Metabolic syndrome (MetS) is a condition characterized by abdominal obesity, insulin resistance, dyslipidaemia and hypertension, that is associated with cardiovascular disease and inflammatory metabolic disorders. This study aimed to ascertain the effect of selected parameters of purinergic and cholinergic systems in lymphocytes of MetS patients. The adenosine deaminase (ADA), dipeptidyl peptidase IV (DPP-IV) and acetylcholinesterase (AChE) activities, as well as γ-glutamyltransferase (GGT) and N-acetyl-b-glucosaminidase (NAG) activities in lymphocytes of patients with MetS ($n=38$) and controls ($n=41$) were evaluated. ADA and DPP-IV activities were markedly higher in lymphocytes of patients with MetS ($ADA=8.44\pm3.79$ U/l, $P < 0.05$; $DPP\text{-}IV=74.26\pm37.84$ U/l, $P < 0.0001$) when compared to the control group ($ADA=6.86\pm2.52$; $DPP\text{-}IV=46.02\pm20.93$). Experimental data also demonstrated that patients with MetS showed a significant increase on AChE activity when compared to the values of healthy subjects ($MetS=0.16\pm0.052$ vs $C=0.1062\pm0.028$ μmol AcSCh/h/ml; $P<0.0001$). However, no significant difference was found in NAG ($MetS=37.46\pm18.75$ vs $C=49.06\pm30.74$ μmol/l) and GGT ($MetS=5.568\pm3.09$ vs $C=5.22\pm2.99$ μmol/L) activities between the groups studied.
Our data suggest that the tissue distress and activation of the immune system observed in MetS patients affects enzymatic activities. The increase of DPP IV-activity observed in the MetS may be related to the interaction of ADA and DPP-IV at the T cells that results in co-stimulatory signs responsible for the activation of the T cell receptor. Also, the increase of AChE activity could be an inflammatory response caused by the insulin resistance state present by the MetS. These findings could most likely represent the sustained activation of lymphocytes in response to inflammatory stimuli of the MetS state.

**Association between osteocalcin and insulin resistance in obese women**

M. Sumarac-Dumanovic[1,2], J. Milin[1], D. Stamenkovic-Pejkovic[1], D. Jeremic[1], G. Cvijovic[1], S. Zoric[1], J. Jorga[2] & D. Micic[1,2]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Belgrade, Serbia; [2]Univeristy of Belgrade, Belgrade, Serbia.

Introduction
Recent animal's studies suggest that osteocalcin have influence on beta cell proliferation, insulin secretion and insulin sensitivity. Osteoblasts appear to regulate energy expenditure by acting on adipocytes and pancreatic islet cells via osteocalcin, a 49-residue polypeptide. In turn, adipose tissue may also influence bone remodeling by regulating the activity of osteoblasts through adipokines, including leptin and adiponectin. Some of the complex mechanisms by which adipose tissue, brain and bone are able to regulate energy expenditure and glucose homeostasis are elucidated by recent studies.
Aim of the study
To investigate relationship between osteocalcin and insulin resistance in obese women with normal glucose tolerance.

Method
Fifty nine obese women (mean BMI = 35.2 ± 5.7 kg/m$^2$, mean age = 36.4 ± 10.2 years) participated in this study. We measured serum osteocalcin, fasting insulin level, fasting glucose level, HOMA-IR (Homeostasis model assessment of insulin resistance), AUC glucose (2 h OGTT), AUC insulin (2 h OGTT), adiponectin level and anthropometric parameters (body mass index, waist to hip ratio, total body fat). Statistics analysis was performed by SPSS 19. Pearson's correlation coefficients were calculated to evaluate the relationship between osteocalcin and other parameters.
Results
Serum osteocalcin was inversely correlated with fasting plasma insulin ($r = -0.379$, $P < 0.05$) and HOMA ir ($r = -0.349$, $P < 0.05$) and positively correlated with adiponectin level ($r = 0.603$, $P < 0.05$). There was no statistically significant correlation between serum osteocalcin and fasting plasma glucose, AUC glucose, AUC insulin and anthropometric values (body mass index, waist to hip ratio, total body fat).
Conclusion
Our results confirmed significant correlation between insulin and insulin sensitivity with osteocalcin as well as with adiponectin, which suggests possible novel role of bone via osteocalcin in regulation of glucose metabolism and insulin sensitivity.

**Serum leptin levels in patients with type 1 gaucher disease**

M. Petakov[1,2], N. Suvajdzic[1,2], M. Lakocevic[1], M. Petakov[1], S. Ognjanovic[1], T. Isailovic[1], D. Macut[1,2], M. Djurovic[1,2], V. Elezovic[1], B. Popovic[1], I. Bozic[1], T. Bogavac[1] & S. Damjanovic[1,2]
[1]Clinic of Endocrinology, Belgrade, Serbia; [2]Medical School of Belgrade University, Belgrade, Serbia.

Introduction
Leptin is an adipocyte-secreted hormone that plays a key part in energy homeostasis but also regulates reproductive, neuroendocrine, immune, and metabolic functions. Inflammatory cytokines may affect leptin secretion. Gaucher disease (GD) is autosomal recessive lysosomal storage disorder caused by the deficiency of enzyme glucocerebrosidase (GCD) with consequent massive acumulation of lipid-laden macrophages in various tissues. The pathology of Gaucher disease primarily results from the storage of sphingolipids in tissues throughout the mononuclear phagocyte system with subsequent macrophage activation and tissue inflammation with cytokine production.
Methods
We studied serum leptin concentration in a cohort of 15 patients with type 1 GD with and without enzyme replacement therapy (ERT) (9 females and 6 males, mean age 44.2+/-3.4 years,) and 20 age and BMI-matched healthy control subjects (13 females and 7 males, mean age 40.9+/−3.2 years).
Results
Serum leptin level is significantly higher in patients with GD type 1 as compared with healthy subjects (mean+/-SE, 21.0+/−5.8 vs 6.3+/-1.3 mcg/l respectively). There was no difference in serum leptin level between untreated ($n = 5$) and treated patients ($n = 10$) with type 1 GD. There was positive correlation between body mass index and leptin levels both, in GD patients irrespective of treatment status and healthy controls.
Conclusion
Our results confirm that serum leptin level is significantly higher in patients with type 1 GD in comparison with healthy subjects, and that this elevation is independent of body mass index. Also there was no effect of treatment status on serum leptin levels in GD patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1250

**Relationship between neck circumference and cardiometabolic parameters in non-obese brazilian adult population**

A. Sales, M. Castelo, C. Ponte, V. Fernandes, P. Mendes, S. de Mesquita, A. Montenegro, A. Quidute, C. Negrato & R. Montenegro Jr
Ceará Federal University, Fortaleza, Brazil.

Recent studies have suggested that upper body adiposity is associated with major cardiovascular risk (CVR). However most of them were conducted in obese patients. This study aimed to evaluate the relationship of neck circumference (NC) in a non-obese Brazilian adult population, considering that it would be a simple and time-saving measurement to identify patients with worse cardiometabolic profile. We evaluated 279 non-obese Brazilian adults [86 men (♂), 193 women (♀)], who had no known major medical conditions and were not receiving any medication living in Northeast of Brazil. Main anthropometric parameters evaluated were: BMI (kg/square meter): ♂25.0 ± 2.8/♀24.9 ± 2.9; NC (cm): ♂37.8 ± 2.0/♀33.0 ± 1.8; waist circumference (WC) (cm): ♂89.5 ± 8.0/♀85.6 ± 8.0; scapular circumference (SC): ♂95.1 ± 9.1/♀87.5 ± 5.2; systolic (SBP): ♂125.6 ± 14.8/♀118.0 ± 13.3, and diastolic blood pressure (mmHg) (DBP): ♂81.8 ± 8.3/♀78.7 ± 8.3; HDL (mg/dl): ♂43.5 ± 11.7/♀53.0 ± 12.6; triglycerides (mg/dl): ♂130.0 ± 76.8/♀107.0 ± 52.2; fasting glucose (mg/dl): ♂92.7 ± 10.7/♀91.4 ± 13.4; fasting insulin (uU/ml): ♂7.2 ± 4.0/♀9.0 ± 7.5; total cholesterol (mg/dl): ♂175.4 ± 37.4/♀182.7 ± 34.0; LDL (mg/dl): ♂104.6 ± 30.7/♀107.8 ± 30.2; HOMA-IR: ♂1.7 ± 1.0/♀2.0 ± 1.7. We found association (Pearson's correlation, $P < 0,05$) between NC and: WC ($r = 0.48$), AC ($r = 0.43$), SC ($r = 0.68$), BMI ($r = 0.35$), SBP ($r = 0.34$), DBP ($r = 0.27$), tryglicerides ($r = 0.24$), HDL ($r = -0.35$. These data suggest that NC could have a potential role in the clinical evaluation of cardiometabolic risk even in non-obese subjects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**A different method in obesity treatment; external gastric balloon**

M. Basak, H. Gozden, H. Aktas & T. Saler
Umraniye Training and Research Hospital, Istanbul, Turkey.

Obesity is an important and chronic disease. It is known that obesity closely related with many chronic disorders.Also it is known as a result of serious morbidity and mortality. For treatment of obesity, dietary, medicine, egzercise and surgery should be useful but they have also some adverse effects and surgery should be cause of mortality and severe morbidity.
Our method of EGB is completely non-invasive and we investigated the efficacy of obesity treatment by using 'External Gastric Balloon' which has no side effects, easy to use and cheap way to loose weight. It's produced by 'variteks company'. In this study we observed 91 patients, including 47 of study group and 44 of control group. In the study group patients used a corset for 2.51 ± 1.07 months with hypocaloric diet. And during this time average weight loss was 6.08 kg. On the other hand the control group was planned to take 1400–1600 kcal/day diet (∼1495.45 ± 256.95 kcal/day). Patients in the control group diet period was ∼6 months. Average weight loss was 6.06 kg. Patients in the study group weight loss with corset usage time between positive and statistically significant relationship at the level of 38.6% was observed ($P < 0.05$). A statistically significant relationship between duration of the diet in the control group patients and weight loss was not seen ($P > 0.05$).The higher weight loss can be seen with long corset using period.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Hyperuricemia and components of metabolic syndrome among patients of different age**

V. Povoroznyuk & G. Dubetska
Institute of Gerontology NAMS Ukraine, Kyiv, Ukraine.

Aim of research
To determine uric acid level in blood serum and incidents of hyperuricemia among women and men of different age and their relation with some components of metabolic syndrome.

Object of research
Women ($n=450$) and men ($n=120$), age of examined patients was from 20 to 89 years old. They were divided into the following groups: I group (BMI = 18.5–24.9), II group (BMI = 25.0–29.9), III group (BMI = 30.0–34.9), IV group (BMI > 35). Average age of examined patients was 60.4 ± 0.7 years.
Methods of research
Uric acid level of blood plasma was determined by uricase-peroxidase method. Statistic analysis was performed by Statistica 6.0.
Results
The level of uric acid increased with age in women and had a significant difference in women of 80–89 years ($r=0.18$, $P<0.05$). In men the maximal level of uric acid was in the group 60–69 years. Incidence of hyperuricemia among women was 17%, in men −30%. We determined that the highest level of triglyceride, cholesterol, systolic and diastolic pressure was among women and men with hyperuricemia. The higher level of uric acid was found among women in postmenopausal period with maximal body mass index (BMI > 35). In the I group level of uric acid was 277.52 ± 8.40 μmol/l; in II group – 286.81 ± 7.79 μmol/l; in III group – 291.81 ± 7.56 μmol/l, in IV group – 327.17 ± 12.17 μmol/l. Incidence of hyperuricemia among women in the I group was 10.2%, in II group – 15.9%; in III group – 21.2%, in IV group – 34.2%.
Conclusions
It was determined that the level of uric acid was increasing with age and the highest level of some components of metabolic syndrome (triglyceride, cholesterol, systolic and diastolic pressure) was among women and men with hyperuricemia. The higher level of uric acid was found among women in postmenopausal period with maximal body mass index (BMI > 35).

## P1253

**The comparison of obesity treatment with intragastric balloon and bihevioral-cognitive approach**

S. Klobucar Majanovic[1], A. Ruzic[1], A. Pokrajac Bulian[2], V. Licul[1], T. Turk[1], Z. Crncevic Orlic[1], V. Persic[3] & D. Stimac[1]
[1]University Hospital Rijeka, Rijeka, Croatia; [2]Faculty of Phylosophy Rijeka, Rijeka, Croatia; [3]Thalassotherapia, Opatija, Croatia.

Objectives
To compare obesity treatment with intragastric balloon (BIB – Bioenterics intragastric balloon) and behavioral-cognitive approach in order to determine the effectivness of these two methods in inducing weight loss, their impact on different features of metabolic syndrome and liver enzymes profile, and finally to evaluate patients attitudes and expectations regarding weight loss together with motivation and readiness to change their behaviour in order to lose weight.
Patients and methods
Subjects were required to be between 18 and 55 years old and to have a BMI between 30 and 45 to be eligible. Additional exclusion criteria, besides those required for BIB placement, were DM type 2, depression and binge-eating disorder. 60 subjects who had undergone the BIB procedure constituted the primary sample and 54 subjects who participated in weight loss cognitive-behavioral program constituted the paralel group. Anthropometric and biochemical parameters were assessed at baseline and after 6 months. Questionnaire assessment was used to evaluate patients attitudes and expectations regarding weight loss as well as their motivation and readiness to lose weight.
Results
The mean BMI during balloon treatment declined from 38.6 ± 3.9 to 32,84,39 kg/m$^2$ ($P<0.001$) with an excess weight loss (%EWL) of 44.6 ± 23.9 comparing with %EWL of 22.5 ± 11.5 in paralel group ($P<0.001$). A significant improvement in blood pressure, glycemia, trygliceride level and liver enzyme profile was seen in both treatment groups, but much more in subjects treated with BIB. Patients motivation and readiness to lose weight were high in both treatment groups, but subjects prior the balloon placement reported greater level of self-efficacy in weight control than those who decided to participate in cognitive-behavioral treatment.
Conclusion
Our results confirmed that intragastric balloon is useful method for promoting weight loss. Due to improvement of metabolic parameters and substantial benefit on liver function, obese people with metabolic syndrome appear to be the best candidates for BIB placement. Combining BIB with behavioral-cognitive approach might prove valuable for even greater weight loss.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1254

**Therapeutic efficacy of obesity treatment methods in teenagers**

L. Viazava, A. Solntsava & A. Sukalo
Belorussian state medical university, Minsk, Belarus.

Aim
The aim of our study was to evaluate the effectiveness of the body mass (BM) decreasing program in pubertal children with alimentary obesity during the year of observation.
Materials and methods
Anthropometric changes in body mass index (BMI) and waist circumflex (WC) were analyzed every 1, 3, 6 and 12 months in 100 obese pubertal children (boys/girls = 50/50) with different treatment methods: the 1st group – only reducing diet (b/g = 30/30), the 2nd – combination with sport (12/11) and the 3rd – combined with metformin hydrochloride (9/8).
Results
There were no differences in initial BMI and WC between the 1st (30.3 ± 3.9 kg/m$^2$ and 92.1 ± 10.8 cm) and 2nd groups (29.8 ± 3.7 kg/m$^2$ and 89.6 ± 11.7 cm; $P>0.05$). The 3rd group's primary BMI and WC surpassed the same parameters in the 1st and 2nd groups (35.5 ± 7.4 kg/m$^2$ and 102.7 ± 15.8 cm), that was in keeping with abdominal obesity ($P=0.001$ and $P=0.007$; $P=0.01$ and $P=0.02$). There were no BMI changes in the 1st group during follow-up period ($P>0.05$). Gradual BMI decreasing was registered relating to initial ones starting from the 1st month of therapy (29.61 ± 3.29; 29.18 ± 3.53; 28.53 ± 3.45; 27.23 ± 3.63 kg/m$^2$, $P=0.003$). BMI reduction trend was observed every 3, 6 and 12 month ($P>0.05$) in the 3rd group. There were no differences between WC rates during the follow-up time regardless of treatment types. However WC decreasing tendency was noted in 3rd group (103.83 ± 17.65; 103.11 ± 17.13; 102.03 ± 16.52; 99.86 ± 15.97 cm).
Conclusions
Reducing nutrition combined with vigorous physical activity is enough for BM reducing in patient with uncomplicated obesity. Dietary intake combined with metformin hydrochloride should be recommended in children with abdominal and morbid adiposity.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1255

**Insulin and C-peptide response after a test meal in obese patients before and 5 days after bariatric gastric by pass surgery**

D. Micic[1,3], D. Bajec[2,3], S. Polovina[1], D. Radenkovic[2,3], M. Sumarac-Dumanovic[1,3], P. Gregoric[2,3], G. Cvijovic[1,2], S. Ignjatovic[1,2], M. Dajak[1], D. Micic[2] & D. Jeremic[1]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Clinical Center of Serbia, Belgrade, Serbia; [2]Clinical Center of Serbia, Belgrade, Serbia; [3]University of Belgrade, Belgrade, Serbia.

Different hypothesis exist about the mechanism of glycose control after bariatric surgery involving intestinal bypass. The aim of our study was to determine the insulin and C-peptide response after test meal (Fresubin drink a 200 ml; 200 kcal, 15% protein, 30% fat and 55% carbohydrate) before (day 0) and 5 days after gastric by pass surgery. Glycaemia (mmol/l; glucose oxidase), insulin (ECLIA, Roche Diagnostics, pmol/l) and C-peptide (ECLIA, Roche Diagnostics, pmol/l) were determined in 22 obese patients (age: 36.22 ± 12.66; BMI: 44.60 ± 4.31 kg/m$^2$) in two separate days in 0, 15, 30, 45, 60, 90 and 120 min. There were no significant difference between areas under the glucose curve (X ± S.D.; 645.562 ± 20.545 vs 621.600 ± 24.071 mmol/l per min; $P=0.304$) and under the C-peptide curve (293 074.125 ± 23 539.975 vs 267 750.375 ± 19 685.409 pmol/l per min; $P=0.317$) while there was significant lower area under the insulin curve in day 5 (38 263.075 ± 6079.509 vs 23 539.875 ± 2571.388 pmol/l per min; $P=0.032$). There was significant difference between basal glucose in 0 vs 5 day

($4.695 \pm 0.168$ vs $4.090 \pm 0.177$; $P = 0.0113$) while there were no significant difference between basal insulin ($100.514 \pm 24.191$ vs $61.229 \pm 7.166$; $P = 0.118$) and C-peptide ($1400.952 \pm 180.160$ vs $1074.571 \pm 96.986$; $P = 0.097$). There were no significant difference between peak levels in glucose ($6.330 \pm 0.218$ vs $6.165 \pm 0.236$; $P = 0.482$), insulin ($635.555 \pm 103.576$ vs $416.145 \pm 52.408$; $P = 0.066$) and C-peptide ($3300.900 \pm 279.453$ vs $3286.800 \pm 280.226$; $P = 0.960$) in day 0 and 5. In conclusion, insulin response after test meal is significantly decreased after gastric by pass surgery after 5 days without significant difference in glucose response, indicating early improvement in insulin sensitivity.

## P1256

### The oxidative stress parameters within the context of metabolic syndrome evolution in men

O. Tsygankova[1], D. Platonov[2,3], Z. Bondareva[1] & L. Latyntseva[4]
[1]Novosibirsk State Medical University, Novosibirsk, Russian Federation; [2]Tver Regional Clinical Hospital, Tver, Russian Federation; [3]Tver State Medical Academy, Tver, Russian Federation; [4]Institute of Therapy of Siberean Branch of Russian Academy of Medical Sciences, Novosibirsk, Russian Federation.

Introduction

The aim of study was to assess diversity of oxidative stress as a dynamic process throughout metabolic syndrome (MS) continuum ending with coronary heart disease (CHD) or diabetes mellitus (DM).

Methods

Main group (MG) of 154 men aged 25–60 years with abdominal obesity (waist circumference above 94 cm) was examined in comparison to 30 healthy men of similar age. In MG 28 men were diagnosed with CHD, 24 – with DM. Fasting glucose (FG) was assessed by hexokinase assay; fasting insulinemia (FI) – by ELISA; malonic dealdehyde (MDA), vitamins A (VA) and E (VE) in precipitated low-density lipoproteins (LDL) – by fluorometry; oxidative metabolism of polymorphonuclear leukocytes (PMN) – by spontaneous (spCLI), zimozan-induced chemoluminescence (indCLI), and stimulation indeces (SI); HOMA-IR index was calculated as FG (mM/l) $\times$ FI ($\mu$U/ml)/22.5.

Results

In MG (excluding DM patients) mean FG was similar to that in controls, whereas HOMA-IR index was higher ($3.54 \pm 0.12$ vs $2.22 \pm 0.24$; $P < 0.05$), reaching $6.08 \pm 0.52$ in DM subgroup. Mean MDA levels were higher in MG ($5.15 \pm 0.19$ vs $2.56 \pm 0.54$ nM/l per mg of LDL-protein; $P < 0.05$), being the highest in CHD ($5.72 \pm 0.26$) and somewhat less in DM patients ($4.78 \pm 0.67$). Mean VA levels were higher in MG than in controls only in patients without CHD and DM ($0.07 \pm 0.011$ vs $0.02 \pm 0.002$ mg/mg of LDL-protein; $P < 0.05$), however they fell down below controls to $0.01 \pm 0.001$ ($P < 0.05$) in CHD and DM patients; whereas VE did not differ between subgroups. Both spCLI (by 3.3 times) and indCLI (by 2.6 times) were higher in MG ($P < 0.05$), being the highest in patients without CHD and DM, whereas SI was the lowest in CHD ($2.18 \pm 0.13$) and DM ($2.14 \pm 0.15$) patients as compared to controls ($2.97 \pm 0.28$; $P < 0.05$).

Conclusion

The MS evolution towards CHD and DM is associated with cellular and humoral oxidative stress reactions with increase in MDA and PMN activation and concomitant deficiency of VA antioxidant potential and decreased PMN reserve reactivity.

Parameters of PMN oxidative metabolism (M $\pm$ S.E.M.).

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Table 1**

| Subgroup | N | spCLI | indCLI | SI |
|---|---|---|---|---|
| Controls | 30 | $0.015 \pm 0.002$ | $0.044 \pm 0.004$ | $2.97 \pm 0.28$ |
| Patients without CHD/DM | 102 | $0.049 \pm 0.005$ | $0.139 \pm 0.007$ | $2.85 \pm 0.25$ |
| Patients with CHD | 28 | $0.039 \pm 0.007$ | $0.085 \pm 0.004$ | $2.18 \pm 0.13$ |
| Patients with DM | 24 | $0.042 \pm 0.006$ | $0.090 \pm 0.010$ | $2.14 \pm 0.15$ |

## P1257

### Relationships between metabolic syndrome components and bone mineral density in ukrainian postmenopausal women

L. Martynyuk[2], V. Povoroznyuk[1] & L. Martynyuk[2]
[1]Institute of Gerontology NAMS Ukraine, Kyiv, Ukraine; [2]2I. Hobachevsky Ternopil State Medical University, Ternopil, Ukraine.

Objective

Postmenopausal period in women is associated with the accelerated bone loss, contributing to the development of osteoporosis, fractures and decreasing of quality and duration of life. The metabolic syndrome (MS), which includes obesity, dyslipidemia, hyperglycemia, and hypertension, is a major public health problem also.

The purpose of our study was to reveal associations between tissue body composition, compounds of MS and BMD in postmenopausal women.

Design & method

The sample consisted of 90 postmenopausal 60–69 years old women (age: mean = 63.9; S.D. = 0.4); duration of menopause: mean = 14.1; S.D. = 0.9). MS was considered according to IDF (2005 years) criteria. Total body, lumbar spine, femoral neck, ulna radius bone mineral density (BMD), lean and fat mass distribution were measured by dual-energy X-ray absortiometry were compared for the cohorts with and without the MS. Other parameters including age, weight, height, the level of glucose, lipids were taken into account. Data were analyzed using Statistical Package 6.0 (Statsoft).

Results

Findings revealed that 55 (61.1%) of these postmenopausal women had MS. In patients with and without MS compared, fat mass was higher in the former group In patients with and without MS compared, BMD was lower in the former group at femoral neck ($0.77 \pm 0.02$; $0.89 \pm 0.03$, respectively; $F = 10.2$; $P = 0.002$), ulna radius ($0.57 \pm 0.02$; $0.64 \pm 0.02$, respectively; $F = 6.4$; $P = 0.01$).and at different body regions also. Lean mass comparing didn't show significant differences. Diabetes mellitus and hyperglycemia in subjects compared with age and body mass index matched non-diabetic subjects were associated with lower BMD. Serum concentration of triglycerides was a negative predictor of BMD. Increasing quantity of the MS components in women during the postmenopausal period had a negative correlation with BMD at every site.

Conclusion

Our findings suggest that body fat mass is not significant protective factor for BMD loss.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Allograft inflammatory factor 1 is a new human adipokine regulating adipose inflammation

K. Ekberg[2], S. Lorente-Cebrián[1], P. Arner[1] & I. Dahlman[1]
[1]Department of Medicine, Stockholm, Sweden; [2]Karolinska Hospital, Stockholm, Sweden.

Introduction

Allograft inflammatory factor 1 (AIF-1) is a putative obesity gene which may influence the function of white adipose tissue (WAT).

Objective

To study the role of AIF-1 in human WAT.

Design and main outcome measures

mRNA expression and WAT secretion of AIF-1 was determined in subcutaneous and visceral WAT from non-obese subjects. Differentiated human adipocytes were treated with recombinant AIF-1 *in vitro*.

Results

AIF-1 was secreted in a time dependent fashion from WAT. The major source of AIF-1 was macrophages followed by lymphocytes; fat cells contributed only to a minimum extent. Expression of AIF-1 was similar in visceral and subcutaneous WAT and was markedly increased in obese subjects; the latter was normalized following weight reduction. AIF-1 stimulated the adipocyte production and secretion of monocyte chemoattractant protein 1 (MCP-1) without influencing other proteins involved in inflammation.

Conclusion

AIF-1 is a novel adipokine involved in the pathophysiology of obesity. It is produced mainly by macrophages within WAT and i. It's expression is increased in obesity as a secondary phenomenon. AIF-1 may play a paracrine role in the

inflammation of WAT through cross-talk between macrophages and fat cells, by enhancing adipocyte production and secretion of MCP-1.

**Body composition and radiation exposure in the Adult Health Study**

Y. Tatsukawa[1], M. Misumi[1], M. Yamada[1], S. Nakanishi[2] & S. Fujiwara[1]
[1]Radiation Effects Research Foundation, Hiroshima, Japan; [2]Hiroshima University, Hiroshima, Japan.

Background
Several studies have shown that medical radiation exposure in childhood might cause alteration in body composition, although all such studies were of a small scale and individual radiation doses were not estimated.
Objective
The aim of this cross-sectional study was to evaluate whether or not atomic-bomb (A-bomb) radiation exposure is associated with alteration of body composition using dual energy X-ray absorptiometry (DXA).
Methods
A total of 1729 participants in the Adult Health Study, comprising A-bomb survivors and their controls, were eligible for the study. Regional fat mass and lean mass were estimated by whole body DXA. Appendicular lean mass (ALM) /height$^2$(ALMH$^2$) and trunk (central) fat and limb (peripheral) fat ratio (trunk-to-limb fat-mass ratio) were calculated. We analyzed association between radiation dose and body composition using multivariate linear regression model.
Results
A-bomb radiation dose was associated with decreased levels of ALMH$^2$, after adjustment for smoking status and other conventional risk factors. Significant negative association between radiation dose and ALMH$^2$ was observed among A-bomb survivors exposed at young ages. Furthermore, there was significant positive association between radiation dose and trunk-to-limb fat ratio in young female survivors.
Conclusions
The observed effects on body composition may be useful information for elucidation of mechanisms behind late effects of radiation exposure on health outcomes including cardiovascular disease.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Usefulness of preoperativee exenatide in control of risk factors for bariatric surgery on type 2 diabetic patients with morbid obesity**

T. Martin-Hernandez[1], G. Clara[1], N. Gonzalez[1], V. Martin[2], A. Torres[1], A. Gentil[1] & A. Morales[1]
[1]University Hospital Virgen Macarena, Seville, Spain; [2]University Seville, Seville, Spain.

Introduction
The aim of this study was to evaluate effects on glycemic control, body weight and cardiovascular risk factors (BP, lipids and Epworth sleepiness scale) in diabetic patients with morbid obesity treated with exenatide.
Material and methods
We studied consecutively 21 T2DM patients, all of them treated with metformin full dosage and insufficient metabolic control referred to our clinic for preoperative control of bariatric surgery. Twelve of these patients (treatment group) were treated in addition with conventional regimen exenatide (5 µg s.c./12 h, 30 days and 10 µg s.c./12 h later) for 6–12 months or until surgery. Not altered any other therapeutic regimen. All of them were attached to a specific program of diet and exercise and reviewed monthly by a specialist nurse practitioner. Mann–Whitney and Wilcoxon test were performed.
Results
The mean patient age was 38.8±10.8 years in treatment group and 44.9±12 years in control group, with a ratio female:male 2:1. The average time of diabetes mellitus in treatment group was 3.1±1.1 years an 3.05±1.5 years in control group. Two thirds of patients had a diagnosis of obstructive sleep apnea (OSA) and ambulatory CPAP used during nocturnal rest, without statistically significant differences between groups. At the end of the study, better results were obtained in the treatment group, with statistically significant differences in clinical parameters of control of OSA (Epworth sleepiness scale): 6.7±3.2 vs 12.1±1.5 $P<0.01$, and in glycemic control (HbA1c: 7.1±0.9 vs 8.6±0.9, $P<0.01$), but not in weight loss (BMI: 42.1±4.5 vs 44,8±6.6, $P=0.7$). The most frequent adverse event in treatment group was nausea mild to moderate. There were no losses to follow up due to this cause during the study period.
Conclusions
Adjunctive therapy with exenatide in morbidly obese T2DM-patients achieved a sustained improvement in glycemic control and OSA and persists after body weight stabilization.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Preclinical anti-obesity activity and safety assessment of a novel drug affecting CB1 receptor**

J. Dugina[1], I. Kheifets[1], L. Bugaeva[2], A. Spasov[2], T. Vorobyova[3] & O. Epstein[1]
[1]Materia Medica Holding Company, Moscow, Russian Federation; [2]Volgograd State Medica University, Volgograd, Russian Federation; [3]Institute of Neurology, Psychiatry and Narcology of the AMS of Ukraine, Kharkov, Ukraine.

Dietressa is a novel drug for the treatment of obesity containing ultra low doses of antibodies to CB1 receptor. A number of new drugs are now at different stages of development, and cannabinoid receptor type 1 is one of the most challenging targets for obesity treatment. However, there are some safety concerns over CB1 receptor antagonists, especially their psychological adverse effects.
The study included two parts: the first one was performed on 33 C57B1 male mice (baseline weight 12–14 g, 28 days) receiving a modified high-fat (45%) diet (MP Biomedicals, USA) in combination with distilled water (control, 0.2 ml/mice ig),

**Table 1** Body weight gain in mice on a high-fat diet, M±m

| Δ from baseline, % | | 21.9 | 31.4** | 47.9 ** | 52.1* | 52.1** | 49.4 | 63.0 | 65.8 |

Differences from the control are significant at *$P<0.05$; **$P<0.01$.

sibutramine (10 mg/kg ig) or Dietressa (0.2 ml/mice ig) for 2 months. The second one was conducted on 20 white outbred laboratory male rats (230–250 g, 6–8 months) administered with distilled water (control, 2.5 ml/kg ig) or Dietressa at 2 (control, 2.5 ml/kg ig) for 5 days. Reinforcing potential was evaluated using the self-stimulation reaction (SSR) in Skinner box.
Starting from week 6 of administration Dietressa reduced body weight gain in mice at a high-fat diet. By the end of the study (week 8) body weight gain in the control group was 76.1%, and in Dietressa and sibutramine groups – 65.8%. Dietressa did not affect SSR frequency in rats. Discontinuation of the drug caused no withdrawal.
Preclinical studies of Dietressa revealed its ability to decrease body weight gain in experimental animals on a high fat diet without withdrawal symptoms.

### Green tea consumption, weight loss and resting energy expenditure

D. Aksoy[1], N. Cinar[1,2], K. Aydin[1,2], M. Mercanligil[1,2], B. Yildiz[1,2], M. Bayraktar[1,2] & A. Usman[1,2]
[1]Etlik Ihtisas Research and Training Hospital, Ankara, Turkey; [2]Hacettepe University School of Medicine, Ankara, Turkey.

Introduction
Green tea consumption has been reported to be associated with weight loss although the results of the studies are inconclusive and potential underlying mechanism is not yet clear. We aimed to evaluate the effect of green tea extract on weight loss, body composition and resting energy expenditure in obesity.
Methods
Twenty-nine obese patients (body mass index (BMI) $>30$ kg/m$^2$) were included in the study. Weight, BMI, waist circumference (WC), body composition and resting energy expenditure (REE) were recorded at baseline. Patients were randomly assigned to receive green tea extract (400 mg standardized green tea extract, 200 mg polyphenols and 100 mg green tela leaf powder) or placebo along with a standard hypocaloric diet. All measurements were repeated after 3 months.
Results
Fourteen patients received green tea exctract and 15 received placebo. Two groups were similar regarding all parameters. Both groups have lost weight significantly with a decrease in BMI, fat mass and WC. REE did not change in both groups. Addition of green tea extract did no increase REE, amount of weight loss or body composition.
Conclusions
Green tea extract does not have any effect on REE, weight loss or body composition in obese patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Waist and abdominal circumference in seven years old children: relationship between methods

R. Braunerová[1], J. Riedlová[3], J. Vignerová[2], M. Hill[1] & M. Kunešová[1]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]National Institute of Public Health, Prague, Czech Republic; [3]Third Faculty of Medicine, Charles University, Prague, Czech Republic.

Introduction
Waist circumference serves as a key indicator of abdominal obesity and predictor of cardiovascular and metabolic risk even in children. Under the current WHO standard methodology, waist circumference is measured midway between the lowest rib and the iliac crest. However, comparison of current and earlier data is complicated as different waist circumference measurement methodologies have been used in the past. For instance, previous Czech studies commonly worked with abdominal circumference measured at the umbilicus level. Therefore, it is necessary to find a formula for comparison of both measurement methods (to enable comparison of waist circumference in Czech 7 years old children who participated in WHO Europe initiated COSI project with older Czech data from National Anthropological Surveys). In our new study we measured both waist circumference and abdominal circumference on a sample of the same age group, using the data to determine an index for recalculation of historic results.
Methods
At the moment, the sample includes 112 children (54 girls, 58 boys). Data were collected during morning classes. Measurements taken included: weight, height, waist circumference, abdominal circumference as specified above, and hip circumference. The relationship between abdominal circumference (AbdC) and waist circumference (WC) was evaluated using polynomial regression.
Results
Sample characteristics (mean $\pm$ S.D.):
Age $6.95 \pm 0.58$; AbdC $56.39 \pm 4.61$; WC $54.50 \pm 4.04$; BMI $15.53 \pm 1.55$; BMI $Z$-score $-0.10 \pm 0.89$.
Polynomial regression analysis of AbdC and WC data provided the following relationship:
Boys: WC $= 5.88661 + 0.868423 \times$ AbdC.
Girls WC $= 5.47176 + 0.866742 \times$ AbdC.
Conclusion
We suggest using the above equations to recalculate abdominal circumference to waist circumference for direct comparison of studies that use different measurement methodologies. We are planning to expand the sample to verify our preliminary results and increase the relevance of our conclusions.

### Bariatric surgery in men: effects on gonadal hormones, body composition, glucose, lipid and bone metabolism

E. Aarts[1], B. van Wageningen[1], S. Loves[1], I. Janssen[1], F. Berends[1], F. Sweep[2] & H. de Boer[1]
[1]Rijnstate hospital, Arnhem, The Netherlands; [2]Radboud University, Nijmegen, The Netherlands.

Background
Obesity-related, isolated hypogonadotropic hypogonadism (IHH) occurs in more then 40% of morbidly obese men.
Hypothesis
IHH and prolonged persistence of low testosterone levels after bariatric procedures may reduce the beneficial effects of surgery.
Objective
To evaluate the impact of IHH on the results of bariatric surgery.
Patients and methods
observational study with measurement of gonadal hormone levels, assessment of body composition and glucose, lipid and bone metabolism during the first year after bariatric surgery in 13 hypogonadal (free testosterone $<225$ pmol/l) and 11 age-matched eugonadal morbidly obese men (free testosterone $>225$ pmol/l).
Results
serum free testosterone rose gradually after bariatric surgery in eugonadal as well as in hypogonadal men. The increase in free testosterone was directly related to the amount of weight loss. Gonadal hormone status prior to surgery did not affect the 1-year outcome of bariatric surgery, but the type of surgery did. Gastric bypass induced a greater loss of fat, but also caused a greater loss of muscle and bone than gastric banding.
Conclusion
Bariatric surgery raised serum T levels, but the improvement was less in hypogonadal than in eugonadal men. Obesity-related IHH did not reduce the efficacy of bariatric surgery.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Outcome of obese adults after laparoscopic adjustable gastric banding: a retrospective follow-up study

T. Evora[1], R. Mirasol[1,2], E. Oliveros[1] & H. Dineros[1,3]
[1]St Luke's Medical Center, Quezon City, Philippines; [2]Manila Doctors Hospital, Manila, Philippines; [3]Cardinal Santos Medical Center, San Juan City, Philippines.

Background
Laparoscopic adjustable gastric banding (LAGB) is now the most common surgical treatment for obesity. However, few data exist on the outcome of LAGB in our setting.
Objective
This study aimed to assess the outcome of obese adults after LAGB in terms of weight loss.
Methods
We conducted a retrospective review of records of all patients who underwent LAGB between January 2004 and December 2009 at St Luke's Medical Center. Patients were included in the analysis if they were at least 18 years old at the time of surgery and had one or more recorded weight measured during the follow-up period. Outcome was assessed using percentage excess weight loss (%EWL) at 1 year $\pm$6 months intervals. Analysis of variance was used to compare three or more groups of continuous variables while chi-square or Fischer's exact were used to analyse categorical variables. Logistic regression was done to determine independent factors that predict successful weight loss after gastric banding.
Results
A total of 97 patients met the inclusion criteria. The majority of the patients were Filipino (77%), and female (61%). Their ages ranged from 18 to 68 (mean 36.1 years $\pm$12.2). The mean BMI was 44.1 $\pm$ 0.1 kg/m$^2$ and mean excess weight was 61.4 $\pm$ 26.5 kg. Greatest %EWL (43.46%) and BMI reduction (21.55%) were attained at 2 years but was not sustained thereafter. The highest success rate (%EWL $>$ 50%) was also achieved at 2 years (48%). Follow up rate was high at 6 months (98%) and 1 year (68%), but, thereafter fell below the accepted value of 61%. Independent predictor of successful LAGB at 1 year was BMI $<$ 43.4 kg/m$^2$.
Conclusion
Obese adults achieved a substantial mean weight loss of 43.46% at 2 years after LAGB.
Outcome measures in obese adults after laparoscopic adjustable gastric banding over time of follow-up at St Luke's Medical Center, Philippines.

### Proteomic analysis of adipose tissue in health and disease

M. Malagon[1], R. Guzman-Ruiz[1], A. Diaz-Ruiz[1], R. Vazquez-Martinez[1], J. Lopez-Miranda[2], F. Tinahones[3] & J. Peinado-Mena[4]
[1]University of Cordoba, IMIBIC, CIBERobn, Cordoba, Spain; [2]Reina Sofia University Hospital, IMIBIC, University of Cordoba, CIBERobn, Cordoba, Spain; [3]Hospital Virgen de la Victoria, CIBERobn, Malaga, Spain; [4]University of Castilla-La Mancha, Ciudad Real, Spain.

Adipose tissue is a highly active metabolic organ which, together with its role as an energy storage depot, produces a wide variety of bioactive molecules (i.e. adipokines) with important roles in the regulation of energy metabolism and homeostasis, immunity and inflammation. Alterations in lipid metabolism and/or in adipokine production associated to the excess of adipose tissue that defines obesity or to adipose tissue deficiency, as occurs in lipodystrophy, are linked to insulin resistance, which represents a major risk factor for the development of type II diabetes, dyslipidemia, hypertension and cardiovascular diseases. In order to identify potential biomarkers of adipose tissue (dys)function, we employed proteomic techniques for the molecular analysis of adipose tissue components (adipocytes and stromal-vascular fraction), adipose tissue depots (subcutaneous (SAT) vs visceral (VAT) adipose tissue), and adipose tissue-related pathologies (insulin resistance associated to obesity). These studies revealed that, in lean individuals, the stromal–vascular faction contributes to major protein differences between VAT and SAT; in particular, we identified several differentially expressed proteins (ezrin, lamin A/C) that could contribute to the distinct association of VAT and SAT to specific adipose tissue-related pathologies (metabolic syndrome and lipodystrophy respectively). Comparative analysis of paired samples of VAT and SAT from lean and obese individuals also unveiled that obesity evokes depot-specific changes in the proteomic profile of adipose tissue. Furthermore, our data support the view that development of insulin resistance linked to obesity involves changes in adipose tissue proteins related to the cytoskeleton, glucose metabolism, cellular iron metabolism and protein folding and stress response. Collectively, our proteomic studies support the relevance of specific biological processes for the maintenance of normal functioning of human adipose tissue and their dysregulation in relation to the development of insulin resistance.

## P1267

### Is fat mass index superior to total fat mass percentage in predicting the metabolic syndrome?

Y. Bozkus, A. Kut, U. Mousa, C. Demir, C. Anil & N. Tütüncü
Baskent University, Ankara, Turkey.

Aim
We aimed to compare the cut off values, defined to express the excess total body fat (TBF) percentange and increased fat mass index (FMI) as predictors of metabolic syndrome (MS).
Subjects and methods
A total of 162 obese (body mass index (BMI) $>$ 30 kg/m$^2$) subjects' TBF were measured by 'Tanita TBF 300 Body Composition Analyzer'. Patients were divided into two groups called normal obese (NO) and fatty obese (FO) according to the cut off values determined in De Lorenzo, NHANES and Switzerland models and cut off value determined for FMI (Table). Then we compared MS (National Cholesterol Education Program critera is used) prevalences in NO and FO groups.
Results
The number of FO patients according to the DeLorenzo, NHANES, Switzerland cut off values and FMI cut off values were respectively 142 (88%), 112 (69%), 119 (73%) and 88 (54%; Table). The prevalences of MS among FO patients were respectively 34% (*P*: 0.916), 35% (*P*: 0.858), 34.5% (*P*: 0.853) and 42% (*P*: 0.02; Table). According to these results, while cut off values for FMI were significantly associated with MS, the others were not. The percentage of MS among FO patients was highest (42%) and the percentage of the patients without MS among NO patients was highest (76%) according to the FMI cut off values.
Conclusion
Different cut of values used to define excess body fat according to gender and age by DeLorenzo, NHANES and Switzerland models seems not to predict the MS; but cut off values for FMI, significantly predicts MS. Contribution of other anthropometric measures such as sex, age, race and height to TBF, may increase its predictive value for MS development
Metabolic syndrome, total body fat, fat mass index

## P1268

**Relationships between hypovitaminosis D, low-grade chronic inflammation, and leptin-to-adiponectin ratio in PCOS: is this a matter of fatness?**

G. Pizza[1], C. Di Somma[2], F. Orio[3], R. Valentino[4], V. Nedi[1], V. Brancato[1], G. Lombardi[1], A. Colao[1] & S. Savastano[1]
[1]University Federico II of Naples, Naples, Italy; [2]IRCCS SDN Foundation, Naples, Italy; [3]Endocrinology, University Parthenope of Naples, Naples, Italy; [4]IEOS-CNR, Naples, Italy.

Introduction
Several cross-sectional studies evidence the association between hypovitaminosis D, obesity, insulin resistance (IR), and polycystic ovary syndrome (PCOS) cohorts, although the role of obesity *per se* is still debatable. Increased leptin-to-adiponectin ratio (L/A) and low-grade chronic inflammation markers, both due to accumulation of dysfunctional adipocytes, have been recently reported in PCOS. Aim of our study was to investigate the relative roles of obesity, low-grade chronic inflammation and dysfunctional adiposity in hypovitaminosis D in PCOS according to BMI.
Methods
Eighty-eight women (age $24.3 \pm 4.3$ years; BMI range 18–47 kg/m$^2$; Ferriman–Gallwey score $\geq 8$) were consecutively recruited in the study from those referred for PCOS to our unit (42 lean and 46 overweight-obese (O/O) subjects). Testosterone, sex hormone-binding globulin, fasting plasma glucose and insulin, 25-hydroxy vitamin D (25OHD), C-reactive protein (CRP), interleukin (IL) 6, leptin and adiponectin were measured using commercially available kits. homeostasis model assessment of IR (HOMA-IR), free androgen index (FAI), and L/A were calculated.
Results
In O/O PCOS women FAI, HOMA-IR, 25OHD, CRP, IL6, L/A, and waist were significantly higher compared to lean PCOS ($P<0.001$). In subgroup analyses, the strengths of the associations between all the study variables were similar between lean and O/O PCOS, out of the association between 25OHD and CPR and IL6 that retained an inverse statistical significance in only O/O PCOS women.
Conclusion
While lower 25OHD and higher L/A were associated in both lean and O/O PCOS, lower 25OHD with higher CRP and IL6 were evidenced only in O/O PCOS. In other terms, in the complex relationships between hypovitaminosis D and PCOS, L/A might represent an early marker of the negative effect of adiposity on circulating 25OHD levels, while an increasing amount of dysfunctional adipocytes were likely required to evidence the association of low 25OHD levels with different markers of low-grade chronic inflammation, such as CRP and IL6.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding

## P1269

**Incidence of glucose and lipid metabolism disorders in overweight children and adolescents in Croatia**

J. Ille, V. Furic-Cunko, N. Cigrovski, A. Bogdanic, N. Rojnic Putarek, A. Radica & M. Dumic
University Hospital Center Zagreb, Zagreb, Croatia.

Prevalence of obesity in children and adolescents is reaching epidemic proportions. It is followed by the increase in incidence of type 2 diabetes (DM2) and dyslipidemia, and both disorders are risk factors of cardiovascular complications.
Aim
The aim was to define the prevalence of impaired glucose tolerance (IGT), DM2, hypercholesterolemia and hypertriglyceridemia in overweight children and adolescents in Croatia.
Subjects and methods
In 498 overweight children (266 girls, 232 boys) aged 1–19 years, with body mass index (BMI) >90%, a standard oral glucose tolerance test was performed (referent values according to American Diabetes Association) and cholesterol and triglyceride levels were determined (referent values according to Lipid Research Clinic Program Percentile Levels Defining, levels >95th percentile were considered increased).
Results
IGT was found in 52 children (10.4%) with no statistically significant difference according to age, sex or BMI. DM2 was found in two children (0.4%). Increased cholesterol levels were found in 86 children (17.3%), significantly more often in boys than in girls (21.6%: 13.5%; $P<0.001$). Increased triglyceride levels were found in 150 children (30.1%), also significantly more frequently in boys (35.8%: 25.2%; $P<0.01$). Increase of both cholesterol and triglyceride levels were found in 90 children (9.8%) with significantly higher BMI ($P<0.05$) and no difference according to age and sex.
Conclusion
Incidence of IGT in overweight children in our population (10.4%) is smaller than in USA (20–25%), and it resembles the incidence in Western Europe (6.3–11%). Incidence of DM2 was fortunately very small (0.4%).
Data of increased cholesterol and triglyceride levels in overweight children (17.3 and 30.1%) are close to those in literature.
Obesity prevention programs and interventional diet regimens in already overweight children are essential for reducing the risk of DM2 and cardiovascular complications.

**Factors determining weight gain in adults and relation with glucose tolerance**

F. Soriguer[1,2], G. Rojo-Martinez[1,2], S. Valdes[1,2], M. Tapias[1], P. Botas[3], E. Delgado[4], I. Esteva[1,2], M. Ruiz de Adana[1,2], F. Diaz-Cadorniga[4] & E. Garcia-Fuentes[1]
[1]Hospital Universitario Carlos Haya, Malaga, Spain; [2]CIBER de Diabetes y Enfermedades Metabólicas asociadas (CIBERDEM), Malaga, Spain; [3]Hospital San Agustín, Aviles, Spain; [4]Hospital Central de Asturias, Oviedo, Spain.

Objective
Modifications in lifestyle and diet are major contributors for the high prevalence of obesity. Very few longitudinal studies have evaluated the changes in body weight over time. Dynamic changes in body weight are also an important indicator of risk for type 2 diabetes. The aim of this study is to assess factors associated with weight gain in a population of Spanish adults.
Methods
The study was undertaken in two population-based cohorts of Spain. The first phase of the 'Asturias Study' (1998–1999) included 1034 persons, of whom 701 were reassessed in 2004–2005. The first phase of the 'Pizarra Study' (1996–1998) included 1226 persons, of whom 783 were re-evaluated in 2002–2004. Both studies involved a questionnaire on socio-demographic variables and an oral glucose tolerance test (OGTT).
Results
During the follow-up, 32.3% of the participants lost weight, 34.5% gained fewer than 4 kg and 33.2% gained more than 4 kg. Weight gain was greater in persons younger than 50 years and in those with an initial body mass index below 30. Weight gain was associated with a greater incidence of diabetes and glucose dysregulation, whereas weight loss in persons with these disorders was associated with a normal OGTT 6 years later. Persons who ate watching TV, those who took less exercise and those who reported a higher daily calorie intake experienced greater weight gain.
Conclusions
The longitudinal changes in weight decisively affect the development of diabetes and glucose dysregulation. The weight is a dynamic phenomenon affected by several social customs.

## P1271

**Obesity prevention: main findings of the EPODE European network project**

J. Borys, H. du Plessis, L. Walter & P. Harper
EPODE European Network, Paris, France

Introduction
EPODE is a coordinated, capacity-building methodology for communities to implement effective and sustainable strategies to prevent childhood obesity. Since 2008, the EPODE European Network (EEN), supported by the European Commission (DG SANCO), is aimed at facilitating the implementation of interventions using the EPODE methodology in other regions and countries.
Methodology
From 2008 to 2011, four committees – gathering universities and experts from different fields – have documented and conceptualized EPODE practices. This has been done through broad literature screening, 75 interviews and 20 committee meetings gathering more than 100 multidisciplinary contributions.
Results
Research results highlight: – The leading role of local authorities to initiate, lead, catalyse, federate and fund targeted and multisectoral actions, with the support of municipal services and local stakeholders;
– The importance of a tight collaboration between central and local coordination structures in order to develop relevant, concrete and tailored actions, addressing real life conditions;
– The interest of public-private partnerships to support actions on a long-term within the framework of a transparent governance and clear rights and obligations for all partners;
– The need of a multidisciplinary and significant evaluation (10–15% of total budget), adapted to the field and not only focusing on obesity prevalence but also on the process of actions.
Conclusion
Since the beginning of EEN, the use of EPODE methodology has been scaled up and is considered to be the largest global obesity prevention initiative at community level. EPODE is used in more than 8 countries, 500 cities and early evaluation suggests encouraging results.

**Dietary habits and body weight in an unselected population of Italian high-school students**

O. Prontera, P. Altieri, C. Cavazza, A. Repaci, G. Di Dalmazi, A. Gambineri & R. Pasquali
S.Orsola-Malpighi Hospital, University Alma Mater Studiorum of Bologna, Bologna, Italy.

Aim
This study was aimed to estimate the nutritional status and the prevalence of weight excess in a wide unselected population of adolescent and young students from Emilia Romagna.
Material and methods
Three thousand and ninety-one high school students, aged 15–19 years were consecutively contacted. One thousand eight hundred sixty out of 3091 (60.2%) accepted to participate in an epidemiologic study, whose procedures included anthropometric measurements and a nutritional assessment, through a personal interview with a trained dietitian that employed the food-frequency questionnaire and multiple 24-h dietary recall. The percentage of males and females in the study population was 38.6 and 61.4% respectively.
Results
We found a prevalence of overweight or obesity (based on BMI values, standardized for age and sex) of 31.6% in the whole sample, with a higher rate in males than in females (38.7 vs 27.3% respectively). Underweight subjects were 5.9% of the whole sample, and 2.8 and 7.7%, of males and of females, respectively. Mean energy intake was 2409 and 1910 kcal/day for males and females respectively. The analysis of macronutrients showed an unbalanced diet, with excess of percent energy from lipids ($35.5 \pm 5.2\%$) and a deficit in percent energy from carbohydrates ($49.5 \pm 5.6\%$), when compared to the recommended daily intake (RDA). That was particularly evident for females, whose percent energy from lipids was slightly but significantly higher than in males (35.8 vs 35.1, respectively; $P = 0.006$). Moreover, among lipid and carbohydrate fraction a larger portion than recommended was represented by saturated fats ($31.6 \pm 5.2\%$) and oligosaccharides ($31.3 \pm 8.9\%$) respectively. As concerns micronutrients, we found a deficit of fibres (significantly more severe in males than in females) and of vitamin D and calcium whose consumption was about a half of the recommended quantity. In conclusion, this study shows that the quality of diet in the young Italian population has reached a critical state. In addition, it shows that the prevalence of overweight or obesity is higher than expected, similarly to published international trends.

## P1273

**Relationship between obesity and Leptin (G-2548A) and Leptin receptor (668A > G (Q223R)) gene polymorphisms in Turkish population**

A. Rustemoglu, S. Sahin, T. Tasliyurt, F. Kutluturk & H. Guven
Faculty of Medicine, Gaziosmanpasa University, Tokat, Turkey.

Obesity is due to the combined effects of genetic, environmental, lifestyle and the interactions of these factors. Leptin (LEP) is an adipocyte-derived hormone that acts to reduce food intake and increase energy expenditure by binding and activating its specific receptor in the hypothalamus. In humans, LEP and LEPR have been mapped to 7q31.3 and lp31, respectively. The LEP and LEPR genes have been investigated in the search for gene variants potentially related to the pathophysiology of obesity in diabetes and its associated complication. In this study, we were investigated LEP gene G-2548A and LEPR gene 668A > G (Q223R) polymorphisms and its association with obesity in Tokat district particular subjects. The study group comprised to 112 obese patients (81 female, 31 male, mean BMI 35.41 kg/m$^2$) ages from 18 to 82 (mean age; $50 \pm 14.25$ year), and 105 non-obese healthy subjects (62 female, 43 male, mean age $34.25 \pm 15.44$ year, and mean BMI 21.57 kg/m$^2$) were used the control group in this study. The obtained results showed that, there is no significant differences for allele and genotype distributions of LEP gene G-2548A and LEPR gene 668A > G (Q223R) polymorphisms between obese and control subjects ($P > 0.05$). In the comparison between BMI > 35 and BMI < 35 obese groups we were obtained significantly difference for GG genotype for LEP gene G-2548A polymorphisms ($P = 0.034$). This results shows that GG genotype for LEP gene G-25248A polymorphism maybe predisposed to morbid obese. There was a significant difference in LEP and LEPR double GG-GG (RR) genotype for frequency when comparing obese (BMI > 35) and control subjects ($P = 0.015$). According to these results, we thinking that, LEP gene G-2548A and LEPR gene 668A > G (Q223R) polymorphisms may be effective on the obesity in Turkish population.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1274

**Atherosclerosis risk factors before and 90 days after bariatric surgery**

S. Polovina, M. Sumarac-Dumanovic, D. Bajec, D. Radenkovic, D. Stamenkovic-Pejkovic, J. Gligorijevic, D. Micic & D. Micic
Clinical Center of Serbia, Belgrade, Serbia.

Introduction
Morbid obesity is associated with systemic inflammation, possible impaired glucose toleration and changes in serum lipids. Association of these parameters is risk for atherosclerosis and cardiovascular diseases.
Methods
We have analyzed body weight, BMI, lipid profile, glucose, HbA1c and C reactive protein in 36 obese subjects, 8 males and 28 females, 37.9 ($\pm 18.6$)

years of age, before and three monts after bariatric surgery. There was performed laparoscopic restrictive-malapsorptive bariatric technique (Roux en Y gastric by pass). All of them were on 1200–1500 kcal balanced, medical nutritive therapy after surgery. Before surgery mean body weight was 130.4±44 kg, BMI 43 ±17.1 kg/m$^2$, blood glucose 5.13±3.8 mmol/l, HbA1c 5.78%, total s-cholesterol 5.23 mmol/, HDL-C 1.15 mmol/l, LDL-C 3.04 mmol/l, triglycerids 2.11 mmol/l, CRP 13.3 mg/l.

Results

Three monts after bariatric surgery body weight loss was 23±9 kg, 17.6% ($P<0.05$), BMI decreased 5.9 kg/m$^2$, 18% ($P<0.05$), glucose lowering was 1.5±1.4 mmol/l ($P<0.05$), HbA1c was lower 0.58, 12.3% ($P<0.05$). Changes in serum lipids was: s-cholesterol decreased 1.97 mmol/l, 37.6% ($P<0.01$), LDL-C 0.91 mmol/l, 29.1% ($P<0.05$), triglycerids 0.97 mmol/l, 42% ($P<0.01$). There was no significant changes in HDL cholesterol level and after 90 days HDL-C was 0.11 mmol/l lower, 9% ($P>0.05$). Decreasing in C reactive protein was 11 mmol/l, and that was most significant change of 82% ($P<0.001$).

Conclusion

Weight reduction due to bariatric restrictive-malabsorptive procedures and following medical nutritive therapy, improves lipid parameters, glycated hemoglobin, lowering systemic inflammation and risk for atherosclerosis and cardiovascular diseases in morbid obesity subjects.

## P1275

### Obesity prevalence in west black sea region of turkey, the Melen Study

Y. Aydin, G. Celbek, A. Kutlucan, E. Önder, A. Gungor, R. Alemdar, H. Coskun & H. Ozhan

Faculty of Medicine, Duzce University, Duzce, Turkey.

Aim

Obesity prevalence increase fastly and become important health problem all around the world. Aim of our study to determine obesity and abdominal obesity prevalence in west black sea region and to display the prevalence of chronic diseases especially diabetes mellitus (DM) in obese population.

Material and method

We evaluate 2222 (1418 female, 804 male, mean age 50) participant in Yigilca region. We took medical history and physical examination of all participant. Body mass indexes (BMI) was described as follows: BMI <18.5 as low body weight; 18.5–24.9 as normal body weight, 25–29.9 as overweight, ≥30 as obese and ≥40 as morbidly obese. According to waist measurement, >94 cm in male and > 90 cm in female accepted as abdominal obesity. Fasting blood glucose (FBG), electrolytes (Na, K), and lipid parameters were recorded.

Results

Mean BMI of participants were 30.6 in females and 27.5 in males. According to BMI obesity prevalence was 53.1% in female and 26.9% in male and mean obesity prevalence was 43.5% in generally. Abdominal obesity prevalence was 63% in female, 46% in male and generally was 57% in all participant. Obesity prevalences were increasing with age in both sex. Especially 3/4 (75%) of female and 1/3 (33%) of male were obese between 50 and 59 ages. Postmenopausal female had very high (64%) obesity prevalence but 43% in premenaposes. Coronary artery diseases, hypertension and especially DM were very high in obese population. While DM prevalence was 12.6% according to history, crude DM prevalence was increased 18.8% adding patients with FBG ≥126 mg/dl.

Conclusion

Obesity especially abdominal obesity and also DM prevalence were determined increased at exaggerated ratio in all section and ages of population especially postmenopausal females.

## P1276

### Association between metabolic syndrome and serum leptin level in postmenopausal women

S. Lee & Y. You

The Catholic University of Korea, Suwon, Republic of Korea.

Menopausal status is associated with weight gain, increased central fat mass, abnormal lipid metabolism, insulin resistance, and susceptibility to metabolic syndrome (MetS). Leptin is synthesized and secreted by adipocytes. Serum leptin levels are highly correlated with fat mass. We determined the association between MetS and serum leptin levels in 153 postmenopausal women. The difference in serum leptin level between MetS and non-MetS groups showed a statistical significance after adjusting for body mass index (BMI; 19.9±9.5 vs 12.1±5.9 ng/ml, $P=0.013$). The indicator of abdominal obesity, waist-to-hip ratio (WHR) and visceral fat area (VFA), had a positive correlation with serum leptin level in non-obese subjects after adjusting for BMI ($P=0.017$, $P<0.001$ respectively). Of the components of MetS, abdominal obesity and the number of MetS components had a positive correlation with serum leptin level ($P<0.05$, $P<0.001$ respectively). In conclusion, our study showed that serum leptin was associated with MetS independent of BMI. The increase in prevalence in MetS in postmenopausal women may increase the risk of CVD; therefore, the prevention and treatment of MetS are important. Further researches are needed to investigate the additional direct and indirect mechanisms of action of leptin associated with MetS and to clarify the role of leptin on MetS.

Mean leptin levels in non-MetS and MetS groups. After adjustment for BMI, the difference of leptin between two groups showed a statistical significance ($P=0.013$). $P$ value was calculated by ANCOVA.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Table 1** Coefficients of correlations between serum leptin and the components of MetS (A1), and partial coefficients of correlations after correction for BMI (A2).

| | A1 | A2 |
|---|---|---|
| WHR | 0.610* | 0.213* |
| Total triglyceride (mg/dl) | 0.270* | 0.163 |
| HDL cholesterol (mg/dl) | -0.254* | -0.111 |
| FPG (mg/dl) | 0.137 | 0.080 |

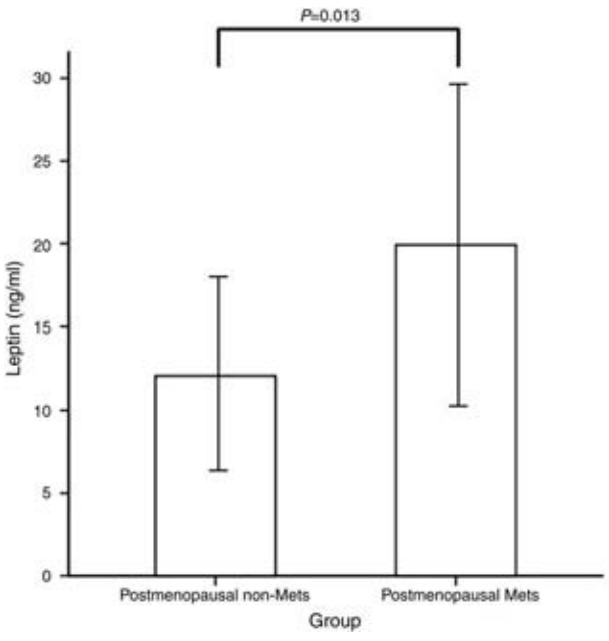
| DBP (mmHg) | 0.332* | 0.083 |

WHR, waist-to-hip ratio; HDL, high-density lipoprotein; FPG, fasting plasma glucose; SBP, systolic blood pressure; DBP, diastolic blood pressure. *$P<0.05$.



## P1277

### Effects of diet and physical activity-induced weight loss on insulin resistance in severely obese patients

M. Tancic Gajic[1,2], S. Vujovic[1,2], M. Ivovic[1,2], M. Vukcevic[3,2], L. Marina[1,2], Z. Arizanovic[1,2] & D. Micic[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade; [2]Faculty of Medicine, University of Belgrade, Serbia, Belgrade, Serbia; [3]Clinical Hospital Center Bezanijska Kosa, Belgrade, Serbia.

Introduction
Insulin resistance is quite common among obese individuals. Lifestyle interventions like diet interventions and regular physical activity are still important and safe first-line therapy.
The aim of this study was to assess the effects of diet and physical activity-induced weight loss on insulin resistance in extremely obese patients.
Methods
Forty-four patients (mean age 41.05±10.23 years) were consecutively recruited at Clinic of Endocrinology. They were on three weeks therapeutic fasting or semi-fasting diet in hospital conditions. At the beginning anthropometric measurements were performed. Subjects underwent an oral glucose tolerance test (OGTT) and insulin resistance/sensitivity was evaluated by the homeostasis model assessment (HOMA) and the oral glucose insulin sensitivity (OGIS). At home, patients underwent low calorie diet and dosed physical activity. After body weight reduction for at least 15%, all mentioned assessments were repeated. Statistics: Wilcoxon Signed Rank Test.
Results
None of the patients had significant adverse effects. The mean weight loss was 27 kg or 17% of the initial weight (149.48±25.52 kg vs 123.89±20.68 kg ($P<0.01$). This was followed by a decrease of body mass index (49.44±10.70 kg/m$^2$ vs 41.41±5.90 kg/m$^2$, $P<0.01$), waist circumference (140.90±17.17 vs 122.55±12.96 cm, $P<0.01$), glucose (4.71±0.80 vs 4.13±0.68 mmol/l, $P<0.01$), insulin (24.95±20.84 vs 16.80±10.06 mU/l, $P<0.05$), HOMA (5.56±4.55 vs 3.10±2.20, $P<0.05$) and OGIS (428.54±72.46 vs 490.92±80.56, $P<0.01$).
Conclusion
Based on aforementioned results, it can be concluded that 17% weight loss of initial weight in severely obese subjects, significantly increases insulin sensitivity and so substantially improve the pro-atherosclerotic milieu associated with obesity.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1278

### Evaluation of depressive symptoms and quality of life in obese patients

S. Angay, F. Haydardedeoglu, S. Kirim, E. Bozkirli & A. Canataroglu
Adana Numune Training and Research Hospital, Adana, Turkey.

