $\geqq 8$ cm - 5%.
Conclusion
Laparoscopic operations became recommended method of surgical treatment of adrenal pathology. Despite greater availability of imaging exams which increase detection of adrenal diseases the proportion between the active and non-active lesions qualified for laparoscopy hasn't changed significantly.

## P842

**Immunohistochemical detection of FSH receptors in endocrine tumors**

M. Pawlikowski, H. Pisarek, R. Kubiak, M. Jaranowska & H. Stepien
Medical University of Lodz, Lodz, Poland.

Introduction
Follicle stimulating hormone receptors (FSHR) are physiologically expressed in gonads. FSHR are also expressed in gonadal cancers, but nothing is known on FSHR appearance in non-gonadal endocrine tumors. The present paper reports on the immunohistochemical detection of FSHR in pituitary, thyroid, adrenal and neuroendocrine tumors (NET).
Materials and methods
The study included samples of 80 endocrine tumors (28 pituitary adenomas, 7 thyroid tumors including 3 cancers, 34 adrenal tumors including 8.pheochromocytomas and 2 adrenocortical cancers and 11 NET).
FSHR immunostaining was performed using the antibody raised against 1–190 amino acid sequence from the human FSH-R (sc-13935).
Results
In the investigated tumors, positive immunostaining with anti-FSHR antibody occurs in the tumoral cells cytoplasm and/or endothelia of the intra- and

peritumoral blood vessels. The cytoplasmic immunostaining was found in 7/8 of pituitary adenomas, 7/8 of pheochromocytomas, 22/22 of adrenal adenomas, 2/2 adrenal cancers, 1/.4 of benign thyroid tumors, 3/3 of thyroid cancers and 11/11 NET. FSHR immunostaining in blood vessels was present 28/28 of pituitary adenomas, 5/8 of pheochromocytomas, 12/22 of adrenal adenomas, 2/2 adrenal cancers, 1/.4 of benign thyroid tumors, 2/3 of thyroid cancers and 6/11 of NET.
Conclusions
FSHR are often detectable in tumoral cells and in the endothelium of intra- and/or peritumoral blood vessels of benign and malignant non -gonadal endocrine tumors. It is hypothesized that FSHR expression in these tumors (like in gonads and gonadal tumors) mediates stimulation of cell growth and angiogenesis. This presumption needs further studies to be proved.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P843

**Tumour-asssociated myofibroblasts in parathyroid tumours**

C. Verdelli[1], L. Avagliano[2], M. Meregalli[3], V. Guarnieri[4], A. Scillitani[4], L. Vicentini[5], G. Steffano[6], E. Costa[1], Y. Torrente[2], A. Spada[5], G. Bulfamante[2] & S. Corbetta[7]
Policlinico S.Donato, San Donato MIlanese, Italy.

Tumour-associated myofibroblasts are activated fibroblasts known to influence many aspects of tumour development. Parathyroid tumours show increased microvessels and atypical/malignant tumours are characterized by fibrous bands suggesting activation of the stromal cells. The aim of the present study was to investigate the role of myofibroblasts in parathyroid tumorigenesis. Human parathyroid tissues were analysed by specific immunostaining for the myofibroblast marker alpha-smooth muscle actin (alpha-SMA). Alpha-SMA+ cells were well represented in the parenchyma of normal parathyroid glands ($n=3$) lining the acinar cellular structures. In typical adenomas (PA, $n=5$) intraparenchymal alpha-SMA+ cells were variably reduced, though they surrounded new microvessels suggesting a role in neoangiogenesis. In atypical adenomas ($n=3$) and carcinomas ($n=3$), the parathyroid chief cells proliferating in sheets were not sustained by myofibroblasts, which were highly represented in the stroma of fibrous bands and capsula. Interestingly, in human fetal parathyroids ($n=2$; 19 and 24 weeks of gestation), myofibroblasts were exclusively found lining blood vessels. By RT-PCR activated fibroblasts markers such as vimentin, stromal derived factor-1 (SDF-1) and fibroblast activated protein (FAP) were detected in PA samples. To characterize alpha-SMA+ cells, tumor explants ($n=5$) were cultured on fibronectin in 10% FBS for 9 days. Large spindle-shaped alpha-SMA+ cells outgrew from explants. By immunofluorescence (IF), a subset of alpha-SMA+ cells co-expressed the specific parathyroid marker GCM2, and TBX1, an embryonic nuclear transcription factor involved in endodermic pharynx development. Moreover, by FACS and IF, cells expressing the SDF-1 receptor CXCR4 were detected in PAs. In conclusions, we identified cells showing features of tumour-associated myofibroblasts in parathyroid tumours. Data suggested that: 1) they might be involved in fetal as well as in tumoral neoangiogenesis; 2) they might contribute to matrix deposition in fibrous bands; 3) they might cross-talk with parathyroid cells by the SDF-1/CXCR4 signalling; 4) they might derived their origin from epithelial-to-mesenchymal transition.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Establishment of a Multidisciplinary Tumor Board for Patients with Neuroendocrine Neoplasms**

A. Bianchi, D. Iacovazzo, F. Plastino, F. Lugli, A. Pontecorvi, G. Doglietto, A. Giordano, C. Barone, L. De Marinis & G. Rindi
Policlinico "A. Gemelli" - Catholic University, Rome, Italy.

Introduction
Neuroendocrine neoplasms are rare and multiform requiring a multidisciplinary approach. We report the experience of a Neuroendocrine tumor board (TB) established at our University Hospital.
Aims
The aim is to share clinical and diagnostic data for best decision-making according to the existing ENETS guidelines.
Materials and methods
According to the indications for ENETS Centers of Excellence, meetings with experts in Endocrinology, Endoscopy, Nuclear Medicine, Oncology, Pathology, Radiology and Surgery are held; interactive computer-assisted presentation of 3 or 4 cases each time presented by one representative of the caring equipe; electronic reports written, circulated and stored; descriptive statistics for data analysis.
Results
TB started in December 2010, 21 biweekly meetings were completed, 50 cases discussed, 18 more than once; the diagnostic-therapeutic decision was tailored for each patient, in approximately 70% of cases according to the ENETS guidelines; the gallium PET/CT was identified as a special need and introduced as diagnostic standard in the second half of 2011; electronic reports constitute a shared database.
Conclusions
Our data indicate a good correlation between ENETS guidelines and clinical practice but underline the need for improvement for selected areas. The TB is a valid tool to develop suitable programs of care according to the best clinical evidence and guidelines.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P845

**Low detection Rate of Primary Aldosteronism when Screening Among Hypertensive Patients with Ongoing Medication**

C. Volpe, H. Wahrenberg, B. Hamberger & M. Thorén
Karolinska Institutet, Stockholm, Sweden.

Objective
Primary aldosteronism (PA) is a common cause of secondary hypertension. Antihypertensive agents interfere with the renin-angiotensin-aldosterone axis, and screening with the aldosterone to renin ratio (ARR) is preferably made without medication. Withdrawal may however be harmful. We examined the detection rate of PA in hypertensive patients taking their prescribed medication, apart from amiloride and spironolactone.
Design and setting
Hypertensive patients recruited from a primary care unit were investigated in a university hospital setting. The cut-off level for a positive ARR, indicative of PA, was set at $>50$ pmol/ng with aldosterone $>350$ nmol/l which is lower than practise to minimize false negatives. A positive ARR was followed by a confirmatory evaluation.
Subjects
233 hypertensive patients aged 25 to 70 were recruited and 78% agreed to participate. The majority had at least two antihypertensive agents.
Results
The frequency of confirmed PA was 1.6% and including cases with positive ARR who refused further investigation it would be 3.3% at most. In primary hypertension ARR decreased with the number of antihypertensive agents used due to increasing renin. Compared to untreated patients, median ARR was reduced by approximately 70% when taking 3 or 4 agents. Angiotensin receptor blockers, ACE inhibitors and thiazide diuretics markedly suppressed the ARR.
Conclusion
The low detection rate of PA does not support screening in the general hypertensive population. The marked suppression of ARR by antihypertensive drugs indicates that other cut-off levels should be defined for patients on treatment. At present, screening for PA should be carried out as far as possible without medication.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P846

**B-Lymphocyte Stimulator in neuroendocrine tumors: a new prognostic marker?**

M. Fabris[1], E. Tonutti[1], F. Vescini[1], N. Blasone[1], D. Visentini[1], S. Pizzolitto[1], G. De Maglio[1], M. Isola[2], F. Curcio[1,2] & F. Grimaldi[1]
University of Udine, Udine, Italy.

Aim of the study
To test B-Lymphocyte Stimulator (BLyS) as a new serological marker in the follow-up of patients with neuroendocrine tumors (NET).
Methods
Eighty-one consecutive patients with NET and 56 age and sex-matched controls were enrolled in the study. According to the clinical course, patients were classified in 2 subgroups: evidence of persistent but stable disease or in remission ($n=45$) and patients with evidence of recurrent disease (progressive patients, $n=36$). BLyS and Chromogranin A (CgA) serum levels were analyzed by ELISA.
Results
BLyS levels were more elevated in NET patients than in controls ($1153\pm529$ pg/ml vs $655\pm158$ pg/ml; $P<0.0001$) and correlated with tumor differentiation ($1058\pm398$ pg/ml in gastroenteric G1 - typical lung vs $1325\pm640$ pg/ml in gastroenteric G2 - atypical lung; $P=0.026$). Stable/remission patients displayed significant lower BLyS levels than patients with recurrent disease ($889\pm251$ pg/ml versus $1461\pm623$ pg/ml; $P<0.0001$). BLyS levels did not change in patients who remained stable after $6.6\pm2.8$ months (from $864\pm283$ pg/ml to $809\pm235$ pg/ml; $P=$ns), while further increased in patients with disease progression (from $1575\pm810$ pg/ml to $1887\pm1163$ pg/ml; $P=0.045$). CgA, instead, showed inconsistent changes. Metastatic patients displayed higher BLyS levels than non metastatic ($1391\pm724$ pg/ml vs $1079\pm422$ pg/ml; $P=0.022$).
Conclusion
Elevated BLyS levels characterize more aggressive NET patients. BLyS appears as a new potential prognostic marker in the follow-up.

## P847

**Clinical and morphological characterization of C cell hyperplastic and neoplastic lesions of thyroid**

F. Lugli, A. Fusco, A. Bianchi, D. Milardi, V. Cimino, S. Piacentini, M. Celico, P. Lanza, M. Raffaelli, C. Lombardi, G. Fadda, R. Bellantone, A. Pontecorvi, G. Rindi & L. De Marinis
Policlinico "A. Gemelli", Catholic University of the Sacred Heart, Rome, Italy.

Introduction
Medullary thyroid carcinoma (MTC) and C cell hyperplasia (CCH) have a variable clinical presentation and prognosis and few data are available on the correlation between immunohistochemical characterization (IIC) and clinical behavior.
Aim
We studied the clinical and morphological characterization of CCH and MTC and we evaluated IIC expression of PTTG-1, SSTR2A, VEGFR-1, VEGFR-2 and VEGFR-3 in 23 cases of CCH and/or MTC, correlating it with clinical features
Material and methods
23 patients, affected by CCH and/or MTC, were included from 1990 to 2010. All patients underwent total thyroidectomy, pre and post operative serum calcitonin assay, staging, histological examination with immunohistochemical evaluation of PTTG, SSTR2A, VEGFR-1, VEGFR-2 and VEGFR-3 expression and 18 of them were tested for RET mutations.
Results
After surgery 3 cases presented only CCH and 10 cases had lymph node metastases (N+) and during follow-up 7 patients (all N+) were considered uncured. PTTG and VEGFR-1 were significantly overexpressed in lympho node metastatic and uncured patients. VEGFR-2 was not much expressed in all of patients, while VEGFR-3 and STTR2A were strongly expressed in about all of patients. Four cases were familiar (2 MEN2B, 1 MEN2A and 1 FMTC).
Conclusions
Our data suggest that PTTG-1 and VEGFR-1 seem related with a poor prognosis, while the expression of VEGFR-3 and SSTR2 in all patients confirms the key role of IIC evaluation for the therapeutic approach of these patients. Finally, a more complete IIC evaluation with new markers can be useful for diagnosis, prognosis and therapy of MTC.

**Hormonal Therapy Promotes Hormone-Resistant Phenotype by Increasing DNMT Activity and Expression in Prostate Cancer Models**

G. Gravina[1,6], C. Festuccia[1], M. Piccolella[2], M. Motta[2], L. Ventura[3], R. Pomante[5], B. Zani[1], R. Pestell[4], V. Tombolini[1], A. Lenzi[6] & E. Jannini[1]
University "La Sapienza, Rome, Italy.

We hypothesized that hormonal therapy favors the development of the hormone-resistant (HR) phenotype through epigenetic mechanisms. Human prostate cancer (Pca) tissues and *in vitro* and *in vivo* models were used to verify this hypothesis. We demonstrated that tumor cells continuously treated with BCLT or cultured in androgen depleted medium progressively acquire higher DNMT activity and expression. Increased DNMT expression and activity also paralleled the up-regulation of truncated AR isoforms which favors the development of the HR phenotype. Following DHT stimulation, DNMT activity was significantly reduced in comparison with hormonal therapy. Consistent with these observations, the silencing of DNMT3-a and DNMT3-b significantly decreased the DNMT activity levels. These findings were also directly correlated with PTEN down-regulation and activation of ERK and PI3K/Akt pathways. The use of a pan-DNMT inhibitor (5-Azaciticine) greatly reduced the development of the HR phenotype induced by long-term BCLT treatment and this finding correlated with DNMT activity decrease. The regulation of DNMT activity was, in some measure, dependent on the AR, as siRNA treatment targeting the AR greatly decreased the modulation of DNMT activity under androgenic and antiandrogenic stimulation. These observations were correlated *in vivo* in patients, as demonstrated by immunohistochemistry. Patients treated by BCLT prior to surgery had higher DNMT3a and DNMT3b expression than patients who had not undergone this treatment. Our findings provide evidence of a relationship between the HR phenotype and DNMT in human Pca.

**Gene expression profile of LNCaP human prostate cancer cells after treatment with an antagonist of growth hormone-releasing hormone**

Z. Rekasi[1], T. Czompoly[2], M. Zarandi[3,4] & A. Schally[4]
Veterans Affairs Medical Center and South Florida VA Foundation for Research and Education, Miami, FL, USA.

Antagonists of growth hormone-releasing hormone (GHRH-ant) may exert their antiproliferative effects directly on cancer cells, which are mediated by the tumoral GHRH receptors identified by us. Furthermore we showed that GHRH-ant are able to induce apoptosis in LNCaP human prostate cancer cells through a Ca2+-dependent pathway. However, the molecular features involved in the antiproliferative effect of GHRH-ant have not yet been elucidated. To study this, gene expression profile of LNCaP cancer cells treated with a GHRH-ant MZ-J-138 (10 μM) for 1, 5 or 18 hours was analyzed and compared to that of untreated control LNCaP cells. The genome-wide cDNA microarray chip type in the experiment was Illumina Human HT-12 v.4 Expression BeadChip. Expression profiling showed 181, 152, 16 up-regulated genes and 98, 43, 8 down-regulated genes in LNCaP cells treated with GHRH-ant for 1, 5, 18 hours, respectively (average fold difference $>1.5$; $P<0.0001$). We observed overexpression of PMEPA1, BRCA1, KLF6, FANCG, RBL1, E2F2 and down-regulation of SLC45A3, TMPRSS2, MYC in LNCaP cells after treatment with GHRH-ant. In addition, many cell cycle genes are constituently activated in treated LNCaP cells. The up-regulated negative regulators of cell proliferation and the down-regulation of some factors expressed in high concentration in prostate cancer cells may

explain why GHRH-ant can reduce cell proliferation of LNCaP cells. Our data suggest also the involvement of p53-dependent and independent mechanisms in the antiproliferative effect of GHRH-ant. Treatment with GHRH-ant may offer a new approach to the therapy of prostate and other hormone-sensitive cancers (supported by OTKA K 068452).

**Evaluation of beta-cell function and insulin sensitivity in a large series of insulinomas in one single tertiary centre**

R. Furnica, J. Gigot, P. Deprez, M. Buysschaert & D. Maiter
Cliniques Universitaires Saint-Luc, Brussels, Belgium.

Background
Patients with an insulinoma are at variable risk of severe hypoglycemia due to wide ranges of both tumoral insulin secretion and peripheral tissue sensitivity to chronic hyperinsulinaemia.
Objectives
In this study we investigated the clinical, biological and tumoral characteristics of a large series of patients with immunohistochemically confirmed insulinoma and we assessed both insulin sensitivity and beta-cell function in fasting steady-state conditions.
Methods
This was a retrospective analysis of 48 patients with an insulinoma, in whom insulin sensitivity and beta-cell function were evaluated by a fasting HOMA test.
Results
The median age at the time of diagnosis was 51 years (range: 17–83) and mean BMI was $26.6 \pm 10.6$ kg/m$^2$. In 8 patients (17%), the diagnosis of malignant insulinoma was considered. Pre-operative localization was possible in 94% of the patients. The most sensitive imaging methods were echo-endoscopy (sensitivity 92%) and intra-operative ultrasonography (sensitivity 97%). The average diameter of the tumors was 20.3 mm and the most frequent localizations were the head (28%) and body (57%) of the pancreas. Successful post-surgical remission was finally obtained in 80% of the cases.
The fasting glucose level was variable, ranging from 25 to 116 mg/dl. Insulin sensitivity (assessed by HOMA-S) ranged from 9.7% to 336% (median value 75%) and beta-cell function (assessed by HOMA-B) varied from 47% to 2544% (median value 563%). No difference of insulin sensitivity was observed as a function of gender or age. A significant negative correlation ($r = -0.30$, $P < 0.05$) was observed between insulin sensitivity and body mass index (BMI) and a negative correlation ($r = -0.18$, $P < 0.05$) was found between insulin sensitivity and tumor size in women but not in men.
Conclusions‘
Patients with an insulinoma usually show slightly decreased but very variable insulin sensitivity which may help to explain their differential susceptibility to undergo severe hypoglycemia.

**Can proteomic approach help us in diagnosis of Riedel's thyroiditis? A case report**

G. Donatini, P. Iacconi, L. Giusti, Y. Da Valle, F. Ciregia, G. Giannaccini, L. Torregrossa, A. Proietti, S. Mazzeo, F. Basolo & A. Lucacchini
University of Pisa, Pisa, Italy.

Background
Riedel's thyroiditis (RT) is a rare thyroid disease. Clinical and citological differential diagnosis with thyroid malignancy is difficult pre-operatively and often only pathological report may confirm the diagnosis.
Methods
We report a case of a 72-year-old Italian woman with a known history of goiter, which showed a rapid increase in size at ultrasound check, suggesting malignancy. Based on non-diagnostic cytology (Thy 1), a total thyroidectomy was performed. Fine needle aspiration (FNA) of the removed thyroid was processed by two dimensional electrophoresis (2-DE) and the proteome compared both with anaplastic cancer and control samples (normal thyroid tissue). Protein spots found to be significantly diffenrently expressed were identified by western blot (WB) analysis using specific antibodies.
Results
The protein pattern of Riedel's FNA revealed a superimposition with that of the control samples (Fig. 1). The comparison of RT FNA protein pattern with anaplastic thyroid cancer evidenced differentially expression of ferritin heavy chains, ferritin light chains and haptoglobins, as previously reported over-expressed in thyroid cancers. Therefore, we performed WB analysis of these proteins and we found that their expression were low or absent in RT and control samples despite the high concentrations present in FNA anaplastic samples.
Conclusions
The concurrent absence or low expression levels of haptoglobin, FLC and FHC in RT FNA sample strongly indicates the benign nature of the thyroid lesion. These results suggest the potential applicability of FNA proteome analysis for RT diagnosis and more generally to differentiate thyroid malignancy into thyroid nodule with non-diagnostic citology.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Effect of dopamine agonists on the tumor size of prolactinomas: are suppressive doses different from those that normalize prolactin serum levels?**

C. Sardella, C. Urbani, M. Lombardi, L. Manetti, C. Cosci, S. Brogioni, A. Marchello, E. Martino & F. Bogazzi
University of Pisa, Pisa, Italy.

Prolactin-secreting (PRL) adenomas are about 40% of all pituitary adenomas. The most important clinical symptoms of PRL excess are gonadal and sexual dysfunction as a result of tumor expansion in patients with macroadenomas. Medical therapy of prolactinomas relies on the use of dopamine agonists which induce normalization of PRL levels and shrinkage of the tumor mass in the majority of patients. The present study evaluated whether doses of dopamine agonist inducing normalization ($2 \leq$ PRL $\leq 20$ ng/ml) or suppression ($<2$ ng/ml) of serum PRL levels may have a different effect on the tumor size.

A total of 145 patients with prolactinomas treated with cabergoline were retrospectively evaluated. Seventy patients had microprolactinomas, 68 had macroprolactinomas and seven had giant invasive prolactinoma. The therapeutic dose of cabergoline was 1 mg/week in 48% of patients, 2 mg/week in 38% and between 2 and 5 mg/week in only 1%. The mean time of the treatment was about 70 month and the overall dosage of cabergoline was $<1000$ mg in 75% of patients. Tumor shrinkage occurred more in patients with macroprolactinomas than in those with microprolactinomas (38 vs 18%, $P=0.016$); particularly, 17.6% of the macroprolactinomas were reduced to microprolactinomas whereas tumor regression was observed in 20.6% of cases. No correlation between shrinking tumor and PRL levels (suppressed, normal or high ($>20$ ng/ml) was found. In conclusion, suppressive doses of cabergoline do not seem to be associated with an increased rate of tumor shrinkage.

### Expressions of estrogen receptor-β splicing variants in papillary thyroid cancer

J. Li[1], W. Dong[2], H. Huang[1], H. Zhang[2], Y. Shan[1] & P. Teng[1]
[1]Institute of Endocrinology, Shenyang, China; [2]Shenyang, China.

The purpose of the present study was to elucidate expressions of ERβ1 and ERβ2 expression in papillary thyroid cancer (PTC). ER β splicing variants expressions were examined on formalin-fixed, paraffin-embedded thyroid tissues from 106 PTCs and 30 nodular thyroid goiters (NTGs) by immunehistochemical methods using Elivision plus two-step system. There was significant difference in the subcellular localization of ERβ1 expression ($P<0.001$), but not ERβ2, between PTCs and NTGs. ERβ1 expression decreased, but ERβ2 expression in PTCs increased in PTCs, comparing with those in NTGs. ERβ1 expression in reproductive-aged female patients with PTC was lower than that in reproductive-aged male patients ($P=0.017$) while ERβ2 expression is just opposite ($P=0.032$). The reproductive-aged female PTC patients (18–45 years) with lower ERβ2 expression were more likely to have lymph node metastases ($P=0.035$). The patients with nuclear ERβ1 expression were less likely to have lymph node metastases and extrathyroidal extension ($P=0.018$ and $P=0.0495$, respectively). ERβ2 expression was positively correlated with Ki-67 expression in female patients ($>45$ years) with PTC ($P=0.030$). ERβ1 expression was negatively correlated with MtP53 expression in reproductive-aged female patients with PTC ($P=0.028$).In reproductive-aged male patients with PTC, ERβ1 expression was negatively correlated with VEGF expression ($P=0.036$), but ERβ2 was just opposite ($P=0.044$). VEGF expression was associated with the subcellular distribution of ERβ1 in PTCs ($P=0.036$). This is the first study to determine the expression patterns of ERβ splicing variants in various types of thyroid lesions and elucidate the importance of ERβ splicing variants in the development and progression of PTC.

### The high-mobility group A1-oestrogen receptor β nuclear interaction impairs in human testicular seminomas

F. Esposito[1], F. Boscia[2], R. Franco[3] & P. Chieffi[1]
[1]SUN, Naples, Italy; [2]Università 'Federico II', Naples, Italy; [3]Fondazione Pascale, Naples, Italy.

It is well established that oestrogens participate in the control of normal spermatogenesis and endogenous or environmental oestrogens are involved in pathological germ cell proliferation including testicular germ cell tumours. The effects of oestrogen are now known to be mediated by oestrogen receptor-α (ERα) and ERβ subtypes, but only ERβ has been found in human germ cells of normal testis. However, its expression was markedly diminished in seminomas, embryonal cell carcinomas, and in mixed germ cell tumours but remains high in teratomas.

The interaction and the expression of ERβ and HMGA1 were studied by using 32 cases of cryopreserved seminomas and the GC1 and TCam-2 germ cell lines.

Here, we shown that ERβ interacts with HMGA1 in normal germ cells, while down regulation of ERβ associates with transcriptional coregulator HMGA1 over-expression and cytoplasmic localization in human testicular seminomas. In addition, we show that 17β-oestradiol induces an HMGA1 increased cytoplasmic expression associated to an ERβ down-regulation in TCam-2 cell line derived from human testicular seminoma.

Taken togheter, our results suggest to hypothesize that exposure to oestrogens or oestrogen-mimics, in some as of yet undefined manner, diminishes the ERβ-mediated growth restraint in human testicular seminoma, due to the HMGA1 cytoplasmic delocalization associated with ERβ down-regulation.

### Long-term outcome of primary endocrine non-Hodgkin lymphomas

E. Hatjiharissi, K. Pazaitou-Panayiotou, A. Chrisoulidou, M. Diamantidis, M. Papaioannou & N. Constantinou
Theagenio Hospital, Thessaloniki, Greece.

Introduction

Primary lymphomas of the endocrine glands are extremely rare entities. We retrospectively evaluated the clinical profile and the patterns of outcome among patients who were treated in our center with the diagnosis of high-grade B-cell primary endocrine lymphomas.

Methods

Between May 1980 and August 2010, 450 patients were diagnosed as extranodal non Hodgkin Lymphomas (NHLs). Among them, 18 cases (4%) were primary testicular lymphomas (PTLs), eight cases (1.78%) were primary thyroid lymphomas (PTHLs), whereas four cases (0.89%) were primary adrenal lymphomas (PALs). The therapeutic approaches were variable, including chemotherapy, surgery and radiotherapy.

Results

Twelve of the PTLs patients (66.67%) achieved complete response (CR), 2 (11.11%) had partial response (PR) and 3 (16.67%) did not respond (NR). However, five of them (28%) relapsed within a median time of 21 months (range 4–52). On the other hand, all patients with PTHL obtained CR after front-line therapy. However, one patient relapsed 35 months after CR. Regarding the PAL patients one achieved CR, two had PR, whereas one did not respond. The responders relapsed shortly after treatment in a median time of 2.5 months.

The PTHLs had better outcome (median OS 43 months) in comparison to the PTLs (median OS 18.50 months) and the PALs (median OS 7 months), which had the worst prognosis.

Conclusions

We conclude that the adrenal lymphomas had the worse outcome. Given the rarity of these entities and the lack of standard therapy the existing treatment strategies for PTLs and PALs fail to provide long-term survival. Therefore, we suggest that new treatment protocols should be applied.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Performances of a new automated chromogranin-A assay

D. Gruson & T. Lepoutre
Cliniques Universitaires Saint Luc, Brussels, Belgium.

Background

Chromogranin A (CgA) is essential for the formation of secretory granules and sequestration of hormones in neuroendocrine cells. Measurement of CgA levels is

included in the diagnostic procedure of neuroendocrine tumors and pheochromocytoma. The aim of this study was to assess the reliability of the Kryptor assay for CgA measurement.
Methods
Imprecision of the Kryptor CgA assay was determined with two levels of CgA concentration. Reference values for the Kryptor CgA (B.R.A.H.M.S GmbH, Thermo Scientific, Germany) assay were obtained from thirty five healthy subjects. Method comparison was performed with our routine CgA assay (Dako, Glostrup, Denmark) with eighty five patients' samples.
Results
Between run imprecision ($n=6$) performed with quality controls materials for the CgA assay were 4.0% and 3.4% for mean concentrations of 98 ng/ml and 481 ng/ml, respectively. CgA levels measured with the Kryptor were significantly correlated with CgA levels obtained with our routine assay ($r=0.96$, $P<0.0001$) .The agreement between the two methods was very good (weighted $\kappa$ coefficient: 0.84). However, seven cases were discrepant between the two methods. For low concentrations (below 23 UI/l with the routine assay), Passing and Bablok regression analysis showed a slope of 5.36 and an intercept of 37.38 ($n=40$). Bland and Altman plot evidenced a positive bias (mean difference of 22.1) with higher values for Kryptor assay. For high concentrations (above 23 UI/l with the routine assay), Passing and Bablok regression analysis showed a slope of 3.49 and an intercept of 10.76 ($n=36$). Bland and Altman plot evidenced a positive bias (mean difference of 526.4) with higher values for Kryptor assay.
Conclusions
Our study showed that the Kryptor assay is reliable for chromogranin-A measurement. However, CgA assays are not commutable and laboratories must inform the physicians of the characteristics of potential new routine assay.
Declaration of interest
I fully declare a conflict of interest. Details below.

**Virilization due to adrenocortical carcinoma in a 7 years-old female: a case report**

M. Furujo[1], Y. Higuchi[1], H. Usui[1], T. Asai[1], T. Goto[1], Y. Shinno[1], I. Yamadori[1], K. Homma[2], T. Hasegawa[3] & T. Kubo[1]
[1]National Hospital Organization Okayama Medical Center, Okayama, Japan; [2]Keio University Hospital, Tokyo, Japan; [3]Keio University School of Medicine, Tokyo, Japan.

Adrenal cortical carcinoma (ACC) is a rare malignancy, especially in children, and the annual worldwide incidence has been calculated as 0.3 cases per million children younger than 15 years old. We present a case of functioning ACC in a 7 years-old female child who manifested with virilization. She presented with low-pitched voice, excessive pubic hair growth, growth acceleration, clitoral enlargement and increased muscle strength at the age of six. Her blood pressure was normal, and her breast was Tanner stage 1, but her bone age was advanced. Hormonal findings were characterized as an increase of androgens, especially serum testsosterone, DHEAS and urinary 17-ketosteroid (17-KS). The abdominal magnetic resonance imaging revealed a large right suprarenal mass sized 55×50×40 mm. The brain, lung and liver were free from metastases in MRI and CT. She had a right adrenalectomy without any complications. The histological diagnosis was ACC according to the criteria of Weiss: nuclear atypia, atypical architecture and atypical mitosis; and Weiss criteria three out of nine. The labeling index of Ki67 staining was 10–15%, and DNA analysis of her peripheral leukocytes for the p53 tumor suppressor gene was negative. After histopathological confirmation of the diagnosis she received mitotane treatment (2 g/day) and radiation therapy. Two weeks after adrenalectomy, her serum testosterone and DHEAS and urinary 17-KS rapidly decreased to the normal level. We must pay attention to recurrences because little is known of ACC's long-term natural history.

**Diagnosis and treatment of the surgical pathology of the suprarrenales glands. Bibliographical revision**

Y. Suleiman-Martos[1], A. Jimenez-Pacheco[2], M. Arrabal-Polo[1], A. Zuluaga-Gomez[1], F. Escobar-Jimenez[1] & M. Arrabal-Martin[1]
[1]San Cecilio University Hospital, Granada, Spain; [2]Santa Ana Hospital, Granada, Spain.

Introduction
The adrenal glands are paired organs neuroendocrine, formed by the adrenal cortex and medulla, two distinct structures for histology, function, and embryological origin. The processes that most frequently affect the adrenals are adenomas 81.8%, 11.8% cysts, metastases, 11.8%, 5.9% carcinoma, pheochromocytoma 2.9%, 2.9% adrenalitis. 20–40% of adrenal masses are afuncionantes and/or discovered incidentally (incidentalomas) scans during abdominal imaging. The objetive of this study is to present a bibliographical update and our experience in the diagnosis and treatment of the surgical pathology of the suprarenal glands.
Methods/design
Retrospective study of 48 patients diagnosed and treaties of suprarenal masses (2000–2011). Clinical history has been reviewed: signs and symptoms of adrenal pathology, radiological, hormonal study, stay average post-operating and anatomo-pathological diagnosis.
Results
Of 48 cases, 48% are men and 52% women. In 4 patients bilateral disease was detected. Average stays post-operating, 12 days. Anatomo-pathological diagnoses: pheochromocytoma 15 cases; functional adenoma 13 cases (Cushing 7; Conn 5; diffuse virilizante adrenogenital syndrome 1), hyperplasia two cases (syndrome of Cushing), hyperplasia to nodular two cases (hyperaldosteronism), suprarenal carcinoma three cases, non-functional masses 13 cases.
Conclusions
Before the hypercortisolims suspicion free cortisol is determined in tinkles of 24 h plasmatic ACTH, and test of weak suppression of dexametasona. In hyperaldosteronism, seric potassium concentration, aldosterone and ratio aldosterone-activity of plasmatic renina. Before pheochromocytoma we determined plasmatic catecholamine's and tinkles of 24 h. If the hormonal study is suspected to a suprarenal carcinoma it will depend on the type of suspected endocrine syndrome. The location of the suprarenal masses is made with computerized tomography, magnetic resonance nuclear, ultrasounds or gammagraphy. At the moment the surgery laparoscopic and 'Da Vinci robotic system' are considered 'gold standard" for the surgical treatment of the suprarenal pathology.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P859

**1,25-Dihydroxyvitamin D inhibits cell proliferation by promoting cell-cycle arrest in the human adrenocortical cancer cell line nci-h295r**

C. Pilon[1], R. Urbanet[1], S. Vettore[1], R. Sirianni[2], V. Pezzi[2] & F. Fallo[1]
[1]University of Padova, Padova, Italy; [2]University of Calabria, Arcavacata di Rende-Cosenza, Italy.

Vitamin D receptor (VDR) and its ligand 1,25-Dihydroxyvitamin D3 (1,25OHD3) play, in general, an inhibitory role on the growth of normal and malignant cells. However, the mechanisms for this anti-proliferative action remain not completely understood. Recently, a 1,25OHD3-mediated effect on hormone production and steroidogenic genes has been reported in the human steroid-secreting adrenocortical cancer cell line NCI-H295R (Lundqvist J *et al.* 2010). The aim of this study was twofold: i) to test expression of vitamin D metabolism genes in normal adrenals and in a series of adrenal tumors as well as in the NCI-H295R cells; ii) to investigate the potential anti-proliferative action of 1,25OHD3 on NCI-H295R cells underlying the molecular mechanisms behind this effect. mRNA levels for CYP2R1 (i.e. the enzyme converting vitamin D3 to 25OHD3), CYP27B1 (i.e. the enzyme converting 25OHD3 to 1,25OHD3) and VDR were measured by RT-PCR and/or western blotting in both NCI-H29R cells and adrenal tissues. DNA synthesis was evaluated according to (3H)TdR cell incorporation after 96 h treatment of NCI-H295R cells with 1,25OHD3 at increasing doses, in comparison to untreated control cells. The effect of 1,25OHD3 on cell apoptosis and cell cycle was analyzed with a flow cytometer. CYP2R1, CYP27B1 and VDR were expressed in NCI-H295R cells and in all adrenal tissues analyzed (non-functioning adenomas, $n=5$; cortisol/aldosterone-

secreting adenomas, $n=9$; cortisol-producing carcinoma, $n=1$). 1,25OHD3 inhibited cell proliferation by 20% at a dose of $10^{-8}$ M and induced a concomitant decrease in aldosterone and DHEA-S production. 1,25OHD3 induced cell cycle arrest, promoting accumulation of cells in G0/G1 phase without inducing apoptosis.
Conclusions
1,25OHD3 has cytotoxic effects on the NCI-H295R cells by promoting cell cycle arrest. Expression of vitamin D metabolism genes in NCI-H295R cells as well as in normal and tumor adrenals suggests a potential paracrine role of vitamin D in adrenal growth and function. Because of its anti-proliferative action 1,25OHD3 could be considered for the treatment of patients with adrenocortical cancer.

## P860

**A case of multiple endocrine neoplasia type 2a associated with rectal adenocarcinoma**

C. Pop-Radu[1,2], Z. Reti[2], S. Radian[3] & N. Al Hajjar[4]
[1]University of Medicine and Pharmacy, Tg.Mures, Romania; [2]County Clinic Hospital, Tg.Mures, Romania; [3]'C.I. Parhon' Institute of Endocrinology, Bucharest, Romania; [4]'Octavian Fodor' Emergency Clinic Hospital, Cluj Napoca, Romania.

Multiple endocrine neoplasia type 2A (MEN2A) is an inherited syndrome caused by the mutation of RET gene. The classic variant of this syndrome includes the presence of medullary thyroid carcinoma (MTC), in association with pheochromocytoma and parathyroid neoplasia. MTC is usually the first presentation, with palpable neck mass and hypercalcitonemia, metastatic spread to local lymph nodes or distant sites.
We report the case of a 41 year old Caucasian man who underwent colorectal surgery for stage IV rectal adenocarcinoma with liver metastases, confirmed by the anatomopathological report. The postoperative evolution was complicated with recurrent hypertensive episodes controlled with medication. An abdominal CT was performed which described multiple bilateral adrenal masses. Hormonal assessment revealed significantly high levels of urinary metanephrines (12.52 µmol/24 h, normal range $<1.62$), normetanephrines (11.72 µmol/24 h, normal range $<2.13$) and calcitonin ($>2000$ pg/ml, normal range $<18.2$). Serum calcium was increased (5.36 mEq/l, normal range 3.5–4.5) and iPTH was to the upper limit (73.97 pg/ml, normal range 14–73). Thyroid ultrasound showed hypodense, irregular macronodules (2.3/1.8 cm, respective 1.34/1.45 cm) in both lobes, with microcalcifications and intranodular intense vascularization on Doppler screen, and laterocervical limfonodules with the same characteristics. After bilateral adrenalectomy (with the removal of left adrenal gland and kidney in block for macroscopic capsule penetration and extension to the surrounding adipose tissue), the patient underwent total thyroidectomy with neck dissection and bilateral inferior parathyroidectomy. The histopathological exam confirmed bilateral pheocromocytoma with extracapsular extension with possible malignancy (PASS score $>4$), MTC with limph node metastasis and parathyroid hyperplasia. Genetic testing revealed the heterozygote mutation of codone 634 (Cys634Trp). Actually the simptomatology of his non-endocrine tumor led to the diagnosis of the second severe condition - a multiglandular endocrine tumor syndrome.

**Leptin affects gene expression in OVCAR-3 ovarian cancer cells. Effects on cell proliferation and apoptosis**

A. Ptak & E. Gregoraszczuk
Jagiellonian University, Krakow, Poland.

Several studies have addressed the possible role of leptin, the product of the obesity gene (Ob), in ovarian cancer development and progression. Herein, we used the OVCAR-3 cell line expressed both the long (ObRb) and short (ObRt) isoforms of the mRNAs of the leptin receptor, to analyse the effect of leptin on the expression of selected genes involved in the cell cycle and apoptosis. OVCAR-3 cells were exposed to 2 and 20 ng/ml of leptin (noted in non-obese women) or 40 and 100 ng/ml of leptin (noted in obese women). Cell proliferation was determined by measuring BrdU incorporation and propidium iodine DNA staining (flow cytometry). Apoptosis was measured by DNA fragmentation using the Cellular DNA Fragmentation ELISA kit and caspase-3 activity by fluorometric assay. Expression of selected genes involved in the cell cycle and apoptosis were evaluated by real-time PCR. At a physiologically relevant concentration, leptin has no effects on cell proliferation, why in concentration noted in an obese women leptin stimulated cell proliferation. 1.2- to 1.9-fold induction of genes responsible for inducing cell proliferation and a 1.2- to 1.9-fold suppression of genes responsible for inhibition of proliferation was noted. A statistically significant inhibition of caspase-3 activity and DNA fragmentation was observed under the influence of leptin at 2, 20, 40 and 100 ng/ml respectively. 1.4- to 1.8-fold suppression of genes involved in the extrinsic apoptotic pathway and a 1.2- to 2.2-fold suppression of pro-apoptotic genes involved in the intrinsic apoptotic pathway were observed. In conclusion, leptin by up-regulating genes responsible for inducing cell proliferation and down-regulating pro-apoptotic genes in extrinsic and intrinsic pathways could contribute to ovarian cancer progression. However, further research with ovarian cancer explants are needed to confirm the relationships between ovarian cancer risk and obesity.

**Malignant adrenal incidentaloma**

N. Kesri[1], A. Boudiba[2] & F. Chentli[1]
[1]CHU BAB EL OUED, Algiers, Algeria; [2]CHU MUSTAPHA, Algiers, Algeria.

With the development of medical imaging, many malignant lesions of the adrenal lodge are incidentally discovered. In this prospective monocentric study we are looking for factors of presumption of malignancy in the preoperative stage on a non-oncological series of 91 IS.
Monocentric prospective study, AI revealed by TDM $\pm$ echo supplemented by a clinic/hormonal adrenal exploration $\pm$ isotopic. In the absence of against indications, the indication of the adrenalectomy has been systematic for histological typing. The diagnosis of malignancy is retained for 26 IS on Weiss criteria $\geq 3$ for 17 unilateral AI removed /22 (10 adrenal cortical carcinoma ACC, 2 malignant PH and 5 non-glandular MAI) and 9 MAI having benefited from palliative treatments: 4 bilateral metastatic AI and 5 secretant expansive ACC.
Results
Prevalence of MAI is 28.5%, 10F/16 M, median 45.6 years. The average axis $=$ $10.2 \pm 5$ cm, median 10 cm (3.4–20 cm). Clinically rare co-morbidities, toxic habits 34.6%, rapid deterioration of general condition 53.8%, painful abdominal syndrome 80.8%, prescription of major analgesics 19.2%, severe general signs 42.3%, weight loose 23.1%, HTA 7.7%, an endocrine syndrome is noted in 19.3% (virilization two cases, moderate Cushing one case, atypical adrenergic syndrome two cases). AI were apparently clinically benign in 34.6%. Biologically: high prevalence of night hypercortisolism (83.3%) in the MAI glandular, freinable in 28.6%. Secretion of androgen precursors or metanephrines is noted only in glandular MAI. Isotopic profile of nine MAI shows lack of fixation in five MIBG and discordant fixation in four norcholesterol scinti scans.
Conclusion
In addition of classical suspicious TDM signs, male sex, age $<45$ans, rapid physical deterioration, mixed hypercortisolism and the lack or discordant scintigraphic fixation are suggestive of MAI; lesions $>3$ cm must be removed.

**Maxillary gland could harbor a neuroendocrine metastasis**

M. Batisse-Lignier[1,2], S. Maqdasy[1,2], B. Lietin[3], C. Darcha[3], F. Desbiez[1] & I. Tauveron[1,2]
[1]CHU Clermont-Ferrand, Clermont Université, Clermont-Ferrand, France; [2]UMR GReD, CNRS 6247, Clermont Université, Clermont-Ferrand, France; [3]CHU Clermont-Ferrand, Clermont-Ferrand, France.

Introduction
Pancreatic neuroendocrine tumors (PNET) are rare with an incidence of 3–4/1000,000. These tumors are non functional in 70–80% of the cases. The vast majority of them are differentiated neuroendocrine carcinoma. Distant metastasis detected frequently at the onset of diagnosis. Liver and lymph node metastases are the most frequent localizations. Cerebral, skeletal and pulmonary are not infrequent. Primary and metastatic small cell carcinomas with NE differentiation in the parotid gland are also documented.
Case report
A 54 years old patient presented with cerebral metastatic lesions in 2005. Post surgical histopathological examination confirmed the neuroendocrine nature of these lesions. Her primary lesion, a PNET, was discovered in 2008 only after discovery of ovarian metastases. One year later, a maxillary nodule was extirpated. This was followed by normalization of CgA levels. Histopathological study of her pancreatic, ovarian, cerebral and maxillary lesions confirmed the same type of neuroendocrine tumour.
Discussion and conclusion
Salivary glands usually harbor metastatic melanomas and other skin cancers. Few cases of metastatic NETs in the parotid glands were documented in the literature. Neuroendocrine differentiation of salivary carcinomas is also reported. We describe a metastatic PNET in the maxillary gland which we treated with surgery followed by radio-chemotherapy. It is wise to include NET in the differential diagnosis of salivary gland tumours and to do immunohistochemical staining by NE markers on a salivary tumour in patients with history of NET.

**Circadian rhythm of prolactin release in patients with breast cancer**

M. Krawczyk & T. Gasinska
Silesian Medical University, Katowice, Poland.

Background
A number of studies have evaluated the association between prolactin (PRL) and breast cancer risk, but some results have been inconsistent.
The aim of this study was to investigate, if the circadian rhythm of PRL was maintained in pre- and post-menopausal patients with breast cancer and if there is a correlation between serum PRL level, serum concentration of insulin-like growth factor 1 (IGF1), tumor staging and expression of estrogen, progesterone and HER2 receptors in tumor tissue.
Patients and methods
Sixty-four women with the breast cancer aged 36–78 years and 20 healthy controls matched for age were studied. Serum PRL was determined using immunoradiometric method. Blood samples for PRL determination were taken four times daily at fixed hours of the 24 h cycle and obtained results were analysed using the Cosinor test.
Results
Sixteen patients with breast cancer (25%) demonstrated high serum PRL level, and 29 (45%) showed high serum IGF1 level. Circadian rhythm of PRL was maintained in all patients with breast cancer. Both in patients and in healthy subjects the circadian rhythm indicated the highest serum concentration of PRL in night hours.
Both in pre-menopausal as well as in post-menopausal patients there was no statistically significant correlation between serum PRL, IGF1 levels, the degree of tumor staging and expression of estrogen, progesterone and HER2 receptors in the tumor.
Conclusions
Patients with breast cancer show a circadian rhythm of prolactin release, not significantly different from rhythm in healthy subjects.
Some patients with breast cancer demonstrated hyperprolactinaemia and/or high serum IGF1 level. These data suggest that higher plasma PRL and IGF1 levels could be associated with an increased risk of breast cancer.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Non-medullary neuroendocrine carcinoma in the thyroid gland: a case-report**

C. Alvarez-Escola, J. Riveiro Villanueva, A. Fernandez Martinez, M. Nistal, A. Castro & J. Barriuso
Hospital La Paz, Madrid, Spain.

Introduction
Neuroendocrine lesions in the thyroid gland are uncommon. The differential diagnosis usually includes medullary thyroid carcinoma, paraganglioma and metastases. There are few non-conclusive reports of primary neuroendocrine carcinomas of the thyroid.
Clinical case
A 49-year-old woman with a past medical history for familial hypercholesterolemia and right oophorectomy for mature teratoma with struma ovarii, was evaluated for a rapidly growing cervical mass. A firm, hard, enlarged right thyroid lobe was detected on physical examination. Neck ultrasound, full-body-computerized-tomography (CT) and PET-CT were performed. The latter showed a $49 \times 32 \times 59$ mm mass with high metabolic activity in the right thyroid lobe infiltrating the trachea, esophagus and sternohyoid and platisma colli muscles as well as ipsilateral cervical adenopathies and an unspecific milimetric nodule in the upper left pulmonary lobe. Full blood count and biochemistry were normal apart from a total cholesterol of 461 mg/dl; she was euthyroid with negative thyroid autoimmunity; undetectable calcitonin, normal catecholamines, 5-HIIA, β2-microglobulin and CEA. Neuron specific enolase was slightly increased (17.32 ng/ml, normal 0–16 ng/ml). Cervical lymph node biopsy consistent with metastases from large cell neuroendocrine carcinoma (LCNC). Total thyroidectomy, total laryngectomy and right cervical lymphadenectomy were performed, revealing a LCNC invading blood vessels, soft tissue and laryngeal adventitia; negative immunostaining for calcitonin and tiroglobulin, positive for TTF-1 and CD56; Ki-67 $>90\%$. Postsurgical $^{111}$In-pentetreotide scintigraphy was negative. She received six cycles of cisplatin-etoposide. One year after diagnosis there is no biochemical or radiological evidence of persistent disease.
Conclusions
We cannot fully exclude the possibility of a metastatic primary lung tumor, but the clinical course, the size of the thyroid mass, the absence of any other clear lesion outside the neck and the immnunostaining pattern suggest a primary thyroid LCNC. To the best of our knowledge, this could be the first case report of these tumors arising in this location.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P866

**Adrenal myelolipomas in CAH: is there role for ultrasound screening of the adrenal glands?**

N. Dauth, M. Friedrich-Rust, G. Meyer, K. Holzer, W. Bechstein, S. Zeuzem & J. Bojunga
J.W.Goethe-University Hospital, Frankfurt/Main, Germany.

Background
Persons with CAH may be at increased risk of developing adrenal myelolipomas, particularly if their CAH is poorly controlled. Adrenal masses can be detected by ultrasound with high sensitivity and specificity. Contrast-enhanced ultrasound (CEUS) may be a useful method in the diagnostic work-up of adrenal mass with excellent sensitivity for the diagnosis of malignancy. However, ultrasound is not included in the diagnostic algorithm of patients with CAH.
Case Report
A 50-year-old man with CAH due to 21-OH-deficiency presented with increasing abdominal girth and abdominal pain. An abdominal ultrasound showed hyperechoic adrenal masses ($3.6 \times 9.5$ cm in the right, $10.4 \times 10.4$ cm in the left

gland), in B-mode and CEUS consistend with myelolipomas. On MRI the diagnosis of mesenchymal tumor or sarcoma was suspected. Because of suspected malignancy a bilateral adrenalectomy was performed, histopathology revealed the diagnosis of benign bilateral myelolipoma.
Discussion
Adrenal myelolipoma has been described in CAH and is a rare benign tumor formed by mature fat tissue admixed with hematopoetic elements. Ultrasound becomes more important in diagnosis of adrenal masses, especially in combination with CEUS. So far, there is no screening for adrenal masses in patients with CAH. In B-mode and Doppler mode myelolipomas are described with homogenous mostly hyperechoic tissue lacking signs of hypervascularisation or irregular tumor vessels, contrast-enhanced sonography shows an early arterial contrast enhancement without any significant wash-out.
With a very high sensitivity in diagnosing malignant lesions and an increasing availability of B-mode and CEUS ultrasound should be used as screening methods in patients with CAH. But there are further data needed on the incidence and prevalence of adrenal masses, especially myelolipomas. In addition, careful follow-up of suspected myelolipomas is needed as it is yet unclear whether there is an increased risk for malignant transformation of this entity.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P867

**An unusual association of hyperparathyroidism, ectopic GHRH secretion and bronchial carcinoid in a MEN1 family**

E. Sala[1], E. Ferrante[1], E. Verrua[1], E. Malchiodi[1], F. Ermetici[1], M. Filopanti[1], S. Ferrero[1], M. Zatella[2], E. Degli Uberti[2], A. Spada[1], P. Beck-Peccoz[1] & U. Verga[1]
[1]Milan, Italy; [2]University of Ferrara, Ferrara, Italy.

Introduction
MEN1 is characterized by tumors of parathyroid glands, pituitary and pancreas. Pituitary tumors frequently produce PRL and GH, but acromegaly due to ectopic GHRH secretion has been reported in $<1\%$ of cases. Here we present a case of two patients belonging to a MEN1 family (c.207delC; p.P69PfsX118 mutation (ENST00000377313), affected by primary hyperparathyroidism, in association with acromegaly due to ectopic GHRH secretion and bronchial carcinoid, respectively.
Case report
A 18-year-old boy came to our observation with clinical, biochemical findings and scintigraphic image diagnostic of primary hyperparathyroidism. He successfully underwent subtotal parathyroidectomy. Given the young age and the presence of multiple parathyroid hyperplasia, the patient underwent genetic analysis that revealed the presence of a MEN1 gene mutation. Despite the absence of signs and symptoms, acromegaly due to ectopic GHRH secretion was diagnosed (RMN negative for pituitary adenoma and GHRH level: 60.14 ng/ml, normal $9.4 \pm 5.5$). Search for an ectopic tumor through chest-abdominal TC scan, total-body PET/CT and 111 In-Pentreotide (Octreoscan) was unsuccessful, and treatment with somatostatin analogs was started. Recently, scintigraphy with somatostatin analogs (68-Ga-DOTATOC-PET) showed three focal areas in the pancreatic tail. Distal pancreasectomy revealed a multiple pancreatic neuroendocrine tumors. The evaluation of the patient's mother, revealed the presence of primary hyperparathyroidism, elevated gastrin, chromogranin A, pancreatic polypeptide and a 4 cm-lung mass radiologically evident. The patient underwent subtotal right pneumonectomy and the histological analysis was consistent with the diagnosis of a typical bronchial carcinoid secreting the above polypeptides.
Conclusions: In this report we emphasize the uncommon presence of acromegaly due to pancreatic ectopic GHRH secretion and bronchial carcinoid in two patients belonging to a MEN1 family. An early and full diagnostic procedure appears to be important in order to recognize this rare syndrome that may be lethal as happened to the proband aunt who died for a malignant gastrinoma.

**Medullary thyroid carcinoma with liver metastasis presenting as watery diarrhea for 1 year**

I. Lam[1], H. Chaing[1], C. Wang[2] & C. Chang[2]
[1]Far-Eastern Memorial Hospital, New Taipei City, Taiwan; [2]National Taiwan University Hospital, Taipei, Taiwan.

A 66-year-old woman had no history of systemic diseases. She had developed watery diarrhea for 4 months initially, without abdominal pain, fever, any aggravating or relieving factor. She visited gastroenterologist, and colonoscopy showed only mixed hemorrhoid. Irritable bowel syndrome was impressed then. Thus, anti-spasmodics and anti-diarrheals were prescribed. However, diarrhea persisted for 1 year, and body weight loss of 7 kg occurred during this period of time. She later visited a general practitioner, and abdominal ultrasonography revealed a 6.9 cm non-cirrhotic hepatic tumor. Her virological markers of HBsAg and anti-HCV were negative, and the serum alpha-fetoprotein level was within normal limits. She was referred to our hospital for further investigation. Tumor markers revealed high CEA (208.5 ng/ml) and normal CA19-9 (35.6 U/ml) levels. Tri-phase abdominal CT scan displayed three non-cirrhotic hypervascular lesions. After admission, core-needle biopsy for the largest hepatic tumor was arranged. Pathology revealed metastatic carcinoma, and immunohistochemical stains showed positive TTF-1, Calcitonin, and Synaptophysin. Thyroid ultrasonogrphy and fine needle aspiration were carried out, by which medullary thyroid carcinoma was impressed. Her serum calcitonin level was more than 10 000 pg/ml. Radical thyroidectomy and liver bi-segmentectomy were done. Amyloid accumulation was noted in the pathological specimens of thyroid and liver. The post-operative serum calcitonin level decreased to 3736 pg/ml, and diarrhea partially improved. Adjuvant chemotherapy was not suggested owing to futile outcome, and further target therapy is under evaluation.
Declaration of interest

**Antiproliferative effect and control of catecholamine release with octreotide in a patient with giant bilateral pheochromocytoma**

D. Katalinic[1], S. Plestina[1], M. Vrkljan[2], I. Aleric[1] & A. Maric[2]
[1]University Hospital Centre (KBC Zagreb), University of Zagreb School of Medicine, Zagreb, Croatia; [2]University Hospital Centre 'Sisters of Charity', University of Zagreb School of Medicine, Zagreb, Croatia.

Introduction
Pheochromocytomas are rare but treacherous catecholamine-producing tumors of the medulla of the adrenal glands (originating in the chromaffin cells), or extra-adrenal chromaffin tissue. We refer a case with stabilization of tumor growth and hormonal improvements following repeated s.c. injections of octreotide.
Case report
We report a female patient aged 35 with a finding of bilateral adrenal mass with sever cardiovascular symptomatology (frequent paroxysms of headache and

palpitations accompanied with hypertensive episodes). Biochemical screening showed 20-times higher level of adrenalin, 13-times higher level of noradrenalin, 27-times higher level of chromogranin A and 30-times higher level of vanillylmandelic acid in 24 h urine. Enhanced MR imaging (Fig. 1A) confirmed the findings of adrenal gland tumors (the left adrenal mass was 11×9 cm, and right adrenal mass was 4×3 cm in size). I-131-MIBG scintigraphy showed uptake in both adrenal glands. As a member of the Jehovah's Witnesses, the patient refused surgery definitively not accepting a possibly needed blood transfusion, but was successfully treated with octreotide at 50 μg s.c. injection twice daily during 2.5 years with relief of symptoms and tumor shrinkage on enhanced MSCT scan (Fig. 1B). We also observed a significant reduction in catecholamines and chromogranin A levels.

Conclusion

We stress the importance of complete hormonal screening in all cases of adrenal masses, especially in patients with cluster of heart symptoms. Pheochromocytomas are best treated surgically to obviate the associated dangerous cardiovascular catecholamine-mediated paroxysmal events. However, successful treatment with somatostatin analogues such as octreotide could be potentially considered as the treatment of choice for patients with pheochromocytoma especially those considered unsuitable for surgery or in cases where the operation is not possible.

### Survival of patients with adrenocortical carcinoma: experience of one center

V. Elezovic, M. Petakov, D. Macut, S. Ognjanovic, T. Isailovic, B. Popovic, I. Bozic, T. Bogavac & S. Damjanovic

Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia.

Adrenocortical carcinoma (ACC) is rare and aggressive malignancy with poor prognosis. Patients present with hormone excess or a local mass effect, or incidentally. ACC has undergone metastatic spread in 40–70% of patients at the time of diagnosis. Surgical removal is treatment of choice. Standard chemotherapy with mitotane has limited efficacy.

The aim of this paper is to present the results of single tertiary center for diagnosis and treatment of ACC in Serbia. A retrospective review was performed of all patients who were hospitalized from 2005 to 2011. Kaplan–Meier curve was used as the univariate version of survival analysis.

We analyzed 46 patient with ACC (28 females, 18 males), median age 47 years at diagnosis. Ten patients were lost during the follow-up. The mean size of the tumor was 11.6 cm. Fifty-two percent of patients were stage IV (ENSAT staging), 44% stage II, and one patient was stage I. Patients with hormone secreting ACC (40%) were presented with Cushing's alone (20%), or combined with androgen excess (17%), 54% were asymptomatic. Primary tumor was operated in 88% of patients. Sixty-five percent of patients were treated with mitotane and 26.5% received chemotherapy. At the time of diagnosis 43% of patients had distant metastasis. Mean overall survival was 68 months (95%CI 54–83) with 5 year overall survival 66.7 and 52% in stage IV, and 80% in stage II. The 3 years overall survival was 74%. Median disease free survival was estimated 11 months (range 7–14 months). Significantly higher overall survival was noted in patient treated with mitotan ($P<0.0001$) comparing to untreated patients. Median overall survival was not statistically different between patient with low, medium and high Ki67 index in this study. In conclusion, we presented the survival in ACC patients in Serbia, our 7 years experience.

## P871

### Leydig cell tumor of ovary: a rare case of virilization

S. Souto[1,2], P. Vieira-Baptista[1], F. Barreto[1], D. Carvalho-Braga[1,2] & D. Carvalho[1,2]

[1]Centro Hospitalar São João, Porto, Portugal; [2]University of Porto,, Porto, Portugal.

Introduction

Leydig cell tumors are a type of steroid cell tumor, account for 0.1% of all ovarian tumors. The clinical presentation is usually a hyperandrogenic state with signs of virilisation. The tumor has a benign behavior, with an excellent prognosis and reversion of symptoms after surgical treatment.

Case report

Woman, 81 years-old, nulliparus, with clinic hyperandrogenism and vaginal bleeding during the last year. She had history of dementia syndrome, dyslipidemia, psoriasis, primary infertility. Her family history was irrelevant. The physical examination revealed hirsutism, androgenic alopecia, masculine voice, and clitoromegaly without adnexial masses in gynecology examination. She had no features of Cushing syndrome. Total testosterone (7.4 ng/ml (0.06–0.82)) and delta 4-androstenedione (>10 ng/ml (0.30–2.99)) were elevated and other hormonal serum levels were normal namely DHEA-S, 17-hidroxiprogesterone, prolactin and TSH. Transvaginal ultrasound revealed intramural fibroid, without visualization of adnexial masses. Abdomino-pelvic computerized tomography (CT) revealed a nodule with 30 mm in the left ovary and normal adrenal glands, confirmed by abdomino-pelvic magnetic resonance. A complete hysterectomy and bilateral oophorectomy were performed. Histological examination revealed a Leydig cell tumor of the ovary. After surgery, the androgen serum levels normalized.

Discussion

The rapid onset of clinical hyperandrogenism with virilism and a serum testosterone level higher than 2.0 ng/ml raised suspicion of an androgen production tumor. In a hyperandrogenism presenting patient, a complete gynecology examination should be performed and an adrenal and ovary CT should be done to exclude an androgen production tumor.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P872

### Lutetium-177 DOTATATE for paraganglioma refractory to conventional chemotherapy: a single case report

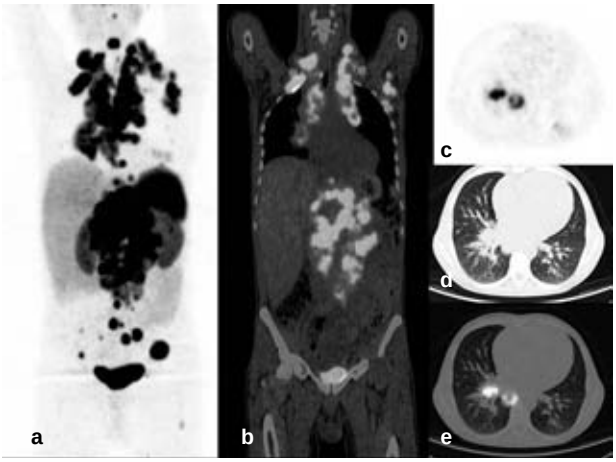
F. Wernig, N. Soneji, I. Klinaki, J. Todd, A. Al-Nahas & K. Meeran

Imperial College Healthcare NHS Trust, London, UK.

A 31-year-old man presented with a two month history of sweating, right-sided abdominal pain and supraclavicular swelling. CT scanning showed widespread lymphadenopathy with multiple retroperitoneal lymph nodes. Biopsy of a left supraclavicular node resulted in a diagnosis of metastatic paraganglioma. Raised urinary catecholamine as well as urinary metanephrine levels further confirmed the diagnosis.

A normocytic anaemia requiring repeated blood transfusions was believed to be due to bone marrow dysfunction. He was also found to have pituitary

insufficiency as evidenced by hypgonadotrophic hypogonadism, undetectable serum prolactin levels and a suboptimal cortisol increase in a glucagon suppression test (pituitary MRI had been unremarkable).
Further imaging demonstrated MIBG uptake in keeping with extensive lymphadenopathy above and below the diaphragm. In addition, Gallium-68 DOTATATE scanning showed uptake in lesions which were not MIBG avid.
He initially completed four cycles of conventional chemotherapy consisting of cisplatin and etoposide as well as palliative radiotherapy to para-aortic nodes. He continued, however, to suffer from extensive lymphoedema, abdominal distension and difficulty in breathing which had necessitated hospital admission and home oxygen therapy. Rising chromogranin A levels as well as repeated CT scans confirmed disease progression.
Therefore, conventional chemotherapy had been discontinued and he was commenced on Lutetium-DOTATATE treatment.
Up to now, he has received four cycles at intervals of 2–3 months. His clinical response was excellent with gradual improvement of both symptoms and quality of life. Prior to his third cycle, the lymphoedema had disappeared and there was significant reduction in the size of overall metastatic disease on repeat CT scanning. He is no longer transfusion-dependent and his only remaining symptom is of occasional night sweats.
This is a unique case which demonstrates successful therapy of a metastatic paraganglioma, refractory to conventional chemotherapy, with Lutetium-DOTATATE. Significant clinical improvement could be achieved with very low toxicity and treatment side effects.



68Ga-DOTATATE PET-CT Scan. Maximum intensity projection a) and fused coronal PET-CT image b) shows the extent of disease above and below the diaphragm. Multiple lymph nodes, both lungs and bones are involved. Lung metastases are demonstrated on axial PET c), CT d) and fused e) images.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P873

**Hypoglycemia by insulinoma: for the purposes of a case**

G. Jorge[1], C. Nogueira[1,2], C. Esteves[1,2], C. Neves[1,2], J. Queiros[1], M. Oliveira[1], J. Pardal[1] & D. Carvalho[1,2]
[1]Hospital de São João, Porto, Portugal; [2]University of Porto, Porto, Portugal.

Clinical case
Introduction
Insulinoma is a rare disorder with an estimated incidence of 1 case per 250 000 people per year.
Case report
37 years old female, with a history of irritable bowel syndrome, dyslipidemia and kidney stones. In December 2010, she developed a headache, dizziness and visual disturbances, predominantly in the evening and amnesia for some of the episodes. Initially interpreted as peripheral vertiginous syndrome, because of recurrence of symptoms, interfering in daily activity, she developed psycho-emotional instability and anxiolytic medication was prescribed. In April she had a similar episode accompanied by syncope and imbalance, she was assisted at the Health Center with 31 mg/dl. She was admitted for hypoglycemic investigation. She performed a fasting test that was stopped an hour later through symptomatic hypoglycemia (serum glucose levels of 25 mg/dl, insulin 36.3 μU/ml, C-peptide 5.06 ng/ml), with increase of the serum glucose levels $>25$ mg/dl after glucagon, suggestive of endogenous hyperinsulinism. CT showed nodular mass in the pancreatic head with 21 mm with the arterial phase uptake suggestive of insulinoma without mesenteric or retroperitoneal lymphadenopathy. She underwent tumor enucleation.. Pathological examination showed well differentiated insulinoma $1.8\times1.5\times1.2$ cm, low mitotic index, Ki 67 3%, with no necrosis and no vascular invasion or surgical margin, synaptophysin positive. After surgery she remains clinically well.
Discussion
This case illustrates the need for high clinical suspicion for insulinoma diagnosis. Neuroglycopenia and adrenergic symptoms are often confused with acute vertigo and anxiety disorders. Although it was the case with this patient, the delay in diagnosis was only five months. Some studies have shown average delays in diagnosis of 1.5 years. In this case, the patient has a tumor with good prognosis (pT1N0M0, stage IA), with an estimated survival at 5 years of 61%.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding

## P874

**Atypical presentation of type 1 gastric neuroendocrine tumor should increase our awareness**

A. Gilis-Januszewska, E. Baczynska, B. Solska-Piwonska, M. Trofimiuk, D. Pach, A. Sowa-Staszczak & A. Hubalewska-Dydejczyk
Jagiellonian University, Krakow, Poland.

Introduction
Among three types of gastric neuroendocrine tumors (GEPNETV) type 1 are most common. At the basis of the pathogenesis of type 1 is atrophic gastritis, which leads to achlorhydria and deficiency of intrinsic factor, resulting in G cell hyperplasia and hypergastrinaemia. Gastric endoscopy usually reveals the multiple and polypoid lesions ($<1$–2 cm) in the corpus. Five-year survival in these patients is not different from survival in the selected age group population. Type 1 GEPNET metastasizes very rare (2–5% of cases).
The aim of our study was to present atypical type 1 GEPNETV.
Case report
In the Department of Endocrinology we follow up 41 cases of GEPNETV, among them 30 of type 1. M.S., 33-aged male, in 2008 due to anemia and epigastric pain had gastroscopy. It reavealed three wide based polypoid lesions bigger than typical lesions (15–30 mm in diameter). In biopsy there was highly differentiated neuroendocrine tumor expressing chromogranin. Ki67 index $<1$%. In addition, atrophic gastritis was found. In abdomen CT and scintigraphy with somatostatin analogues (SS scintigraphy) no speciphic changes were found. Patient refused proposed surgery and for 1 year was lost for follow up. In the next gastroscopy in 2010 there were three polypoid lesions up to 30 mm in diameter, with similar biopsy to former examination. In 2011 total gastrectomy was performed. Histopatology revealed neuroendocrine cancer with metastases to the local lymph nodes. In postoperative SS scintigraphy no uptake of the tracer was found, patient is treated with somatostatin long acting analoque.
Conclusions
Atypical presentation of type 1 GEPNETV should increase our awareness and influence the treatment decision making.

## P875

**A case of multiple endocrine neoplasia type 1 associated with multicentric VIPoma**

S. Ognjanovic, M. Petakov, D. Macut, T. Isailovic, V. Elezovic, B. Popovic, I. Bozic, T. Bogavac & S. Damjanovic
Clinic for Endocrinology, Diabetes and Metabolic Diseases, Belgrade, Serbia.

Introduction
Multiple endocrine neoplasia type 1 syndrome (MEN1sy.) is a complex disease predisposing to a variety of multifocal neuroendocrine tumors (NET). Approximately 5% of pancreatic VIPomas and glucagonomas are associated with MEN1sy., most of them with metastases at diagnosis.
Case report
A 15-year-old boy was admitted with primary hyperparathyroidism, pituitary microadenoma (6 mm) and suspected MEN1sy. His father had primary hyperparathyroidism and pancreatic gastrinoma. While hospitalized, the patient had intense abdominal pain, facial flushing and massive diarrhea, severe volume depletion, hyperchloremic hypokalemic acidosis and aggravated hypercalcaemia. Endoscopic ultrasound (EUS) and MRI showed two tumors localised in the pancreatic head and tail. Octreoscan revealed one lesion in the pancreatic head. Gastrin and 5-HIAA values were in normal range. Chromogranin A (CgA) was increased (562 ng/l). Direct sequencing of MEN1 gene identified germline mutation at codon 395 of exon 8 (CAG→TAG). Somatostatin analogue therapy was started before surgery. Near total parathyroidectomy with profilactic thymectomy was performed. Parathyroid glands showed diffuse hyperplasia. Pancreatic resection with total tumor exscision was also performed. Histopathological analysis revealed four well-differentiated NETs, three of them showed VIP-ma imunoprofile, but one was pure glucagonoma (Ki67-1%, MI 0/50 HPF, CgA+++, VIP+++, glucagon++). Peritumorous pancreatic tissue showed microadenomatous proliferation. There were no regional lymphonodal metastases. Postoperatively the patient remained asymptomatic with persistant hypoparathyroidism and normal CgA values. After 18 months, MRI and EUS showed one lesion in the pancreatic tail, of the same dimensions (10 mm) as preoperatively, without other dissemination. Patient also had microprolactinoma. Prior and after pancreatic surgery (independently of VIP stimulation) serum PRL levels were up to 3000 mIU/l, without PRL response to TRH stimulation.
Conclusions
We present a case with multicentric pancreatic VIPomas and one glucagonoma in association with MEN1sy. The persistant solitary lesion in the pancreatic tail can be either clinically non-functional NET or microadenomatosis associated with MEN1sy.

**Disseminated insulinoma in 13-year-old patient**

S. Szpak-Ulczok, K. Hasse-Lazar, J. Krajewska, B. Michalik & B. Jarzab
MSC Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Gliwice, Poland.

Neuroendocrine tumors are rare in young patients and usually have favorable course. We present a case of young, 13-year-old girl diagnosed with insulinoma. The diagnosis was stated on the basis of the presence of neuroglycopenic symptoms. An abdominal CT scan demonstrated a tumor localized in the head of pancreas. The patient received diazoxide as a preparation to surgery. Therapy was effective, but discontinued due to side effects. Patient underwent the Whipple operation. During this surgery pathological local lymph nodes and liver metastases were also stated. Histopathological examination confirmed well differentiated neuroendocrine tumor WHO grade1 with Ki67 index $<1\%$. Hypoglycemia persists after surgery. Four months after operation liver metastases grew up to 28 mm dimension and pathological lymph nodes were observed. PET–FDG was negative whereas PET-Ga68-DOTATATE was positive (about half of known disease foci showed tracer uptake). Despite the fact of only partially positive PET we decided to introduce somatostatin analogue into the treatment of hypoglycemia. The patient continues therapy with a very good control of glycemia. In the case of disease progression systemic therapy will be considered.
The presented case is an example of unfavorable course of rare neoplastic disease in young patient.

**Management of ectopic Cushing's syndrome caused by bronchial carcinoid: four case reports**

O. Nemes, T. Molnar, E. Schmidt, T. Doczi, Z. Tarjanyi, B. Ruzsa, L. Bajnok, K. Zambo & E. Mezosi
University of Pecs, Pecs, Hungary.

During the evaluation of hypercortisolism, distinction between Cushing's disease (CD) and ectopic ACTH syndrome (EAS) may be problematic. Detailed medical history, diagnostic procedures and pitfalls associated with EAS of four cases are presented. All the four patients had ectopic Cushing's syndrome due to typical bronchial carcinoids. Their mean age was 39 years, and the mean time from the presentation of Cushing's symptomes until diagnosis and definitive cure was 2.3 years (from 9 months to 5 years). The high-dose dxm suppression test was misleading in Cases 1 and 2, indicating CD. In Case 2, bilateral inferior petrosal sinus sampling (BIPSS) indicated a central source of ACTH overproduction, which led to hypophysectomy, despite of negative sella MRI findings. In Case 3, the BIPSS results were inconclusive and the sella MRI scan was negative, so renewed search for an ectopic origin was decided. In Case 4, the cortisol response to high-dose dxm was negative, but on the sella MRI pituitary microadenomas were visible. This led to a retrospectively unnecessary hypophysis surgery.
$^{111}$In-octreotide SPECT correctly localized lung carcinoid in every case. Hybrid imaging using SPECT–CT allowed an accurate anatomic description, detection of additional sites of disease, and higher specificity by exclusion of false-positive uptake at sites of physiologic tracer activity.
Conclusion
$^{111}$In-octreotide SPECT-CT was the most valuable and decisive method in the detection of ectopic ACTH-secreting tumors. A more favorable place in the diagnostic algorithm of ACTH-dependent hypercortisolism should be considered for such an image-fusion method applying simultaneous SPECT and CT acquisitions.

**Metastatic malignant insulinoma**

C. Moreno, A. Rodrigues, L. Gomes, L. Ruas, L. Barros, S. Paiva, A. Vieira, M. Alves, S. Gouveia, J. Saraiva & M. Carvalheiro
University Hospitals of Coimbra, Coimbra, Portugal.

Introduction
Insulinomas are the most common form of functioning pancreatic neuroendocrine tumors (NET) with an estimated incidence of 1–3/million per year. Less than 10% are malignant and rarely with distant metastases, carrying a poor prognosis.
Case report
We report a case of a 73-years-old woman attended at our ER for recurrent syncope, with irrelevant medical history. Several radiology exams were preformed, revealing numerous liver metastases and a probable metastatic lesion in L3 vertebral body, justifying a complete investigation for occult malignancy. The chest, pelvis and abdominal CT scan showed a lesion with tumor-like characteristics in the tail of the pancreas. The PET scan, bone scintigrafy and somatostatin receptor scintigrafy also suggested extensive metastization in the liver, cervical spine and both humerus of a primitive NET of the pancreas. Biopsy of a hepatic metastatic nodule was preformed, and the anatomopathological examination confirmed the diagnosis of a well differentiated NET (G2-WHO 2010(Ki-67 index of 6%)). The laboratory findings were:chromogranin A 91 nmol/l ($<6.0$), gastrin 392 pg/ml ($<90.0$), fasting insulin 34 μUI/l ($<30$), random insulin 54 μUI/l for a random glycemia of 33 mg/dl. Other biochemical tests were unremarkable and the screening for MEN1 was negative.
The patient was discharged under octreotide 100 μg, t.i.d. but kept frequent and severe hypoglycemias which motivated a re-admittance. In spite of an intensive treatment with octreotide 100 μg, t.i.d., diazoxide 100 mg, t.i.d., dexamethasone

0.5 mgq.d. and isotonic or hypertonic continuous glucose solutions, the patient kept severe hypoglycemia and chemotherapy was proposed because there was no surgical eligibility. After three cycles of chemotherapy(streptozocin 725 mg combined with epirubicin 87 mg), under monthly octreotide 30 mg, diazoxide 100 mg, t.i.d., prednisolone 20 mg, q.d. and a nutritional plan, the patient was discharged and remains with no further hypoglycemia or pain complaints (ECOG 0).
Conclusion
The rarity of this case and the absence of clear guidelines illustrate the difficulties in its treatment and the need for a multidisciplinary approach. The severity of the patients' symptoms imposed the use of multiple therapies and the option of a classic systemic chemotherapy, with good results. In spite of the poor prognosis carried by an advanced malignancy (T2NxM1 – ENETS and AJCC/UICC 2011), the patient is asymptomatic and has a good quality of life.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### A rare case of hirsutism: mucinous cystoadenoma of the ovary with stromal luteinization and hilar cell hyperplasia

P. Senes, R. Paragliola, M. Ricciato, E. Rossi, G. Fadda, A. Pontecorvi & S. Corsello
Catholic University School of Medicine, Rome, Italy.

Introduction
Mucinous ovarian cystoadenoma with stromal luteinization and hilar cell hyperplasia is a rare cause of hirsutism and virilization and only few cases are described in literature. We present a rare case of mucinous cystadenoma with hypertestosteronemia.
A 38-years old woman came to our observation for severe hirsutism and oligomenorrhea. Hormonal work-up showed severe hypertestosteronemia (total testosterone: 4.39 ng/ml) with high levels of DHEA-S (3574 ng/ml) and 17 OH progesterone (3.6 ng/ml). 17 OH progesterone after ACTH test stimulation was 18 ng/ml leading to the diagnosis of late onset congenital adrenal hyperplasia. However testosterone levels were, in our opinion, too high to be related only to a 21-hydroxilase deficiency. In the suspicion of an androgen secreting tumor, abdominal US and CT scan were performed, showing a right ovarian cystic mass of about 10 cm. Then the patient underwent right ovariectomy. Histology confirmed a mucinous cystoadenoma with hilar cell hyperplasia and stromal luteinization. After surgery, testosterone levels suddenly decreased, confirming our suspicion of an ovarian secretion of testosterone.
Conclusion
Mucinous cystoadenoma represents 15–20% of ovarian tumors. They often become very large and can extend up into the abdomen, so that the typical clinical presentation is usually related to the abdominal mass. Hypertestosteronemia is a rare clinical finding when hyperplasia of stromal cells and Leydig cells occur.
Declaration of interest

## P880

### Neuroendocrine tumors of the gastrointestinal tract: a descriptive study

B. León de Zayas, M. del Olmo García, A. Ramos Prol, M. Argente Pla, M. Muñoz Vicente, A. Gilsanz Peral & J. Merino Torres
Hospital La Fe, Valencia, Spain.

Introduction and objective
Neuroendocrine tumors (NETs) are relatively rare tumors. The majority are located in the gastrointestinal (GI) tract and bronchopulmonary system. The aim of this report is to study the characteristics of gastrointestinal NETs at diagnosis.
Material and methods
Descriptive study about 18 patients diagnosed of gastrointestinal NETs during 1993–2011 in our hospital. Data regarding demographic, clinical, analytical, anatomopathological and diagnostic variables were collected. Statistical analysis was perfomed using SPSS 18.0, results are expressed as mean $\pm$ S.D.
Results
Eighteen patients (50% men) with a mean age at diagnosis of $52.7 \pm 14.4$ years were studied. Seven (38.9%) presented typical carcinoid clinical syndrome. The rest presented symptoms due to growth of the primary tumor such as appendicitis, intestinal obstruction or diffuse abdominal pain. The mean time since symptoms appeared until diagnosis was 10 months. The ileum was the most common location (61.1%) followed by stomach (16.7%), appendix (11.1%), rectum (5.6%) and colon (5.6%). Eleven (61.1%) had metastases at diagnosis, all of them hepatic. Six of the seven patients with carcinoid syndrome presented metastases at diagnosis. Tumors were diagnosed more frequently by CT scan (50%), ultrasound (16.6%) and MRI (5.5%). Inmunohistochemical markers resulted positive for: chromogranin A (88.9%), enolase (61.1) synaptophysin (44.4%) and cytokeratin (33.3%). Ki67 was determinated in 50% of cases. It was $<3\%$ in seven cases (38.9%) and $>20\%$ in two (11.1%). The mitotic rate was determinated only in four patients (22.2%), in three of them was $<2\%$ (16.7%) and between 2 and 20% in one case (5.6%).
Conclusions
The ileum is the most common location of NETs of gastrointestinal tract. The mitotic and proliferation rate must be a priority in the anatomopathological study as it may condition different therapeutical approaches. In our serie these tumors are diagnosed in an advanced metastasic stage probably due to a low suspicion of these tumors.

### Prediction of remission of gestational trophoblastic disease based on initial levels of prolactin

A. Violante[1], A. Baptista[1,2], R.. Luiz[1] & P. Belfort[1]
[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [2]Santa Casa da Misericordia do Rio de Janeiro, Rio de Janeiro, Brazil.

Objective
A prospective study to research the relationship between initial levels of prolactin in the development and outcome of patients with gestational trophoblastic disease.
Material and method
A longitudinal study including 51 women attending the Reference Center of Gestational Trophoblastic Neoplasia of Rio de Janeiro- Brazil, with complete mole, and comproved histopatologic examination. All women were followed up until remission was achieved. The criteria of selection was the level of hCG above 100,000 mIU/ml, a risk factor included in the FIGO 2000 staging and risk factor scoring system for gestational trophoblastic neoplasia. Two groups were established: the first one with prolactin level $>30$ ng/ml and the second one with prolactin level $<30$ ng/ml. The serum levels of hCG and prolactin followed the same time interval established by the consensus protocol for the monitoring of gestational trophoblastic disease.
Results
Of 208 patients registered in the GTN Reference Center in Rio de Janeiro during the period analyzed, 51 presented with βhCG serum levels $\geq 100.000$ mUI/ml: 36 (70.6%) had prolactin levels above 30 ng/ml (group 1) and 15 (29.4%) had prolactin levels $<30$ ng/ml (group 2). In group 1, 25 presented with vaginal bleeding, 12 with uterus large for gestational age, four had hypertension and 18 hyperemesis. Six patients were diagnosed with bilateral ovarian cists. Spontaneous remission occured in 27 patients, nine requiring chemotherapy. In group 2, three patients presented with vaginal bleeding, none had uterus large for gestational age, none had hypertension, four patients had hyperemesis and two were diagnosed with bilateral ovarian cists; 14 went into spontaneous remission, one was submitted to chemotherapy.
Conclusion
In this study of 51 patients with complete mole there was not found any correlation between baseline prolactin levels, progression to spontaneous remission, indication for chemotherapy or time interval for remission.

**Radioguided cortical-sparing approach for recurrent pheocromocytoma/paragangliomas**

G. Donatini, P. Iacconi, G. Bernini, G. Boni, G. Manca, C. Spinelli, G. Mariani & P. Miccoli
University of Pisa, Pisa, Italy.

Background
A 27-years-old women affected by recurrent pheocromocytoma/paragangliomas. We describe the evolution of disease and the surgical approach. The patient underwent a two-steps bilateral adrenalectomy for pheocromocytoma. At 15 years she underwent a left adrenalectomy. At 19 a right adrenalectomy + removal of paracaval paraganglioma were performed. After 8 years of good health she experienced again headache, tachycardia and hypertension not responsive to therapy. A diagnosis of recurrent disease was made.
Methods
Nor-colesterol and MIBG scintigraphy were performed and stated respectively for a hyperfixation in the left adrenal bed and two spot of hyperfixation on paracaval and paraortic area (Default 1). The last two spots were concurdant with a MRI imaging. The patient underwent surgical exploration using an intraoperative radionuclear scanning probe. A target/background ratio (T/B ratio) was calculated. All lesion with a T/B ratio level more than 1.2 (239 mBq) were considered suspected.
Results
Three lesions with a value respectively of 270, 2020 and 2600 mBq were removed. Pathological report classified the latter two lesions as paragangliomas. At 5 years follow-up the patient has no biological evidence of disease and does not need any replacement therapy.
Conclusions
The easier finding of the lesions by radioguidance allowed the surgeon to perform a focused approach, obtaining a radical procedure, to achieve a successful treatment of a recurrent disease. Sparing the remnant of cortical adrneal tissue on the left side also had a great impact in the quality of life preserving the patient from life-long steroid replacement therapy (Figure 1).

**Clinically palpable parathyroid adenoma**

M. Kaushal & M. Nagar
MGM Medical College and MY Hospital, Indore, India.

A palpable parathyroid mass, in a patient with primary hyperparathyroidism, is presumed to be parathyroid carcinoma until proven otherwise, with other less common causes including parathyroid cysts and adenomas.
In developing world primary hyperparathyroidism presented in different way not only in the disease age group as well as in clinical symptoms and signs. More cases of symptomatic PHPT are presented in younger age group and some time large adenomas can presented a palpable neck swellings.
We have 13 cases of clinically palpable parathyroid tumors out of 58 cases. In all palpable cases except one proved benign adenomas.
Large parathyroid adenomas can be presented clinically palpable swelling. Cytology and imaging of parathyroid adenomas may, on occasion, mimic follicular thyroid neoplasms.

**Special diagnostic, therapeutic and evolutive aspects of insulinoma: a tunisian experience**

I. Oueslati, I. Kammoun, T. Riahi, S. Ouannes, H. Kandara, Z. Turki & C. Ben Slama
Nutrition National Institute, Tunis, Tunisia.

Insulinoma is a very rare type of islet cell tumor. The aim of our study is to report our clinical experience with insulinoma in order to determine clinical, biological, radiological and therapeutic particularities of this tumor type.
It's a retrospective study, including five patients (three women and two men) referred to our department between 2005 and 2011 for hypoglycemia exploration. Mean age of our group is 39.8 ± 15.4 years (ranges: 20–60 years). Two women were type 2 diabetic patients.
All our patients showed neuroglycopenic symptoms associated with a blood glucose level < 0.5 g/l. Three patients had a weight gain of 16 ± 13.5 kg (ranges: 3–30 kg).
The fasting test was interrupted after 6.6 ± 4 h (ranges: 3–11 h), showing an inadequate high insulin (ranges: 4.2–240.5 UI/ml) and C-peptide (ranges: 2.91–14.4 ng/ml) secretion with hypoglycemia (ranges: 1.5–2 mmol/l). The screening for sulfonylurea was negative in all patients confirming the diagnosis of insulinoma. It was a sporadic form of insulinoma in all patients.
Endoscopic ultrasonography and CT-scan showed a tail pancreatic tumor measuring 17 mm in one case, and were negative in the other cases. In this group, the tumor was detected using per-operative ultrasonography. All our patients underwent enucleation without any per or post-operative complications.

Postoperative glucose metabolism was normalized in all patients even in diabetic patients.
The combination of hypoglycemia and endogenous hyperinsulinemia with a negative screening for sulfonylurea confirm the diagnosis of insulinoma. However, preoperative localization techniques can be negative especially in very small tumor. In this case, Intraoperative ultrasonography is helpful.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**The ovarian failure associated Y235 residue of human BMP15 gene is target of evolutionary positive selection**

R. Rossetti[1,2], S. Auclair[3,4,5], C. Meslin[3,4,5], G. Pascal[3,4,5], S. Fabre[3,4,5] & L. Persani[1,2]
[1]Università di Milano, Milano, Italy; [2]Istituto Auxologico Italiano IRCCS, Milano, Italy; [3]INRA, Nouzilly, France; [4]CNRS, Nouzilly, France; [5]Université François Rabelais de Tours, Tours, France.

BMP15 is a TGFβ-like oocyte-derived growth factor involved in ovarian folliculogenesis as a critical regulator of many granulosa cell processes. BMP15 is synthesized as a pro-protein which dimerizes and then is processed in the bioactive mature domain and a large prodomain. The proregion has an important role in the BMP15 processing by driving the dimerization and secretion of the active mature dimers. Since several mutations in the BMP15 gene have been found with different ovarian phenotipic effects, its role seems to differ between mono- and poly-ovulatory species. In fact, heterozygous natural mutations in mono-ovulating sheep cause increased ovulation rates, while poly-ovulating $bmp15^{-/-}$ null mice are subfertile. In humans, almost all the identified BMP15 mutations are located in the proregion, in heterozygosity and associated with Primary Ovarian Insufficiency (POI). To investigate the BMP15 role in controlling ovarian function in mammals, a phylogenetic analysis of sereval TGFβ/BMP family members was performed. BMP15 shows a very early divergence and a more rapid evolution than other members of the family. Using branch-site models from PAML packages, we detected signals of positive selection for the following residues: F146, L189, I229, Y235, R244. Among them, the Y235C mutation was previously identified in association with primary amenorrhea and ovarian dysgenesis. By luciferase reporter assay, the biological activity of the wild-type (wt) BMP15 was compared to those of mutant variants, obtained by replacing the positively selected aminoacid by alanine or cysteine. The L189A, Y235A and Y235C mutants showed a significant increase of BMP signalling compared to wt. In conclusion, present analysis evidences that Y235 residue is important for BMP15 biological activity, indirectly confirming its role in the onset of POI. Moreover, the BMP15 gene seems to have specialized in regulating proper ovarian function during evolution so that, if altered, poly-ovulation or POI could occur.

**Coordinate regulation of heterogeneous nuclear ribonucleoprotein dynamics by steroid hormones in the human Fallopian tube and endometrium *in vivo* and *in vitro***

R. Shao
The Sahlgrenska Academy at Gothenburg University, Gothenburg, Sweden.

Context
The regulation of heterogeneous nuclear ribonucleoproteins (hnRNPs) and their interactions with steroid hormone signaling in Fallopian tubes and endometrium are not clearly understood.
Objective
We determined whether hnRNP expression is regulated during the menstrual cycle and correlates with estrogen receptor (ER) and progesterone receptor (PR) levels in human Fallopian tubes *in vivo*. We also explored the mechanisms of hnRNP regulation in human endometrium *in vitro*.
Design and methodology
Fallopian tissue was obtained from patients in early, late, and postovulatory phases and mid-secretory phase, and endometrial tissue from premenopausal and postmenopausal women undergoing hysterectomy. We measured expression of hnRNPs and assessed their intracellular localization and interactions with ERs and PRs. We also determined the effects of human chorionic gonadotropin (hCG), 17β-estradiol ($E_2$), and progesterone ($P_4$) on hnRNP expression.
Results
In Fallopian tubes, mRNA and protein levels of hnRNP A1, AB, D, G, H, and U changed dynamically during ovulation and in the mid-secretory phase. In coimmunolocation and coimmunoprecipitation experiments, hnRNPs interacted with each other and with ERs and PRs in Fallopian tubes. After treatment with $E_2$ and/or $P_4$ to activate ERs and PRs, hnRNP A1, AB, D, G, and U proteins displayed overlapping but distinct patterns of regulation in the endometrium *in vitro*.
Conclusion
Our findings expand the physiological repertoire of hnRNPs in human Fallopian tubes and endometrium and suggest that steroid hormones regulate different hnRNPs directly by interacting with ERs and/or PRs or indirectly by binding other hnRNPs. Both actions may contribute to regulation of gene transcription.

**Role of the CRH receptors and brainstem noradrenergic nuclei in the gonadotropins secretion induced by acute stress at proestrus morning**

G. Traslaviña & C. Franci
University of São Paulo, School of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil.

Acute stressors can active the reproductive function depending on estrogen priming. Corticotropin-releasing hormone (CRH) has been implicated as mediator of stress-induced effects on hypothalamus–pituitary–gonadal axis (HPG), acting in the limbic system, paraventricular nucleus and noradrenergic (NA) neurons. Antalarmin and astressin2-B are selective CRH-R1 and CRH-R2 antagonists, respectively. We investigated the mediation of CRH-R1 and/or CRH-R2 receptors and of locus coeruleus (LC), A1 and A2 neuron groups in the effects of acute stress on LH and FSH secretion at proestrus morning. Wistar rats showing regular estrous cycles received a catheter in the jugular vein one day before acute stress. At proestrus morning, it was injected antalarmin (1 mg/kg i.v.), asstressin2-B (4.2 nmol i.c.v.) or vehicle and 30 min later was performed the restraint stress for 30 min. Blood samples were collected before, during and after restraint stress to measure FSH and LH by RIA. At the end of the experiment, the rats were perfused and brain were removed to carry out immunofluorescence for tiroxine hydroxylase (TH) and /FOS in LC, A1 and A2 cell groups. Restraint stress increased FSH and LH levels for 30 min. Antalarmin blocked stress-induced increase of FSH and LH whereas astressin2-B only blocked the increase of FSH secretion. The TH activity increased in the LC and A2 groups and a minor magnitude in A1 group. Only the antalarmin injection reduced this effect principally in the LC. These data indicate different roles of CRH receptors in the stress restraint-effects on gonadotropins secretion at proestrus. The CRH-R1 more than CRH-R2 receptor would be essential to the HPG axis stimulation by acute stress and this response would be mediated at least in part by NA neurons, principally in the LC.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### P888

**An invdup (15) associated with premature ovarian insufficiency**

D. Viola[1], A. Valetto[2], V. Bertini[2], P. Simi[2] & P. Vitti[1]
[1]University of Pisa, Pisa, Italy; [2]Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy.

Premature ovarian insufficiency (POI) is a disorder in which amenorrhea, associated to elevated levels of gonadotropins, occurs before the age of 40 years.

The proband, a 36-year-old woman, was born at term after an uneventful pregnancy and delivery from healthy non-consanguineous parents. Growth and mental developmental milestones were normal. At the age of 12 years she presented menarche followed by regular menses, she had no miscarriage and had a successful pregnancy at the age of 27 years. At 35 years of age she experienced asymptomatic abrupt amenorrhea. Physical examination was unremarkable with no evidence of major malformations as well as facial dysmorphisms. Hormonal profile was normal except for LH and FSH values that were in the menopausal range (55.0 and 166.4 mU/ml respectively) and were confirmed over a period of one year.
Environmental, metabolic, iatrogenic and autoimmune causes of POI were excluded. FRAXA expansion was analyzed by standard methods and excluded.
Cytogenetic analyses showed the presence of a supernumerary marker chromosome (SMC) that was characterized by FISH and array-CGH (comparative genomic hybridization).
This marker chromosome derived from chromosome 15 and contained only heterochromatic material. The Prader Willi/Angelman region, that is associated with an abnormal phenotype, was not present. Patients with invdup(15) chromosomes with only the heterochromatin of the proximal 15q have a normal phenotype. Interestingly, an aspect that is sometimes overlooked in these cases is infertility and amenorrhea that is also described in cases with SMC derived by other acrocentric chromosomes and aneuploidies (trisomy 13, 18, 21 and 45,X0). This case constitutes a further example that etiology of POI is not always associated with a defective gene, but in some cases oocytes atresia can be the consequence of the abnormal meiotic pairing of chromosomes.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Impact of thyroid status and thyroid autoimmunity on assisted reproduction technology outcome**

G. Mintziori, E. Gialamas, K. Dosopoulos, D. Zouzoulas, G. Gitas, C. Venetis, E. Kolibianakis, D. Goulis & B. Tarlatzis
Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece.

Introduction
The current evidence on the association between thyroid function or thyroid autoimmunity (TAI) and reproductive outcomes after assisted reproduction techniques (ART) is scarce and inconclusive.
Objective
To record ART outcome according to function and TAI status of thyroid gland.
Methods
A group of 226 subfertile women that underwent any method of ART (IVF, ICSI, intra-uterine insemination (IUI)) from January 2006 to December 2010 were included in the study. Women were excluded if they had failed to complete the ART protocol or if they had a history of thyroid disease. In case more than one ART cycle was applied to a certain woman, only the first one was included in the study.
Results
Studied women were divided into subgroups according to serum TSH concentrations and presence of TAI. Nine had TSH $<0.05$ μIU/ml, 156 between 0.05 and 2.5 μIU/ml, 51 between 2.5 and 4.5 μIU/ml and nine $>4.5$ μIU/ml. Overall, 37% of women achieved biochemical pregnancy, 33% clinical pregnancies and 2% miscarried. The live birth rate was 29%. No difference was found among the four TSH or the two TAI subgroups regarding reproductive outcomes. Age was negatively correlated to numbers of retrieved ($r=-0.349$, $P<0.001$) and fertilized oocytes ($r=-0.344$, $P<0.001$).
Conclusion
This study was not able to demonstrate a relationship between thyroid function or TAI and reproductive outcome after ART. Nevertheless, further prospective trial should be made, studying thyroid function not only before but also during the ART cycle.

**The association of thyroid hormones with menstrually related mood disorder, sexual abuse histories and mood symptoms**

A. Bunevicius, J. Leserman & S. Girdler
University of North Carolina at Chapel Hill, Chapel Hill, NC.

Introduction
Our previous research suggested that a history of sexual abuse (SA) may impact thyroid axis profiles differently in women with menstrually related mood disorder (MRMD) compared with non-MRMD women but was limited by a small sample of non-MRMD women with SA. The current study was designed to study a larger sample of MRMD and non-MRMD women with SA to evaluate whether MRMD status moderates the effects of SA on thyroid axis function.
Methods
A total of 109 women (aged $34\pm8$ years) were prospectively evaluated for current diagnosis of MRMD according to the DSM-IV criteria; for SA histories using a validated interview; for depressive symptoms using the beck depression inventory (BDI); and for serum concentrations of free $T_3$ ($FT_3$) and free $T_4$ ($FT_4$). The $FT_3/FT_4$ ratio, that provides an index of the peripheral conversion of $T_4$ to $T_3$, was also calculated.
Results
Fifty-seven women met criteria for MRMD (23 with SA histories and 34 without SA histories) and 52 women were enrolled as non-MRMD controls (18 with SA histories and 34 without SA histories). There was a significant MRMD$\times$SA interaction for $FT_3$ concentrations ($F(108,3)=4.07$; $P=0.04$), since non-MRMD women with SA histories had lower $FT_3$ concentration than all other groups (ps$<$ 0.05). Only for non-MRMD women with SA histories, lower $FT_3$ predicted higher BDI scores ($\rho=-0.51$, $P=0.046$).
MRMD women, when compared to non-MRMD women, had lower $FT_4$ concentrations ($F(108,1)=5.82$; $P=0.02$) and higher $FT_3/FT_4$ ratio ($F(108,1)=$ 14.99; $P<0.001$).
Conclusions
Our results suggest that MRMD diagnosis moderates the influence of SA on $FT_3$ concentrations. Lower $FT_3$ concentrations are associated with increased depressive symptoms in non-MRMD women who have SA histories. For MRMD women, regardless of SA history, there is increased peripheral conversion of $T_4$ to $T_3$, consistent with a defense reaction and more recently conceptualizations that PMDD represents a stress-related disorder.

**Androgen profiling in adolescent females by liquid chromatography–tandem mass spectrometry**

F. Fanelli, I. Belluomo, V. Di Lallo, O. Prontera, A. Repaci, G. Di Dalmazi, U. Pagotto, A. Gambineri & R. Pasquali
S.Orsola Hospital – University of Bologna, Bologna, Italy.

Polycystic ovary syndrome (PCOS) has an early onset. However, its prevalence in the youngest age groups has not been assessed, mostly due to the poor specificity of the criteria for defining PCOS in adolescents, including the testosterone references generated only on adult women. Moreover, the current references for testosterone were mostly built by immunoassays, known to have poor accuracy. This study was aimed at defining androgen and pro-androgen reference intervals in 149 healthy normal weight and drug-free young women, aged 16–20 y, by using liquid chromatography–tandem mass spectrometry (LC–MS/MS). All had 11–13 menses/year and no signs of hyperandrogenism. Median values (2.5th–97.5th centiles, ng/ml) for testosterone, androstenedione, DHEA, 17OHprogesterone and progesterone were 0.275 (0.129–0.519), 0.898 (0.407–1.665), 6.78 (2.58–18.34), 0.646 (0.210–2.443) and 0.132 (0.049–13.950) respectively. After excluding 36 subjects who did not report their last bleeding day and 9 subjects in ovulatory peak, subjects were sub-grouped according to menstrual phases: follicular phase (day 1–13, LH $<20$ μU/ml, estradiol $<100$ pg/ml, FSH $<10$ uU/ml, n=48); luteal phase (day 14 on, LH $<20$ uU/ml, estradiol $<100$ pg/ml, FSH $<10$ uU/ml, n=56). Follicular and luteal phase median values (2.5th–97.5th centiles, ng/ml) were: 0.247 (0.126–0.416) and 0.274 (0.131–0.553) for testosterone, 0.884 (0.384–1.514) and 0.839 (0.317–1.556) for androstenedione, 6.91 (2.84–21.09) and 7.01 (2.29–17.23) for DHEA, 0.375 (0.160–0.847) and 1.275 (0.261–2.516) for 17OHprogesterone, 0.067 (0.049–0.337) and 4.177 (0.060–14.575) for progesterone respectively. Confirming higher progesterone ($P<0.0001$) and 17OHprogesterone ($P<0.0001$), increased

testosterone was found in the luteal compared to the follicular phase ($P=0.037$). Within the luteal phase subgroup, 23 anovulatory (progesterone $<2$ ng/ml) and 20 normo-ovulatory subjects (progesterone $>7$ ng/ml) were found. Notably, testosterone was significantly higher in anovulatory than ovulatory subgroup ($P=0.021$). Using LC– MS/MS, we defined androgen and pro-androgen reference intervals in young females according to menstrual phase, highlighting the link between testosterone and ovulatory efficiency.

### Expression of CRH/urocortin gene family in mouse gestational tissues during late pregnancy

C. Voltolini[1], S. Battersby[2], F. Petraglia[1] & J. Norman[2]
[1]University of Siena, Siena, Italy; [2]The Queen's Medical Research Institute, Edinburgh, UK.

Introduction

There is increasing evidence for a role of the CRH/urocortin family in human pregnancy, since they have been implicated both in physiological processes and pathogenesis of diseases such as spontaneous preterm labour. However, little information is available on the presence or function of the CRH/urocortin genes in mouse pregnancy. The study aimed to investigate the expression of CRH, urocortins and their receptors in mouse utero-placental tissues during late pregnancy.

Design

All animal care and experimental protocols were approved by the appropriate animal ethics authorities. Placental, uterine and fetal membrane tissues were separated and collected from timed-pregnant mice on days 16–19 of pregnancy ($n=10$ for each group; parturition occurred on D20). RNA was extracted from the tissues and Taqman real time RT-PCR was performed using standard techniques.

Results

CRH and urocortin were expressed at low levels in the murine placenta and did not vary significantly during late pregnancy. Urocortin2 was the most abundant urocortin in mouse placenta and levels increased significantly from D16 to D19 ($P<0.001$). Urocortin2 levels were lower in fetal membranes, but increased significantly on D19 of pregnancy ($P<0.05$ D16, D17, D18 vs D19). In contrast, urocortin3 concentrations were higher in fetal membranes than in placenta and decreased significantly on D17–19 compared with D16 ($P<0.05$). CRH-R1 was predominantly expressed in placenta and concentrations did not vary significantly. However, CRH-R2 was more widely expressed and the level in the fetal membranes increased significantly on D18 compared with D16 ($P<0.05$).

Conclusions

Urocortin2 is a major urocortin in mouse gestational tissues, with the up-regulation in placenta and fetal membranes in late pregnancy suggesting a role for the gene in parturition. Moreover, the co-incident decrease in urocortin3 in fetal membranes suggests that the balance between the two urocortins, which both act via CRH-R2, may have a key role in pregnancy and parturition.

### Hypoxia-induced oxidative stress regulates the expressions of calcium transport channels in the duodenum, kidney and placenta of rats

H. Yang, S. Hyun & E. Jeung
Chungbuk National University, Cheongju, Republic of Korea.

Introduction

Preeclampsia is a pregnancy-specific disease characterized by *de novo* development of concurrent hypertension, proteinuria and oxidative stress in placenta. Hypoxia occurs during the development of placenta in the first trimester and is implicated in trophoblast differentiation. The oxidative stress, resulting from deficient remodeling of spiral arteries, is an important inducer of preeclampsia. The potassium-dependent sodium/calcium exchangers including NCKX3 and NCX1 play critical roles in the transport of intracellular calcium that is exchanged with extracellular sodium ions. Calcium related proteins, NCXs, calbindin, calcium pumping proteins (TRPV5-6, PMCA1b) transcripts are abundant in the smooth muscle, uterus, aorta and intestine.

Methods

The expressions of calcium related proteins in the kidney, duodenum and placenta after hypoxic stress in rats at gestation 19.5 day (GD 19.5) was examined by real-time PCR and western blot analysis.