Objective
Obesity is a chronic disorder and a serious public health problem. Obesity which affects quality of life cause several physical and psychological problems. The aim of the current study was to evaluate depressive symptoms and quality of life in a group of obese patients.
Material and methods
A total of 203 subjects, 103 obese patients with no chronic disorders except diabetes mellitus and hypertension and 100 healthy subjects with normal weight were included the study. As subgroups, patients were assessed as obesity group and obesity with diabetes mellitus and/or hypertension. Data was collected through a face to face questionnaire and by body weight and height measurements. Obesity was defined as body mass index of >30 kg/m$^2$. All subjects were evaluated with the Beck depression inventory (BDI) and short form-36 (SF-36).
Results
In total, 26.1% of individuals had combined obesity, diabetes mellitus and hypertension; 24.6% had only obesity. The mean age was 39.8±10.1 years. The mean BMI was 28.4±6 (min: 19.0, max: 39.0). There was a statistically significant difference between the study groups in terms of age, sex, education, marital status, number of pregnancy, smoking story and socioeconomic status ($P<0.05$ for each). There was not a statistically significant correlation between obesity and BDI ($P>0.05$). SF-36 scores of the healthy subjects with normal weight were higher than the scores of the obese patients and also SF-36 scores of the pure obese patients were higher than the scores of the obese patients with diabetes and hypertension ($P<0.05$ for each).
Conclusion
In this study, it was demonstrated that obesity and the accompanying chronic disorders like diabetes mellitus, hypertension poorly affected to the quality of life. Preventive measures are necessary before the complications afflict to the patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1279

### Plantar heel pain and relation with different diseases in obese Turkish patients

S. Topsakal, T. Erürker, F. Akin, G. Yaylali, E. Yerlikaya & B. Kaptanoglu
Pamukkale University, Denizli, Turkey.

Plantar heel pain (PHP) is one of the most common musculoskeletal disorders of the foot, yet its etiology is poorly understood. Although obesity is the most common cause of PHP, there is little information available about the prevalence and associated factors in obese patient with PHP. The aim was to determine prevalence of various co-morbidities in obese patients with PHP and assess associations. A hundred and fourthy nine obese and overweight participants (29 males, 120 females and mean age 44 years) were matched by with and without PHP (34 with PHP and 115 without PHP). The two groups were then compared on various fatness, hormone and blood parameters. Diabetes mellitus (DM), coronary heart disease (CHD), chronic obstructive lung disease (COLD), asthma, smoking, varice, hemorrhoid, lumbago, constipation, osteoporosis, hormone replacement therapy (HRT), goiter, reflux were compared between the groups. Statistical analysis demonstrated that significantly greater increase in PHP prevalence with COLD ($P<0.001$), hemorrhoid ($P<0.01$), lumbago ($P<0.001$), constipation ($P<0.01$), reflux ($P<0.05$) prevalence but decreased prevalence of PHP with asthma ($P<0.05$) and varice ($P<0.01$) in patients. No statistically significant difference was identified between the PHP (+) and (−) groups for DM, CHD, smoking, osteoporosis, HRT and goiter in this study. This study showed that PHP is closely associated with obesity and the most important factor is duration of the obesity. The combination of obesity with different co-morbidities like as COLD, hemorrhoid, lumbago, constipation and reflux may be risk factors for PHP, but combination obesity with asthma or varice do not appear to play a role in PHP in this study.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1280

### Relationship between visceral fat and neck circumference in patients with metabolic syndrome

H. Gulmez & A. Kut
Baskent University Faculty of Medicine, Ankara, Turkey.

The metabolic syndrome is a combination of multi-factorial risk factors, which affects more people because of increased incidence of obesity and diabetes. The

metabolic syndrome is one of the major health problems for the 21st century.
In this study, we compared neck circumferences measurements with some of the metabolic and anthropometric measurements in patients presenting with complains of weight, and aimed to show the correlation between visceral fat rates and neck measurements especially in patients with metabolic syndrome. 179 patients with complains of weight were included from 01.02.2009 to 01.02.2011, in Baskent University Umitkoy Polyclinic, diabetes and obesity clinic. This is a retrospective case–control study.
Research data were transferred to the statistic program SPSS version 16.0. The data control and analysis made with the same program. Pearson $\chi^2$ test used for the analysis of hypothesis, and $\chi^2$ test used for levels of significance of the data. Metabolic Sendrom was identified based on criteria of the National Cholesterol Education Program Adult Treatment Panel III (NCEP ATP III).
Of the 179 patients, 77% ($n=137$) were women, 23% ($n=42$) were men (W: M ratio=3.26). The mean age was $37\pm13.15$. 40 of our patients (22.3%) were diagnosed the metabolic syndrome. The mean neck circumference was $35.15\pm3.48$ cm in those without metabolic syndrome, and $38.40\pm4.13$ cm in those with metabolic syndrome ($P=0.000$). Statistically significant positive correlation is demonstrated between neck circumference measurements and visceral fat rates in patients with metabolic syndrome ($r=0.71$, $P=0.01$; Table).
Our study revealed that, neck circumference measurement is a valuable and indicating statistically significant positive correlation measurement such as the waist circumference measurement which is one of the NCEP ATP III criteria, in metabolic syndrome.

### Morbid child obesity-possible Rohhadnet syndrome: case report

A. Valea, A. Silaghi, A. Paul & I. Duncea
'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Introduction
ROHHADNET syndrome is a newly described condition characterized by rapid-onset obesity, pulmonary hypoventilation, hythalamic, autonomic dysregulation and, neural tumors. The severity of the clinical manifestations can rapidly lead to death by cardiorespiratory arrest.
Case report
We present the case of a 5.10 years old girl, who was admitted in the Endocrinology department for evaluation of a significant weight gain began 2.5 years ago.
Clinical examination releaved morbid obesity with facio-troncular distribution, height=123 cm (+2.5 SD Prader), weight =49.5 kg (+7.5 SD Prader), acrocyanosis, eyelid and, legs edema. The biochemical and hormonal profile releved increased natremia and transaminases, hypokalemia, increased urinary free cortizol with adequate suppression at Bricaire test, increased value for ACTH, TSH and prolactin. MRI exam at hypothalamic-pituitary and abdomen level showed a suggestive image for pituitary microadenoma.
Based on the clinical and laboratory investigations the possible diagnosis of ROHHADNET syndrome. The treatment followed correction of overweight and biochemical and hormonal changed parameters. At the age of 6 years and one month the patient died from renal failure and cardiopulmonary arrest.
Conclusions
Frequent associations of hypothalamicpituitary endocrine dysfunction creates real difficulty in diagnosis of ROHHADNET syndrome. This case illustrates the importance of complex endocrine evaluation and multidisciplinary approach to all forms of obesity with early onset and rapid evolution in order to establish the correct diagnosis and appropriate treatment.

### The correlation between metabolic syndrome and serum resistin, adiponectin, TNFα, leptin levels and abdominal adipose tissue thickness

M. Basak, H. Gozden, T. Ayeser & T. Saler
Umraniye Training and Researh Hospital, Istanbul, Turkey.

Advanced research to investigate possible methods of treatment in patients with metabolic syndrome is required. Adipocytokines are secreted by the adipose tissue. These polypeptides and their functions are also known last few years.
Adipocytokines are also anti-inflammatory and antiatherogenic, and they increase insulin sensitivity. As result of these skills, adipocytokines should be useful for diagnosis and treatment for metabolic syndrome. In this study we investigated the relationship between metabolic syndrome and adipocytokines levels.
In our study, 40 patients (22 males, 18 females) were divided into three groups according to the number of metabolic syndrome diagnostic criteria. Serum adiponectin, resistin, leptin, EGF, TNF-α levels and abdominal fat tissue thicknesses were compared.
At the end of this study there was no significant relationship between abdominal adipose tissue thickness, serum TNF-α, adiponectin, resistin levels and the number of diagnostic criteria for metabolic syndrome.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1283

### Study of insulin resistance in overweight and obese children by: M Hesham El Hefnawy and Ibrahim Emara

M. El Hefnawy
NIDE, Cairo, Egypt.

Obesity is a major risk factor for chronic non communicable diseases and plays a central role in the insulin resistance or metabolic syndrome, which includes hyperinsulinemia, hypertension, hyperlipidemia, type 2 diabetes mellitus, and an increased risk of adult onset obesity and atherosclerotic cardiovascular disease (1). Insulin resistance is a state in which a given concentration of insulin produces a less than expected biological effect. The metabolic syndrome is a clustering of cardiovascular risk factors that arises from insulin resistance accompanying abnormal adipose deposition and function.
Aim of the work
The aim of this study was to the insulin resistance in overweight and obese children as insulin resistance resistance could be used an early marker of type 2 diabetes.
Subjects and method
overweight and obese children aged from 6 to 18 years (mean=11.94+3.51 years), were selected from the outpatient pediatric endocrinology clinic in National Institute of Diabetes & Endocrinology. Another 20 lean children were selected as a control group.
Results
The results of this study showed that All subjects were investigated for body mass index (BMI), study of HOMA-IR, B.P. measurements, serum cholesterol and triglycerides for study group were 33.09+6.07, 2.96+1.46, 152.16 +28.84 mg/dl respectively. There was a positive significant correlations between BMI and HOMA-IR, HOMA-IR and Cholesterol and between HOMA-IR and BMI.
Concussions
It could be concluded that we have to measure HOMA-IR in any overweight and obese for early detection of insulin resistance. It could be recommended to try to control overweight and obesity as obesity is the golden gate to insulin resistance and diabetes.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Insulin secretion and sensitivity in GH deficient children at the end of rhGH therapy and after 1 year of follow-up: influences of d3GH receptor polymorphism on metabolic parameters**

V. Agarla, F. Prodam, S. Savastio, A. Petri, C. Balossini, R. Ricotti, G. Genoni, G. Aimaretti, G. Bona & S. Bellone
University of Piemonte Orientale, Novara, Italy.

Introduction
A rise in serum insulin levels during GH therapy is reported. Insulin resistance is a risk factor for type 2 diabetes, atherosclerosis, dyslipidemia, and hypertension. Few data describe insulin secretion and sensitivity after the end of GH therapy in children.
Methods
Aim of our study was to evaluate changes in insulin secretion and sensitivity in 24 children with isolated GHD at 3 times: i) during the last year of therapy (T0); ii) 6 months (T6) and iii) 12 months (T12) after stopped therapy. We measured glucose and insulin levels at fasting and after an oral glucose tolerance test (OGTT). Insulin resistance and sensitivity were estimated with classical indexes. Disposition index (DI) and insulinogenic index (INS) were also evaluated. The presence (Del) or absence (Ndel) of exon 3 deletion in the GH receptor was investigated (GHD: 4 Del, 16 Ndel). They were compared with 30 healthy puberty matched subjects.
Results
No subjects showed dysglycemia or hypertension. Fasting insulin, insulin and glucose levels at each point after OGTT were progressively lower at T6 and T12 compared to T0 ($P<0.001$). HOMA-IR and HOMA2 indexes were higher, and Matsuda and QUICKI indexes were lower at T0 respect to T6 and T12 ($P<0.01$). All the metabolic parameters were similar to controls at T12. INS and DI progressively decreased unexpectedly only in GHD Ndel arriving to values lower at T12 than NW ($P<0.05$). No alterations were found in GHD Del.
Conclusions
Insulin sensitivity decreased during rhGH therapy without the onset of dysglycemia and was associated with a compensatory insulin secretion and a reduction in DI only in GHD Ndel. Insulin and glucose secretion progressively restored after stopping treatment being similar to controls in the next 12 months. The presence or absence of exon 3 deletion, could affect some metabolic effects of rhGH in GHD children.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### P1285

**ACTH and cortisol are differently associated with metabolic syndrome components in a large cohort of Caucasian obese children and adolescents**

R. Ricotti, F. Prodam, S. Bellone, G. Walker, S. Parlamento, S. Savastio, G. Genoni, V. Agarla, G. Aimaretti & G. Bona
University of Piemonte Orientale A. Avogadro, Novara, Italy.

Introduction
Higher cortisol levels and, in particular, hyperactivity of the HPA axis might play a role in the development of MS at least in adults. Data on the pediatric age are scanty.
Aim of our study was to evaluate ACTH and cortisol association with MS, its components, phenotypic parameters, family history of metabolic derangements in pediatric obesity.
Methods
Cross-sectional study. 271 Caucasian overweight or obese children and adolescents (age range: 1.8–18.0 years) were evaluated for: family history, detailed clinical examinations, fasting morning ACTH, cortisol, glucose, insulin, lipid profile and OGTT test; HOMA, ISI and QUICKI were calculated. We divided patients according to pediatric NCEP criteria for MS.
Results
62.4% of the subjects had MS (73.9% had hypertension, 58.4% HDL-cholesterol $<$10th percentile, 23.1% triglycerides $>$90th percentile, and 8.2% IFG, IGT or type 2 diabetes). Children and adolescents with MS presented higher ACTH ($P<0.0001$) and cortisol levels ($P<0.03$) than those without MS. Increasing numbers of features of MS were associated with higher ACTH, but not cortisol, also when adjusted for confounding factors ($P<0.001$). Subjects with IFG, IGT or type 2 diabetes, or altered HDL-cholesterol or triglycerides respect to the MS cut-offs had higher ACTH, but not cortisol levels ($P<0.01$). Subjects with hypertension had increased levels of both ACTH and cortisol levels ($P<0.02$) if the cut-off was 95th percentile, and only cortisol ($P<0.05$) if the cut-off was reduced to 90th percentile as suggested by MS criteria. ACTH and cortisol levels were associated with insulin resistance. Subjects with a family history of hypertension ($P<0.003$) had higher cortisol levels.
Conclusions
In obese pediatric subjects, MS is associated with higher ACTH and cortisol levels. The features of MS could be differently modulated by ACTH and cortisol. Cortisol secretion seems mainly involved in hypertension and its family history.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### P1286

**Subclinical hypothyroidism in obese children and metabolic implications**

G. Genoni, F. Prodam, S. Parlamento, C. Balossini, E. Pozzi, R. Ricotti, V. Agarla, S. Bellone & G. Bona
University of Piemonte Orientale A. Avogadro, Novara, Italy.

**Abstract**
Introduction
Aim of this study was to assess the prevalence of subclinical hypothyroidism in a paediatric population of overweight and obese children and its association with metabolic parameters and with metabolic syndrome (MS).
Subjects and methods
Clinical and metabolic evaluations in 600 overweight and obese children and adolescents (310 females, 290 males, 260 prepubertal, 240 pubertal, mean age: $10.7\pm3.1$ years) were performed. MS was defined according to paediatric NCEP-ATPIII criteria. TSH levels were evaluated both in quartiles and according to a fixed cut-off level (pathological value $>3.500$ μUl/ml). The presence of autoimmune thyroiditis was assessed in those subjects with abnormal TSH values.
Results
75 subjects (12.5%) had abnormal TSH levels and 10 of them (13.3%) showed antithyroid antibodies. Age decreased ($P<0.0001$) and the number of prepubertal children increased ($P<0.006$) with the rise of TSH levels. non-HDL cholesterol ($P<0.03$), triglycerides ($P<0.0001$), PNFI index ($P<0.0001$), fasting glucose ($P<0.04$), HOMA-IR ($P<0.04$), glucose peak ($P<0.03$) and glucose area ($P<0.01$) during OGTT increased with the rise of TSH levels. No differences in the prevalence of MS were found among the TSH quartiles and in subjects with altered TSH levels. A negative correlation between age and TSH levels was found ($\beta=-0.122$; $P<0.003$). Furthermore a positive correlation between TSH and non-HDL cholesterol ($\beta=0.095$; $P<0.02$), triglycerides ($\beta=0.232$; $P<0.0001$), PNFI ($\beta=0.185$; $P<0.0001$) and fasting glucose ($\beta=0.107$; $P<0.01$) was shown independently of confounding factors.
Conclusions
Subclinical hypothyroidism and autoimmune thyroiditis are frequent in overweight and obese children. The association between TSH levels and metabolic parameters suggests a role of the hypothalamus–pituitary–thyroid axis in the regulation of lipids and glucose metabolism. Conversely the absence of an association with the metabolic syndrome suggests that this axis may modulate specific metabolic alterations.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1287

**Addressing issues of diabetes patients community: Role of NGO's in resource poor settings**

S. Pramod
Health Alert Organization of India (NGO), Dhule, India.

Adolescent diabetes social stigma in India. Such diabetics needs proper guidance/information/treatment-counselling outlets. This is burning issue in developing-nations like India. Hence we all need to unite and form a comprehensive diabetes care and counselling policy plan at ICE/ECE-meeting-2012. Treatment options must be suitable for developing-nations considering cost of Rx. Incorporating NGO's in such efforts is very effective.

Our project methodology

Our 15-year-old NGO started diabetes education-project in rural India from 2005. we started s education and surveillance project to analyze social and anthropological issues facing those affected by adolescent diabetes. Total 62 adolescents subjects enrolled by Feedback questionnaires to get their feedback on special needs, perceptions, social attitude on diagnosis of diabetes. Factors like community-inhibition, social-ostracism, economic-difficulties, marital discord, non-availability of treatment-guidance centres, lack of trained-staff analysed and draft policy is recommended to Govt-agencies.

Lessons learned

diabetes management must include care of nursing and psycho-social needs. Here role of NGO's is very effective in terms of cost-management, better impact and better-compliance of diabetics. Community mass intervention projects has proven useful in rural communities of resource poor-nations. ICE/ECE-Florence-congress-participants can collaborate with NGO-activists to address this issue. Uniform public health policy needed to implement and expand newer strategies to include broader range of diabetes care-issues.

Recommendations

Promoting dialogue between Government-health-services and NGO's accelerates diabetes education/awareness programs. NGO participation improves cost-efficacy of such initiatives in economically poor populations. This would reduce difficulties faced by young diabetics from Asian countries. It is essential that WHO, ICE/ECE form common guideline manual on this issue affecting developing-countries. We graphically present our NGO's project on diabetes patients education project in four phases to ICE/ECE-2012-congress-participants.

## P1288

**Influence of cranial and craniospinal irradiation in childhood on reproductive system of women and men cancer survivals**

E. Gubernatorova[1], M. Pavlova[1], T. Kaznacheeva[2], N. Mazerkina[3], O. Zheludkova[4] & Y. Sich[1]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; [2]Moscow State Medical Dental University, Moscow, Russian Federation; [3]Institute of Neurosurgery. N. Burdenko, Moscow, Russian Federation; [4]Russian Children's Clinical Hospital, Moscow, Russian Federation.

Introduction

Childhood cancer incidence increases all over the world, but it are optimistic that more than seventy percent of children with cancer survive due to radiation and chemotherapy. However cancer treatment may impair reproductive function. The aim of this study is to investigate level of pituitary hormones, testis/ovarian volume in women and men undergo cranial and craniospinal irradiation in childhood.

Methods

Participators were examined with ultrasound, hormonal analyze. 22 women and 12 men were included in this study.

Group 1 included 11 women and 11 men, after treatment for brain tumors in childhood. The median age of participators was 19.5 (16–25), the median age at original diagnosis was 11.4 (5–15). All patient received craniospinal irradiation 55 Gy and chemotherapy M-2000.

Group 2 included 11 women and 2 men after treatment for lymphoblastic leukemia. The median age of participators was 21.5 (16–30), age at original diagnosis – 7.7 (2.5–13). All patients received cranial irradiation 18 Gy, chemotherapy BFM-90.

Results

women after cranial irradiation had amenorrhea with depletion of follicles, high gonadotropin levels. Survivors after craniospinal irradiation had smaller ovarian volume per ovary than after cranial irradiation (average, 3,3 vs. 8.7 $cm^3$; $P < 0.001$), and higher LH (13.17 vs 4.5)and FSH (31.6 vs 5.65).

In men after craniospinal irradiation was detected lower testicular volume (7.03 vs 11.25), FSH level (13.4 vs 7.62). There were no significant differences in LH, testosterone, prolactin levels.

Conclusion

Women after craniospinal irradiation more likely had primary hypogonadism. Survivors with preserved menstrual cycles had sonographic and endocrine changes suggesting impairment of ovarian reserve. Men after cranspinal had lower testicular volume and FSH level with normal testosterone, LH that suggested impaired spermatogenesis. None of participates had low gonado-tropins. Thus craniospinal irradiation has a great impact on reproductive function in childhood cancer survivals.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Etiology of delay of puberty in adolescents with different neuroendocrine diseases**

Y. Urmanova & U. Mavlonov
Tashkent Pediatric Medical Institute, Bogishamol Street 223, Tashkent 100140, Uzbekistan.

Aim

The work was initiated to compared extent of physical and sexual development retardation in adolescents with various neuroendocrine abnormalities.

Materials and methods

We examined 63 adolescents, 41 boys (59.4%) and 22 girls (34.9%) among them with various endocrine abnormalities. Mean age of boys and girls was 11.3 and 12 years, respectively. All patients underwent general clinical examination. Levels of STH, LH, FSH, prolactin, TSH, ACTH, cortisol were measured, biochemical and roentgenologic investigations, such as, CT, MRI of Turkish saddle, hand X-ray, clinical ultrasound of the thyroid and genitals as well as anthropometric measurements were performed. The patients' endocrine status was assessed with Tanner's score to determine puberty stage.

Results

By etiology of the abnormalities the patients were divided into four groups. The 1st group included 18 patients (28.6%) with the Turkish saddle neoplasms, 20 patients (31.7%) with empty Turkish saddle syndrome comprised the 2nd group; diabetes insipidus was diagnosed in 15 patients (23.8%) of the 3rd group, juvenile dyspiuitatarism being registered in 9 patients (14.3%) of the 4th group. Of 63 patients physical and sexual development retardation was observed in 26 (41.3%), growth retardation in 23 (36.5%), puberty arrest in 8 (12.7%), cryptorchidism and micropenis being found in two patients (3.2%) and 1 (1.6%) patient, respectively. As a whole, incidence of puberty retardation in 63 examinees exceeded isolated growth retardation by two times (44 vs 23). More than in 41.3% of cases growth retardation paralleled growth retardation suggesting panhypopituitarism in these patients. The isolated puberty arrest occurred less frequently, that is, in one patient (5.5%) of the 1st group, in two patients (10%) of the 2nd group, in three patients (20%) of the 3rd group and in one patient (11%) of the 4th.

Conclusions

i) Physical and sexual development retardation can be considered as a marker for high severity of neuroendocrine pathology. ii) Physical and sexual development retardation was observed in patients with the empty Turkish saddle syndrome (70%) and in those with the Turkish saddle neoplasms (60%).

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Noonan syndrome: short stature and pubertal delay**

M. Alves[1], J. Barreiro[2], C. Heredia[2], P. Cabanas[2], L. Castro-Feijóo[2], M. Bastos[1], M. Carvalheiro[1] & M. Pombo[2]
[1]Hospitais da Universidade de Coimbra, EPE, Coimbra, Portugal; [2]Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela, Spain.

Background
Noonan syndrome (NS) is a relatively common disease, clinically and genetically heterogeneous. It is characterized by facial dysmorphia, growth retardation, congenital heart disease, lymphatic dysplasia, among others. The diagnosis is clinical, according to van der Burgt criteria. In 61% of cases genetic mutations in the signaling pathway of RAS-MAPK are identified.
Clinical case
BVM, male, NS suspected. At 3 years old sent to Pediatric Endocrinology for macrogenitossomy. Personal history: polyhydramnios at 22 weeks of pregnancy, amniocentesis: karyotype 46XY; term birth, weight 4090 g (1.36 SDS), length 50 cm (0.09 SDS), Apgar score 9/10 and congenital heart disease (hypertrophic cardiomyopathy and pulmonary stenosis). Heart disease corrected at 2 years by pulmonary valvuloplasty. Family history: irrelevant. Physical examination (PE): weight 17.6 kg (0.62 SDS), height 103.2 cm (1.05 SDS), growth velocity (GV) 8.2 cm/year (0.1 SDS); dolichocephaly, ptosis, hypertelorism, antimongoloidal palpebral fissures, low-set ears and hair, extended filtrum, high-arched palate, short and broad neck, pterygium colli, shield chest and cubitus valgus, edema of lower limbs, scrotum and penis, without Godet's sign, Tanner: P1G1. Evaluation: target height 1.71 cm ($-0.82$ SDS). Bone age: 3 years. Laboratory: TSH 1.44 mIU/ml (RR: 0.35–5.50), IGF1 90 ng/ml (RR: 50–237), IGFBP3 4 μg/ml (RR: 0.2–6.6). Diagnosis of lymphedema. Referred to physical rehabilitation department for medical lymphatic drainage. At 15 years he returned to Endocrinology for delayed puberty. Presented progressive growth delay since 8 years, several hospitalizations for cellulitis and lymphangitis of lower limbs and genitals, and chylothorax. PE: weight 47.3 kg ($-1.45$ SDS), height 157.2 cm ($-1.94$ SDS), GV 3.5 cm/year ($-2.10$ SDS), lymphedema of lower limbs, scrotum and penis, Tanner P1G1. Bone age: 13 years. Laboratory: IGF1 70 ng/ml (RR: 143–996), IGFBP3 3.2 μg/ml (RR: 1.3–10), testosterone 0.1 ng/ml (RR: 3.5–13.5); LHRH test: FSH peak 11.3 IU/l, LH peak 7.1 IU/l. Testosterone therapy was initiated. Molecular study of PTPN11, SOS1, RAF1 and KRAS1 genes was negative; awaits further genetic study.
Conclusions
The case described points to clinical suspicion of Noonan syndrome and the need for regular endocrine evaluation. The GH–IGF1 and gonadal axis are the most affected. Early detection and treatment of endocrine abnormalities contributes to life quality improvement of these patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1291

**The neuroendocrine complications of teenagers with diabetes insipidus of central genesis**

SI. Ismailov, Yu M. Urmanova & U Kh Mavlonov
Tashkent Medical Pediatric Institute, Bukhara State Medical Institute, 223, Bogishamol Street, Tashkent 100125, Republic of Uzbekistan.

Aim
to study features of growth and development in teenagers with Diabetes Insipidus of central genesis.
Material and methods
During 2009–2010 years we examined 37 teenagers with Diabetes Insipidus of central genesis. 19 boys (51.3%) and 18 girls (48.6%) among them. Mean age of boys and girls was 13.5 years.
All patients underwent general clinical examination. Levels of STH, LH, FSH, prolactin, TSH, free thyroxin, cortisol, etc. were measured, biochemical (blood and urine analysis, Zimnitskiy test of urine), and roentgenologic investigations, such as, CT, MRI of Turkish saddle, hand X-ray, clinical ultrasound of the thyroid and genitals as well as anthropometric measurements on the base of international growth-weight chart of Tanner-Whitehouse with evaluation of centile, growth insufficiency, SDS of growth and weight, growth velocity were performed. The patients' endocrine status was assessed with Tanner's score to determine puberty stage.
We have comparison of our data with healthy teenagers (10 boys and 10 girls).
Results
We founded, that average centile was 50. Besides that, our patients have very big growth and weight insufficiency. The average growth insufficiency in boys was on our data $8.3 \pm 0.7$ sm and $10.3 \pm 0.5$ sm in girls. The weight insufficiency in boys was $7.3 \pm 0.5$ kg and in girls $5.6 \pm 0.4$ kg. We founded that growth SDS $< -2$, and weight SDS $<$ -2 in boys and girls.
The evaluation of sexual development by Tanner's stages showed, that in 18 cases from 37 (48.6%) was founded delay of puberty, in this cases in 10 boys (55.5%) and in 8 (44.4%) girls. Three boys have criptorhism.
All of our patients have delay of skeletal development and bone age/passport age was 0.7 in boys and girls. The average bone age was small on 2.7 years from chronological (passport) age.
The hormonal investigation showed, that more of our patients have insufficiency of pituitary hormones: STH – in 32 patients (86.4%), LH – in 28 (75.6%), FSH – in 28 (75.6%), TSH – in 15 (40.5%) with functional hyperrolactinemiya.
Conclusions
The stage of delay of puberty and growth in teenagers with Diabetes Insipidus directly correlated with condition of compensation of electrolytes, which submitted insufficiency of our pathogenetic therapy and decompensation of patient.
The evaluation of sexual development by Tanner's stages showed, that in 18 cases from 37 (48.6%) was founded delay of puberty, in this cases in 10 boys (55.5%) and in 8 (44.4%) girls.
All of our patients have delay of skeletal development (100%).

## P1292

**Systemic administration of C-type natriuretic peptide rescues impaired endochondral bone growth in mice model of achondroplasia**

A. Yasoda, T. Fujii, E. Kondo, K. Nakao, N. Koyama, Y. Yamashita, Y. Ueda, N. Kanamoto, M. Sone, M. Miura, H. Arai & K. Nakao
Kyoto University Graduate School of Medicine, Kyoto, Japan.

Introduction
Recent studies have elucidated that C-type natriuretic peptide (CNP), a member of natriuretic peptide family, is a potent stimulator of endochondral bone growth; CNP and its membranous guanylyl cyclase receptor, GC-B are expressed in growth plate, and mice with targeted overexpression of CNP in growth plate exhibit prominent skeletal overgrowth, whereas CNP or GC-B knockout mice develop severely short stature phenotype owing to their impaired endochondral bone growth. We are trying to translate the strong stimulatory effect of CNP on bone growth into a medical treatment for patients with skeletal dysplasia, a group of genetic disorders characterized by disturbances in skeletal development. In the present study, we performed systemic administration of CNP to mice model of achondroplasia, the most common form of skeletal dysplasia.
Methods and results
We performed continuous i.v. administration of CNP to 3-week-old achondroplastic model mice for 4 weeks, and investigated the effects on their impaired skeletal growth. CNP stimulated the longitudinal growth of achondroplastic model mice dose-dependently, and the naso-anal length of achondroplastic mice treated with CNP at the dose of 1 μg/kg per min was almost comparable to that of wild-type mice treated with vehicle. CNP administration at the dose of 0.1 μg/kg per min considerably recovered the impaired growth of long bones in achondroplastic mice, and at the dose of 1 μg/kg per min, some bones grew rather longer than those in wild-type mice treated with vehicle. Histological examination revealed that narrowed growth plate observed in achondroplastic mice was recovered by administration of 1 μg/kg per min CNP to the extent of wild-type growth plate treated with vehicle.
Conclusion
We demonstrated that systemic administration of CNP is effective for the recovery of impaired skeletal growth in mice model of achondroplasia. Systemic administration of CNP is a potential therapeutic strategy for the treatment of skeletal dysplasia including achondroplasia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Exclusion of aldosterone signaling pathway genes as candidates for renal pseudohypoaldosteronism type 1 in 32 families**

F. Fernandes-Rosa[1,2], I. Giscos-Douriez[1,2], E. Hubert[1,2], H. Delacour[1,2], X. Jeunemaitre[1,2,3] & M. Zennaro[1,2,3]
[1]INSERM, U970, Paris Cardiovascular Research Center-PARCC, Paris, France; [2]Faculté de Médecine, University Paris Descartes, Paris, France; [3]Hôpital Européen Georges Pompidou, Assistance Publique-Hôpitaux de Paris, Paris, France.

Background
Pseudohypoaldosteronism type 1 (PHA1) is a primary form of mineralocorticoid resistance presenting in the newborn with renal salt wasting, failure to thrive and dehydration. Inactivating mutations of the *NR3C2* gene, coding for the mineralocorticoid receptor (MR) are responsible for the vast majority of autosomal dominant and sporadic cases of renal PHA1. The underlying pathogenic mechanism involves both haploinsufficiency as well as a dominant negative mechanism. However, ~30% of kindreds with clinical signs of renal PHA1 do not present NR3C2 gene mutations or deletions.
Objective
To assess whether mutations in aldosterone signalling genes could be responsible for renal PHA1.
Design and methods
Five genes involved in the aldosterone-MR epithelial sodium reabsorption pathway (*SGK-1*, *NDRG2*, *GILZ*, *NEDD4-2*, *GPR48*) were sequenced in 32 patients with clinical signs and symptoms of renal PHA1 and without NR3C2 mutations.
Results
Different already described intronic and exonic single nucleotide polymorphisms (SNP) were found in the five genes sequenced. The frequency of these SNPs was similar to that previously observed in population studies. Three intronic variations were found in the sequence of *NEDD4-2* gene. No disease-causing gene mutation or new SNP were detected in the studied PHA1 patient group.
Conclusions
We present further evidence for locus heterogeneity in PHA1. Our data do not support that *SGK-1*, *NDRG2*, *NEDD4-2*, *GILZ* or *GPR48* gene variations are disease-causing factors in genetically unexplained renal PHA1. Further studies of genes encoding intracellular molecules involved in transduction of the signal from the mineralocorticoid receptor to ENaC are warranted.

**Serum adiponectin levels in adolescents and young adults with GH deficiency**

J. Oswiecimska, K. Ziora, M. Stojewska, E. Swietochowska & Z. Ostrowska
Silesian University of Medicine in Katowice, Zabrze, Poland.

Introduction
Effect of GH deficiency on the endocrine function of adipose tissue (AT) is poorly understood. Data on serum adiponectin (ADIPO) concentrations in patients with GH deficiency (GHD) are scarse.
The aim of the study was the assessment of ADIPO serum concentrations in adolescents and young adults with GHD and evaluation of their correlations with the degree of GH/IGF1 axis function impairment as well as anthropometric and body composition parameters.
Subjects and methods
The study was performed in a group of total 122 subjects aged 16-25 years. Based on current peak serum GH concentrations in insulin tolerance test (ITT) patients were qualified for the following groups: i) severe GH deficiency – GHD (peak GH $<5.0$ ng/ml, $n=26$), ii) partial GH deficiency – PGHD (peak GH 5.0–110.0 ng/ml, $n=22$), iii) normal GH secretion – NGH (peak GH $>10.0$ ng/ml, $n=28$) and iv) healthy subjects – H ($n=46$). Following examinations were performed: i) anthropometric measurements, ii) analysis of body composition using BIA, iii) serum concentrations of ADIPO (Millipore, USA) and IGF1. Based on the analysis of body composition the total ADIPO content in the extracellular fluids per the unit of body fat mass (CADIPO/FM) was calculated.
Results
Mean serum concentrations of ADIPO did not differ significantly among the examined groups, however CADIPO/FM values were significantly lower ($P<0.05$) in GHD (8.6 mg/kg) compared with PGHD (30.1 mg/kg), NGH (27.9 mg/kg) and H (24.5 mg/kg) and well correlated with a degree of GH/IGF1 axis depletion ($r=0.54$; $P<0.0001$ for peak GH in ITT and $r=0.45$; $P<0.001$ for IGF1). A significant negative correlation between serum ADIPO and percentage of body fat (FM%) was found in GH sufficient subjects ($r=-0.30$; $P<0.01$), whereas it was positive in GHD and PGHD group ($r=0.37$; $P<0.05$)
Conclusion
Severe GHD impairs ADIPO secretion in the degree that correlates with GH–IGF1 depletion.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1295

**Serum concentrations of chemerin, omentin and vaspin in girls with anorexia nervosa**

A. Suwala[1], K. Ziora[2], J. Oswiecimska[2], E. Swietochowska[2] & Z. Ostrowska[2]
aa[1]Ipsen Poland, Warsaw, Poland; [2]Medical University of Silesia, Katowice, Poland.

Introduction
Production of chemerin (CHEM), omentin-1 (OMENT), and vaspin (VASP) in adipose tissue is determined by nutritional status. There is no data on CHEM, OMENT and VASP blood serum concentrations in patients with anorexia nervosa (AN).
Objectives
i) Assessment of CHEM, OMENT and VASP serum concentrations in girls with AN. ii) Analysis of correlations between the CHEM, OMENT, and VASP serum concentrations and body weight, BMI, serum insulin (INS) concentration in these patients.
Methods
Seventy-six girls: 46 with AN (mean age: $15.17\pm0.49$ years; mean BMI: $15.34\pm0.55$ kg/m$^2$; mean BMI–SDS: $-2.44\pm0.35$) and 30 healthy (H; mean age: $15.4\pm0.8$ years; mean BMI: $20.95\pm0.75$ kg/m$^2$; mean BMI–SDS: $0.131\pm0.41$). CHEM, OMENT and VASP serum concentrations were determined by ELISA method and the INS by IRMA.
Results
The CHEM and INS average serum concentrations were significantly lower in AN group than in H group ($130.24\pm2.15$ ng/ml and $2.35\pm0.09$ mIU/l vs $191.12\pm8.15$ ng/ml and $4.24\pm0.2$ mIU/l respectively, $P<0.00001$) but OMENT and VASP were higher ($46.19\pm0.92$ ng/ml and $0.52\pm0.01$ vs $34.09\pm0.96$ and $0.41\pm0.01$ ng/ml, respectively, $P<0.00001$). In the AN group the negative correlation was found between CHEM concentration and body weight ($r=-0.33$, $P<0.05$), and INS and BMI ($r=-0.31$, $P<0.05$). The positive correlation between serum CHEM and INS, and negative relationship between serum OMENT and VASP concentrations and body weight as well as BMI in all subjects was found ($P<0.00001$).
Conclusions
In anorexia nervosa CHEM concentrations are decreased in comparison with healthy but OMENT and VASP are increased.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1296

**Evaluation of circulating kisspeptin as a biomarker for differential diagnostic of central precocious puberty**

A. Caragheorgheopol, A. Padure, C. Dumitrescu, C. Procopiuc & I. Gherlan
National Institute of Endocrinology 'C.I.Parhon', Bucharest, Romania.

Introduction
Kisspeptins and their cognate receptor GPR-54 (Kiss-1) were found to be regulators of the hypothalamo-pituitary–gonadal axis. It is under debate if the

onset of central precocious puberty (CPP) could be triggered by early increase of kisspeptin. We aimed to assess serum kisspeptin levels in girls in order to evaluate its potential as a reliable biochemical marker for differential diagnosis of CPP.
Materials and methods
The girls enrolled in our study were divided into three groups: central precocious puberty (CPP), premature telarche (T) and age-matched healthy controls (H). Hormonal serum levels (LH, FSH, estradiol) were measured by an automated immunochemiluminiscent assay. Kiss-1(112–121)amide was measured in sera, using EIA kit (Phoenix Pharmaceutical, Inc.), sensitivity 0.12 ng/ml, range 0–100 ng/ml, CV intra-assay 5–10%, CV interassay $<15\%$. Statistical analysis – SPSS version 16.0.
Results and discussions
Differential diagnosis between CPP and T was made by basal hormonal levels and after triptorelin test, ovarian ultrasound exam and bone age (BA) assessment. There were no differences between demographic characteristics in all three groups. No correlations were found between kisspeptin levels and age, body mass index, BA, LH, FSH (basal or stimulated), ovarian/uterus volume respectively, neither in the whole lot, nor in each group. A wide range of kisspeptin values in CPP girls (0.85–11.52 ng/ml) was obtained.
Surprinsingly, kisspeptin values were greater in healthy group than in CPP group ($P=0.04$) and than in T group (NS), showing a decreasing tendency with pubertal evolution.
Conclusions
Our results do not sustain circulating kisspeptin levels as useful biomarkers in differentiating between girls with idiopathic CPP and premature telarche.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.
Key words: kisspeptins, central precocious puberty.

## P1297

**Two novel IGF1R gene heterozygous mutations in two unrelated children with pre and postnatal growth retardation, and microcephaly**

G. Guercio, D. Warman, M. Aziz, C. Riu, M. Aguiar, M. Juanes, R. Marino, M. Ciaccio, E. Berensztein, E. Chaler, M. Rivarola & A. Belgorosky
Hospital de Pediatria Garrahan, Buenos Aires, Argentina.

Several IGF1R gene mutations have been described as a cause of growth retardation due to IGF1 insensitivity. The IGF1R gene was analyzed in two children suspected to have IGF1 insensitivity. Both were born small for gestational age (SGA) and showed no postnatal catch-up growth. Both patients presented microcephaly and developmental delay. A boy (P1) was born at 37 weeks, birth weight was 1900 g ($-2.98$ SDS) and body length 42 cm ($-4.7$ SDS). At 18 months chronological age (CA), height SDS was $-2.17$, weight SDS $-3.3$ and head circumference SDS $-4$. At 2.75 years CA, bone age (BA) was 1.5 years. He showed a mild dysmorphic phenotype. External genitalia and scrotal testes were normal. Basal serum GH (8 ng/ml), IGF1 ($+2.94$ SDS) and IGFBP3 ($+3.37$ SDS) were high for sex and age. A girl (P2) was born at 38 weeks, birth weight was 2650 g ($-1.4$ SDS), and body length 44 cm ($-3.3$ SDS). At 3.2 years CA, height SDS was $-2.95$, weight SDS $-2.73$ and head circumference SDS $-2.2$. At 2.6 years CA, BA was 1 years. She presented a Klippel Feil malformation. Basal serum GH (8.51 ng/ml) was high but serum IGF1 ($+0.42$ SDS) and IGFBP3 ($+0.61$ SDS) were normal for sex and age. No chromosome 15 anomalies were detected. Two novel heterozygous mutations, *de novo* R1256S (P1) and R1337C (P2) were detected in exon 21 of the IGF1R gene. The aminoacid substitutions were located at highly conserved aminoacid residues in the protein. These mutations were predicted to affect protein function using the sequence homology based SIFT tool and the structure-based PolyPhen approach. Given that phenotype, serum IGF1 and serum GH in IGF1R haploinsufficiency are quite variable, IGF1R molecular studies should be considered in children with an undiagnosed history of SGA without postnatal catch-up growth, and microcephaly.

**Pediatric and adolescent somatotrop adenomas**

F. Chentli[1], S. Azzoug[1], F. Belhimer[1], M. Amani[2] & D. Meskine[3]
[1]Bab El Oued Hospital, Algiers, Algeria; [2]Oran Hospital, Oran, Algeria; [3]Bologhine Hospital, Oran, Algeria.

Introduction
Pituitary somatotrop adenomas are very rare in children and adolescents. They are supposed to be more invasive (invasion of cavernous sinuses or meninges $\pm$compression of adjacent neural structures) than adults'ones. We aimed to analyze their characteristics, and their complications.
Patients and subjects
are studied subjects whose clinical symptoms began before 20 years old. They all had biological, hormonal, ophthalmological, radiological explorations (TDM and or cerebral MRI) and histological study.
Results
From this retrospective study, we have collected 27 cases: 21 pures GHomas and 6 mixed adenomas (PRL/ GH). 20 were males and seven females. Mean age at diagnosis was $24.5\pm8.5$ years (12–55). Clinical symptoms were: 16 gigantisms $\pm$acromegaly, and 11 acromegalies without gigantism. 18 tumors invaded the cavernous sinuses and/or the meninges (66.6%), and 11 were giants (height $\geq$4 cm) or huge ($\geq$6 cm)$=40.7\%$. Mean plasma GH$=125.7\pm200$ ng/ml (7–840). Complications were: pituitary insufficiency ($\geq$1 deficit: $24=88.8\%$, $\geq$2 deficits:$13=48\%$), hydrocephaly$=7=25.9\%$, psychiatric troubles$=4=14.8\%$, epilepsy$=3$ (11%), blindness of one or both eyes: $5=18.5\%$, glucose disorders$=12=44.4\%$, dyslipidemia$=13=48\%$, systemic hypertension$=1$, dilated or hypertrophic cardiomyopathy$=6=22.2\%$, arterioneuropathy$=1$, bone problems$=5$. Association with a benign tumor was observed in 3 cases$=11\%$.
Conclusion
Children and adolescents somatotrop adenomas are diagnosed late. They prevail in males. They are often invasive, and giant or even huge which explains their numerous and severe cerebral complications. The resulting severe hypersomatotropism is responsible of metabolic, bone, and heart complications. On another side, a possible vicious circle between large tumors and severe hypersomatotropism is not excluded.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1299

**Wolfram syndrome: new cases and new mutations**

F. Abbasi, R. Abbasi, A. Ebrahim-Habibi, M M. Amoli & F. Sayahpour
Endocrinology and Metabolism Research Center, Tehran University of Medical Sciences, Tehran, Islamic Republic of Iran.

Introduction
Wolfram syndrome (WS) is a genetic disorder that affects the quality of life of very young Patients. This condition is also referred to as DIDMOAD (diabetes insipidus-diabetes mellitus-optic atrophy-deafness).characterized by non immunogenic diabetes mellitus, and a progressive atrophy of the optic nerve, which occurs generally in the first decade of life.
In order to prevent and treat this condition, a better understanding of WS pathogenesis is needed through more detailed analysis of WFS1 gene product, i.e. wolframin protein.
Material and method
Seven new cases of WS were detected and WFS1 gene exon 8 was screened for mutations by PCR amplification followed by direct sequencing. Topology prediction of the protein was performed and the selected prediction was schematically drawn with the help of TOPO2 (Johns S.J., TOPO2, transmembrane protein display software (http://www.sacs.ucsf.edu/TOPO2/).
Results and conclusion
Five mutations were found to affect wolframin in these patients. From these mutations, W588X, A684G, and E752K are novel. E717K, which is a rare mutation in other populations, was observed in all WS patients in this study, and is suggested to be further investigated to be proposed as a WS marker in the Iranian population. Positions 684 and 752 of wolframin appear to be hot spots for mutations, as other missense mutations have been reported in these positions in other populations. W588X is a novel deletion that would lead toa truncated protein after the eighth transmembrane segment, and is related to the severity of symptoms observed in the patients who bears it.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Growth and response to rhGH treatment in patients with congenital combined pituitary hormone deficiency younger than 3 years of age**

D. Braslavsky[1], A. Keselman[1], G. Bastida[2] & I. Bergadá[1]
[1]Hospital de Niños Ricardo Gutiérrez, Centro de Investigaciones endocrinológicas (CEDIE), Ciudad Autónoma de Buenos Aires, Argentina; [2]Hospital Castro Rendan, Neuquen, Argentina.

Congenital combined pituitary hormone deficiency (CCPHD) is a rare disease. Although most of them are growth hormone deficient, growth retardation is not always the presenting symptom.. There is no normative data in children younger than 3 years regarding dose and frequency with rhGH treatment. The objective was to evaluate the timing of growth retardation and the first and second year growth response to rhGH compared to the mathematical growth prediction model in a large cohort of patients with CCPHD younger than 3 years of age. Twenty seven children were included. The occurrence of growth retardation analyzed as time to event showed that median age was $0.89 \pm 0.74$ years with a mean height of $-3.55$ SDS ($n=19$). The remaining 8 grew well after a follow up of 2.29 years (range 0.42–3.64) despite low serum IGF1 in 6. rhGH treatment was started at a mean age of $1.76 \pm 1.0$ years with a mean dose of $0.23 \pm 0.05$ mg/kg per week($n=14$).
rhGH induced an increment in height SDS of $1.81 \pm 0.98$ and $0.88 \pm 0.81$ at the first and second year respectively. Distance of target height from height at onset of treatment and GH doses were correlated with gain in height SDS throughout the first year of treatment ($r=0.64$, $P$0.01 and $r=-0.66$, $P=0.01$ respectively).
Predicted growth velocity was similar to observed growth velocity at the first year $15.1 \pm 4.1$ vs $13.6 \pm 3.8$ ($P$=NS) and second year $11.02 \pm 4.1$ vs $10.09 \pm 2.3$ ($P$=NS) respectively.
In summary most of the patients with CCPHD presented growth retardation before the first year of life. However, a normal growth pattern could be seen in face of abnormal IGF1 levels. All patients grew according to the mathematical model of growth prediction.
The significant correlation between GH doses and gain in height SDS represent an additional tool for those patients urged to attain a better catch-up growth.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1301

**Hyperandrogenism and PCOS in adolescent girls with type 1 diabetes treated with intensive and continous insulin therapy**

A. Zachurzok-Buczynska, G. Deja, A. Gawlik, A. Drosdzol-Cop & E. Malecka-Tendera
Medical University of Silesia, Katowice, Poland.

Women with T1DM experience high prevalence of hyperandrogenic disorders. Study aim was to examine whether they are present at adolescents and related to metabolic control and type of insulin therapy. Clinical characteristics, hormonal profile and ovarian volume were studied in 49 adolescent girls with T1DM. PCOS criteria were fulfilled in 11 (22.5%). Although girls with poor metabolic control had higher T ($P=0.02$) and 17-OH progesterone ($P=0.03$), frequency of PCOS did not correlate with T1DM duration and mean HbA1c and was independent of the type of insulin therapy. Girls with T1DM and PCOS were compared to 23 non-diabetic peers with PCOS (Table 1) and were found to have shorter cycle and lower ovarian volume and hirsutism score. This may be due to higher SHBG and lower FAI.
Conclusions
Although, irrespective of the type of insulin therapy, more than 20% of adolescents with T1DM experience PCOS, they show milder clinical and ultrasonographic symptoms of hyperandrogenism than their non-diabetic peer with PCOS.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Diagnosis of glycemic abnormalities in thalassemic adolescents: continuous glucose monitoring versus glucose tolerance, and insulin: glucose parameters**

A. Soliman[1], A. Elawwa[1] & M. Yassin[2]
[1]Hamad Medical Center, Doha, Qatar; [2]AlAmal Hospital, Doha, Qatar.

We assessed glycemic status using oral glucose tolerance, 72-h continuous blood glucose concentrations by CGMS, calculate HOMA and QUICKI indices.
Population
15 adolescents with β thalassemia major.
Results
Oral glucose tolerance test (OGTT) In the 15 thalassemic adolescents (age=$19.75 \pm 3.08$ years) showed that four had impaired fasting blood glucose level (IFG)>5.6 mmol/l. One of them had diabetes (BG=16.2 mmol/l at 2-h, and two of them had impaired glucose tolerance IGT (>7.8<11.1 mmol/l). Maximum (postprandial) glucose levels recorded during CGM diagnosed IGT in six adolescents (>7.8<11.1 mmol/l) and diabetes (RBS>11.1 mmol/l) in two. HOMA and QUICKI revealed levels <2.6 ($1.6 \pm 0.8$) and >0.33 ($0.36 \pm 0.03$) respectively denoting non-insulin resistance state. There was a significant negative correlation between the β-cell function (B %) and the fasting and the 2-h blood glucose levels ($r=-0.6$, and $-0.48$, $P<0.01$)respectively. The average and maximum blood glucose levels during CGM were positively correlated with the FBS ($r=0.69$ and 0.6 respectively with $P<0.01$) and with the glucose level at 2 h after oral glucose intake ($r=0.87$and 0.86 respectively with $P<0.01$). The ferretin level was positively correlated with the fasting blood glucose (FBS), 2-h blood glucose levels in the OGTT, average, and the maximum blood glucose levels from the CGM ($r=0.69$, 0.43, 0.75, and 0.64 respectively, $P<0.01$) and negatively correlated with the β-cell function ($r=-0.41$, $P<0.01$).

Conclusion
CGM appears to be superior to standard OGTT for diagnosing glycemic abnormalities in TM. The glycemic abnormalities in our adolescents with TM is due to defective β-cell function with no evidence of insulin resistance state.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Linear growth of children with congenital hypothyroidism detected by neonatal screening compared to normal children and their mid-parental height**

A. Soliman, A. Alsaied, A. Elawwa & A. Sabt
Hamad Medical Center, Doha, Qatar.

We studied the growth data and bone maturation of 45 CH children (25 girls, 20 boys) with CH, diagnosed through the national screening program in Qatar, for 6 years or more to examine the effects of initial $T_4$ dosage (50 μg/day) with adjustment of $T_4$ dose to maintain serum $fT_4$ concentrations within the upper quartile of normal range and TSH < 4 mIU/ml. Birth weight, length and head circumference of patients (3.21 ± 0.43 kg, 50.5 ± 3.21 and 34.1 ± 1.5 cm respectively) did not differ than those for 10 560 normal newborns with normal thyroid function (3.19 ± 0.59 kg, 50.5 ± 2.2 cm and 34.2 ± 1.7). In CH children linear growth velocity during the first year (25.8 ± 2.8 cm/year) was similar to those for normal infants (25.5 ± 0.75 cm/year). During the first 6 years stature growth was normal in all children with CH. The mean HtSDS of CH children showed adjustment (± 0.5 S.D.) towards their mid-parental height SDS (MPHtSDS) only during the second year of life. Children mean HtSDS was higher by an average of 0.4 S.D. between the 2nd and 7th year of life. These data proved that effective screening and treatment completely assures normal linear growth in patients with CH. In conclusion, this treatment protocol maintains normal linear growth with HtSDS that slightly exceeds their MPHtSDS during infancy and childhood.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1304

**A novel splicing mutation of the POU1F1 gene in Japanese identical twins with mild combined pituitary hormone deficiency**

T. Mukai[1,3], H. Inoue[2], Y. Ito[3], M. Itakura[2] & K. Fujieda[3]
[1]Asahikawa Kosei General Hospital, Asahikawa, Japan; [2]Institute for Genome Research, The University of Tokushima, Tokushima, Japan; [3]Asahikawa Medical University, Asahikawa, Japan.

Background
Mutations in POU1F1/PIT1 gene, a pituitary-specific transcription factor, affect the development and function of the anterior pituitary and lead to combined pituitary hormone deficiency (CPHD).
Objective
The clinical and genetic analysis of the twin patients presenting with mild form of CPHD and functional characterization of identified mutation.
Cases
Five-year-old identical twin brothers were referred to determine the etiology of their short stature in 1993. They were the first children of unrelated Japanese parents, born small for gestational age by caesarean section at term. Their heights were both less than −2.5 S.D. with delayed bone ages. Both parents were healthy, normal height father and rather small mother (−1.9 S.D.). Based on the clinical and endocrinological findings, they were diagnosed as having partial CPHD, with mild GH and PRL deficiencies and borderline TSH deficiency. It was decided that medical therapy, including GH and levothyroxine administration, was not necessary. Their growth chart showed similar growth curves throughout the entire period of growth, and indicated lack of pubertal growth spurt. Their adult heights were −1.8S.D. and −1.9S.D..
Results
A novel heterozygous splice site mutation (Ex2 + 1G > T; c.214 + 1G > T) was detected. This mutation was also present in their undiagnosed mother, but not in any of the controls. In vitro splicing studies suggested this mutation to result in an in-frame skipping of exon2. Heterologous expression studies of the mutated POU1F1 protein showed only modest reductions in its transactivation activities in HEK293T cells, while acting as a dominant-negative inhibitor of the endogenous activities of POU1F1 in pituitary GH3 cells.
Conclusions
This is the first report of a mutation at the exon2 donor splice site of POU1F1. The addition of this mutation to the growing list of pathological POU1F1 mutations may provide deeper insights into clinical heterogeneity and better understanding of the structure-function relationships of POU1F1.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Analysis of selected FOXP3 gene polymorphisms in children and adolescents with Graves' disease and Hashimoto's thyroiditis**

N. Wawrusiewicz-Kurylonek[1], A. Bossowski[1], A. Kretowski[1], B. Sawicka[1], H. Borysewicz-Sanczyk[1], E. Piertewicz[1], M. Szalecki[2], B. Wikiera[3], E. Barg[3], M. Mysliwiec[5], A. Kucharska[6], M. Hilczer[4], J. Goscik[1] & M. Gorska[1]
[1]Medical University of Bialystok, Bialystok, Poland; [2]Memorial Health Institute, Warsaw, Poland; [3]Wroclaw Medical University, Wroclaw, Poland; [4]Medical University in Lodz, Lodz, Poland; [5]Medical University in Gdansk, Gdansk, Poland; [6]Medical University in Warsaw, Warsaw, Poland.

Introduction
FOXP3 is a critical determinant of T regulatory cells (Tregs) development and function. Treg cells play a crucial role in modulating potentially self-reactive clones, and dysfunction of this cell type contributes to autoimmune disease such as Graves' disease (GD) and Hashimoto's thyroiditis (HT). The aim of our study was to estimate the association of three polymorphism of FOXP3 gene with the predisposition to GD and HT in Polish population.
Description of methods
The study was performed in the group consisting of 98 patients with GD (mean age, 17.3 ± 6), 39 patients with HT (mean age, 18 ± 4.5) sequentially recruited from the endocrinology outpatient clinic and 158 healthy volunteers (mean age, 16.3 ± 3). DNA was extracted from the peripheral blood leukocytes using a classical salting out method. The three SNPs rs3761549 (−2383C/T), rs3761548 (−3279G/T) and rs3761547 (−3499T/C) in the FOXP3 gene were genotyped by TaqMan SNP genotyping assay using the real-time PCR method. The levels of thyroid hormones, TSH and anti-thyroid autoantibody were determined using chemiluminescence method.
Results and conclusion
In our study the frequencies of −3279TT (rs3761548) genotype was less frequent in female patients with HT in comparison to healthy female (1 vs 18%, $P = 0.033$). There were no differences in the distribution of other analyzed polymorphisms of FOXP3 gene between the studied group. This result may suggests that −3279G/T polymorphism in FOXP3 gene could have a protective role in predisposition to HT.

**Characterization of a population of patients with 46,XX disorders of sex development followed at a Pediatric Center of Argentina**

M. Costanzo, G. Guercio, R. Marino, P. Ramirez, D. Warman, M. Ciaccio, N. Saraco, E. Vaiani, M. Bailez, L. Ongaro, M. Rivarola & A. Belgorosky
Hospital de Pediatria Garrahan, Buenos Aires, Argentina.

Disorders of sex development (DSD) are those congenital conditions in which development of chromosomal, gonadal, or anatomical sex is atypical. The main aim of this study is to characterize a cohort of 46,XX DSD patients followed at the Garrahan Pediatric Hospital, Buenos Aires, Argentina. Medical records of all patients followed at the Endocrinology Department because of DSD between January 1, 2000 and January 1, 2011 in whom laboratory tests were requested were reviewed. We analyzed the records of 156 patients with the 46,XX karyotype. In 133 patients (85.3%) the final diagnosis was congenital adrenal hyperplasia (CAH) due to 21-hydroxylase deficiency. This diagnosis was established on the basis of consistent hormonal measurements (in all cases basal serum 17OH-progesterone was higher than 100 ng/ml). Diagnosis was confirmed by genotyping of the CYP21A2 gene in 90% of the cases. Diagnoses of the remaining 23 patients were the following: ovotesticular DSD in 5 patients (3.2%), testicular DSD in 6 (3.8%), aromatase (CYP19) deficiency in 7 (4.5%), oxidoreductase deficiency (POR) in 2 (1.3%), CAH due to 11-hydroxylase deficiency in 2 (1.3%), and CAH due to 3βhydroxysteroid dehydrogenase in 1 patient (0.6%). In patients with testicular and ovotesticular DSD the presence of the SRY gene was investigated. SRY was positive in two patients, one with testicular DSD and the other with ovotesticular DSD. As it has been previously described, CAH is the most common diagnosis in patients with 46,XX DSD. Testicular and ovotesticular DSD was the second most frequent diagnosis. Further studies should be performed to better characterize the ovotesticular and testicular 46,XX DSD population. Aromatase deficiency is believed to be a rare disease, but in our experience, it was as frequent as ovotesticular DSD.

**Randomized multicenter trial on patients with childhood craniopharyngioma (KRANIOPHARYNGEOM 2007): update after 49 months of recruitment**

H. Müller[1], U. Gebhardt[1], R. Kortmann[2], M. Warmuth-Metz[3], A. Faldum[4], T. Pietsch[5], N. Sörensen[6] & G. Calaminus[7]
[1]Klinikum Oldenburg, Oldenburg, Germany; [2]University Hospital Leipzig, Leipzig, Germany; [3]University Hospital Würzburg, Würzburg, Germany; [4]University Mainz, Mainz, Germany; [5]University Hospital Bonn, Bonn, Germany; [6]Evangelisches Krankenhaus Oldenburg, Oldenburg, Germany; [7]University Hospital Münster, Münster, Germany.

Despite high survival rates (92%) in patients with childhood craniopharyngioma (CP), quality of life (QoL) is frequently impaired due to sequelae such as severe obesity resulting from hypothalamic involvement of CP. Based on the results of the multicenter prospective study KRANIOPHARYNGEOM 2000 radical surgery is no appropriate treatment strategy in patients with hypothalamic involvement. Furthermore, tumour progression/relapses are frequent early events in CP patients. The analysis of event-free survival-rates (EFS) in 117 prospectively evaluated patients with CP showed a high rate of early events in terms of tumour progression after incomplete resection (EFS: $0.31 \pm 0.07$) and relapses after complete resection (EFS: $0.63 \pm 0.09$) during the first 3 years of follow-up.

Accordingly, in KRANIOPHARYNGEOM 2007 QoL, and survival rates in CP pts (>5 years at diagnosis) are analyzed after randomization of the time point of irradiation (XRT) after incomplete resection (immediate XRT vs XRT at progression of residual tumour). Up to now (November 2011) 93 pts with CP were recruited (53 pts in the randomization arm; 40 pts in the surveillance arm; 4 pts in the process of review of imaging). 15 of 53 pts were randomized. 34 pts could not be randomized due to parental decision (13 pts), late schedule (12 pts) and due to decision of the physician (5 pts).

In conclusion, KRANIOPHARYNGEOM 2007 represents the first randomized trial in CP and the first study in pediatric neurooncology analyzing QoL as an endpoint. Aim of the study is to analyze the appropriate time point of XRT in order to improve QoL in patients with hypothalamic involvement. The recruiting compliance is high. However, the randomization compliance has to be improved in order to reach cohort sizes necessary for reliable statistical analysis and to answer the questions assessed by the randomized trial KRANIOPHARYNGEOM 2007.

**Effect of calcitriol on bone metabolism in adolescents with type 1 diabetes**

N. Napoli[1], R. Strollo[1], D. Pitocco[2], C. Bizzarri[3], E. Maddaloni[1], D. Maggi[1], S. Manfrini[1], A. Schwartz[4], P. Pozzilli[1] & IMDIAB group[1,2,3]
[1]Univesity Campus Bio-Medico, Rome, Italy; [2]Catholic University, Rome, Italy; [3]Bambino Gesù Children's Hospital, Rome, Italy; [4]Univesity of California, San Francisco, CA, USA.

Vitamin D supplementation in childhood improves the achievement of peak bone mass. We investigated the effect of calcitriol on bone turnover in recent-onset type 1 diabetes (T1D). Moreover, the association between osteocalcin (OC) and metabolic control was examined.

We conducted a *post-hoc* analysis of a double-blind, placebo-controlled study of calcitriol supplementation to preserve β-cell function. Twenty-seven recent-onset T1D, mean age 25.6 years (range 10–35) were randomized to calcitriol (0.25 μg/die) or placebo (1:1) and followed-up for 1 year. Changes in bone formation (OC) and resorption (β-CTx) markers, and differences between placebo and calcitriol-treated group were evaluated.

At T1D diagnosis, OC levels were lower in females than in males ($P<0.01$). No significant correlations were found in relation to HbA1c, insulin requirement and C-peptide. At 1 year follow-up, OC levels were increased (11%) in the placebo group while dropped by 25% in the calcitriol group, but their levels were not significantly different compared to diagnosis. By stratifying patients according to age, we found that at 1 year follow-up as compared to diagnosis, calcitriol-treated patients $\geq 18$ years of age ($n=6$) showed significant 61% drop of OC ($P=0.04$) and a 67% reduction in β-CTx ($P=0.09$). In the same subgroup, OC tended to be lower ($P=0.08$) and β-CTx were significantly reduced ($P=0.03$) compared to placebo. Differences were not significant in patients >18 years of age ($n=13$). In the placebo group, OC levels were inversely related to C-peptide ($r=-0.79$; $P<0.01$) and tended to be positively related to insulin requirement ($r=0.59$; $P=0.07$). Baseline OC levels were inversely related to C-peptide changes from baseline ($r=-0.68$; $P=0.03$).

Our preliminary data suggest that calcitriol decreases bone remodeling in T1D adolescents and may preserve bone mass. After 1 year of insulin treatment in the placebo group, OC was negatively associated with C-peptide, thus questioning the role of OC as stimulator for β-cells.

**Vitamin D levels in a paediatric population of normal weight and obese subjects**

S. Bellone, V. Agarla, G. Genoni, R. Ricotti, A. Petri, E. Pozzi, S. Parlamento, A. Monzani, F. Prodam & G. Bona
University of Piemonte Orientale, Novara, Italy.

Introduction

Vitamin D plays an important role on musculoskeletal composition, but new evidences highlight others possible pleiotropic effects on many tissues and also metabolic functions. Vitamin D insufficiency should be associated with all-cause mortality, in particular with cardiovascular disease and metabolic syndrome. International studies suggested that 25(OH)D level sufficiency should be established at 30 ng/ml, insufficiency between 30 and 20 ng/ml and deficiency lower than 20 ng/ml.

Methods

To evaluate vitamin D status, we studied vitamin D levels in a population of normal weight (NW) and obese (OB) children: 113 were NW children, 105 M and 8 F, 46 prepubertal and 67 pubertal children and 444 were OB, 219 M and 225 F, 299 prepubertal and 145 pubertal children.

Results
Only 28.3% of NW children showed normal levels of vitamin D, 49.6% showed vitamin D insufficiency while 22.1% showed a clear vitamin D deficiency. Among vitamin D deficient children, 8.8% demonstrated vitamin D levels lower than 14.5 ng/ml. Obese children showed 18.9% of subjects with normal levels of vitamin D, 36.7% of subjects with vitamin D insufficiency and 44.4% of subjects a status of vitamin D deficiency. Among these, 23.2% showed vitamin D levels lower than 14.5 ng/ml. Mean vitamin D levels in NW children ($27.3 \pm 1.2$ ng/ml) resulted higher than in OB children ($21.8 \pm 0.6$ ng/ml). No differences have been found between prepubertal and pubertal children in terms of vitamin D levels.
Conclusions
Our pediatric population demonstrates a low percentage of vitamin D levels sufficiency. In particular obese children show only 19% of subjects with normal levels while almost half of this population show a clear insufficiency. Further studies are needed to support these results and to evaluate the possible metabolic consequences.

**A particular phenotype in a case of Down-Turner syndrome**

S. Bergamaschi[1,6], C. Giavoli[1,6], E. Profka[1,6], E. Ferrante[1,6], R. Fortuna[2], S. Guerneri[2], D. Milani[3], F. Menni[4], M. Cerutti[4,6], G. Manzoni[5], A. Berrettini[5], S. Vallasciani[5], A. Spada[1,6] & P. Beck-Peccoz[1,6]
[1]Endocrinology and Diabetology Unit, Milan, Italy; [2]Medical Genetics Laboratory, Milan, Italy; [3]Medical Genetics Unit, Milan, Italy; [4]Pediatric Unit, Milan, Italy; [5]Pediatric Urology Unit, Milan, Italy; [6]University of Milan, Milan, Italy.

Introduction
Double aneuploidy involving both sex and autosomal chromosomes (chr) is very rare, Down–Turner syndrome being the most frequent. Fourty-seven cases of Down–Turner mosaicism have been reported, only nine with a karyotype containing Y chr (phenotype: seven male, two ambiguous genitals).
Case report
We describe a girl affected with Down-Turner syndrome. The cytogenetic analysis on peripheral lymphocytes, performed 2 months after birth because of mild facial dysmorphisms, showed a karyotype 45,X/47,XY,+21 (84/16%). Analysis of cultured skin fibroblasts confirmed the karyotype, with similar proportion of mosaicism (79/21%). The girl came to our attention at the age of 15.4 years. She presented few, if any characteristics of Down syndrome apart from primary autoimmune hypothyroidism. The phenotype of Turner syndrome was mild too: wide thorax with a large internipple distance, short neck, no signs of puberty with female external genitals, no mental retardation. Hormonal assessment showed hypergonadotropic hypogonadism (FSH 93.2 U/l, LH 37.7 U/l, estradiol 5 pg/ml, AMH $<$ 0.1 ng/ml, testosterone 0.24 ng/mL). MRI abdominal imaging showed streak dysgenetic gonads with an infantile uterus. Because of the presence of Y chr, along with streak non-functioning gonads, a prophylactic gonadectomy was performed and estrogenic replacement was started. Histological examination revealed a mixed gonadal dysgenesis, with the presence of both ovarian and testis tissue. Cytogenetic analysis performed with conventional techniques confirmed the karyotype 45,X/47,XY,+21 (77/23%) in gonadal fibroblasts. FISH analysis with SRY probe showed the presence of a hybridization signal on the Y chr.
Conclusions
We report the first case of Down–Turner syndrome presenting a Y chr with a female phenotype. To confirm the mosaicism as causative event, ongoing genetic studies will be carried out to exclude the presence of chimerism.

## P1311

**Dysfunction of adrenal steroidgenesis in preterm infants with late-onset circulatory collapse**

N. Tagawa[1], Y. Kobayashi[1], S. Oda[1], H. Aoyagi[2], K. Masumoto[2] & S. Kusuda[2]
[1]Kobe Pharmaceutical University, Kobe City, Japan; [2]Tkyo Women's Medical University, Tokyo, Japan.

Objective
To investigate if the event of late-onset circulatory collapse (LCC) implicated in dysfunction of adrenal steroidgenesis due to impairment of adrenal remodeling in preterm infants.
Methods
Eleven in the patient group (case) with clinical signs compatible with LCC diagnosis (hypotension, oliguria, and hyponatremia) and 11 in the control group (control) matched them for gestational age without such signs. Steroids in serum were separated and purified by HPLC. Then, all samples were analyzed using ELISA or a gas chromatography-mass spectrometry.
Results
Serum levels of sulfoconjugated steroids (pregnenolone sulfate (Preg S), 17-hydroxypregnenolone sulfate (17-OH-Preg S) and dehydroepiandrosterone sulfate (DHEA S)) in case were significantly higher than those in control. However, there was no significant difference of unconjugated steroid levels (Preg, 17-OH-Preg and DHEA) between case and control. To investigate 3β-hydroxysteroid dehydrogenase (3β-HSD) activity, serum concentration ratio (17-OH-progesterone (17-OH-P)/(17-OH-Preg + 17-OH-Preg S)) was measured in case and control. The ratio was significantly decreased in Cace compared with control. Preg-$>$P-$>$-$>$cortisol is a major pathway for cortisol synthesis. 3β-HSD catalyzes step Preg-$>$P. Serum concentration of Preg in case (8.7 ng/ml (3.1–14.1), median and quartiles) was ten-times higher than control (0.8 ng/ml (0.7–6.1). However, there were no significant differences of serum P and cortisol levels in case (P: 1.1 ng/ml (1.0–1.5); cortisol: 7.8 μg/dl (3.1–11.3)) and in control (0.5 ng/ml (0.1–1.7); 2.5 μg/dl (1.4–5.5)).
Conclusion
Cause of the event of LCC is at least in part dysfunction of steroidgenesis due to impaired adrenal remodeling.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1312

**Thyroid abnormalities in a 13 year old girl with an androgen secreting juvenile granulosa cell tumor of the ovary: insight into the thyroid-androgen axis in girls**

S. Bendre
West Virginia University, Charleston, West Virginia, USA.

Introduction
Granulosa cell tumors account for ~ 2–3% of all ovarian malignancies. There are two types: adult granulosa cell tumor (AGCT) and juvenile granulosa cell tumor (JGCT). JGCTs are rare and constitute 5% of all granulosa tumors. Androgen production by a JGCT is even rare and may produce virilization in patients. Thyroid abnormalities in female patients with androgen-secreting JGCT has not been documented before.
Objective:
We describe a unique case of a 14 year pubertal Caucasian girl presenting with hoarseness, hirsutism, irregular menstrual cycles and a large multi-nodular goiter with three large complex solid-cystic nodules measuring $>$ 2 cm.
Results
Thyroid function was normal and thyroid antibodies were negative. Thyroid nodule FNAC showed benign follicular changes. Testosterone level was 488 ng/dl and androstenedione levels were elevated. Karyotype, α fetoprotein and beta HCG were normal. LH was normal but FSH and estradiol levels were suppressed. Computed tomography revealed a dense, cystic solid, heterogeneous 14 cm left ovarian mass. Unilateral oophorectomy was performed. Histopathology showed intermediate grade juvenile granulosa cell tumor positive for inhibin, calretinin and negative for thyroglobulin, TTF1, PAX8 and aromatase.

Testosterone (13 ng/dl), inhibin and androstenedione levels dramatically decreased immediately after surgery; LH and FSH normalized, with return of normal menstrual cycles. TSH steadily increased as $FT_4$ dropped over the next few months. Thyroid US showed reduction of thyroid size and nodule size by 30%. Patient was treated with L-thyroxine for hypothyroid symptoms and was stable 6 months after surgery.

Conclusion

This is the first pediatric case in the literature of ovarian androgen secreting JGCT associated with multiple large thyroid nodules. The effect of testosterone withdrawal leading to a reduced thyroid size, low FT4 with elevated TSH, has never been described before. We feel that thyroid function needs to be checked in female patients with high testosterone levels, especially after normalization of testosterone. Larger studies need to be done to look at this relationship in detail.

## P1313

**Clinical practice guideline on linear growth measurement of children**

J. Foote[1,2]

[1]Blank Children's Hospital, Des Moines, Iowa, USA; [2]The University of Iowa, Iowa City, Iowa, USA.

Introduction

Growth is an important and sensitive indicator of child health. Abnormal growth is a common consequence of many conditions, therefore its identification acts as a useful warning of possible pathology. Effective growth monitoring requires precise linear growth measurements; however, measurements are often inaccurate and unreliable. Measurement error influences the interpretation of growth patterns resulting in failure to identify underlying pathology or apparent growth divergence in normally growing children.

Purpose

The purpose of this project was to develop a clinical practice guideline to assist professionals in applying evidence-based knowledge in measuring children using standardized instruments and techniques to facilitate accurate and reliable growth assessments.

Methods

Systematic methods were used to identify evidence to answer focused clinical questions about linear growth measurement. A multidisciplinary team of health professionals critically appraised and synthesized the evidence to develop explicit clinical practice recommendations using an evidence-based practice rating scheme. The guideline was prospectively evaluated through internal reviews, external expert reviews, and a pilot study.

Results

Data analyses were used to improve guideline clarity, applicability, and feasibility, while demonstrating validity and intraexaminer and interexaminer reliability ($P<0.0001$). The guideline provides clinical practice recommendations for measurement techniques, measurement instruments, use of less expensive instruments, calibration of instruments, diurnal height variation, measuring height versus length, replicate measurements, and special considerations. Each recommendation is linked with scientific rationale and supporting references. Tools are available to facilitate guideline implementation.

Conclusions

The clinical practice guideline on linear growth measurement is based on the best available evidence and was developed using rigorous methods. Health professionals and parents need accurate and reliable growth information. Guideline use will improve timely recognition, diagnosis, and treatment of growth disorders, while reducing unnecessary and costly evaluations in normally growing children. Widespread dissemination and adoption of the guideline can significantly impact child health around the globe.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1314

**The presence of thyroid nodules in our morbid obese patients and its relation with metabolic parameters**

M. Sahin, H. Temizhan, B. Ucan, E. Cakal, M. Ozbek, H. Karakose Dogan, I. Ozturk Unsal, A. Gungunes, N. Colak Bozkurt, M. Sayki Arslan, E. Cakir Ozkaya, B. Karbek, H. Yilmaz, E. Tutal Akkaya & T. Delibasi

Diskapi Training and Research Hospital, Ankara, Turkey.

Objective

Insulin resistance may contribute to the development of nodular thyroid disease. Changes in thyroid morphology have been reported in obese patients. In this study, we examined the frequency of nodular thyroid disease in morbid obese patients ($BMI>40\ kg/m^2$) and investigated the metabolic parameters which may play a role in thyroid nodule formation.

Methods

Three hundred and six morbid obese patients (296 women, 10 men) (age 46.2 $\pm$11) without known thyroid disease were included in the study. Thyroid ultrasonography was performed, HOMA-IR, HOMA-% B and HOMA-% S was measured in all patients.

Results

Age, waist circumference, HOMA-% B, vitamin-D3, LDL-cholesterol, TSH was significantly correlated with thyroid volume after regression analysis ($P<0.05$) (adjusted $R^2$ value is 0987). A 153 (50%) patients had nodules which was greater then normal population. Presence of nodules were significantly correlated with the age, weight, waist circumference, and HDL-cholesterol level of free $T_4$ after logistic regression analysis ($P<0.05$). Nodule volume was significantly associated with age, HOMA-% B, HOMA-IR, vitamin B12, and fasting glucose after regression analysis ($P<0.05$) (adjusted $R^2$ value 0689). There were no significant differences in the incidence of nodules according to presence of insulin resistance or presence of diabetes in these patients. There was no correlation with metabolic syndrome criteria and nodule presence.

Conclusion

Unlike low frequency of thyroid nodule in obese people in recent studies, we found higher frequency of thyroid nodule in our morbid obese patients. In obese patients, metabolic parameters may play an important role in thyroid volume, nodule formation and nodule volume.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Mutations of the SRD5A2 gene in patients with 5 $\alpha$-steroid reductase deficiency**

I. Shabir, M. Khurana, M. Eunice, R. Khadgawat & A. Ammini

All India Institute of Medical sciences, New Delhi, India.

Introduction

5 $\alpha$-steroid reductase deficiency (5$\alpha$ SRD) is a rare autosomal recessive disorder.

Aim

To identify mutations in the SRD5A2 gene in patients with 5$\alpha$ SRD.

Methods

Patients registered in the endocrine clinic of our hospital and new patients with diagnosis of 5$\alpha$ RD were eligible to be included in this study. The study was approved by AIIMS ethics committee, written informed consent was obtained from patients (parents in case of children). All patients had detailed history, physical examination, chromosomal analysis and hormonal studies done. Electrochemiluminiscence method was used for the estimation of LH, FSH and T. DHT was done after Celite chromatography by (RIA)(kit based method (Immunotech,Prague)). DNA was isolated from the blood samples,quantified and subjected to PCR amplification using specific primers for all five exons of the SRD5A2 gene.

Results

There were 32 patients (from 28 families) with 5$\alpha$ RD.The age of the patients ranged from 2 to 28 years (13.01$\pm$7.4) and the mean age at which medical attention was sort was 5.6 years. Molecular genetic studies were performed in 13 cases from 11 families. Five patient had homozygous mutation of R246Q and nine patients had mutation of V89L on exon 5,one patient had mutation of A52T on exon 1. Besides an intronic insertion of C at g.31805880-5881 was present in all samples.

Conclusion
Mutation of V89L and R246Q (two cases reported earlier) on exon 5 and a new mutation of A52T has been found in our patients and needs further work for significance.

## P1316

**Lipid storage myopathy in a child with idiopathic short stature**

E. Bivoleanu[1], A. Constantinescu[1], M. Alexianu[2], C. Rusu[1], I. Vasiliu[1], J. Idriceanu[1], I. Potorac[1], R. Popovici[1] & C. Vulpoi[1]
[1]UMF « Gr T Popa », Iasi, Romania; [2]Spitalul Colentina, Bucuresti, Romania.

Introduction
Lipid storage myopathy (LSM) is characterized by increased lipid droplets in muscle fibers. Primary carnitine deficiency is the most frequent cause of LSM, clinical presentation ranging from asymptomatic to progressive muscle weakness or cardiomyopathy, carnitine supplementation being effective with remission of symptoms.
Case report
In february 2007 R.A. born in 1996 presented progressive muscle weakness with elevated muscular enzymes (LDH = 1155 μI/ml $n$ = 125–234, CPK = 1082 μI/ml N = 25–195). Starting from a muscular biopsy, which suggested polymyositis, a glucocorticoid trial was initiated with partial amelioration followed by clinical relapse. Development of cushingoid syndrome and growth retardation (height 123 cm, −3 s.d.; weight 22 kg, −2.5 s.d.; normal parental heights) determined endocrinological evaluation which revealed normal IGF I (172 ng/ml $n$ = 111–551), and basal GH (3.3 μI/ml) with response at stimulation (stimulated GH 125 μI/ml) and delayed bone age of 8,5 years. Functional pituitary evaluation was normal.
Reevaluation by muscular biopsy revealed presence of increased lipid droplets in type 1 muscle fibers suggesting LSM. Carnitine supplementation was started in december 2008 and continued without pause (1 g/day) with progressive clinical improvement and normalization of muscular enzymes.
Absence of GH deficiency justified expectative but the stagnant height after 6 months was an argument for hGH therapy, which was started in October 2008 followed by a satisfactory growth rate.
Reevaluation in December 2011 revealed Tanner pubertal stage IV, growth velocity of 0.7 cm/month, actual height of 147 cm (−2s.d.), delayed bone age of 13 years.
Conclusion
We report a patient with idiopathic short stature and LSM who responded well to hGH therapy and carnitine supplementation. To our knowledge, children with LSM do not usually associate short stature or GH deficiency. Impact of hGH therapy on body composition and muscle structure in LSM cases needs to be further evaluated.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1317

**Care of patients with childhood onset growth hormone deficiency before and after the transition period**

C. Courtillot, R. Baudoin, T. Du Souich, J. Golmard, L. Saatdjian & P. Touraine
GH Pitie Salpetriere, PARIS, France.

Objectives
To investigate how CO-GHD patients are taken care of in paediatrics, during the transition period and in long-term adult follow-up.
Methods
Retrospective cohort study of CO-GHD patients, transferred in our adult department between 1994 and 2011. Paediatric charts were available for all patients. For adult follow-up, parameters of metabolic, bone and cardiovascular status were recorded at several hospitalisations: the first one (V0) and at 1 (V1), 3 (V3) and 5 (V5) years after transition. Three groups of patients were studied: treated (G1) and untreated (G2) persistent GHD, and resolutive GHD (G3).
Results
We present a cohort of 113 patients with median age at transition of 19.5 years. Aetiologies of GHD were acquired in 54%, congenital in 34% and idiopathic in 12% of cases. GHD was complete in 72% of patients. Other pituitary deficits were often associated in congenital (70%) or acquired GHD (78%), idiopathic GHD were generally isolated (64%). In childhood, GH was started at a mean dose of 34.6 μg/kg/day. Mean difference between final and target heights was −0.4s.d.. At transition, 14% of patients had a normal GH axis. 48 patients completed V1, among whom 30 were under GH (mean dose 0.62 mg/day). At V3 and V5, 32 and 22 patients were studied respectively (18 and 5 under GH). Preliminary data show that, over time, mean IGF1 drops in G1, in parallel with GH doses, but always remains higher than in G2, in which it is stable. Mean BMI shows overweight in both G1 and G2: it remains stable in G1, but tends to rise in G2. Surprisingly, mean spine BMD tends to increase in G2 and drop in G1.
Conclusion
This is the largest cohort of CO-GHD patients followed until adulthood. It allows us to evaluate our medical practices, in times when adult GH supplementation remains controversial.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1318

**Psychiatric symptoms in Addison's crisis in childhood: the complexity of diagnosis**

C. Maggioli, E. Maseroli, P. Dirindelli, M. Stefanini, E. Innocenti, C. Pupilli, L. Petrone, G. Forti & M. De Feo
Careggi Hospital, Florence, Italy.

Introduction
Since Addison disease is relatively rare and difficult to recognize in childhood delayed diagnosis is common. Patients with adrenal insufficiency generally show hypotension, hypoglycaemia, hyponatriemia, but can also manifest mild symptoms like chronic fatigue, nausea, vomiting, weight loss, recurring abdominal pain and psychiatric symptoms. In this regard mild disturbances in mood, motivation and behavior represent the main clinical features showing a prevalence between 64 and 84%.
Case report
The patient was admitted at age of 12 years old with severe physical impairment; in the past 3 years he had a marked decrease in height and weight growth velocity with values below 3rd centile and BMI 12. He presented hyponatremia, food refusal, vomiting and psychiatric symptoms like emotional lability, depressed mood and fear of dying. He alternated these symptoms with episodes of euphoria with rapid cycles, strong opposition temper tantrums. During hospitalization the patient was fed by parenteral nutrition and then by enteral nutrition by Nasogastric Tube with poor weight recover and costant hyponatriemia. In this period psychiatric symptoms had been slightly improving with antipsychotic therapy. After several weeks an endocrinological assessment was requested, with subsequent diagnosis of autoimmune adrenal insufficiency (serum cortisol 48 nmol/l, ACTH 3330 ng/l and antiadrenal antibodies positivity).
Replacement therapy with corticosteroids, led to correction of electrolyte disturbances and a dramatic improvement of the eating disorder, with fast weight recovery (BMI 16 two months later). After a temporary exacerbation of psychiatric symptoms a gradual improvement was observed with a complete remission. Despite a good compliance to therapy, the delay in growth velocity persisted. After 1 year GH deficiency was diagnosed, likely related to autoimmune pituitary disease.
Conclusions
Symptoms in Addison's disease can be heterogeneous and difficult to recognize in childhood; a careful evaluation is therefore necessary. Furthermore psychiatric symptoms can be prevalent, leading to incorrect or delayed diagnosis.

**Insulin like growth factor-I (IGF-I) levels and metabolic parameters in a population of obese children and adolescents**

F. Prodam, S. Bellone, R. Ricotti, E. Pozzi, C. Balossini, G. Genoni, G. Walker, G. Aimaretti & G. Bona
University of Piemonte Orientale, Novara, Italy.

Introduction
The risk association between the insulin like growth factor-1 (IGF1) and cardiovascular risk is inconclusive in adults and under-explored in the pediatric population. We aimed to investigate the associations between serum concentrations of IGF1 and cardiovascular risk factors in obese children and adolescents.
Methods
Cross-sectional study. Clinical and metabolic evaluations including an oral glucose tolerance test (OGTT) were performed at fasting in 594 overweight an obese children and adolescents (295 males and 299 females). IGF1 levels were measured by Immulite and IGF-SDS for each age and gender subgroup was calculated and, then, divided into quartiles.
Results
Two hundred and thirty-nine subjects were in Tanner 1, 206 in Tanner 2 or 3, 149 in Tanner 4 or 5 stages, respectively. Subjects in the lowest quartile of IGF1 SDS were older ($P<0.01$) and with higher BMI ($P<0.03$) respect to the highest quartile. After correction for age, gender and pubertal stages, subjects in the highest quartile presented higher insulin levels at fasting ($P<0.01$), post-OGTT ($P<0.03$) and higher HOMA-index ($P<0.01$). No significance was detected for glucose, lipids or pressure with exception of higher triglycerides in the lowest quartiles of IGF-SDS in the crude ($P<0.03$) but not in the corrected models. Continuous IGF-I levels maintained the same associations observed for IGF SDS. Acanthosis index did not correlate with IGF-I levels.
Conclusions
IGF-I levels were directly associated with insulin levels and insulin resistance in obese children and adolescent irrespective of gender and puberty. The association with other cardiovascular risk factor observed in adults could be modulated by age.
Declaration of interest

**The median age of the onset of puberty in Uzbek boys of Tashkent city**

G. Rakhimova, K. Gilyazetdinov, N. Alimova & A. Akbarov
Republican Specialized Scientific-practical Medical Centre of Endocrinology under the Ministry of Health of the Republic of Uzbekistan, Tashkent, Uzbekistan.

Background
The age of the onset of puberty is much lower today than in the past century, due to the stability of the socio-economic conditions, improved quality of life and overall health of the population.
Materials and methods
We examined healthy 818 boys aged from 7 to 18 years, the study was conducted between 2009 and 2011.
Boys were examined in three urban districts of Tashkent city (i.e. Mirzo-Ulugbek, Shakhantaur, Yunus-Abad). Testicular volume was evaluated with a Prader orchidometer. The age of the onset of puberty was defined as the age at attainment of testicular volume of 4 ml or greater.
Results
The earliest age of the onset of puberty was 9.0 years (3.3%). All healthy boys had testicular volume greater than 4 ml by 14 years. The data suggest for healthy Uzbek boys is defined upper reference value of the age of the onset of puberty. Thereby the diagnosis of delayed puberty may be established at 14 years, which generally coincides with the international guidelines for the diagnosis of delayed sexual development. The median age of the onset of puberty for Uzbek boys of Tashkent city was 11.9 (95% CI 11.1–12.7), this data agree with Great Britain (11.9) and Byelorussia (11.9), but different from USA (11.5), Netherlands (11.5).
Conclusion
1. The earliest age of the onset of puberty in healthy Uzbek boys of Tashkent city was 9.0 years and 14 years ultimate one.
2. The median age of the onset of puberty for Uzbek boys of Tashkent city was 11.9 years.
3. We have defined criteria for the diagnosis of delayed puberty at 14 years.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1321

**Thyroid function in a group of type 1 diabetes children without clinical evidence of thyroid diseases**

A. Reghina[1], A. Albu[1], N. Petre[1], M. Mihu[3], S. Florea[2] & S. Fica[1]
[1]UMF Carol Davila; Elias University Hospital, Bucharest, Romania; [2]Elias University Hospital, Bucharest, Romania; [3]Marie Curie Hospital, Bucharest, Romania.

Background
Type 1 diabetes mellitus is frequently associated with endocrine autoimmune diseases especially thyroid disorders. These could have a negative impact on glycemic control even if there is no clinical evidence of thyroid dysfunction.
The aim of the study was to evaluate thyroid function in a group of children with type 1 diabetes mellitus (T1DM) and no clinical evidence of thyroid diseases and to determine its impact on glycemic control.
Material and methods
We collected demographic data from 72 children with T1DM and no clinical evidence of thyroid disorders, physical examination data, and laboratory data: glycated hemoglobin, thyroid peroxidase antibodies (TPOAb), TSH. Subclinical hypothyroidism has been defined as TSH above 4.5 μU/ml without clinical evidence of hypothyroidism.
Results
Thirty-eight (52.7%) patients were boys; mean age $10.89 \pm 4.26$ years, mean span of type 1 DM $3.41 \pm 2.56$ years. TPOAb were present in 23.6% of patients. Mean glycated hemoglobin was higher in patients with thyroid autoimmunity (9.7% $\pm 2.05$ vs $8.6\% \pm 2.11$ ($P=0.05$)). TSH was significantly higher in patients with thyroid autoimmunity (3.39 vs 2.15 μU/ml; $P<0.05$). A number of 8 patients of 72 (11%) had TSH over 4.5 μU/ml (range 4.5–5.76 μU/ml) and only one child had TSH under 0.5 μU/ml. Subclinical hypothyroidism was observed in 29.4% (5/17) among patients with thyroid autoimmunity compared with only 5.4% (3/55) in patients without thyroid autoimmunity ($P<0.001$).
Conclusions
Thyroid autoimmunity was found in 23.6% children with T1DM and no clinical evidence of thyroid disorders. Patients with thyroid autoimmunity had significantly higher glycated hemoglobin and higher TSH versus patients negative for TPOAb. The most frequent subclinical thyroid dysfunction found out was hypothyroidism. Subclinical hypothyroidism was much more prevalent in patients with thyroid autoimmunity.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**The EURO-WABB project**

P. Maffei[1], A. Farmer[2], G. Milan[1], F. Favaretto[1], V. Bettini[1], S. Aymé[3], M. de Heredia[4], S. McCafferty[5], W. Mlynarski[6], V. Nunes[4], K. Parkinson[7], V. Paquis[8], R. Sinnott[5], V. Tillman[9], R. Vettor[1] & T. Barrett[10]
[1]Padua University Hospital, Padua, Italy; [2]Birmingham Children's Hospital, Birmingham, UK; [3]INSERM, Paris, France; [4]IDIBELL, Barcelona, Spain; [5]University of Glasgow, Glasgow, UK; [6]Medical University of Lodz, Lodz, Poland; [7]Alstrom Syndrome UK, Paignton, UK; [8]CNRS, Nice, France; [9]University of Tartu, Tartu, Estonia; [10]University of Birmingham, Birmingham, UK.

Introduction
EURO-WABB is a European research project within the field of rare diabetes diseases. The general objective is to support efficient diagnosis, treatment and research for the overlapping rare genetic diseases Wolfram, Alstrom and Bardet-Biedl (WABB) syndromes.

Methods
The project is supported by the EU DG-SANCO by the collaboration of 8 Associated Partners (AP) and 15 Collaborating Partners. University of Birmingham work as the Project Leader (TB) and coordinating centre. A web-platform was launched in 2011 (www.euro-wabb.org) and a virtual registry will be soon available.
Results
Key achievements of the project are yet on the ground and include: i) coordination: Project Management and Scientific Advisory Committee established; ii) dissemination: awareness raising through conference attendance and development of multi-language website; iii) evaluation: regular conference calls with AP to monitor project progress; iv) core datasets: core and extended dataset agreed in September 2011; 44 + 370 data fields respectively; phenotyping information standardised used ICD-10 and ESPE classification coding systems; v) genetics: mutation database completed for ALMS1, WFS1, SLC19A2 and EIF2AK3; vi) Virtual Registry and Information Environment: prototype core dataset registry developed for testing in November 2011. First recruitment of patients started in August 2011 and local Ethical Committee approval was obtained in UK, Italy and Poland. In the period from 20th June–2nd January 2012, 2814 visits from 73 countries accessed the website (2295 from EU). Actually, 22 people have formally registered and include a mix of patients, families, clinicians and other interested parties.
Conclusion
EURO-WABB is a new reality in the world of rare diseases. By the virtual registry and the website it will be possible in the next future to address the main topics of this project. Next milestones will include the publication of consensus management guidelines, diagnostic criteria, health professional education and patient information material to support the registry.

**Kearns-Sayre syndrome: clinical and molecular diagnosis of the disease and treatment with recombinant GH (rGH) complicated by a severe cardiac conduction deficit and cardiomyopathy**

M. Obara-Moszynska, J. Maceluch, W. Bobkowski, A. Baszko, O. Jaremba, M. Krawczynski & M. Niedziela
Poznan University of Medical Sciences, Poznan, Poland.

Introduction
Kearns-Sayre syndrome (KSS) is a rare mitochondrial cytopathy. The diagnosis of KSS is made on the classical triad of symptoms: onset of the disease $<20$ years of age, progressive external ophthalmoplegia (PEO) and pigmentary retinopathy (PR). KSS is manifested also by other systemic abnormalities: cardiac conduction defects, different neurological abnormalities and several endocrine disorders. A variety of deletions and/or duplications in mtDNA, affecting genes encoding respiratory chain proteins, are found in most cases. The mutated mtDNA coexists with normal molecules (heteroplasmy) and the proportion of mutated to normal mtDNA correlates with the severity of clinical symptoms.
Case report
The adopted boy was born small for gestational age at term. From the 2nd year of life chronic PEO was observed. Additionally the PR was observed. From early childhood he presented short stature. In the age of 11 years, in the EMG the myogenic pattern was revealed and KSS was diagnosed. MRI of the head showed hypoplasia of pituitary gland. Long-range PCR analysis disclosed a 7663 bp long deletion in mtDNA in 6340–14 003 nucleotide region. In the age of 12 years GH deficiency was recognized and the rGH therapy was started. In the age of 15 years complete atrioventicular block was diagnosed. The patient was applied with pacemaker. During next 6 months progressive insufficiency of left ventricle was observed, the echo sound showed the features of dilated cardiomyopathy. The rGH treatment was finished with final height 163 cm.
Conclusions
The effect of rGH therapy in our patient was satisfactory even a big mtDNA deletion and severe cardiac disturbances occurred. Cardiac disturbances were a part of the syndrome, not related to rGH therapy. Based on the literature and the examined patient we state that growth of KSS patients, spontaneous or promoted with rGH, is unpredictable.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1324

**Newborn screening for congenital hypothyreoidism(CH) in Georgia**

N. Beridze[1], R. Takaishvili[1], T. Azikuri[1], M. Mumladze[1] & M. Iashvili[2]
[1]'Express Diagnostics'Ltd, Tbilisi, Georgia; [2]St Joakim and Annmaterniti Home, Tbilisi, Georgia.

Background and aim
Revelation of the incidence of CH is of great value at the background of iodine deficiency (ID) existing in Georgia. Screening on CH in our company with consequent monitoring of the newborns with neonatal hyperthyreotropinemia (NHT) started in September 2010.
Materials and methods
During the first year period 70 731 newborns from all over Georgia underwent TSH (mU/l) determination from blood spots, taken at 24–72 h after birth and venous blood $FT_4$ (ng/dl) and TSH at two weeks after birth using DELFIA kits were measured. Infants with NHT(cut off level 20 mU/l) were consulted by pediatrician, endocrinologist and their blood thyreoglobulin (TG) level(ng/dl) and thyroid volume ($cm^3$), using ultrasound investigation were examined.
Results
Transitory NHT had 280 infants (1:253 live births), mediana 46.5(range 28.7–210), boys 151, girls 129.23 infants had CH (1:3075 live births), girls -boys ratio-2,8/;ten with subclinical CH (Gr.1) and 13 -overt CH (Gr.2). Most of the babies were clinically euthyroid except 8.3% having prolonged jaundice, 5%-constipation, 3.3%-sleepiness and 0.33% macroglossia. Most of the mothers with high NHT did not receive iodide supplementation during pregnancy. No one received high doses of iodine or anti-thyroid drugs. Heredity for thyroid pathology ranged 34–41%. No case of goiter and thyroid agenesis was detected. Gr.1 thyroid volume median- 1.3 was 2.6 times greater than of Gr.2- 0.5 ($P<0.001$) and their neonatal and 2-weeks TSH levels were lower compared to GR.2 $P<$O.O5. Two infants of Gr.2 with pronounced thyroid hypoplasia (volume 0.2 $cm^3$) had low TG level-2.5–3.6. The rest had moderately elevated TG levels with median of Gr.2- 168.5, that was significantly higher compared to Gr.1- 72.1, $P<0.01$.
Conclusion
Thus, CH in Georgia develops without goiter and with marked hypoplasia in severe cases that is possibly conditioned by ID and hereditary predisposition to thyroid pathology.

## P1325

**GH deficiency in the transitional age: retesting and reassessment of ninety personal cases**

B. Marianna
ospedali Riuniti Villa Sofia-Vincenzo Cervello, palermo, Italy.

Transition is defined as the period of the life of a subject ranging from the conclusion of puberty to full adulthood (20–24 y. o.).
The management of patients with GH deficiency in this period of life is related to: assessment deficit etiology: idiopathic or organic; dose of the drug; gain of the full somatic development; maturation of the sexual-reproductive; cardio-metabolic risk assessment; educational aims.
Purpose of the study
In our DH service, since 1999, 1800 children was referred for growth failure. 638 patients was enrolled for GH treatment The average age for the start of therapy was 11.3 years and mean age at discontinuation of therapy was 16.3 years. The mean duration of therapy was 5 years. Currently 250 children with GH are on GH therapy and are monitored with a six months follow-up. All patients have stopped GH treatment after final height attainment (transition phase), we are re-evaluating them for residual GH supply, performing stimulation tests. 90 patients (54 males and 38 females) performed GHRH + arginine re-testing to assess GH secretory capacity after 6 $\pm$ months of discontinuation of therapy.
Materials and methods
Patients undergoing stimulation test with GHRH + arginine: GH was measured at the time 0 '30' 60 '90' and 120 '. We also have evaluated basal value of IGF1. Fully auxological and clinical examination evaluation of body composition, was performed at the time of retesting.
Results
The results obtained so far show that many patients with idiopathic GH deficiency recover secretion of the hormone. Rarely, patients with organic (multiple congenital onset pan-hypopituitarism) or acquired deficits (radio-and chemo-treated tumors) recovering residual GH secretion.
Conclusions
It's essential to identify patients whose GH deficiency persists in the transition phase until to adulthood. In these patients the treatment with GH needs to be

evaluated balancing benefits vs the overall systemic costs and adverse effect. Complications (survival, quality of life, cardiometabolic outcome), that could result from untreated GH deficit, should be correctly predicted.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Building a Brazilian national network for pediatric endocrinology: the RUTE SIG experience**

R. Arrais[1], C. Alves[2], L. Castro[8], C. Kopacek[7], L. Calliari[6], D. Damiani[11], L. Garcia[4], C. Hoineff[10], M. Lobe[5], P. Solberg[9], R. Liberatori[13], G. Graça[12] & G. Guerra[3]
[1]Federal University of Rio Grande do Norte, Natal, Brazil; [2]Federal University of Bahia, Salvador, Brazil; [3]UNICAMP, Campinas, Brazil; [4]Federal University of Pará, Belém, Brazil; [5]Fundação Universidade Regional de Blumenau, Blumenau, Brazil; [6]Santa Casa de Misericórdia de São Paulo, São Paulo, Brazil; [7]Santa Casa de Misericórdia de Porto Alegre, Porto Alegre, Brazil; [8]Universidade de Brasília, Brasília, Brazil; [9]UNI-GRANRIO, Rio de Janeiro, Brazil; [10]IEDE – Instituto Estadual de Diabetes e Endocrinologia, Rio de Janeiro, Brazil; [11]Universidade de São Paulo, São Paulo, Brazil; [12]Universidade Federal do Paraná, Curitiba, Brazil; [13]FAMERP, Rio Preto, Brazil.

Providing good information, exchanging expertise and stimulating clinical discussions are usually main goals when structuring academic services. Nowadays, especially in large countries with social/economic differences between regions, such as Brazil, telemedicine and telehealth are resources with main strategic importance in a country's Public Health System. Since its creation, RUTE network (Rede Universitária de Telemedicina, supported by brazilian Ministry of Science and Technology in association with the Ministry of Health) is enforcing the creation of SIG (Special Interest Groups) with the purpose of integrating and enhancing collaboration between universities and educational health institutions with graduation and/or post graduation medical programs, including medical residences, in a great (and ever expanding) array of subjects and themes. Starting in august, 2011, the SIG of Pediatric Endocrinology was structured to integrate services from all over the country, in monthly videoconferences, following a program previously discussed. These conferences are designed to stimulate the full participation of top specialists and also residents and medical students. Presently, six institutions are enlisted (UFRN – Universidade Federal do Rio Grande do Norte; UNICAMP – Universidade de Campinas; UFBA – Universidade Federal da Bahia; UnB- Universidade de Brasília; Santa Casa (Porto Alegre); USP – Universidade de São Paulo; UFPR – Universidade Federal do Paraná e FAMERP – Faculdade de Medicina de Rio Preto). After each one of the first four videoconferences, conclusions were summarized in order to subsidize national politics in critical pediatric endocrinology issues, like national protocols of growth hormone and insulin analogues dispensation by federal and state governments. The main effort is to expand the group of institutions, which, even in this very initial moment, includes institutions from four of five great regions of the country. In a such a large and diverse country as Brazil, this activity must be enforced, since its advantages and potential usefulness had already been shown.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1327

**Peculiarities of autoimmune thyroiditis in children**

O. Zagrebaeva & A. Solntseva
Belarusian State Medical University, Minsk, Belarus.

Aim
Evaluate anamnesis, clinical and laboratory parameters in children with autoimmune thyroiditis (AT).
Methods
We analyzed retrospectively 211 children in the endocrinological department of University hospital (Minsk) over 2002–2011 years. The number of boys (B) 42 (19.9%), of girls (G) -169 (80.1%) (stage on Tanner1- 15 (35.7%) B, 58 (24.3%) G; stage2-3 – 19 (70.3%) B, 65 (58.6%) G; stage 4-5 – 8 (29.7%) B, 46 (41.4%) G). Ultrasound of thyroid gland, levels of TSH, free $T_4$, Anti-TPO were analyzed. The results were processed using the Statistic 6.1.
Results
Positive family history on the endocrinopathies were in 87 (41.2%) patients (thyroid diseases – 61 (28.9%), DM2 – 22 (10.4%), DM1 – 2 (0.95%), other endocrinopathies – 2 (0.95%) cases). The average volume of the thyroid was $138.4 \pm 40.4\%$ – B, $153.4 \pm 64.8\%$ – G from the age norms ($P = 0.1$). 97 (45.9%) patients – subclinical hypothyroidism, 74 (35.1%) – euthyroid, 40 (19%) – primary hypothyroidism.
TSH level in prepubertal B – $18.7 \pm 8.36$ (0.23–3.4 μIU/l), G – $12 \pm 2.76$ ($P = 0.5$); early pubertal B – $10.5 \pm 6.8$, G – $10.4 \pm 1.9$ ($P = 0.8$); late pubertal B – $3.3 \pm 0.5$, G – $12.36 \pm 5.14$ ($P = 0.5$).
Free T4 level in prepubertal B – $15.46 \pm 1.01$ (10–23.2 pmol/l), G $-14.67 \pm 0.55$ ($P = 0.2$); early pubertal B $-17.48 \pm 1.46$, G $-14.26 \pm 0.38$ ($P = 0.3$); late pubertal B – $19.57 \pm 0.7$, G $-15.7 \pm 0.77$ ($P = 0.1$).
Anti-TPO level in prepubertal B – $331.2 \pm 78.6$ ($< 30$ U/ml), G – 581, $7 \pm 100.8$ ($P = 0.04$); early pubertal B – $613.5 \pm 140.5$, G – $710.4 \pm 100.5$ ($P = 0.3$); late pubertal B – $584 \pm 293$, G – $376 \pm 53.2$ ($P = 0.6$).
There was positive correlation between Anti-TPO level and thyroid volume in all cases ($r = 0.18$ $P = 0.007$).
Conclusions
AT was manifested with the development of subclinical hypothyroidism and goiter. The maximum volume of the thyroid and level of Anti-TPO was in early puberty. The most pronounced decrease of thyroid function was in prepubertal boys, in girls reliable differences of TSH level with the development of puberty was not observed.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1328

**Short stature due to late-onset congenital adrenal hyperplasia**

P. Rodrigues[1,2], S. Souto[1,2], S. Costa[1], R. Moura[1], D. Alves[1], P. Freitas[1,2], C. Correia[1,2], C. Costa[1,2] & M. Fontoura[1,2]
[1]Centro Hospitalar de São João EPE, Porto, Portugal; [2]University of Porto, Porto, Portugal.

Introduction
Precocious pubarche is defined as pubic hair onset before age eight in girls and age nine in boys. In 5–20% of cases the cause is late-onset congenital adrenal hyperplasia (LO-CAH), which is due mainly to non-classic 21-hydroxylase deficiency. If not promptly diagnosed, it can lead to accelerated bone maturation, short final height, and in adulthood to severe acne, hirsutism and infertility.
Case report
Adolescent male, 15 years-old, had a first Pediatric Endocrinology consultation in May 2011 due to short stature. No complications reported during pregnancy and neonatal period. Pubarche occurred at age 7. No information about age of onset of testes and penis development. No relevant family history. Family estimated target height 168 cm (10th–25th percentiles). On physical examination with weight 69 kg (90th percentil), height 159 cm (3rd–10th percentiles) and Tanner stage 5 for genital and pubic hair development. Stature growth chart with few records in the last years but crossing four percentiles curves from age 12 to 15. Laboratory assays showed an increase of baseline 17-hydroxyprogesterone (7.57 ng/ml) and Δ4-androstenedione (4.71 ng/ml; *n*: 0.60–3.10). Measurements of free testosterone, dehydroepiandrosterone sulfate, gonadotropins, IGF1, IGFBP-3 and thyroid function were normal for age group. LO-CAH diagnosis was confirmed by ACTH stimulation test (17-hydroxyprogesterone increased to 27.7 ng/ml 60 min after). Genetic testing detected the mutation p.Val281Leu in homozygosity in gene CYP21A2. Radiography of non-dominant hand and wrist revealed a bone age of 17 years. Testicular ultrasound showed no adrenal rest tumors.
Conclusions
In this clinical case, earlier onset of pubarche was not identified and LO-CAH was not promptly diagnosed, leading to accelerated bone maturation and subsequent committed final height. Early diagnosis of LO-CAH is fundamental to control signs and symptoms related to androgen excess.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1329

**Actual preparation of the growth hormone treatment for small-for-gestational-age children**

S. Hirayama, M. Furujo, T. Kubo & S. Kuyama
NHO Okayama Medical Center, Okayama, Japan.

In 1997, Japanese Child Life Specialist (CLS) was born by earning license in the United States, and then the concept of 'preparation' has spread in Japan. Needs for 'preparation' has been established as the channel to enhance child abilities with an increase in Hospital Specialists (HPS) got licenses in Britain. However, CLS and HPS do not exist in all facilities, so nurses had individually provided explanation of examinations and procedures through pictures or picture-story-shows to these children previously in Japan.

In our facility, nurses has provided the 'preparation' of the GH treatment (i.e. admitting into the hospital, having examinations and procedures, and receiving growth hormone injections) using picture-story-shows and/or stuffed toys for hospitalized small-for-gestational-age (SGA) children and their families, since 2008 when the growth hormone treatment cost became reimbursed for SGA by the national medical insurance. Actual practices will be reported.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1330

**47XYY syndrome is one of the cause of tall in children**

M. Galina, S. Anzhalika & D. Tatiyana
Belarussian State Medical University, Minsk, Belarus.

Symptom of tall is manifestation of many endocrine and genetic diseases. Their early detection is necessary for timely therapy, for improvement of disease state and prognosis for a disease. 47 XYY syndrome is one of frequent occurrence diseases that are accompanied with primary tall. Materials and methods. Patient L., 12 years old, was under our observation. Chief complaint – tall height. Intracranial hypertension, delay in speech development and gross motor delay were registered on the first year of life.

Results

Children's weight – 97.3 kg, height – 195 sm. Rate of growth for current year made up 12 sm. Physical growth and development – high and disharmonious, body mass index – 25.5 kg/m$^2$. Sexual formula of Tanner: P3, Ax1, gonads in marsupium 12 ml. Predict final height of bone age (14 years old 6 months) constituted 204 sm. This data exceed significant index of genetic height (188.5 sm). Indices of biochemical blood assay, glucose loading had normal values. Levels of thyroid-stimulating hormone (TSH), free thyroxin, follicle-stimulating hormone, interstitial cell-stimulating hormone, chondrotropic hormone, prolactin and of cortisol were within the established norms. Values of insulin-like growth factor-1 (761.0 ng/ml, *n* 249 – 642 ng/ml) and of testosterone (18.9 ng/ml, *n* 2.8 – 8.0 ng/ml) had high normative indices. In the process of karyotyping chromosome pathology (karyotype 47 XYY) was established in child. Consultation of neurologist: asthenia, pseudoneurotic tics.

Conclusions

i) It was mad the exclusion: 47 XYY syndrome. ii) Treatment: testosterone enanthate at doses 500 mg, 2 weeks, in the course 6 months. iii) At this moment present patient do not require treatment (bone age > 13.5 years old, treatment is prescribed at the age of 13–13.5 years old, after effect of exogenous androgens on precipitation of closing of bone growth plate is insignificant). It is necessary supervision of endocrinologist, control of rate of height, of rate of sexual maturation.

**A recessive mutation resulting in a disabling amino acid substitution (T194R) in the LHX3 homeodomain causes combined pituitary hormone deficiency**

R. Malik[1], S. Park[1], S. Bechtold-Dalla Pozza[2], S. Hiedl[2], J. Roeb[2], P. Lohse[2], M. Durán-Prado[3] & S. Rhodes[1,4]
[1]Indiana School of Medicine, Indianapolis, Indiana, USA; [2]Ludwig-Maximilians University of Munich, Munich, Germany; [3]University of Castilla la Mancha, Ciudad Real, Spain; [4]Indiana University-Purdue University, Indianapolis, Indiana, USA.

LHX3, a LIM-homeodomain transcription factor, plays a critical role in pituitary and nervous system development. Mutations in the LHX3 gene are associated with combined pituitary hormone deficiency disease (CPHD). Two female siblings with neonatal complications were diagnosed with CPHD resulting from a novel, recessive mutation in LHX3. The index patient presented with classical symptoms of CPHD, featuring deficiencies of GH, LH, FSH, prolactin, TSH and later onset ACTH deficiency. Other complications included a hypoplastic anterior pituitary, respiratory distress, hearing impairment, hypoglycaemia and limited neck rotation. Upon sequencing of the LHX3 gene, it was found that the patients harboured a homozygous C→G transversion mutation in the fourth coding exon of the LHX3 gene, resulting in a change in amino acid 194 from threonine to arginine (T194R) in the DNA-binding homeodomain. Computer modeling predicted that the homeodomain structure resulting from the T194R mutation would be altered. Consistent with this prediction, biochemical analyses demonstrated that the T194 protein did not bind tested LHX3 DNA recognition sites nor did it activate the α glycoprotein subunit and prolactin target genes. This study describes a novel mutation altering a critical residue of the LHX3 protein and thus expands our understanding of the phenotypic features, molecular mechanism, and developmental course associated with mutations in the LHX3 gene.

**Evidence of the involvement of gherline and obestatin in the regulation of GH secretion during pubertal development in boys**

N. Kausar[1], A. Naseem[1], S. Bibi[1], S. Aslam[2], M. Irfan[1], M. Qayyum[1], R. Yousaf[1], R. Mansoor[3], S. Murtaza[4] & S. Rizvi[5,1]
[1]PMAS Arid Agriculture University, Rawalpindi, Pakistan; [2]Government College University, Lahore, Pakistan; [3]Rawalpindi Medical College, Rawalpindi, Pakistan; [4]Nuclear Oncology and Radiotherapy Institute, Islamabad, Pakistan; [5]Pakistan Science Foundation, Islamabad, Pakistan.

The oxyntic mucosa of digestive tract secretes two peptide hormones, ghrelin and obestatin, which are derived from the same gene transcript and play an important role in food intake, metabolic responses and growth and reproduction. Ghrelin and obestatin bind GH secretagogue receptor GHSR1α and G-protein coupled receptor GPR39 respectively, in the pituitary. A limited data in the literature demonstrate that levels of ghrelin peak during first 2 years of life and thereafter decline until the end of puberty, whereas the sensitivity of GHSR increases during puberty since hexareline, a synthetic GHSR analogue, induces greater GH responses in pubertal boys compared to prepubertal boys. Though a role of obestatin in augmentation of GH secretion *in vitro* has recently been observed, the involvement of obestatin in GH secretion in vivo especially at puberty is 1. A possible association of ghrelin and obestatin with increase in GH secretion during puberty was aimed at. Blood samples were collected from 10 to 20 years old 407 boys and plasma concentrations of T, GH, ghrelin and obestatin were determined using specific ELISA. Data were analyzed using Student's *t* test, ANOVA and Pearson correlation. The concentrations of T remarkably increased during mid puberty. Ghrelin showed 1st peak at 14 year, followed by a peak of GH at 15 years and a 2nd peak of ghrelin at 17 years. Obestatin exhibited an abrupt increase at early puberty, gradually augmented during mid puberty and peaked at 17 years. T, ghrelin and obestatin were positively correlated with GH secretion at early and mid puberty. GH, T, ghrelin and obestatin were positively correlated with linear growth velocity at early and mid puberty. The present study demonstrates that the secretion of ghrelin and obestatin increases during puberty and may play a role in increase in GH secretion at puberty.

## P1333

**T3 and T4 rapidly regulate the TSH, FSH and LH $\alpha$ subunit gene expression at posttranscriptional level**

P. Souza, R. Romano, F. Silva, E. Brunetto & M. Nunes
Institute of Biomedical Sciences of University of São Paulo, São Paulo, Brazil.

Several studies demonstrated that the thyroid hormones (TH) downregulate the transcriptional rate of beta and alpha TSH subunits. Recent data showed that $T_3$ also acts posttranscriptionally reducing the polyadenylation and translational rate of the beta TSH mRNA, when acutely administered to thyroidectomized (Tx) rats. This study aimed to investigate whether similar effects occur for the alpha subunit synthesis after acute administration of $T_3$ or $T_4$, which would also influence the synthesis of LH and FSH. For this, euthyroid (sham-operated, SO) and Tx rats were treated with physiological or supraphysiological doses of $T_3$, $T_4$ or saline, and killed by decapitation, 30 min thereafter. Some Tx rats were also subjected to $T_3$ treatment with supraphysiological dose for 5 days. The pituitaries were removed for evaluation of the fraction of alpha subunit mRNA associated with ribosomes, the total mRNA content and its degree of polyadenylation and the total protein content by RT/qPCR, RACE-PAT assay and western blotting, respectively. It was shown in Tx group an increased alpha mRNA content, without alterations on the polyadenylation degree, and reduced protein content compared with SO group. $T_3$ administration for 30 min or 5 days reduced the content of mRNA associated with ribosomes, and increased the total protein content; $T_4$ treatment for 30 min decreased the total mRNA content, and increased the poly(A) tail length and the total protein content in pituitary. Thus, both $T_3$ and $T_4$ rapidly regulate the posttranscriptional steps of alpha subunit synthesis modifying the content, stability and translational rate of its mRNA, as well as its secretion, which might affect TSH, FSH and LH economy.

**Development of novel AIP (Aryl hydrocarbon receptor-interacting protein) gene study models using the fruitfly and the zebrafish**

E. Aflorei[1], C. Chen[2], I. McGonnell[3], R. Fowkes[3], A. Grossman[1,4], N. Tapon[5], R. Stanewsky[2] & M. Korbonits[1]
[1]Bart's and the London School of Medicine, Queen Mary University of London, London, UK; [2]Queen Mary University of London, London, UK; [3]The Royal Veterinary College, London, UK; [4]Churchill Hospital, University of Oxford, Oxford, UK; [5]Cancer Research UK, London, UK.

Introduction
Mutations in AIP have been associated with the familial isolated pituitary adenoma (FIPA) syndrome, an autosomal dominant disease with incomplete penetrance characterised by pituitary adenomas in a familial setting. However, the mechanisms by which AIP inactivation promotes pituitary tumorigenesis are unknown. Studies of AIP in model organisms, such as the fruitfly, harbouring the AIP orthologue CG1847, as well as the zebrafish, are theoretically promising models in discovering possible functions of the AIP gene and understanding pituitary tumorigenesis.
Aim
To establish AIP study models in fruitfly and zebrafish.
Methods
We used RT-PCR and *in-situ* hybridization (ISH) to study the expression of AIP orthologues in fruitfly and zebrafish, and we have generated transgenic AIP-knockdown fruitfly strains by RNA interference using GAL4/UAS-system.
Results
FlyBase RNA ISH showed that CG1847 gene is expressed in fruitfly from early stages (stage I). We generated several fruitfly crosses, using two different GAL4 drivers (actin and elav, expressed in all cells or all neurons respectively) and two different CG1847 RNAi lines (same RNAi construct on ChrII and ChrIII respectively). When actin-GAL4 flies were crossed with CG1847-R2 RNAi line no viable adult offspring were observed suggesting that complete AIP-knockdown is lethal. When using the nervous system-specific elav-GAL4driver, we were able to confirm CG1847 knockdown in the viable offsprings. Wing-targeted knockdown of AIP resulted in specific wing abnormalities. In zebrafish we were able to prove AIP expression from very early stages of development with a wide-spread expression profile.
Conclusions
We have shown that equivalents of mammalian AIP are present and well conserved in the fruitfly and the zebrafish. We have demonstrated that complete AIP deficiency is lethal in the fruitfly, similar to results in the AIP-KO mice. We suggest that these model organisms are useful to identify AIP protein interactions and to explore possible mechanisms of tumour suppression.

**Multiple enhancers regulate expression of the human LHX3 gene in the developing pituitary**

S. Park[1], R. Mullen[1,2] & S. Rhodes[1,3]
[1]Indiana University, Indianapolis, Indiana, USA; [2]University of Texas M.D. Anderson Cancer Center, Houston, Texas, USA; [3]Indiana University-Purdue University Indianapolis, Indianapolis, Indiana, USA.

LHX3 is a LIM homeodomain transcription factor necessary for proper development of the pituitary and central nervous system. Patients with mutations in coding regions of the LHX3 gene have complex syndromes including combined pituitary hormone deficiency and nervous system defects resulting in symptoms such as dwarfism, thyroid insufficiency, infertility, and developmental delay. Although previous studies from our group and others have identified promoter and intronic elements of LHX3 that are important for basal gene expression *in vitro*, the mechanisms by which the LHX3 gene is regulated *in vivo* were not known. Using transgenic mouse models and bioinformatic approaches, we have mapped conserved enhancer and repressor regions that direct tissue-specific expression to the pituitary gland and spinal cord in a pattern consistent with endogenous expression. Several transferable cis elements can individually guide nervous system expression; however, a 180 bp minimal enhancer is alone sufficient to confer specific expression in the developing pituitary. Within this sequence, tandem binding sites recognized by the ISL1 LIM homedomain protein are essential for enhancer activity in the pituitary and spine and a PITX1 bicoid class homeodomain element is required for spatial patterning in the developing pituitary. This study establishes ISL1 as a novel transcriptional regulator of LHX3 and describes a mechanism for regulation by PITX1. Ongoing research focuses on lineage tracing experiments using an enhancer-directed Cre recombinase mouse model. This approach will identify what differentiated cells and their progeny originated from cells with enhancer-directed expression. Characterization of novel genetic defects will facilitate patient treatment and enable genetic counseling. Sources of Research Support: NIH HD42024 to SJR.

**Role of a preformed signalosome in GnRH-stimulated FAK and paxillin phosphorylation by ERK at focal adhesions: possible role in gonadotropes migration**

L. Rahamim-Ben Navi, M. Dobkin-Bekman & Z. Naor
Tel Aviv university, Tel Aviv, Israel.

Introduction
We have recently described a preformed signalosome associated with the GnRH receptor (GnRHR), which undergoes dynamic rearrangement upon stimulation with GnRH. This signaling complex included c-Src, focal adhesion kinase (FAK), paxillin, vinculin, tubulin, caveolin-1, protein kinase C (PKC) δ, PKCε, PKCα, Ras, kinase suppressor of Ras-1 (KSR), MAPK kinase (MEK) 1/2, ERK1/2 and

the GnRHR. To sort out the role of the signalosomes associated with the GnRHR we investigated the activation of ERK1/2 and its substrates in the complex. First, caveolin-1, FAK, vinculin, and paxillin were phosphorylated on Tyr residues by the GnRH-activated c-Src. Then, GnRH activated ERK1/2 in the complex in a c-Src-dependent manner, and the activated ERK1/2 subsequently phosphorylated FAK and paxillin.
Methods
LβT2 gonadotrope cells were transfected with GnRHR-mCherry and paxillin-GFP, or GnRHR-mCherry and ERK-GFP, stimulated with GnRH and visualized in live imaging.
Results
Addition of GnRH to LβT2 gonadotrope cells transfected with GnRHR-mCherry and ERK-GFP resulted in bleb formation and ERK accumulation in the blebs. Furthermore, the cells seem to be migrating after GnRH stimulation. Also, addition of GnRH to LβT2 gonadotrope cells transfected with GnRHR-mCherry and paxillin-GFP resulted in enrichment of paxillin in focal adhesions in the newly formed blebs.
Conclusion
We therefore propose that the role of the signalosome is to sequester a cytosolic pool of activated ERK1/2 to phosphorylate FAK and paxillin at focal adhesions apparently to mediate gonadotropes migration.

### T3 acts posttranscriptionally reducing the poly(a) tail length and the translational rate of alpha and beta TSH mRNA in TαT1 cells

P. Souza, F. Silva & M. Nunes
Institute of Biomedical Sciences of University of São Paulo, São Paulo, Brazil.

Recent data have shown that, in parallel to its transcriptional action down-regulating TSH synthesis, triiodothyronine ($T_3$) also acts on posttranscriptional steps of beta TSH synthesis, reducing the polyadenylation and translational rate of the beta TSH mRNA, when acutely administered to thyroidectomized rats. This study aimed to investigate whether these effects also occur in TalphaT1 cells, and if they are dependent on gene transcription, which would characterize novel actions of $T_3$ on its own regulatory axis. Cells were seeded on matrigel-coated plates, plated in DMEM high glucose and firstly divided in two groups: control (C) containing 10% FBS and hypothyroid (H) – cells plated with 10% FBS depleted of TH by treatment with AG1X-8 resin for 48 h. After this, 5,6-dichloro-1-β-D-ribobenzimidazole (DRB-50 mM) was administered to inhibit the gene transcription for 2 h, followed by the $T_3$-treatment in the doses of $10^{-8}$M or $10^{-10}$M for 30 min or $10^{-7}$M for 4 h. The total RNA and the fraction correspondent to the polisomes were extracted for investigation of mRNA content by RT/qPCR and polyadenylation degree by RACE-PAT assay. The results obtained showed that the $T_3$ rapidly reduces the total content of both subunits of TSH mRNA, and that this reduction is lost by DRB treatment only for alpha TSH mRNA subunit. Moreover it was shown that the $T_3$ ($10^{-10}$M) specifically decreased the poly(A) tail length of beta TSH mRNA, and diminished the content of mRNA of both subunits associated with ribosome, which indicates that the translational rate of TSH synthesis was reduced. These data led us to conclude that the $T_3$ down-regulates TSH synthesis in TalphaT1 cells acting in several posttranscriptional steps of gene expression.

### Estradiol induces the rapid trafficking of membrane-associated ERα isoforms in pituitary cells

S. Zárate, G. Jaita, J. Ferraris, G. Eijo, M. Magri, D. Pisera & A. Seilicovich
School of Medicine, University of Buenos Aires, Buenos Aires, Argentina.

In the pituitary, estrogens regulate several cell functions via the activation of membrane-associated estrogen receptors (mERs). We have previously reported that both 17β-estradiol ($E_2$) and membrane-impermeable E2-BSA induce rapid apoptotic actions in anterior pituitary (AP) cells, lactotropes and somatotropes through the activation of mERs.
In the present study, we investigated the involvement of mERα in the apoptotic action of E2 in lactotropes. We also studied the expression of mERα variants in AP cells during the estrous cycle and the regulation of this receptor expression by E2.
Cultured anterior pituitary cells from ovariectomized (OVX) Wistar rats were incubated with E2-BSA ($10^{-9}$ M) in the presence of an ERα selective antagonist, MPP ($10^{-7}$ M), for 120 min. Apoptotic lactotropes were identified by TUNEL and immunocytochemistry for prolactin. The expression of mERα isoforms was studied in AP cells from rats at proestrus (P) or diestrus I (D) by surface biotinylation and Western Blot. The expression of mERα was also studied in AP cells from OVX rats incubated with E2 ($10^{-8}$ M) for 0–120 min.
E2-BSA increased the percentage of TUNEL-positive lactotropes ($P<0.001$, $\chi^2$) but failed to induce apoptosis in lactotropes coincubated with MPP. Three mERα isoforms of 66, 39 and 20–24 kDa were detected in AP cells. mERα66 expression was higher at $P$ vs D ($P<0.05$), whereas mERα20-24 was lower ($P<0.05$). E2 increased the expression of mERα66 and mERα39 ($P<0.05$, ANOVA) but not of mERα20-24 at 30 min. Intracellular ERα isoforms remained unchanged during the estrous cycle or after E2 incubation.
Our results suggest that E2 induces the rapid trafficking of mERα isoforms to the plasma membrane of AP cells. At proestrus, the high circulating E2 levels could participate in the transient expression of mERα66, which may be involved in the apoptotic action of E2 in the pituitary at this stage of the estrous cycle.

### Pasireotide (SOM230) prevents sulfonylurea-induced hypoglycemia in fasted male rats

H. Schmid
Novartis Institutes for Biomedical Research, Basel, Switzerland.

Introduction
Severe hypoglycemia induced by sulfonylurea overdose is a result of insulin hypersecretion. Pasireotide (SOM230) is a multireceptor-targeted somatostatin analogue with high affinity for somatostatin receptor subtypes $sstr_{1,2,3}$ and especially $sstr_5$, which are expressed on rat and human β cells; pasireotide has been shown to inhibit insulin secretion in both species. The aim of these studies was to investigate the effect of pasireotide on glyburide (glibenclamide)-induced hypoglycemia in fasted male Lewis rats.
Methods
Adult male Lewis rats ($n=6$ per group) were fasted for 24 h and received glyburide 30 mg/kg by oral gavage alone (group 1) or in combination with pasireotide 10 or 30 μg/kg by s.c. injection (groups 2 and 3, respectively). Blood samples were taken by sublingual bleeding 1 h before treatment and 1, 3 and 6 h after treatment. Glucose levels were measured using Accu-check.
Results
Overall, 24 h food restriction significantly reduced plasma glucose levels from $8.0\pm0.4$ mmol/l on day $-1$ to $6.4\pm0.3$, $6.1\pm0.4$ and $6.1\pm0.2$ mmol/l at 1, 3 and 6 h, respectively, on day 1. Following glyburide application in group 1, plasma glucose levels were further reduced to $5.5\pm0.2$, $4.2\pm0.2$ and $3.5\pm0.4$ mmol/l at 1, 3 and 6 h after application. Co-application of glyburide with pasireotide 10 μg/kg in group 2 resulted in glucose plasma levels of $7.0\pm0.4$, $6.2\pm0.4$ and $6.5\pm0.5$ mmol/l at 1, 3 and 6 h after application. In group 3, co-application of glyburide with pasireotide 30 μg/kg resulted in plasma glucose values that were close to those seen in non-fasted animals (ranging between 7.0 and 7.6 mmol/l) 1–6 h after the application.
Conclusion
In rats with glyburide-induced hypoglycemia, low-dose pasireotide increased plasma glucose levels to those seen in fasted rats, and high-dose pasireotide resulted in plasma glucose values similar to those seen in non-fasted rats. These preclinical results suggest that pasireotide may have a role in managing patients with severe hypoglycemia induced by excessive insulin levels, such as those due to glyburide overdose.

**mTOR inhibitor Torin1 induces antiproliferative effects in MtT/E cell line and human pituitary tumors**

H. Rubinfeld[1], O. Cohen[1], I. Fratty[1], M. Hadani[2] & I. Shimon[1]
[1]Rabin Medical Center; Tel Aviv University, Petach Tikva, Israel; [2]Sheba Medical Center; Tel Aviv University, Ramat-Gan, Israel.

As for many tumor types, it has been shown that the Akt pathway is overexpressed and activated in human pituitary tumors. Thus, pituitary tumors may be sensitive to the anti-proliferative effects of mTOR inhibitors. However, part of non-functioning pituitary tumors are rapamycin-resistant. Torin1, second-generation ATP-competitive mTOR kinase inhibitor, suppresses both mTORC1 and mTORC2 complexes. To evaluate the *in vitro* effects of the mTOR inhibitor Torin1 on pituitary cells, a rat non-secreting pituitary tumor cell line, MtT/E, and human non-functioning pituitary adenoma (NFPA) cells were used.
Treatment of MtT/E cells with Torin1 induced a significant dose- and time-dependent decrease of cell viability and cell number. Incubation of cells from four NFPAs with Torin1 significantly reduced the number of viable cells by 25–45%. The anti-proliferative effects of Torin1 on pituitary tumor cells were found to be mediated by G0/G1 cell cycle arrest associated with cyclin D1 and cyclin D3 suppression, apoptosis reflected by increased fraction of cleaved caspase and subG1 events, and autophagy tested with autophagy markers, LC3 and p62. Torin1 increased p53 levels and p53 inhibitor, pifithrin-alpha, blocked the effects of Torin1 on both cleaved caspase and p62 expression. Expression of phosphorylated-p70S6K and phosphorylated-Akt was significantly reduced by Torin1. Interestingly, the protein expression of the negative regulator of PI3K, the PTEN phosphatase, was significantly decreased by Torin1 in MtT/E cells.
Our results show that Torin1 potently inhibits pituitary cell proliferation suggesting that mTOR inhibitors may be a promising antiproliferative therapy for pituitary adenomas. This therapeutic manipulation may have beneficial effects particularly for patients harboring invasive pituitary tumors unresponsive to current treatments.