Results

Hypoxic condition did not change fetal weight, however, it significantly increased the weight of placenta compared to normoxic condition. In GD 19.5, renal NCKX3 and TRPV6 expressions were increased, while the levels of NCX1 were decreased in hypoxic rats compared to normoxic pregnant rats. The expressions of CaBP-9k, TRPV5 and PMCA1b were not altered in normoxic- or hypoxic rat tissues. Duodenal expressions of CaBP-9k, TRPV5-6 and PMCA1 were decreased in hypoxic rats, while NCXs were not changed. The transcripts of NCKX3, TRPV5-6 and PMCA1b were highly expressed in the placenta of hypoxic rat.

Conclusions

The expressions of renal, duodenal and placental calcium related proteins appear to be modulated by hypoxia-induced oxidative stress, implying that calcium related proteins may be involved in preeclamptic oxidative stress.

### Daily serum testosterone during the menstrual cycle by ID-LC–MS/MS

H. Bui[1], P. Sluss[2], S. Blincko[3], M. Blankenstein[1] & A. Heijboer[1]
[1]VU University Medical Center, Amsterdam, The Netherlands;
[2]Massachusetts General Hospital, Boston, Massachusetts, USA;
[3]Abbott Diagnostics, Wiesbaden, Germany.

Testosterone levels in normally cycling women are generally assumed to be elevated during ovulation. The clinical relevance of changing testosterone levels during the menstrual cycle, however, is unclear, due to poor performance of current direct immunoassays for testosterone at low concentrations.

An isotope dilution-liquid chromatography–tandem mass spectrometry (ID-LC–MS/MS) method with sufficient reliability and sensitivity[1] was used to measure testosterone in serum samples obtained daily during the menstrual cycles of 25 healthy women, characterized by biochemical and physical examination. Since ID-LC–MS/MS is not accessible to all clinical laboratories, we also evaluated the performance of the recently available direct immunoassay Architect 2nd Generation Testosterone.

Performance of the ID-LC–MS/MS method was comparable to the reference method[2] (weighted Deming regression: $y=1.007\times-0.056$ nmol/l; $r=0.9998$). Comparison of the 2nd generation immunoassay results to ID-LC–MS/MS yielded $y=1.095\times+0.104$ nmol/l ($r=0.90$). Testosterone levels were significantly higher mid-cycle, although a peak was not discernable in all individuals. Intra-individual variation exceeded the group average in the menstrual cycle; the ratio of extremes (max/min) found in individuals ranged from 1.6–3.7. Apart from a persistent positive bias, the immunoassay measured the same testosterone profiles. The reference interval was 0.30–1.69 nmol/l for ID-LC–MS/MS and 0.50–2.00 nmol/l for the immunoassay.

Our ID-LC–MS/MS method measured low testosterone levels accurately. The Architect 2nd generation testosterone immunoassay had acceptable performance across the entire range measured in women. On average, the elevation of mid-cycle testosterone levels is statistically significant, although not relevant for clinical practice since the day-to-day variation is higher and independent of menstrual cycle. In light of this, we recommend measuring testosterone on at least two independent occasions for diagnostic purposes.

**NT-pro-BNP levels in patients with polycystic ovarian syndrome**

A. Gateva, Z. Kamenov & A. Tsakova
Medical University-Sofia, Sofia, Bulgaria.

Polycystic ovarian syndrome (PCOS) is a common endocrine disturbance in women of reproductive age, thought to be linked to increased cardiovascular risk in later life. Cardiovascular risk factors are usually present even at younger age and this suggests that the chronic disturbances in hormonal and metabolic status typical for the syndrome predispose the patients to development of early atherosclerosis and premature clinical presentation of cardiovascular disease. NT-pro-BNP was shown to have a high predictive value regarding cardiovascular events in patients with hypertension and left ventricular hypertrophy especially in those without overt cardiovascular disease.

The aim of the study is to investigate the importance of NT-pro-BNP as a predictive factor in relation to other classical cardiovascular risk factors.

Methods

Seventy Bulgarian women aged 18–45 years with PCOS (ESHRE-ASRM criteria) and/or obesity (BMI $\geq 30$ kg/m$^2$) participated in this cross-sectional study. NT-pro-BNP was determined with electrochemiluminescence sandwich immunoassay method.

Results

There was no statistical difference between NT-pro-BNP levels (mean $\pm$ S.D.) in obese ($46.9 \pm 57.0$), lean PCOS ($43.5 \pm 52.9$) and obese PCOS ($47.9 \pm 37.7$) patients, between patients with or without metabolic syndrome and between patients with different cardiovascular risk according to androgen excess and polycystic ovary syndrome (AE-PCOS) society consensus. The rate of patients with NT-pro-BNP levels above the cut-off of 103 pg/ml is not statistically different between the groups. NT-pro-BNP does not show significant correlation to age, weight, body mass index, waist-to-hip ratio, waist-to-stature ratio, systolic or diastolic blood pressure and results from OGTT except from immunoreactive insulin levels on 120 min. NT-pro-BNP correlates weakly with HDL-C, but not with other indices of lipid profile.

Conclusions

In this relatively young female population NT-pro-BNP levels did not show to be an important marker for increased cardiovascular risk.

**Differential expression and regulation of $Mg^{2+}$ inorganic phosphate transport channels by hypoxia stress in human placental cells**

H. Yang, H. Kang & E. Jeung
Chungbuk National University, Cheongju, Republic of Korea.

Introduction

Preeclampsia is a pregnancy-specific disease characterized by *de novo* development of concurrent hypertension, proteinuria and oxidative stress in the placenta. Hypoxia occurs during the development of placenta in the first trimester and is implicated in trophoblast differentiation. Last trimester of gestation, the calcium and mineral transport from mother to fetus are dramatically increased in response to the accelerated demand for bone mineralization in the fetus. Two channels of this subfamily, TRPM6 and TRPM7, are permeable for various divalent cations, including $Ca^{2+}$, $Mg^{2+}$ and $Zn^{2+}$. Adequate phosphate homeostasis is of critical importance for a wide variety of functions including bone mineralization and energy metabolism. Signaling mechanisms mediating hormonal regulation of $Mg^{2+}$ and inorganic phosphate channels are not well understood in the placenta during pregnancy.

Methods

The expression of cell membrane $Mg^{2+}$ and inorganic phosphate channels was investigated when oxidative stress was induced in human placental cells BeWo, JEG3 and human placental primary cells (hPC). The mRNA and protein levels were examined by real-time PCR and western blot analysis.

Results

The transcriptional and translational levels of $Mg^{2+}$ and inorganic phosphate channels were altered in hypoxic condition. The expression of $Mg^{2+}$ channels was down-regulated by hypoxia. The transcripts of inorganic phosphate channels were increased in BeWo and JEG3 cells, while decreased in the hPC.

Conclusions

$Mg^{2+}$ and inorganic phosphate channels were distinctly expressed after oxidative stress in human placental cells, suggesting that altered expression of $Mg^{2+}$ and inorganic phosphate channels may be involved in placental hypoxic stress, a determinant factor causing preeclamptic abnormality in human placental cells.

**Progesterone levels on the hCG day and outcomes IVF in women with polycystic ovary syndrome**

C. Peng[1,2], X. Long[2] & G. Lu[2]
Hengyang, China; Changsha, China.

Background

The purpose of this study was to determine the incidence of premature luteinization in patients with polycystic ovary syndrome and compared the main determinants of success in IVF in PCOS patients with and without premature luteinization.

Methods

Retrospective analysis of 180 PCOS women of Chinese Han origin with infertility who underwent controlled ovarian hyperstimulation (COH) with an exogenous gonadotropin/GnRH antagonist protocol. Hormone levels on the hCG day and IVF outcomes were assessed.

Results

The incidence of premature luteinization was 23.3%. Compared with PCOS patients without premature luteinization, PCOS patients with premature luteinization (PL) had a higher number of oocytes retrieved ($18.20 \pm 6.6$ vs $15.08 \pm 7.3$, $P = 0.037$) and a higher fertilization rate ($72.9 \pm 1.9$ vs $63.1 \pm 2.3$, $P = 0.033$), but clinical pregnancy rates were no statistical significance (53.3 vs 56.0, $P = 0.836$). Though the implantation rate was higher in no premature luteinization patients, but the difference was not statistically significant (37.7 vs 30.3, $P = 0.115$).

Conclusion

The PCOS patients with premature luteinization had a higher fertilization rate and high number of oocytes retrieved, and the similar implantation rate and clinical PRs as PCOS patients without premature luteinization.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P898

**State of care in women affected by early premature ovarian failure (ePOF) within the first two years of treatment in a center for reproductive medicine and endocrinology (RME)**

I. Benabbad[1,2,4], A. Bachelot[1,3], M. Bidet[1], J. Dulon[1], E. Thibaud[1,2], M. Polak[1,2] & P. Touraine[1,3]
Assistance Publique-Hôpitaux de Paris (APHP), Paris, France; Université Paris Descartes, Paris, France; Université Pierre et Marie Curie, Paris, France; Université Mohammed V, Rabat, Morocco.

Context

Early premature ovarian failure (ePOF) defined by cessation of ovarian function before age 18 is a rare condition. The link between puberty progression and POF hasn't been explored in details.

Aim of study

To describe pubertal development and clinical practices of women with ePOF in a referral center for RME within the first 2 years follow-up.

Description method/design

A mixed retrospective and prospective study was performed. A total of 358 consecutive POF patients were followed from 1997 to 2010. From this cohort 108 patients with ePOF (young girls, adolescents $<18$ years of age at diagnosis of POF) with karoytype excluding Turner syndrome, and no iatrogenic cause are the focus of our study.

Their clinical (age, pubertal evolution, circumstance diagnosis), hormonal (FSH, LH, $E_2$) and morphological features (pelvic ultrasonography, laparoscopy) were analyzed. We also documented their management's characteristics (type of/age of hormonal treatment).

Results
Primary amenorrhea (PA) was more often associated with Tanner breast's stage 1–2–3 and delayed or partial puberty (28.7%) than breast's stage 5 and normal puberty (12%). Secondary amenorrhea (SA) was associated to stage 5 and normal puberty (27.7%). SA's mean age was 16.22 (15–18) years with menarchy at 13.56 (10.5–17) years. The diagnoses are made on high FSH and mean level was 94.76 UI/l. LH was 32 UI/l and estradiol 17 ng/ml.
Mean age at start of hormonal treatment was 17.55 (15–28) years; progestogen's onset was one year later. Combined treatment started at 18 years old. During these two years 1/5 of patients were lost for follow-up.
Conclusion
The fact to complete puberty doesn't exclude PA. However in SA a normal puberty is most often found then in PA. Suboptimal care of these ePOF is documented therefore widespread guidelines to improve care of patients with early POF are needed.

**Nutritional status and reproductive morbidity among women (age 15–40 years) in Dhaka city**

U. Khan[1] & A. Rahman[2]
Ritsumeikan Asia Pacific University, Beppu, Japan; BIRDEM, Shahbag, Dhaka, Bangladesh.

Introduction
Reproductive health is closely related with nutritional status of a country. Nutritional problems are different between developed and developing countries. In the context of Bangladesh there is no recent assessment. This study aims to assess the nutritional status and reproductive morbidity among women in Dhaka city.
Description of methods
A cross-sectional study was performed in 400 women, aged 15–40 years, in Dhaka city. Sample was selected using multistage cluster sampling method. For measuring nutritional status standard techniques of anthropometric indices were used. Social status and reproductive morbidity related data were collected using a pre-designed questionnaire. Results were expressed as frequency, bivariate correlation and $\chi^2$ test.
Results
The average age of the respondents is 25 years and monthly family income is 9216 TK. 31% of women were illiterate. Body mass index (BMI) is an important indicator for nutritional status of the women. This study found that, among the women the proportion of underweight is 19% and overweight is 17%. 32% respondents suffered pregnancy related complication during their pregnancy or delivery time. Anemia is a risk factor for pregnancy related complications. Based on their self-reported information, 74% women had anemia and 33% women had irregular menstruation during their reproductive age. 13% hypertension was found among the respondents in this study. Hypertension is a risk factor during pregnancy for pre-eclampsia and eclampsia. Among the women 3% had diabetes. About half of the respondents had poor appetite. That means they might be suffering from anorexia or bulimia nervosa. BMI is significantly ($P<0.05$) associated with respondents age ($r=0.25$), education level ($r=0.19$) and monthly family income ($r=0.21$). In this study anemia, hypertension, diabetes and respondents appetite are measuring variables of reproductive morbidity and BMI is a measuring variable of the nutritional status. BMI is significantly ($P<0.05$) associated with reproductive morbidity.
Conclusion
i) Among the respondents one third women are malnourished. ii) Approximately 60% women are suffering from reproductive morbidity in Dhaka city. iii) There is a strong association between socio demographic and nutritional status. iv) Reproductive morbidity is associated with nutritional status.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P900

**Anthropometric indices of visceral obesity and cardiovascular risk factors in patients with polycystic ovarian syndrome**

A. Gateva & Z. Kamenov
Medical University-Sofia, Sofia, Bulgaria.

Patients with polycystic ovarian syndrome (PCOS) have an increased risk for diabetes mellitus and often show an adverse cardiovascular risk profile. Among the anthropometric variables for evaluation of central obesity widely used are the waist circumference (WC), waist-hip ratio (WHR) and, more recently, waist-to-stature ratio (WSR).
The aim of the present study is to investigate the link between some anthropometric indices of visceral obesity and cardiovascular risk factors according to androgen excess and polycystic ovary syndrome (AE-PCOS) Society consensus.
Patients and methods
Sixty four PCOS subjects (45 lean; 19 obese) aged 18-40 years were included in this cross-sectional study. Obesity was defined as BMI $\geq 30$ kg/m$^2$ and visceral fat predisposition was considered according to WHR $>0.85$, WC $>80$ cm and WSR $>0.5$. OGTT with determination of immunoreactive insulin (IRI) and Homeostatic model assessment index (HOMA) were performed and testosterone, DHEAS and androstenedione were measured.
Results
Obese PCOS patients had significantly higher rate of visceral obesity than lean PCOS subjects although $\sim 1/3$ of lean patients had visceral predisposition despite lower BMI. Both WSR and WC but not WHR showed to be good markers of adverse metabolic profile in women with PCOS. The cut-off point for WSR of 0.50 is useful and the cut-off of 80 cm for WC is more appropriate than 88 cm in detecting cardiovascular risk in PCOS patients. Unlike fasting IRI on 0 min and HOMA, androgen levels did not correlate to increased cardiovascular risk (AE-PCOS) in PCOS patients. Of the studied androgens only DHEAS showed significant correlation to anthropometric indices – WSR, WC and WHR (($r=0.36$ ($P=0.012$); 0.32 ($P=0.027$) and 0.26 ($P=0.074$) respectively).
Conclusions
WSR and WC are stronger associated with composite cardiovascular risk factors as defined by AE PCOS consensus than WHR. WSR and WC have similar diagnostic value in detecting adverse metabolic profile in PCOS patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P901

**Health related behaviour and understanding of menopausal therapies among women with premature menopause**

M. Gibson-Helm[1], H. Teede[1,2], S. Ranasinha[1] & A. Vincent[1,1,2]
[1]University, Clayton, Victoria, Australia; [2]Southern Health, Clayton, Victoria, Australia.

Premature menopause (PM) occurs spontaneously as premature ovarian failure (POF), or is medically induced (MIPM) by oophorectomy, chemotherapy or radiotherapy. PM is associated with increased health risks, including osteoporosis. This study explored understanding of menopausal therapies, medication use and health-related behaviour in women with and without PM.
Methods
Cross-sectional, questionnaire-based study involving 23 premenopausal, 25 POF and 29 MIPM women, aged 20–41 years.
Results
Mean age $\pm$ s.d. of each group was: control $=30\pm7.0$ years, POF $=35.8\pm4.3$ and MIPM $=37.4\pm3.2$ ($P<0.001$). Compared to premenopausal women (44%), more MIPM (79%), and POF women (56%) perceived hormone replacement therapy (HRT) was associated with increased breast cancer risk ($P=0.03$) and prevented fractures (56% POF, 40% MIPM, 13% controls, $P=0.008$). More controls (48%) reported not knowing risks/benefits of HRT compared to 16% POF and 11% MIPM groups ($P=0.006$). Most premenopausal women (86%) and MIPM women (75%) reported not knowing risks/benefits of bioidentical hormones compared to POF women (56%, $P=0.06$). All groups reported lack of knowledge regarding herbal therapies (67–74%, $P=0.9$).
More PM women (80% POF, 83% MIPM) reported currently taking prescription medication compared to 52% premenopausal women ($P=0.04$); most women overall reported taking non-prescription medication (61–72%, $P=0.7$). More PM women reported blood pressure checks (92% POF, 100% MIPM, 82% controls,

$P=0.03$), cholesterol tests (84% POF, 69% MIPM, 39% controls, $P=0.005$) and breast examinations (72% POF, 90% MIPM, 30% controls, $P<0.001$). Bone density tests were reported less frequently overall although more commonly in PM women (64% POF, 59% MIPM, 4% controls, $P<0.001$).
Conclusion
Differences in understanding of menopausal therapies and health-related behaviour exist between women with PM of differing aetiology and premenopausal women. While perceived understanding of HRT was greater than other therapies, targeted education is needed regarding specific risks/benefits of menopausal therapies. Health professional education, especially regarding the importance of bone density tests after PM, is also indicated.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P902

**The effects of the therapy with ethinylestradiol 30 μg-drospirenone + metformin on endothelial dysfunction in the polycystic ovary syndrome**

I. Ilie[1], R. Ilie[1], I. Marian[1], T. Mocan[1], G. Hazi[2], I. Duncea[1] & C. Georgescu[1]
[1]UMF Iuliu Hatieganu, Cluj-Napoca, Romania; [2]County Emergency Hospital,
Cluj-Napoca, Romania.

Introduction
Recent data indicate that women affected by the polycystic ovary syndrome (PCOS) are at a greater risk for cardiovascular disease (CVD). The objective of this study was to evaluate the effect of the association ethinylestradiol 30 μg–drospirenone 3 mg (DRP/EE30 μg) plus metformin and weight loss on surrogate markers of CVD in PCOS.
Methods
Twenty-five young women with PCOS (mean age $22.76\pm0.83$ years, body mass index (BMI): $28.44\pm6.23$) completed this 6-month study. The oral contraceptive- DRP/EE30 μg (21 days/month) and metformin (1700 mg daily) were administered to the PCOS group. Additionally, the 15 overweight and obese patients (BMI $>25$ kg/m$^2$) were instructed in a diet of no more than 1500 cal daily. The main outcome measures were surrogate markers of cardiovascular disease and included endothelial function, i.e. flow-mediated dilatation (FMD) on the brachial artery and endothelin-1 levels, as well as body composition, insulin resistance and serum lipid profile. Variables were assessed at baseline, as well as after six cycles of treatment.
Results
The combination between DRP/EE30 μg plus metformin combined with weight loss triggered a significant improvement in the FMD values (FMD-PCOS basal $3.48\pm1.00$ vs FMD–PCOS 6 months$7.43\pm1.04$, $P=0.033$), as well as body composition and insulin insensitivity while negatively affecting lipid profile ($P<0.05$).
In conclusion, a 6-month course of metformin – DRP/EE30 μg (associated with weight loss) improves the endothelial dysfunction in PCOS. These results suggest that the medical therapy of PCOS should be reconsidered, especially for women with additional metabolic and cardiovascular risk factors.

**Hormonal contraception and female sexual function**

B. Zilaitiene & L. Ciaplinskiene
Lithuanian University of Health Sciences, Medical Academy, Institute of Endocrinology, Kaunas, Lithuania.

Summary
To establish the relations of women's sexual function with social factors and use of hormonal contraception.
Methods
There has been performed a pilot study. 20–43 years old participants with regular menstrual cycles (22–35 days) were randomly selected and have been interviewed. The test group consisted of 113 women who use any of hormonal contraception method. The control group consisted of 51 women not using hormonal contraception. Participants had to fill two questionnaires: socio-demographic and medical factors questionnaire prepared by the author and the female sexual function index (FSFI).
Results
The FSFI desire domain score of the women who used contraceptive agents comparing with women who did not use contraceptive agents was 3.95 (SN 1.08) vs 4.33 (SN 0.92; $P=0.006$), their FSFI arousal domain score was 4.19 (SN 1.48) vs 4.59 (SN 1.59; $P=0.005$), the FSFI lubrication domain score was 4.72 (SN 1.68) vs 5.32 (SN 1.2; $P=0.02$). The women's who had had permanent sexual partners comparing with women's who hadn't had permanent sexual partners mean of FSFI arousal domain score reached 4.4 (SN 1.45) vs 3.3 (SN 1.98; $P=0.01$), their mean of FSFI lubrication domain score reached 5.03 (SN 1.46) vs 3.55 (SN 2.17; $P=0.003$), the mean of FSFI pain domain score reached 4.88 (SN 1.61) vs 2.77 (SN 2.22; $P<0.001$). The means of FSFI arousal domain ($P=0.05$) and orgasm domain ($P=0.04$) scores were significantly different taking into consideration the BMI groups. The means of the women whose BMI $<18.5$ kg/m$^2$ were significantly higher than of those whose BMI 18.5–24.9 and $\geqq 30$ kg/m$^2$.
Conclusion
The presence of permanent sexual partners had a positive effect on the women's sexual function.

**Table 1** FSFI scores in participants according to investigative groups (dependent on having permanent sexual partner).

| Scale | Permanent sexual partner Had Mean (S.D.) | Permanent sexual partner Didn't have Mean (S.D.) | *P* value |
|---|---|---|---|
| Desire | 4.11 (1.04) | 3.6 (0.98) | 0.06 |
| Arousal | 4.4 (1.45) | 3.3 (1.59) | 0.01 |
| Lubrication | 5.03 (1.46) | 3.55 (3.17) | 0.003 |
| Orgasm | 4.4 (1.72) | 3.75 (2.27) | 0.3 |
| Satisfaction | 4.91 (1.29) | 4.36 (1.32) | 0.06 |
| Pain | 4.88 (1.61) | 2.77 (2.22) | <0.001 |
| FSFI total | 27.85 (6.92) | 23.77 (7.83) | 0.02 |

**Metformin in treatment of polycystic ovaries syndrome in women of birthing age**

Y. Urmanova, S. Ismailov, Z. Khalimova, A. Akbutaev, D. Nagmutdinova, L. Murtazaeva, F. Khodgaeva, L. Sharafutdinova & N. Rikhsieva
Tashkent Pediatric Medical Institute, Bogishamol Street 223, Tashkent 100140, Uzbekistan.

Aim
To study the effectiveness of metformin in treatment of polycystic ovaries syndrome (PCOS) in women of birthing age.
Materials and methods
We followed 31 women with PCOS. Mean age of patients was 29.8 years old. All patients were evaluated for hormones levels (LH, FSH, TSH, estradiol, progesterone, testosterone, prolactin, coritsole, free thyroxine, dehydroepiahn-drostendione etc.), glucose tolerance test, lipids profile, uterus and ovaries ultrasonography, pituitary MRI etc.
All these evaluations were repeated in 6 months after metformin therapy. Medication was given 500 $mg^3$ times a day during meals for 6 months.
Results
Before treatment patients had significant changes both in hormonal and imaging evaluations. Hyperandrogenemia was revealed in 83.8%, hyperprolactinemia in 77.4%, elevated LH in (48.3%), hypoestrogenemia in 93.5% of patients. Of all patients, 23 females (74.1%) had impaired glucose tolerance test, whereas 16 women 51.6% had dyslipidemia. 22 patients (70.9%) had increased body mass and 13 women (41.9%) had arterial hypertension indicating that these patients with PCOS had metabolic syndrome.
In 6 months' time after therapy with metformin we observed reliable bilateral improvement of ovaries structure, including cysts regression, size normalization in all of patients (100%), while laboratory and hormonal measurements improved in 29 patients (93.5%), whereas body mass decreased in 20 women (90%) of 22.
Conclusion
(1) Metformin therapy significantly improves clinical and biochemical values in women with PCOS which confirmed by ultrasonography (2) it should be recommended to administer metformin therapy to women with PCOS in short breaks (3 months).
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P905

**Letrozole induces metabolic and reproductive disorders in female rats: a dose response study**

M. Maliqueo[1], J. Johansson[1], H. Svensson[1], F. Labrie[2], L. Malin[1] & E. Stener-Victorin[1]
[1]University of Gothenburg, Gothenburg, Sweden; [2]Laval University, Quebec, QC, Canada.

Continuous administration of 400 μg/day of letrozole (LET), a non-steroidal inhibitor of P450 aromatase, with start pre-pubertally to female rats, induces hyperandrogenemia and reproductive abnormalities similar to those observed in women with polycystic ovary syndrome (PCOS). However, these rats do not develop metabolic abnormalities, despite high circulating testosterone. A possible explanation may be that the dose was too high and thus completely inhibited the estrogen synthesis in insulin-sensitive tissues. Therefore, lower doses of LET may induce not only reproductive disturbances, but also metabolic abnormalities. Here, we present a dose-response study with continuous administration of three different doses of LET during 12 weeks and their effects on metabolic and reproductive variables. At 21 days of age, 61 female Wistar rats were divided into four groups: LET1: 83 μg/day; LET2: 100 μg/day; LET3: 200 μg/day or control: placebo. The body weight development and food intake (FI) were registered. Respiratory exchange ratio (RER) during 24-h was determined by indirect calorimetry and body composition by dual-emission X-ray absorptiometry. Blood samples were taken for analysis of sex steroids. Insulin sensitivity (IS) was evaluated by euglycemic-hyperinsulinemic clamp. All LET-groups were acyclic and gained more in body weight compared with control ($P<0.001$). Body fat and lean body mass in relation to body weight, FI and RER were comparable between groups. Testosterone concentration was higher in LET-groups after five ($P<0.001$) and 10 weeks ($P<0.001$) of LET-exposure, compared to control. The IS index was lower in all LET-groups compared to controls ($P<0.001$) and the mean adipose size in inguinal and mesenteric depot was higher in LET3 compared to controls ($P<0.01$). These results highlight the importance of the dose of LET for development of metabolic abnormalities. The LET doses applied in this study may be used to develop a rat PCOS model including both reproductive and metabolic abnormalities.

## P906

**Increased prevalence of polycystic ovary syndrome in overweight and obese premenopausal women with nonalcoholic fatty liver disease**

E. Vassilatou, D. Vassiliadi, K. Salambasis, H. Lazaridou, G. Betsi, N. Kelekis, D. Kassanos, D. Hadjidakis & G. Dimitriadis
Athens University Medical School, 'Attikon' University Hospital, Athens, Greece.

Background
Increased prevalence of abnormal aminotransferase levels and/or ultrasonographic evidence of hepatic steatosis have been found in women with polycystic ovary syndrome (PCOS), being more pronounced in overweight and obese patients. However, few data exist concerning the prevalence of PCOS in premenopausal women with nonalcoholic fatty liver disease (NAFLD).
Objective
To investigate the presence of PCOS in overweight and obese premenopausal women with NAFLD.
Patients/methods
Forty apparently healthy overweight and obese (BMI: 26.0–46.9 $kg/m^2$) premenopausal women (age: 18–45 years) with a history of none or minimal alcohol consumption, were evaluated prospectively for the presence of NAFLD with abdominal ultrasonography and biochemical testing, after excluding causes of secondary liver disease. Insulin resistance was assessed by homeostasis model assessment (HOMA-IR). Hepatic steatosis was detected in 22/40 women, who were further studied for the presence of PCOS with hormonal evaluation and pelvic ultrasonography. Free androgen index (FAI) was calculated.
Results
PCOS was diagnosed in 10/22 patients with NAFLD (45.5%), according to the Androgen Excess Society criteria. Patients with NAFLD and PCOS compared to patients with NAFLD without PCOS were younger ($29.3\pm6.5$ vs $35.8\pm7.2$ years, $P=0.04$), more obese ($40.9\pm7.4$ vs $34.4\pm5.6$ $kg/m^2$, $P=0.03$), with an increased waist circumference ($108.7\pm10.4$ vs $95.3\pm15.9$ cm, $P=0.03$) and had higher levels of serum testosterone ($60.4\pm20.4$ vs $33.1\pm13.6$ ng/dl, $P<0.01$), lower SHBG levels ($17.6\pm6.0$ vs $30.5\pm6.3$ nmol/l, $P<0.001$) and higher FAI values ($12.7\pm5.2$ vs $3.8\pm1.4$, $P<0.001$).
Conclusions
These findings indicate an increased prevalence of PCOS in overweight and obese premenopausal women with NAFLD. Evaluation for PCOS should be considered in premenopausal NAFLD patients.

**Association of the (TAAAA)*n* repeat polymorphism of *SHBG* gene with age at menopause in Greek postmenopausal women**

A. Markatseli, E. Hatzi, I. Bouba, N. Xita, S. Tigas, I. Georgiou & A. Tsatsoulis
University of Ioannina, Ioannina, Greece.

Introduction
Sex hormone-binding globulin (SHBG) regulates the bioavailability of sex steroid hormones, which in turn regulate reproductive function. The potential association of SHBG gene polymorphisms with the age at menopause has not been examined.
Objective
The present study aimed to assess the possible relationship between the pentanucleotide (TAAAA)*n* repeat polymorphism in the promoter of the SHBG gene and the age at menopause in a Greek female population.

Methods
Two hundred and ten postmenopausal women aged 46–63 years were included in the study. The age (year and month) at the last menstrual period as well as anthropometric parameters were recorded in all participants. Genotyping of the (TAAAA)*n* repeat polymorphism was performed by PCR.
Results
Genotype analysis revealed (TAAAA)*n* pentanucleotide alleles of 6–11 repeats. Regarding the allele with seven TAAAA repeats, the age at menopause was higher in carriers of this allele (50.2 ± 3.1 years) than in non carriers (48.0 ± 4.8 years, $P = 0.026$). Furthermore, the age at menopause was lower in women carrying the allele with eight TAAAA repeats (47.5 ± 4.8 years) than in women not carrying this allele (48.8 ± 4.4 years, $P = 0.048$). The associations remained significant after statistical adjustment for body mass index (BMI) and smoking ($P = 0.019$ and $P = 0.043$ respectively). No association of the other alleles with the age at menopause was detected.
Conclusions
Our results indicate that the (TAAAA)*n* repeat polymorphism of SHBG gene is associated with the age at menopause in Greek postmenopausal women. Additional studies are required to explore the biological importance of this SHBG polymorphism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P908

**Prevalence of elevated glycated hemoglobin in women with polycystic ovary syndrome: according to the recently defined criteria**

S. Chae[1], J. Kim[2,3], Y. Choi[2], K. Hwang[2,4], S. Yoon[5] & K. Kim[2,3]
[1]Maria Fertility Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Seoul National University Borame Medical Center, Seoul, Republic of Korea; [5]Dongguk University Ilsan Hospital, Goyang, Republic of Korea.

Background
Insulin resistance is a core pathophysiology of polycystic ovary syndrome (PCOS). The screening recommendations for type 2 diabetes in PCOS patients have varied according to organizations, but the AE-PCOS Society recommended that a OGTT be performed in obese patients or in lean patients with advanced age (>40 year), with a history of gestational diabetes, or with a family history of type 2 diabetes. Recently, the American Diabetes Association (ADA) newly includes hemoglobin A1c (A1C) as a component of diagnostic criteria of 'diabetes' (≥6.5%) or 'increased risk for diabetes' (5.7–6.4%). This study was performed to examine the prevalence and the risk factors for elevated A1C (≥5.7%) in women with PCOS compared to age matched control women.
Methods
A1C was evaluated in 154 patients and 469 controls.
Results
One-third (31.2%) of the PCOS patients had elevated A1C. The prevalence of elevated A1C was similar in obese PCOS and obese controls (23.5 and 20.0%, respectively, $P = 1.0$), but non-obese PCOS women (mean age 29.8 ± 5.4 years) had a higher prevalence of elevated A1C than non-obese controls (31.2 vs 6.6%, respectively, $P < 0.001$). The prevalence of elevated fasting plasma glucose was not different. The odds that a woman has an elevated A1C was 6.7 times higher if she has PCOS (adjusted OR 6.67, 95% CI 3.50–12.70).
Conclusions
Non-obese PCOS patients presented a significantly higher prevalence of elevated A1C than non-obese controls, whereas in obese subjects, the prevalence of elevated A1C was similarly elevated. Since substantial proportion of young and non-obese PCOS women are at an increased risk for diabetes, screening for type 2 diabetes may be necessary even in these young and non-obese PCOS patients. Future studies is mandatory to assess whether A1C is as effective as OGTT as a diagnostic tool in patients with PCOS.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P909

**Most of type 2 diabetes associated loci identified in genome-wide association studies are not associated with polycystic ovary syndrome**

S. Yoon[1], J. Kim[2,3], Y. Choi[2], K. Hwang[2,4], S. Chae[5] & K. Kim[2,3]
[1]Dongguk University Ilsan Hospital, Goyang, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Hospital, Seoul, Republic of Korea; [4]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [5]Maria Fertility Hospital, Seoul, Republic of Korea.

Objective
Insulin resistance is a core feature of polycystic ovary syndrome (PCOS), thus, it may be the common link between PCOS and type 2 diabetes (T2DM).
Although the etiology of PCOS has not been elucidated, a number of studies have suggested that genetic factors may play important roles in its etiology and pathogenesis. If PCOS and T2DM share a common genetic background, genetic variants determining the risk of T2DM may also be associated with PCOS. Recently, genome-wide association studies (GWAS) have reported a number of SNPs with reproducible associations and susceptibilities to T2DM, which were also replicated in Koreans. Thus, we compared the genotype distributions of the diabetogenic genes, identified in GWAS, between PCOS patients and age-matched controls in Korean women.
Measurements
Genotyping was performed on DNA samples from 377 PCOS patients and 386 age-matched controls.
Results
Genotype distributions for all investigated SNPs were in Hardy–Weinberg equilibrium in controls. None of the 12 SNPs in the six genes (KCNJ11, TCF7L2, SLC30A8, HHEX, FTO and CDKAL1), discovered in GWAS, were found to be associated with PCOS. For further analysis, PCOS patients were divided into two or three subgroups according to its genotype, and we also assessed the associations between the genotypes and insulin resistance or insulin secretary capacity. No SNPs were significantly associated with HOMA-IR, HOMA β-cell (%), or 75 g OGTT 2 h insulin levels in PCOS patients, neither other serum hormonal and metabolic markers such as androgen or glucose levels.
Conclusions
Our results suggest that the most of type 2 diabetes associated loci identified in GWAS are not associated with PCOS. Although our data do not demonstrate an association between diabetogenic SNPs discovered in GWAS and PCOS, the relationship between T2DM susceptibility gene and PCOS remains to be investigated because both diseases share a common link, insulin resistance.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This work was supported, however funding details unavailable.

## P910

**Optimization of a uterine leiomyoma xenograft model using different immunodeficient mice and grafting procedures**

H. Ishikawa[1], G. Wang[1], S. Takizawa[1], K. Sone[1], K. Ohmi[2] & M. Shozu[1]
[1]Graduate School of Medicine, Chiba University, Chiba, Japan; [2]Chiba Aoba Municipal Hospital, Chiba, Japan.

Introduction
Uterine leiomyoma (fibroid) is the most common solid tumor in reproductive-age women. Symptomatic leiomyomas affect millions of women through menorrhagia, abnormal uterine bleeding, and infertility. No effective treatment except surgery is available, partly because of the lack of effective animal models for screening new therapies. We established a new xenograft model by grafting primary cultured leiomyoma cells beneath the kidney capsule in super-immunodeficient mice; however, this model is not suitable for screening tests because of the expensive host and difficult grafting procedure. To resolve these issues, we investigated whether this model could be replicated using different types of immunodeficient mice and grafting procedures.
Methods
All specimens were obtained from patients who had undergone hysterectomy for symptomatic leiomyomas. We primarily cultured leiomyoma smooth muscle cells and mixed them with type 1 collagen gel to form cell pellets. We then grafted the pellets beneath the kidney capsule in non-obese diabetic /severe combined immunodeficient (NOD/SCID) mice, SCID mice, and BALB/c nude mice. Next we grafted the pellets beneath the kidney capsule and subcutaneous space in NOD/SCID and NOD/SCID IL2Rγ null (NOG) mice. All mice were ovariectomized at the time of grafting, and both 17β-estradiol and progesterone

were injected subcutaneously every week. Eight weeks later, we performed immunohistochemical evaluation of the xenografts with regard to their gross appearance, histology, and expression of estrogen and progesterone receptors.
Results
The xenografts beneath the kidney capsule were significantly enlarged in NOD/SCID mice compared with those in SCID or BALB/c nude mice. Furthermore, similar to subrenal xenografts, subcutaneous xenografts were enlarged in both NOD/SCID and NOG mice. Histologically, all enlarged xenografts within the mice mimicked human uterine leiomyomas and expressed both estrogen and progesterone receptors.
Conclusions
NOD/SCID mice are suitable hosts for the leiomyoma xenograft model. A subcutaneous xenograft is superior to a subrenal one. The easy grafting procedure can avoid the risk of intraoperative death of the host mice. The optimized xenograft model is suitable for screening new therapies that generally requires large number of subjects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P911

**The polymorphic variants K121Q of the plasma cell membrane glycoprotein and G972R of the insulin receptor substrate-1 modulate in opposite ways the clinical and biochemical profiles of women with polycystic ovary syndrome**

M. Pappalardo[1], F. Trimarchi[1] & S. Benvenga[1,2]
[1]Università degli Studi, Messina, Italy; [2]AOU Policlinico 'G. Martino', Messina, Italy.

Background
Insulin resistance (IR) is the common denominator of three multigenic disorders: type 2 diabetes mellitus, obesity, and PCOS. IR can result from genetic abnormalities involving proteins of the insulin signalling pathway, including PC-1 and IRS-1. The IRS-1 G972R variant had the highest world frequency and correlated with IR in PCOS Sicilian women (*Horm Metab Res*, 2010).
Objective and methods
To determine: i) the rates of the G972R IRS-1 and K121Q PC-1 polymorphisms in Sicilian PCOS women ($n=100$) and age-matched controls ($n=45$); ii) the association of the polymorphisms with the clinical/biochemical phenotypes of PCOS.
Results
The rate of the IRS-1 G972R polymorphism in PCOS and controls was 50 and 24.4% ($P=0.004$), while the rate of the PC-1 K121Q was 20 and 13.3% ($P=0.33$). Carriers were always heterozygous (Het), except four PCOS women (two IRS-1 homozygous (Hom), and another two PC-1 Hom). Distribution of genotypes (wild type (WT) or Het-Hom) in PCOS vs controls was: IRS-1/PC-1 WT/WT (44 vs 68.9%, $P=0.0055$), IRS-1/PC-1 Het-Hom/Het-Hom (14 vs 6.7%, $P=0.20$), IRS-1 Het-Hom/PC-1 WT (36 vs 17.8%, $P=0.027$) and IRS-1 WT /PC-1 Het-Hom (6 vs 6.7%, $P=0.88$). The IRS-1 Het-Hom/PC-1 WT PCOS women had: i) the worst metabolic profile (fasting insulin, HOMA-IR and triglycerides, significant vs IRS-1 WT/PC-1 Het-Hom and IRS-1/PC-1 WT/WT; lower Matsuda index, significant vs IRS-1/PC-1 WT/WT); ii) the worst hormone profile (higher total testosterone and lower estradiol, significant vs IRS-1/PC-1 WT/WT; lower FSH, significant vs IRS-1 WT/PC-1 Het-Hom and IRS-1/ PC-1 Het-Hom/Het-Hom); iii) the youngest age and the lowest hirsutism index (both significant vs IRS-1/PC-1 WT/WT).
Conclusion
Only the G972R IRS-1 polymorphism is significantly more frequent in PCOS women. When this variant is not associated with the K121Q PC-1 variant, the metabolic profile and testosteronemia are worse and age at presentation is anticipated. However, the modest hirsutism suggests relative androgen resistance.

## P912

**Exposure to soy isoflavones during postnatal life disrupts structural development of reproductive organs in female mice**

J. Kaludjerovic[1], J. Chen[1] & W. Ward[1,2]
[1]University of Toronto, Toronto, Ontario, Canada; [2]Brock University, St Catharines, Ontario, Canada.

Exposure to soy isoflavones (ISO), abundant in soy protein infant formula, during early postnatal life has benefits to bone health in female mice. Moreover, exposure during the first 10 or 21 days of life has been shown to interfere with structural development of female reproductive organs and results in heavier body weight. The study objective was to compare if shorter exposure to ISO, during the first 5 vs 10 days of life, results in lesser adverse effects on ovarian and uterine structure in adult mice. At birth, female pups (8–12 pups/l) were cross-fostered and litters were randomized to corn oil or ISO (7 mg/kg of body wt/day) treatment for the first 5 or 10 days of life. The 5-day protocol was selected to mimic previously published studies investigating the effects of environmental estrogens (i.e. diethylstilbestrol) on reproductive and skeletal development. Body and organ weights, and histology of ovaries and uterus were analyzed. There were no differences in the ovary or uterus weight, number of ovarian follicles, number of multiple oocyte follicle or percent of ovarian cysts with 5 or 10 day ISO intervention compared to respective controls. Ten day ISO group had higher body weight from 6 days to 4 months of age and higher percent of ovarian hyperplasia than their respective control. Lower number of ovarian corpus luteum and a higher incidence of abnormal changes were reported in the uteri of both ISO groups compared to their respective control. In conclusion, 5 and 10-day exposure to ISO had similar long-lasting adverse effects on the structure of ovaries and uterus in adult mice, identifying the first five days of life as a susceptible window for programming reproductive development. Only the 10-day ISO exposure resulted in greater body weight gain at adulthood.

## P913

**The kisspeptin levels in girls**

O. Gumenyuk[1,2], Y. Chernenkov[1], N. Zakharova[1], A. Kunina[1] & S. Kunina[1]
[1]Saratov Medical University, Saratov, Russian Federation; [2]University Hospital 5, Saratov, Russian Federation.

The kisspeptin, the peptide product of *KiSS-1* gene has recently emerged as essential gatekeeper of pubertal activation of gonadotropin-releasing hormone neurons and the reproductive axis. Mutations or targeted disruptions in the gene cause hypogonadism or premature sexual development and sterility.
Purpose
The study was undertaken to research the kisspeptin levels in healthy girls and girls with endocrine and gynaecological disorders.
Patients and methods
Serum kisspeptin levels were determined in and 69 girls (aged 7 months and 8 years) healthy, adolescent girls with menstrual disorders, girls with premature isolated thelarche, adolescent girls with dyshormonal mammary dysplasia and adolescent girls with polycystic ovary syndrome. The concentration of kisspeptin was measured using Kisspeptin-10 (metastin) and competitive enzyme immunoassay. The SPSS 16.0 Software package was used to perform statistical analyses. Results were analyzed using two-way ANOVA. Data are expressed as median, $P$ value of $<0.05$ were considered statistically significant.
Results
The investigation shows that healthy adolescent girls had kisspeptin median levels 0.03 ng/ml. Among the girls with secondary amenorrhea and opsomenorrhea kisspeptin levels was lower 0.01 ng/ml ($P=0.014$). Girls with premature isolated thelarche had kisspeptin levels 0.04 ng/ml ($P=0.04$); girls with mastopathy (dyshormonal dysplasia) had kisspeptin levels 0.05 ng/ml ($P=0.033$). Serum kisspeptin levels were significantly higher in adolescent girls with polycystic ovary syndrome than in control group (0.3 vs 0.03 ng/ml, $P<0.01$).
Conclusion
Kisspeptin levels is various for healthy adolescent girls, for girls with menstrual disorders, mastopathy, isolated thelarche, with polycystic ovary syndrome. In this study, we demonstrated that serum kisspeptin level was significantly lower in girls with amenorrhea and opsomenorrhea and higher in girls with premature thelarche, mastopathy and polycystic ovary syndrome. Serum kisspeptin may be used as a marker of sexual disorders, mammary diseases and polycystic ovary syndrome in girls.

**Subcutaneous adipose tissue in women with polycystic ovary syndrome**

A. Aydogdu[1], I. Tasci[1], O. Kucukerdonmez[1], S. Tapan[1], S. Aydogdu[2], G. Uckaya[1], C. Meric[1], Y. Basaran[1], A. Sonmez[1], C. Haymana[1], K. Baskoy[1], A. Taslipinar[1] & O. Azal[1]
[1]Gulhane School of Medicine, Ankara, Turkey; [2]Mevki Military Hospital, Ankara, Turkey.

The present study was performed to search whether SCAT increase in women with PCOS. Fifty-two women with PCOS patients and 53 matched healthy controls were participated in the study. Caliper device was used to measure skinfold thickness (SFT). Body fat distributions were determined by bioelectrical impedance analysis. SFT in all defined areas, total body and trunk fat free mass (FFM), and HOMA score were higher in women with PCOS, while adiponectin was significantly lower. SFT values correlated positively with HOMA score, and negatively with adiponectin. SFT in triceps and supscapular areas, trunk fat mass, trunk fat ratio, trunk fat mass and trunk fat free mass values were the most powerful predictors of HOMA score. In conclusion SCAT and FFM are increased in women with PCOS, with relation to insulin resistance.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Plasma anti-Müllerian hormone concentration in women with polycystic ovary syndrome and type 1 diabetes mellitus**

A. Lebkowska[1], M. Karczewska-Kupczewska[1], A. Nikolajuk[1,2], A. Adamska[1], E. Otziomek[1], S. Wolczynski[1], M. Gorska[1] & I. Kowalska[1]
[1]Medical University of Bialystok, Bialystok, Poland; [2]Polish Academy of Science, Bialystok, Poland.

Introduction
A high prevalence of polycystic ovary syndrome (PCOS) and hyperandrogenism has been described in adult women with type 1 diabetes mellitus (T1DM). Anti-Müllerian hormone (AMH) is secreted by granulosa cells of antral ovarian follicles and its plasma concentration is correlated with the number of small antral follicles. AMH levels are increased in women with PCOS and higher plasma concentration has been observed in prepubertal girls with T1DM. The aim of this study was to estimate plasma AMH concentrations in women with PCOS with and without T1DM and its relation to hormonal profile.
Study participants and methods
We studied seven women with PCOS and T1DM (T1DM + PCOS), seven women with PCOS without T1DM (PCOS), 10 women with T1DM without PCOS (T1DM), and eight healthy women (control). The clinical examination, estimation of plasma AMH, sex hormones and ultrasonographic evaluation were performed in all study participants.
Results
Plasma AMH concentration was markedly higher in PCOS group vs controls ($P=0.041$) and was not different between T1DM + PCOS and control group, and both PCOS group (PCOS vs T1DM + PCOS). Plasma SHBG was higher in T1DM + PCOS in comparison to PCOS ($P=0.024$). Ovarian volume and follicles number were higher in PCOS and T1DM + PCOS vs controls ($P=0.013$, $P=0.045$ and $P=0.029$, $P=0.011$ respectively). T1DM + PCOS had increased plasma AMH concentration ($P=0.011$), higher ovarian volume and follicles number vs diabetic women without PCOS. In the entire studied group plasma AMH correlated significantly with FSH ($r=-0.385$, $P=0.03$), testosterone ($r=0.434$, $P=0.013$) and number of ovarian follicles ($r=0.705$, $P<0.0001$).
Conclusion
Obtained results suggest that AMH might be involved in pathogenesis of PCOS in type 1 diabetic patients.

## P916

**The role of subclinical hypothyroidism and vitamin D deficiency in the development of menstrual disorders in women with PCOS**

Z. Velija-Asimi
University Clinical Centre, Sarajevo, Bosnia and Herzegovina.

Subclinical hypothyroidism (SH) may affect the gonadotropic axis at different levels, causing changes in the hypothalamic–pituitary unit, functions of the gonads, and changes on peripheral metabolism of sex hormones. Polycistic ovary sndrome (PCOS) is a complex endocrine syndrome characterized by the combination of reproductive aberrations, namely hyperandrogenism and chronic anovulation, with metabolic defects.
The aim
To determine the role of SH and vitamin D deficiency (VDD) in the development of menstrual disorders in women with PCOS.
Materials and methods
The study included 100 women with PCOS (diagnosed by respecting the Rotterdam criteria). Patients to be included in the study required not to receive any medication within the last 6 months. Fasting serum glucose, basal insulin, insulin during OGTT, HOMA-IR index, TSH, $FT_3$, $FT_4$, thyroid autoantibodies (anti-Tg, anti-TPO), FSH, LH, PRL, total testosterone, DHEA-S, androstendione and free testosterone were determined.
Results
The mean age of subjects was 30.91±9.21 years and mean BMI was 29.24±3.85 kg/m$^2$. The mean TSH was 5.89±2.01 mIU/l. Approximately 61% of PCOS had SH. 26% have elevated anti-Tg and 45% had elevated anti-TPO. Patients with SH had in the same time and VDD (<20 nmol/l). PCOS were divided in two groups: PCOS with SH/VDD and PCOS without SH/VDD. Most patients were with normal values of FSH, $E_2$, progesterone and PRL. The level of testosterone (3.08±0.95 vs 2.03±0.64 nmol/l), androstendione (3.94±1.03 vs 2.56±0.87 ng/ml), DHEA-S and LH was higher in PCOS group with SH/VDD. HOMA-IR index was increased in 26% PCOS with SH. Disruption of menstrual cycle, usually oligomenorrhea type, was present in 36% of subjects. SH was significantly correlated with disorders of the menstrual cycle in PCOS women ($r=0.76$). VDD and SH were significantly correlated with PCOS, estimated based on the LH/FSH ratio ($r=0.76$).
Conclusion
SH and VDD significantly correlated with disorders of the menstrual cycle in PCOS women, thereby confirming their role in the occurrence of menstrual disorders in women with PCOS.

## P917

**Treatment of androgen excess in adolescent girls: ethinylestradiol–cyproteroneacetate vs low-dose pioglitazone–flutamide–metformin**

L. Ibañez[1], M. Díaz[1], M. Rodriguez-Chacón[2], E. Maymo-Masip[2], C. Salvador[3], A. López-Bermejo[4], J. Vendrell[2] & F. de Zegher[5]
[1]Sant Joan de Déu, University of Barcelona & CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Instituto de Salud Carlos III, Esplugues, Barcelona, Spain; [2]CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Instituto de Salud Carlos III & University Hospital of Tarragona Joan XXIII, Pere Virgili Institute, Tarragona, Spain; [3]Hospital Sant Joan de Déu, University of Barcelona, Esplugues, Barcelona, Spain; [4]Girona Institute for Biomedical Research, Hospital de Girona Dr Josep Trueta, Girona, Spain; [5]University of Leuven, Leuven, Belgium.

Objective
To compare the effects of a classic therapy to those of a novel treatment for androgen excess in adolescent girls.
Study design
Randomized, open-labeled trial over 12 months.
Study participants
Adolescents ($n=34$; mean age 16 year, BMI 23 kg/m$^2$) with hyperinsulinemic androgen excess and without risk of pregnancy.
Interventions
Ethinyl estradiol-cyproterone acetate (EE-CA; Diane 35 Diario) vs a low-dose combination of pioglitazone 7.5 mg/day, flutamide 62.5 mg/day, and metformin 850 mg/day (PioFluMet) for 12 months.
Main outcome measures
Hirsutism and acne scores; androgen excess; circulating C-reactive protein and high-molecular-weight adiponectin; carotid intima-media thickness; body composition (by absorptiometry); abdominal fat partitioning (by MRI); gene expression in consecutive biopsies of subcutaneous adipose tissue at the abdominal level.
Results
EE-CA and PioFluMet reduced the clinical and biochemical androgen excess comparably but had divergent effects on C-reactive protein and high-molecular-weight adiponectin; on carotid intima-media thickness; on lean mass; on abdominal and visceral fat; and on the expression of genes, for example, those related to macrophage activation and lipid storage in adipose tissue. All these divergences pointed to a healthier condition on low-dose PioFluMet.
Conclusion
Over 12 months, PioFluMet compared favorably to EE-CA in adolescents with androgen excess and without pregnancy risk. Further study of low-dose PioFluMet seems warranted, not only to strengthen its safety side over the longer term and in larger cohorts, but also to verify further whether the efficacy of this low-dose combination holds enough potential to allow it to become a first-choice therapy for the majority of young adolescents with androgen excess, namely those who are not at pregnancy risk and who are nowadays nevertheless exposed to supraphysiological doses of estro-progestagens.
Declaration of interest

## P918

**Hyperandrogenism is related to adipose tissue dysfunction as reflected by VAI in polycystic ovary syndrome patients**

A. Albu[1], S. Florea[2], S. Radian[1], F. Grigorescu[3] & S. Fica[1]
[1]Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]Elias Hospital, Bucharest, Romania; [3]IURC, Montpellier, France.

A large body of evidence suggests that in polycystic ovary syndrome (PCOS) there is a link between abdominal adiposity, visceral adiposity dysfunction and hyperandrogenism and this relationship could be bidirectional. However a well designed study of adipose tissue distribution reported no significant differences between PCOS and controls. Visceral adiposity index (VAI) is a recently reported marker of the cardiovascular risk, strongly correlated with visceral adipose tissue (VAT) dimension and it was suggested to be a measure of VAT dysfunction.
We hypothesised that there is an association between PCOS and VAT dysfunction as reflected by VAI and aimed to study the relationship between VAT dysfunction and hyperandrogenism in PCOS patients.
We studied 256 PCOS patients (mean age 24.7$\pm$5.34 years, mean body mass index (BMI) 28.76$\pm$7.68 kg/m$^2$) and 102 controls (mean age 28.27$\pm$7 years, mean BMI 30.1$\pm$8.53 kg/m$^2$) selected from our PCOS research database. VAI was calculated based on waist circumference (WC), BMI, triglycerides and HDL-cholesterol values.
We found that PCOS patients were younger ($P<0.001$) and had higher waist-hip ratio (WHR; $P<0.05$) compared to controls, but the two groups were similar in terms of BMI and WC. In PCOS group VAI value was significantly higher compared to controls ($P<0.01$) and the association was statistically significant ($P<0.01$) even after adjustment for age and WHR in logistic regression analysis. In PCOS group multivariate analysis showed that free androgen index (FAI) was independently associated with VAI after adjustment for BMI, WC and WHR.
Conclusions
PCOS is associated with higher VAI values, suggesting the presence of visceral adiposity dysfunction in these patients that seems to be related to hyperandrogenism independent of anthropometrical measures of adiposity.

## P919

**Effects of berberine on the clinical, metabolic and reproductive features of obese polycystic ovary syndrome women**

F. Orio[1,2], S. Palomba[3], G. La Sala[3], A. Falbo[3], M. Orio[4], A. Colao[5], S. Savastano[5], L. Vuolo[5], G. Lombardi[5], G. Colarieti[2], A. Volpe[4], V. Di Stasi[4] & P. Putignano[6]
[1]University 'Parthenope' of Naples, Naples, Italy; [2]Hospital University of Salerno, Salerno, Italy; [3]'Arcispedale S. Maria Nuova' Reggio Emilia, University of Modena and Reggio Emilia, Reggio Emilia, Italy; [4]University of Salerno, Salerno, Italy; [5]University 'Federico II' of Naples, Naples, Italy; [6]'San Gerardo' Hospital, Monza, Italy.

Objective
Polycystic ovary syndrome (PCOS) is a multifaceted disease characterized by metabolic and reproductive disorders associated with hyperandrogenism and insulin resistance. Berberine (BBR) is an isoquinoline derivative alkaloid extracted from chinese medicinal herbs that has been used as an insulin sensitizer.BBR could represent a potential therapeutic tool for PCOS.
The aim of this study was to evaluate the effects of BBR on the clinical, metabolic and reproductive features of PCOS women compared to healthy control women.
Design and methods
Fifty PCOS obese women and fifty healthy obese women (control group) were enrolled in Salerno Hospital University outpatient of Endocrinology of Fertile Age and Monza 'San Gerardo' Hospital outpatient of Diabetic Clinic. PCOS women were undergone to BBR treatment (Berberol, 500 mg berberine hydrochloride and 105 mg Silymarin, Pharmaextracta, Italy) that was administered twice for 3 months. Obese healthy women were encouraged to lifestyle changes by: a restriction intake (hypocaloric diet of 1200 Kcal/day) and aerobic physical exercise (running or bicycle at least 5 h/week).
Clinical, (anthropometric and hormonal) metabolic and reproductive parameters were assessed before and after the period of treatment in both groups of obese PCOS and healthy women.
Results
Treatment with BBR showed decreased waist circumference (WC) and waist-to-hip ratio (WHR; $P<0.05$), triglycerides (TG) and low-density lipoprotein cholesterol (LDL-c; $P<0.05$) as well as increased high-density lipoprotein cholesterol (HDL-c) and sex hormone binding globuline (SHBG; $P<0.05$) in comparison to healthy women. Similarly, BBR treatment showed a reduction in several metabolic parameters, like: fasting plasma glucose, fasting insulin, HOMA-IR and AUCINS ($P<0.01$) and also ovulation rate improved in PCOS group compared to healthy women ($P<0.01$).
Conclusions
BBR improved several clinical, metabolic and reproductive features in obese PCOS women and main effects could be related to the improvement of insulin sensitivity and reduction of hyperandrogenemia. BBR also seemed to have a greater effect on the changes in body composition and dyslipidemia. However, the underlying mechanisms of its actions remain to be clarified in wider and longer term clinical trials.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Large-for-gestational-age and macrosomic neonates born by women with gestational diabetes mellitus diagnosed by the new IADPSG criteria: a case–control study of 301 patients and 839 controls**

E. Kintiraki, D. Goulis, S. Mameletzi, C. Tsametis, G. Mintziori, A. Athanasiadis, E. Assimakopoulos, A. Tsapas & B. Tarlatzis
Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece.

Introduction
Gestational diabetes mellitus (GDM) has been associated with adverse maternal and fetal/neonatal outcomes. The aim of this case-control study was to compare women whose pregnancy was complicated with GDM, diagnosed by the new International Association of Diabetes and Pregnancy Study Groups (IADPSG) criteria, with a control group of healthy pregnant women as far as large-for-gestational-age (LGA) neonates and macrosomia are concerned.
Methods
The study included 301 pregnant women with singleton pregnancies complicated by GDM and 839 controls. Women were followed-up every two (GDM group) or four weeks (control group). Fetal ultrasonography was performed every 4 weeks. The main metabolic parameters recorded in every visit were body mass index (BMI), fasting plasma glucose (FPG), home blood glucose measurements (HBGM) and glycozylated hemoglobin A1c (HbA1c). The main ultrasonographic parameters were estimated fetal weight (EFW), head (HC) and abdominal circumference (AC). Decisions on treatment modification in the GDM group were based on both metabolic and ultrasonographic parameters. Main study outcomes were cumulative incidence of LGA neonates and macrosomia.
Results
The cumulative incidence of LGA was 5.3% in GDM and 4.8% in control group ($\chi^2$, $P=0.755$). The cumulative incidence of macrosomia was 4.3% in GDM and 4.1% in control group ($\chi^2$, $P=0.866$). There were no significant differences in EFW, HC or AC between GDM and control groups in serial fetal ultrasounds from gestational week 16–37.
Conclusions
Women with GDM, diagnosed by the new IADPSG criteria and followed-up by both metabolic and ultrasonographic parameters, had cumulative incidence of LGA and macrosomia similar to that of women whose pregnancy was not complicated by GDM.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P921

**Factors affecting time to pregnancy: lithuanian women cohort study**

B. Zilaitiene & M. Dirzauskas
Lithuanian University of Health Sciences, Kaunas, Lithuania.

Numerous studies provided data on possible decline in human fertility over the last decades and geografic differences in it. So, recently research interest in these tendencies and possible factors affecting fertility is increased.
Objective
In this study, we aimed to explore women's fertility expressed as time to pregnancy (TTP) – the number of contraceptive-free cycles needed to conceive – in a large cohort of Lithuanian women and the effect of biological and social factors along with sexual behaviour on TTP.
Methods
Data were gathered from 1813 women who delivered babies during the 16 months-period at one hospital. The information was collected retrospectively by using self-administered questionnaires. Odds ratios were determined for many factors. Multivariate models were used to determine which factors had the most impact on TTP.
Results
The mean TTP was 3.88 months (S.D. = 9.0). Advanced age at conception was associated with an increase in TTP, especially in the age group between 30 and 35 ($P<0.001$). Women who had achieved higher levels of education had longer TTPs ($P=0.049$), as did women who had irregular menstrual cycles ($P<0.001$) and those who did not use contraception prior to conceiving ($P=0.01$). Financial and marital status did not affect fecundity, nor did contraceptive method.
Conclusions
Women's age and irregular menstrual cycle were the most important factors predicting TTP of 12 and more months. Surprisingly contraception use before conception negatively influenced TTP either.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P922

**Insulin and androgens but not androgen receptor CAGn polymorphysm are determinant factors for hirsutism severity in PCOS**

N. Baculescu[1], S. Radian[1,2], I. Gussi[1], D. Aflorei[1], C. Poiana[1,2], F. Grigorescu[3] & M. Coculescu[1,2]
[1]Davila University of Medicine, Bucharest, Romania; [2]C. I. Parhon Institute of Endocrinology, Bucharest, Romania; [3]IURC, Molecular Endocrinology, Montpellier, France.

Background
Hirsutism is a major feature of the polycystic ovary syndrome (PCOS) and the only accepted clinical sign of hyperandrogenism for its diagnosis, according to the androgen excess society (AES) recommendations. Previous studies demonstrated that hirsutism can be influenced by factors other than hyperandrogenism *per se*.
Aim
To detect factors influencing hirsutism severity in PCOS.
Patients and methods
Hundred and seventy-five PCOS patients (AES criteria), of Romanian origin. Hirsutism was defined as a modified Ferriman–Gallwey (mFG) score of $\geq 8$. Other clinical and laboratory parameters were assessed, including total testosterone (TT), free androgen index (FAI), DHEA-S, 17-hydroxyprogesterone (17OH-P), fasting glycemia, insulinemia and calculated homeostatic assessment for insulin resistance (HOMA-IR). Androgen receptor (AR) CAG repeat genotyping and X-chromosome inactivation analysis were performed in a subset of 94 PCOS.
Results
Univariate correlations revealed that mFG score was significantly associated with fasting insulin ($r^2=0.11$, $P<0.01$) and HOMA-IR ($P<0.01$), after adjustment for BMI. A multiple regression model using androgens (TT and DHEA-S) as independent variables and mFG score as dependant was significant ($r^2=0.11$, $P<0.01$), but mFG univariate associations with FAI, DHEA-S were non-significant. AR CAG repeat number biallelic means and X-weighted biallelic means did not differ significantly between hirsute and non-hirsute PCOS and were not correlated with mFG scores.
In a multivariate regression mFG model including fasting insulinemia, TT, DHEA-S, BMI and age as independent variables, only insulin was associated significantly with mFG score, while the whole model did not reach significance ($r^2=0.21$, $P=0.068$).
Conclusions
Our results show that both hyperinsulinism and hyperandrogenism are determinants of the degree of hirsutism in PCOS, but insulinemia appears as a better marker of hirsutism than serum androgens. Androgen-sensitivity, evaluated by the AR CAG repeat genotypes is not associated with mFG score.

## P923

**Frequency of insulin resistance, assessed by the glucose clamp technique, in 132 PCOS women**

F. Tosi[2], D. Di Sarra[1], F. Zambotti[1], M. Dall'Alda[1], M. Donati[1], R. Moretta[1], M. Peroni[1], C. Signori[2], B. Caruso[2], G. Spiazzi[2], C. Bonin[2], E. Bonora[1,2] & P. Moghetti[1,2]
[1]University of Verona, Verona, Italy; [2]Azienda Ospedaliera Universitaria Integrata, Verona, Italy.

Introduction
Insulin resistance is a common finding in women with polycystic ovary syndrome (PCOS) and is considered a major aspect in this condition, as it likely plays a role

in the pathogenesis of both hyperandrogenism and several metabolic abnormalities, frequently found in these women. Despite its significance, prevalence of insulin resistance in PCOS subjects is still unclear, as it was assessed in small samples and/or by using surrogate parameters of insulin action. Moreover, it remains also unclear whether this is a feature of lean PCOS subjects.
Methods
To address this issue, 132 consecutive PCOS women were submitted to a careful metabolic phenotyping, including a hyperinsulinemic euglycemic clamp, the gold standard for measurement of *in vivo* insulin sensitivity. Insulin infusion rate in the glucose clamp was 80 mU/m$^2$ per min, to completely suppress endogenous glucose production.
Results
Mean (S.D.) age of PCOS women was 24 (6) year, and BMI 29.6 (8.0) kg/m$^2$. Thirty-four percent of these subjects were lean, 24% overweight and 42% obese. Mean fasting plasma glucose was 87 (10) mg/dl and insulin 17 (12) mU/l. As compared to reference values of insulin-induced glucose utilization during the clamp, 84% of these subjects were insulin resistant. In particular, 61% of PCOS women with a normal weight, 86% of those overweight and 100% of the obese subjects showed an impaired insulin action. The metabolic syndrome, diagnosed according to the ATP-III criteria, was found in 5% of lean, 26% of overweight and 62% of obese patients. Among the specific metabolic abnormalities, the most common was reduction of HDL-cholesterol, found in 56% of subjects. Fifteen percent of these women had abnormal glucose levels, at fasting and/or after oral glucose.
Conclusions
Our findings show that insulin resistance is a very common finding in PCOS women, even in lean subjects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P924

**Propranolol prevents stress induced polycystic ovary syndrome**
P. Silva Barros, B. Kalil & J. Anselmo-Franci
University of São Paulo, Ribeirão Preto, Brazil.

We have shown that repeated cold stress increases ovarian sympathetic tonus and induces typical polycystic ovary syndrome (PCOS) features. Lesion of the noradrenergic nucleus Locus Coeruleus decreases ovarian noradrenaline release and prevents stress-induced PCOS in rats exposed to chronic intermittent cold stress. The aim of this study was to assess whether the alterations on ovarian morphology, ovulation rate and hormonal secretion induced by cold stress could be prevented by the beta-adrenergic blocker propranolol. Female rats were exposed to repeated sessions of cold stress (4°C/3 h per day from monday to friday), during 4 weeks. The rats had free access to water (S groups) or water with propranolol (4 mg/kg; SP group). Then after, the animals were kept at room temperature for four additional weeks with free access to water. Unstressed animals were maintained at room temperature for 8 weeks with free access to water (US group) or water + propranolol in the first 4 weeks (US + P group). Rats were decapitated, trunk blood was collected for hormone measurements, the oviducts removed to assess the number of oocytes, and ovaries for histological analysis. In S group there was a decreased number of healthy preantral and antral follicles, an increased number of atretic preantral and antral follicles, pre-cystic and cystic follicles and follicles with hyperthecosis compared to US rats. The number of oocytes was reduced and estradiol and DHEA plasma levels were higher than in unstressed rats. Propranolol treatment *per se* did not alter the parameters evaluated in the US + P group but prevented the majority of alterations in the SP group. The number of all disarranged structures, oocytes and DHEA levels in propranolol treated rats were similar to the US rats. Therefore, blocking ovarian beta-adrenergic receptor was shown to be a good tool to prevent the onset of PCOS induced by sympathetic hyperactivation.

**Variants of the *NR5A1* gene in a large cohort of patients with primary ovarian insufficiency**
A. Voican[1,2], A. Bachelot[3], J. Bouligand[1,4], B. Francou[1,4], M. Lombès[1], P. Touraine[3] & A. Guiochon-Mantel[1,4]
[1]Faculté de Médecine Paris Sud, Le Kremlin-Bicêtre, France; [2]University of medicine and Pharmacia, Craiova, Romania; [3]GH Pitié Salpétrière, Paris, France; [4]GH Paris Sud, Hopital Bicetre, Paris, France.

Premature ovarian insufficiency (POI) is a disorder which affects ~1% of women under 40 years of age. Genetic component has been suggested in the majority of cases of nonsyndromic forms, and recently mutations of *NR5A1* have been reported to be associated with POI. In order to evaluate the frequency of NR5A1 mutations in POI together with the functional characterisation of the existing variants, we conducted a genetic study on a large cohort of POI patients.
Patients and method
Hundred and eighty eight patients diagnosed with idiopathic POI and 82 control subjects from the general population were screened for NR5A1 mutations and *in vitro* functional analysis was performed for the identified variants. HEK293T cells were transiently transfected with either wild type (WT) or mutant NR5A1-containing plasmid. The DNA binding capacity of the variants was evaluated by electrophoretic mobility shift assay (EMSA), while the transcriptional activity was assessed by luciferase assay.
Results
Sequencing NR5A1 gene revealed the presence of four missense variants in three patients (including two missense variants previously described in a patient with POI), nine intronic changes in thirteen patients and six polymorphisms. The three patients with missense variants were 20–33 years old and presented secondary amenorrhea. There was no family history of reproductive disorders, adrenal failure or DSD. Ovarian ultrasonography showed the presence of follicles in two of the three patients. Functional analysis was carried out for three missense variants not present in the control group. EMSA showed no difference in the DNA binding between the studied variants and the WT-NR5A1. Furthermore, no significant differences in the transcriptional activity of the respective variants compared to the WT were found when the luciferase assays was performed.
Conclusions
The results of our study conducted in a large cohort of patients show that NR5A1is not a major cause of idiopathic POI. We suggest that genetic investigation of NR5A1 in POI might be restricted to familial cases.

**Aberrant expression of TRAIL in placenta and maternal serum in early pregancy complications**
K. Rull[1], K. Tomberg[1], S. Kõks[1], J. Männik[1], M. Möls[1], M. Sirotkina[2], S. Värv[1] & M. Laan[1]
[1]University of Tartu, Tartu, Estonia; [2]Tartu University Hospital, Tartu, Estonia.

Recurrent miscarriage (RM) is defined as $\geq 3$ consecutive pregnancy losses and occurs in 1–3% of fertile couples. No specific early biomarkers with high predictive value of threatening miscarriage have been identified. Using GeneChips (Affymetrix), we profiled whole-genome differential gene expression in RM placental tissue compared to uncomplicated pregnancies matched for gestational age. In cases of RM, significantly increased placental mRNA expression of TNF-related apoptosis-inducing ligand (TRAIL; $P<0.005$) and S100A8 ($P<0.001$) encoding for inflammatory marker calprotectin (S100A8/A9) was confirmed by Taqman RT-qPCR. Using ELISA, the concentrations of soluble TRAIL and calprotectin in maternal serum in normal first trimester ($n=35$) and failed pregnancies (early, $n=18$ and late miscarriage, $n=4$; tubal pregnancy, $n=11$) were determined. When compared to normal first trimester pregnancy, significantly higher maternal serum concentration of sTRAIL was detected at the RM event ($P<0.001$), in women with tubal pregnancy ($P<0.05$), and in pregnant women, who developed an unpredicted miscarriage 2–50 days after prospective serum sampling ($P<0.05$). Maternal serum levels of calprotectin were neither diagnostic nor prognostic to early pregnancy failures ($P>0.05$). sTRAIL may have a potential as a predictive biomarker in maternal serum for early pregnancy complications.

**Blood cell mitochondrial DNA content and premature ovarian aging**

C. Cacciatore[1], M. Bonomi[1], E. Somigliana[2], M. Busnelli[1], R. Rossetti[1], A. Paffoni[2] & L. Persani[1]
[1]Istituto Auxologico Italiano, Milano, Italy; [2]Fondazione IRCCS Ca' granda Ospedale Maggiore Policlinico, Milano, Italy.

Primary ovarian insufficiency (POI) is a critical fertility defect characterized by a progressive and silent impairment of the follicular reserve. POI aetiology is heterogeneous and largely unknown, but a maternal inheritance often characterizes idiopathic forms. Therefore, we hypothesized a possible involvement of a mitochondrial defect in the pathogenesis of this disease since mitochondrial biogenesis and bioenergetics play an essential role in ovarian folliculogenesis. Our aim was to verify whether the content of mitochondrial DNA (mtDNA) was significantly reduced in the peripheral blood cells of POI women. We recruited 101 women with an impaired ovarian reserve: 59 women with premature ovarian failure (POF) and 42 poor responders (PR) to ovarian hyperstimulation. A Taqman copy number assay revealed a significant mtDNA depletion ($P<0.001$) in both trial groups in comparison with two control groups: 43 women of similar age and with intact ovarian reserve (normal responders to ovarian hyperstimulation, NR) and 53 very old women with a previous physiological menopause (CPM). No variations in a mitochondrial DNA polymerase gene (POLG) were detected in POF women with mtDNA depletion. Due to the ethical impossibility to test the direct correlation of the mtDNA content between the oocyte obtained by assisted reproductive techniques and the blood cell from the same individual, we demonstrated that the mtDNA content in the peripheral blood cells is representative of the one in the granulosa cells. Our results indicate that blood cell mtDNA depletion is a frequent finding among women with premature ovarian aging, suggesting that blood cell mtDNA determination could become an useful tool for POI risk prediction.

**Fetal growth parameters and outcome of pregnancies complicated with thyroid disease**

M. Poulasouchidou, G. Mintziori, K. Toulis, E. Kintiraki, P. Poulakos, D. Goulis & B. Tarlatzis
Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece.

Introduction
Thyroid dysfunction and thyroid autoimmunity (TAI) have been associated with adverse pregnancy outcomes for both the mother and the fetus. The aim of this study was to describe fetal growth parameters of pregnancies complicated with thyroid diseases/TAI and to construct predictive models for their outcome.
Methods
The study included 196 consecutive singleton pregnancies in women with thyroid diseases, during the period 2007–2010. A cohort of 809 singleton pregnancies in euthyroid women without TAI was used as fetal growth control. The main metabolic parameters evaluated were: thyroid hormones (TSH, $fT_4$), thyroid autoantibodies (TPOAb, TgAb, TSI) and doses of levothyroxine ($LT_4$) and antithyroid medications for women with hypothryroidism and hyperthyroidism respectively. The main fetal growth parameters evaluated were: estimated fetal weight (EFW), head circumference (HC) and abdominal circumference (AC). Predictive models were constructed for pregnancies complicated with hypothyroidism.
Results
In the study population, 16% of women were euthyroid, having either TAI or nodular thyroid disease, 19% hyperthyroid and 65% hypothyroid. Of the studied pregnancies, 88% resulted in live birth, 10% in spontaneous abortion, 1% in iatrogenic abortion and 1% in intrauterine death. Maternal complications included pregnancy-induced hypertension, pre-eclampsia, hyperemesis gravidarum, placental abruption and poly-hydramnion/oligoamnion. Neonatal complications included jaundice, tachypnoea, respiratory distress syndrome and hypothyroidism. Fetuses of mothers with hypothyroidism had increased AC in comparison to fetuses of normal pregnancies but did not differ with respect to EFW or HC. In pregnancies complicated by hypothyroidism, thyroid auto-antibodies or serum TSH did not predict neither pregnancy outcome nor occurrence of maternal or neonatal complications.
Conclusions
The increment in fetal AC in pregnancies complicated by hypothyroidism needs to be confirmed in further prospective studies. The outcome of pregnancies complicated by thyroid dysfunction does not seem to be predicted by hormonal or ultrasonographic parameters.

**Endocrine effects of the FSHB −211 promoter polymorphism in females**

A. Busch, A. Schüring, J. Gromoll & F. Tüttelmann
Münster University Hospital, Münster, Germany.

Introduction
FSH is a key player in reproductive functions, the expression of its unique subunit FSHB is regulated by the FSHB promoter. Recently, a single nucleotide polymorphism (SNP) at a highly conserved position in the FSHB promoter (rs10835638; −211G>T) has been found to be associated with decreased serum FSH levels in men and with male infertility. Because to date no information is available on possible endocrine consequences of this SNP in women, we conducted this study to analyze well characterized female individuals.
Patients and methods
Three hundred and sixty five normally cycling women undergoing diagnostics prior to assisted reproductive techniques (ART) were included. Anthropometric and endocrine data were assessed. An independent cohort of 438 fertile females was additionally analyzed. Customized TaqMan technology was used to detect the FSHB SNP in DNA extracted from lymphocytes.
Results
Comparing genotyped patients of our study population with controls, allele and genotype frequencies were not different between groups (T-allele: 14.7 vs 16.6%; TT-homozygotes: 2.4 vs 3.4%). However, we observed strong associations of the T-allele with elevated serum FSH (0.99 U/l per T-allele, $P=0.006$) and LH (1.30 U/l per T-allele, $P<0.001$). Additionally, T-allele carrier status was significantly associated with a reduced serum progesterone (−1.96 ng/ml per T-allele, $P=0.047$) in the studied subjects.
Conclusion
This is the first report on genotype-phenotype correlations of rs10835638 in females. Unexpectedly, the association of this SNP with an elevated FSH in our subjects stands in contrast to previous findings in male. On the other hand, elevated LH-levels in T-allele carriers seem to be present also in males. Together with the observed associations of this SNP with progesterone these novel findings could be indicative of a gender specific regulatory feedback mechanism involving sexual steroids and progesterone responsive elements of the FSHB promoter.

**The prevalence of endometrial hyperplasia and endometrial cancer in Danish women with PCOS or hyperandrogenism**

P. Ravn, D. Glintborg, M. Andersen, N. Holm & D. Scledermann
Odense University Hospital, Odense, Denmark.

Objective
PCOS may be associated with an increased risk of endometrial hyperplasia (EH) and endometrial cancer (EC), but substantial evidence remains to be established. We investigated the prevalence of EH and EC in a well-characterized group of women with PCOS and/or clinical/biochemical hyperandrogenism.

Design
Retrospective, trans-sectional study.
Setting
Out-patient clinic at the Departments of Endocrinology and Gynecology, Odense University Hospital, Denmark.
Population
Nine hundred and sixty three premenopausal women consecutively referred with the diagnoses PCOS and/or hirsutism during 1997–2008.
Methods
All women underwent a standardized evaluation program. In 2011, The Danish Data Bank of Pathology was used to identify patients with endometrial histology diagnoses (year range of diagnosis 1982–2011).
Main outcome measures
Histology diagnoses, demographic variables.
Results
EH was diagnosed in 10 (1.0%) women and EC in 1 (0.1%) woman. The median BMI in the EH/EC group was 30.6 kg/m$^2$ compared to 26.8 kg/m$^2$ in the total cohort. There were no differences between the cases and total cohort in terms of individual Rotterdam Criteria. In Denmark, 70 yearly cases of EC are diagnosed in women 40–55 years corresponding to a prevalence of 0.4% in the corresponding time period.
Conclusion
The results of the present study do not suggest a higher prevalence of EC in women with PCOS and/or clinical/biochemical hyperandrogenism compared to the general population.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Conformational control of P450aromatase by lipid membrane interactions and protein associations

L. Martin[1], S. Praporski[1], R. Rodgers[3], C. Corbin[2], A. Conley[2] & D. Mizrachi[4]
[1]Monash University, Clayton, Victoria, Australia; [2]University of California, Davis, California, USA; [3]The University of Adelaide, Adelaide, South Australia, Australia; [4]University of Texas Southwestern Medical School, Dallas, Texas, USA.

Cytochrome P450 aromatase is a membrane bound enzyme that synthesises estrogens. This reaction involves electron delivery from NADPH via cytochrome P450 reductase (CPR). Little is known as to how the P450arom performs the aromatase reaction or how it associates with CPR in the endoplasmic reticulum (ER). In humans, there is only one P450arom, however pigs have three isozymes. The catalytic efficiency of one of these, the porcine gonadal P450arom, is much lower than the human and the porcine placental isozymes despite the high amino acid sequence homologies.
We have used *in vivo* and *in vitro* techniques to study the interaction of P450arom proteins and lipid membranes. Forster resonance energy transfer (FRET) studies explored the protein-protein interactions in the ER. A quartz crystal microbalance (QCM) was used to measure the mass of protein(s) binding to a lipid membrane and in association with the Western blot data the stoichiometry for P450arom and CPR was determined. QCM also provides information about the conformational and structural organisation of proteins in the lipid membrane. Molecular mechanics calculations were also used to further probe the human and porcine P450arom.
Our FRET studies showed that the human P450arom forms dimers *in vivo*. The QCM showed that all the recombinant P450arom enzymes examined bound tightly to the lipid membranes; both truncated and full length. The P450arom: CPR complexes bound to the membranes exhibited good catalytic turnover. However, the human P450arom 'associated' very differently with the lipid membrane than the porcine gonadal P450arom. The rate of porcine P450arom binding was most influenced by the amount of CPR present. Thus the structural organisation within the membrane is very different between porcine and human, despite the similarities in amino acid sequence. The minimum energy structures for the human and porcine gonadal P450arom also differ and thus may influence the mechanism of P450arom function.

### Metabolic characteristics in women with polycystic ovary syndrome by phenotypes based on various diagnostic criteria

Y. Sung[1], D. Kim[2], S. Baik[3], K. Won[4], H. Kim[5], J. Oh[1] & H. Lee[1]
[1]Woman University, Seoul, Republic of Korea; [2]Hanyang University, Seoul, Republic of Korea; [3]Koprea University, Seoul, Republic of Korea; [4]Eulji University, Seoul, Republic of Korea; [5]Yeungnam University, Daegu, Republic of Korea.

The metabolic features of Polycystic ovary syndrome (PCOS) can vary based on the definition used. The aim of this study is to compare the metabolic characteristics of PCOS according to the phenotypes from various diagnostic criteria and help to establish a optimal diagnostic criteria.
Subjects with PCOS defined by the NIH criteria ($n=494$) and the Rotterdam criteria ($n=568$) and regular cycling non-hirsuite control women ($n=1000$) were recruited. All subjects underwent blood samples for fasting glucose, lipids, insulin and reproductive hormones and a transvaginal ultrasound.
Women with PCOS have significantly higher prevalence for abnormal glucose metabolism and metabolic syndrome (MetS) compared to control (4 vs 0% for diabetes 11 vs 3.4% for IFG/IGTand 19 vs 2.4% for MetS) and it is not different among PCOS women according to diagnostic criteria. Women with PCOS were divided into following four different phenotypes; i) oligomenorrhea(OM)/hyperandrogenism (HA)/PCO, ii) OM/ HA, iii) HA /PCO, and iv)OM/PCO. Women with PCOS by NIH criteria (OM/HA $\pm$ PCO) have higher frequency of obesity, diabetes, IGT/IFG and metabolic syndrome compared to subjects with OM/PCO or HA/PCO (Table 1).
Regarding metabolic derangement, PCOS without HA may be different phenotype. Further studies will be required to observe the development of various disease in women with PCOS diagnosed by different criteria to establish a fine definition which can represent morbidity of disease.

**Table 1** Metabolic characteristics according to various phenotypes of PCOS.

### Prevalence of chronic autoimmune thyroiditis in patients with polycystic ovary syndrome

A. Vryonidou[1], E. Vassilatou[2], D. Ioannidis[3], M. Panagou[3], K. Katsoulis[3], K. Stefanaki[1] & I. Tzavara[3]
[1]Red Cross Hospital, Athens, Greece; [2]'Attikon' Hospital, Athens, Greece; [3]'Amalia Fleming' General Hospital, Athens, Greece.

Introduction
Polycystic ovary syndrome (PCOS) is a common endocrinopathy in women of reproductive age and is characterized by chronic anovulation and clinical and/or biochemical hyperandrogenism. Chronic autoimmune thyroiditis (AIT) is a common disease of organ-specific autoimmunity affecting predominantly women, that is attributed to an interaction between a genetic background and environmental factors. There are few data showing higher AIT prevalence in PCOS patients.

Objective
To investigate the prevalence of AIT in women with PCOS.
Patients/methods
We studied 272 women diagnosed with PCOS according to the NIH (1990) criteria and 164 age- and weight-matched control women. All patients underwent a hormonal and biochemical evaluation. AIT was diagnosed in women with high levels of anti-Tg and/or anti-TPO antibodies who were further evaluated with thyroid ultrasound. Insulin resistance was assessed by homeostasis model assessment (HOMA-IR).
Results
No significant difference was found in the prevalence of AIT between the two groups (34/272 (12.5%) PCOS patients and 24/164 (14.6%) controls were diagnosed with AIT). PCOS patients with AIT compared to PCOS patients without AIT were significantly older ($P<0.01$), more obese ($P<0.001$) and had lower serum SHBG levels ($P<0.001$). Control women with AIT compared to control women without AIT were significantly older ($P<0.001$), had lower serum total testosterone and DHEAS levels ($P<0.05$ and $P<0.001$ respectively) and were more insulin resistant as assessed by HOMA-IR ($P<0.001$).
Conclusion
In our cohort, the prevalence of AIT was similar in PCOS women and normal ovulatory women. Further studies with a greater number of participants are needed in order to clarify a possible relationship between these two common entities.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P934

**Lean muscle mass in classic or ovulatory PCOS: association with central obesity and insulin resistance**

F. Mario[1], F. Amarante[1], M. Toscani[1] & P.. Spritzer[1,2]
[1]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil; [2]Federal University of Rio Grande do Sul, Porto Alegre, Brazil.

Central obesity and insulin resistance are more prevalent in women with PCOS, affecting both normal weight and obese subjects. The metabolic effects of insulin are partially dependent on the amount of lean mass and insulin resistance seems to selectively affect the metabolic, but not the mitogenic, actions of insulin. Therefore, this age-matched case-control study assessed total and segmental lean muscle mass in classic or ovulatory polycystic ovary syndrome (PCOS) patients and investigated whether lean mass is associated with hormone and metabolic features. PCOS was diagnosed according to the Rotterdam Consensus criteria. Participants underwent anthropometric and clinical evaluation. Habitual physical activity was assessed with a digital pedometer, and body composition by dual-energy X-ray absorptiometry. Laboratory measurements included total cholesterol, cholesterol fractions, triglycerides, glucose, total serum testosterone, serum insulin, estradiol, luteinizing hormone, and SHBG. Energy intake was calculated using a food frequency questionnaire. Classic PCOS patients had higher body mass index (BMI), waist circumference, testosterone and lipid accumulation product values than ovulatory PCOS and controls ($P<0.05$). Energy consumption, homeostasis model assessment index, SHBG, free androgen index and triglycerides, total and trunk lean mass were higher only in classic PCOS women vs controls. Arm, leg, trunk, total or limb lean masses were not correlated with hormone levels in any of the groups. However, in PCOS women lipid accumulation product was positively correlated with total ($r=0.56$, $P=0.001$), trunk ($r=0.59$, $P=0.001$), arm ($r=0.54$, $P=0.001$), leg ($r=0.44$, $P=0.03$) and limb ($r=0.48$, $P=0.001$) lean masses. BMI was positively correlated with all lean mass segments and independently associated with total lean mass. Lipid accumulation product and BMI were independently associated with trunk lean mass variation. In conclusion, the increase in lean mass in classic PCOS appears to be associated with insulin resistance and central obesity rather than with energy intake, physical activity or androgens.

## P935

**Candidate pathway genetic analysis of PCOS**

M. Urbanek[1], O. Garcia[1], T. Woodruff[1], R. Legro[2], A. Dunaif[1] & P. Mutharasan[1]
[1]Northwestern University, Chicago, Illinois, USA; [2]Pennsylvania State University, College of Medicine, Hershey, Pennsylvania, USA.

Polycystic ovary syndrome (PCOS) is a characterized by hyperandrogenism and irregular menses and is associated with insulin resistance, type 2 diabetes and obesity. While there is a strong genetic component to PCOS, candidate gene analyses and genome wide association studies (GWAS) have identified only a handful of replicated PCOS susceptibility loci. Therefore, we employed a candidate pathway approach to identify additional PCOS susceptibility loci. This approach is more comprehensive than single candidate gene analyses but also more targeted than GWAS, there is a reduced penalty for multiple testing allowing the detection of genes with smaller effect sizes. We tested for association between PCOS and 4930 SNPs mapping to 299 genes belonging to four pathways (ovarian rigidity (117 genes), TGF β signaling (77 genes), insulin resistance, diabetes and obesity (28 genes), and inflammation (77)) in a European ancestry cohort of 931 women with PCOS according to NIH criteria and 957 control women. After adjusting for population substructure and body mass index, the strongest evidence for association was with genes previously implicated in obesity, diabetes or insulin resistance (39% of genes with $P$ values $<0.01$) and genes whose expression is altered in a murine model of ovarian rigidity (22% of genes with $P$ values $<0.01$). The five genes with the strongest evidence for association with were RAMP1 (receptor G protein-coupled activity modifying protein 1; rs13405506 allele T, odds ratio = 0.57, $P$ value = 0.00010), FTO (fat mass and obesity associated; rs8056199 allele A, odds ratio = 1.47, $P$ value = 0.00015), ADAMTS19 (ADAM metallopeptidase with thrombospondin type 1 motif, 19; rs246246 allele G, odds ratio = 0.56, $P$ value = 0.00035), TBC1D4 (TBC1 domain family, member 4; rs9318332 allele C, odds ratio = 1.43, $P$ value = 0.00054), and SERPINA12 (serpin peptidase inhibitor, clade A, member 12; rs12433377 allele G, odds ratio = 1.63, $P$ value = 0.00056). This study provides convincing evidence that the ovarian and metabolic environment contribute to the PCOS phenotype.

**Sex hormones and sexual function in postmenopause**

B. Zilaitiene, G. Jonusiene, V. Adomaitiene & R.. Aniuliene
Lithuanian University of Health Sciences, Kaunas, Lithuania.

The aim of the study was to explore the relation of female sexual function to the concentration of estradiol ($E_2$), total testosterone (T), DHEA-S in the sample of Lithuanian women in postmenopause.
Methods and participants
Two hundred and forty six postmenopausal women who fulfilled inclusion criteria were asked to fill in female sexual functioning index (FSFI) and socio-demographic questionnaire. A blood sample from all participants was taken for $E_2$, testosterone, SHBG, DHEA-S analysis.
Results
The mean age of study participants was 55.5 (5.2) years (range 45–65 years). Week positive correlation of total testosterone (nmol/l) with desire ($r=0.13$, $P=0.04$) and arousal ($r=0.12$, $P=0.05$) was detected.
$E_2$ (pmol/l) positively correlated with desire ($r=0.17$, $P=0.01$), arousal ($r=0.17$, $P=0.008$), lubrication ($r=0.16$, $P=0.01$), orgasm ($r=0.13$, $P=0.04$), pain ($r=0.16$, $P=0.02$), total score of sexual function ($r=0.16$, $P=0.01$). $E_2$ did not influence sexual satisfaction in our sample.
DHEA-S (μmol/l) had positive effect on sexual desire ($r=0.14$, $P=0.02$), lubrication ($r=0.14$, $P=0.03$), pain ($r=0.15$, $P=0.02$) and total score of sexual function ($r=0.14$, $P=0.03$).
Risk to have sexual dysfunction (FSFI $\leq 26.55$) was lower for women with higher $E_2$ – odds ratio 0.99 (0.99–1.00; $P<0.02$), and higher DHEAs concentration – odds ratio 0.85 (0.76–0.95; $P< 0.004$). But these hormones were not significant predictors of sexual dysfunctions when results were adjusted for age.
Conclusion
Sex hormones concentration along with age factor are significant determinants of female sexual function in postmenopause.

**Hypoandrogenemia at women with hypogonadotropic hypogonadism**

I. Ilovayskaya[1], V. Zekster[2], D. Mikhaylova[1], N. Goncharov[3], G. Melnichenko[2,3] & I. Dedov[2,3]
[1]Moscow Regional Research & Clinical Institute named by MF Vladimirsky, Moscow, Russian Federation; [2]1st Moscow State Medical University named by IM Sechenov, Moscow, Russian Federation; [3]Federal Endocrinology Research Centre, Moscow, Russian Federation.

We estimated androgen status at 111 female patients (pts) with HH before and after hormonal therapy (HT) by estadiol 2 mg + dydrogesterone 10 mg in sequence manner not <12 months. Median age of pts was 28 y.o., mean duration of HH 6.2 year, isolated HH $n=56$ group 1, HH as a part of hypopituitarism $n=55$ group 2, 45 healthy women of the same age were included in control group. Total T, SHBG and DHEA-S levels were measured, free T levels were calculated using standard formula. To estimate the quality of life the General Health Questionnaire (GHQ-28) was used.
Initially in both 1 and 2 groups total and free T levels were significantly lower compared to the controls ($P<0.05$), decrease was more appreciable in group 2 (see Table 1). DHEA-S levels were significantly lower in group 2 but not in group 1 compared with controls. There are some data that estrogen therapy can provoke depression of androgen levels. During HT the total and free T levels did not changed considerably so position had not worsened. DHEA-S levels even increased and the difference was statistically significant in group 2.
Total T levels positively correlated with the quality of sleep ($r=0.47$; $P=0.02$), social and physical activities ($r=0.54$; $P=0.000003$) and negatively correlated with depression ($r=-0.67$; $P<0.001$) and nervousness ($r=-0.57$; $P=0.0001$). Free testosterone levels positively correlated with the positive emotional reactions ($r=0.33$; $P=0.04$), social and physical activities ($r=0.6$; $P<0.001$), quality of sleep ($r=0.46$; $P=0.003$) and negatively correlated with depression ($r=-0.7$; $P<0.001$) and nervousness ($r=-0.6$; $P<0.001$). DHEA-S levels positively correlated with the positive emotional reactions (0.46; $P=0.003$), social and physical activities ($r=0.5$; $P<0.001$), quality of sleep ($r=0.45$; $P=0.003$), daily activities ($r=0.56$, $P<0.001$) and negatively correlated with depression ($r=-0.55$; $P<0.001$) and nervousness ($r=-0.45$; $P=0.004$).
Thus, hypogonadotropic hypogonadism is the disease associated androgen deficit with which influences on quaity of life. Hypoandrogenemia is more severe in patients with hypopituitarism

**Nonalcoholic fatty liver disease in pregnant women.**

V. Castracane, G. Davis, B. Martinez, C. Maguire & R. Kauffman
Texas Tech HSC, Odessa, Texas, USA.

Introduction
NAFLD has become the leading cause of liver disease in the Western world and has a strong association with obesity and diabetes. There are no studies of NAFLD in pregnant women.
Methods
Pregnant volunteers ($n=57$) were recruited in the first or third trimester and evaluated for the presence of NAFLD using abdominal ultrasound scans using accepted criteria. Liver biopsies were not performed since this invasive procedure would present undue risks in otherwise healthy pregnant subjects. Fasting liver enzymes (AST and ALT), triglycerides, adiponectin, leptin, glucose, and insulin, were drawn. Gestational diabetes was defined in third trimester subjects using criteria developed by Carpenter and Coustan. Subjects were subsequently subdivided into lean, obese, and gestational diabetics.
Results
Half of the subjects enrolled had ultrasound evidence of NAFLD. NAFLD was observed equally among those presenting in the first or third trimesters. Additionally, the prevalence of NAFLD was similar between those with normal BMI vs obese women. No liver enzymes elevations were encountered. Serum adiponectin levels were significantly higher in the lean subjects irrespective of gestational age while obese and gestational diabetic subjects had lower adiponectin concentrations. Serum leptin levels in the first trimester were significantly lower in lean subjects compared to the obese and GDM women. In the third trimester, levels were elevated (compared to first trimester levels) in the lean and obese, and gestational diabetic groups. No relationship between adipokine levels and the presence of NAFLD was detected.
Conclusions
This is the first study to report on NAFLD in pregnant women. Pregnant women with NAFLD have normal AST and ALT and hence, are not reliable diagnostic tests to distinguish NAFLD in pregnancy. Distribution of NAFLD is comparable in lean, obese and gestational diabetic subjects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P939

**AMH and INSL3 levels in ovulatory and anovulatory women with the polycystic ovary syndrome**

C. Pelusi[1], A. Gambineri[1], F. Fanelli[2], M. Pariali[2] & R. Pasquali[1,2]
[1]University of Bologna, S.Orsola-Malpighi Hospital, Bologna, Italy; [2]S.Orsola-Malpighi Hospital, Bologna, Italy.

Introduction
Anti-Mullerian hormone (AMH) and insulin-like factor 3 (INSL3) represent ovarian functional markers of granulosa and theca cells respectively. This study investigated AMH and INSL3 plasma levels in two groups of ovulatory or anovulatory women with polycystic ovary syndrome (PCOS), and their relationship with ovarian morphology and androgen levels.
Methods
AMH and INSL3 were measured in a cohort of 57 patients with PCOS classified in two groups according to progesterone (P) levels ($n$: 21 ovulatory; $n$: 36 anovulatory) and in 27 age and body-weight matched controls with normal menses. Progesterone levels were randomly measured in those with amenorrhea and on the day 21 of the cycle in those with oligomenorhea or normal cycles. Clinical and endocrine characteristics and ovarian morphology were compared between the two PCOS groups.
Results
Compared to controls, plasma AMH and INSL3 were higher in PCOS women ($P<0.001$ and $P=0.01$ respectively) and, among them, in those with chronic anovulation with respect to the ovulatory ones ($P=0.003$ and $P=0.01$ respectively). The anovulatory group had lower number of cycles per year ($P<0.001$) and presented with higher number of ovarian follicles ($P=0.004$) and serum levels of testosterone ($P=0.001$), LH ($P<0.001$) and FSH ($P<0.001$) compared with the ovulatory group. Intriguingly, levels of INSL3 correlated with those of AMH in all PCOS women ($r=0.45$; $P=0.001$). Moreover, both INSL3 and AMH significantly and positively correlated with LH values in all PCOS women ($r=0.31$; $P=0.02$ and $r=0.53$; $P=0.001$ respectively).
Conclusion
These data show for the first time that blood levels of INSL3 significantly correlate with AMH plasma concentrations, and that levels of both peptides are specifically altered in anovulatory women with PCOS.

## P940

**Increased risk of glucose metabolism impairment after gestational diabetes in polycystic ovary syndrome**

F. Orio[1,2], A. Colao[3], A. Falbo[4], T. Russo[4], M. Orio[5], R. Vero[6], C. Capula[6], A. Volpe[5], V. Di Stasi[5], S. Savastano[3], G. Lombardi[3] & S. Palomba[4]
[1]University 'Parthenope' of Naples, Naples, Italy; [2]Hospital University of Salerno, Salerno, Italy; [3]University 'Federico II' of Naples, Naples, Italy; [4]University 'Magna GraeciaI' of Catanzaro, Catanzaro, Italy; [5]University of Salerno, Salerno, Italy; [6]Hospital 'Pugliese' of Catanzaro, Catanzaro, Italy.

Objective
The aim of the present study was to test the hypothesis that the risk of persistent glucose impairment after gestational diabetes (GDM) is increased in patients with polycystic ovary syndrome (PCOS).
Research design and methods
The prospective case–control study included 42 pregnant patients with PCOS and GDM and 84 pregnant control patients with GDM but without clinical and biochemical hyperandrogenism, polycystic ovaries and oligo-anovulation. The cases and controls were matched one to two for age and body mass index. The glycemic profiles were studied in all subjects 6 weeks, 12 weeks and 18 months after delivery. The incidence and the relative risk (RR) were calculated for overall persistence of an abnormal glycemic pattern and for each specific alteration, i.e. impaired glucose tolerance (IGT), impaired fasting glucose (IFG), and diabetes mellitus (DM).
Results
At 18 months after delivery, the incidences of IFG, IGT and IFG–IGT were significantly ($P<0.05$) higher in the cases than in the controls. At the 18-month follow-up, the RR for the composite outcome of glucose metabolism impairment in PCOS women was 3.45 (95% confidence interval (CI) 1.82–6.58).
Conclusions
Patients with PCOS are at increased risk for a persistent impaired glucose metabolism after GDM.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Effect of antiandrogens on spontaneous apoptosis in cultured porcine granulosa cells**

M. Duda, M. Knet, K. Knapczyk-Stwora & M. Slomczynska
Jagiellonian University, Krakow, Poland.

Androgens are one of the most important agents influencing folliculogenesis. They can modulate follicular function by interactions with various factors and promote granulosa cells differentiation. On the other hand, androgens can antagonize follicular development by inducing apoptosis in granulosa cells. Therefore, androgens can promote follicular atresia. The purpose of the present study was to test the hypothesis that androgen receptor antagonists (2--hydroxyflutamide (2-Hf) or vinclozolin (Vnz)) in the presence of T inhibit granulosa cell apoptosis. Granulosa cells, isolated from mature pig follicles (6–8 mm in diameter), were cultured for 24 h in McCoy's 5A medium supplemented with 10% fetal bovine serum to cause attachment cells to the plastic. After that, media were changed and T, 2-Hf, Vnz, or both T + 2-Hf and T + Vnz were added to the culture media. Finally, 24 h later cells were fixed for morphological assessment of apoptotic cells utilizing a Hoechst staining technique and measurement of caspase-3 activity in cultured granulosa cells were performed.
It was shown that the addition of 2-Hf or Vnz to the culture media caused an increase in the incidence of apoptotic bodies and caspase-3 activity. Furthermore, testosterone treatment also enhanced apoptosis in granulosa cells. On the other hand apoptotic bodies were very sparse among granulosa cells cultured with T + 2-Hf and T + Vnz. Moreover, caspase-3 activity was suppressed in cultures treated with combination of androgen receptor agonist and antagonists.
In conclusion, our results indicate that both 2-hydroxyflutamide and vinclozolin appear to be atretogenic, but when tested with high level of testosterone they trigger anti-apoptotic effects. The nature of this protective mechanism as yet is unknown and requires further research.

## P942

**Prenatal exposure to anti-androgen flutamide influences connexin 43 expression in the porcine fetal gonads**

K. Knapczyk-Stwora[1], M. Durlej[1], M. Koziorowski[2] & M. Slomczynska[1]
[1]Jagiellonian University, Krakow, Poland; [2]University of Rzeszow, Rzeszow, Poland.

All evidence so far indicates a role of different connexins during gonadal development, gamete formation and testicular and ovarian functions. Connexin 43 (Cx43) is one of the predominant gap junction proteins in the testis and ovary. It is well established that gonads development is highly sensitive to hormonal disruption induced by various endocrine active compounds during fetal period. Therefore, it was interesting to study whether communication via gap junctions is altered in gonads of pig fetuses exposed to anti-androgen flutamide prenatally. To perform this project, pregnant sows were injected with flutamide (50 mg/kg body weight, seven times, every day) starting at 83 or 101 day of gestation. On days 90 and 108 the fetuses were excised during a surgical procedure. Fetal gonads were fixed in Bouin's fixative for immunohistochemistry or frozen in liquid nitrogen for real-time PCR analysis. Immunohistochemistry was performed on tissue sections using a polyclonal rabbit antibody against Cx43 (dilution 1:2000; Sigma–Aldrich) followed by a goat anti-rabbit IgG (dilution 1:300; Vector Lab.) and the standard ABC method. Binding of antibody to the antigen was visualized by diaminobenzidine. To assess Cx43 mRNA expression real-time PCR was performed using the TaqMan Gene Expression Assay (Applied Biosystems).
In the fetal ovaries, Cx43 protein was localized between interstitial cells surrounding egg nests and between granulosa cells of primary follicles. In the fetal testes, Cx43 was detected between Leydig cells. In the fetal gonads Cx43 expression was up-regulated after flutamide treatment.
Detection of changes in Cx43 gene expression in developing porcine fetal gonads after exposure to flutamide may indicate the role of androgens in the regulation of cell-to-cell communication within the testes and ovaries.

## P943

**Long term health status of POI Patients**

A. Bachelot, S. Gricourt, M. Coudert, J. Dulon & P. Touraine
Pitié-Sapêtrière Hospital, Paris, France.

Premature ovarian insufficiency (POI) is a disorder which affects approximately 1% of women under 40 years of age. Besides infertility and estrogen deficiency altering the quality of life, the impact of this disease on the long-term health status of these women, especially bone status, has received little attention. We therefore designed a cross-sectional study of patients with POI, 5–10 years after a first evaluation in our department. We evaluated their anthropometric, hormonal replacement treatment (HRT) and bone health status. One hundred and ninety four patients were proposed to participate to this study, and 130 agreed to participate (77%). The mean follow-up period was $8 \pm 2.5$ years (4.6–19.3). Eighty five patients had bone mineral density (BMD) determination. Forty six patients (54%) presented osteopenia, 8 osteoporosis (10%) and 31 (36%) had normal BMD. No fractures were reported. Thirty women (59%) with vitamin D deficiency exhibited bone demineralization. Forty five patients had BMD evaluation at the time of POI diagnosis and during the present evaluation. Thirteen (28.8%) of them had stopped their HRT for over a year. Twenty three (51%) had progressed to osteopenia or osteoporosis. In univariate analysis, discontinuation of HRT and POI duration were associated with a significant loss of BMD, while BMI was associated with a gain in BMD. In multivariate analysis, time since HRT discontinuation was significantly associated with a loss of BMD; BMI and occurrence of a pregnancy were associated with a gain in BMD, but POI duration had no significant impact.
In conclusion, our study was the first to analyse long-term consequences on these women's health of POI. We showed that impairment of BMD is common in POI women, especially in patients who stopped their HRT. These patients must be carefully monitored to improve their final outcome.

## P944

**Neonates of women with polycystic ovary syndrome display increased oxidative stress markers and metabolic aberrations comparable to gestational diabetes offspring**

G. Boutzios, S. Livadas, C. Piperi, N. Vitoratos, C. Adamopoulos, D. Hassiakos, C. Iavazzo & E. Diamanti-Kandarakis
Medical School, National and Kapodistrian University of Athens, Athens, Greece.

Context
Polycystic ovary syndrome (PCOS) and gestational diabetes (GDM) are two common metabolic disorders. The serum oxidative stress markers advanced glycation end products (AGEs) and advanced oxidation protein products (AOPPs) have been found to be elevated in women with PCOS and GDM compared to controls. However the impact of these harmful molecules to their offspring is under investigation.
Objective
To evaluate AGEs and AOPPs serum levels along with the hormonal/metabolic profile, their possible relationship as well as their potential impact in a cohort of PCOS(N) and GDM (N) neonates and their mothers PCOS(M) and GDM(M). As control was studied a group of normal mothers C(M) and their neonates C(N).
Design and setting
Prospective controlled study conducted in an Academic Medical Center.
Patients
The study population comprised 151 mothers/neonates pairs.
Main outcome measures
Anthropometric, metabolic, hormonal parameters and oxidative stress markers.
Results
AGEs and AOPPs were higher in PCOS(M) and GDM(M) mothers compared to controls(CM; $P<0.05$; AGEs: PCOSM: $7.19\pm1.8$ vsGDM: $7.28\pm2.4$ vs CM: $5.68\pm1.3$ U/ml, AOPPs: $10.18\pm1.76$ vs $10.06\pm2.02$ vs $5.3\pm1.8$ μmol/l) respectively. The same significant difference ($P<0.05$) was observed in the corresponding neonates groups (N; AGEs: PCOSN: $5.67\pm1.42$ vs GDMN: $5.74\pm1.52$ vs CN:$5.05\pm1.28$ U/ml, AOPPs: $9.56\pm1.49$ vs $11.24\pm5.49$ vs $6.2\pm2.51$ μmol/l respectively). A strong relationship between mothers' and neonates' AGEs ($r=0.605$, $P<0.001$) and AOPPs ($r=0.735$, $P<0.001$) was disclosed. Analogous findings were observed regarding androgens and insulin resistance in the subgroups of mothers and neonates.
Conclusion
The present study demonstrated that in PCOS neonates, the oxidative stress status and metabolic/hormonal profile was similar to that of GDM neonates and strongly associated with their mother's oxidative status. These findings may have clinical implications, since PCOS diagnosis can be achieved before pregnancy, thus enhancing pre-pregnancy health precautions for a better health outcome in their offspring.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P945

**Impact of dietary advanced glycation end products modifications on metabolic and hormonal profile in women with polycystic ovary syndrome**

E. Tantalaki, C. Piperi, S.. Livadas, A. Kollias, C. Adamopoulos, A. Koulouri, C. Christakou & E. Diamanti-Kandarakis
Medical School, National and Kapodistrian University of Athens, Athens, Greece.

Objective
To investigate the impact of dietary intervention of advanced glycation end products (AGEs) intake on hormonal and metabolic profile in women with polycystic ovary syndrome (PCOS).
Methods
After baseline evaluation, 23 women with PCOS (mean$\pm$S.D., age: $23.4\pm5.7$ years; body mass index (BMI): $26\pm5.7$ kg/m$^2$) underwent the following consecutive 2-month dietary regimens: a hypocaloric diet with *ad-libitum* AGEs content (Hypo), an isocaloric diet with high AGEs (HA) and an isocaloric diet with low AGEs (LA). Metabolic, hormonal and oxidative stress status was assessed as well as AGEs levels were determined in all subjects, after the completion of any dietary intervention.
Results
Serum levels of AGEs, testosterone, oxidative stress, insulin and HOMA-IR index were significantly increased on HA compared to Hypo diet and subsequently decreased on LA diet (compared to HA; $P<0.05$ for all parameters). BMI remained unaltered throughout the HA and LA periods compared to Hypo period. Dietary AGEs were associated with serum AGEs ($r=0.45$, $P<0.001$), insulin ($r=0.3$, $P=0.005$), HOMA-IR index ($r=0.31$, $P=0.006$) and oxidative stress ($r=0.32$, $P=0.002$). Testosterone was correlated with insulin ($r=0.36$, $P=0.001$) and HOMA-IR index ($r=0.36$, $P=0.002$).
Conclusions
Modifications on dietary AGEs intake are associated with parallel changes in serum AGEs, metabolic, hormonal and oxidative stress biomarkers in women with PCOS. These findings support the advice of a low AGEs dietary content along with lifestyle changes in women with PCOS.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P946

**Inhibin-α gene promoter polymorphisms in patients with idiopathic premature ovarian failure**

S. Yoon[1], J. Kim[2], S. Chae[3], K. Hwang[4] & Y.. Choi[5]
[1]Graduate School of Medicine, Dongguk University, Seoul, Republic of Korea; [2]Seoul National University Hospital, Seoul, Republic of Korea; [3]Maria Fertility Hospital, Seoul, Republic of Korea; [4]Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea.

Background
Premature ovarian failure (POF) is a complex disorder defined as the cessation of ovarian function before or at the age of 40. Although the etiology of POF remains unknown in a large proportion of cases, it has been suggested that variations in the Inhibin α gene (INHA) may affect the ovarian function of women. This study was performed to investigate whether the genetic polymorphisms of the INHA gene are associated with idiopathic POF in a Korean population.
Methods
The subjects consisted of 159 idiopathic POF patients and 233 postmenopausal controls. Genotyping for $-16C>T$ polymorphism was performed by MGB primer/probe Taqman assay, and $-124A>G$ polymorphism was identified using polymerase chain reaction (PCR)-restriction fragment length polymorphism (RFLP) analysis. Haplotypes were deduced by using the Haploview version 4.1.
Results
There were no significant differences in the genotype distributions or allele frequencies of the *INHA* gene $-16C>T$ and $-124A>G$ polymorphisms between the POF and the control group. Haplotype analysis also showed no significant difference between groups.
Conclusion
The distribution of the *INHA* gene promoter polymorphisms in a Korean POF population was not significantly different from controls, implying that the INHA gene polymorphisms may not be associated with the risk of idiopathic POF.
Keywords: inhibin-α, polymorphism, premature ovarian failure.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P947

**Skeletal frame size in females with polycystic ovary syndrome**

L. Zabuliene[1,2], J. Tutkuviene[1], E. Jakimaviciene[1], Z. Miliauskiene[1] & J. Urboniene[3]
[1]Vilnius University, Vilnius, Lithuania; [2]Antakalnio Out-Patient Clinic, Vilnius, Lithuania; [3]Vilnius University Hospital 'Santariskiu Klinikos', Vilnius, Lithuania.

Background
Body composition of females with polycystic ovary syndrome (PCOS) varies considerably. The literature lacks of skeleton size description in women with PCOS. Objective of the present study was to investigate skeleton robustness in PCOS women.
Material and methods
Hundred and one PCOS women (by androgen excess society criteria, mean age 26.85 ± 3.91 years) and 81 healthy control women (mean age 27.95 ± 3.65 years) were investigated in Vilnius city in 2009–2011. Height, body mass, seven longitudinal and ten transversal skeletal parameters were measured using standard anthropometric methods. 11 derivative indices including body mass index (BMI), frame index (FI), metric index (MI) and chest-to-pelvis ratio (ChPR) were calculated. Gonadotropins and androgens tests were carried out.
Results
Height did not differ between PCOS and controls. BMI of PCOS women was significantly higher compared to controls. PCOS women had longer trunk by 2.74 cm due to higher pelvis, 2.05 cm shorter arms and 1.90 cm shorter legs, wider shoulders (by 2.16 cm), chest (by 3.3 cm) and pelvis (by 1.81 cm), higher FI, MI and ChPR ($P < 0.01$). After the adjustment for BMI women with PCOS presented 0.67 cm wider chest, but 0.98 cm narrower pelvis, higher FI, MI and ChPR than healthy women ($P < 0.05$). 72.3% of women with PCOS had large frame size. 44.6% of PCOS women had picnomorphic somatotype, whereas 85.2% of the controls had leptomorphic somatotype. The study showed an inverse correlation between transversal skeletal measurements and luteinizing hormone, positive correlation between transversal skeletal measurements, FI, MI and free androgen index in women with PCOS. Area under ROC curve discriminating PCOS for FI was 0.830.
Conclusions
Women with PCOS have larger frame size, longer trunk, higher and narrower pelvis, shorter extremities in comparison to healthy women. Skeletal parameters may aid the identification of PCOS in women; frame index demonstrates the best PCOS predictive ability.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P948

**Quality of life and the frequency of anxiety and depression in women with PCOS**

K. Krepula, B. Bidzinska-Speichert, A. Lenarcik & U. Tworowska-Bardzinska
Wroclaw Medical University, Wroclaw, Poland.

Background
Polycystic ovary syndrome is the most common endocrine disorder among women in their reproductive years. Apart from reproductive and metabolic manifestations, recently more attention has been paid to psychological features of this syndrome. The aim of the study was to evaluate the effect of PCOS on quality of life and to estimate the frequency of anxiety and depression in Polish women with PCOS.
Methods
One hundred seventy five women with PCOS aged 16–44, diagnosed accordingly to the Rotterdam criteria, recruited from the Department of Endocrinology, Diabetology and Isotope Treatment, Wroclaw Medical University and Outpatient Endocrinological Department of Provincial Health Care Specialist Clinics in Wroclaw, Poland, completed two questionnaires: Polish versions of hospital anxiety and depression scale (HADS) and the World Health Organization's Quality of Life-BREF (WHOQOL-BREF). The control group consisted of 30 healthy women.
Results
PCOS patients reported the lowest QoL in the psychological health domain. Environment and social relationships domains were also lower. The overall quality of life was 3.64 ± 0.76 in the five-point Likert's scale. 36.3% showed clinically relevant HADS anxiety scores and 9.6% had clinically relevant HADS depression scores, 8.3% had comorbid anxiety and depression. Lack of anxiety was significantly related with the better QoL.
Conclusions
Polycystic ovary syndrome decreases quality of life. PCOS may also increase risk for anxiety or comorbid anxiety and depression.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P949

**Examination of the generation of vaginal epithelium of the new vagina formed using oxidized regenerated cellulose**

T. Nagata, H. Sakakibara, A. Kawano, Y. Oshima, T. Nakamura, T. Nakajima, T. Sato & F. Hirahara
Yokohama City University, Yokohama, Japan.

Purpose
For vaginoplasty of Rokitansky syndrome, we use oxidized regenerated cellulose instead of bio-craft that has been used in the past because it requires a less invasive and more physiological surgery. However, the mechanism of epithelialization of this procedure is still not clear. There is a report that differentiation and proliferation of the vaginal epithelium of newborn mice is promoted by administration of basic fibroblast growth factor (bFGF).
To characterize the epithelium of new vagina and to determine how it is formed, we examined the new vaginal epithelium for the presence of keratin, estrogen receptor α (ERα) and bFGF.
Methods
Four patients with Rokitnsky syndrome who underwent this operation were enrolled in this study. Patients' consent was obtained with the approval of the ethics committee.
Samples of vaginal epithelium were removed at the time of the operation, in the reproducing phase, and after completion of epithelialization. Samples of the vaginal epithelium and bdominal skin of patients who underwent total hysterectomy were also obtained as controls with their consent.
Immunostaining of ERα, keratin 13 and keratin 14 were performed using human monoclonal antibodies. Real-time PCR of four subtypes of fibroblast growth factor receptor (FGFR; FGFR-1, FGFR-2, FGFR-3, and FGFR-4) was also performed.
Results
Immunohistochemical staining revealed that keratin 13 and ERα were expressed in normal vagina and the new vagina, while keratin 14 was expressed only in the abdominal skin.
It appeared that the expression of FGFR-1, was markedly increased in the reproducing phase and decreased after the completion of vaginal epithelialization, while there were no significant changes in the other FGFR subtypes.
Conclusion
The characterization of the new vaginal epithelium with this surgery was demonstrated to be similar to that of normal vagina. Moreover, it was suggested that FGF may be an important growth factor which promotes new vaginal epithelialization.

**Efficacy of sex hormone replacement therapy on induction of puberty in patients with Turner syndrome**

A. Tokinaga[1], H. Sakakibara[1], H. Taniguchi[1], R. Kitayama[1], Y. Imai[1], S. Ohori[2], A. Yoshizaki[1], T. Nagata[1], T. Nakamura[1] & F. HIrahara[1]
[1]School of Medicine, Yokohama City University, Yokohama, Japan; [2]Kanagawa Children's Medical Center, Yokohama, Japan.

**Abstract**
Introduction
Since primary amenorrhea because of ovarian dysfunction is a common complication in women with Turner syndrome (TS), sex hormone replacement therapy (HRT) is mandatory for induction of puberty, such as acquisition of

secondary sexual characteristics and increased bone density. However, appropriate treatment protocols have not yet been established. To evaluate the efficacy of HRT on puberty induction in our department, a retrospective analysis was conducted.
Methods
The clinical profiles of 62 TS patients with primary amenorrhea and five patients with spontaneous cycles were examined with their consent. Uterine length (UL) was measured by an ultrasonic examination and bone mineral density (BMD) of the lumbar vertebrae (L2–4) was measured by DEXA. Student's *t*-test was used for statistical analyses.
Results
There were 48 patients who had received HRT and 14 patients who had not. The mean ($\pm$S.D.) age at first visit was 24.4$\pm$4.7 years and at initiation of HRT was 19.7$\pm$3.0 years. The mean height and BMI were 145.7$\pm$4.6 cm and 21.9$\pm$2.8 kg/m$^2$ respectively. At the time of the first visit, the UL of patients receiving HRT (45.2$\pm$10.1 mm: $n=36$) was significantly longer than that of patients without HRT (37.0$\pm$6.0 mm: $n=8$). The BMD of patients receiving HRT (0.810$\pm$0.087 g/cm$^2$: $n=47$) was significantly higher than that of patients without HRT (0.7129$\pm$0.090 g/cm$^2$: $n=14$). However, both were significantly lower than in the patients with spontaneous cycles (1.007$\pm$0.09 g/cm$^2$). After receiving HRT in our department, the UL ($n=44$) of the patients increased significantly from 43.7$\pm$9.7 to 55.2$\pm$4.6 mm and the BMD of the patients without HRT increased from 0.7172$\pm$0.117 to 0.7924$\pm$0.083 g/cm$^2$, while there were no significant changes in the BMD of the patients with HRT.
Conclusions
HRT was effective for acquisition of secondary sex characteristics and increased bone density. It is suggested that early initiation of HRT may be more effective.

### Different effects of electrical and manual acupuncture stimulation on estrous cyclicity and neuroendocrine function in rats with DHT-induced polycystic ovary syndrome

Y. Feng[1,2], J. Johansson[1], R. Shao[1], L. Manneråas Holm[1], H. Billig[1] & E. Stener-Victorin[1]
[1]Institute of Neuroscience and Physiology, Department of Physiology, Sahlgrenska Academy, Gothenburg, Sweden; [2]Department of Integrative Medicine and Neurobiology, Shanghai, China.

Both low-frequency electro-acupuncture (EA) and manual acupuncture improve menstrual frequency and decrease circulating androgens in women with polycystic ovary syndrome (PCOS). We sought to determine whether low-frequency EA is more effective than manual stimulation in regulating disturbed estrous cyclicity in rats with PCOS induced by 5$\alpha$-dihydrotestosterone (DHT). To identify the central mechanisms of the effects of stimulation, we assessed hypothalamic mRNA expression of molecules that regulate reproductive and neuroendocrine function. From age 70 days, rats received 2-Hz EA or manual stimulation of the needles five times/week for 4–5 weeks; untreated rats served as controls. Specific hypothalamic nuclei were obtained by laser microdissection, and mRNA expression was measured with TaqMan low-density arrays. Untreated rats were acyclic. During the last 2 weeks of treatment, seven of eight (88%) rats in the EA group had epithelial keratinocytes, demonstrating estrous cycle change ($P=0.034$ vs controls). In the manual group, five of nine (56%) rats had estrous cycle changes (NS vs controls). mRNA expression of the opioid receptors Oprk1 and Oprm1 in the hypothalamic arcuate nucleus was lower in the EA group than in untreated controls. mRNA expression of the steroid hormone receptors Esr2, Pgr, and Kiss1r was lower in the manual group than in the controls. In rats with DHT-induced PCOS, low-frequency EA restored disturbed estrous cyclicity but did not differ from manual stimulation group. Thus EA cannot be considered superior to manual stimulation. The effects of low-frequency EA may be mediated by central opioid receptors, while manual stimulation may involve regulation of steroid hormone/peptide receptors.
Declaration of interest
I fully declare a conflict of interest. Details below.

### The influence of endocannabinoid receptor 1 gene variations on anthropometric and metabolic parameters in women with polycystic ovary syndrome

A. Lenarcik, L. Laczmanski, M. Pawlak, A. Milewicz & B. Bidzinska-Speichert
Wroclaw Medical University, Wroclaw, Poland.

Introduction
Polycystic ovary syndrome (PCOS) is one of the most commonly diagnosed endocrinopathies in women of reproductive age and is associated with an increasing number of metabolic comorbidities. About 50% of PCOS patients are obese, while insulin resistance affect up to 70% of these women. The endocannabinoid system contributes to human energy homeostasis. CNR1 is a biological candidate for human obesity and related metabolic disorders.
Aims
The aim of the study was to determine the relationships between CNR1 polymorphisms (A4895G (rs806368); A1422G (rs1049353); rs806381; rs10485170; rs6454674; rs2023239) and anthropometric and metabolic parameters in PCOS women.
Material and methods
In total, 130 women diagnosed with PCOS according to the Rotterdam criteria are recruited from the Endocrinology Department of the Medical University in Wroclaw, Poland. Medical history, physical examination, assessment of anthropometric parameters (body mass, height, waist and hip circumference,

BMI, WHR), metabolic parameters (glucose and insulin, insulin resistance index – HOMA, lipidogram) were carried out in all subjects. Genetic studies to detect six CNR1 gene polymorphisms were assessed. In order to amplify the genetic material the PCR technique was used. To polymorphisms identification minisequencing was used. Reaction products were separated on Genetic Analyser ABI 3100. For statistical analysis ANOVA test was used.
Results
The total cholesterol and LDL cholesterol levels in PCOS women carrying T/T genotype of rs2023239 CNR1 polymorphism were higher than in those with C/T and C/C ($P=0.02807$). There were no statistic differences in other metabolic parameters (glucose, insulin and HOMA levels) and also in value of BMI and WHR between the variants of rs2023239 CNR1 polymorphism. The other of studied polymorphisms of CNR1 gene were not associated with anthropometric and metabolic parameters in PCOS women.
Summary
On the basis of our study, it seems to CNR1 polymorphisms were not associated with obesity and metabolic disorders, including insulin resistance, in PCOS women.
Declaration of interest

**Androgens profile in Cushing's disease with hirsutism**

E. Haouat, L. Ben Salem, I. Kamoun, N. Zrig, Z. Turki & C. Ben Slama
National Institute of Nutrition, Tunis, Tunisia.

Introduction
Cushing's disease (CD) is a condition due to an ACTH-secreting pituitary adenoma and leading to hypercorticism. Hirsutism is common in CD but its exact frequency has been poorly studied. It results from the stimulating effect of ACTH on adrenal production of androgens.
The aim of this study is to determine the androgenic profile in hirsute patients with CD.
Patients and methods
It is a retrospective study of nine female patients having a CD with hirsutism. Positive diagnosis of CD was made in the association of an ACTH-dependant hypercorticism, with a positive response to the high-dose-dexamethasone-suppressing test, and a pituitary adenoma on MRI.
Testosterone and DHEAS assays were carried out in all patients and δ-4-androstenedione assay was performed in five of them.
Results
Mean age at diagnosis was 32 (ext: 24–45). Hirsutism was severe in at least three patients. Menstrual irregularities were present in six of the nine patients and minor signs of hyperandrogenia (seborrhoea, acne) in two of them. Pituitary adenoma was a macroadenoma in 5/9 cases. ACTH was elevated in all patients with a mean ACTH value at 113.4 pg/ml (ext: 65–184). Mean values of testosterone, DHEAS and δ-4-androstenedione were respectively: 2.56 nmol/l (ext:1.4–3.3), 461 ng/ml (ext: 125–821) and 348 ng/ml (ext: 219–487). Six patients had a concomitant elevation of at least two androgens. Both testosterone and DHEAS were elevated in these six patients and δ-4-androstenedione was elevated in three of them. Only one patient had normal rates of testosterone and DHEAS.
Conclusion
Androgens are almost consistently mildly elevated in patients with CD and hirsutism. All hirsute patients with CD have an elevated ACTH, the majority of them has a pituitary macroadenoma. Further studies comparing these parameters in a larger cohort of patients having a CD, with and without hirsutism and hyperandrogenia, would be more conclusive.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P954

**Action of elevated leptin levels on steroidogenic enzymes expression in porcine small and medium size follicles collected from prepubertal and cycling pig**

E. Gregoraszczuk & A. Rak-Mardyla
Jagiellonian Univeristy in Krakow, Krakow, Poland.

Cystic ovarian disease is a common reproductive disorder in women and females of domestic animals, leading to temporal or permanent infertility. Over one in three women with polycystic ovarian syndrome (PCOS) are overweight and have higher serum leptin concentration. Leptin may thereby mediate some of the adverse effect of obesity on ovarian function.
In the presented data, we decided to compare the action of two high doses of leptin (20 ng and 40 ng/ml) on progesterone ($P_4$), androstenedione ($A_4$), testosterone (T) and estradiol ($E_2$) secretion by small- and medium-sized follicles collected from pubertal and cycling pig. Taking into consideration previously published data reported that alterations in the content of steroid hormones in the cystic ovaries of swine was accompanied by changes in the expression and cellular distribution pattern of steroidogenic enzymes we evaluated action of leptin on CYP11A1, CYP17, 17β-HSD and CYP19 protein expression by western blot. During prepubertal time, leptin in both doses had no effect on steroids secretion by medium-size follicles, why increased $P_4$ and testosterone secretion with concomitant decrease in $A_4$ secretion and no effect on $E_2$ secretion by small size follicles. It was accompanied by increasing the expression of CYP11A1 in both size of follicles and 17 β-HSD in small follicles. In cycling animals, increase in $P_4$ and testosterone secretion with concomitant decrease in $A_4$ secretion and no effect on $E_2$ secretion by small and medium size follicles was noted. It was accompanied by increasing the expression of CYP11A1 and 17 β-HSD in both size of follicles.
These results suggested that leptin by action on above-mentioned enzymes, and influencing the ovarian steroid synthesis, may play an essential role in the creation and/or course of cystic ovarian disease both in prepubertal and regular cycling animals.

**The role and mechanisms of action of leptin in control of ovarian functions**

A. Sirotkin
Animal Production Research Centre Nitra, Luzianky, Slovakia.

The results concerning the role of leptin in mediating effect of food restriction on ovarian functions, in controlling these functions, as well as the endocrine and intracellular mechanisms of leptin action are reviewed.
In our experiments, food restriction resulted in a reduction in rabbit and chicken plasma leptin, GH, IGF1 and gonadal steroid hormone levels and ovulation rate. Malnutrition (serum deprivation) inhibited hormone release and the expression of proliferation- and apoptosis-related substances (PCNA, cyclin B1, bax, bcl-2, ASK-1, MAP kinase, protein kinase A, CDC2 kinase, transcription factors p53, CREB1, STAT-1 and NFkB) and promoted the accumulation of heat shock proteins mRNA in cultured rabbit, human, porcine and chicken ovarian cells. Administration of leptin or IGF1 both *in vivo* and *in vitro* altered hormone release and the expression of these proliferation- and apoptosis-related substances, oocyte maturation, response of ovarian cells to gonadotropin and other hormones, and prevented effect of malnutrition. Immunoneutralisation of IGF-I reversed the effects of leptin on the secretory activity of human granulosa cells. Inhibitors of protein kinases PKA, MAPK and CDC2, as well as the transfection of ovarian cells with cDNA constructs encoding ASK-1, p53, STAT-1 and CREB-1 were able to affect ovarian functions listed above, as well as to promote or prevent effects of leptin and IGF1.
The present data suggest that leptin/IGF1 axis plays an important role in control of ovarian functions in mammals and birds. It is proposed, that food restriction can control reproductive functions via changes in leptin output, which in turn, through IGF1, protein kinases, transcription factors and heat shock proteins, can affect ovarian cell proliferation, apoptosis, secretory activity, response to hormonal stimulators and fecundity.

**What is the earliest predictor of atherosclerosis in normal weight polycystic ovary syndrome; carotid intima media thickness or visceral fat ratio?**

F. Besir, H. Yildirim, S. Yazgan, R. Buyukkaya, S. Kose, A. Karatas, B. Erdogmus & Y. Aydin
Duzce University Medicine School, Duzce, Turkey.

Purpose
The aim of this study in new diagnosed adult women with polycystic ovary syndrome (PCOS) was to evaluate carotid intima media thickness (CIMT) and visceral fat thickness (VFT) measurement by ultrasonography and which method can be used for atherosclerosis risk follow-up.
Methods
A case-control study was conducted on 22 PCOS women (18–30 years of age) and 22 controls. BMI was matched volunteer controls. Two different criteria were used to assess atherosclerosis risk. CIMT and VFT were measured by ultrasonography. In addition, visceral fat ratio (VFR) was calculated. The variables were compared using the $\chi^2$ test and Mann–Whitney $U$ test.
Results
In PCOS women, impaired lipid profiles were not determined. Also, the mean CIMT and VFT were no significantly higher in PCOS subjects. But, VFR was significantly higher in PCOS women ($1.21 \pm 0.33\%$) compared to controls ($0.85 \pm 0.3\%$, $P = 0.001$).
Conclusions
These findings indicate that CIMT which used early diagnosing of atherosclerosis have not increase in newly diagnosed PCOS women. In the other hand, VFR is increasing in newly diagnosed PCOS women. So, VFR can be used for diagnosis and follow-up of suspicions atherosclerosis as an early diagnostic method.
Keywords: Polycystic ovary syndrome (PCOS), atherosclerosis, carotid intima media thickness (CIMT), visceral fat thickness (VFT), visceral fat ratio (VFR).
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P957

**Prevalence of hyperandrogenism, polycystic ovary syndrome and metabolic syndrome in female-to-male transsexuals**

A. Becerra Fernandez[1], R. Villar[2], G. Perez Lopez[3] & M. Menacho Roman[1]
[1]Hospital Universitario Ramon y Cajal, Madrid, Spain; [2]Hospital Universitario de Fuenlabrada, Madrid, Spain; [3]Hospital Comarcal de Melilla, Melilla, Spain.

Introduction
Gender identity disorder (GID) is a disagreement between biological sexual differentiation and self-declared gender identity. The aetiology of GID remains unclear, although endocrinological, neuroanatomical and psychosocial factors are all thought to be causally involved. Polycystic ovary syndrome (PCOS) is characterized by chronic anovulation, polycystic ovarian morphology, and biochemical and/or biological signs of hyperandrogenism. Most women with PCOS also exhibit insulin resistance and hyperinsulinaemia, which is independent of obesity. Several studies have found a high prevalence of PCOS in FTM patients. In addition, it has been suggested that hyperandrogenism could be related to the development of GID in male transsexuals
Objectives
To determine the prevalence of hyperandrogenism, polycystic ovary syndrome (PCOS) and metabolic syndrome (MS) in female-to-male transsexuals (FMT).
Design and methods
In total, 77 FMT were assessed clinically and biochemically to hyperandrogenism, before the beginning of the treatment with testosterone. We also assessed cardiovascular risk factors and other parameters of MS.
Results
About 26.0% of the sample had overweight, and 19.5% were obese patients. The prevalence of hyperandrogenism was 49.35% and those of PCOS was 36.4%, and 51.9% of patients had MS.
By adjusting the parameters of MS and PCOS, for the body mass index (BMI), we observed that the higher BMI, regardless of the concentrations of free testosterone (FT), increases insulin resistance (HOMA-IR 2.43 vs 2.93 vs 3.85, $P < 0.001$). Of all patients, 27.3% had HDL-cholesterol below 50 mg/dl.
Conclusions
The general hyperandrogenism, and PCOS in particular, are highly prevalent in FMT. The high prevalence of PCOS appears to be related to body weight.
The hyperandrogenism is associated with the development of MS, and other factors such as insulin resistance and decreased HDL-C, which globally increase the cardiovascular risk. These data suggest that gender dysphoria, at least in FMT, could be related to hyperandrogenism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P958

**Examination of the role of gynecologists in the management of patients with disorders of sex development**

H. Sakakibara, K. Imai, T. Hyama, T. Nagata, T. Nakamura & F. Hirahara
Yokohama City University, Yokohama, Japan.

Purpose
Disorders of sex development (DSD) are defined as having, 'A chromosome, germinal gland, or anatomical structure that is atypical in the native state'. There are two types of patients with DSD who consult a gynecologist: patients diagnosed in childhood (group A), and patients diagnosed based on unusual secondary sex characteristics in adolescence (group B). In group A, gynecologists are required as a member of a multidisciplinary medical team for DSD. On the other hand, in B group they should take the initiative in the diagnosis, treatment, and follow-up for unusual presentations of secondary sex characteristics. To examine the status of the management of DSD patients, a retrospective analysis was conducted.
Methods
In total, 106 patients with DSD who consulted in our department were enrolled in this study with their consent. Clinical data were extracted from their medical records.
Results
There were 53 patients (50%) in group A, most of whom (45 patients, 84.9%) had Turner syndrome and who were referred by pediatricians for hormone replacement therapy (HRT). There were 53 patients (50%) in group B, of whom 15 patients had an abnormality of the uterus and vagina, ten had Rokitansky syndrome, and eight had androgen insensitivity syndrome. All patients in group B were referred by gynecologists in other hospitals for diagnosis, medical treatment, and follow-up of primary amenorrhea. HRT was administered to most patients in group A while surgical treatments, such as removal of vaginal septum, vaginoplasty or prophylactic gonadectomy were performed.
Conclusion
In our department, the percentage of DSD patients diagnosed in childhood and in adolescence were the same (50%). It was demonstrated that management based on the individual anatomical or functional abnormality was important. DSD patients also require reproductive care, such as management of ovarian function and fecundity by gynecologists throughout their life.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P959

**Polycystic ovary syndrome, hyperprolactinemia, hyperinsulinemia and congenital adrenal hyperplasia**

J. Suárez-Ledó
Hospital de León (Sacyl) Ambulatorio Condesa, León, Spain.

Objective
To research the frequencies of HPRL, HI and CAH in PCOS, as well deducing their significance.
Material and methods
For five years, 96 patients and their clinical histories were examined by the author, as each patient was visited.
HI was proven by 3 h OGGT, testing glucose and insulin simultaneously, ovarian ultrasonography, testosterone, androstenedione, DHEA, 17-hydoxyprogesterone, PRL and LH/FSH were also investigated.
The percentages and the confidence intervals (IC) were calculated with $P < 0.05$.
Results
Percentages: HPRL in PCOS: 52.08% (50/96); CI = (0.393–0.602). All cases with HI: 78.12% (75/96); CI = (0.6732–0.8502). All cases with CAH: 34.3575% (33/96); CI = (0.26–0.4596). Only HI: 29% (28/96); CI = (0.2042–0.3994). Only HPRL: 5.2% (5/96); CI = (0.0168–0.1178). Only CAH: 7.29% (7/96); CI = (0.0302–0.145). HPRL + HI + CAH: 16.66% (16/96); CI = (0.0984–0.2574). HPRL + HI: 26.04% (25/96); CI = (0.1766–0.361). HPRL + CAH: 4.166% (4/96) ; CI = (0.0114–0.1034). HI + CAH: 6.25% (6/96); CI = (0.0232–0.1316). None of these three: 5.2% (5/96); CI = (0.0168–0.1178).
Thus HPRL is very common in PCOS
These findings are basically coincidental with other authors. We can deduce PCOS may be the offspring of a complex aetiology: HI, CAH and HPRL, separately or jointly, all cause hyperandrogenemia by different pathways, although there is another group with none of these three causes. Recently, another cause: stress, was proven in rats; this was neutralized by cutting the ovarian nerves. Is this similar in human females?
Conclusion
PCOS is most frequently caused by HI, but other aetiologies are possible, among them CAH and HPRL. All three can be found together or separately; furthermore, stress may be another cause in some patients. Hyperprolactinemia is very common, appearing in around 52.08%, IC = 39.3–60.2%.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P960

**The future of HRT**

J. Suárez-Ledó
Hospital de León (Sacyl) Ambulatorio Condesa, León, Spain.

Objective
This work sets forth the current status and perspectives of HRT.
Material and methods
In total, 547 medical works dealing with this subject are evaluated.
Results
The beneficial effect of estrogens on the lipids, as well as the antagonistic influence of progestogens, have long been known.
After MWS, HERS and WHI, the beneficial effects on several organs – the arterial system included – have been confirmed. Currently, it is clear that the sooner HRT is established, the better.
The ASRM have recently published a matched 10 000/10 000 study reporting Alzheimer diminishment by 34% and only an eight case (41/33) increase in breast cancer diagnoses. This small increase is related by several works to continuous, but not cyclic, therapy and does not exist in Japanese women; this is thus attributed to a western life style. Tobacco tar was once blamed for this increase, because it yields alquilestrogens in the first passage of estrogens through the liver; percutaneous administration of estradiol prevents this increase in breast cancer frequency and also thromboenbolism peril.
In addition, when HRT is given in cycles, using bio-identical hormones, the carcinogenic effect is non-existent; continuous dosage stimulates breast and PRL secretion, the contribution of which latter to breast cancer growth is now well known.
Presently, lung cancer is attributed to HRT; this is surprising because the lung is not a hormonal target organ, but estrogen receptors were reported by these authors to be found in the lung.
Male HRT is commended by most authors, however, PSA, prostate size, and red blood cells must be controlled.
Conclusion
The cyclic therapy with bio-identical hormones via the skin might be the future of HRT, because it is the safest method and permits longer use of the HRT, solving the problems of breast cancer increase and thromboembolism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P961

**Plasma adiponectin levels in women with polycystic ovary syndrome: impact of metformin treatment in a case–control study**

S. Singh, N. Akhtar & J. Ahmad
Aligarh Muslim University, Aligarh, India.

Objective
An interaction between adiponectin, steroid synthesis or action and measures of insulin resistance (IR) have been reported in the pathogenesis of polycystic ovary syndrome (PCOS). The present study was done to determine plasma adiponectin concentration (PAC) in women with and without PCOS and to assess its correlation to the hormonal and metabolic parameters including measures of IR. The effect of metformin for 6 months in PCOS was also evaluated.
Patients
In total, 72 selected women were classified as follows: 17 obese (body mass index (BMI)) $>25$ kg/m$^2$ with PCOS; 19 normal weight (BMI 18–22.9 kg/m$^2$ with PCOS; 17 obese BMI $>25$ kg/m$^2$ without PCOS and 19 normal weight (BMI) 18–22.9 kg/m$^2$ without PCOS.
Interventions
Blood samples were collected from all women with PCOS between 0800 and 1100 h, after an overnight fast.
Main outcome measures
Serum level of LH, FSH, TSH, total $T_4$, testerosterone, 17-$\alpha$-hydroxyprogesterone (17OHP), DHEAS, insulin, adiponectin and glucose. Measures of IR included fasting serum insulin (FSI), glucose-to-insulin ratio, and homeostasis model assessment (HOMA).
Result
Waist-hip ratio (WHR), insulin, and HOMA index were significantly higher in the lower adiponectin group than in the higher adiponectin group. By using stepwise multiple regression analysis, in model 1 (including BMI, FSI, fasting plasma glucose (FPG) with other variables such serum as testerosterone and DHEAS), the weight and contributions from other variables, namely FSI and FPG were significant independent determinants of fasting PAC (adjusted $r^2 = 0.66$); and in model 2 (including BMI, HOMA, FPG only as an index of IR with other variables such as serum testerosterone, DHEAS), BMI, HOMA, were significant independent determinants of fasting PAC (adjusted $r^2 = 0.59$). FPG, HOMA Index and FSI were significantly lower after metformin treatment in both obese and non-obese PCOS while adiponectin levels increased significantly.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P962

**Impaired beta cell function in Chinese women with polycystic ovary syndrome**

T. Tao[1], S. Li[1], W. Liu[1], A. Zhao[1] & G. Ning[2]
[1]Renji Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China; [2]Shanghai Clinical Center for Endocrine and Metabolic Diseases, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai, China.

Objective
The role of pancreatic insulin secretion in Chinese women with polycystic ovary syndrome (PCOS) is not clear. To evaluate insulin sensitivity (IS) and β-cell function in lean and obese women with PCOS, either separately or by using an disposition index (DI).

Methods
Cross-sectional study involving 137 Chinese women with PCOS and 123 normal women were examined by anthropometry, lipid profile, sex hormone, high-sensitivity C-reactive protein, oral glucose tolerance tests (OGTTs), and insulin tolerance tests. Statistical analysis used one-way ANOVA, Kruskal–Wallis, and Mann–Whitney *U* tests, as appropriate.
Results
After controlling for BMI status, the Matsuda index was significantly lower in women with PCOS in comparison to those of normal women ($P<0.01$). With regard to the insulin resistance in the homeostasis model it was found that the assessment index was significantly higher in women with PCOS in comparison to those of normal woman ($P<0.001$). On the other hand, early phase insulin secretion (insulinogenic index) remained significantly lower in lean women with PCOS than those of both lean and obese women of the control group ($P=0.007$, and $P=0.10$ respectively). The mean Log HOMA-F values were significantly lower ($P=0.045$) in obese women with PCOS than those with BMI-marked women. Further, all disposition indexes (DIs) derived from non-fasting state indexes in women with PCOS were significantly lower than those of BMI- and WHR-matched control women ($P<0.001$ for all). Lastly, DIs derived from fasting states indexes in obese women with PCOS were significantly lower than those of lean women with PCOS.
Conclusion
Impaired β-cell function was detected in both the lean and obese women with PCOS. However, more serious primary defect in insulin action was observed in lean women with PCOS compared to obese women with PCOS. These findings imply that early screening and intervention for PCOS could be therapeutic for Chinese women.

### Epicardial adipose tissue thickness in patients with polycystic ovary syndrome

A. Aydogdu[1], G. Uckaya[1], I. Tasci[1], O. Baysan[1], S. Tapan[1], B. Bugan[1], M. Serdar[1], S. Aydogdu[2], H. Akbulut[1], U. Aydogan[1], A. Sonmez[1] & O. Azal[1]
[1]Gulhane School of Medicine, Ankara, Turkey; [2]Mevki Military Hospital, Ankara, Turkey.

EAT has been linked to the presence and severity of cardiovascular disease. EAT has been linked to the presence and severity of cardiovascular disease. We searched if the patients with PCOS have increased EATT, or not.
Total of 41 subjects with PCOS and 46 age and body mass index (BMI) matched healthy controls were enrolled. EAT was measured by echocardiography.
EATT and HOMA-IR score were significantly higher ($P=0.0001$ for both) while plasma adiponectin concentration was significantly lower ($P=0.048$) in PCOS patients. EATT correlated positively with total cholesterol, triglyceride, insulin, LH, LH/ FSH, HOMA-IR score and negatively with SHBG ($P<0.05$ for all), whereas it displayed no correlation to plasma adiponectin level ($P=0.924$). Triglyceride level and LH/FSH ratio were the significant determinants of EATT in logistic regression analysis ($P=0.0001$, $P=0.024$ respectively).

**Table 1** Anthropometrics and basic laboratory results of patients with PCOS and healthy controls.

| Parameter | PCOS subjects ($n=41$) | Controls ($n=46$) | *P* value |
|---|---|---|---|
| Age (year) | 20.9±3.2 | 21.3±3.0 | 0.159 |
| BMI (kg/m$^2$) | 23.6±4.3 | 22.4±2.6 | 0.138 |
| Waist-to-hip ratio | 0.7±0.0.4 | 0.7±0.04 | 0.923 |
| Fasting plasma glucose (mg/dl) | 87.3±8.1 | 82.2±6.4 | 0.002 |
| Total cholesterol (mg/dl) | 162.1±38.7 | 159.7±32.6 | 0.947 |
| HDL-cholesterol (mg/dl) | 50.0±11.7 | 53.8±9.7 | 0.102 |
| LDL- cholesterol (mg/dl) | 90.7±28.5 | 93.0±27.7 | 0.710 |
| Triglyceride (mg/dl) | 105.7±71.7 | 64.1±21.2 | 0.002 |
| LH (mIU/ml) | 7.4±4.8 | 5.3±3.1 | 0.016 |
| FSH (mIU/ml) | 4.9±1.9 | 5.5±1.6 | 0.151 |
| Total testosterone (ng/dl) | 63.1±28.8 | 43.4±15.6 | 0.0001 |
| SHBG (nmol/l) | 32.9±16.8 | 59.8±26.3 | 0.001 |
| DHEA-S (μg/dl) | 345.0±135.0 | 283.5±95.1 | 0.018 |
| LH/FSH | 1.6±1.0 | 1.0±0.6 | 0.002 |
| HOMA-IR value | 2.2±1.2 | 1.3±0.5 | 0.0001 |
| Insulin (mIU/ml) | 10.3±5.1 | 6.5±2.2 | 0.0001 |
| Adiponectin (μg/ml) | 10.0±3.7 | 12.5±6.1 | 0.048 |
| EAT thickness (mm) | 4.4±1.5 | 3.2±1.1 | 0.0001 |

BMI, body mass index; HDL, high density lipoprotein; LDL, low high density lipoprotein; SHBG, sex hormone binding globulin; HOMA-IR, homeostasis model assessment of insulin resistance; EAT, epicardial adipose tissue.

EATT is increased in patients with PCOS and may be an effective tool to determine those PCOS subjects at the risk of cardiovascular events.

### High plasma level of long pentraxin 3 is associated with insulin resistance in women with polycystic ovary syndrome

A. Aydogdu[1], I. Tasci[1], S. Tapan[1], Y. Basaran[1], U. Aydogan[1], C. Meric[1], A. Sonmez[1], S. Aydogdu[2], H. Akbulut[1], A. Taslipinar[1], C. Haymana[1], G. Uckaya[1] & O. Azal[1]
[1]Gulhane School of Medicine, Ankara, Turkey; [2]Mevki Military Hospital, Ankara, Turkey.

PCOS is characterized by insulin resistance. Inflammation has been anticipated to play role in the pathogenesis of both insulin resistance and atherosclerosis. Pentraxin 3 (PTX3) is an inflammatory mediator synthesized in a variety of cells and tissues. In the present study, serum PTX3 level and its relationship with insulin resistance were investigated in patients with PCOS. In total, 40 patients with PCOS and 40 age and body mass index (BMI) matched healthy controls were enrolled in the study. Plasma levels of PTX3, hs-CRP and HOMA-IR scores were all significantly higher ($P=0.021$, $P=0.002$, and $P=0.0001$ respectively) in women with PCOS compared to healthy controls. Blood PTX3 level correlated positively with hs-CRP, BMI, waist-to-hip ratio, HOMA-IR, and negatively with high-density lipoprotein cholesterol level ($P<0.05$, for all). After adjustment for age and BMI, PTX3, total testosterone levels and BMI remained as independent predictors of HOMA-IR scores ($P<0.05$, for all). PTX3 level is increased in patients with PCOS in concordance with insulin resistance.
Declaration of interest
I fully declare a conflict of interest. Details below:

### Sertoli cells ovarian tumor- an ovarian incidentaloma?

C. Poiana[1,2], M. Carsote[1], R. Trifanescu[1,2], C. Ene[2], C. Neamtu[2], C. Iosif[3] & D. Terzea[1,2,3]
[1]UMPh Davila, Bucharest, Romania; [2]I.Parhon, Bucharest, Romania; [3]I.Babes, Bucharest, Romania.

Introduction
Infertility investigations include uterine–ovarian ultrasound. The incidental finding of a tumor in a young female might associate a potential severe prognosis in otherwise completely asymptomatic patient.

Aim
We present a case of a young female with an accidentally discovered ovarian tumor.
Case report
S.M. 35-year female patient is admitted for infertility. Her family and personal medical history is irrelevant. The biochemistry and endocrine profile is normal, including plasma testosterone, LH, FSH, TSH and 21-day plasma progesterone of 11.7 ng/ml. The pelvic ultrasound pointed a uterus of 39 by 39 mm, normal right ovary and a hypoecogen solid tumor of 31 by 30 mm with penetrating vessels at the level of the left ovary. The pelvic CT showed a left ovarian, homogenous, well shaped, iodophile tumor of 29 by 27 by 32 mm, and no lymph nodes. Left ovarectomy was performed and the pathological report showed a Sertoli cells (annular tubes variant). The immunohistochemistry revealed a ki67 of 1–3%, positive ck7 and vimentin into the tumor cells and negative CROMO, CEA, ck20, inhibin, 34βE12 and positive actin into the stroma but not into the tumor. The benign profile of the tumor did not make necessary any additional therapy, except for follow up. For the moment, no fertility procedures are indicated.
Conclusion
Practitioners should be aware of the possibility that an ovarian incidentaloma might be associated with fertility issues.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Clinical, hormonal and metabolic profile in overweight and obese women with polycystic ovary syndrome**

L. Leustean, C. Preda[1], S. Fica[2], M. Ungureanu[1], C. Cristea[1], D. Ungureanu[1], V. Mogos[1] & C. Vulpoi[1]
[1]University of Medicine and Pharmacy 'Gr. T. Popa', iasi, Romania;
[2]University of Medicine and Pharmacy 'Carol Davila', Bucharest, Romania.

Polycystic ovary syndrome (PCOS) is a heterogeneous condition affecting 5–10% of reproductive -age female population.
The aim of this study was to determine the clinical features, metabolic and hormonal profile in obese and overweight women with PCOS.
Patients and method
A total of 102 women (age 31.28 ± 6.05 and BMI 33.02 ± 5.93) with PCOS and 110 (age 32.35 ± 4.96 and BMI 33.05 ± 5.87) matched controls were investigated. In all patients the basal glucose, oral glucose tolerance test, cholesterol (total, HDL, LDL), triglycerides, testosterone, FSH and LH were determined in the follicular phase of the menstrual cycle. Also, the blood pressure, presence of acanthosis nigricans and smoking were recorded in both groups.
Results
PCOS patients compared with controls had increased levels of: total cholesterol (214 ± 40.08 mg/dl PCOS vs 206.61 ± 38.72 mg/dl non-PCOS $P < 0.05$), 2 h OGTT glucose (122.21 ± 36 mg/dl PCOS vs 112.06 ± 24.30 mg/dl non-PCOS $P < 0.05$), LH (8.37 ± 4.56 mUI/ml PCOS vs 4.14 ± 2.84 mUI/ml non-PCOS $P < 0.001$), testosterone (1.65 ± 1.14 ng/dl PCOS vs 0.34 ± 0.32 ng/ml non-PCOS $P < 0.001$). A significant difference existed also for high blood pressure (20% PCOS vs 13% non-PCOS $P < 0.05$) and acanthosis nigricans (16% PCOS vs 5% non-PCOS $P < 0.001$). No difference was mentioned regarding smoking between the PCOS and non-PCOS groups.
Conclusions
Comparing the two groups there is a significant difference regarding the incidence of hypertension and achantosis nigricans. Even the values of total cholesterol and 2 h OGTT glucose are in the normal range, the differences between are statistical significant pointing out the necessity of screening for glucose intolerance and cardiovascular risk factors in all PCOS patients.
Declaration of interest

**Serum 17β-estradiol concentration and depression symptoms presence in climacteric women**

R. Slopien, M. Maciejewska & A. Warenik-Szymankiewicz
University of Medical Sciences, Poznan, Poland.

We studied 74 women admitted to the Department of Gynecological Endocrinology University of Medical Sciences of Poznan because of climacteric symptoms. All the studied women were older than 40 years of age, all were still menstruating or had their last menstruation not later than 1 year ago.
The aim of the study was evaluation of possible relationship between serum 17β-estradiol concentration and depression symptoms presence in climacteric women.
We evaluated climacteric syndrome severity with the use of Kupperman index, the severity of depression symptoms with the use of Hamilton scale, serum FSH, LH and 17β-estradiol concentration with the use of immunoenzymatic assay.
The mean value of Kupperman index in the study group was 27 points (S.D. ± 14 points), the mean value of Hamilton scale was 12 points (S.D ± 6 points). The mean serum FSH concentration was 53.2 IU/l (S.D ± 41.8 IU/l), the mean serum LH concentration was 33 IU/l (S.D ± 22.4 IU/l) and the mean 17β-estradiol serum concentration was 87.9 pg/ml (S.D ± 123.3 pg/ml). Among the depression symptoms included in the Hamilton scale we found statistically relevant differences in 17β-estradiol concentration in relation to sleep disturbances, lack of interest and psychic symptoms of fear and restlessness (all Mann–Whitney $U$ test $P < 0.05$).
We concluded that 17β-estradiol plays an important role in the etiology of depression symptoms in climacteric women.

**Assessment of insulin resistance and carotid intima media thickness, cardiovascular risk factors in PCOS with normal OGTT**

I. Yildir, F. Kutluturk, T. Tasliyurt & B. Yelken
Gaziosmanpasa University Faculty of Medicine, Tokat, Turkey.

The patients with polycystic ovary syndrome (PCOS) are at increased risk for insulin resistance, central obesity, dyslipidemia and hypertension. In our study, we aimed to detect whether women with PCOS who had normal OGTT results have had insulin resistance. Moreover we investigated the association of probable insulin resistance with cardiovascular risk indicators such as hs-CRP and carotid intima media thickness (CIMT).
In total, 34 untreated PCOS patients (mean age 24.06 ± 5.20 years) who had normal oral glucose tolerance test were included in our study. The control group was comprised of 20 healthy subjects with concordant age and BMI values with patient group. Exclusion criteria were the following: use of any drug (such as oral contraceptive, glucocorticoids, antiandrogens, anti-hypertensive drugs), history of diabetes mellitus, hypertension, anaemia, renal disease, liver disease, and systemic illness. Complete blood count, fasting blood glucose, hs-CRP, fasting insulin and hormone profile analyses were performed in patient and control groups. The HOMA-IR index was calculated in both groups. In this study, insulin resistance was determined in 22 (58%) patients with PCOS and normal OGTT results. Elevated hs-CRP levels and increased CIMT were determined in the patients with PCOS who had insulin resistance but the difference was not statistically significant. The hs-CRP levels were significantly higher in the patient group than control group ($P < 0.05$). A strong positive correlation between BMI and hs-CRP levels, CIMT was found in the patients ($P = 0.009$ and $P = 0.006$ respectively).
In conclusion, we suggested that there is a close relationship between PCOS and insulin resistance and cardiovascular morbidity even if OGTT results are normal.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P969

**Relation of hyperandrogenism and metabolic derangements in women with polycystic ovary syndrome**

T. Bogavac[1], D. Macut[1], I. Bozic[1], J. Bjekic-Macut[2], B. Popovic[1], M. Petakov[1], S. Ognjanovic[1], T. Isailovic[1], V. Elezovic[1] & S. Damjanovic[1]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Cinical Center of Serbia, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [2]Clinical-Hospital Center 'Bezanijska kosa', Belgrade, Serbia.

Introduction
Polycystic ovary syndrome (PCOS) is associated with a higher risk for development of metabolic syndrome. In this study, we evaluated the degree of metabolic disorders in women with different PCOS phenotypes.
Methods
We analyzed 162 women with PCOS (BMI: 24.9±6.1 kg/m$^2$, age:25.6±5.6 years) diagnosed on the basis of ESHRE/ASRM criteria, and 39 women without PCOS who comprised the control group (CG; BMI: 21.4±4.1 kg/m$^2$, age: 28.4 ±5.4 years). Women with PCOS were divided into three subgroups according to the presence of hyperandrogenism (HA): A – with biochemical HA ($n=97$), B – with clinical HA ($n=28$), and C – without clinical or biochemical HA ($n=37$). In all subjects basal blood samples were collected in follicular phase of menstrual cycle for determination of glucose, insulin, total cholesterol (TC), HDL, LDL, triglycerides, apolipoproteins (Apo) A1, A2, B and E, lipoprotein (a), C-reactive protein (CRP), testosterone and SHBG. We used the standard formula to calculate HOMA, FAI, and lipid ratios TC/HDL, LDL/HDL, triglycerides/HDL, ApoB/ApoA1. PCOS and CG differed ($P<0.01$) in age and body mass index (BMI), and the calculations were done with the correction for these parameters.
Results
In PCOS subgroups, significant difference was found in concentrations of Apo A1 ($P=0.017$) due to the difference between subgroups A and C (1.49±0.24 vs 1.72±0.32 g/l). PCOS subgroup A had significantly higher ($P<0.001$) FAI index compared to subgroup B and C (A: 14.4±11.0%, B: 4.3±1.0%, C: 4.3±1.4%). FAI and ApoA1 had significant positive correlation ($\rho=-0.32$, $P<0.01$).
Conclusion
Women with hyperandrogenic PCOS phenotype have a significantly lower value of favorable ApoA1 in comparison to the PCOS phenotype without hyperandrogenism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding

## P970

**Micronized progesterone: a beneficial new modality of treatment for Egyptian patients with hyperemesis gravidarum**

M. Aboul-Seoud, A. Shams El-Din, M. Elabd, A. Abdel-Rahman & M. Zaitoun
Faculty of Medicine, Alexandria University, Alexandria, Egypt.

Aim
Progesterone is thought to be associated with hyperemesis gravidarum (HG). Pregnancies in which progesterone is administered for luteal phase support do not exhibit an increased incidence of HG, suggesting that high progesterone levels alone do not cause HG. The aim of the present study was to evaluate the therapeutic role of progesterone therapy as a new modality in the management of hyperemesis.
Subjects
In total, 40 Egyptian women below 40 years of age, pregnant 20 weeks with no preconception history of any other medical illnesses. They were randomly subdivided into: Group I: 20 patients managed by i.v. fluids and micronized progesterone 300–400 mg vaginally/day for 2 weeks. Group II: 20 pregnant women who received the traditional lines of treatment of HG. A control group composed of 15 pregnant women.
Methods
Assessment of fasting serum progesterone and serum estradiol level was done. Transabdominal ultrasound examination was carried out to exclude vesicular mole and multiple pregnancies.
Results
Before treatment: the mean value of serum estradiol in patients treated with micronized progesterone was found to be not significantly different from that of patients treated conventionally. The mean serum progesterone values of patients treated with micronized progesterone was found to be not significantly different from that of patients treated conventionally or that of control subjects. Patients treated conventionally had a significantly higher $E_2$/progesterone ratio than normal controls. After treatment: The $E_2$/progesterone ratio was significantly lower in patients treated with micronized progesterone when compared to those patients treated conventionally, but it was still significantly higher than that of control subjects.
Conclusions
Serum levels of estradiol are significantly higher in hyperemetic patients compared to normal pregnant women. When balance is restored by increasing natural progesterone levels, these symptoms typically disappear. Therefore, micronized progesterone has a significant beneficial effect to treat Egyptian pregnant women suffering from HG.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P971

**Significance of obesity in the genesis of metabolic syndrome in women with polycystic ovary syndrome**

J. Bjekic-Macut[1], D. Macut[2], I. Bozic[2], D. Vojnovic-Milutinovic[3], O. Stanojlovic[4], B. Popovic[2], T. Bogavac[2], M. Petakov[2], S. Ognjanovic[2], T. Isailovic[2], V. Elezovic[2], M. Civcic[2], S. Erceg[2], G. Matic[3] & S. Damjanovic[2]
[1]Clinical-Hospital Center 'Bezanijska kosa', Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [3]Institute for Biologic Investigation 'Sinisa Stankovic', University of Belgrade, Belgrade, Serbia; [4]Medical Faculty, Institute for Physiology, University of Belgrade, Belgrade, Serbia.

Introduction
Metabolic disturbances that are common in polycystic ovary syndrome (PCOS), represent a risk factor for cardiovascular disease. The aim of this study was to define contribution of obesity for the development of dyslipidemia and insulin resistance in PCOS.
Methods
PCOS was diagnosed using ESHRE/ASRM criteria. We evaluated 158 women with PCOS who were divided into two subgroups according to body mass index (BMI) cut off value 25 kg/m$^2$: non-obese PCOS ($n=93$; 20.65±2.0 kg/m$^2$; 24.9±4.6 years) and overweight/obese PCOS ($n=65$; 31.0±4.6 kg/m$^2$; 26.7 ±6.7 years). Controls group consisted of 30 healthy, non-obese (19.9 ±2.1 kg/m$^2$, 27.5±5.3 years). In all subjects fasting blood samples were collected in follicular phase of menstrual cycle for determination of glucose, insulin, total cholesterol (TC), LDL, HDL, triglycerides, apolipoproteins (Apo) A1, A2, B and E, Lp(a), C-reactive protein (CRP), testosterone and SHBG. Blood pressure (BP), waist circumference (WC), free androgen index (FAI), homeostatic model (HOMA index), and ratios TC/HDL, LDL/HDL, triglycerides/HDL, ApoB/ApoA1 were also determined.
Results
In comparison to non-obese PCOS, obese PCOS had significantly higher levels of TC, LDL, triglycerides, ApoB, ApoE, CRP, HOMA, FAI, TC/HDL, LDL/HDL, triglycerides/HDL, ApoB/ApoA1, and significantly lower levels of HDL and ApoA1 ($P<0.001$). After adjustment for age, non-obese PCOS had borderline higher ApoB/ApoA1 than Controls ($P=0.051$). In PCOS group BMI significantly correlated with TC, HDL, triglycerides, HOMA, ApoB, and CRP ($P<0.001$). There were no significant correlations between FAI and metabolic indices. HOMA significantly correlated only with BMI ($P<0.001$).
Conclusion
Proaterogenic lipid profile and insulin resistance are metabolic consequences of PCOS. Obesity significantly worsens metabolic profile in women with PCOS.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P972

### Lipid accumulation product as a marker of metabolic syndrome in women with polycystic ovary syndrome

D. Macut[1], I. Bozic[1], J. Bjekic-Macut[2], D. Panidis[3], N. Spanos[3], D. Vojnovic-Milutinovic[4], O. Stanojlovic[5], B. Popovic[1], T. Bogavac[1], M. Petakov[1], S. Ognjanovic[1], T. Isailovic[1], V. Elezovic[1], M. Civcic[1], S. Erceg[1], G. Matic[4] & S. Damjanovic[1]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, Clinical Center of Serbia, University of Belgrade, Belgrade, Serbia; [2]Clinical-Hospital Center 'Bezanijska kosa', Belgrade, Serbia; [3]Second Division of Endocrinology and Human Reproduction, Second Department of Obstetrics and Gynecology, Aristotle University of Thessaloniki, Thessaloniki, Greece; [4]Institute for Biologic Investigations 'Sinisa Stankovic', Belgrade, Serbia; [5]Medical Faculty, Institute for Physiology, University of Belgrade, Belgrade, Serbia.

Introduction
Women with polycystic ovary syndrome (PCOS) have higher prevalence of metabolic syndrome (MS) than healthy, age and BMI matched women. The aim of this study was to determine if novel abdominal adiposity index – lipid accumulation product (LAP), could predict MS in women with PCOS.
Methods
PCOS was diagnosed using ESHRE/ASRM criteria. We evaluated 159 PCOS women (PCOS group: $24.9\pm6.2$ kg/m$^2$; $25.8\pm5.4$ years) and 56 healthy women (control group: $22.9\pm5.8$ kg/m$^2$; $27.6\pm5.3$ years). MS was diagnosed according to JIS criteria (waist circumference cut off 80 cm) in 39/159 (25%) PCOS women, while no woman in controls group had MS. PCOS group was divided in subgroups: PCOS with MS ($31.9\pm5.4$ kg/m$^2$; $27.9\pm7.1$ years) and PCOS without MS ($22.8\pm4.6$ kg/m$^2$; $25.0\pm4.6$ years). In all subjects blood pressure (BP) and waist circumference (WC) were determined. Blood samples were collected in follicular phase of menstrual cycle for determination of basal glucose, insulin, HDL-cholesterol, triglycerides, testosterone, SHBG and homeostatic model (HOMA) index. LAP was calculated using formula ((WC-58)$\times$ triglycerides). All statistical analyses were adjusted for age and body mass index.
Results
PCOS had significantly higher LAP than controls ($37.3\pm43.5$ vs $18.5\pm17.1$, $P<0.001$). PCOS without MS had significantly lower LAP than PCOS with MS ($20.6\pm17.5$ vs $90.6\pm57.3$, $P<0.001$) and significantly higher LAP than controls ($P=0.016$). JIS criteria for MS, testosterone, SHBG and LAP entered binary logistic regression analysis which showed that independent predictors for MS in PCOS group were: LAP ($P=0.002$), systolic BP ($P=0.003$) and HDL-cholesterol ($P=0.004$). In PCOS, LAP significantly correlated with HOMA ($P=0.42$, $P<0.001$).
Conclusion
LAP is useful surrogate marker for the assessment of metabolic syndrome in women with PCOS.
Declaration of interest

### Serum 25-hydroxyvitamin D and hsCRP levels in young obese women with polycystic ovary syndrome

Y. Sung[1], J. Oh[1], H. Lee[1], D. Kim[2], S. Baik[3], K. Won[4] & H. Kim[5]
[1]Ewha Womans University, Seoul, Republic of Korea; [2]Hanyang University, Seoul, Republic of Korea; [3]Korea University, Seoul, Republic of Korea; [4]Yeungnam University, Daegu, Republic of Korea; [5]Eulji University, Seoul, Republic of Korea.

Insulin resistance is one of the common features of the polycystic ovary syndrome (PCOS), and recent studies indicate the possible role of vitamin D in the pathogenesis of insulin resistance and inflammatory response. We aimed to investigate the association between 25-hydroxyvitamin D (25(OH)D) and insulin resistance and inflammatory marker in obese women with PCOS and controls.
We recruited 50 obese women with PCOS (age $25\pm5$ years, BMI $27.5\pm2.3$ kg/m$^2$) and 50 age, BMI-matched controls (age $26\pm5$ years, BMI $27.3\pm2.1$ kg/m$^2$). Anthropometric measurements were obtained and metabolic and hormonal parameters were determined. Serum 25(OH)D levels were measured by IRMA (COBRA Quantum 5002) and hsCRP by TIA (ADVIA 2400). Glucose tolerance status was assessed by 75 g OGTT, and insulin resistance index was calculated from OGTT data.
The prevalence of insufficient 25(OH)D levels ($<30$ ng/ml) were 90% in women with PCOS and 88% in controls. Serum 25(OH)D and hsCRP concentrations are not different between women with PCOS and controls. 25(OH)D and hsCRP did not correlate with metabolic and hormonal parameters, and no significant association was found between 25(OH)D and insulin resistance index and hsCRP in both women with PCOS and controls.
25(OH)D insufficiency was prevalent in young obese women, but 25(OH)D and hsCRP levels were not associated with insulin resistance or PCOS itself. Future studies will be required to ascertain the relationship between 25(OH)D and insulin resistance in large number of subjects with various age and BMI.

### Association of metabolic disturbances and carotid intima-media thickness in women with polycystic ovary syndrome

I. Bozic[1], D. Macut[1], M. Civcic[1], S. Erceg[1], J. Bjekic-Macut[2], B. Popovic[1], T. Bogavac[1], M. Petakov[1], T. Isailovic[1], V. Elezovic[1], S. Ognjanovic[1] & S. Damjanovic[1]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, Cinical Center of Serbia, University of Belgrade, Belgrade, Serbia; [2]Clinical-Hospital Center 'Bezanijska kosa', Belgrade, Serbia.

Introduction
Polycystic ovary syndrome (PCOS) is associated with higher risk of cardiovascular disease. Measurement of carotid intima-media thickness (CIMT) is a simple non-invasive procedure for assessment and measurement of atherosclerotic plaque. It is a valuable tool for evaluation of cardiovascular disease risk, as increase in CIMT is associated with cardiovascular events, mainly stroke. In this study we evaluated association and influence of metabolic disturbances on CIMT in women with PCOS.
Methods
PCOS was diagnosed using ESHRE/ASRM criteria. Ultrasound CIMT measurement was obtained on right and left common carotid artery in 98 women with PCOS (group PCOS: $24.6\pm5.5$ kg/m$^2$; $25.9\pm5.1$ years) and 37 healthy women (group controls: $22.9\pm5.1$ kg/m$^2$; $27.2\pm4.1$ years). Groups did not differ in age ($P=0.65$) and body mass index (BMI, $P=0.71$). In all subjects fasting blood samples were collected in follicular phase of menstrual cycle for determination of glucose, insulin, total cholesterol, HDL-cholesterol, LDL-cholesterol, triglycerides, C-reactive protein (CRP), testosterone and SHBG. Homeostatic model (HOMA index), free androgen index (FAI), mean CIMT and blood pressure (BP) were determined.
Results
In comparison to controls, PCOS had significantly higher mean CIMT ($0.56\pm0.68$ vs $0.47\pm0.59$, $P=0.022$), systolic BP ($P=0.042$), triglycerides level ($P=0.01$), and lower HDL-cholesterol level ($P=0.024$). All determined parameters entered multiple linear regression analysis which revealed significant model ($R^2=0.12$) where triglycerides level was the only independent predictor of CIMT in PCOS group ($P=0.002$).
Conclusion
CIMT is a surrogate marker for atherosclerosis. In this study we showed that women with PCOS have significantly higher CIMT in comparison to healthy, age and BMI matched women. Higher CIMT in PCOS women is associated with higher triglycerides level.

### Prevalence of dyslipidemia in Algerian PCOS women

S. Ouldkablia[1], M. Semrouni[2] & Z. Kemali[1]
[1]Central Hospital of the Army, Algiers, Algeria; [2]CPMC, Algiers, Algeria.

Polycystic ovary syndrome (PCOS) is a common endocrinopathy affecting 6–10% of reproductive aged women. In young women with PCOS, multiple risk

factors for cardio vascular disease (CVD) including dyslipidemia may be found and prevention is needed.
Objective
This study aims to investigate the prevalence of dyslipidemia in Algerian PCOS women.
Materials
A prospective study was performed (since 2004–2008) on 181 PCOS and 90 age and BMI matched controls.
The data of anthropometric measurements, oral glucose tolerance test, serum lipids levels, total cholesterol, triglyceride, high-density lipoprotein and low-density lipoprotein cholesterol were collected from PCOS and controls women.
Results
PCOS women have higher prevalence of hypertriglyceridemia (59.6 vs 29% $P=0.001$) and low HDL cholesterol (12.3 vs 6.8% $P=0.002$) than their counterparts. At the same time the mean level of triglyceridemia was higher ($1.04\pm0.08$ mmol/l vs $0.91\pm0.04$ $P=0.02$) and the mean level of HDL.C was lower ($1.28\pm0.04$ vs $1.52\pm0.004$, $P=0.01$) than the controls.
The prevalence of hypertriglyceridemia increased with BMI respectively 5.9, 14.6, and 16.9% for BMI $<25$; BMI 25–30 BMI more than 30 $P=0.002$. The prevalence of low level of HDL-C also increased with BMI respectively 45.5, 56.09 and 70.4% for BMI $<25$; BMI 25–30 BMI more than 30 $P=0.01$.
Conclusion
In our study the prevalence of dyslipidemia was found to be high in PCOS women. PCOS should be screened for dyslipidemia. Diet, physical exercise and if necessary lipid lowering medication should be used to normalize dyslipidemia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Serial serum levels of vitamin D in lean and obese pregnant women**

V. Castracane, B. Martinez, U. Shah, T. Loi, S. Durham, C. Maguire & R. Kauffman
Texas Tech HSC, Odessa, Texas, USA.

Objective
Obesity is a major problem in pregnancy. Obesity has been associated with decreased vitamin D levels, diabetes and reproductive risks. Women were followed through pregnancy with frequent blood samples to determine any differences between lean and obese subjects. We present data on vitamin D levels through gestation in these subjects.
Methods
Normal pregnant women at 6–9 weeks GA provided blood samples every 2 weeks and body weights were recorded. We report serial serum levels of vitamin D in lean ($n=8$) and obese ($n=6$) pregnant women, and in one subject with gestational diabetes. Samples from singleton ($n=35$) and twin ($n=31$) pregnancies between 15 and 20 weeks of gestation were also analyzed in order to determine whether increased placental mass (twins) would increase vitamin D levels over singleton pregnancies. Vitamin D levels were measured by chemiluminescent immunoassay (immunodiagnostic systems).
Results
For each subject, the mean of all serial results was calculated and then the mean $\pm$S.E.M. of individual means was calculated for the lean and obese groups. Mean ($\pm$S.E.M.) vitamin D levels for the lean subjects was $28.39\pm1.98$ ng/ml and for the obese subjects was $19.80\pm3.05$ ng/ml. Of six lean subjects, five had a least two values or more above the sufficiency level for vitamin D ($>30$ ng/ml) and only one subject in the obese or gestational diabetic subjects had a value $>30.0$ ng/ml. Most subjects, either lean or obese, had a slight increase in serum vitamin D levels over the course of gestation. In the singleton and twin comparison at 15–20 weeks, there were no differences vitamin D levels plotted against BMI.
Discussion
Vitamin D levels are greater in lean than in obese pregnant women. Vitamin D levels are generally insufficient in the obese group and slightly increased in the lean group.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P977

**Erythrocytosis and thrombocytosis secondary to hypertestosteronemia caused by ovarian leydig cell tumor**

G. Mirošević, D. Butorac, I. Kruljac & M. Vrkljan
University Hospital Center 'Sestre Milosrdnice', Zagreb, Croatia.

Testosterone has a dose-dependent stimulatory effect on erythropoiesis but the mechanism is poorly understood. Although both erythroblasts and megakaryocytes express androgen receptors, testosterone's effect on thrombopoiesis in humans has never been studied.
We report a case of 53-years-old woman presented with androgenic alopecia, hirsutism, facial redness and hoarse voice. She was a non-smoker and had a history of well-controlled diabetes mellitus type 2. Endocrinological evaluation disclosed total serum testosterone level of 34.8 nmol/l (normal range 0.1–1.4), free serum testosterone of 693 pmol/l (normal range 1–33) and suppressed FSH and LH levels. Blood routine samples taken on two separate occasions disclosed erythrocytosis and trombocytosis. White blood cell count, erythrocyte sedimentation rate and C-reactive protein were all within normal ranges. Abdominal and pelvic computed tomography, transvaginal ultrasonography, and pelvic magnetic resonance imaging failed to localize tumor. Normal dehydroepiandrosterone-sulphate levels indicated ovarian origin of hypertestosteronemia. Therefore, laparoscopic bilateral ovariectomy was performed. Focal tumor mass was not found on macroscopic examination. Microscopic examination disclosed a part of tumor tissue in the hilus of the left ovary. Tumor mass was torn apart and cauterized during surgery and therefore it is true size could not be measured. Tumor tissue stained positively for inhibin and calretinin and the diagnosis of hilus Leydig cell tumor was established. Testosterone level decreased to 1.7 nmol/l, RBC decreased from 5.7 to $4.7\times1012$/l, hematocrit level from 0.520 to 0.420, haemoglobin from 170 to 141 g/l and PC decreased from 480 to $378\times109$/l level normalized 2 weeks after the surgery and remained normal 3 months postoperatively.
Ovarian Leydig cell tumors are rare. Their association with erythrocytosis was reported in one case and concomitant erythrocytosis and thrombocytosis have never been reported. Substantial, immediate and persistent decrease in both RBC and PC after tumor removal suggests testosterone's synergistic effect on erythropoiesis and thrombopoiesis. Further studies are worthy.

**Quality of life in patients affected by polycystic ovary syndrome**

A. Panico, G. Lupoli, L. Granieri, R. Lupoli, F. Fonderico, A. Tortora, M. Cacciapuoti & G. Lupoli
University of Naples 'Federico II', Naples, Italy.

Background and aims
Polycystic ovary syndrome (PCOS) is characterized by phenotypic heterogeneity and a wide variety of consequences. About half of PCOS women are overweight or obese and their obesity may be a contributing factor to PCOS pathogenesis. The aim of this study was to evaluate if PCOS alone affects the patients' quality of life and to what extent obesity contributes to worsen this disease.
Methods and results
In total, 200 women with PCOS, 100 with BMI $>25$ and 100 with BMI $<25$ were recruited. They were evaluated with the 36-items short-form health survey (SF-36) and the polycystic ovary syndrome questionnaire (PCOQ20) and were compared with a healthy control group of 80 women, adequately matched.
The univariable analysis evidenced that PCOS patients, compared with controls, had decreased scores, indicating lower HRQoL, in all domains, excluding Bodily pain and Social role functioning; the most significant differences ($P<0.001$) between PCOS and control patients with BMI $\geq25$ were evidenced for emotional role functioning and summary mental health (SF-36), weight and acne (PCOQ20). Multivariable regression analysis evidences that in subjects with BMI $\geq25$, high values of BMI itself predict the possibility of being affect by PCOS; low scores in physical functioning, Physical role functioning, vitality, emotional role functioning and Mental health were identified as multivariate predictors of PCOS. Therefore, PCOS determines a relevant impairment of psycho-social functions in women; moreover, higher is the BMI, worse is the score of mental and emotional domains.
Conclusions
PCOS itself is a great cause of psychological morbidity and contributes to an overall diminished HRQoL; overweight-obesity, when present, considerably

concurs to worsen it. PCOQ20 is a very sensitive test to evaluate HRQoL in PCOS patients.

### Effects of dopamine agonist administration during seasonal cyclicity in the mare

S. King[1], C. Bass[1], J. Roser[2], L. Murphy[1] & K. Jones[1]
[1]Southern Illinois University, Carbondale, Illinois, USA; [2]University of California, Davis, California, USA.

Prolactin is associated with seasonal transitions into and out of anestrus in the mare. The earliest anestrous transitional changes are declining progesterone secretion and a concomitant prolactin decline. Ovarian changes include slowed follicular development and prolonged luteal activity. Dopamine antagonist administration during the autumnal transition prevented a seasonal progesterone decline, suggesting a cause-and-effect between prolactin and progesterone production. The present study sought to mimic decreased autumn prolactin secretion during summer cyclicity to investigate the prolactin–progesterone secretion relationship, possible prolactin influence over ovarian events and sexual behavior.
In total, 20 mares were divided into treatment (T) or control (C) groups (May 15–Aug 10) and assessed regularly for sexual behavior (teasing), endocrine function (plasma collection and RIA) and ovarian function (ultrasonography). Treatment mares received cabergoline, a long-acting dopamine agonist (5 mg orally every third day). Comparisons between groups (repeated measures ANOVA) included plasma prolactin and luteal progesterone concentrations, length of estrous cycle and its luteal and follicular phases, average daily follicular growth rates and numbers of small, medium and large-sized follicles. Sexual behaviors were scored as positive and negative and aggregate daily scores were compared between groups.
Plasma prolactin declined ($P<0.05$) within 24 h post-cabergoline treatment and remained lower than controls during the study. Luteal progesterone was not statistically different between groups, but there were some indications of progesterone decline in response to cabergoline. Although estrous cycle intervals were not different between T and C groups, late summer luteal phases tended to be shortened in T mares. Late diestrus (day 15) follicular growth wave suppression was demonstrated in T mares. Sexual behavior was different ($P<0.05$) between groups insofar as T mares demonstrated greater sexual ambivalence to the stallion, often displaying both positive and negative behaviors simultaneously.
Results suggest that prolactin/dopamine does influence some aspects of reproduction in the mare.

### Differences in gonadal axis reaction to ketoconasole between PCOS and healthy individuals

M. Stojkovic[1], S. Savic[1], B. Beleslin[1,2], J. Ciric[1,2], B. Trbojevic[1,2] & M. Zarkovic[1,2]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; [2]School of Medicine, University of Belgrade, Belgrade, Serbia.

Background
Ketoconazole is a synthetic antifungal drug, and powerful inhibitor of steroidogenesis. Oral ketoconazole blocks both ovarian and adrenal androgen biosynthesis, and glucocorticoid synthesis, leading to a reduction in circulating testosterone and cortisol levels. In subjects with an intact HPA axis, ketoconazole by decreasing cortisol levels leads to compensatory rise an ACTH level.
Objectives
To assess influence ketoconasole induced changes in steroid synthesis on the hypothalamo-pituitary–gonadal axis and adrenal activity in PCOS.
Methods
The study group consisted of 44 women (i. PCOS group, $n=21$; ii. control group, $n=23$). During the follicular phase of menstrual cycle, $2\times400$ mg of oral ketoconazole was given. We measured FSH, LH, testosterone, DHEA-s, progesterone and 17-OH progesterone before ketoconazole and the morning after ketoconazole. Changes in the hormone concentrations were analyzed using Wilcoxon test, and presented as median (range) of the hormone change after ketoconazole. Positive values indicate increase and negative decrease after ketoconazole.
Results
FSH: $0.61\pm1.19$ vs $0.84\pm1.86$ IU/l; $P=0.47$; LH: $2.34\pm3.81$ vs $-0.11\pm2.4$ IU/l; $P=0.02$; testosterone $-1.19\pm0.83$ vs $-0.35\pm0.48$ nmol/l; $P<0.01$; DHEA-s $-1.28\pm1.19$ vs $-0.99\pm2.11$ nmol/l; $P=0.18$; progesterone $15.86\pm15.10$ vs $18.71\pm22.60$; $P=0.89$; 17OH progesterone: $1.71\pm1.79$ vs $0.95\pm1.07$; $P=0.15$; testosterone was significantly more suppressed in PCOS compared to control group. There was significant increase in LH in PCOS compared to control group.
Conclusions
Androgen synthesis in PCOS is more sensitive to ketoconazole inhibition than in non-PCOS subjects. This implies that it has a potential role in the PCOS treatment.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P981

### Metabolic and hormonal parameters in lean PCOS women

J. Dolfing[1], P. van Haard[2], D. Schweitzer[2] & B. Wolffenbuttel[3]
[1]Twente Group of Hospitals, Hengelo, The Netherlands; [2]Reinier de Graaf Group of Hospitals, Delft, The Netherlands; [3]University Medical Center Groningen, Groningen, The Netherlands.

Background
A minority of women with polycystic ovary syndrome (PCOS) is lean, and several individuals have no signs of hyperandrogenaemia. Earlier we showed that lean PCOS patients have no increased visceral adiposity. The aim of the present study was study is to characterize the metabolic and hormonal status a group of lean PCOS cases.
Methods
In this cross-sectional study ten Caucasian women with PCOS and ten controls carefully matched for age and BMI were studied. Mean age was $31\pm2$ years, and all had BMI between 19 and 25 kg/m$^2$ and similar total fat contents, according to bioelectrical impedance analysis (BIA) and magnetic resonance imaging (MRI). Glucose, insulin, testosterone, SHBG, gonadotrophins, anti-Müllerian hormone (AMH), inhibin B and adipokines (adiponectin, leptin, TNF-α, IL6 and RBP-4) were assessed by standard techniques.
Results
BMI's were $21.6\pm1.1$ vs $21.8\pm2.1$ kg/m$^2$, waist-hip ratios $0.83\pm0.07$ vs $0.85\pm0.03$, fat mass 13.2 (4.9–19.7) vs 14.4 (4.0–22.5) kg and lean body mass 52.4 (45.2–59.4) vs 53.4 (44.4–59.7) kg for PCOS and control women, respectively (all $P=$NS). Fasting blood glucose and insulin levels were similar, and HOMA-IR was $0.55\pm0.19$ and $0.63\pm0.18$. Also the levels of adipokines were similar between both groups. PCOS cases had significant higher free androgen index (FAI), lower estradiol and lower FSH, but similar inhibin B. AMH levels were $11.1\pm3.0$ ng/ml in PCOS vs $3.3\pm1.8$ ng/ml in controls ($P<0.01$). Pooled ovarian volumes correlated positively with AMH levels, calculated for the largest ovary of each individual ($r=0.75$, $P<0.0001$) vs the smallest ovary ($r=0.70$, $P<0.001$), while positive correlations were only demonstrated between Inhibin B levels and the largest ovaries ($r=0.58$, $P<0.01$).
Conclusions
We observed no differences in metabolic parameters and insulin resistance between lean PCOS cases vs controls. Also in lean PCOS patients, AMH levels are increased. Similar ovarian-AMH relationships but different volume-inhibin B relationships confirm that both hormones originate from different ovarian cells (early antral vs granulosa cells). The differences in FSH need to be explored further.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P982

**Adiponectin, resistin, leptin and selected cytokines in association with insulin resistance in lean women with polycystic ovary syndrome**

S. Stanicka, M. Vankova, H. Kvasnickova, J. Vrbikova, J. Vcelak, M. Hill, K. Dvorakova, P. Lukasova & B. Bendlova
Institute of Endocrinology, Prague, Czech Republic.

The polycystic ovary syndrome (PCOS) is associated with features of the insulin resistance syndrome and altered glucose homeostasis. Factors that play an important role in these processes are still emerging. Adipokines and pro-inflammatory cytokines may be involved in development of insulin resistance in PCOS. The purpose of this study was to determine if a relationship exists between adiponectin, resistin, leptin, interleukin (IL) 4, IL6, IL10, tumor necrosis factor α (TNF α) and insulin resistance indices in lean women with PCOS.

Methods

Fasting insulin, glucose, C-peptide, lipid profile, FSH, LH, prolactin, testosterone, sex hormone binding globulin, 17-hydroxyprogesterone, adiponectin, resistin, leptin, IL4, IL6, IL10, TNF α serum concentrations were analyzed at basal conditions in 12 lean women with PCOS (BMI $<25$ kg/m$^2$) and 17 age- and weight-matched healthy controls. Oral glucose tolerance test was performed. Homeostasis model assessment insulin resistance (HOMA-IR), Matsuda and Cederholm index were calculated. Statistics: Mann–Whitney *U* test and Spearman correlation.

Results

Matsuda and Cederholm index were significantly lower in lean women with PCOS than in control group ($P<0.05$ for both). Fasting glucose, insulin, C-peptide and HOMA-IR did not differ between groups. Adiponectin tended to be lower in PCOS ($P<0.054$). Resistin was significantly lower in PCOS than in control group ($P<0.05$). Leptin, IL4, IL6, IL10, TNF α levels did not differ between groups. In women with PCOS i) IL4 correlated significantly negatively with fasting glucose ($P<0.01$), ii) leptin correlated significantly positively with LDL cholesterol ($P<0.05$) and significantly negatively with Matsuda index ($P<0.05$).

Conclusions

In lean women with PCOS, the insulin sensitivity was decreased, however, serum levels of resistin were lower than in control group, leptin levels were associated with markers of insulin resistance and IL4 was connected with fasting blood glucose. Supported with the grants NS/9839-4 and CZ.2.17/1.1.00/32386.

**Solution of an old endocrinological puzzle the rise and fall of an endocrinological doctrine Dr. László Makay, DVM H-2000 Szentendre, Sztaravodai u. 42, Hungary Tel./Fax: +36 26 316 791 E-mail: makay27@freemail.hu**

L. Makay
University of Veterinary Sciences, Budapest, Hungary.

Already a long time ago, the subtle adaptability of the reproductive endocrine system made it possible to elaborate a hormonal castration method for female pigs, which was based on the administration of a high-dose oestrogen (diethylstilboestrol) injection. The phenomenon was believed to be the result of a negative feedback reaction. However, this theory could not explain why more than 20% of the animals treated did not respond properly to the treatment. Therefore, the goal of these investigations was to get proper insights into the functioning of the relevant reproductive endocrine system. Although the treatment is no longer in use and the studies took place long ago, the results of the study presented here demonstrate a specific, so far unknown reproductive endocrine feedback phenomenon. Accordingly, the pig's reproductive endocrine system can respond to the administration of high-dose oestrogen injection by developing either of two different, opposite kinds of reactions, i.e. two distinct mechanisms of action. Whenever the reproductive endocrine system is able to do so, it always reacts by achieving a positive feedback reaction (the successful variant of reactions) rather than a negative one as had been believed previously. In the absence of this ability the negative feedback reaction (the unsuccessful variant of reactions) develops. However, this latter can be prevented by stimulating the activity of the reproductive endocrine system.

These findings disprove an old endocrinological doctrine and establish a new one.

Left: Ovaries of untreated gilts.
Middle: Follicular depression evoked by treatment.
Right: Luteal phase elicited by treatment.

Images of the ovaries
Left: ovaries of untreated gilts.
Middle: follicular depression evoked by the treatment (negative feedback reaction).
Right: luteal phase brought about by the treatment (positive feedback reaction).

**Evidence of direct mitogenic activity of insulin and the insulin receptor in prostate cancer cell lines**

D. Weinstein[1], Z. Laron[2] & H. Werner[1]
[1]Tel Aviv University, Tel Aviv, Israel; [2]Schneider Children's Hospital, Petah Tikva, Israel.

Background

In addition to its normal spectrum of metabolic effects, insulin has been identified as a growth factor capable of promoting mitogenic activities. Thus, hyper-insulinemia, a consequence of insulin resistance, is regarded as a potential risk factor for the development of cancer in patients with diabetes. However, the mechanism of action of insulin in prostate cancer has not yet been completely elucidated. The aim of this study was to investigate whether insulin can directly induce mitogenic activity in prostate cancer-derived cell lines and to evaluate the role of the insulin receptor (IR) in mediating this activity.

Methods

A number of prostate cancer cell lines (LNCaP, P69, C4-2 and PC3), representing early and advanced stages of the disease, were employed. Insulin doses ranged between 0 and 500 ng/ml. Insulin-stimulated proliferation rates were measured by hemocytometer cell counting and MTT assay. Cell-cycle dynamics were evaluated by propidium iodide staining and FACS analysis. Activation of the IR was assessed by immunoprecipitation assays. Expression levels of the receptor were measured by western immunoblotting.

Results

Insulin induced cell proliferation in a dose-dependent fashion in the LNCaP and C4-2 cell lines, but not in P69 or PC3 lines. Cell cycle analyses showed that insulin can positively influence LNCaP and C4-2 lines to progress towards the G2/M phase. Immunoprecipitation assays show that in all of the cell lines expressing the IR, insulin activates IR but not IGF1R.

Conclusion

In the model studied, insulin exhibited direct mitogenic activities mediated exclusively through the IR. Further research is needed to fully dissect the molecular mechanism underlying the biological actions of insulin in prostate cancer.

## P985

**Insulin receptor compensates for IGF1R inhibition and induces mitogenic activity in prostate cancer cell lines**

D. Weinstein, Z. Laron[2] & H. Werner[1]
[1]Tel Aviv University, Tel Aviv, Israel; [2]Schneider Children's Hospital, Petah Tikva, Israel.

Background
IGF1R targeting emerged in recent years as a promising therapeutic approach in prostate cancer (PCa). The insulin receptor (IR) shares high structure homology with the IGF1R and activates similar signaling cascades. In recent studies we have shown that insulin's mitogenic activities in PCa cells are mediated via the IR. Given the central role of IR in regulation of metabolism, most anti-IGF1R therapeutic strategies were designed to specifically inhibit IGF1R, but not the IR. Therefore, the aim of this study was to investigate IR ability to compensate and mediate IGF1 mitogenic signals after IGF1R inhibition.
Methods
We employed P69 and C4-2 prostate cancer-derived cell lines, which express both IGF1R and IR. To specifically inhibit IGF1R we used monoclonal antibody IMAC-A12 (ImClone) or Thyrphostin (AG1024). Activation of receptors was assessed by immunoprecipitation assays. Expression levels of receptors and activation of signaling cascades were measured by western immunoblotting. Cells viability was measured by MTT assays.
Results
IGFI mainly activates its own receptor but also led to significant cross-activation of the IR. Results of IP assays showed that specific inhibition of IGF1R in C4-2 cells did not affect cross-activation of IR by IGF1. In P69 cells, on the other hand, there was a minor inhibition of cross-activation. In neither cell line, IGF1R inhibition affected the activity of signaling cascade proteins Akt and ERK. Finally, MTT assays revealed that, despite a significant reduction in IGF1R abundance on cell membranes, IMAC-A12 had no effect on cells viability.
Conclusion
In our model, specific inhibition of IGF1R had no effect on the activation of IR by IGFI, providing evidence for a compensation mechanism by IR following IGF1R inhibition. The evidence for a compensatory mechanism between the two receptors may be of future use for the local targeting of both IGF1R and IR in PCa.

**Designing long acting recombinant proteins: from bench to clinics**

F. Fares
University of Haifa, Haifa, Israel.

One major issue regarding the clinical use of many peptides is their short half-life span in the body, due to the rapid clearance from the circulation. Thus, at the clinical level, there is a need for a regime of frequent injections of the peptides into the patients to overcome this low stability factor. To overcome this problem, we succeeded to add the signal sequence of *O*-linked oligosaccharides to the coding sequence of the hormones. The cassette gene that has been used contains the sequence of the carboxyl-terminal peptide (CTP) of human chorionic gonadotropin-β (hCG-β) subunit. The CTP contains 28 amino acids and four *O*-linked oligosaccharide recognition sites. It was postulated that the *O*-linked oligosaccharides add flexibility, hydrophilicity and stability to the protein. On the other hand it was suggested that the four *O*-linked oligosaccharides play an important role in preventing plasma clearance and thus increasing the half-life of the protein in circulation. Using this strategy we succeeded to ligate the CTP to the coding sequence of follitropin (FSH), TSH, erythropoietin (EPO) GH, interferon β and thus to increase the longevity and bioactivity of these proteins *in vivo*. Interestingly, the new analog of FSH was found not immunogenic in humans and it is already passed successfully clinical trials phase III and approved by The European Commission (EC). In addition, our results indicated that long acting GH is not toxic in monkeys and it passed successfully clinical trials phases I and II and the protocol for phase III was approved. The preliminary results regarding interferon β seem to be promising. Thus, using this technology seems to be promising in designing long acting peptides. Development of long acting peptides will diminish the cost of these drugs and perhaps reduce the number of injections in clinical protocols.

**GH harmonisation: it sounds simple…,?**

P. Menheere
Dutch Foundation For Quality Assesment in Medical Laboratories, Nijmegen, The Netherlands.

Objective
The concentration of GH (hGH) is important in the attribution of hGH therapy, for which in The Netherlands a national committee is responsible. Without this authorization re-imbursement is impossible. Therapy is permitted if all hGH concentrations after two stimulation tests are below 20 mU/l and in some clinical conditions independent of hGH. However, different assays produce different results and nationwide hGH results varied with CV ~30%. Consequently, authorization for hGH therapy depends on the laboratory that analyzes the samples, leading to social inequality. The national committee asked the Section of Endocrinology of the Dutch Foundation for Quality Assessment in Medical Laboratories to diminish nationwide variation.
Method
Since, standardization of assays is impossible, it was decided to harmonize hGH assays. A commutable sample was developed, being defined as behaving in all assays exactly as patients samples would do. The sample was obtained by mixing sera from healthy volunteers after 20 min of intensive exercise. Such samples contain all relevant isoforms due to *de-novo* synthesis of hGH. This sample was diluted with serum with low hGH concentration to obtain concentrations around the clinical decision limit of 20 mU/l. Next, it was freeze-dried and distributed to all participating laboratories. This harmonization sample was used to recalculate all hGH concentrations with a harmonization factor being the ratio of the measured and attributed concentration. In external quality control assessment schemes the reduction of variation was verified.
Results
After the introduction of the harmonization sample the nationwide variation of hGH assays dropped to <10%. Consequently, it was decided that laboratories must use the harmonizing method to assure that patients eligible for hGH therapy receive authorization with respect to social equality.
Conclusion
Harmonization of hGH assays is a valid method to reduce variation and to promote equality between patients when prescribing hGH therapy.

**Plasma ghrelin levels appeared to be elevated in patients with medium-chain acyl-CoA dehydrogenase deficiency and glutaric aciduria type II: evidence for that acyl-CoA is the substrate for ghrelin acylation**

T. Akamizu[1,5], N. Sakura[2], Y. Shigematsu[3], G. Tajima[2], A. Ohtake[4], H. Hosoda[6], H. Iwakura[5], H. Ariyasu[5] & K. Kangawa[6]
[1]Wakayama Medical University, Wakayama, Japan; [2]Hiroshima University Graduate School of Biomedical Sciences, Hiroshima, Japan; [3]University of Fukui, Fukui, Japan; [4]Saitama Medical University, Saitama, Japan; [5]Kyoto University, Kyoto, Japan; [6]National Cerebral and Cardiovascular Center Research Institute, Osaka, Japan.

Ghrelin requires a fatty acid modification for binding to the GH secretagogue receptor. Octanoylation of the Ser3 residue of ghrelin is essential for

ghrelin-mediated stimulation of GH secretion and regulation of energy homeostasis via increased food intake and adiposity. Other than octanoylation (C8:0), the hormone is subject to other types of acyl modification, decanoylation (C10:0), and possibly decenoylation (C10:1). The fatty acid substrate that contributes to ghrelin acylation, however, has not been clarified, although the presumed donor is acyl-CoA. Medium-chain acyl-CoA dehydrogenase (MCAD) deficiency causes elevated serum octanoylcarnitine levels, reflecting elevated octanoyl-CoA levels. Glutaric aciduria type II (GA2) is characterized by elevated serum acylcarnitine levels, including octanoyl carnitine. We hypothesized that acyl-CoA is the fatty acid substrate for ghrelin acylation. Because serum octanoyl-CoA levels are altered in these disorders, we examined blood levels of acyl (A) and desacyl (D) forms of ghrelin in affected patients. Plasma acyl ghrelin levels and A/D ratios appeared to be elevated in patients with MCAD deficiency or GA2 in comparison to those in normal subjects. Reverse-phase high-performance liquid chromatography confirmed that n-octanoylated ghrelin levels were elevated in these patients. In addition, serum C10-acylcarnitine levels were also elevated in patients with GA2. In conclusion, changing serum medium-chain acylcarnitine levels may affect circulating acyl ghrelin levels, suggesting that acyl-CoA is the substrate for ghrelin acylation. Moreover, acylation of ghrelin may be linked to energy homeostasis and fat metabolism. In other words, ghrelin may play an important role in metabolic balance via its own fatty acid metabolism. Finally, our results may have pathophysiologic implications for these disorders. Alterations of plasma ghrelin levels in these disorders may reflect and/or influence the patient's metabolic status.

### Ghrelin suppresses angiotensin II-induced tissue damages by reducing oxidative stress

K. Fujimura, S. Wakino, H. Minakuchi, H. Tokuyama, K. Hayashi & H. Itoh
Keio University, Shinjuku-ku, Japan.

Objectives

Angiotensin II (AngII) induces renal premature senescence by multiple mechanisms including by increasing oxidative stress. Recent study revealed that growth hormone secretagogue ghrelin exerts anti-senescence effects. In this study, we examined whether ghrelin inhibits AngII-induced renal senescence and damages.

Methods

Renal senescence was induced by infusion of Ang II in C57BL/6 mice with osmotic mini-pump. Ghrelin was administered by the daily intraperitoneal injection. Eight weeks after the treatment, kidneys were removed and utilized in the various experiments. In *in vitro* experiment, cultured human proximal cell line, HK-2 cells were incubated with 1 μM of AngII for 72 h and ghrelin were administered 30 min prior to AngII stimulation.

Results

AngII infusion induces senescence and oxidative stress as accessed by senescence-associated (SA) β-Gal and 4-hydroxy-2-nonenal (4-HNE) staining, respectively. The expressions of markers for senescence, p21 and p53 as well as senescence-associated cytokines, TGF-β and PAI-1 in the kidney were increased by AngII. AngII infusion also induced renal damages as assayed by the urinary excretion of renal tubular marker, *N*-acetyl-glucosaminide (NAG) and neutrophil gelatinase-associated lipocalin (NGAL) as well as by urinary protein excretion. Finally, AngII infusion provoked interstitial fibrosis as evaluated by Masson-trichrome staining. These changes were attenuated by the treatment with Ghrelin. In HK-2 cells, the receptors for both Ghrelin and AngII were expressed. SA β-Gal assay revealed tubular cell senescence by AngII. AngII also increased the expression of p21 and p53 as well as TGF-β and PAI-1. These changes were attenuated by pretreatment with Ghrelin. In addition, AngII reduced the mitochondria (Mt) number, which was restored by Ghrelin as measured by staining cells with Mt-specific fluorescent dye. Ghrelin treatment increased the expression of Mit-specific uncoupling protein UCP-2 and master regulator of Mit biogenesis, PGC-1α expression. Finally, in HK-2 celsl, Ghrelin reducued Mit-derived ROS levels and Mit membrane potential.

Conclusions

Our data indicated that ghrelin suppressed AngII-induced renal premature senescence and AngII-induced renal damages presumably through reducing the mitochondrial membrane potential and resultant ROS production.

### The effect of ghrelin on the mitochondrial dysfunction in muscle and physical disability associated with aging

M. Mitsuishi, K. Miyashita, A. Muraki, M. Tamaki, K. Tanaka & H. Itoh
Keio University, Tokyo, Japan.

Aim

We investigated the influence of mitochondrial dysfunction associated with aging on physical performance in mice, and the effect of hormone replacement on physical performance.

Method

Using 8, 20, 50 and 100 week-old C57bl6 mice, we evaluated skeletal muscle mass, mitochondrial activity, glucose tolerance and physical performance (muscle power and exercise endurance). In addition, we treated 50-week-old mice with ghrelin or insulin like growth factor 1 (IGF1), which are representative hormones that are decreased associated with aging, and investigated the effect on physical performance.

Result

Skeletal muscle mass and mitochondrial activity was decreased associated with aging. Muscle mass was decreased drastically between 20- and 50-week-old, and the time-course was paralleled to decrease in muscle power. Mitochondrial activity was diminished continuously from 8- to 100-week-old, and this change was paralleled to decrease in exercise endurance. As regulatory factors of muscle mass and the mitochondrial function, we focused on mammalian target of rapamycin complex1 (TORC1) and AMP-activated protein kinase (AMPK) in muscle, respectively. Activity of TORC1 was diminished with aging in parallel to muscle mass and power, and that of AMPK was paralleled to muscle mitochondrial activity and exercise endurance. The treatment with IGF1 in 50-week-old mice recovered muscle mass and power; however, it did not improved mitochondrial activity or exercise endurance. The treatment with ghrelin recovered not only muscle mass and muscle power; but also mitochondrial activity and exercise endurance, which were deteriorated in aging mice. The ghrelin-induced recovery was associated with dual activation of TORC1 and AMPK in muscle.

Conclusion

Muscle mitochondrial dysfunction was closely associated with decrease in exercise endurance. Ghrelin replacement would be a hopeful strategy for the decrease in physical performance associated with aging.

Declaration of interest

### Health related quality of life and psychological functioning of short statured German children and adolescents: findings form the quality of life in short stature youth study

J. Quitmann[1], J. Behncke[1], J. Chaplin[6], A. Pleil[2], M. Herdman[4], A. Rohenkohl[1], E. Mimoun[7], H. Wollmann[3], M. Bullinger[5] & M. Power[1]
[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]UniverPfizer Specialty Care Business Unitsity Medical Center Hamburg-Eppendorf, San Diego, California, USA; [3]Pfizer GmbH, Tübingen, Germany; [4]Insight Consulting & Research S.L., Barcelona, Spain; [5]The University of Edinburgh, Edinburgh, UK; [6]University of Gothenburg, Gothenburg, Sweden; [7]Hopital Des Enfants, Toulouse, France.

Background

About 3% of all children are short statured. Clinically GH deficiency (GHD) or idiopathic short stature (ISS) is frequently diagnosed. GH (GH−) treatment, which is primarily indicated for GHD patients, is provided not only to increase height, but also to improve psychological functioning and raise health related quality of life. The present study examines these psychosocial outcomes in young German patients and their parents, and analyzes differences according to clinical and sociodemographic sample characteristics.

Methods
As part of the international QOLISSY study 143 German patients between 4 and 18 years and their parents filled out the strengths and difficulties questionnaire (SDQ) assessing psychological functioning and a generic health-related quality of life questionnaire (KIDSCREEN 52). Patient self-report and parent reported data were compared with representative German norm data.
Results
In the KIDSCREEN 52, short statured children and adolescents reported a significantly lower total health related quality of life (HrQOL) score compared to a representative German sample ($P<0.01$), and especially regarding their psychological wellbeing ($P=0.04$). No differences within the patient sample were found regarding gender, age, diagnosis and treatment status or actual height. Height also had no significant impact on psychological problems or psychosomatic complaints. Analysing the SDQ data no significant differences ($P=0.83$) were found between this sample and a representive sample.
Parent and patient perspectives, however, differed: parents rated the HrQOL of their children significantly higher than their children did ($P<0.01$), and patients self-report of psychological difficulties was higher than the report from the parental perspective ($P<0.01$).
Conclusion
This cross-sectional study found impairments in self-reported psychological functioning and HRQOL of short statured children as compared to norms, but no differences between patient subgroups. Differences between patient and parent perspectives, however, suggest conflicting viewpoints and specific problems for children which need to be addressed in respective psychosocial interventions.

### C677T methylenetetrahydrofolate reductase gene polymorphism and colorectal neoplasms in acromegalic patients

M. Torre[1], G. Russo[1], M. Ragonese[1], A. Giandalia[1], S. Puglisi[1], E. De Menis[2], G. Arnaldi[3], G. Romanello[2], D. Cucinotta[1], F. Trimarchi[1] & S. Cannavò[1]
[1]University of Messina, Messina, Italy; [2]General Hospital of Montebelluna, Montebelluna (TV), Italy; [3]Polytechnic University of Marche Region, Ancona, Italy.

Introduction
Acromegalic patients have an increased risk of developing colorectal neoplasms (CN). A common polymorphism (C677T) in gene coding for methylenetetrahydrofolate reductase (MTHFR), a key enzyme in folate metabolism and in DNA synthesis, reparation and methylation, has been associated with CN risk in general population, but its role in acromegalic patients has never been explored yet.
Aim
To investigate the contribution of MTHFR C677T polymorphism, folate status, and other lifestyle, nutritional and biochemical parameters on CN risk in acromegalic patients.
Patients and design
MTHFR C677T genotype was analysed by restriction fragment length polymorphism (RFLP) in 115 acromegalic patients (40 men; mean age 59.1 $\pm$1.6 years). In all cases, colonoscopy was performed at diagnosis and/or during follow-up. Hormone (GH, IGF1 and insulin) and metabolic parameters (HOMAIR, Hb1AC) were measured in all patients. Fasting homocysteine (tHcy), folate and vitamin B12 levels and lifestyle (alcohol consumption and smoking habit) data were also collected.
Results
The distribution of MTHFR C677T was in the Hardy–Weinberg equilibrium and was similar in patients with or without CN. CN were detected in 51 patients (adenocarcinoma in three male T allele-carriers patients). Occurrence of CN was significantly correlated with TT genotype ($P=0.03$). There was a significant interaction between folate levels and MTHFR genotype on CN risk ($P=0.037$). In the low folate levels subgroup, TT patients had a 2.4 higher OR for CN than C allele-carriers (95%CI: 0.484–11.891; p NS). At multivariate analysis, smoking habits ($P=0.007$), HbA1c levels ($P=0.021$), dyslipidaemia ($P=0.05$) and uncontrolled acromegaly ($P=0.05$) were independently associated with CN.
Conclusions
In this large cohort of acromegalic patients, risk for CN seems increased, despite not significantly, in patients with MTHFR 677TT and low folate levels. HbA1c, dyslipidaemia, smoking, and disease activity were associated with increased CN risk.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### Clinical characteristics and outcome of acromegaly induced by ectopic secretion of GHRH: a French nationwide series of 21 cases

L. Garby[1], P. Caron[2], F. Claustrat[1], P. Chanson[3], A. Tabarin[5], V. Rohmer[6], G. Arnault[7], F. Bonnet[8], O. Chabre[9], S. Christin Maitre[4], H. Du Boullay[10], A. Murat[11], I. Nakib[12], J. Sadoul[13], G. Sassolas[1], B. Claustrat[1], G. Raverot[1] & F. Borson Chazot[1]
[1]Hopitaux de lyon, Groupement Hospitalier Est, Lyon, France; [2]Hopital Larray, CHU Toulouse, Toulouse, France; [3]Hopital du Kremlin Bicêtre, Assistance publique – Hôpitaux de Paris, Paris, France; [4]Hopital Saint Antoine, Assistance publique – Hôpitaux de Paris, Paris, France; [5]Hopital Haut Levêque, CHU Bordeaux, Bordeaux, France; [6]Hopital Universitaire d'Angers, Angers, France; [7]Centre hospitalier général de Vannes, Vannes, France; [8]Hopital Anne de Bretagne, CHU Rennes, Rennes, France; [9]Hopital de la Tronche, CHU Grenoble, Grenoble, France; [10]Hopital de Chambéry, Chambéry, France; [11]Hopital Nord Laennec, CHU Nantes, Nantes, France; [12]Clinique Courlancy, Reims, France; [13]Hopital L'Archet, CHU Nice, Nice, France.