## P1341

**Effect of estrogen and FGF-2 interaction on lactotroph cell proliferation mediated by membrane-initiated signaling**

L. Sosa, S. Gutierrez, J. Petiti, A. Vaca, A. De Paul & A. Torres
Facultad de Ciencias Médicas, Universidad Nacional de Córdoba, Córdoba, Argentina.

Estradiol ($E_2$) may directly interact with growth factors stimulating cell proliferation and differentiation. Previously, we have demonstrated that $E_2$ through membrane estrogen receptor α (mERα) modulates the lactotroph cell population which exhibit noticeable changes in the pituitary gland. The aim of this study was to analyze the mERα contribution on lactotroph cell proliferation in response to $E_2$ and FGF-2 interaction evaluating the pathway involved in this effect. Pituitary cell cultures from Wistar female rats were treated with 10 nM of $E_2$, $E_2$ membrane-impermeable conjugated ($E_2$-BSA), PPT (ERα agonist), DPN (ERβ antagonist) alone or combined with FGF-2 (0.6 nM) for 30 min or 4 h. The lactotroph cell number was quantified by BrdU/PRL and PKCα and ε; phosphorylated (p) and total Akt or ERK1/2, and β-actin protein expression by western blot. In addition, MEK (PD98059) and ER (ICI 182780) inhibitors were used. The subcellular translocation of PKCα and ε was visualized by confocal microscopy. FGF receptors were identified by immuno-electron-microscopy. Statistical analysis: ANOVA-Tukey. In serum free condition, $E_2$, $E_2$-BSA, PPT, DPN or FGF-2 alone did not modify the lactotroph cell number, whereas $E_2$/FGF-2, $E_2$-BSA/FGF-2 or PPT/FGF-2 co-incubation significantly increased the mitogenic activity of these cells after 30 min or 4 h, being this effect blocked by ICI 182780 or PD98059 pre-treatment. The subcellular distribution of PKCα and pAkt did not exhibit any significant variation after treatments. However, the stimulation for 30 min with the combined treatments described above induced a remarkable increase of pERK1/2 and PKCε translocation to lactotroph plasma membrane that was accompanied with a significant increase of PKCε expression after 4 h. These findings show a cooperative effect of $E_2$ and FGF-2 on lactotroph proliferation triggered by signaling initiated at the plasma membrane with the contribution of mER α and the activation of PKCε/ERK1/2. This regulatory effect could participate in the homeostasis of pituitary cell populations.

## P1342

**Importance of topoisomerase IIα and Ki-67 as markers of invasiveness and predictors of recurrence in pituitary tumours**

F. Golkowski, G. Sokolowski, I. Wierzbicka-Tutka, A. Baldys-Waligorska, D. Adamek, M. Trofimiuk & A. Hubalewska-Dydejczyk
Jagiellonian University Medical College, Krakow, Poland.

Introduction
During clinical observation the behaviour of pituitary tumours is frequently unpredictable. The work was aimed at evaluating Ki-67 and topoisomerase II alpha indices as markers of tumour invasiveness and prognostic factors for postoperative course of disease.
Material and methods
The Ki-67 and topoisomerase IIα (Topo IIα) indices were determined by immunochemistry in specimens excised from neurosurgically removed pituitary tumours. In 48 examined patients (29 females and 19 males, mean age $46.5 \pm 18.9$ years) who underwent pituitary tumour surgery, micro- and macroadenoma occurred in 13 and 35 cases, respectively.
Results
The Ki-67 index, unlike the Topo IIα index, was significantly related to tumour size category (median Ki-67 value 0.1 vs 1.8 in micro- and macroadenoma, respectively, $P<0.005$) while both indices were correlated with tumour size (for Ki-67: $r=0.4$, $P<0.005$; for Topo IIα $r=0.3$, $P<0.05$). Local tumour invasiveness was significantly related to both Ki-67 and Topo IIα indices. Postsurgery tumour recurrence (confirmed by MRI) was significantly related to Topo IIα ($P<0.01$) and not related to Ki-67 index ($P>0.05$). No correlation between Ki-67 and Topo IIα indices, nor between either index and patient age was found.
Conclusion
Ki-67 and topoisomerase IIα expression, as determined in pituitary tumour specimens, is related to the tumour size and invasiveness. Topoisomerase IIα appears to be a more valuable predictor of further disease course than Ki-67 (specifically for local recurrence) and may be helpful in planning postoperative therapy.

## P1343

**Aryl hydrocarbon receptor interacting protein in somatotroph adenomas: a molecular target for somatostatin analogues?**

M. Jaffrain-Rea[1,2], M. Angelini[1], G. Occhi[3], A. Turchi[1], E. Castermans[4], F. Ceccato[3], A. Arcella[2], V. Esposito[2], F. Giangaspero[2], G. Pennelli[3], A. Daly[4], E. Alesse[1], C. Scaroni[3] & A. Beckers[4]
[1]University of L'Aquila, L'Aquila, Italy; [2]Neuromed Institute, IRCCS, Pozzilli, Italy; [3]University of Padova, Padova, Italy; [4]CHU, University of Liège, Liège, Belgium.

The aryl hydrocarbon receptor interacting protein (AIP) gene is abundantly expressed in normal somatotrophs. Somatotropinomas in patients with germline AIP mutations (AIPmut) are typically more aggressive than non-AIPmut adenomas and associated with higher GH/IGF1 secretion. AIP downregulation may also occur in sporadic somatotropinomas, especially in invasive tumours. We wished to evaluate the impact of somatostatin analogues (SSA) pre-treatment on AIP expression in sporadic somatotropinomas.
Patients and methods
46 sporadic somatotropinomas have been operated on in 44 Italian patients, including 20 cases treated by SSA pre-operatively. Pre-operative clinical, radiological and hormonal data were collected. AIP sequencing was performed in most cases and AIP expression was determined by immunohistochemistry (AIP–IHC). $\chi^2$ and non-parametric tests were used for statistical analysis.

Results
A single AIP mutation was identified and 17 macroadenomas displayed a faint or negative AIP staining (36.9%). Low AIP–IHC was significantly associated with the presence of suprasellar extension ($P=0.003$), cavernous sinus invasion ($P=0.024$), higher MIB1 proliferation indexes ($P=0.026$), with a trend in higher pre-operative GH levels ($P=0.066$) and no significant difference in PRL/IGF1 levels. Pre-operative SSA treatment was associated with a significantly higher AIP expression, only three pre-treated adenomas displaying low AIP–IHC (15 vs 53.6% in untreated cases, $P=0.007$): all were male GH/PRL-secreting adenomas, poorly responsive to SSA, including the AIPmut case. Introducing SSA pre-treatment as a covariant in statistical analysis, low AIP was confirmed to be associated with tumour characteristics but not with GH secretion. Significant correlations between tumour characteristics and AIP–IHC were also confirmed in untreated tumours taken as a subgroup, but not in treated tumours.
Conclusion
While confirming that AIP downregulation is associated with tumour aggressiveness in sporadic somatropinomas, regardless of AIP mutations, these data also suggest a role for AIP in SSA signalling in these tumors. This could contribute to the frequent pharmacological resistance of AIPmut somatotropinomas.

**Estradiol regulates the expression of c-FLIP in anterior pituitary cells**

G. Jaita, S. Zárate, J. Ferraris, G. Eijo, M. Magri, M. Gottardo, D. Pisera & A. Seilicovich
School of Medicine, University of Buenos Aires, Buenos Aires, Argentina.

Our previous results demonstrate that estrogens increase the expression of death receptors TNFRI and Fas in the anterior pituitary and sensitize anterior pituitary cells to pro-apoptotic factors. c-FLIP is a protein that interacts with procaspases 8 and 10 modulating death receptor activity. In normal tissues, two isoforms of c-FLIP have been identified, the short isoform (c-FLIPs) and the long one (c-FLIPL). c-FLIPs has an anti-apoptotic action whereas c-FLIPL has either anti-apoptotic, pro-apoptotic or proliferative actions depending on the tissue and its level of expression. To investigate whether c-FLIP is involved in the apoptosis of anterior pituitary cells, we evaluated the action of estradiol on c-FLIP expression in anterior pituitary cells from ovariectomized (OVX) Wistar rats and in the somatolactotrope cell line GH3. Both c-FLIPL and c-FLIPs, identified by Western blot, were detected in the anterior pituitary gland and GH3 cells. In cultured anterior pituitary cell from OVX rats, 17β-estradiol ($E_2$, 10-9M) increased the expression of c-FLIPL (control: $1.50\pm0.42$, $E_2$: $1.91\pm0.59$, $P<0.05$, *t*-test) but did not modify the expression of c-FLIPs (control: $0.30\pm0.05$; $E_2$: $0.37\pm0.08$). Also, the administration of $E_2$ (ip, 20 mg/100 g body weight) to OVX female rats increased the expression of c-FLIPL in the anterior pituitary (OVX: $5.7\pm0.40$, OVX+$E_2$: $6.8\pm0.41$, $P<0.05$, t-test) but did not modify the expression of c-FLIPs (OVX: $1.08\pm0.10$; OVX+$E_2$: $1.18\pm0.05$). The effect of $E_2$ on c-FLIPL expression was not observed in GH3 cells (control: $1.1\pm0.29$; $E_2$: $0.9\pm0.13$)
These results indicate that estrogens regulate the long isoform expression of cFLIP in the anterior pituitary suggesting that this action could be involved in the pro-apoptotic effect of estrogens in this gland.

**Increased interleukin 22 circulating levels in patients with tumors involving the hypothalamic-pituitary region**

O. Cotta, S. Gangemi, F. Ferrau, S. Saitta, M. Torre, S. Puglisi, F. Trimarchi & S. Cannavo
University of Messina, Messina, Italy.

Introduction
Cytokines have been suggested to be involved in modulating anti-tumor responses and promoting tumor growth. Some studies have indicated that cytokines could also be involved in the pathogenesis of pituitary tumors. Th17 cells, characterized by expression of several cytokines as interleukin 22 (IL 22), might have a role in tumor immune-surveillance. IL-22 is a cytokine involved in the modulation of tissue responses during inflammation and, through activation of Stat3-signaling cascades, in the proliferative and anti-apoptotic pathways. Moreover, IL 22 expression requires the ligand-dependent transcription factor aryl hydrocarbon receptor. The aim of our study was to evaluate serum IL 22 levels in patients with tumors involving hypothalamic-pituitary region.
Design
Serum IL 22 levels were measured by a quantitative enzyme immunoassay technique in 38 consecutive patients (27 with secreting or non functioning pituitary macroadenomas; six with craniopharyngiomas; five with meningiomas or disgerminomas; 26 M, mean age $50.3\pm17.7$ years) and in 37 healthy subjects (C: 23 M, mean age $44.9\pm11.72$ years). Other diseases, causing increased IL 22 levels, were excluded in all cases.
Results
Serum Il 22 levels were significantly higher in patients overall than in C ($28.6\pm13.8$ vs $7.2\pm5.7$ pg/ml, $P<0.001$). No differences were observed between patients with pituitary macroadenomas and those with other brain tumors. No correlation was found between serum IL 22 levels and age, gender and positive family history of autoimmune disease. Multivariate analysis did not demonstrate significant association of increased IL 22 levels with hormone hypersecretion (in pituitary adenomas), hypopituitarism or concomitant hormone replacement.
Conclusion
Patients with pituitary tumors show increased serum IL 22 levels, suggesting its hypothetical role in tumor proliferation. Nevertheless, further studies need to elucidate the involvement of this intriguing cytokine in pituitary tumorigenesis.

**Expression of Ras related proteins in ES cell-derived AVP secreting cells**

A. Kiyota[1], Y. Sugimura[1], H. Takagi[1], K. Fukuoka[1], H. Nagasaki[2] & Y. Oiso[1]
[1]Nagoya University Graduate School of Medicine, Nagoya, Japan; [2]Fujita Health University, Toyoake, Japan.

Rab proteins (Rab GTPase) have been implicated in the trafficking and exocytosis of secretary vesicle and play a central role in the secretion of hormones or neurotransmitters. However, the involvement of Rabs and Rab effectors in the regulation of AVP secretion is still unknown. Embryonic stem (ES) cells are pluripotent cells that differentiate into all cell types. Recently, it has been reported that when dissociated ES cells are quickly reaggregeted in low cell-adhesion culture wells and cultured as floating aggregates in growth fator free chemically defined medium (SFEBq/gfCDM culture), ES cells differentiate into rostral hypothalamic progenitor cells including vasopressin (AVP) secreting cells. The aim of this study is to examine the involvement of Rab proteins in SFEBq/gfCDM cultured ES-cell aggregates (SgESa). To examine the expression of Rabs in SgESa, whole cell lysates from SgESa cultured for day 28 were subjected into SDS-PAGE and immunoblotting was performed. We confirmed that AVP was expressed in the SgESa and found that Rab3a, Rab27a, and Rabphilin3a were expressed in the SgESa. Next, AVP release upon high potassium and osmolality stimulation in SgESa on day 28 was analyzed. AVP concentrations in conditioned media were higher in high potassium- or osmolality- stimulated SgESa (incubated with high K+ artificial cerebrospinal fluid (aCSF) or high mannitol aCSF respectively) compared to control (incubated with aCSF). These results confirmed that ES cell-derived AVP secreting cells (ES–AVP cells) were successfully induced. Immunocytochemical analysis of ES–AVP cells using confocal laser scanning microscopy showed that rabphilin3a was mainly distributed in the subplasma membrane region, and partially colocalized with copeptin (precursor of AVP). After the high potassium and osmotic stimulation, the distribution of copeptin colocalized with rabphilin3a seemed to be enriched in plasma membrane region. Our results revealed that Rab proteins and Rab effectors may be involved in AVP release in ES-AVP cells.

### Inhibition of methylation stimulates *POMC* expression and ACTH secretion in human pituitary ACTH-secreting tumors

M. Cassarino[1], A. Sesta[1], L. Pagliardini[1], M. Losa[3], G. Lasio[4], F. Cavagnini[1] & F. Pecori Giraldi[1,2]
[1]Istituto Auxologico Italiano, Milan, Italy; [2]University of Milan, Milan, Italy; [3]Ospedale San Raffaele, Milan, Italy; [4]Istituto Clinico Humanitas, Rozzano, Italy.

DNA methylation has recently been shown to play a role in postnatal as well as developmental gene regulation. Transfer and removal of methyl groups from CpG islands in the promoter region of specific genes has been associated with gene silencing or activation, respectively. *POMC* is known to present several methylation sites and demethylation of these sites has been shown to be linked to *POMC* expression by neuroendocrine tumors outside the pituitary.

Aim

Of the present study was to evaluate whether inhibition of methylation by DNA-metyltransferases (DNMTs) modulates *POMC* expression and ACTH secretion by pituitary corticotroph tumors.

Methods

Thirteen human pituitary ACTH-secreting tumors were collected at surgery and established in culture. Cells were incubated with 1 μM Aza-2′-deoxycytidine (AZA), an inhibitor of DNMTs, with or without 10 nM CRH. After 24 and 48 h, medium was collected for measurement of ACTH by IRMA and RNA extracted for evaluation of *POMC* expression by real-time PCR. Data was normalized to control wells (DMEM and BSA alone) and analyzed by Wilcoxon's test.

Results

Incubation with AZA for 24 h increased *POMC* expression and ACTH secretion compared to control wells; lesser effects were observed after 48 h incubation. AZA did not appear to exert an additional stimulatory effect on *POMC* and ACTH stimulated by CRH.

Conclusions

The present study shows that inhibition of methylation increases *POMC* gene expression and ACTH secretion in human pituitary ACTH-secreting tumors. This can be taken to indicate that methylation plays a role in the regulation of gene expression in tumoral corticotrophs and paves the way to further study on epigenetic changes in Cushing's disease.

### Effect of valproate on inositol 1,4,5 triphosphate and protein kinase C pathways activity in anterior pituitary cells of female rat

E. Wasilewska-Dziubinska[1], A. Gajewska[2], A. Herman[3], E. Wolinska-Witort[1], J. Skrzypska[1], L. Martynska[1], M. Chmielowska[1] & M. Kalisz[1]
[1]Medical Centre of Postgraduate Education, Warsaw, Poland; [2]Polish Academy of Science, Jablonna, Poland; [3]Academy of Cosmetics and Health Care, Warsaw, Poland.

Introduction

VPA, antiepileptic drug, may cause a number of side effects including reproductive deficits in humans. Previously we found that VPA (1 μM) may suppress GnRH-stimulated release of LH from rat anterior pituitary cells *in vitro* without affecting its basal secretion (*Neuroendocrinol Lett* 2011 **32** 101–106). However mechanism of VPA suppressive activity is still unknown. Since pharmacological effects of VPA require GnRH-R activation, the mechanism of its action might occur via modulation of $IP_3$/PKC pathway activity.

Aim

The aim of this study was to evaluate: firstly – an effect of VPA on phorbol ester - PKC activator (TPA) -induced LH release, secondly – an effect of VPA treatment on $IP_3$ synthesis in the primary culture of female rat anterior pituitary cells.

Material and methods

Dispersed cells ($5\times10^5$/ml) were incubated for 3 h with TPA (100 nM), VPA (10 nM–10 μM) or both (TPA+VPA). As controls, incubations with GnRH (100 nM) as well as GnRH+VPA (1–10 μM) were prepared. In the second experiment cells were preincubated (37°C) for 24 h with 1 μCi myo-[$^3$ H]-inositol, then for 30 min with 10 mM LiCl and finally for 3 h in the presence of GnRH (100 nM), VPA (100 nM, 1 μM) or both (100 nM GnRH+100 nM or 1 μM VPA). Medium rLH concentration were estimated by RIA method, cellular $IP_3$ concentrations were estimated by ion-exchange chromatography analysis.

Results

VPA administration did not affect TPA-induced LH release from anterior pituitary cells at any VPA dose tested. VPA treatment resulted in a dose independent significant increase of $IP_3$ cellular concentrations. Moreover, VPA-induced $IP_3$ synthesis reached the same level as was detected after GnRH stimulation.

Conclusions

Obtained data suggest that the inhibitory effect of VPA on GnRH-stimulated LH release is not exerted via down-regulation of $IP_3$/PKC pathway activity.

### The role of familial pituitary adenoma gene, aryl hydrocarbon receptor-interacting protein, in the proliferative and invasive activity of a malignant pancreatic cell line

S. Barry, J. Saleh & M. Korbonits
William Harvey Research Institute, Barts and the London School of Medicine, Queen Mary University of London, John Vane Science Centre Charterhouse Square, London, UK.

Background

Heterozygote mutations in AIP predispose carriers to young-onset pituitary adenomas, most often somatotroph or lactotroph adenomas. No other tumour type has been consistently detected in AIP mutation positive families, despite the fact that AIP is ubiquitously expressed. Current clinical and experimental data suggest that AIP is a tumour suppressor gene.

Aims

To investigate the tumour suppressor role of AIP in a non-pituitary malignant cell line by exploring whether silencing of AIP would affect the invasive and proliferative properties of a highly invasive human pancreatic cancer cell line BxPC3.

Methods

Functional assays (invasion, MTS and colony formation) were carried out after silencing of AIP in BxPC3 using siRNA targeting human AIP. Invasion assays were performed using BioCoat-Matrigel Invasion Chambers. MTS assays were used to measure the metabolic activity at 24, 48, 72, 96 and 120 h after transfection. Colony formation assays were also performed to detect changes in proliferation rates of these cells.

Results

Silencing endogenous AIP in BxPC3 cells significantly increased the number of invading cells compared to non-targeting siRNA controls ($P<0.04$). MTS assays showed AIP silencing caused an increase in metabolic activity compared to non-targeting siRNA controls at 72, 96 and 120 h ($P<0.01$ for all). Furthermore, knockdown of AIP led to an increase in the number of colonies compared to siRNA controls ($P<0.01$).

Conclusion

These results indicate that lack of AIP increased the proliferative and invasive behaviour of this non-pituitary malignant cell line, suggesting an inhibitory role in cell invasion and proliferation and supporting the function of AIP as a tumour suppressor. These data suggest that the tumour suppressor effect of AIP is not limited to pituitary cells and can counteract aggressive behaviour of a cancer cell line. This raises questions as to why AIP mutations are solely associated with pituitary adenomas and no other tumour types.

### Combined intra- and inter-individual variability in macroprolactinaemia

D. de Boer, J. Wiersma & P. Menheere
Maastricht University Medical Centre, Maastricht, The Netherlands.

Objective
Macroprolactinaemia is the phenomenon of forming immunoglobulins (Igs) against prolactin (PRL). The Ig–PRL complex has an increased half-life resulting in elevated levels of immunoreactivity in most PRL immunoassays without having any significance. Identifying macroprolactinaemia-induced hyperprolactinaemia is essential in order to prevent unnecessary testing and treatment. This study is to establish the combined intra- and inter-individual variability in macroprolactinaemia and to verify if multiple measurements to diagnose macroprolactinaemia are justified.
Method
Macroprolactinaemia was determined by size-exclusion chromatography (SEC) combined with the AutoDelfia PRL immunoassay. The percentages of monomeric PRL (%PRL), dimeric PRL (%BIG–PRL) and Ig–PRL complex (%BIG–BIG–PRL) were calculated. Abnormal macroprolactinaemia was diagnosed if the measured %PRL $>$ reference %PRL. From a group of 298 patients suspected for macroprolactinaemia and subjected to SEC combined with immunological testing, 17 patients, who had undergone multiple testing, were selected; 15 patients had been tested twice and two patients three times. The combined intra- and inter-individual variability was calculated based on inter-individual coefficient of variance (CV) of the relative intra-individual change (RIC) according to the model of running means between two time points: $RIC = (abs(A-B))/((A+B)/2) \times 100\%$ in which A is the percentage of the respective PRL form at one time point and B that of the subsequent time point.
Results
CVs of %PRL, %BIG–PRL and %BIG–BIG–PRL were 21, 32 and 27% respectively. The period between the time points was not standardized, varied significantly and was $16 \pm 19$ months (mean $\pm$ s.d.; $n = 19$). The presence of absence of abnormal macroprolactinaemia proved to be unchanged in subsequent samples; 12 patients suffered from abnormal macroprolactinaemia of which nine patients had normoprolactinaemia after correction.
Conclusion
The combined intra- and inter-individual variability's of the PRL forms were $\leq 33\%$ and the diagnosis of macroprolactinaemia was consistent during the time period evaluated. Therefore, no indications were found that justify multiple measurements to diagnose macroprolactinaemia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1351

### Reduced expression of glucocorticoid stimulated genes in large and dedifferentiated corticotroph adenomas

J. Evang[1,2], J. Bollerslev[1,2], O. Casar-Borota[3], T. Lekva[1,2], J. Ramm-Pettersen[4] & J. Berg[2,4]
[1]Oslo University Hospital, Rikshospitalet, Oslo, Norway; [2]University of Oslo, Oslo, Norway; [3]Uppsala University Hospital, Uppsala, Sweden; [4]Oslo University Hospital, Oslo, Norway.

Introduction
E-cadherins are found in epithelial tissue. Reduced expression in somatotroph pituitary adenomas has been demonstrated to correlate with dedifferentiated phenotype; reduced tumour size, increased invasiveness, and reduced somatostatin analog response. Recently, correlations between corticotroph tumour dedifferentiation and both E-cadherin immunostaining and reduced E-cadherin gene (*CDH1*) mRNA was demonstrated.
Glucocorticoids induces transcription of some genes, and inhibit others. Corticotroph adenomas are characterised by a relative resistance to the normal inhibitory effect of glucocorticoids on proopiomelanocortin (*POMC*) gene expression and ACTH secretion.
Our aims were to explore if glucocorticoid resistance in corticotrophs was associated with both positively and negatively regulated genes, and if the resistance correlated with level of tumour dedifferentiation.
Methods/design
Twenty patients with verified Cushing's disease or Nelson's syndrome, operated at Rikshospitalet, Oslo, were included. RT-qPCR of *CDH1*, growth arrest-specific 5 (*GAS5*), *POMC*, the reference gene *GAPDH* and the normally glucocorticoid stimulated genes *GILZ* and thioredoxin-interacting protein (*TXNIP*), as well as immunohistochemical analysis of E-cadherin, were performed. Correlations between expression of the *POMC*, *GILZ* and *TXNIP* genes in different stages of corticotroph adenomas, defined clinically (microadenomas, macroadenomas or Nelson tumours), by *CDH1* gene expression, and by E-cadherin immunoreactivity (nuclear, intermediate or membranous), were evaluated. Expression of the glucocorticoid regulated genes, *GAS5* expression and preoperative 24-h urinary cortisol excretion were investigated.
Results
*TXNIP* and *GILZ* expressions were positively correlated to *CDH1* expression, and were highest in microadenomas and in tumours with high membranous E-cadherin reactivity. In contrast, *POMC* expression was not significantly different between the groups. No correlations to *GAS5* expression or urinary cortisol were found.
Conclusions
The expression of the glucocorticoid responsive genes *POMC*, *GILZ* and *TXNIP* in corticotroph adenomas shows a remarkable variation. The pattern and mechanism of glucocorticoid resistance in corticotroph adenomas seem dynamic, and covariate with loss of epithelial phenotype associated with corticotroph tumour dedifferentiation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1352

### Effects of the combined treatment with AMPK activator and somatostatin-14 on hormone secretion and cell proliferation in cultured GH-secreting pituitary tumor cells

G. Tulipano[1], L. Faggi[1], M. Losa[2], P. Mortini[2], M. Spinello[3], D. Cocchi[1] & A. Giustina[1]
[1]University of Brescia, Brescia, Italy; [2]Istituto Scientifico San Raffaele, Università Vita-Salute, Milano, Italy; [3]Novartis Farma, Origgio (Varese), Italy.

AMP-activated protein kinase (AMPK) activation decreased GH release and intracellular GH storage in rat pituitary cell cultures and reduced cell proliferation in rat pituitary adenomatous cells (GH3) cultures.
We investigated the effects of the AMPK activator 5-aminoimidazole-4-carboxamide ribonucleoside (AICAR) as compared to somatostatin-14 on cell viability (MTT assay after 48-h) and GH secretion (over 24 h) in 16 human GH-secreting pituitary adenomas *in vitro*.
AICAR (0.4 mM) reduced cell viability in four adenomas out of fourteen (mean decrease vs control: $16 \pm 9\%$). Four adenomas were responsive to SS-14 (100 nM; mean decrease vs control: $15 \pm 6\%$). One adenoma was responsive to both somatostatin and AICAR. The effects of cotreatment with SS-14 and AICAR was investigated in eight adenomas. In two adenomas, the effects of AICAR + SS-14 did not exceed the effect of AICAR. In three adenomas which were not responsive to either AICAR or SS-14, the cotreatment was able to reduce cell viability by $27 \pm 5\%$ vs control. Three adenomas were not responsive to any treatment. As to the effects on GH secretion, nine adenomas out of fourteen were responsive to AICAR (mean decrease $35 \pm 20\%$). Ten adenomas were responsive to SS-14 (mean decrease $40 \pm 15\%$). Seven adenomas were responsive to both AICAR and SS-14. Cotreatment exceeded the effect of single treatments in three adenomas out of seven.
Overnight treatment with AICAR induced a clear-cut increase in phospho-(threonine-172) AMPK (activated AMPK) whereas SS-14 did not alter significantly AMPK phosphorylation in cultured human adenomas.
In GH3 cells, AICAR reduced the activity of p70S6 kinase, which plays an important role in cell growth. SS-14 did not affect significantly AMPK phosphorylation and p70S6K activity but it was able to enhance the inhibitory effect of AICAR on p70S6K.
Our studies suggest that AMPK activators and SS-14 may cooperate in the control of a subset of GH-secreting pituitary adenomas *in vitro*.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**The relationship between Ki-67 labeling index and p53 with age, gender, number of surgeries, cure after surgery and cavernous sinus invasion in pituitary adenomas of patients with acromegaly**

Y. Altuntas, S. Zuhur, C. Tanik, S. Velet & F. Yener Ozturk
Sisli Etfal Training and Research Hospital, Istanbul, Turkey.

Introduction
Evidence suggests a relationship between high tumoral Ki-67 LI with persistence of tumor after surgery and lower response rate to medical therapy. Therefore, we aimed to determine the relationship between Ki-67 LI and p53 with age, gender, number of surgeries, cure after surgery and cavernous sinus invasion in pituitary adenomas of patients with acromegaly.
Methods
The paraffin-embedded tissue sections of 30 patiets with acromegaly, operated at our center during 2003–2010 via transsphenoidal route were immunostained for Ki-67 and p53, using avidin–biotin–peroxidase complex method. Clinical and radiological data were obtained through chart review. High Ki-67 LI and diffuse p53 immunoreactivity was defined as immunopositivity for $\geq 4$ and $\geq 50\%$ of cells respectively.
Results
The current study included 30 patients (17 female, 13 male), ranging in age between 23 and 65 years old. According to MRI, 3 (10%) of the tumors were microadenoma and 27 (90%) were macroadenoma. Cavernous sinus invasion was present in 14 (47%) cases. Seven (23%) of the patient were operated for at least two times and 23 (77%) were operated on once. Six (20%) patients were cured at first surgery and 24 (80%) had active disease. Fourteen tumors (47%) had Ki-LI $\geq 4\%$ and 2 (6.7%) tumors demonstrated $\geq 50\%$ p53 immunoreactivity. We could not find a relationship between age, gender, cure at first surgery and number of surgeries with high Ki-67 LI and diffuse p53 immunoreactivity ($P > 0.05$). However, KI-67 LI $\geq 4\%$ and diffuse p53 immunoreactivity were significantly higher in tumors with cavernouse sinuse invasion ($P = 0.007$ and $P = 0.03$ respectively).
Conclusion
High Ki-67LI and diffuse p53 immunoreactivity are associated with cavernouse sinuse invasion in pituitary adenomas of patients with acromegaly.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Characterization of mutant AIPV49M in somatotroph cells**

García-Rendueles[1], E. Díaz-Rodríguez[1], G. Trivellin[2], M. García-Lavandeira[1], T. Vila Vila[1], C. Dieguez[1], M. Korbonitz[2] & C. Alvarez[1]
[1]CIMUS-IDIS: School of Medicine and Hospital Clinico Universitario (CHUS), University of Santiago de Compostela (USC), Santiago de Compostela, Spain; [2]Barts and the London School of Medicine, London, UK.

Introduction
About 30% of all familial isolated pituitary adenoma (FIPA) and 50% of acromegaly families have a mutation in the aryl hydrocarbon receptor-interacting protein gene (AIP; Chahal, *TEM*, 2010). The functional role of AIP in somatotroph cells is unknown. Recently, it has been proposed that wild type AIP (wtAIP) is a tumor suppressor gene, role that is lost in the different mutant AIPs (mAIP; Leontiou, *JCEM*, 2008). In the adenomas, mAIPs are usually found as loss of heterozygosity with both alleles mutated. However, the point mutant V49M-AIP was found in a single giant male patient but there was no LOH, coexisting with a normal allele. Previous and different functional studies found that V49M-AIP was behaving as the wtAIP.
Aims
To study the effects of V49M-AIP in comparison to wtAIP in the proliferation and apoptosis of somatotroph cells.
Matherials and methods
We use the somatotroph rat pituitary cell line GH4C1 cell line that express basal levels of AIP. Thus they are a good model for heterozygosis. The cells were transiently transfected by nucleofection. As a standard of transfection efficiency a vector expressing GFP under a CMV promoter was co-transfected. Cells were counted with a cytometer. Apoptosis was detected by Hoechst staining.
Results
The nucleofection provided a transfection efficiency over 90% in all cases. In the presence of complete medium with growth factors we observed no difference in the proliferation between the empty vector, wtAIP or V49M-AIP. In deprived medium (0.1% serum) the cells transfected with the mutant V49M-AIP presented a 40% apoptosis. There was no relevant apoptosis in cells transfected with empty vector or with wtAIP.
Conclusions
In somatotroph cells V49M-AIP mutation does not affect proliferation but induces apoptosis. In cells expressing endogenous AIP this mutant seems to act as a toxic mutation. This would explain why this mutant is always in heterozygosis. The results also suggest that pro-tumoral effects of mutant AIP require other factors still unknown.

**Lycopene and β-carotene induce growth-inhibitory and proapoptotic effects on pituitary tumor cells: the mechanism could involve Connexin 43**

N. Haddad, A. Teodoro, N. Soares, F. Oliveira, R. Mattos, F. Gomes, M. Gadelha, L. Nasciutti & L. Miranda-Alves
Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.

Pituitary adenomas account for ~10–15% of intracranial tumors and result in morbidity due to both altered hormonal patterns as well as side effects of therapy. Currently, great attention has been given to natural coumpouds from functional foods. Among these substances, we highlight that the consumption of carotenoids is associated with reduced risk of chronic diseases including cancer and vascular diseases. In this study we evaluate the influence of β-carotene and lycopene on cell viability, colony formation, cell cycle, apoptosis, intercellular communication and expression levels of Connexin 43 on mouse ACTH-secreting pituitary adenoma cells, the AtT-20 cells. Cells were cultivated with DMEM supplemented with 10% fetal bovine serum under an atmosphere of 5% $CO_2$ at 37 °C, and incubated with different concentrations of carotenoids (0.5,1.25, 2.5, 5,10,20 and 40 μM) for 48 and 96 h. Using MTT assay, it was showed an important decrease of cell viability after 48 and 96 h with both lycopene and β-carotene treatments. For colony formation assay in 21-day period there was a significant decrease in clonogenic capacity. By flow cytometry, the cell cycle analysis revealed that β-carotene induced an accumulation of cells in S and G2/M phases after 96 h; furthermore, lycopene increased the proportion of cells in G0/G1 phase and decreased in S and G2/M phases also after 96 h. Using the annexin V-fluorescein isothiocyanate apoptosis detection kit, it was demonstrated that lycopene and β-carotene 5 and 10 μM concentrations induced apoptosis after 96 h. To evaluate intercellular communication, microinjections were performed with Lucifer Yellow and it was observed that a few coupled cells in control cells but none lycopene and β-carotene treatment. By the other hand, the phospho-Connexin 43 expression was increased under cell treatment. These results show that lycopene and β-carotene reduced cell viability, induced apoptosis, blocked the clonogenic capacity and promoted cell cycle arrest in AtT-20 cell culture by a mechanism that probably involves phospho-Connexin 43. This data suggests that these compounds may be in the future a new pharmacological approach for the treatment of pituitary adenomas.

**Somatostatine receptors expression in various pathological types of clinically non-functioning pituitary adenomas**

F. Gabalec[1], M. Drastikova[1], M. Beranek[1], D. Netuka[2], V. Masopust[2], T. Cesak[1], J. Marek[3] & J. Cap[1]
[1]Charles University Hospital and Faculty of Medicine in Hradec Kralove, Hradec Kralove, Czech Republic; [2]Central Military Hospital and 1st Faculty of Medicine, Charles University, Prague, Czech Republic; [3]1st Faculty of Medicine, Charles University, Prague, Czech Republic.

Clinically non-functioning pituitary adenomas account for about one-third of pituitary tumors. The majority of them are pathologically classified as gonadotropinomas or null-cell adenomas without hormonal expression. The rest represent silent corticotroph adenomas and plurihormonal tumors. Conservative therapy with dopamine agonists and somatostatine analogues is effective in some cases only depending on the expression of somatostatine (SSTR) and dopamine 2 receptors (D2R).
Objective
The aim of this study was to quantitatively estimate SSTR2, SSTR3 and SSTR5 receptor expression in clinically non-functioning pituitary adenomas and correlate the results with immunohistochemical profile of adenoma.
Methods
Quantitative real-time RT-PCR technique.
Results
Quantitative analysis was performed in 78 clinically non-functioning pituitary adenomas for sst2, sst3 and sst5. All adenomas expressed SSTR2 and SSTR3. SSTR5 was expressed in 42% of adenomas. High variability of expression for each sst type was present. SSTR2 mRNA was expressed from 1174.8 to 146 680.8 copies/5 µl cDNA, SSTR3 62.9–46 914.3 and SSTR5 mRNA 0–43 776.6 copies/5 µl cDNA.
The median of relative quantity (after normalization to housekeeping gene) for SSTR2,3 and 5 was 5.5 and 0.3 for null-cell adenomas (SSTR5 not expressed); 0.5, 0.2 and 0.01 for gonadotrophs; 0.65, 0.1 and 0.14 in silent corticotrophs and 1.7, 0.7 and 0.05 in plurihormonal adenomas respectively.
Conclusion
SSTR2 and SSTR3 expression was not statistically different in regard to histological type of adenoma. SSTR5 expression was significantly higher in silent corticotroph adenomas. There was a correlation between SSTR2 and 3 expression. A very heterogeneous level of SSTR expression may be the reason why experimental use of somatostatine analogs and dopastatins is not clinically effective in the majority of CNFAs.

**Lymphocyte subpopulations in Sheehan's syndrome**

H. Atmaca[1], M. Arasli[2], Z. Yazici[3], F. Armutçu[4] & I. Tekin[2]
[1]Ondokuz Mayis University Medical School, Samsun, Turkey; [2]Zonguldak Karaelmas University Medical School, Zonguldak, Turkey; [3]Rize University Medical School, Rize, Turkey; [4]Fatih University Medical School, Ankara, Turkey.

There are a limited number of studies investigating the immunological alterations accompanying the Sheehan Syndrome. The aim of this study was to evaluate lymphocyte subsets in these patients.
Flow cytofluorometry was used for the immunophenotyping of peripheral blood leukocytes from 15 patients (mean age 61.6±11.3, range 34–75 years) and 25 healthy controls (mean age 56.7±10.6, range 34–80 years). The percentages of $CD3^+$, $CD19^+$, $CD16^+/56^+$, $CD8^+28^+$, $CD8^+28^-$, $\gamma\delta TCR^+$, $CD8^+$; and the ratio of $CD8^+28^-/CD8^+28^+$ were similar ($P>0.05$) between patients and controls. Whereas the leucocyte counts ($P=0.004$), the percentage of CD3DR ($P=0.000$), $CD4^+CD25^+$ ($P=0.003$), the ratio of CD3DR/CD3 ($P=0.000$) were higher, the percentage of CD4 ($P=0.000$) and the ratio of CD4/CD8 ($P=0.006$) were lower in patients with Sheehan's syndrome compared to healthy controls (Table 1).
In conclusion, some peripheral lymphocyte cell subsets show marked variation in patients with Sheehan's syndrome in comparison to matched healthy subjects, which may have implications for altered immune regulation in these patients.

## P1358

**Modulation of intrapituitary CRH gene expression**

M. Cassarino[1], A. Sesta[1], F. Cavagnini[1] & F. Pecori Giraldi[1,2]
[1]Instituto Auxologico Italiano, Milan, Italy; [2]University of Milan, Milan, Italy.

Corticotropin-releasing hormone (CRH) is known to be produced and secreted by normal rat corticotropes and to contribute in a paracrine manner to *POMC* synthesis and ACTH secretion in these cells. The regulation of intrapituitary CRH however still has to be clarified.
Aim
This study was to establish whether *CRH* gene expression can be measured in rat pituitaries *in vitro* and whether CRH modulates its own gene expression within the pituitary.
Methods
Rat anterior pituitary primary cultures were incubated with 10 nM CRH and RNA extracted after 24 and 48 h incubation. Control wells were incubated with serum-free DMEM. RNA was reverse-transcribed and subjected to real-time PCR using probes specific to rat *CRH* and *HPRT*. Data were analyzed as $2^{-\Delta\Delta C_t}$ and are expressed as fold increase over control wells.
Results
Low levels of *CRH* gene expression were detected in rat pituitary primary cultures. Wells incubated with 10 nM CRH presented increased *CRH* levels at both 24 h (1.7-fold ±0.4 higher than control wells) and 48 h (2.1-fold ±0.1 higher than control wells).
Conclusions
This study shows that *CRH* mRNA can be detected at low levels in normal rat pituitary cells, in keeping with its paracrine role. Interestingly, incubation with exogenous CRH induced an up-regulation in *CRH* gene expression, indicative of a positive intrapituitary feed-back loop. Further studies are needed in order to fully clarify the modulation of locally produced CRH.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Resveratrol induces apoptosis in GH3 pituitary adenoma cells of the rat**

B. Voellger, E. Kirches, C. Mawrin & R. Firsching
Otto-von-Guericke-Universitaet, Magdeburg, Germany.

Objective
Resveratrol is a phytoestrogen with various antiproliferatic and proapoptotic effects. One of the underlying mechanisms is downregulation of apoptosis inhibitors, such as Survivin. In human pituitary adenoma cells, Survivin expression is increased as compared to healthy pituitary gland tissue. This *in vitro* study aims to analyze the effect of Resveratrol on GH3 pituitary adenoma cells of the rat.
Methods
GH3 cells were cultivated in F-12K medium containing 2.5% fetal bovine serum and 15% horse serum. Ethanol served as solvent for Resveratrol. GH3 cells were incubated with Resveratrol concentrations from 20 to 100 µM for 48 to 72 h. Culture medium and Ethanol served as controls. Cells were counted using a hemocytometer. Apoptosis was quantified using an ELISA. Relative expression of Survivin as compared to β-2-microglobuline (B2MG) was measured using quantitative real time PCR (qRT-PCR). *T* served as statistical test, whereas $P<0.05$ was supposed to be statistically significant.
Results
GH3 cell counts significantly decreased with growing concentrations of Resveratrol ($P<0.005$). ELISA significantly demonstrated apoptosis in two cell passages treated with 100 µM Resveratrol ($P<1\times10^{-8}$). In two cell passages, qRT-PCR detected a relative increase in Survivin expression (SE) in the Ethanol control and a relative decrease in SE after treatment with 100µM Resveratrol as

compared to culture medium (culture medium SE: 0.009, 0.008; Ethanol control SE: 0.011, 0.014; SE after Resveratrol treatment: 0.007, 0.007).
Conclusions
Resveratrol decreases GH3 cell counts in a dose-dependent manner by inducing apoptosis, which may possibly be mediated by Resveratrol-dependent down-regulation of Survivin. Further investigation of the potential effects of Resveratrol on pituitary adenoma cells is warranted.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Effects of Brazilian palm tree extract on ACTH-secreting mouse pituitary tumor cells**

F. Moscardini, M. Domingos, N. Haddad, L. Cabral, L. Miranda-Alves & L. Nasciutti
Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.

Cushing Disease (CD) is a serious endocrine disorder that is primarily caused by an ACTH-secreting pituitary adenoma. Current treatments of CD present low efficiency in controlling the tumor mass growth and reducing the release of ACTH. This work investigates a possible new therapy for the treatment of pituitary tumors. Using a nanoparticle extract (nanoOse) of a typical Brazilian palm tree, we verify the *in vitro* effects of this extract on a ACTH-secreting mouse pituitary tumor cell line AtT20. AtT20 cells were maintained in a culture incubator at 37 °C in humidified air containing 5% $CO_2$ in a DMEM culture medium supplemented with 10% fetal bovine serum (FBS). AtT20 cells were treated with nanoOse at concentrations ranging from 100 to 300 μg/ml, and after that it was performed these experiments: morphological analysis by phase-contrast microscopy, cell viability MTT assay, cell proliferation assay using violet crystal, colony formation assay using the CFU method and cell necrosis index by LDH release assay. Experimental results show that even with the lowest concentration (100 μg/ml), nanoOse treatment was able to modify the morphological characteristics of AtT20 cells, to decrease 50% of cell viability and proliferation, to lose their clonogenic capacity and also to increase the cell necrosis index.These results indicate that nanoOse treatment negatively modulate AtT20 tumor cell progression, and suggest that this extract could be a new therapeutic strategy for the ACTH-secreting pituitary adenoma.

**Case series of diabetic ketoacidosis as the first presentation of 860 patients with acromegaly**

N. Yoshida, H. Suzuki, K. Nagasawa, M. Okubo, A. Takeshita, M. Miyakawa, Y. Mori, T. Fukui, N. Fukuhara, H. Nishioka, S. Yamada & Y. Takeuchi
Toranomon Hospital, Tokyo, Japan.

Background and aims
Excess GH causes insulin resistance resulting in impaired glucose metabolism. Although diabetes mellitus (DM) is common in patients with acromegaly, diabetic ketoacidosis (DKA) is rarely associated with acromegaly. Actually only 11 DKA patients have been anecdotally reported as the first presentation of acromegaly so far. Here we present nine cases of DKA as the first presentation of 860 consecutive patients with acromegaly and their clinical characteristics.
Materials
Data of 860 consecutive acromegaly patients with pituitary surgery in our hospital from 1980 to 2011 were collected.
Results
Nine cases were found to be complicated with DKA before diagnosis of acromegaly, seven males and two females. None of them had been diagnosed as DM. Their average age was 38.8±14.2-year-old, HbA1c 12.1±1.8%, plasma glucose 41.4±21.0 mmol/l, arterial blood pH 7.27±0.09 (means±s.d.). All patients were negative for antibodies related to type 1 DM. The precipitating factor of DKA in six cases was an excessive ingestion of sugar-containing soft drink. After pituitary surgery, plasma glucose levels were in good control without insulin in all cases; furthermore six patients needed no oral hypoglycemic agents. Their insulin secretion capacities were well preserved estimated with 75 g oral glucose tolerance test after surgery.
Conclusion
As we reported, acromegaly enhanced insulin resistance but some acromegalic patients could not compensate insulin secretion accordingly (*Eur J Endocrinol* **164** 467, 2011). Thus, an excessive ingestion of soft drink might predispose them to metabolic failure due to further glucose toxicity. Increased lipolysis by GH could also be involved in the development of DKA. In conclusion, patients with acromegaly may be prone to severe metabolic failure, such as DKA that is the first presentation in 1% of acromegaly. Acromegaly should be added to the list in background diseases of DKA.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Markers of recurrence and long-term morbidity in craniopharyngioma**

A. Gautier[1], A. Godbout[3], C. Grosheny[1], I. Tejedor[1], M. Coudert[1], C. Courtillot[1], C. Jublanc[2], M. De Kerdanet[5], J. Poirier[1], L. Riffaud[6], C. Sainte-Rose[7], R. VanEffenterre[4], G. Brassier[6], F. Bonnet[1] & P. Touraine[1]
[1]Hôpital Sud, Université Rennes 1, Rennes, France; [2]Groupe Hospitalier Pitié-Salpêtrière, Pierre and Marie Curie University, Paris VI, Paris, France; [3]Centre de Recherche du Centre Hospitalier de l'Université de Montreal, Montreal, Quebec, Canada; [4]Groupe Hospitalier Pitié-Salpêtrière, Paris, France; [5]Hôpital Sud, Université Rennes 1, Rennes, France; [6]Hôpital Pontchaillou, Université Rennes 1, Rennes, France; [7]Hôpital Necker, Université Paris Descartes, Paris, France.

Context
Craniopharyngiomas are often associated with an unfavorable prognosis but data on their long-term consequences are sparse.
Objective
To identify markers of recurrence and factors associated with compromised social rehabilitation and altered quality of life (QoL) in a large cohort of patients with either childhood onset (CO) or adult onset (AO) craniopharyngioma.
Methods
Retrospective analysis was performed for 171 patients treated for craniopharyngioma in two academic centers in France between 1972 and 2009. For each subject, data were collected concerning clinical presentation, imaging features, visual sequelae, endocrine and metabolic impact, treatment modalities (surgery, radiotherapy), recurrence-free survival rate and social insertion, as well as answers to the WHOQOL-BREF questionnaire.
Results
A total of 65 CO and 106 AO patients were reviewed. If CO was diagnosed before the age of 10 years, this was associated with a higher incidence of obesity, blindness and panhypopituitarism, and only 40.7% of subjects had adequate work or school attendance compared to 72.4% of patients with later disease onset. Initial symptoms of intracranial hypertension (SIHT), pterional surgery and multiple surgery were associated with obesity and poorer social insertion. No determinant of QoL was identified. In the subgroup of patients treated in the 90's and later, the progression rate was 59.4% in patients with residual tumor on MRI and the recurrence rate was 19.8%. Recurrence/progression correlates significantly with male gender, early onset (before 10 years) and SIHT, but only SIHT at presentation remained a significant predictor with multivariate analysis.
Conclusions
Craniopharyngioma continues to be associated with severe outcomes. Higher morbidity rates are found in patients with early onset disease (before 10 years),

**Table 1**

| | <10 years | 10–18 years | P | >18 years | *P* (CO Vs AO) |
|---|---|---|---|---|---|
| At least three anterior pituitary insufficiencies | 100% | 82.3% | 0.03 | 73.8% | 0.01 |
| Diabetes insipidus | 96.4% | 82.3% | 0.12 | 68.0% | <0.01 |
| Major visual acuity and field impairment | 53.8% | 50.0% | 0.77 | 48.0% | 0.66 |
| Blindness | 37.0% | 5.9% | <0.01 | 13.6% | 0.30 |
| Epilepsy | 32.1% | 18.7% | 0.23 | 15.5% | 0.14 |
| Median BMI | 33.1 | 26.2 | <0.01 | 27.7 | 0.80 |
| BMI >30 | 67.9% | 24.2% | | 41.5% | |

initial SIHT or in whom pterional surgery was required. Markers of recurrence are difficult to identify, with SIHT being the most powerful predictor.

### Familial isolated pituitary adenoma: review of four families

S. Belo[1,2], J. Mesquita[1,2], C. Nogueira[1,2], A. Magalhães[1,2], M. Basto[2], J. Pereira[1] & D. Carvalho[1,2]

[1]Centro Hospitalar S. João, Porto, Portugal; [2]Universidade do Porto, Porto, Portugal.

Introduction

Pituitary adenomas are frequent brain tumors, with prevalence of about 1:1000. Most occur sporadically. The familial forms represent 5% of cases. These can be found associated with other endocrine neoplasia (MEN 1, Carney complex, MEN 4) or as a clinical isolated entity – FIPA. This is characterized by the presence of pituitary tumors in two or more family members, in the absence of features of other endocrine syndromes. AIP gene mutation, which may or may not be present, has been linked to FIPA. A review of four FIPA families was made. The Table 1 summarizes their main characteristics.

Conclusion

FIPA are characterized by the predominance of prolactinomas and somatotrophynomas (GH; 75%). They can be divided into families of homogeneous phenotype (only one tumor type, ex. isolated familial somatotrophynomas (IFS)) or heterogeneous (all types can occur, including non-functioning, but as a rule, at least one prolactinoma or GH producing tumor). This is a heterogeneous entity in which virtually all phenotypic combinations are possible. FIPA patients, especially with AIP gene mutation (positive in 15% of the heterogeneous phenotype and 50% of the IFS), are younger, have larger, more aggressive and resistant to therapy tumors.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### A prospective study of cardiac valvular status in patients treated with cabergoline for endocrine disease

L. Vroonen, P. Lancellotti, M. Tome, J. Magne, R. Auriemma, A. Daly, L. Pierard & A. Beckers

Liege University Hospital, Liege, Belgium.

Introduction

Since the 1990's cabergoline has become the treatment of choice in prolactinomas, allowing rapid and efficient hormonal and tumoral control in most cases. Evidence of cardiac valculopathy was demonstrated in patients treated by dopamine agonists for Parkinson disease, which led to curtailment of their use in this disease. Retrospective studies in hyperprolactinemia patients treated with cabergoline did not show such an effect, probably due to much lower doses commonly used. However, prospective data with long-term follow-up are generally not widely available.

Aim

To undertake a novel prospective study of cardiac valvular function in patients treated by cabergoline for endocrine disease.

Methods

One hundred and four patients (34M, 70F; mean age 50.43 years) treated with cabergoline for endocrine disease (hyperprolactinemia $n=98$, other $n=6$) were included. All patients and controls underwent a complete transthoracic echocardiographic study (TES) using the same equipment. All TES were performed by two experienced echocardiographers, with special attention towards valvular status and were interpreted by a third echocardiographer. The mean interval between TES while on cabergoline was 28.66 months $\pm$11.26 months.

Results

The mean total duration of cabergoline treatment was 75.81 months ($\pm$75.25 months) and the mean total dose of cabergoline was 253.33 mg ($\pm$515.76 mg) at last follow-up. Cardiovascular risk factors included: dyslipidemia ($n=29$), obesity ($n=28$), hypertension ($n=22$), diabetes ($n=10$), smoking ($n=16$). Three patients developed mild aortic insufficiency while one case had improved aortic valvular function on follow-up. One case developed a mild tricuspid insufficiency and one case developed a mild pulmonary valvular insufficiency, while three cases had normalization of pre-existing grade one valve dysfunction deficiency. No variation in mitral function was found (Fig. 1).

Discussion

In this prospective study, we found no relevant alteration in cardiac valvular function with cabergoline treatment. This suggests that findings from retrospective analyses are correct and that cabergoline remains a safe chronic treatment at the doses commonly used in endocrine disease.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### IGF1 as a risk factor for insulin resisitance and glucose intolerance in acromegaly

D. Niculescu[1], M. Purice[2], R. Lichiardopol[3] & M. Coculescu[1]
[1]Carol Davila University, Bucharest, Romania; [2]C. I. Parhon Institute of Endocrinology, Bucharest, Romania; [3]N. Paulescu Institute of Diabetes, Nutrition and Metobolic Disorders, Bucharest, Romania.

Introduction
In normal subjects GH is a hyperglycemic hormone as opposed to insulin-like growth factor 1 (IGF1). Active acromegaly is associated with insulin resistance (IR) and glucose intolerance although both GH and IGF1 are elevated. Our objective was to assess whether GH, IGF1 or both are risk factors for IR and glucose intolerance in acromegaly.
Methods
Basal serum IGF1 and GH, glucose and insulin during an oral glucose tolerance test were measured in 111 patients with active ($n=97$) or cured ($n=14$) acromegaly. 53 patients were assessed before any treatment and 58 after surgery and/or radiotherapy. Patients treated with somatostatin analogs, GH-receptor antagonists or antidiabetic drugs were excluded. IR was assessed by various basal and stimulated indices. Glucose intolerance (impaired fasting glucose ($n=20$), impaired glucose tolerance ($n=11$) and/or diabetes mellitus ($n=12$)) was defined according to American Diabetes Association criteria.
Results
Homeostatic model assessment 2-insulin resistance (HOMA2-IR) index correlated more closely with IGF1 ($r=0.64$, $P<0.0001$) than nadir ($r=0.25$, $P=0.008$) or random GH ($r=0.28$, $P=0.002$). Also, IGF1 correlated better than nadir or random GH with all other IR indices (fasting insulin, HOMA1-IR, QUICKI and Matsuda index). In multivariate logistic regression analysis IGF1 (OR=1.55, $P=0.01$) but not nadir (OR=1, $P=0.9$) or random (OR=0.99, $P=0.9$) GH was a significant risk factor for glucose intolerance after adjusting for age, sex, weight and acromegaly duration.
Conclusions
In acromegaly IGF1 correlates more closely than GH with IR. IGF1 levels but not GH are associated with glucose intolerance.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1366

### An insight into the mechanisms underlying the sympathoinhibition of acromegaly

C. Carzaniga[1,2], G. Seravalle[2], R. Attanasio[3], G. Grassi[4], L. Lonati[2], C. Facchini[2], R. Cozzi[5], L. Fatti[3], M. Montini[6], G. Vitale[1,2], G. Sciortino[1], S. Damanti[1], G. Brambilla[4], F. Cavagnini[1], G. Mancia[4], M. Scacchi[1,2] & L. Persani[1,2]
[1]University of Milan, Milan, Italy; [2]Istituto Auxologico Italiano, Milan, Italy; [3]Istituto Galeazzi, Milan, Italy; [4]University of Milano Bicocca, Milan, Italy; [5]Ospedale Niguarda Cà Granda, Milan, Italy; [6]Ospedali Riuniti, Bergamo, Italy.

By direct measurement of muscle sympathetic nerve activity (MSNA) we previously demonstrated a markedly decreased adrenergic tone in newly diagnosed acromegalic patients. The present study was aimed at confirming this finding in a larger group of patients and establishing the pathophysiological role of insulin resistance, GH and IGF1 levels, circulating leptin and extracellular water (ECW) in this abnormality.
Study design
Fifteen *de novo* patients with active acromegaly without obstructive sleep apnoea and cardiac hypertrophy, and 15 healthy subjects matched for age, sex and BMI were recruited. After evaluating ECW by BIA and glucose metabolism, and measuring circulating GH, IGF1 and leptin, direct recording of sympathetic outflow via the microneurographic technique was performed.
Results
A marked sympathetic inhibition was confirmed in patients compared to controls (MSNA $18.3\pm8.10$ vs $37.3\pm6.48$ bursts/min, $P<0.0001$) in spite of a significatly increased HOMA index ($4.2\pm2.39$ vs $1.6\pm0.19$, $P<0.001$). ECW was comparable in patients and controls. A clear-cut reduction of plasma leptin ($1.6\pm1.04$ vs $6.5\pm2.01$ μg/l, $P<0.0001$) was recorded in the patients. In these latter MSNA was not correlated with ECW, GH or IGF1, but was positively correlated with leptin ($P<0.0001$). Leptin was the only independent predictor of MSNA in a multiple regression analysis.
Conclusions
Acromegalic patients display a decreased sympathetic outflow in spite of insulin resistance. The lack of correlation between ECW and MSNA does not support the hypothesis of a sympathoinhibition due to baroreceptor activation by volume expansion. A putative role of the GH–IGF1 system as direct central inhibitor of sympathetic drive is not likely, given the lack of correlations between these two parameters and MSNA. On the contrary, the highly significant correlation with leptin points to hypoleptinemia as a major contributor to the sympathoinhibiton of acromegaly, consistent with previous studies in obese animal models.

### Aneurysmal subarachnoid haemorrhage is a rare cause of acute glucocorticoid deficiency and long term hypopituitarism

M. Hannon, L. Behan, M. O'Brien, B. Rogers, M. Sherlock, D. Smith, A. Agha & C. Thompson
RCSI Medical School, Beaumont Hospital, Dublin 9, Ireland.

Subarachnoid haemorrhage (SAH) is a well reported cause of hypopituitarism but the precise incidence is controversial. We aimed to prospectively determine the incidence of acute and long term hypopituitarism in SAH.
We prospectively recruited 100 patients (61% female, median age 53 (range 16–82)) with non-traumatic aneurysmal SAH. Each patient had plasma sodium, urea, osmolality, glucose, and 0900 h cortisol (PC) measured on days 1, 2, 3, 4, 6, 8, 10 and 12 following SAH. Results were compared with 15 patients admitted to ITU following vascular surgery. A PC $<300$ nmol/l in a patient in ITU was regarded clinically as inappropriately low. Survivors attended for insulin tolerance testing at $\geq 6$ months following SAH. Those in whom insulin tolerance testing was contraindicated underwent glucagon stimulation testing. If patients refused either of these tests, a short synacthen test was offered.
14% of SAH patients had at least one PC $<300$ nmol/l; in 4/14 (28.6%) hyponatraemia due to acute cortisol deficiency ensued, which responded to hydrocortisone treatment. In contrast, all controls had PC $>500$ nmol/l on day 1, and $>300$ nmol on days 2–12. 11% of SAH patients developed acute cranial diabetes insipidus (CDI); mortality in this group was 100%.
39/89 (43.8%) of SAH survivors attended for dynamic pituitary testing. The median time to testing was 15 months (range 7–30 months). 24/39 (61.5%) underwent insulin tolerance testing. 4/39 (10.3%) underwent glucagon stimulation testing and 11/39 (28.2%) underwent short synacthen testing. 2/39 (5.1%) were ACTH deficient, one of whom previously had low PC. 7/39 (17.9%) were GH deficient; one GH deficient patients previously had low PC. No patients were gonadotropin, TSH, or prolactin deficient. None had long term CDI.
In the largest prospective study of its kind, acute glucocorticoid deficiency occurs in 14% of SAH patients, and causes hyponatraemia in 28.6% of these. Long term hypopituitarism is uncommon following SAH and predominantly manifests as GH deficiency.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1368

### Hyponatraemia in aneurysmal subarachnoid haemorrhage is due to the syndrome of inappropriate antidiuresis and acute glucocorticoid deficiency

M. Hannon[1], L. Behan[1], B. Rogers[1], M. Sherlock[1], D. Smith[1], A. Agha[1], S. Ball[2] & C. Thompson[1]
[1]RCSI Medical School, Beaumont Hospital, Dublin, Ireland; [2]Royal Victoria Infirmary, Newcastle Upon Tyne, UK.

Hyponatraemia is the most common electrolyte abnormality following subarachnoid haemorrhage (SAH). Retrospective data suggests that the Syndrome of Inappropriate Antidiuresis (SIAD) is the most common cause,

although glucocorticoid deficiency and rarely cerebral salt wasting may also cause hyponatraemia.
We prospectively studied 100 patients (61% female, median age 53 (range 16–82)) with non-traumatic aneurysmal SAH. Each patient had plasma sodium (pNa), urea, osmolality, glucose, 0900 h cortisol (PC) and vasopressin (AVP), and urinary sodium and osmolality measured on days 1, 2, 3, 4, 6, 8, 10 and 12 following SAH. Fluid balance and haemodynamic parameters were recorded daily. A PC $<$300 nmol/l was regarded clinically as inappropriately low.
49% developed pNa $<$ 35 mmol/l, including 14% with pNa $<$130 mmol/l. 36/49 (73.4%) developed hyponatraemia between days 1 and 3 post SAH. The median duration of hyponatraemia was 3 days (range 1–10 days).
In 35/49 (71.4%), hyponatraemia was due to SIAD as defined by standard diagnostic criteria. In 4/49 (8.2%) hyponatraemia was preceded by acute cortisol deficiency and responded to hydrocortisone treatment. Overall, 14/100 patients developed acute cortisol deficiency, of whom 4 developed hyponatraemia due to the cortisol deficiency and 1 developed hyponatraemia due to SIAD. In 5/49 (10.2%) hyponatraemia was due to volume depletion and in 5/49 hyponatraemia was due to inappropriate fluid resuscitation. There were no cases of cerebral salt wasting. Patients with SIAD had a failure of osmoregulation of AVP release, with detectable AVP levels despite hypoosmolality. Patients with SIAD had higher AVP levels than those with hyponatraemia due to acute cortisol deficiency or inappropriate fluid administration ($P=0.03$).
In the first prospective study of its kind, hyponatraemia occurs in over half of aneurysmal SAH cases, predominantly due to SIAD. Acute glucocorticoid deficiency is a infrequent but treatable cause of hyponatraemia. We found no evidence of cerebral salt wasting syndrome.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Pregnancy outcomes following cabergoline treatment in hyperprolactinemic patients: an observational survey study**

R. Auriemma, L. Grasso, A. Di Sarno, Y. Perone, R. Pivonello & A. Colao
University 'Federico II', Naples, Italy.

Cabergoline (CAB) and other dopamine agonists are usually discontinued shortly after hyperprolactinemic patients become pregnant. Data on maternal and foetal exposure to CAB and on recurrence of hyperprolactinemia after pregnancy are still limited. The current survey study aimed at elucidating the safety of exposure to CAB during early pregnancy and the recurrence rate of hyperprolactinemia after pregnancy. Thus, 68 pregnancies in a cohort of 59 patients with hyperprolactinemia (age 37.2$\pm$5.5 years), including 51 patients with prolactin-secreting microadenomas, six with macroadenomas and two with non tumoral hyperprolactinemia, were evaluated. In all patients CAB therapy was recommended to be discontinued when pregnancy was confirmed. Pregnancies were monitored until delivery or termination according to routine clinical practice. Outcomes examined include the incidence of abortions, premature delivery and foetal malformations or abnormalities, as well as the recurrence rate of hyperprolactinemia after pregnancy. Pregnancies resulted in 10 (15%) spontaneous abortions and 58 (85%) live births. No neonatal malformations and/or abnormalities were recorded in our cohort. Only in five out of 59 patients treatment with CAB had to be restarted after pregnancy because of recurrence of hyperprolactinemia, whereas in 91.5% of cases no further therapy was required and patients were classified as in complete clinical and biochemical remission at last follow-up (48 months). In conclusion, foetal exposure to CAB at the time of conception and/or during pregnancy does not induce any increase in the risk of miscarriage or malformation. CAB withdrawal does not increase the risk of recurrence of hyperprolactinemia after pregnancy and pregnancy itself seems to increase the remission rate in CAB-treated hyperprolactinemia.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Sleep apnea in acromegaly: pathogenetic factors and long-term follow up**

C. Castellani, G. Francia, M. Ferrari, E. Viva & M. Davì
Verona, Italy.

Background
Sleep apnea syndrome (SAS) is a common disease in acromegaly and it can persist during remission in up to 58% of the patients. Data regarding long term outcome of SAS in acromegalic patients are lacking. Moreover it is still unknown which component, either craniofacial deformation or soft tissue hypertrophy of the palate and upper airways, may play the major role in the pathogenesis of this complication.
Aim
To assess the presence of SAS in a series of acromegalic patients including active and controlled patients and to perform follow up in patients with SAS after biochemical control or during long-term remission. Moreover to evaluate site, degree and possible cause of upper airways obstruction by MRI and fiberoptic nasopharyngoscopy with the Muller maneuver (FNMM).
Patients and method
Polysomnography was performed in 58 acromegalic patients: 33 active and 25 controlled and was repeated in 25 patients with SAS of whom 16 after achieving biochemical control and 9 after long term remission (mean 6.6 years, S.D. $\pm$3.2). In 29 patients morphological study of the upper airways by MRI and FNMM was carried out.
Results
The prevalence of SAS was 64% in active and 52% in controlled patients. Among 16 active patients 8 (50%) showed SAS improvement and 2 (12.5%) recovered after biochemical control, whereas in 9 out of 13 (69.2%) controlled patients SAS persisted. Uvula alone or with tongue base was the main site of obstruction assessed by FNMM in 90% of patients. Uvula diameters correlated with the severity of airways narrowing at FNMM and tongue measure with the severity of the AHI.
Conclusions
SAS can improve after biochemical control of acromegaly, but can persist even after long term follow up despite recovery from acromegaly. Hypertrophy of soft palate and tongue is relevant factor responsible for occurrence and severity of SAS.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1371

**Japan National Survey of metastatic pituitary tumor: preliminary report on 164 cases**

M. Habu[3], S. YUnoue[3], S. Fujio[3], A. Shimatsu[1], A. Teramoto[2] & K. Arita[3]
[1]National Hospital Organization, Kyoto Medical Center, Kyoto, Japan; [2]Nippon Medical School, Tokyo, Japan; [3]Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan.