Context
Ectopic GHRH secretion is a rare cause of acromegaly described mainly in isolated case reports.
Setting
From the registry of the sole laboratory performing plasma GHRH assays in France, we identified cases of ectopic GHRH secretion presenting with acromegaly between 1983 and 2008.
Patients
In total, 21 patients aged 14–77 years, from 12 French hospitals. Median GHRH was 548 ng/l (270–9779).
Main Outcome Measures
Description of tumor features and outcome, relation between plasma GHRH values and tumor site, size and spread.
Results
The primary neuroendocrine tumor was identified for 20/21 patients (12 pancreatic, seven bronchial, one appendicular). Tumors were large (10–80 mm), identified on CT scan in 18 cases and by endoscopic ultrasound and somatostatin receptor scintigraphy (SRS) in two cases. SRS had a similar sensitivity to CT scan (81 vs 86%). Tumors were all well-differentiated; 47.6% had metastasized at the time of diagnosis of acromegaly. After a median follow-up of 5 years, 85% of patients were alive. About 91 percent of patients whose tumor was completely removed were considered in remission and most had normalized plasma GHRH. Remaining patients were treated with somatostatin analogs: IGF1 normalized except for one patient who required pegvisomant, but GHRH levels remained elevated. No correlations were found between GHRH levels and tumor site, tumor size nor the existence of metastases. Determination of plasma GHRH during follow-up was an accurate indicator of recurrences.
Conclusions
The prognosis of endocrine tumors responsible for GHRH secretion appears relatively good. Plasma GHRH assay is an accurate tool for diagnosis and follow-up.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Comparison of intuitiveness, ease of use and preference in two disposable GH injection devices

A. Kappelgaard[1], M. Qvist[1], F. Winter[2], B. Müller[2] & R. Pfäffle[3]
[1]Novo Nordisk, Søborg, Denmark; [2]ikfe CRO GmbH, Mainz, Germany; [3]University of Leipzig, Leipzig, Germany.

Aim
GH is used to treat short stature in children with GH deficiency (GHD), Turner syndrome (TS) and born small for gestational age (SGA). As GH is injected daily, treatment adherence may be problematic. To maximise adherence, improvements in injection devices have been targeted. This report compares intuitiveness and ease of use of two disposable GH devices: Norditropin NordiFlex (NF; Novo Nordisk A/S, Bagsværd, Denmark) and GoQuick (GQ, Pfizer, Inc., New York, USA).

Methods
Children with GHD, TS or SGA, treated with GH (≥6 months) were randomised to intuitiveness (Int, $n=32$; mean (S.D.) age, 13.1 (2.1) years) or instruction (Ins, $n=32$; age, 13.4 (2.0) years) groups. All patients participated in a usability test involving dose setting and injection into an Eppendorf tube for both devices. The Int group was given brief instruction on device use. The Ins group received full instructions according to the patient user guide. Time taken for dose delivery and handling errors was assessed. Following the usability test, participants assessed intuitiveness of use, ease of use and overall preference by questionnaire.
Results
In both groups, fewer errors were made by participants using NF than GQ (Int, 3 vs 19; Inst, 2 vs 5). Time for dose delivery was lower with NF than GQ (Int, 43s vs 66s; $P<0.001$; Inst, 43s vs 48s, NS (Student's *t*-test)). Both groups scored NF higher than GQ in 9/13 categories including: easiest to use, most intuitive, and device of overall preference. In the Int group, 30/32 (94%) participants reported that they would feel safe operating NF without instruction, compared with 10/32 (31%) for GQ.
Conclusions
NF was rated as more intuitive to use; the majority of patients felt safe using it without instruction. The majority of patients preferred NF to GQ, ranking it as easier and more convenient to use.
Declaration of interest
The authors declare that there is a potential conflict of interest.

## P995

**Diabetic retinopathy and GH the case of acromegaly**
S. Azzoug, S. Namani, A. Adem & F. Chentli
Bab El Oued Hospital, Algiers, Algeria.

Although GH has been implicated in the pathogenesis of retinopathy in diabetic subjects, the frequency of retinopathy in diabetic acromegalic subjects is deemed to be rare. The aim of our study is to evaluate the prevalence of retinopathy in hypersomatotropic patients.
Subjects and methods
In total, 40 acromegalic diabetic patients (21 M, 19 F, mean age=50 years) underwent funduscopy to search for diabetic retinopathy
Results
Among 40 patients, only five have retinopathy (prevalence=12.5%), it was at an early stage in three cases (background retinopathy) and at a more advanced stage in two cases (proliferative retinopathy). The mean age was 44.6±15.12 years in patients with retinopathy vs 51.31±13.13 years in patients without retinopathy. There was no correlation with GH levels: 56.8±42.87 ng/ml in patients with retinopathy vs 65.15±70.49 ng/ml in patients without retinopathy, but there was correlation with glycemic control: all patients with retinopathy had bad glycemic control whereas 50% of those without retinopathy had bad glycemic control.
Conclusion
We conclude from this study that diabetic retinopathy is rare in acromegaly. Among different factors only glycemic control seems to be implicated in its pathogenesis
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P996

**Assessing the quality of life of children and adolescents with short stature: development and psychometric testing of the QOLISSY: instrument**
J. Quitmann[1], M. Bullinger[1], J. Chaplin[6], A. Rohenkohl[1], H. Wollmann[3], E. Mimoun[7], A. Pleil[2], M. Herdman[4] & M. Power[5]
[1]University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Outcomes Research Pfizer Incorporated, San Diego, California, USA; [3]Pfizer GmbH, Tübingen, Germany, [4]Insight Consulting and Research S.L., Barcelona, Spain, [5]University of Edinburgh Morningside Park Royal Edinburgh Hospital, Edinburgh, UK, [6]University of Gothenburg, Gothenburg, Sweden, [7]Hopital Des Enfants, Toulouse, France.

In children whose height is substantially below norms, behavioural and emotional problems can be experienced. When evaluating the outcomes of treatments or making treatment decisions, health related quality of life (HrQoL) should be taken into consideration. At present, no standardised HrQoL instrument for short stature youth exists. Through consensus building in five countries, the objective of this study was to develop and psychometrically test a growth-related HrQoL instrument for use in clinical and epidemiologic research.

The target population consists of short stature children (height $<-2$ SDS) with a diagnosis of GHD/ISS, treated/untreated with GH. Children (8–12) and adolescents (13–18) were included as well as their parents and parents of children between 4 and 7 years. The project followed international instrument development guidelines and a patient-centred methodology. Focus groups eliciting statements about HrQoL, cognitive debriefing, pilot testing and a field test with a retest of the eventual questionnaire were conducted simultaneously in all five countries. Both qualitative and quantitative analyses were carried out.

Following item generation through focus groups with a total of 196 participants, 124 items for children and 156 for parents were included in a pilot test with cognitive debriefing. Statistical analysis of the pilot test results identified the psychometric properties of the instrument. A total of 336 families participated in the field test. Of these, 162 completed a re-test questionnaire. Further item reduction was performed using differential item functioning and structural equation modelling. The final questionnaire consists of a 3-domain core structure with 21 items, the full questionnaire being 49 items for children in six domains and 65 items for parents across eight domains. The questionnaire demonstrated good criterion and construct validity. In addition the questionnaire has good face validity and has been shown to provide reliable results over time.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Factors affecting IGF1 response to GH during transition**
A. Thankamony[1], D. Capalbo[1], J. Heywood[1], R. Williams[1], K. Ong[1,2], D. Dunger[1] & H. Simpson[2]
[1]University of Cambridge, Cambridge, UK; [2]Institute of Metabolic Science, Cambridge University Hospitals Foundation Trust, Cambridge, UK.

Background
GH replacement during the childhood-adult transition period is important for somatic maturation. The aim of the study was to explore the factors influencing IGF1 response to GH during transition.
Methods
KIMS (Pfizer International Metabolic Study) database in UK was interrogated, and 98 patients (55 male, median age 20.7 years (15.7–25.8)) with childhood-onset GH deficiency (Co-GHD), who were started on adult dose of GH during transition (age <26 years) were identified. IGF1 SDS were estimated using age and gender specific normative data. 'IGF1 response' was calculated from baseline IGF1 levels prior to GH therapy, mean IGF1 levels and the corresponding GH doses from 6 to 24 months of starting treatment, using the formula: ΔIGF1 SDS/GH dose (mg/surface area).
Results
During GH treatment, mean IGF1 SDS ±S.D. of the patients increased from -2.90±1.96 to 0.054±1.79 after a median period of 12 months. However, the IGF1 levels were lower than the recommended ranges (0–2 SDS) in 43 patients (44%). In women, baseline IGF1 levels were lower ($P=0.006$), and was associated with a higher GH dose ($P<0.001$) and reduced IGF1 response ($P=0.021$) (Table). IGF1 response was also reduced in younger patients ($r=0.29$, $P=0.006$). Among women, oral oestrogen therapy ($n=27$) was associated with a higher GH dose (0.34±0.12 vs 0.24±0.09 mg/m$^2$, $P=0.007$), but lower IGF1 levels (−0.84±1.70 vs 0.69±1.42, $P=0.004$) and thus a lower IGF1 response (10.0±4.7 vs 13.8±6.7 mg/m$^2$, $P=0.001$). In contrast, testosterone therapy in men ($n=30$) was related to a higher IGF1 response (16.6±8.2 vs 9.9±5.8 mg/m$^2$, $P=0.016$). The number or type of other hormonal deficiencies did not affect the response to GH.
Conclusions
In this study, IGF1 response to GH during transition was evaluated in a large group of patients for the first time, and associations with age, gender and sex hormone replacement therapy were observed. Further studies are required to explore the effects of these factors on other endpoints of GH replacement during this period of somatic development.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Quality of life in adult patients with GH deficiency and neurosecretory dysfunction at the end of GH therapy

J. Quitmann[1], U. Kammerer[1], M. Bullinger[1], C. Schöfl[2] & H. Dörr[2]
[1]University Medical Center Hamburg-Eppendorf, D20246 Hamburg, Germany; [2]Universität Erlangen-Nürnberg, 91054 Erlangen, Germany.

GH is used primarily to increase adult height in short children with GHD/NSD with little knowledge about the impact of GH on health-related quality of life (HRQoL). Therefore this study was carried out to evaluate HRQoL in adult patients with childhood onset GHD/NSD at the end of GH therapy.

HrQoL was measured by patient self-report using two generic questionnaires, SF36 and NHP. Patient data were compared to representative norm data. Clinical data as well as socio-demographic data was collected.

The patient group comprised 53 men (M = 22.2 years) and 32 women (M = 24.2 years). About, 53% patients were diagnosed with GHD and 46% were diagnosed with NSD. At the beginning of treatment the mean height of male and female patients was 126 cm, with no significant difference between males and females. Patients were treated between 1 and 13 years with GH. Mean age at start of GH therapy was 10.5 years, mean height gain was 41 cm. Subject reported mean final height was 167 cm, males were significantly taller than females (172 vs 158 cm).

In the SF-36 significantly lower scores were found on the scales vitality ($P<0.001$) and social functioning ($P=0.037$) as compared to the reference population. Males reached higher vitality scores than females ($P=0.043$). In the NHP patients reported lower scores in the dimensions energy ($P<0.001$) and social isolation ($P=0.003$) compared to the reference population; no gender differences were found.

Earlier studies reported conflicting results concerning the HrQOL of GHD patients after GH treatment. The present study found impairments in HrQOL compared to the reference population, especially regarding vitality/energy and social functioning/-isolation. However, due to the cross-sectional nature of this study, HrQOL at start of treatment could not be included in the analysis.

### Hypertension and cardiovascular risk factors in GH deficiency

N. Fedala, F. Chentli & A. Haddam
BAB EL OUED, Algiers, Algeria.

Studies showed an increase of cardiovascular risk (CVR) and reduction of the life expectancy observed in the anterior pituitary insufficiency (API) subjects. The morbimortality would be related to GH deficiency not substituted.

Aim
To seek the frequency of the hypertension and analyse the predictive factors in subjects with API.

A retrospective study relating 55 (47 women, eight men) subjects with API: interrupted pituitarystalk n:6, Sheehan syndrom n:45, non-functioning pituitary adenoma n:4 followed during 10 years and substituted apart from the GH. The average of PAS and PAD were compared with a reference group (n:60:51 women, nine men).

API subjects with HTA (API+) were compared with non-hypertensive subjects (API−)

Results
The average of PAS and PAD were higher than the witness: 120.86 vs 120.23 mmHg ($P<0.064$); 70.76 vs 70.27 mmHg ($P<0.01$) for men 120.90 vs 120.60 mmHg ($P<0.05$); 70.88 vs 70.30 mm Hg ($P<0.005$) for women.

Hypertension was found in 20% of cases (11/55). Its appeared 8 years after (1–15) diagnosis.

IAPI+ARE OLDER 552.45±3 vs 35.65±2 years $P<0.001$) and have more important hypercholesterolemia than others (CT = 2.27±0.11 vs 1.86±0.08 g/l $P<0.02$).

In the other hand we did not found significant difference for family history, BMI (31.02±2.7 vs 22.2±0.81 kg/m $P<0.106$), triglyceridemia 1.91±0.3 vs 1.39±0.15 g/l $P<0.12$) glycemia (0.81 vs 0.84 g/l $P=0.59$ and GH (1.66±0.68 vs 2.17±0.4 mUI/l $P<0.52$).

Our results joint the literature regarding the frequency of the hypertension, the age and the dyslipidemia as predictive factors, the familiar history, the BMI and the degree of GHD do not seems to be CVR. Its necessary to substituted with growth hormone and to treat the others CVR.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Anti-androgen flutamide alters gene expression in the porcine fetal ovary

K. Knapczyk-Stwora[1], M. Durlej[1], M. Duda[1], J. Galas[1], M. Koziorowski[2] & M. Slomczynska[1]
[1]Jagiellonian University, Krakow, Poland; [2]University of Rzeszow, Rzeszow, Poland.

In pigs, the assembly of primordial follicles and their subsequent transition to the primary stage occur in the late gestational and neonatal period. Previously, we reported the presence of androgen receptors in the porcine fetal ovary on different days of gestation, which suggests a fetus capacity to respond to androgens. Since testosterone was detected in the plasma of porcine female fetuses during the second half of pregnancy, it is possible that androgens are involved in prenatal folliculogenesis. Hence, we hypothesize that androgen deficiency during critical prenatal windows may alter expression of genes associated with ovarian development. Therefore, pregnant sows were injected with anti-androgen flutamide (50 mg/kg bw, seven times, every day) starting at day 43, 83 and 101 of gestation. Fetal ovaries were obtained on days 50, 90 and 108 of gestation, fixed in Bouin's fixative for histology and immunohistochemistry or frozen in liquid nitrogen for real-time PCR analysis.

Immunohistochemistry was performed using a mouse monoclonal anti-Ki67 antibody (cell proliferation marker; dilution 1:75, Dako) or a goat polyclonal anti-GATA4 antibody (transcription factor involved in gonadal gene regulation; dilution 1:2000, Santa Cruz). Afterwards, to show Ki67 and GATA4 mRNA in the fetal porcine ovaries real-time PCR was carried out.

Immunohistochemical reaction revealed a higher number of proliferating cells in the fetal ovaries of flutamide-treated animals. Moreover, GATA4 expression has changed after flutamide exposure. Interestingly, prenatal antiandrogen administration resulted in GATA4 mRNA and protein up-regulation in the ovaries from days 50 and 108 of gestation, and their down-regulation on day 90 of gestation.

Our preliminary results suggest that diminished androgens action via blocking of androgen receptors leads to changes in the expression of genes crucial for ovarian development. It seems that androgens exhibit diverse biological actions depending on the gestational period.

### Relationship between GH activity and reproductive hormones: a randomized cross-over study in healthy male volunteers treated with GH and a GH receptor antagonist for three weeks

M. Andreassen[1], J. Frystyk[2], A. Juul[3], J. Faber[1] & L. Kristensen[1]
[1]Herlev Hospital, University of Copenhagen, Herlev, Denmark; [2]Arhus University Hospital, Arhus, Denmark; [3]Rigshospitalet, Uiversity of Copenhagen, Copenhagen, Denmark.

Introduction
The GH/insulin-like growth factor 1 (IGF1) system may modulate the pituitary-gonadal axis in males. Direct pituitary and/or testicular effects might be involved, as well as indirect effects on sex hormone binding globulin (SHBG) and aromatase activity.
Methods/design
Nine healthy male volunteers (mean age 37, range 29–49 years) were treated in random order with increasing doses of GH for three weeks (1st week 0.01, 2nd week 0.02, 3rd 0.03 mg/kg per day) or a GH receptor antagonist (pegvisomant; 1st week 10, last 2 weeks 15 mg/day), separated by eight weeks of wash-out. Before and after three weeks of GH treatment or GH receptor blockage circulating levels of testosterone, estradiol, LH and SHBG were measured.
Results
During GH treatment IGF1 increased ((mean $\pm$ 1S.D.) $140 \pm 41$ vs $448 \pm 97$ μg/l, $P < 0.001$) together with estradiol ($77 \pm 22$ vs $107 \pm 30$ pmol/l, $P = 0.015$) and the estradiol/testosterone ratio ($P = 0.001$). By contrast LH tended to decrease ($4.3 \pm 1.9$ vs $3.6 \pm 1.7$ U/l, $P = 0.053$). The opposite was found during pegvisomant treatment where IGF1 ($151 \pm 35$ vs $103 \pm 29$ μg/l, $P = 0.001$) and estradiol ($86 \pm 27$ vs $79 \pm 23$ pmol/l, $P = 0.038$) decreased. No changes in testosterone, SHBG or calculated free testosterone (testosterone $\times$ 100/SHBG) occurred during the two treatment regimens.
Conclusions
High GH/IGF1 activity was positively associated with serum estradiol. The study supports that GH/IGF1 action stimulates aromatase activity *in vivo* with subsequent increased conversion of testosterone to estradiol during GH treatment and visa versa during GH receptor blockage. The decrease in LH during GH treatment may support increased oestrogen activity with increased negative feedback at the pituitary gland. High levels of endogenous GH/IGF1 during puberty might chance the estradiol/testosterone-ratio thereby contributing to development of pubertal gynaecomastia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Baseline characteristics and differences in short- and long-term response to rhGH between GHD adults with craniopharyngioma and nonfunctioning pituitary adenoma

E. Profka[1,2], C. Giavoli[1,2], S. Bergamaschi[1,2], E. Ferrante[1,2], E. Malchiodi[1,2], E. Sala[1,2], E. Verrua[1,2], A. Spada[1,2] & P. Beck-Peccoz[1,2]
[1]Milan Italy; [2]Unit of Endocrinology and Diabetology, Milan, Italy.

Patients with craniopharyngioma (CP) are more often operated by transcranial route than patients with nonfunctioning pituitary adenoma (NFPA), have higher prevalence of pituitary deficiencies, are more obese and dyslipidemic and have a higher mortality rate. A previous study in a large group of GHD subjects, showed that the effects of 2-year rhGH replacement are similar in patients operated for CP and in patients operated for NFPA, except for less reduction in fat mass in CP patients. Aim of the study was to compare both short- (12 months) and long-term (mean follow-up 8 years, range 3–14 years) effects of rhGH in 26 GHD adults patients, 12 operated for CP and 14 for NFPA. Serum IGF-I, lipid profile, glucose metabolism, insulin resistance (HOMA-IR), anthropometric parameters and body composition (BF%) were evaluated. At baseline, no difference between the two groups was observed. After 12 months, SDS IGF-I normalized and BF% significantly decreased in both groups. Concerning long-term effects, increase in IGF-I levels was maintained, while persistent decrease in BF% was observed only in NFPA group. Comparing the data between groups at each follow-up, CP group had a lower ΔBF% than NFPA group ($-3.4 \pm 2$ vs $-10.1 \pm 10$, at short-term, $P < 0.04$ and $-0.7 \pm 11$ vs $-11 \pm 13.7$, at long-term, $P < 0.05$, respectively), as well as higher serum insulin levels ($19 \pm 15$ vs $9.4 \pm 6.5$, $P < 0.04$ and $16.2 \pm 10.4$ vs $9 \pm 4$ uIU/mL, $P < 0.03$ respectively) and higher HOMA-IR ($4.1 \pm 3.2$ vs $2 \pm 1.3$, $P < 0.04$ and $4.4 \pm 4.5$ vs $1.9 \pm 0.9$, $P < 0.05$, respectively). In conclusion, we confirm in the long term study the minor BF% reduction in CP versus NFPA patients. Moreover, patients with CP were more prone to develop insulin resistance than NFPA patients.

### A new somavert (pegvisomant) 30 mg/ml formulation compared to the currently marketed 15 mg/ml formulation: pharmacokinetics, safety, and tolerability in healthy subjects

J. Jen, R. LaBadie, Y. Liang, P. Crownover, X. Gao & J. Hey-Hadavi
Pfizer, Inc., New York City, New York, USA.

Introduction
Pegvisomant is indicated for acromegaly. Doses $>20$ mg are not commercially available, although daily doses up to 30 mg are approved.
Objectives
1. To estimate the relative bioavailability (relBA) of single-dose pegvisomant s.c. administrations, one injection of 30 mg/ml ($1 \times 30$) vs two injections of 15 mg/ml ($2 \times 15$), and 2. To evaluate their pharmacokinetics (PK), safety and tolerability.
Methods
This was a 2-period, single-dose, crossover study in 14 healthy male and female subjects. All subjects received both doses, $1 \times 30$ and $2 \times 15$, during two treatment periods separated by two weeks. The injection instructions were given in great details and closely followed to reduce variability. Intensive serum samples were collected up to 16 days post injection and were assayed by a validated ELISA for pegvisomant. PK parameters including AUC and Cmax were derived by noncompartmental analyses. Mixed effects model was used to obtain bioavailability estimates. Safety and tolerability were assessed by clinical monitoring, including adverse events, laboratory assessments and injection site reactions.
Results
All subjects completed the study. The relBA of $1 \times 30$ relative to $2 \times 15$ was 123.89% with a 90% CI (112.91–135.93%). The PK parameters are summarized in Table 1. Adjusted for the difference between actual and nominal pegvisomant amounts in both formulations the difference in dose-adjusted AUC reduced to 13%. Different injection solution concentrations and different number of injections might also have a role. No laboratory abnormalities, vital signs, ECG, or injection site reactions of clinical concern were observed in either treatment.
Conclusions
Comparable BA, safety and tolerability of the new 30 mg/ml strength to the currently marketed 15 mg/ml strength were established in this study.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Thyroid function during long-term GH treatment in children affected by idiopathic GH deficiency**

A. Ciresi, V. Guarnotta, C. Perrone, A. Galluzzo & C. Giordano
[1]Dipartimento Biomedico di Medicina Interna e Specialistica (Di.Bi.Mi.S), University of Palermo, Palermo, Italy.

Alterations in the thyroid axis have been reported following GH therapy both in adults and children with GH deficiency (GHD), even if the clinical significance of these changes, in small and short-term studies, remains uncertain. To evaluate the impact of GH replacement on thyroid status in a large selected cohort of prepubertal children with idiopathic GHD during a 3-years follow-up. Study outcome considered FT3, FT4 and TSH modifications (delta) during therapy and their correlations with IGF-1, biochemical and auxological data. Data of 105 children (82 M, 23 F; mean age 11.13) were retrospectively analysed. At diagnosis, the areas under the curve of GH (AUCGH) were calculated during GHRH-Arg test and ITT. At baseline and yearly up to 36 months during GH treatment, we measured height-velocity, BMI, IGF-1, FT3, FT4, TSH. A significant FT3 delta ($P<0.001$) was documented in 89/105 (84.7%) patients at 12 months after starting GH treatment, without any further change at 24 and 36 months. No significant FT4 and TSH delta were observed during the follow-up. Grouping all patients according to FT3 delta at 12 months in those with lower (No 80, 76%) or greater value than 75 percentile (No 25, 24%), the latter showed significantly lower AUCGH during GHRH-Arg ($P=0.018$) and ITT ($P=0.023$). These children also showed lower FT3 levels at baseline ($P<0.001$), without difference in FT4 and TSH. No significant differences in auxological parameters were detected between the two groups. In GHD children, GH treatment is associated with a significant increase in FT3 levels in the first 12 months. However, the lack of significant effects of these changes in relation to the auxological parameters does not suggest the routinely monitoring of thyroid function in initially euthyroid patients.

**Variations of IGF1 in GH deficiency and Algerian health children**

N. Fedala, F. Chentli, A. Haddam & L. Griene
BEO Hospital, Algiers, Algeria.

IGF1 represent an important key player in several physiologic process, so it can be implicated in different pathologies among delays of growth. A comparative study was realized comparing a group of healthy Algerian children of normal size (*n*: 266) and a group presenting a GH deficiency (GHD *n*: 107)to a group of healthy westerners children of normal size(Serie of ROSENFIELD).

The results are as follows

Before the age of 04 years, there is a great overlapping in the results of IGF1 between children who suffer from GHD and those of the comparative group.

After this age, results of IGF1 are significantly low in GHD subjects, compared to the Algerian reference group.

The values of IGF1 found in the Algerian healthy subjects are significantly lower than those observed in the western healthy children. So this parameter must be carefully interpreted when investigating a delay of growth in Algerian and must take into account the clinical and biological context of the patient. It is necessary to establish Algerian standards for IGF1. The introduction of the IGFBP3 not yet available would be more interesting in our context.

**Association Turner's syndrome and GH deficiency**

I. Oueslati, I. Hadj Ali, K. Khiari, N. Mchirgui & N. Ben Abdallah
Charles Nicolle Hospital, Tunis, Tunisia.

One of the most clinical characteristic of Turner's syndrome is the final short stature.

In order to cure this handicap, several teams were interested to treat these patients by the GH.

We report two cases of Turner syndrome associated with GH deficiency.

In the first, a 17 years old girl, having a delayed growth lower than −4 S.D. associated with delayed puberty and dysmorphic syndrome. A karyotype made confirmed the diagnosis of Turner's syndrome. In front of the short stature lower than that usually found in the Turner syndrome, GH was measured during insulin induced hypoglycaemia test and L-dopa test. The two tests revealed a GH deficiency.

The second observation is about a 21 years old girl having a delayed growth between −2 and −3 S.D. associated with delayed puberty and dysmorphic syndrome.

The karyotype finds a chromosomal formula with 45×0 confirming the Turner's syndrome.

GH was measured under stimulation test, showing a GH deficiency.

The dosage of the GH in Turner's syndrome appears interesting and must be of current practice especially when the short stature is lower than that usually found in Turner syndrome.

**The homologous hormones lutropin and choriogonadotropin are interacting differently with the LH/CG receptor**

P. Grzesik[1], A. Teichmann[1], A. Kreuchwig[1], J. Furkert[1], C. Rutz[1], B. Wiesner[1], R. Schülein[1], J. Gromoll[2] & G. Krause[1]
[1]Berlin, Germany; [2]Reproduktionsmedizin und Andrologie, Münster, Germany.

Activation of the human LH/CG receptor (LH/CGR) by lutropin (LH) and choriogonadotropin (CG) is essential in the human reproduction. Deletion of the Exon10 (LH/CGR-delExon10) resulting in a lack of 27 amino acids within the extracellular hinge-region of LH/CGR causes Leydig cell hypoplasia type II. To clarify why this deletion impairs LH but not CG action, we investigated the molecular determinants of LH/CGR activation elucidating the different behaviour of both hormones.

It is reported that the LH/CGR exist as oligomers in a unitary signalling unit when activated with CG, since individual binding- and signalling-defective mutants can be rescued by combining both. We performed a similar strategy including also LH/CGR-delExon10 as signalling defective mutant. However, in contrast to CG,

the functional rescue was not possible by stimulation with LH, which fails to bypass the lack of Exon10 by trans-activating the neighbouring protomer. Our results indicate different activation mechanisms for LH and CG at LH/CGR-delExon10. Moreover, similar results were also achieved with a complete hinge-region but different signalling disturbing positions. Fluorescence correlation spectroscopy indicates no disturbance in oligomerization of the LH/CGR-delExon10. Homology modelling suggest a helical entity for exon10 region. Substitution of block wise alanine mutations showed no effect on both LH and CG activation.
We conclude that residues comprising Exon10 form a structural interface with helical portion, which might be necessary for cis-interaction of LH and LH/CGR. Thus the LH related dysfunction of LH/CGR-delExon10 is likely caused by disturbed native cis-interaction between LH and receptor in which each protomer bind and signal on its own, rather than by an interrupted LH related trans-activation.

**Differential expression of pseudoautosomal region genes in patients with Klinefelter syndrome**

D. Zuccarello, E. Speltra, L. Perilli, R. Selice, A. Ferlin & C. Foresta
University of Padova, Padova, Italy.

Klinefelter syndrome (KS) was first described in 1942 and the cause for the syndrome was identified as a supernumerary X chromosome resulting in the karyotype 47,XXY. 80–90% of KS cases bear this karyotype, whereas the remaining exhibit (in decreasing frequency) varying mosaicism (e.g. 47,XXY/46,XY), carry additional sex chromosomes (48,XXXY; 48,XXYY; 49,XXXXY) or structurally abnormal X chromosomes. The prevalence of KS is up to 1 in 500 boys, and it is the most common chromosomal aberration in men (0.1–0.2% of the male population). Although KS has been extensively studied in the last decades, the pathophysiology, i.e. the link between the supernumerary X and the phenotype, largely remains unclear and the variability unexplained. Apart from normal interindividual genetic variation, several genetic mechanisms may be involved in the variability of the phenotype: in principal, the parental origin of the X chromosome and gene-dosage effects (GDE) in conjunction with (possibly skewed) X chromosome inactivation. In order to clarify the role of GDE in KS, we analyzed 63 patients with non-mosaic karyotype by Quantitative Real Time PCR, comparing the results of expression of 12 genes (ASMTL, CSF2RA, DHRSXY, DXYS155E, MIC2, P2RY8, PGPL, PR48, SLC25A6, SPRY3, SYBL1, ZBED1) located in the pseudoautosomal region1 and 2 (PAR1 and 2) of X-chromosome with the results obtained from 38 XY fertile male, 35 XX fertile female and 4 non-mosaic Turner syndrome patients. The obtained results showed a differential expression of PAR1 and 2 genes between KS and controls (male and female), and for many of these genes this is the first description of their expression behaviour in male and KS. Finally, a genotype–phenotype correlation for the genes whose function is known was attempted, disclosing appealing pathogenetic hypothesis.

## P1009

**Rab-like 2 (RABL2) function in male fertility, intra-flagella transport and sperm tail assembly**

J. Lo & M. O'Bryan
Monash University, Melbourne, Victoria, Australia.

Infertility affects 1 in 20 Australia men of reproductive age, and for the majority, the causes remain unknown. In an effort to identify addition key pathways and proteins involved in male fertility we undertook a random mouse mutagenesis screen. In the process we identified the Mot1 line which carries a point mutation in the *Rabl2* gene. Mot1 homozygous male are sterile, have a reduced daily sperm output, short sperm tails and drastically reduced progressive sperm motility.
RABL2 is an uncharacterised member of the RAS GTPase superfamily. Many RAS proteins are involved in membrane trafficking and cell signaling. Some small GTPases are capable of switching between an inactive and active state and of binding to a specific set of effector proteins that they transport around the cell. Our data shows that RABL2 is expressed highly in male haploid germ cells and other ciliated tissues and interacts with a key pathway involved in flagella development. Specifically RABL2 binds to intra-flagella transport (IFT) complex B particles. Further, GTP-bound RABL2 binds to a specific set of effector proteins, including key components in glycolytic pathway that it delivers into the growing sperm tail.
Further, molecular modeling shows the Mot1 mutation is located within a β-sheet required for protein–protein interactions. The Mot1 mutation leads to a delayed conversion of RABL2 from the inactive GDP-bound state into the active GTP-bound state. Ultimately this leads to decreased RABL2-effector protein binding and a failure of effector proteins delivery into the tail and sterility. The above results demonstrate the function of previously uncharacterised protein, RABL2, as an essential regulator of sperm flagellum formation and function and raise the possibility that mutations in RABL2 may underlie cases of human infertility.

**Prevalence of olfactory and other developmental anomalies in patients with central hypogonadotropic hypogonadism**

E. Della Valle[1], S. Vezzani[1], V. Rochira[1], A. Granata[1], C. Carani[1], E. Genovese[2] & M. Simoni[1,3]
[1]University of Modena and Reggio Emilia, Azienda Unità Sanitaria Locale of Modena, Modena, Italy; [2]University Hospital of Modena, Modena, Italy; [3]University of Modena and Reggio Emilia, Modena, Italy.

Introduction
Hypogonadotropic hypogonadism (HH) is a heterogenous disease caused by mutations in several genes. Based on the presence of hyposmia/anosmia it is distinguished into Kallmann syndrome and isolated HH. The prevalence of other developmental anomalies is not well established.
Methods
We studied patients with HH (29 males, 3 females, mean age 41.5), 9 with familial and 23 sporadic HH (29 congenital, 3 adult-onset), by physical examination, smell test (BSIT Sensonics), audiometry, renal ultrasound, and magnetic resonance imaging of the olfactory structures.
Results
Based on the smell test, patients were classified as normosmic ($n=19$, 59.4%) and hypo/anosmic ($n=13$, 40.6%). Hypoplasy/agenesis of olfactory bulbs was found in 38% of patients (8/21), (80% hypo/anosmic, 8.3% normosmic, $P< 0.05$, $X^2$-test). Remarkably, olfactory structures were normal in 2 anosmic patients, while 1 normosmic patient presented a monolateral hypoplastic bulb. 9 of 22 patients (40.9%) presented neurosensorial hearing loss of various degrees (36.3% hypo/anosmic, 41.6% normosmic, $P=$NS). Renal ultrasound revealed 28.1% of cases with renal anomalies (30.7% hypo/anosmic, 26.3% normosmic, $P=$NS). At least one midline defects was found in 48.3% of patients (58.3% hypo/anosmic, 42.1% normosmic, $P=$NS): 13/31 abnormal palate (41.6% hypo/anosmic, 42.1% normosmic, $P=$NS), 6/31 agenesis of one or more teeth (25% hypo/anosmic, 15.7% normosmic, $P=$NS), 2/31 pectus excavatum (8.3% hypo/anosmic, 5.2% normosmic, $P=$NS), 2/31 bimanual synkinesis (8.3% hypo/anosmic, 5.2% normosmic, $P=$NS), 2/31 iris coloboma and absent nasal cartilage (15.3% hypo/anosmic, 0% normosmic, $P=$NS). Anamnestically 4/26 patients reported cryptorchidism (30% hypo/anosmic, 6.2% normosmic, $P=$NS).
Conclusions
Hypo-anosmia is significantly related to anatomical anomalies of the olfactory bulbs/tracts but the prevalence of other developmental anomalies, especially hearing loss, is high both in HH and Kallmann syndrome and independent of the presence of anosmia/hyposmia. From the clinical standpoint Kallmann syndrome and isolated HH should be considered as the same complex, developmental disease.

**Total Testosterone levels and predisposing criteria for metabolic syndrome in healthy young men**

A. Hlazkova[1], N. Murashko[1], L. Danilova[1], A. Romanouski[1], N. Yaroshevich[1], D. Raduk[1], E. Dashkevich[2] & V. Pishchik[2]
[1]Medical Academy of Post-Graduate Education, Minsk, Belarus; [2]10-th Clinical Hospital, Minsk, Belarus.

Object of the study
To evaluate total testosterone (TT) levels in healthy young men and determine its possible influence on metabolic syndrome risk factors.
Materials and methods
One hundred and twenty-six practically healthy young men, mean age 20.16 ± 1.42 years old (18–29) were included in the study. Individuals with any clinical manifestations suspicious for hypogonadism, chronic liver and kidney diseases in the anamnesis or receiving any kind of long-term medical therapy were excluded from the study. Evaluation of every patient consisted of general examination, anthropometric data, blood pressure, blood samples for serum glucose, lipid spectrum, total testosterone and LH.
Results please see Table 1.
During the correlation analyses of total testosterone and its dependence of following indicators of metabolic syndrome: BMI, WC, systolic and diastolic blood pressure, TG and HDLP, positive correlation with serum HDLP level ($r=0.2016$, $P<0.05$) has been established. Despite the fact that, obesity and overweight indicators - BMI and WC are not connected with the level of total testosterone in healthy young men, we managed to establish significant correlation between total testosterone level and % of VF ($r=0.2014$, $P<0.05$)
Conclusion
In young men without metabolic syndrome manifestation has been established significant correlation between total testosterone level and % of visceral fat and HDLP level.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Functional status of pituitary–gonads axis in males with obesity**

Y. Urmanova & I. Nabieva
Tashkent Pediatric Medical Institute, Bogishamol Street 223, Tashkent 100140, Uzbekistan.

Aim
– to study functional status of pituitary–gonads (PG) axis in males with obesity.
Materials and methods
We evaluated 15 males with obesity without other associated pathology. Mean age of patients was 28.3 years old. Control group constituted by 20 healthy men with different age.
All patients underwent clinical and biochemical evaluations including endocrine check, lipids profile, hormonal profile (LH, FSH, prolactin, sex steroid binding globulin, free testosterone), genitalia ultrasonography, height, body mass, waist circumference (WC), hip circumference (HC), waist-hip ratio, questioning and other studies.
Results
Hormonal profile showed normogonadotrphemia in nine patients (60%) (mean LH ranged 8.7 ± 1, 2 mIU/l, FSH 6.4 ± 1.5 mIU/l) and significantly low free testosterone levels (mean 5.6 ± 0.3 ng/ml). Most of the patients had central obesity with BMI > 35 kg/m$^2$. WC was in normal range 104.3 ± 7, 4 cm, HC = 85, 6 ± 5.3 cm, whereas waist-hip ratio > 1, 22. Blood tests showed dyslipidemia in all patients (100%).
Conclusion
i) Most fertile men with obesity (60%) have normogonadotrophemia with partial decrease of free testosterone in all patients. ii) To discover the pathogenesis of PG axis disorders in men with obesity further researches are needed.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Deletion of FSTL3 increases testicular size and delays testicular regression**

A. Mukherjee[1], K. Oldknow[1], J. Seebacher[2], J. Villen[2], T. Goswami[2], S. Gygi[2], P. O'Shaughnessy[3] & A. Schneyer[4]
[1]Royal Veterinary College, London, UK; [2]Harvard Medical School, Boston, Massachusetts, USA; [3]University of Glasgow, Glasgow, UK; [4]Pioneer Valley Life Sciences Institute, University of Massachusetts, Springfield, Massachusetts, USA.

Follistatin-like 3 (FSTL3) is a secreted glycoprotein known to act as an inhibitor of TGFβ ligands such as activin and myostatin. Like activin, FSTL3 is expressed strongly in the testis but the role FSTL3 plays in testis development and physiology is not clearly understood. Here we show that FSTL3 is a key regulator of testicular size and a promoter of age-dependent testicular regression. FSTL3 deletion in mice leads to the development of enlarged testes that show delayed age-related regression. Importantly, testosterone production and spermatogenesis are not altered in FSTL3 KO mice. Increased testicular size in FSTL3 KO mice was associated with increased Sertoli cells and germ cell numbers although Leydig cell numbers were not affected. To identify and investigate molecular pathways contributing to these phenotypes we undertook a quantitative proteomics approach. We find increased AKT signalling, a promoter of cell proliferation, and increased expression of Sirt1, an anti-ageing protein, in FSTL3 KO testis. Survival and maintenance of species depend on timed testicular development and regression, testicular regression being particularly relevant in seasonal breeders. We therefore demonstrate that FSTL3 is a protein that normally blocks inappropriate cellular proliferation in the testis and regulates the maintenance of testicular function.

## P1015

### High prevalence and interaction of hypogonadism and the metabolic syndrome in long-term survivors with germ cell tumours

M. Zitzmann, F. Gottardo, L. Grunwald, G. Pühse, A. Secker & S. Kliesch
University Clinics Muenster, Muenster, Germany.

Introduction and objectives
Testicular cancer survivors (TCS) are at a putative risk to develop premature testosterone deficiency (TD). The clinical and biochemical components of TD and the metabolic syndrome have not been thoroughly described in such patients.
Material and methods
Prospective clinical trial: 163 TCS took part in the study, clinical parameters, sex hormones and biochemical values were assessed in fasting blood samples, MS was defined according to the harmonized criteria of 2009 (IDF&NCEP). Intima-media thickness of carotid arteries was measured. Validated German Questionnaires of AMS scale and IIEF 15 were administered.
Results
Mean age at presentation was $40.3 \pm 8.4$ years and median follow-up was 7 years. 102/163 pts. (62,6%) had received polychemotherapy, 49 (30%) radiotherapy. 15 pts. had undergone bilateral orchiectomy and are under T substitution, 24 pts. with unilateral tumour were at the time of the study already under T substitution. 39/163 pts. (23.9%) had a total T level of $<12$ nmol/l. 57/163 pts. (35.0%) fulfilled the criteria for the MS. In multivariate models, waist circumference, high triglyceride levels and decreased insulin sensitivity (QUICKI) were markedly associated with low testosterone levels ($P=0.006$, $P=0.005$ and $P=0.002$ respectively). TD was predictive for overall presence of MS ($P=0.01$) and the number of fulfilled criteria ($P=0.01$). Tumour characteristics and type of chemotherapy were not associated with a increased risk to develop TD.
Conclusions
Data confirm the high prevalence of TD and MS in long-term TCS. Pivotal clinical and biochemical components of TD as well as the MS are strongly exhibited in TCS. TCS should be closely monitored beyond a 10-years-follow-up-period and according to risk-prediction models encompassing pertinent markers for both clinical entities, TD and MS. This could help to identify patients who could benefit from an early T replacement, thus improving their quality of life and probably reducing their cardiovascular risk.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Mutation analysis of *NR5A1* gene encoding steroidogenic factor 1 in cryptorchidism and male infertility

A. Ferlin, C. Vinanzi, D. Zuccarello, M. Ghezzi & C. Foresta
University of Padova, Padova, Italy.

The gene *NR5A1*, which encodes steroidogenic factor 1 (SF-1), is a pivotal transcriptional regulator of genes involved in adrenal and gonadal function, including several steroidogenic enzymes and key genes necessary for male sex determination and differentiation, testicular descent and reproduction (such as SOX9, AMH, INSL3, and AR). The most severe phenotypes associated with NR5A1 mutations include gonadal dysgenesis, disorders of sex development (DSD) and adrenal insufficiency. However, recent studies are revealing that the spectrum of phenotypes caused by variations in this gene might be broader and include partial gonadal dysgenesis, hypospadias, microphallus with anorchia, and primary ovarian insufficiency. Preliminary studies also suggested that male infertility and cryptorchidism might be linked to mutations in NR5A1, but the data are not conclusive and replication studies in different populations have not been performed.
To clarify the role of NR5A1 variations in these conditions we sequenced the gene in 404 cryptorchid subjects (279 infants with cryptorchidism and 125 men with history of orchidopexy), 237 idiopathic infertile men with azoo-oligozoospermia, and 187 fertile normozoospermic men (controls).
No variations in *NR5A1* gene was found in controls. A previously described polymorphism (*P*.G146A) was significantly associated with cryptorchidism (6.7% of the cryptorchid population, $P=0.002$) and to a lesser extent with spermatogenic impairment (2.1% of the azoo-oligozoospermic population, $P=0.046$). Furthermore, seven novel predicted damaging missense mutations were found in heterozygous condition in 5/404 (1.2%) cryptorchid subjects and 3/237 (1.3%) infertile subjects.
This study strongly suggests that variations in *NR5A1* gene might be associated also with 'mild' phenotypes represented by spermatogenic impairment and especially cryptorchidism. Although none of our patients have evidence of adrenal insufficiency, long-term follow up of infants with cryptorchidism is needed to verify its possible development, particularly in cases with one of the 7 novel missense mutations identified in this study.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1017

### The Muenster EXAKT project: cardiovascular risk factors in Klinefelter patients and healthy controls

M. Zitzmann, R. Bongers, S. Werler, F. Tüttelmann, C. Rittstieg, L. Edelbrock, J. Gromoll & S. Kliesch
University Clinics Muenster, Muenster, Germany.

Background and Aim
Klinefelter syndrome (47,XXY; KS) is a very common chromosomal disorder, affecting 1:600 men. Klinefelter men have been described to exhibit clinically relevant metabolic patterns related to a pro-inflammatory status, resulting in a high prevalence of insulin resistance and cardiovascular impairment. Testosterone deficiency in form of primary hypogonadism is a common feature in these men.
EXAKT (epigenetics, X-chromosomal features and clinical applications in Klinefelter syndrome trial) is a Muenster-based prospective project involving Klinefelter patients ($n=130$), and their parents assessing a wide area of cardiovascular, inflammatory and metabolic factors as well as sex steroids and questionnaires in comparison to age-matched healthy male and female controls ($2 \times n=50$). A broad range of genetic and epigenetic investigations completes the approach.
Here, we present first and novel clinical data comparing Klinefelter patients to healthy male controls with regard to cardiovascular and metabolic parameters.
Results
KS patients had a higher waist circumference and Body Mass Index in comparison to controls. Further on, decreased insulin sensitivity, higher levels of triglycerides and lipoprotein type a as well as lower concentrations of HDL-cholesterol were found in patients. Levels of high-resolution C-reactive protein were elevated in Klinefelter patients. Consequently, the prevalence of the metabolic syndrome according the Harmonized Criteria was markedly higher in Klinefelter men than in controls (52/130 vs 5/50). Corroboratingly, carotid artery intima-media thickness was increased and flow mediated dilatation of the brachial artery was decreased in patients vs controls. These differences were statistically significant. Metabolic disadvantages of patients were further enhanced by low testosterone concentrations and already present in the sub-cohort younger than 40 years.
Conclusion
The EXAKT project revealed an unfavorable pattern of cardiovascular risk factors in KS in comparison to healthy male controls. This picture is already present in younger patients and enforced by testosterone deficiency.

## P1018

**Cellular distribution, regulated expression and functional role of the anorexigenic peptide, NUCB2/nesfatin-1, in the testis**

D. Garcia-Galiano[1,2,3], R. Pineda[1,2,3], T. Ilhan[4], J. Castellano[1,2,3], F. Ruiz-Pino[1,2,3], M. Sanchez-Garrido[1,2,3], M. Vazquez[1,2], S. Sangiao-Alvarellos[1], A. Romero-Ruiz[1,3], L. Pinilla[1,2,3], C. Dieguez[2], F. Gaytan[1,2,3] & M. Tena-Sempere[1,2,3]
[1]University of Cordoba, Cordoba, Spain; [2]CIBERobn, Cordoba, Spain; [3]IMIBIC, Cordoba, Spain; [4]University of Uludag, Bursa, Turkey.

Nesfatin-1, product of the precursor NEFA/nucleobindin 2 (NUCB2), was initially identified as anorectic hypothalamic neuropeptide, acting in a leptin-independent manner. In addition to its central role in the control of energy homeostasis, evidence has mounted recently that nesfatin-1 is also produced in peripheral metabolic tissues, such as pancreas, adipose and gut. Moreover, nesfatin-1 has been shown to participate in the control of body functions gated by whole-body energy homeostasis, including puberty onset. Yet, whether, as is the case for other metabolic neuropeptides, NUCB2/nesfatin-1 participates in the direct control of gonadal function remains unexplored. We document here for the first time the expression of NUCB2 mRNA in rat, mouse and human testes, where NUCB2/nesfatin-1 protein was identified in interstitial mature Leydig cells. Yet, in rats NUCB2/nesfatin-1 became expressed in Sertoli cells upon Leydig cell elimination, and was also detected in Leydig cell progenitors. While NUCB2 mRNA levels did not overtly change in rat testis during pubertal maturation and after short-term fasting, NUCB2/nesfatin-1 content significantly increased along puberty-to-adult transition and was markedly suppressed following fasting. In addition, testicular NUCB2/nesfatin-1 expression was up-regulated by pituitary LH, since hypophysectomy decreased, whereas human choriogonadotropin (hCG; super-agonist of LH receptors) replacement enhanced, NUCB2/nesfatin-1 mRNA and peptide levels. Finally, nesfatin-1 increased hCG-stimulated testosterone secretion by rat testicular explants *ex vivo*. Our data are the first to disclose the presence and functional role of NUCB2/nesfatin-1 in the testis, where its expression is regulated by developmental, metabolic and hormonal cues, as well as by Leydig cell-derived factors. Our observations expand the reproductive dimension of nesfatin-1, which may operate directly at the testicular level to link energy homeostasis, puberty onset and gonadal function.

Declaration of interest

**Neurocognitive phenotype and personality profile in men with Klinefelter syndrome and their vulnerability to psychiatric symptoms**

A. Jensen[1], A. Pedersen[2], A. Bojesen[3], J. Hertz[4], M. Wallentin[1], J. Østergård[1] & C. Gravholt[1]
[1]University Hospital, Aarhus, Denmark; [2]Aarhus University Hospital, Hammel, Denmark; [3]Vejle Hospital, Sygehus Lillebælt, Vejle, Denmark; [4]Odense University Hospital, Odense, Denmark.

Background

Klinefelter syndrome (KS) is associated with increased risk of psychiatric disease and behavioral problems, as well as social problems. The background for these risks is not known.

Aim

The aim was to describe the cognitive function, personality traits and the vulnerability to psychiatric symptoms in patients with KS.

Methods

Fourty one KS patients and 41 age- and educational-matched control subjects participated in the study. 30 (73%) KS patients received testosterone treatment. All participants were tested with standardized neuropsychological tests and 4 questionnaires investigating psychological problems.

Result

KS patients scored significantly lower in processing speed, working memory, verbal abilities and showed a selective deficit in executive function compared to control subjects, whereas visual cognitive abilities and cognitive response inhibition was preserved. The KS patients displayed significantly higher levels of cognitive failures, emotional distress and autism traits as reported in questionnaires. Furthermore symptoms of anxiety were also significantly higher among KS patients, whereas there were no difference in depressive symptoms between KS patients and control subjects. On the NEO PI-R personality test KS patients scored high on the neuroticism scale, low on the extraversion scale and low on the conscientiousness scale. We could not discriminate between those KS receiving testosterone supplementation or those who did not, which is likely due to a small sample size.

Conclusion

Men with KS have deficits in several cognitive domains and have an altered personality phenotype. Furthermore our results suggest that KS may be associated with an increased vulnerability to psychiatric symptoms. In future analyses, we are going to assess the neuroanatomical, neurofunctional, endocrine and genetic basis for the cognitive deficits, altered personality phenotype and increased psychiatric symptoms seen in KS patients. Whether testosterone therapy or other interventions can alleviate these deficits remain to be proven.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1020

**FSHB promotor polymorphism influences male reproductive parameters**

F. Tüttelmann[1], M. Grigorova[2], N. Terwort[1], M. Punab[3], J. Gromoll[1] & M. Laan[2]
[1]University of Münster, Münster, Germany; [2]University of Tartu, Tartu, Estonia; [3]Tartu University Clinics, Tartu, Estonia.

Introduction

Recently, a single nucleotide polymorphism (SNP) in the FSH (FSH)-β gene (*FSHB* −211G>T, rs10835638) that leads to reduced mRNA transcription was associated with serum FSH levels in an Estonian cohort of young men (Grigorova *et al., Hum Reprod* 2008). Further investigations showed an increased frequency of the T-allele in patients with oligozoospermia compared to men with normozoospermia (Grigorova *et al., JCEM* 2010). Another Baltic study (Grigorova *et al., JCEM* 2011) revealed significant associations with additional reproductive parameters (e.g. testicular volume). Since the three previous studies are limited to men from the Baltic area, a comparable approach was undertaken with patients from the Centre of Reproductive Medicine in Münster.

Methods

A large number of 1213 patients visiting for infertility workup (615 with normal and 598 with reduced sperm concentration, cut-off 20 Mill./ml) were retrospectively selected. Patients with known causes for male infertility (e.g. cryptorchidism, infections, chromosomal aberrations) were excluded. The SNP in the *FSHB* gene was analysed by TaqMan assay.

Results

The T-allele frequency was higher in the oligozoospermic group compared with men with normal sperm concentration (18.1 vs 14.7%, $P=0.023$). The T-allele showed significant dosage effects (each $P<0.05$) for FSH (−0.56 U/l per T-allele), LH (0.27 U/l) and bi-testicular volume (−5.0 ml). Fitting trends were found for associations with sperm concentration (−7.5 Mill./ml, $P=0.057$) and total sperm count (−24.1 Mill./ml, $P=0.088$). Meta-analysis of all published studies – comprising 3017 men in total – confirmed highly significant associations for FSH, LH and testicular volume. In addition, a significantly different distribution of genotypes between normo- and oligozoospermic men was found in the pooled analysis for the first time ($P=0.0052$).

Conclusions

The associations between *FSHB* genotype and serum FSH as well as testicular volume were confirmed in our study population and in the meta-analysis and further substantiate the *FSHB* −211G>T SNP as a novel risk factor for male infertility. Whether T-allele carriers benefit from FSH treatment remains to be elucidated.

Supported by a grant from the Alexander-von-Humboldt foundation.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

## P1021

### Side effect profile of long-term treatment of hypogonadal men with testosterone undecanoate

F. Saad[1,2], A. Haider[3] & L. Gooren[4]
[1]Bayer Pharma AG, Berlin, Germany; [2]Gulf Medical University, Ajman, United Arab Emirates; [3]Private Practice, Bremerhaven, Germany; [4]VUMC Amsterdam, Amsterdam, The Netherlands.

Introduction
Testosterone therapy for hypogonadal men has been used for decades. However, there are still concerns regarding the safety of this treatment, particularly in elderly men.
Methods
Prospective registry study of 252 men (mean age 60.6±8.0 years), with testosterone levels between ≤3.5 ng/ml. They received parenteral testosterone undecanoate 1000 mg at day 1, week 6 and every 12 weeks thereafter for up to 66 months.
Results
After 60 months the following changes were observed.
Erythropoiesis
Haemoglobin increased from 14.44±0.72 to 14.99±0.45 g/dl ($P<0.0001$ vs baseline). Haematocrit increased from 43.18±2.83 to 48.78±1.7% ($P<0.0001$ vs baseline). Four patients had haematocrit levels >52% which resolved without intervention.
Prostate
PSA increased from 1.76±0.96 to 1.82±0.96 ng/ml ($P<0.0001$ vs baseline) with a plateau after 24 months. 3/255 patients were diagnosed with prostate cancer following elevated PSA at 18 weeks of treatment. Tumour grade was T2 in all three and Gleason score 3+3 in two and 3+2 in one patient, resp. They all underwent radical prostatectomy and were excluded from the analysis. Prostate volume increased from 28.3±11.12 to 30.23±12.4 ml ($P<0.0001$ vs baseline). The International Prostate Symptom score (IPSS) improved from 6.7±4.22 to 2.83±1.25. This was statistically significant vs baseline ($P<0.0001$) and the decrease remained statistically significant compared to the previous year over the first 48 months.
Liver enzymes
Aspartate transaminase (AST) decreased from 43.34±17.31 to 20.16±3.21 U/l, alanine transaminase (ALT) from 44.04±18.16 to 20.54±3.92 U/l ($P<0.0001$ vs baseline with a plateau after 24 months).
Conclusions
The incidence of 3/255 patients with prostate cancer is similar to that in screening programmes. Long-term treatment with testosterone undecanoate with monitoring according to the guidelines is acceptably safe.
Declaration of interest
I fully declare a conflict of interest. Details below.

## P1022

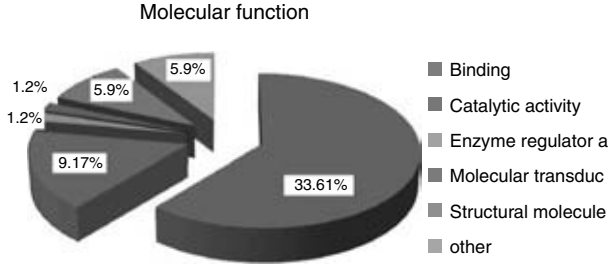
### Effect of testosterone on seminal proteome in male hypogonadism

D. Milardi[1], G. Grande[1], F. Vincenzoni[1], A. Giampietro[1], A. Bianchi[1], I. Messana[2], A. Pontecorvi[1], L De Marinis[1], M. Castagnola[1] & R. Marana[1]
[1]Università Cattolica del S. Cuore, Rome, Italy; [2]Università di Cagliari, Cagliari, Italy.

Seminal plasma (SP) contains proteins secreted by testis, epididymis and male accessory glands, involved in the successful fertilization of the oocyte. The function of epididymis, prostate and seminal vesicles are dependent upon the presence of androgenic stimuli.

To investigate the role of testosterone in the modulation of the proteomic pattern in SP, we analyzed human SP proteome comparing the panel of common seminal proteins in five fertile normogonadal males with the proteome by five patients with severe hypogonadism. In patients and control hormonal assays and standard semen analysis were performed; proteomic analysis was performed by an Ultimate 3000 Nano/micro-HPLC apparatus equipped with an FLM-3000-Flow manager module, and coupled with an LTQ Orbitrap XL hybrid mass spectrometer. In addition, GO annotation analysis was performed in the panel of androgen-dependent proteins.

88 to 1529 unique proteins were identified per individual subject sample. 83 proteins were present in all samples of normogonadal men, while 50 of these 83 proteins were absent in all hypogonadal patients. Some of these proteins may be involved in male fertility, such as ubiquitin carboxyl-terminal hydrolases 36, the olfactory receptor 5R1, the human cathelicidin antimicrobial peptide (hCAP18), complement factor H and spindlin1. GO annotation analysis (Figure 1: molecular function) provided further information to clarify which molecular function and biological process are mainly affected by androgen deficiency.



This is the first study that used a proteomic approach to offer a complete description of the proteic panel in severe male hypogonadism, indicating possible physiological targets for testosterone action, which might represent indicators of androgen-mediated protein synthesis at cellular level. Furhermore, the finding of the absence of seminal proteins involved in fertility in hypogonadal patients may explain the association between male hypogonadism and infertility.

### Comparing effects of weight loss on sexual, urinary and endothelial function, insulin resistance and quality of life in obese men with and without erectile dysfunction

J. Khoo, R. Chen, L. Cho, T. Tay, E. Tan, V. Au, S. Soh & B. Ng
Changi General Hospital, Singapore, Singapore.

Introduction
Abdominal obesity and insulin resistance are risk factors for erectile dysfunction (ED). ED is associated with hypoandrogenism, endothelial dysfunction, lower urinary tract symptoms (LUTS), and reduced quality of life (QoL). We aimed to compare effects of lifestyle modification-induced weight loss on insulin resistance, endothelial and sexual function, LUTS and QoL in obese non-diabetic men with and without ED.
Methods
Seventy abdominally obese Asian (body mass index ≥30 kg/m$^2$, waist circumference (WC) ≥90 cm) men (mean age 43.1 years, range 30–61) were tested with International Index of Erectile Function 5-item (IIEF-5) questionnaire. 68.5% ($n=48$) had ED (IIEF ≥21). Weight loss was induced using caloric restriction (500 kcal/day below basal metabolic rate) and moderate-intensity exercise (2000 kcal/week). IIEF-5, Sexual Desire Inventory (SDI), International Prostate Symptom (IPSS) and 36-item Short Form Survey Instrument (SF-36) scores, plasma sex-hormone binding globulin (SHBG), total testosterone (TT), insulin and glucose, endothelial function (by reactive hyperaemia index (RHI) using finger plethysmography on EndoPAT), were measured at baseline and 12 weeks later. Homeostasis model assessment (HOMA) was used to estimate insulin resistance.
Results
At baseline, men with ED had lower IIEF-5 and SDI scores, TT, SHBG and calculated free testosterone (FT), and higher WC, HOMA, and IPSS score. Men with ED had significantly greater increases in IIEF-5 (2.83 vs 0.05), SDI (8.27 vs 2.45) scores and decrease in IPSS score (1.90 vs 0.82) and HOMA (2.03 vs 0.65). Improvements in weight, WC, RHI, TT, SHBG, and SF-36 scores were similar (Table 1). IIEF-5 score normalized in 12 (25%) men.
Conclusions
Weight loss through diet and exercise in obese men reverses ED and improves sexual desire, endothelial function, LUTS, insulin resistance and quality of life, producing significantly greater benefits on insulin resistance, sexual and urinary function in men with ED.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Inhibitors of 5α-reductase-related side effects in patients seeking medical care for sexual dysfunction

G. Rastrelli[1], G. Corona[1,2], E. Maseroli[1], A. Sforza[2], G. Forti[1], E. Mannucci[a] & M. Maggi[1]
[1]University of Florence, Florence, Italy; [2]Maggiore-Bellaria Hospital, Bologna, Italy.

Introduction
Despite their efficacy in the treatment of benign prostatic hyperplasia (BPH) the popularity of inhibitors of 5α-reductase (5ARIs) is limited by their association with adverse sexual side effects. However, the real impact of 5ARIs on sex hormones and sexual function is controversial.
Aim
The aim of this study is to investigate the role of 5ARIs therapy on hormonal parameters and sexual function in men already complaining of sexual problems.
Methods
A consecutive series of 3837 men (mean age 63.5±12.8 years) attending our outpatient clinic for sexual dysfunction was retrospectively studied.
Main outcome measures: Several clinical, biochemical and instrumental (penile color doppler ultrasound; PCDU) factors were evaluated.
Results
Among the patients studied, 78.7% reported erectile dysfunction, 51.1% hypoactive sexual desire (HSD), 86.7% perceived reduced sleep-related erections (PR-SREs) and 19.1% premature ejaculation. The use of 5ARIs was associated with an increased risk of HSD and PR-SRs whereas no relationship was found with erectile dysfunction and ejaculation disturbances. Subjects using 5ARIs also more frequently had gynaecomastia along with reduced SHBG and higher calculated free testosterone levels. All these associations were confirmed in a case-control study comparing 5ARIs users with age-body mass index-smoking status and total testosterone matched controls.
Conclusions
Our data indicates that use of 5ARIs in men with sexual dysfunction does not significantly exacerbate pre-existing ejaculatory or erectile difficulties, but can further impair their sexual life by reducing sexual drive and spontaneous erection.

### Multiplex ligation dependent probe amplification analysis of KAL1, GnRH1, GnRHR, PROK2 and PROKR2 in male patients with idiopathic hypogonadotropic hypogonadism

Y. Basaran, H. Unal, E. Bolu, R. Sagkan, A. Taslipinar, T. Ozgurtas & U. Musabak
Gulhane School of Medicine, Etlik, Turkey.

Introduction
To date, several mutations have been identified as the underlying cause of hypogonadotropic hypogonadism. However, they account for a small minority of cases, suggesting that other genes play a significant role in the pathogenesis. The aim of the present study was to examine the prevalence of KAL1, GnRH1, GnRHR, PROK2 and PROKR2 mutations. Because it has several advantages over traditional screening methods, multiplex ligation dependent probe amplification (MLPA) was used to identify genomic rearrangements.
Description of methods/results
Eighty six hypogonadal young male patients (76 with nIHH and 10 with KS) and 95 age-matched, healthy control subjects participated in our study. Following DNA denaturation, hybridization of MLPA probes, ligation reaction, PCR reaction and separation of amplification products by electrophoresis data were evaluated using Genotyper 2.0 Software. Peak areas for each exon were converted into an Excel file and the relative DNA copy number ratios of each fragment were compared to the same fragments from 2 to 3 healthy subjects.
Result
Using MLPA for the described genes, seven mutations were present in 6 of the 86 patients with IHH. three patients with KS had heterozygous deletions in exon 9 of the KAL1 gene, one of whom also carried a duplication in exon 11 of the same gene, and 3 patients with nIHH possessed a duplication in exon 3 of the PROK2 gene, a heterozygous deletion in exon 1 and a duplication in exon 2 of the GnRHR gene, respectively. No abnormalities were identified in the healthy control individuals.
Conclusion
Defining the genetic basis of disease is essential to improve our understanding of this complex disorder, and can be useful for genetic counseling and for directing therapy. For detecting genomic deletions and duplications, MLPA is advantageous over the traditional methods because of its simplicity, relatively low cost and efficiency.

### Cimetidine induces testosterone reduction and impairs leydig cell-microvasculature paracrine interaction in adult rats

F. Beltrame[1], P. Cerri[2] & E. Sasso-Cerri[2]
[1]Universidade Federal de São Paulo (UNIFESP/EPM), São Paulo, Brazil; [2]Univ. Estadual Paulista (UNESP-Araraquara), Araraquara, Brazil.

Cimetidine, an antagonist of histamine H2-receptors used for treatment of gastric ulcers, exerts antiandrogenic effect. In testes, cimetidine causes histopathological disorders in the seminiferous tubules and impairs spermatogenesis. Additionally to testosterone, Leydig cells (LC) produce several paracrine factors, including EG–VEGF (endocrine gland-derived vascular endothelial growth factor) which participates in the testicular microvasculature control. Regarding the importance of histamine and androgens for the blood vessels maintenance, we purposed to evaluate whether cimetidine impairs testicular microvasculature and/or structural and functional integrity of LC. Adult rats received 100 mg/kg BW of cimetidine (CMTG) and saline solution (CG) for 50 days. The testes were fixed in buffered 4% formaldehyde and embedded in historesin and paraffin. Some testicular fragments were embedded in Araldite for analysis under transmission electron microscopy. The serum levels of testosterone were also evaluated. In the PAS-stained historesin sections, the microvascular density (MVD) was obtained. Paraffin sections were submitted to the following reactions: TUNEL method; 17β-HSD6 (for LC quantification); 17β-HSD6+TUNEL (for detection of LC undergoing cell death); and Prokineticin-1 (for detection of EG–VEGF expression). The semiquantitative score (1+, 2+, 3+) of EG–VEGF-immunolabeled LC was obtained. Statistical analyses were performed ($P \leq 0.05$). In CMTG, a significant decrease (17%) in the MVD was observed. The presence of 17β-HSD6+TUNEL positive LC and the typical ultrastructural features of apoptosis confirm the harmful effect of cimetidine in LC. This is reinforced by the significant reduction in the number of LC and in the serum

levels of testosterone (42%). The immunoexpression of EG–VEGF in LC was also reduced in CMTG. The results indicate that cimetidine induces LC apoptosis. As vascular cells express ARs and VEGF receptors, the testicular microvasculature impairment may be caused by the interference of cimetidine treatment in the Leydig cell-microvasculature paracrine control due to LC death.

### Gonadal status in adult male survivors of childhood cancer

F. Felicetti[1], A. Castiglione[1], A. Corrias[2], P. Chiabotto[2], F. Fagioli[2], G. Ciccone[2], G. Boccuzzi[1] & E. Brignardello[3]
[1]University of Turin, Turin, Italy; [2]Regina Margherita Children's Hospital, Turin, Italy; [3]San Giovanni Battista Hospital, Turin, Italy.

Introduction

Survival rates in childhood cancer survivors (CCS) have enormously increased in the last 40 years. However, this improvement has been achieved at the expense of serious late effects, including the potential for severe gonadal damage. Here we report the effects of anticancer therapies on gonadal function in male long-term survivors of childhood cancer.

Methods

We estimated, at the last follow up available, the prevalence of primary hypogonadism, central hypogonadism and spermatogenesis damage in 151 male CCS mainly treated for hematologic malignancies (72%), brain tumors (13%) or sarcomas (7%). Since CCS are often reluctant to provide semen sample, in the absence of semen analysis we considered to have spermatogenesis damage all male patients with FSH values $>10$ IU/l and/or inhibin B $<100$ pg/ml. Statistical analysis was performed comparing the prevalence of gonadal dysfunction by treatments and some patient characteristics, using the $\chi^2$ test.

Result

Mean age at the last follow up was 25.6 years (S.D. = 5.1). Median follow-up time was 16.0 years. At the last follow-up visit, 69 patients (46%, CI = 38–54) showed gonadal dysfunction. Central hypogonadism was found in four brain tumor and in one acute lymphoblastic leukemia survivors who underwent cranial irradiation. Primary hypogonadism was found in 14 patients, mainly cured for hematologic malignancies (71%) or medulloblastoma (14%), all of them treated with radiation therapy involving the testis. Spermatogenesis damage was found in 50 CCS (33%). The main risk factors for gonadal dysfunction were radiation therapy involving the testis, busulfan, platinum-based chemotherapy agents, cyclophosphamide and hematopoietic cell transplantation (Fig. 1).

Conclusion

Male CCS have a very high risk to develop impaired spermatogenesis and, to a lower extent, primary or central hypogonadism. Semen cryopreservation is mandatory in post-pubertal patients. Moreover, new reliable techniques of fertility preservation in pre-pubertal males are needed.

### Cyclooxygenase-1 (COX-1) and COX-2, differently expressed in human sperm from normal and pathological patients, might be considered molecular markers in the diagnosis of male infertility disorders

I. Perrotta, M. Santoro, C. Guido, P. Avena, F De Amicis, M. Cesario, P. Maris, S. Tripepi & S. Aquila
University of Calabria, Cosenza, Italy.

Varicocele and diabetes mellitus (DM) have long been recognized to impair male fertility by interfering with both sperm parameters and production, however the molecular mechanism by which these effects occur remains largely unknown. Cyclooxygenases are important in spermatogenesis, but their ultrastructural localization in sperm cells and their role in male infertility have not yet established in humans. In the present study we presented the evidence of constitutive (COX-1) and inducible (COX-2) cyclooxygenase expression in healthy human sperm as well as their expression pattern associated with varicocele and DM. By Western blot analysis the comparison between normal and pathologic samples, showed a constitutive expression of both COX isoforms in the spermatozoa from healthy donors, a significant increase in COX-1 and COX-2 protein levels in both 'varicocele' and 'diabetic' semen samples. Our transmission electron microscopic (TEM) data with immunogold analysis provide the first morphological evidence of COX isoforms particular distribution in both healthy and pathological sperm, intriguingly revealing modifications in the amount of these enzymes. Taken together, our finding suggest that varicocele and DM may lead to male factor infertility by a mechanism involving an increased COXs expression in human spermatozoa evidencing that a detrimental effect at the molecular level exists, thus going beyond the abnormal sperm morphology described to date. In conclusion COX isoforms might play an important role in the pathogenesis and/or manteinance of infertility states and might represent a potential therapeutic targets in future strategies designed for the treatment of fertility disorders.

## P1029

### Activation of selective human sperm functions by EGF and TGF-β3 is mediated by an ERK-depended mechanism

G. Band[1], N. Etkovitz[2], H. Breitbart[2] & Z. Naor[1]
[1]Tel Aviv University, Tel Aviv, Israel; [2]Bar Ilan University, Ramat Gan, Israel.

Introduction

The signaling involved in ligand-stimulated spermatozoa is not yet clarified. Moreover, the main question in sperm biology is the identification of the sperm ligands. Analysis of the role of MAPK in mammalian sperm physiology is a prerequisite for assigning a role for MAPK in mammalian sperm functions. The unique opportunity to study ERK1/2 in human spermatozoa, which are differentiated cells lacking active transcriptional machinery, will enable to correlate it to differentiated responses such as: capacitation, motility, acrosome reaction and fertilization. We examined the effect of EGF and TGF-β3, as potential sperm ligands upon ERK1/2 activation and the role of ERK1/2 in forward and hyperactivated motility, capacitation and acrosome reaction.

Methods

Human semen was obtained from healthy donors with normal sperm concentration, motility and morphology according to WHO guidelines (WHO, 2010), or from males attending the Male Infertility Unit, Sheba medical center, Tel-Ha'shomer hospital, Israel.

Results

We have shown that ERK1/2 is activated during EGF and TGF-β3 activation of sperm after 5–15 min of incubation. Both ligands elevated total motility after 15 min of incubation and this stimulatory effect was abolished by adding, U0126 a selective inhibitor of MEK1/2. EGF also induced hyperactivated motility after 180 min, while TGF-β3 did not seem to induce hyperactivation. Both ligands elevated the percentage of acrosome reacted sperm cells after capacitation in both healthy donors, and OTA patients. This effect was also abolished after adding U0126, a selective inhibitor of MEK1/2. Regarding capacitation, we have identified several

proteins that were phosphorylated on tyrosine residues during capacitation, the effect was markedly reduced in the presence of the MEK1/2 inhibitor.
Conclusions
We conclude that EGF and TGF-β3 activation of selective sperm functions are mediated by an ERK-depended mechanism.

## P1030

### Leydig and sertoli cell failure in myotonic dystrophy

E. Passeri[1], E. Bugiardini[1], V. Sansone[1], C. Fulceri[2], E. Costa[2], F. Bandera[2], S. Borgato[3], L. Persani[3], A. Pizzocaro[4], G. Meola[1], B. Ambrosi[1] & S. Corbetta[1]
[1]IRCCS Policlinico San Donato, University of Milano, San Donato Milanese, Italy; [2]IRCCS Policlinico San Donato, San Donato Milanese, Italy; [3]Istituto Auxologico Italiano, Cusano Milanino, Italy; [4]Istituto Clinico Humanitas, Milano, Italy.

Introduction
Hypogonadism occurs in myotonic dystrophy (DM) type 1 and 2, a multisystemic autosomal dominant disorder with insulin resistance and visceral obesity. DM patients provide a model to investigate the impact of metabolic alterations on hypogonadism.
Methods
We assessed Leydig and Sertoli cell functions and metabolic features in 32 DM1 (44 + 11 years),13 DM2 patients (54 + 9 years) and 32 age and BMI-matched controls.
Results
Overt primary hypogonadism (sexual dysfunction, total T < 320 ng/dl) occurred in 26% of DM1 and 38% of DM2 patients. Increased LH was detected in 68% of DM1 and in all DM2. INSL3, marker of Leydig cell function, was lower in hypogonadal than in eugonadal patients and in controls. Anamnestic recall suggested reduced fertility in 34% of DM patients. AMH and inhibin-B, markers of Sertoli cell function, were dramatically reduced in DM than controls. FSH levels were elevated in 68% DM1 and in all DM2. DM patients showed an increased visceral body fat: waist/hip and body fat mass were higher than in controls; hepatosteatosis and increased epicardial fat thickness occurred in > 50% of cases. Dyslipidemia also was frequent (62%). Diabetes mellitus and insulin resistance were higher in DM2 (38 and 61%) than in DM1 (3 and 21%). Both HOMA-IR and body fat mass negatively correlated with freeT levels in DM patients. In DM1 patients AMH levels correlated positively with muscle strength, muscle mass, resting energy expenditure and negatively with clinical score. Furthermore, AMH negatively correlated with fat mass and waist/hip. In DM2 patients AMH was positively related with muscle strength, while it is not influenced by metabolic features and fat mass.
Conclusion
Hypogonadism is very frequent in DM patients and linked with muscle impairment. This study firstly demonstrates that hypogonadism in DM is associated with reduced levels of INSL-3, AMH and inhibin B and is negatively influenced by visceral adiposity.

### Decreased osteoprotegerin levels during testosterone therapy in ageing men were associated with changed distribution of regional fat

D. Glintborg[1], L. Frederiksen[1], D. Hougaard[2], K. Brixen[1], L. Rasmussen[1] & M. Andersen[1]
[1]Odense University Hospital, Odense C, Denmark; [2]Statens Seruminstitut, Copenhagen S, Denmark.

Objective
The cardiovascular effects of testosterone treatment are debated. Osteoprotegerin (OPG) is an independent marker of cardiovascular risk. We investigated the effect of testosterone therapy on OPG levels in ageing men with low normal bioavailable testosterone levels.
Design
A randomized, double-blinded, placebo-controlled study of six months testosterone therapy (gel) in 38 men aged 60–78 years with bioavailable testosterone < 7.3 nmol/l and waist circumference > 94 cm.
Methods
Clinical evaluation, OPG, and C-reactive protein measurements. Bone mineral density (BMD), lean body mass (LBM) and total fat mass were established by dual X-ray absorptiometry and visceral adipose tissue (VAT) and subcutaneous adipose tissue (SAT) were measured by magnetic resonance imaging. Power calculation was based on an increase in LBM during testosterone therapy and responders were defined as testosterone treated patients with increased LBM (ΔLBM positive), $n = 14$. Data were presented as median (interquartile range).
Results
Testosterone therapy decreased total fat mass and SAT, whereas VAT was unchanged ($n = 38$). OPG levels decreased during testosterone therapy (from 2.0 (1.9–2.5) to 1.9 (1.6–2.2) ng/ml, $P < 0.05$ vs placebo), whereas CRP levels were unchanged. In responders for testosterone therapy ($n = 14$), ΔOPG levels were inversely associated with ΔSAT ($r = -0.60$, $P = 0.03$) and positively associated with ΔVAT ($r = 0.56$, $P = 0.04$). BMD levels were unchanged during testosterone therapy.
Conclusion
OPG levels decreased during testosterone therapy suggesting decreased cardiovascular risk. Decreased OPG levels were associated with changes in regional fat distribution and future studies are needed to further evaluate the association between OPG and regional fat mass distribution.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1032

### New insights into sperm DNA methylation: intra-and inter individual stability and a comparative analysis versus somatic cells

C. Krausz[1], J. Sandoval[2], C. Chianese[1], C. Giachini[1], S. Sayols[2] & M. Esteller[2]
[1]University of Florence, Florence, Italy; [2]Bellvitge Biomedical Research Institute (IDIBELL), Barcelona, Catalonia, Spain.

Data about the entire sperm DNA methylome are limited to two sperm donors whereas studies dealing with a greater number of subjects focused only on a few genes or were based on low resolution arrays. This implies that information about what we can consider as a normal sperm DNA methylome and whether it is stable among different normozoospermic individuals is still missing. The definition of the DNA methylation profile of normozoospermic men, the entity of inter-individual variability and the epigenetic characterization of quality-fractioned sperm subpopulations in the same subject (intra-individual variability) are fundamental issues for a better understanding of pathological conditions. We addressed these questions by using the high resolution Infinium 450K methylation array and compared normal sperm DNA methylomes against somatic and cancer cells. Our study, based on the largest number of subjects ($n = 8$) ever considered for such a conspicuous number of CpGs ($n = 487{,}517$), provided clear evidence for i) a highly conserved DNA methylation profile among normozoospemic subjects; ii) a stable sperm DNA methylation pattern in different quality-fractioned sperm populations of the same individual. In addition, our analysis provided both confirmatory and novel data concerning the sperm DNA methylome, including its peculiar features in respect to somatic and cancer cells. Our description about a highly polarized sperm DNA methylation profile, the clearly distinct genomic and functional organization of hypo- versus hypermethylated loci as well as the association of histone-enriched hypomethylated loci with embryonic development provides solid basis for future basic and clinical research.

## P1033

### Complete reversal of isolated idiopathic hypogonadothropic hypogonadism in men

M. Rabijewski, L. Papierska & W. Zgliczynski
Medical Centre for Postgraduate Education, Warsaw, Poland.

Idiopathic hypogonadotropic hypogonadism (IHH) is caused by an isolated defect in GnRH release or action and classified as the Kallmann syndrome with associated anosmia or normosmic IHH in the presence of a normal sense of smell. Patients with IHH have absent or incomplete sexual maturation and infertility. Usually long term GnRH or gonadotropin therapy in these patients can induce spermatogenesis and puberty and is followed by testosterone therapy to maintain normal virilization. But in some patients with IHH brief discontinuation of testosterone replacement therapy probably results in reversal of IHH.
Material and methods
We observed prospectively 16 men with delayed of puberty and IHH (two had anosmia). At initial evaluation, all men had absent puberty and all had abnormal secretion of GnRH-induced LH and FSH levels and mean testosterone levels $0.81 \pm 0.14$ ng/ml ($2.75 \pm 0.61$ nmol/l). All men had received testosterone replacement therapy to induce virilization and after 9–12 months the treatment was followed by 8 weeks of treatment discontinuation with next evaluation. Reversal IHH was defined as testosterone levels above 2.5 ng/ml.
Results
In two men serum levels of endogenous testosterone increased from 0.82 $\pm 0.19$ ng/ml ($2.78 \pm 0.64$ nmol/l) to $3.69 \pm 0.81$ ng/dl ($12.5 \pm 2.75$ nmol/l, $P < 0.001$), LH and FSH levels also increased ($2.3 \pm 1.8$ to $7.9 \pm 2.9$ IU/l ($P < 0.001$) and $2.7 \pm 1.9$ to $8.9 \pm 9.6$ IU/l ($P < 0.01$) respectively). The mean testicular volume increased from $7 \pm 4$ to $15 \pm 4$ ml ($P < 0.001$) and spermatogenesis was initiated. In 14 men we did not observed statistical significant changes of LH and FSH levels after discontinuatopn of testosterone replacement therapy.
Conclusions
We documented reversal IHH in men with delay of puberty after relative short-time testosterone replacement therapy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1034

### G protein-coupled estrogen receptor 1- and estrogen receptor α-dependent pathways regulate spermatocytes apoptosis

A. Chimento, R. Sirianni, I. Casaburi, C. Ruggiero, M. Maggiolini, S. Andò & V. Pezzi
[1]University of Calabria, Rende, Italy.

In mammals, spontaneous apoptosis is observed particularly in differentiating spermatogonia and spermatocytes. We have previously demonstrated that 17β-estradiol ($E_2$) in primary rat pachytene spermatocytes (PS) binds ESR1 and GPER1 to activate EGFR/ERK/c-Jun pathway leading to up regulation of bax, a pro-apoptotic factor. Aim of this study was to clarify the effector pathway(s) controlling spermatocytes apoptosis using as model GC-2 cells, an immortalized mouse pachytene spermatocytes cell line, reproducing primary cells responses to $E_2$. Like in primary PS, ESR1 and GPER1 activation in GC-2 cells caused rapid ERK and c-Jun phosphorylation, bax up-regulation associated with apoptosis. We further demonstrated that apoptosis is induced by $E_2$, as well as by specific ESR1 and GPER1 agonists, through sustained ERK, c-Jun and P38 phosphorylation, cytochrome *c* release, caspases 3 and endogenous substrate poly (ADP-ribose) polymerase (PARP) activation and increased expression of cell cycle inhibitor P21. When ESR1 or GPER1 expression were individually silenced, $E_2$ was still able to decrease cell proliferation, only the concomitant silencing abolished $E_2$ effect. These results indicate that GC-2 cells are a valid cell model to investigate the effects of $E_2$ on spermatocytes apoptosis and show that $E_2$, activating both ESR1 and GPER1, is able to induce an ERK1/2-, c-Jun- and P38-dependent mitochondrion apoptotic pathway in this type of cells. The definition of the molecular components of germ cells apoptosis will help us to better understand the consequences of the exposure to environmental estrogens, to provide new potential targets for the development of a non-androgen male contraceptive or for the development of novel therapeutic regimens to control germ cell tumors.

### Single nucleotide polymorphism (SNP) of endothelial nitric oxide synthase (eNOS) gene (Glu298Asp variant) in infertile men with asthenozoospermia

E. Buldreghini, F. Paggi, A. Gioia, Ndelli Muti, L. Macrì, A. Vignini & G. Balercia
[1]Polytechnic University of Marche, Torrette di Ancona, Italy.

Objective(S)
Single nucleotide polymorphism (SNP) in endothelial nitric oxide synthase (eNOS) G894T may affect the oxidative stress response. Our objective was to examine G894T SNP eNOS genotype frequencies and its potential role with sperm motility in infertile men. Through this prospective controlled study in the Andrology Unit, we have enrolled infertile ($n = 70$) and healthy ($n = 60$) men. Sperm motion kinetics assessed by computer assisted semen analysis (CASA), and allele-specific polymerase chain reaction (PCR-RFLP) to investigate the frequency of guanine (G) Thymine (T) at position -894 within exon 7 of the eNOS gene. Finding(S)
An increased frequency of the G894T eNOS (T) allele observed in asthenozoospermic patients ($P = 0.02$). In asthenozoospermic men, homozygotes eNOS (TT) genotyping showed low percentages of rapid motile sperm (a + b) compared to wild-type eNOS (GG) ($P = 0.02$) or heterozygotes eNOS (GT) genotyping ($P = 0.01$). In Fertile men, wild-type eNOS showed high percentages of rapid motile sperm (a + b) compared to eNOS (TT) ($P = 0.03$) or eNOS (GT) genotyping ($P = 0.04$).
Conclusion(S)
Our findings suggest that the T allele, encoding for aspartic acid, of the eNOS (Glu298Asp) gene may play a role with low sperm motility.

### Severe depressive symptoms and cardiovascular risk in subjects with erectile dysfunction

A. Fisher[1], E. Bandini[1,2], G. Corona[1], V. Ricca[2], M. Monami[3], V. Boddi[1], D. Balzi[4], C. Melani[4], G. Forti[1], E. Mannucci[4] & M. Maggi[1]
[1]Sexual Medicine and Andrology Unit, Florence, Italy; [2]Psychiatry Unit, Florence, Italy; [3]Diabetes Section, Geriatric Unit, Florence, Italy; [4]Epidemiological Unit, Florence, Italy.

Introduction
Although penile blood flow (PBF) has been recommended as an additional diagnostic test in identifying erectile dysfunction (ED) patients at risk for latent cardiovascular disease, no study has ever assessed the possible association of PBF and the relational component of sexual function with incident major cardiovascular events (MACE).
Aim
The aim of this study is to investigate whether severity of ED, PBF and other factors related to a couple's relationship predict incident MACE.
Methods
A consecutive series of 1687 patients was studied. Different clinical, biochemical and instrumental (penile flow at color doppler ultrasound: PCDU) parameters were evaluated.
Main outcomes measures
Information on MACE was obtained through the City of Florence Registry Office.
Results
During a mean follow-up of $4.3 \pm 2.6$ years, 139 MACE, of which were fatal, were observed. Cox regression analysis, after adjustment for age and Chronic Disease Score, showed that severe ED predicted MACE (hazard ratio (HR) 1.75; 95% confidence interval (CI) 1.10–2.78; $P < 0.05$). In addition, lower PBF, evaluated both in flaccid (before) and dynamic (after PGE1 stimulation) conditions, was associated with an increased risk of MACE (HR $= 2.67$ (1.42–5.04) and 1.57 (1.01–2.47) respectively for flaccid ($< 13$ cm/s) and dynamic ($< 25$ mc/s) peak systolic velocity; both $P < 0.05$).
Reported high sexual interest in the partner and low sexual interest in the patient proved to have a protective effect against MACE.

Conclusions
the investigation of male sexuality, and in particular penile blood flow and sexual desire, could provide insights not only into present cardiovascular status but also into prospective risk.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1037

### The protective role of ginger against Di-(2-ethylhexyl) phthalate-induced reproductive toxicity and oxidative stress in male rabbits

M. Yousef[1], H. Hassan[2], A. Mohammed[2], K. Kamel[3] & F. Khaled[2]
[1]Institute of Graduate Studies and Research, Alexandria University, Alexandria, Egypt, Egypt; [2]Faculty of Science, Mansoura, Egypt; [3]Animal Production Research Institute, Giza, Egypt.

**Abstract**
The experiment was designed to study toxic effects of Di-(2-ethylhexyl) phthalate (DEHP) on semen characteristics, testosterone levels, testicular lipid peroxidation and testicular antioxidants in male New-Zealand white rabbits for 12 weeks. Ginger has been reported to be an important antioxidant. Therefore, the protective effect of ginger against DEHP-induced reproductive toxicity and oxidative stress was studied. Rabbits were orally administered the doses of ginger, DEHP and ginger plus DEHP every day for 12 weeks. Results obtained showed that DEHP significantly ($P<0.05$) decreased libido (by increasing the reaction time), ejaculate volume, sperm concentration, total sperm output, sperm motility (%), total motile sperm per ejaculate (TMS), packed sperm volume (PSV), total functional sperm fraction (TFSF), normal and live sperm and semen initial fructose. While, initial hydrogen ion concentration (pH), and dead and abnormal sperm were increased ($P<0.05$). Also, testosterone levels, body weight (BW), relative weights of testes (RWT) and epididymis (RWE) were decreased. Thiobarbituric acid-reactive substances and lactate dehydrogenase were increased, while glutathione S-transferase, transaminases and phosphatases were decreased in seminal plasma of rabbits treated with DEHP compared to control. Ginger alone significantly increased testosterone levels, BW, RTW, REW, semen characteristics and seminal plasma enzymes, and decreased the levels of free radicals and lactate dehydrogenase. Furthermore, the presence of propolis with DEHP alleviates its toxic effects. From the present study, it can be concluded that ginger can be effective in the protection of DEHP-induced reproductive toxicity.

### Mutations and polymorphism of FSH and LH receptors and sperm quality in men with hypergonadotropic hypogonadism without obvious testicular noxa

G. Di Cairano, S. Cantara, G. Collodel, E. Moretti, S. Taglianetti, L. Mazzi & F. Pacini
University of Siena, Siena, Italy.

Introduction
Inactivating mutations in LH or FSH receptors (R) are known causes of gonadotrophins resistance.
Aim
This study aims at evaluating the presence of mutations and polymorphisms of FSHR and LHR and sperm quality in men with hypergonadotropic hypogonadism without obvious testicular noxa.
Patients and methods
We selected 8 males with elevated levels of FSH and/or LH and normal levels of testosterone. Sperm parameters were analysed following WHO (1999) guidelines and by transmission electron microscopy (TEM). Elaborated TEM data provided the percentage of sperm pathologies and the number of structurally normal sperm (fertility index). The PCR technique, followed by DHPLC analysis and direct sequencing, enabled to investigate FSHR and LHR gene mutations.
Results
For LHR, 2/8 patients were heterozygous for Ile374Thr mutation and 1/8 for Glu354Lys substitution. Regarding FSHR, 4/8 were heterozygous for Ala419Thr mutation and 2/8 were homozygous for Ala307Thr mutation. We also found in one patient a new mutation (Cys338Arg) localized in the extracellular domain of FSHR. Minor allele frequencies of 43.75% for polymorphism rs6708637 and of 37.5% for polymorphism rs1922464 were observed, both similar to those reported in the general population. A minor allele frequency of 37.5% of polymorphism rs2091787, higher than that reported for the general population (24%), was observed. Two patients were azoospermic, 4/6 patients showed reduced sperm concentration, 6/6 reduced sperm motility, 4/6 high percentage of apoptosis and immaturity, 5/6 increased percentage of necrosis. The fertility index was reduced in all patients.
Conclusions
The relationship between the different mutations (included the new found mutation Cys338Arg in FSHR) and altered semen parameters deserves attention and further studies.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1039

### Poor response to alprostadil ici test is associated with arteriogenic erectile dysfunction and higher risk of major adverse cardiovascular events

G. Rastrelli[1], G. Corona[1,2], M. Monami[1], C. Melani[3], D. Balzi[3], A. Sforza[2], G. Forti[1], E. Mannucci[1] & M. Maggi[1]
[1]University of Florence, Florence, Italy; [2]Maggiore-Bellaria Hospital, Bologna, Italy; [3]Azienda Sanitaria Locale 10, Florence, Italy.

Introduction
Intracavernous alprostadil injection (ICI) test has been considered useless in assessing the vascular status of subjects with erectile dysfunction (ED).
Aim
To analyze the clinical correlates of ICI test in patients with ED and to verify the value of this test in predicting major adverse cardiovascular events (MACE).
Methods
A consecutive series of 2,396 men (mean age $55.9 \pm 11.9$ years) attending our outpatient clinic for sexual dysfunction was retrospectively studied. A subset of this sample ($n=1,687$) was enrolled in a longitudinal study.
Main outcome measures
Several clinical, biochemical, and instrumental (penile color Doppler ultrasound; PCDU) factors were evaluated. All patients underwent an ICI test, and responses were recorded on a four-point scale ranging from 1= no response to 4= full erection.
Results
Among the patients studied, 16.4, 41.2, 40.2 and 2.2% showed grade 4, 3, 2, and 1 ICI test response, respectively. After adjusting for confounders, subjects with grade 1 ICI test response showed reduced perceived sleep-related, masturbation-related, and sexual-related erections when compared with the rest of the sample. In addition, a worse response to ICI test was associated with a higher prevalence of hypogonadism-related symptoms and signs along with lower testosterone levels. The prevalence of both diabetes mellitus and metabolic syndrome was inversely related to ICI test response. Accordingly, dynamic and basal peak systolic velocity (PSV), as well as acceleration at PCDU, decreased as a function of ICI test response. In the longitudinal study, after adjusting for confounders, grade 1 response was independently associated with a higher incidence of MACE (hazard ratio $=2.745$ (1.200–6.277); $P<0.05$). These data were confirmed even when only subjects with normal PSV ($>25$ cm/s) were considered.
Conclusions
Our results demonstrate that poor ICI test response is associated with several metabolic disturbances and higher incidence of MACE. We strongly recommend performing ICI test with alprostadil in all ED subjects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Hormonal associations and sexual dysfunctions in patients with impaired fasting glucose

G. Rastrelli[1], G. Corona[1,2], G. Balercia[3], F. Lotti[1], A. Sforza[2], M. Monami[1], G. Forti[1], E. Mannucci[1] & M. Maggi[1]
[1]University of Florence, Florence, Italy; [2]Maggiore-Bellaria Hospital, Bologna, Italy; [3]Ospedale Umberto I, Ancona, Italy.

Introduction
The category of impaired fasting glucose (IFG) denotes a state of non-diabetic hyperglycemia, considered a risk factor of the further development of diabetes mellitus (DM) and cardiovascular (CV) diseases.
Aim
The aim of the present study is to evaluate the impact of IFG on sexual health in men. In addition its effect on CV morbidity and mortality will also be addressed.
Methods
A consecutive series of 3451 men (mean age $57.3 \pm 10.1$ years) attending our outpatient clinic for sexual dysfunction was retrospectively studied. A subset of this sample ($n = 1687$) was enrolled in a longitudinal study.
Main outcome measures: Several clinical, biochemical (including testosterone) and instrumental (penile color doppler ultrasound; PCDU) factors were evaluated. IFG was defined by fasting glucose concentrations between 5.6 and 6.9 mmol/l (100–125 mg/dl). A higher threshold (6.1–6.9 mmol/l, 110–125 mg/dl) was also considered.
Results
Among the patients studied, 747 (21.7%) had DM. In addition, 659 (19.1%) subjects were classified as IFG. Patients with IFG, however defined, more often had severe ED, reduced penile blood flow and overt hypogonadism when compared to patients with normal glucose levels. In addition, men with ED and IFG showed poorer blood pressure and lipid profile with an overall increase in CV risk. Unadjusted incidence of major adverse CV events was significantly associated with baseline DM whereas there was a trend toward higher risk also for IFG, but this did not reach statistical significance. Conversely, both IFG and DM were significantly associated with a higher risk of fatal and non fatal cerebral events.
Conclusions
Checking glucose and testosterone levels is mandatory in subjects with ED, because testosterone substitution in impotent IFG subjects might not only ameliorate their sexual life but also their overall health.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### The relationship between total testosterone, cognitive function, depressive behavior and sleep quality in chronic renal failure patients not on dialysis

B. Afsar
[1]Konya Numune State Hospital, Konya, Turkey.

Purpose
Studies have shown that testosterone levels were associated with cognitive function, depression and sleep quality in general population. However these relationships between testosterone, cognitive function, depressive behavior, and sleep quality in chronic renal failure (CRF) patients not on dialysis were not evaluated before.
Methods
All patients underwent history taking, physical examination, blood pressure measurement, routine urine and biochemical analysis, 24-h urine collection to measure urinary protein excretion and creatinine clearance, evaluation of cognitive function, depressive behavior and sleep quality.
Results
In total 109 CRF patients were enrolled. The total testosterone levels in stage 3, 4 and 5 CRF patients were $8.32 \pm 4.35$, $6.71 \pm 3.12$, and $4.22 \pm 1.28$, ng/ml respectively ($P < 0.0001$). Post hoc analysis revealed that total testosterone levels were different between stage 3 and stage 5 CRF patients ($P < 0.0001$), between stage 4 and stage 5 CRF patients ($P < 0.0001$) but not different between stage 3 and stage 4 patients ($P$:0.094). Standardized Mini Mental State Examination (SMMSE) Score, Pitssburg Sleep Quality Index Score, Beck Depression Inventory (BDI) Score of the patients were $26.2 \pm 1.9$, $7.1 \pm 3.4$ and $8.6 \pm 6.4$ respectively. In linear regression analysis total testosterone levels were found to be independently associated with SMMSE score (b: 0.170, Confidence Interval: 0.047–0.293, $P$: 0.008) and BDI score (b: $-0.750$, Confidence Interval: $-1.283$–($-0.216$), $P$: 0.006) but not with sleep quality.
Conclusion
Serum total testosterone levels were independently associated with cognitive function and depressive behavior but not with sleep disorders in stage 3 to 5 CRF patients not on dialysis
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1042

### Premature ejaculation and erectile dysfunction in a cohort of infertility men: clinical and ultrasonographic correlations

F. Lotti[1], G. Corona[1], G. Rastrelli[1], G. Forti[1], E. Jannini[2] & M. Maggi[1]
[1]University of Florence, Florence, Italy; [2]University of L'Aquila, L'Aquila, Italy.

Introduction
Premature ejaculation (PE) and erectile dysfunction (ED) are considered pre-testicular causes of male subfertility. No previous study systematically evaluated the prevalence of ED and PE along with their possible correlations with clinical and colour-Doppler ultrasound (CDU) features in infertile men.
Methods
Ejaculatory status, erectile function, prostatitis symptoms and psychopathological traits of 244 men complaining of couple infertility were evaluated by Premature Ejaculation Diagnostic Tool (PEDT), International Index of Erectile Function-15 (IIEF-15), National Institutes of Health-Chronic Prostatitis Symptom Index (NIH-CPSI) and Middlesex Hospital Questionnaire (MHQ), respectively. PEDT score $\leq 8$ indicates no-PE. IIEF-15 erectile function domain (IIEF-15-EFD) score $< 26$ indicates erectile dysfunction. All patients underwent simultaneous hormone evaluation, seminal analysis and interleukin 8 (sIL8), a reliable surrogate marker of prostatitis, along with penile, scrotal and transrectal CDU, before and after ejaculation.
Results
PE was found in 38 (15.6%) and ED in 43 (17.8%) subjects. After adjusting for age, a positive association between PEDT score and prostatitis symptoms (NIH-CPSI score) and signs (sIL8) was observed. In addition, subjects with a higher PEDT score more often had CDU features suggestive of prostate inflammation, including hypoechoic texture, hyperaemia and a higher arterial peak systolic velocity (APSV). Finally, they showed a higher prevalence of psychopathological traits (MHQ score). In a multivariate model including age and calculated free testosterone (also positively related to PEDT score), APSV, NIH-CPSI and MHQ score were independently positively associated with PEDT score. IIEF-15-EFD score was positively associated with mean arterial blood flow acceleration at basal penile CDU, while a negative association with NIH-CPSI and MHQ score was observed. No correlation between IIEF-15-EFD or PEDT score and semen parameters was observed.
Conclusions
PE and ED should be ruled out in infertile patients. However, they have no impact on semen parameters. PEDT score is positively associated with prostatitis symptoms and signs including CDU features.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1043

### Maternal malnutrition alters the leptin expression in the rats epididymis

F. Gombar, F. Sampaio & C. Ramos
[1]State University of Rio de Janeiro, Rio de Janeiro, Brazil.

Several papers show that maternal malnutrition can affect the reproductive capability of the offspring. Leptin is an important regulator of the reproductive system, however little is known about its role in the epididymis. The goal of this

study was to evaluate whether the maternal malnutrition during lactation can alter the expression of leptin and its receptors in the epididymis of rats. Six rat dams were randomly assigned to the control group (C), with free access to a standard laboratory diet containing 23% protein; and to a protein-energy-restricted group (PER), with free access to an isoenergy and protein-restricted diet containing 8% protein. After weaning, four male pups of each group had free access to the standard laboratory diet until 90 days of age, when they were killed. The gene expression of leptin and leptin receptors, ObRa and ObRb, were evaluated by qPCR, while the protein expression was evaluated by immunohistochemistry in the caput, corpus and cauda of epididymis. Values were expressed as mean $\pm$S.E.M. Data were analysed using Student's *t*-test and the level of significance was set as $P<0.05$. Maternal malnutrition increased the gene expression in the caput (ObRa-C $=0.5\pm0.1$, PER $=2.1\pm0.6$, $P<0.04$; ObRb-C $=0.2\pm0.1$, PER $=0.8\pm0.2$, $P<0.02$; leptin – C $=0.7\pm0.3$, PER $=2.2\pm0.3$, $P<0.04$) decreased in the cauda (ObRa-C $=1.4\pm0.1$, PER $=0.8\pm0.1$, $P<0.04$; ObRb-C $=0.02\pm0.003$, PER $=0.006\pm0.005$, $P<0.007$; leptin – C $=1.2\pm0.2$, PER $=0.4\pm0.1$, $P<0.02$) while there was no statistical difference in the corpus of epididymis. Imunohistochemistry show positive stain for leptin and leptin receptor in all epididymis regions. The epididymis role in the maturation of spermatozoa is well established. The fact that maternal malnutrition during lactation altered leptin and its receptors expression in a region specific way raise the possibility that this hormone could have an important role in the molecular mechanisms that govern the epididymis function that are still poorly defined.

### Scrotal and transrectal ultrasound correlates of prostatitis-like symptoms in a cohort of infertility patients

F. Lotti, G. Corona, E. Filimberti, SDegli Innocenti, G. Forti & M. Maggi
University of Florence, Florence, Italy.

Introduction

Prostatitis-like symptoms (PLS) may originate from the prostate or from pelvic or scrotal organs. The National Institutes of Health-Chronic Prostatitis Symptom Index (NIH-CPSI) is considered the gold-standard instrument to assess PLS severity. Although several studies previously investigated the impact of prostatitis, vesiculitis or epididymitis on semen parameters, only a few studies evaluated the correlations between PLS and scrotal or transrectal colour-Doppler ultrasound (CDU) characteristics. We here evaluate these correlations, along with PLS and semen parameters possible associations, in infertile men.

Methods

PLS of 400 men complaining of couple infertility were assessed by NIH-CPSI. Index pain score $\geq 8$ has been previously defined as indicative of 'moderate-severe' symptoms. All patients underwent, during the same CDU session, seminal analysis and interleukin 8 (sIL8), a reliable surrogate marker of prostatitis, urino and seminal cultures, along with scrotal and transrectal CDU, before and after ejaculation.