Background and objective
The number of reports of metastatic (secondary) pituitary tumors has been increasing with progression of diagnostic and treatment skills for cancer patients. However, there were no nation-wide epidemiologic surveys or epidemiologic reviews about this topic. We have started a multi-institutional joint research in Japan to understand clinical features of metastatic pituitary tumors.
Subjects and methods
We distributed 1069 closely-monitored questionnaires to the institutions with members of the Japan Society for Hypothalamic and Pituitary Tumor, the Japan Society of Stereotactic Radiosurgery and the Japan Endocrine Society. As of end of 2011, we have identified 164 patients with metastatic pituitary tumor treated during the period from 1996 through 2011.
Results
The patients were predominantly male (89 vs 75). The mean age of onset was 59.1 years ranging 26–86. The mean latency between the diagnosis of metastasis and the diagnosis of initial tumor was 744.5$\pm$884.4 (S.D.) days in 58 reported patients. Metastatic lesion was reported to be found earlier than the initial sites in eight

patients. The main sites of primary lesions included lung (37.8%), breast (22%), kidney (7.3%), colon (6.1%), and miscellaneous (26.8%). The frequent symptoms were diabetes insipidus (24.3%), general fatigue (24.3%) and extra-ocular muscle palsy (18.3%). 36 patients had surgery for the tumor removal (22%), 108 patients (65.9%) had stereotactic radiation, and 25 patients (14.6%) underwent conventional radiation therapy. The mean survival time was 11.6 months in total 117 reported cases, in which the 3-year survival rate was 28.3%. The median survival time tended to be longer in stereotactic radiation group than in conventional radiation group; 11.6 vs 8.8 months, but not statistically significant ($P=0.26$, Logrank)
Conclusion
The Japanese Survey for Metastatic Pituitary Tumor is accumulating data on metastatic pituitary tumor, which must be conducive for early diagnosis and proper treatment of this pathologic entity.

## P1372

**Effects of previous GH excess and current medical treatment for acromegaly on cognition**

P. Brummelman[1], J. Koerts[2], R. Dullaart[1], G. van den Berg[1], O. Tucha[2], B. Wolffenbuttel[1] & A. van Beek[1]
[1]University Medical Center Groningen, University of Groningen, Groningen, The Netherlands; [2]University of Groningen, Groningen, The Netherlands.

Context
In untreated acromegalic patients, decreased cognitive functioning is reported to be associated with the degree of GH and IGF1 excess. Whether previous GH excess or current medical treatment for acromegaly specifically affects cognition remains unclear.
Objective
To compare cognitive functioning in patients who are treated for acromegaly and non-functioning pituitary adenomas (NFA). In addition, we assessed the influence of prolonged medical treatment after initial transsphenoidal surgery (TSS) on cognition.
Methods
In this cross-sectional study 128 patients participated, who were previously treated for acromegaly ($n=50$; median (IQR) age: 53 (45–65) years) or NFA ($n=78$; age: 61 (55–70) years). In all patients, TSS was performed, followed by radiotherapy in 39%. Of the acromegalic patients, 28 had achieved cure, while 22 were still treated with long-acting somatostatin analogs and/or somavert. Memory and executive functioning were assessed by the 15 words test (15 WT) and the Ruff figural fluency test (RFFT), and reported as $z$-scores.
Results
All patient groups scored significantly poorer than the reference population on memory and executive functioning ($P<0.05$). However, cognitive test performance was not significantly different between patients with acromegaly and NFA (15 WT total memory $-0.90$ ($-1.60$; 0.05), $-0.95$ ($-1.60$; 0.13), $P=0.891$; RFFT unique designs $-0.52$ ($-1.47$; 0.30) and $-0.90$ ($-1.60$; 0.14), $P=0.232$) although acromegalic patients had a significantly higher IGF1 $z$-score mean$\pm$S.D., $0.24\pm1.02$ vs $-1.04\pm1.15$, $P<0.001$. Acromegalic patients with medical treatment at time of study had similar test results compared to patients who achieved cure for acromegaly (15 WT total memory $-0.85$ ($-1.63$; 0.23), $-0.90$ ($-1.53$; $-0.10$), $P=0.853$; RFFT unique designs $-0.83$ ($-1.51$; 0.00), $-0.29$ ($-1.42$; 0.74), $P=0.379$). The IGF1 $z$-scores between both acromegaly patient groups were comparable ($P=0.381$).
Conclusion
We found no association between previous GH excess and cognition. In addition, current medical treatment for GH excess was not related to memory and executive functioning.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Circulating total and high molecular weight adiponectin levels are lower in adult GH deficient subjects**

M. Caputo[1], F. Prodam[1], V. Garbaccio[1], M. Samà[1], M. Zavattaro[1], L. Pagano[1], P. Marzullo[1,2] & G. Aimaretti[1]
[1]University of Piemonte Orientale, Novara, Italy; [2]Reaserach Institute, Istituto Auxologico Italiano, S. Giuseppe Hospital, Piancavallo (VB), Italy.

Introduction
Regulation of adiponectin in GH deficiency (GHD), which presents visceral obesity, is still a matter of debate. No studies have evaluated circulating adiponectin isoforms in adult GHD subjects. Aim of this study was to evaluate total adiponectin (TA) and its isoforms (high molecular weight: HMW, medium molecular weight: MMW, low molecular weight: LMW) in hypopituitary adult subjects with and without GHD, in relation to weight, IGF1 and GH levels.
Methods
Cross-sectional study. 38 patients with hypothalamic-pituitary diseases (age, mean$\pm$S.E.M.: $48.8\pm3.7$ years, 13 F) and suspected of GHD were evaluated at fasting for: i) GHRH+arginine test, ii) baseline IGF1 (Immulite), TA, HMW, MMW, LMW (EIA).
Results
22/38 patients presented GHD according to BMI-dependent cut-off values. Patients with and without GHD had an overlapped BMI ($28.1\pm1.3$ vs $27.8\pm1.7$ kg/m$^2$). GHD patients showed lower TA ($5.6\pm0.9$ ng/ml) and HMW levels ($1.7\pm0.5$ ng/ml) compared to subjects without GHD (TA $9.0\pm1.4$ ng/ml, $P<0.01$; HMW: $4.6\pm1.1$ ng/ml, $P<0.004$). MMW and LMW levels showed a comparable trend, without reaching statistical significance. TA and HMW levels negatively correlated with BMI ($r$: $-0.393$, $P<0.007$, $r$: $-0.357$, $P<0.01$ respectively). HMW levels negatively correlated with GH peak ($r$: $-0.251$, $P<0.05$), even when controlled for BMI. No association was found with IGF1 levels. HMW and TA levels correlated with the GHD diagnosis, but, when controlled for BMI, the significance was maintained for HMW only ($r$: 0.290, $P<0.05$). Subjects in the lowest quartile of HMW had a low probability of not being GHD (OR 0.056, CI 95% 0.006–0.491, $P<0.01$).
Conclusions
In hypopituitary adult subject, the presence of GHD seems to be associated with reduced TA and HMW levels independently from BMI.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1375

**Quality of life and mood disturbances in patients with acromegaly followed-up in a single center**

P. Anagnostis[1], Z. Efstathiadou[1], A. Vounaki[2], C. Maria[3], D. Selalmatzidou[1], G. Gotoufa[1] & M. Kita[1]
[1]Hippokration Hospital of Thessaloniki, Thessaloniki, Greece; [2]Municipality of Pavlos Melas, Thessaloniki, Greece; [3]Aristotle University of Thessaloniki, Thessaloniki, Greece.

Introduction
Acromegaly is a chronic disease associated with impairment of quality of life (QoL) and psychological status. The aim of the present study was to assess QoL and mood disturbance in patients with acromegaly.

Description of methods/design
It was a comparative, cross-sectional study conducted in the department of Endocrinology at a tertiary medical centre of northern Greece in 2011. AcroQoL questionnaire was used to assess QoL in acromegalics and the short-form of POMS to assess psychological distress in acromegalics compared with a group of patients with other chronic disease and healthy subjects.
Results
Cronbach's alpha analysis showed high reliability of the total AcroQoL (0.887) and POMS score (0.877). Forty patients with acromegaly (15 males, mean age 57.9±12.4 years) were included. Forty patients with chronic disease and 80 healthy subjects, all age- and sex-matched were also included.
Acromegalics showed a mean AqroQoL score of 83.4±17.6 (range 34–108). Males had better QoL than females ($P=0.034$). Moreover, women suffered from more anxiety ($P=0.043$), depression ($P=0.003$), fatigue ($P=0.001$) and confusion ($P=0.007$). No association between AcroQoL and age, hypopituitarism, size of adenoma, disease remission, IGF1, basal or nadir GH levels was observed. AcroQoL scores were negatively associated with POMS subscales, including tension, depression, anger, fatigue, confusion and distress.
Regarding POMS, better scores were noticed in patients with microadenoma ($P=0.019$) and in those who had not undergone radiotherapy ($P=0.035$). Compared with healthy controls, acromegalics suffered more from depression ($P=0.027$) and hostility ($P=0.044$), associations which remained significant after adjustment for age and sex. However, compared with chronic-disease controls there were no significant differences regarding POMS scale and subscales in acromegalics.
Conclusions
Acromegaly has a negative impact on psychological distress comparable to other chronic diseases, especially in those with macroadenomas and those having undergone radiotherapy. QoL is affected more in females.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1376

**Low total cortisol correlates closely with low free cortisol in traumatic brain injury and predicts mortality and long term hypopituitarism**

M. Hannon, R. Crowley, L. Behan, E. O'Sullivan, B. Rogers, M. O'Brien, D. Rawluk, R. O'Dwyer, A. Agha & C. Thompson
Beaumont Hospital/RCSI Medical School, Dublin 9, Ireland.

Published data has demonstrated that low 0900 h plasma total cortisol (PTC) immediately following traumatic brain injury (TBI) predicts mortality. However, potential discrepancies exist between PTC and plasma free cortisol (PFC). We hypothesised that low PTC would correlate closely with PFC and predict mortality and long-term hypopituitarism.
One hundred patients (84 men, median age 33, range 18–75) with TBI (mean GCS±s.d.=8.59±4.2) were recruited. Each had PTC and CBG, albumin, electrolytes, glucose, and urine osmolality measured on days 1, 3, 5, 7, and 10 following TBI. GCS and fluid balance were recorded daily. Results were compared with 15 controls admitted to ITU following major vascular surgery. A PTC <300 nmol/l in a patient in ITU was regarded clinically as inappropriately low. PFC was calculated for 25% of TBI samples and all control samples using Coolens' equation[1]. TBI patients reattended for dynamic pituitary testing (using the insulin tolerance test unless contraindicated) ≥6 months after TBI.
All controls had PTC >300 nmol, whereas 78/100 TBI patients had at least one PTC <300 nmol/l. TBI patients in the lowest quartile of PTC had the highest mortality ($P=0.0187$). PTC correlated closely with PFC in both TBI patients ($r=0.99$, $P<0.0001$) and controls ($r=0.99$, $P<0.0001$). 40/100 developed transient cranial diabetes insipidus (CDI) and 11/100 developed persistent CDI. When compared with those who did not develop CDI, mortality was significantly higher in those with persistent CDI ($P=0.0003$) and transient CDI ($P=0.0002$). 32/79 (40.5%) of TBI survivors attended for dynamic pituitary testing. The median time to testing was 14 months (range 6–24 months). 6/32 (18.8%) were ACTH deficient, 6/32 were GH deficient, and 1/32 (3.1%) was gonadotropin deficient. No patients were TSH or prolactin deficient. Lower mean PTC was associated with the development of chronic hypopituitarism ($P=0.049$).
Acute hypocortisolaemia and acute DI are common in TBI and predict mortality. PTC measurement correlates closely with plasma free cortisol estimate. Acute hypocortisolaemia may predict long term hypopituitarism.

## P1377

**Array-comparative genomic hybridization in congenital morphological alteration of the pituitary gland**

D. Ribichini, M. Romagnoli, M. Baccini, R. Pasquali, U. Pagotto & M. Seri
S'Orsola-Malpighi Hospital, Bologna, Italy.

Congenital morphological alteration of pituitary gland is a rare disease often associated with isolated or multiple hormonal deficiency. So far only few genes have been shown to be implicated in a small number of these cases.
Aim of this study was to evaluate putative genetic alteration by an array-based comparative genomic hybridization (array-CGH) in 19 adulthood patients, 16 males and 3 females, affected by congenital morphological alteration of the pituitary.
Eleven patients were panhypopituitaric, two were affected by GH, LH–FSH and TSH deficits; two by GH and LH–FSH; one by isolated GH; one by GH, ACTH and TSH; one by GH, LH–FSH and AVP and one patient by GH and AVP. Nuclear magnetic resonance study showed an hypoplasic adenohypophysis and ectopic neurohypophysis in 16 subjects and an hypoplasic adenohypophysis associated to an undetectable neurohypophysis in three.
The array-CGH showed unbalanced chromosomal rearrangements in 6 out of 19 patients; in 4 of these 6 patients, the rearrangements were already described as normal genomic variants. In a patient we found a microdelection of chromosome 2 (del2q37.2) not yet described, but present in his healthy father. In another patient was detected an undescribed 359Kb duplication on chromosome 11 (dup11q21), containing six genes including GPR83, ANKRD49, MRE11A, expressed in central nervous system. Unfortunately we could not confirm the origin of the duplication since the parents are still not available for the analysis.
In conclusion, we confirm that hypoplasic adenohypophysis and ectopic or undetectable neurohypophysis are associated with single or multiple hormonal deficits. The CGH-array experiments were not able to detect any significant genetic alteration in our cohort, although further studies are needed to evaluate the role of dup11q21 in pituitary malformation. Our plan is to follow up this search by including new patients and by implementing the study with the exome sequencing technique.

## P1378

**Low IGF1 levels are associated with a lower prevalence and incidence of anxiety disorders in primary care patients (DETECT cohort) and the general population (SHIP cohort)**

C. Sievers[1], M. Auer[1], J. Klotsche[2], L. Pieper[2], A. Athanasoulia[1], H. Schneider[3], W. März[4,5,6], M. Nauck[7], H. Völzke[7], U. John[7], H. Freyberger[7], N. Friedrich[7], R. Biffar[7], H. Wittchen[2], G. Stalla[1], H. Wallaschofski[7] & H. Grabe[7]
[1]Max Planck Institute of Psychiatry, Munich, Germany; [2]Technische Universitaet, Dresden, Germany; [3]Ludwig-Maximilian-University, Innenstadt, Munich, Germany; [4]Synlab Medizinisches Versorgungszentrum Heidelberg GmbH, Eppelheim, Germany; [5]Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany; [6]Medical University, Graz, Austria; [7]University Medicine, Greifswald, Germany.

Objective
*In vitro* and *in vivo* models revealed that the somatotropic system exerts central effects on the central nervous system. The objective of this study was to

investigate for the first time whether varying endogenous IGF1 levels are associated with mental health outcomes, namely affective disorders, in humans.
Design and methods
We included 6773 subjects from the DETECT study, a representative study on primary care patients in Germany with a 4.5-year follow-up period and 4079 subjects from the Study of Health in Pomerania (SHIP), a population-based study with a 5-year follow-up period. Main predictor was the baseline IGF1 value categorized as <10th percentile, between the 10th and the 90th percentile (reference) and >90th percentile. Outcome measures were affective disorders.
Results
In both cohorts (DETECT and SHIP), we found a strong association in the male population with low IGF1 levels and a lower prevalence and incidence of any anxiety disorder and general anxiety disorder (GAD), respectively, in all adjusted models (DETECT; any anxiety disorder: OR 0.59; 95% CI 0.36–0.95; SHIP; GAD OR 0.57; 95% CI 0.35–0.94) compared to subjects with IGF1 levels in the normal range. In the SHIP, but not in the DETECT cohort, this association was also seen for female subjects (SHIP; GAD: OR 0.53; 95% CI 0.34–0.83).
Conclusion
Low IGF1 levels are associated with lower rates of anxiety disorders in men and possibly in women.

## P1379

**Epidemiology, histophatological characteristics and clinical manifestations of aggressive pituitary tumors, evaluated on the basis of KI-67 immunostaining: a single center experiense**

L. Grasso, M. De Angelis, C. Di Somma, C. Savanelli, M. Galdiero, A. Cozzolino, L. Cavallo, P. Cappabianca, M. Del Basso De Caro, R. Pivonello & A. Colao
Federico II University, Naples, Italy.

Aggressive pituitary tumors are classically defined as pituitary tumors with large size, rapid growth and massive invasion of surrounding anatomical structures. This is a group of pituitary tumors with biological behavior between pituitary adenomas and carcinomas and includes a new group of pituitary tumor, defined atypical adenoma, characterized by the presence of invasive growth and combination of increased mitotic activity and a Ki-67 labeling index >3%. The aim of this retrospective study was to evaluate the epidemiology, histophatological characteristic, including tumor subtype and invasion of surrounding anatomical structures, and clinical characteristics of aggressive pituitary tumors, defined on the basis of a Ki-67 labeling index >3%. The analysis was performed in a cohort of 308 patients who underwent neurosurgery for pituitary tumor between 2007 and 2011. Twenty-three patients (14 women, 9 men, aged 17–62 years, mean 40 years) were classified as patients with an aggressive pituitary tumors (prevalence = 7.5%). The Ki-67 labeling index ranged from 4 to 23% with a mean of 6.9%. Among this group of tumors, 21 (91.3%) were macroadenomas. Moreover, five (21.7%) of the aggressive pituitary tumors and 21 with pituitary adenoma (7.3%) had evidence of invasion of the surrounding anatomical structures ($\chi^2 = 5.69$, $P = 0.01$). Twelve patients (52.1%) had hormone-secreting and eleven had nonfunctional pituitary tumors (47.8%). At the immunohistochemical analysis the tumor subtype were: eight (34.7%) null-cell tumors, six (26%) PRL-secreting tumors, four (17.3%) GH-secreting tumors, three (13%) ACTH-secreting tumors and two silent FSH–LH tumors (8.6%). Based on available post-operative data, 11 out of 18 (47.8%) patients with aggressive pituitary tumors and 29 out of 130 (22.3%) patients with pituitary adenoma had evidence of recurrence ($\chi^2 = 12.07$, $P = 0.001$). In conclusion, aggressive pituitary tumors, evaluated on the basis of Ki-67, were identified in 7.5% of patients underwent neurosurgery for pituitary tumors.These tumors are mainly nonfunctional macroadenomas. The evidence of a higher rate of tumor invasiveness and recurrence suggest the Ki-67 labeling index can be considered a reliable method to individuate an aggressive pituitary tumor.

## P1380

**Congenital hypopituitarism with ectopic posterior pituitary and pulmonic stenosis: hormonal and radiologic followup into adulthood**

C. Vaz & S. Dhindsa
State University of New York, Buffalo, New York, USA.

We describe the course of a now 24y/o M with congenital hypopituitarism, severe micropenis, cryptorchidism, hypoplastic testes, hypospadiasis and pulmonic stenosis. He presented with neonatal hypoglycemia. MRI showed small anterior pituitary and ectopic posterior pituitary near tuberous cinereum. Pulmonic stenosis detected after auscultation of a murmur, was mild grade on echo. Free $T_4$ 1 ng/dl (1–2.5) TSH 6.7 μU/ml (0.2–6) glucagon stimulation for GH and cortisol were blunted at 2.9 ng/ml and <1 mg/dl respectively prolactin 3.3 ng/ml (3–14.7). He received thyroxine and hydrocortisone from infancy. Total testosterone and gondotropin were undetectable (<10 ng/dl and <3 mIU/l respectively). He received intermittent testosterone to augment penis size. Inspite of testosterone level 315–921 ng/dl (241–827) he had subnormal penis size. Height increased at constant rate until age four when it fell 2.2 S.D. below mean. GH deficiency was confirmed with flat response to arginine and dopamine, peak GH 1.8 ng/ml. GH therapy was started and he attained nl adult height. Panhypopituitarism persists into adulthood with gradual diminution of pituitary size. MRI age 24 showed small sella only containing the infundibulum. Gland itself was not visualized. Adult hormone levels are undetecetable LH and FSH, IGF 92 ng/ml (83–456) ACTH 6 pg/ml (6–50) am cortisol <0.5 mg/dl prolactin 4.7 ng/ml (2–18) TSH <0.01 mIU/l (0.4–4.5) free $T_4$ 1.6 ng/dl (0.8–1.8) testosterone 280 ng/dl (25–1100) free testosterone 30.8 pg/ml (35–155). He remains on thyroxine, hydrocortisone, testosterone and adult GH. Previous associations of multiple pituitary hormone deficiency were with septooptic dysplasia, cranial nerve and cerebral midline defects. This is the first case demonstrating the association of congenital hypopituitarism and cardiac anomaly specifically pulmonic stenosis. One should consider screening patients with congenital hypopituitarism for cardiac anomalies at birth. Congenitally low gonadotrophins tend to improve with age. Contrary to this FSH and LH remained low such that he required testosterone to treat micropenis. This case illustrates that pituitary size and function continues to decline. Congenital hypopituitarism diagnosed initially in adults has been reported. Gradual diminution of our patient's pituitary size suggests need for close follow up when no or partial hormonal abnormalities are found on initial tests.
MRI age 24.

**Childhood onset craniopharyngiomas have normal selfrating quality of life but impaired neurocognitive function in adult life**

S. Fjalldal[1], H. Holmer[2] & E. Erfurth[1]
[1]Skånes University Hospital, Lund, Sweden; [2]Central Hospital, Kristianstad, Sweden.

Introduction
Hypothalamic damage in craniopharyngiomas (CP) is associated with poor functional outcome. Data on quality of life (QoL) in CP on complete hormone replacement, including GH, is missing. The aim of this study was to assess QoL and neurocognitive function in childhood onset (CO) CP on complete hormone substitution.
Methods and design
Forty-two (20 women) patients, aged $\geq$17 years were recruited from the South Medical Region of Sweden (population 2.5 million). The patients were surgically treated for a CO CP, between 1958 and 2000. Most (86%) patients were receiving GH therapy, panhypopituitarism was present in 32 patients and 48% had received cranial radiotherapy. Three self-rating questionnaires were applied: the Symptom Checklist-90 (SCL-90), the Interview Schedule for Social Interaction (ISSI) and the social network concept. All subjects were examined with a battery of neurocognitive tests with high sensitivity for subtle brain dysfunction.
Results
No statistically significant group differences were observed across any of the nine SCL-90 subscales. The CP patients had lower performance in neurocognitive tests, reaching statistical significance in 11 of the 20 test variables, including executive function and memory. The patient group had a lower summary measure of performance ($P=0.004$) with this difference becoming insignificant when extracting patient with tumour growth towards third ventricle (TGTV; $P=0.18$). While patients with TGTV, compared to controls had significantly lower mean total score ($P=0.006$). A significant negative correlation was recorded between mean $z$ score of neurocognitive performance and years since operation ($r=-0.331$, $P=0.049$).
Conclusions
A normal QoL was shown on this first study of GH substituted adult survivors of CO CP, which mirrors an adaptation to their present situation. Lower scores of neurocognitive performance were recorded and patients with TGTV had the lowest score. Therapeutic and rehabilitative efforts are highly warranted in the follow up of CP patients.

## P1382

**Orexin A concentration is reduced in acromegaly, regardless activity of the disease**

A. Jawiarczyk & M. Bolanowski
Medical University, Wroclaw, Poland.

It has been reported that orexins play an important role in the regulation of GH secretion. It is suggested that the defect in orexins synthesis could be responsible for the disturbances in GH synthesis and consequently aggravate metabolic disturbances. The aim of the study was to assess plasma orexin A levels in patients with acromegaly in relation to the activity of disease and hormonal and metabolic profiles. Fifty-five patients with acromegaly divided into three groups accordingly to minimal GH during OGTT and IGF1 concentrations were studied: 18 with surgically cured acromegaly (SCA), 17 during treatment with a long-acting octreotide were well controlled acromegalic group (WCA), 20 ones, who did not meet the criteria for the cure or disease control, were included in the active acromegalic group (AA). Twenty-nine healthy subjects were enrolled to the control group (CG). In all subjects the concentration of orexin A, GH, IGF1, lipids, glucose, insulin, and other hormones were analyzed. Adipose tissue content was studied by the DXA method.
Results
The concentration of orexin A was the highest ($39.29\pm11.51$ pg/ml) in CG and the lowest ($26.76\pm17.17$ pg/ml) in WCA group. Orexin A concentrations were statistically significantly lower in each group of acromegalics when compared to CG. There were no differences in orexin A among the groups of acromegaly patients. The tendency to negative correlation between orexin A and GH in 0 and 60 min during OGTT was observed, it was statistically significant in AA group. In AA group orexin A concentrations correlated negatively with serum lipids. In each group of the studied patients the tendency to negative correlation between orexin A and insulin was observed. Conclusions: Orexin A concentration is reduced in patients suffering from acromegaly, regardless the activity of the disease. Orexin A deficiency may increase the metabolic abnormalities in acromegaly.

**No evidence for detrimental effect of cabergoline therapy on cardiac valves in patients with acromegaly**

L. Maione[1,2], C. Garcia[2], N. Kallel[2], A. Bouchachi[2], P. Maison[3], P. Kamenicky[1,2], S. Salenave[2], J. Young[1,2], P. Assayag[1,2] & P. Chanson[1,2]
[1]Université Paris-Sud, Le Kremlin-Bicêtre, France; [2]Assistance Publique-Hôpitaux de Paris, Hôpitaux Universitaires Paris-Sud, Le Kremlin-Bicêtre, France; [3]Assistance Publique-Hôpitaux de Paris, Hôpital Henri-Mondor, Créteil, France.

Context
The effects of cabergoline on cardiac valves have been extensively studied in Parkinson's disease and hyperprolactinemia but not in acromegaly, a condition at risk of cardiac valve abnormalities.
Objective
We examined the prevalence of heart valve disease and regurgitation in a series of patients with acromegaly treated with cabergoline, by comparison with matched patients who had never received this drug.
Design and setting
Cross-sectional study in a single referral center.
Patients and methods
Forty-two patients who had received cabergoline at a median cumulative dose of 275.6 mg for a median of 34.5 months were compared to 46 patients with acromegaly who had never received cabergoline and who were matched for age, sex and disease duration. Two-dimensional and Doppler echocardiographic findings were reviewed by two cardiologists blinded to treatment.
Results
Demographic and clinical features were not significantly different between the groups. Cabergoline was not associated with a higher prevalence of valve abnormalities. Unexpectedly, a slightly higher prevalence of aortic valve regurgitation and remodeling was found in the controls relative to the cabergoline-treated patients ($P<0.02$ and $P<0.03$ respectively) but this was likely related to the presence of an aortic dilation, more prevalent in controls. A prospective study comparing incidence of valve abnormalities in patients with acromegaly treated with cabegoline compared with acromegalics never treated with this drug is ongoing and results will soon be available.
Conclusions
Cabergoline therapy in acromegalic patients is not associated with an increased risk of cardiac valve regurgitation or remodeling.
Declaration of interest
I fully declare a conflict of interest. Details below:

## P1384

### Prevalence and incidence of pituitary adenomas; a population based study in Malta

M. Gruppetta[1,2], C. Mercieca[1] & J. Vassallo[1,2]
[1]University of Malta, Msida, Malta; [2]Mater Dei Hospital, Msida, Malta.

Context
Epidemiological data is important to correctly quantify the extent of disease and needed health care resources. There are no reports on both incidence and prevalence rates for pituitary adenomas (PAs) together in the same population.
Objective
The objective of the study was to establish the prevalence and incidence of pituitary adenomas with in-depth analysis of their various subtypes in a well defined population.
Design
This was a restrospective cross-sectional analysis of PA patients diagnosed prior to 31 July 2011 for prevalence estimates and those diagnosed between July 2000 and July 2011 for estimating incidence figures.
Methods
Prevalence rates /100 000 and standardised incidence ratios (SIR)/100 000/year were worked out.
Results
The prevalence rates for PAs overall was 75.7/100 000, for prolactinomas it was 35.0/100 000, for nonfunctioning PA 25.9/100 000 and for GH-secreting PAs it was 12.5/100 000. The SIR for PAs overall was 4.27/100 000 per year, for prolactinomas it was 2.05/100 000 per year, for nonfunctioning PA 1.79/100 000 per year and for GH-secreting PAs it was 0.31/100 000 per year. The overall prevalence for macroadenomas was 32.8/100 000 and SIR was 1.49/100 000 per year. The prevalence rate in males for PAs overall was 46.3/100 000 and SIR was 2.08/100 000 per year. For females the prevalence rate for PAs overall was 104.8/100 000 and SIR was 6.58/100 000 per year. Females had a lower proportion of macroadenomas than males (29.5 vs 75.0%; $P<0.001$) and macroadenomas tended to present at a later age compared to microadenomas (48 vs 34.5; $P<0.001$). The highest SIR was reached in the 30–39 age group at 7.42/100 000 per year. Those tumours presenting with apoplexy had a prevalence rate of 2.87/100 000 and a SIR of 0.15/100 000 per year.
Conclusion
This study brings together uptodate prevalence and incidence figures which complement each other. The quoted figures help to further quantify the extent of disease burden that PAs bear on health care resources.

## P1385

### Markers of disease activity correlate with cephalometric parameters in acromegalic patients

A. Carvalho[3], T. Pinho[3], J. Pinto[2], A. Santos[2] & D. Carvalho[1]
[1]Hospital São João-Porto, Porto, Portugal; [2]Faculty of Medicine University of Porto, Porto, Portugal; [3]CESPU-ISCS Norte, Porto, Portugal.

Introduction
Acromegaly, a rare disorder resulting of tumor GH excess, is frequently associated with prognathism and facial dysmorphia. Characteristics and mechanisms responsible for the malocclusion and the craniofacial changes in acromegalic patients (ACR) are not clarified.
Aims
To evaluate the craniofacial changes in an acromegalic group.
Methods
We observed 59 individuals, 33 with ACR and 26 controls with nonfunctioning pituitary adenomas (NFA) matched for age and sex. Craniofacial skeletal variables related to the cranial base, maxilla and jaw assessment was performed through a basic graphics program Nemoceph.
Results
The mandibular length was significantly higher in ACR ($71.8\pm6.6$ mm) than in NFA (NFA $67.4\pm5.0$ mm, $P=0.007$). We observed a significant correlation between the length of the skull base and mandibular length, both in ACR ($r=0.42$, $P=0.01$), and NFA ($r=0.46$, $P=0.01$). We found a significant correlation between GH levels and jaw length in ACR ($r=0.357$, $P=0.05$). The IGF1, expressed as % upper limit of normal, was significantly correlated with the skull and jaw length and with borderline significance with mandible length ($r=0.351$, $p<0.05$/$r=0.377$, $P=0.033$/$r=0.334$, $P=0.06$ respectively). GH levels did not correlate with other cephalometric parameters, however we observed a statistically significant relationship between the amount of IGF1 and mandibular length adjusted to delayed diagnosis. The ACR have a mean convexity smaller than ANF ($2.30\pm5.66$ vs $4.62\pm3.25$ mm, $P=0.106$), which may represent an effective growth at the level of the chin. In our study, GH hypersecretion was associated with an increase in mandibular length, probably by stimulation of growth at chin level, also considered an extremity.
Conclusion
GH and IGF1 excess induce craniofacial changes. The role of normalization of the GH/IGF1 in the reduction of these comorbidities needs to be evaluated.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1386

### Management of giant cystic invasive prolactinoma-the role of medical therapy revisited

J. Bukowczan, P. Kane & S. Nag
James Cook University Hospital, Middlesbrough, UK.

Introduction
Giant prolactinomas are uncommon tumours and typically exceed 40 mm. These tumours are locally invasive but still respond to dopamine agonist therapy. The medical management of cystic giant prolactinomas with dopamine agonists is controversial as the non-solid components of these aggressive tumours are believed to respond poorly to drug therapy. We present a case of a giant cystic invasive prolactinoma masquerading as a multilobular schwannoma that was successfully treated with cabergoline.
Case report
A 35-year-old man presented with severe headaches, left sided lancinating facial pain and bitemporal hemianopia. MRI brain revealed 52 mm large irregular mixed solid and cystic mass involving the pituitary fossa with optic chiasmal compression. MR angiography showed encasement of the internal carotid, left anterior and middle cerebral arteries. The differential diagnosis included cystic craniopharyngioma or multilobular schwannoma. Serum prolactin was markedly elevated at 87 900 mIU/l (normal: 53–360 mIU/l) and associated with hypogonadotrophic hypogonadism (serum testosterone: 3.0 nmol/l, LH 1.4 IU/l, FSH 4.3 IU/l). Thyroid, adrenal and posterior pituitary function was normal. The marked hyperprolactinaemia was suggestive of macroprolactinoma.
Cabergoline was commenced and titrated to maintenance dose of 3 mg/week which resulted in a rapid fall in serum prolactin. There was complete resolution of the visual field deficit, headaches and facial neuropathic pain in twelve weeks. Repeat pituitary MRI scanning demonstrated a progressive and dramatic reduction in the size of the pituitary mass. Nadir serum prolactin was 141 mIU/l.
Conclusion
Giant cystic prolactinomas can be locally invasive and mimic other primary intracranial neoplasms. Surgery has historically been the mainstay of treatment of cystic pituitary tumours but this case demonstrates that carefully supervised medical therapy with dopamine agonists is an effective first line option for cystic macroprolactinomas. This strategy obviates the risks of pituitary surgery with its attendant complications and risk of postoperative hypopituitarism.

## P1387

### Surveillance study on the prevalence of manifestations, complications and illness associated to acromegaly

F. Guaraldi, M. Maccario, N. Prencipe, S. Di Giacomo, V. Gasco, A. Berton, A. Mainolfi, E. Ghigo & S. Grottoli
San Giovanni Battista Hospital, Turin, Italy.

Introduction
Acromegaly is a rare disease caused by chronic exposure to excessive levels of GH, usually related to the presence of a pituitary adenoma, and associated to

somatic and visceral hypertrophy, metabolic alterations, respiratory and cardiovascular complications, and increased risk of neoplasias.
Materials and methods
The prevalence of manifestations, complications and associated illness was evaluated in 137 acromegalic subjects (52 M, 85 F; age at diagnosis mean ± S.D. 51 ± 13.4 years), diagnosed between 1980 and 2011 and followed at our Endocrinology Division, using a specific standard protocol. The study cohort included patients with active disease and cured, treated medically, surgically and/or by radiotherapy. Medical history was collected using electronic medical records and a questionnaire administered to patients.
Results
Data analysis revealed the presence of disease manifestations (carpal tunnel in about 20% of the patients, sleep apnea in 10%, thyroid nodular hyperplasia in 68%) similar to expected and a remarkable rate of complications (hypertension in 55% of the patients, cardiomegaly in 24%, alterations of glucose metabolism in 37%, alterations of lipid metabolism in 44%, decreased bone density in 37%, dolicocolon in 15%, colic diverticulosis in 20%, kidney stones in 23%, gallbladder sludge or stones in 47%) and neoplasias (114 total, mostly affecting gut and genitourinary system). Prevalence of disease manifestations and complications was higher in patients with higher mean GH and IGF1 levels (corrected for age) at diagnosis and follow up, even if the correlation did not reach statistical significance ($P > 0.005$). Prevalence of neoplasias was independent from IGF1, GH and HbA1c levels at diagnosis and follow up, and pituitary tumor size.
Conclusions
Attentive surveillance for manifestations, complications and associated diseases is fundamental at diagnosis and follow up in acromegaly patients, independently from biochemical values, with the aim to provide a prompt diagnosis and treatment.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1388

**Diabetes insipidus could be the initial sign of primary hypophysitis**

S. Suh, S. Park, J. Joung, Y. Cho, S. Jin, S. Kim, H. Kim, J. Bae, J. Kim, S. Kim, J. Chung, Y. Min, M. Lee, M. Lee & K. Kim
Samsung Medical Center, Seoul, Republic of Korea.

Introduction
The natural history of primary hypophysitis is incompletely understood and best treatment remains controversial.
Methods
We performed a retrospective study of 19 patients (mean age of 47 years, fifteen women and four men) who were diagnosed with primary hypophysitis in Samsung Medical Center in Seoul, Korea, from January 2001 to October 2011.
Results
Two patients had recent pregnancy and underlying autoimmunity. Most common clinical feature was polyuria and polydipsia (78%) and most common endocrinological finding was also diabetes insipidus (DI, 73%). The initial presumptive diagnosis was pituitary adenoma or lymphoma in eight patients (42%) and inflammatory hypophysitis in eleven (57%). The first eight patients underwent transsphenoidal surgery but only four (21%) proceeded to total tumor removal. Four patients (21%) received steroid therapy of whom one patient relapsed with pressure symptoms and later underwent surgery. Half of the patients under steroid treatment suffered from side effects such as facial swelling and body weight gain. Only one patient (25%) did not respond satisfactorily to steroid therapy and later underwent surgery. Altogether, the histological diagnoses were confirmed in nine patients, seven lymphocytic hypophysitis (77%), each one of granulomatous and xanthomatous hypophysitis (11% respectively). All patients who underwent surgery required long-term hormone replacement, three (75%) relapsed and needed additional radiotherapy or steroid therapy. Eleven (57%) patients who had no pressure or visual symptoms received only conservative management with hormone replacement (i.e. vasopressin for DI). All these eleven patients have been regularly followed up without recurrence.
Conclusion
Diabetes insipidus could be the initial sign of primary hypophysitis and controlled satisfactorily without aggressive treatment.
Follow-up status of patients with primary hypophysitis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1389

**Evaluation of metabolic parameters in patients with craniopharyngiomas using visceral adiposity index**

M. Savanelli, V. Brunelli, E. Scarano, R. Esposito, M. Rubino, P. Contaldi, S. Savastano, A. Colao & C. Di Somma
University Federico II, Napoli, Italy.

Background
Craniopharyngiomas are benign tumors of the parasellar and sellar region. Patients with craniopharyngioma, treated with surgery, have comorbidities such as obesity and multiple pituitary deficiencies.
Aim
To evaluate the metabolic parameters of patients with craniopharyngioma treated with surgery.
Methods
We recruited 20 patients with craniopharyngioma ($M = 11$, $46.6 \pm 12.6$) and 20 patients ($M = 10$, $53.5 \pm 8.8$) with non functioning adenomas (NFA) followed-up at the Department of Endocrinology of the University 'Federico II' of Naples as controls. The majority of patients have multiple pituitary deficiencies. In all patients the following parameters were assessed: blood glucose, HbA1c, insulin, total-, HDL-, and LDL-cholesterol, triglycerides and BMI. We also calculated the visceral adiposity index (VAI) that is a sex-specific mathematical index, indirectly expressing visceral adipose function and insulin sensitivity.
Results
Patients with craniopharyngioma showed lower levels of HDL ($1.14 \pm 0.24$ vs $1.40 \pm 0.28$ mmol/l, $P < 0.04$) and higher blood glucose ($93.1 \pm 9.72$ vs $85.7 \pm 9.72$ mg/dl, $P < 0.021$) compared with patients with NFA. There was no significant difference between two groups in BMI ($32.65 \pm 5.92$ vs $29.47 \pm 5.03$), total- cholesterol ($191.9 \pm 43.09$ vs $209.1 \pm 33.05$ mg/dl), LDL-cholesterol ($111 \pm 42.88$ vs $122.5 \pm 28.19$ mg/dl), triglycerides ($1.8 \pm 1.49$ vs $1.66 \pm 0.48$ mmol/l), insulin ($7.43 \pm 5.97$ vs $9.9 \pm 5.79$ ng/ml) and HbA1c ($5.55 \pm 0.5$ vs $5.55 \pm 0.8\%$). No significant difference was found in the VAI index between two groups ($2.55 \pm 2.32$ vs $2.12 \pm 0.93$; $P = 0.441$). However, VAI index was higher in craniopharyngioma ($2.55 \pm 2.32$ vs 1.92) and in NFA patients ($2.12 \pm 0.93$ vs 1.93) according with a standard population age-matched.
Finally, there are no significant differences in presence of metabolic syndrome in two groups of patients (35 vs 15%, $P = 0.27$).
Conclusions
Our study shows no significant differences in metabolic parameters between patients with craniopharyngioma and patients with NFA. However, a difference was in VAI between two groups of patients and the general population. Thus, VAI can be considered an accurate index of visceral adiposity in these patients.

## P1390

**Oxidative stress and reduced anti-oxidative status, along with endothelial dysfunction in acromegaly**

P. Anagnostis[1], Z. Efstathiadou[1], S. Gougoura[2], S. Polyzos[1], E. Karathanasi[1], P. Dritsa[2], M. Kita[1] & G. Koukoulis[2]
[1]Hippokration Hospital of Thessaloniki, Thessaloniki, Greece; [2]University of Thessaly, Biopolis, Larissa, Greece.

Introduction
Acromegaly is characterized by high cardiovascular morbidity and mortality. Oxidative stress and endothelial dysfunction are underlying mechanisms of atherosclerosis. The aim of this study was to evaluate the blood redox status and endothelial function by means of nitric oxide (NO) levels in patients with acromegaly.
Description of methods/design
Total antioxidant capacity (TAC), catalase activity and glutathione concentration (GSH), as measures of anti-oxidative capacity, total oxidized glutathione (GSSG) and thiobarbituric acid reactive substances (TBARS), as indices of oxidative stress, and NO levels were assessed in 15 patients with acromegaly (age 55.4 $\pm$2.7 years; six males) and 15 age- and sex-matched controls (age 58.4$\pm$2.1 years; seven males).
Results
Active disease was present in 12 patients: 11 on current pharmacotherapy and one newly diagnosed. Three acromegalics were in remission after successful treatment.
Compared to controls, acromegalics had significantly lower levels of catalase activity (8.2$\pm$1.5 vs 51.3$\pm$7.5 μmol/ml per min, $P<0.001$), GSH (0.97$\pm$0.14 vs 1.41$\pm$0.09 mmol/l, $P=0.006$), GSSG (0.27$\pm$0.05 vs 2.04$\pm$0.34 mmol/l, $P=0.002$) and NO levels (6.0$\pm$0.8 vs 43.0$\pm$7.7 μmol/l, $P<0.001$), but higher TBARS (16.3$\pm$2.3 vs 10.1$\pm$2.8 nmol/ml, $P=0.019$). After adjustment for confounders, differences in catalase activity, NO levels and TBARS remained significant ($P=0.004$, $P<0.001$ and $P=0.025$, respectively).
No association between IGF1/GH and oxidative stress markers was noticed, except for a positive correlation between nadir GH and GSSG ($r^2=0.563$, $P=0.036$).
Conclusion
Acromegaly is associated with increased levels of oxidative stress coupled by diminished antioxidant capacity that may be implicated.

**Evaluation of clinical presentation, treatment approach and outcome of a cohort of patients with acromegaly: a single centre experience**

S. Gouveia, I. Paiva, C. Ribeiro, A. Vieira, M. Alves, J. Saraiva, C. Moreno & M. Carvalheiro
Coimbra's University Hospital, Coimbra, Portugal.

Introduction
Acromegaly is a rare disease with a high morbidity and mortality rate.
Our aim was to characterise the population with acromegaly that is currently under supervision at our Department.
Materials and methods
We included 104 patients with acromegaly (mean age at the diagnosis 44.0 $\pm$13.0; with 71.2% females).
The referred population was analysed on what concerns disease's duration, clinical manifestations and complications, other pituitary hormone hyper/hyposecretion, adenoma size, histological type, treatment option and adverse effects.
Results
On average, these patients have been followed for 15.8$\pm$8.8 years. At diagnosis, 99% were symptomatic (86.7% with morphologic complaints). 39.1% had concomitant hyperprolactinemia and 32.6% hypopituitarism (86.7% hypogonadism, 26.7% hypothyroidism and 16.7% hypoadrenalism). At least one complication was developed in 88.3%.
A pituitary adenoma was found in 99% cases (77% macroadenomas). A familial syndrome was identified in 1.9% (one MEN1; one Carney complex).
Taking into account therapeutic options, 94.2% underwent at least one surgery (75.5% one, 19.4% two and 5.1% three surgical interventions). Regarding the first surgical approach (87.8% transsphenoidal), an adverse outcome occurred in 22.4% patients (77.3% hypopituitarism; 18.2% diabetes insipidus). Biochemical and significant size reduction was respectively achieved in 29.9 and 59.8%; the disease persisted in 40.2%. A full/partial recovery from other pituitary hormone hyper/hyposecretion was accomplished in 65.2%.
Pharmacotherapy was performed in 80.8% (9.5% as primary treatment); one third displayed a side effect.
From the 19.2% subjected to radiotherapy (85% conventional), 50% progressed to hypopituitarism.
Conclusion
In this cohort the majority of patients was symptomatic at diagnosis, revealing typical morphologic features. Furthermore, 77% had a macroadenoma, which could account for worse surgical outcome. Still, the disease is under control in 59.8% and improvement of presurgical hyperprolactinemia/hypopituitarism was noticed in 65.2% cases.
An endocrine, cardiac, respiratory, renal, gastrointestinal or osteoarticular complication was detected in 88.3% patients, decreasing their quality of life and life expectancy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Permanent panhypopituitarism is a rare complication of acute bacterial sinusitis**

A. Lavan, M. Hannon, M. O'Brien & C. Thompson
Beaumont Hospital / RCSI Medical School, Dublin 9, Ireland.

Permanent pan-anterior hypopituitarism is a rare complication of bacterial sinusitis, with only six cases reported worldwide. However, all were reported before the advent of MR imaging and most did not have what is now regarded as gold standard evaluation of pituitary function. Also, all previous cases noted an interval of months between resolution of sinusitis and development of hypopituitarism. We report two cases of previously healthy Caucasian adults who developed pan-anterior hypopituitarism immediately following acute severe bacterial sinusitis.
The first patient presented with a 2 week history of frontal headache, sinus pain and fever and a three day history of right periorbital oedema. Clinical examination revealed partial bilateral third cranial nerve palsy, right sided sixth cranial nerve palsy and bilateral palsy of the ophthalmic branch of the trigeminal nerve. CT and MR brain scanning showed severe maxillary, sphenoid and ethmoid sinusitis. MR venogram showed no cavernous sinus thrombosis. The patient had endoscopic sphenoidotomy with decompression. There was no intraoperative hypotension. Histology revealed inflammatory disease. Following discharge he felt constantly fatigued, had reduced libido and facial hair growth. An insulin tolerance test was performed indicating pan-anterior hypopituitarism. He had no symptoms of diabetes insipidus. Repeat MR scanning revealed an atrophic pituitary gland.
The second patient had a long history of chronic sinusitis. MR scanning was performed to evaluate the sinuses and brain; this revealed a 1.5 cm mass in the pituitary fossa which was thought represent a pituitary macroadenoma. No focal neurological signs were present. Trans-sphenoidal surgery was performed which revealed pus in the pituitary fossa, biopsy was performed which revealed chronic inflammatory changes on histology. Again, there was no intraoperative hypotension. Post operative insulin tolerance testing revealed pan-anterior hypopituitarism. Diabetes insipidus was not present.
Pananterior hypopituitarism is a rare complication of severe sinusitis, which should be remembered if no response is seen to standard antibiotic treatment.

## P1393

**Carboplatin is a novel cause of the syndrome of inappropriate antidiuresis**

M. O'Brien, M. Hannon, A. Lavan & C. Thompson
Beaumont Hospital/RCSI Medical School, Dublin 9, Ireland.

The syndrome of inappropriate antidiuresis (SIAD) is characterised by plasma hyponatraemia and plasma hypoosmolality with a high urinary sodium in a

clinically euvolaemic patient. We describe only the second reported case of SIAD due to carboplatin administration, with consequent acute severe hyponatraemia. A 61-year-old lady with no background history of note received neoadjuvant carboplatin and paclitaxel for stage III ovarian carcinoma. Five days after the administration of chemotherapy she developed headache, vomiting and generalised weakness. Biochemical investigation revealed a plasma sodium of 109 mmol/l, with a plasma osmolality of 235 mOsm/kg and a high urinary sodium (75 mmol/l). She was clinically euvolaemic; blood urea was 5.8 mmol/l and serum creatinine was 42 μmol/l, indicating adequate hydration status. Thyroid function was normal and 0900 serum cortisol was normal at 472 nmol/l, indicating adequate glucocorticoid reserve. After seven days of fluid restriction to 1 l/day, she made a full clinical recovery and her sodium improved to 132 mmol/l. Her chemotherapy regime was subsequently changed to cisplatin/paclitaxel with no further complications and normal plasma sodium levels.

Although cisplatin is well known to cause SIAD, this is only the second report worldwide of carboplatin induced SIAD. Patients with cisplatin induced SIAD (which is common) are often changed to carboplatin to avoid this complication; however this report shows that carboplatin can also cause severe hyponatraemia. Patients receiving carboplatin should have their plasma sodium urgently measured if they develop severe nausea, headache or altered mental status.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1394

### Evaluation of ejaculatory function in acromegalic men: preliminary study

M. Galdiero[1], P. Vitale[1], L. Grasso[1], F. Lo Calzo[1], F. Cariati[1], F. Lotti[2], M. Maggi[2], A. Colao[1] & R. Pivonello[1]
[1]'Federico II' University of Naples, Naples, Italy; [2]University of Florence, Florence, Italy.

Introduction
Acromegaly is a systemic disease frequently characterized by hypogonadotropic hypogonadism, endothelial dysfunction and diseases classically associated with an increased incidence of erectile dysfunction (ED) (hypertension, dyslipidemia, impaired glucose metabolism) and premature ejaculation (prostatic disease). Furthermore, the high prevalence of ED may negatively affect ejaculatory function. The purpose of this study was to evaluate the ejaculatory function of patients with acromegaly.
Patients and methods
Seventy-two patients (47.8 ± 8.6 years) were enrolled into the study. Among these patients, 48 were in remission (7 after surgery and 41 in medical therapy) and 26 in active disease (21 newly diagnosed and 5 in medical therapy). All patients were subjected to the questionnaire for the assessment of sexual function (IIEF-15), to a questionnaire for the detection of premature ejaculation (PEDT-premature ejaculation diagnostic tool) consisting of five questions and to a transabdominal prostatic ultrasound. Patients were divided into two groups according to normal (group A) or high (group B) levels of IGF1.
Results
ED was present in 23 of 72 patients (32%) and premature ejaculation (PE) was present in 13 patients (18%). No statistically significant difference was found between groups A and B with respect to the scores of all IIEF scales, the score of PEDT and the prevalence of erectile dysfunction and premature ejaculation (9/49 vs 4/23). The prevalence of PE in acromegalic patients with ED (4/23, 17%) was not different from that of patients without ED (9/49, 18%). The score of desire was significantly lower in patients with PE compared to patients without PE (7.6 ± 1.6 vs 6.4 ± 2, $P < 0.005$). Prostate disorders (prostatitis and hypertrophy) were observed in 50% of patients. The prevalence of PE was not significantly different between patients with and without prostatic diseases.
Conclusions
Premature ejaculation does not have a high prevalence in patients with acromegaly, despite the high presence of prostatic diseases. Further studies may clarify these observations.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1395

### Evaluation of male sexual function in active acromegalic patients and after disease remission: preliminary study

M. Galdiero[1], P. Vitale[1], L. Grasso[1], F. Lo Calzo[1], F. Cariati[1], F. Lotti[2], M. Maggi[2], A. Colao[1] & R. Pivonello[1]
[1]Federico II University of Naples, Naples, Italy; [2]University of Florence, Florence, Italy.

Introduction
Acromegaly is frequently characterized by hypogonadotropic hypogonadism, endothelial dysfunction, hypertension and impaired glucose and lipid metabolism, classically associated with impaired sexual function (SF). There are no literature data on the SF in acromegaly. The purpose of this study was to evaluate the SF of patients with acromegaly.
Patients and methods
Twenty-two patients (47.8 ± 8.6 years) were enrolled into the study. Among these patients, 48 were in remission (7 after surgery and 41 in medical therapy) and 26 in active disease (21 newly diagnosed and 5 in medical therapy). All patients were subjected to the questionnaire for the evaluation of the SF (IIEF-15), together with the evaluation of the clinical profile and of glycolipid and hormonal status. Patients were divided into two groups according to normal (group A) or high (group B) IGF1 levels.
Results
ED was found in 23 patients (32%). In particular, 15 of 49 (30.6%) patients of group A showed ED (14 with mild ED and one with moderate ED) whereas 8 of 23 (35%) patients of group B showed ED (four with mild ED and four with severe ED) ($P$ = NS). There was no significant difference in the scores of all IIEF-15 scales subjects between group A and group B. Testosterone ($P < 0.05$), 17β-oestradiol ($P < 0.005$) and LH ($P < 0.05$) levels were lower while PRL ($P < 0.05$), HbA1c ($P < 0.05$) and insulin ($P < 0.005$) levels were higher in group B than in group A. In patients with ED, BMI ($P < 0.05$) and waist circumference ($P < 0.05$) were significantly higher while the score of desire ($P < 0.001$) was significantly lower than those without ED. The score ED-IIEF correlated positively with orgasm ($P < 0.05$), desire ($P < 0.01$) and the presence of testosterone replacement therapy ($P < 0.05$) and negatively with BMI ($P < 0.05$) , PRL ($P < 0.05$), history of previous cardiovascular events ($P < 0.05$) and GH levels ($P < 0.05$). BMI was the major predictor of the score-DE of IIEF. Overall satisfaction correlated negatively with PRL ($P < 0.05$) levels and use of drugs altering sexual function ($P < 0.05$).
Conclusions
Acromegaly is associated with a high prevalence of ED that does not seem to be completely resolved by normalization of IGFI after disease remission.

## P1396

### The clinical outcome of pituitary adenomas in the cavernous sinus

C. Marathe[1,2], G. Irish[1] & D. Torpy[1,2]
[1]University of Adelaide, Adelaide, South Australia, Australia; [2]Royal Adelaide Hospital, Adelaide, South Australia, Australia.

Introduction
Pituitary adenomas with cavernous sinus involvement (CSI) are associated with serious clinical sequelae but are often incompletely excised during surgery. Contradictory viewpoints exist regarding management of residual tumors in the cavernous sinus with some authors suggesting use of adjuvant radiotherapy post-operatively for long term tumor control. But radiotherapy has been associated with hypopituitarism and increased mortality due to cerebrovascular causes. We investigated the clinical outcome of pituitary adenomas in the cavernous sinus.
Methods
Patients with pituitary adenoma and CSI (diagnosed radiologically ± surgical exploration) and subsequently managed with surgery alone (S), radiotherapy alone (R), surgery with adjuvant radiotherapy (S + R) or medical management (M) were prospectively observed for adverse clinical events. Adverse clinical events were defined as i) impingement on cranial nerves (III, IV, V1, V2 and VI) situated in the cavernous sinus and ii) increase in size of the residual tumor of more than 30%. Data are as mean ± S.D.
Results
Sixty patients (31 males, 29 females) with pituitary adenomas (31 non functioning pituitary adenoma, 16 acromegaly, 4 cushing's disease, 9 prolactinoma) with age at CSI diagnosis 51.4 ± 14.5 years, were followed up post CSI for 67.4 ± 50.1

months. Thirty-four patients were managed with S, 6 with S + R, 2 with R and 18 with M. Patients in all four groups had stable disease and no adverse clinical events were noted over this follow-up period.
Conclusion
The outcome with post-operative radiotherapy for residual pituitary adenomas was similar to management with surgery or radiotherapy alone. Moreover, medical management alone, in selected cases, also yielded similar results. From this data, it appears that risk of progression of the residual pituitary adenoma in the cavernous sinus is low and routine radiotherapy for prophylaxis in this subgroup may not be justified.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1397

**Outcome of transsphenoidal surgery for Cushing's disease dependent on tumor size: a single center experience**

C. Dimopoulou & G. Stalla
Max-Planck-Institute of Psychiatry, Munich, Germany.

Introduction
Transsphenoidal surgery (TSS) currently presents treatment of choice for Cushing's disease (CD). Dependent on tumor size, remission rates after initial TSS range from 66 to 94%. In ACTH-secreting pituitary macroadenomas, remission rates are reported to be lower. Visible adenomas on preoperative MRI or intraoperatively and neurosurgical expertise might contribute to successful TSS.
Design
A retrospective, single center analysis in 51 CD patients.
Results
All patients with ACTH-secreting pituitary micro- or macroadenomas underwent TSS as initial treatment for CD. Overall, 45.9% of the CD patients were in remission after initial TSS. In the subset of microadenomas, a remission rate of 48% was observed, followed by a lower remission rate in the group of macroadenomas (41.7%).
54.1% of the patients (52% with microadenomas, 58.3% with macroadenomas) experienced a relapse after initial TSS. Mean time until relapse was $27.58 \pm 26.00$ months. 29.7% of the patients with persistent hypercortisolism after initial TSS (28% with microadenomas, 33.3% with macroadenomas) underwent second TSS. In 17.6% of these patients, second TSS was carried out in the same neurosurgical center where initial TSS took place. After second TSS, biochemical remission of the disease was documented in 67.6% of the patients (72% with microadenomas, 58.3% with macroadenomas). A subset of patients (27%, 24% with microadenomas, 33.3% with macroadenomas) experienced a relapse after second TSS. Mean time until second relapse was shorter ($13.25 \pm 16.76$ months).
68.6 and 13.7% of the CD patients, respectively, underwent TSS in a center of neurosurgical expertise. There was no significant correlation between lack of neurosurgical expertise and relapse rate after initial or repeated TSS.
Conclusion
CD patients with macroadenomas presented with lower remission rates after initial or repeated TSS and a higher chance of experiencing a relapse postoperatively. Interestingly, lack of neurosurgical expertise did not correlate with a higher relapse rate after initial or repeated TSS.

## P1398

**Effects of medical therapy of acromegaly on glucose metabolism**

C. Urbani, A. Calevro, I. Scattina, M. Lombardi, C. Sardella, A. Nuzzo, A. Marchello, E. Martino & F. Bogazzi
University of Pisa, Pisa, Italy.

Introduction
Acromegaly is associated with alterations of glucose metabolism. The effect of somatostatin analogues (SMS) and pegvisomant (PEG) on glucose metabolism is still argument of debate.
Study design
The purpose of this historical-prospective study was to compare, in a cohort of 47 patients with active acromegaly, the effects of SMS and PEG alone or in combination on glucose metabolism. All subjects were evaluated at baseline and at least 6 months after therapy changes with fasting chemistry evaluation and OGTT. All patients were initially treated with SMS; 21 were controlled (SMS-contr); those uncontrolled received pegvisomant in combination with SMS (PEG-SMS), and, thereafter only PEG (PEG).
Results
Fasting blood glucose was higher in groups receiving SMS (SMS, SMS–PEG) than at baseline or PEG even after correction for biochemical control of disease ($P < 0.0001$). Mean glucose concentrations at OGTT's were higher in SMS groups ($P = 0.0004$; associated with a higher prevalence of IGT and DM) than in the PEG group. The insulin was reduced in all groups compared to baseline ($P < 0.05$) regardless of the type of treatment. The insulin sensitivity, reduced at baseline, improved after therapy (HOMA-IR, QUICK-I), especially in groups with biochemical disease control (SMS-cont, SMS-PEG and PEG, $P < 0.05$). Moreover, in subjects receiving SMS was observed a reduction in HOMA-$\beta$ values.
Conclusion
PEG, at variance with SMS, is not associated with changes in blood glucose levels. Either SMS or PEG therapy were associated with improvement in insulin sensitivity, probably due to the reduction in GH levels or to the reduction of its action. The deterioration in glycaemic control observed with SMS may be secondary to inhibition on direct insulin secretion as suggested by the reduction in the values of HOMA-$\beta$. In conclusion, the type of medication used in acromegaly may have a significant impact on glucose metabolism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1399

**Insulin resistance and the effect of treatment on insulin resistance in patients with prolactinoma**

S. Soytac Inancli[1], A. Usluogullari[2], Y. Ustu[2], S. Caner[2], A. Tam[2], R. Ersoy[2] & B. Cakir[2]
[1]School of Medicine, Near East University, Lefkosa, Cyprus; [2]Ankara Ataturk Education and Research Hospital, Ankara, Turkey.

Aim
The relationship between hyperprolactinoma and insulin resistance has been shown in many studies. It is also known that hyperprolactinoma causes changes in carbohydrate and lipid metabolism. The aim of our study is to evaluate insulin resistance in patients with prolactinoma and see the effect of treatment on insulin resistance and karotis intima media thickness (CIMT).
Material and methods
Twenty-two female patients diagnosed biochemically and radiographically with prolactinoma were included in the study. None of the patients were treated previously. Median age of the patients was $30.0 \pm 10.2$ years. Cabergolin was given as treatment, starting with 0.5 mg/day and tapered necessarily. Boold samples were taken for prolactin, sensitive CRP(s-CRP), homocystein, LDL-cholesterol, HOMA score, prior to treatment and 6 months after starting treatment. The body mass index (BMI) was measured and CIMT was evaluated for each patient prior to and 6 months after the treatment.
Results
The prolactin levels before and after treatment was $145.5 \pm 66.4$ and $12.4 \pm 7.2$ µg/l respectively ($P < 0.001$). This decrease was not related to the decrease in BMI($r = -0.057$, $P = 0.808$). HOMA score before and after treatment was 1.25 (0.22–4.5) and 1.02 (0.24–4.1) respectively ($P = 0.024$). This decrease was not related to the decrease in prolactin levels ($r = -0.248$ vs $P = 0.279$). Homocystein levels before and after treatment was 13.8 (7.0–28.0) and 8.5 (2.3–26.4) ($P < 0.001$) respectively. CIMT before and after treatment was $0.58 \pm 0.15$ and $0.52 \pm 0.12$ ($P < 0.05$) respectively. The decrease in CIMT was not found to be related with the decrease in prolactin levels, HOMA score and BMI ($r = 0.250$, $P = 0.274$).
Conclusion
Treatment with cabergolin causes decrease in HOMA score and decrease in CIMT after 6 months of treatment independant from the decrease in BMI.

## P1400

### Effects on GH/IGF1 hypersecretion and tumor size of long-acting somatostatin analogue (Sandostatin LAR) in patients with untreated acromegaly and in previously treated with surgery and/or radiotherapy

T Hasan[1], G Pemovska[2], B Jovanovska[2] & S Subeska[2]
[1]8th September Town Hospital, Skopje, The Former Yugoslav Republic of Macedonia; [2]Clinic of Endocrinology Metabolism and Diabetes, Skopje, The Former Yugoslav Republic of Macedonia.

Objectives
To comperate the efficacy of sandostatin LAR therapy in patients with untreated acromegaly and in previously treated with surgery and/or radiotherapy.
Material and methods
We studied 16 consecutive patients (seven women and nine men, aged 29–71 year). Fourteen patients harboured a macroadenoma and two microadenoma. The study was retrospective examination of untreated and previously treated patients with surgery and/or radiotherapy based on the macedonian acromegaly registry. Six patients had received surgery + radiotherapy and seven patients had received only surgery prior to receiving medical therapy. Three patients due to their co-morbidity were unable to receive surgery and as a primary treatment received sandostatin LAR.
Results
Sandostatine LAR was administered i.m. at a dose 20 mg every 28 days for 6 months. Three patients were inoperable due to severe LVH and received SSA as a first line therapy. This treatment induced a significant decrease of GH ($2.1 \pm 0.4$ ng/ml) and IGF1 ($156 \pm 6.2$ ng/ml) in all 16 patients. After six months of treatment, the percent IGF1 suppression was $74.1 \pm 4.5\%$ and serum GH/IGF1 values were normalized in 13 patients. Tumour shrinkage occurred in 18.7% of patients. Among 16 patients two improved glycaemic control based on fasting and postprandial plasma glucose levels.
Conclusion
OCT-LAR is an effective agent in alleviating symptoms, suppressing GH, normalizing IGF1 and inducing tumour shrinkage in many acromegalic patients. Overall, OCT-LAR is well tolerated and should be recommended for nonsurgically cured acromegalics, and also be considered as primary therapy for selected cases, mainly for those with a low probability of surgical cure.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1401

### Management of hyponatremia in the hospital: interim results from a prospective, observational, multi-center, global registry

J Haymann[1,2], J Verbalis[3], A Makin[4] & S Chase[5]
[1]UPMC et Inserm UMR_S 702, Paris, France; [2]Hôpital Tenon, Paris, France; [3]Georgetown University Medical Center, Washington, District of Columbia, USA; [4]Otsuka Pharmaceutical Europe Ltd, Uxbridge, UK; [5]Otsuka America Pharmaceutical, Inc., Rockville, Maryland, USA.

Background
Hyponatremia (HN) is the most common electrolyte disorder of hospitalized patients. It occurs in up to 28% of in-patients, is more common in the elderly and patients with multiple co-morbidities, increases the in-hospital risk of death by 1.47-fold, and is associated with significantly higher mortality risk following discharge. The HN Registry is the first large-scale, international effort to document the clinical characteristics, choice of therapies, and impact of HN in the hospital setting.
Methods
After informed consent or waiver, medical records of patients meeting the registry entry criteria, principally age >18 years and euvolemic or hypervolemic HN (serum sodium ($(Na^+)$) <130 mmol/l) were abstracted. Accrual to date is ~59% of the projected enrollment of 3500 patients. Data are summarized by sample size (*n*) and percentage (%) for categorical data, and mean and standard deviation for continuous data.
Results
A total of 812 of the 2051 patients enrolled at 215 (US = 143, EU = 72) sites between study initiation in September 2010 and December 2011 had sufficient data for analysis. The mean entry and discharge ($Na^+$) values were $126.8 \pm 7.3$ and $131.8 \pm 5.0$ mmol/l respectively for all patients and $125.9 \pm 7.6$ and $132.1 \pm 4.6$ mmol/l respectively for SIADH patients. Additional results are below.
Conclusions
These interim data suggest that initiation of tolvaptan therapy is delayed and often used as therapy after fluid restriction or saline has failed. Hypertonic saline had the highest response rate but was associated with a greater risk of overly rapid correction (>12 mmol/l in 24 h) than other therapies. Some patients received multiple therapies and are therefore represented in multiple categories, limiting between group interpretations. Additional data, including results for other pharmacologic therapies, will be reported as sufficient data becomes available for meaningful analysis. An adjudication process will be performed to eliminate patients inadvertently enrolled with hypovolemic HN.

### Cardiac magnetic resonance imaging detects myocardial fibrosis in patients with active acromegaly

J Feldkamp[1], J Reinhardt[1], S Gottschalk[1], T Rommel[1], H Gehl[1], D Buschsieweke[2] & C Stellbrink[1]
[1]Klinikum Bielefeld, Bielefeld, Germany; [2]Endocrine Practice, Guetersloh, Germany.

Background
Acromegaly affects almost all organs, including the cardiovascular system. Long-term exposure to high levels of IGH and insulin-like-growth-factor 1 (IGF1) may lead to cardiomyopathy.
Study design
Aim of our investigation was to study cardiac function in patients with active acromegaly using magnetic resonance imaging of the heart (cardiac-MRI) and echocardiography. Eleven patients with active acromegaly could be evaluated within a period of 6 months.
Results
Mean age of the patients (six woman, five men) was 51.5 years (range 23–78). As IGF1 levels have age-related normal ranges, *Z*-scores were used to compare the endocrine tumor activity. Mean IGF1 value was 416.2 ng/ml ± 228.9 with a mean *Z*-score for all patients with 2.7.
Echocardiographic evaluation revealed a hypertrophic left ventricle in five patients (45.5%) with an enlarged left atrium in six patients (54.5%). Interventicular septal thickness was enlarged in seven acromegalic patients (63.6%). Mean septal thickness was 12.5 mm (24) ±2.3 in men and 12.3 mm ±3.0 in women. Diastolic dysfunction measured by early (E) to late (A) atrial peak velocities (E/A ratio) could be seen in three patients (27.8%). Systolic left ventricular ejection fraction (LVEF) was within the low normal range (mean 57.2% ±3.6) in all but one patient.
Cardiac MRI confirmed left ventricular hypertrophy in five patients. In four patients (36.4%) a late enhancement could be found in MRI imaging as a sign of myocardial fibrosis. Intramyocardial oedema coud nor be detected. All but one patient with pathologic findings in cardio-MRI or in echocardiography had *Z*-scores for IGF1 levels above 2.2.

Conclusion
Cardio-MRI gives additional information to standard echocardiographic examinations in the cardiovascular work-up of patients with acromegaly. For the first time cardiac fibrosis could be detected in a relevant proportion of patients with acromegaly by MRI.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Pregnancies in a large cohort of patients on growth hormone replacement therapy**

G Vila[1], A. Akerblad[2], B. Biller[3], M. Koltowska-Haggstrom[2], F. Lundgren[2], M. Riedl[1] & A. Luger[1]
[1]Medical University of Vienna, Vienna, Austria; [2]Pfizer Endocrine Care, Sollentuna, Sweden; [3]Massachusetts GH and Harvard Medical School, Boston, Massachusetts, USA.

Introduction
Growth hormone replacement (GHRT) during conception and pregnancy is an off-label treatment. Reports on pregnancy outcomes in women with growth hormone deficiency (GHD) are derived from single center studies with small sample sizes and show conflicting results.
Methods/design
We evaluate pregnancies reported in the KIMS (Pfizer International Metabolic Database) patients on GHRT. KIMS includes 4651 women aged 15–50 years (followed for 19348 patient-years; median 3.10 years) and 7438 men aged above 16 years (followed for 36074 patient-years; median 3.89 years).
Results
There were 151 pregnancies reported in 131 patients of which 116 were in women (aged 22–41 years) and 15 in partners of male patients (aged 26–68 years). Only 14 women (10%) and one man had stopped GHRT before conception. Reported GHRT during pregnancy in females was as follows: continuation in 24% of the cases, withdrawal in 56% and dose reduction in 2%. Within the cohort that stopped GH during the pregnancy, 46% gave birth to healthy babies, 12% reported fetal loss, and outcome is not reported in 42% of the cases. Within the cohort that continued GH during pregnancy, 41% gave birth to healthy babies, 34% reported fetal loss, and outcome is not reported in 24% of the cases. At the time of abstract submission, birth of 82 healthy children (including twins and triplets) has been confirmed; 14 in women who continued GH during pregnancy and 6 with paternal exposure to GH.
Conclusions
In summary, here we provide the first demographic data on pregnancy rates in a large cohort of patients receiving GHRT. It appears that in the clinical practice setting, nearly all patients taking GH replacement continue treatment during the time when they seek fertility, and one-fourth continue it during pregnancy, but further data are needed and the work is ongoing.

**Pasireotide LAR vs octreotide LAR in patients with acromegaly: double-blind, crossover, extension period to a randomized, double-blind, multicenter, phase III study**

M Fleseriu[1], M Sheppard[2], M Bronstein[3], P Freda[4], F Gu[5], C Shen[6], M Gadelha[7], K Hermosillo Reséndiz[8], M Ruffin[9], Y Chen[8] & A Colao[10]
[1]Oregon Health and Science University, Portland, Oregon; [2]University of Birmingham, Edgbaston, Birmingham, UK; [3]University of São Paulo Medical School, São Paulo, Brazil; [4]Columbia University, College of Physicians and Surgeons, New York, USA; [5]Ministry of Health, Peking Union Medical College Hospital, Beijing, China; [6]National Yang-Ming University, Taipei, Taiwan; [7]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [8]Novartis Pharmaceuticals Corporation, Florham Park, New jersey, USA; [9]Novartis Pharma AG, Basel, Switzerland; [10]University of Naples 'Federico II', Naples, Italy.

Introduction
In a large, randomized, double-blind, phase III trial in patients with acromegaly, pasireotide LAR was significantly more effective than octreotide LAR at inducing GH $<$ 2.5 μg/l and normal IGF1 after 12 months of therapy (core study). The crossover phase of this trial allowed patients without full biochemical control at month 12 to switch treatments. This abstract reports the results of patients who switched therapy.
Methods
Medically-naïve patients with active acromegaly (GH $>$ 5 μg/l or GH nadir $\geq$ 1 μg/l post-OGTT, and IGF1 $>$ ULN) who were *de novo* with a visible adenoma on MRI or post-surgical, and who completed 12 months' therapy with pasireotide LAR 40–60 mg/28day or octreotide LAR 20–30 mg/28day, could enter a double-blind extension phase. Patients with GH $<$ 2.5 μg/l and normal IGF1 at month 12 could continue on their randomized therapy, whereas patients with GH $\geq$ 2.5 μg/l and/or IGF1 $>$ ULN (age and sex related) could switch treatment at month 13 to either pasireotide LAR 40 mg/28day or octreotide LAR 20 mg/28day, with dose titration allowed at 3-month intervals. Significance testing was not planned or performed during the extension phase.
Results
80.1% (141/176) and 85.7% (156/182) of pasireotide LAR and octreotide LAR recipients completed the 12-month core study. 81 patients switched to pasireotide LAR; 38 patients switched to octreotide LAR. GH $<$ 2.5 μg/l *and* normal IGF1 was achieved by 21.0% (17/81) and 2.6% (1/38) of patients 6 months after switching to pasireotide LAR and octreotide LAR, respectively; GH $<$ 2.5 μg/l was recorded in 43.2% (35/81) and 31.6% (12/38); normal IGF1 was recorded in 30.9% (25/81) and 7.9% (3/38). The most common AEs (pasireotide LAR and octreotide LAR) were hyperglycemia (25.9 and 7.9%), diarrhea (21.0 and 15.8%), nasopharyngitis (16.0 and 18.4%) and headache (18.5 and 10.5%).
Conclusions
In patients with uncontrolled acromegaly after 12 months' therapy with octreotide LAR, switching to pasireotide LAR improved biochemical control. The safety profile of pasireotide LAR was similar to that of octreotide LAR, with the exception of hyperglycemia. Pasireotide LAR may provide a pituitary-targeted alternative treatment option for patients inadequately controlled with currently available somatostatin analogues.

## P1405

**Long-term use of pasireotide in Cushing's disease: 24-month safety results from a randomized phase III study**

J Bertherat[1], W Ludlam[2], R Pivonello[3], M Maldonado[4], A Trovato[4], G Hughes[4], F Gu[5], J Schopohl[6] & L Salgado[7]
[1]Hôpital Cochin, Paris, France; [2]Swedish Neuroscience Institute, Seattle, WA; [3]University of Naples 'Federico II', Naples, Italy; [4]Novartis Pharma AG, Basel, Switzerland; [5]Ministry of Health, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China; [6]Campus Innenstadt, University of Munich, Munich, Germany; [7]Hospital das Clínicas, University of São Paulo Medical School, São Paulo, Brazil.

Introduction
Rapid and sustained decreases in UFC and significant improvements in signs and symptoms were seen in a large, randomized, 12-month phase III study of pasireotide in Cushing's disease. The safety profile of pasireotide was found to be similar to that of other somatostatin analogues, with the exception of hyperglycemia-related AEs (reported in 72.8% of patients). This abstract reports safety data from a 12-month extension to this phase III trial.
Methods
Patients with persistent/recurrent or *de novo* (if not surgical candidates) Cushing's disease and UFC levels $\geq$1.5xULN were randomized to pasireotide 600 μg ($n$=82) or 900 μg ($n$=80) sc bid. Patients who had mean UFC $\leq$ ULN or were achieving clinical benefit from pasireotide at month 12 (end of core) were eligible to enter the extension. Dose titration was permitted at the investigator's discretion (min: 300 μg sc bid; max: 1200 μg sc bid). Data on AEs were collected throughout the extension.
Results
Fifty-eight patients entered the extension phase and 19 discontinued prior to month 24. After 24 months' pasireotide treatment, UFC was decreased by a mean of 59.5% (95% CI: −68.6, −50.5). During the core and extension phases, 98.1% of patients experienced $\geq$1 AE, and 25.9% experienced $\geq$1 SAE. There were no deaths. The safety profile in the extension phase was similar to that in the core; the majority of reported AEs were mild-to-moderate GI events. During the 24-month treatment period, 40.1% and 29.6% of patients had an AE of hyperglycemia and diabetes mellitus respectively. Mean $HbA_{1c}$ increased from 5.8% at baseline to 7.2, 6.8 and 6.8% at months 12, 18 and 24 respectively. In addition to the patients who reported these events during the core study, 2 additional patients experienced

SAEs during the extension, 3 reported mild-to-moderate cholelithiasis, one reported a newly occurring QTcF >480 ms, and 2 had a >30 ms increase in QTcF. Three patients discontinued because of an AE during the extension. Further 24-month efficacy results are reported in a separate abstract (Schopohl *et al.*).
Conclusion
The long-term safety profile of pasireotide was similar to that reported following 12 months' pasireotide treatment, including the proportion of patients with hyperglycemia-related AEs. These results support the use of pasireotide as a long-term treatment for Cushing's disease.
Declaration of interest
I fully declare a conflict of interest. Details below:

## P1406

**Pasireotide treatment is associated with improvements in hypertension: 12-month results from a large phase III study in Cushing's disease**

R Pivonello[1], S Petersenn[2], J Newell-Price[3], F Gu[4], M Maldonado[5], A Trovato[5], G Hughes[5], L Salgado[6], A Lacroix[7], J Schopohl[8] & B Biller[9]
[1]University of Naples 'Federico II', Naples, Italy; [2]ENDOC Center for Endocrine Tumors, Hamburg, Germany; [3]University of Sheffield, Sheffield, UK; [4]Ministry of Health, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China; [5]Novartis Pharma AG, Basel, Switzerland; [6]Hospital das Clínicas, University of São Paulo Medical School, São Paulo, Brazil; [7]Centre hospitalier de l'Université de Montréal, Montréal, Quebec, Canada; [8]Campus Innenstadt, University of Munich, Munich, Germany; [9]Massachusetts General Hospital, Boston, Massachusetts, USA.

Introduction
Patients with Cushing's disease (CD) have an increased risk of hypertension (HTN). phase III data have shown that pasireotide leads to rapid reductions in UFC levels and significant improvements in CD symptoms. We now present further analyses of these data, evaluating the effects of pasireotide on HTN in patients with CD.
Methods
Patients with persistent/recurrent or *de novo* (if not surgical candidates) CD and UFC ≥ 1.5 times the upper limit of normal (ULN) were randomized to pasireotide 600 μg ($n=82$) or 900 μg ($n=80$) sc bid. Systolic (SBP) and diastolic blood pressure (DBP) were evaluated by single measurements at baseline ($n=162$) and month 12 ($n=78$). Baseline HTN was defined as at least one of: history of anti-HTN medications; medical history of HTN; SBP > 130 mmHg; or DBP > 90 mmHg. Addition of medications for HTN was allowed per investigator discretion.
Results
At baseline, 77.8% of patients had HTN ($n=126$), of whom 97 took anti-HTN medication during the study. Mean SBP decreased from 133.5 mmHg at baseline to 126.1 mmHg at month 12 (−6.1; 95% CI: −9.8, −2.4). Mean DBP decreased from 86.3 to 82.8 mmHg (−3.7; 95% CI: −6.2, −1.2). When stratified by UFC response, these improvements were only significant in those with UFC ≤ ULN at month 6. Significant improvements from baseline to month 12 were seen in patients with baseline HTN (SBP: −8.0 (−12.4, −3.6); DBP: −4.7 (−7.7, −1.7)). There were no significant changes in SBP or DBP in patients without baseline HTN (SBP: 0.2 (−6.1, 6.4); DBP: −0.4 (−4.6, 3.9)). Decreases in DBP tended to be larger in patients with higher baseline DBP (Fig. 1); similar trends were seen with SBP. A >5 mmHg decrease in DBP was seen in 42% (33/78) of patients at month 12. This was higher in those with baseline HTN (50% (30/60)) than in those without (17% (3/18)). Of those with baseline HTN, a >5 mmHg decrease in DBP was seen in 63% (10/16) of patients who did not take anti-HTN medication during the study and in 46% (20/44) of those who did. Adverse events of hypotension and adrenal insufficiency were reported by 11 and 9 patients, respectively; others were as expected for a somatostatin analogue, except degree of hyperglycemia.
Conclusions
In addition to rapid and sustained decreases in UFC, pasireotide treatment is associated with significant decreases in SBP and DBP in patients with CD.
Declaration of interest
I fully declare a conflict of interest. Details below:

## P1407

**GH Secretion response to triple secretagogue stimulus (ghrh, ghrelin and arginine) is gender and BMI dependent in healthy postmenopausal women and older men**

C Norman[1], D Erickson[1], J Miles[1], C Bowers[2] & J Veldhuis[1]
[1]Mayo Clinic, Rochester, Minnesota, USA; [2]Tulane University, New Orleans, Louisiana, USA.

Objective
Identify predictors of pulsatile GH secretion following a triple secretagogue stimulus (TSS, Ghrelin and GHRH preceded by an infusion of Arginine) in a cohort of healthy postmenopausal women and healthy older men.
Hypothesis
Even in older subjects, total GH secretory capacity is gender dependent.
Design
23 men and 19 women participated in 6 separate, overnight 16-h infusion sessions at Clinical Research Center. At the end of each visit, all volunteers received TSS infusion (arginine, 30 gm for 30 min IV infusion followed by GHRH and ghrelin boluses, both at 1.0 μg/kg). GH response was monitored by sampling blood (0.75 ml) every 10 min at the start of the arginine infusion and for 2 hours afterwards.
Methods
We used deconvolution analysis to characterize pulsatile GH release after triple secretagogue infusion. We analyzed time to peak, peak GH and GH mass/burst responses in both men and women by multivariate analysis, using baseline GH, gender, BMI, IGF-I, IGFBP1, and IGFBP3 as independent variables (results reported in table as mean ± SEM).
Results
Total and peak GH responses to TSS are two-fold greater in women than in men and inversely correlated with BMI in both genders (see figure).
Conclusion
Positive effect of female gender on GH secretion might reflect capability of estrogen to increase synergy between GHRH and Ghrelin and blunt inhibition by somatostatin, possibly via greater inhibitory effect of arginine on somatostatin in women. Negative effect of obesity implies reduced GHRH release and/or heightened somatostatin inhibition. These data are the first to show a major gender effect on total GH secretory capacity.

**Table 1** Basic characteristics and Results

| | Women ($n=19$) | Men (n=23) | *t*-test(p-value) |
|---|---|---|---|
| Age (years) | 64 ± 1.4 | 61 ± 1.9 | 0.210 |
| BMI (kg/m2) | 26 ± 0.7 | 28 ± 0.6 | 0.198 |
| Baseline GH (μg/L) | 0.63 ± 0.3 | 0.26 ± 0.07 | 0.155 |
| GH mass/burst (μg/L) | 209 ± 23 | 98 ± 11 | 0.001 |
| Peak GH (μg/L) | 99 ± 10 | 45 ± 4.8 | 0.001 |
| AUC (μg/L*min) | 5665 ± 581 | 2591 ± 290 | 0.001 |
| IGF-I (μg/L) | 150 ± 15 | 175 ± 15 | 0.368 |
| IGFBP1 (μg/L) | 40 ± 4 | 30 ± 3 | 0.044 |
| IGFBP3 (mg/L) | 3 ± 0.1 | 3 ± 0.2 | 0.068 |
| GH time to peak (min) | 11 ± 0.5 | 10 ± 0.5 | 0.212 |

Results analyzed by deconvolution analysis for GH pulses, stepwise regression analysis for GH response based on gender and BMI and paired t-test for basic characteristics analysis based on gender.

## P1408

### Pasireotide treatment is associated with clinically meaningful improvements in health-related quality of life in Cushing's disease: results from a large, randomized, double-blind phase III trial

S Webb[1], X Badia[2], W Zgliczynski[3], L Portocarrero-Ortiz[4], M Maldonado[5], A Trovato[5], A Forsythe[6], L Nelson[7], L McLeod[7], C De Block[8] & M Gadelha[9]
[1]Hospital Sant Pau, Universitat Autònoma de Barcelona, Barcelona, Spain; [2]IMS Health, Barcelona, Spain; [3]Centre for Postgraduate Medical Education, Warsaw, Poland; [4]National Institute of Neurology and Neurosurgery 'Manuel Velasco Suárez', Mexico City, Mexico; [5]Novartis Pharma AG, Basel, Switzerland; [6]Novartis Pharmaceuticals Corporation, Florham Park, New Jersey, USA; [7]RTI Health Solutions, Research Triangle Park, North Carolina, USA; [8]University Hospital, Antwerp, Belgium; [9]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.

Introduction
Patients with Cushing's disease have significantly impaired health-related quality of life (HRQoL). Effective treatment is needed to treat Cushing's disease and improve HRQoL; however, there are currently no approved medical treatments for Cushing's disease. The effect of pasireotide on HRQoL in patients with Cushing's disease was evaluated as part of a randomized, phase III study.
Methods
Patients with persistent/recurrent or *de novo* (if not surgical candidates) Cushing's disease and UFC levels $\geq$1.5 times the upper limit of normal (ULN) were randomized to pasireotide 600 µg ($n=82$) or 900 µg ($n=80$) SC bid. Dose titration (max: 1200 µg bid) was allowed after month 3. UFC control was defined as UFC $\leq$ ULN, partial control as UFC $>$ ULN and $\geq$50% reduction from baseline, and uncontrolled as UFC $>$ ULN and $<$50% reduction from baseline. HRQoL was assessed at baseline and months 3, 6 and 12 using the 12-item CushingQoL questionnaire. Items were scored on a 5-point scale, resulting in a score of 12 (worst) to 60 (best) standardized to 1–100. A change in CushingQoL score of $>$10.1 has been estimated to be clinically meaningful.

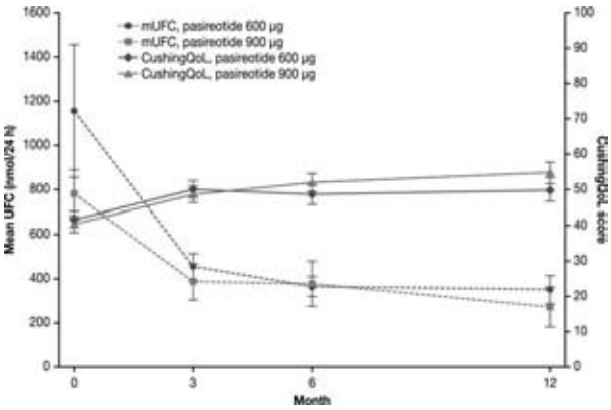

**Figure 1** Mean UFC and CushingQoL scores

Results
Overall, HRQoL increased from 41.1 at baseline ($n=159$) to 52.5 at month 12 ($n=76$) (mean increase: 11.1; 95% CI: 6.8, 15.5). In both dose groups, HRQoL improved from baseline along with rapid and sustained decreases in UFC levels (Fig.1). There was a clinically meaningful improvement in HRQoL at month 12 in patients whose UFC levels were controlled ($n=29$; mean improvement: 12.8; 95% CI: 7.1, 18.5) or partially controlled at month 6 ($n=17$; mean improvement: 10.7; 95% CI: 0.8, 20.5), but the improvement in HRQoL did not reach the 10.1 change threshold in the uncontrolled group ($n=30$; mean improvement: 9.9; 95% CI: 2.3, 17.6). The greatest HRQoL improvements ($\geq$20 points) were seen in patients with the greatest UFC decreases (from $>$10xULN to $\leq$5xULN; $n=5$). Significant correlations ($P<0.01$) were seen between changes in CushingQoL scores and changes in mean UFC ($r=-0.40$; $n=68$), BMI ($r=0.31$; $n=74$), weight ($r=0.32$; $n=74$), and Beck depression inventory score ($r=-0.59$, $n=72$).
Conclusion
Pasireotide treatment decreases UFC level and improves HRQoL. Clinically meaningful improvements in HRQoL are seen regardless of achieving fully normalized UFC.
Declaration of interest
I fully declare a conflict of interest. Details below:

## P1409

### Increased risk of hypothalamic pituitary dysfunction amongst naso-pharyngeal cancer survivors with the use of concurrent chemo-irradiation

J Ratnasingam, N Karim, S Paramasivam, A Tan Tong Boon, S Vethakkan, K Choong, R Pendek & S Chan
University Malaya, Kuala Lumpur, Malaysia.

Background
Radiotherapy is the mainstay of NPC (nasopharyngeal carcinoma) treatment and recently there is increased use of concurrent chemo-irradiation (CCRT) to improve survival. The irradiation field for NPC includes the base of skull, risking radiation damage to the hypothalamic–pituitary (HP) axis.
Aims
To evaluate the prevalence of HP dysfunction in NPC survivors post-irradiation and to compare the risk of developing HP dysfunction amongst patients who had CCRT versus radiotherapy alone.
Methods
We recruited 58 patients (33 males/25 females) with no known hormonal dysfunction, who completed radiotherapy for NPC more than 3 years ago. All patients had baseline cortisol, ACTH, GH, IGF1, $fT_4$, TSH, FSH, LH, oestradiol/testosterone and prolactin measured at 8am after an overnight fast. In addition 49 of the 58 patients underwent dynamic testing with the insulin tolerance test (ITT).
Results
All patients received a standard dose of external beam radiotherapy of 70 Gy to the posterior nasal space. 43 patients received concurrent chemo-irradiation while 15 had radiotherapy alone. Median age: 56 (48.75–63.25) years and median time post-irradiation 8 (6.0–11.25) years. Hypopituitarism was present in 84% of patients, 31% with involvement of a single axis, 29% with two axes, 18% with three axes and 6% with four axes. The prevalence of GH, corticotroph, gonadotroph, thyrotroph deficiency and hyperprolactinaemia was 80, 41, 19, 3 and 25% respectively. The development of HP dysfunction was significantly associated with the use of CCRT when compared with the radiotherapy alone group, OR: 14.57 (2.42–28.6), $P=0.01$.
Conclusion
HP dysfunction post-irradiation is widespread amongst NPC survivors with the most common being GH-deficiency. Radiation-induced damage appears to be profoundly increased with the use of radio-sensitising chemotherapy. As these endocrinopathies result in significant morbidity/mortality we recommend periodic assessment of pituitary function post-irradiation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Long-term pasireotide use leads to improvements in the biochemical parameters of Cushing's disease: 24-month results from a randomized phase III study

J Schopohl[1], J Bertherat[2], W Ludlam[3], M Maldonado[4], A Trovato[4], G Hughes[4], F Gu[5], L Salgado[6] & R Pivonello[7]
[1]Campus Innenstadt, University of Munich, Munich, Germany; [2]Hôpital Cochin, Paris, France; [3]Swedish Neuroscience Institute, Seattle, Washington, USA; [4]Novartis Pharma AG, Basel, Switzerland; [5]Ministry of Health, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences, Beijing, China; [6]Hospital das Clínicas, University of São Paulo Medical School, São Paulo, Brazil; [7]University of Naples 'Federico II', Naples, Italy.

Introduction
The large, randomized, phase III study of pasireotide in Cushing's disease found that pasireotide treatment resulted in rapid and sustained decreases in UFC levels and in significant improvements in signs and symptoms over 12 months of treatment. A 12-month extension of this trial has recently completed, and the results are reported here.
Methods
Patients with persistent/recurrent or *de novo* (if not surgical candidates) Cushing's disease and UFC levels $\geq$1.5 times the upper limit of normal (ULN) were randomized to pasireotide 600 μg ($n=82$) or 900 μg ($n=80$) SC bid. Patients who had mean UFC $\leq$ ULN at month 12 or who were achieving clinical benefit from pasireotide were eligible to enter an additional 12-month extension. Dose titration was permitted at the investigator's discretion (min: 300 μg SC bid; max: 1200 μg SC bid). UFC, serum cortisol and plasma ACTH were recorded every 3 months during the extension.
Results
Fifty-eight patients entered the extension, and only these patients are included in the analyses below. A mean decrease in UFC of 54.7% (95% CI: −71.8, −37.6) was observed from baseline to month 12, which was sustained throughout the extension phase; mean decreases of 55.7% (95% CI: −71.1, −40.3) and 59.5% (95% CI: −68.6, −50.5) were seen at months 18 and 24, respectively. Using a last observation carried forward analysis, 34.5% of patients had UFC $\leq$ ULN at month 24. A significant decrease from baseline in mean serum cortisol was observed at month 12 (−15.5%; 95% CI: −22.4; −8.6) and at month 24 (−17.8%; 95% CI: −26.9; −8.7). A similar trend was observed for plasma ACTH, with a reduction from baseline to month 12 of 16.2% (95% CI: −29.1, −3.4) and to month 24 of 13.9% (95% CI: −25.5, −2.2). Adverse events (AEs) during the extension phase were consistent with those reported during the core study and were predominantly gastrointestinal and hyperglycemia related. Further safety results are reported in a separate abstract (Bertherat *et al.*).
Conclusion
Long-term pasireotide use resulted in sustained improvements in UFC, serum cortisol and plasma ACTH over 24 months. These results support the use of pasireotide as a long-term treatment for Cushing's disease in responsive patients.

### Hyperprolactinemic patients are prone to increased protein oxidation: a risk for low grade inflammation?

I Cakir[1], G Baskol[1], G Elbuken[1], Z Karaca[1], M Mert[2], Y Simsek[1] & F Bayram[1]
[1]Erciyes University, Kayseri, Turkey; [2]Kayseri Teaching Hospital, Kayseri, Turkey.

Objective
Hyperprolactinemia is reported to be associated with impaired glucose metabolism, and low-grade inflammation. There is some data regarding increased oxidative stress- particularly protein oxidation in the conditions like metabolic syndrome or diabetes, but not in hyperprolactinemic subjects in the literature. We aimed to investigate advanced oxidation protein product (AOPP) levels-an established marker of protein oxidation and antioxidant thiol levels in hyperprolactinemic patients with prolactinomas.
Patients and Methods
Thirty- four patients (24 women and 10 men) with prolactinoma, aged 37.50 ± 10.98 years and twenty (age, gender and BMI matched) healthy volunteers as a control group were enrolled to the study. The patients with macroadenomas and mass effects were underwent to transsphenoidal adenomectomy, while the others received medical therapy with a dopamine agonistic agent- cabergoline (1–8 mg/week). AOPP and thiol levels were measured at baseline and after 3–6 months following normalisation of prolactin levels.
Results
Advanced oxidation protein product levels were higher in patients compared to healthy controls at baseline ($P=0.002$), a significant decrease was observed in patient group following prolactin normalisation. Thiol levels were found to be increased in hyperprolactinemic patients and remained higher ($P=0.016$, $P=0.008$ respectively) after treatment.
Conclusion
Our results revealed the presence of protein oxidation in hyperprolactinemic patients. We conclude that thiol levels increase to protect these patients from oxidative stres. The controlling duration may not be enough long to observe normalization of antioxidant thiol levels. Further studies are required in order to determine the role of oxidative stress in the pathogenesis of impaired glucose metabolism, and low-grade inflammation seen in hyperprolactinemic patients.
Key Words: Hyperprolactinemia, oxidative stres, AOPP, thiol.

### Fifteen years of GH replacement improves body composition and metabolic parameters

M Elbornsson, G Götherström, I Bosaeus, B Bengtsson, G Johannsson & J Svensson
Sahlgrenska University Hospital, Gothenburg, Sweden.

Objective
Few studies have determined the effects of more than 5-10 years of GH replacement in adults on body composition and metabolic parameters.
Design/Patients
In this prospective, single-center, open-label study, the effects of 15 years of GH replacement on body composition and metabolic parameters were determined in 156 hypopituitary adults (93 men) with adult onset GH deficiency (GHD). Mean age was 50.5 (range 22–74) years at study start. Body composition was measured using dual-energy X-ray absorptiometry (DXA).
Results
The mean initial GH dose of 0.55 (SEM 0.03) mg/day was gradually lowered to 0.40 (0.01) mg/day after 15 years. The mean serum insulin-like growth factor 1 (IGF1) SDS increased from −1.53 (0.10) at baseline to 0.74 (0.13) at study end ($P<0.001$ vs baseline). Body mass index (BMI) increased from 27.7 (0.4) to 28.3 (0.4) kg/m$^2$ ($P<0.01$). Lean soft tissue increased to 3% above baseline level after 15 years ($P<0.001$). Body fat decreased 9% during the first year of treatment ($P<0.001$ vs baseline), then increased and had returned to baseline level after 15 years. Total cholesterol decreased from 6.0 (0.1) to 5.5 (0.1) mmol/l and LDL cholesterol decreased from 4.0 (0.1) to 3.3 (0.1) mmol/l (both $P<0.001$ vs baseline). HDL cholesterol increased from 1.2 (0.03) to 1.4 (0.04) mmol/l ($P<0.001$ vs. baseline). There was an increase in fasting plasma-glucose from 4.4 (0.1) at baseline to 4.8 (0.1) mmol/l at study end ($P<0.001$). However, HbA1c decreased from 5.0 (0.1) % to 4.6 (0.1) % ($P<0.001$).
Conclusions
Fifteen-year GH replacement in GHD adults induced a transient decrease in body fat and sustained improvements of lean soft tissue and lipid profile. Fasting plasma glucose increased whereas HbA1c was reduced.

## P1413

**Incidence of hypogonadism and evaluation of its impact on cardiovascular risk factors and quality of life in acromegalic patients**

A Rebora, E. Nazzari, D Malpassi, S Moretti, U Goglia, M Boschetti, F Minuto & D Ferone
Department of Endocrinology, DiMI and Centre of Excellence for Biomedical Research, IRCCS Azienda Ospedaliera Universitaria San Martino - IST - Istituto Nazionale per la Ricerca sul Cancro, Genoa, Italy.

Acromegaly and hypogonadism represent independent cardiovascular risk factors, worsening either different metabolic parameters or quality of life (QoL).

In our cohort of 41 acromegalic males (20–82 years), 35 resulted affected by hypogonadotropic hypogonadism, while only six were eugonadal. Twenty-nine out 35 had low testosterone levels at diagnosis and six developed a post-surgical hypogonadism (testosterone cut-off: 350 ng/dl). Among hypogonadal subjects, only ten initiated hormone replacement therapy (HRT) while 25 do not. At diagnosis and at the last follow-up, we evaluated in the entire cohort: i) QoL by the AcroQoL questionnaire; ii) hormonal (GH, IGF1, prolactin, total testosterone) and iii) clinical and metabolic parameters (BMI, blood pressure, total cholesterol, HDL, LDL, triglycerides, fasting glucose, HbA1, uric acid). These parameters were correlated with disease control and testosterone levels at diagnosis and at the last follow-up.

Based on the latest criteria for disease control, at the last visit 28 patients were controlled, 4 uncontrolled and 9 partially controlled. As expected, IGF1 levels at the last visit were significantly lower than at diagnosis ((IGF1 SDS group 1:1.8$\pm$1.1, group 2 IGF1 SDS: $-0.9\pm1.3$ ($P<0.01$)), whereas testosterone levels were significantly increased, compared to the levels at the diagnosis, even in patients who did not underwent to HRT ($P<0.05$). AcroQol showed a corresponding score's improvement, while clinical and metabolic parameters were similar in both groups.

In conclusion, the incidence of hypogonadism in acromegalic subjects is very high at diagnosis, however, it improves significantly with disease control, independently from the therapeutic strategies. Hypogonadism may be partially related to the presence of the adenoma and improves with the treatment of the disease (improvement of testosterone levels also in subjects without HRT). Finally, the main factor that can reduce cardiovascular risk seems to be the achievement of disease control.

**GH secretory function is well preserved in surgically cured acromegalics**

K Arita[1], S Fujio[1], H Tokimura[1], R Hanaya[1], S Yunoue[1], Y Kinoshita[2] & A Tominaga[2]
[1]Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan; [2]Graduate School of Biomedical Science, Hiroshima University, Hiroshima, Japan.

Objective
To know the GH secretory function in surgically cured acromegaly and its impact on quality of life of the patients.
Subjects and methods
Sixty-seven acromegalics were judged to be surgically cured according to the Cortina consensus criteria and underwent postoperative insulin tolerance test (ITT) provoking hypoglycemia with nadir blood sugar under 50 mg/dl. All the patients underwent surgery under combined microscopic and endoscopic observation by skilled pituitary surgeons with experiences of more than 500 transsphenoidal surgeries. The incidence of GH impairment and GH deficiency (GHD) was determined based on the peak GH during ITT. QOL was evaluated by two sets of questionnaire (SF-36 and JAHQ: Japan adult hypopituitarism questionnaire) studies.
Results
The postoperative incidence of impairment of GH secretory function was 6.0% (4/67) for severe GHD; peak GH during ITT $<1.8$ ng/ml, 6.0% (4/67) for moderate GHD; 1.8 $<$ peak GH $<3.0$ ng/ml, and 13.4% (9/67) for slightly impaired GH; 3.0 $<$ peak GH $<6.0$ ng/mL. GH secretory function was perfectly preserved, peak GH $>6$ ng/mL, in 74.6% (50/67) of the subjects. Physical component of SF-36 QOL score of the patients positively correlated with peak GH during postoperative ITT. Both physical function score and social & mental QOL scores of Japan adult hypopituitarism questionnaire (JAHQ) tended to correlate with peak GH during postoperative ITT.
Conclusion
The incidence of GHD (peak GH during ITT $<3$ ng/ml) was low as 12% in our surgically cured acromegaly. The low incidence seems owing to the sophisticated surgical technique for selective adenomectomy under combined microscopic and endoscopic observation. Considering patients' QOL positively related to the peak GH during postoperative ITT, pituitary surgeon must pay further attention to preserve pituitary function during adenomectomy.

**The effect of GH replacement therapy on exercise capacity, fat mass, ectopic lipids intramyocellular and intrahepatocellular lipids and insulin resistance in hypopituitary patients with GH deficiency**

A Egger[1], S Allemann[1], C Stettler[1], P Diem[1], T Buehler[2], C Boesch[2] & E Christ[1]
[1]University Hospital of Bern, Inselspital, Bern, Switzerland; [2]University of Bern, Bern, Switzerland.

Introduction
Increased levels of ectopic lipids (IMCL and IHCL) have been related to insulin resistance. Aerobic exercise affects IMCL. GHRT is known to increase exercise capacity, insulin resistance and decrease fat mass. The effect of GHRT on ectopic lipids is not known.
Methods
Ten patients with GHD and ten sedentary control subjects (CS; matched for gender, age, BMI and waist) were recruited. $VO_{2max}$ was assessed using an exercise test on a treadmill. Insulin sensitivity was determined by a two-step hyperinsulinaemic euglycaemic clamp. By MR-imaging visceral (VAT) and subcutaneous (SCAT) fat compartments were quantified. IHCL and IMCL were measured before and after a 2-h aerobic exercise at 50–60% of $VO_{2max}$ using MR-spectroscopy. Free fatty acid concentrations (FFA) were determined during exercise. Identical investigations were performed after 6 months GHRT.
Results
Four female, 6 male GHD patients and matched CS volunteered for this study. $VO_{2max}$ tended to be reduced in GHD compared to CS and significantly increased after GHRT. Basal FFA and AUC FFA during exercise were similar in GHD, CS and following GHRT. SCAT and VAT was similar in GHD and CS. GHRT significantly decreased SCAT and VAT. Pre-exercise ectopic lipid levels were similar in CS, GHD and GHRT. 2h-aerobic exercise resulted in a significant decrease in IMCL (δ-IMCL) and increase in IHCL (δ-IHCL) in CS, GHD and GHRT. GHRT did not significantly impact on δ-IMCL and δ-IHCL. HOMA-value tended to be decreased in GHD compared with CS. GHRT resulted in a non-significant increase in HOMA. Endogenous glucose production and glucose disposal rate were similar in GHD, CS and following GHRT.
Conclusions
-GHRT results in an increase in $VO_{2max}$ and a decrease in SCAT and VAT.
-Aerobic exercise acutely impacts on ectopic lipids in GHD, CS and GHRT.
-Ectopic lipids (IMCL and IHCL) are similar in GHD, CS and following GHRT.
-GHD is not associated with insulin resistance when compared with CS matched for waist.

### Prevalence of central adrenal insufficiency during lifespan in Prader–Willi syndrome

G Grugni[1], L Beccaria[2], A Crinò[3], S Andrulli[2], M Cappa[3], C De Medici[1], S Di Candia[4], L Gargantini[5], L Iughetti[6], B Mariani[4], A Mussa[7], L Ragusa[8], A Sartorio[1], A Salvatoni[9], S Spera[3], G Chiumello[4] & A Corrias[7]
[1]Italian Auxological Institute, Research Institute, Verbania, Italy; [2]A. Manzoni Hospital, Lecco, Italy; [3]Bambino Gesù Children's Hospital, Research Institute, Rome, Italy; [4]S. Raffaele Hospital, Research Institute, Milan, Italy; [5]Treviglio Civic Hospital, Treviglio, Italy; [6]University of Modena and Reggio Emilia, Modena, Italy; [7]University of Turin, Turin, Italy; [8]Oasi Maria SS, Research Institute, Troina, Italy; [9]University of Insubria, Varese, Italy.

Introduction
The etiology of the increased mortality seen in Prader–Willi syndrome (PWS) is not completely known. In this context, it has been suggested that central adrenal insufficiency (CAI) due to hypothalamic dysfunction may be responsible for unexplained deaths. However, data on hypothalamic-pituitary–adrenal (HPA) axis in PWS are still conflicting. Because adrenal insufficiency is a life-threatening disease, its diagnosis should be precise, urgent and reliable. In this light, low dose short synachten test (LDSST) seems to be highly sensitive in the evaluation of the integrity of the HPA in patients with CAI. Aim of this study we investigated the prevalence of CAI during a LDSST in a group of children and adults with PWS.
Methods
132 subjects with genetically confirmed PWS, 66 males, were evaluated. 79 patients were younger than 18 years (PED) (mean age 7.4 + 4.8 years) whereas 53 were adults (ADU) (mean age 27.8 + 6.9 years). Baseline morning ACTH and cortisol were measured, following which, the LDSST started with the i.v. injection of 1 μg tetracosactrin. A peak cortisol response at 30 min $<$ 18.1 μg/dl was considered for diagnosing CAI.
Results
Basal ACTH and cortisol levels were 19.8 ± 11.8 ng/l (mean ± S.D.) (nv: 8; –50 ng/l) and 12.7 ± 6.2 μg/dl (nv: 5-25 μg/dl) in PED, and 22.4 ± 17 ng/l and 12.2 ± 5.1 μg/dl in ADU. The mean peak cortisol after LDSST was 27.0 + 7.5 μg/dl in PED and 22.3 + 4.9 μg/dl in ADU ($P < 0.001$). Pathological cortisol peak response to the LDSST was registered in seven PED (8.8%) and eight ADU (14.8% $P < 0.01$).
Conclusions
Our results support the view that CAI may be part of the PWS. Moreover, it seems that HPA axis gradually declines with age. On the basis of these data, we suggest to perform adrenal testing as soon as possible in all PWS. In case of normal results, further retesting should be scheduled periodically.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1417

### Limited effects of temozolomide monotherapy on aggressive pituitary tumors. -Based on our own experiences of three cases-

M Habu[1], S Yunoue[1], S Fujio[1], A Tominaga[2], Y Kinoshita[2] & K Arita[1]
[1]Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan; [2]Graduate School of Biomedical Science, Hiroshima University, Hiroshima, Japan.

Back ground
Encouraging responses of pituitary adenomas and pituitary carcinomas to temozolomide treatment have been well described and loss of immunopositivity of *O*6-methyl-guanine-DNA methyltransferase (MGMT) reportedly serves a predictor of good response. Recently some nonresponsive cases, however, also appeared. We describe here our own experiences of temozolomide treatment on three aggressive pituitary tumors.
Subjects and methods
Three pituitary tumors, a prolactin producing carcinoma, a prolactin producing atypical adenoma, and a growth hormone producing atypical adenoma were treated with 25, 3, 5 cycles, respectively, of temozolomide with dose of 200 mg/m$^2$ × 5 days/ month. The immunohistochemical expression of MGMT in these tumor specimens was also evaluated.
Results
All the patients well tolerated to the treatments and no serious adverse effects were recorded. The prolactin producing carcinoma with sparse positivity (8%) to MGMT responds well to the treatment until 19 cycles but recurred under the continuation of the treatment. But the prolactin producing atypical adenoma negative to MGMT and the growth hormone producing atypical adenoma with sparse positivity (5%) to MGMT did not show any response to the three cycle or five cycles of treatment.
Conclusion
Considering good tolerance to the regimen, and good response in at least one carcinoma case of our series, and prior encouraging reports, temozolomide treatment may be a choice for aggressive pituitary tumors resistant to multimodality of treatment. But, true response ratio of aggressive pituitary tumors to this treatment, predictive factors of response and escape from effect, and long term effect should be elucidated by prospective and longitudinal multicenter study.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1418

### The impact of long-acting somatostatin analogs treatment on glucose tolerance and insulin resistance in acromegaly.

M Stelmachowska-Banas, P Zdunowski & W Zgliczynski
Medical Centre of Postgraduate Education, Warsaw, Poland.

Introduction
Impaired glucose tolerance and insulin resistance are frequently associated with acromegaly. The aim of this study was to assess the impact of long-acting somatostatin analog treatment on glucose homeostasis in acromegalic patients.
Patients and methods
In this prospective study 16 naïve acromegalic patients (eight females, eight males; aged 51.5 ± 10.9 years) were studied before and after 3-month therapy with long-acting somatostatin analog (i.e. octreotide LAR 20 mg i.m. every 28 days). Diagnosis of active acromegaly was established on the basis of widely recognized criteria. In each patient glucose and insulin concentrations were assessed during the 75 g oral glucose tolerance test (OGTT) before and after 3 months of treatment. HbA1c levels were evaluated baseline and after 3 months of therapy. To estimate insulin sensitivity we performed hyperinsulinemic euglycemic clamp and calculated homeostasis model assessment (HOMA-IR) and quantitative insulin sensitivity check index (QUICKI).
Results
We did not found any statistically significant change in plasma glucose concentrations either fasting or during OGTT ($P > 0.05$). A significant reduction in HbA1c levels was observed (6.54 ± 1.72% vs. 6.02 ± 0.78%) after 3 months of treatment. A prominent decrease in insulin secretion during OGTT was found after octreotide LAR treatment compared to the baseline (4.4 ± 2.0 vs 12.1 ± 9.6 mIU/ml, $P < 0.001$). After 3 months of therapy there was an improvement in insulin resistance: a significant reduction in HOMA-IR (0.92 vs 2.27, $P < 0.05$) and a significant increase in QUICKI (0.39 vs 0.34, $P < 0.05$) values. In euglycemic clamp method we found a statistically significant increase in glucose disposal rate, i.e. *M* value (4.52 ± 2.34 vs. 2.37 ± 1.24 mg/kg per min).
Conclusions
We concluded that the treatment of acromegaly with octreotide LAR improve insulin sensitivity and HbA1c levels, even if it does not show any effect on glucose concentrations during OGTT.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1419

**Immunohistochemical detection of sstr2 and 5 ligand binding domains in 110 pituitary tumors**

V. Rossi[1], G. Ilardi[2], M. Massimo[2], G. Bellastella[1], D. Visconti[1], S. Staibano[2], M. Del Basso De Caro[2], C. Abbondanza[1], L. Cavallo[2], A. De Bellis[1], P. Cappabianca[2], A. Colao[2], G. De Rosa[2], A. Bellastella[1] & A. Sinisi[1]
[1]Seconda Università di Napoli, Napoli, Italy; [2]Univ. Federico II, Napoli, Italy.

Classical somatostatin analogues (SST-A), such as octreotide and lanreotide, bind mainly SSTR2 whilst the multiligand pasireotide binds with the highest affinity SSTR5. The selective immunodetection of ligand binding domain (LBD) of SSTR subtypes with specific monoclonal antibodies may be useful to explain the potential efficacy of different SSTA on pituitary tumours growth and/or secretory activity.
Patients and Methods
We applied new monoclonal antibodies (Y-SSTR MoAbs, Ypsilon biotechnology, Naples, Italy) recognizing the second extracellular loop of SSTR2 and SSTR5 for the immunohistochemical screening of SST-LBD expression in an archival series of 110 pituitary tumours: 43 PRL-secreting, 45 ACTH-secreting, 22 non secreting. We used formalin fixed/paraffine embedded tissue sections from pituitary adenomas and, as control, sections from normal tissue areas surrounding the same tumor. A standard streptavidin-biotin-labeled peroxidase immunostaining was performed. Negative controls were performed with non immune serum. The degree of immunopositivity was evaluated semi-quantitatively according to an arbitrary scale.
Results
A specific immunostaining reaction for SSTR2 was detectable in 90% of PRL-secreting tumors with medium-high intensity and in 80% of ACTH-secreting tumors with low-medium intensity. Immunostaining for SSTR5 was found in all but 2 of PRL-secreting adenomas with variable intensity from low-medium to high and in 100% of ACTH secreting adenomas with intensity from medium to high. No immunostaining for SSTR2 and SSTR5 was observed in non-secreting adenomas.
Conclusions
Y-SSTR2 and 5 MoAbs can be used to detect the presence of SST-LBD on the membrane of pituitary cells in classical paraffin embedded histological sections. The presence of SSTR LBD on adenomatous cells may address the choise of either classical or panligand SST analogues for the medical treatment of pituitary adenomas, when surgery is not indicated or fails.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1420

**Symptomatic hypotonic hyponatraemia after endoscopic transsphenoidal surgery: results from two large series**

M. Faustini-Fustini[1], M. Zoli[1], D. Mazzatenta[1], G. Frank[2], J. Kunicki[1], I. Sherry[2], B. Garni[2] & E. Laws[2]
[1]Bellaria Hosptal, Bologna, Italy; [2]Brigham & Women's Hospital, Boston, Massachusetts, USA.

Introduction
The incidence of hyponatremia as a delayed complication of transsphenoidal surgery varies widely from study to study and much of the debate has focused on the symptomatic hypotonic hyponatremia (SHH) occurring usually after discharge.
Aim/Design
We studied the incidence, risk factors, course and management of postoperative SHH in two large series of endoscopic transsphenoidal surgery (ETS) for pituitary tumors.
Results
The first series included 1199 consecutive surgical procedures carried out during the last 13 years by a single surgeon in Italy (87% adenomas, 10% craniopharyngiomas/Rathke's cleft cysts, 3% miscellaneous lesions). 103 patients were excluded on the basis of exclusion criteria (postoperative triphasic diabetes insipidus, diuretics, drug-induced SIADH, scant lab data). A total of 1096 eligible patients were identified. Of these, 50 (4.5%) developed SHH, which occurred after discharge in any patients but three. Nadir of medians of SHH (126 mmol/l) occurred on postoperative day 8. Clinical data and laboratory tests were consistent with SIADH in all the patients. Age, tumor size and tumor type did not correlate with the development of SHH. Conversely females were more likely to develop SHH than males (F/M: 2.8/1). Treatment consisted of fluid restriction in 42% and hypertonic saline in the remaining 52%. No case of osmotic demyelination syndromes occurred. The second series included 316 consecutive surgical procedures done during a 34-month period ending March 2011 by a single surgeon in USA (72.8% adenomas, 15% craniopharyngiomas/Rathke's cleft cysts, 2.8% arachnoid cysts, 9.2% miscellaneous lesions). SHH developed in 16 patients (5%). Again, clinical and laboratory data were consistent with SIADH in all the patients. Nadir of medians of SHH (123 mmol/l) occurred on postoperative day 7. The major risk factor was the presence of a macroadenoma.
Conclusion
The incidence of SHH in patients undergoing ETS was about 5% in both series, but different risk factors were identified (i.e. gender in the first series, macroadenoma in the second series). Interestingly, the incidence of SHH in this study was identical to that found in a previous study designed by one of us for the standard microscope transsphenoidal approach some years ago.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1421

**Audit of pituitary dysfunction after traumatic brain injury: caution in interpretation of glucagon stimulation test in diagnosis of GH and ACTH deficiency.**

C. Tenorio Jimenez[1], M. Niemi[1], A. Malik[1], D. Papadopoulou[1], T. Ham[1,2], D. Baxter[1,2], D. Sharp[1,2] & A. Goldstone[1,2,3]
[1]Imperial College Healthcare NHS Trust, London, UK;[2]Imperial College London, London, UK; [3]Imperial College London, Hammersmith Hospital, London UK.

Introduction
Traumatic brain injury (TBI) is the leading cause of death and disability in young adults. It is important to recognise pituitary dysfunction following TBI as it can cause significant morbidity.
Methods
179 TBI patients (137 males) age 41.0 ± 15.7 years (17.6–88.1 years) attended Charing Cross Hospital clinic (July 2009–August 2011). Median time since TBI was 0.27years (0.05–46.5 years, 26% > 1 years). 34% had an intracranial bleed and 9% needed craniotomy. 20% had an absolute contraindication for insulin tolerance testing (ITT) and 42% a relative contraindication. Glucagon stress test (GST) was performed in 135 patients to assess GH and ACTH deficiency. A cortisol < 350 nmol/L or GH < 5 μg/l was considered abnormal. To confirm deficiency, patients who failed GST had a GHRH-Arginine test (GHRH-A) to assess GH response; a Metyrapone suppression test (MST) to assess ACTH deficiency; or a water deprivation test (WDT ) to assess for diabetes insipidus.
Results
No patients had TSH deficiency (0/174) or diabetes insipidus (11/174 had normal WDT), one patient had syndrome of inappropriate ADH. Two patients had asymptomatic hyperprolactinaemia (2/169) and three had gonadotrophin deficiency (3/170). 30/135 had a GST peak cortisol < 350 nmol/l, but only 1/19 had confirmation of ACTH deficiency by failing a MST. None of the 14 patients with GST peak cortisol > 350 nmol/l failed a MST. 35/135 had a GST peak GH < 3 μg/l (25.9%) and 55/135 peak GH < 5 μg/l (40.7%), but only 3/12 failed GHRH-A. Initiation of GH replacement in appropriate patients resulted in symptomatic improvement.
Conclusions
GST has a high false positive rate in diagnosing both GH and ACTH deficiency, likely due to the low pre-test probability of true pituitary dysfunction in this group. Thus, a second confirmatory test should be performed. In our cohort, clinically significant pituitary dysfunction was confirmed in 10/174 patients (5.7%). It is important to identify these patients, as treating the hormonal dysfunction is therapeutically beneficial.

**Body composition has a higher impact on peak GH during the pyridostigmine–GHRH test than the insulin tolerance test in healthy individuals**

T. Eriksen, M. Klose & U. Feldt-Rasmussen
Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark.

Objective
To evaluate the association between body-composition and peak GH, during two standard GH stimulation tests; the pyridostigmine-GHRH (PDGHRH) test and an insulin tolerance test (ITT).
Method
83 healthy subjects (56 men), aged 18–65 years with a median BMI of 24 kg/m$^2$ (range 17–35) underwent a PDGHRH test and an ITT in random order 1 week to 1 month apart. Women had both tests performed in the same phase of their menstrual cycle. Body composition was assessed by BMI, waist circumference, waist-to-hip (W/H) ratio, total fat percent (TF%) and total (TFM) and abdominal fat mass (abdFM) assessed by dual energy X-ray absorptiometry.
Results
Peak GH was significantly higher in response to PDGHRH stimulation compared to the ITT (mean 73.8 mU/l versus 42.1 mU/l; $P < 0.0001$). Men and women had similar peak GH values during both tests ($P > 0.5$). In men peak GH in response to the PDGHRH test was negatively correlated to BMI ($r = -0.64$), waist ($r = -0.62$), W/H ($r = -0.59$), TF% ($r = -0.69$), TFM ($r = -0.69$) and abdominal fat mass ($r = -0.68$) (all $P < 0.0001$). In women similar associations were present for BMI ($r = -0.69$), TFM ($r = -0.70$) and abdFM ($r = -0.71$).
Neither men nor women demonstrated significant correlations between peak GH in response to the ITT and body-composition measures.
Conclusion
Body composition had a more prominent inhibitory effect on the results of the PDGHRH test as compared to the ITT in healthy individuals. No gender differences were observed. Measures of central adiposity were not superior to BMI in predicting peak GH in response to the PDGHRH test in healthy individuals. The GH response by ITT seems more resistant to influence from adiposity.

**Progression of acromegalic arthropathy despite long-term biochemical control: a prospective, radiological study**

K. Claessen, S. Ramautar, A. Pereira, J. Smit, F. Roelfsema, H. Romijn, H. Kroon, M. Kloppenburg & N. Biermasz
Leiden University Medical Center, Leiden, The Netherlands.

Background
Leiden University Medical Center, Leiden, The Netherlands; [2]Leiden University Medical Center, Leiden, The Netherlands; [3]Leiden University Medical Center, Leiden, The Netherlands
Background
Arthropathy is an invalidating complication of acromegaly, despite persisting biochemical disease control, which has a high impact on the quality of life (QoL). The prognosis and determinants are currently unknown.
Objectives
To investigate radiographic progression of arthropathy during 2.5-year follow-up and to assess determinants of outcome in patients with long-term well-controlled acromegaly.
Methods
Fifty-eight patients (mean age 62, women 41%) with controlled acromegaly for a mean of 17.6years were included in a prospective cohort study. 40 patients(69%) were cured by surgery and, if necessary, additional radiotherapy, 18 (31%) patients were controlled by somatostatin (SMS) analogs. Radiographic progression of joint disease was defined by the Osteoarthritis Research Society International (OARSI) classification as a one point increase in joint space narrowing (JSN) or osteophyte scores on radiographs of the hands, knees, and hips obtained at the first study visit and after 2.5 years. Potential risk factors for progression were assessed.
Results
Progression of osteophytes and JSN was observed in 72% and 74% of patients, respectively. Higher severity of radiographic arthropathy features at the first study visit was associated with more radiographic progression over 2.5years. Higher age and presence of d3-GH receptor (d3-GHR) polymorphism predisposed for osteophyte progression. Patients with biochemical control by SMS analogs had more progression of osteophytosis than surgically cured patients (OR = 18.9, $p = 0.025$), independently of age, sex, BMI, insulin-like growth factor1 (IGF1) SDS at baseline and d3-GHR. This was also evident for progression of JSN, as were higher age and higher baseline IGF1 SDS.
Conclusions
Acromegalic patients have progressive arthropathy according to both osteoarthritis (OA) features, despite long-term biochemical control. Parameters reflecting GH/IGF1 activity were associated with progressive joint disease. Remarkably, biochemical control by SMS analogs was associated with more progression than surgical cure, which may indicate insufficient GH control according to current criteria and the need of more aggressive therapy.

**Cavernous Sinus Sampling (CSS) - a specific method for localization of minute ACTH secreting adenomas in Cushing Disease (CD)**

D. Ludecke, P. van Leyen & J. Flitsch
University Hospital, Hamburg, Germany.

Introduction
Diagnosis and exact localization of minute adenomas in Cushing disease (CD) can be problematic, leading to unsuccessful trans-sphenoidal pituitary explorations (TSS). In addition to the well established inferior petrosal sinus sampling (IPS) first described in 1989, direct intraoperative cavernous sinus sampling (CSS) and in 1993, preoperative CSS with very small catheters, have been published (1,2). The experience in relatively small series had been promising, but is rarely discussed as an alternative to IPS (3). Therefore, we present our good results with CSS in a reasonably large number of CD cases.
Methods
consecutive trans-sphenoidal surgeries (1999 to 2010) in patients with CD were included in this prospective study. All had the triad of high cortisol in night salivary cortisol, dexamethasone suppression and stimulation of ACTH and cortisol after CRH. 60 patients (15%) were referred to our neuro-radiologists for CSS according to the technique of Teramoto (2). The indications for CSS were unclear endocrine tests in 7 and inconclusive high standard magnetic resonance imaging (MRI) in all 60.
Results
In two patients (3%) CSS was technically inadequate. Since the Cushing triad was positive, TSS was performed. No central-peripheral (CP) gradient was found in 7 patients with equivocal tests. In two the ectopic source was confirmed. Thus, we cannot exclude some false negative CSS as published for IPS (4, 5). From 51 patients with a clear CP gradient, the lateralisation was correct in 41 (80%). Of 6 patients with no lateralisation in CSS, four had midline, and two had bilateral adenomas. No severe complications related to CSS were encountered.
Conclusion
With CSS non-pituitary ACTH dependent Cushing could be diagnosed in 7 patients. In 92% of cases with unclear MRI, CSS was of essential help for the accurate detection of ACTH microadenomas and seems to be superior to IPS.

## P1425

**Effects of medical treatment on proliferation parameters MIB-1 and topoisomerase-II$\alpha$ in GH secreting pituitary adenomas**

S. Schlaffer[1], F. Lin[1], W. Saeger[2] & M. Buchfelder[1]
[1]University Hospital Erlangen, Erlangen, Germany; [2]Marienkrankenhaus, Hamburg, Germany.

Introduction
In this present study, we assessed the effects of the last preoperative medical treatment (dopamine-agonists, somatostatin-analogous and GH receptor

antagonists) on the proliferation parameters Ki-67 and Topoisomerase-IIα in pituitary adenomas of patients with acromegaly.
Material and methods:
We retrospectively studied the clinical characteristics, neuroimaging, histology and immuno-histochemistry (Ki-67 and topoisomerase-IIα labelling index) of 365 specimens of GH expressing pituitary adenomas collected between 2002 and 2010. According to the last medical treatments before surgery, these cases were divided into five groups: no medication, dopamine agonist, somatostatin analogues, combination of both or GH receptor antagonist.
Results:
As compared with adenomas which had no medical treatment, the group of somatostatin analogues treated tumours as well as those who have been treated with GH-receptor antagonists showed significant lower values of Ki-67- and topoisomerase-IIα -labelling index ($P<0.001$, $P=0.001$ respectively), while the other groups showed no significant difference. However, no significant correlation was found between the dosages or the duration of the medical treatment. In the group of macro- and invasive adenomas higher values of both proliferation parameters were observed as compared with microadenomas ($P<0.001$) or non-invasive adenomas ($P<0.001$, $P=0.001$ respectively).
Conclusions:
Interestingly in this analysis as well as somatostatin-analogue and GH-receptor antagonist treatment is associated with a lower proliferation profile in GH secreting adenomas instead of the supported idea that peripheral GH-receptor blockade might lead to an increased tumour proliferation. From our point of view the reduced proliferation indices in the GH receptor group is the result of the previous attempt of somatostatin-analogue treatment which failed to control GH-secretion and therefore patients were put on GH-receptor antagonists.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1426

**Comprasion of cycline D1 gene (Ccnd1) polymorphism in invasive and non-invasive prolactinomas**

S. Cander[1,2], E. Erturk[1], M. Karkucak[1], O. Oz Gul[1], T. Yakut[1], O. Unal[1], C. Ersoy[1], E. Tuncel[1] & S. Imamoglu[1]
[1]Uludag University Medicine School, Bursa, Turkey; [2]Bursa Sevket Yilmaz Education and Research Hospital, Bursa, Turkey.

Cycline D1 gene that plays a crucial role in a cell cycle, have been shown to be expressed more in nonfunctioning pituitary adenomas and functioning invasive pituitary adenomas compared to normal hypophisis tissue and noninvasive pituitary adenomas. A/G polymorphism in CyD1 gene exon 4/intron 4 regions have been demonstrated to affect clinical outcomes and survey in some tumors. Objective of this study was to investigate the effect of polymorphism of cycline D1 gene on the tumor invasiveness in prolactinomas.
A hundred and thirteen patients followed-up in the Uludag University, Department of Endocrinology and Metabolic Diseases, with the diagnosis of prolactinoma were included in the study. The patients were divided into two groups as noninvasive and invasive tumors according to radiological findings. The cyclin D1 gene A870G polymorphism was determined in all patients with PCR.
Rates of GG, GA and AA genotypes were found as 11.8, 55.9 and 32.4%; respectively, in the noninvasive group, while these rates were defined as 15.6, 44.4 and 40.0%; respectively, in the invasive group. Although the rate of AA genotype was found higher in the invasive than in the noninvasive group, the difference was not statistically significant. The rate of A allele was found as 60.3 and 62.2%, while the rate of G allele was defined as 39.7 and 37.7% in the noninvasive and invasive groups; respectively. A/G ratio in the total alleles was found as 1.52 in the noninvasive group and 1.65 in the invasive group.
Although A allele incidence was slightly higher in the invasive adenomas compared to the noninvasive adenomas, this difference also was not statistically significant. It did not affect the features of the tumor defined in the imaging findings, reveals the result of this could not be demonstrated as a factor in prognosis of the disease.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1427

**Control of GH and IGF1 in acromegaly in the UK: responses to medical treatment**

T. Howlett, D. Willis, G. Walker, J. Wass, P.. Trainer & UK National Acromegaly Register Investigators
Society for Endocrinology, Bristol, UK.