Results

After adjusting for age, a positive association between NIH-CPSI total score and positive urino and/or seminal cultures, leukocytospermia and sIL8 levels was observed. Conversely, no correlation with semen parameters was found. Subjects with a higher NIH-CPSI total score more often had CDU features suggestive of inflammation of the prostate (including a higher arterial peak systolic velocity, APSV), seminal vesicles and epididymis. As assessed by ROC curve, at 10.4 cm/s APSV discriminates subjects with an index pain score $\geq 8$ with a sensitivity and specificity of 76%. When subjects with an index pain score $\geq 8$ were compared to the rest of the sample, a higher prevalence of prostate-vesicular and epididymal CDU abnormalities, positive cultures, leukocytospermia and higher sIL8 levels were observed, but no differences in semen parameters.

Conclusions

PLS are positively associated with positive cultures, leukocytospermia and sIL8 levels, along with prostate-vesicular and epididymal CDU abnormalities suggestive of inflammation. We suggest a 10.4 cm/s APSV cut-off to predict moderate-severe symptoms.

## P1045

### Elevated body mass index correlates with higher seminal interleukin 8 levels and ultrasound prostate abnormalities in infertile men

M. Maggi[1], F. Lotti[1], G. Corona[1], G. Colpi[2], E. Filimberti[1], S. Degli Innocenti[1], M. Mancini[2], E. Baldi[1], I. Noci[1], L. Adorini[3] & G. Forti[1]
[1]University of Florence, Florence, Italy; [2]University of Milan, Milan, Italy; [3]Perugia, Italy.

Introduction

It is general acknowledgement that obesity is associated with a systemic, low-grade inflammatory state. Although the relationship between obesity and semen parameters or prostate diseases has been previously investigated, the association between body mass index (BMI), prostate inflammatory diseases and colour-Doppler ultrasound (CDU) features of the male genital tract (MGT) has been poorly studied. This study was aimed at evaluating the association between BMI and CDU features of the MGT, signs and symptoms of prostate inflammation, along with semen parameters.

Methods

We studied 222 men seeking medical care for couple infertility. According to WHO classification, subjects were divided into 3 groups: normal weight ($n=131$, BMI $=18.5$–$24.9$ kg/m$^2$), overweight ($n=71$, BMI $=25.0$–$29.9$ kg/m$^2$), obese ($n=20$, BMI $\geq 30.0$ kg/m$^2$). All patients underwent simultaneous testosterone evaluation and seminal analysis, including interleukin 8 (sIL8), along with scrotal and transrectal CDU, before and after ejaculation. Prostatitis symptoms were evaluated by National Institutes of Health-Chronic Prostatitis Symptom Index questionnaire.

Results

After adjusting for age and testosterone levels, higher BMI was significantly related to higher prostate volume and several CDU features of the prostate, including macro-calcifications, inhomogeneity, higher arterial peak systolic velocity (the latter adjusted also for blood pressure), but not with abnormalities of testis, epididymis, seminal vesicles. Furthermore, higher BMI and BMI class were significantly related to higher sIL8, a reliable surrogate marker of prostate inflammatory diseases, even after adjustment for age. Conversely, no associations among BMI, clinical symptoms of prostatitis or semen parameters were observed.

Conclusions

Subjects with higher BMI might develop CDU and biochemical signs suggestive of prostate inflammation, although not clinically overt.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1046

### Ultrasonographic and clinical correlates of seminal plasma interleukin 8 levels in patients attending an Andrology Clinic for infertility

M. Maggi[1], F. Lotti[1], G. Corona[1], M. Mancini[2], E. Filimberti[1], S. Degli Innocenti[1], G. Colpi[2], E. Baldi[1], I. Noci[1], L. Adorini[3] & G. Forti[1]
[1]University of Florence, Florence, Italy; [2]University of Milan, Milan, Italy; [3]Perugia, Italy.

Introduction

Interleukin 8 (IL8) is a proinflammatory cytokine highly expressed in seminal plasma. Seminal IL8 (sIL8) has been proposed as a reliable surrogate marker of prostatitis and as a potential marker of male accessory gland infection (MAGI). So far, no study systematically evaluated the correlations of sIL8 with colour-Doppler ultrasound (CDU) features of the male genital tract. Hence, we investigated these possible correlations in infertile patients with MAGI.

Methods

Out of 250 subjects seeking medical care for couple infertility, 79 (mean age $36.4\pm7.5$ years) met the criteria of MAGI and scored higher than the rest of the sample on the National Institutes of Health-Chronic Prostatitis Symptom Index score. All patients underwent, during the same CDU session, hormone evaluation and seminal analysis (including sIL8), along with scrotal and transrectal CDU, before and after ejaculation.

Results

After adjusting for age, sIL8 in patients with MAGI was significantly related to several abnormal semen and CDU parameters. In particular, leukocytospermia was closely associated with sIL8. Ejaculate volume, unlike other semen or hormonal parameters, was negatively associated with sIL8. When transrectal CDU was performed, sIL8 was positively related to prostate abnormalities including calcifications, inhomogeneous or hypo-echoic texture, hyperaemia and

high arterial blood flow. In addition, an association between sIL8 and ejaculatory ducts dilatation and calcifications was observed. Finally, an association with seminal vesicles hyper-echoic texture was found. When scrotal CDU was performed, sIL8 was positively related to epididymal abnormalities including inhomogeneous, hypo- or hyper-echoic texture, calcifications, hyperaemia and an increased size of the tail. Conversely, no association was found with testis parameters.
Conclusions
sIL8 levels in patients with MAGI are associated with leukocytospermia and CDU abnormalities of the prostate, seminal vesicles and epididymis, but not of the testis. Furthermore, sIL8 correlates with signs suggestive of ejaculatory duct inflammatory subobstruction.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1047

**Visceral adiposity index and the effect of testosterone treatment in young men with congenital hypogonadotropic hypogonadism**

C. Haymana, A. Sonmez, A. Aydogdu, A. Taslipinar, C. Meric, Y. Basaran, K. Baskoy, S. Tapan, G. Uckaya, E. Bolu & O. Azal
Gulhane School of Medicine, Etlik, Turkey.

Introduction
Visceral adipose tissue (VAT) is closely related to metabolic derangement, such as dyslipidemia insulin resistance and type 2 diabetes. Also, there is an increase in deposition of visceral adipose tissue in hypogonadal subjects. The visceral adiposity index (VAI) is a sex-specific mathematical index, based on waist circumference (WC), body mass index (BMI), triglycerides (TG) and HDL cholesterol (HDL) levels, indirectly expressing visceral adipose function. We investigated the VAI in treatment-naive, young men with congenital hypogonadal hypogonadism (CHH) and searched for the effect of testosterone replacement on the VAI of this specific patient group.
Description of methods/design
A total of 190 patients (age 21.9±2.25 years) were enrolled. The control group included 200 age and BMI matched healthy young men (age 21.7±1.5 years). Standard regimen of testosterone esters (250 mg/3 weeks) was given to patients.
Results
The levels of VAI was higher in CHH ($P<0.0001$) according to healthy controls. The patients had higher WC, TG, HDL cholesterol ($P<0.001$ for all) levels (Table 1). After 5.52±2.5 months of testosterone treatment WC ($P<0.0001$), TG ($P<0.019$), VAI ($P<0.002$) levels were increased and HDL cholesterol levels were decreased ($P<0.0001$; Table 1).

**Table 1** The metabolic profiles of the patients with hypogonadism and healthy volunteers

| | Patients (*n*: 190) | | Controls (*n*: 200) | p1 | p2 |
|---|---|---|---|---|---|
| | Before treatment | After Treatment | | | |
| Age (years) | 21.9±2.25 | – | 21.7±1.5 | 0.23 | – |
| BMI (kg/m$^2$) | 22.0±3.74 | 22.9±3.3 | 21.9±1.1 | 0.179 | 0.0001 |
| WC (cm) | 82.8±10.8 | 85.6±9.9 | 76±4.7 | 0.0001 | 0.0001 |
| SBP (mmHg) | 112.4±9.6 | 116.1±10.5 | 107.5±10.7 | 0.0001 | 0.001 |
| DBP (mmHg) | 71.9±8.0 | 72.4±8.6 | 67.7±9.0 | 0.0001 | 0.23 |
| TG (mg/dl) | 102.5±46.8 | 109.2±43.5 | 81.4±42.9 | 0.0001 | 0.019 |
| HDL (mg/dl) | 46.7±11.4 | 42.6±10.6 | 53.1±9.8 | 0.0001 | 0.0001 |
| VAI | 3.1±1.8 | 3.6±1.6 | 2.0±1.4 | 0.0001 | 0.002 |

p1, patients vs controls; p2, before treatment vs after treatment; BMI, body mass index; WC, waist circumference; SBP, systolic blood pressure; DBP, diastolic blood pressure; TG, trigliseride; HDL, high density lipoprotein; VAI, visceral adiposity index.

Conclusion
This study shows that VAI levels are increased in treatment-naive, young men with CHH and after the testosterone replacement, the VAI levels are increased further.

**Prevalence of erectile dysfunction is greater in young middle-aged HIV-infected men than in hiv-uninfected men**

B. Madeo[1], D. Santi[1], S. Zona[2], G. Guaraldi[2] & V. Rochira[1]
[1]University of Modena & Reggio Emilia, Azienda USL of Modena-NOCSAE of Baggiovara,, Modena, Italy; [2]Metabolic Clinic, Infectious Diseases Unit, Modena, Italy.

Introduction
Erectile dysfunction (ED) is common among elderly men and patients suffering from chronic diseases, the latter probably including also HIV infection. No studies, however, compared the prevalence of ED in HIV-infected and -uninfected individuals using the IIEF-15.
Aim
To compare ED prevalence in young-middle aged men with and without HIV infection using the International Index of Erectile Function (IIEF-15) questionnaire.
Methods
We conducted a cross-sectional, observational, controlled study on 444 HIV-infected and 71 -uninfected men. The IIEF-15 questionnaire was used to assess ED. A cutoff score of <25 of the erectile domain was used to diagnose ED. Serum testosterone, demographic and anthropometric (weight, height, BMI) characteristics were obtained from all participants. Statistics included the T-test, the Fisher's test, univariable and multivariable logistic regression and univariate and multivariate Spearman's correlation analysis.
Results
HIV-uninfected group was significantly younger than HIV-infected and presented a higher BMI ($P<0.001$). The prevalence of mild, moderate, and severe ED was higher in HIV-infected than in HIV-uninfected men of all decades of age (Fig. 1). In univariate analysis, HIV infection was associated with ED (OR=34.19, $P<0.001$). In multivariable logistic regression analysis, HIV infection remained the strongest predictors of ED (OR=42.26, $P<0.001$) followed by hypogonadism, after adjusting for age and BMI.
Conclusions
This study demonstrates a clear association between ED and HIV infection, after adjusting for age and BMI. Other than HIV infection, hypogonadism was associated with ED. In addition, the prevalence of ED was higher in HIV-infected than in HIV-uninfected men, in all decades of age. The early onset of ED in HIV-infected men could be considered a peculiar clinical hallmark of HIV and confirms precocious aging in these patients. ED should be of concern to clinicians when managing HIV-infected men even if the latter are young or middle aged.

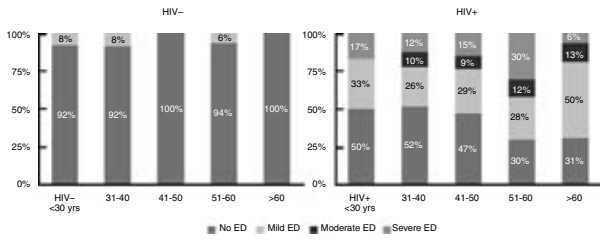

**Figure 1** Prevalence of erectile dysfunction in HIV-infected and HIV-uninfected patients in all decades of age.

**Effectiveness of gonadotropin treatment for spermatogenesis induction in hypogonadotropic hypogonadism: a possible role of androgen receptor CAG repeat polymorphism**

V. Giagulli[1], V. Triggiani[2], E. Tafaro[2], G. Corona[3,4], B. Licchelli[2], F. Resta[5], C. Sabba'[5], M. Maggi[3] & E. Guastamacchia[2]
[1]O.U. Metabolic Diseases and Endocrinology P.O. Monopoli-Conversano, Conversano, Italy; [2]O.U. of Endocrinology and Metabolic Diseases, University of Bari, Bari, Italy; [3]Sexual Medicine and Andrology, University of Florence, Florence, Italy; [4]O.U. of Endocrinology, Maggiore-Bellaria Hospital, Bologna, Bologna, Italy; [5]Rare Diseases Center, University of Bari, Bari, Italy.

Prepuberal-onset HH (PRHH) and postpuberal-onset HH (PSHH) men required GnTh by means of administration of both the β human chorionic gonodadotropin (ηHCG) and the FSH to induce a complete spermatogenesis. However, the response to GnTh is always unpredictable concerning either the effectiveness or the duration of the therapy. Consequently, different studies have been carried out to identify clinical and biochemical markers that can be useful to predict the effectiveness of GnTh. As testosterone plays an essential role in inducing and maintaining spermatogenesis, we measured the AR CAG in HH men, in order to examine whether the AR-CAG extensions could co-regulate the GnTh effectiveness. Twenty-three HH subjects subdivided according to the age at onset (pre- and postpubertal), were treated with the same scheme and doses of GnTh up to 30 months. Thirty-five healthy and fertile men served as a control group (CG).Twelve HH men (three PRHH and nine PSHH), who reached complete spermatogenesis within 12 months, showed AR CAG repeat number (20 (19–23) = median (interquartile range 25th – 75th percentile)) not statistically different from our CG (20 (19–22)), while CAG repeat number (23 (20–25)) of 11 HH patients (nine PRHH and two PSHH) who reached complete spermatogenesis beyond a year to within 30 months, was significantly higher. Our results suggest that AR CAG length might affect the response to GnTh in HH men, especially in PRHH patients.

**Phosphodiesterase type 5 expression in human and rat lower urinary tract tissues and the effect of tadalafil on prostate gland oxygenation in spontaneously hypertensive rats**

A. Morelli, E. Sarchielli, P. Comeglio, S. Filippi, R. Mancina, M. Gacci, L. Vignozzi, M. Carini, G. Vannelli & M. Maggi
University of Florence, Florence, Italy.

Introduction
In humans, prostate PDE5 expression was prominently localized in the endothelial and smooth muscle cells of the vascular bed, suggesting a possible action of PDE5 inhibitors on prostate blood flow.

Aim
To investigate PDE5 expression in human and rat lower urinary tract (LUT) tissues and determine the effects of PDE5 inhibition with tadalafil on prostatic blood perfusion.

Main outcome measures
Human vesicular-deferential arteries (which originate from the inferior vesical artery) were analyzed for PDE5 expression and activity. The effects of tadalafil on prostate oxygenation were studied in spontaneously hypertensive rats (SHR), characterized by ischemia/hypoxia of the genitourinary tract.

Methods
PDE5 expression was evaluated by quantitative reverse transcription-polymerase chain reaction and immunohistochemistry. SHR were treated with tadalafil (2 mg/kg per day) for 1, 7, or 28 days and compared with untreated SHR and the unaffected counterpart Wistar–Kyoto (WKY) rats. Prostate oxygenation was detected by hypoxyprobe-1 and hypoxia markers (hypoxia-inducible factor-1α (HIF-1α) and endothelin-1 type B (ETB)) immunostaining.

Results
Human vesicular-deferential artery expressed high levels of PDE5, similar to corpora cavernosa, immunolocalized in the endothelial and smooth muscle layer. In these arteries, tadalafil inhibited cGMP breakdown (half maximal inhibitory concentration in the low nanomolar range, as in corpora cavernosa) and increased the relaxant response to sodium nitroprusside. SHR prostate resulted markedly hypoxic (hypoxyprobe immunopositivity) and positive for HIF-1α and ETB, while tadalafil treatment restored oxygenation to WKY level at each time point. The mRNA expression of the HIF-1α target gene, BCL2/adenovirus E1B 19 kDa interacting protein 3, was significantly increased in SHR prostate and partially restored to WKY level by tadalafil.

Conclusion
Human vesicular-deferential artery is characterized by a high expression and activity of PDE5, which was inhibited by tadalafil in vitro. In SHR, tadalafil increases prostate tissue oxygenation, thus suggesting a possible mechanism through which PDE5i exert beneficial effects on LUT symptoms.

**Ten years of EAA/EMQN quality control scheme for microdeletions of the Y chromosome**

F. Tüttelmann[1], L. Hoefsloot[2], S. Patton[3], M. Simoni[4] & C. Krausz[5]
[1]University of Münster, Münster, Germany; [2]Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands; [3]St Mary's Hospital, Manchester, United Kingdom; [4]University of Modena and Reggio Emilia, Modena, Italy; [5]University of Florence, Florence, Italy.

Introduction
Y-chromosomal azoospermia factor (AZF) microdeletions are one of the few well-established genetic causes of male infertility, specifically azoospermia or severe oligozoospermia. Since the introduction of a PCR-based method to easily detect the distinct deletion patterns, the screening of infertile men for Y microdeletions has become a very common genetic test performed frequently by a large number of laboratories. An external quality control scheme was established in 1997 upon initiative of the Institute of Reproductive Medicine, University of Münster, Germany, shortly thereafter continued in cooperation with the European Academy of Andrology (EAA), and from 2004 onward within the framework of the European Molecular Quality Network (EMQN). Best practice guidelines describing methodology and interpretation of results are also available (Simoni *et al., Int J Androl*. 2004 **27** 240–9).

Methods
In most of the annual quality control schemes, three validated DNA samples with mock clinical case descriptions were distributed to participating labs. We retrospectively analysed the final results of each year.

Results
Between 2000 and 2010 the number of participating laboratories almost tripled from 57 to 144. The diagnostic error rate (an incorrect genotype that would lead to a misdiagnosis), decreased steeply during the first five years from almost 8% and now fluctuates at around 2%. While also variable, an assessment of the quality of diagnostic report content shows that around 50% of analyses in the last four years have scored full marks which is also an improvement on the previous early time of the scheme. Recurrent interpretation problems still arise due to laboratories using an unnecessary high number of markers, which are specifically included in commercially available kits.

Conclusions
This established external quality control scheme is a successful tool to improve the performance of participating labs and has demonstrated an improvement on reporting practice and decreasing diagnostic error rates.

### SIEDY scale 3, a new instrument to detect intrapsychic component in subjects with erectile dysfunction

G. Corona[1,2], V. Ricca[2], E. Bandini[1], G. Rastrelli[1], H. Casale[1], E. Jannini[3], A. Sforza[1], G. Forti[3], E. Mannucci[1] & M. Maggi[1]
[1]University of Florence, Florence, Italy; [2]Azienda Usl Bologna, Maggiore-Bellaria Hospital, Bologna, Italy; [3]University of L'Aquila, L'Aquila, Italy.

Introduction
We previously developed and validated a structured interview (SIEDY) dealing with the organic (scale 1), relational (scale 2) and intrapsychic (scale 3) components of erectile dysfunction (ED). The aim of the present study is to identify a pathological threshold for SIEDY scale 3 and to analyze scale 3 score with biological and psychological correlates in subjects with sexual dysfunction.
Method
A pathological threshold of SIEDY scale 3 score in predicting subjects with a medicals history of psychopathology and using psychiatric drugs was identified through receiver operating characteristic (ROC) curve analysis, in a sample of 484 patients (sample A). Sensitivity and specificity, along with possible interactions with biological and psychological (Middlesex Hospital Questionnaire, MHQ-score) correlates were verified in a further sample of 1275 patients (sample B).
Results
In sample A, 39 (8%) and 60 (12.4%) subjects reported a positive medical history for psychiatric disturbances or for the use of psychotropic medication respectively. The association with both conditions was present in 28 (5.8%) subjects. ROC curve showed that SIEDY scale 3 score predicts psychopathology with an accuracy of $69.5 \pm 5.9\%$ ($P < 0.002$), when a threshold of 3 was chosen. When the same threshold was applied in Sample B, it identified a higher ranking in MHQ-A (free-floating anxiety), MHQ-S (somatized anxiety) and MHQ-D (depressive symptoms) subscales, even after adjustment for age and $\Sigma$-MHQ (a broader index of general psychopathology). In the same sample, we also confirmed that pathological scale 3 score was related to a higher risk of psychopathology at medical history or to the use of psychotropic drugs as well as with risky lifestyle behaviours, including smoking and alcohol abuse, and elevated BMI.
Conclusions
SIEDY represents an easy tool for the identification of patients with a relevant intra-psychic component who should be considered for psychological/psychiatric treatment.

### Immunogold localization of testosterone and immunohistochemical detection of AR, SHBG, CYP1A1, ERβ and PCNA indicate a participation of steroid hormones in primordial germ cells of adult male bullfrogs

B. Caneguim[1], F. Beltrame[2], I. de Andrade Rosa[2], P. Cerri[3] & E. Sasso-Cerri[3]
[1]Universidade Federal de São Paulo, São Paulo, Brazil; [2]Universidade Santa Úrsula, RJ, Brazil; [3]Univ. Estadual Paulista-UNESP, Araraquara, Brazil.

In vertebrates, ARs have been detected in spermatogonia and also fetal gonocytes, confirming the importance of testosterone for the initial process of spermatogenesis. During seasonal spermatogenesis of adult bullfrogs (Lithobates catesbeianus), primordial germ (PG) cells show testosterone immunoexpression in winter; however, a weak or none testosterone immunoexpression was detected in summer. With the aim to confirm the role of testosterone in these cells, the immunogold localization of testosterone and the immunohistochemical (IHC) detection of AR and SHBG in PG cells were performed. Regarding the important role of estrogen for spermatogenesis, the immunoexpression of aromatase (CYP1A1), ERβ and PCNA was also evaluated in PG cells according to seasonality. The bullfrog testes were collected in winter and summer and were embedded in glycol methacrylate, for PG cells quantitative analysis; or in paraffin, for detection of stem cell markers (alkaline phosphatase activity and GFRα1), AR, SHBG, CYP1A1, ERβ and PCNA. The mitotic index of PG cells and the semiquantitative score (HSCORE) of ERβ-immunolabeled PG cells were obtained. Some fragments were processed for transmission electron microscopy for testosterone immunocytochemistry. PG cells were positive to stem cell markers. Immunogold-labeling of testosterone was usually observed in the cytoplasmic regions next to mitochondria. Moreover, cytoplasm immunoexpression of ARs and SHBG was also detected in the winter PG cells, confirming the participation of testosterone in these cells. In summer, the cytoplasm immunoexpression of CYP1A1 and the high ERβ HSCORE in PG cells confirm that testosterone is converted into estrogen. At winter, the number of PG cells was significantly higher ($P \leq 0.05$) than summer; however, a high number of PCNA-positive PG cells was coincident to the high ERβ HSCORE at summer. Therefore, the results indicate that testosterone and estrogen seems to play a role in the control of the seasonal mitotic activity of PG cells during spermatogenesis of bullfrogs.

### The high prevalence of testosterone deficiency in population of Polish men over 65 years with erectile dysfunction

M. Rabijewski, L. Papierska & W. Zgliczynski
Medial Centre for Postgraduate Education, Warsaw, Poland.

About 8–10% of erectile dysfunction (ED) is caused by hormonal causes, but in men over 65 years testosterone deficiency due to aging seems to play important role. In population of Polish men with relative poor health status, the prevalence of testosterone deficiency in elderly men with ED is probably higher. We evaluated the prevalence of low and low-normal testosterone levels in men with ED in population of Polish men over 65 years.
Material and methods
286 men (mean age 72.2 years) wit ED completed a sexual activity questionnaire (International Index of Erectile Function - IIEF-5). Possible scores on the IIEF-5 are 1 to 25 and erectile dysfunction was classified into 5 categories namely severe - 1 to 7, moderate - 8 to 11, mild to moderate - 12 to 16, mild - 17 to 21 and none - 22 to 25 points. Serum total testosterone was measured in all men.
Results
The prevalence of testosterone deficiency was 17, 33, 42 and 57% for testosterone levels of $<200$, $<250$, $<300$, and $<350$ ng/dl respectively. The degree of ED was significant higher in men with lowest testosterone levels ($P < 0.002$). The degree of ED in all group was mild in 39.5% of cases, mild to moderate in 26.2%, moderate in 18.2% and severe in 16%. We observed a statistically significant inverse relationship between age and total testosterone levels ($r = -0.3328$, $P < 0.05$), similar to IIEF-5 score and total testosterone ($r = -0.3149$, $P < 0,05$) and IIEF-5 score and age ($r = -0.3463$, $P < 0.05$).
Conclusions
Testosterone deficiency was very common in population of Polish men with ED and testosterone levels correlated negatively with age and IIEF-5 score.

**Production of nitric oxide and peroxynitrite by human spermatozoa and their possible role on sperm motility**

A. Vignini, E. Buldreghini, L. Nanetti, F. Raffaelli, F. Paggi, L. Mazzanti, E. Salvolini & G. Balercia
Polytechnic University of Marche, Torrette di Ancona, Italy.

Spermatozoa generate small amounts of O2°- and NO°. Under physiological condition these compounds exist at very low concentration and the formation of peroxynitrite (ONOO−) appears likely. Peroxynitrite reacts rapidly with proteins, lipids and DNA. Moreover, tyrosine nitration is a widely used marker of peroxynitrite. The nitration of protein residues gives rise to 3-nitrotyrosine which represents a protein modification specific for ONOO− formation *in vivo*. We determined NO and ONOO− production in semen and their potential role with sperm motility in infertile men, and we set out to determine whether protein tyrosine nitration takes place in sperm cells motility. Semen samples from 25 normal fertile donors and 40 infertile patients were analyzed. NO was measured by Griess Reaction while peroxynitrite concentration through the fluorescence of the DCFDA probe. Protein tyrosine nitration was determined by Western Immuno Blot as well as the presence of eNOS and iNOS. The controls exhibited both NO and ONOO− productions that was significantly lower than asthenozoospermic patients and were inverse correlated with the motility parameters. Moreover, the western immuno blots showed an increase in the nitration of the tyrosine residues in the asthenozoospermic samples compared to controls and the presence of both iNOS and eNOS proteins. The same pattern was confirmed by means of immunohistochemistry. The present data suggest a critical negative effect of NO and peroxynitrite on sperm motility when spermatozoa concentration is normal. Thus, a possible pathogenic role in infertile men when asthenozoospermia is the main critical problem may be suggested.

**Two infertile patients with 45X/46XY mosaicism and structural rearrangements of chromosome Y present with different phenotypes**

D. Ibarra Gasparini, C. Pelusi, A. Gambineri, P. Altieri, E. Scarano, L. Mazzanti & R. Pasquali
S.Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy.

Introduction
Within the high prevalence of male infertility there is the rare 45,X/46,XY mosaicism, associated or not with hypogonadism. The phenotypes of this genetical disorder present with a wide variability ranging from Turner stigmata to apparent normal male.
Case report
Two men who presented with azoospermia in the context of couple infertility were subsequently found to be affected by 45,X/46,XY mosaicism. Physical examination revealed a complete different phenotype; case 1 presented with normal weight and short stature, whereas case 2 presented with abdominal obesity and normal height. Case 2 had also bilateral gynecomastia, micropenis and a history of monolateral gonadectomy for criptorchidism at puberty. Both cases presented with small and soft testes, decreased bone mineral density and perceptive hearing loss at audiometric testing. No cardiorenal alterations were found. Assessment of gonadal function showed an increase of LH and FSH with normal testosterone levels (3.5 ng/ml) in case 1 and low testosterone levels in case 2 (2.2 ng/ml). A state of glucose intolerance with normal insulin levels at baseline (4.0 μU/ml) and after glucose load (peak: 37 μU/ml) was found in case 1, whereas case 2 had normal glucose tolerance, basal hyperinsulinemia (19 μU/ml) but normal insulin response to glucose load (peak: 77 μU/ml). The lipid profile was normal with unexpected high HDL-cholesterol levels (case 1: 78 mg/dl; case 2: 61 mg/dl). Cytogenetic examination revealed a different prevalence of 46,XY cells between case 1 and 2. Structural Y chromosome abnormalities were found in both: 45,X/46,X,idic(Y) (pter->q12::q12->pter) in case 1; 45,X/46,Xinv(Y)(q.11.2q12) in case 2.
Conclusion
Assessment of karyotype should be a key part of the initial evaluation of male patients with azoospemia regardless of the phenotype. The prevalence of 46,XY cells and the presence of Y rearrangements should always be evaluated for the potential explanation of different phenotypes, including comorbidities.

**Seminal vesicles ultrasound features in a cohort of infertility patients**

F. Lotti[1], G. Corona[1], G. Colpi[2], E. Filimberti[1], SDegli Innocenti[1], M. Mancini[1], E. Baldi[1], I. Noci[1], G. Forti[1] & M. Maggi[1]
[1]University of Florence, Florence, Italy; [2]University of Milan, Milan, Italy.

Introduction
Previous studies concerning ultrasound evaluation of the seminal vesicles (SV) have been performed on a limited series of subjects, taking into consideration few parameters, often only before ejaculation and without assessing sexual abstinence of the patients. The aim of this study is to evaluate the volume and the emptying characteristics of the SV and their possible correlations with scrotal and transrectal ultrasound features.
Methods
The SV of 368 men seeking medical care for couple infertility have been evaluated by ultrasound. All patients underwent simultaneous seminal analysis, along with scrotal and transrectal ultrasound, before and after ejaculation. A new parameter, SV ejection fraction, calculated as ((SV volume before ejaculation − SV volume after ejaculation)/SV volume before ejaculation)×100, was evaluated.
Results
After adjusting for sexual abstinence and age, both pre-ejaculatory SV volume and SV ejection fraction were positively associated with ejaculate volume. As assessed by receiver operating characteristic (ROC) curve, at 21.6% SV ejection fraction discriminates subjects with normal ejaculate volume ($\geq$ 1.5 ml) and pH ($\geq$7.2 ml) with a sensitivity and specificity of 75%. Subjects with reduced SV ejection fraction ($<$21.6%) more often had higher post-ejaculatory SV volume and ejaculatory duct abnormalities. Furthermore, a higher post-ejaculatory SV volume was associated with a higher prostate volume and SV abnormalities. Higher epididymal and deferential diameters were also detected in subjects with a higher post-ejaculatory SV volume or reduced SV ejection fraction. No association between SV and testis ultrasound features or sperm parameters was observed. Associations with SV ejection fraction were confirmed in nested 1:1 case–control analysis.
Conclusions
SV mainly contribute to ejaculate volume. A new parameter, SV ejection fraction, has been investigated, and could be useful in assessing SV emptying. Reduced SV ejection fraction ($<$21.6%) is associated with prostate-vesicular and epididymal ultrasound abnormalities.

## P1059

**Nitric oxide synthase and tyrosine nitration in idiopathic asthenozoospermia: an immunohistochemical study**

E. Salvolini, E. Buldreghini, G. Lucarini, A. Vignini, R. Di Primio & G. Balercia
Polytechnic University of Marche, Torrette di Ancona, Italy.

It has been previously shown that human spermatozoa produce nitric oxide (NO), a short-lived free radical synthesised by three isoforms of NO synthase (NOS): endothelial (eNOS), neuronal (*n*NOS), and inducible (iNOS), which are responsible for the conversion of L-arginine to L-citrulline and NO. Spermatozoa of fertile men express both eNOS and nNOS. The specific roles of NOS isoforms in gametes are not well understood, even if iNOS seems to negatively affect sperm function through the production of large amounts of NO. NO plays a relevant role in sperm physiology, although at high concentrations it could combine with superoxide to produce peroxynitrite, which can rapidly react with proteins, lipids, and nucleic acids. In the present study we aimed to assess the immunohistochemical expression of NOS isoforms in human spermatozoa isolated from normospermic fertile donors and infertile subjects affected by idiopathic asthenozoospermia. In addition we evaluated the immunoexpression of citrulline, to achieve the microscopic visualisation of NOS catalytic activity, and nitrotyrosine, since ample evidence supports the tyrosine nitration of proteins *in vivo* in different pathological conditions.
Our results show that constitutive NOS expression was greater in spermatozoa isolated from normospermic fertile donors. On the contrary, the immunohistochemical expression of inducible iNOS and nitrotyrosine was higher in asthenozoospermic samples. Our data concerning citrulline indicated an enhanced NOS activity in sperms from idiopathic asthenozoospermic patients.
In conclusion, our study strongly support the hypothesis that an increased NOS activity, and consequently an excess of tyrosine nitration are involved in the pathogenesis of idiopathic asthenozoospermia that causes male infertility, furthering the development of new therapeutic strategies in the near future.

**Testosterone replacement therapy: A comparison of testosterone mixed esters, extended release testosterone implants and testosterone undecanoate depot**

Helen M. Conaglen[1], Tania Yarndley[2], Jozef Kamp[1], Ryan G Paul[1], Kingsley Nirmalaraj[3], Marianne S Elston[1,2] & John V Conaglen[1,2]
[1]Waikato Clinical School, Department of Medicine, University of Auckland, New Zealand; [2]Waikato Hospital Endocrine Unit, Hamilton, New Zealand; [3]Tauranga Hospital Endocrine Unit, Tauranga, New Zealand.

Introduction
Male hypogonadism is one of the most common endocrine disorders affecting 5.6% of men aged between 30–79 years. Testosterone deficiency (TD) is an independent risk factor for multiple cardiovascular risk factors including obesity, diabetes mellitus, hypertension, dyslipidaemia and endothelial dysfunction. The aims of testosterone replacement treatment (TRT) in hypogonadism are to improve or ameliorate the clinical features and to restore the serum T to physiological levels. Treatment with TRT for hypogonadism is typically lifelong so needs to be safe, effective, convenient and minimise impact on lifestyle. Therefore the frequency of administration, mode of delivery, efficacy and side-effect profile are important.
Methods/design
Records of 155 hypogonadal males treated at the Waikato Endocrine Unit from 1998–2011 were examined to compare use of testosterone mixed esters, extended-release testosterone pellet implants and testosterone undecanoate depot (TUD). Efficacy of types of TRT in terms of achievement of physiological levels of T over two years, and changes in known risk factors such as Hb & Hct changes, PSA, and lipid profile changes were examined retrospectively.
Results
Mean T levels of men on Sustanon ($n=22$) ranged 1.6 to 54 nmol/l. Normal serum T trough levels were found in 53% of men using T implants ($n=134$) compared with 75.5% while using TUD ($n=155$), $P<.0001$. Mean Hct levels were higher on TUD than implants, $P<.0001$, with elevations in Hct managed by dose alterations. PSA elevations were no different on each TRT. HDL levels were sig lower using TUD than T implants, $P<.0001$, but total cholesterol, triglycerides and LDL were not significantly different by TRT. Only 4.5% of men elected to stop TUD or return to another TRT.
Conclusion
Testosterone undecanoate depot therapy maintained serum T at more physiological levels and was more acceptable to men as compared to other TRT options.

**Reduced fatigue and improved sexual function in hypogonadal men treated with TESTIM in routine daily practice**

H. Behre[2], A. Tolle[1] & M. Gedamke[1]
[1]Ferring Arzneimittel GmbH, Kiel, Germany; [2]University of Halle, Halle, Germany.

Introduction
Hypogonadal men frequently suffer from fatigue and reduced sexual function. International guidelines recommend testosterone replacement therapy (TRT) for symptomatic hypogonadal men. Our aim was to document testosterone changes and the impact of TRT with TESTIM on quality of life in routine daily practice.
Methods
In this non-interventional-study (NIS) data from 117 hypogonadal patients from 43 office-based-study-sites were evaluated. Data were collected at baseline, 3 and 6 months of TRT. Laboratory values, BMI and relevant clinical symptoms (loss of libido, obesity, erectile dysfunction and others; scale 0–4) were recorded. Patients were asked to fill in quality of life questionnaires: aging males symptoms scale (AMS), multidimensional fatigue inventory (MFI) and international index of erectile function (IIEF-5). Common pharmacovigilance monitoring was conducted.
Results
Testosterone increased significantly within 6 months from a median of 2.38 to 4.99 ng/ml. All recorded clinical symptoms improved significantly under TESTIM therapy. The most prominent clinical symptoms at baseline improved by 1.23, 1.53 and 0.78 points for erectile dysfunction, loss of libido and obesity respectively ($P<0.0001$).
Quality of life (AMS, MFI and IIEF-5) improved significantly under TESTIM therapy by 32.4, 28.6 and 48.3%, respectively ($P<0.0001$). We found significant associations of higher testosterone levels with freedom of symptoms from hypogonadism in AMS and IIEF-5 after 6 months of therapy ($rs=0.279$, $P=0.0045$).
Frequency of adverse events was 5.1%, with only 1.7% attributed to therapy. The most frequent adverse event was nausea (1.7%).
Conclusion
This NIS in hypogonadal men substantiates the clinical efficacy of TESTIM. Overall quality of life as well as sexual function improved significantly within 6 months of therapy, and fatigue was significantly reduced. A good or excellent efficacy and safety was demonstrated in the vast majority of patients in routine daily practice.

**The mitochondrial citrate carrier regulates insulin secretion by human male gamete**

A. Cappello, C. Guido, A. Santoro, M. Santoro, F. De Amicis, D. Montanaro, S. Marsico, V. Dolce & S. Aquila
University of Calabria, Cosenza, Italy.

Sperm energy management is poorly studied and understood. The present study provides biochemical and morphological evidence that ejaculated human sperm

express the mitochondrial citrate carrier (CIC) which is restricted to the midpiece. CIC inhibition by the specific substrate analogue 1,2,3-benzenetricarboxylate (BTA) reduced cholesterol efflux, proteins tyrosine phosphorylation, *P*-AKT, *P*-*P*60src addressing to its functional role in sperm acquisition of fertilizing ability. Worthy, CIC inhibition reduced sperm insulin secretion, glucose-stimulated insulin secretion (GSIS) and glucose-6-phosphate dehydrogenase (G6PDH) activity, supporting its role in the regulation on insulin secretion. In this study, we discovered a novel sperm factor involved in the regulation of metabolism and acquisition of sperm fertilizing ability. It may be taken into account as molecular target in the therapies designed for male infertility disorders.

**Mild androgen insensitivity syndrome due to novel mutation in androgen receptor gene**

E. Ivannikova[1], L. Dzeranova[1], L. Kurilo[2], A. Polyakov[2], V. Chernykh[2] & E. Pigarova[1]
[1]Endocrinology Research Centre, Moscow, Russian Federation; [2]Research Center for Medical Genetics of Russian Academy of Medical Sciences, Moscow, Russian Federation.

We describe a clinical case of the patient with the syndrome of partial resistance to androgens. The patient, a man 25 years old, complained of a barren marriage. Lab and clinical findings included high gonadotropin and testosterone levels, hypogonadal appearance, coronal hypospadias, left-sided varicocele, oligoasthenoteratozoospermia. The results of cytogenetic analysis showed a normal male karyotype (46, XY). Molecular genetic studies identified mutation in exon 1 of androgen receptor gene – s.731_736delCGGTGT, which allowed a precise diagnosis – Reifenstein syndrome.

**Semen quality in patients with newly diagnosed Hodgkin's disease**

K. Peros[1], T. Bozek[1], J. Zmire[1], B. Colak[1], M. Stakor[2], I. Prkacin[2] & A. Karakas[2]
[1]Vuk Vrhovac University Clinic, Zagreb, Croatia; [2]Clinical Hospital Merkur, Zagreb, Croatia.

Objective
To analyse the semen quality in patients with newly diagnosed Hodgkin's disease before starting the treatment.
Materials and methods
We evaluated semen quality in 67 patients with Hodgkin's disease who underwent sperm banking in our clinic over a 10-year period. Semen samples were collected by masturbation after 2–7 days of sexual abstinence. Age at banking, semen volume, sperm concentration, and total and progressive sperm motility were recorded. Semen parameters were compared to established World Health Organisation (WHO) reference values (WHO Laboratory Manual for the Examination and Processing of Human Semen, Fifth Edition, 2010).
Results
The median age of the patients was 27 years (range 17–43); median semen volume was 2.0 ml (range 0.2–6.5); median sperm concentration was 57.9 $\times$106 per ml (range 0–413); median total and progressive sperm motility were 42 (range 0–79) and 24% (range 0–69) respectively. According to the reference values of the WHO 18 of 67 patients (26.9%) in this series had a semen quality within the normal range, and 49 of 67 patients (73.1%) had abnormal semen quality. In 2 patients (3%) the semen samples were not frozen because of azoospermia (no spermatozoa in the ejaculate). 35 patients (52.2%) had single damages (oligozoospermia or asthenozoospermia) and 12 patients (17.9%) had combined damages (oligoasthenozoospermia).
Conclusion
Patients with Hodgkin's disease have an increased risk for inadequate semen quality before any treatment. 73.1% of these men in our study had abnormal semen parameters according to the WHO. Generally, all patients with newly diagnosed Hodgkin's disease need counselling about their reproductive function and semen cryopreservation should be offered before undergoing gonadotoxic treatment.

**Subcutaneous gonadotropin therapy for male infertility by hypogonadotropic hypogonadism**

P. Moreno, M. Gálvez Moreno, M. Alhambra Expósito, I. Prior Sánchez, C. Muñoz Jimenez, R. Palomares Ortega & P. Benito López
Hospital Universitario Reina Sofía, Córdoba, Spain.

Objetive
Evaluate the efficacy of subcutaneous HCG with or without FSH in male infertility associated to hypogonadotropic hypogonadism (HH).
Patients and methods
Descriptive study of patients with HH treated with HCG s.c. with or without FSH, for fertility objective (2004–2011). The Treatment was initiated with HCG 500 UI/72 h s.c., periodic monitoring of testosterone and semen analysis was realized, adjusting doses up to 2500 UI/72 h. If no answer obtained after 1 year, combined treatment with FSH s.c. was started. Analyzed data: cause of HH, age, testosterone levels, semen, dose of HCG and FSH treatment. The result has been assessed to the achievement of pregnancy.
Results
Ten patients. 30.6$\pm$2.9 years old. Cause of HH: 50% idiopathic, 20% nonfunctioning pituitary adenoma, 10% prolactinoma, 10% acromegaly and 10% craniopharyngioma. Fertility 60%, 22.6$\pm$13.5 months treatment time. Only one patient discontinued treatment without success. No presence of side effects.
Subgroup result:
Conclusions
Subcutaneous gonadotropin therapy is effective in infertility HH. Treatment with subcuataneous HCG alone is successful. No presence of side effects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Translation of EMAS sexual functions questionnaire from English to Lithuanian**

E. Prakapiene[1], V. Matulevicius[1], S. Nikulina[1], R. Preiksa[1], D. Velickiene[1], L. Lasaite[1], A. Buteikis[2], A. Buteikiene[3], V. Adomaitiene[1] & R. Sakalauskas[4]
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Klaipedos Jurininku ligonine, Palanga, Lithuania; [3]Kaunas Vocational Training Centre for Bussines Specialists, Palanga, Lithuania; [4]Lithuanian University of Health Sciences Kaunas Clinics, Kaunas, Lithuania.

EMAS - SFQ is recently available instrument, validated and prooved valid in multicentral European study of more than 3000 eldery men (O'Connor DB,

Corona G & Forti G *et al*. 2008). This questionnaire assess male sexual functions rather than only erection disturbances.
The aim of this study was to perform translation of EMAS - SFQ from English to Lithuanian for assessing elderly Lithuanian men suffering of prostate cancer. Permission for translation was kindly offered by I Huhtaniemi and J Finn as well as detailed procedure when having the questionnaire translated to Lithuanian.
The procedure consisted of translation – backtranslation of two pairs of persons, resulting in two versions of Lithuanian EMAS – SFQ followed by expert evaluation, resulting in the only final version. Instructions for translators were: <no deadline, no hurry, but quality>. Quality of translation was considered text to be close to English original and Lithuanian language and understanding.
Permission for translation - 6th October, Final version pair 1st–26th October. Final version pair 2nd–6th December. Final version of EMAS – SFQ – 10th December.
1st pair – psychiatrist–endocrinologist/ andrologist, 2nd pair – endocrinologist–psychologist, expert evaluation–endocrinologist/andrologist/sexologist and endocrinologist/sexologist/English philologist.
197 positions for translation were found in EMAS – SFQ.
63 positions (32%) were evaluated by experts as the same in sense and grammar between 1st and 2nd pairs.
57 positions (28.95%) were evaluated by experts in favour of the 1-st pair translation, and 27 positions (13.7%) – in favour of the 2-nd pair translation.
In 21 position (10.65%) text was finally modified by experts.
Final version of EMAS - SFQ was approoved by experts.
The final version was composed of positions with the same sense and grammar in both pairs of translators, favoured positions of 1-st or 2-nd pair of translators and all the positions with modified text.
Proposed procedure of translation proves that the only translation - back-translation may be insufficient for optimal result.
Model of translation using two pairs of translators – backtranslators plus expert evaluation elucidates coincidences and differences in translation and permits the emission of final optimal version.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**A surprising diagnosis in a man with high testosterone levels**
L. Srbova
The Institute of Endocrinology, Prague, Czech Republic.

Introduction
Marked elevation of testosterone levels can be caused by tumors with hormonal hypersecretion. However, we should be aware of the relationship between thyroid and sexual hormones, including changes of SHBG.
Case report
A 48-year-old man was recommended by an urologist to endocrinological examination due to high levels of total testosterone.
CT scan of abdomen, pelvis and the pituitary did not show any abnormalities.
The patient did not complain of any problems, but after inquiry he admitted a weight loss of 15 kg during last year which he related to his effort of eating less because of obesity. Apart of that we did not find any deviations from physical normal status including thyroid palpation, skin temperature and heart rate. Laboratory tests revealed the following results: $fT_4$ 48 pmol/l, $fT_3$ 16 pmol/l, TSH 0.005 mIU/l, total testosterone 59 nmol/l and SHBG 190 nmol/l (34–66). Free androgen index was still within the normal range 31 (30–152).
Within four months of therapy by antithyroid drugs, both the levels of thyroid hormones and total testosterone returned to norm.
Conclusions
Hyperthyroidism may lead to an elevation of total testosterone in males due to an increase of hepatic synthesis of SHBG. The metabolic clearance of testosterone is also decreased and the peripheral conversion of androstendion to testosterone is increased. Despite this, the levels of free testosterone are usually normal.
The restoration of all these parameters is in most cases achieved after euthyroidism is established.
This report shows the need of judging the levels of sexual hormones in connection with the levels of thyroid hormones (and SHBG) with respect to the fact that thyroid disorders may be clinically silent.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1069

**Recapture of the study on the reproductive function of Estonian, Latvian and Lithuanian Young Men after 8 years**
S. Nikulina[1], S.. Abramavicius[1], R. Preiksa[1], V. Matulevicius[1], V. Adomaitiene[1], R. Linkevicius[1], R. Verkauskiene[1], N. Sabeckiene[1], B. Zilaitiene[1], J. Pundzius[2] & I. Saukiene[3]
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences Kaunas Clinics, Kaunas, Lithuania; [3]Delfi.lt, Vilnius, Lithuania.

In 2003–2004 year a study named The Reproductive Function of Estonian, Latvian and Lithuanian Young Men, 18–25 year aged, was performed (QLK4-CT-1999-01422, NAS: QLK4-CT-2001-02911). Determination of semen quality, physical appearance and testicular size in relation to the level of reproductive hormones and environment, including life style factors was performed.
The aim of our study was to recapture young men, who had participate in the study 7–8 years ago and repeat the same examination also to examine the sexuality of these young men using EMAS- Sexual Functions Questionnaire, translated and approved for using in Lithuania. This group will be one of the groups in which relationship between general health, sexuality and physical activity and fitness will be performed.
Using the contacts (name, surname, address, phone number) we have, but keeping one's confidenciality, searched for everyone, who had participated at the study in 2003– 2004 year. The search was performed by phone, sending a posted letter; inviting through internet news-portal www.Delfi.lt, social network www.Facebook.lt, and internet phone network Skype.
Ninety nine (30.27%) men were recaptured. 86 (86.86%) men were recaptured by phone; 9 (9.09%) men- using internet news portal www.Delfi.lt; 4 (4.04%) men- by internet phone network Skype; 1 (1.01%) man by post; and none by social network www.Facebook.lt. 4 (4.04%) of recaptured men refused to continue the research.
Using given contact data (phone number and address) were recaptured 87 (87.87%) men, and using modern technologies (internet news portal, social networks)- 13 (13.13%) men.
It is known that 7 (2.14%) men live in foreign countries today, and one man was killed few years ago.
According to young age of our participants we believed that majority of them could change their living place, phone number or emigrate. Despite that, most of participants were found using given contact data by phone. And modern technologies didn't approved our expectations and minority was recaptured using internet news portal, phone network or social network.

**SNPs and CNVs genotyping analysis of patients with idiopathic central hypogonadism (ICH). A novel approach to detect new candidate mechanisms**
D. Libri[1,2], M. Bonomi[1], P. Duminuco[1], F. Guizzardi[1], D. Gentilini[1] & L. Persani[1,2]
[1]Istituto Auxologico Italiano, Milan, Italy; [2]University of Milan, Milan, Italy.

Introduction
Idiopathic central hypogonadism (ICH) is a rare and heterogeneous disease due to defects of GnRH secretion or action. ICH could be associated or not with hypo-anosmia respectively identifying the Kallmann's syndrome (KS) or the normosmic ICH (nICH). Even though 14 disease genes have been identified, in 70% of patients no genetic cause could be identified, suggesting additional regulatory genes and still unknown mechanisms. Thus, with the aim to identify new candidate genes, we decided to use a new and genome-wide approach on a group of ICH patients that resulted negative to the previous genetic analysis.

Methods
A total of 32 DNA samples from KS and nICH patients and their unaffected relatives were analyzed together with 1864 negative controls from the normal population. Samples were genotyped using 660W-Quad BeadChip Illumina (660.000 SNPs and 100.000 CNVs). The data obtained were analysed using statistical and bioinformatics tools.
Results and conclusions
Our results showed a statistically significant difference in the number of deletions between cases and controls which might indicate a genetic predisposition to ICH. The SNPs analysis allowed us to identify some candidate loci and in particular one gene with strong brain expression and two different microRNA clusters, thus indicating a possible involvement of microRNA in the pathogenesis of ICH. Loss of Heterozygoisity region analysis showed an enrichment for some pathways/families of protein, such as FGFR pathway, cadherins, brain-expressed GPCR and proteins involved in axon guidance. Furthermore analyzing the chromosomal position we found that 8 of the identified genes mapped in a cluster on chromosome 10 originated by an event of genetic duplication from the primitive block that contains the GNRH1. This may indicate that even though the GNRH1 function in this locus is lost during evolution, it is possible that this chromosome block has maintained or developed new functions in the control of reproduction.
Declaration of interest

**Cidea as a posible mediator of ghrelin resistance induced by high fat diet**

L. Martins, P. Martinez de Morentin, N. Martinez-Sanchez, C. Dieguez, R. Nogueiras & M. López
University of Santiago de Compostela, Santiago de Compostela, Spain.

Ghrelin is a peptide hormone secreted by the stomach with orexigenic properties that induce food intake trough the activation of hypothalamic AMP activated kinase (AMPK). In rodents fed on normal diet the central administration of ghrelin induces an increase in food intake, however, when fed a high fat diet (HFD) rodents are resistant to the orexigenic effect of ghrelin. Recent data show that Cidea interacts with AMPK β-subunit and promotes AMPK degradation trough ubiquitin-dependent pathway.
The main goal of this work was to study the mechanism mediating ghrelin resistance in the hypothalamus under HFD.
For this purpose male Sprague–Dawley rats were fed either a low fat diet (LFD) or a HFD. These animals were i.c.v. injected with ghrelin (5 μg/μl) or saline. The hypothalamic levels of different proteins were analyzed by western blot using specific antibodies.
Food intake induction by ghrelin administration was blunted in rats fed on HFD when compared with rats fed on LFD, which indicated resistance to ghrelin effect caused by HFD. In rats fed on LFD, ghrelin injection induced an increase in hypothalamic levels of phosphorilated forms of AMPK (pAMPK) and its downstream target acetyl-CoA carboxylase (pACC). However in rats fed under HFD, ghrelin treatment caused no changes in pAMPK and pACC levels. Of note, these animals showed a decrease in AMPK β1 and AMPK β2 levels, which was associated with the increase of the hypothalamic levels of Cidea.
These results may suggest that the mechanism of ghrelin resistance could be associated with dysregulation of Cidea and consequently of AMPK in the hypothalamus.

**Effects of obestatin on proliferation and survival of adult rat hippocampal progenitor cells**

E. Gargantini, A. Baragli, F. Settanni, M. Tagliano, E. Ghigo & R. Granata
University of Turin, Turin, Italy.

Obestatin (Ob) is a peptide recently identified as a product of the ghrelin gene. It was claimed to bind to the orphan receptor GPR39, but this finding is still a matter of debate. Ob exerts peripheral effects, for example, it promotes cell survival and has antiapoptotic actions in different cell lines. In addition, Ob has central effects, such as inhibition of thirst, modulation of anxiety, sleep and mnemonic functions. Mnemonic processes involve neurogenesis; in particular, hippocampal neurogenesis, which is fundamental for learning, comprise proliferation and differentiation of progenitor cells. Interestingly, both acylated ghrelin and the synthetic peptidyl GH secretagogue hexarelin have been previously shown to stimulate proliferation of adult rat hippocampal progenitor cells (AHPs). In the present study, we investigated Ob effects on proliferation and apoptosis of AHPs and the underlying signaling pathways. Ob effects were assessed in AHPs cultured in the absence of growth factors, a condition which reduces cell survival and proliferation, and increases apoptosis. Cell survival was measured by MTT assay; cell proliferation by BrdU incorporation and apoptosis through caspase-3 activity and Bcl-2 expression. Western blot analysis was performed to determine Ob-induced activation of neuroprotective pathways. Ob was found to promote cell survival and proliferation and to protect against growth factor deprivation-induced apoptosis. Furthermore, Ob effects involved PI3K/Akt, ERK1/2, Wnt/β-catenin and mTOR, as demonstrated by both activation of these pathways and by use of specific inhibitors. These results indicate that Ob promotes survival and proliferation, and inhibits apoptosis of AHPs through activation of neuroprotective pathways. Moreover, they suggest a possible role of Ob in neuronal precursor cell protection and candidate Ob as potential therapeutic molecule in conditions such as hippocampal damage.

## P1073

**Normalization of cortisol levels in Cushing's disease after medical pretreatment before surgery: effects on somatostatin receptor subtype expression and *in vitro* response to somatostatin analogs.**

R. van der Pas[1], R. Feelders[1], C. de Bruin[1], A. Pereira[2], D. Sprij-Mooij[1], M. Waaijers[1], S. Schulz[3], S. Lamberts[1] & L. Hofland[1]
[1]Erasmus Medical Center, Rotterdam, The Netherlands; [2]Leids Universitair Medisch Centrum, Leiden, The Netherlands; [3]University Hospital, Friedrich Schiller University, Jena, Germany.

Introduction
Corticotroph pituitary adenomas that cause Cushing's disease (CD) predominantly express the dopamine 2 receptor (D2) and somatostatin receptor subtype (sst) 5. The expression of sst2 is relatively low because of downregulating effects of high endogenous cortisol levels. This may explain why the sst2-preferring somatostatin analog octreotide is not effective in CD. To assess whether normalization of urinary free cortisol (UFC) excretion modulates the sst expression pattern, sst expression profiles of corticotroph adenomas from patients with normalized or elevated preoperative cortisol levels were compared. Moreover, the effects of pasireotide and octreotide on ACTH production were examined *in vitro*.
Methods
Corticotroph adenoma tissue was examined from patients from group 1 ($n=11$; mean duration of normocortisolism 10.3 weeks) and group 2 ($n=21$; elevated preoperative UFC). RT-PCR and immunohistochemical studies were performed to determine sst expression of these adenomas and to compare them to somatotroph adenomas ($n=10$).
Results
At mRNA level, adenomas from group 1 had tenfold higher sst2 expression levels compared to group 2 ($P<0.01$). Sst2 mRNA expression in group 1 was even comparable to that in somatotroph adenomas. There were no differences in sst5 and D2 mRNA expression levels between groups 1 and 2. At the protein level, no differences were found in sst2, sst5 or D2 receptor expression between group 1 ($n=7$) and 2 ($n=5$). Finally, octreotide was significantly less potent than pasireotide (both 10 nM) with respect to inhibition of ACTH secretion by adenomas of group 1 ($-18.9\pm9.1\%$ ($n=4$) vs. $-36.3\pm11.2\%$ ($n=6$); $P<0.001$).
Conclusion
After 10 weeks of normocortisolism induced by medical therapy, cortisol-mediated sst2-downregulation on corticotroph adenomas appears to be reversible at mRNA, but not yet at protein level. Octreotide remains less potent than pasireotide with respect to *in vitro* inhibition of ACTH secretion. This suggests that a sustained period of normocortisolism induced by medical therapy is required to induce re-expression of sst2 protein in corticotroph adenomas.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1074

**Mechanisms for the protective effects of 17-β-estradiol: relevance to depressive symptoms in Parkinson's disease**

P. Kumar, R. Kale, S. Cowsik & N. Baquer
Jawaharlal Nehru University, New Delhi, India.

Background
Parkinson's disease (PD) is a neurodegenerative disease and a movement disorder characterized by loss of dopaminergic neurons in the substantia nigra causing dopamine depletion in the striatum. Neurodegeneration in PD occurs due to multiple pathways including oxidative stress, mitochondrial damage, protein aggregation. These changes increase during menopausal condition in females when the level of estradiol is decreased. Recently, there has been a growing interest in the action and functions of the ovarian steroid hormone estradiol, particularly on whether they are neuroprotective for such age related disease and neurodegenerative conditions like stroke, PD and Alzheimer's disease.
Objective
The objective of this study was to investigate protective potential of 17β estradiol ($E_2$) treatment on the activity of monoamine oxidase, calcium homeostasis, membrane polarization, genomic DNA degradation, 4- hydroxynonenal and protein oxidation levels occurring in brains of female rats of 3 months (young), 12 months (adult) and 24 months (old) age groups, and to see whether these changes are restored to normal levels after exogenous administration of estradiol.
Methods
The aged rats (12 and 24 months old) ($n=8$ for each group) were given subcutaneous injection of 17β-estradiol (0.1 μg/g body weight) daily for 1 month. After 30 days of hormone treatment, experimental animals of all the groups were sacrificed and brains were isolated for further study.
Results
The results obtained in the present work revealed that normal aging was associated with significant increases in the activity of monoamine oxidase, calcium homeostasis, genomic DNA degradation, 4- hydroxynonenal and protein oxidation levels in the brains of aging female rats, and a decrease in membrane polarization. Our data showed that exogenous administration of $E_2$ brought these changes to near normalcy in aging female rats.
Conclusions
It can therefore be concluded that $E_2$'s beneficial effects seemed to arise from its, antioxidant and antilipidperoxidative effects, implying a therapeutic potential drug for age related changes. Based on our studies and others, we conclude that $E_2$ have therapeutic potential for adjunctive therapy along with dopamine replacement in PD.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Transient inhibition of the resolvin system in the hypothalamus of diet-induced obese mice**

L. Pascoal, L. Ignacio-Souza & L. Velloso
State University of Campinas, Campinas, Brazil.

Inflammation and dysfunction of the hypothalamus is a common feature of experimental diet-induced obesity. As in any inflammatory process, both pro- and anti-inflammatory activity is expected to take place in the hypothalamus of obese animals. Here, we test the hypothesis that consumption of a saturated fatty acid-rich diet can modulate the activity of the important immunomodulatory system of the resolvins in the hypothalamus. Swiss mice were fed for 8 or 16 weeks (w) either on a control chow (CT) containing 4% total fat, or on a high-fat diet (HF) containing 36% fat, mostly from lard. In addition, some mice were initially fed for 8 weeks on HF and then shifted to a high-fat diet containing 9.6% omega-3 oil (W3) for another 8 weeks. At 8 weeks, the hypothalamic expression of the phospholipase A2 (PLA2) was increased. However, 15-lipoxigenase (15LO) and GPR32 (resolvin D1 receptor) expression which catalyze initial steps of the resolvin synthesis and activity, were reduced. At 16 weeks, PLA2, 15LO and GRP32 were increased as compared to control. When mice were fed on W3, significant reduction of markers of inflammation in the hypothalamus was accompanied by reduction of PLA2 and 15LO expression. Finally, a direct acute intracerebroventricular injection of resolvin D1 in the hypothalamus increases the expression of the anti-inflammatory cytokine IL10 while reducing the expression of the p65 subunit of NFkB. Thus, this is the first evidence that during diet-induced inflammation of the hypothalamus the activity of the resolvin system is modulated. This modulation seems to occur in two phases, being initially suppressed and then activated. Because the resolvin system can be activated by nutrients, we believe it may be an interesting potential target for dietary approaches to tackle obesity.

**Predictors of neuropsychiatric side effects of dopamine-agonist therapy in patients with prolactinomas**

A. Athanasoulia, C. Sievers, M. Ising, A. Brockhaus, A. Yassouridis, G. Stalla & M. Uhr
Max Planck Institute of Psychiatry, Munich, Germany.

Introduction
Treatment with dopamine agonists in patients with prolactinomas and Parkinson's disease is associated with central side effects. Central side effects may depend on a substance's ability to pass the blood-brain barrier which can be actively controlled by transporter molecules such as the P-glycoprotein encoded by the ABCB1 gene.
Aim of the study
To determine whether cabergoline is transported by the P-glycoprotein and whether polymorphisms of its encoding ABCB1 gene predict central side effects of cabergoline therapy in patients with prolactinomas.
Methods
i) In an experimental mouse model lacking the homologs of the human ABCB1 gene (abcb1ab double-knockout mice), we examined whether cabergoline is a substrate of P-glycoprotein. ii) In a human case–control study, we investigated the association of four selected ABCB1 gene SNPs (rs1045642, rs2032582, rs2032583, rs2235015) with the occurrence of central side effects under cabergoline therapy in 92 prolactinoma patients treated at the Max Planck Institute of Psychiatry in Munich.
Results
i) In the experimental mouse model, we observed that brain concentrations of cabergoline were tenfold higher in the mutant mice compared to their wild-type littlemates implying that cabergoline is indeed a substrate of the transporter P-glycoprotein at the blood–brain barrier level. ii) In humans, we found significant negative associations for the C-carriers and heterozygous CT-individuals of SNP rs1045642 with two central side effects (frequency of fatigue and sleep disorders) and for the G-carriers of SNP rs2032582 with the enhancement of dizziness under cabergoline. For the SNPs rs2235015 and rs2032583, no associations with central side effects under cabergoline were found.
Discussion/conclusion
This is the first study demonstrating that individual ABCB1 gene polymorphisms reflecting a different expression and function of P-glycoprotein could predict the occurrence of central side effects under cabergoline. Our findings can be viewed as a step into personalized therapy in patients with prolactinomas.

### Shift work at young age is associated with elevated long-term cortisol levels and body mass index

L. Manenschijn[1], Rvan . Kruysbergen[2], F. de Jong[1], J. Koper[1], S. Lamberts[1] & E. van Rossum[1]
[1]Erasmus MC, Rotterdam, The Netherlands; [2]Arbo Unie Nijverdal, Nijverdal, The Netherlands.

Introduction
The incidence of obesity and other features of the metabolic syndrome is increased in shift workers. This may be due to a misalignment between the internal circadian rhythm and the behavioral rhythm. The stress hormone cortisol could play a role in this phenomenon, because it is secreted in a circadian rhythm, and long-term elevated cortisol levels leads to components of the metabolic syndrome. Our aim was to study changes in long-term cortisol levels due to shift work.
Methods
This study consists of two parts. Part 1 (pilot study): hair samples were collected in 33 shift workers and 89 day workers. Height and weight were measured, and BMI was calculated[1]. Part 2: hair samples were collected in 100 males working in shifts or only during the day. Hair samples were collected together with height, weight, hip and waist circumference and questionnaires concerning diet, exercise and perceived stress. Cortisol was extracted from the hair samples with methanol, and cortisol levels were measured using ELISA.
Results
Part 1: Hair cortisol levels were higher in shift workers than in day workers: 47.32 pg/mg hair (95% CI = 38.37–58.21) vs 29.72 pg/mg hair (95% CI = 26.18–33.73; $P < 0.001$). When divided in age groups based on the median age, elevated cortisol levels were present particularly in younger shift workers: 48.53 pg/mg hair (95% CI = 36.56–64.29) vs 26.42 pg/mg hair (95% CI = 22.91–30.55) ($P < 0.001$). BMI was increased in younger shift workers as well: 27.2 (95% CI = 25.5–28.8) vs 23.7 (95% CI = 22.8–24.7) in young day workers ($P = 0.001$). Hair cortisol and BMI were positively correlated ($\beta = 0.262$; $P = 0.005$)[1]. The results of the second part will be presented at the congress.
Conclusion
Shift work at young adult age is associated with elevated long-term cortisol levels and increased BMI. Elevated cortisol levels and BMI may contribute to the increased cardiovascular risk found in shift workers.

### The limited screening value of insulin-like growth factor-I as a marker for alterations in body composition in very long term adult survivors of childhood cancer

K. Blijdorp, M. Van den Heuvel, R. Pieters, A. Van der Lely & S. Neggers
Erasmus University Medical Center, Rotterdam, Netherlands.

Introduction
The clinical relevance of low IGF-I levels, caused by cranial radiotherapy, in adult childhood cancer survivors has not been studied extensively. We evaluated whether IGF-I is a useful marker for altered body composition and growth hormone deficiency in this group.
Methods
We analyzed retrospective data from 610 adult childhood cancer survivors, retrieved from the late effects clinic. Median age at diagnosis was 6 years (interquartile range 3–11) and follow-up time was 18 years (13–24). We assessed IGF-I standard deviation scores (SDS), anthropometrical measures, growth hormone stimulation tests in patients with clinical signs of GHD and measures of body composition (assessed by dual X-ray absorptiometry, Lunar Prodigy).
Results
In 58 cranially irradiated acute leukemia survivors (25 Gy (24–25)) and 56 locally irradiated brain tumor survivors (42 Gy (35–54)) we found significantly lower IGF-I SDS ($P < 0.001$), lower height SDS ($P < 0.001$), higher body mass index ($P = 0.01$), higher waist-hip ratio ($P = 0.001$), higher total fat percentage SDS ($P < 0.001$) and lower lean body mass SDS ($P < 0.001$), as compared to 452 not cranially irradiated survivors. IGF-I showed a weak inverse correlation with BMI ($r = -0.12$, $P = 0.04$), waist hip ratio ($r = -0.15$, $P = 0.01$), total fat percentage ($r = -0.14$, $P = 0.02$) and a positive correlation with lean body mass ($r = 0.15$, $P = 0.01$). In patients with low IGF-I levels, IGF-I did not significantly differ between subjects with and without GHD as determined by GH-stimulation testing ($P = 0.39$).
Conclusion
This study shows that IGF-I has limited value as a marker for alterations in body composition in adult childhood cancer survivors.

### Timing determines the suppressive effect of sleep loss on testosterone

S. Schmid[1], M. Hallschmid[1], K. Jauch-Chara[1], H. Lehnert[1] & B. Schultes[1,2]
[1]University of Luebeck, Luebeck, Germany; [2]Kantonsspital St Gallen, Rorschach, Switzerland.

Background
Sleep loss in the early morning has been shown to reduce secretory activity of the pituitary–gonadal axis in men, but the determinants of this effect are unknown.
Objective
To assess the effects of sleep restriction on serum concentrations of LH, testosterone , and prolactin (PRL).
Methods
Fifteen young, healthy men were examined in a condition of sleep time restriction to 0245–0700 h for two consecutive nights and in a control condition of regular sleep (2245–0700 h). After the second night, serum concentrations of LH, testosterone, and PRL were monitored over a 15 h period. In addition, these hormones were measured in serum samples obtained in eight healthy men in the morning after one night of total sleep deprivation, of 4.5 h sleep (2230–0300 h), and of regular 7 h sleep.
Results
Serum LH, testosterone, and PRL concentrations showed characteristic diurnal variations across the 15-h period without any differences between the 4 and 8 h sleep conditions. However, total sleep deprivation and 4.5 h of sleep restricted to the first night-half markedly decreased morning testosterone and PRL concentrations (both $P \leq 0.05$).
Conclusion
Collectively, our data indicate that the effect of sleep restriction on pituitary-gonadal secretory activity depends on the timing of sleep restriction. While sleep loss in the early part of the night does not affect testosterone and PRL, early awakening and wakefulness during the second part of the night profoundly reduce circulating testosterone and PRL.

### CT Scan of the anterior skull base in Kallmann syndrome reveals specific ethmoid abnormalities

L. Maione[1], S. Benadjaoud[1], D. Ducreux[1], A. Sinisi[2], P. Chanson[1], F. Benoudiba[1] & J. Young[1]
[1]Univ Paris Sud, Assistance Publique Hopitaux de Paris, Bicetre Hospital, Le Kremlin-Bicetre, France; [2]Second University of Naples, Napoli, Italy.

Context
Kallmann syndrome (KS) is a developmental disease associating congenital hypogonadotropic hypogonadism (CHH) and sense of smell impairment owing to olfactory structures (OS) aplasia/hypoplasia. Although rhinencephalic MRI allows to detect specific KS OS abnormalities useful to discriminate KS from normosmic CHH (nCHH), this technique is not efficient enough to study anterior skull bone structures.

Objectives
To search for specific anterior skull base abnormalities in KS through CT scan.
Patients
Thirty seven KS patients were compared to matched nCHH ($n=15$) and controls ($n=30$).
Design
Prospective case–control study. All patients and controls underwent a high resolution three-plane CT scan in bone window with axial, coronal and sagittal reconstructions. Olfactory gutter (OG) height, width, surface and foveo-lateral angle were measured. Cribriform plate foramina were counted bilaterally. Rhinencephalic MRI were performed in parallel and OS abnormalities were scored as normal, hypoplasic or aplastic and compared to CT scan findings.
Results
In KS patients OG height, width and surface were all significantly lower than in nCHH and controls ($P<0.0001$). OG height $<3.6$ mm discriminates KS with the higher sensitivity and specificity. A correlation between OG height at CT scan and OS abnormality scores at MRI was found. KS subjects also presented a wider foveo-lateral angle than nCHH and controls ($P<0.0001$). Cribriform plate foramina median number was similar in KS, nCHH and controls (7 vs 8 and 9 respectively).
Conclusions
This study allowed us to discover specific ethmoid abnormalities in KS patients. OG height $<3.6$ mm at CT scan specifically discriminates KS from nCHH, providing a new diagnostic tool. The presence of cribriform plate foramina in KS patients indicates that OS integrity is not mandatory for their formation and maintenance, unraveling original aspects on KS pathophysiology.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Wrist actigraphy detects sleep disorders in patients with Cushing's syndrome

V D' Angelo[1], M. Balbo[1], G. Beccuti[1], R. Berardelli[1], I. Karamouzis[1], A. Picu[1], E. Marinazzo[1], B. Fussotto[1], C. Zichi[1], R. Giordano[2], E. Ghigo[1] & E. Arvat[1]
[1]University of Turin, Turin, Italy; [2]University of Turin, Orbassano, Italy.

Interrelationships between HPA axis and sleep architecture are well documented and increased glucocorticoid levels seem associated with quantitative and qualitative sleep disruptions. The knowledge about sleep parameters in chronic hypercortisolism in humans is scanty. Our aim was to evaluate sleep efficiency in patients with Cushing's syndrome (CS) at time of diagnosis, without ongoing specific therapy, using wrist actigraphy, a methodology that provides good estimations of sleep duration and consolidation. In 12 CS patients with different etiology (eight ACTH-secreting pituitary adenoma, CD, and four cortisol-secreting adrenal adenoma, AA) (11 F, 1 M, 40.0 ± 10.9 year) and in 12 age- and sex-matched healthy control subjects (NS), sleep recording was performed by Actiwatch (Mini Mitter Co, Inc.; Bend, OR, USA) on three consecutive working days under free living conditions. Data were analysed using Actiware-Sleep Software. All the subjects completed questionnaires about sleep habits. In CS patients morning circulating levels of ACTH, cortisol and free urinary cortisol (UFC) levels were measured. Wrist actigraphy revealed no significant difference between CS and NS in terms of time in bed ((mean ± S.D.) 8 h4' ± 0 h55' vs 7 h40' ± 0 h53'), actual sleep time (7 h8' ± 0 h 54' vs 6 h48' ± 0 h44'), sleep efficiency (88.47 ± 2.44 vs 88.9 ± 2.88%), sleep latency (0 h6' ± 0h3' vs 0h8' ± 0h7'). However, some sleep parameters were deranged in CS, such as an higher actual wake time (0h43' ± 0h10' vs 0h33' ± 0h12'), total activity score (8318 ± 4308 vs 4971 ± 2372), mean activity score (8.67 ± 4.23 vs 5.44 ± 2.16), mean score in activity time (104.83 ± 39.23 vs 74.81 ± 23.15), sleep fragmentation (16.17 ± 4.21 vs 13.01 ± 3.6). compared to NS ($P<0,05$). No positive correlation between sleep efficiency parameters and UFC was found. In conclusion, these results, though preliminary, indicate that hypercortisolism is associated with a deranged sleep efficiency, in a dose-independent manner. Further studies in a larger cohort of patients and the use of more accurate instruments, such as in-home polysomnography, are needed to confirm these findings.

### Comparison of Chinese herbal mixture and electro-acupuncture on regulating endocrine disturbances and hypothalamic androgen receptor in rats with DHT-induced PCOS

T. Xu[1], L. Song[2], X. Li[1], S. Ma[1,3], L. Li[2] & Y. Feng[1]
[1]Fudan University, Shanghai, China; [2]Hubei University of Traditional Chinese Medicine, Wuhan, China; [3]Shanghai Medical College. Fudan University, Shanghai, China.

Polycystic ovary syndrome (PCOS) is one of the most common endocrine disorders affecting reproductive women. Treatments with Chinese herbal mixtures (HM) and electro-acupuncture (EA) have been proven efficient in clinic. This study evaluated the peripheral and central effects of HM and EA in dihydrotestosterone (DHT)-induced PCOS rats. The female Wistar rats were divided into control (C), control with placebo (CP), DHT-induced PCOS model (PCOS), PCOS model exposed to herbal mixture (PCOS + HM) and EA (PCOS + EA) groups. At age 3 week, DHT or DHT placebo pellets were inserted to slow release. From 10 week of age, PCOS + HM group were continuously intragastric administrated with the herbal mixture (1 ml/100 g BW, twice a day) while PCOS EA rats received 2-Hz EA (30 min, once a day, five times/week), totally 4 weeks. The results showed that PCOS rats presented with increased body weight, disturbed estrus cycles, cysts follicles and disordered level of steroid hormone, whereas these were restored both in HM and EA group. Interestingly, the fat depots and muscles of rats in EA group are significantly reduced, while the HM is mainly effect the weight of uterus and ovaries. Moreover, HM and EA also reduced the elevated hypothalamic androgen receptor (AR) protein expression and GnRH-immunoreactive (GnRH-IR) in medial preoptic area (MPO) and the ventro medial hypothalamus (VMH) compared with PCOS rats by immunohistochemistry. Therefore, we suggested that there might be differentially particular emphasis of HM and EA on endocrinology and metabolism of PCOS rats.

### Endogenous estradiol levels in female acute stroke patients: an independent determinant of stroke severity and early outcome

T. Pappa[1], E. Mantzou[2], K. Vemmos[2], K. Stamatelopoulos[2], V. Vassileiou[1] & M. Alevizaki
[1]Alexandra Hospital, Athens, Greece; [2]Evgenideion Hospital, Athens, Greece.

Introduction
Data on the role of endogenous sex steroids in cerebrovascular disease is sparse. Our aim was to investigate the clinical relevance of circulating sex steroids in a postmenopausal acute stroke population and search for associations with disease severity and short-term outcome.
Patients and methods
We prospectively studied 302 postmenopausal female patients hospitalized for an acute stroke in two tertiary hospitals, during a time period of 2 years. A detailed medical history and physical examination were performed and risk factors for stroke were recorded. Stroke severity was assessed using the National Institutes of Health Stroke Scale (NIHSS). One month after stroke onset, the functional outcome and degree of handicap were evaluated with the modified Rankin Scale (mRS). In all patients, we performed basal biochemical investigation and hormonal testing, measuring circulating estradiol, using a high sensitivity assay, as well as androgen (dehydroepiandrosterone sulfate, Δ4-androstenedione and testosterone) and sex hormone binding globulin levels.
Results
Estradiol levels were the only hormonal parameter significantly related to stroke severity on admission, as expressed by NIHSS, after correcting for confounding factors in the multivariate analysis ($\beta$0.262, $P<0.001$). Estradiol was an independent determinant of 1-month mortality (odds ratio (OR) with 95% confidence intervals (CI): 1.012 (1.005–1.019), $P$ 0.001), along with stroke severity and history of arterial hypertension. Estradiol levels remained an independent predictive factor of the adverse functional outcome (mRS $\geq 4$) in the multivariate analysis (OR with 95% CI: 1.011 (1.000–1.021), $P$ 0.047), along with stroke severity and hemorrhagic stroke type.
Conclusions
We found an independent association of endogenous estradiol levels with stroke severity and short-term mortality and outcome. Circulating estradiol might

represent an adjunctive biomarker to identify patients at increased risk for death and disability.

### Long term evolution of patients with transsphenoidal surgery due to pituitary adenomas

J García . Arnés, I. González-Molero & M. Domínguez-López
Carlos Haya Hospital, Málaga, Spain.

Aim
To study the results of transsphenoidal surgery in our Neuroendocrinology Unit in last 10 years.
Methods
We reviewed all patients operated in our hospital and followed in our Neuroendocrinology Unit in the last 10 years. We excluded patients with previous surgery or irradiation on this area. We obtained data about type and size of tumor, previous hormonal deficit, local symptoms,complications of surgery and the status after this (remission, persistence or recurrence).
Results
One hundred and six patients, mean age 46.2±16.1 years, 42.4% women. Diagnosis:non-functioning adenomas :57.2%, acromegaly: 23, 6% and others 19.2%. The size: 92.5% macroadenomas. Prior to surgery, 16% had hyperprolactinemia, 22.6% TSH deficiency, 22.6% FSH/LH deficiency, 15.1% ACTH deficiency and 11.6% GH deficiency. Local symptoms (62%): the most frequent symptom was visual disturbance (43.4%) followed by headache (39.6%) and cranial nerve impairment (2.8%). Early complications were: 17.4% diabetes insipidus, 5.4% cerebrospinal fluid fistula, 6.5% both simultaneously, one case of obstructive hydrocephalus and one case of intratumoral bleeding. Late complications: two patients diabetes insipidus, two cerebrospinal fluid fistula and two patients both. 48.9% had postoperative hormone deficiency: FSH/LH deficiency 37%,TSH 37%,ACTH 35.9% and GH deficiency 27.4%. There was local symptoms improvement in 54.4% of patients.After surgery,tumor mass remained in 46.7% (100% of prolactinomas, 50.8% of non-functioning and 48% of acromegaly), 6.5% recurred and 29.3% are in remission (the rest are in postoperative evaluation period). After the first surgery, 16.9% required further medical treatment, 17% were reoperated and 33.7% received radiotherapy. Age over 40 years was associated with an increased likelihood of remnant mass ($P=0.03$) regardless of tumor size. The presence of ACTH deficiency before surgery was significantly associated with the possibility of hormonal deficit after surgery ($P=0.00$) and possibility of remnant mass ($P=0.05$) The presence of local clinic was related to the appearance of early complications after surgery ($P=0.007$).
Conclusions
After transsphenoidal surgery, there is a low incidence of local complications but high incidence of postoperative hormonal deficits (as described in other literature). Age over 40 years, preoperative ACTH deficiency and the presence of local symptoms are related to worse outcomes after surgery.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1085

### Panhypopituitarism treated and untreated with GH: long term evolution of echocardiographic parameters

J. García Arnes, I. González-Molero, M. Domínguez López,
M. Gonzalo Marín, R. Peñafiel & G. Fernandez Madero
Carlos Haya Hospital, Málaga, Spain.

Objective
To evaluate the effects of GH on cardiac structure and function of patients with panhypopituitarism.
Material and methods
We performed echocardiographic studies of patients with panhypopituitarism treated and not treated with GH at baseline and after 12 years of follow up. We collected clinical and echocardiographic data (systolic and diastolic ventricular diameter (LVEDD and DTSVI), interventricular septum thickness (IVS), left ventricular posterior wall thickness (PPV), left ventricular mass and diastolic and systolic volume of left ventricle (LVEDV and LVESV), ejection fraction (EF) and size of the waves E, A, E /A ratio, deceleration time (DT) and isovolumic relaxation time (IVRT).
Results
Data were obtained from 30 patients, mean age 48.9±13.7 years, 63.3% men. Etiology of GH deficit: 40% nonfunctioning adenomas, 20% macroprolactinoma, 20% craniopharyngioma, empty sella 13.3 and 6.6% other causes. The years of evolution at the time of first echocardiogram was 8.5 years in treated patients and 4.5 years in untreated patients. There were no differences in other cardiovascular risk factor. There were no differences in the mass or the dimensions of the left ventricle, aorta and left atrium in both groups basal and after reevaluation. The ejection fraction was 63% basal vs 70% in reevaluation in the treated group ($P<0.05$) and 57 vs 66% respectively in untreated group ($P<0.05$). There were differences in treated patients in the E wave (44.11 cm/s in basal ECO vs 73.11 cm/s in reevaluation, $P<0.05$) and E/A ratio (0.73 in vs 1.06 respectively, $P<0.05$), while there were no differences in untreated patients after reevaluation.
Conclusions
In patients treated with GH there was a significant improvement in diastolic function parameters (E wave and E/A).
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1086

### Relationship between sex hormones, cognitive performance and substance use

M Zilbermint[1], X. Xu[2], A. Wisniewski[3], O. Selnes[2] & A. Dobs[2]
[1]Saint Agnes Hospital, Baltimore, Maryland, USA; [2]Johns Hopkins University School of Medicine, Baltimore, Maryland, USA; [3]University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma, USA.

Hypogonadism is prevalent with opiate-like drug use and might be a factor in cognitive abnormalities. With the increasing substance use (SU) worldwide, it is critical to recognize its impact on cognition, which may decrease adherence to treatment and alter quality of life. We hypothesized that men with SU, by virtue of hypogonadism secondary to HIV and/or drug use, may demonstrate impaired cognitive function.
We recruited men aged 18–50 from a low-income population in Baltimore, Maryland. Details of HIV and SU status, blood levels of total testosterone (TT), free testosterone (FT) and estradiol ($E_2$) were assessed. All subjects were administered ten neuropsychological tests that tested cognition, visuomotor and visuospatial abilities, graphomotor and psychomotor speed, and verbal learning and memory.
Our sample consisted of 68 men (mean age: 43.2 (s.d. 5.8), African Americans: 86.6%). The studied population was primarily uneducated and unemployed. The mean level of TT was 553.9 ng/dl (s.d. 262.0), median 507 ng/dl, the mean level of FT was 69.5 pg/ml (s.d. 34.8), median 70.5 pg/ml, mean $E_2$ was 3.2 pg/ml (s.d. 4.4), median 2.1 pg/ml. We found that 30.9% were hypogonadal (TT<300 ng/dl or FT<50 pg/ml) and it was associated with higher SU.
We observed some relationships between sex hormones and cognitive domains, however, after adjustment for age, drug use category, education, depression, and HIV, there was no statistically significant correlation between cognitive performance and sex hormone levels.
In this cross-sectional study of men with a high prevalence of SU and hypogonadism (30.9%), endogenous levels of TT, FT or $E_2$ were not related to cognitive performance. Future research should identify alternative factors that affect poor cognitive functioning in the setting of SU.
Non-users = no substance use in the past three years Occasional users = cocaine and/or heroin use less than three times per week Heavy users and methadone = methadone, cocaine and/or heroin use more than three times per week or being on methadone maintenance

## P1087

### The proliferation and apoptosis activity of blood lymphocytes in acromegaly

M Dudina[1], S Dogadin[1] & A Savchenko[2]
[1]Krasnoyarsk State Medical University named after Prof. V. F. Voino-Yasenetsky, Krasnoyarsk, Russian Federation; [2]Institute for Medical Problems of the North, Siberian Division, Russian Academy of Medical Sciences, Krasnoyarsk, Russian Federation.

Introduction
The number of cells in tissue is governed by two processes – the proliferation and 'programmed cell death' – apoptosis. Both processes in the body are controlled by enabling or inhibiting factors that are expressed on the surface of CD25+ and CD95+-lymphocytes. Somatotropin (GH) and insulin-like growth factor 1 (IGF1) stimulate proliferation, differentiation, and division of immune cells simultaneously inhibits their apoptosis and can cause tumor growth in acromegaly.
Aim
To study the expression of CD25+ and CD95+-lymphocytes level depending on the acromegaly stage.
Methods
The study population consist 47 acromegalic patients (38 with active acromegaly and 9 in disease remission, mean age $50.4 \pm 12.58$, range 27–73 years, the latent period duration of acromegaly was $5.72 \pm 5.02$ years) and 65 age-matched controls. The surface lymphocytes markers expression was assessed by indirect immunofluorescence method using the FITC-marked monoclonal antibodies to CD25 and CD95. The concentrations of GH and IGF-I were measured by ELISA.
Results
Compared to the control both acromegalics – with active phase and disease remission had significantly higher level of CD25+- (respectively; $P<0.001$ and $P<0.01$) and CD95+-lymphocytes ($P<0.01$ and $P<0.05$). However it was found that the expression of apoptotic activation markers was higher in patients with disease remission compared to active acromegaly group respectively: CD25+- (median 66.5 vs 37.0%; $P<0.05$) and CD95+-cells (43.5 vs 18.0%; $P<0.05$).
Conclusion
Stimulating and antiapoptotic effect of GR/IGF1 in acromegaly simultaneously promotes proliferation and expression of apoptotic activation markers of lymphocytes, but causes an accumulation in the body of acromegalics the long-lived immunoreactive cells. Long-term effects of IGF-I in acromegaly mediate the intensity of proliferation and apoptosis in patients with the disease remission. According to these, it can be suggested that increased oncological risk in active acromegaly patients ongoing even in remission period.

## P1088

### Long term evolution of patients with prolactinoma in a neuroendocrinology unit

JGarcía Arnés, I González-Molero & M Domínguez-López
Carlos Haya Hospital, Málaga, Spain.

Aims
To know characteristics and long term evolution of patients with prolactinoma in our Neuroendocrinology Unit.
Material and methods
We studied retrospectively all patients with diagnosis of prolactinoma in our Neuroendocrinology Unit in last 12 years.
Results
We studied 126 patients. Predominant sex was female (69.07%), 56.7% were macroadenomas. The time from the onset of symptoms until they are seen by the specialist ranges 12 to 24 months. The clinical presentation and hormones values were: menstrual disorders 56.7%, galactorrea 43.3%, erectile dysfunction 18.55%, headache 41.23% and visual disorders 18.55% (In men,the most frequent symptom was headache and in women menstrual disorders). Dysfunction of other axis: decrease of LH/FSH 25.8%, GH deficiency 6.4%, TSH 8.2% and ACTH 6.4%.
93.8% were pharmacologically treated (95.6% cabergoline). Four patients needed surgery as first treatment. Only one case was familiar: a patient with giant macroadenoma that belonged to a FIPA family with a new AIP mutation non described before in literature. There was total cure(asymptomatic, normal prolactin and disappearance of tumour in RM) in 11.34% (19.5% of microadenomas and only three cases of the macroadenomas) all of them with more than 2 years of medical treatment. The size of the tumour and basal levels of prolactin were inversely related to the possibility of cure.
Conclusion
In our serie, although prolactinomas have a relatively benign course, long-term definitive cure is infrequent.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1089

### Influence of various doses of Cabergoline in dynamics of long-term treatment on the level of blood soluble apoptosis markers in patients with inactive pituitary adenomas

Z. Khalimova & D. Kholova
Republican Specialized Scientific-Practical Medical Centre of Endocrinology under the Ministry of Health of the Republic of Uzbekistan, Mirzo Ulugbek Street, 56, Tashkent 100125, Uzbekistan.

Aim
Studying of influence of various doses of cabergoline in dynamics of 6, 12 and 24 months of treatment on level of blood serum soluble apoptosis markers *P*53, Bcl-2 and TNF-α in patients with IPA.
Materials and methods
One hundred and twenty-seven patients with IPA (38 men, 89 women) were observed, among them 65 (51.2%) with microadenoma and 62 (48.8%) with macroadenoma/ patients were at the age from 35 till 60 years.Patients with pituitary micro-and macroadenomas were divided into two groups by method of casual sample: the 1st group was made by 34 patients with microadenoma and 31 patients with macroadenoma which in course of treatment were prescribed small doses of Cabergoline by 0.4–0.6 mg/week. The 2nd group was made by 31 patients with microadenoma and 31 with macroadenoma (doses of Cabergoline from 1.0 to 3.0 mg/week).
Results
In patients with IPA with microadenoma before treatment the level of blood serum soluble apoptosis markers exceeded similar indicators in the control group: *P* 53, Bcl-2 and TNF-α in 1st and 2nd groups on the average by 25.4, 26.0 and 38.3% ($P<0.01$), and in patients with macroadenoma by 43.1, 47.2 and 59.5% ($P<0.001$). It is established, that increase of TNF-α was associated with increase of *P* 53 ($r=0.73$; $P<0.01$) and Bcl-2 ($r=0.75$; $P<0.01$), and *P* 53 with Bcl-2 had stronger association - $r=0.86$ ($P<0.001$). Long-term use of Cabergoline in patients with IPA promoted the expressed decrease in all observed apoptosis factors. In patients of the 1st and 2nd groups with microadenoma apoptosis indices *r*53 and Bcl-2 were basically within the control level in 6–12 months of treatment and maintained in such condition up to 24 months of therapy, whereas

TNF-α only by 24 month of Cabergoline therapy. At the same time in patients with macroadenoma restoration of level of apoptosis indices depended on the dose of Cabergoline prescribed.
Conclusion
In blood of 127 patients with IPA with pituitary micro-and macroadenoma high level of apoptosis markers *P* 53, Bcl-2 and TNF-α was revealed. Cabergoline prescribed during 6, 12, 24 months in big doses (from 1.0 to 3.0–mg/week) restored apoptosis markers in blood of patients with IPA with pituitary micro-and macroadenoma more effectively and by 12 months earlier, than at prescription of small doses of the drug (from 0.4 to 0.6 mg/week).
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1090

**The blood lymphocytes oxidoreductases activity in patients with active acromegaly**

M. Dudina[1], S. Dogadin[1] & A. Savchenko[2]
[1]Krasnoyarsk State Medical University named after Prof. V. F. Voino-Yasenetsky, Krasnoyarsk, Russian Federation; [2]Institute for Medical Problems of the North, Siberian Division, Russian Academy of Medical Sciences, Krasnoyarsk, Russian Federation.

Introduction
Somatotropin (GH) and insulin-like growth factor 1 (IGF1) realize their influence on the system of intracellular metabolism and a number of important biochemical lymphocytes reactions through the receptor apparatus. It is allows to use the peripheral blood lymphocytes as the investigations object of intracellular metabolism disorders in acromegaly.
Aim
To study the NAD- and NADP-dependent dehydrogenases activity in blood lymphocytes in patients with active acromegaly.
Methods
The activity of NAD(P)-dependent dehydrogenases in blood lymphocytes was studied in a group of 88 patients (35 men and 53 women) with active acromegaly, mean age $51.0 \pm 12.5$ years. The NAD(P)-dependent dehydrogenases activity was determined by biochemiluminescence method. The concentrations of GH and IGF1 were measured by ELISA.
Results
In active acromegaly were revealed the decreasing activity of all studied oxidoreductases: glucose-6-phosphate dehydrogenase ($P<0.01$), NAD-lactate dehydrogenase (LDH) ($P<0.001$), NADH-LDH ($P<0.001$), NAD-malate dehydrogenase (MDH) ($P<0.001$), NADH-MDH ($P<0.001$), NADP-MDH ($P<0.001$), NAD-glutamate dehydrogenases (GDH) and NADH-GDH ($P<0.001$), NADP-GDH and NADPH-GDH ($P<0.001$), NAD- isocitrate dehydrogenases (IDH) and NADP-IDH ($P<0.01$ and $P<0.001$ respectively), glutathione reductase ($P<0.001$). Our data further observed that decreasing activity of NADP-GDH positively correlated with the basal GH level ($r=+0.23$, $P=0.04$) and NADP-MDH activity with IGF1 level ($r=+0.30$, $P=0.008$). The low NADH-MDH activity negatively correlated to the basal GH concentration ($r=-0.23$, $P=0.04$).
Conclusion
The chronic excess of GH and IGF1 in acromegaly causes a significant depletion of metabolic lymphocytes reserves. The main indicators of functional lymphocytes impairment in acromegaly are: the reduction of intermediates formation for the reactions of macromolecular synthesis and aerobic processes, the low intensity of glycolysis, nitrogen metabolism and inhibition of glutathione complex activity.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1091

**Hypercortisolism in patients with diabetes mellitus, adrenal incidentaloma and obesity**

A. Dreval, I. Komerdus, A. Murzina & O. Nechaeva
Moscow Regional Research Clinical Institute n.a. Vladimirsky, Moscow, Russian Federation.

Some studies reports the high prevalence of unsuspected hypercortisolism in high-risk populations.
Aim
To evaluate the prevalence of undiagnosed hypercortisolism in patients with diabetes mellitus (DM), adrenal incidentaloma and obesity.
Material and methods
We prospectively evaluated 30 DM patients (8 male, 22 female, 53.5 years old (18; 73), HbA1c-7.1% (5.6; 13.8)), 22 patients with adrenal incidentaloma (6 male, 16 female, 53.5 years old (20;73)) and 31 obese patients (21 male, 10 female, 22 years old (18;62)). The overnight 1-mg dexamethasone suppression test (DST-1) was done first. If cortisol level exceeded 50 nmol/l after DST-1 (positive result) the additional evaluation was done (2 mg/day for 48 h dexamethasone suppression test (DST-2), urine free cortisol (UFC), midnight salivary cortisol. If the hypercortisolism confirmed the additional examination prepared to found it's source.
Results
i) DST -1 was positive in 9 of 31 (29%) obese patients. DST-2 reduced the number of positive results to 3 (9.6%). UFC and salivary cortisol were normal in all of them. They did not have clinically apparent hypercortisolism so the DST-2 results interpreted as false-positive. ii) DST-1 was positive in 18 of 30 (58%) patients with DM. After DST-2 the only four (12.9%) of them had positive result. Further investigations revealed Cushing's syndrome and Cushing's disease in two of these four patients. Other two patients are in under our observation. It should be noted that patients with confirmed hypercortisolism had clinical signs of hypercortisolism, but referred to our clinic because of uncontrolled DM. iii) DST-1 was positive in 13 of 22 (59%) patients with adrenal incidentaloma. DST-2 was positive in 7 (31.8%) of them. Six of them have Cushing's syndrome and one is on under observation.
Conclusion
The highest percentage of hypercortisolism revealed in patients with adrenal incidentaloma. High percent of hypercortisolism in DM was due to the fact that their doctor did not suspect overt hypercortisolism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1092

**Levothyroxine therapy in patients with secondary hypothyroidism in nonfunctioning pituitary adenomas**

V. Aripova, M. Shakirova, G. Saydalieva, D. Nagmutdinova, Y. Urmanova, L. Murtazaeva, A. Akbutaev, D. Alieva, N. Salakhova & N. Kayumova
Tashkent Pediatric Medical Institute, Bogishamol Street 223, Tashkent 100140, Uzbekistan.

Aim
To study the effectiveness of levothyroxine therapy in patients with secondary hypothyroidism in nonfunctioning pituitary adenomas (NFPA).
Materials and methods
We followed 35 patients with NFPA. Of them, 17 were females and 18 males. Mean age of patients was 37.2 years old. All patients were evaluated for hormones levels (GH, LH, FSH, TSH, estradiol, progesterone, testosterone, prolactin, cortisole, free thyroxine, etc.), visual fields, pituitary MRI, thyroid ultrasonography, etc. None of the patients had thyroid disorders.
All evaluations were repeated in 6 months after levothyroxine (Euthyrox, Nycomed, Germany) therapy with the dosage of 100 μg a day before meals.
Results
In patients with long disease background we revealed hypopituitarism with GH, LH, FSH, and TSH deficit as well as IGF1, estradiol, testosterone and thyroxine (100%).

All patients had symptoms characteristic for hypothyroidism including sleepiness, loss of memory, dry skin, constipations etc. Blood tests showed dyslipidemia.
Six months therapy with levothyroxine showed significant improvement in well-being of patients such as regression of applicable complaints, laboratory and biochemical values improvement in 25 patients (71.4%).
Conclusion
i) Levothyroxine therapy significantly improves clinical and biochemical values in patients with NFPA ii) it should be recommended to administer levothyroxine therapy to patients with NFPA.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1093

**Neuroendocrine abnormalities in adolescents with the Turkish saddle volume formations**

Y. Urmanova, U. Mavlonov & M. Shoraimova
Tashkent Pediatric Medical Institute, Tashkent, Bogishamol str 223, Uzbekistan.

Aim
To study character of neuroendocrine disorders in children and adolescents with the Turkish saddle volume formations.
Materials and methods
we examined 35 children and adolescents, 17 girls and 18 boys among them with the Turkish saddle volume formations at the neuroendocrine department of the Center for the scientific and clinical study of endocrinology. All examinees underwent general clinical examination as well as biochemical and hormonal investigations (levels of pituitary hormones), Turkish saddle CT and MRI and hand roentgenogram, clinical ultrasound of the thyroid and sex organs, anthropometric examination, having their sexual development stage by Tanner assessed.
Results
By character of pathology the examinees were divided into five groups. The 1st group included 23 patients (63%) with nonfunctional pituitary adenomas, the 2nd group including five patients (14.3%) with Cushing disease comprising the 3rd group, two patients (77.1%) with prolactinomas comprising the 4th group and one patient (2.9%) having germinoma and pinealoma combination was in the 5th group. By character of tumor (by Kadashev B.A., 2007) the patients were distributed as follows: 1st group of endosellar localization comprised i) 27 patients (77.1%) with microadenomas (under 1 cm) and ii) one patient (2.9%) with macroadenoma, 2nd group of endoextrasellar localization comprising (a) five patients (14.3%) with tumors of suprasellar growth and two patients (5.7%) with tumors of supra-parasellar growth.
Examination of 35 patients allowed diagnosing a number of neuroendocrine disorders, such as, growth and puberty delay ($n=9$, 25.7%), physical development delay ($n=6$, 17.1%), dysplastic obesity ($n=5$, 14.3%), precocious puberty development ($n=3$, 8.6%), diabetes insipidus ($n=3$, 8.6%), gigantism ($n=2$, 5.7%) and secondary hypocorticoidism ($n=1$, 2.9%). Delay of puberty and growth more often was founded in patients with nonfunctional pituitary tumours, cranyopharingiomas and prolactinomas – 15 cases from 35 patients (42, 8%); but precocious puberty – only in patients with Cushing disease – three patients from 5 (60%).
Conclusions
i) Growth and puberty disorders are the most frequent Turkish saddle volume formations with growth and puberty retardation predominating (25.7%), ii) the Turkish saddle tumors in children and adolescents result in hypo- and panhypopituitarism ($n=19$, 54.2%).
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1094

**Somatostatin analogue treatment of acromegaly**

A. Khalikova & Z. Khalimova
Scientific Medical Center of Endocrinology, Tashkent, Uzbekistan.

Aim
To study complications in patients with acromegaly receiving somatostatin after radiotherapy.
Materials and methods
We examined 16 patients with mean disease duration $8.5\pm4.2$ years (mean age $41.5\pm5.6$ years) receiving distant gamma-therapy in the total dose of 60 Gy. The patients were divided into two groups: eight patients receiving somatostatin in the dose of 0.5 mg thrice a day and symptomatic therapy for 2 months were included into the 1st group, other eight patients received only symptomatic therapy. To establish the disease activity we examined diurnal GH secretion at 8.00, 11.00, 13.00, 15.00 and 18.00
Results and discussion
At first examination (6 months after radiotherapy) GH diurnal secretion showed the presence of active acromegaly. Average daily GH level was $58.6\pm8.2$ and $49.8\pm9.3$ mIU/l in two groups of patients respectively. 98% patients of the 1st group had endocrine-metabolic disorders, in 85% the disease was complicated with cardio-vascular disorders, 80% had neuromuscular-skeletal-joint complications, in 42% the disease was complicated with the respiratory disorders, 25% having neoplasms. In the 2nd group endocrine-metabolic disorders were found in all patients, in 80% and 30% the disease was complicated with cardio-vascular and respiratory complications respectively, neuromuscular-skeletal-joint disorders and neoplasms being found in 85 and 20% respectively. Two months later the repeated examination of the 1st group patients showed that average daily GH level was $5.6\pm1.2$ mIU/l, the one remaining high in the 2nd group patients ($26.6\pm8.5$ mIU/l). In the 1st group the decrease in the incidence of endocrine-metabolic (78%), cardio-vascular (45%) and respiratory (15%) disorders was observed. In the 2nd groups patients the incidence of endocrine-metabolic disorders preserved (100%), cardio-vascular (90%) and respiratory (40%) disorders tended to increase.
Conclusions
Somatostatin and its analogues are the first line drugs in treatment of acromegaly. Post-radiotherapy use of sandostatin as the part of the combined therapy of acromegaly reducing both the process activity and complications is the evidence for its efficacy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1095

**Clinical manifestations of depression in patients with primary hyperparathyroidism**

N. Rikhsieva & S. Ismailov
Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan.

Aim
The work was initiated to study depression manifestations in patients with primary hyperparathyroidism.
Materials and methods
Symptoms of anxiety and depression were assessed in 67 patients with primary hyperthyroidism aged from 16 to 30 years examined by means of Spielberger–Khanin's test and Beck's Depression Inventory.
Problem of marginal psychoneurotic disturbances in patients with various somatic pathologies has become urgent for the last decade. Psychoneurotic disturbances can be leading for quite a long time masking other manifestations of an underlying disease. Prevalence of depressive conditions was found to grow for the last years; by 2020 depression is estimated to occupy a leading place in general structure of disease incidences.
Results
Parameters of both personal ($n=62$, 92, 3%) and situational ($n=60$, 88.3%) anxiety were found high. (Spielberger-Khanin's test).
Fatigability ($n=60$, 88.3%), sleep disturbance ($n=58$, 89.4%), irritability ($n=52$, 79.1%), work inhibition ($n=46$, 68.6%), sadness ($n=44$, 66.7), self accusations ($n=38$, 56.7%), pessimism and dissatisfaction ($n=33$, 49.2%), self dislike ($n=28$, 41.7%), were among clinical manifestations of depression

registered among the examinees. (Beck's Depression Inventory).
Conclusions
Registered in most examinees with primary hyperthyroidism depressive reactions were found to aggravate severity of general illness. The study demonstrates necessity to timely diagnose affective impairments in patients with primary hyperparathyroidism to be corrected by means of combined therapy with antidepressants aiming at improvement of the patients' life quality.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1096

**Discovery of a novel peptide, neuroendocrine regulatory peptide-2 regulating feeding behavior and glucose metabolism**

T. Matsuo[1], K. Toshinai[1], H. Yamaguchi[1], K. Sakai[2], N. Minamino[2] & M. Nakazato[1]
[1]University of Miyazaki, Miyazaki, Japan; [2]National Cerebral and Cardiovascular Center Research Institute, Suita, Japan.

Discovery of novel peptides leads to the elucidation of unknown regulatory systems in the body and to the clinical development of diagnosis and therapeutics for diseases. We have used peptidomics approach to profile a complete set of secretory peptides from cultured human endocrine cells and identified two novel carboxy-terminally amidated peptides, 25-amino acid neuroendocrine regulatory peptide (NERP)-1 and 38-amino acid NERP-2, derived from a neurosecretory protein VGF (JBC 2007). NERPs modulate vasopressin release in both *ex vivo* and *in vivo* experiments. *Vgf* unll mice exhibited dwarfism and hypermetabolic rates, suggesting that VGF or VGF-derived peptides play important roles in energy metabolism. NERP-2 was abundant in the lateral hypothalamus, one of orexigenic centers, and colocalizes with orexigenic neuropeptides, orexins. NERP-2 stimulated orexin release from isolated hypothalamic explants. Central administration of NERP-2 activated orexin neurons to enhance feeding, body temperature, oxygen consumption and locomotor activity (AJP 2010). NERP-2's activities did not appear in orexin-deficient mice. C-terminal amidation of NERP-2 was essential for its biological activities. NERP-2 was also abundant in the pancreatic islets of humans and rodents and colocalizes extensively with insulin in double immunohistochemistry. NERP-2 enhanced glucose (16.7 mM)-stimulated insulin secretion from MIN6 β cells and isolated islets in a dose-dependent manner. Peripheral administration of NERP-2 significantly elevated plasma insulin in both normal rats and mice and melanocortin 4 receptor knockout mice, an obese diabetic mouse model. Fura-2 calcium imaging showed that NERP-2 elevated cytosolic calcium level in MIN6 β cells. NERP-2 is a novel regulator of food intake and glucose metabolism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1097

**Effects of low sodium concentrations on neuronal cell models**

C. Deledda, P. Luciani, S. Benvenuti, C. Giuliani, B. Fibbi, I. Marone, E. Chelli, R. Squecco, F. Francini, G. Forti & A. Peri
University of Florence, Florence, Italy.

Hyponatraemia is the most frequent electrolyte disorder encountered in hospitalized patients. Hyponatraemia causes a wide variety of neurological signs and symptoms, depending on the rate and degree of serum sodium drop. The negative effects of low extracellular sodium concentrations ((Na+)) on neuronal cells are known to be due to the entry of fluids into the cells, as a consequence of reduced plasma osmolality. To date, it has not been investigated whether low (Na+) have direct effects on neuronal cells. To this purpose, by generating media with physiological or low (131, 127, 121, 115, 100 and 90 mM; Na+), we studied whether low (Na+) are able *per se* to cause negative biological effects in two different neuronal cell lines (SK-N-AS and SH-SY5Y). We evaluated cell viability and adhesion after adapting to and maintaining cells in culture for 7 days at target (Na+) media. Results showed a significant decrease in cell viability starting from 115 mM (Na+) for SK-N-AS (49.6±1% vs control) and from 90 mM (Na+) for SH-SY5Y (22 ±0.4% vs control). Cell adhesion was also decreased vs control cells (SK-N-AS 58±0.7%; SH-SY5Y 48.7±2%). Similar results were obtained also when the reduced osmolality due to low (Na+) were corrected by adding mannitol. Moreover, we observed a downregulation of the expression of antiapoptotic genes (*bcl2, mdm2*) and of the neuroprotective gene *DHCR24* at the same reduced (Na+). Finally, by using electrophysiological techniques, we observed that 115 mM (Na+) for SK-N-AS and 90 mM (Na+) for SH-SY5Y significantly shifted the reversal potential towards more negative voltages, also when osmolality was corrected. This result could be mainly ascribed to a decrease of intracellular ($Ca^{2+}$) possibly involving $Ca^{2+}$ and Na/K pumps and could lead to a reduced cell response in hyponatraemic conditions. In summary, these findings show for the first time that low (Na+) directly cause detrimental effects on neuronal cells, independent of extracellular osmolality.
Declaration of interest

**SEMA3A deletion in a family with Kallmann syndrome validates the role of semaphorin 3A in human puberty and olfactory system development**

J. Young[1,5], C. Metay[2,5], J. Bouligand[1,5], B. Tou[1,5], B. Francou[1,5], L. Maione[1,5], L. Tosca[3,5], J. Sarfati[1,5], F. Brioude[4,5], B. Esteva[4], A. Briand[2,5], M. Goossens[2,5], G. Tachdjian[3,5] & A. Guiochon-Mantel[1,5]
[1]Univ Paris Sud-Assistance Publique hôpitaux de Paris, Le Kremlin Bicêtre, France; [2]Univ Paris 12-Assistance Publique hôpitaux de Paris, Creteil, France; [3]Univ Paris Sud-Assistance Publique hôpitaux de Paris, Clamart, France; [4]Univ Paris 6-Assistance Publique hôpitaux de Paris, Paris, France; [5]INSERM, Paris, France.

Background
Kallmann syndrome (KS) is a genetic disorder associating pubertal failure with anosmia/hyposmia. KS is related to defective neuronal development affecting both the migration of olfactory nerve endings and GnRH neurons. The discovery of several genetic mutations responsible for KS led to the identification of signaling pathways involved in these processes, but the mutations so far identified account for only 30% of cases of KS. Here we attempted to identify new KS responsible genes by using a pangenomic approach.
Methods
From a cohort of 120 KS patients, we selected 48 propositi with no mutations in known KS genes and normal caryotype. They were analyzed by CGHarray, using Agilent 105K oligonucleotide chips with a mean resolution of 50 kb. Copy-number variations were considered significant if they were defined by three or more oligonucleotides spanning at least 50 kb, contained at least one gene, and were not listed in the Database of Genomic Variants.
Results
One propositus was found to have a heterozygous deletion of 213 kb at locus 7 q21.11, confirmed by real-time qPCR, deleting 11 of the 17 SEMA3A exons. This deletion was absent in 520 subjects without KS analyzed with the same CHGarray, was also absent in the BACH genomic database and co-segregated in this family with the KS phenotype, that was transmitted in autosomal dominant fashion. The KS was not associated with other neurological or non neurological clinical disorders in all affected kindred.
SEMA3A codes for semaphorin 3A, a protein that interacts with neuropilins and KO mice lacking semaphorin 3A expression have been very recently showed to have a Kallmann-like phenotype.
Conclusion
SEMA3A is therefore a new gene whose loss of function is involved in KS. These findings validate the specific role of semaphorin 3A in the development of the olfactory system and in neuronal control of puberty in humans.

### Stimulatory role of neurokinin B in the control of the gonadotropic axis in the rat: developmental changes, sexual dimorphism and regulation by gonadal steroids

F. Ruiz-Pino[a,b,c], V. Navarro[a,c], A. Bentsen[e], M. Sanchez-Garrido[a,b,c], D. Garcia-Galiano[a,b,c], M. Manfredi-Lozano[a,b,c], S. Leon[a,b,c], D. Clifton[d], R. Steiner[d], J. Mikkelsen[e], L. Pinilla[a,b,c] & M. Tena-Sempere[a,b,c]
[1]University of Cordoba, Cordoba, Spain; [2]CIBERobn, Cordoba, Spain; [3]IMIBIC, Cordoba, Spain; [4]University of Washington, Seattle, WA; [5]Rigshospitalet, Copenhagen, Denmark.

Recent studies in various species have pointed out that Neurokinin B (NKB), encoded by Tac2 in rodents, and its receptor, NK3R, are important regulators of reproduction. NKB is co-expressed in Kiss1 neurons of the arcuate nucleus (ARC) and stimulates, via auto-regulatory loops, kisspeptin output onto GnRH neurons, therefore stimulating gonadotropin secretion. However, important aspects of the roles of NKB as regulators of the gonadotropic axis remain unknown. We report here that in the rat, LH secretory responses to the agonist of NKB, senktide, display sexual dimorphism, with greater responses in females regardless of the stage of postnatal maturation, and null NKB-induced LH secretion in males from puberty onwards. Such a sexual dimorphism manifested also in a higher number of NKB-positive neurons in the ARC in adult females. This may stem from differences in the sex steroid milieu during early critical periods of brain differentiation, as neonatal exposures to high doses of estrogen markedly decreased the number of NKB neurons and the circulating levels of LH, which were normalized by exogenous administration of senktide. Of note, estrogen also inhibited Tac2 expression in adult female rats in the ARC, while enhancing it in the lateral hypothalamus. Finally, despite null gonadotropic responses to senktide in adult male rats, adult females supplemented with testosterone retained LH responses to the NKB agonist. In sum, our study provides a comprehensive developmental analysis of the role of NKB in the control of the gonadotropic axis in the rat. Our observations disclose key aspects of this system, such as its maturational changes, sexual dimorphism and differential regulation by sex steroids, which may help to explain the spectrum of reproductive effects of the NKB system and the pathophysiological manifestations of its inactivation.

### Intracerebroventricular administration of metformin inhibits ghrelin-induced hypothalamic AMP-kinase signalling and food intake

D. Stevanovic[1], K. Janjetovic[1,2], M. Misirkic[1,2], L. Vucicevic[1,2], M. Sumarac-Dumanovic[1], D. Micic[1], V. Starcevic[1] & V. Trajkovic
[1]School of Medicine, University of Belgrade, Belgrade, Serbia; [2]University of Belgrade, Belgrade, Serbia.

The antihyperglycaemic drug metformin reduces food consumption through mechanisms that are not fully elucidated. The present study investigated the effects of intracerebroventricular administration of metformin on food intake and hypothalamic appetite-regulating signalling pathways induced by the orexigenic peptide ghrelin. Rats were injected intracerebroventricularly with ghrelin (5 μg), metformin (50, 100 or 200 μg), AICAR (25 μg) and L-leucine (1 μg) in different combinations. Food intake was monitored during the next 4 h Hypothalamic activation of AMP-activated protein kinase (AMPK), acetyl-CoA carboxylase (ACC), Raptor, mammalian target of rapamycin (mTOR) and *P*70 S6 kinase 1 (S6K) after 1 h of treatment was analyzed by immunoblotting. Obtained results showed that metformin in a dose-dependent manner suppressed the increase in food consumption induced by ICV ghrelin. Ghrelin increased phosphorylation of hypothalamic AMPK and its targets ACC and Raptor, which was associated with the reduced phosphorylation of mTOR. The mTOR substrate S6K was activated by ICV ghrelin despite the inhibition of mTOR. Metformin treatment blocked ghrelin-induced activation of hypothalamic AMPK/ACC/Raptor and restored mTOR activity without affecting S6K phosphorylation. Metformin also reduced food consumption induced by the AMPK activator AICAR, while ghrelin-triggered food intake was inhibited by the mTOR activator L-leucine. Thus, metformin could reduce food intake by preventing ghrelin-induced AMPK signalling and mTOR inhibition in the hypotalamus.

### Genetic variation of the hypothalamo-pituitary axis may increase susceptibility of postnatal depression

N. Engineer[1], L. Darwin[1], N. Deole[1], K. Ngianga-Bakwin[2], S. Smith[1] & D. Grammatopoulos[1,2]
[1]University Hospitals Coventry and Warwickshire NHS Trust, Coventry, UK; [2]University of Warwick, Coventry, UK.

Objective

To investigate whether genetic variants in the glucocorticoid receptor (GR) and corticotropin releasing hormone receptor 1 (CRHR1) genes are associated with increased susceptibility for postnatal depression (PND).

Methods

A prospective longitudinal cohort study at University Hospital, Coventry, England. Two hundred pregnant women were recruited and assessed for PND using the Edinburgh postnatal depression score (EPDS) upon recruitment and again 2–8 weeks post-natally. Five SNPs with established association to depression were genotyped. Association analysis was carried out in 140 patients that completed the study protocol.

Results

The bcl1 SNP of the GR and rs242939 SNP of the CRHR1 genes were over-represented in women with PND with significant allele association. Risk ratios for development of PND associated with presence of each minor allele were 2.9 (95% confidence interval: 1.2–6.9) for bcl1 and 4.9 (2 to 12) for rs242939. In contrast, no significant association was found between PND and the R23K, rs1876828 or rs242941 SNPs.

**Table 1** Patient demographics and single nucleotide polymorphism distribution in the study population

| Variable | Cases without postnatal depression number (%) | Cases with postnatal depression number (%) | *P*value |
|---|---|---|---|
| Total number | 106 (75.7) | 34 (24.3) | |
| SNPs Bcl1 HET/HOM WT | 51 (48.6) 54 (51.4) | 25 (73.5) 9 (26.5) | 0.011* |
| R23K HET/HOM WT | 9 (8.6) 96 (91.4) | 2 (5.9) 32 (94.1) | 0.61 |
| rs1876828 HET/HOM WT | 34 (32.4) 71 (67.6) | 14 (41.2) 20 (58.8) | 0.35 |
| rs242939 HET/HOM WT | 13 (12.4) 92 (87.6) | 14 (41.2) 20 (58.8) | 0.003** |
| rs242941 HET/HOM WT | 62 (59.6) 42 (40.4) | 26 (76.5) 8 (23.5) | 0.076 |

Het/hom, Heterozygous/homozygous allele, WT: wild type allele.

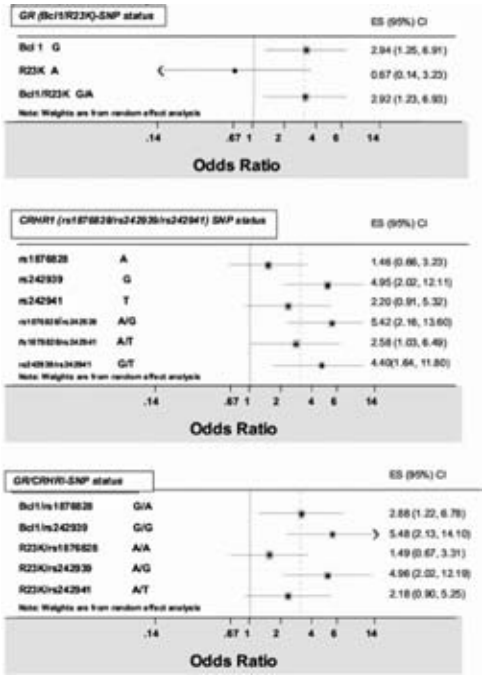

Figure 1. Forest plot for glucocorticoid and cortico tropin releasing hormone single nucleotide polymorphisms.

Conclusions

This is the first demonstration that specific SNPs of the GR and CRHR1 genes are associated with PND and might represent promising genetic biomarkers to help early identification of women at risk of PND.

**Differential diagnosis of acromegaly: a new gene for pachydermoperiostosis**

N. Dalantaeva[1,3], L. Dzeranova[1], T. Atamanova[1], C. Diggle[2], D. Bonthron[2], G. Trivellin[3] & M. Korbonits[3]
[1]Research Centre for Endocrinology, Moscow, Russian Federation; [2]University of Leeds, Leeds, UK; [3]William Harvey Research Institute, Barts and the London Medical School, Queen Mary University of London, London, UK.

Case report
24-year. old man presented with change in facial appearance and joint pain. His symptoms began at puberty with the thickening and folding of the skin on the forehead and scalp and thickening of his fingers. These changes progressed over the next 5 years with marked seborrhoea, hyperhidrosis and linear palmar–plantar keratosis. The lower legs and forearms are cylindrically thickened, hands and feet increased in size, the terminal phalanges of the fingers show pronounced clubbing. Change of appearance was accompanied by swelling and pain in the joints, particularly in the knees. The patient complained of diarrhoea and abdominal pain, a colonoscopy revealed ulcerative colitis. This state was maintained for 4–5 years. At the age 22 he noticed slight improvement in the joint pains. His younger brother presented with very similar symptoms and signs at the age of 17. The parents were not related to each other. Acromegaly, Sotos syndrome, McCune–Albright syndrome and Carney complex were ruled out with clinical tests.
We diagnosed hypertrophic osteoarthropathy (pachyder moperiostosis). Due to the familial nature of the disease and no other underlying disease we considered primary hypertrophic osteoarthropathy, which can be due to deficiency of the enzyme 15-hydroxyprostaglandin dehydrogenase (HPGD), but no mutations were detected in this gene. As the phenotype of these patients is slightly different (teenager rather than childhood-onset, severe cutis gyrate on the forehead, lack of acroosteolysis), another causative gene was sought. A novel gene SLCO2A1 (solute carrier organic anion-transporter family member-2A1), also part of the PDE-pathway, was found to have compound heterozygote mutations c.(838C>T)+(1693T>G), P.(R280X)+(W565G) in both subjects. SLCO2A1 is a transporter, which mediates active uptake of prostaglandins, prior to their intracellular degradation. Hypertrophic osteoarthropathy can develop due cancer-induced reactive osteoarthropathy or in response to therapy with PDE1. These findings implicate local prostaglandin excess as the stimulus to hypertrophic osteoarthropathy.

**Magnetic risonance imaging (mri) of olfactory bulbs and other brain structures in kallmann syndrome**

G. Bellastella[1], A. Elefante[2], V. Palumbo[1], A. D'Errico[2], M. Napoli[2], L. Maione[1], D. Visconti[1], O. Vargas[1], F. Briganti[2], A. Brunetti[2] & A. Sinisi[1]
[1]Seconda Università di Napoli, Napoli, Italy; [2]Università Federico II, Napoli, Italy.

Kallmann syndrome (KS) is characterized by hypogonadotropic hypogonadism and other non-reproductive disorders including smell deficiency due to olfactory bulb developmental abnormalities. The aim of our study was to evaluate retrospectively the role of MRI in patients with clinical diagnosis of KS, searching for any abnormalities of the brain structures involved.
Methods
We evaluated 25 KS pts (14–32 years, 4F, 21 M). KS cases were classified as hyposmic (KSHO, *n* 9) or anosmic (KSAO, *n* 16) by using a modified smell test. Brain MRIs (SE T1 sagittal and coronal planes, TSE $T^2$ axial and coronal planes 2 mm thick, volumetric MPRAGE) of olfactory bulbs and sulci, corpus callosum and pituitary were blind assessed by two radiologists.
Results
In KSAO group eight showed olfactory bulbs and sulci agenesis, four bulbs agenesis (3 normal, one hypoplastic sulci), 4 bulbs and sulci hypoplasia. In KSHO two showed bulbs and sulci agenesis, two bulbs agenesis, two bulb and sulci hypoplasia, 1 hypoplastic bulbs, one normal bulbs and sulci but turbinates abnormalities. three cases were not evaluated for technical reasons. The pituitary was abnormal in 8% of cases: three pituitary hypoplasia, 1 a mucinous cysts of the pars intermediate, three a sellar arachnoid diverticulum. Hypoplastic corpus callosum was done in 2 out 25 pts.
Conclusions
Clinical and MRI data are sometimes not correlated. 50% of KSAO presented agenesis of both sulci and bulbs, 25% only bulbs agenesis and 12% bulbs and sulci hypoplasia. KSHO showed a highly variable phenotypic framework. Associated abnormalities of sellar and suprasellar regions are less frequent. MRI is important to detect abnormalities of olfactory structures, especially in prepubertal patients, where clinical diagnosis is not always easy. Moreover, imaging study may reveal other possible causes of smell dysfunction, allowing to minimize any diagnostic bias.

## P1104

**Kisspeptin is the peptide linking metabolism and reproduction**

J. Sliwowska & P. Kaczmarek
Poznan University of Life Sciences, Poznan, Poland.

There is a strong correlation between metabolic status (e.g. obesity, diabetes, alcohol use and abuse) and reproductive functions. Disruptions of metabolic status affecting the reproductive system are often manifested as decrease in secretion of hormone (GnRH) and (LH), disruptions of secretion of sex steroids and estrus cycles (in animals) or menstrual cycles (in women), and may even lead to infertility. Diabetes and obesity are also correlated with hypogondism, which is reported in adult and older men.
Kisspeptin is a hypothalamic peptide that has a key function in the regulation of reproduction. Recently it was shown that kisspeptin plays a role in the integration of metabolic and reproductive systems. However, the neuronal mechanisms responsible for integration between these systems and its disruptions by metabolic stressors are not well known yet.
Two rats models
i) prenatal ethanol/alcohol exposure (PAE); ii) diet induced obesity, diabetes typ her 1 and 2, are discussed in the context of the role of metabolic stressors on the reproductive and kisspeptin systems.
Data from the first model suggest that: i) PAE delays onset of puberty in females (delays vaginal opening) in females; ii) PAE causes lack of increase of estradiol and progesterone with age in females but has no effect on changes in testosterone levels with age in males; iii) In adult PAE females, in sex steroids replacement paradigm, kisspeptin neurons in the arcuate nucleus of the hypothalamus show increased sensitivity to estradiol and decreased sensitivity to progesterone.
Currently experiments are preformed to study the changes in the kisspeptin system in the second model.
Obtained data may allow us to better understand the role of kisspeptin in linking metabolic and reproductive systems, its disruptions under metabolic stress, as well as search for new treatment strategies for patients with fetal alcohol spectrum disorder (FASD), obesity and diabetes.

**Topiramate treatment improves hypothalamic insulin and leptin signaling and action and reduces obesity in mice**

A. Caricilli[1], Penteado[1], F. Mittestainer[1], L. Abreu[1], P. Quaresma[1], A. Santos[1], D. Guadagnini[1], D. Razolli[1], L. Velloso[1], M. Saad[1] & P. Prada[1,2]
[1]State University of Campinas, Campinas, Brazil; [2]State University of Campinas, Limeira, Brazil.

Topiramate (TPM) is an anticonvulsant drug used for the treatment of epilepsy and prophylaxis of migraine. Weight loss is a side effect frequently reported in patients and animal models treated with TPM. Some studies showed that TPM may decrease energy storage, and thus increase energy expenditure and thermogenesis. However, the mechanisms by which TPM reduces body weight are not completely understood. Anorexigenic hormones such as insulin and leptin regulate the activity of distinct neuron populations that control energy balance via IR/PI3K/Akt/Foxo1 pathway or OBR/JAK2/STAT3 pathway respectively. However, whether TPM alters hypothalamic insulin or leptin sensitivity is not known. Thus, in the present study, we investigated whether TPM treatment alters energy balance by altering insulin and leptin action/signaling in the hypothalamus from control and diet-induced obesity (DIO) mice. Swiss mice fed with standard chow or high-fat diet were orally treated with TPM (100 mg/kg/day) during 7 days. TPM treatment led to decreased body weight gain in DIO mice, but not in control mice, with increased oxygen consumption, fat oxidation and UCP-1 expression in brown adipose tissue. Moreover, TPM treatment followed by intracerebroventricular insulin and leptin infusion increased hypothalamic insulin and leptin signaling and action in obese mice, respectively, which led to decreased food intake and increased energy expenditure, with higher levels of CRH, TRH and CART, and reduced levels of NPY, MCH and orexin mRNA expression. However, when mice were pair-fed, no significant differences were observed concerning body weight gain and hypothalamic insulin and leptin signaling in TPM-treated mice compared with non-treated animals. In conclusion, the reduced food intake and increased energy expenditure induced by TPM are associated with hypothalamic insulin and leptin regulation and may reduce obesity in mice on high-fat feeding, presenting an alternative therapy for the treatment of obesity.

**Insulin improves memory and cognition via protein kinase c delta (δ)**

A. Apostolatos[2], D. Cooper[1,2] & N. Patel[1,2]
[1]JAH Veterans Hospital, Tampa, FL; [2]University of South Florida, Tampa, FL.

Older population and people with type II diabetes have a significantly higher rate of decline in cognitive function. However, the mechanisms are poorly understood. There are strong links between insulin and cognitive function supported by epidemiological data from humans and animal studies and *in vitro* research. Protein kinase C (PKC) signaling cascades and insulin pathways are closely integrated. The consequences of PKC activation by insulin in the CNS influence memory, cognition, synaptogenesis, and neuronal repair. In addition, PKCδ, a novel PKC has been implicated in memory, neuronal survival and proliferation. Insulin regulates the alternative splicing of mouse PKCδ splice variants: PKCδI promotes apoptosis while PKCδII functions as pro-survival protein. In vitro and *in vivo* studies demonstrated that apoptosis accounted for the neuronal loss and cognitive decline in the aging and diabetic mouse models. Our *in vivo* data demonstrates that intranasal insulin improves memory and cognition in aging and diabetic mice. Our *in vivo* data in mouse neural cells derived from the hippocampus, which is the seat of learning, memory and cognition, demonstrates that insulin increases the expression of PKCδII. PKCδII expression is not influenced by high glucose or thiazolidinediones thereby establishing that insulin increases PKCδII expression via its signaling pathways. To determine which pathways are involved in insulin-mediated PKCδ alternative splicing in neuronal cells, we used inhibitors of several pathways targeted by insulin in other tissues and show that insulin increases PKCδII expression via PI3K-Akt pathway. Constitutively active Akt2 kinase mimicked insulin effects in increasing PKCδII levels while WT-Akt2 kinase had no effect without insulin. Further, we show that PKCδII increases expression of pro-survival proteins Bcl-2 and Bcl-xL thereby increasing neurogenesis. In conclusion, we demonstrate that insulin improves cognitive functions via PKCδ.

**The Tuebingen Cushing's disease quality of life inventory: development and normative data from 1784 healthy people**

T. Psaras, J. Honegger & M. Milian
University Hospital Tuebingen, Tuebingen, Germany.

Objective

In part I of the study a health related quality of life (HRQoL) inventory for Cushing's disease (CD), the Tuebingen Cushing-25 quality of life inventory (Tuebingen CD-25) was developed. In the second part, we assessed normative data from healthy controls (HC) with which the individual patients' scores can be compared.

Methods

Sources for item generation consisted of technical literature, interviews with patients and the rating of neurosurgeons, endocrinologists and a neuropsychologist. A preliminary inventory with 64 items was handed out to 63 CD patients. Item reduction and scale generation followed the principles of Classical Test Theory. Validation was performed with the WHOQoL-BREF. For assessing normative data, the inventory was filled out by 1784 HC omitting the introductory sentence 'Because of my Cushing's disease' that was included in the CD group.

Results

The final version of the Tuebingen CD-25 contained 25 items, showed high reliability (Cronbach's $\alpha = 0.93$) and validity ($r = -0.65$) and includes the subdomains depression, sexual activity, environment, eating behavior, bodily restrictions and cognition. We found a non-linear correlation between the Tuebingen CD-25 scores and patients' age, younger and middle-aged patients having inferior HRQoL than patients between 31 and 50 years and older than 61 years. Preoperative 24 h UFC levels correlated significantly with the subscale cognition and only marginally failed significance level for the subscale Eating Behavior, while preoperative cortisol and ACTH levels did not correlate with any scale. In 28.6% of our CD patients we found slight and in 41.3% severe impairment in the Total Score of the Tuebingen CD-25 compared to HC. Less than one-third of our patient sample presented with unimpaired HRQoL.

Conclusion

The Tuebingen CD-25 is a feasible instrument to assess HRQoL in CD in a clinical and investigative setting and provides normative data for all age groups and genders.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Oligogenicity in the idiopathic central hypogonadism**

M. Bonomi[1,2], D. Libri[1], A. Pincelli[3], F. Guizzardi[1], E. Maiolo[4], M. Maghnie[5], C. Krausz[6], L. Persani[1,2,7] & On behalf of the Italian Network for ICH[8]
[1]Istituto Auxologico Italiano IRCCS, Cusano Milanino, Italy; [2]Istituto Auxologico Italiano IRCCS, Milano, Italy; [3]Ospedale San Gerardo dei Tintori, Monza, Italy; [4]EO Ospedali Galliera, Genova, Italy; [5]Università di Genova, Genova, Italy; [6]Università di Firenze, Firenze, Italy; [7]Università di Milano, Milano, Italy; [8]Italy.

Introduction

ICH is a rare and heterogeneous condition due to defects of GnRH secretion or action. Recent data indicate that ICH, though characterized by a strong genetic component, is a disease of multifactorial origin. Indeed, digenic defects have been described as a possible pathogenic explanation for ICH.

Subjects

We present two familial cases with particular clinical and genetic profiles, out of a cohort of 300 ICH patients.

Results

Proband 1 is a male diagnosed with normosmic ICH when he was 18 and then treated with testosterone. After 6 years of therapy he showed a complete recovery of a spontaneous GnRH function. Genetic analyses showed a heterozygous new nonsense mutation of the PROKR2 gene (15fsX43) and a known heterozygous loss-of-function mutation of the GnRHR (Q106R) respectively inherited from the unaffected father and mother. His sister has wild-type sequences but his brother,

despite a normal puberty and eugonadism, shows the same digenic genotype. Proband 2, a male diagnosed at 24 years with Kallmann syndrome (KS), was found to carry a new heterozygous missense substitution in the FGFR1 gene (L713P) and a disrupting duplication of the exons 4 to 14 of KAL1 gene. His father, younger brother and sister are unaffected with normal sequences. His mother and a elder brother were carriers of the KAL1 duplication but not of the FGFR1 variation. This brother had a normal puberty but is affected by daltonism and arched palate (two minor stigmata of KS), while the mother only by daltonism.
Conclusions
we describe two ICH families displaying a highly variable penetrance of the underlying multiple genetic defects. The first case shows that heterozygous digenic defects may not be sufficient to cause ICH, thus giving rise to the idea of a multifactorial origin of this heterogeneous condition.

### Investigating glucose responsive neuropeptide release using a static hypothalamic incubation system

S. Hussain[1], E. Richardson[2], G. Bewick[1], S. Bloom[1] & J. Gardiner[1]
[1]Imperial College, London, UK; [2]King's College London, London, UK.

The activity of certain hypothalamic neuronal populations is altered by changes in glucose. *in-vitro* studies have identified several glucose-sensitive neuronal populations in hypothalamic regions controlling energy homeostasis. Subsets of orexigenic arcuate nucleus Neuropeptide Y (NPY)-releasing neurones are known to be glucose responsive. These neurones may allow glucose to influence appetite. Cocaine and amphetamine regulated transcript (CART) is a neurotransmitter abundantly expressed in regions of the hypothalamus involved in energy homeostasis. At present, it is not clear if CART releasing neurones are glucose-sensitive. To assess hypothalamic neuropeptide release in response to changes in glucose, we investigated NPY and CART release by the hypothalamus at different concentrations of glucose, using a static hypothalamic incubation system.
Hypothalami from 20 male Wistar rats were incubated in artificial CSF (aCSF) for a 2-h equilibration period. The hypothalamic explants were then incubated for three 45 min periods in 600 µl aCSF containing 3, 8 (baseline) and 15 mM glucose in random order. Finally, the viability of the tissue was verified by 45-min incubation of aCSF containing 56 mM KCl. At the end of each incubation period, supernatants were removed and assayed for NPY and CART release by radioimmunoassay. Only explants that showed a greater secretion of NPY or CART with 56 mM KCl as compared to baseline were considered viable. Release of neuropeptide was expressed as percent of basal release.
There was a significant increase in NPY release with aCSF containing 3 mM glucose versus baseline glucose (3 mM: $285.2 \pm 92.8$ vs 8 mM: $100 \pm 36.1$ vs 15 mM $130.7 \pm 25.8$). There was a decrease in CART release with aCSF containing 15 mM glucose versus baseline glucose (3 mM: $95.1 \pm 10.6$ vs 8 mM: $100 \pm 6.8$ and 15 mM: $78.8 \pm 3.9$). These results suggest an important role for glucose-sensitive NPY-releasing hypothalamic neurones in mediating changes in energy homeostasis in response to glucose. They also suggest that subsets of CART-releasing hypothalamic neurones may be glucose responsive.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Expanding the clinical and genetic spectrum of the reversal of congenital hypogonadotropic hypogonadism

E. Laitinen[1,2], J. Tommiska[1,2], T. Sane[3], K. Vaaralahti[1,2], J. Toppari[4] & T. Raivio[1,2]
[1]University of Helsinki and Helsinki University Central Hospital, Helsinki, Finland; [2]University of Helsinki, Helsinki, Finland; [3]Helsinki University Central Hospital, Helsinki, Finland; [4]University of Turku, Turku, Finland.

Introduction
Up to 10% of patients with congenital hypogonadotropic hypogonadism (HH) may undergo reversal of hypogonadotropism and some of them even attain normal sperm count in adulthood. However, clinical and molecular genetic features of these patients and the triggers leading to reversal of HH are not well understood. We studied whether Finnish reversal variants displayed a common phenotypic or genotypic feature that would predict the clinical course of HH.
Patients and methods
Thirty-two male HH patients with anosmia/hyposmia (Kallmann Syndrome, KS; $n=26$) or normal sense of smell (nHH; $n=6$), were enrolled (age range, 18–61 years). The patients were clinically examined, and reversal of HH was assessed after treatment withdrawal. KAL1, FGFR1, FGF8, PROK2, PROKR2, CHD7, WDR11, GNRHR, GNRH1, KISS1R, KISS1, TAC3, TACR3, and LHβ were screened for mutations.
Results
Six HH patients (2 KS, 4 nHH) were verified to have reversal of HH (median age, 23 years; range, 21–39 years). All of them had spontaneous testicular growth while on testosterone replacement therapy (TRT). One nHH subject was restarted on TRT due to a decline in serum T. Two KS patients had a mutation in CHD7 (p.Q51X) or in FGFR1 (c.91+2T>A), two nHH patients were compound heterozygotes for mutations in GNRHR (R139H/R262Q and R262Q/del309F), while only two remained without a molecular genetic diagnosis.
Conclusions
Considerable proportion of patients with HH recovered in early adulthood. Spontaneous testicular enlargement during TRT was highly suggestive for reversal of HH, but we did not find phenotypic features that would have predicted reversal. However, those with the GNRHR mutation R262Q accompanied by another GNRHR mutation may be prone to reversal. Conversely, even patients with a truncating mutation in CHD7 or a splice-site mutation in FGFR1 can recover. We recommend that all adolescents and young adults with congenital HH should be informed on the possibility of reversal.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1111

### Retinoic acid regulates growth-related gene expression in the rat hypothalamus

P. Stoney, P. Morgan & P. McCaffery
University of Aberdeen, Aberdeen, UK.

The vitamin A-derived hormone retinoic acid (RA) is best known for its essential role in development, but components of the RA signalling pathway are also expressed in regions of the adult brain, including the hypothalamus, which regulates feeding behaviour, metabolism and body weight. RA is synthesised by the tanycytes lining the third ventricle and has recently been found to regulate cell proliferation in the hypothalamus. Some animals, such as the hamster and F344 rat, alter their feeding and body weight in response to changes in day length and photoperiod manipulation is a useful system for investigating growth- and weight-related changes in the hypothalamus. Expression of the RA synthetic enzyme retinaldehyde dehydrogenase 1 (RALDH1) is photoperiodically regulated in the hypothalamus of the photoresponsive F344 rat, with higher RALDH1 expression in rats kept on a long-day photoperiod (16 h light:8 h darkness; LD), relative to short-day (8 h light:16 h darkness; SD.). This suggests that RA levels are higher, and RA signalling more active, under LD conditions. To further investigate the role of RA signalling, hypothalamic slices from P10 male Sprague-Dawley rats were cultured in the absence of vitamin A for 4 days, then treated for 48 h with either DMSO or $10^{-6}$ M RA. qPCR analysis of treated tissue showed that RA treatment increased hypothalamic expression of GHRH, AGRP and POMC, genes known to be upregulated in LD-exposed rats. PCSK2, which encodes a prohormone convertase necessary for posttranslational processing of POMC, was also upregulated by RA. NPY and CART, genes associated with SD photoperiod, were unaffected by RA treatment. These results demonstrate that increasing hypothalamic RA levels is sufficient to upregulate genes associated with LD photoperiod and suggest that RA signalling contributes to the control of body weight by regulating the expression of growth-promoting genes in the hypothalamus.

**Crf type 2 receptor mediates estradiol-induced increase in hypothalamic leptin sensitivity**

P. Marangon, J. Antunes-Rodrigues & L. Elias
School of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil.

Energy homeostasis is controlled by neural, endocrine and adipocyte factors and CNS plays a key role in this control. We have previously observed that ovariectomized (OVX) rats treated with estradiol have lower body weight gain associated with an increased hypothalamic CRF mRNA expression. We investigated the role of CRF on activation of hypothalamic CART neurons by leptin in estradiol-treated OVX rats. Female Wistar rats (200–250 g) were subjected to both OVX and cannula implantation into the lateral ventricle and treated with estradiol cypionate (OVX + E, 10 μg/kg Bw, s.c.) or vehicle (OVX, corn oil: 0.2 ml/rat, s.c.) for 8 days. I C V injection of recombinant leptin (10 μg/5 μμ) was performed with i c v pre-treatment with CRF-R2 antagonist (antisauvagin − 30. 5 μg/5 μl) or vehicle. Anesthetized rats were perfused 90 min after leptin or vehicle injection. Fos/CART expressions were analyzed in the arcuate nucleus (ARC) of the hypothalamus by immunohistochemistry. Leptin induced body weight loss and reduced food intake both in OVX and OVX + E and increased neuronal activation in the ARC in OVX animals with this effect being amplified by estradiol treatment (OVX: 5.0 ± 0.6 vs 17.8 ± 2.7; OVX + E: 3.3 ± 1.3 vs 28.3 ± 6.1; $n = 3$-5; $P < 0.05$; vehicle vs leptin, respectively). These effects of leptin were abolished by CRF-R2 antagonist pre-treatment only in OVX + E rats (5.2 ± 1.9; $n = 5$; $P < 0.001$). Leptin treatment increased Fos/CART double-labeling in the ARC in OVX and OVX + E animals (OVX: 1.7 + 0.9 vs 9.5 + 1.6; OVX + E: 0.3 + 0.3 vs 9.5 + 2.2; $n = 3$-5; $P < 0.001$), with no differences between these groups. CRF-R2 antagonist abolished leptin effect on Fos/CART double labeled neurons only in OVX + E rats (10.5 + 0.3; $n = 5$; $P < 0.001$). In conclusion, our data suggest that estradiol increases hypothalamic sensitivity to leptin and this central effect is mediated, at least in part, by CRF type 2 receptors.

**Retinal growth hormone: local regulation by GH-releasing hormone (GHRH)?**

S. Harvey, W. Qiang, W. Lin & E. Sanders
University of Alberta, Edmonton, Alberta, Canada.

Introduction

The (GH) gene, identical to that in the pituitary, is expressed in retinal ganglion cells (RGCs) in chickens, rats, mice and humans. Retinal GH is a neuroprotective factor, as it promotes RGC survival and, in humans, the concentration of GH in vitreous fluid may be a marker for ocular disease. Increasing retinal GH expression could thus have therapeutic potential. The factors regulating retinal GH expression are, however, unknown. The possibility that GH-releasing hormone (GHRH) might be involved in the expression of retinal GH was therefore investigated.

Methodology

The possible presence of GHRH was determined by immunohistochemistry, using retinal sections from embryonic chicks and fixed QNR/D cells (a - commercial quail neuroretinal cell line). The possible GH-releasing activity of GHRH was determined by the *in vitro* culture of QNR/D cells with exogenous GHRH and by the measurement of mRNA, using of quantitative PCR.

Results

GHRH immunoreactivity was abundantly present in the cytoplasm of chick retinal RGCs and in QNR/D cells and in both cases was co-localized with GH immunoreactivity. After a 24 h incubation in exogenous GHRH (at 10–6 M) GH mRNA in the QNR/D cells was significantly increased.

Conclusion

These results demonstrate, for the first time, that GHRH is present in retinal RGCs and that exogenous GHRH promotes retinal GH expression. The co-localization of GH and GHRH also suggests that retinal GH regulation occurs locally by autocrine or paracrine mechanisms. Increased GHRH signaling might therefore be utilized therapeutically to increase retinal GH secretion.

**Cu–gnrh and pacap-induced cAMP/PKA and cGMP/PKG pathways activity in anterior pituitary cells *in vitro*.**

A. Gajewska[1], E. Wolinska-Witort[2], M. Zielinska[1], A. Krawczynska[1] & H. Antushevich[1]
[1]Institute of Animal Physiology and Nutrition, Polish Academy of Sciences, Jablonna n. Warsaw, Poland; [2]Medical Centre for Postgraduate Education, Warsaw, Poland.

Hypothalamic neuropeptide PACAP is a potent endogenous stimulator of adenylate cyclase synthesis in gonadotrope cells. Previously we found that, in contrast to GnRH, also Cu–GnRH complex is able to induce cAMP/PKA pathway activity.

The aim of the study was to determine whether Cu–GnRH can act via GnRH-R and/or PAC-1 receptors to stimulate cAMP/PKA intracellular signaling. Moreover, we compared PACAP and Cu–GnRH ability to activate cGMP/PKG system in anterior pituitary cells.

$5 \times 105$/ ml cells obtained from cycling female rats were preincubated for 72 h and then stimulated for 30 min, 1 and 3 h by $10^{-7}$ M of Cu–GnRH or PACAP. Peptides were also incubated with cells pretreated with $5 \times 10^{-7}$ M of specific receptor antagonists: PACAP 6–38 (for PAC-1 receptor) or antide (for GnRH receptor). Intracellular and extracellular cAMP, cGMP and LH medium concentration were measured by specific RIAs.

PACAP as well as Cu–GnRH activated cAMP synthesis although pattern of activation was different for both peptides. PACAP-induced increase in cAMP concentration was detected after 30 min, whereas Cu–GnRH -induced elevation required 1 h of incubation. In contrast to Cu–GnRH, PACAP-stimulated cAMP/PKA pathway activity remained time-dependent since an increase of cAMP concentration was found up to 3 h of incubation. cAMP synthesis was reduced when Cu–GnRH complex was incubated in the presence of PAC-1 receptor antagonist but was not changed in the presence of GnRH receptor antagonist. Obtained data also revealed that Cu–GnRH potently stimulated cGMP synthesis and inhibition of endogenous PKA activity resulted in an inhibition of cGMP production in anterior pituitary cells.

In conclusion, results indicate that Cu–GnRH-induced cAMP/PKA pathway activation might occur, at least partially, through an involvement of specific PACAP receptor. Moreover, Cu–GnRH complex may induce a cross-talk between cAMP/PKA and cGMP/PKG pathways in anterior pituitary cells.

**Corticosterone interferes with the stimulatory effect of cAMP on proTRH transcription by promoting a GR–PKAc interaction and not through chromatin remodelling**

I. Sotelo-Rivera, A. Cote-vélez, A. Pérez-Maldonado, J. Charli & P. Joseph-Bravo
Instituto de Biotecnología, Universidad Nacional Autónoma de México (UNAM), Cuernavaca, Mexico.

The activity of hypothalamus–pituitary–thyroid (HPT) axis is essential for energy homeostasis. TRH expression in the PVN is rapidly stimulated by energy demanding situations as cold exposure or locomotion, but blunted by stress-induced increased corticosterone serum levels. In primary cultures of rat hypothalamic cells (RHC), PKA activators as forskolin (Fsk) increase TRH mRNA levels, effect reverted by coincubation with dexamethasone. Fsk-dex coincubation also impedes binding of GR and pCREB to GRE and CRE in TRH-promoter (Díaz Gallardo, *J.Neuroendocrinol* 2010). In an attempt to elucidate the mechanism involved, we determined whether 1 h coincubation with dex or Fsk-dex induced chromatin condensation. ChIP analyses of RHC-isolated chromatin from Fsk treated cells revealed increased PCR signal of TRH promoter (−246/+69) in immunoprecipitates of pCREB, RNA-Pol II, H3ACK10 or H3ACK14 antibodies (Ab), and of GR from dex-treatment; these signals were diminished in Fsk-dex coincubates. No recruitment was obtained with Ab against deacetylases HDAC3 H99 in Fsk-dex compared to that detected in cells treated $T^3$. These results demonstrate that simultaneous activation of GR and PKA does not affect chromatin remodeling but impede GR and pCREB binding to TRH promoter. Antibodies against the catalytic subunit of PKA (PKAc), or against pCREB, incubated with a GR-immunoprecipitate from subcellular fractions of RHC

treated with dex-Fsk allowed to demonstrate the interaction of GR:PKAc. In living Fsk treated RHC, cytoimmunochemical analysis demonstrated increased pCREB in nuclei that was diminished with Fsk-Dex treatment. Furthermore, co-transfecting GR and TRH-Luc on SH-SY5Y cells reproduced the interfering effect dex-Fsk on Fsk stimulation; dex interference on Fsk stimulation was lost transfecting GR mutated on DBD site (L501P), and with GR-T171A or GR-S224A mutants that affect nuclear translocation and interaction with coregulators, supporting GR intrinsic characteristics for protein-protein interactions. These results demonstrate that GR interaction with PKAc provides a fast mechanism for avoiding pCREB activation of TRH transcription.

**Effects of mineralocorticoid agonists and antagonists on survival, proliferation and differentiation of adult rat hippocampal progenitor cells**

I. Gesmundo, E. Gargantini, F. Settanni, E. Ghigo, E. Arvat & R. Granata
University of Turin, Turin, Italy.

Introduction

Hippocampus is a key area in the brain and influences the neuroendocrine functions, especially the hypothalamo–pituitary–adrenal (HPA) axis that is mainly regulated by corticotrophin-releasing hormone (CRH), vasopressin (ADH) and glucocorticoid (GC). This feed-back action is mediated by both glucocorticoid (GRs) and mineralocorticoid (MRs) receptors. GRs are distributed throughout the brain, but mostly in hypothalamic neurons, while the MRs highest expression has been detected in the hippocampus. Aim of the study was to clarify the role of fludrocortisone (MRs agonist) and spironolactone (MRs antagonist) on cell proliferation, differentiation and survival in adult rat hippocampal progenitor (AHP) cells, a totipotent cell line that can differentiate in neurons and glial cells. Furthermore we investigated the effect of fludrocortisone on AHP cell survival after treatment with amyloid β-protein (fragment 1–42).

Methods

AHP cells were cultured with neural stemline medium enriched with FGF-basic. The presence of GRs and MRs was evaluated by RT-PCR. Cell survival was measured by MTT assay and cell proliferation by BrdU incorporation. Apoptosis was studied by Caspase-3 activity analysis. Activation of survival signalling pathways was determined by Western blotting, i.e. phosphorylation of phosphatidylinositol 3-kinase/Akt (PI3K/Akt), glycogen synthase kinase-3 (GSK-3β) and of cAMP response element binding (CREB).

Results

Fludrocortisone, but not spironolactone, stimulates proliferation, and protects against growth factor deprivation-induced apoptosis. Fludrocortisone activates the GSK-3β, the PI3K/Akt and the CREB pathways. Moreover it counteracts the effect of the amyloid β-protein (1–42) on cell death and inhibition of cell proliferation.

Conclusion

The survival and proliferative effect of fludrocortisone in neuronal precursors candidate MRs agonists as potential molecules in the treatment of neurodegenerative conditions, such as Alzheimer′s disease.

**Sleep deprivation-induced changes in rat hypothalamic arginine–vasopressin content**

J. Gardi[1], S. Magony[1], T. Nyári[1], Z. Valkusz[1], J. Julesz[1] & J. Krueger[2]
[1]University Of Szeged, Szeged, Hungary; [2]Washington State University, Spokane, USA.

Neurohypophysial hormone, arginine–vasopressin (AVP) concentrations in human plasma and in the plasma, and hypothalamus of the rat display diurnal variations with rising levels over the hours of sleep. Previous reports indicate that AVP infusions reduce rapid-eye-movement sleep in humans and increase the amount of time spent in waking in rats. Our aim was to determine whether AVP content of the rat hypothalamus is altered by sleep deprivation (S.D.). Adult male Sprague-Dawley rats were acclimated to a 12:12-h light–darkness cycle and were sleep deprived by gentle handling starting at light onset. Hypothalamic samples ($n = 8$–10 per group) were obtained after 4 and 8 h of S.D.and after 1 and 2 h of recovery following 8 h of S.D. Control samples were collected from undisturbed rats at corresponding time points. After extraction, AVP was determined by means of radioimmunoassay. The changes in AVP during and after S.D. were evaluated with respect to the time-matched control samples by means of two-way ANOVA. Hypothalamic AVP contents differed significantly between the control groups and the sleep deprived animals. AVP was normal after 4 h of S.D..and dropped to a low level by the end of h 8 of S.D.. AVP was significantly suppressed after 1 and 2 h of recovery. Similarly to our data S.D.. induced a significant fall in nighttime plasma AVP in healthy children. Current results confirm that diurnal variations in AVP secretion are in fact associated with sleep thus AVP could play a role in the physiological regulation of sleep.

**Ghrelin, leptin and adiponectin plasma levels in narcolepsy with cataplexy**

M. Lakočević[1], M. Petakov[1], M. Barišić[2], B. Radosavljević[3], J. Antić[1] & S. Damjanović[1]
[1]Clinic of Endocrinology, Belgrade, Serbia; [2]Faculty of Organizational Sciences, Belgrade, Serbia; [3]Institute of Medical Chemistry, Belgrade, Serbia.

Introduction

Narcolepsy is a rare sleep disorder characterized by excessive daytime sleepiness and REM-sleep abnormalities. Lateral hypothalamic hypocretin/orexin neurones are critical for normal wakefulness and energy expenditure, and the reduction of their activity has been linked with narcolepsy. Their activity is inhibited by extracellular glucose and the 'satiety' hormone leptin but stimulated by the 'hunger' hormone ghrelin. Patients with narcolepsy and cataplexy are often overweight and display an increased prevalence of type 2 diabetes mellitus. Because of possible ghrelin/adypocytokines disbalance, we assessed plasma ghrelin, leptin and adiponectin periferial levels.

Description of methods

Plasma ghrelin, leptin and adiponectin concentrations were measured in 25 narcoleptic patients with cataplexy (mean age 40.76 ± 13.81 years, mean BMI 26.44 ± 5.21) and 20 healthy age and BMI matched controls (mean age 41.25 ± 14.05, mean BMI 26.04 ± 3.94). Body composition was measured using bioimpedance method. Levels of parameters were measured by RIA (kits LINCO Research).

Results

There were no stastically siugnificant differencies in plasma ghrelin, leptin, and adiponectin concentrations between narcoleptic and healthy individuals. As expected there was a positive correlation between leptin levels and fat mass in patients with narcolepsy and cataplexy.

Conclusion

Our study suggests that possible metabolic changes and tendency to owerweight previously reported in narcolepsy with cataplexy may be caused by other mechanisms but not ghrelin/adypocitokines disbalance.

## P1120

### High serum cortisol levels in patients with Alzheimer's Disease

A. Rizoulis[1], S. Karaoulanis[1], E. Dardiotis[1], K. Rizouli[2] & A. Papadimitriou[1]
[1]University of Thessalia, Larissa, Greece; [2]TEI of Larissa, Larissa, Greece.

Introduction
Alzheimer's Disease (AD) is a multifactorial disease. The hypothalamo-pituitary–adrenal (HPA)-axis shows extensive changes in AD. It is observed a hyperactivation of corticotropin-releasing hormone (CRH) neurons with age, which is significantly present in men. The aim of this study is to compare serum levels of cortisol in patients with Alzheimer's disease and normal controls.
Material and Methods
Ninety patients with AD and 95 normal controls matched for age and gender were included. The diagnosis of Alzheimer dementia was based on standard criteria provided by the DSM-IV TR system and the NINDS-ADRDA. Blood samples were frozen at $-80^{\circ}$C until analysis. Cortisol levels were measured using a commercial routine immunoassay (electrochemiluminescent assay, ECLIA). Differences in cortisol levels were assessed between the two groups using the Mann–Whitney method. Linear regression analysis was also used to adjust for characteristics shown to be associated with cortisol and cognitive decline. These characteristics were sex, age, weight and smoking. The significant level was set at $P<0.05$.
Results
From the patients with AD, 74 were women and 16 were men (mean age $80.53\pm6.03$, mean body weight $71.49\pm8.33$) and from the control group 78 were women and 17 men (mean age $79.27\pm6.86$, mean body weight $70.23\pm6.73$). Serum cortisol levels were significantly higher in patients with AD compared to normal controls ($16.95\pm9.53$ in AD patients vs $9.90\pm5.49$ in normal controls, $P<0.001$, Mann–Whitney $U$).
Conclusions
The study showed that patients with AD have high serum cortisol levels. Because of the inhibitory control of the hippocampus on the HPA-axis, damage to this structure was expected to disinhibit the HPA-axis, and to cause a positive feedforward cascade of increasing glucocorticoid levels over time. This 'glucocorticoid cascade hypothesis' of stress and hippocampal damage was proposed to be causally involved in age-related accumulation of hippocampal damage in disorders like Alzheimer's disease.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1121

### Melatonin levels, sleep and psychosocial impairment in patients after radiotherapy for brain tumors or leukemia

I. Kreitschmann-Andermahr[1,2], S. Siegel[1,2], A. Thissen[2], E. Rosenkranz[2], M. Piroth[1] & G. Brabant[3]
[1]University Hospital Erlangen, Erlangen, Germany; [2]University Hospital RWTH Aachen, Aachen, Germany; [3]Luebeck University, Luebeck, Germany.

Objective
Melatonin is a hormone secreted by the pineal gland which modulates sleep and wakefulness rhythms. Decreased melatonin secretion has been shown to be associated with increased daytime sleepiness and disturbed circadian rhythm in (irradiated) survivors of childhood craniopharyngeoma. The present study was performed to explore possible relationships between disturbed sleep, psychosocial impairment and melatonin secretion in patients treated with cranial radiotherapy as a part of brain tumour or leukaemia treatment.
Patients and methods
Thirty four (16 m, 18 f) patients who had received radiotherapy as part of brain tumour treatment or leukaemia were investigated at least 3 year after completion of radiotherapy. In all patients overnight urine was collected and melatonin concentration and melatonin secretion/h was measured. Sleep quality was assessed using the pittsburgh sleep quality index (PQ3I) and daytime sleepiness using the epworth sleepiness scale (ESS). Quality of life was assessed with the short form- 36 (SF–36) and depression with the beck depression inventory-II (BDI-II). Tumors were divided into midline or near-midline tumours ($n=15$; i.e. germinoma medulloblastoma), non-midline ($n=12$; i.e.hemispheric) tumours and patients with leukaemia ($n=7$).
Results
Self-assessed sleep quality in the PQ3I or daytime sleepiness (ESS) were not linked to melatonin secretion and neither were BDI-II nor SF-36 scores. Melatonin concentrations were not dependent on radiation dose, elapsed time since radiotherapy, age at radiotherapy, or childhood versus adult-onset of brain tumour disease (n.s.). Patients irradiated for midline tumours had a significantly lower overall melatonin secretion and hourly melatonin secretion than patients irradiated for non-midline tumours ($P=008$).
Conclusion
Melatonin secretion was linked to brain tumour site and, thus, perhaps also radiation dose to the pineal gland. Since melatonin secretion was not associated with sleep quality or psychosocial impairment, the medical use of exogenous melatonin in such patients must be questioned.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

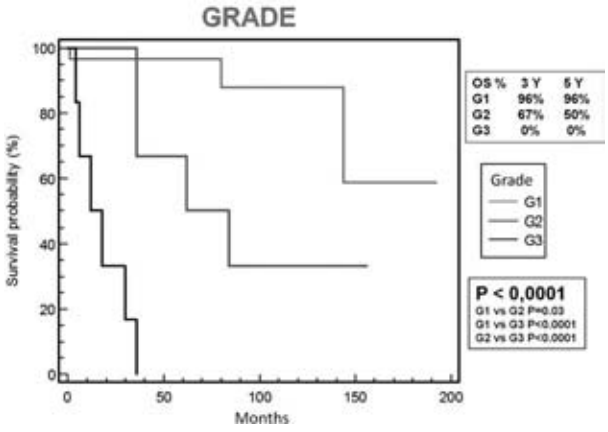
### Ten years of gastroenteropancreatic neuroendocrine tumours: evolution of the classification and correlation with follow-up in 50 patients

M. Albertelli, F. Grillo, A. Giannone, L. Mastracci, F. Annunziata, M. Arvigo, F. Minuto, R. Fiocca & D. Ferone
University of Genova and IRCCS Azienda Ospedaliera Universitaria San Martino - IST - Istituto Nazionale per la Ricerca sul Cancro, Genova, Italy.

Gastroenteropancreatic (GEP) neuroendocrine tumours (NETs) are rare neoplasms with heterogeneous clinical behavior and potential long-term survival. In the last decade GEP–NET nomenclature has been twice reviewed. However, the 2000 WHO classification had poor prognostic power in well differentiated (WD) neoplasms. This led to the introduction of two new important parameters by the European Neuroendocrine Tumors Society (ENETS), grade and stage; the former became part of the new 2010 WHO classification. Considering the recent introduction of grade and stage, their external validation has been strongly requested.
Since these are important tools in the management of patients with NETs, our aim was to reclassify retrospectively, with grade and stage, our series and correlate with follow-up results.
From the histopathology archive at our centre, 170 GEP–NETs (1993–2011) were identified. Only 50 patients have been reclassified so far and the work is still in progress. Mean age at diagnosis was 56 years, F:M ratio was 1:1.2 and mean follow-up was 56 months (2–196).
Correlating differentiation with overall survival (OS), WD NETs had strikingly better outcome with respect to poorly differentiated ones. However only grade identified a subgroup of patients with WD lesions with less favorable clinical behavior (OS at 5 years: G1–96% vs G2–50%). Stage was also useful, though not statistically significant in our series so far.
Our data confirm the importance of grade and stage in prognostic stratification. Indeed, the new 2010 WHO classification has a better prognostic power and better predict the clinical course of WD disease. Therefore, in view of the long survival of patients with NETs, the retrospective classification of patients who may not



have been previously graded or staged, may influence the choice of therapeutic options, especially in the future.
Overall survival of GEP NETs stratified according to the grading.

**Orexigenic neuropeptide 26RFa: new evidence for an adaptive profile of appetite regulation in anorexia nervosa**

B. Galusca[1], L. Jeandel[2], N. Germain[1], N. Chartrel[2] & B. Estour[1]
[1]CHU Saint Etienne, Saint Etienne, France; [2]University of Rouen, Rouen, France.

Background
Restrictive anorexia nervosa (AN) presents an adaptive appetite regulating profile including mainly high levels of ghrelin. Because this adaptive mechanism is not effective on food intake, other appetite regulating peptides need to be explored. 26RFa is a hypothalamic neuropeptide that stimulates appetite, gonadotropin release and bone metabolism. The aim of the current study was to evaluate circadian levels of 26RFa in AN patients compared with healthy subjects, other eating disorders and constitutional thinness (CT).
Subjects and methods
Twelve-point circadian profiles of plasma 26RFa levels were measured in five groups of age-matched young women were included in the study: 19 restrictive AN (AN-R), 10 AN with bingeing/purging episodes (AN-BP), 14 with CT, 10 bulimic (BN) and 10 normal weight controls.
Results
Significant circadian variations of 26 RFA were noticed in controls with higher values in the morning and abrupt decrease at noon. 24-h mean 26RFa levels were significantly increased in AN-R and AN-BP ($P<0.001$), predominantly in the afternoon and evening when compared to controls. Pre-prandial rises of 26 RFA were noticed in AN patients. Mean 26RFa trend to be higher in CT than in controls ($P=0.06$) and significantly lower than in AN. BN patients presented a circadian profile of 26RFa similar to that of controls.
Conclusion
High levels of circulating 26RFa observed in AN patients reflects an adaptive mechanism of the organism to promote energy intake and to increase fat stores in response to a deficit in energy balance.

## P1124

**Autoimmune thyroid disease and neuroendocrine gastric tumors: early detection and efficacy of somatostatin analogue treatment**

G. Accardo[1], A. Renzullo[1], A. De Bellis[1], A. Bizzarro[1], M. Romano[1], A. Federico[1], A. Gravina[1], A. Faggiano[2], V. Marotta[2], D. Esposito[1], A. Bellastella[1] & D. Pasquali[1]
[1]Second University of Naples, Naples, Italy; [2]University Federico II, Naples, Italy.

Autoimmune chronic thyroid disease (AITD) is associated with atrophic gastritis (CAG) in 29–42% of the cases. CAG and the consequent hypergastrinemia, listed as precancerous lesion, can predispose to neuroendocrine cells hyperplasia and the development of neuroendocrine gastric tumors (NET). Aim of this study was to evaluate the association of AITD with risk of gastric NET and the efficacy of somatostatin analogues treatment.
Patients
From 2009 to 2011, we selected 92 AITD patients referred to the author's endocrinology practice (83 female, 9 male, aged 16–70 years). All cases underwent hormonal profile, including serum gastrin, CgA, parietal cell antibodies (PCA). Patients with gastrin and CgA significantly higher than normal level (cut off were $>$ 250 pg/ml and $>$80 ng/ml respectively) underwent to gastro esophageal endoscopy (EGDS). The patients positive for neuroendocrine cells hyperplasia at EGD, underwent somatostatin receptor scintigraphy and treatment with Sandostatina LAR 30 mg 1 fl i.m. each 28 days. Gastrin and CgA assays were repeated every three months and after one year they performed EGDF.
Results
Out of 92, only 58 patients exhibited gastrin and CgA. In 11 patients (18%) gastrin and CG were higher than normal (552,6 $\pm$ 250 pg/ml; 288 $\pm$ 152.3 ng/ml respectively), and only eight were PCA positive. Eleven patients with hypergastrinemia underwent EGDS, that showed in 2 patients diffused hyperplasia of the neuroendocrine cells of the body and in one a carcinoid. These patients, all negative to Octreoscan, were treated with Sandostatina LAR 30 mg fl every 28 days. After 3 months of treatment gastrin and CG levels were significantly reduced ($P<0.001$) and patients referred a decrease of clinical symptoms. After one year they showed normal gastrin and CgA values and EGDS detected absence of neuroendocrine hyperplasia.
Conclusions
We show that in 18% of AITD with hypergastrinemia was found neuroendocrine hyperplasia, a precancerous condition predisposing to NET risk. The remission, shown by EGDS, after one year of treatment, gives us evidence of the efficacy of somatostatin analogue in the prevention of gastric NET risk.

## P1125

**Contemporary microsurgical treatment of Cushing's disease**

J. Honegger & T. Psaras
University Hospital Tuebingen, Tuebingen, Germany.

Introduction
Transsphenoidal surgery (TSS) is the treatment option of first choice for Cushing's disease (CD). The traditional microsurgical technique has recently been challenged by endoscopic surgical methods. We present endocrine outcome of TSS in CD with a modified contemporary microsurgical concept.
Methods
Eighty three patients underwent TSS for newly-diagnosed CD (72 micro-adenomas and 11 macroadenomas). An enlarged resection was performed in 36 patients. A modified exploration technique with radial incisions was performed in 19 patients in whom an adenoma was not readily detectable. Inferior petrosal sinus sampling (IPSS) was performed in only nine cases. Normal (or decreased) urinary cortisol and suppression below 2 μg/dl during a low-dose dexamethasone suppression test were required for endocrinological remission.
Results
An initial remission rate of 87.5% (63/72) was achieved in microadenomas. Six patients with microadenomas were re-operated for persistence and hypercortisolism was corrected in five of them. With re-operation included, the overall remission rate for microadenomas was 94.4%. In macroadenomas, a remission rate of 63.6% was achieved. No procedure-related complications occurred in primary surgery.
Of the patients in remission, 72.5% had early postoperative random cortisol levels below 2 μg/dl, 17.4% had cortisol levels between 2 and 5 μg/dl, and 10.1% had cortisol levels $>$5 μg/dl.
15.2% of the patients with microadenomas developed postoperative partial hypopituitarism and 3% diabetes insipidus. No increased rate of hypopituitarism was found with enlarged adenomectomy compared to selective adenomectomy. Only a slightly higher rate of partial hypopituitarism (23.1%) was found if extensive exploration was required.
Conclusion
Transsphenoidal microsurgery is highly effective as initial therapy of CD. Early re-operation is a successful option if CD persists. If pituitary dependence has been established on the basis of endocrine functional testing, IPSS is not obligatory even if MRI is negative. Enlarged resection for poorly-demarcated micro-adenomas yields a high remission rate without compromising pituitary function.

**Effect of ghrelin on aromatase gene expression and estradiol 17-β concentrations in ventromedial and lateral hypothalamic area**

H. Khazali
Shahid Beheshti University, Tehran, Islamic Republic of Iran, Iran.

The goal of this study was to determine whether ghrelin increase aromatase gene expressions and estradiol 17-β concentrations in ventromedial (VMH) and lateral hypothalamic area (LH). Forty rats were randomly divided into four groups. Animals in different groups were received either saline, 1, 2 or 4 ng ghrelin into their VMH and LH. After infusion of ghrelin, VMH and LH tissue were separated and homogenized. Homogenized sample were assayed for aromatase gene expression by PCR technique and estradiol 17-β ($E_2$) concentrations by RIA techniques. Infusion of 2 and 4 ng ghrelin into VMH and LH area significantly increased the mean aromatase gene expressions and $E_2$ concentrations in the VMH and LH of the rats. Infusion of 1 ng ghrelin into VMH and LH area did not change the mean aromatase gene expressions and $E_2$ concentrations in the VMH and LH of the rats.The result of this study indicated that ghrelin may depolarize neurosteroids of VMH and LH and consequently increase aromataze gene expressions and $E_2$ concentrations in the brain of the rats.

**Regional distributions of kisspeptin and gonadotropin-inhibiting hormone peptides in ovine and rat brains**

Y. Hasegawa[1], O. Hashimoto[1] & K. Tsutsui[2]
[1]Kitasato University, Towada shi, Japan;[2]Waseda University, Tokyo, Japan.

The reproductive system is controlled by (GnRH) secretion from the brain, which is finely modulated by a number of factors, including gonadal sex steroids and inhibins. It was recently claimed that kisspeptin (KP) and gonadotropin inhibitory hormone (GnIH) neurons are regulators of GnRH secretion. Therefore, we have developed highly specific and sensitive fluoro-immunoassays (FIAs) using Eu-labeled antigens for KP 10 and GnIH. In this study, the distributions of KP 10 and GnIH in rat and ovine brains were determined by FIA, and they were compared those of GnRH.

Using Eu-labeled KP-10 and GnIH, highly sensitive immunoassays for KP-10 (IC50, 87 pg/ml) and GnIH (IC50, 15 pg/ml). After decapitation, rat and ovine brain tissues were boiled for 10 min in 1-N acetic acid, after which they were homogenized in 10 volumes (v/w) in 1-N acetic acid. Aliquots of supernatant were evaporated and dissolved well in assay buffer.

When the distribution of KP was examined in rat brain, KP was detected only in the hypothalamus (35 pg/100 mg wt), with negligible KP in other tissues. However, the amount of GnIH was high in rat brain; the highest concentration was found in the thalamus (410 pg), followed, in order, by the hypothalamus, medulla oblongata, telencephalon, and cerebellum. In ovine brain tissues, the highest concentration of KP (116 pg) was observed in the diencephalon, and the amount of KP in other tissues ranged between 20 and 40 pg. On the other hand, the concentration of GnIH in ovine brain was highest in the diencephalon (155 pg), followed, in order, by the midbrain, pons, and medulla oblongata, with GnIH concentration in other brain tissues being $<60$ pg.

**Right hemicolectomy in the treatment of patients with appendiceal neuroendocrine tumors: does size matter?**

S. Grozinsky-Glasberg[1], K. Alexandraki[2], D. Barak[1], G. Kaltsas[2] & D. Gross[1]
[1]Hadassah University Medical Center, Jerusalem, Israel; [2]National University of Athens, Athens, Greece.

Background

A recent study of a small series of patients with appendiceal neuroendocrine tumors (ANETs) fulfilling various criteria for right hemicolectomy (RHC) revealed that $\approx$ 25% may harbor identifiable extra-appendiceal disease. The residual disease might not have been detected using the latest European Neuroendocrine Tumors Society (ENETs) revised pathological criteria.

Aims

To evaluate the latest pathological criteria for completion right hemicolectomy in an extended series of patients with ANETs.

Methods

The medical files of 27 consecutive patients who underwent RHC for ANETs in three tertiary hospital NETs clinics were retrospectively assessed. Demographic, clinical, laboratory data were collected; surgical specimens were reviewed for the indications for completion RHC: tumor diameter of $\geq 2$ cm, tumor location at the appendiceal base, extensive mesoappendiceal invasion (EMI) of $>3$ mm, vascular invasion (VI) or a KI67 proliferation index of $\geq 2\%$.

Results

5/27 patients were found to have residual disease. In 8/27 patients (30%) the tumor diameter was $<1$ cm; the indications for RHC included: tumor presence in surgical margins (3), EMI (5), VI (2), KI67 $\geq 2\%$ (3); residual disease was present in one patient (13%). In 12/27 patients (44%) the tumor diameter was 1–2 cm; the indications for RHC were as follows: tumor presence in surgical margins (1), EMI (10), VI (2), KI67 $\geq 2\%$ (2); residual disease was present in two patients (17%). In 7/27 patients (26%) tumor diameter was $\geq 2$ cm. In this subgroup, RHC is accepted practice; the tumor was present in surgical margins (3), EMI (7), VI (5), KI67 $\geq 2\%$ (5). Residual disease was present in two patients (28%).

Conclusions

In patients with ANETs it is well established that tumor size and the EMI are the most significant factors in taking the decision about the extension of the surgery. Our present data suggests that in the subgroup of patients with a primary tumor size between 1–2 cm (the 'gray zone') the risk of residual disease high. Using the latest criteria for RHC, residual disease may be missed in 7% of ANETs patients.

**Delay in the onset of puberty of intrauterine growth retarded female rats cannot be rescued by hypernutrition after birth**

T. Matsuzaki, G. Gereltsetseg, T. Iwasa, R. Kinouchi, H. Nakazawa & M. Irahara
The University of Tokushima Graduate School, Tokushima-shi, Japan.

Perinatal undernutrition is known to disturb reproductive development, in particular by delaying the onset of puberty in certain species. Using a rat model, we studied whether hypernutrition after birth can rescue the delayed onset of puberty in intrauterine undernourished female rats. Pregnant rats were divided into two groups the maternal normal nutrition (mNN, $n=8$) and maternal undernutrition (mUN, $n=9$) groups. In the mUN group, dams received 50% of the daily food intake of the mNN group from day 15 of pregnancy until delivery. Pups from both the mNN and mUN dams were then separated into two groups, based on their postnatal feeding

Conditions

control-normal nutrition (control-NN), control-hypernutrition (control-HN), IUGR-normal nutrition (IUGR-NN), and IUGR-hypernutrition (IUGR-HN). Litter sizes of the hypernutrition groups were controlled to five pups per dam, and normal nutrition groups to 12–13 pups per dam. From postnatal day 30, pups were inspected daily for vaginal opening (VO). The age of VO in the IUGR-NN group was $35.7 \pm 2.4$ days (mean $\pm$ S.D.), which was significantly delayed compared to that of the control-NN group ($33.8 \pm 0.8$ days). The age of VO in the IUGR-HN group was $35.5 \pm 2.3$ days, which was significantly delayed compared to that of the control-HN group ($33.5 \pm 0.8$ days). Interestingly, the age of VO did not differ between the IUGR-NN and IUGR-HN groups. In conclusion, maternal undernutrition delays puberty in female offspring, and this delay in puberty cannot be rescued with hypernutrition after birth.

### Fasting induces a delayed increase of thyrotropin-releasing hormone degrading ectoenzyme activity in the tanycytes of the median eminence of the rat hypothalamus

I. Lazcano[1], P. Joseph-Bravo[1], E. Sanchez[2] & J. Charli[1]
[1]Universidad Nacional Autonoma de Mexico, Cuernavaca, Mexico; [2]Instituto Nacional de Psiquiatria, Mexico DF, Mexico.

Fasting produces a rapid reduction of the activity of the central arm of the hypothalamic–pituitary–thyroid (HPT) axis, with a drop in biosynthesis of thyrotropin releasing hormone (TRH) in periventricular and medial parvocellular neurons of the paraventricular nucleus (PVN), and decreased TRH release into the pituitary portal capillaries. These events contribute to fasting-induced suppression of serum thyroid hormone levels, an adaptive mechanism to conserve energy. Pyroglutamyl peptidase II (PPII), the TRH degrading ectoenzyme, is expressed by the β2 tanycytes, in close apposition with TRH nerve endings in the external layer of the median eminence, and controls TRH levels in the extracellular space and serum TSH levels. To test the hypothesis that tanycyte PPII activity is regulated during fasting, we measured PPII expression and activity in the median eminence of 250 g BW male Wistar rats. Rats were transferred into individual cages and submitted to fasting for 24–72 h, with water ad libitum. Control animals were submitted to isolation for the same time than food-deprived animals. Animals were sacrificed at various time points after fasting initiation, but always 3–5 h after lights were on. Compared to isolation, fasting reduced animal weight, PVN TRH mRNA levels, and concentration of total $T_4$ (but not $T_3$) in serum; a delayed drop in serum TSH concentration was observed between 48–60 h. Semi-quantitative *in situ* hybridization indicated that PPII mRNA levels increased in β2 tanycytes 48 h after fasting initiation. This increase was transitory (not detected at 72 h), and followed by an increase of PPII activity in the median eminence, with a peak response between 60 and 72 h. We conclude that during fasting a delayed increase in median eminence PPII activity may facilitate the maintenance of the profound reduction of HPT axis activity.

### Estradiol effects on hypothalamic stat3 phosphorylation induced by leptin

G. Goncalves, B. Borges, P. Marangon, C. Melo, L. Elias & J. Antunes-Rodrigues
School of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil.

Besides its critical functions as a reproductive hormone, 17β-estradiol ($E_2$), plays an important role in the control of energy homeostasis. In experimental animals, reduction of circulating estrogen levels by bilateral ovariectomy leads to the development of obesity, which can be reversed or prevented by $E_2$ treatment. $E_2$ effects on energy balance resemble many similarities to the actions of leptin, key molecule involved in the control of energy homeostasis. In this study, to assess the effects of $E_2$ in the activation of STAT3 by leptin in the hypothalamus, we used ovariectomized Wistar rats treated with $E_2$ (OVX +E) or corn oil (OVX), during eight consecutive days. At the eighth day of treatment, they received i.c.v injection (ICV) of leptin or vehicle. We evaluated the phosphorylation of STAT3 protein in the mediobasal hypothalamus (MBH) by Western Blotting or in the hypothalamic nucleus retrochiasmatic (RCA), arcuate (ARC), paraventricular (PVN) and ventromedial (VMN) by the quantification of p- STAT3 positive neurons by immunochemistry. Leptin induced a significant increase in p-STAT3 expression in the MBH, with no difference between OVX e OVX +E groups. Similarly, compared with respective saline group, leptin increased the number of p-STAT3 positive neurons in the RCA, ARC, PVN and VMN of the groups OVX and OVX +E, with no difference between both groups. Interestingly, we observed a higher number of p-STAT3 positive neurons in the VMN of OVX +E rats that received vehicle ICV, compared to OVX rats. These findings suggest that $E_2$ could act directly in the VMN, activating the STAT3-mediated signaling and this $E_2$ effect can facilitate leptin actions to reduce body weight and food intake.

### Evaluation of cushings disease remission and serum cortisol dynamic early after transsphenoidal surgery

T. Rodrigues[1,2], F. Costenaro[1], G. Rolim[1] & M. Czepielewski[1,2]
[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [2]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil.

Aim

serum cortisol dynamic after transsphenoidal pituitary surgery (TSS) in predicting remission and recurrence of CD.

Methods

A cohort of 103 CD patients from a referral center was prospectively analyzed at 111 TSS in 6.0±4.8 years of follow-up. Twenty patients received glucocorticoids in transoperative and had serum cortisol measured at 10–12 days after TSS (Protocol I). Eighty six patients had serum cortisol measured at each 6 h in the first 24 h, at 48 h and 10–12 days after TSS and glucocorticoid administration only if adrenal insufficiency (Protocol II).Remission (defined as clinical hypercortisolism absence plus serum cortisol $< 3$ μg/dl in overnight dexamethasone test and/or normal free urinary cortisol) during follow-up and recurrence (loss of remission criteria at least a year after TSS.

Results

Eighty percentage of remission after first TSS, and 8% of the patients had recurrence Serum cortisol nadir $\leq 3.5$ μg/dl at 48 h after TSS had specificity of 100% and sensitivity of 73%, and serum cortisol nadir $\leq 5.7$ μg/dl at 10–12 days after surgery had specificity of 100% and sensitivity of 92% in predicting surgery remission.

Conclusion

Recurrence could not be predicted. These results state the importance of serum cortisol values after TSS in predicting CD remission.

Relative risk for postoperative cortisol as Cushing's disease predictor, in different adjusted models.

### Hyponatremia in hospitalised patients: are we investigating and managing them properly?

A. Murtaza, K. Al-Hourani & P. De
City Hospital, Birmingham, UK.

Introduction
Hyponatremia is common in hospitalised patients and can be due to a number of aetiologies. Investigations and management are often quite varied.
Aims
To find out the prevalence, aetiology, investigations and management of hyponatremia in our hospitalised patients over a 2 week period (1 May and 15 May 2011).
Methods
Case notes and electronic data assessment of all patients admitted with sodium level $<$130 mmol/l.
Results
One hundred and seventy patients had hyponatremia (hospital range 136–143 mmol/l). Complete data was available in 27/46 patients (15 males, 12 females, average age 65 years) with sodium $<$one hundred and thirty mmol/l. Mean sodium was 127 mmol/l. 6 (4%) had sodium $<$ 125 mmol/l. Hyponatremia was mentioned as a diagnosis in 7(26%) and SIADH specifically in only 2 (7%). Hydration status recorded were as follows: euvolemic–seven (26%), hypovolemic–five (18%), hypervolemic–six (22%), not mentioned–nine (33%). Only 2 patients had proper investigations for SIADH. Speciality ward allocation were Acute Medicine - 8, Cardiology - 3, Gastroenterology - 2, Endocrinology - 2, Care of Elderly - 1, Respiratory - 1, Orthopaedics - 3, Surgery (various) - 3, Obstetrics - 2, Gynaecology oncology - 1. Working diagnosis on admission were reported as: Hypovolemia - 6 (22%), Hypervolemia - 1, SIADH (cancer lung and ovary) - 2, Sepsis - 7 (26%). 6 (22%) patients received fluid restriction, IV fluid - 1, Demeclocycline - 1, diuretics withheld - 1, IV antibiotics - 3, ITU admission - 3. 5 (18%) patients died and 8 (30%) were discharged with Sodium level $<$ 130 mmol/l. Average Length of stay was 15.6 days (range 1–51 days).
Conclusions
Hyponatremia is poorly understood & recorded, frequently overlooked and inadequately investigated and managed in hospitalised patients. A variety of specialities deal with hyponatremia. Endocrinologists are rarely consulted to investigate and rule out SIADH - which can often be challenging. Plan is to increase awareness among clinical staff and develop pathways to enable correct investigations and management and re-audit the whole process.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Epidemiology, clinical behaviour and prognostic factors of gastro-enteropancreatic neuroendocrine tumours in Castilla-La Mancha (Spain) from 1995 to 2010

A. Marco[1], A. Vicente[1], L. Lohuibi[2], M. Alramadan[3], M. Aguirre[4], I. Gomez[5], S. Herranz[6] & C. Roa[4]
[1]Complejo Hospitalario Toledo, Toledo, Spain; [2]Hospital General Universitario de Albacete, Albacete, Spain; [3]Hospital Virgen de La Luz, Cuenca, Spain; [4]Hospital General Universitario de Ciudad Real, Ciudad Real, Spain; [5]Hospital General La Mancha Centro, Alcázar de San Juan, Spain; [6]Hospital Universitario de Guadalajara, Guadalajara, Spain.

Neuroendocrine gastroenteropancreatic tumours (GEP–NETs) are considered rare malignancies that are characterized by their ability to produce a great variety of peptides that may cause characteristic hormonal syndromes. In this study, we examined the epidemiology, clinical behaviour and prognostic factors of GEP–NETs identified in Castilla La Mancha (Spain) from 1995–2010.

Patients and methods
Two hundred and sixteen patients with GEP–NETs were analyzed in retrospect. Data regarding demographic characteristics, functional syndrome, diagnostic procedures,localization of the primary tumour and stage at diagnosis, therapeutic interventions and survival were collected.
Results
The estimated prevalence was 11.9 cases/1,00,000. 47.7% men, mean age 56.9 $\pm$ 18 years, 13% hypersecretion symptoms, 4.6% associated with MEN. No significant differences according to gender were observed. Incidental diagnostic in 47.6% of cases. Computed tomography (69.9%), ultrasound (47.7%) and octreotide scintigraphy (39.8%) were the most commonly imaging studies carried out. Chromogranin A and urinary 5-hydroxyindole acetic acid were done in 41% and 14.3% and were increased in 79.8% and 28.6% of tested patients respectively. Tumour characteristics are expressed in Table 1. Two-thirds of the patients underwent surgery. Local-regional therapies (chemoembolization, radiofrequency or other ablative techniques) were uncommon ($<$3%). 35.7% received systemic therapy (18.5% somatostatin analogues, 2.3% interferon, 13% chemotherapy).The median overall survival was 12 years, with 72.9% alive at 5 years (95% CI 65.5%–80.32%) and was significantly greater in younger patients, in patients with hormonal syndrome, early stage and lower grade. Prognosis differed according to tumour type and primary tumour site. Multivariate analysis confirmed Ki-67 index as the only independent prognostic factor for survival.
Conclusions
This study provided comprehensive information on the prevalence, management and outcome of this type of tumours from a region of Spain.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Leptin resistance and desensitization of hypophagia during prolonged inflammatory challenge are associated with high ptp1b expression in the hypothalamus**

B. Borges, R. Rorato, P. Marangon, E. Uchoa, J. Antunes-Rodrigues & L. Elias
School of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil.

Repeated exposure to lipopolysaccharide (LPS) leads to endotoxin tolerance. Desensitization of hypophagia in response to repeated exposure to endotoxin is related to an inability of leptin to phosphorylate STAT-3 protein. Protein tyrosine phosphatase 1B (PTP1B) activity is known to contribute to leptin resistance by inhibiting leptin signaling. In this study, we induced endotoxin tolerance, injecting repeated LPS doses (6LPS) (100 μg/kg, i.p.) in comparison with single (1LPS) treatment and control group treated with saline. Food intake, body weight and plasma leptin levels were determined after lps or saline injection. Brain tissue was collected from another set of rats for determination of PTP1B expression in the mediobasal hypothalamus by western blotting. A third set of rats was pre-treated with PTP1B inhibitor (3 nM/rat in 5rl, i.c.v.v) for determination of food intake and body weight after LPS or saline injection. 1LPS group, but not 6LPS group, showed decreased food intake and body weight, associated with an increased plasma leptin concentration. 6LPS, but not single LPS rats, showed higher expression of PTP1B in the mediobasal hypothalamus. Hypophagia and body weight loss induced by 1LPS were potentiated by PTP1B inhibitor, when compared with vehicle treatment. Interestingly, pre-treatment with PTP1B inhibitor induced hypophagia in animals treated with 6LPS. The present data suggest that increased PTP1B activity contributes to the development of leptin resistance during tolerance to endotoxin. The present model of prolonged inflammatory challenge may contribute to further investigations on mechanisms of leptin resistance.

**Obestatin does not modify weight and nutritional behavior but is associated to metabolic syndrome in old women**

M. Mora[1], M. Granada[2], R. Puig[2], M. Roca[3], E. Palomera[3], I. Olaizola[2], M. Julián[2], M. Serra-Prat[3] & M. Puig-Domingo[2]
[1]Hospital Clínic of Barcelona, Barcelona, Spain; [2]Hospital Germans Trias i Pujol, Badalona, Spain; [3]Hospital of Mataró, Mataró, Spain.

Introduction
Ghrelin gene products ghrelin and obestatin have apparent opposite orexigenic and anorexigenic effects, although this latter has not been firmly demonstrated for obestatin in humans. So far, no information has been reported in relation to its potential association to metabolic syndrome (MS).
Objective
To study obestatin concentrations in relation to nutritional parameters and eating behavior in old women.
Methods
One hundred and ten women (age 76.93 ± 6.32) from the Mataró Ageing Study were included. Individuals were phenotypically characterized by anthropometric variables, lipids, glucose, blood pressure, MS components (ATP-III criteria), anorexia assessed by a questionnaire and nutritional status by MNA-SF. A further reevaluation was performed at 2-years follow-up. Obestatin was measured by an IRMA.
Results
58.2% of the subjects had metabolic syndrome; at 2-y follow-up 24.1% had a weight loss > 5% and 7.2% > 10%, and 26.4% changed their MNA score to risk of malnutrition category. Anorexia was present in 38.4%. Obestatin levels were not related to either change of weight, MNA and anorexia, but a positive correlation was found with waist circumference (WC) ($P = 0.039$, rs = 0.200), to the absolute Δ between basal vs 2-y WC ($Ps < 0.001$; rs = 0.459), relative Δ between basal vs 2-y WC ($Ps < 0.001$; rs = 0.447); both absolute and relative WC Δ remained significant after adjusting for age and BMI. When obestatin was divided in quartiles, a significant lineal trend was observed in relation to WC ($P = 0.049$), absolute and relative Δ between basal vs 2-y WC (both $P < 0.01$). Glucose impairment was associated to obestatin (69.0% in 4th quartile had glucose impairment vs 44.4% in 1st; $P = 0.021$) and to MS by ATP-III (77.8% had MS in 4th quartile, 36% in 3rd, 60% in 2nd vs 57.7% in 1st; $P = 0.025$).
Conclusions
Obestatin is elevated in aged women bearing MS but is otherwise not associated to other nutritional parameters, weight loss or anorexia.

**Hypopituitarism 3 and 12 months after TBI and SAH**

A. Jonasdottir[1,2], P. Sigurjonsson[1,2], I. Olafsson[1], G. Sigthorsson[1], S. Karason[1,2], G. Karlsdottir[1] & H. Sigurjonsdottir[1,2]
[1]Landspitali University Hospital, Reykjavik, Iceland; [2]University of Iceland, Reykjavik, Iceland.

Introduction
Recent studies have found hypopituitarism (HP) to be a common complication of traumatic brain injury (TBI) and subarachnoid hemorrhage (SAH). In Iceland most patients with moderate TBI and all patients with severe TBI and SAH are transferred to Landspitali University Hospital (LSH). The aim of this study was to assess the prevalence of HP following TBI/SAH in Iceland, 3 and 12 months after the incidence.
Methods
All adult patients with moderate and severe TBI and SAH transmitted to LSH through one year were included, a total of 40 patients. Four patients died shortly after admission. Twenty-four patients accepted participation 3 months after TBI/SAH, 12 and 12 patients respectively. Twenty-five patients were screened 12 months after TBI/SAH, 14 and 11 patients respectively. Baseline hormone levels were measured and an insulin tolerance test (ITT) was performed. If ITT was contraindicated a Synachten test and a GHRH-arginine test were performed.
Results
Three months after TBI/SAH, 7 of the 24 patients (29.2%) had HP, 4 TBI patients (33.3%) and 3 SAH patients (25%). Two had (GHD), confirmed with GHRH-arginine test. One had elevated prolactin level. Two premenopausal women had oligomenorrhea. Three men had low testosterone and inappropiately low gonadotropin levels, one of them also had GHD. Twelve months after TBI/SAH, 6 of the 25 patients (24%) had HP, 5 TBI patients (35.7%) and 1 SAH patient. Three patients had GHD confirmed with GHRH-argine test (1 SAH patient). Two men had low testosterone and inappropiately low gonadotropin levels. One patient had mildly raised prolactin levels.
Conclusion
HP was confirmed in 29.2% and 24% of patients after 3 and 12 months respectively. Interestingly none of the GHD patients were diagnosed using the ITT. These results do emphasize the need for screening of pituitary function after TBI and SAH.

### Pituitary incidentaloma: clinical presentation and endocrine evaluation in a Spanish population

M. Alhambra Expósito, M. Gálvez Moreno, C. Tenorio Jiménez, P. Moreno Moreno & P. Benito López
Reina Sofia University Hospital, Córdoba, Spain.

Introduction
The incidence of previously unrecognized lesions within the pituitary has been studied by MRI. The data suggest that up to 10% of people have clinically unsuspected pituitary tumors, the majority being $<10$ mm. Currently, little information is available about the prevalence of incidentally-discovered sellar masses.
Objective
To perform a clinical audit on pituitary incidentalomas in order to establish an appropriate clinical approach to them.
Patients and Methods
Twenty three patients were referred to our endocrine department between January 1990 and July 2011 for evaluation of incidentally-discovered pituitary lesions. All patients underwent a complete history, physical examination, laboratory evaluation for hormone hypersecretion and hypopituitarism and a formal visual field examination. Clinical presentation, type of imaging used and endocrine status are evaluated retrospectively.
Results
Twenty three patients (16 female) with a mean age of $41.3 \pm 19.2$ years were included. 91.3% of them were diagnosed through brain magnetic resonance imaging (MRI) and 8.7% through Computed Tomography (CT). The reasons for head CT and/or MRI are shown in Table 1. 16 patients were diagnosed with non-functioning pituitary adenomas (69.5%), two with microprolactinomas (8.6%), two with hypophysitis (8.6%), one with Cushing's Disease (4.3%) and one with craneopharingyoma (4.3%). Of 16 patients diagnosed with non-functioning pituitary adenoma (mean size $7.9 \pm 6.3$ mm, range 2–23 mm), 13 patients had a microadenoma without pituitary dysfunction. Of the three macroadenomas, 2 had hypogonadotrophic hypogonadism.
Conclusions
Despite the high prevalence of pituitary incidentalomas, the literature reporting on the natural history of this entity is scarce. In our study we found an important prevalence of endocrine abnormalities whose adequate diagnosis is essential.

### Comparison of the effect of chronic restraint and crowding on hypothalamic-pituitary-adrenocortical response to acute restraint stress

P. Rachwalska, J. Tadeusz, A. Gadek-Michalska & J. Bugajski
Institute of Pharmacology PAS, Krakow, Poland.

Stressful events affect numerous physiological processes including central nervous system and endocrine responses. Repeated stress alters basic mechanisms for the maintenance of hypothalamic-pituitary-adrenocortical (HPA) homeostasis. The purpose of the present study was to determine whether, and to what extent prior repeated restraint or social crowding stress during 3 days affects the HPA response to an acute short-lasting restraint stress. Male Wistar rats were restrained 2 times a day for 3 days or subjected to crowding stress for 3 days before exposure to acute restraint stress in metal tubes for 10 min. Immediately after the restraint or 1 h, 2 and 3 h later the rats were decapitated and their trunk blood was collected for the measurement of plasma ACTH and corticosterone levels. Chronic stress alone (restraint 2 x 10 min/day for 3 days and crowding for 3 days) induced a moderate increase in plasma ACTH level compared to the corresponding level in control rats without prior stress exposure. Acute restraint stress for 10 min considerably increased plasma corticosterone and ACTH levels immediately after restraint and no substantial increase was observed 1, 2 or 3 h after stressor termination. Restraint and crowding for 3 days significantly and to a similar extent inhibited the restraint stress-induced increase in ACTH and corticosterone secretion. These results indicate that repeated restraint or crowding stress potently attenuates the acute restraint stress-induced stimulatory action of the HPA axis what suggests adaptive action of moderate stress on the HPA axis response to acute stress. The results also suggest that a short-lasting hypersecretion of corticosterone during psychological stress may induce a prolonged feedback inhibition of the HPA axis activity.

### Circulating interleukin 6 and soluble forms of interleukin 6 receptor and glycoprotein 130 in women with anorexia nervosa

M. Karczewska-Kupczewska[1], I. Kowalska[1], A. Nikolajuk[1,2], A. Adamska[1], E. Otziomek[1], M. Gorska[1] & M. Straczkowski[1,2]
[1]Medical University of Bialystok, Bialystok, Poland; [2]Institute of Animal Reproduction and Food Research, Polish Academy of Sciences, Olsztyn, Poland.

Introduction
Anorexia nervosa (AN) is an eating disorder, resulting in sustained low weight and marked decrease in fat mass. Interleukin 6 (IL-6) may play a role in appetite, energy expenditure and body weight control in central nervous system. IL-6 acts through binding with membrane receptor (IL-6R) and activates glycoprotein 130 (gp130) signaling. Both IL-6R and gp130 are present in the blood in the soluble forms (sIL-6R and sgp130, respectively). sIL-6R sensitizes cells towards IL-6, whereas sgp130 inhibits gp130 signaling. The aim of the present study was to estimate circulating IL-6/sIL-6R/sgp130 system and its relationships with body weight and resting energy expenditure (REE) in AN women.
Methods
We examined 19 women with AN and 27 healthy normal weight female controls. Euglycemic hyperinsulinemic clamp, indirect calorimetry and the measurement of serum IL-6, sIL-6R and sgp130 concentrations were performed in all the subjects.
Results
We did not observe differences in insulin sensitivity between AN and control subjects. REE was decreased in AN women ($P<0.001$). Serum IL-6 was higher in AN women in comparison with control group ($P=0.04$). Serum sIL-6R was lower ($P=0.009$) and serum sgp130 was higher ($P=0.004$) in AN women in comparison with controls. In the entire study population, BMI and REE were inversely related to IL-6 ($r=-0.45$, $P=0.02$ and $r=-0.62$, $P<0.001$, respectively) and positively to sIL-6R ($r=0.36$, $P=0.015$ and $r=0.42$, $P=0.013$, respectively). Correlation between IL-6 and REE was also present in AN group ($r=-0.55$, $P=0.013$).
Conclusions
Increased IL-6 in AN seems to be compensated by the changes in sIL-6R and sgp130 which are directed towards inhibition of IL-6 action. The balance between these factors might play a role in the regulation of energy expenditure in AN.

### Ghrelin and growth hormone levels are decreased in Saudi autistic children

A. Alhader[1], F. Al-Zaid[1,2] & L. AL-Ayadhi[1,2]
[1]King Saud University, Riyadh, Saudi Arabia; [2]College of Medicine, King Saud University, Riyadh, Saudi Arabia.

Introduction
Autism is a neurodevelopmental disorder with a pathogenesis that is not completely understood. Although a genetic origin has been recognized, a potential role for environmental factors, immune dysfunctions, and variations of hormonal levels was suggested. Ghrelin is a peptide hormone which can stimulate growth hormone (GH) release by activating GH secretagogue receptor. In addition, ghrelin exerts neuroprotective effects, inhibits apoptosis in hypothalamic neurons and has positive effects on learning and memory.
Design
A case-control study was employed to investigate acylated ghrelin (AG), des-acyl ghrelin (DAG), leptin and growth hormone (GH) levels in Saudi autistic children.
Methods
We investigated AG, DAG, leptin and GH in 31 Saudi autistic male patients in comparison to those levels in 28 healthy age-matched children. Hormones were measured in blood samples using commercially available ELISA kits. Independent t-test was used to investigate statistical significance in study groups with a (p) value of less than 0.05 was considered significant.
Results
In autistic group AG, DAG and GH levels were significantly lower compared to the control group by 31.6, 28.4, and 47.9%, respectively. Leptin concentration was significantly higher by 106.2% in autistic children. While leptin levels showed positive correlation ($r = +0.57$) with body mass index (BMI) in autistic group, DAG levels had no significant correlation with BMI in the same group.
Conclusion
Our results demonstrate a novel decrease of AG, DAG and GH levels in autistic children in comparison with age-matched control group. Considering ghrelin's capacity to affect neuroinflammatory and apoptotic processes that were shown to be linked to autism, this study indicates a potential role for ghrelin in the pathogenesis of autism and further studies are needed to elucidate the role of ghrelin as a diagnostic biomarker and a potential therapeutic agent in autism.

## P1143

### Basal and stimulated GH secretion in active cushing's syndrome and 2 years after remission

A. Picu[1], V. D'Angelo[1], I. Karamouzis[1], R. Berardelli[1], E. Marinazzo[1], B. Fussotto[1], C. Zichi[1], R. Giordano[2], E. Ghigo[1] & E. Arvat[1]
[1]University of Turin, Turin, Italy; [2]University of Turin, Orbassano, Italy.

Impaired GH secretion occurs in Cushing's syndrome (CS), reflecting hypothalamic and pituitary alterations, without IGF-I impairment. Obesity is known to blunt GH release, leading to BMI-related tests for GHD. Evaluation of GH in CS after remission is difficult, due to chronic previous hypercortisolism and persistent overweight. Aim of this study was to evaluate in 22 patients with Cushing's syndrome (16 Cushing disease, CD, 6 adrenal adenomas, CS) GH response to GHRH + ARG during active disease and 2 years after surgical-induced remission, according to BMI-related cut-off levels. Basal IGF-I and pituitary function were also assayed. Active disease: 10 patients were obese (45%), 8 overweight (36%), 4 normal (18%). A severe GHD was shown in 12 patients (54%) (8 CD and 4 CS, 3 obese, 6 overweight and 3 normal). IGF-I were in the normal range. 8 CD showed 1 or multiple pituitary deficiencies.
Remission
5 patients persisted obese (22,7%), 7 overweight (31%) and 10 became normal (45%). A severe GHD was shown in 8 patients (36%, CD only, 2 obese, 3 overweight, and 3 normal). 13 CD showed 1 or more pituitary deficiencies. No CS patient showed pituitary deficiencies. GHRH + ARG-induced GH levels were independent of either age/BMI. No correlation between GH peaks and HPA parameters were found, while IGF-I levels were positively correlated ($P < 0.01$) with UFC during active disease and after surgery.
In conclusion
(1) CS shows an impaired GH release even according to BMI-related cut-off levels, together with a dissociation between GH and IGF-I secretion, due to a stimulatory cortisol action on the liver; (2) chronic hypercortisolism seems to override the influence of age and BMI on GH/IGF-I activity; (3) glucocorticoid-induced GHD is no longer evident 2 years after remission, thus suggesting that this could be a good time for the evaluation of GHD in patients suspected for surgery-induced hypopituitarism.

### Overly rapid correction of severe hyponatremia with vasopressin receptor antagonists poses a risk of inducing osmotic demyelination syndrome

H. Takagi, Y. Sugimura, H. Suzuki, A. Kiyota, K. Fukuoka & Y. Oiso
Nagoya University Graduate School of Medicine, Nagoya, Japan.

Rapid correction of chronic hyponatremia can cause osmotic demyelination syndrome(ODS). Recent days, vasopressin receptor antagonists(VAs) are clinically used for the treatment of congestive heart failure or hyponatremia including SIADH. To date, few cases of ODS caused by VAs have reported; however, it is presumed that the treatment with VAs for severe hyponatremia may be associated with an increased risk of ODS. Therefore, in this study, we investigated whether rapid correction of hyponatremia with tolvaptan has a risk of inducing ODS in SIADH model rats. Hyponatremia was induced by liquid diet feeding and subcutaneous desmopressin infusion using osmotic pumps. Seven days later, hyponatremia(approximately 105 mEq/l) was corrected by the following ways; i) bolus administration of hypertonic saline (HS group), ii) oral administration of tolvaptan 1 mg/kg (T1 group), iii)5 mg/kg (T5 group), iv)10 mg/kg (T10 group), or v)removal of osmotic pumps (PO group). The serum sodium levels were increased approximately by 30 mEq/l in 24 h in all groups and there was no significant difference in the degree of sodium elevation. Accordingly, most rats in all groups showed serious neurological impairment. Five days after the correction, the incidence of neurological findings including gait abnormality, paralysis, seizure, or death was respectively 75%, 50%, 66%, 66%, and 88% in HS, T1, T5, T10, and PO group, respectively. Immunohistochemical analysis confirmed the demyelination and the accumulation of microglia in the cerebral cortex and the neighborhood of the red nucleus in the midbrain in all groups. These results suggest that overly rapid correction of severe hyponatremia with a relatively high dose of VAs associated with the blockage of vasopressin action as well as hypertonic saline poses a risk of inducing ODS and that clinicians using VAs to treat hyponatremia need to monitor serum sodium carefully to avoid overcorrection.

## P1145

### Relationship between leptin, markers of bone turnover, bone mineral density, and body weight in patients with schizophrenia treated with long acting risperidone (LAIR)

M. Doknic[1,3], N. Maric[2,3], D. Britvic[2,3], S. Pekic[1,3], D. Miljic[1,3], M. Stojanovic[1], A. Damjanovic[2,3], M. Jasovic-Gasic[2,3] & V. Popovic[1,3]
[1]Clinic for Endocrinology, Clinical Center of Serbia, Belgrade, Serbia; [2]Clinic for Psychiatry, Clinical Center of Serbia, Belgrade, Serbia; [3]University of Belgrade, Belgrade, Serbia.

Introduction
Leptin, adipose-tissue-derived hormone has a prominent role in bone remodeling by activating, through CNS relay, the sympathetic tone which inhibits bone formation. Schizophrenia is a CNS disease associated with low bone mass and changes in bone remodeling. Risperidone, atypical antipsychotic, may be related to increase in body weight (BW). Increased BW is thought to be protective to the bone.
Aim
To determine relations between leptin, bone remodeling parameters (osteocalcin and C-terminal telopeptide of type I collagen-CTx), bone mineral density (BMD-

lumbar spine et femoral neck) and BW in patients with schizophrenia treated with LAIR for at least 6 months up to 3 years.
Patients
Cross-sectional study, we investigated 26 out-patients(12 males, age 31.3±1.3 years, BMI 28.2±1.0 kg/m2) with stable schizophrenia in real-life conditions. They were treated with LAIR for mean 18.0±1.6 months with mean dose 38±2 mg/two weeks. Thirty-five matched subjects (11 males) served as healthy controls.
Results
The increase in BW was confirmed in 14(54%) patients treated with LAIR on average 8.7±1.6 kg. Leptin levels adjusted for BMI in females were significantly higher in patients than in healthy female subjects ($P=0.018$). Significant positive correlations between leptin and BW was found in patients and healthy controls. BMD tended to be lower but did not reach significance in patients with schizophrenia ($p=0.094$). CTx, was slightly increased in patients on LAIR ($P=0.023$). Significant negative correlation between leptin and osteocalcin ($r=-0.376$, $P=0.050$) was found only in patients with schizophrenia. Leptin did not correlate with BMD in schizophrenic patients while it did in healthy subjects (femoral neck $r=0.366$, $P=0.031$).
Conclusion
Higher serum leptin levels in female patients after adjusting for BMI may suggest leptin resistance. Leptin has been shown to inhibit bone formation so it is tempting to speculate that weight gain together with leptin resistance during long term therapy with LAIR may be protective to the bone in patients with schizophrenia.

## P1146

**Estrogen receptor alpha PvuII polymorphism in female acute stroke patients: no associations with disease severity and short-term prognosis**

T. Pappa[1], K. Vemmos[1], E. Mantzou[2], K. Stamatelopoulos[3], K. Saltiki[1], E. Anastasiou[1] & M. Alevizaki[1]
[1]"Alexandra" General Hospital, Athens, Greece; [2]Evgenideion Hospital, Athens, Greece; [3]"Alexandra" General Hospital, Athens, Greece.

Introduction
Several studies have examined the association of the common PvuII polymorphism of the estrogen receptor alpha (ERα) gene with the risk of stroke. Data linking the polymorphism with the severity and outcome of cerebrovascular disease is lacking. We looked for possible associations of the PvuII polymorphism with stroke severity and short-term prognosis in a cohort of female stroke patients.
Patients-Methods
We studied 302 postmenopausal Caucasian female patients suffering an acute stroke, hospitalized in two tertiary hospitals over a period of two years. In all patients, a detailed medical history and recording of classical stroke risk factors was performed. The neurological severity on admission was assessed using the National Institutes of Health Stroke Scale and the one month functional outcome using the modified Rankin Scale. ERα polymorphism at position c.454–397 T>C (PvuII) was genotyped. Circulating androgen and estradiol levels were measured in all patients, the latter using a high sensitivity assay.
Results
The prevalence of CC genotype was 21%, CT 50% and TT 29%. There was no difference in the neurological severity on admission or in the short-term functional outcome and mortality between the three genotype groups. No association was found between the PvuII polymorphism and classical stroke risk factors. Estradiol levels were higher with increasing frequencies of the C allele ($P$ 0.04). An association of the CC genotype with venous thromboembolism history was recorded ($P$ 0.05).
Conclusions
There was no association between the PvuII polymorphism and stroke severity and short-term outcome in the studied female stroke population. One cannot exclude the possibility that the long-term estrogenic action reflected by the genetic polymorphism may be attenuated in older age.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1147

**The incidence of acromegaly in iceland from 1955 through 2010**

G. Hoskuldsdottir, S. Fjalldal & H. Sigurjonsdottir
Landspitali University Hospital, Reykjavik, Iceland.

Objective
Acromegaly is a rare disease with multiple serious comorbidities. The aim of this study was to gather information on patients diagnosed with Acromegaly from 1955 through 2010.
Materials and methods
Information on patients with pituitary adenomas diagnosed from 1950 has aldready been gathered and and imported to patient journals at the National University Hospital in Iceland. In this retrospective study information on patients diagnosed with Acromegaly in the years 1955–2010 was gathered from these journals as well as from files at private clinics where some patients recieved follow-up care. All practising endocrinologists in Iceland were contacted to make sure all known cases were included.
Results
Forty-six ($n=46$, 19 women, 27 men) were diagnosed with Acromegaly during the study period. During the years 1955–1964: 2 patients were diagnosed; 1965 – 1974: 3 patients; 1975–1984: 7 patients, 1985–1994: 11 patients, 1995–2004: 7 patients and in the last 7 years, from 2005–2010: 16 patients. The average age at diagnosis was 43.11 years. Seven patients have died. Symptoms had been present for more than three years in most cases but in three cases for at least 15 years. The most common symptoms at presentation were enlargement of hands and feet as well as changes in facial features. At diagnosis, 21 patients had hypertension.
Conclusion
We found the incidence for Acromegaly to be much higher than earlier reported. During the last 6 years of the study 8.6 patients were diagnosed per million per year which is more than two times higher than what should be expected according to earlier reports (3–4 cases per million per year). Interestingly almost 46% of the patient population had hypertension at diagnosis indicating the importance of endocrine disorders in the aetiology of hypertension.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1148

**The incidence of hypoglycaemia in non-diabetic hospital patients outside critical care estimated by a capture-recapture technique: retrospective analysis**

K. Nirantharakumar[1,2], T. Marshall[1], J. Hodson[2], P. Narendran[1,2], J. Deeks[1], J. Coleman[1,2] & R. Ferner[1,3]
[1]University of Birmingham, Birmingham, United Kingdom; [2]University Hospital Birmingham, Birmingham, United Kingdom; [3]City Hospital, Birmingham, United Kingdom.