UK National Acromegaly Register collects data on real-life clinical practice in 34 centres. We analysed all GH and IGF1 data to assess adequacy of control on medical treatment (Rx) with somatostatin analogs (SMS) and dopamine agonists (DA).
Methods
All GH records (basal, profile or GTT) in database were correlated with IGF1, Rx, surgery (TSS) and radiotherapy (RT), then processed to derive summary data for each patient and each course of Rx. GH considered controlled if $\leq 2$ μg/l or $\leq 5$ mU/l.
Results
GH records identified in 2572 patients (50% ♂). 23 107 patient-years of observation. 70% patients had TSS, 45% RT; 4206 courses of Rx included SMS in 40.6% and DA 41.4% of patients. Overall control of GH and IGF1 improved with time both on and off Rx, e.g. on Rx, post-TSS + RT, GH was controlled in 18/34/60% pre1990/1990's/2000's (IGF1 –/36/52%, both –/19/40%). Table shows responses in 2000's to all Rx courses + to latest course of duration >360 days (last). Overall SMS were more effective than DA, but differences were less marked where this was last chosen treatment. Control achieved with octreotide LAR and lanreotide autogel was similar at last treatment, but review suggested that maximum effective dose was not always used. For DA, control on cabergoline in 2000's was better than on bromocriptine in 1990's, but the responsive minority who continued bromocriptine long-term in 2000's achieved better control. For both SMS and DA, % age control of GH/IGF1 worsened substantially with increasing GH levels pre-course off-Rx. Overall, control was less good in courses on Rx before TSS/RT and better in courses after TSS/RT, probably representing a lower pre-course GH.
Conclusions
GH and IGF1 control is improving with time but control of both is still only achieved on Rx in a minority of courses. SMS and DA can both achieve control in a useful proportion of patients. Unsuccessful TSS/RT may still improve responses to subsequent medical Rx.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1428

### Low tumoral mRNA IGF2 might balance the mechanism of tumorigenesis in GH-secreting adenomas

A. Diaz[1], A. Barlier[2], M. Kral[1], F. Garcia[1], A. Paes de Lima[1], M. Manavela[1], A. Enjalbert[2] & O. Bruno[1]
[1]Hospital de Clinicas, Buenos Aires University, Buenos Aires, Argentina; [2]CRN2M, UMR 7286 CNRS Aix-Marseille University, Marseille, France.

Pituitary adenomas may show alterations of PI3K/Akt pathway. IGF2, binding the IGF1-R, is able to active it. LOI of IGF2 has been implicated in the pathogenesis of many tumours. Activation of PI3K produces phosphorylation of p27 and its cytoplasmic mislocalization. Loss of nuclear p27 was associated with worse prognosis. In this study we correlated IGF2 imprinting with activation of PI3K/Akt pathway in a series of 29 somatotropinomas. After surgery, tumors were embedded in RNAlater and stored at −20 °C. Macroadenomas ($n=25$) were defined as tumors >10 mm and 18 of them as aggressive, because of cavernous and/or sphenoidal sinus invasion and/or Ki-67 ≥3%. Tumoral total RNA was isolated and RT-PCR was performed. ApaI polymorphic site in exon 9 of IGF2 was used to evaluate allelic expression. qPCR showed the tumoral expression of IGF2 normalized with β-glucuronidase (high expression: IGF2 copies/β-glu copies >2). Immunohistochemistry analysis with p-Akt (Ser 473) and p27 (C-19) antibodies was perfomed in 21 tumours. Cytoplasmic or nuclear staining was assessed as negative (negative or weak, <10% of the cells) or positive (moderate or strong). Fourteen out of 29 patients (48.2%) exhibited LOI of IGF2 in the tumour. Thirteen of 14 tumours with LOI had IGF2 <2 vs 7/15 without LOI ($P=0.009$). Seventy-six % (19/25) of macroadenomas presented IGF2 <2 vs 25% (1/4) of microadenomas ($P=0.076$). Most aggressive tumours (15/18, 83%) showed IGF2 <2, whereas 6/11 (54.5%) non-aggressive tumours had IGF2 >2 ($P=0.043$). The pattern of nuclear p27 immunostaining seemed opposed to that of cytoplasmic p-Akt ($P=0.063$). Tumors with LOI of IGF2 tended to show loss of nuclear p27 staining ($P=0.063$), without reaching statistical significance. In conclusion, LOI seems not to alter IGF2 gene expression in GH-secreting tumours. Low levels of IGF2 mRNA would be related to aggressive clinical traits, suggesting that IGF2 might counteract somatotropic tumorigenesis.

### Synergistic effects of combined stimulation with CRH + ghrelin on ACTH and cortisol responses in patients with Cushing's disease: a pilot study

D. Miljic, M. Doknic, S. Pekic, M. Stojanovic, S. Damjanovic & V. Popovic
Clinic for Endocrinology, Diabetes and Metabolic Diseases, University Clinical Center, School of Medicine University of Belgrade, Belgrade, Serbia.

Background

Several stimulatory tests for differential diagnosis of ACTH dependent Cushing's syndrome are avilable, CRH being the most valuable test in patients with Cushing's disease (CD). Exaggerated responses to ghrelin have also been shown in patients with CD mainly due to overexpression of GHS receptors on corticotrope tumor cells. However, the effects of combined stimulation with CRH + ghrelin on ACTH and cortisol secretion have not been tested before in these patients.

Objective

To compare ACTH and cortisol responses to ghrelin, CRH and CRH + ghrelin in patients with Cushing's disease.

Patients and methods

Six consequtive patients with diagnosed CD were included in the study. All patients were females, mean age 54.8 ± 16.7 years, with microadenomas on magnetic resonance imaging. Ghrelin test (1 μg/kg of body weight, i.v. bolus), CRH test (100 μg i.v. bolus) and combined CRH + ghrelin test were performed at least a week apart in random fashion. Blood was sampled at 0, 15, 30, 45, 60 and 90 min. Plasma ACTH (Cisbio Bioassays, France) and cortisol (Cisbio Bioassays, France) responses were measured and compared in all three tests. GH and prolactin (PRL) responses were also measured.

Results

Baseline mean ACTH and cortisol values were 31.5 ± 32.9 pg/ml and 562.5 ± 257.4 nmol/l respectively. No significant differences were found between peak ACTH and cortisol responses during ghrelin (ACTH 200.5 ± 344.9 pg/ml, cortisol 846.2 ± 351.9 nmol/l) and CRH stimulation (ACTH 90.7 ± 72.2 pg/ml and cortisol 1070.9 ± 141.9 nmol/l). However, significantly higher peak ACTH (359.6 ± 593 pg/ml, $P<0.05$) and cortisol (1312.8 ± 117.1 nmol/l, $P<0.05$) responses were found after combined stimulation with CRH + ghrelin compared to CRH test alone, suggesting a synergistic effect. Significant mean GH (peak 13 ng/ml) and PRL (peak 909.6 mU/l) responses were also noted after stimulation with CRH + ghrelin.

Conclusion

Combined stimulation with CRH + ghrelin exerts synergistic effect on ACTH and cortisol release in patients with CD. Combined stimulation with CRH + ghrelin is more powerful test than CRH alone.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1430

### Bone turnover in patients with active acromegaly in relation to glucose metabolism

S. Pekic Djurdjevic[1,2], D. Miljic[1,2], M. Stojanovic[1], M. Doknic[1,2], V. Jeremic[3], M. Jovanovic[3] & V. Popovic[1,2]
[1]Clinic for Endocrinology, University Clinical Center, Belgrade, Serbia; [2]School of Medicine, University of Belgrade, Belgrade, Serbia; [3]Faculty of Organizational Sciences, University of Belgrade, Belgrade, Serbia.

Objective

There is a complex cross-talk between bone and glucose metabolism. The surrogate markers of bone metabolism are osteocalcin (for bone formation) and CTx (for bone resorption). The osteoblast-derived protein osteocalcin has recently been shown to affect glucose homeostasis.

Aim of the study

To investigate the relationship between markers of bone metabolism and parameters reflecting bone composition, glucose homeostasis and insulin resistance in patients with chronic GH and IGF1 excess.

Patients

Twenty-three patients with active acromegaly were studied (11 males, age: 50.6 ± 3.4 years, BMI: 26.7 ± 0.9 kg/m$^2$, duration of disease 5.3 ± 0.6 years, IGF1 735 ± 46 ng/ml, GH level 15 ± 3 μg/l). Seven patients had microadenoma. Five patients were operated, one was treated with radiotherapy and none with somatostatin analogue. Eight patients had T2DM.

Methods

At baseline glucose, insulin, GH, IGF1, osteocalcin and CTx were measured. In nondiabetic patients an oral glucose tolerance test (OGTT) was performed. Peak and area under the curve (AUC) for glucose and insulin, indexes of basal insulin resistance (HOMA-IR) and basal insulin secretion (HOMA-%B) were analyzed. Body composition (body fat, lean body mass) was analyzed using dual-energy X-ray absorptiometry.

Results

In patients with active acromegaly both serum osteocalcin (49.9 ± 7.1 ng/ml) and CTx (1072 ± 139 pg/ml),as well as HOMA-IR (5.6 ± 0.6) were significantly increased,irrespective they had or did not have T2DM. HOMA-%B was significantly lower in diabetic patients (56.7 ± 30.6) compared with nondiabetic patients (137.4 ± 25.9; $P=0.05$). Osteocalcin positively correlated with CTx ($R=0.928$, $P=0.0001$). Osteocalcin and CTx inversely correlated with BMI ($P=0.01$) and CTx inversely correlated with percentage of fat mass ($R=-0.473$, $P=0.05$). Both bone markers correlated positively with IGF1 ($P=0.01$). Osteocalcin positively correlated with peak insulin during OGTT ($R=0.643$, $P=0.018$) and with AUCOGTT insulin ($R=0.522$, $P=0.05$).Bone markers were not associated with HOMA-IR, HOMA-%B or lean mass.

Conclusion

Active acromegaly is associated with high bone turnover. Serum osteocalcin is positively associated with IGF1 and insulin during OGTT. It is tempting to speculate that insulin and IGF1 promote osteocalcin production which in turn may act to improve glucose metabolism by stimulating beta cell secretion.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1431

**Relationship between gsp mutations and clinico-pathological features in GH producing pituitary adenomas**

K. Arita[1], Y. Bakhtiar[1], S. Yunoue[1], M. Habu[1], A. Tominaga[2], H. Hirano[2], J. Yasufuku-Takano[3] & K. Takano[3]
[1]Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan; [2]Graduate School of Biomedical Science, Hiroshima University, Hiroshima, Japan; [3]Faculty of Medicine, University of Tokyo, Tokyo, Japan.

Purpose
To know the relationship between gsp mutations and clinico-pathological features in GH producing pituitary adenomas.
Subjects and methods
Somatotropinomas resected from 43 acromegalic patients, 18 males and 25 females, were examined for gsp mutation analysis. The mutation was detected in 25 of 43 (58.1%) tumours with alternations of Arg to Cys in codon 201 (68%), Arg to Ser in codon 201 (8%), Gln to Leu in codon 227 (20%) and Gln to Arg in codon 227 (4%).
Results
Incidence of gsp mutation tended to be higher in non-dot pattern (or densely granulated) adenomas (66.7%) than in dot in cytokeratin staining pattern (or sparsely granulated) adenomas (38.5%) ($P=0.083$). The tumour size was significantly smaller ($P=0.006$) and the GH-producing index was significantly larger ($P=0.007$) in adenoma with gsp mutations than those without gsp mutations. While all tumours with the mutation manifested an abnormal response to TRH challenge, this was the case in 50% of adenomae without gsp mutations ($P=0.001$). The ratio of abnormal response to LHRH also tended to be higher in adenoma with gsp mutations ($P=0.095$) We observed a good response to octreotide in 44.4% of adenoma with gsp mutations and in 18.2% of tumours without the mutation; the difference was not significant ($P=0.217$), possibly due to small sample size of cases who underwent octreotide test ($n=20$). The other clinico-pathological features (including age, sex, basal GH level and MIB-1 index) of the 43 patients were not significantly different, irrespective of their mutation status.
Conclusion
The existence of gsp mutation relates well to clinico-pathlogic features of growth hormone producing adenomas such as cytokeratin staining pattern, tumor size, and response to challenge test with TRH or LHRH.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1432

**Decreased IGF1 levels and GH-resistant hepatic state to estrogens during the first trimester of pregnancy in non-acromegalic women**

M. Persechini[1], I. Gennero[2], S. Grunenwald[1], D. Vezzosi[1], A. Bennet[1] & P. Caron[1]
[1]CHU Larrey, Toulouse, France; [2]CHU Purpan, Toulouse, France.

Introduction
In women with GH-secreting pituitary adenoma, a decrease of IGF1 levels has been reported during the first trimester of pregnancy, before placental GH (pGH) secretion inducing a progressive increase in IGF1 levels throughout gestation. This decrease has been related to hepatic GH-resistant state, via JAK2/STAT pathway, due to increased estrogen ($E_2$) levels.
Objectives
Evaluate IGF1 change in non-acromegalic women during the first trimester of pregnancy.
Patients and methods
Nine women (mean age $30.7\pm3.9$ years) were seen before and during pregnancy in the follow-up of benign thyroid disease. Plasma IGF1, GH, IGF-BP3, TSH and $E_2$ levels were measured before conception and during the first trimester of gestation ($6.7\pm1.5$ weeks of amenorrhea) before the onset of pGH secretion.
Results
Before conception, all women had normal GH/IGF1 secretion and euthyroid function tests (TSH before $=1.89\pm0.95$, 1st trimester $=1.79\pm1.17$ mU/l). During pregnancy, mean IGF1 levels decreased (before $=186\pm51$ ng/ml, 1st trimester $=141\pm44$ ng/ml, $P<0.05$) without significant change in GH (before $=2.03\pm2.01$ ng/ml, 1st trimester $=1.54\pm2.34$ ng/ml) or IGF-BP3 (before $=2.30\pm0.32$ ng/ml, 1st trimester $=2.07\pm0.31$ ng/ml) levels while $E_2$ levels increased (before $=56\pm35$ pg/100 ml, 1st trimester $=675\pm820$ pg/100 ml, $P<0.05$).
Conclusion
In this preliminary study we report a significant IGF1 decrease without change in GH and IGF-BP3 concentrations during the first trimester of pregnancy in non acromegalic women. Therefore, as previously reported in acromegalic women, the results suggest the existence of a GH-resistant state due to physiological $E_2$ secretion in normal pregnant women.

**Coexistence of macroprolactinaemia and hyperprolactinaemia in women with oligo-/amenorrhoea is associated with high risk of pituitary adenomas**

D. Gasior-Perczak[1], K. Lewandowski[2], A. Kowalska[1] & A. Lewinski[2]
[1]Hollycross Cancer Centre, Kielce, Poland; [2]'Polish Mother' Memorial Research Institute, Lodz, Poland.

Background
The so called 'big-big' prolactin, also known as macroprolactin is formed by prolactin-immunoglobulin complexes, is considered to be biologically inactive, but may cause elevation of serum prolactin (Prl) concentrations measured by standard assays. In women presenting with oligo- and/or amenorrhoea the cause of menstrual irregularity needs to be explained even in the setting of concomitant macroprolactinaemia. We have therefore attempted to assess the prevalence of pituitary pathology in women with macroprolactinaemia and oligo-/amenorrhoea.
Material and methods
We performed pituitary MRI scans in 60 women with oligo- and/or secondary amenorrhoea aged $31.0\pm6.7$ years (mean $\pm$ S.D.), range 18–45 years who were found to have raised Prl concentrations due to macroprolactinaemia, detected by the polyethylene glycol (PEG) precipitation method.
Results
After PEG precipitation of macroprolactin, 'free' Prl concentrations were still raised (i.e. above 530 mIU/l) in 35 (58%) women with macroprolactinaemia. Furthermore, pituitary microadenomas were detected in 9/60 (15%) and pituitary macroadenomas in 3/60 (5%) of women with macroprolactinaemia and oligo-/amenorrhoea. In all of these cases there was a concomitant elevation of 'free' Prl after PEG precipitation. The highest value of 'free' Prl was in a case of microadenoma (total Prl 19207 mIU/l, 'free' Prl after PEG precipitation 7738 mIU/l), while in the case of macroadenoma the highest concentration of 'free' Prl was 2798 mIU/l (total Prl 7441 mIU/l before PEG precipitation). Hence, in case of coexistence of macroprolactinaemia and raised 'free' Prl after PEG precipitation of macroprolactin, the chance of finding of either a micro- or a macroadenoma was as high as 34% (12 cases out of 35).
Conclusions
Hyperprolactinaemia and macroprolactinaemia may coexist in the same patient. If 'free' prolactin is still raised after PEG precipitation of macroprolactin, then the chance of finding of a pituitary micro- or macroadenoma in women with oligo-/amenorrhoea is about 30%. Therefore pituitary magnetic resonance imaging is mandatory in all such cases.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1434

### Mortality rates in childhood and adult onset GH deficient patients enrolled in the Global Hypopituitary Control and Complications Study (HypoCCS)

H. Jung[1], A. Zimmermann[2], D. Mo[2], L. Robison[3], E. Erfurth[4], S. Melmed[5], S. Lamberts[6] & A. Attanasio[7]
[1]Eli Lilly and Company, Bad Homburg, Germany; [2]Eli Lilly and Company, Indianapolis, Indina, USA; [3]St. Jude Children's Research Hospital, Memphis, TN; [4]SUS, Lund University, Lund, Sweden; [5]Cedars-Sinai Medical Center, Los Angeles, California, USA; [6]Erasmus Medical Center Rotterdam, Rotterdam, The Netherlands; [7]Cascina del Rosone, Agliano Terme, Italy.

Preliminary data suggested an increased mortality in a French cohort after childhood somatropin treatment compared to the French reference population[1]. This cohort included patients (pts) with idiopathic-isolated GH-deficiency (GHD), and a similar cohort is also under follow-up for adult GH-replacement in HypoCCS.

We therefore assessed all-cause mortality rates (*n*/1000 person-years (PY), (95% CI), standardized to the age/gender structure of HypoCCS or the general population) in 7946 GH-replaced adult HypoCCS pts with available post-baseline information. Overall standardized (general population) mortality rate was 5.8 (4.3, 7.2) in the US HypoCCS cohort compared to 7.6/1000 PY in the US general population[2], and 5.2 (4.4, 6.1) in Europe, the rate in comparable populations ranging from 5.1/1000 PY in Italy to 6.4/1000 PY in Belgium[3]. As shown in the table, mortality rates were not different between onset-types overall and for non-idiopathic GHD, but were lower in childhood onset (CO) compared to adult onset (AO) pts with idiopathic GHD replaced with GH.

Of a total of 174 deaths, 14 occurred in CO pts and only in the non-idiopathic GHD group (acute illness/suicide (7), second/recurrent neoplasm (2), cerebral hemorrhage/carotid artery stenosis (2) or unknown reason (3)).

Although the Carel *et al*. study[1] raises the important question of increased adult mortality after somatropin treatment in childhood, the present analysis does not confirm an increased mortality in GH-replaced adult pts, either with CO or AO GHD, compared to reference populations. However, the present results are limited by selection bias and relatively short follow-up time.

### Experience in the use of tolvaptan in patients with syndrome of inappropriate antidiuretic hormone secretion (SIADH)

M. Mijares Zamuner, M. Sanchez-Pacheco, Tardón, J. Serrano Gotarredona, O. Moreno Perez, G. Negueruela Avellá, R. Cerezo Vidal, R. Sanchez Ortiga & A. Picó Alfonso
Hospital General Universitario de Alicante, Alicante, Spain.

Introduction

Hyponatremia is the most common electrolyte disorder in hospitalized patients. SIADH is characterized by euvolemic hyponatremia with sodium and urine osmolality inappropriately high. The selective antagonist of the vasopressin V2 receptor (tolvaptan) helps to eliminate water free of solute (aquaresis), being effective in treating this condition.

Objetive

Evaluate the efficacy and safety of tolvaptan in the treatment of SIADH.

Subjects and methods

Prospective observational study, sequential sampling of 9 patients with SIADH treated with tolvaptan. We evaluated causes associated with SIADH, clinical manifestations of hyponatremia, changes in plasma sodium during use of tolvaptan. Descriptive statistics, median (P25–P75) (SPSS 11.0).

Results

Age 65 (53–78) years, 33% male, 33% asymptomatic. Main symptoms: somnolence (50%), nausea (37%), disorientation (37%), headache (37%), lethargy (25%), visual hallucinations (12%). Causes associated with SIADH: cancer (3), hip surgery (1), brain pathology: subarachnoid hemorrhage (1), basilar artery acute thrombosis (1), pituitary surgery (1), meningioma surgery (1), transverse myelitis (1). Center protocol: indication of tolvaptan in patients with SIADH that do not improve with fluid restriction and sodium intake (i.v./oral), analytical control at 8 and 24 h, if rise $>8$ mEq (8 h) and $>12$ mEq (24 h) did not repeat new dose, indicated monitoring. Starting dose was 15 mg, increased to 30 mg in four patients and 45 mg in two. The duration of treatment was 17 (5–40) days, except for two patients who continues to this day. Plasma sodium value for initiation of tolvaptan 127 (122–127) mEq/l. Changes in sodium: 131 (122–132) ($n=7$) in the first 8 h, 132 (127–135) ($n=9$) at 24 h and 131 (130–133) ($n=8$) in the 48 h. One patient gained 15 mEq/l at 12 h and another reached 14 mEq/l in 24 h, in the last two patients discontinued treatment had to be reset by further decline. One patient was administered a single dose.

Conclusion

Treatment with tolvaptan in patients with SIADH is a safe and effective treatment, determining a progressive slow-rising serum sodium.

## P1436

### Blast concussion is associated with high frequency of pituitary dysfunction

C. Wilkinson[1,2], K. Pagulayan[1,2], E. Colasurdo[1], J. Shofer[2] & E. Peskind[1,2]
[1]VA Puget Sound Health Care System, Seattle, Washington, USA; [2]University of Washington, Seattle, Washington, USA.

Introduction

Studies of traumatic brain injury from all causes have found evidence of chronic hypopituitarism, defined by deficient production of one or more pituitary hormones at least 1 year after injury, in 25–50% of cases. Most studies found the occurrence of posttraumatic hypopituitarism (PTHP) to be unrelated to injury severity. Growth hormone deficiency (GHD) and hypogonadism were reported most frequently. Hypopituitarism, and in particular adult GHD, is associated with symptoms that resemble those of PTSD, including fatigue, anxiety, depression, irritability, insomnia, sexual dysfunction, cognitive deficiencies, and decreased quality of life. However, the prevalence of chronic PTHP after blast-related concussion, or mild TBI (mTBI), an extremely common injury in modern military operations, has not been characterized.

Design

We measured concentrations of 12 pituitary and target-organ hormones in two groups of male US Veterans of combat in Iraq or Afghanistan. One group consisted of participants with blast-related mTBI whose last blast exposure was at least 1 year prior to the study. The other consisted of Veterans with similar military deployment histories but without blast exposure.

Results

In total, 11 of 26, or 42% of participants with blast concussions were found to have abnormal hormone levels in one or more pituitary axes, a prevalence similar to that after other types of TBI. Five members of the mTBI group were found with markedly low age-adjusted IGFI levels indicative of probable GHD, and three had testosterone and gonadotropin concentrations consistent with hypogonadism. Five of the blast concussion group exhibited abnormal vasopressin and/or oxytocin levels suggestive of posterior pituitary dysfunction. Indications of dysfunction in multiple hormonal axes were observed in five Veterans with mTBI. None of the deployment control subjects exhibited any hormonal abnormalities.

Conclusion

Blast mTBI is associated with a high frequency of PTHP. If symptoms characteristic of both PTHP and PTSD can be linked to pituitary dysfunction, they may be amenable to treatment with hormone replacement. Routine screening for

chronic hypopituitarism after blast concussion shows promise for appropriately directing diagnostic and therapeutic decisions that otherwise may remain unconsidered and for markedly facilitating recovery and rehabilitation.

**Efficacy of transsphenoidal surgery for Cushing's disease: the role of combined dexamethasone desmopressin test**

P. Witek[1,2], P. Glinicki[2], K. Szamotulska[3] & G. Zielinski[1]
[1]Military Institute of Medicine, Warsaw, Poland; [2]The Medical Centre of Postgraduate Education, Warsaw, Poland; [3]Institute of Mother and Child, Warsaw, Poland.

Introduction
The treatment of choice in Cushing's disease (CD) is transsphenoidal surgery (TSS). The success of surgical procedure is of particular importance in terms of patient's prognosis. The aim of this study was the prospective evaluation of compatibility of coupled 1 mg dexamethasone suppression test and 10 μg desmopressin stimulation test (CDDT) with standard criteria of remission in CD.
Methods
The study population consisted of 36 patients with CD operated on using the same protocol and followed-up for a period of at least 18 months (median: 30 months). The adopted criteria of remission were: subnormal serum cortisol level on the 1st postoperative day, normalization of urinary free cortisol and serum cortisol $\leq$1.8 μg/dl following 1 mg of dexamethasone. In total, 28 patients (77.8%) agreed to undergo CDDT – 15 out of 23 cured (65.2%) and all 13 non-cured subjects. CDDT was performed between 12 and 18 months of follow-up. A positive result of CDDT was indicated by the increase in plasma ACTH and serum cortisol by more than 35 and 20%, respectively.
Results
In total, 15 patients (53.6%) were regarded as surgically cured from Cushing's disease. In 13 patients (46.4%) persistent hypertcortisolemia was confirmed. Positive result of CDDT was observed in 12 non-cured (92.3%) and in one cured subject (6.7%). Negative result was obtained in 12 cured (80%) and in one non-cured subject (6.7%). Equivocal result was observed in two cured subjects (13.3%). The qualitative results of CDDT were compared with results of standard hormonal assessment performed at the end of follow-up. They were found to be highly compatible ($\kappa=0.846$; $P<0.001$).
Conclusion
Negative result of CDDT can be treated as a confirmation of successful surgical treatment for CD. During follow-up period CDDT can serve as a valuable supplement to hormone assessment performed in basic conditions.

## P1438

**Improved renal function after five years of GH therapy in GH deficient (GHD) adult survivors of childhood leukaemia**

C. Follin, T. Wiebe, C. Moëll & E. Erfurth
Institution of Clinical Sciences, Lund, Sweden.

Introduction
Acute lymphoblastic leukaemia (ALL) is the most common childhood malignancy. The survival rate is now 85% which emphasis the importance of long-term treatment complications. GH-deficiency (GHD) is common among these survivors treated with cranial radiotherapy (CRT) and chemotherapy. Renal impairment has been reported in childhood (CO) cancer survivors and glomerular filtration rate (GFR) is decreased in hypopituitarism. GH therapy to CO GHD patients has been shown to increase GFR.
Methods
In 44 (21 women) ALL patients, treated with 24 Gy CRT and chemotherapy and 44 matched controls GFR (ml/min) was investigated. We used Cystatin C (CysC) to estimate GFR. The level of CysC in serum is less influenced by body composition than creatinine. The median age was 25 years (19–31 years) and 91% of the patients were GHD. In 16 GHD ALL patients the effect of 5 years of GH therapy on GFR was evaluated and compared to 16 matched controls.
Results
At baseline the ALL patients had significantly lower GFR compared to controls ($P=0.01$). After 5 years of GH therapy GFR improved among the ALL patients ($P=0.04$). Two patients had subnormal GFR ($<$60 ml/min) at baseline and GFR was normalized in these patients after GH therapy. After 5 years no significant difference in GFR between patients and controls was recorded ($P=0.2$). When stratified for gender, GFR improved significantly among the men ($P=0.01$), but not among the women ($P>0.3$).
Conclusion
GHD adult survivors of CO ALL have impaired renal function compared to matched controls 20 years after ALL diagnosis. Five years of a low dose of GH therapy improved renal function among the ALL patients, particularly among the men. Whether higher GH doses in women will improve their renal function needs further investigation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1439

**Thyrotropin-secreting pituitary adenomas: experience of a single centre**

E. Malchiodi[1,2], G. Mantovani[1,2], E. Ferrante[1,2], E. Sala[1,2], E. Verrua[1,2], C. Giavoli[1,2], E. Profka[1,2], S. Bergamaschi[1,2], M. Filopanti[1,2], A. Lania[2,3], A. Spada[1,2] & P. Beck-Peccoz[1,2]
[1]Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, Milan, Italy; [2]University of Milan, Milan, Italy; [3]Istituto Clinico Humanitas, IRCCS, Milan, Italy.

Thyrotropin-secreting pituitary adenomas (TSH-omas) account for less than 1% of all pituitary adenomas. Here we report retrospective data of 17 patients (seven M and 10 F) with TSH-oma followed at our centre from 1990 to present. Median follow-up time was 9.7 years. The mean age at diagnosis was $43\pm12$ years. Radiological evaluation revealed macroadenomas in 11 of 17 patients (71.6%). Macroadenomas were extrasellar in 58.4% of cases, while only one microadenoma had extrasellar extension. At baseline, TSH levels were measurable in all patients ($4.8\pm3.2$ μIU/ml) in the presence of elevated free thyroid hormones. Serum SHBG concentrations were in the hyperthyroid range in all patients. Serum α-GSU levels were normal in all microadenomas. All patients had abnormal TSH suppression during $T_3$ administration but in three patients, serum TSH did not increase after TRH injection. A mixed GH/TSH secreting adenoma was observed in two patients, whereas a mixed gonadotropin/TSH adenoma was seen in one. In total, 16 patients were treated with trans-sphenoidal adenomactomy (TNS), 10 with somatostatin analogue (SSA) and six with radiotherapy (RT). About 35% of patients received one treatment, 24% two and 41% three. Combination of therapies were more frequent in macroadenomas (63%). At last follow-up nine patients (56%) were cured, three patients had normal free thyroid hormones but did not respond to TRH test, four patients were on SSA and one was recently treated with RT. Macroadenomas were cured in 45% of cases, 36% after TNS and 9% after TNS + RT, microadenomas in 80%, all after TNS alone. Last MRI was negative for residual/recurrence of adenoma in 11 patients. In conclusion, our series confirms the importance of $T_3$ suppression test and measurement of serum SHBG for the diagnosis of TSH-omas and the efficacy of TNS surgery, in particular for microadenomas.

## P1440

### Detection of somatostatin receptors in aggressive non-functioning pituitary adenomas and effects of somatostatin analogs therapy in these tumors

J. Kunert-Radek, M. Pawlikowski, H. Pisarek, M. Gorska-Chrzastek, N. Zawada & M. Radek
Medical University of Lodz, Lodz, Poland.

Clinically non-functioning pituitary adenomas (CNFPA) represent a heterogenous group of tumors. Most of CNFPA are aggressive, usually diagnosed relatively late and surgery often fails to achieve the complete excision of tumor and the recurrence rate is high. About 80% of CNFPA are characterized by intense expression of somatostatin receptors (SSTR) inspiring use of somatostatin analogs (SSTa) in the medical cure of CNFPA. Scintigraphy with visualization of SSTR2 expression and/or immunohistochemistry with selective recognition of all five SSTR subtypes are used for justify the long-acting SSTa treatment of CNFPA.
The aim of the study was to correlate the expression of SSTR determined with immunohistochemistry or receptor scintigraphy techniques (group of 48 patients) and verify effects of long-acting SSTa in the treatment of CNFPA (11 patients).
Results
All 11 patients with CNFPA treated with SSTa indicated expression of SSTR2 in immunohistochemistry but only nine patients of this group were SSTR2 positive in scintigraphy. Absence of SSTR2 expression in scintigraphy was not always associated with absence of SSTR2 visualization in immunohistochemistry. Intense expression of SSTR1 and SSTR5 was observed in most CNFPA. In all patients treated with SSTa stabilization of the tumor growth and stabilization or improvement of visual disturbances were observed.
Conclusion
Both scintigraphy and immunohistochemistry methods must be combined to assess the presence of SSTR in CNFPA. The treatment of CNFPA with SSTa is connected with the positive effect on tumor size progression – stabilize the tumor mass. SSTR1 and SSTR5 expression in CNFPA justifies the trials to treatment CNFPA with broad spectrum SSTa, like SOM230.

## P1441

### Effect of a modulation of somatostatin release on TSH secretion in healthy volunteers

N. Bouali, B. Corvilain & F. Devuyst
Hopital Erasme, Brussels, Belgium.

Objectives
In normal subjects, inhibitory effect of a glucose load (OGTT) on GH secretion is probably mediated by an increase in hypothalamic release of somatostatin whereas the stimulatory effect of arginine on GH secretion is probably mediated by a decrease in somatostatin release. In humans and animals, somatostatin infusion inhibits basal and TRH-stimulated TSH secretion but little is known on the role of endogenous somatostatin in the regulation of TSH secretion. The aim of this study was to evaluate TSH response to situations known to modulate somatostatin release *in vivo* (OGTT and arginine infusion).
Methods
OGTT (75 g) or arginine infusion (30 g in 30 min) were performed in seven healthy male volunteers. In five subjects results were also obtained after TRH injection. Isotonic saline infusion was used as control. Tests were begun 60 min after a catheter has been inserted ($T=0$ min). Blood samples were taken every 15 min from $-60$ to 240 min for glucose, TSH, PRL, GH measurements. Basal level for TSH and PRL was chosen as the mean of the value at $T-15$ and 0 min. Results were expressed as % of basal value (mean$\pm$S.E.M.). GH values were expressed in ng/ml.
Results
Statistical analysis was performed employing one-way ANOVA followed by Bonferroni's multiple comparison tests. OGTT exerted a typical inhibitory effect on GH secretion (Nadir GH $<0.25$ ng/ml) and arginine a stimulatory effect (peak GH: $11\pm3.64$ and $7.46\pm1.51$ ng/ml when combined with TRH; $P<0.01$).
As expected, PRL secretion was stimulated by arginine and TSH by TRH. Effects of a glucose load and of arginine on TSH secretion were less clear. TSH nadir observed during OGTT was statistically different from basal values but not from the nadir obtained with saline. The stimulatory effect of Arginine on TSH secretion was not significant when compared to basal value but statistically significant when compared to he value obtained during saline perfusion. No changes were observed on TSH stimulated values.
Conclusions

### Are "*in silico*" predictions reliable regarding splice-site mutations? – Studies in the aryl hydrocarbon receptor-interacting protein (AIP)

F. Martucci[1,2], G. Trivellin[2], B. Khoo[2], S. Owusu-Antwi[2], K. Stals[3], A. Kumar[2], S. Ellard[3], A. Grossman[2], P. Bouloux[2] & M. Korbonits[2]
[1]Universita' degli Studi Milano, Milano, Italy; [2]Queen Mary's School of Medicine, London, UK; [3]Royal Devon and Exeter NHS Foundation Trust, Exeter, UK.

Background
It is often difficult to define the clinical relevance of a novel gene variant. *In silico* analyses of variants located close to exon–intron-junctions are utilised to predict the result of these basepair changes. We have previously identified two splice-site variants in AIP and confirmed the predicted changes for c.249G>T, p.G83AfsX15 and c.807C>T. We identified the c.469-2A>G heterozygous variant located at the end of intron-3 in a childhood-onset acromegaly patient. This change has been previously described and was suggested to result in the loss of exon-four based on *in silico* analysis.
Methods
RNA has been extracted from our patient's peripheral blood sample and it was amplified using RT-PCR with primers located on exon-2 and exon-6. After electrophoresis DNA bands were extracted from agarose gel and sequenced. *In silico* prediction was carried out by the ALAMUT software (www.interactive-biosoftware.com).
Results
The agarose gel revealed two bands in the patient sample and a single band in the control sample. The common band showed the expected wild-type sequence. The additional lower-size band revealed the loss of 84-nucleotides at the 5′ end of exon-4, while the rest of exon-4 was normal. This change is not predicted to result in a frameshift.
Conclusion
The disruption of intron-3 acceptor splice-site resulted in the appearance of a cryptic splice-acceptor site in the middle of exon-4. The resulting RNA is predicted to yield a shorter protein missing 27 amino acids in the second alpha-helix of the first tetratricopeptide repeat motif of the AIP molecule. This variant has been identified in our childhood-onset acromegaly patient and previously in an adult-onset case, but has not been reported in normal subjects, except for family members of the above patients. We suggest that experimental confirmation of *in silico* predictions of gene variants is helpful for appropriate genetic counselling and clinical management of these families.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Effectiveness of cyberknife in the management of pituitary adenomas and craniopharyngiomas**

F. Marini, A. Conti, A. Pontoriero, F. Granata & S. Cannavò
University of Messina, Messina, Italy.

Introduction
CyberKnife (CK), an innovative LINAC-based robotic device for frameless stereotactic surgery, is an emerging approach in the management of tumours of the sellar region.
Patients and methods
In total, 14 patients (six men, mean age 52.7 years) with sellar tumours (three craniopharyngiomas and 11 pituitary adenomas) were evaluated. Pituitary adenomas (PA) were non-functioning (7), GH-secreting (2), one GH/TSH-secreting (1) or PRL-secreting (1). Before CK, hypopituitarism had been diagnosed in six patients. CK was performed as first line treatment in one patient with non-functioning adenoma, in one with GH/TSH-secreting adenoma and in one with craniopharyngioma. Tumours were treated with a median coverage of $96.11 \pm 2.2\%$ (range, 93.7–98.6%), a median conformity index of 1.37 (range, 1.2–1.63), and a median treatment isodose line of 70% (range, 60–84%). Patients were treated with multiple (2–5) fractions with a BED of 85–105 Gy for alfa/beta 2. The mean follow-up period was 17.7 months (range 4–48 months).
Results
CK induced tumour disappearance in three cases with non-functioning PA (CK was first line treatment in one) and decrease in one with non-functioning PA and in two with craniopharyngioma (CK was first line treatment in one). Five out of eight patients with previously normal pituitary function developed hypopituitarism (one GH deficit and four multiple impairments). Among six patients with previous hypopituitarism, two developed panhypopituitarism while no worsening of pituitary function was seen in the other cases. One acromegalic patient, resistant to medical therapies, reached IGF1 normalization.
Conclusions
This mid-long term evaluation shows that CK induced tumor shrinkage in 43% of cases and in 2/3 of those treated as first line approach. However, hypopituitarism occurred in 62% of patients with normal pituitary function and adjunctive pituitary deficiencies were demonstrated in 33% of the others. Acromegaly control was reached in the patient resistant to other therapies.

**Evaluation of cardiovascular risk factors and metabolic profile in hyperprolactinemic subjects**

M. Sayki Arslan[1], M. Sahin[2], T. Esra[1], E. Cakir Ozkaya[1], N. Bozkurt Colak[1], B. Karbek[1], I. Ozturk Unsal[1], B. Ucan[1], A. Gungunes[1], E. Cakal[1], M. Ozbek[1], O. Topaloglu[1], T. Demirci[1], M. Karakose[1], M. Caliskan[1], Z. Ginis[3] & T. Delibasi[1]
[1]Diskapi Yildirim Beyazit Training and Research Hospital, Ankara, Turkey; [2]School of Medicine, Ankara University, Ankara, Turkey;[3]Diskapi Yildirim Beyazit Training and Research Hospital, Ankara, Turkey.

Objective
Hyperprolactinemia has been reported to be associated with abnormalities of glucose metabolism and cardiovascular inflammatory markers. However, the metabolic effects of high prolactin levels are not adequately clarified. The aims of this study were to evaluate the effects of hyperprolactinemia on endothelial function, insulin sensitivity and inflammatory markers in prolactinoma diagnosed subjects.
Methods
In total, 58 hyperprolactinemic subjects, 18 men and 40 women, aged $38.9 \pm 10.6$ years with newly diagnosed pituitary adenomas were recruited from our outpatient clinic. In total, 30 healthy subjects, without any known disease, of similar age, gender and body mass index (BMI) were included to serve as control group. The study was approved by the Hospital Ethical Commitee and informed consent was obtained from all patients. All subjects underwent measurements of height, weight, waist and hip. BMI and homeostasis model assessment of insulin resistance (HOMA-IR) was calculated. Metabolic variables were obtained after an overnight fasting. Metabolic syndrome (MS) was diagnosed using the Adult Treatment Panel III criteria. Endothelial function was determined by measuring carotid intima media thickness (CIMT) on high resolution external ultrasound.
Results
Serum levels of glucose, insulin, HOMA-IR, total cholesterol, triglyceride and waist circumference were significantly higher in the patient group in comparison with the controls. No significant difference were observed in blood pressure measurements. Although high sensitive C-reactive protein levels were similar between groups ($P = 0.094$), CIMT measurements were significantly higher in hyperprolactinemia patients ($P = 0.002$). The prevalance of obesity, overweight, MS, and IR was 43.1%, 29.2 and 27.6% respectively in patient group.
Conclusion
Based on the results of this study, hyperprolactinemia is associated with endothelial dysfunction and decreased insulin sensitivity, which are early markers of atherosclerosis. Metabolic control must be considered in the clinical management of patients diagnosed prolactinoma.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1445

**Pituitary tumor apoplexy: overview of 14 cases diagnosed during the last 12 years at a central hospital**

A. Caldas, M. Ferreira, S. Moreira, I. Ribeiro, H. Cardoso, I. Palma & F. Borges
Centro Hospitalar do Porto, Porto, Portugal.

Introduction
Pituitary apoplexy is a potentially life-threatening syndrome due to acute infarction and/or hemorrhage of the pituitary gland. In many cases it is the first form of presentation of a pituitary adenoma. The purpose of the study is to analyze the clinical presentation, diagnosis and treatment of this syndrome.
Patients and methods
A retrospective analysis of the patients diagnosed with pituitary tumor apoplexy at Santo Antonio's Hospital from 2000 to 2011 was done. Their medical records were reviewed.
Results
In total, 14 cases of pituitary tumor apoplexy were reviewed: 10 males and four females (mean age 47.8 years, range 21–71). They were followed for up to 10 years (mean 3.9 years, range 1–10). Only one case occurred on a previously known pituitary macroadenoma; all other occurred as first manifestation of the tumor. At the presentation, headache occurred on 11 cases (78.6%), visual changes on 10 (71.4%) and nausea/vomits on eight (57.1%); one patient was asymptomatic. MRI was done on 11 cases (78.6%); pituitary tumor hemorrhage and/or necrosis was correctly identified on all. Surgical treatment with transfenoidal surgery was done on 12 cases (85.7%), on average 4.5 days after hospital admission (range 1–13 days). Visual changes improved on all surgically treated. By immunostaining criteria, of the 12 surgically removed tumors, five (41.7%) were null-cell adenomas, three (25%) were GH-positive, two (16.7%) were FSH-positive and two were GH and PRL-positive.
Overall, nine patients needed long-term hormone replacement: steroid and thyroid hormones were required in eight cases (88.9%), testosterone therapy in five (55.6%). One patient needed long-term desmopressin therapy.
Conclusions
Pituitary apoplexy diagnosis relies on the presenting symptoms and it is usually confirmed by an imaging method, preferably MRI. Transfenoidal surgery is the most used technique and a sooner intervention carries a better prognosis. A significant percentage of patients need long-term hormone replacement.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1446

**Copeptin is not associated with menstrual cycle hormones**

C. Blum[1,2], U. Mirza[1], M. Christ-Crain[2], B. Mueller[1] & J. Puder[3]
[1]Kantonsspital Aarau AG, Aarau, Switzerland; [2]University Hospital Basel, Basel, Switzerland; [3]University Hospital Lausanne (CHUV), Lausanne, Switzerland.

Background
Copeptin (CP), a derivate from the antidiuretic hormone (ADH) precursor pre-pro-vasopressin, stochiometrically mirrors ADH secretion. CP is increasingly evaluated as a diagnostic and prognostic biomarker in different diseases. It is therefore important to recognize possible confounding factors when interpreting CP levels. In healthy regularly menstruating women, there is a small but measurable physiological variability of hormones involved in fluid regulation. ADH plasma levels have been found to be lowest at menstruation, increasing during the follicular phase with a peak at ovulation and a drop in the luteal phase. We investigated the variability of CP during the menstrual cycle (MC) and its correlation to MC hormones.
Methods
In total, 15 healthy women with regular MC (from 26 to 33 days) were included in this study. Ovulation was confirmed by progesterone (prog) levels on day 21 of the MC before entering the study and during the study. Blood collection was performed on days 3, 5, 8–16, 18, 21, 24 and 27 of their MC. Serums were assayed for prog, estradiol ($E_2$), LH, and CP. Mixed linear regression analysis for repeated measures was performed to study the changes of CP, prog, $E_2$ and LH during the MC, and to test the correlation of CP with sex hormones during the MC.
Results
Mean MC length in all subjects was $28.5 \pm 2.2$ d. $E_2$, prog, and LH exhibited characteristic changes during the MC (all $P < 0.05$). All cycles were ovulatory (peak prog $54 \pm 15$ nmol/l). CP levels did not change significantly throughout the MC, and were not associated with changes in prog, $E_2$ or LH-levels (all $P$=ns).
Conclusion
CP levels remain stable during the MC and are not influenced by changes in sex hormones. This implicates that it is not necessary to consider MC phases when using CP as a biomarker in premenopausal women.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Acylated ghrelin as provocative test for the diagnosis of gh deficiency in adults**

V. Gasco, G. Beccuti, C. Baldini, N. Prencipe, F. Guaraldi, S. Di Giacomo, A. Berton, M. Maccario, E. Ghigo & S. Grottoli
University of Turin, Turin, Italy.

ITT is the test of reference for the diagnosis of adult GH deficiency (GHD), but also GHRH in combination with arginine (ARG) or GH secretagogues (GHS) are considered equally reliable tests. Testing with GHS alone is, anyway, a potent stimulus exploring the integrity of hypothalamic pathways controlling somatotropic function.
We therefore aimed to clarify the diagnostic reliability of testing with ghrelin, the natural GHS.
We studied the GH response (every 15 min from $-15$ to $+120$ min) to acylated ghrelin (1 μg/kg i.v. at 0 min) in 78 patients with history of pituitary disease (49 M, 29 F; age [mean ± SD]: $52.1 \pm 18.7$ years; BMI: $26.7 \pm 5.3$ kg/m$^2$). As gold standard for the diagnosis of GHD we assumed the lack of GH response to GHRH + ARG and/or ITT. We identified the best GH cut-off to ghrelin test, defined as the one with the best sensitivity (SE) and specificity (SP), using the ROC analysis.
The best GH cut-off to ghrelin test was 7.3 μg/l in lean subjects with a SE and SP value of 88.2 and 90.9%, 2.9 μg/l in overweight subjects with a SE and SP value of 92.6 and 100%, and 0.6 μg/l in obese subjects with a SE and SP value of 50 and 100%. The diagnostic accuracy was 89.3, 94.1 and 62.5%, respectively.
In conclusion, these findings indicate that testing with acylated ghrelin would represent a reliable diagnostic tool for the diagnosis of adult GHD, at least in lean and overweight subjects provided that appropriate cut-off limits are assumed. Obesity strongly reduces the GH response to ghrelin, its weight-related cut-off limit, and its diagnostic reliability.

## P1448

**National incidence and prevalence of TSH-secreting pituitary adenomas in Sweden**

L. Önnestam[1], K. Berinder[2], M. Bramnert[3], P. Burman[3], P. Dahlqvist[4], B. Edén-Engström[5], J. Wahlberg Topp[6] & H. Filipsson Nyström[1]
[1]Sahlgrens' Academy at University of Gothenburg, Sahlgrenska University Hospital, Gothenburg, Sweden; [2]Karolinska University Hospital Solna, Stockholm, Sweden; [3]Skåne University Hospital, Malmö-Lund, Sweden; [4]Umeå University, Umeå, Sweden; [5]Uppsala Academic Hospital, Uppsala, Sweden; [6]University Hospital in Linköping, Linköping, Sweden.

Introduction
TSH-secreting pituitary adenomas (TSHoma) are rare. Epidemiological data are scant and there are no reports on national incidence. The aim of this study was to estimate the national incidence and prevalence of TSHomas in Sweden.
Methods
This is an observational study from all tertial referral centers where the Swedish Pituitary Registry and WHO ICD coding were used to identify patients diagnosed with TSHomas in Sweden 1990–2010. Medical records were studied for identified patients until latest follow-up (median 5.0 years (range <1–20)). Incidence, prevalence, demography, tumor characteristics, treatment outcome and thyroid hormone level at diagnosis were studied.
Results
The age-standardized national incidence of the 28 TSHoma patients was estimated to 0.15/million inhabitants/year for the period, with an increasing incidence over time (0.05/million/year in 1990–1994 to 0.26/million/year in 2005–2009). The national prevalence of patients followed for TSHomas in 2010 was 2.8/million inhabitants. Most patients ($n=22$) underwent surgery, three had radiotherapy and six had somatostatin analogues. In total, 18 patients were considered cured at latest follow-up; 25% remained uncontrolled. Subjects treated for putative thyroid illness prior to diagnosis ($n=8$) had TSH levels more than two times compared with those with intact thyroid at diagnosis of TSHoma, $P=0.013$. Women had longer time to diagnosis than men, median 4 vs <1 years, $P=0.026$ and had more often surgery, 94.1 vs 54.5%, $P=0.022$.
Conclusion
This is the first estimation of a national incidence of TSHomas. Additional epidemiological studies are needed to compare this result with other geographical areas. The study implies an increased incidence of TSHomas, in parity with reports on other pituitary adenomas.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1449

**High mean platelet volume and lipid abnormalities in prolactinoma patients without insulin resistance**

B. Ayçiçek Dogan[1], M. Tuna[1], A. Arduç[1], Y. Tütüncü[1], M. Yilmaz[2], D. Berker[1] & S. Güler[1]
[1]Ankara Numune Training and Research Hospital, Ankara, Turkey; [2]Dokuz Eylul University, Faculty of Medicine, Izmir, Turkey.

Introduction
Hyperprolactinemia has been associated with dyslipidaemia, hypercoagulability, impaired endothelial function and decreased insulin sensitivity. Recent data show that prolactin hormone (PRL) could contribute to atherogenesis. The aim of our study was to investigate the relationship between MPV and PRL, androgen hormones, lipid profiles in premenopausal prolactinoma patients, who did not have insulin resistance (IR).
Methods
Thirty-nine newly diagnosed premenopausal prolactinoma patients (mean age $28,6 \pm 6,6$ years, mean body mass index (BMI) $23,6 \pm 1,9$ kg/m2, mean HOMA-IR $1,33 \pm 0,4$.) and twenty normoprolactinemic, age- and BMI- matched healthy control females were involved in the study. Blood samples were taken for total blood count including MPV, FSH, LH, estradiole, total testosterone (TT), free testosterone (FT), androstenedione (A), dehydroepiandrosterone-sulfate

(DHEAS), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), triglycerides (TG), insulin and fasting glucose (FG). IR was calculated by HOMA-IR(fasting glucose (mg/dl) x serum insulin (μIU /ml) /405).
RESULTS
There was no difference between prolactinoma and control group regarding to age, BMI and and waist circumference ($P>0.05$, for all). PRL, FT and MPV in women with prolactinoma were significantly higher than the control group ($P<0.01$, $P<0.01$, $P=0.013$). No significant differences were observed in the groups according to HDL-C, LDL-C, triglyceride, HOMA-IR, gonadotropin and the other androgen hormone levels ($P>0.05$, for all). Both PRL and triglyceride levels showed a positive correlation with MPV levels ($r=0.727$, $P<0.001$, $r=0.357$, $P=0.026$, respectively) and a negative correlation between HDL-C and MPV levels was found in our study group ($r=-0.437$, $P=0.005$).
Conclusion
Our study demonstrated the positive correlation between MPV levels with both PRL and triglyceride levels. Also a negative correlation between HDL-C and MPV in prolactinoma patients. Hyperprolactinemia and hypertriglyceridemia might be cause platelet reactivity through elevating MPV levels in prolactinoma patients. Similarly, it could be said that, high HDL-C may be protect from atherosclerosis by lowering MPV in prolactinoma patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1450

**Asymptomatic nonfunctioning pituitary macroadenomas take advantage of surgery**

J. Dubourg[1], M. Messerer[2], R. Daniel[2], D. Bervini[2], M. Berhouma[3], G. Perrin[4], G. Iype[4], A. Chacko[4], J. Trouillas[5,6], G. Raverot[1,6] & E. Jouanneau[3,6]
[1]Groupement Hospitalier Est, Hospices Civils de Lyon, Lyon, France; [2]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [3]Hôpital Neurologique Pierre Wertheimer, Groupement Hospitalier Est, Hospices Civils de Lyon, Lyon, France; [4]Christian Medical College, Vellore, India; [5]Groupement Hospitalier Est, Hospices Civils de Lyon, Lyon, France; [6]INSERM U1028, CNRS UMR5292, Université Lyon1, Lyon, France.

Introduction
Pituitary incidentalomas (PIs) defined as pituitary tumors discovered by systematic neuroimaging constitute an increasingly clinical problem. Most of PIs are nonfunctioning tumors (NFPIs) with systematic investigation revealing visual and/or endocrinological impairment in some patients while others remained asymptomatic. If the therapeutic management is well codified for functioning PIs and symptomatic NFPIs, a debate still remain for asymptomatic NFPIs between surgery and a "wait and see" approach.
Design
To answer this point, we conducted a retrospective study on 76 patients with newly diagnosed symptomatic or asymptomatic NFPIs operated on from 2005 to 2011 by three experimented neurosurgeons. We compared age, tumor size and surgical results (quality of resection, endocrinological and ophthalmological results, morbidity) of the two patient groups.
Results
After the initial exploration, 48 (63%) patients were symptomatic and 28 were asymptomatic. Mean age ($60.9\pm13.1$ versus $52.9\pm11.9$ years) and tumor height ($25\pm6$ versus $20\pm7$ mm) were significantly higher in symptomatic compare to asymptomatic patients ($P<0.001$, $P<0.01$, respectively). There was no significant difference regarding the Knosp's classification. Gross total removal was significantly better in asymptomatic (82%) than in symptomatic patients (58%; $P=0.03$). Postoperative pituitary function was normalized/improved (41%), unchanged (48%) or worsened (11%) in the 27 symptomatic patients with initial endocrinological impairment. It was worsened in 19% of the symptomatic patients without preoperative endocrinological impairment versus 14% in asymptomatic patients ($P=0.7$). The postoperative ophthalmological function was normalized/improved (88%) or unchanged (12%) in the 35 symptomatic patients with initial ophthalmological impairment whereas there was no worsening in all other patients. No significant difference was found regarding postoperative morbidity: cerebrospinal fluid leakage (5%), meningitis (1%), epistaxis (1%) and definitive diabetes insipidus (2.5%).
Conclusions
The knowledge that natural history of NFPIs makes them symptomatic and the quality of the resection without worsening of visual function give arguments to propose surgery for asymptomatic macro NFPIs by experimented neurosurgeons.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1451

**Mortality and survival in a large series of adult patients with hypopituitarism followed for 10 years**

E. Fernandez-Rodriguez[1], M. Lopez-Raton[2], C. Cadarso[2], F. Casanueva[1,3] & I. Bernabeu[1]
[1]Complejo Hospitalario Universitario de Santiago, Santiago de Compostela, Spain; [2]Faculty of Medicine. University of Santiago de Compostela, Santiago de Compostela, Spain; [3]Instituto Salud Carlos III, Santiago de Compostela, Spain.

Hypopituitarism is associated with increased morbidity and mortality compared to healthy population. However, the factors influencing prognosis are still not well known.
Objectives
To determine the causes of mortality in adult patients with hypopituitarism and compare the mortality rate with general population
To identify the factors associated with mortality and survival.
Patients
Two hundred and nine adult patients followed because of hypopituitarism during a 10-year period.
Results
The most frequent cause of hypopituitarism was a pituitary or peri-pituitary tumour (55.5%), 87.3% operated and 61% irradiated. FSH/LH was the most frequent deficiency (80.4%), followed by TSH (72.2%), ACTH (60.3%), GH (60.3%) and ADH (19.6%).
Prevalence of obesity was 44.8% (BMI) and 56.6% (waist circumference). 15.4% had diabetes (59.3% well controlled), 34.3% hypertension and 38.8% dyslipidemia. Cardiovascular, chronic respiratory, cerebrovascular disease and malignancy were diagnosed in 16.9, 2.5, 4.8 and 7.2% respectively.
Thirty-two patients died due to cardiovascular disease (46.8%), infections (28.1%), malignancy (15.6%) and cerebrovascular disease (9.4%). Standardized mortality rate was 8.05, higher in males (8.92 vs 7.43) and young patients (84.93 vs 5.26). Previous radiotherapy ($P=0.02$), acromegaly ($P=0.033$), higher BMI ($P=0.04$) or waist circumference ($P=0.032$), diabetes ($P=0.03$), uncontrolled diabetes ($P=0.026$) and cancer ($P<0.0001$) were associated with mortality.
Stepwise multivariate analysis showed that reduced life expectancy was related to older age, previous radiotherapy, uncontrolled diabetes and malignancy, while tumoral causes prolonged survival.
Discussion
Mortality in these patients was eight times higher than general population. Lower survival since diagnosis was related to older age, non-tumoral causes, malignancy, uncontrolled diabetes and previous radiotherapy. Diagnosis of acromegaly, higher BMI and waist circumference were related to mortality, although in these cases differences in survival were not detected.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1452

**Gastric and colonic pathology at patients with active acromegaly**

A. Dreval, S. Tereschenko, A. Titaeva, L. Gurevich & I. Ilovayskaya
Moscow Regional Research and Clinical Institute named by MF Vladimirsky, Moscow, Russian Federation.

We examined gastroenterocolonic tract condition at 92 patients with active acromegaly (male 30, female 66, age 26–78 y.o., most of the patients 45–59 y.o.). Gastroduodenoscopy ($n=92$) and colonoscopy ($n=74$) were performed. Median GH levels were 22.7 (12.5; 51) mMe/l, median IGF1 levels – 640 (507; 800) ng/ml. Esophagitis was diagnosed at 22 (23.9%) patients, incompetence of cardia – 33 (35.8%) patients. There was one case of gastric cancer (operated before). Helicobacter pylori was found at 78% of patients (predominantly 2–3 degree). Gastroduodenitis was found in all patients (100%), additionally chronical or acute stomach erosions were revealed at 20 (21.7%) patients. Stomach polyps were found

at 28 (30.4%) patients (hyperplastic polyps $n=5$). Polyps localized predominantly at distal parts of the stomach (mostly antrum), size up to 5 mm 14 cases, 6–10 mm – 11 cases, >10 mm – three cases. Duodenal ulcer was found at six patients, duodenal erisions – in seven cases. Duodenal polyps were found at 2 other patients (hyperplastic polyp $n=1$).
Colonic pathology were found in 64 patients (86.5%), including sigmoiditis ($n=13$, 17.6%), colitis ($n=7$, 9.5%), colonic diverticula ($n=22$, 30%), dolichocolon ($n=21$, 28.4%). Colonic polyps were found in 39 (52.7%) cases and consisted of hyperplastic polyps ($n=26$, 35.1%) and adenomatous polyps ($n=13$, 17.6%), including 7 (9.5%) cases of joint presence of hyperplastic and adenomatous polyps, and adenocarcinoma ($n=1$, 1.4%). Polyps were single in 20 cases (27%), 2–8 polyps in 8 (10.8%) cases, and >8 polyps in 12 (16.2%). Polyps were in size up to 5 mm in two cases, 6–10 mm in 20 cases, 11–15 mm in 14 cases, and >15 mm in three cases. We did not found association of stomach and colonic polyps in any case. Median GH levels were higher at patients with stomach polyps comparing with colonic polyps (33 (12.5;58) vs 18.8 (12.5;40) mMe/l) however the difference was not statistically significant. Median IGF1 levels were similar in both groups (655 (507; 812) vs 600 (500; 710) ng/ml respectively).
Thus, gastro/colonic pathology is common among acromegalic patients. Stomach polyps like colonic polyps are also associated with acromegaly.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1453

**Pituitary dysfunction in adult patients after cranial radiotherapy for non-pituitary tumors: a long-term follow-up study**

N. Appelman-Dijkstra, N. Kokshoorn, F. Malgo, K. Neelis, N. Biermasz, J. Smit & A. Pereira
LUMC, Leiden, The Netherlands.

Background
Hypopituitarism after cranial radiotherapy for non-pituitary tumors is well recognized. However structured endocrine assessments are not incorporated into routine clinical practice
Aim of the study
To evaluate pituitary function in adult patients irradiated for non-pituitary tumors at our center
Patients and Methods
Cross-sectional evaluation of pituitary function of all available patients treated with irradiation at our center for non-pituitary cerebral or nasopharyngeal tumors and hematological malignancies
Results
497 patients were identified from the archives of Radiotherapy and Endocrinology. Of these, 60 patients(12%) had been subjected to endocrine testing. 392 were excluded for evaluation. 231 were diseased, 102 had progressive disease, 26 did not meet inclusion criteria, 13 were unavailable and 20 declined evaluation. A total of 105 patients were eligible for this study. 63 treated for cerebral tumors, 15 for nasopharyngeal tumors, 25 for hematological malignancies, and two for cerebral metastasis. Median age at radiotherapy was 29(2–74) years and median radiation dose 54 (6–74) Gy. Median follow-up was 11.5 years (0.5–38). Endocrine evaluation included morning hormonesampling and ITT ($n=63$), metyrapone($n=4$), CRH ($n=26$), ACTH ($n=15$), or GHRH/Arginine ($n=19$). Any hypopituitarism was present in 51/105(48.6%) of cases. The prevalence of GHD was 29%. ACTH-deficiency in 25%, TSH-deficiency in 16% and LH/FSH-deficiency in 20%. Hyperprolactinemia was present in 25%. A higher irradiation dose (>25 Gy) was associated with a significantly higher prevalence of hypopituitarism. The mean period of onset of pituitary insufficiency was 4.5 years (0.5–35) for GH deficiency, 3 (1–16)years for TSH deficiency, HPA-axis after 6 years (0–24) and FSH/LH insufficiency after 7 years (0–16). Hyperprolactinemia occurred after approximately 2.5 years (0–21) years.
Conclusion
After long-term follow-up, hypopituitarism is highly prevalent in adult patients after cranial radiotherapy for non-pituitary tumors, but only 12% of patients at our center was subjected to endocrine testing. Periodical endocrine evaluation should be incorporated in the follow-up of all patients treated by cranial radiotherapy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1454

**The treatment of results of endoscopic transsphenoidal surgery for GH-secreting pituitary adenomas**

S. Tahara, Y. Ishii, N. Sanno & A. Teramoto
Nippon Medical School, Tokyo, Japan.

Objective
With the progress of neuroendoscopic surgery in recent years, the application of endoscopy to transnasal surgery for pituitary tumors is increasing. At our institution, endonasal surgery using an endoscope alone (eTSS) has been performed in 825 patients with pituitary adenomas since November 2001. Among them, 156 patients (18.9%) had GH-secreting pituitary adenoma (GHoma), so the outcome and complications of eTSS-treated GHomas were investigated in the present study.
Materials and methods
Rigid endoscopes with an outer diameter of 4 and 2.7 mm (visual field angle: 0, 30, and 70 degrees) manufactured by Machida Endoscope Co., Ltd. were used. These endoscopes were mounted on a new floor stand manufactured by Mitaka Kohki Co., Ltd. A CT navigation system set for bone conditions was used in all patients.
Results
The range of supracellar tumor resection was increased by employing a rigid endoscope with a visual field angle of 70 degrees. Resection of tumors invading the cavernous sinus was evaluated in patients with GHomas classified according to Knosp for which clear criteria are available. As a result, the curing rate improved to 84.2% in grades 0, 1, and 2, while it was a low 16.7% in grades 3 and 4. Also, Capsulectomy could even be performed by endoscopy in patients with GHomas of enclosed type. As complications, epistaxis, transient visual dysfunction due to postoperative hematoma, and abducens nerve paralysis were noted in 1.4, 0.7, and 0.7% of the patients, respectively.
Conclusion
Tumors could be approached accurately by eTSS with a wide visual field, and the incidence of complications could be minimized. Since the suprasellar excision rate was increased owing to a wide visual field, eTSS can also improve the QOL of patients. However, further studies will be necessary to improve the resection rate of tumors with extensive invading into the cavernous sinus.

**Glucose metabolism in children with GH deficiency before and after GH therapy**

L. De Martino, D. Capalbo, R. Di Mase, A. Esposito, M. Rezzuto, F. Barbieri & M. Salerno
University Federico II, Naples, Italy.

Background
Adults with untreated GH deficiency (GHD) may have a cluster of cardiovascular risk factors. The effects of GH replacement therapy on insulin homeostasis in GHD subjects are still debated. Only a few studies investigated the effects of GHD and GH therapy on glucose metabolism in children.
Objective
To evaluate the effects of GHD and GH treatment on glucose metabolism in a large cohort of GHD children before and after GH replacement therapy.
Subjects and methods
Fasting glucose, insulin, HbA1c, and HOMA were assessed in 60 GHD children, aged 9.8±0.3 years, before and after 1, 2 and 4 years of GH therapy. 60 healthy, age-, sex- and BMI-matched healthy controls were enrolled.
Results
In GHD children at baseline, fasting glucose (77.8±1 vs 77.9±1.2 mg/dl), insulin (4.7±0.4 vs 4.6±0.4 μU/ml), HOMA (1.26±0.2 vs 1.12±0.1) and HbA1c (5.29±0.1 vs 5.29±0.04%) levels were comparable to healthy controls. One year of GH therapy (33 μg/kg per day) was associated with significant increase in insulin (7.69±0.6, $P<0.0001$) and HOMA (1.64±0.15, $P=0.009$), without significant changes in fasting glucose and HbA1c levels. Insulin and HOMA levels did not further increase after 2 (7.56±0.6 and 1.85±0.2 respectively) and 4 years (7.65±0.7 and 1.5±0.1 respectively) of treatment, remaining significantly elevated compared to pre-treatment levels. Fasting glucose and HbA1c did not change after 2 and 4 years of GH therapy.
Conclusions
Untreated GHD was not associated with significant alterations of insulin homeostasis. One year of GH treatment was associated with a slight impairment

in insulin sensitivity without further change during long-term GH therapy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Endocrine disturbances and quality of life in adult patients after multimodal treatment for brain tumors or leukemia**

S. Siegel[1,2], E. Rosenkranz[2], A. Thissen[2], M. Piroth[1], R. Mertens[1], C. Streetz-van-der-Werf[1], G. Brabant[3] & I. Kreitschmann-Andermahr[1,2]
[1]University Hospital Erlangen, Erlangen, Germany; [2]University Hospital RWTH Aachen, Aachen, Germany; [3]Luebeck University, Luebeck, Germany.