Introduction
Unexplained or a cluster of non diabetic hypoglycaemia has at times been the only clue to malicious use of Insulin in hospitals. We wished to establish the incidence of hypoglycaemia in non-diabetic adult patients outside the intensive care unit (ICU) in a 1200-bed university hospital.
Methods
We retrospectively analysed data for 2010 from three distinct sources to identify patients: bedside and laboratory blood glucose measurements; medication records for those treatments (high-strength glucose solution and glucagon) commonly given to reverse hypoglycaemia; and diagnostic codes for hypoglycaemia. We excluded from the denominator admissions of patients with a diagnosis of diabetes or prescribed diabetic medication. The denominator included patients admitted to ICU, as they almost always have a period of stay outside ICU (susceptible population).Case notes of all patients identified were reviewed to ascertain hypoglycaemia and where it occurred. We used capture-recapture methods based on log linear models to establish the likely true rate of hypoglycaemia in non-diabetic in-patients outside ICU. Analysis was carried out at different cut-off points for hypoglycaemia. We also recorded co-morbidities that might have given rise to hypoglycaemia.
Results
Among the 37 898 admissions we identified a total of 71 admissions of non-diabetic patients with hypoglycaemia at or below 3.3 mmol/l and 37 admissions at or below 2.7 mmol/l. Using capture-recapture methods the estimated incidence was 50 (95% CI 33–93) and 13 (95% CI 11–19) per 10 000 admissions at

3.3 mmol/l and 2.7 mmol/l cut-off values. Admissions of patients aged above 65 years were 50% more likely to have an episode of hypoglycaemia. Commonest relevant co-morbidities linked to hypoglycaemia were sepsis, renal disease, alcohol dependence, pneumonia, liver disease, cancer and self harm with hypoglycaemic agents.
Conclusion
Hypoglycaemia is rare in non-diabetic patients, and usually associated with important co-morbidity. Our study suggests a way to monitor an unusual increase in hypoglycaemia in hospital.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1149

### An initial dose of 7.5 mg Tolvaptan is safe and effective in the treatment of hyponatremia caused by SIADH

M. Cuesta, E. Gomez-Hoyos, C. Montañez, P. Martin, C. Marcuello, P. de Miguel, A. Calle & I. Runkle
Hospital Clinico San Carlos, Madrid, Spain.

Tolvaptan (TV), an ADH V2-receptor blocker, is useful in treating SIADH-induced hyponatremia. Maximum aquaresis following 15 mg TV occurs on day 1, when excess body water is greatest. This can cause a sharp rise in natremia, and poses a risk of overcorrection. Our aim was to evaluate an initial dose of 7.5 mg.
Methods
We studied 7 hospitalized patients with SIADH (4 females), median age 80 (57–95), with nadir natremias ($Na_p$) ranging from 111 to 126 mmol/l, $Na_u$ 39–92 mmol/l, $Osmolality_p$ 224–257 mOsmol/kg, $Osmolality_u$ 152–462 mOsmol/kg. Patients were euvolemic, with normal adrenal, thyroid, and renal function. 5 patients with initial $Na_p < 120$ mmol/l were first treated with 3% hypertonic saline and/or furosemide and oral salt. All 7 had presented an inadequate response to water restriction, or a Furst formula predicting non-response. TV dose was 7.5 mg (day 1), and was increased to 15 mg on day 2 (patients 2-7) or on day 3 (patient 1).
Results
$Na_p$ increments are all calculated from baseline. Day 1: Median baseline $Na_p$: 126 mmol/l (121–133). After 6 hours median $Na_p$ variation was 2 mmol/l (0–4), with median $Na_p$ 128 mmol/l (122–135). Day 2: median $Na_p$ increase was 5 mmol/l (1–10), median $Na_p$ 134 mmol/l (125–136). Day 3: patients 2–7: Median $Na_p$ rise was 7 mmol/l (5–12), Median $Na_p$ 134 mmol/l (128–138). Patient 1's $Na_p$ had risen 6 mmol/l on day 3 and 13 mmol/l on day 4. 12 h $Na_p$ was determined in the first 3 patients, descending 1 mmol in 2/3 and rising 2 mmol in a 3rd vs 6-h natremia. Maximum 24-h and 48-h $Na_p$ increments were 10 and 12 mmol/l respectively. Side Effects: one woman experienced intense thirst.
Conclusion
In our patients, starting tolvaptan at a dose of 7.5 mg was both safe and effective.
Evolution of natremia following initiation of tolvaptan therapy

**Table 1**

| Patient | Nadir $Na_p$ - mmol/l | Baseline (Day 1) $Na_p$ - mmol/l | 6-hour $Na_p$ (increase from baseline) mmol/l | Day 2 $Na_p$ (increase from baseline) mmol/l | Day 3 $Na_p$ (increase from baseline) mmol/l |

### Role of endocrine nurse in simultaneous bilateral inferior petrosal sinus sampling (BIPSS): single center experience

M. Pantovic, M. Stamenovic, S. Simic, V. Zivkovic, M. Tosic, B. Jevtic & A. Kujovic
Clinic for Endocrinology. Diabetes and Metabolic Diseases, Belgrade, Serbia.

Background
Simultaneous bilateral petrosal sinus sampling is valuable in differentiating the etiology of ACTH dependent Cushing's syndrome. It is used to locate the source of ACTH production when pituitary magnetic resonance imaging is negative.
Nurses' role
Specially trained endocrine nurses are part of the team for inferior petrosal sinus sampling. They prepare necessary material and documentation, mark all test tubes, handle the samples taken from both catheters record the time and localization of each sample, take samples from the peripheral vein, give iv bolus of CRH and keep track of time for sampling after CRH administration. Nurses are also responsible for adequate and timely transportation of samples for ACTH (on ice) and cortisol measurement to laboratory and proper material submission to the lab. They prepare patient for the procedure and monitor him/her through and after the procedure.
Aim
To analyze results of all bilateral inferior petrosal venous sampling studies performed in our center during period 2009/2010.
Patients and methods
In six patients with ACTH dependent Cushing's syndrome BIPSS was performed. Patients' records, catheter and laboratory protocols were analyzed retrospectively for the period 2009/2010.
Results
During 2009/2010 period 7 studies were performed in our (tertiary) center. In all 7 cases simultaneous bilateral petrosal venous sampling with CRH administration was performed. In two patients whole body venous sampling was performed disclosing the ectopic source of ACTH secretion in one patient. In two patients unilateral venous malformations were encountered and samples were taken from the inferior jugular vein. In one patient results were inconclusive and study was repeated. In 5 cases results of the catheter study confirmed the diagnosis of Cushing's disease.
Conclusion
Role of endocrine nurse in coordination with other members of the team is important for the success of catheter studies in patients with Cushing's syndrome.

### PTHrP-induced hypercalcemia: a rare and challenging presentation in metastatic pancreatic neuroendocrine tumour

S. Pan[1], S. Curran[1], P. Corrie[2] & H. Simpson[1]
[1]Institute of Metabolic Science, Addenbrooke's Hospital, Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK; [2]Cambridge University Hospitals NHS Foundation Trust, Cambridge, UK.

Introduction
Hypercalcemia due to parathyroid-hormone-related-peptide (PTHrP) is rare in neuroendocrine tumours.
A 63-year-old lady initially presented to ENT surgeons with symptoms of reflux, dysphagia, and weight loss. Past medical history included hysterectomy eight years previously for uterine prolapse. There was no family history of note. Investigations revealed corrected calcium was elevated at 2.94 (2.1–2.5) mmol/l. ALP: 184 (30–135) U/l. CA19-9 was normal. PTH was suppressed <3 (14–72)

ng/l. PTHrP was elevated 4.1 (0–1.8) pmol/l.
CT scan demonstrated an 11×9 cm pancreatic mass arising from the tail of pancreas involving spleen, left kidney, left colon and para-aortic lymph nodes. There were multiple lesions in the liver. EUS guided FNA was performed revealing well differentiated neuroendocrine carcinoma of the pancreas. Subsequent biochemistry revealed chromogranin-A 154 (0–60) pmol/l, Chromogranin B 152 (0–150) pmol/l. Urinary 5-HIAA was normal.
The tumour was locally advanced and surgical resection was not possible. Patient was treated with somatostatin analogues for tumour stasis of NET. Hypercalcemia was treated with intravenous pamidronate but recurred rapidly and was >3 mmol/l 1 week after. Prednisolone 10–15 mg po od was added with no improvement in calcium concentration. Zolendronic acid was administered with a rapid and sustained normalisation of calcium to 2.25 mmol/l.
Conclusions
Hypercalcemia due to parathyroid hormone related-peptide (PTHrP) is rare in neuroendocrine tumours. Managing hypercalcemia was initially challenging however responded to zolendronic acid. Sunitinib is being considered as systemic therapy and it will be interesting to see if calcium concentration falls with use of this agent.

## P1152

**Profile of neurosarcoidosis observed in internal medecine practice**

D. Zemmour, D. hakem, S. Fédala-Haddam, M. Yagoubi, M. Abada-Bendib, F. Kessaci & A. Berrah
Dr Mohammad-Lmaine Debaghine, Bab-El-Oued Universitary Hospital, ALGIERS, Algeria.

Introduction
Neurological achievements of sarcoidosis or neurosarcoidosis 'NS' is rare (5%), but revealing of the disease in 50%. Neurological and endocrinous signs vary according to the topography of the damage. Cerebral forms results from the infiltration of the meningeal spaces, the granulomatous process spreads secondarily in the cerebral and spinal nerves, in the vessels and in the cerebral parenchyma. NS are individualized better with the contribution of the neuro-imaging. Precocity of the diagnosis improves the prognosis.
Objectives
To review through some case reports clinical polymorphism of the NS and the diagnostic and therapeutic difficulties observed.
Patients and methods
Retrospective Study over five consecutive years on January 2005-December 2010.
Results
In total, 11 inclusive patients, 9 Women and 2 Men, age means 37 2 years (24–56). Achievement is encephalic (5), medullar (2) and orbital (3). Its joins to a hypothalamic-pituitary localization (4), thoracic (5), cutaneous (4, liver (2), eyes (3) and is inaugural at three patient's. Revealing clinical pictures are intracranial hypertension 'ICH' (4), inflammatory tumour of the orbit (2), myelitis (2) and endocrine's signs as insipid diabetes or hypopituitarism (4). Treatment imposes hormonal substitution, immunosuppressive drugs (4) and peritoneal derivation (2). The course is fatal (1), conducts to cognitive disorders (2), to definitive endocrine insufficiency (3), sever osteoporosis (3), optic atrophy (1) and to meningeal infections (2).
Discussion
NS is polymorphous with hypothalamic-pituitary achievements, ICHT, pseudo-tumour of the orbit, etc. witch constitute circumstances of diagnostic wandering, and sometimes compromise the prognosis by their resistance of corticoadrenal therapy and the secondary infections caused by a lymphocytopenia and an adverse effects of therapy.
Conclusion
NS diagnosis is based (after exclusion any infectious or tumour process), on the identification of a neurological localization accessible to identify the sarcoidal granuloma. MRI is at present a decisive element for the diagnosis and the monitoring of the NS. Considering the functional and vital risks of this a corticotherapy must be prematurely prescribed.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Effects of estradiol on tight junction in the human breast cancer cell line MCF-7**

J. Jiménez-Salazar[1], L. González-Nuñez[1], A. Luna-López[2], M. Königsberg-Fainstein[1], L. Gómez-Quiroz[1], R. Lazzarini-Lechuga[1], A. Zentella-Dehesa[3,4] & P. Damián-Matsumura[1]
[1]Metropolitan Autonomous University, Mexico City, Mexico; [2]Geriatric institute, Mexico City, Mexico; [3]National Institute of Medical Sciences and Nutrition, Mexico City, Mexico; [4]National Autonomous University, Mexico City, Mexico.

Tight junctions (TJ) exist as macromolecular complexes comprised of several types of membrane proteins, cytoskeletal proteins and signaling molecules. Recently, it has been observed that some components are regulated during epithelial–mesenchymal transition in cancer cells; however, the effects of estradiol ($E_2$) have been poorly studied. This study sought to determine the role of $E_2$ on the expression and cell localization of the TJ-associated proteins Zonula Occluden-1 (ZO-1), occludin and the ZO-1-associated transcription factor (ZONAB), and in the activation of the epidermal growth factor receptor-2 (HER-2) and Rous sarcoma virus (SRC), in the human breast cancer cell line MCF-7. We demonstrated that $E_2$ increases ZO-1 and ZONAB mRNA and protein expression after 6 h of incubation, and HER-2 after 24 h. Since it is known that ZO-1 and ZONAB act as co-activator and transcription factor respectively, in the promoter of the HER-2 gene, immunolocalization assays (Western blot and confocal microscopy) were performed. After 30 min of incubation with $E_2$, maximal translocation of ZO-1 and ZONAB proteins to cell nucleus was observed. This effect was not precluded when an estrogen receptor (ER) antagonist was used; therefore, ZO-1 and ZONAB protein translocation can be associated to SRC protein, since active SRC increased significantly after $E_2$ incubation. We also demonstrated that $E_2$ decreased dramatically occluding levels in MCF-7 cells, effect that can be associated with an increase in paracellular permeability. We conclude that $E_2$ can induce genomic and non-genomic changes in TJ proteins that induce epithelial-mesenchymal transition and cell proliferation in breast cancer cells.

**Insufficiency of the chaperones GRP78 and GRP94 links TLR4 signaling to endoplasmic reticulum stress**

A. Coope, M. Milanski, A. Arruda, L. Ignacio-Souza, G. Anhê & L. Velloso
[1]UNICAMP, Campinas, Brazil.

TLR4 activation and the induction of endoplasmic reticulum stress (ERS) are two of the most important mechanisms connecting excessive dietary fat with insulin resistance. TLR4 activation is a primary event in the induction of cellular stress that contributes to increased inflammatory gene expression in metabolic diseases. However, the mechanisms linking these molecular events are unknown. The chaperones GRP78 and GRP94 play an important role during the assembly of newly translated TLR4 molecules. In addition, GRP94 escorts TLR4 to the cell membrane. Under prolonged activation the demand for newly synthesized TLR4 molecules increase, and thus, the demand for new chaperones. Therefore, we hypothesized that under increased activation of TLR4 the synthesis of the protein would not be matched by the expression of chaperones, thus, triggering ERS. To test this hypothesis, the monocyte cell line THP-1 was incubated with LPS and the expression/activation of proteins involved in ERS was determined. Time-course experiments revealed that LPS led to a 2.5-fold increase of TLR4 expression starting as early as 8 h, peaking after 24 h and remaining significantly increased after 48 h. The expression of GRP78 underwent a three-fold increase with a sharp rise at 24 h, while GRP94 increased by only 1.5-fold with a peak at 2 h and an early return to base-line levels. None of the chaperones were increased after 48 h. LPS-induced ERS was detected as early as 4 h after stimulus as detected by the evaluation of PERK/eIF2α, IRE1 and ATF6 pathways. Strong signals of ERS were still present after 48 h. The pre-incubation of THP-1 in glucose-deprived medium produced 2.5- and 11-fold increases of GRP94 and GRP78, respectively. Upon glucose deprivation, LPS could no longer induce ERS. Inhibition of chaperone expression by siRNA completely abrogated the effect of glucose deprivation to protect cells from LPS-induced ERS. Thus, insufficient LPS-induced chaperone expression links TLR4 signaling to ERS.

**Central diabetes insipidus associated with impaired renal aquaporin-1 expression in mice lacking the oxysterol receptor liver X receptor β**

C. Gabbi[1,2] & J. Gustafsson[1,2]
[1]University of Houston, Houston, Texas, USA; [2]Karolinska Institutet, Houston, Sweden.

We have previously shown that in pancreatic ductal epithelial cells, the expression of the water channel aquaporin-1 is under the control of the oxysterol receptor liver X receptor β. The aim of the present study was to investigate water balance in mice lacking each LXR isoform.
Given free access to water, LXRβ−/− mice demonstrated an abnormal daily excretion of highly diluted urine, polyuria, with increased water intake compared to WT animals, polydipsia. After 24-h dehydration, LXRβ−/− mice were able to decrease the 24-h urine volume and to concentrate urine but the urine output was higher than that in dehydrated WT mice. Interestingly, in LXRα−/− there were no detectable defects in urine volume and concentration.
Polyuria and polydipsia are the clinical features of a condition called diabetes insipidus that according to the etiology may be classified in central and nephrogenic. The first one results from a defective production/secretion of the antidiuretic hormone arginine vasopressin while the nephrogenic one is due to a defective vasopressin action in the kidney.
To pinpoint the genesis of the LXRβ-diabetes insipidus, WT and LXRβ−/− mice were injected intraperitoneally with arginine vasopressin. There was no change in the urine volume after 3 and 6 h, but the urine osmolality was significantly increased at 6 h in LXRβ−/− mice indicating a partially conserved kidney capability to respond to vasopressin. Therefore the central vasopressin production was investigated. Surprisingly, in LXRβ−/− mice, there was an important loss of vasopressin-producing neurons both in the supraoptic and in paraventricular nuclei of the hypothaluamus. In addition, the vasopressin content of the 24-h urine was lower than that in WT mice, indicating a central genesis of their diabetes insipidus. Moreover, in addition to the central effects, there was a nephrogenic involvement since aquaporin-1 expression in the kidney was reduced in LXRβ−/− mice.
In conclusion this paper shows that LXRβ plays a crucial role in regulating water balance both centrally and peripherally and it can be suggested both as genetic predisposition in human central diabetes insipidus and as possible therapeutic target in disorders of water balance.

**PAK1-Nck interaction regulates prolactin-dependent cyclin D1 promoter activity**

M. Diakonova, J. Tao, P. Oladimeji & L. Rider
University of Toledo, Toledo, Ohio, USA.

Introduction
Prolactin (PRL) is a hormone utilized at both endocrine and autocrine levels. PRL regulates cyclin D1 expression through JAK2-mediated transcriptional activation of cyclin D1 promoter. Serine–threonine kinase PAK1 is also implicated in regulation of cyclin D1 gene expression. We previously showed that PAK1 binds to and is Tyr phosphorylated by JAK2. Herein we linked PRL and PAK1 as JAK2 substrate to stimulation of cyclin D1 promoter activity.
Methods
Two-dimensional peptide mapping and LC–MS/MS mass spectrometry identified three Tyr(s) of PAK1 (153, 201 and 285) which are phosphorylated by JAK2. We measured induction of cyclin D1 promoter activity in T47D cells expressing cyclin D1 promoter-luciferase and either PAK1 WT or PAK1 Y3F (three tyrosines are mutated). We used confocal immunofluorescence and cell fractionation to study a role of PAK1 nuclear localization for cyclin D1 promoter regulation.
Results
PAK1 activates cyclin D1 promoter in response to PRL. Mutation of JAK2 phosphorylation sites on PAK1 decreases both PRL-induced PAK1 nuclear translocation and cyclin D1 promoter activity by 55%. Mutation of PAK1 nuclear-localization signals (NLS) decreases PRL-induced cyclin D1 promoter activity by 46%. A PAK1 Y3F mutant lacking NLSs decreases cyclin D1 activity by 68% suggesting that there is another PAK1-dependent mechanism to activate cyclin D1 promoter. We found that adapter protein Nck sequesters PAK1 in cytoplasm and co-expression of PAK1 and Nck inhibits amplifying effect of PRL-induced PAK1 on cyclin D1 promoter activity (95% inhibition). This inhibition is partially abolished by disruption of PAK1-Nck binding.
Conclusion
We propose two PAK1-dependent mechanisms to activate cyclin D1 promoter activity in response to PRL: via nuclear translocation of Tyr-phosphorylated PAK1 and via formation of Nck-PAK1 complex that sequesters PAK1 in cytoplasm.

**Estrogen priming is critical for effective progesterone receptor engagement with DNA in breast cancer cells: ChIP sequencing and microarray studies**

E. Swinstead, E. Need, P. Grover, E. Smith & G. Buchanan
University of Adelaide, Adelaide, South Australia, Australia.

One in 11 women develop breast cancer before the age of 75, and mortality is significant. Estrogens and progesterone (PROG) are mediators of breast cancer aetiology and progression, and are targets for both diagnostics and therapy. The actions of estrogens via estrogen receptor alpha (ERα) have been extensively studied, but the genomic actions of PROG via the progesterone receptor (PGR) are still not fully understood. This study investigates the genomic actions of PGR in breast cancer cells treated with PROG with or without 17-β estradiol ($E_2$).
Microarray expression analysis in breast cancer ZR-75-1 cells identified virtually no effect of PROG-$E_2$ co-treatment on global transcription. However, priming with $E_2$ markedly increased transcriptional response to subsequent PROG treatment. Analysis of PGR binding sites by ChIP-seq supports these findings, with PROG treatment alone generating $<10\%$ of the number of PGR binding sites following priming with $E_2$ (444 vs 4566 at equivalent peak threshold). Compared to PROG alone, the primed PGR cistrome was highly conserved amongst species, and enriched for 3-keto steroid receptor response elements and binding sites for the pioneer factor, FOXA1. Candidate ChIP confirmed these findings in 100% (12/12) of sites. Importantly, $E_2$ enhancement of PGR binding could be virtually eliminated by tamoxifen co-priming, but not by short-term tamoxifen co-treatment. In T-47D cells that have naturally high PGR levels, $E_2$ priming was not required for efficient PGR/DNA interaction.
Our data suggests that the effective engagement of PGR in genomic activity is dependent on cellular PGR levels, which is modulated by $E_2$ activity, and steroid receptor collaborations such as FOXA1. Further, $E_2$ and PROG collaboratively shape a distinctive transcriptional response in breast cancer cells. These findings suggest a need to reevaluate the meaning of ERα and PGR levels in breast cancer, and better define the context of PGR contribution to breast cancer.

## P1158

**Hypoxia-induced estrogen receptor alpha activation is mediated by both the MAPK and PI3K phosphorylation pathways**

J. Park & Y. Lee
Sejong University, Seoul, Republic of Korea.

The estrogen receptor (ER) plays an important role in breast cancer development and progression. Hypoxia was shown to modulate the level of ERα expression and induce ligand-independent transcriptional activation of ERα, which may be intimately associated with the biology of breast carcinomas. Given that phosphorylation affects the transcriptional activity and stabilization of ERα, we examined the changes in phosphorylation of ERα under hypoxic conditions. Hypoxia induced phosphorylation of ERα at serine residues 118 and 167 in the absence of estrogen. Phosphorylation-defective ERα mutants with serine-to-alanine replacements at residues 118 and 167 had impaired hypoxia-induced ERα activation, showing that serine residues 118 and 167 are involved in hypoxia-induced ERα activation. The hypoxia-induced ERα-mediated transcriptional response was dependent on both the ERK1/2 MAPK and PI3K pathways, but not the p38 pathway, as assessed using chemical inhibitors. Both the A/B and DEF domains of ERα were activated by hypoxia, indicating that both the N- and C-termini are involved in activation. These data show that ERα phosphorylation via both the MAPK and PI3K pathways is one mechanism leading to ERα activation under hypoxia.

**GH-STAT5 signaling pathway is down-regulated by Liver X Receptor agonists in liver**

L. Fernandez-Perez[1], F. Zadjali[3,4], R. Santana-Farre[1], E. Elllis[4], M. de MIrecki-Garrido[1], G. Norstedt[4] & A. Flores-Morales[2,4]
[1]University of Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain; [2]University of Copenhagen, Copenhagen, Denmark; [3]Sultan Qaboos University, Qaboos, Oman; [4]Karolinska Institutet, Stockholm, Sweden.

The Liver X Receptor (LXR) agonists have been shown to influence the development of hyperlipidemia and atherosclerosis in mouse models. It has also been demonstrated that some LXR agonists can cause hepatic steatosis in experimental animals. GH is also known to regulate hepatic metabolism and absence of the hepatic GH receptors leads to hepatic steatosis. In this study we analyzed whether actions of LXR agonists could involve interference with GH signaling. We showed that LXR agonist impairs GH signaling in hepatocytes. LXR agonist treatment attenuated GH induction of SOCS2, SOCS3, and CIS mRNA levels in BRL-4 cells. Likewise, the activity of the GH sensitive reporter vector was inhibited by a simultaneous treatment with LXR agonist. The inhibitory effect of LXR agonist on GH signals can be mimicked by overexpression of the LXR regulated factors SREBP1a and SREBP2 in hepatic cells. In both cases, total and phosphorylated STAT5b protein levels were significantly reduced. DNA binding assays demonstrated that SREBP1 binds to an E-box within a previously defined GH responsive element in the SOCS2 gene promoter but does not compete with STAT5b binding to a nearby site in the same response element. Taken together, our findings indicate that the inhibitory effects of LXR agonists on GH signaling are mediated by SREBP1, through the downregulation of STAT5b gene transcription and stimulation of STAT5b protein turnover. The described findings provide new insight in understanding the molecular actions of LXR agonists, which may be of relevance for their pharmacological actions.

**Post-translational modification of the thyroid hormone receptor interferes with its transcriptional activity**

J. Weitzel
FBN Dummerstorf, Dummerstorf, Germany.

The thyroid hormone receptor (TR) belongs to a family of transcription factors which activity is modulated by the presence or absence of their particular ligand. Additionally, the transcriptional activity of TR is modulated by post-translational modifications such as phosphorylation, acetylation or ubiquitination. Here, I investigate whether TR might also be regulated by sumoylation. Sumoylation of transcription factors at defined lysine residues often leads to an alteration of their transcriptional activity.

Various fusion proteins of the Gal4 DNA binding domain (Gal4) fused to different fragments of TRα were investigated in reporter gene assays. These fusion constructs show a strong activation of reporter gene activity in the mammalian one-hybrid assay upon stimulation with $T_3$ (up to 100-fold induction rates). Several point mutations at suggested sumoylation sites were introduced into the Gal4-TR construct. These mutated constructs show (i) an increased basal reporter activity in the absence of $T_3$ and (ii) reduced fold induction rates upon stimulation with $T_3$. These data indicate that sumoylation defective point mutants of TR have defective repressor function. TR wild type and sumoylation deficient mutants were investigated on natural promoter sequences of both positively and negatively regulated $T_3$ target genes. These investigations confirmed an alteration of ligand-depending activation by some of the mutants. Chromatin immunoprecipitation assays revealed an increased concentration of the transcriptional corepressor NCoR in the presence of TR wild type compared to its sumoylation deficient mutant in the absence of the ligand $T_3$.

All these data suggest that post-translational modifications of TR are essential for appropriate transcriptional silencing by unliganded TR.

## P1161

**Impact of receptor tyrosine kinase ErbB2/Her-2 and chemokine receptor CXCR4 crosstalk on estrogen receptor β activity**

K. Sauvé, N. Heveker & A. Tremblay
Ste-Justine Hospital Research Centre, Montreal, Quebec, Canada.

Objective

Estrogen receptors α and β are members of the nuclear receptor family which regulate target gene expression in response to estrogens and to growth factor receptors-mediated pathways. CXCR4 is a chemokine receptor whose physiological ligand is the stromal-derived-factor-1 (SDF-1), a chemokine with proliferative and chemotactic functions. Recently, we reported that ERβ activity can be modulated by the tyrosine kinase ErbB2/ErbB3 receptors and also by the CXCR4 receptor. We sought to determine the crosstalk between ErbB2, CXCR4 and the transcriptional regulation of ERβ.

Methods

The interplay between CXCR4 and ErbB2 receptors was analyzed by co-immunoprecipitation and Western analyses, as well as the signaling pathways involved. The effect on ERβ transcriptional activity was determined by luciferase reporter assay.

Results

Our results indicate that ERβ transcriptional activity was repressed by ErbB2 activation, an effect which was relieved by CXCR4. However, addition of CXCR4 ligand SDF-1 did restore the reduction in ERβ activity, suggesting a ligand-dependent effect of CXCR4. Under these conditions, Akt kinase activity was diminished in presence of CXCR4 and increased with SDF-1 treatment. We also found that CXCR4 altered PI3-K recruitment to ErbB2/ErbB3 receptor dimer, resulting in a decreased interaction between ERβ and Akt in response to ErbB2 when CXCR4 was expressed. Interestingly, these interactions were restored back in presence of SDF-1.

Conclusion

These results indicate a regulatory crosstalk that impacts ERβ transcriptional activity through the ErbB2 signaling pathway modulated by the presence of CXCR4 and its ligand SDF-1, and suggest that it is a PI3-K/Akt dependent process.

**Characterisation of the N321K mutation in the type-2 vasopressin receptor causing nephrogenic diabetes insipidus**

L. Erdélyi, A. Balla, M. Tóth & L. Hunyady
Semmelweis University, Budapest, Hungary.

Background
Loss of function mutations of the type-2 vasopressin receptor (V2R) in kidney lead to nephrogenic diabetes insipidus (NDI). The function of mutant receptors can be rescued using ligands resulting sufficient amount of plasma membrane localized V2Rs in a conformation which are able to generate cAMP signal. We examined a previously described, not characterized mutation. In order to determine personalized therapy for the individual the properties of the mutant receptor were characterized. Based on the findings we could frame a therapeutical strategy.
Materials and methods
We constructed a highly sensitive Epac-based BRET (bioluminescence resonance energy transfer) biosensor to perform real-time cAMP measurments. The β-arrestin binding of the receptors was examined with luciferase-tagged β-arrestin and mVenus-tagged V2Rs using BRET technique. The BRET measurements were performed on transiently transfected HEK293 cells using 96-well plates and Berthold Mithras LB 940 multilabel reader. Cell surface expression and localization examinations were implemented with fluorescent tagged receptors visualised with with Zeiss LSM510 confocal laser-scanning microscope.
Results
The previously described N321K mutation is in the 7th transmembrane helix of the V2R. Determination of the ligand induced cAMP generation of the mutant receptor showed increased EC50 in arginine-vasopressin (AVP) stimulation and lack of signal in desmopressin stimulation. BRET experiments revealed decreased β-arrestin binding of N321K-V2R. The mutant receptor also showed different sensitivity for V2R antagonists compared to wild-type receptor.
Conclusions
N321K mutant V2R showed cell surface expression, the physiologically essential cAMP generation of the receptor can be rescued with elevated dose of AVP, while with clinically used desmopressin was not efficient. Different internalization of the receptor may occur through altered β-arrestin binding. Administration of vasopressin receptor antagonists may be useful to avoid the side effects of high dose AVP in an NDI patient.

## P1163

**Protein metabolism in human skeletal muscle after 72 h fasting; increased muscle protein breakdown and impaired insulin signaling**

M. Vendelbo, J. Jørgensen, N. Jessen & N. Møller
Aarhus University Hospital, Aarhus, Denmark.

Background
Intermittent fasting increase maximum lifespan in several species and this effect is associated with reduced protein synthesis signaling. During fasting, a progressive loss of protein in human skeletal muscle is evident. Furthermore, fasting is associated with increased lipid oxidation and insulin resistance.
Aim
To define which protein metabolic mechanisms are activated in skeletal muscle during fasting.
Methods
We investigated the response to 72 h of fasting in eight healthy men. Skeletal muscle protein metabolism was assessed using labelled phenylalanine tracer combined with arteriovenous catheterization technique. Insulin sensitivity was assessed by hyperinsulinemic–euglycemic clamp. In addition, substrate oxidation and intramyocellular signaling to protein synthesis and breakdown was assessed.
Results
Peripheral insulin sensitivity was reduced and substrate oxidation shifted toward lipid oxidation during fasting. Net muscle protein breakdown was increased, mTOR signaling to protein synthesis was reduced, and FOXO3a signaling to local protein breakdown was unaltered. Furthermore, insulin signaling to protein synthesis was impaired downstream of Akt. However, fasting did not affect the upstream kinases Akt and AMPK or amino acid sensitive phosphorylation of eIF2a.
Conclusion
This work defines the physiological adaptations to fasting. The findings suggest that the increased net protein breakdown is due to reduced mTOR mediated protein synthesis. Furthermore, impaired insulin signaling to protein synthesis is not due to amino acid deprivation or AMPK activation. Our findings suggest that inhibition of mTOR signaling is a central mechanism triggering reduction of protein synthesis in muscle during fasting – and perhaps increasing longevity in humans and other species.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Chronic and acute effect of IL1β on sex hormone-binding globulin by decreasing HNF-4α via JNK/c-Jun pathway**

R. Simo, A. Barbosa Desongles, C. Hernandez & D. Selva
Research Institute Hospital Vall d'Hebron, Barcelona, Spain.

Patients suffering from low-grade chronic inflammatory diseases such as rheumatoid arthritis, osteoarthritis, diabetes and obesity have low plasma SHBG levels. These diseases are characterized among other features by high plasma IL1β levels. The aim of the present study is to explore whether IL1β could regulate hepatic SHBG production to account for low SHBG levels in these diseases. We provide evidence that daily IL1β treatment reduces SHBG production in HepG2 cells. The IL1β effect on human SHBG expression was mediated by the downregulation of HNF-4A via the JNK/c-Jun signalling pathway. Daily TNFα treatment of human SHBG transgenic mice reduced plasma SHBG and hepatic HNF-4α mRNA and protein levels. Importantly, SHBG levels were reduced by IL1β within 24 h *in vitro* in HepG2 cells and *in vivo* in human SHBG transgenic mice. The human SHBG promoter did not respond directly to c-Jun and its transcription was reduced by the rapid decrease in HNF-4α levels that occurs within 2–4 h of IL1β treatment. Our results show the molecular mechanisms by which IL1β reduces hepatic SHBG production suggesting that IL1β plasma levels are an important factor in accounting for the low SHBG levels in chronic low-grade inflammatory diseases.

**LPS administration modulates hypothalamic AMPK and glucose homeostasis in mice**

G. Santos[2], D. Vitorino[3], R. Moura[2], E. Roman[2], L. Velloso[2], A. Torsoni[1] & M. Torsoni[1]
[1]UNICAMP, Limeira, Brazil; [2]FCM-UNICAMP, Campinas, Brazil; [3]IB-UNICAMP, Campinas, Brazil.

Introduction
Hypothalamic AMP-activated protein kinase (AMPK) has emerged as a key molecular player in energy homeostasis. It participates of glucose homeostasis modulating liver glucose production. It is known that endotoxin shock presents various complicated metabolic aspects. Among them, in later phase circulatory collapse and hypoglycemia are induced with a deterioration of energy metabolism. Here we evaluated the participation of hypothalamic AMPK in the modulation of hepatic gluconeogenesis by lipopolysaccharide (LPS).
Methods
Swiss mice were used to this study. When necessary the mice were submitted to stereotaxic surgery to implant of guide cannula into the lateral ventricle (I.C.V.).

Lypopolissacaride (1 mg/kg) was administered via I.P. in fasted mice and after 4 h it were killed by decapitation and hypothalamus and liver were quickly removed and stored at −80°C. When necessary the food intake was measured during dark period. The protein analyses (AMPK, ACC, PEPCK and STAT3) were performed by western blot and the level of mRNA of PEPCK and G6Pase were evaluated by real time PCR. Blood glucose was determined by glucose oxidase method.
Results
The administration of LPS IP reduced food intake (60%) and glycemia (56%) as well as the AMPK (45%) and ACC (70%) phosphorylation when compared to control mice. Besides, total NFkB expression in the hypothalamus was higher in LPS-mice than control mice. These effects were accompanied by reduced level of mRNA and protein of PEPCK (25 and 40%, respectively) and increase in tyrosine phosphorylation of STAT3 (40%) in the liver. However, the ICV injection of AICAR prevented the dephosphorylation of hypothalamic AMPK and hypoglycemia associated to LPS-IP administration. In TNFR1−/− mice the glycemia was not significantly modified by LPS injection.
Conclusion
These results suggest that hypoglycemia associated to endotoxin shock also can be triggered by TNFα signaling and inactivation of hypothalamic AMPK leading to metabolic complications.

**Evaluation of K+ flux-dependent regulation of mitochondrial potential (ΔΨm) by α-adrenergic agonist phenylephrine in single hepatocytes**

M. Malyukina & N. Kavok
Institute for Scintillation Materials, Kharkov, Ukraine.

It is generally accepted that hepatic responses to α-adrenergic agonists are dependent on the redistribution of intracellular and also extracellular $Ca^{2+}$. Besides, phenylephrine induces significant $^{K+}$ flux changes and plasma membrane hyperpolarisation. Earlier it was shown that $^{K+}$ channel blockers as well as chelating of extracellular $Ca^{2+}$ with EGTA could inhibit phenylephrine-induced metabolic responses and activation of mitochondrial processes. Taking into account the significance and interplay of $Ca^{2+}$ and $^{K+}$ ions in α-adrenergic regulation of liver metabolism and mitochondrial responses we have investigated phenylephrine-induced ΔΨm changes in single hepatocytes at different conditions of $Ca^{2+}$ or $^{K+}$ fluxes.
Quantitative microfluorimetry with using mitochondrial probe JC-1 allowed evaluating the ΔΨm changes in single hepatocytes. The fluorescence of J-aggregates at 590 nm gives an index of ΔΨm.
It was shown that ΔΨm increased within 15 min of the phenylephrine action on hepatocytes (140±7% relative to control) and fell gradually to 104±6% during 30 min experiment. $^{K+}$ channel blockers – $Ba^{2+}$(2 mM) and 4-aminopyridine (5 mM) decreased the mitochondrial response. ΔΨm was 115±8% and 102±9% in the presence of $Ba^{2+}$ and 4-AP, respectively (15 min). ΔΨm progressively fell down below the control values (up to 75% in both cases at 30 min). But 0.1 mM $Ba^{2+}$ did not change the agonist-simulated ΔΨm response (147±14% and 112±10% 15 and 30 min, respectively). Plasma membrane depolarization with elevated extracellular $^{K+}$(140 mM) turned effect of phenylephrine to opposite and decreased ΔΨm below control values (49±8% within 15 min). 1 mM EGTA influenced on phenylephrine-induced ΔΨm changes in the same way as extracellular high $^{K+}$(49±9%).
The data obtained suggest that complete or partial plasma membrane depolarization due to alterations of $^{K+}$ fluxes causes changes in transmission of α-adrenergic agonists signal to mitochondrial compartments.

**Altered muscle mitochondrial amount and physical performance in 5/6 nephrectomy CKD model mice**

M. Tamaki, K. Miyashita, S. Wakino, M. Mitsuishi, K. Tanaka & H. Itoh
School of Medicine, Keio University, Shinjuku, Japan.

Background
Chronic kidney disease (CKD) in human has been believed to decrease muscle weight and physical performance. High protein diet would increase muscle mass and strength especially in athletes, but is not recommended for CKD patients because of the risk for exacerbation of uremia. Therefore, we investigated the muscle character especially focused on the mitochondrial activity and physical performance in 5/6 nephrectomy CKD model mice, which fed on different protein contents in diets.
Methods
C57bl/6 mice which were 5/6 nephrectomized at 6–7 weeks old were fed on diets containing 3–50%Kcal protein. Muscle strength and exercise endurance were examined at 16 weeks old. Muscle weight, the mitochondrial activity, and the phospholization levels of S6K1 and AMPK were examined at 20 weeks old. C2C12 myotubular cells were treated with amino acids cocktail and investigated for mitochondrial energy metabolism.
Results
Exercise endurance was decreased in 5/6 nephrectomized mice at 16 weeks old with decreasing phosphlization level of AMPK and mitochondrial amount in skeletal muscle, although muscle weight and strength were preserved. Exercise endurance and mitochondrial function were further decreased in 30% Kcal protein diet group compared with 10% Kcal protein group. Serum lactate level after exercise was remarkably elevated in the high-protein diet group, associated with a decrease in muscle pyruvate dehydrogenase (PDH) activity. Amino acids cocktail treatment in the C2C12 cells decreased oxygen utilization and ATP content and increased lactate level in the culture medium, associated with a decrease in the PDH activity.
Conclusion
We found that muscle mitochondrial amount and exercise endurance were decreased in 5/6 nephrectomy CKD model mice at 16 weeks old, associated with a decrease in muscle AMPK phospholization and mitochondrial amount. A protein-restricted diet containing 10% Kcal protein contributed to maintain exercise endurance in the CKD model mice.

## P1168

**PPARγ activator may improve sepsis symptom by inhibiting inflammation in adipose tissue**

M. Kutsukake[1], M. Kobayashi[1], K. Tamura[1], M. Yoshie[1], E. Tachikawa[1], A. Matsuda[2], E. Uchida[2] & T. Matsutani[2]
[1]Tokyo University of Pharmacy and Life Sciences, Tokyo, Japan; [2]Nippon Medical School, Tokyo, Japan.

Introduction
Postoperative sepsis exhibits high mortality. Prevention of postoperative infection and palliation of sepsis symptom are important issues in the patient's care after surgical operation. Adipose tissue as an endocrine organ that secretes various cytokines. Circulating adiponectin, an anti-inflammatory cytokine, and inflammatory cytokines such as interleukin (IL)-6 and tumor necrosis factor (TNF)-α are derived partially from adipose tissues. Recent studies have suggested that adipose tissue may play an important role in systemic inflammatory response. Our previous report also demonstrated that preoperative circulating adiponectin levels may be a risk factor of postoperative infection. We examined here whether a PPARγ activator, pioglitazone (PGZ) which increases serum adiponectin level may suppress excessive inflammatory reaction accompanying with sepsis in the mouse sepsis model.
Method
Seven-week old mice were treated with PGZ (10 mg/kg, i.p.) for 7 days and sepsis was induced by cecal ligation and puncture (CLP). The survival rate was monitored, and inflammatory factors in peritoneal fluid (PF) and abdominal adipose tissue were analyzed by real-time PCR and ELISA 24 h after CLP. In addition, abdominal adipocyte was cultured in the presence or absence of CLP mice-derived PF with PGZ to determine direct effects of PF on inflammatory cytokine expressions in adipocytes.
Result and conclusion
Serum adiponectin levels before CLP were elevated after PGZ treatment and the survival rate after CLP was improved. CLP increased IL-6 and TNF-α mRNA expressions in abdominal adipose tissues, and also TNF-α and endotoxin levels in PF. PGZ pretreatment inhibited TNF-α expression without the suppression of endotoxin. PF collected from CLP mice stimulated IL-6 and TNF-α expression in cultured abdominal adipocytes. However, these cytokines levels were significantly lower when PF derived from PGZ-treated CLP mice was applied in adipocytes. These results suggest that pretreatment of PPARγ activator possibly improves the survival rate by down-regulating excessive inflammation in adipose tissues.

## P1169

**Effects of benzbromarone on serum CRP in patients with gout**

T. Yamamoto, C. Sumida, M. Kurajoh, T. Shoji, Z. Tsutsumi, H. Koyama & Y. Moriwaki
Hyogo College of Medicine, Nishinomiya, Japan.

Introduction
C-reactive protein (CRP), an acute reactant protein and member of the pentraxins family has a primitive defense function against exogenous organisms. Although its production is predominantly under the control of IL-6, IL-1 and tumor necrotic factor also contribute to hepatic synthesis and CRP secretion. CRP is mainly produced in the liver and possibly other tissues, such as atherosclerotic lesions. C-reactive protein (CRP) is associated with increased risk for cardiovascular diseases (CVD), while increased serum uric acid level is suggested to be independently associated with an increased risk of CVD. Accordingly, in the present study, we compared serum CRP levels between healthy controls and patients with gout who were matched in regard to parameters associated with serum CRP levels. In addition, since benzbromarone decreases the level of urate in serum, based on its uricosuric action and activates peroxisome proliferater-activated receptor alpha (PPARalpha), we also examined whether benzbromarone had effects on serum CRP levels in patients with gout and the expression of the messenger mRNA in hepatoma cell line, HuH7.
Methods
In the first experiment, blood samples were drawn from 40 healthy males and 40 male patients with gout after an overnight fast. In the second experiment, 42 male patients with gout were given uric acid-lowering therapy with benzbromarone. Blood samples were drawn after an overnight fast before and 1 year after beginning benzbromarone treatment. In the third experiment, the effects of benzbromarone on IL1beta-induced CRP expression were determined in HuH7 cells
Results
Serum CRP levels were not significantly different between the patients with gout and healthy subjects, while serum CRP levels were decreased by 11% after benzbromarone treatment, as compared to the values before treatment ($P<0.01$). In addition, our *in vitro* findings suggested that benzbromarone, as well as fenofibrate, down-regulated IL1beta-stimulated CRP gene expression via PPARalpha pathway.
Conclusions
These results suggest that hyperuricemia may not contribute to an increase in serum CRP level, while benzbromarone may have a favorable effect on CRP.

**Association of 3111t/c polymorphism of the clock gene with binge eating disorder in obese children and adolescents**

T. Arthur, S. Deram, E. Frazzatto, I. Guazzelli & S. Villares
Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil.

Introduction
The etiopathogenesis of obesity is represented by the endogenous circadian clock system, which has been shown to have a part in the regulation of body weight and energy homeostasis. The gene Circadian locomotor output cycles kaput (CLOCK) is part of the positive regulatory branch of the system. Polymorphism in CLOCK genes in human disorders characterized by alterations of endogenous circadian rhythms. Moreover, since in up to 30% of obese subjects seeking treatment obesity seems to be associated with binge eating disorder (BED) we explored whether the 3111T/C CLOCK gene SNP was associated specifically to this phenotype.
Objective
To investigate the association of 3111T/C CLOCK gene SNP with BED in obese children and adolescents.
Methods
A total of 319 obese children and adolescents (35.7% boys; aged $10.6 \pm 1.4$ years, BMI $30.2 \pm 4.5$ kg/m$^2$, ZBMI $2.3 \pm 0.3$, 45.7% pubertal) were genotyped using Assay by Design kits Applied Biosystem. 121 cases completed the Binge Eating Scale questionnaire and were classified about the grade of eating compulsivity. SPSS v16 (SPSS Inc.) was used for data preparation and initial analysis of the data.
Results
Genotype frequencies did not significantly differ between sex ($X2 = 1.78$; d.f. $= 2$; $P = 0.41$). According to Binge Eating Scale questionnaire the sample consisted of 39.6% patients have BED, and allele CC was found in 75.0% of them, only 37.9% of the patients with allele TT presents BED ($P = 0.015$). BED score was strongly associated in girls with presence of allele CC ($19.8 \pm 2.36$ vs $14.6 \pm 0.90$; $P = 0.047$) as compared to the TT genotype.
Conclusions
Present findings show the 3111T/C SNP of the CLOCK gene is associated to BED in obese children and adolescents. This association provides a critical starting point for an understanding of the likely polygenic contributions towards eating disorders.

### Nicotine induces negative energy balance through hypothalamic AMP-activated protein kinase

P. Martínez de Morentin[1,2], A. Whittle[3], N. Martínez-Sánchez[1,2], L. Martins[1,2], J. Ferno[4,5], R. Nogueiras[1,2], C. Diéguez[1,2], A. Vidal-Puig[3] & M. López[1,2]
[1]University of Santiago de Compostela-Instituto de Investigacion Sanitaria (IDIS), Santiago de Compostela, Spain; [2]Instituto Carlos III (ISCIII), Madrid, Spain; [3]NIHR Cambridge Biomedical Research Centre Addenbrooke's Hospital, University of Cambridge, Cambridge, UK; [4]University of Bergen, Bergen, Norway; [5]Haukeland University Hospital, Bergen, Norway.

Introduction
Smokers around the globe commonly report increased body weight after smoking cessation as a major factor that interferes with their attempts to quit. In addition, numerous controlled studies in both humans and rodents have reported that nicotine exerts a marked anorectic action. Nicotine's effects on energy homeostasis have been mostly pinpointed in the central nervous system, but the molecular mechanisms controlling its action are still not fully understood.
Objective
The aim of this study was to investigate the effect of nicotine on hypothalamic AMPK and its effect on feeding and brown adipose tissue function.
Methods
We used adult male Sprague–Dawley rats. Subcutaneous and intracerebroventricular treatments. Stereotaxic microinjection of adenoviral expression vectors. Analysis by *in situ* hybridization, enzymatic assays, western blotting and real-time quantitative PCR. Analysis of energy expenditure, locomotor activity, respiratory quotient and lipid utilization. Nuclear magnetic resonance analysis.
Results
Here, we demonstrate that nicotine-induced weight loss is associated with decreased orexigenic signaling in the hypothalamus, inactivation of hypothalamic AMP-activating protein kinase, alterations in fuel substrate utilization and upregulation of thermogenic markers in brown adipose tissue. Conversely, nicotine withdrawal or genetic activation of hypothalamic AMPK in the ventromedial nucleus of the hypothalamus reversed nicotine-induced hypophagia and weight loss.
Conclusions
Overall, these data demonstrate that nicotine's effects on energy balance involve specific modulation of the hypothalamic AMP-activating protein kinase-brown adipose tissue axis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1172

### Ac 2-26, an annexin A1-derived peptide, reduces inflammation in human SGBS adipocytes after hypoxia treatment

A. Kosicka-Knox[1], A. Cunliffe[2], R. Mackenzie[1], M. Zariwala[1] & D. Renshaw[1]
[1]University of Westminster, London, UK; [2]London South Bank University, London, UK.

Previous studies demonstrated that the N-terminal peptide of annexin A1 (AnxA1) (peptide Ac2-26) can mimic the anti-inflammatory actions of the full-length protein in various systems. In the current study, we report the effectiveness of the peptide Ac2-26 as an anti-inflammatory agent in a model of human SGBS adipocytes. We have previously demonstrated that plasma AnxA1 protein is significantly inversely correlated with BMI, body fat level and waist to hip ratio. We have also shown that ANXA1 gene is expressed in human SGBS adipocytes and hypoxia reduces the expression of ANXA1 gene showing that AnxA1 may act as a counter regulator of adipose tissue inflammation. Given that low-level systemic inflammation is seen in metabolic syndrome-associated chronic pathologies, here, we investigate if Ac2-26 peptide can have an effect on the inflammatory markers in human SGBS cells. To mimic the relative hypoxia found in the white adipose tissue of obese humans, mature adipocytes (14 days post-confluent) were treated with 4, 8 and 24 h hypoxia treatment (1% $O_2$). The cells were also treated with 10-5 M Ac2-26 peptide or vehicle (DMEM/F12 medium supplemented with insulin (20 nM). Cells were collected and SYBR green PCR analysis performed for CRP, IL-6, adiponectin and leptin genes which have been all shown previously to be altered by hypoxia (1% $O_2$) in SGBS cells. We found that CRP expression was significantly down-regulated following 4, 8 and 24 h of hypoxia treatment in the cells also treated with Ac2-26 peptide compared to vehicle alone ($P=0.027$, $P=0.042$ and $P=0.014$, respectively). IL-6 was also found to be significantly down-regulated after 24 h hypoxia treatment in the Ac2-26 treated cells compared to vehicle ($P=0.013$). There was no significant difference in the expression of adiponectin, or leptin at any of the time points measured with either Ac2-26 treated cells or vehicle controls.
Here, we demonstrate for the first time that an AnxA1 mimetic, Ac2-26 peptide, regulates pro-inflammatory markers in human SGBS adipocytes. These data show the effectiveness of the peptide Ac2-26 as an anti-inflammatory therapeutic agent in a human SGBS adipocyte model. Furthermore, AnxA1 may be an important modulator of inflammatory and pro-resolution pathways necessary to restore homeostasis in the inflamed adipose tissue of the obese.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1173

### Pro-inflammatory wnt5a and anti-inflammatory sFRP5 are differentially regulated by nutritional factors in obese human subjects

D. Schulte[1], N. Müller[1], K. Neumann[1], F. Oberhäuser[2], M. Faust[2], H. Güdelhöfer[2], W. Krone[2] & M. Laudes[1]
[1]UKSH, Campus Kiel, Kiel, Germany; [2]University of Cologne, Cologne, Germany.

Background
Obesity is associated with macrophage infiltration of adipose tissue. These inflammatory cells affect adipocytes not only by classical cytokines but also by the secreted glycopeptide wnt5a. Healthy adipocytes on the other site are able to release the specific wnt5a inhibitor sFRP5. This protective effect, however, was found to be diminished in obesity. The aim of the present study was to examine i) whether obese human subjects exhibit increased serum concentrations of wnt5a and ii) whether wnt5a and/or sFRP5 serum concentrations in obese subjects can be influenced by caloric restriction.
Methodology
In total, 23 obese human subject (BMI $44.1 \pm 1.1$ kg/m$^2$) and 12 age- and sex-matched lean controls (BMI $22.3 \pm 0.4$ kg/m$^2$) were included into the study. Obese subjects were treated with a very-low-calorie-diet ($\sim$ 800 kcal/d) for 12 weeks. Body composition was assessed by impedance analysis, insulin sensitivity was estimated by the leptin-to-adiponectin ratio and wnt5a and sFRP5 serum concentrations were measured by ELISA. sFRP5 expression in human adipose tissue biopsies was further determined on protein level by immunohistology.
Principal findings
Pro-inflammatory wnt5a was not measurable in any serum sample of lean control subjects. In patients with obesity, however, wnt5a became significantly detectable consistent with low-grade inflammation in such subjects. Caloric restriction resulted in a weight loss from $131.9 \pm 4.0$ to $112.3 \pm 3.2$ kg in the obese patients group. This was accompanied by a significant decrease of the leptin-to-adiponectin ratio, indicating improved insulin sensitivity. Interestingly, these metabolic improvements were associated with a significant increase in serum concentrations of the anti-inflammatory factor and wnt5a inhibitor sFRP5.
Conclusions/significans
Obesity is associated with elevated serum levels of pro-inflammatory wnt5a in humans. Furthermore, caloric restriction beneficially affects serum concentrations of anti-inflammatory sFRP5 in such subjects. These findings suggest a novel regulatory system in low grade inflammation in obesity which can be influenced by nutritional therapy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Zinc-α2-glycoprotein in adipose tissue is related with insulin resistance and lipolytic genes in morbidly obese patients**

L Garrido-Sanchez[1], X Escote[1], D Fernandez-Garcia[2], J Vendrell[1], F J Tinahones[2,3] & E Garcia-Fuentes[3,4]
[1]CIBERDEM, Hospital Universitari Joan XXIII, Pere Virgili Institute, Tarragona, Spain; [2]Servicio de Endocrinología y Nutrición, Hospital Clínico Virgen de la Victoria, Málaga, Spain; [3]Ciber Fisiopatología Obesidad y Nutrición (CIBEROBN), Málaga, Spain; [4]Fundación IMABIS, Málaga, Spain.

Objective
Zinc-α2 glycoprotein (ZAG) stimulates lipid loss by adipocytes and may be involved in the regulation of adipose tissue metabolism. We analyze ZAG expression levels in adipose tissue from a group of morbidly obese patients, and their relationship with lipogenic and lipolytic genes and with insulin resistance (IR).
Design
mRNA expression levels of PPARgamma, IRS-1, IRS-2, lipogenic and lipolytic genes and ZAG were quantified in visceral (VAT) and subcutaneous adipose tissue (SAT) of 25 nondiabetic morbidly obese patients, 11 with low IR and 14 with high IR. Plasma ZAG was determined by ELISA.
Results
The morbidly obese patients with low IR had a significantly higher ZAG gene expression in VAT as compared with the patients with high IR ($P=0.023$). In the patients with low IR, the VAT ZAG gene expression was significantly greater than that in SAT ($P=0.009$). ZAG expression correlated strongly between SAT and VAT ($r=0.709$, $P<0.001$). In VAT, ZAG expression correlated significantly and positively with the expression of PPARgamma, ACSS2, DGAT1, ATGL, IRS-1, IRS-2 and adiponectin. In SAT, ZAG expression correlated significantly and positively with PPARgamma, ACC1, DGAT1, ATGL, HSL and adiponectin. VAT ZAG expression was mainly predicted by insulin, HOMA-IR, circulating adiponectin levels and expression of adiponectin and ACSS2. SAT ZAG expression was only predicted by expression of ATGL.
Conclusions
ZAG is involved in modulating lipid metabolism in adipose tissue and is associated with insulin resistance.
Declaration of interest

**Longitudinal changes in body mass index and body composition among 417 adult survivors of childhood cancer**

K. Blijdorp[1,2], M. van den Heuvel[2], R. Pieters[2], A. Boot[3], A. van der Lelij[1] & S. Neggers[1]
[1]Erasmus MC, Rotterdam, The Netherlands; [2]Erasmus MC-Sophia Children's Hospital, Rotterdam, The Netherlands; [3]University Medical Center Groningen, Groningen, The Netherlands.

Introduction
Obesity, represented by high body mass index (BMI), is a major complication after treatment for childhood cancer. High amount of total and visceral fat and low lean body mass are described as more reliable determinants, predicting the development of cardiovascular disease. In this study longitudinal changes of BMI and body composition in adult childhood cancer survivors were evaluated.
Methods
Data of 417 adult childhood cancer survivors, who had visited the late effects clinic twice, were analyzed retrospectively. Median follow up time was 16 years (interquartile range 11–21) and time between visits was 3.2 years (2.9–3.6). At both time points BMI was measured and body composition was assessed by dual X-ray absorptiometry (Lunar Prodigy). BMI and body composition measures were compared with those of healthy Dutch references and calculated as standard deviation scores (SDS). Pituitary dysfunction and hormonal replacement were evaluated in all survivors. GH deficient subjects treated with GH replacement at time of follow up were excluded from further analyses.
Results
BMI SDS at first assessment was only significantly higher in female cranial radiotherapy (CRT) survivors as compared to healthy Dutch references (SDS = 0.40, $P=0.02$). Increase of BMI over time (expressed as units per year) was only significantly higher in male survivors (0.27 vs 0.02 in controls ($P<0.001$)). Percentage fat was significantly higher than controls in both men (SDS 1.37, $P<0.001$) and women (SDS 1.05, $P<0.001$) in all therapy groups, with the highest SDS after CRT (mean SDS 1.73 in men, 1.48 in women, $P<0.001$). Only in men, increase in total fat percentage was significantly higher as compared to controls (delta SDS = 0.22, $P<0.001$). Lean body mass did not significantly change over time.
Conclusion
Significantly greater increase of BMI and total fat percentage as compared to healthy references was found, especially in adult male survivors of childhood cancer.

**Brown rice and its component, γ-oryzanol, attenuate the preference for dietary fat by decreasing hypothalamic endoplasmic reticulum stress in mice**

C. Kozuka[1], K. Yabiku[1], S. Sunagawa[1], R. Ueda[1], S. Taira[1], T. Ikema[1], K. Yamakawa[1], M. Higa[2], M. Shimabukuro[3] & H. Masuzaki[1]
[1]Graduate School of Medicine, University of the Ryukyus, Okinawa, Japan; [2]Tomishiro Central Hospital, Okinawa, Japan; [3]University of Tokushima Graduate School of Health Biosciences, Tokushima, Japan.

It is known that brown rice (BR) prevents obesity and type 2 diabetes in humans. Previous studies have shown that exaggerated endoplasmic reticulum (ER) stress in the hypothalamus of obese mice is linked to hyperphagia. Here we tested the hypothesis that BR might decrease ER stress in hypothalamus, leading to the attenuation the preference for dietary fat.
Eight-week-old mice were randomly divided into three groups: the control, BR-containing diet, and the WR-containing diet groups. To explore the impact of BR on the preference for dietary fat, we performed the food choice tests between CD and HFD. The mice were allowed free access to both diets. The control group strongly preferred the HFD. On the contrary, BR group preferred CD (∼12.5-fold vs control, ∼3.7-fold vs WR), leading to the suppression of body weight gain. To assess the effect of BR on hypothalamic ER stress, the mRNA levels of ER stress-responsive genes were analyzed. BR significantly decreased the mRNA levels of these genes in the hypothalami of the mice fed HFD. In the food choice tests, the mice treated with 4-phenyl butyric acid (120 mg/kg per day i.p.), a well known ER stress eraser, significantly preferred CD. We investigated the effect of γ-oryzanol (Orz), a mixture of major bioactive components in BR, on the hypothalamic ER stress and the preference for dietary fat. Oral administration of Orz (20, 80, 320 mg/kg per day p.o.) decreased hypothalamic ER stress in the mice fed HFD. In the food choice tests, Orz-treated mice preferred CD (∼2.1-fold vs vehicle).
Our study is the first demonstration that BR and its component, Orz, decrease hypothalamic ER stress and consequently attenuate the preference for dietary fat in mice. BR and Orz may be unique tools to ameliorate metablic syndrome through modulating feeding behavior.

**Weight-perception in male career US firefighters and its association with cardiovascular risk factors**

D. Baur[1,2], C. Christophi[1,3] & S. Kales[1,2]
[1]Harvard School of Public Health, Boston, Massachusetts, USA; [2]The Cambridge Health Alliance, Cambridge, Massachusetts, USA; [3]Cyprus University of Technology, Limassol, Cyprus.

Objective
To evaluate the associations among body mass index, weight perception and cardiovascular risk factors in male career US firefighters.
Design
The present cross-sectional study was nested within a federally-funded multicenter, prospective cohort investigation of cardio-respiratory fitness (CRF),

health and employment outcomes among career firefighters.
Subjects
Seven hundred and sixty-eight male career firefighters from two US Midwestern States. A physical examination was performed. Fasting blood samples were taken. CRF was determined from symptom- limited maximal treadmill exercise testing with ECG monitoring and estimation of oxygen consumption (METS) following the Bruce protocol. Self-reports of weight perception were extracted from responses to a health and lifestyle questionnaire with standardized written instructions to complete the multiple choice survey regarding eating, health, exercise, sleep, and work habits.
Results
We found that a high proportion of overweight and obese male career firefighters underestimate their weight categories (68%) and the risk of underestimating one's weight category increased by 24% with each additional unit of BMI after adjustment for age and CRF. When divided into six groups based on combination of measured BMI category and weight self-perception, there were significant differences among the groups for most cardiovascular risk factors. After adjustment for age and BMI, these differences remained statistically significant for CRF, amount of weekly exercise, prevalence of metabolic syndrome, body fat percentage and cholesterol measurements.
Conclusion
The majority of overweight and obese firefighters incorrectly perceive themselves as belonging to lower weight categories. As a result, they are unlikely to fully appreciate the negative health consequences of their excess weight, which were clearly demonstrated on objective testing. Efforts to improve the accuracy of weight status awareness are probably needed in order to reverse the trend of increasing obesity among public safety occupations.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### GH secretagogue receptor gene 171 C/T polymorphism association with metabolic features in obese children and adolescents

T. Arthur, S. Deram, I. Guazzelli, E. Frazzatto & S. Villares
Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil.

Introduction
Ghrelin, enhances appetite and increases food intake in healthy humans. The endogenous ligand ghrelin is the GH secretagogue receptor (GHSR), and effects of ghrelin are mediated via GHSR. The GHSR system plays a significant role in regulating the process of obesity and type 2 diabetes that are linked to metabolic syndrome (MS). Therefore, the GHSR gene 171C/T (rs495225) polymorphism is a good candidate for susceptibility to obesity and excellent MS.
Objective
To assess the frequencies of 171C/T (rs495225) GHSR polymorphism in obese children and adolescents (OCA) comparing to normal weight healthy controls and to investigate associations with MS and metabolic features in OCA.
Methods
A total of 428 Brazilian children: 91 normal healthy weight (43.9% boys; aged $10.6 \pm 1.5$ years; BMI $17.0 \pm 2.4$ kg/m$^2$; ZBMI $-0.3 \pm 0.9$, 40.6% pubertal) and 337 obese (35.5% boys; aged $10.7 \pm 1.4$ years; BMI $30.6 \pm 4.7$ kg/m$^2$; ZBMI $2.3 \pm 0.3$; 46.3% pubertal; 43.0% with MS) participated into the study. The polymorphic region of GHSR gene was amplified by PCR and products were bidirectional sequenced. MS was diagnosed by adult treatment panel III (ATP III) adapted for children. SPSS v16 (SPSS, Inc.) was used for data preparation and initial analysis of the data.
Results
Genotype frequencies did not significantly differ between normal weight controls and obese children ($X^2 = 0.66$; df = 2; $P = 0.7$). However, obese patients carrying the TT genotype in 171C/T polymorphism had significantly higher values of HOMA ($4.21 \pm 0.19$ vs $3.66 \pm 0.26$; $P = 0.02$), higher frequency of MS (44.1 vs 15.2%; $P = 0.04$), hypertriglyceridemia (47.7 vs 14.1%; $P < 0.001$) and trend toward a hyperglycemia (56.5 vs 17.4%; $P = 0.08$) as compared to the CC genotype.
Conclusions
The results support the notion that the studied 171C/T (rs495225) polymorphism of GHSR might be a genetic risk factor for MS in OCA. Our findings also suggest a complex genotype-environmental interaction on obesity risk.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Using $^1$H-nuclear magnetic resonance spectroscopy to identify changes in the plasma metabolome of rats fed low-carbohydrate/high fat diets

M. Bielohuby[1], N. Friedrich[2], S. Meurer[1], K. Budde[2], H. Wallaschofksi[2] & M. Bidlingmaier[1]
[1]Endocrine Research Unit, Munich, Germany; [2]Institute of Clinical Chemistry and Laboratory Medicine, Greifswald, Germany.

We previously reported the impact of low-carbohydrate/high-fat (LC–HF) diets on different endocrine systems in rats. To unravel metabolic pathways involved, we now studied if pair-feeding isoenergetic amounts of three different diets – all composed of macronutrient from the same sources but at different relative abundance, – leads to specific changes of the plasma metabolic profile.
Methods
Plasma was collected from male Wistar rats ($n \geq 7$/group) which were pair-fed for 4 weeks either a control chow diet (CH), or two LC–HF diets (LC–HF-1: high in fat and matched in protein content to CH; LC–HF-2: very high in fat, but low in protein). $^1$H-NMR spectra were recorded on a DRX-600 NMR spectrometer (Bruker BioSpin). OPLS-DA models were carried out between diet groups. Statistical analyses were performed with SIMPCA P + 12.0 (Umetrics AM, Sweden).
Results
The best separation was found between LC – HF-2 and CH. The OPLS-DA model had a predictive ability Q2Y = 94.9% and explained a total variance of R2X = 61.0%. Furthermore, the model showed that the variance related to the class separation was R2pX = 24.5%. As expected, NMR spectra revealed the ketone metabolite 3-hydroxybutyrate as one major metabolite allowing clear discrimination of the groups. After exclusion of 3-hydroxybutyrate corresponding ppm-regions the OPLS-DA model still showed a Q2Y of 91.9% and a R2X of 73.6% (R2pX was 20.3%). Also LC–HF-1 and CH groups were clearly distinguishable, although no differences in 3-hydroxybutyrate were detected. When comparing spectra from LC–HF-1 and LC–HF-2 groups and excluding the metabolite 3-hydroxybutyrate, the OPLS-DA model showed a Q2Y of 72.3% and a R2X of 81.0%.
In conclusion, NMR-spectroscopy and OPLS-DA allowed precise discrimination between dietary groups. As expected, 3-hydroxybutyrate is one major metabolite differing between LC-HF-2 and LC-HF-1 or CH fed rats. However, even exclusion of this metabolite allows good group separation paving the way to indentifying previously unexpected metabolic pathways.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Metabolic syndrome after liver transplantation: pre- and post-operative risk factors

M. Lunati, V. Grancini, F. Agnelli, B. Masserini, D. Zimbalatti, G. Rossi, P. Beck-Peccoz & E. Orsi
IRCCS Ca' Granda Foundation, Milan, Italy.

Background
Metabolic syndrome (MS) is a common condition among liver transplanted patients and it contributes to late morbidity and mortality by favoring the development of cardiovascular disease (CVD).
The aim of this study was to assess the prevalence of MS in the first 6 months after orthotopic liver transplantation (OLT) and the associated pre-operative and post-operative risk factors.

Methods
Seventy-one cirrhotic patients were evaluated at baseline and after OLT. The presence of MS was assessed accordingly to 2004 revised ATP III criteria. Nutritional habits were assessed using 3-day-food records.
Results
The prevalence of MS was 8/71 (11.3%) before OLT, and 23/71 (32.4%) and 21/71 (29.6%) 3 and 6 months after OLT respectively ($P=0.006$). The factors independently associated with MS were older age ($P=0.042$), family history of diabetes ($P=0.005$) and excess body weight at baseline ($P=0.025$). The analysis of daily food intake after transplantation showed an increase in caloric intake, with redistributions of macronutrients. As compared to subjects without MS, MS patients showed an higher intake of total energy (3 months: $2607\pm873$ vs $2155\pm595$ kcal/die, $P=0.03$; 6 months: $2132\pm500$ vs $1864\pm417$ kcal/die, $P=0.074$), saturated fatty acids (3 months: $11\pm3.6$ vs $8.0\pm2.6\%$, $P=0.007$; 6 months: $11.5\pm3.5$ vs $8.8\pm2.8\%$, $P=0.065$) and cholesterol (3 months: $367\pm170$ vs $275\pm174$ mg, $P=0.02$; 6 months: $276\pm122$ vs $208\pm83$ mg, $P=0.04$). MS patients showed higher prevalence of graft rejection (45.4 vs 31.7% respectively), infections (41 vs 26.8% respectively) and major cardiovascular events (11.6 vs 6.7% respectively), as compared with non-MS patients, although these differences did not reach statistical significance.
Conclusion
Transplanted patients are at high risk of developing MS. Both pre- and post-operative factors predispose patients to the onset of MS. Control of modifiable risk factors, such as body weight and dietary intake, may reduce the prevalence of MS after liver transplantation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1181

**Metformin in normoglycemic obesity: a systematic review**

S. Li[1], J. Guo[1], X. Lv[1], Y. Liu[1,2], T. Chen[1] & H. Tian[1]
[1]West China Hospital, Sichuan University, Chengdu, China; [2]West China Second Hospital, Sichuan University, Chengdu, China.

Objective
Metformin was considered as a weight lowering agent in diabetes patients, while it remained unclear in simple obesity patients. We aimed to investigate if metformin is effective and safe in the therapy of normoglycemic obesity.
Methods
We systematically searched MEDLINE (1950–2011), EMBase (1950–2011), and CCTR (4th Issue 2011), and collected and screened all randomized controlled trials compared metformin and placebo in obese participants excluding hyperglycemia, hypertension, and other chronic diseases.
Results
Twelve trials with follow-up duration 3–24 months were included in our study, eight of which included adolescence as subjects. Compared with placebo, metformin can effectively reduce BMI (overall MD $-1.14$ kg/m$^2$, 95% CI $-1.61$ to $-0.67$ kg/m$^2$, $P<0.00001$) and body weight (overall MD $-2.52$ kg, 95% CI $-3.84$ to $-1.20$ kg, $P=0.0002$), especially in adolescent patients (BMI, overall MD $-1.61$ kg/m$^2$, 95% CI $-2.61$ to $-0.61$ kg/m$^2$, $P=0.002$; body weight, overall MD $-3.11$ kg, 95% CI $-4.28$ to $-1.95$ kg, $P<0.00001$). The overall fat mass (overall MD $-1.77$ kg, 95% CI $-4.19$ to 0.66 kg, $P=0.15$) and waist circumferential (overall MD 0.57 cm, 95% CI $-1.33$ to 0.20 cm, $P=0.15$) reduction due to metformin did not meet statistical significance, while waist circumference could be reduced by metformin in adolescent subgroup (overall MD $-1.20$ cm, 95% CI $-2.18$ to $-0.22$ cm, $P=0.02$). Furthermore, fasting insulin (overall MD $-18.09$ pmol/l, 95% CI $-28.92$ to $-7.26$ pmol/l, $P=0.001$) and HOMA-IR (overall MD $-3.13$, 95% CI $-5.95$ to $-0.31$, $P=0.03$) but not fasting blood glucose (overall MD $-0.15$ mmol/l, 95% CI $-0.3$ to 0.01 mmol/l, $P=0.06$) decreased significantly after metformin therapy compared with placebo. Gastrointestinal adverse effects in metformin group were not significantly different from those in placebo.
Conclusion
Metformin could markedly reduce body weight and insulin resistance in the treatment of normoglycemic obesity, especially in adolescent patients.

## P1182

**Growth differentiation factor-15 and transforming growth factor-β1 in healthy adults with and without obesity**

C. Sasse, M. Look, E. Albers, B. Zur & B. Stoffel-Wagner
University Hospital Bonn, Bonn, Germany.

Introduction
GDF-15 and TGF-β1 are growth factors involved in immune modulation and development of arteriosclerosis. Aim of this study was to assess whether GDF-15 and TGF-β1 concentrations are higher in adipose vs non-adipose individuals and whether this indicates early immune modulation with higher risk of arteriosclerosis.
Description of methods
We examined 84 healthy individuals: 38 non-obese (average age 24.9 years) with mean BMI of $20.5+0.2$ (S.E.M.) and 46 adipose (average age 34.8 years) with mean BMI of $37.7+0.9$ (S.E.M.). In both groups, we determined GDF-15 and TGF-β1 concentration in plasma with ELISA (Quantikine, R&D Systems, Inc., MN, USA).
Results
GDF-15 concentration did not differ significantly between non-obese individuals (mean value 433 pg/ml $+25$ S.E.M.) and adipose individuals (mean value 434 pg/ml $+38$ S.E.M.) (Mann–Whitney $U$ test, $P=0.3185$). TGF-β1 concentrations were significantly higher in adipose individuals (mean value 5784 pg/ml $+308$ S.E.M.) than in non-adipose individuals (mean value 3061 pg/ml $+133$ S.E.M.) (Mann–Whitney $U$ test, $P<0.0001$).
Conclusion
In the tested adipose individuals, TGF-β1, but not GDF-15 concentrations were significantly higher than in the non-adipose individuals. Hence, in young adipose individuals, changes in immune modulation may be assessed earlier with TGF-β1 than with GDF-15.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**The effect of 'The Programme of weight loss' in women, Arkhangelsk, Russia**

A. Postoeva[1] & A. Uutela[2]
[1]Northern State Medical University, Arkhangelsk, Russian Federation;
[2]University of Tampere, Tampere, Finland.

Background
Different programmes are offered to help people to reduce weight. 'The Programme of Weight Loss' is working in the outpatient clinic in the Arkhangelsk, Russia, but its effectiveness was not assessed before.
Aim of the study was to assess the effect of the complex course 'The Programme of Weight Loss'.
Methods
The panel study was conducted and included women participated in the two-week Programme from the 1st of January to the 31st of July 2010 with following observation during 6 months. We collected anthropometric and laboratory data, questioned them with the impact of weight on quality of life questionnaire (IWQOL-Lite) before the course and after six months. Statistical analysis was performed using Student's paired *t*-test, non-parametric tests, multiple linear regression and logistic regression.
Results
We analyzed the results of 55 women. After 6 months the reduction of body mass (−11.32 kg, 95% CI: −9.24; −13.4), body mass index (−2.74 kg/m$^2$; 95% CI: −0.69; −6.18), waist (−9.76 cm; 95% CI: −7.13; −12.39) and hip (−12.66 cm; 95% CI: −6.28; −19.04) circumferences, mass (−5.86 kg; 95% CI: −0.11; −11.84) and volume (−4.69%; 95% CI: −3.3; −6.08) of fat tissue, systolic (−12.97 mm Hg; 95% CI: −4.18; −21.76) and diastolic (−9.55 mm Hg; 95% CI: −5.68; −13.41) blood pressure, and total cholesterol (−1.1 mmol/l; 95% CI: −0.63; −1.57) were estimated. Lower basal waist circumference, shorter the length of the disease and lower basal level of total cholesterol were significantly associated with waist circumference reduction. Lower level of cholesterol also significantly predicted better decrease of body mass. Data from IWQOL-Lite indicated the significant improvement in self-assessment after six months. Initial body mass (OR = 1.16; 95% CI: 1.02; 1.33), smoking habits (OR for ex-smokers = 0.17; 95% CI: 0.04; 0.8); OR for current smokers = 0.05; 95% CI: 0.00; 0.7) significantly influenced on possibility to refuse from the follow-ups.
Conclusions
«The Programme of Weight Loss» was effective in reduction of body mass, waist and hip circumference, blood pressure and level of total cholesterol after 6 months.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1185

**Efficacy of orlistat vs placebo in the improvement of lipid profile among overweight and obese patients: a meta-analysis**

C. Malong, J. Delgado & E. Cunanan
University of Santo Tomas Hospital, Manila, Philippines.

Background
According to the 6th National Nutrition Health Survey, the Filipino is generally unfit, with increasing incidences of major risk factors for cardiovascular disease like hypertension, abnormal lipid profile, obesity and diabetes over the last 5 years. Orlistat, a lipase inhibitor is one of the medications used to facilitate weight loss in obese patients. Given that weight loss is known to be associated with an improvement in the serum lipid profile, concurrent improvement in concentrations of cholesterol and triacylglycerols should result from therapy with orlistat.
Objective
To determine the efficacy of orlistat compared with placebo in lowering lipid levels among overweight and obese patients with or without other comorbidities
Methodology
We performed a systematic literature search of Randomized Controlled Trials (RCTSs) using MEDLINE, Cochrane Library Cochrane Register of Controlled Trials, ScienceDirect, and Herdin from inception to 2008. Manual searching was also done through reviews of bibliographies of previous meta-analysis for orlistat. RCTs comparing orlistat and placebo reporting mean changes from baseline in serum lipid levels in both overweight and obese patients were included.
Results
A total of seven (7) RCTs met out inclusion criteria. All studies compared patients receiving orlistat 120 mg/tab TID with placebo. Statistically significant improvement in mean change from baseline levels of total cholesterol (mean difference was −0.33 (95% CI −0.45, −0.42)), low density lipoprotein (mean difference was −0.28 (95% CI −0.36, −0.19) and trigylceride (mean difference was −0.13 (95% CI −0.19, −0.06)) was seen in orlistat group than the placebo, but no statistically significant improvement in mean change from baseline level in high density lipoprotein (mean difference was −0.03 (95% CI −0.05, −0.02)).
Conclusion
Orlistat produces statistically significant improvement in total cholesterol, low density lipoprotein and triglyceride levels in overweight and obese patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1186

**Insulin resistance and acne: a new risk factor for men?**

M. Del Prete, A. Faggiano, M. Mauriello, C. Di Somma, G. Monfrecola, G. Fabbrocini & A. Colao
Federico II University, Naples, Italy.

Introduction
Acne is a common skin disease that occasionally can be influenced by endocrine abnormalities. In females, a clear relationship has been highlight between acne onset and peripheral insulin resistance and hyperinsulinemia, whereas few data are available in male. The aim of this study was to investigate the relationship between acne and insulin resistance as well as other metabolic impairment in male subjects with acne.
Methods/design
Twenty-two subjects with inflammatory acne, resistant to common therapy guidelines of acne treatment, have been compared to 22 healthy subjects matched for age and gender. Acne was gradued using the global acne grading system score (GAGS). Clinical and biochemical parameters of glucose and lipid metabolism and serum levels of androgens were evaluated. Oral glucose tolerance test (OGTT) was performed and the homeostasis model assessment of insulin-resistance (HOMA-IR) was calculated.
Results
Males with acne had higher BMI ($P<0.01$), WHR ($P<0.05$), SBP ($P<0.01$), DBP ($P<0.01$), basal ($P<0.05$) and 120 min. OGTT serum insulin concentrations ($P<0.01$), basal glucose concentrations ($P<0.05$), HOMA-IR ($P<0.01$) and lower HDL cholesterol than controls ($P<0.01$). Among the subgroup of subjects with BMI <25, HDL cholesterol ($P<0.05$) and 120 min. OGTT serum insulin concentrations ($P<0.05$) resulted to be independent predictors of acne at the multivariate analysis.
Conclusions
These findings highlight that male subjects with acne are affected with a metabolic imbalance. Insulin resistance and low HDL-cholesterol seem to play the main role for the development of acne in males and could represent effective targets for therapy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Metabolic syndrome in benign and malignant nodular thyroid diseases**

S. Can, C. Anil, A. Nar, A. Gursoy & N Bascil Tutuncu
Faculty of Medicine, Baskent University, Ankara, Turkey.

Introduction
Metabolic syndrome (MetS) is a group of metabolic abnormalities where insulin resistance (IR) plays a major role. Previous studies have shown that thyroid volume and nodule prevalence were increased in patients with IR. The aim of our study is to evaluate MetS and its components in patients with benign and malignant nodular thyroid disease (NTD).
Methods
A total of 800 patients (430 euthyroid benign and 370 euthyroid malignant NTD) followed in the outpatient clinic of Endocrinology department were analyzed. Fine needle aspiration cytology and histopathological examination, whichever eligible, was considered for the pathological classification of nodules. Serum insulin levels and the level of IR estimated by homeostasis model assessment, as well as other MetS parameters were evaluated. The results were also compared with a reference population study on MetS prevalance.
Results
MetS was detected in 59.8 percent ($n=478$) of 800 patients. The prevalance was 33.8% in the reference population study ($P<0.001$). There was no significant difference between benign and malignant NTD groups related to prevalence of the MetS (61.4 and 57.8% respectively, $P>0.05$). When MetS components were analysed, the most common component was abdominal obesity ($n=520$, 65%), followed by low HDL-C level ($n=518$, 64.8%), and high blood glucose level ($n=246$, 30.8%). There was no significant difference between benign and malignant NTD groups in terms of insulin levels ($9.06\pm5.3$ and $8.68\pm4.8$ respectively, $P>0.05$) and insulin resistance ($2.74\pm2.9$ and $2.4\pm2.2$ respectively, $P>0.05$). Conclusion: When the reference population data is considered, the results suggest that patients with NTD have significantly increased metabolic syndrome prevalence compared to patients without NTD (59.8%, 33.9% respectively). There was no significant difference between benign and malignant NTD in terms of prevalence and distribution of components of MetS.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**A pilot study in obese patients who refer to plastic surgery: temperamental-personality traits**

M. Azzi, V. Vindigni, L. Lancerotto, F. Bassetto, M. Marini, G. Grasso & C. Pavan
University of Padua, Padova, Italy.

Literature evidenced correlation between psychiatric disorders and overweight/-obese (BMI>25) conditions, management and treatment. There are involved psychiatric diseases and temperamental traits. Our study, born from collaboration between Psychiatric and Plastic Surgery Clinic of Padua University, wants to detect psychiatric disorders, temperamental traits and body image perception in overweight-obese patients who seek surgical liposuction or abdominoplastic. We studied (March 2008–June 2011), 28 consecutive patients who refer for surgical enhancement (age 18–60 years) with BMI <34.9 at the recruitment. Exclusion criteria are: organic disorders or drugs that could interfere with obesity; cognitive deficit and psychosis. Thirty patients refused psychiatric evaluation. This clinical population has been compared to a control group ($n=25$) from general population. Psychiatric evaluation was based on clinical information, Mini-International Neuropsychiatric Interview, Beck Depression Inventory, Yale Brown Scale, Paykel Life Events Scale, NEO Five Factory Inventory, Tridimensional Personality Questionnaire, Body Shape Questionnaire. Case group evidenced higher scores in lifetime depression and BQ6 scores with a moderate/mild concern with body shapes; focus on personality traits, TPQ revealed higher score in subscale dependence/independence and significant higher presence at YBS for obsessive-compulsive characteristics; NEO-FFI Openness to experience is higher in control. It's unmistakable that affective sphere is relevant but also obsessive-compulsive and temperamental traits and negative body shape perception. These aspects are implicated in treatments adhesion and clinical outcome. Possibility to individuate patients who present those characteristics is an instrument to avoid early post-treatment relapse and give the possibility to refer to psychiatric care before and after surgery.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Evaluation of success of an obesity consultation (2004–2010)**

A. Domingues, I. Sequeira, P. Chambel, M Santana Lopes, M. Marcelino, D. Passos, L Oliveira Lopes, N. Gonçalves & J. Jácome de Castro
Military Hospital, Lisbon, Portugal.

Introduction
Moderate weight loss (5–10%) translates into health benefits, including improvement in cardiovascular risk. It is essential to assess the results and indicators of success in treating obesity, which is the objective of this work.
Methods
A retrospective study of patients with overweight and obesity, followed in Nutrition consultation between 2004 and 2010. We analyzed biodemographic and anthropometric variables, consultation reason and weight history and treatments. We used the *t*-test for independent samples, $\chi^2$ tests to statistical differences and repeated measures model assessed the weight gain. We estimated a multiple linear regression model to identify risk factors in weight loss. The significance level was 5%.
Results
Of 1947 patients with diagnostic of overweight or obesity, we analyzed 389, mean age 52 years ($\pm15.3$), 53% female. Overweight was the main reason for the consultation (63.8%). To all were prescribed a personalized meal plan, encourage physical activity and prescribed drugs to 10.8%. The mean follow-up was 12 months. The greatest weight loss, it was up to 12 months ($P<0.005$). At 3, 6 and 12 months, 66.8, 68.4 and 71.9%, respectively, lost weight. At 12 months, 39.5% lost more than 5% of their initial weight. The women lost more weight at 6 and 12 months ($P=0.045$). The reason for the consultation and number of visits has proven to be indicators of success in weight loss.
Conclusions
Most of the patients lost weight at all assessments and the bigger lost was at 12 months. Motivation and follow-up are indicative of greater success in weight loss.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Regulation of lipid droplet function in adipocytes: role of RAB18**

M. Malagon, Y. Rabanal, M. Pulido, F. Almabouada, S. Garcia-Navarro, F. Gracia-Navarro & R. Vazquez-Martinez
University of Cordoba, IMIBIC; CIBERobn, Cordoba, Spain.

Adipocytes are cells highly specialized in storing excess energy as neutral lipids in lipid droplets (LDs). These organelles act not only as mere fat reservoirs, but

also as active modulators of lipid storage and mobilization in response to hormonal signals. This role is accomplished through a plethora of proteins associated with the LD surface that spatially and temporally coordinate lipid metabolism and traffic on demand. Recently, we have shown that the LD-associated protein Rab18 is involved in insulin-mediated lipogenesis and in β-adrenergic-induced lipolysis in 3T3-L1 adipocytes. Given the involvement of the endoplasmic reticulum (ER) in the biogenesis, maintenance, and regression of LDs, herein we investigated whether Rab18 modulates LD mobilization and LD/ER relationship. Double immunocytochemistry and confocal microscopy revealed that both insulin and the β-adrenergic agonist isoproterenol increased Rab18 recruitment to LDs and the rapprochement of these organelles to ER membranes. However, unlike isoproterenol, insulin treatment induced Rab18-labeled LDs to contact specific regions of the ER membrane enriched in lipogenic enzymes (i.e. diacylglicerol-acyltransferase 2 (DGAT2)). Furthermore, disruption of ER traffic impaired insulin-induced Rab18 association with LDs, whereas isoproterenol effect was unaffected. These data suggest that, depending on the nature of the extracellular stimuli reaching the adipocytes, Rab18 is recruited to LDs from the ER membrane (upon insulin treatment) or, likely, from the cytosol (upon isoproterenol treatment). We also analyzed the role of microtubules in Rab18 association to LDs and LD/ER apposition. Thus, we found that microtubule depolymerization by nocodazole did not affect insulin- and isoproterenol-induced Rab18 mobilization towards LDs but increased LD rapprochement to the ER. Finally, we explored Rab18-interacting proteins by proteomic analysis. Altogether, our data suggest that Rab18 plays a role in the control of lipogenesis- and lipolysis-induced LD/ER association, probably through its interaction with the cytoskeleton.

### Frequency of obesity, insulin resistance, cardio-metabolic risk factors and genetic variation in the genes encoding ADIPOQ and PPAR-γ in urban adults

F. Dzgoeva, A. Ilyin & S. Prokofjev

Russian Endocrinology Research Center, Moscow, Russian Federation.

The aims of the study were to analyze the relationship among insulin resistance, obesity, dysglycemia, dyslipidemia and to evaluate the role of common variants in candidate genes for their ability to predict the metabolic syndrome and cardio-metabolic risk factors.

Subjects and methods

752 non-diabetic individuals (190 males and 562 females; age 35.05 + 4.47 years, BMI 26.72 + 5.92 kg/m$^2$) participating in the study were genotyped for variants in peroxisome proliferator-activated receptor gamma (PPAR-γ2 Pro12Ala) and in adiponectin (ADIPOQ 45T > G; 276C > T) genes. Fasting blood sample was examined: lipids (total cholesterol, HDL-C, LDL-C, TAG), adiponectin (Adp), insulin; HOMA-IR was calculated. Regression analyses were used to find the associations of single nucleotide polymorphisms with cardio-metabolic risk factors.

Results

We found higher frequency of abdominal obesity in females, but frequency of lipid disorders, prediabetes, arterial hypertensive and insulin resistance was higher in males.

The frequency of SNPs PPAR-γ Pro12Ala, ADIPOQ +45T > G (rs2241766), and +276G > T (rs 1501299) in the whole study population ($n$ = 752) and in the obesity subjects ($n$ = 368) is comparable (0.158 and 152; 0.064 and 0.058; 0.256 and 0.276, respectively).

In men T allele ADIPOQ rs 1501299 is consistently associated with obesity ($P$ = 0.002), abdominal obesity ($P$ = 0.04), prandial hyperglycemia ($P$ = 0.002); G allele ADIPOQ rs 1501299 plays a protective role for HDL cholesterol level ($P$ = 0.047).

In women the PPAR-γ2 Ala12 variant plays a protective role in hypercholesterolemia ($P$ = 0.01). T allele ADIPOQ rs2241766 is significantly associated with reduced risk of obesity ($P$ = 0.004).

Conclusion

The allelic variation of the genes encoding adiponectin and PPAR-γ is gender-dependently associated with obesity and cardio-metabolic risk factors.

### Melanocortin 4 receptor genetics in defining the morbid obesity in general population: common polymorphisms vs mutations

J. Klovins[1], V. Ignatovica[1], H. Schioth[2] & V. Pirags[3]

[1]Latvian Biomedical Research and Study Centre, Riga, Latvia; [2]Uppsala University, Uppsala, Sweden; [3]University of Latvia and Department of Endocrinology, Pauls Stradins Clinical University Hospital, Riga, Latvia.

Since the discovery of melanocortin 4 receptor (MC4R) as an important regulator of food intake it has been recognised as one of the major monogenic factors of obesity. However the mutations identified are usually very rare, not found in control subjects from the background population and can explain only a minor part of heritability (2–3%). Here we explore the role of non-synonymous mutations identified by MC4R sequencing in cohort of 380 severely obese individuals (BMI 39.3–67.9 kg/m$^2$) selected from Genome Database of Latvian Population comparing to 380 controls with normal BMI (18.5–24.9 kg/m$^2$). We also investigated the role of SNP rs17782313 located upstream of the MC4R that have been previously identified from GWAS in the same case-control samples. The genetic association revealed no correlation between rs17782313 and obesity or related traits. The sequencing of the MC4R coding region revealed four non-synonymous substitutions: V103I, S127L, V166I and I251L. Two subjects had double V103I and S127L mutations. Noticeably, V166I is a novel substitution that has not been reported before. S127L, V166I and double V103I/S127L mutant receptors had significantly decreased expression on cell surface compared to wt MC4R. Intriguingly, despite the low abundance in cell membrane the newly discovered V166I variant demonstrated higher cAMP response upon αMSH activation than wt receptor, while S127L mutation did not display any significant cAMP response. In opposite to MC4R we found that three SNPs in another obesity related fat mass and obesity-associated protein gene locus (FTO) are associated with obesity in our study group (the lowest $P$ value = 0.019). In conclusion, we show that non-synonymous mutations can only explain 1% of morbid obesity. Thus, neither the common SNP nor rare mutations are the major genetic cause of obesity in general population in opposite to FTO gene.

### Effects of bezafibrate treatment on pancreatic remodeling and insulin resistance in ovariectomized C57BL/6 mice fed high-fat diet

T. Faria, A. Ludgero-Correia, M. Aguilla & C. Mandarim-de-Lacerda

Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil.

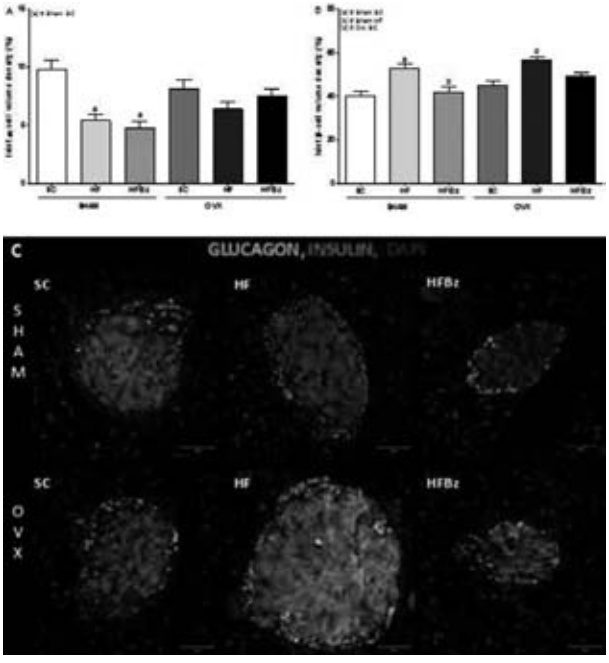
Introduction

Ovariectomized C57BL/6 mice are a good model to study the postmenopausal stage. It has been reported that high-fat diet (HFD) augments the body fat mass

and insulin resistance (IR) in animal models. Goal of this study was to investigate the combined effects of ovariectomy (OVX) and HFD on insulin sensitivity and pancreatic remodeling in C57BL/6 mice treated with bezafibrate.
Methods
Female C57BL/6 mice were subjected to surgical OVX and surgery without removal of the ovary (SHAM). Animals received standard chow diet (SC 10% lipids) or high-fat diet (HF 60% lipids). After 13 weeks of diet, the animals were subdivided in six groups ($n=5$), diet and/or bezafibrate: SHAM-SC, SHAM-HF, SHAM-HF-Bz, OVX-SC, OVX-HF and OVX-HF-Bz. After treatment of 5 weeks, the pancreas was removed and analyzed by morphometry, immunostaining and biochimical assay.
Results
OVX groups showed atrophied uterus compared to the SHAM groups, ensuring the success of surgically-induced menopause. Analyzing the effects of OVX and HF, the SHAM-HF and OVX-HF mice showed higher fasting glucose, plasma insulin, and HOMA-IR; increased body mass, islet hypertrophy, β-cells mass, and insulin immunostain; and decreased GLUT2 immunostain. Bezafibrate treatment reduced body mass, plasma insulin and HOMA-IR, and prevented islet hypertrophy.

**Table 1** Statistics results in C57BL/6 mice.

| Parameters | Groups | | | | | |
|---|---|---|---|---|---|---|
| | SHAM | | | OVX | | |
| Food intake (g)/day per mouse | 2.27±0.03 | 1.94±0.04a | 1.95±0.04 a | 2.21±0.04 | 1.91±0.03d | 1.89±0.04d |
| Body mass at 18 week (g) | 21.90±0.34 | 23.32±0.71 | 23.39±0.43 | 23.19±0.49 | 29.95±0.92bd | 26.52±0.53cde |
| Uterus mass (g) | 0.14±0.01 | 0.14±0.02 | 0.13±0.02 | 0.03±0.01a | 0.04±0.01b | 0.03±0.01c |
| Basal glucose (mmol/l) | 5.63±0.19 | 6.30±0.32 | 7.14±0.01a | 6.71±0.10 | 8.01±0.37bd | 8.21±0.30d |
| OGTT, AUC | 1518±568 | 1561±1390 | 1902±593 | 1719±793 | 2429±1403bd | 2294±983d |
| Serum insulin (μUI/l) | 11.86±0.76 | 10.23±0.77 | 9.91±0.77 | 15.07±1.08 | 19.37±1.19bd | 9.70±0.80de |
| HOMA-IR | 3.06±0.22 | 3.00±0.24 | 3.14±0.25 | 4.47±0.27 | 7.18±0.50bd | 3.57±0.36e |
| Pancreas mass (g) | 253.6±0.01 | 266.5±0.01 | 222.2±0.01 | 261.5±0.01 | 318.2±0.01bd | 282.0±0.01 |
| Vv islet (%) | 9.36±0.54 | 14.05±0.60a | 8.10±0.66b | 11.36±0.83 | 14.19±0.79 | 10.34±0.70e |
| Islet mass (mg) | 24.30±1.48 | 38.32±1.84a | 19.21±1.71b | 32.13±2.76 a | 44.02±2.45d | 29.16±2.08ce |
| b-cell mass (mg) | 17.51±2.18 | 24.54±2.06 | 10.37±2.00b | 20.54±2.27a | 20.63±2.55e | 20.63±2.55e |



Conclusion
The model of ovariectomy associated with HFD accentuated the effects of menopause, leading to the development of IR. Bezafibrate treatment reduces body mass, and also reduces plasma insulin and pancreatic islet hypertrophy in mice fed HFD.

### Prediabetes in adult GH deficiency is associated with a substantial reduction in serum and adipose tissue expression levels of zinc-α2-glycoprotein

M. Balaz[1], B. Ukropcova[1], T. Kurdiova[1], A. Penesova[1], P. Skyba[2], M. Vlcek[1], V. Belan[3], I. Klimes[1], J. Payer[3], R. Imrich[1], S. Smith[4], R. Tkacova[2], D. Gasperikova[1] & J. Ukropec[1]
[1]Institute of Experimental Endocrinology SAS, Bratislava, Slovakia; [2]Faculty of Medicine, Kosice, Slovakia; [3]Comenius University School of Medicine, Bratislava, Slovakia; [4]Pennington Biomedical Research Center, Baton Rouge, Louisiana, USA.

Adult GH deficiency (GHD) is associated with prediabetes and low levels of GH are found in obesity. We hypothesized that zinc-α2-glycoprotein (ZAG), a novel adipokine reduced in obesity, is regulated by GH. ZAG serum and adipose tissue expression were measured in three study populations: i) cachectic (BMI=19.3 ±0.5 kg/m$^2$), lean/overweight (BMI=26.0±0.5 kg/m$^2$) and obese (BMI=36.0±1.6 kg/m$^2$) patients with chronic obstructive pulmonary disease (COPD, 62.5±1.1 years); ii) GHD adults ($n=16$, 30.6±1.1 years, BMI=27.1 ±1.2 kg/m$^2$) and 16 healthy matched controls; iii) patients with metabolic syndrome subjected to 6-months therapy with rhGH ($n=10$, 40–70 years, BMI=27–35 kg/m$^2$). Metabolic phenotyping included insulin sensitivity (EHC), body composition (MRI), OGTT and muscle lipid content ($^1$H-MRS). Adipose tissue samples were taken by needle biopsy. Adipocyte diameter was measured histomorphometrically. Gene expression was assessed by qRT-PCR, protein by immunoblotting and serum ZAG with ELISA. Compared to obese, cachectic COPD patients had fourfold increased ZAG in adipose tissue and serum ($P<0.01$). Both ZAG serum and mRNA levels correlated positively with circulating GH ($r=0.40$, $P<0.01$; $r=0.60$, $P<0.001$). Furthermore, serum and adipose tissue of prediabetic GHD adults displayed 71 and 62% decrease in ZAG mRNA and serum levels ($P<0.001$). Treatment with rhGH led to 1.8-fold increase in ZAG mRNA ($P<0.001$). ZAG protein decreased in response to euglycemic hyperinsulinemia. In addition, ZAG mRNA was positively associated with insulin sensitivity ($r=0.69$, $P<0.001$), serum adiponectin ($r=0.48$, $P<0.01$) and adiponectin mRNA ($r=0.49$, $P<0.01$). Negative correlations were found with fat cell size ($r=-0.56$, $P<0.001$) and intramyocellular lipids ($r=-0.61$, $P<0.05$). Our results clearly demonstrate the down-regulation of ZAG in serum and adipose tissue of prediabetic GHD adults as well as positive regulation of ZAG by rhGH, suggesting the regulatory role for GH independent on obesity. Associations of ZAG with insulin sensitivity, molecular adipose tissue phenotypes and intramyocellular lipids suggest the role for reduced ZAG in the development of metabolic disease.

**Signalling properties of the melanocortin 3 receptor are modified by interaction with different ghrelin receptor variants in heterodimers**

C. Piechowski, H. Krude, A. Grüters, G. Kleinau & H. Biebermann
Institute of Experimental Pediatric Endocrinology, Berlin, Germany.

It is a widely accepted concept that G-protein-coupled receptors (GPCRs) are able to form homo- and heterodimers. The physiological relevance of these interactions is of utmost importance.
Recently, we demonstrated that due to co-expression of two key players of hypothalamic body weight regulation, the melanocortin 3 receptor (MC3R) and ghrelin receptor (GHSR), signalling of the MC3R is enhanced (hyperstimulation) as compared to activation of MC3R alone. By using two naturally occurring GHSR mutations (GHSR-A204E, GHSR-F279L) that silence the basal ligand independent activity we showed that the basally active conformation of GHSR is a crucial factor for modified signalling properties in MC3R/GHSR heterodimers.
The aim of this study was to confirm these previous findings by investigation of further naturally occurring GHSR-mutants in co-expression studies with MC3R.
We tested seven already published GHSR variants. Most of these mutations lead to a decreased ligand independent activity and/or to a decreased cell surface expression of GHSR. We measured Gs-induced cAMP accumulation of the co-expressed MC3R and the GHSR-mutants in COS-7 cells after stimulation with 1 μM α-MSH.
The co-expression of six tested GHSR-mutants with the MC3R and α-MSH challenge prevented MC3R hyperstimulation in contrast to the MC3R co-expressed with the GHSR-WT. Only one GHSR-mutant resemble the characteristic MC3R/GHSR hyperstimulation.
Taken together, by testing seven GHSR-mutants we here show that our initial finding of the importance of high basal GHSR activity in a heterodimeric constellation with MC3R is a general phenomenon and that specific GHSR variants almost always modulating MC3R signalling in heterodimers.
This study therefore gives general pathological implications and mechanistic insights into the role of GHSR and MC3R in the appetite regulation by interactive mutual effects on each other. Finally, our study support that elevated basal signalling activity is of high importance to understand the signalling network of GPCRs.

**Metabolic signature of visceral and subcutaneous obese adipose tissue secretomes reveal altered tissular amino acid metabolism**

F. Hanzu[1], M. Vinaixa[2], K. Papageorgiu[1], S. Delgado[3], F. Carmona[3], X. Correig[2], R. Goms[1] & J. Vidal[1]
[1]H Clinic/IDIBAPS, Barcelona, Spain; [2]CIBERDEM, Tarragona, Spain; [3]H Clinic, Barcelona, Spain.

Introduction
Obesity and its associated chronic comorbidities represent a worldwide health problem in epidemic increase. Recent researches have reported notable differences in the amino acids metabolism signatures between obese, mild insulin resistant but non-diabetic, and lean individuals. Moreover, amino acids metabolites are emerging as strong predictors in the development of diabetes in obesity. The contribution of the obese adipose tissue from various depots to the systemic altered amino acids pool is still under debate.
Goal
In the present study we applied a metabolomic approach to direct analyze the amino acids metabolites pattern of the secretomes of visceral and subcutaneous obese adipose tissue in obese subjects, without other major metabolic risk factors, as compared to lean controls.
Subjects and methods
Fat pads were isolated from obese ($n=8$) and non-obese ($n=8$) subjects during laparoscopic surgery. Subcutaneous (periumbilical) and visceral (omental) adipose tissue were incubated with serum-free medium to obtain their secretomes. Metabolite comparative profiling of the lean versus obese secretomes was performed by untargeted gas chromatography-mass spectrometry approach and results analyzed using standard tools.
Results
A significant increased release of alanine, 4-hydroxiproline and 2-ketoisocaproic acid was accounted for all the obese adipose tissue secretomes. Net visceral depot uptake of visceral obese adipose tissue of essential and branched-chain amino acids (BCAA: lysine, leucine; methionine and threonine) and glutamate was significantly diminished in obese as compared to the non-obese visceral adipose tissue secretomes.
Conclusion
This is the first translational metabolomic study reporting that obesity markedly affects the metabolic signature of adipose tissue secretomes. The highest alteration of the amino acids metabolite pattern is present in the visceral adipose fat depot secretome.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Time-course of changes of GLUT4 expression in insulin-sensitive tissues in an animal model of metabolic syndrome**

A. Lehnen[1], N. Leguisamo[1], J. Borges[1], U. Machado[2], M. Okamoto[2], M. Markoski[1], G. Pinto[1], L. Meurer[3] & B. Schaan[1,3]
[1]Instituto de Cardiologia do Rio Grando Sul/Fundação Universitária de Cardiologia, Porto Alegre, Brazil; [2]Universidade de São Paulo, São Paulo, Brazil; [3]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil.

Background
Reduced GLUT4 expression in insulin-sensitive tissues, insulin resistance, inflammation, nonalcoholic steatohepatitis (NASH) and hypertension are pathophysiologic changes expected in metabolic syndrome animal models.
Aims
To fully characterize the development and maintenance of metabolic syndrome features over time (GLUT4 in insulin-sensitive tissues, insulin resistance, inflammation, blood pressure and liver changes) in spontaneously hypertensive rats (SHR) treated with monosodium glutamate (MSG).
Methods
Spontaneously neonate hypertensive rats (18/group) were treated with MSG (MetS) during 9 days, and compared with Wistar-Kyoto (C) and saline-treated SHR (H). Insulin resistance (glucose decay constant rate, kITT), blood pressure (BP), C-reactive protein (CRP), interleukin 6 (IL6), TNF-α, adiponectin, GLUT4 protein (heart, white adipose tissue and gastrocnemius), liver histology and immunohistochemistry for IL1β were evaluated at 3, 6 and 9 months of age.
Results
MetS rats were more insulin resistant ($P<0.001$ for all ages) and had higher BP ($P<0.05$ for all ages) as compared to C. At 6 months, CRP, IL6 and TNF-α were higher ($P<0.001$ for all comparisons) in MetS rats vs H; adiponectin was lower in MetS at 9 months (MetS: $32\pm2$, H: $42\pm2$, C: $45\pm2$ pg/ml; $P<0.001$). GLUT4 protein was reduced in MetS as compared to C: in the heart and gastrocnemius, GLUT4 was 30–40% lower at 3-mo, and it was maintained at 6- and 9-mo. In white adipose tissue, GLUT4 was reduced by ~50% at 3-mo, and at 6- and 9-mo

it was still 20% lower. Histological analysis showed hepatocyte ballooning and fibrosis in the MetS group at 9-mo, and increased IL1β staining when compared with C and H at all ages.
Conclusions
Spontaneously hypertensive rats treated with MSG presented and maintained all metabolic syndrome characteristics, including insulin resistance, high BP and inflammatory marker levels, NASH characteristics and also reduced GLUT4 content in insulin-sensitive tissues.
GLUT4 protein expression at 3, 6 and 9 months of age. The western blot bands and their respective quantitative analyses are represented. C: Wistar-Kyoto rats that did not receive any treatment; H: spontaneously hypertensive rats that did not receive any treatment; MetS: spontaneously hypertensive rats that received MSG during the neonatal period. $n=5$ in all groups. Two-way ANOVA panel A: group, time and interaction ($P<0.001$); Panel B: group ($P=0.006$), time ($P<0.001$) and interaction ($P=0.003$); Panel C: group, time and interaction ($P<0.001$), followed by the Bonferroni's *post hoc* test: ***$P<0.001$ vs. C; $^{\dagger}P<0.05$ and $^{\dagger\dagger\dagger}P<0.001$ vs H at same time. The time course changes inside groups are also showed.

**Acute ghrelin effects on depressive-like behavior in bulbectomyced mice: a possible mechanism of action**

V. Carlini[1], A. Martini[1], P. Kumar[3], R. Sawant[3], M. Rask-Andersen[3], R. Fredriksson[3], S. Rubiales de Barioglio[2], H. Schiöth[3] & M. Fiol de Cuneo[1]
[1]Instituto de Fisiología, Córdoba, Argentina; [2]Facultad de Ciencias Químicas, Universidad Nacional de Córdoba, Córdoba, Argentina; [3]Section of Pharmacology, Uppsala University, Uppsala, Sweden.

Ghrelin (Ghr) is an orexigenic peptide investigated by Lutter and col. 2008 for its potential role in the development of depressive symptoms induced by chronic stress, suggesting that Ghr defends against depressive-like symptoms. Rodent bilateral olfactory bulbectomy (OB) is an animal model that appears to fulfill many of the criteria required for the study of depression; hence, Ghr could be an alternative therapeutic tool for depression therapy. We study the possibility that Ghr could reverse some depressive-like behaviors induced by OB in mice, using the tail suspension test (TST), a test predictive of antidepressant activity, and Ghr effect on mood regulatory hormones. Adult female Albino's Swiss mice were divided in sham and OB, and subsequently infused with intracerebroventricular (ICV) saline (S) or Ghr (0.03 or 3.0 nmol/μl). After the TST was applied, mice were sacrificed and the hypothalamus was dissected in order to study the mRNA expression of genes related to mood using real time PCR.
The OB animals treated with S (OB-S) presented an increase on immobility time compared to sham ($P<0.05$), but the acute infuse of Ghr 3.0 nmol/μl induced a decrease on immobility time ($P \leq 0.05$). The OB infused with Ghr 0.3 nmol/ul showed higher expression of delta opioid receptor (DOR) compared to OB-S ($F=5.484$, $P=0.009$) and sham that received the same dose of Ghr ($F=8.243$, $P=0.0072$). Similar effect was observed in the expression of kappa ($P<0.05$) and Mu ($P<0.01$) opioid receptor. The results show that Ghr 3.0 nmol/μl could reverts the immobility response in OB mice and provide information about the molecular mechanisms of this effect, showing its potential as antidepressant drug.
Declaration of interest

## P1201

**Association of the obesity/type 2 diabetes-related genetic variants with visceral fat acccumulation in obese, overweight and lean subjects**

N. Wawrusiewicz-Kurylonek, A. Citko, J. Goscik, K. Maliszewska, E. Adamska, M. Gorska & A. Kretowski
Medical University of Bialystok, Bialystok, Poland.

Introduction
It has been recently suggested the genetic predisposition to obesity leads to increased risk of type 2 diabetes by its obesity predisposing effect. Surprisingly genetic loci that contribute to the development of obesity identified by genome-wide association studies (GWAS) account for only 2% of the variance in BMI. Visceral fat accumulation has an important role in increasing the risk of developing metabolic disorders, such as type 2 diabetes, dyslipidemia and CVD, but data concerning the genetic background of body fat distribution are limited. The aim of our study was to analyze whether there are specific genetic factors that influence the risk of visceral fat accumulation.
Description of methods
We genotyped 64 SNPs within 40 genes associated with obesity and/or type 2 diabetes (identified by GWAS) in 468 overweight/obese patients and 245 healthy volunteers with normal weight (302 men and 411 women), who underwent anthropometry (BMI, WHR) and body composition analysis: body fat percentage, visceral (VAT) and subcutaneous abdominal adipose tissue (SAT) by multi-frequency bio-impedance method.
Results and conclusion
The association of visceral fat content and VAT/SAT ratio with the distribution of genotypes of the following SNPs: MC4R rs1350341 ($P=005$; $P=0.015$), MC4R rs17782313 ($P=0.035$, $P=0.002$), PPARG rs1801282 ($P=0.02$, $P=0.0019$); BDNF rs6265 ($P=0.034$, $P=0.006$) and SH2B1 rs7498665 ($P=0.042$, $P=0.0038$) has been found in the studied subjects. Our results suggest that there are VAT-specific genetic factors that influence the risk of visceral fat accumulation. The identified genetic variants may help to understand the mechanisms of body fat distribution and serve as early biomarkers of increased risk of metabolic disorders development in overweight/obese patients.

**Loss of hypothalamic-pituitary-adrenal axis improves obese phenotype and restores hypothalamic agouti-related protein mRNA in leptin-deficient ob/ob mice**

M. Nishiyama[1], S. Nakayama[1], M. Okazaki[1], M. Tsugita[1], T. Taguchi[1], S. Makino[2], Y. Okada[1], M. Tsuda[1], Y. Iwasaki[1] & Y. Terada[1]
[1]Kochi Medical School, Nankoku, Japan; [2]Osaka Gyomeikan Hospital, Osaka, Japan.

Purpose
Glucocorticoid excess causes obesity and hyperphagia (e.g. Cushing syndrome), but the molecular mechanism of glucocorticoid-induced hyperphagia is not fully understood. To clarify this point, we investigated here the phenotype of leptin and Corticotropin-releasing hormone (CRH) double knockout mice (DKO).
Methods
Leptin-deficient ob/ob mice were bred with CRH-deficient mice for generation of DKO mice. We examined body weight, food consumption and hypothalamic appetite-related neuropeptide mRNA levels [neuropetide Y (NPY), proopiomelanocortin (POMC) and Agouti-related protein (AgRP)] by quantitative real time PCR, in wild-type littermates (WT), ob/ob and DKO. We also examined the effect of glucocorticoid replacement (corticosterone pellet implantation for 4 weeks) on DKO.
Results
Circulating glucocorticoid levels were markedly high in ob/ob but low in DKO (CORT: WT 4.2±3.5, ob/ob 206.1±48.1, DKO 0.0±0.0 ng/ml). At 9 weeks old, body weight and food intake in DKO were decreased compared with ob/ob, but still increased compared with WT (body weight: WT 25.4±0.3, ob/ob 42.7±1.6, DKO 35.2±0.5 g). The changes of hypothalamic appetite-related neuropeptide levels observed in ob/ob, such as increased in NPY and AgRP mRNA and decreased in POMC mRNA, were attenuated in DKO, especially, hypothalamic AgRP mRNA were dynamically changed (AgRP/GAPDH: WT 100.0±6.7, ob/ob 509.4±33.2, DKO 90.8±8.3). Finally, glucocorticoid replacement on DKO caused to increase food intake and hypothalamic AgRP mRNA (AgRP/GAPDH: WT 100.0±7.8, ob/ob 521.3±59.5, DKO 94.2±8.8, DKO +CORT 243.4±20.0), but there were no alteration in NPY or POMC.
Conclusion
These results suggest that ob/ob mice require glucocorticoid excess and related changes in hypothalamic neuropeptides (NPY, POMC and AgRP) to maintain their body weight and appetite. Because hypothalamic AgRP expressions are quite parallel to circulating glucocorticoid levels in the present study, hypothalamic AgRP is considered as a key molecule in glucocorticoid-induced hyperphagia.

**Different metabolic response to intagastric balloon treatment between non-morbid and morbid type of obesity**

M. Nikolić, G. Mirošević, I. Kruljac, M. Vrkljan, V. Supanc, N. Ljubičić, M. Duvnjak, I. Budimir, B. Pezo Nikolić, M. Sabol, I. Nikolac & M. Bekavac Bešlin
University Hospital Center 'Sestre milosrdnice', Zagreb, Croatia.

BioEnterics Intragastric Balloon (BIB) is a non-invasive procedure which proved to be effective in short-term treatment of obesity. It's effect on alterations in metabolic parameters is poorly understood. Since our previous study showed different ghrelin and leptin response between groups of morbidly (M) and non-morbidly (NM) patients after BIB placement, we aimed to investigate the alteration dynamics in metabolic parameters between these two groups.
Our prospective single-center study included 44 Caucasians treated with BIB for six months, with age range of 20–59, and divided to NM or M type of obesity based on body mass index (BMI) cutoff of 40 kg/m$^2$. Control blood samples were collected at 1, 3, 6 and 12 months after BIB placement. Serum glucose, insulin, C-peptide, glycated hemoglobin, GH, uric acid, lipidogram and homeostatic model assessment 2 (HOMA2) were determined.
Significant differences were observed in anthropometrics without differences between genders or comorbidities. The baseline BMI for NM vs M was 37.65 vs 44.60 kg/m$^2$. Weight loss was statistically different ($P<0.001$) between the studied groups with a median control weight at 6 months of 33.05 vs 39.65 kg/m$^2$. Fasting insulin, HOMA2, glycated hemoglobin and uric acid decreased to similar values in both groups during sixth month, but significantly greater decrease was observed in NM group during first and third month. GH increased substantially in both groups but significantly greater increase occurred in NM group during third month. Fasting serum glucose, C-peptide, cholesterol and triglycerides slightly decreased but without the difference in dynamics.
To our knowledge this is the most detailed study on metabolic parameters in obesity treatment. The results suggest a potential pattern of individualization between NM and M obese patients which could influence future indications for BIB use. Additionally, further studies are needed in order to enlighten the pathophysiologic mechanisms of obesity.

**Metabolic and hormonal consequences of circadian rhythm disruption in Bmal1 null mice**

D. Kennaway, M. Boden & T. Varcoe
University of Adelaide, Adelaide, South Australia, Australia.

There is compelling evidence that shiftworkers are at risk of developing metabolic disturbances, diabetes and obesity as a result of disruption to circadian rhythms, but the mechanisms by which this may occur are not clear. The *Bmal1* null mouse, which lacks both central and peripheral tissue rhythms, was used in this study to address the role of circadian rhythmicity in metabolic homeostasis. Male Bmal1 null mice and wild-type litter mates (2 months) were killed 4 hourly over 24 h and blood, liver and adipose tissue collected. Separate groups were subjected to glucose, pyruvate and insulin tolerance tests. Male and female Bmal1 null mice fed a 22% fat (w/w) diet were killed at 2 months and blood and tissues collected.
Across 24 h plasma insulin was lower and adiponectin and leptin were higher in *Bmal1* null mice compared to wild-type mice while glucose and NEFA were unchanged. Liver *pfkfb3* mRNA in *Bmal1* null mice was decreased, but expression of *per2*, *gck*, *pck1* and *adipor2* mRNA was unchanged and the rhythm of *per2*, *gck*, and *pfkfb3* mRNA absent. In adipose tissue, *per2*, *adipoq*, *retn* and *nampt* mRNA expression was decreased in *Bmal1* null mice and the rhythm of expression of *per2*, *adipoq* and *nampt* mRNA absent.
*Bmal1* null mice had normal glucose and insulin tolerance, but both male and female *Bmal1* null mice had *improved* pyruvate sensitivity. *Bmal1* mice of both sexes weighed less than wild type mice, but had larger epigonadal and retroperitoneal fat depots, although they responded similarly to the high fat diet with respect to increased adiposity and hormone changes.
These studies provide further evidence for a role of circadian rhythmicity in the glucose/insulin and adipoinsular axes. Disruption of tissue rhythmicity in shiftwork, in conjunction with poor diet and sleep loss may contribute to the health burden experienced by shiftworkers.

**Aldosterone increases oxidative stress in differentiated, but not in undifferentiated 3T3-L1 adipocytes via activation of mineralocorticoid receptors**

R. Limor, M. Uda, E. Knoll & N. Stern
Tel Aviv Sourasky Medical Center and Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.

In the cardiovascular system, aldosterone promotes inflammation, tissue remodeling and endothelial dysfunction. In diet-induced obesity, lipid accumulation involves acceleration of preadipocyte differentiation into mature adipocytes. Mutually exerted control mechanisms may exist between aldosterone secretion and fat: circulating aldosterone is increased in proportion to fat mass in humans and fat tissue expresses mineralocorticoid receptors (MR). Here we tested whether or not aldosterone affects oxidative stress in 3T3-L1 cells, a rodent line of preadipocytes which undergoes differentiation to mature fat cells under the

combined influence of serum, dexamethasone and insulin. First, both undifferentiated and differentiated 3T3-L1 cells expressed MR as quantified by Real Time PCR. Second, aldosterone (at a physiological concentration-1 nmol/l) had no effect on cell differentiation as assessed by the expression of fat cell differentiation markers, including AP2 and PPARγ. Third, aldosterone (1 nmol/l) induced a ∼3.5 increase in the formation of intracellular reactive oxygen species (ROS) as determined by oxidative conversion of cell-permeable chloromethyl-2′,7′-dichlorodihydroflurescein diacetate to fluorescent dichlorofluorescein (DCF) in both differentiating and fully differentiated adipocytes but not in undifferentiated 3T3-L1 preadipocytes. This effect was fully blocked by the specific MR antagonist eplerelone (100 nmol/l). We identified three isoforms of lipoxygenase (LO), dioxygenase enzymes which incorporate molecular oxygen into unsaturated fatty acids such as arachidonic acid and linoleic acid in these cells, platelet 12(S)-LO, leukocyte type (12/15)- and an epidermal LO, of which the expression of the platelet and leukocyte type increased with aldosterone treatment. One LO product, 12 hydroxyeicosatetraenoic acid (12HETE) was able to increase ROS formation in differentiated 3T3-L1 cells (X2-3 folds). These results suggest that aldosterone can increase oxidative stress in differentiated, but not undifferentiated adipocytes, indicating that fat accumulation in mature fat cells predisposes adipose tissue to the pro-oxidative effect of aldosterone, and perhaps serves as a means to increase ROS through oxidation of fatty acids such as 12HETE.

### Testosterone protects from metabolic syndrome-associated prostate inflammation: an experimental study in rabbit

L. Vignozzi[1], A. Morelli[1], E. Sarchielli[1], P. Comeglio[1], S. Filippi[1], I. Cellai[1], E. Maneschi[1], S. Serni[1], M. Gacci[1], M. Carini[1], M. Piccinni[1], F. Saad[2], L. Adorini[3], G. Vannelli[1] & M. Maggi[1]

[1]University of Florence, Florence, Italy; [2]Gulf Medical University, Ajman, United Arab Emirates; [3]Intercept Pharmaceuticals, Corciano - Perugia, Italy.

Metabolic syndrome (MetS) and benign prostatic hyperplasia (BPH)/lower urinary tract symptoms (LUTS) are often associated. One of their common denominators is hypogonadism. However, testosterone supplementation is limited by concerns for potential prostatic side effects. The objective was to determine whether MetS-associated prostate alterations are prevented by testosterone supplementation. We used a previously described animal model of MetS, obtained by feeding male rabbits a high-fat diet (HFD) for 12 weeks. Subsets of HFD rabbits were treated with testosterone or with the farnesoid X receptor agonist INT-747. Rabbits fed a standard diet were used as controls. HFD-animals develop hypogonadism and all the MetS features: hyperglycemia, glucose intolerance, dyslipidemia, hypertension, and visceral obesity. In addition, HFD-animals show a prostate inflammation. Immunohistochemical analysis demonstrated that HFD-induced prostate fibrosis, hypoxia, and inflammation. The mRNA expression of several proinflammatory (IL8, IL6, IL1β, and TNFα), T lymphocyte (CD4, CD8, Tbet, Gata3, and ROR γt), macrophage (TLR2, TLR4, and STAMP2), neutrophil (lactoferrin), inflammation (COX2 and RAGE), and fibrosis/myofibroblast activation (TGFβ, SM22α, αSMA, RhoA, and ROCK1/-ROCK2) markers was significantly increased in HFD prostate. Testosterone, as well as INT-747, treatment prevented some MetS features, although only testosterone normalized all the HFD-induced prostate alterations. Interestingly, the ratio between testosterone and estradiol plasma level retains a significant, negative, association with all the fibrosis and the majority of inflammatory markers analyzed. These data highlight that testosterone protects rabbit prostate from MetS-induced prostatic hypoxia, fibrosis, and inflammation, which can play a role toward the development/progression of BPH/LUTS.

### GPR83 in interaction with GHSR and MC3R: lessons from *in vitro* studies

A. Müller[1], T. Müller[2], G. Kleinau[1], A. Grüters-Kieslich[1], H. Krude[1], M. Tschöp[2,3] & H. Biebermann[1]

[1]Institute of Experimental Pediatric Endocrinology, Berlin, Germany; [2]Institute for Diabetes and Obesity, Neuherberg, Germany; [3]Dept. of Metabolic Diseases, Munich, Germany.

GPR83 is an orphan G-protein coupled receptor (GPCR) and is expressed in thymus and brain. Within the brain GPR83 mRNA is identified at high levels in the hypothalamic arcuate nucleus that is known to control for body weight regulation.

Expression of GPR83 in the arcuate nucleus and the protection of GPR83 knock-out mice against diet induced obesity prompted us to investigate GPR83 signaling properties as well as potential interaction with the melanocortin 3 receptor (MC3R) and the growth hormone secretagogue receptor (GHSR). Both receptors are also localized in the arcuate nucelus and they are known to be key-players of body weight regulation. Recently we demonstrated that MC3R and GHSR are able to form heterodimers which modulates mutually the signaling properties of both receptors.

In this study investigation of cAMP accumulation and IP3 formation *in vitro* revealed no basal activity of GPR83 in Gs nor Gi, but significant basal activity in Gq/11 mediated signaling. Due to unknown GPR83 ligands we designed and tested a potential constitutively active mutant in transmembrane helix 6 and confirmed thereby activation of Gq/11 signaling. To test for GPR83/MC3R and GPR83/GHSR heterodimerization a sandwich ELISA as well as Yellow fluorescent protein complementation assay were utilized and both methods confirmed interaction of GPR83 with MC3R or GHSR *in vitro*. Functional characterization of the GPR83/MC3R and GPR83/GHSR heterodimers in coexpression studies revealed a modification of signaling properties compared to monomers or homodimers: down-regulation of GHSR signaling in response to ghrelin and up-regulation of MC3R in response to its ligands alpha- and gamma-MSH.

In conclusion, GPR83 might be a new important key-player in hypothalamic body weight regulation and could therefore represent a value target to modulate energy metabolism. This receptor couples intracellularly to Gq and is able to modify by formation of heterodimers the signaling capacities of MC3R and GHSR.

**Metabolic effects of 3-iodothyronamine in hepatocytes**

S. Ghelardoni, G. Chiellini, S. Frascarelli & R. Zucchi
University of Pisa, Pisa, Italy.

3-iodothyronamine (T1AM) is an endogenous thyroid hormone derivative which produces profound metabolic effects such as a shift in fuel substrate utilization from carbohydrates to lipid. Thus, in the present work we investigated the effects of T1AM on hepatic glucose metabolism.

To assess metabolite release, human hepatocellular carcinoma cells (HepG2) were exposed for 4 h to different concentrations of exogenous T1AM (0.1, 1 and 10 μM) in glucose production buffer (DME base containing pyruvate and lactate). Cell culture medium was then collected and glucose and ketone body (acetoacetate and β-hydroxybutyrate) levels were evaluated. In addition, isolated rat liver preparations were perfused either with Krebs-Henseleit buffer or glucose production buffer containing 1 μM T1AM. The effluent perfusate was then collected for 60 min at 5 min intervals to measure the release of glucose and ketone bodies (acetoacetate and β-hydroxybutyrate).

In HepG2, only infusion with 1 μM T1AM induced a significant increase in glucose production ($9.11 \pm 0.37$ vs $7.48 \pm 0.14$ μg/mg of total proteins in cell lysate, $P < 0.01$), and a significant decrease in acetoacetate release ($252.4 \pm 10.5$ vs $286.8 \pm 7.2$ nmol/ mg of total proteins in cell lysate $P < 0.05$).

Liver perfusion with glucose production buffer in the presence of 1 μM T1AM also showed a significant increase of glucose production ($0.555 \pm 0.062$ vs $0.369 \pm 0.043$ mg/min per g $P < 0.05$), while infusion with Krebs-Henseleit buffer did not produce any significant change in glucose metabolism.

In conclusions our preliminary data suggested that T1AM stimulated gluconeogenesis and inhibited ketogenesis under conditions of glucose deprivation.

**The adipokines TNF-α and IL6 predicted incident cancer development in a Chinese community-based cohort**

C. Yeung[1], A. Tso[1], A. Xu[1], T. Lam[1], S. Lo[2], C. Fong[1], N. Wat[1], J. Woo[3], B. Cheung[1] & K. Lam[1]
[1]The University of Hong Kong, Hong Kong SAR, China; [2]The Hospital Authority of Hong Kong, Hong Kong SAR, China; [3]The Chnese University of Hong Kong, Hong Kong SAR, China.

Adipose tissue is recognized as an active endocrine organ. Cytokines released from adipocytes induce chronic low-grade inflammation, which is linked to the development of cardiovascular diseases and malignancy.In this study, we examined the relationship between baseline adipokines level and incident cancer risk in a community-based cohort of Chinese subjects. Subjects were recruited from the Hong Kong Cardiovascular Risk Factors Prevalence Study 2(CRISPS 2) cohort. Those with known malignancy were excluded. Fasting blood forglucose, insulin, lipids, the adipokines interleukin-6 (IL6), soluble tumor necrosis factor receptor 2 (sTNFR2, as a surrogate marker of tumor necrosis factor-alpha), adiponectin and adipocyte-fatty acid binding protein (A-FABP) levels was collected at baseline. Incident cancer cases were identified after a median follow up of 9.6 years. 1897 subjects were included in the final analysis. During the study period, 94 subjects developed cancers. Compared to subjects with no cancer, subjects who developed cancer were older at baseline ($61.0 \pm 11.5$ vs $51.9 \pm 11.8$, $P < 0.001$), had a higher proportion of males (59.6 vs 45.9%, $P = 0.009$), central obesity (38.3 vs 29.6%, $P = 0.008$), diabetes (27.7 vs 14.8%, $P = 0.036$), hypertension (36.2 vs 26.7%, $P = 0.045$) and dyslipidemia (71.9 vs 60.6%, $P = 0.013$). They had a higher serum level of IL6 (0.78 vs 0.58 pg/ml in male, 0.65 vs 0.54 pg/ml in female, $P < 0.001$), sTNFR2 (2419.2 vs 1991.7 ng/ml in male, 2051.7 vs 1816.0 ng/ml in female, $P < 0.001$) and A-FABP (21.0 vs 19.0 ng/ml in male, 24.2 vs 27.9 ng/ml in female, $P = 0.02$). Adiponectin level between the two groups was not significantly different. After adjustment for conventional risk factors, only baseline IL6 (HR 1.51, 95% CI 1.16–1.97) and sTNFR2 (HR 2.36, 95%CI 1.16–4.81) predicted incident cancer development. Our data supported the hypothesis that chronic low grade inflammation caused by obesity could increase the risk of malignancy.

## P1211

**ASP injection promotes macrophage infiltration and M1 polarization in obese adipose tissue**

A. Fisette[1], K. Oikonomopoulou[2], M. Munkonda[1], J. Lambris[2] & K. Cianflone[1]
[1]Centre de Recherche de l'Institut Universitaire de Cardiologie et de Pneumologie de Québec, Quebec, Quebec, Canada; [2]University of Pennsylvania, Philadelphia, Pennsylvania, USA.

Recent integrative approaches showed that adipose tissue play a major endocrine role. Molecules secreted by the expanding adipose tissue modulate systemic inflammation and contribute heavily to the pathology of obesity co-morbidities. Acylation stimulating protein (ASP) is an adipokine that has been linked with energy metabolism and lipid metabolism. The ASP receptor, C5L2, is widespread within tissues in the organism, yet ASP effects outside the adipose tissue remain explored. Both ASP and its receptor, C5L2, are also linked to immunity and inflammation. We hypothesized that ASP could play an inflammatory role in addition to its metabolic effects and investigated ASP acute effects in mice.

In the present study, we show that acute ASP injection influences substrate partitioning. ASP increases glucose uptake in the skeletal muscle and adipose tissue and decreases liver glucose absorption. A more rapid glucose clearance is seen after ASP injection, with lower associated insulin levels. Insulin sensitivity is left unaltered by ASP treatment.

In addition, we show that macrophage infiltration within the adipose tissue, skeletal muscle and liver is mildly increased by ASP injection. While anti-inflammatory M2 macrophage tissue content is unaltered, pro-inflammatory M1 macrophages population is increased. ASP also increases the plasmatic concentration of several circulating adipocytokines including IL6, TNF-a and MIP-1a.

Our results suggest that ASP has inflammatory effects in addition to its metabolic role. Plasma ASP concentration is elevated in obesity, type 2 diabetes and cardiovascular diseases. A better understanding of the inflammatory role of ASP in these pathologies could potentially set the basis for the development of a therapeutic avenue based on ASP neutralization.

**Regulation of adiponectin by free fatty acids in lean and obese subjects**

K. Kim[1], S. Nam[1], C. Ahn[1], J. Yu[2], K. Kim[1], B. Cha[1,2], H. Lee[1] & B. Richelsen[3]
[1]Yonsei University Hospital, SEOUL, Republic of Korea; University Medical Center, SEOUL, Republic of Korea; [3]Aarhus University Hospital, Aarhus, Denmark.

Objective
To evaluate the effects of free fatty acids (FFAs) on the regulation of plasma and adipose tissue mRNA adiponectin expression in lean and obese subjects.
Methods
Seven obese men ($31.3 \pm 1.1$ kg/m$^2$) and eight lean men ($21.3 \pm 0.4$ kg/m$^2$) were studied. Subjects received an Intralipid 20% infusion over 180-min with sodium heparin. Blood sampling and abdominal subcutaneous adipose tissue biopsy were taken before and after.
Results
The FFA concentration was increased six fold after Intralipid/heparin infusion in both lean and obese groups. Adipose tissue adiponectin mRNA was significantly reduced by Intralipid/heparin infusion ($38.0 \pm 7.7$ vs $21.1 \pm 3.0.0$, $P<0.05$), and plasma level of adiponectin was reduced from 5.72 to 5.37 which, however, was a non-significant reduction ($P=0.16$). If the two groups were separated, in the lean subjects, adiponectin mRNA was significantly lower after Intralipid/heparin infusion ($48.3 \pm 12.5$ vs $23.2 \pm 5.0$, $P<0.05$), whereas there was no difference in plasma adiponectin before and after ($5.89 \pm 0.6$ vs $5.84 \pm 0.8$, $P=0.88$). In obese subjects, plasma adiponectin concentration was significantly lower after Intralipid/heparin infusion ($5.5 \pm 0.8$ vs $4.8 \pm 0.8$, $P<0.05$), whereas there was no difference in adiponectin mRNA expression ($26.0 \pm 6.3$ vs $18.7 \pm 3.1$, $P=0.24$).
Conclusions
Albeit the other data on the effect of FFAs on adiponectin concentrations are not consistent, we could get that FFAs suppress the expression of adiponectin in lean and obese human. The issue of possible FFA-induced regulation of adiponectin warrants further investigations.

## P1213

**SUR2a gene is upregulated in skeletal muscle insulin resistance of obese rats: correlation with GLUT4 gene**

M. Felipe dos Santos Ferreira Marques, R. Cristina Tieko Mori, M. Mitiko Okamoto & U. Fabres Machado
University of São Paulo, São Paulo, Brazil.

Objective
The aim of this study was to investigate whether SUR2A (sulfonylurea receptor type 2A, ABCC9) MEF2a (myocyte enhancer factor-2a) and HIF1a (Hypoxia-inducible factor-1) can influence glucose uptake in oxidative muscle soleus by regulating GLUT4 expression.
Methods
Insulin resistance was induced in male Wistar rats by inducing obesity with monosodium glutamate (MSG). At the age 3 months, half control and MSG-treated animals started receiving 0.1 mg/kg/day of glimepiride in the drinking water, and distributed in 3 experimental groups: control rats (C), MSG-obese rats (O) and MSG-obese rats treated with glimepiride (OG). Animals were submitted to insulin tolerance test (ITT) and samples of soleus muscle were excised for quantification of gene expression by Real Time RT-PCR and GLUT4 protein.
Results
OG rats presented a ~51% increase in SUR2A mRNA content in comparison to O and C rats ($P<0.001$). O rats showed 16% increase in GLUT4 mRNA content ($P<0.01$ vs C), without any increase in GLUT4 protein. After glimepiride treatment, OG rats increased GLUT4 mRNA (21%, $P<0.01$ vs C) and protein (131%, $P<0.01$ vs C; and 73%, $P<0.05$ vs O). No significant differences ($P>0.05$) in mRNA expression of MEF2a and HIF1a were found.
Conclusion
We conclude that the glimepiride increased the GLUT4 expression in soleus of the insulin resistant animals which could be associated to SUR2A genes expression.

**Circulating oxidized LDL in patients with visceral obesity**

A. Giestas, I. Palma, J. Oliveira, M. Ferreira & H. Ramos
Hospital Santo António, Centro Hospitalar do Porto, Oporto, Portugal.

Background
Visceral obesity has been associated with systemic oxidative stress, measured by oxidized LDL (oxLDL).
Aim
Investigate circulating oxLDL levels in patients with visceral obesity, and its relationship with metabolic abnormalities found in visceral obesity.
Methods
We evaluated blood pressure (BP), waist circumference (WC), fasting glucose, total cholesterol, LDL, HDL, triglycerides, ApoA1, ApoB, ApoCIII, Lp(a) and oxLDL in 100 asymptomatic non-smoking patients (56 men/44 women) aged 50–60 years, without cardiovascular disease.
Subjects were grouped as it follows: i) WC < 102 cm in men and WC < 88 cm in women; ii) WC ≥ 102 cm in men and WC ≥ 88 cm in women. Data processed in SPSS 16.0.
Results
Subjects with increased WC had higher systolic BP (women: 135+/−24 vs 146+/−27 mmHg, $P<0.05$; men: 134+/−22 vs 145+/−25 mmHg, $P<0.05$), higher levels of triglycerides (women: 129.5+/−54.0 vs 172.9+/−13.0 mg/dl, $P<0.05$; men: 132.2+/−18.0 vs 183.6+/−76.0 mg/dl, $P<0.01$) and ApoCIII (women: 8.8+/−4.3 vs 12.3+/−9.9 mmHg, $P<0.01$; men: 9.4+/−5.3 vs 14.4+/−7.4 mmHg, $P<0.01$), and lower HDL (women: 56.8+/−11.8 vs 47.3+/−13.4 mg/dl, $P<0.05$; men: 44.5+/−11.1 vs 36.8+/−10.4 mg/dl, $P<0.05$) and ApoA1 (women: 170.0+/−22.6 vs 152.6+/−27.6 mg/dl, $P<0.05$; men: 144.6+/−22.3 vs 133.2+/−24.2 mg/dl, $P<0.05$). There was no significant difference ($P>0.05$) between the groups in fasting glucose, LDL, ApoB and Lp(a) levels; however, those with increased WC had higher levels of oxLDL (women: 59.8+/−14.7 vs 67.8+/−14.8 mg/dl, $P<0.05$; men: 61.3+/−21.1 vs 69.0+/−19.5 mg/dl, $P<0.05$).
OxLDL was positively correlated with WC ($r=0.86$, $P<0.01$), systolic BP ($r=0.27$, $P<0.05$), plasma triglyceride ($r=0.29$, $P<0.05$), ApoCIII ($r=0.38$, $P<0.05$), LDL ($r=0.51$, $P<0.01$) and ApoB ($r=0.54$, $P<0.01$); and negatively correlated with HDL ($r=-0.26$, $P<0.01$) and ApoA1 ($r=-0.20$, $P<0.01$).
Conclusion
The study showed that high WC was strongly associated with high levels of oxLDL.

**Leptin modulates brain neural activity associated with feeding behavior in patients with lipodystrophy**

D. Aotani, K. Ebihara, N. Sawamoto, T. Kusakabe, M. Aizawa-Abe, S. Kataoka, T. Sakai, C. Ebihara, J. Fujikura, K. Hosoda, H. Fukuyama & K. Nakao
Kyoto university, Kyoto, Japan.

Introduction
Markedly decreased plasma leptin concentrations in patients with lipodystrophy commonly lead to overeating. Leptin-replacement therapy improves feeding behavior in these patients. The aim of the present study is to clarify neural networks influenced by leptin signals for appetite regulation in the patients with lipodystrophy.
Methods
We measured neural responses to visual food stimuli by use of functional magnetic resonance imaging (fMRI) and investigated subjective feeling on appetite under both fasting and postprandial conditions in ten patients with or without leptin-replacement therapy and age- and sex-matched ten healthy subjects.
Results
In fMRI analysis, significant difference of food-related neural activity between controls and patients was detected in many regions under postprandial condition,

while only in a few area under fasting condition. Leptin increased neural activity in a region involved in satiety and suppressed in regions involved in hunger in patients under postprandial condition, while altered only in a few areas under fasting condition. In subjective feeling, there was no apparent difference of hunger feeling under fasting condition, while postprandial satiety feeling in patients was significantly reduced compared to controls, which was effectively increased by leptin.
Conclusion
These findings may suggest that improvement of feeding behavior by leptin is associated with modulation of neural processing in the brain regions involved in energy homeostasis and appetite regulation.

**Age variations in adiposity and body fat composition among spanish women**

J. Pedrera-Zamorano, R. Roncero-Martin, J. Calderon-García, T. Rodríguez-Domínguez, P. Rey-Sanchez & M. Canal-Macias
University of Extremadura, Caceres, Spain.

Objective
To characterize the age variations of fatness pattern in Spanish women
Research methods and procedures:
A cross-sectional study of 2226 Spanish women (16 to 74 years old) women was undertaken to study age variations in adiposity, body composition, obesity and central fat distribution. The women were divided into seven groups: Group I (G I, 15–24 years), Group II (G II, 25–34 years), Group III (G III, 35–44 years), Group IV (G IV, 45–54 years), Group V (G V, 55–64 years), Group VI (G VI, 65–74) and Group VII (G VII, > 74 years). Body composition measures were obtained, and regional fat and lean mass patterns were characterized with the use of electrical bioimpendance (BIA) (Body Composition Analyzer BC-418MA TANITA). Significant differences were assessed with Student's t test and ANOVA adjusting for age and BMI.
Results
A significant increasing age trend was observed in adiposity and body fat composition measures. Women in G I had significantly lower means compared with those in G V and above. However, there was no significant age trend in lean mass measurements and a significant decrease was observed in group VII. The results revealed that significantly more women in G I-G III (45.8%) were normal weighted (BMI 18.5 to 24.9), while significantly more women in G IV and above were overweighed (BMC $\geq$ 25) and obese (BMI $\geq$ 30). Age had significant positive correlations with measures of adiposity and body fat composition. This significant positive impact of age remained even after controlling for the effect of BMI.
Conclusion
In conclusion, the present investigation revealed that among Spanish women there is a significant positive age trend in adiposity and body fat composition, which is independent of overall adiposity (BMI). However, with ageing, muscle trends to decrease. Furthermore, with increasing age, there is a trend of increasing levels of overweight and obesity.

## P1217

**Serum liver fatty acid binding protein levels correlate positively with obesity and insulin resistance in chinese young adults**

J. Shi[1], J. Hong[1], W. Gu[1], Y. Zhang[1], B. Cui[2], Q. Yan[1], W. Wang[1] & G. Ning[1]
[1]Ruijin Hospital, Shanghai, China; [2]Institute of Health Sciences, Shanghai, China.

Clear evidence on the specific impact of fatty acid binding proteins (FABPs) on cell biology and lipid metabolism in complex systems had been lacking until FABP-deficient mice models were created. Surprisingly, no change in appearance, gross morphology or viability was observed in FABP1-deficient mice. However, metabolic parameters in mice upon exposure to high-fat/cholesterol diet differed between studies. Therefore, liver fatty acid-binding protein (also called FABP1) plays an inconclusive role in adiposity. We investigated the association of serum FABP1 levels with obesity and insulin resistance in Chinese young people lower than 30 years old. Cross-sectional analysis including 200 obese and 172 normal-weight subjects matched for age and sex, anthropometric measurements were performed and serum FABP1 and biochemical characteristics were measured. Insulin resistance was determined by homeostasis model assessment of insulin resistance (HOMA-IR) and by the insulin sensitivity index (Si). FABP1 levels in obese subjects were significantly higher than those in normal-weight subjects ($P<0.001$) and the significance remained after adjustment for age, gender, alanine aminotransferase and aspartate aminotransferase ($P<0.001$). Serum FABP1 levels were significantly correlated with many metabolic-related indices, with BMI and triglycerides as the independent determinants. FABP1 levels remained an independent risk factor of insulin resistance assessed by HOMA-IR ($\beta=0.119$, $P=0.006$) and Si values lower than 0.990 (OR = 2.107 per S.D. unit, 95% CI [1.230–3.611], $P=0.007$) after adjustment for age, sex, BMI, waist circumference, systolic blood pressure, and fasting blood glucose. Serum FABP1 correlate positively with obesity and insulin resistance in Chinese young adults. Our data supports the fact that FABP1 might be an important mediator participating in fatty acid metabolism and energy balance.

## P1218

**Gender differences in measurements of total and regional body composition in preschool children**

J. Dahlgren[1], A. Karlsson[1] & J. Kullberg[2]
[1]University of Gothenburg, Gotenburg, Sweden; [2]Uppsala University, Uppsala, Sweden.

Background
Generally, abdominal adipose tissue correlates stronger to decreased insulin sensitivity than what BMI does. In adults, males have more visceral adipose tissue (VAT) and less subcutaneous adipose tissue (SAT) than females. Comparisons between measures of body composition from magnetic resonance imaging (MRI), dual x-ray absorptiometry (DXA) and anthropometry have been studied previously; however not in preschool children.
Aim
This study compares abdominal and whole-body measures of body composition from MRI, DXA and anthropometry in preschool children and examined whether there are differences in the abdominal fat distribution between genders.
Methods
One-hundred-five children (57 boys, 48 girls) were recruited. Body composition was measured using a GE Lunar Prodigy DXA. Weight, height and waist circumference (WC) were recorded. In a subgroup of 33 boys and 18 girls, MRI was performed using sixteen T1-weighted slices over the entire abdomen. SAT and VAT volumes were measured using semi-automated segmentation.
Results
BMI, WC (cm), WHtR did not differ between genders. Total FM% and truncal FM% measured with DXA differed between genders (21 and 17% in girls versus 17 and 13% in boys, respectively ($P<0.01$)), but this was not the case in the subgroup. Total LM (kg) and truncal LM (kg) was increased in boys compared with girls (11.7 kg and 6.5 kg in girls, and 12.7 kg and 7.1 kg in boys, ($P<0.001$)). This gender difference was also seen in the subgroup ($P<0.01$). Boys had significantly more VAT than girls (0.17 (L) vs 0.10 (L), $P<0.001$). Abdominal SAT measured with MRI correlated to truncal fat mass measured with DXA ($r=0.91$, $P<0.001$) while VAT did not. Neither BMI nor WC correlated to VAT. Conclussion: DXA and anthropometric fat measures correlate stronger to MRI measures of SAT than of VAT. From these data boys seem to have more VAT than girls already at this young age.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1219

**Comparison of serum high-molecular-weight (HMW) adiponectin and homeostasis model assessment of insulin resistance (HOMA-IR) as markers for metabolic syndrome (MS) in estonian adult population**

T. Eglit, T. Rajasalu, I. Ringmets & M. Lember
University of Tartu, Tartu, Estonia.

Introduction
The MS is a cluster of metabolic risk factors which are closely associated with insulin resistance and hypoadiponectinemia. The HMW adiponectin has been acknowledged as a predictive marker for MS. The prevalence of MS increases worldwide. Recently, the prevalence of MS among Estonian adults was estimated to be 26%. In the current study, we aimed to compare the utility of HMW adiponectin and HOMA-IR for the identification of MS.
Methods
Our study was a cross-sectional, population-based sample of the general population in Estonia aged 20–74 years and included 458 subjects (191 men). MS was diagnosed by National Cholesterol Education Program Adult Treatment Panel III criteria. Insulin resistance was estimated using the HOMA-IR. HMW adiponectin was measured by ELISA. The areas under the receiver operator characteristic curves (AUROC) were calculated to compare the ability of HMW adiponectin and HOMA-IR to identify subjects with MS.
Results
The median (interquartile range) HMW adiponectin level (μg/ml) was significantly lower among subjects with MS compared with subjects without MS in both genders: in men 2.1 (1.3–3.0) vs 2.8 (1.7–4.3) respectively ($P=0.002$) and in women 3.1 (2.1–4.8) vs 5.1 (3.5–6.9), respectively ($P=0.0001$). Subjects with MS had significantly higher HOMA-IR ($\pm$S.D.) compared with subjects without MS: $2.9\pm2.0$ vs $1.1\pm1.0$, respectively ($P=0.0001$). The AUROC for HMW adiponectin and HOMA-IR to predict the presence of MS were in men 0.64 vs 0.864 respectively ($P=0.0001$) and in women 0.702 vs 0.839 respectively ($P=0.0008$). After adjustment for age and BMI the AUROC for HMW adiponectin and HOMA-IR were in men 0.833 vs 0.88 respectively ($P=0.02$) and in women 0.897 vs 0.907, respectively ($P=0.5$).
Conclusions
The lower HMW adiponectin level and higher HOMA-IR are clearly associated with MS. HOMA-IR was superior to HMW adiponectin to predict the presence of MS in Estonian adult population.

## P1220

**Local inflammatory response in adipose tissue dysfunction**

G. Cantini[1], M. Francalanci[1], A. Di Franco[1], S. Baglioni[1], G. Poli[1], J. Samavat[1], V. Querci[1], F. Liotta[1], G. Perigli[1], M. Lucchese[2], G. Forti[1] & M. Luconi[1]
[1]University of Florence, Florence, Italy; [2]AOU Careggi, Florence, Italy.

Chronic low-grade inflammatory condition is associated with metabolic pathologies such as obesity. However, the role exerted by local inflammation occurring in different fat depots, such as subcutaneous (SAT) versus visceral (VAT) adipose tissue (AT), is still under evaluation. Aim of the present study was to characterize the inflammatory state in adipose tissue of obese (OB: $n=58$, mean$\pm$S.D. BMI$=47\pm9$) vs normoweight (NOR: $n=28$, mean$\pm$S.D BMI$=24\pm2$) patients subjected to bariatric or general abdominal surgery at our University Hospital.
Blood, VAT and SAT biopsies were collected at surgery for analyses. Cytofluorimetric immunophenotyping of blood cells and stromal vascular fraction obtained from AT revealed a higher presence of gammadelta lymphocytes in blood and AT from OB vs NOR. Moreover, TaqMan analysis of gene expression confirmed a significant increase in specific inflammatory markers in AT of OB (n = 38) vs NOR ($n=26$), being VAT from OB interested by a significantly worse inflammatory state characterized by M1 macrophage polarization (CD40+SE expression fold increase$=3.76+0.68$ in VAT of OB/NOR, $P<0.005$; CD206+SE expression fold increase$=0.39+0.04$ in VAT of OB/NOR, $P<0.05$) and decreased regulatory components (IL10 VAT/SAT$\pm$SE expression$=10.6\pm3.9$ in NOR and $1.6\pm0.4$ in OB, $P<0.05$; foxp3/CD3$\pm$SE expression: $27.7\pm12.3$ SAT and $5.5+1.5$ VAT of NOR, $17.4+1.8$ SAT and $3.2+0.5$ VAT of OB; $P<0.05$ VAT NOR vs OB and $P<0.001$ OB SAT vs VAT). This condition was associated with a reduced VAT functionality in OB vs NOR evaluated by adiponectin expression (adiponectin$\pm$SE expression: 29.1E6$\pm$10.1E6 SAT and 18.0E6$\pm$.9E6 VAT in 17 NOR, 10.2E6$\pm$1.7E6 SAT and 6.5E6$\pm$1.1E6 VAT in 26 OB; $P<0.01$ SAT and VAT NOR vs OB, $P<0.05$ OB SAT vs VAT).
In conclusion, these data suggest that obese AT is characterized by a local inflammation associated with functional metabolic alterations, more evident in VAT than SAT, which may play a pivotal role in the development of metabolic pathologies.

**Effect of two different types of bariatric surgery on metabolic profile in obese type 2 diabetic women**

O. Bradnova[4], T. Halkova[4], J. Vcelak[1], M. Vankova[1], K. Dvorakova[1], T. Grimmichova[1], S. Stanicka[1], P. Sramkova[1,2], K. Dolezalova[2], M. Fried[2], I. Kyrou[3], M. Hill[1], V. Hainer[1], B. Bendlova[1], P. McTernan[3], S. Kumar[3] & J. Vrbikova[1]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]OB clinic, Prague, Czech Republic; [3]University Hospital Coventry and Warwickshire, WISDEM, Warwick Medical School, University of Warwick, Coventry, United Kingdom; [4]Department Of Anthropology and Human Genetics, Charles University, Prague, Czech Republic.

Introduction
Bariatric surgery has been proved to be the most effective treatment for type 2 diabetes mellitus (T2D). Post-operative improvement in insulin sensitivity seems to be partly independent of weight loss and may be affected by changes in incretin secretion. Previous studies reported that the glucose-dependent insulinotropic polypeptide (GIP)-induced enhancement of fat stores may lead to increased insulin resistance. We determinated the effect of laparoscopic adjustable gastric banding (LAGB) and biliopancreatic diversion (BPD) on glucose profile and on secretion of GIP in response to meal test.
Methods
Our cohort included 23 obese T2D women who underwent bariatric surgery: 11 BPD (age:$50\pm6.2$y; BMI:$47\pm7.8$), 12 LAGB (age:$54\pm9.5$y; BMI:$44\pm7.3$). Meal test (300 ml protein drink) and euglycaemic hyperinsulinaemic clamp were performed before, 1 month after surgery and at time when 15% weight loss was achieved. Investigated parameters: BMI, insulin resistance/sensitivity, and GIP. Statistical analysis: ANOVA with repeated measures.
Results
We confirmed that BPD had more significant impact on weight loss than LAGB ($P=0.0002$). Both surgeries significantly reduced HbA1c ($P=0.001$), but in the long-term perspective, BPD seems to be more efficient with regard to HbA1c reduction ($P=0.06$). In response to surgery insulin resistance measured by HOMA-IR significantly decreased ($P=0.0001$) while insulin sensitivity measured by clamp increased ($P=0.0002$) but there was no interaction with the type of surgery. No difference in fasting levels of GIP between the study groups was observed. On the other hand, stimulated levels of GIP after the meal test were significantly reduced in BPD group in comparison with LAGB group ($P=0.003$).
Conclusion
Both BPD and LAGB positively affected insulin sensitivity. However, a better glucose control was observed with 15% body weight reduction after BPD. Decreased GIP levels revealed during the meal test may contribute to the positive changes in glucose metabolism in patients who underwent BPD.

## P1222

**Visceral-to-subcutaneous fat ratio using fat measurement CT is essential for the assessment of risk for diabetes, hypertension and early atherosclerosis**

H. Kim[1], S. Bae[1], E. Kim[1] & C. Kim[2]
[1]Asan Medical Center, Seoul, Republic of Korea; [2]Soonchunhyang University College of Medicine, Bucheon, Republic of Korea.

Background and aims
Obesity is an important risk factor for metabolic and cardiovascular disease. Although body mass index (BMI) and waist circumference are convenient and economic methods for assessment of obesity, those could not fully reflect risk for diabetes, hypertension and early atherosclerosis.
Materials and methods
We cross-sectionally analyzed anthropometric and laboratory data of 868 Korean adults (age 53.2±11.2 years) which were recorded during regular health check-ups. Visceral fat area was determined by computed tomography, and brachial-ankle pulse wave velocity was measured as an indicator of arterial stiffness. Visceral fat obesity (VFO) was defined with our own reference value of visceral-to-subcutaneous fat ratio (VSR; median value of subjects without hypertension, diabetes, or cardiovascular disease, ≥0.74 for men and ≥0.4 for women).
Results
Subjects with generally or abdominally not obese but VFO were older and higher proportion of men, (higher prevalence of hypertension and diabetes only in abdominally obese analysis), lower BMI, waist circumference, fat mass, total and subcutaneous FA but higher visceral FA and VSR (and baPWV only in abdominally obese analysis) than those with generally or abdominally obese without VFO.
Logistic regression analysis including sex, age, BMI, waist circumference, PBF and VSR quartile showed that higher quartile of VSR was 1.7 times and 2.6 times independently increased risk for type 2 DM and 1.7 times increased risk for hypertension. Logistic regression analysis including sex, age, BMI, waist circumference, PBF, VSR quartile, hypertension and diabetes showed that higher quartile of VSR was 2.1 times independently increased risk for the presence of arterial stiffness.
Conclusion
These results suggest that measurement of visceral-to-subcutaneous fat ratio would be useful for assessment of cardio-metabolic risk to identify individuals who need more intensive intervention to prevent the metabolic diseases and atherosclerosis in overweight or obese subjects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1223

**Effect of obesity on vitamin d and parathormone levels**

H. Baser[1], D. Tuzun[1], F. Saglam[1], S. Caner[1], R. Ersoy[2] & B. Cakir[2]
[1]Ankara Ataturk Training and Research Hospital, Ankara, Turkey; [2]Yildirim Beyazit University, Faculty of Medicine, Ankara, Turkey.

Aim
In this study our aim was to investigate the relationship between obesity and vitamin D and hyperparathyroidism.
Material and Method
127 healthy persons included in this study. Study group were divided into four groups according to body mass index (BMI). Group 1 ($n=35$) BMI 18.5–24.9 kg/m$^2$, Group 2 ($n=35$) BMI 25–29.9 kg/m$^2$, Group 3 ($n=35$) BMI 3.0–34.9 kg/m$^2$, Group 4 ($n=22$) BMI 35–40 kg/m$^2$. Anthropometric measurements were performed. Serum calcium (Ca), phosphorus (P), parathormone (PTH), 25(OH) D levels were evaluated.
Results
Negative linear relationship was found between BMI and serum Ca and Vit D (respectively, $P=0.040$ $r=-0.181$, $P=0.016$ $r=-0.214$). There was no significant relationship between BMI and PTH levels ($P>0.05$). A significant reduction was observed in vitamin D levels while waist circumference increases ($P=0.049$). There was no significant decrease in Serum Ca level ($P>0.05$). Significant decrease was observed in vitamin D and serum Ca while body fat mass increases (respectively, $P=0.026$, $P=0.021$). Serum Ca levels of group 2 was significantly higher than group 3 and 4 (respectively, $P=0.049$, $P=0.000$). vitamin D levels in group 4 was significantly lower than group 2 (respectively, 18.96±9.88 μg/l, 30.06±18.48 μg/l) ($P>0.05$). There was no significant difference in PTH levels between groups.
Conclusion
As a result of our study, we determined low vitamin D and calcium levels in obese patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1224

**Limited effects of leptin and adiponectin on proliferation and protein metabolism of porcine myoblasts under serum-free culture conditions**

K. Will[1], C. Kalbe[1], J. Kuzinski[1], D. Lösel[1], T. Viergutz[1], M. Palin[2] & C. Rehfeldt[1]
[1]Leibniz Institute for Farm Animal Biology, Dummerstorf, Germany; [2]Agriculture & Agri-Food Canada, Sherbrooke, Quebec, Canada.

Cross-talk between adipose tissue and skeletal muscle via endocrine and paracrine mechanisms may be important in determining nutrient partitioning and lean-to-fat ratio. Such interactions could be mediated in part by adipokines secreted from adipose tissue. Little is known, however, about the role of adipokines in influencing growth and development of skeletal muscle.
The aim of this study was to determine the direct effects of leptin and adiponectin on the growth of porcine skeletal muscle cells *in vitro*. Adiponectin receptors (ADIPOR1, ADIPOR2) were abundant at mRNA and protein level in proliferating and differentiating myoblast cultures derived from *semimembranosus* and *semitendinosus* muscles of newborn piglets, whereas the long-form leptin receptor (LEPR) expression was close to the detection limit. In serum-free medium (SFM) adiponectin (10, 20, 40 μg/ml) attenuated the proliferation of porcine myoblasts, measured as [$^3$H]-thymidine incorporation and live cell monitoring in response to 24-h and 48-h exposure, in a dose-dependent manner. This effect resulted from suppressed basic fibroblast growth factor (bFGF)-mediated stimulation of DNA synthesis that remained unchanged by adiponectin in serum-free medium (SFM) without bFGF. No effects of leptin (5, 10, 20, 40, 80 ng/ml) on myoblast proliferation in SFM were detectable. Neither leptin nor adiponectin altered protein synthesis and degradation, recorded as incorporation or release, respectively, of [$^3$H]-phenylalanine, in differentiating porcine myoblasts cultured in SFM. The results on receptor abundance suggest that porcine skeletal muscle cells may be sensitive to adiponectin and leptin. However, except via inhibitory interaction of adiponectin with bFGF, these adipokines appear not to affect *in vitro* proliferation and protein metabolism of porcine muscle cells directly under serum-free culture conditions.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1225

**Effect of secreted frizzled-related protein 2 (sFRP2) from adipose tissue on pancreatic cell function**

I. Bujalska, E. Rabbitt, L. Gathercole & P. Stewart
University of Birmingham, Birmingham, UK.

The detrimental effect of excessive obesity on insulin resistance is well established. The expansion of adipose tissue is dependent on two processes: adipogenesis and angiogenesis and the Wnt signalling pathway has been reported to affect both. In adipose tissue the Wnt signalling pathway functions in a converse manner: increasing commitment of mesenchymal stem cells to preadipocytes and inhibiting differentiation of preadipocytes to mature adipocytes by decreasing expression of CEBPα and PPARγ.
One of the antagonists of the canonical Wnt signalling pathway is secreted frizzled-related protein 2 (sFRP2) however, recent studies have identified sFRP2 as a novel factor stimulating angiogenesis via a non-canonical, calcineurin/NFAT signalling pathway.
Expression of sFRP2 and Wnt receptors, Fzd1 and Fzd2, mRNA has been reported in preadipocytes and Wnt signalling is also known to be involved in pancreatic islet function, insulin production and secretion. We hypothesised that sFRP2 secreted from adipose tissue could provide a link between obesity and

diabetes through a deleterious action on beta cells/ insulin secretion.
Human omental (OM) and subcutaneous (SC) adipose tissues expressed high levels of sFRP2 mRNA with more in OM than SC adipocytes (3.6-fold increase, $n=8$, $p=0.003$). In mouse, sFRP2 mRNA was present in gonadal and subcutaneous fats but absent in liver, pancreas and pancreatic α- and β-cell lines. All mouse tissues and cells studied were positive for Wnt signalling receptors Fzd1 and Fzd2. Proliferating mouse pancreatic α- and β-cells treated with recombinant mouse sFRP2 protein (10 ng to 200 ng/ml) for 4 days, showed a dose-dependent decrease in proliferation rates in β-cells (10 ng/ml: 96%, 100 ng/ml: 84%, 200 ng/ml: 72 vs 100% control, $P<0.01$) but not α-cells or the human preadipocyte cell line, ChubS7.
We postulate that secreted sFRP2 from expanding adipose tissue could have a harmful effect on pancreatic beta cell function and contribute to the pathogenesis of insulin resistance in human obesity.

## P1226

**Curcumin inhibits the upregulation of cathepsin L by palmitate in fat**

J. Yoo[1,2], Y. Lee[2], J. Kim[2], S. Kang[2], J. Nam[1], J. Park[2], C. Ahn[2], Y. Song[1] & K. Kim[2]
[1]NHIC Ilsan Hospital, Goyang-si, Republic of Korea; [2]College of Medicine, Yonsei University, Seoul, Republic of Korea.

Objective
Cathepsin L can control adipogenesis and relate to acute coronary syndrome. However, it is not clear whether cathepsin L can be affected by saturated fatty acid and decrease by curcumin. We examined the hypothesis that palmitate upregulates cathepsin L expression in adipose tissue and curcumin can be block that effect.
Methods
3T3-L1 cells were fully differentiated for 8 to 10 days and treated with palmitate, LPS, IL6, TNF-α, IL6 neutralizing Ab, curcumin. Six-week-old C3H/HeN with normal TLR4 and C3H/HeJ with TLR4 mutation got LPS injection ip (1 mg/kg) or were fed with high fat diet for 13 weeks and sacrifice to harvest epididymal fat.
Results
Real-time PCR revealed that cathepsin L expression was upregulated by palmitate. But there was no additional effect when we use palmitate-treated RAW264.7 cells' media instead of direct treatment to 3T3-L1 cells. Cathepsin L was upregulated after treatment of TNF-α or IL6 like palmitate. IL6 neutralizing Ab and curcumin attenuated this effect of palmitate. Cathepsin L increased in both kinds of mice fed high fat diet compared with chow diet. But we cannot find similar pattern at mice which got LPS ip injection.
Conclusions
We concluded that cathepsin L expression in fat are upregulated by palmitate via inflammatory cytokines, not TLR4, thereby might have a critical role in developing acute coronary syndrome of metabolic syndrome and there are no additional effects of infiltrating macrophages. In addition, curcumin can be a candidate of drug which can amilorate the metabolic syndrome.

## P1227

**Preventing childhood obesity by community based intervention approaches**

J. Borys, H. du Plessis, L. Walter & P. Harper
EPODE European Network, Paris, France.

Introduction
EPODE is a coordinated, capacity-building approach for communities to implement effective and sustainable strategies to prevent childhood obesity.
Methods
At central level, a coordination team using social marketing and organizational techniques trains and coaches a local project manager nominated in each EPODE town by the local authorities. The local project manager is also provided with tools to mobilize local stakeholders through a local steering committee and local networks. The added value of the methodology is based on a strong scientific input, institutional endorsement, evidence-base and social marketing techniques, sustainable resources, brand dynamics and evaluation. EPODE Monitoring and Evaluation practices to date include not only outcome but also process and output indicators at central, local, setting, child levels.
Results
The EPODE methodology is now implemented in more than 300 towns in six countries (Spain, Belgium, Greece, France, South Australia, Mexico) and concerns more than five million people. At child level the prevalence of overweight and obesity in children aged 5 to 12 is monitored. In the 8 French pilot towns, the response rate is high (95%). The prevalence of children overweight including obesity decreased in these pilot towns between 2005 and 2009 (from 20.6 to 18,8%, $P<0.0001$). From 2008, the EPODE European Network project is enriching the EPODE methodology and facilitating the implementation of similar initiatives in other European countries.
Conclusion
Childhood obesity is a complex issue and needs a multistakeholder involvement at all levels to foster healthier lifestyles in a sustainable way. The EPODE methodology contributes to this approach.

**Reduction of body weight and waist circumference after long-term treatment of hypogonadal men with testosterone undecanoate**

F. Saad[1,2], A. Haider[3] & L. Gooren[4]
[1]Bayer Pharma AG, Berlin, Germany; [2]Gulf Medical University, Ajman, United Arab Emirates; [3]Private Practice, Bremerhaven, Germany; [4]VUMC Amsterdam, Amsterdam, The Netherlands.

Introduction
Obesity is associated with reduced testosterone, and low testosterone induces weight gain. This study analysed the effects of normalization of serum testosterone in mainly elderly, hypogonadal men.
Methods
Prospective registry study of 252 men (mean age 60.6±8.0 years), with testosterone levels between ≤ 3.5 ng/ml. They received parenteral testosterone undecanoate 1000 mg at day 1, week 6 and every 12 weeks thereafter for up to 66 months.
Results
After 60 months the following changes were observed: weight declined from 106.28±16.98 to 90.07±9.51 kg, waist circumference from 107.23±9.15 to 98.46±7.39 cm and body mass index from 33.95±5.56 to 29.17±3.09 kg/m$^2$. All changes were progressive over 60 months and statistically significant vs baseline and vs previous year ($P<0.0001$). In addition, total cholesterol declined from 281.97±39.86 to 188.12±11.31, LDL from 163.75±41.62 to 109.84 ±35.41 and triglycerides from 276.38±51.57 to 189.78±11.33 mg/dl. The decline was progressive over 24 months and statistically significant vs baseline and vs previous year ($P<0.0001$) until a plateau was reached after 2 years. HDL declined from 62.06±27 to 52.45±16.82 mg/dl after 60 months, however, with fluctuations. There was a statistically significant increase vs baseline at 24 months ($P=0.0254$) and a decrease vs baseline at 36 months ($P<0.0001$) with a plateau after 36 months.
Conclusions
Raising serum testosterone to normal resulted in continuous loss of body weight, waist circumference and BMI. These improvements were progressive over the full 5 years of the study. Levels of total cholesterol, LDL and triglycerides decreased over the first 2 years. HDL showed some fluctuations but means remained above 47 mg/dl. Long-term administration of testosterone to middle-aged, hypogonadal men improves body composition and lipid profile.
Declaration of interest
I fully declare a conflict of interest. Details below:

**Connection of adipocitokines and inflammatory markers in obese woman: influence of body weight reduction**

M. Velojic Golubovic, D. Dimic, D. Stojic, S. Radenkovic & S. Antic
Clinical Center Nis, Nis, Serbia.

Fat tissue is highly active tissue, both metabolically and as endocrine tissue, which produced large number of bioactive peptides, known as adipocitokines. They seem to contribute in pathogenesis of obesity, insulin resistance, diabetes mellitus type 2, hypertension, hyperlipidemia, and vascular disease. Adipocitokines and low grade inflammation could be connection between obesity and coexisting diseases. This is the reason we believe that body weight reduction could have positive effects on decreasing the risk for those diseases. The aim of this study is to evaluate the effect of hypo caloric diet and body weight reduction on serum levels of leptin, adiponectin and inflammatory markers in obese woman and their correlations. Methodology and material: We included in the study 90 obese women, with body mass index (BMI) $36.43 \pm 5.42$; waist circuference (WC) $103.12 \pm 14.33$; weist circuference/hip circuference ratio (WC/HC) $0.89 \pm 0.08$. In all subjects we determined serum levels of leptin,adiponectin, CRP and fibrinogen before and after six months of hypo caloric diet and body weight reduction. Results: Average weight loss was $8.73 \pm 1.98$ kg or $8.64 \pm 1.96\%$ ($P < 0.001$). That results in significant decreasing of anthropometric parameters, BMI, WC and WC/HC ratio, ($P < 0.001$). Serum levels of leptin, CRP and fibrinogen decreased and serum level of adiponectin increased, all on maximum level of statistical significance ($P < 0.001$). There is statistically significant positive correlation between anthropometric parameters and inflammatory markers, before and after body weight reduction. There is positive correlation between leptin, and negative correlation between adiponectin and anthropometric parameters. Before and after body weight reduction there is statistically positive correlation between leptin and negative correlation between adiponectin and serum levels of CRP and fibrinogen. Conclusion: Our results suggests that changes in adipocitokines and state of low grade inflammations are connected and that body weight reduction has significant positive effect on all parameters, what emphasizes the importance of restricted dietary regime as therapy of obesity.

**Proteomic analysis identifies adiponectin as a key plasma protein associated to vitamin D deficiency in pediatric obesity**

G. Walker[1], F. Prodam[2], R. Ricotti[2], S. Riccomagno[1], S. Moia[1], M. Roccio[1], S. Bellone[2], G. Genoni[2], A. Petri[2] & G. Bona[2]
[1]University of Piemonte Orientale, Novara, Italy; [2]Oespedale Maggiore della Carità, Novara, Italy.

Key circulating molecules that link the emerging role of vitamin-D to pediatric obesity and its co-morbidities remain unclear. To identify potentially involved regulators, this study analyzed plasma proteoma from obese children dichotomized by 25OH-vitamin D (25OHD) levels and upon vitamin-D3 therapy in 25OHD deficient subjects.

A total of 42 obese children (M/F = 18/24, bmi > 95° centile) were selected and divided according to 25OHD levels into deficient (G1; $n = 18$; 25OHD < 14.5 ng/ml) or normal 25OHD (G2; $n = 24$; > 30 ng/ml). Eight subjects from G1 underwent a 12mo treatment with 400 UI/die vitamin-D3. Proteomic analyses by 2D-electrophoresis with different IPG ranges were performed at baseline with spots quantitated by PDQuest.

2D-electrophoresis with IPG3-10 identified 28 spots significantly different between groups ($P < 0.05$). Among these, 57% were localized within PI3-6. Analysis restricted to this range revealed 20 spots significantly different between groups ($P < 0.05$). Overall, 20% of IPG3-6 associated spots were downregulated in G1 compared to G2. Adiponectin was selected for confirmational studies due to strong correlations with obesity and its co-morbidities, as well as its localization within a susceptibility gene loci. WIB analysis of 2D-gels showed down-regulation of adiponectin in 25OHD-deficient subjects. Adiponectin expression was lower in plasma from G1 than G2 ($7187 \pm 383$ vs $8594 \pm 587$ AU; $P < 0.035$) and increased following 12mo vitamin-D3 treatment in 80% of G1 subjects by an average of 8% ($P < 0.02$). Analysis of HMW adiponectin, a surrogate indicator of insulin sensitivity, demonstrated significantly lower levels in G1 subjects ($697.1 \pm 127.7$ vs $1270.5 \pm 198$ AU; $P = 0.015$), which improved upon vitamin-D3 therapy ($583.3 \pm 162.1$ vs $1412.1 \pm 251.7$ AU; $P < 0.02$).

Our proteomic approach to identify key circulating molecules that link 25OHD levels to pediatric obesity, has demonstrated that vitamin-D deficiency is associated with an altered adiponectin expression, specifically the HMW form, which can be significantly improved by vitamin-D3 administration. Direct effects of vitamin-D on adiponectin production in the adipose tissue remain to be elucidated.

**Plasma adipokines and improvement of insulin sensitivity during multi-phase long-term dietary intervention**

V. Stich, L. Rossmeiselova, L. Malisova & M. Siklova
Charles University, Third Faculty of Medicine, Praha, Czech Republic.

Context

Weight-reducing dietary intervention (DI) promotes an improvement in insulin sensitivity (IS) since early stage of the diet. The diet-induced changes of plasma levels of cytokines and chemokines that are expressed in adipose tissue (adipokines) have been suggested to play a role.

Aim

To examine relationship between the diet-induced changes of IS (assessed using homeostatic model assessment of insulin resistance (HOMA-IR)) and those of plasma adipokines during different time-points of a 6 months multi-phase DI.

Subjects and methods

obese women (BMI $34.8 \pm 3.8$ kg/m$^2$) were followed during 6 months DI that consisted of a 28 days very-low-calorie-diet (VLCD) and subsequent 5 months weight stabilization phase (WS) including 2 months low-calorie-diet and subsequent 3 months weight maintenance diet. Plasma sampling for analysis of a number of adipokines (serum amyloid A (SAA), haptoglobin, interleukines $-6, -8, -1\beta$, tumor-necrosis-factor-$\alpha$, monocyte-chemoattractant-protein-1, plasminogen-activator-inhibitor-1) using Luminex technology and of relevant hormones and metabolites were performed before the diet and at the the end of each phase.

Results

Body weight (BW) and HOMA-IR decreased during VLCD and during the entire DI (BW: $95.9 \pm 12.5$ vs $88.5 \pm 12.0$ ($P < 0.001$) vs $85.3 \pm 12.4$ ($P < 0.001$), HOMA-IR: $2.9 \pm 1.7$ vs $1.6 \pm 0.8$ ($P < 0.001$) vs $1.7 \pm 0.9$ ($P < 0.001$) respectively). The pre-diet levels of plasma adiponectin correlated positively with HOMA-IR decrease during the early stage of the diet, i.e. during VLCD. The decrease of plasma SAA and haptoglobin levels during VLCD correlated positively with the increase of HOMA-IR during the entire DI. No such correlations were found for other examined adipokines.

Conclusion

Among the adipokines examined, the pre-diet level of plasma adiponectin and the response (decrease) of acute phase proteins (SAA and haptoglobin) during the early stage of the DI appear as determinants of the diet-induced improvement of IS.

**Obesity the first year of life: influence of glycemia at pregnancy, breastfeeding and sleep**

A. Dávalos-Pérez, M. Garay-Sevilla & J. Malacara
Universidad de Guanajuato, León, Mexico.

Introduction

Pre- and postnatal factors have an influence on obesity the first year of life. Among them maternal glucose levels, breastfeeding, ablactation and recently sleep duration are under study in diverse populations.

Methods

In a prospective study, we recruited 139 pregnant women and obtained fasting and post-load (75 g) glucose levels. We studied children robustness

(waist girth/height) at 6 months and one year of age, and the influence of altered fasting and post-load glucose levels at 6 months of pregnancy, breastfeeding, ablactation, and duration of sleep, leptin and insulin levels.
Results
Altered glucose levels (fasting $\geq 100$, $< 126$ mg/dl or post-load $\geq 140, < 200$) were found in 21 women. Their children, compared with those from mothers without altered glucose did not have significantly different anthropometric measures at birth, at 6 months or at 1 year of age. At 6 months leptin levels were associated with the mother's fasting glucose at pregnancy ($P < 0.000001$). At this time, duration of breastfeeding was negatively correlated with waist girdle/height index ($P < 0.00001$) and with leptin ($P < 0.00002$) and insulin levels ($P < 0.000001$), but these associations were not maintained at 1 year of age. Ablactation was associated with insulin levels at 6 months ($P < 0.00007$) and with the waist girdle/height index at one year of age ($P < 0.0001$). We interpreted that the effects of breastfeeding and early ablactation under our conditions have protective effect against obesity. Duration of sleep was associated with the robustness index negatively at 1 year of age ($P < 0.002$), but positively at 6 months ($< 0.0044$). These results suggest that sleep duration the first 6 months of age is related to different metabolic influences than at later months.
Conclusions
We concluded that limited alteration of glucose levels at pregnancy may influence children's adiposity. Breastfeeding, ablactation and sleep have influences on children robustness during the first year of life.

## P1233

### Anthropometric, hormonal and nutritional correlates of epicardial fat in obese women

V. Vicennati[1], C. Cavazza[1], S. Garelli[1], C. Pizzi[2], R. Bugiardini[2], E. Rinaldi[1], U. Pagotto[1] & R. Pasquali[1]
[1]UO Endocrinologia, Bologna, Italy; [2]Medicina Interna, Bologna, Italy.

Background and aim
Epicardial fat (EF) is a metabolically active organ as well as visceral fat (VF). EF has been recognized as a potential additional marker of cardiac risk in obesity and type 2 diabetes. This study wants to assess the relation between EF and VF and the correlation with nutritional and hormonal parameters.
Material and Methods
Fifty-nine overweight/obese women were enrolled in the study. All women underwent anthropometric measurements, nutritional assessment and oral glucose tolerance test; HOMA-IR and ISIcomposite were calculated to assess insulin resistance and sensitivity respectively. Twenty-four hours urine were collected for urinary free cortisol determination (UFC/24 h). They underwent echocardiography for detection of EF. A subgroup of 27 obese women with stress related obesity (SRO) was also examined. They were characterized by rapid weight gain after a stressful event exposure (Vicennati V. et al, 2009).
Results
BMI was $33.4 \pm 3.28$ kg/m$^2$ and waist circumference $104 \pm 8.8$ cm. EF was $133 \pm 62$ cm$^2$. EF was positively and significantly correlated with BMI ($P = 0.001$), waist circumference ($P = 0.000$), ISIcomposite ($P = 0.025$), HOMA-IR ($P = 0.05$). No significant relationship was present between EF and total testosterone and UFC/24 h. EF was also positively and significantly correlated with dietary lipid intake ($P = 0.009$), satured fatty acids ($P = 0.017$), polyunsaturated ($P = 0.018$) and monounsaturated fatty acids ($P = 0.002$). EF was also significantly correlated with dietary cholesterol ($P = 0.0461$). In a multiple correlation model, only waist circumference persisted significant ($P = 0.036$). In the SRO group, EF ($120 \pm 54$ cm$^2$) was positively correlated to BMI ($P = 0.017$), HOMA-IR ($P = 0.012$), UFC/24 h ($P = 0.018$). In a multiple regression model, only waist circumference persisted significantly correlated to EF ($P = 0.03$).
Conclusion
These findings suggest that EF represent a target visceral fat depots. Further studies should investigated the specific relationship between EF and the endocrine and metabolic milieu in a larger population with different obesity phenotypes.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1234

### How informative is visceral fat measurement by bioelectrical impedance?

U. Mousa, A. Kut, Y. Bozkus, C. Cicek Demir, C. Anil & N. Bascil Tutuncu
Baskent University, Ankara, Turkey.

Although obesity is a powerful risk factor for developing metabolic syndrome (MetS), it is not present in all obese individuals. Increased visceral adipose tissue is the hallmark of this syndrome. In this cross sectional survey abdominal bioelectrical impedence was used to measure the visceral adipose tissue (VAT) and trunk fat percentages (TF%) in participants. A total of 286 patients (196 female and 90 males) were enrolled in the study. In both sexes VAT was significantly positively correlated with body mass index, waist circumference, TF%, HOMA IR, fat percentage, fasting plasma glucose and triglycerides. Strongest correlations were between VAT and TF%, VAT and device measured waist circumference and between VAT and manual waist circumference ($r = 0.95$, $r = 0{,}94$, $r = 0.92$ respectively in female and $r = 0.99$, $r = 0{,}93$, $r = 0.94$ respectively in male participants). The mean VAT and TF% in MetS(+) groups were significantly higher than patients in MetS(−) groups in both sexes. The areas under the ROC curves were 0.730 (95% CI: 0.661–0.791) for female VAT and 0.702 (95% CI: 0.654–0.749) for male VAT in predicting MetS. We suggest that using such a device in clinical practice is an alternative technique for examining and follow up of patients with MetS.
Sensitivity and spesificity of VAT for predicting MetS at certain cut off values in male and female

**Table 1**

| VAT | Male Senstivity | Male Spesifisity | Female Senstivity | Female Spesifisity |
|---|---|---|---|---|
| 7.250 | | | 100 | 29 |
| 9.750 | | | 90 | 50 |
| 11.750 | | | 57 | 69 |
| 14.750 | 92 | 28 | 25 | 90 |
| 16.000 | 90 | 40 | | |
| 19.750 | 70 | 53 | | |
| 30.250 | 15 | 90 | | |

## P1235

### A selective androgen receptor modulator, S42 possesses beneficial metabolic effects

K. Murase[1], L. Min[2], T. Tanaka[1], Y. Akehi[1], T. Nomiyama[1], H. Nawata[3] & T. Yanase[1]
[1]School of Medicine, Fukuoka University, Fukuoka, Japan; [2]Graduate School of Medical Science, Kyushu University, Fukuoka, Japan; [3]Fukuoka Prefectural University, Fukuoka, Japan.

Androgen is an important factor for determining body composition in males. Abdominal obesity is inversely correlated with serum androgen levels in men. Androgen receptor (AR) null male mice revealed late-onset visceral obesity, accompanying energy balance abnormality. We previously reported a novel synthetic steroid, S42 as a promising candidate of a selective androgen receptor modulator (SARM). When orchiectomized Sprague-Dawley rats were administered with S42 for 3 weeks, the muscle weight of the levator ani was increased as markedly as that induced by dihydrotestosterone (DHT), but the weight of the prostate was not elevated at any doses in contrast to DHT. In addition, although the plasma triglyceride level was unaffected by DHT, it was significantly reduced by S42. Taken together, S42 works as an AR agonist in muscle and as an AR antagonist in the prostate, accompanying beneficial potentials on lipid metabolism. We then administered S42 (10 mg/kgBW) by intraperitoneal injection in high-fat diet induced obese mouse model for 16 weeks and found that S42 significantly decreased the body weight (BW) compared with the placebo administration without affecting the food intake. The BW reduction was accompanied by the marked reduction of visceral fat determined by the CT analysis. The aggravated insulin sensitivity by high fat diet was also improved by the S42 treatment but not by placebo. A similar effect of S42 was also observed when S42 was administered

to ob/ob mouse for 4 weeks. S42 could reduce the BW with marked reduction of visceral fat in ob/ob mouse. These results suggest that S42 have some beneficial metabolic effect on fat accumulation and insulin sensitivity *in vivo*.

## P1236

**Effect of orlistat in Russian adolescents with metabolic syndrome: a randomized controlled trial**

G. Melnichenko, V. Peterkova, L. Savelyeva, N. Zubkova, O. Vasyukova & A. Kosygina
Endocrinology Research Center, Moscow, Russian Federation.

Background
Metabolic syndrome (MS) in children is associated with future risk of developing type 2 diabetes mellitus and cardiovascular disease in adults. In the pediatric population lifestyle interventions alone are often insufficient.
Objective
To evaluate the efficacy and safety of orlistat in obese adolescents with MS.
Design
A 6 month open, comparative, randomized study of 60 obese adolescents (aged 12–17 years; mean body mass index (BMI) 32 kg/m$^2$) with MS. The main group ($n=30$) was treated with a hypocaloric diet, aerobic exercises and orlistat 120 mg three times daily for 6 months. The control group ($n=30$) was subjected to the same diet and exercise regimen without the orlistat application. Changes in BMI, waist circumference, body composition, blood pressure, fasting serum lipid and glycemic parameters were evaluated.
Results
BMI decreased by 3.09 kg/m$^2$ in the orlistat group and only by 1.11 kg/m$^2$ in the control group ($P=0{,}033$). The orlistat group compared with the control group also had a significant reduction of body fat ($-6600{,}0$ vs $-2235{,}5$ g, $P=0.011$), waist circumference ($-6.50$ vs $-2.50$ cm, $P=0.019$), LDL-cholesterol ($-0.33$ vs $-0.20$ mmol/l, $P=0.024$) and total cholesterol levels ($-0.25$ vs $-0.05$ mmol/l, $P=0.025$). HDL-cholesterol, triglyceride levels and blood pressures improved similarly within both groups; comparisons between groups, however, were not statistically significant. After 6 months of orlistat therapy 68% of the adolescents achieved clinically meaningful weight loss. In the control group only 41% of patients reduced their weight by more than 5%. Orlistat was well tolerated by patients. Most adverse events were mild and can be attributed to the expected adverse reactions.
Conclusion
The study demonstrated significant efficacy and safety when orlistat was combined with the complex therapy in obese adolescents with MS.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1237

**Extreme obesity partly blunts the discriminative metabolic effects of polycystic ovary syndrome (PCOS)**

P. Marzullo[1,2], A. Brunani[1], E. Uccelli[1], S. Maestrini[1], S. Mai[1], M. Berselli[1], M. Rinaldi[1], G. Guzzaloni[1], A. Tagliaferri[1], G. Aimaretti[2] & A. Liuzzi[1]
[1]IRCCS Istituto Auxologico Italiano, Piancavallo, Verbania, Italy; [2]Università del Piemonte Orientale 'A. Avogadro', Novara, Italy.

The epidemic of obesity and diabetes is increased worldwide, and both are more prevalent in PCOS than non-PCOS ovulatory women. In the general population, the risk of cardiovascular mortality is at least doubled in women with extreme obesity (BMI $>40$ kg/m$^2$). To explore if PCOS adds further metabolic detriment to extreme obesity, this prospective study compared the metabolic profiles, OGTT-derived insulin sensitivity and body composition between 30 adult PCOS and 30 non-PCOS women with extreme obesity (age, $27.8\pm5$ vs $27.7\pm7$ years; BMI, $44.8\pm4.4$ vs $43.7\pm3$ kg/m$^2$; WHR, $0.87\pm0.1$ vs $0.89\pm0.1$) seen consecutively at the IRCSS Istituto Auxologico Italiano for workup of obesity. None had a history of cardiometabolic disorders and PCOS was diagnosed by Rotterdam and AE-PCOS criteria. PCOS and non-PCOS women had similar levels of glucose and insulin, total or fractionated cholesterol and C-reactive protein. HbA1c ($5.5\pm0.4$ vs $5.6\pm0.4\%$), HOMA-IR ($3.2\pm1.2$ vs $3.1\pm2.1$) and microalbuminuria ($52.4\pm60.5$ vs $73.7\pm52$ mg/l) were comparable between groups. OGTT-derived measures of insulin sensitivity in PCOS and non PCOS women revealed equivalent values of early phase insulin secretion (insulinogenic index, $1.8\pm1.2$ vs $1.8\pm1.5$) and β-cell function (oral disposal index, $4.8\pm3.1$ vs $6.1\pm5.3$). Alternatively, the Matsuda index of insulin sensitivity was lower in PCOS than non-PCOS women ($2.8\pm0.8$ vs $3.7\pm2$, $P<0.05$). DXA-derived measures of fat body mass were similar between groups ($52.5\pm4.1$ vs $50.5\pm4.8\%$), while trunk-fat was increased in PCOS ($30.9\pm5.8$ vs $25\pm5.5\%$, $P<0.01$) and coexisted with an increase in leptin levels ($58.8\pm24.6$ vs $44.7\pm16.4$ mcg/l, $P<0.05$). Adiponectin levels were not different between the study groups ($14.7\pm11.2$ vs $10.4\pm5.8$ mcg/ml). Current data suggest that many indices of metabolic homeostasis are superimposed between PCOS obese and non-affected obese counterpart. However, dissimilarities in insulin sensitivity and fat accumulation emphasize the importance of adequate long-term management of PCOS women suffering from extreme obesity.

## P1238

**Low dose 3-iodothyronamine increases acute lipolysis followed by protein catabolism in mouse**

G. Chiellini[1], F. Assadi-Porter[2], J. Haviland[2], D. Butz[2], H. Reiland[2], S. Ghelardoni[1], M. Tonelli[2], T. Scanlan[3] & R. Zucchi[1]
[1]University of Pisa, Pisa, Italy; [2]University of Wisconsin-Madison, Madison, WI; [3]Oregon Health & Science University, Portland, Oregon, USA.

3-iodothyronamine ($T_1AM$) is a recently discovered fast-acting thyroid hormone derivative. To date, the physiological effects of endogenous$T_1AM$ remain elusive, although there is increasing interest in its physiological function and pharmaceutical potential due to the role it plays in lipid and glucose metabolism (1.2).The present study monitored the effect of weeklong, daily, low dose $T_1AM$ administration on weight and metabolism in spontaneously overweight mice. Mice treated with exogenous $T_1AM$ (10 mg/Kg/day) lost 8.2% of their initial body weight by day 9 and regained only 1.8% of initial weight in the following 2 weeks, indicating lasting effects of $T_1AM$ on weight maintenance. Real-time analysis of exhaled $^{13}CO_2$ by cavity ringdown spectroscopy (CRDS) detected increased lipolysis shortly after $T_1AM$ administration followed by a shift, later in the week, towards protein catabolism. Blood based metabolomics data obtained by nuclear magnetic resonance spectroscopy (NMR) were in agreement with the results from breath analysis, as indicated by the alterations found in key metabolites: valine, glycine, and 3-hydroxybutyrate. While this study begins to decode longer-term effects of $T_1AM$ on metabolism, additional studies with mildly feed restricted mice are currently underway to develop an appropriate dosing schedule for $T_1AM$ to be used as an effective weight loss and weight maintenance drug.

**Lipid metabolism is impaired in obesity/diabetes model mice**

Y. Kobayashi & N. Tagawa
Kobe Pharmaceutical University, Kobe City, Japan.

A new genetic animal model of type 2 diabetes, the Tsumura Suzuki Obese Diabetes (TSOD) mouse, has been developed in 1999. The TSOD mouse

develops a moderate degree of obesity and diabetes. The aim of this study was to investigate the potential association of impairment of lipolysis and lipid metabolism on the development of obesity and diabetes in TSOD mice.
Methods
Three month old TSOD and the age-matched control (TSNO: Tsumura Suzuki Non-Obesity) male mice were obtained from The Institute for Animal Reproduction (Ibaraki, Japan). Serum glucose, total cholesterol (T-Cho), triglycerides (TG) and insulin were measured. Adipose tissues were removed and extracted lipids by acetone. Extracted lipids were analyzed by TLC and LC-MS. The expressions of mRNA of adipose tissue glycerol lipase (ATGL), hormone sensitive lipase (HSL), adipose phospholipase A2 (AdLPA2) and perilipin in epididymal adipose tissue were also measured by real-time PCR.
Results
Serum levels of glucose, TG and insulin were significantly elevated in TSOD mice than those of TSNO. Clear spot corresponding to diacylglycerol (DG) was observed in the sample from TSOD but not from TSNO by TLC. Ratio of total DG levels against total TG ones in TSOD mice were higher than those in TSNO by LC-MS. Expression of ATGL, HSL and perilipin was lower in TSOD than that in TSNO. However, mRNA expression of AdPLA2 in TAOD was significantly higher than that in TSNO.
Conclusion
Dysregulation of lipolysis and lipid metabolism in adipose tissue contribute in part to the development of obesity and diabetes in TSOD mice.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1240

**Comparing effects of lifestyle modification-induced weight loss on androgen levels, endothelial, sexual and urinary function, and quality of life in obese men with and without androgen deficiency**

J. Khoo, R. Chen, L. Cho, E. Tan, T. Tay, V. Au, S. Soh & B. Ng
Changi General Hospital, Singapore, Singapore.

Introduction
Androgen deficiency (AD) is associated with endothelial and erectile dysfunction, lower urinary tract symptoms (LUTS) and reduced quality of life (QoL) in obesity. We aimed to compare effects of weight loss induced by lifestyle modification on endothelial and erectile function, LUTS and QoL in obese men with and without AD.
Methods
abdominally obese Asian (body mass index $\geq 30$ kg/m$^2$, waist circumference [WC] $\geqq$ 90 cm) men (mean age 43.1 years, range 30–61) with low libido were put on a weight loss program of caloric restriction (500 kilocalories/day below basal metabolic requirement) and moderate-intensity exercise (2000 kilocalories/week). Plasma sex-hormone binding globulin (SHBG) and total testosterone (TT), endothelial function (by Reactive Hyperaemia Index [RHI] using finger plethysmography on EndoPAT), International Index of Erectile Function 5-item (IIEF-5), Sexual Desire Inventory (SDI), International Prostate Symptom (IPSS) and 36-item Short Form Survey Instrument (SF-36) scores were measured at baseline and 12 weeks later. 34.2% (24/70) had AD, defined as TT $<$10.4 nmol/l.
Results (Table 1)
At baseline, men with AD had significantly lower SDI score, TT, SHBG and calculated free testosterone (FT), and higher IPSS score, but similar age, weight, WC, RHI, IIEF$-$5 and SF$-$36 scores. Similar weight losses were seen in men with (4.2$\pm$3.4%) and without (4.0$\pm$3.1%) AD. Men with AD had significantly greater increases in TT (30.2 vs9.3%), FT (27.5 vs 5.5%), and SDI score (37.1 vs 13.1%), and decrease in IPSS score (31.6 vs 22.9%). Improvements in WC, RHI, SHBG, IIEF-5 and SF-36 scores were similar. TT normalized in ten men (41.7%) with AD.
Conclusions
Weight loss induced by diet and exercise improves endothelial, sexual and urinary function, quality of life and sex hormones in obese men regardless of androgen status, with significantly greater improvements in testosterone, sexual desire and LUTS particularly in androgen-deficient men.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**How safe is the use of herbal weight-loss products sold over the Internet?**

B. Ozdemir, I. Sahin, H. Kapucu, O. Celbis, Y. Karakoc, S. Erdogan & Y. Onal
Inonu University, Faculty of Medicine, Malatya, Turkey.

Aim/background
The consumption of herbal weight-loss products sold over the Internet has rapidly increased, but the safety profile of these products has not been well known yet. Likewise, the declared ingredients in these products could be different than the marketed contents.
Material and Methods
Nine different herbal weight-loss products sold over the Internet were included. The content of each product were evaluated in the Laboratory of Forensic Medicine and the Scientific and Technological Research Laboratory of Inonu University.
Results
Even though analyzed weight-loss products were declared as pure herbal, three of them contain sibutramine, three contain caffeine, and three contain caffeine $+$temazepam. Sibutramine dosage in each capsule was found over 10 mg. We also measured toxic and trace element levels of nine herbal products and, we observed that these herbal products contain low amounts of Pb, Al, Ni and Ba.
Conclusions
Our results showed that herbal weight-loss products available without prescription and declared to be purely herbal may contain pharmaceutical substances like sibutramine or temazepam in high doses. Furthermore, they may also be contaminated with toxic metals. Without the suggestion or control of a physician, these products might cause various health problems that might be harmful. Strict legal rules and control mechanisms must be established to prevent their possible harmful effects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1242

### Obesity related comorbidities 2 years following bariatric surgery in a group of 215 German subjects

N. Sauer[1], J. Wienecke[1], C. Schulze zur Wiesch[1], F. Reining[1], S. Wolter[2], A. Dupree[2], O. Mann[2] & J. Aberle[1]
[1]III. medizinische Klinik, Sektion Endokrinologie und Stoffwechsel, Hamburg, Germany; [2]Viszeralchirurgie, Hamburg, Germany.

Background
Bariatric surgery has shown to effectively reduce body weight and the prevalence of obesity associated comorbidities. However, especially data concerning diabetes is still conflicting. Also the benefit of surgical therapy varies strongly depending on individual patient characteristics.
Methods
Therefore we intended to investigate a heterogeneous group of obese patients ($n=215$) undergoing bariatric surgery in terms of related comorbidities and subgroup benefits.
Results
After one year mean reduction of body weight was $45\pm17$ kg (BMI $15.4\pm5.1$ $P<0.05$). High density cholesterol (HDL) increased on average by 8.0 $\pm9.2$ mg/dl ($P<0.05$), low density cholesterol (LDL)-Levels were reduced by $14.5\pm27.3$ mg/dl ($P<0.05$). The amount of patients who suffered from sleep apnoea reduced from 29.6 to 5.2% ($P<0.05$) after one and 5.3% after two years, those suffering from arthropathia from 83 to 20.7% ($P<0.05$) and 11.1% ($P<0.05$) respectively after one and two years. The prevalence of hypertension declined from 65.3 to 34.7% after 1 year ($P<0.05$) and 33, 3% after two years. If albuminuria was initially above 20 mg, available data demonstrated an average decrease of $126.9\pm214.3$ mg without reaching statistical significance.
Diabetes parameters showed a u-shaped curve with initial amelioration but deterioration of values from visit three on. However 85% of patients taking antidiabetics reduced the amount of oral antidiabetics and 100% the injected amount of insulin.
Subgroup analysis demonstrated a greater overall benefit regarding comorbidities for women or patients below 40 years (except for sleep apnoea). Reduction of HbA1c and loss of insulin was seen to a greater extent in patients with BMI $>50$ kg/m$^2$.
Conclusion
Bariatric surgery is an effective treatment of obesity which leads to a significantly lower BMI and has an immense impact on the improvement of comorbidities. Regarding the effect on diabetes close follow-up should be provided in order to optimise therapy after bariatric surgery.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Changes in gut hormone levels and glucose homeostasis in obese patients during the first year after laparoscopic sleeve gastrectomy

D. Papamargaritis[1,2], C. le Roux[2], E. Sioka[3], R. Vincent[4], A. Kapelouzou[5], G. Tzovaras[3], G. Koukoulis[1] & D. Zacharoulis[3]
[1]University Hospital of Larissa, Larissa, Greece; [2]Imperial College London, London, UK; [3]University Hospital of Larissa, Larissa, Greece; [4]King's College Hospital NHS Foundation Trust, London, UK; [5]Biomedical Research Foundation of the Academy of Athens (BRFAA), Athens, Greece.

Background
Changes in gut hormone levels after laparoscopic sleeve gastrectomy (LSG) has been proposed as a possible mechanism that explains the long-term weight loss and the improvement in glucose homeostasis after bariatric operations. In this prospective study we evaluated the changes in the fasting and postprandial levels of glucagon like peptide-1 (GLP-1), peptide YY (PYY), insulin and glucose during the first postoperative year after LSG.
Methods
Twelve morbid obese patients (three male, nine female, mean BMI $46.7\pm6.59$) were evaluated preoperatively and 6 weeks, 6 months and 12 months postoperatively. None of the patients had established diabetes preoperatively, however 85.7% of them (10/12) were insulin resistant. A standard 75 g oral glucose tolerance test (OGTT) was given after an overnight fast and blood samples were collected before and 30, 60, 90, 120 min after the OGTT for measurement of GLP-1, PYY, insulin and glucose.
Results
Body weight, body mass index (BMI) and waist circumference decreased markedly after LSG (all, $P<0.0001$). GLP-1 and PYY fasting levels did not change significantly postoperatively. GLP-1 and PYY postprandial responses as measured by Area Under the Curve (AUC) were significantly higher from the sixth postoperative week ($P<0.0001$). Fasting insulin levels were lower from 6 weeks postoperatively ($P<0.0001$), while insulin AUC decreased at 6 and 12 months postoperatively ($P=0.0093$). Finally, glucose AUC decreased at 6 and 12 months ($P<0.0001$) but glucose fasting levels decreased only at 12 months postoperatively ($P=0.0091$). Insulin sensitivity measured by Matsuda Index increased progressively postoperatively ($P<0.0001$) when the early insulin secretion measured by insulinogenic index did not change ($P=0.21$).
Conclusion
After LSG, GLP-1 and PYY postprandial responses in obese non- diabetic patients increased after an oral glucose tolerance test and was maintained for at least one year. Glucose and insulin levels decreased postoperatively showing a significant improvement in glucose homeostasis after LSG.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1244

### Changes of peripheral α-melanocortin stimulating hormone (α-MSH) in childhood craniopharyngioma patients in comparison with other forms of childhood obesity

H. Müller[1], P. Enriori[2], U. Gebhardt[1], A. Hinney[3], J. Hebebrandt[3], T. Reinehr[4], M. Cowley[5] & C. Roth[6]
[1]Klinikum Oldenburg, Oldenburg, Germany; [2]Oregon Health and Science University, Beaverton, Oregon, USA; [3]University of Duisburg-Essen, Essen, Germany; [4]University Witten / Herdecke, Datteln, Germany; [5]Monash University Clayton, Clayton, Victoria, Australia; [6]University Hospital, Seattle, Washington, USA.

Objective
Relationships of blood circulating melanocortins to childhood obesity are not well established. We evaluated serum α-melanocyte stimulating hormone (α-MSH) in lean children and different study groups of childhood obesity.
Methods
We examined serum α-MSH in 52 otherwise healthy children with childhood obesity (Ob, mean age 11 years, 32 girls / 20 boys), 27 normal-weight children of same age, 7 additional obese patients with reduced melanocortin-4 receptor function (MC4Rmut), and 22 patients with craniopharyngioma (CP). Fasting serum α-MSH and leptin were measured by RIA. Serum α-MSH was also evaluated one hour after 500 kcal liquid meal (CP and Ob) and at the end of 1 year lifestyle intervention in 24 Ob patients.
Results
α-MSH levels were similar in obese vs. lean children but significantly lower in CP ($P<0.001$) and significantly higher ($P<0.05$) in MC4Rmut patients compared to Ob. 1 h after liquid meal, α-MSH increased in patients with SO but not with CP. After one year, α-MSH levels increased significantly in the successful weight reduction Ob subgroup despite unchanged cortisol levels. α-MSH changes correlated to weight status changes ($r=0.67$; $P=0.0003$) but not to changes of cortisol, insulin or insulin resistance index HOMA.
Conclusions
Persistently low α-MSH levels in CP patients are suspected to be due to pituitary or hypothalamic damage. High peripheral levels in MC4Rmut carriers indicate up-regulation of α-MSH. Changes of weight status are associated with changes of peripheral α-MSH. Synthetic α-MSH analogues might offer a promising therapeutic option for treatment of hypothalamic obesity in craniopharyngioma patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1245

**Measurement of serum high-molecular-weight (HMW) adiponectin level using recently-developed chemiluminescence enzyme immunoassay (CLEIA) at health check-up**

H. Hirose[1,2], H. Kawabe[1,2] & I. Saito[1,2]
[1]Keio University, Tokyo, Japan; [2]School of Medicine, Keio University, Tokyo, Japan.

Aim
A chemiluminescence enzyme immunoassay (CLEIA) for high-molecular-weight adiponectin (HMW-ADPN) was recently developed, and has been shown to be faster, more accurate and less expensive than conventional ELISA. In this study, we investigated the relationships between metabolic parameters and the HMW-ADPN level measured by CLEIA in a health check-up setting.
Methods
Informed consent was obtained from 1036 male and 416 female Japanese, 40 to 71 years of age, who participated in this study. Subjects receiving anti-diabetic medication or with suspected inflammation (serum CRP level $>$ 1 mg/dl) were excluded from the analyses.
Results
Median levels of serum HMW-ADPN measured by CLEIA were 2.5 μg/ml in males and 4.95 μg/ml in females. The correlation with the levels measured by ELISA was very good ($r=0.984$, $n=297$). The serum HMW-ADPN level in males with metabolic syndrome (MetS) ($2.13\pm1.14$, $n=173$) was significantly lower than that in those without MetS ($3.02\pm3.43$, $n=860$, $P < 0.0001$). HMW-ADPN correlated positively with the serum HDL-cholesterol level in both males and females ($r=0.41$ and 0.38, respectively, $P < 0.0001$ for both), and inversely correlated with the BMI, waist circumference and triglycerides ($r=-0.30$ to $-0.33$, $P < 0.0001$ for all). HMW-ADPN correlated also with insulin resistance index (HOMA-IR) and serum CRP levels in both males and females ($r=-0.33$ and $-0.28$ in males, and $r=-0.36$ and $-0.30$ in females, $P<0.0001$ for all). Stepwise multiple regression analysis revealed the serum HMW-ADPN level to correlate independently with serum HDL-cholesterol, sex, HOMA-IR and CRP ($F>20$, $P< 0.0001$, $R^2=0.392$).
Conclusions
These results suggest that measuring serum HMW-ADPN by CLEIA is useful, and that the serum HMW-ADPN level is closely correlated with parameters related to MetS and/or cardiovascular diseases.
Declaration of interest

## P1246

**Anti-inflammatory effects of full-length and globular protein fragments of the new adipokine CTRP-3**

A. Schmid, A. Kopp, C. Buechler & A. Schaeffler
University Hospital of Regensburg, Regensburg, Germany.

Introduction
C1q/TNF-related protein-3 (CTRP-3) is a newly discovered adipokine with anti-inflammatory impact on monocytes by down-regulation of pro-inflammatory cytokines, e.g. interleukine 6 (IL6) and tumor necrosis factor alpha (TNF-alpha), in both adipocytes and monocytes. So far it is unclear which kind of interactions and molecular mechanisms are underlying the observed effects. Our aim is to characterize the differential effects of the globular and the collagenous domain of CTRP-3 and to compare these with the effects exerted by the full length protein.
Methods
DNA of recombinant full-length CTRP-3, its globular domain, and its collagen domain were transfected into and expressed in H5 insect cells. The secreted proteins were extracted from the cell culture supernatant and purified by affinity chromatography.
Costimulation experiments were performed in 3T3-L1 and monocyte-like THP-1 cells with pro-inflammatory stimuli lipopolysaccharide (LPS) and free fatty acids (FFA) plus CTRP-3 or its globular domain, respectively. Gene expression and secretion of pro-inflammatory cytokines were measured by real time RT-PCR and ELISA techniques. Protein levels of intracellular components of pro-inflammatory signaling were analysed by Western blot.
Results
Both full-length CTRP-3 and its globular domain were shown to decrease the amount of secreted IL6, MCP-1 and resistin after costimulation with LPS and FFA in differentiated 3T3-L1 cells. RT-PCR results confirmed down-regulation of these pro-inflammatory factors on mRNA level. Decrease of secreted IL6 in THP-1 cells upon costimulation with LPS and CTRP-3 globular domain could be shown as well.
Conclusion and outlook
The results suggest that the observed anti-inflammatory impact of CTRP-3 is mediated by its globular domain, whereas the collagen like domain is still to be tested on these effects. As a next step we plan to investigate the anti-inflammatory effects of CTRP-3 in an animal model of LPS-induced SIRS.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