Objective
Brain tumour treatment with radio- and chemotherapy may lead to endocrine and other medical sequelae. Still, many countries lack tailored surveillance programs for such patients so that potential health problems may remain unrecognized. The present study was performed to investigate endocrine and psychosocial impairment in a single centre university setting in Germany in patients treated with cranial radiotherapy as a part of brain tumour or leukaemia treatment.
Patients and methods
38 (18 m, 20 f) brain tumour patients were investigated at least three year after completion of radiotherapy. 26 had been operated upon and 19 had received additional chemotherapy. 16 patients were childhood cancer survivors, 22 were diagnosed and treated as adults. In all patients basal 0800 h hormone levels (cortisol, ACTH, GH, IGF1, $fT_3$, $fT_4$, TSH, LH, FSH, testosterone or estrogen) were assessed. In case of abnormal basal hormone readings or clinical suspicion of hormonal abnormalities, functional endocrine assessment was additionally performed. An extensive self-rating battery pertaining to quality of life, sleep disturbances and depression was also completed by all patients.
Results
In one patient previously undetected deficiency of three pituitary hormone axes was noted, a total of eight patients had abnormally low IGF1 levels, three secondary and three primary hypogonadism. Primary hypothyroidism, probably associated with brain tumour treatment (radiotherapy of the neuroaxis in medulloblastoma patients) was noted in two patients. Patients presented with a wide range of psychosocial impairment with women and overweight patients being more impaired than others. Higher testosterone levels were related to better psychological quality of life as indicated by the psychological sum score of the SF-36 ($r=0.494$, $P<0.05$).
Conclusion
The results of the present study underscore the need for organized assessment and treatment of medical and psychosocial late sequelae even years after multimodal brain tumour treatment.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1457

**Anterior pituitary autoantibodies in patients with diabetes mellitus**

C. Pisanu, E. Cossu, M. Baroni, G. Frau, F. Pigliaru, C. Cocco, G. Ferri & S. Mariotti
University of Cagliari, Monserrato, Cagliari, Italy.

Objective
The presence of APA has been reported in patients with autoimmune polyendocrinopathies, but their prevalence in type 1 diabetes mellitus (T1D) is still unknown. The aim of this study was to assess APA prevalence in T1D patients as compared to patients with type 2 diabetes mellitus (T2D) and healthy subjects.
Research design and methods
The presence of APA was assessed by indirect immunofluorescence (IF) technique, with bovine adrenal gland and pituitary as substrates. To avoid non-specific interference only sera giving IF signal at 1:200 dilution were considered as positive. The study groups included 100 patients with T1D of varying duration (median 14 years, range 1 month to 43 years), 32 patients with T2D and 62 healthy controls.
Results
APA were detected in 7 of 100 (7%) patients with IDDM, 0 patients with NIDDM and 0 non diabetic subjects, corresponding to a significant increase ($P=0.033$ by $\chi^2$ test) in T1D patients vs healthy controls, while the difference vs T2D was slightly above the level of statistical significance ($P=0.124$). Evaluation of anterior pituitary function of the seven APA-positive T1D patients is presently under study.
Conclusions
This study indicates that the prevalence of APA is higher in patients with T1D than in the patients with T2D and in non diabetic controls. This observation, which confirms and extends previous reports, suggests that the spectrum of autoimmune disorders associated with T1D should be further expanded. The functional significance of autoimmunity against anterior pituitary requires further investigation, presently ongoing at our Institutions.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1458

**Pitfalls in Cushing's disease: report of an ectopic ACTH-producing pituitary adenoma in the sphenoid sinus**

M. Ritter[1], T. Burkhardt[2], S. Schmid[3], C. Bernreuther[4], B. Winterberg[5], H. Lehnert[3] & J. Flitsch[2]
[1]Endokrinologikum, Osnabrück, Germany; [2]University Medical Center Hamburg-Eppendorf (UKE), Hamburg, Germany; [3]University Clinic Schleswig-Holstein, Campus Lübeck, Lübeck, Germany; [4]Marienhospital, Emsdetten, Germany

Cushing's disease is caused by ACTH-secreting pituitary adenomas. Gold standard therapy is the resection of the adenoma by transsphenoidal surgery with high cure rates even in cases of negative MR imaging. Surgical failure despite clear endocrinological test results is possible and mostly explained by hidden minute adenomas within the gland.
We report on a 50-year-old woman suffering from ACTH-dependent Cushing's syndrome. Endocrinological work-up was most compatible with a pituitary origin. Although an MRI showed no pituitary tumor, CRH-stimulated petrosal sinus sampling revealed a clear central-peripheral ACTH gradient. The patient underwent transsphenoidal surgery with negative exploration of the pituitary gland. After intraoperative re-evaluation of the preoperative MRI, a 'polyp' at the bottom of the sphenoid sinus was identified. The intraoperative microscopic aspect as well as instantaneous sections and cytology of a biopsy confirmed an adenoma, which was removed. Histological analysis demonstrated an ACTH-producing pituitary adenoma adjacent to respiratory mucous membrane consisting of ciliated epithelium with submucous connective tissue. Histological evaluation of biopsies from the pituitary gland revealed normal pituitary tissue. Thus, an ACTH secreting adenoma was only detectable in the sphenoid sinus. Postoperatively, ACTH concentrations dropped and after 3-month of follow up, Cushing's stigmata were found to regress and a temporary hydrocortisone substitution could be reduced.
The adenohypophysis originates from the floor of the nasopharynx, that is partly located in the precursor of the sphenoid bone. Ectopic pituitary tissue is thought to arise from remnants of Rathke's pouch, and ectopic adenomas are believed to originate from remaining cells resting along the path of the embryological formation of the pituitary gland. Ectopic adenomas growing in the sphenoid sinus have been reported in only 10 cases so far[1]. Keeping in mind that ectopic pituitary tissue may exist in a patient with Cushing' disease can potentially prevent failure of surgery.

## P1459

### The effect of Ki67 index on tumor behavior in proloctanimas

S. Cander[1,2], E. Erturk[1], O. Oz Gul[1], O. Saraydaroglu[2], O. Unal[1], C. Ersoy[1], E. Tuncel[1] & S. Imamoglu[1]
[1]Bursa Sevket Yilmaz Education and Research Hospital, Bursa, Turkey; [2]Uludag University Medicine School, Bursa, Turkey.

Majority of prolactinomas consists of the small microadenomas that can be treated with dopamine agonists, but they can present different biological behavior features and not infrequently seen as macroadenomas or in giant adenoma size. There are different results on finding of studies which investigate the relationship between high levels of cell proliferation indicators with tumor behavior in pituitary adenomas. In this study, Ki 67 index to investigate the relationship between tumor behavior and treatment response rates.
Thirty-one patients with the diagnosis of operated prolactinoma were included the study. The patients were divided into two groups as having non-invasive tumor and invasive tumor. The patients with a Ki67 index $\geq$3/100 were considered as having a tumor with high proliferative property. The patients cured with surgical treatment those had a normal level of prolactin after the surgery or with the primary medical therapy with at least 50% reduction in the tumor diameter and without worsening of these responses after cessations of the medical therapy were grouped as the patients with good responses.
High proliferation values were found in 14 (45.2%) patients, while Ki67 indices $<$0.03 were defined in 17 (54.8%) patients. Rate of the patients with Ki67 $\geq$0.03 was 37.5% in the noninvasive group and 47.8% in the invasive group. The difference between two groups was not found statistically significant. Reduction in tumor size and prolactin level were found respectively 75.19 and 90.96% in low Ki67 group while 86.36 and 88.16% in high Ki67 group ($P=0.561$, $P$: 0.922). When the responses to the treatment were evaluated in terms of the Ki67 cell proliferation indices, no statistically different was found between the groups with high and low indices in terms of the change in tumor size or prolactin level.
Mean levels of Ki 67 index were determined quite close in non-invasive and invasive prolactinomas. Three patients (37.5%) in Invasive group and 11 patients (47.8%) in non-invasive group were high level of Ki67 index. In addition, Ki67 index does not change the results of treatment. According to these results, Ki67 index has not prognostic indicator in patients with prolactinoma.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1460

### Cyclin D1 gene exon 4/intron 4 region A / G polymorphism and allele ratios in patients with prolactinoma

M. Karkucak[1], S. Cander[1,2], O Oz Gul[1], T. Yakut[1] & E. Erturk[1]
[1]Uludag University Medicine School, Bursa, Turkey; [2]Bursa Sevket Yilmaz Education and Research Hospital, Bursa, Turkey.

Excessive expression of CyD1 in CCND1 gene increase G1-S phase transition and cellular proliferation. In various tumor types and of the few studies of pituitary adenomas, over expression of CyD1 or amplification in the locus of CCND1 gene, have been demonstrated. In this study, we aimed to investigate the effect of cyclin D1 gene polymorphism on tumor formation in prolactinoma patients.
A hundred and thirteen patients and 108 age and gender matched control subjects with the diagnosis of prolactinoma were included in the study.
Male/female ratio was 27/86 and mean age of diagnosis was 34.4$\pm$10.0 years in 113 patients included to the study. Mean age of diagnosis was found as 40.3 $\pm$12.6 years in the male and 32.6$\pm$8.3 in the female patients. A and G allele rates were found as 41.7 and 58.3% in the controls, while these rates were 61.1 and 39.9% in the patients; respectively. GA genotype was the the most common genotype subgroup in the control and patient groups by 40.7 and 51.3%; respectively, while GG genotype was found significantly lower in the patient group compared to the controls. Differences between the groups in terms of the allele rates and genotype distribution were found statistically significant.
Rate of AA genotype and A allele incidence were seen to be significantly higher in the prolactinoma patients than in the controls. Genotype distribution and allele incidences of 113 cases (68 noninvasive, 45 invasive) are given in Table 1 with the values from the previous studies. Accordingly, the rate of AA genotype and A allele incidence are seen higher compared to other studies. This high rate compared to other studies may be resulted from the differences in the measurement methods as well as in the time of the studies. From this point, the rate of increase in A alleles supports the concept of the increase rates may be related to the increase in the incidence of prolactinomas, and Cycline D1 protein may play a role in the occurrence of prolactinomas.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Cancer detection in long-term follow-up of patients with acromegaly

S. Vallette, C. Beauregard, N. Aris-Jilwan, H. Beauregard & O. Serri
CHUM-Hôpital Notre-Dame, Montreal, Quebec, Canada.

Objective
To evaluate the prevalence of cancer in patients with acromegaly followed in our institution.
Design and Patients
Retrospective analysis of clinical data from our Quebec pituitary tumor registry. A total of 107 patients with acromegaly (49% females) followed at the Centre de l'Université de Montréal (CHUM) from 1980 to 2011 for a median of 7 years (Q1–Q3: 3–12).
Results
Thirteen cancers were detected in 11 (10.3%) patients over a period of 12 years. Thyroid (papillary) carcinoma was found in four patients, urologic cancer in three, two different skin cancers (basocellular carcinoma and melanoma) in the same patient, breast cancer in one, ovary adenocarcinoma in one, oesophageal cancer in one and acute leukemia in one patient. Cancer was more common in male patients (73%). Cancer was diagnosed prior to, simultaneously and after diagnosis of acromegaly in four, one and eight cases, respectively. Age of patients at cancer diagnosis was 59 years (56–62). Age of patients at diagnosis of acromegaly was significantly higher in patients with cancer compared to patients without (56 (45–62) vs 42 (33–52) years, $P=0.02$). Time delay from reported acromegaly symptoms onset to diagnosis seemed to be longer, as well as diabetes seemed to be more frequent in acromegalic patients with cancer than in those without, but these differences did not reach statistical significance. There were no significant differences between patients with cancer and those without for initial GH and IGF1 levels, follow-up duration, as well as control of the disease defined by IGF1 normalization.
Conclusion
In our series, cancer seemed to be more frequent in aged patients with acromegaly. Thyroid cancer was the most common cancer associated with acromegaly. Therefore, routine medical follow-up of patients with acromegaly should include a careful assessment for thyroid nodules and cancers.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Study on IGF(CA)19 gene polymorphism in adults with GH deficiency**

C Giavoli[1,2], E Profka[1,2], L Olgiati[1,2], M Filopanti[1,2], S Bergamaschi[1,2], E Ferrante[1,2], M Arosio[1,3], B Ambrosi[1,4], A Spada[1,2] & P Beck-Peccoz[1,2]
[1]University of Milan, Milan, Italy; [2]Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy; [3]Ospedale San Giuseppe, Multimedica, Milan, Italy; [4]IRCCS Policlinico San Donato, San Donato Milanese, Italy.

A highly polymorphic microsatellite in the IGF1 gene promoter, composed of variable cytosine-adenine (CA) repeats ($n=10$–24) has been linked to IGF1 serum concentrations in normal, acromegalic and GHD subjects with conflicting results. Aim of this study was to investigate whether this polymorphism may influence the clinical and biochemical characteristics of adult patients with GHD ($n=97$). Moreover, the response to 12-month rhGH replacement in terms of IGF1 levels, body composition (BF%), lipid profile and glucose homeostasis was evaluated. According to the most frequent 192 bp allele (equivalent to 19 CA-repeats) patients were divided in three genotype-groups: homozygous for 192 bp allele (192/192, $n=7$, 7.2%), heterozygous for the 192 bp allele (192/X, $n=68$, 70.1%) and non-carriers of the 192 bp allele (X/X, $n=22$, 22.7%). The IGF1 genotype did not influence the clinical and biochemical phenotype of GHD adults at baseline. However, when analyzing 12-month rhGH effects separately in the 3 groups, the increase in IGF1 levels and decrease in BF% were similar, while a worsening of insulin sensitivity, documented by a significant increase in glucose levels and HOMA-IR and by a significant decrease of QUICKI, was observed only in groups carrying at least a wild type allele (192/192 and 192/X). In conclusion, longitudinal follow-up of each genotype group showed that the absence of the wild type allele of the IGF1 gene promoter might protect GHD patients from the short-term worsening of insulin sensitivity induced by rhGH.

## P1463

**META-analysis on the effects of octreotide on tumor mass in acromegaly**

G Mazziotti[1,2], V Torri[3], M Spinello[4], I Floriani[3], S Melmed[5] & A Giustina[1]
[1]University of Brescia, Brescia, Italy; [2]Azienda Ospedaliera Carlo Poma, Mantova, Italy; [3]Istituto di Ricerche Farmacologiche Mario Negri, Milano, Italy; [4]Novartis Farma, Origgio, Italy; [5]Cedars Sinai Medical Center, Los Angeles, California, USA.

The long-acting somatostatin analogue octreotide is used either as an adjuvant or primary therapy to lower GH levels in patients with acromegaly and may also induce pituitary tumor shrinkage. However, inconclusive evidences in this respect have been produced by either single-center research paper or pooled analyses. Therefore, we performed a meta-analysis to thoroughly assess the current literature on the effect of octreotide on pituitary tumor shrinkage. A computerized Medline and Embase search was undertaken to identify potentially eligible studies. Eligibility criteria included treatment with octreotide, availability of numerical metrics on tumor shrinkage and clear definition of a clinically relevant reduction in tumor size. Primary endpoints included the proportion of patients with tumor shrinkage and mean percentage reduction in tumor volume.

The electronic search identified 2202 articles. Of these, 41 studies fulfilling the eligibility criteria were selected for data extraction and analysis. In total, 1685 patients were included in the analysis, ranging from 6 to 189 patients per trial.

Octreotide was shown to induce tumor shrinkage in 52% (95% CI: 49–54%) of treated patients. In patients treated with the LAR formulation of octreotide, this increased to 70%, (95% CI: 67–74%). In the nine studies in which tumor shrinkage was quantified, the overall weighted mean percentage reduction in tumor size was 29.3% (95% CI: 24.6–34.0%), rising to 49.5% (95% CI: 39.0–59.9%) with octreotide LAR.

Declaration of interest

I fully declare a conflict of interest. Details below:

## P1464

**Parasellar masses: experience in 47 patients**

J Saraiva, L Gomes, I Paiva, A Vieira, M Alves, S Gouveia, C Moreno & M Carvalheiro
Coimbra University Hospital, Coimbra, Portugal.

Introduction

The differential diagnosis of nonpituitary sellar masses is broad. Clinical presentation may be similar to that of pituitary adenomas. Sometimes certain findings are particular to some lesions and may help in their differentiation. Correct preoperative diagnosis is important to better guide therapeutic management. The aim of this work was to analyze patients with parasellar lesions (craniopharyngiomas excluded), attended in the Department of Endocrinology of our hospital.

Methods

We studied clinical presentation, laboratorial and imaging results of different parasellar lesions of 47 patients before and after treatment.

Result

Sixty-six percent female, mean age $45.2 \pm 17.4$ years old. Meningiomas (18) and Rathke's cleft cyst (16) were the most frequent lesions. We also found arachnoid cysts (5), chordomas (3), gangliogliomas (2), germinomas (2) and hamartoma (1). At presentation 80.9% of patients had visual complaints, 46.8% headaches. Preoperatory evaluation: 26.2% with hypogonadism, 21.4% hypothyroidism, 11.9% adrenal and 16.7% GH insufficiencies. 11.9% of patients had panhypopituitarism, 31.5% hyperprolactinemia. Lesion location: 37.8% intrasellar with extrasellar extention, 35.6% exclusively suprasellar, 26.7% intrasellar. 80.9% of patients were submitted to surgical treatment, 52.6% of those to transcranial approach. Nine patients submitted to radiotherapy and seven reoperated. Major surgical complications: CSF leakage (seven patients) and III pair injury (six patients). After treatment, headache improved in 66.7%. Visual complaints improved in 13%, persisted in 43.5% and worsened in 39.1%. Post-operatory analytical study showed worsening of hormonal deficits (panhypopituitarism in 26.3%, hypogonadism and hypothyroidism in 52.6%, GH and adrenal insufficiencies in 44.7 and 42.1% respectively). 47.4% maintained residual tumor, 21.1% relapsed. There were no deaths, 42 patients maintain follow-up.

Conclusion

Parasellar lesions represent a very heterogeneous group. In this series, where craniopharyngiomas were excluded, meningiomas and Rathke's cleft cyst were the most frequent lesions. They originate variable clinical presentation and some degree of hormonal dysfunction. Surgical treatment leads to clinical improvement but worsening of hormonal dysfunction.

Declaration of interest

## P1465

**Colonic neoplasms in acromegaly: are there serum risk factors?**

M Lombardi, I Scattina, C Urbani, C Sardella, A Marchello, A Nuzzo, E Dell'Unto, E Martino & F Bogazzi
University Pisa, Pisa, Italy.

Hyperinsulinemia has been associated to an increased risk of colorectal cancer and adenomas, while higher serum 25-hydroxy vitamin D3 and folate seem to reduce the development of colonic lesions in general population. Acromegalic patients have an increased risk of colonic tumors and an association between higher fasting insulin levels and risk of colonic adenomas has been previously demonstrated. No data are available about the influence of vitamin D and folate-homocysteine levels on the development of colorectal lesion in acromegaly.

To investigate the role of insulin levels, 25-hydroxy vitamin D3 and folate-homocysteine status on the occurrence of colonic lesions in acromegalic patients, 146 acromegalic patients were submitted to a first colonoscopy screening after diagnosis. At the same time they were evaluated for fasting insulin levels, serum 25-hydroxy-vitamin D (25(OH)D3), homocysteine and folid acid. Data were collected retrospectively.

Colonic lesions were detected in 46 patients (31.5%) and consisted in hyperplastic polyps in 32 cases (21.9%), and adenomatous polyps in 14 patients (9.6%). Acromegalic patients with ($n=14$) or without ($n=132$) colonic adenomas did not significantly differ as to gender, age, BMI, family history of colorectal cancer, smoking habits, estimated duration of disease and baseline IGF1 even after excluding patient with drugs interfering with insulin levels. Fasting insulin, 25(OH)D3, folate and homocysteine levels, had not significant differences in

patients with or without colonic adenomas (7.00±3.83 vs 9.93±7.3 $P=0.66$; 16.85±10.85 vs 18.18±9.92 $P=0.64$; 7.35±2.59 vs 7.49±2.94 $P=0.94$; 7.74±2.55 vs 8.38±2.58 $P=0.36$). All the parameters evaluated were not associated to colonic adenomas at univariate and multivariate analysis.
No relationship was identified between insulin, 25(OH)D3, folate and homocysteine serum levels and risk of developing colonic lesions in this subset of acromegalic patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1466

**No long-term weight reduction after gastric banding in obese patients with craniopharyngioma involving hypothalamic structures: experiences from KRANIOPHARYNGEOM 2000**

H Müller[1], U Gebhardt[1], J Maroske[2] & E Hanisch[3]
[1]Klinikum Oldenburg, Oldenburg, Germany; [2]Verbundklinikum Rothenburg o.d. Tauber, Rothenburg o.d. Tauber, Germany; [3]Asklepios Klinik, Langen, Germany.

Background
Craniopharyngiomas are embryogenic malformations which lead to eating disorders and morbid obesity due to hypothalamic involvement. The experience with laparoscopic adjustable gastric banding (LAGB) in obese craniopharyngioma patients is limited especially in regard to long-term effects and tolerability.
Patients and methods
We are reporting on four patients with childhood craniopharyngioma diagnosed at age 2, 13, 12, and 20 years.
Results
Body mass index (BMI SDS) at diagnosis was −0.9, +4.5, +4.7 and +0.23 SD. All patients developed morbid obesity (BMI SDS: +10,87, +10.36, +11.4, +6,2) so that 11, 5, 9 and 3 years after diagnosis LAGB were performed. LAGB were well tolerated. During long-term follow-up, the nadir BMI SDS (+6.9, +9.5, +7.8, +4.9) were reached 2.0, 0.5, 1.0, 0.8 years after LAGB. At last evaluation 9.1, 5.3, 7.1, 7.1 years after LAGB, the patients BMI (BMI SDS at last evaluation: +10.2, +13.9, +10.2, +6.3) had increased again but remained at a constant level comparable with baseline BMI SDS at the time of LABG. Quality of life was not decreased due to LAGB and tolerability was sufficient.
Conclusions
We conclude that LAGB is feasible and could have clinical relevant effects on long-term weight stabilization of obese craniopharyngioma patients with hypothalamic syndrome. However, a significant weight reduction was not achieved after LAGB in patients with childhood craniopharyngioma. Non-reversible bariatric procedures such as gastric bypass are not recommended for treatment of obese children and adolescents with craniopharyngioma due to ethical considerations.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Predictors of the acromegaly-associated mortality in the last decade**

S Galoiu[1,2], S Ioacara[1,3], I Baciu[1] & M Coculescu[1,2]
[1]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania; [2]'C.I.Parhon' Institute of Endocrinology, Bucharest, Romania; [3]'N. Paulescu' National Institute of Diabetes, Nutrition and Metabolic Diseases, Bucharest, Romania.

Introduction
Acromegaly is associated with an increased mortality in untreated patients. Recent papers suggest an improvement of survival in the last years.
Aims
To assess mortality ratio and to identify prognostic factors associated with mortality in acromegaly in the last decade.
Methods
297 patients (186 F/111 M, mean age 49.8±0.7 years) with acromegaly admitted in a single Neuroendocrinology Department between Jan 2001 and Dec 2010 were retrospectively studied. Serum GH levels were measured by IRMA (sensitivity 0.1 ng/ml). PAMCOMP computation program was used to calculate standardized mortality ratio (SMR). Cox regression analysis revealed independent factors associated with mortality.
Results
During follow-up (median 5.9 years −1689.85 person years), 21 patients died (7.07%), corresponding to a death rate of 12.5 deaths/1000 person years. All causes mortality was not statistically different from that of general population: SMR was 0.94 (95% confidence interval (CI) 0.58–1.45). Those dying (mean death age 62.7±2.8 years) were significantly older at diagnosis (age at diagnosis 50.3±2.6 years in dying patients vs 43.7±0.7 years in survivors, $P=0.02$) and had higher posttreatment serum GH levels (16.4±4.1 ng/ml in dying vs 8.1±0.9 ng/ml in surviving patients, $P=0.04$). Survivors were more likely to be treated by pituitary surgery (160/274 patients), and/or somatostatin analogues (79/274 patients) than dying patients (7/21 received operation, $P=0.02$ and 2/21 received somatostatin analogues, $P=0.04$); radiotherapy did not seem to influence overall mortality. When assessed by Cox-regression analysis, last serum GH levels (hazard ratio (HR) 1.06, 95% CI 1.03–1.09), acromegaly duration (HR 1.08, 95% CI 1.02–1.1) and age at diagnosis (HR 1.06, 95% CI 1.02–1.1) were independent predictors of mortality. Patients with posttreatment GH levels above 5.5 ng/ml had an increased SMR: 1.7 (95% CI 1.003–2.853).
Conclusions
Patients with acromegaly admitted in the last decade had a mortality rate close to the expected level, mainly due to modern therapy. Posttreatment serum GH levels and acromegaly duration were the main predictors of survival.

**Endoscopic transsphenoidal surgery as the therapy of choice for acromegaly: a 13-year experience in a single centre**

M Faustini-Fustini[1], M Zoli[1], D Mazzatenta[1], V Sciarretta[2], E Pasquini[2] & G Frank[1]
[1]Bellaria Hospital, Bologna, Italy; [2]University of Bologna, Bologna, Italy.

Aim of the study
To assess the efficacy of endoscopic transsphenoidal surgery (ETS) in acromegalic patients.
Methods
Over the past 13 years, 207 consecutive patients (117 females; median age, 46 years, range 14–78) affected with GH-secreting adenoma (79 microadenomas, 38%) were operated on in our centre by the same surgical team. Age, gender, tumor size, extension, invasiveness of surrounding structures, and histopathologic features (ki67, mitoses, hystotype) have been considered together with preoperative clinical history and postoperative follow-up. An early postoperative assessment was carried out 3–6 months after surgery. The follow-up period ranged from 3 to 160 months. A statistical analysis was performed to assess a correlation with poor outcome.
Results
In the early postoperative assessment, biochemical control rate with normalization of IGF1 was 72%. Control rate remained the same during the follow-up. After surgical debulking, pharmacological treatment (somatostatin analogues and/or pegvisomant) further increased the control rate, which achieved 97%. The remaining 3% of patients still remains uncontrolled after surgery and complementary treatments (pharmacological therapy and/or radiotherapy). No mortality was observed. Diabetes insipidus (DI) and pituitary insufficiency (three and four cases, respectively) accounted for permanent postoperative morbidity. Transient morbidity encompassed transient DI (13 cases), symptomatic SIADH (seven cases), epistaxis (two cases), and CSF leak requiring intervention (one case). Both invasiveness and previous surgery correlated with unfavorable outcomes ($P<0.01$, $\chi^2$ test). In the multi-variate analysis, only invasiveness of the cavernous sinus and/or the surrounding bone structures was related with worse results ($P<0.01$).
Conclusion
Our data confirm that ETS performed by dedicated and experienced surgeons is the treatment of choice for acromegaly. Invasiveness was the main factor responsible for poor outcome. Control rate further improved by pharmacological treatments in patients with surgical debulking of the tumor, while a low percentage (3%) did not respond satisfactorily to any treatment.

**MALE macroprolactinomas: response to medical treatement**

F Chentli, S Azzoug, N Ould Driss, D Belkhamsa, F Kessaci & B Mansouri
Bab El Oued Hospital, Algiers, Algeria.

Introduction
Male macroprolactinomas are very rare and more invasive compared to female ones. So, they are few reports concerning their response to medical treatment. We aimed to appreciate their response to Bromocriptine: the only product available in our country.
Subjects and methods
55 men (mean age: 36.3 years) with mean height pituitary tumor $=38.3$ mm (12–118) and mean PRL: 2942 ng/ml (132–28 000) were analyzed. Bromocriptine was given twice/day, mean dose: 24.8 mg/day (3.75–80), and mean duration: 32 months (1–195). After taking Bromocriptine, our patients underwent clinical, biological, visual and radiological control based on cerebral MRI.
Results
The treatment was considered as irregular in 57%. Side effects were present in 45% (hypotension and/or gastro intestinal troubles). Mean PRL was significantly reduced (2942 vs 192 ng/ml, $P<0.001$). PRL was normalized in 70% and significantly reduced in 93%. Tumor height decreased significantly (38.3 mm vs 18, $P<0.001$). Pituitary process disappeared in 20%, was significantly reduced (26–91%) in 69%. A decrease $<20\%$ was seen in 9%. The tumour increased in 1.8%. Headaches and visual abnormalities improved in almost all cases.
Conclusion
Although the treatment was irregular in 57%, the response to Bromocriptine was very good in male macroprolactinomas, as PRL was normalized or had significantly decreased in 93%, and tumor shrinkage was observed in more than 89%.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Evaluation of pituitary gland with magnetic resonance imaging in hypogonadic patients**

D Arpaci[1], N Cuhaci[1], D Ozdemir[1], G Kaya[1], M Gumus[1], R Ersoy[2] & B Cakir[2]
[1]Ankara Ataturk Training and Research Hospital, Ankara, Turkey; [2]Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey.

Aim
Hypogonadism is a result of testicular failure and/or insufficient pituitary stimulation. Various hypothalamo-pituitary abnormalities or lesions can contribute to hypogonadism. Benign or malign tumoural lesions of cellar or paracellar region, may lead to hypogonadism. Therefore, pituitary magnetic resonance imaging (MRI), is needed in hypogonadic patients. In our study, we aimed to investigate our hypogonadic patients' hypothalamo-pituitary MRI findings.
Method
We evaluated 49 hypogonadic patients followed in our clinic. These patients' pituitary MRI findings are evaluated retrospectively.
Results
79.4% of patients had hypogonadotrophic hypogonadism, whereas 20.6% had hypergonadotrophic hypogonadism. 80.9% of the hypogonadotrophic patients' were male. 19.1% were female. Pituitary MRI findings of hypogonadotrophic patients revealed that; 59.5% were normal, 16.7% pituitary microadenoma, 11.9% partial empty cella, 4.7% pituitary macroadenoma, 2.4% empty cella, 2.4% ectopic neuropituitary, and 2.4% empty cella and ectopic neuropituitary together. In the hypergonadotrophic group, all of the patients were male. In this group pituitary MR findings were respectively; 71.4% normal, 14.3% ectopic neuropituitary, 14.3% pituitary microadenoma.
Conclusion
In half of the patients with hypogonadotrophic hypogonadism, Pituitary MRI findings may be normal. In these patients, if clinic and labarotuary results are harmonious, to determine the diagnosis dynamic tests are required and appropriate therapy must be done, even if pituitary MRI is normal. In the hypergonadotrophic hypogonadic patients, although etiology is not associated with hypothalamus and/or pituitary gland, we can find pathologic pituitary MRI results. So, we suggest, carrying out hipothalamo-pituitary imagining with hypergonadotrophic patients.

## P1471

**Is acromegaly associated with irritable bowel syndrome?**

E Caglar, E Hatipoglu, M Niyazoglu, O Celik, M Tuncer & P Kadioglu
Cerrahpasa Medical School, University of Istanbul, Istanbul, Turkey.

Introduction
Gastrointestinal system is under the influence of excessive GH and IGF1 in acromegaly. Increased bowel length and delayed transit time may cause functional disturbence of the bowel in acromegaly. The objective of the current study is to evaluate the frequency of irritable bowel syndrome (IBS) in cases with acromegaly.
Methods
Twenty-five active cases with acromegaly who were newly diagnosed between 2010–2011 and 16 inactive acromegaly patients followed at Endocrinology–Metabolism out-patient clinic of Cerrahpasa Medical Faculty between 1983 and 2011 were included in the study. Twenty gender and age matched healthy subjects (HS) composed the control group. All cases were questioned for presence of IBS using Rome III criteria. Abdominal ultrasonography (USG) and colonoscopy results of acromegalic patients were obtained. In addition, cases with acromegaly were evaluated for their quality of life and status of depression by using acromegaly quality of life questionnaire (AcroQoL) and Beck depression inventory (BDI) respectively.
Results
IBS was present in 4 of 25 (16%) newly diagnosed active cases with acromegaly whereas one of 16 (6%) active acromegaly patients and 2 of 29 HS had IBS (6.8%) ($P=0.28$). Four of 5 patients with IBS had no pathologic finding in abdominal USG or colonoscopy that could explain their symptoms. One patien refused to have USG or colonoscopy. The median BDI and Acroqol scores in active and inactive acromegaly groups were 16 (IQR: 10.00–22.50), 11.5 (IQR: 4.50–19.50) ($P=0.25$) and 56 (IQR: 42.50–68.00), 65.50 (IQR: 40.63–76.75) ($P=0.45$), respectively.
Conclusion
A higher percentage of IBS was observed in acromegaly patients with active disease compared to inactive patients although there was not a statistically significant difference.
Declaration of interest

## P1472

**Acromegaly, does tumor size matters?**

F Serra, S Duarte, R Ferreira, C Moniz, H Simões, C Marques, J Azinheira, C Saraiva & M Saraiva
Hospital Egas Moniz, Centro Hospitalar Lisboa Ocidental, Lisbon, Portugal.

Introduction
Acromegaly is a rare disease which results from a GH producing adenoma. Around 70–80% are macroadenomas. The therapeutic options currently available are surgery, radiotherapy (RT) and medical treatment (MT). According to literature microadenomas have a higher remission rate, around 80%.

Methods
A retrospective chart review of the patients with acromegaly treated in our centre from 1976 to 2011 was performed. In terms of disease control at present it was considered: Controlled with therapy when GH and IGF1 were normal but under medical therapy, persistent disease when the disease was not controlled and remission. Remission was considered when a period longer than 6 months without therapy on the last visit day, with GH $<2.5$ ng/ml, normal IGF1 and GH nadir with PTGO $<1$ ng/ml. This were the safe criteria.
Results
Among 57 patients, there were 42 (73.7%) female. Mean age of diagnosis 49.3 $\pm$14.9 and a mean follow up duration of 10.8$\pm$7.9 years. The median GH values on the diagnosis were 18.35 ng/ml, and IGF1 761 ng/ml. There was 44 (77.2%) macroadenomas. Remission was observed in 5 (50%) of the microadenomas and 23 (52.3%) of the macroadenomas, 9 (39.1%) with extension out of sella turcica. Eighteen (31.6%) were controlled under therapy and 11 (19.3%) had persistence of disease. All of the cases in remission were first treated with transfenoidal surgery, 10 (35.7%) were also treated with MT (three microadenomas and seven macroadenomas), and 5 (17.8%) macroadenomas with MT plus RT.
Conclusions
The results of these study shows a similar remisson rate between micro and macroadenomas, (52.3 vs 50%) even though the macroadenomas less frequently have safe criteria just with surgery. This results also showed that the macrodenomas confined to the sella gets in remission more frequently than the invasive tumours.

**Clinical and histological characteristics of giant GH producing pituitary adenomas**

T Fukui[1], N Fukuhara[1], H Nishioka[1], N Kobayashi[1,2], N Inoshita[1], N Yoshida[1], H Suzuki[1], A Takeshita[1], Y Takeuchi[1] & S Yamada[1]
Toranomon Hospital, Tokyo, Japan; Yuai Memorial Hospital, Furukawa, Japan.

Introduction
Surgical treatment of giant GH cell adenomas ($>4$ cm in maximum diameter; GHomas) has been considered difficult. However, clinical and histological characteristics of these adenomas are still enigmatic. We retrospectively analyzed data of 17 giant GHomas experienced at Toranomon hospital to clarify their characteristics.
Methods
These 17 patients, accounting for 3.1% of 549 acromegalic patients undergoing surgery between 2006 and 2011, who consisted of 7 females and 10 males ranging from 17 to 48 years of age.
Results
Visual disturbance was found in 6 of 17 patients and serum GH and IGF1 levels were ranging from 2.6 to 427.6 ng/ml and 418 to 1390 ng/ml, respectively. Most tumors showed invasion to the cavernous sinus (11 patients showed Knosp's Grade 4). Preoperative medication was applied in 12 patients and tumor shrinkage was found in 10 patients. TSS, TSS followed by craniotomy, and simultaneous combined transsphenoidal & transcranial approach was performed in 11, 3, and 3 patients, respectively. Total tumor removal was accomplished in ten patients (59%; endocrinological cure was in five patients). As surgical complications, anterior hormone deterioration occurred in three patients and new postoperative diabetes insipidus was in two patients. In addition, transient CSF leakage was found in one, carotid artery injury in one and transient ophthalmoplegia in four patients. Postoperative medication was used in six patients, whereas radiotherapy was administered in five patients. Histological findings were also various as follows; pure GH adenoma 11 patients, GH–PRL adenomas three, GH–TSH adenoma one, and GH–PRL–TSH adenomas two. Interestingly, Ki67 index $<1$% was in nine patients, suggesting lower biological tumor activity.
Conclusion
Our study confirmed that giant GHomas showed various endocrinological and histological findings. Moreover, they are generally very difficult to be treated and therefore multidisciplinary treatment including various surgical approaches is required to control giant GHomas.

**Long-term outcomes after sterotactic radiosurgery for non-functioning pituitary adenomas**

Y Suleiman[1], R Vilchez[2], A Román[2], A Soto[3], E Venegas[3], A Soto[3], A Atutxa[3], J Martín[2] & E Torres[1]
[1]San Cecilio Hospital, Granada, Spain; [2]Virgen de las Nieves Hospital, Granada, Spain; [3]Virgen del Rocío Hospital, Sevilla, Spain.

Introduction
Sterotactic radiosurgery (SR) has been used to treat recurrent adenomas and also as a primary treatment. The objective is to evaluate long-term tumor control, development of hypopituitarism and other side effects in the follow-up.
Patients and method
Retrospective analysis of 21 patients with non-functioning pituitary adenomas (NFA) treated with modified linear accelerator (LINAC) between 1998 and 2009 in three tertiary Spanish hospitals. Control of tumor size was defined as unchage or decrease of tumor size.
Results
The average follow-up period was 6.2 years. The cohort consisted of 61.9% of women and 30.1% of men with an average age of 45.3 years. LINAC was the primary treatment in 3 patients, while the remaining 18 patients had undergone one/two prior surgical resections. Inmunohistochemical data shows 9 silent pituitary tumors, 4 patients were catalogued as "null cell " and the remaining 8 as NFA in the strict sense. The mean dose of treatment was 16.2 Gy ($\pm$2.01 SD). Prior to radiosurgery, pituitary hormone deficits were observed in 66.7% patients. New endocrine deficiencies were described in 11 patients during the follow-up. Tumor volume decreased in 52.3% patients, increased in 38.1% patients, and was unchanged in 9.5% patients. Tumor size decrease was statistically significant 12 months after radiosurgery (14.5 mm vs 12.3; $P=0.03$). Side effects presented in half of the patients were transitory. Seven patients presented cognitive problems 12–18 months after radiosurgery, one patient suffered a stroke in the fourth year after SR and other patients developed a second tumor nine years after SR.
Conclusions
LINAC resulted in a tumour size control of 61.8% in patients with NFA. Response to SR was statistically significant 1 year after treatment. Precocious side effects are usually transitory. The follow-up allows to detect new endocrine deficits and other side effects that may appear in the long term.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector

## P1475

**Long-term outcomes after sterotactic radiosurgery for functioning pituitary adenomas**

Y Suleiman[1], R Vilchez[2], A Román[2], A Soto[3], E Venegas[3], A Leal[3], A Atutxa[3], J Martin[2] & E Torres[1]
[1]San Cecilio Hospital, Granada, Spain; [2]Virgen de las Nieves Hospital, Granada, Spain; [3]Virgen del Rocío Hospital, Sevilla, Spain

Introduction
Sterotactic radiosurgery (SR) has been used to treat recurrent adenomas after failure of medical and surgical procedures and also as a primary treatment. The aim of this paper is to evaluate long-term control of functioning pituitary adenomas (FPA).
Patients and method
Thirty-eight patients with FPA treated with modified linear accelerator (LINAC) between 1998 and 2009 in three tertiary Spanish hospitals. Hormonal control was defined as hormonal normalization. Control of tumor size was defined as an unchange/decrease of tumor size.
Results
The average follow-up period was 7.3 years. The cohort consisted of 78.9% of women and 21.1% of men with an average age of 39.9 years. LINAC was the primary treatment in 16 patients, while the remaining 22 patients had undergone one/two prior surgical resections. There were 4 prolactinomas,

17 adrenocorticotropic hormone-secreting and 17 GH secreting tumors. Prior to radiosurgery, pituitary hormone deficits were observed in 23.6% of patients. New endocrine deficits occurred of 75–82.3% patients during the follow-up. Seven patients achieved remission after SR treatment. The mean dose of treatment was 17 Gy. Tumor volume decreased in 68.4% patients, increased in 5.2% of patients, and was unchanged in 26.3% of patients. Three patients presented cognitive deterioration after radiosurgery and two acromegaly patients suffered strokes two and three years after radiosurgery. The decrease in levels of IGF1 and 24 h urine cortisol after 3 months of SR was statistically significant ($P=0.011$ and $P=0.017$ respectively), but not in prolactine levels ($P=0.144$). There were no differences between radiosurgery as primary or adjuvant treatment.
Conclusions
LINAC resulted in a durable rate of tumor control in 94.7% of patients with FPA; nevertheless hormonal normalization without treatment is more difficult to reach. Follow-up is important to detect new hormonal deficits and other side effects that may appear in the long term.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1476

### Comparison of immunoassay and mass spectrometry measurement of cortisol during $ACTH_{1–24}$ stimulation tests

M Burt[1,2], B Mangelsdorf[1], M Whiting[2,3], A Rogers[2], J Ho[1,2], W Inder[4] & M Doogue[1,2]
[1]Repatriation General Hospital, Adelaide, South Australia, Australia; [2]Flinders University, Adelaide, South Australia, Australia; [3]Flinders Medical Centre, Adelaide, South Australia, Australia; [4]Princess Alexandra Hospital, Brisbane, Queensland, Australia.

Measurement of plasma cortisol by immunoassay after $ACTH_{1–24}$ stimulation is used to assess the hypothalamic–pituitary–adrenal (HPA) axis. Liquid chromatography–tandem mass spectrometry (LC–MS/MS) has greater specificity and equilibrium dialysis allows measurement of free plasma cortisol. We investigated whether measuring cortisol by LC–MS/MS improves the sensitivity of $ACTH_{1–24}$ stimulation testing in pituitary patients. We studied 60 controls (34 female, age $61\pm12$ years, BMI $27.7\pm5.6$ kg/m$^2$) and 21 patients with pituitary disease in whom HPA sufficiency ($n=8$) or deficiency ($n=13$) had been defined by insulin tolerance test (peak cortisol cut-off 550 nmol/l) or morning cortisol (deficient $\leq$100 nmol/l, sufficient $\geq$500 nmol/l). Subjects received 1 μg $ACTH_{1–24}$ intravenously and 250 μg $ACTH_{1–24}$ intramuscularly about 7 days apart. Total and free (following equilibrium dialysis) plasma cortisol were measured by in-house LC–MS/MS assay and total plasma cortisol by immunoassay (Elecsys 2010, Roche Diagnostics). The lower limits of the 95% confidence intervals derived from normal subjects were used to define the pituitary patients HPA status. The 30 min cortisol during the 1 μg $ACTH_{1–24}$ stimulation test and the 30 and 60 min cortisols during the 250 μg $ACTH_{1–24}$ stimulation tests were equally concordant with previous HPA axis assessment. Measurements of total cortisol by immunoassay were concordant with previous HPA axis assessment in 19/21 and 20/21 patients using the 1 and 250 μg $ACTH_{1–24}$ tests respectively. The sensitivities of total and free cortisol by LC–MS/MS were similar to those derived from the immunoassay (Table). We conclude that measurement of total or free plasma cortisol by LC–MS/MS after $ACTH_{1–24}$ stimulation provides similar results to immunoassay in pituitary patients.

**Table 1**

| | 0 min | 30 min | 60 min |
|---|---|---|---|
| | 1 μg $ACTH_{1–24}$ stimulation test | | |
| Total cortisol (immunoassay, nmol/l)[a] | 199–763 | 441–919 | 317–864 |
| Concordance ($n$, (%))[b] | 17 (81) | 19 (90) | 17 (81) |
| Total cortisol (LC–MS/MS, nmol/l)[a] | 213–933 | 497–1125 | 327–1067 |
| Concordance ($n$, (%))[b] | 16 (76) | 20 (95) | 16 (76) |
| Free cortisol (LC–MS/MS, nmol/l)[a] | 4.0–45.8 | 31.6–94.6 | 15.3–62.5 |
| Concordance ($n$, (%))[b] | 16 (76) | 20 (21) | 18 (86) |

### Cushing's disease: prospective assessment of factors influencing the efficacy of transsphenoidal surgery

P Witek[1,3], G Zielinski[1], K Szamotulska[2] & W Zgliczynski[3]
[1]Military Institute of Medicine, Warsaw, Poland; [2]Institute of Mother and Child, Warsaw, Poland; [3]The Medical Centre of Postgraduate Education, Warsaw, Poland.

Introduction
Assessment of the efficacy of surgical treatment for Cushing's disease (CD) is one of the biggest challenges in contemporary endocrinology. The aim of this study was prospective evaluation of factors influencing the result of transsphenoidal surgery for CD.
Methods
The study population consisted of 36 consecutive patients with CD hospitalized in the Department of Endocrinology from 2005 to 2009 and operated on using the same surgical protocol in the Department of Neurosurgery. Preoperative hormonal assessment, results of MRI and histopathological examination were taken into account. Particular attention was paid to the early postoperative cortisol levels measured at 6.00 on the first day after surgery.
Results
Mean serum cortisol level on the 1st postoperative day was $6.0\pm9.02$ μg/dl (median: 1.98 μg/dl). Twenty three patients (63.9%) were regarded as surgically cured from CD using commonly adopted criteria. In all cured cases, the serum cortisol level on the 1st postoperative day was $\leq$ 2.5 μg/dl. In the cured group, there was a significantly greater number of patients with pituitary microadenoma clearly visualized in the preoperative MRI than in the non-cured group (73.9 vs 38.5%; $P=0.036$). A difference was also demonstrated with regard to results of immunohistochemical examination. The confirmation of corticotroph adenoma was more frequently observed in the cured group in comparison with the non-cured group (87 vs 53.8%; $P=0.028$). There was no difference in terms of preoperative ACTH ($P=0.88$) and cortisol levels ($P=0.71$).
Conclusion
The optimal cut off value suggesting remission of CD is serum cortisol level $\leq$ 2.5 μg/dl on the 1st postoperative day. Other factors influencing the remission of CD are: the distinct pituitary microadenoma visualized in the MRI and the histopathologically confirmed presence of corticotroph adenoma. However, any of preoperative hormone measurements affected the efficacy of surgical treatment.

### The results of surgical treatment on prolactinomas in females of child bearing ages

S Fujio, M Habu, S Yunoue, H Hirano & K Arita
Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan.

Introduction
Medical therapy with dopaminergic drugs is the preferred initial treatment for symptomatic prolactinoma. However, some drawbacks of medical therapy are still of concern. Surgery is indicated in cases of resistance or intolerance to drugs or where patients prefer definitive cure to lifelong drug treatment. In addition, young women with small and enclosed type tumor may be good candidates for surgical treatment because of high curability and safety. We evaluated the

long-term effect of surgery in patients who had been followed up longer than 1 year postoperatively.
Methods
Subjects are 16 females of child bearing ages who underwent transsphenoidal resection of prolactinomas from 2006 through 2010.
Results
Mean age at surgery was 25.8±6.2 years. Preoperatively, 37.5% patients had received medical treatment. Mean preoperative PRL concentration was 224.2 ±138.4 ng/ml. Mean tumor diameter was 12.1±6.0 mm. At the time of diagnosis, 81.3% patients had amenorrhea, and 18.7% patients had oligomenorrhea. Mean postoperative PRL concentration was 6.2±4.5 ng/ml. Surgical cure was achieved in all patients, and they had regular menstruation. No operative severe morbidity occurred. Gonadotropin secretory function was also well preserved. At the latest follow-up, 42.9±17.4 months after surgery, four patients have given birth, but a patient whose PRL level increased again has received cabergoline therapy.
Conclusion
The surgical treatment by skillful hands on small and enclosed prolactinomas in young females is still one of reasonable choices for its safety and efficacy.

### Treatment outcomes in prolactinomas with and without cavernous sinus invasion

O Oz Gul[1,3], S Cander[1,2], E Erturk[1], O Unal[1], C Ersoy[1], E Tuncel[1] & S Imamoglu[1]
[1]Uludag University Medicine School, Bursa, Turkey; [2]Bursa Sevket Yilmaz Education and Research Hospital, Bursa, Turkey; [3]Bursa Cekirge State Hospital, Bursa, Turkey.

In prolactinomas, today first choice of treatment is medical treatment with dopamine agonists. Cavernous sinus invasion is not uncommon in prolactinomas and stands out as a blocking factor for surgical removal of the tumor fully. In our study, the presence of cavernous sinus invasion was to investigate the effect on the results of surgical and medical treatment in prolactinomas.
Eighty-seven patients followed up with a diagnosis of prolactinoma were included in the study. Presence or absence of cavernous sinus invasion were defined by examining detailed the coronal images of pituitary magnetic resonance imaging scans. Adenomas that surrounding 67% (2/3) of the internal carotid artery in the cavernous sinus segment were defined as adenomas with cavernous sinus invasion. Respond to treatment determined consider with before and after treatment tumor sizes, prolactin levels and recurrence rates of patients. Accordingly this, remission (tumor shrinkage of at least 50%, normalization of prolactin level) or complete recovery provided that patients respond well to treatment was classified as a group.
In 23 patients with cavernous sinus invasion (CSI group), male/female (M/F) ratio was determined as 16/7 with 37.7 average age at diagnosis and 7/57 with 33.5 average age at diagnosis in 64 patients without invasion (nCSI group). 73.4 and 78.3% of patients respond well to treatment with 70.2 and 69.2% average percentage of reduction in tumor size had been established in CSI and nCSI groups respectively. The percentage of operated patients was found 87% in CSI group while 32.8% in nCSI group. Twenty patients in total of 41 operated patients was in CSI group and only of them was found cured surgically while 10 patients were found cured surgically in nCSI group ($P<0.01$). The remission rates with surgery were similar in both groups (75 and 81%).
According to our study results, response to medical therapy is not affected by cavernous sinus invasion state but invasion state affects the results of surgical treatment. Accordingly these results, patients with cavernous sinus invasion are not suitable candidates for surgical treatment. When surgical treatment is recommended to prolactinoma patients, cavernous sinus invasion should be considered.

### Change in somatostatinergic tone of acromegalic patients according to the size of GH-producing pituitary tumors

S Chin, S Oh & S Kim
Kyung Hee University School of Medicine, Seoul, Republic of Korea.

Objective
Change in somatostatinergic tone (SST) is one of the key features of acromegaly, but the effect of tumor size on SST is not clear.
Design
The aim of this study was to determine how SST changes depending upon the size of GH-producing pituitary tumors.
Method
GH levels of 29 patients with newly diagnosed acromegaly were measured using a 75 g oral glucose tolerance test (OGTT), an insulin tolerance test (ITT) and an octreotide suppression test (OST). GH/glucose ratio during the OGTT and the ITT were calculated, and GH levels during the OGTT were subtracted from those during the ITT and the OST at the same time point (ΔGHIO and ΔGHSO respectively). These values were compared according to the size of tumors and the response pattern to the OST.
Results
Twenty-two of 29 tumors were macroadenomas. The ratio between GH and glucose (GH/glucose) during the OGTT but not the ITT was also higher in macroadenomas than microadenomas with borderline significance. ΔGHIO and ΔGHSO during the entire test time also were different between macroadenomas and microadenomas with borderline significance. According to the further analyses with macroadenomas based upon the response pattern to the OST, GH/glucose for both the OGTT and the ITT were higher in non-responders with borderline significance while ΔGHIO nor ΔGHSO did produce significant differences between responders and non-responders.
Conclusion
Our study suggests that, as the size of the tumor becomes large, the effect of glucose on SST was attenuated. Macroadenomas with non-responders to the OST had the portion of GH secretion beyond the range of regulation by SST. This is the first study to examine changes in SST of GH-producing pituitary tumors through the additional manipulation of test results necessary to confirm the diagnosis of acromegaly.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Two cases of sever congenital central hypothyroidism with TSH and prolactin deficiency-possible new syndrome

N Matsuura[1], A Koike[2], S Ohtsu[3], N Takubo[3], K Kikuda[3], K Shibayama[3], S Narumi[4] & T Hasegawa[4]
[1]Seitoku University, Matsudo, Japan; [2]Koike Pediatric Clinic, Sapporo, Japan; [3]Kitasato University School of Medicine, Sagamihara, Japan; [4]Keio University School of Medicine, Tokyo, Japan.

Instruction
Most of cases reported before who were detected by $FT_4$ or $T_4$ newborn screening are, TSH and GH deficiency or CNS anomalies, and their hypothyroidism is mild. We report two cases of sever congenital hypothyroidism with TSH and Prolactin (PRL) deficiency, detected by TSH and $FT_4$ screening.
Case report
Case 1. K.W. boy, was born at 38 gestations, weighted 3.17 kg. Thyroid function at 5 days of age was TSH 5.6 mU/l, $FT_4$ 0.07 ng/dl. Epiphysis of distal femur was not detected. L-$T_4$ treatment was started followed by TRH loading test. Thyroid studies were performed at 6 9/12 years after discontinued L-$T_4$. TSH 4.6 mU/l, PRL 1.0 ng/ml, $FT_4$ 0.13 ng/dl at baseline and low delayed response was observed after TRH loading. IQ was 94. Growth and development, MRI is normal.
Case 2, H.F. boy, was born at 38 gestations, weighted 3.37 kg. Thyroid function at 5 days of age was TSH 5.9 mU/l, $FT_4$ 0.14 ng/dl. Epiphysis of distal femur was 1×3 mm. L-$T_4$ treatment was started followed by TRH loading test. Thyroid studies were performed at 5 10/12 years after discontinued L-$T_4$. TSH 2.8 mU/l, PRL 1.1 ng/ml, $FT_4$ 0.1 ng/dl at baseline and low delayed response was observed after TRH loading. IQ was 100. Growth and development, MRI is normal.

Methods and result
TRH, TRH-receptor, GATA2 and TSH-β genes were analyzed and not found any mutations. Metoclopramide, 10–20 mg, was given intravenously and serum PRL was determined. Although prompt response was observed in controls, no response was observed in two patients.
Conclusion
This is the first report of severe congenital central hypothyroidism with TSH and PRL deficiency. Etiologies of patients have to be resolved.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1482

**Treatment response and comorbilities in acromegalic patients**

S Maraver Selfa, J García-Quirós Muñoz, M Roca Rodríguez & F Tinahones Madueño
University Hospital 'Virgen de la Victoria', Málaga, Spain.

To evaluate the prevalence of comorbilities related to acromegaly and the grade of response to the different therapeutic alternatives.
Material-methods
A retrospective study of 25 acromegalic patients diagnosed between 1990–2010 was made. It included a descriptive analysis on sex, age, hypertension, impaired glucose metabolism when diagnosed acromegaly, screening for dygestive and cardiac pathology, tumoral size, and percentage of disease control and healing depending on the treatment modality.
Results
The mean age at diagnosis was 44.4 years. 64% women and 34% men. 44% of the patients had hypertension and 32% impaired glucose metabolism (7 patients type 2 diabetes mellitus and 1 patient impaired fasting glucose) at the moment of diagnosis of Acromegaly. 16% had echocardiographic alterations (2 left ventricle hypertrophy, 1 mild aortic insufficiency and 1 cardiac insufficiency). Colonoscopy was made to 64% of patients being normal 62.5% and pathologic 37.5% of the patients explored (3 hyperplasic polyps, 2 tubular-villous adenoma and 1 mild dysplasia). The pituitary MR showed 24% microadenoma (none extrasellar) and 76% macroadenoma (79% invasives). Surgery was elected in 88% with a curative rate of 27.7%. Conventional/fractioned stereotactic radiotherapy was adiministered to 32% of patients. Currently, 9 patients have healing criteria (5 with surgery and 4 receiving radiotherapy after surgery) and another 10 patients have disease control criteria (4 with medical treatment, 3 with surgery and medical treatment and 3 with surgery, radiotherapy and medical treatment).
Conclusions
The curative rate after surgery still compromises a wide range depending on several factors such the surgeon experience.
The different therapeutical alternatives aims to reduce morbimortality to acromegalic patients in order to have the same as general population. However, two or more treatment modalities are often needed.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1483

**Reproductive function in acromegalic women: a one-center experience**

R Attanasio[1], M Albizzi[1], L Cortesi[1], M Pagani[1], M Montini[2] & G Pagani[1]
[1]Ospedali Riuniti Bergamo, Bergamo, Italy; [2]Humanitas Gvazzeni, Bergamo, Italy.

Background
It is well-known that gonadal function is impaired in acromegalic females, due to several mechanisms.
Aim and design
Retrospective survey of our series.
Patients
Our electronic database encompassing data of 180 acromegalic patients collected over 30 years was searched, extracting first data of women ($n=91$) and then of females aged less than 50 years at diagnosis of acromegaly ($n=34$).
Results
Among the 34 women of potentially fertile age, 18 patients had had 28 pregnancies (24 singleton at term) before the diagnosis of acromegaly (group 1) and 9 patients had no pregnancy at all (group 2). Seven patients had 11 spontaneous pregnancies (9 at term, 2 twin) after the diagnosis of acromegaly (group 3): two conceived after non-curative surgery, 4 while on GH-suppressive treatment (3 on dopamine-agonists and 2 on somatostatin analogs), and the last without any treatment. One patient had 3 pregnancies before and one after the diagnosis. On comparing patients of groups 1 and 3, the former group was older (36 vs 28 years), with lower levels of GH at diagnosis (31 vs 83 ng/ml) and lower prevalence of hyperprolactinemia (4/18 vs 4/7) but without difference in adenoma size distribution (microadenoma vs intrasellar macroadenoma vs extrasellar adenoma). On comparing patients of groups 2 and 3, unexpectedly the former had lower levels of GH at diagnosis (32 vs 83 ng/ml) and lower prevalence of hyperprolactinemia (2/7 vs 4/7) but no difference in age and adenoma size was observed.
Conclusions
In our experience 20% of acromegalic patients conceived spontaneously in spite of ongoing disease. On considering that the diagnosis of acromegaly is often delayed by several years, at least a few pregnancies in patients of group 1 might be added to the total. Furthermore, patients can be reassured that even very high GH levels and extrasellar macroadenoma at diagnosis are not an absolute barrier to conception.

## P1484

**Evaluation of bone mass and fracture in patients with prolactinoma**

E Guerra, M Rubino, A Di Sarno, L Vuolo, P Contaldi, E Scarano, V Brunelli, L Grasso, G Lombardi, A Colao & C Di Somma
University Federico II, Napoli, Italy.

Patients with hyperprolactinemia have impaired bone metabolism and bone mineral density (BMD) partially represents bone's health.
To evaluate vitamin D levels, PTH, Ca and P, BMD and bone morphometry in patients with prolactin-secreting pituitary adenomas.
Forty-four patients (30 W, $40\pm11$ years, BMI $27.6\pm5$ kg/m$^2$) underwent to lumbar and femoral DEXA, to vertebral morphometry by X-ray and was calculated the SDI (spinal deformity index), a surrogate method for the estimation of microarchitecture and bone quality. Forty-two age and BMI matched served as controls.
Vitamin D were lower in patients than in controls ($24.1\pm10$ ng/ml vs $30.4\pm14$, $P=0.018$). Vitamin D deficiency was present in 39.5% (<20 ng/ml) vs 12% of controls ($P<0.01$), insufficiency in 32.6% (20–30 ng/ml) vs 32% ($P=$NS) and normal levels of vitamin D in 27.9 vs 56% (>30 ng/dl) in patients and controls ($P<0.01$). Lumbar spine $T$-score was $-0.2\pm1$ vs $0.11\pm1.15$ in patients and in controls ($P=$NS) and $-0.3\pm1.1$ vs $-0.16\pm0.5$ ($P=$NS) at femoral neck. At lumbar spine 37.5% of patients had osteopenia and 56.3% had normal BMD while in controls 7.1% had osteoporosis, 45.2% osteopenia and 47.6% normal BMD. At femoral neck 3.4% of patients had osteoporosis, 31% osteopenia and 65.5% had a normal BMD, and in controls 7.1% showed osteopenia and 92.9% a normal BMD. The SDI was higher in patients than in controls ($2\pm1$ vs $0.4\pm0.2$; $P<0.01$).
In hyperprolactinaemic patients vitamin D is lower than in controls; although BMD values are normal, our data seems to show that there is a higher prevalence of vertebral fractures and worse bone quality than expected by BMD values.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1485

**Prolactin levels are correlated with tumor size and invasiveness in prolactinomas**

S Cander[1,2], E Erturk[2], O Oz Gul[2], O Unal[2], C Ersoy[2], E Tuncel[2] & S Imamoglu[2]
[1]Bursa Sevket Yilmaz Education and Research Hospital, Bursa, Turkey; [2]Uludag University Medicine School, Bursa, Turkey.

Prolactinomas are more common tumors by 60% among the hypophysis adenomas. These are often benign, but may present differences in terms of tumor size and treatment responses. Aim of this study was investigate the relationship of serum prolactin levels with tumor size and invasiveness in the prolactinomas.

113 patients with the diagnosis of prolactinoma were included to study. Pretreatment plasma levels of prolactin in the time of diagnosis and sella MR imaging findings. According to the sella MR imaging findings during the diagnosis, the tumors were defined as microadenoma (the longest diameter $<1$ cm), macroadenoma (the longer diameter between 1 and 4 cm), giant adenoma (the longest diameter $>4$ cm), invasive and non-invasive adenoma.

The mean age at the time of diagnosis was $34.4 \pm 10.0$ years in 113 patients. The mean age of diagnosis was found as $40.3 \pm 12.6$ in the male and $32.6 \pm 8.3$ in the female patients. The mean size of adenoma was found as $17.9 \pm 18.1$ mm in all the patients, $38.6 \pm 21.6$ mm in the male and $10.8 \pm 9.4$ mm in the female patients. Pre-treatment serum levels of prolactin were mean $1926 \pm 6662$ ng/ml. Positive correlation was defined in the correlation analysis between the pre-treatment serum levels of prolactin and tumor size. The correlation coefficient was found as 0.805 in the correlation analysis applied between log10 values of the prolactin levels (ng/ml) and tumor size (mm) (Figure ). When the case with a serum level of prolactin higher than 3300 ng/ml were examined (*n*:8), all are seen to fall into the invasive adenoma group. Of patients with a lower serum level of prolactin, 61 were seen to be in the noninvasive and 32 in the invasive group. When the cut-off value was taken as 400 ng/ml, sensitivity was calculated as 70% and specificity as 100%.

These findings show serum levels of prolactin to be an important factor in the definition of tumor behavior. As it is indicated in the previous studies, a strong correlation was found between the prolactin levels and the size and invasiveness of tumors in our study.

Figure 1 Correlation between pretreatment prolactin level and tumor size.

## P1486

**Is every joint symptom related to acromegaly?**

G Oruk[1], F Tarhan[1], M Argin[2] & M Ozmen[3]
[1]Ataturk Training and Research Hospital, Izmir, Turkey; [2]Ege Medical School, Izmir, Turkey; [3]Ataturk Training and Research Hospital, Izmir, Turkey.

Introduction

Acromegaly is a chronic endocrinopathy characterized by hypersecretion of GH and insulin-like growth factor 1 (IGF1). Musculoskeletal pain is a frequent problem encountered in acromegaly and is associated with a reduction in quality of life. In this study we investigated the presence of inflammatory, rheumatologic and degenerative disease retrospectively.

Methods

Fourty acromegaly patients who were in remission as laboratory findings but whose joint symptoms had not subsided and were referred to the rheumatology clinic with complaints of joint pain between 2006–2010 were evaluated in the study. Clinical, radiologic and laboratory data were examined.

Results

Mean age of the acromegalic patients were 47.1 (22–75). All patients were in remission as clinically and laboratory findings. When the radiologic data were evaluated, bilateral sacroilitiis was found at sacroiliac joint graphy and magnetic resonance imaging (MRI) in 1 patient and degenerative joint changes in 24 patients; however, there was no pathology at the radiologic data of 15 patients. Laboratory data revealed antinuclear antibody (ANA) positivity (3 nucleolar, 1 homogeneous) in 4 patients, rheumatoid factor (RF) positivity in 4 patients and cyclic citrullin peptid (CCP) positivity in 1 patient. After the evaluation of the patients with clinical, laboratory and radiologic methods, 3 patients were diagnosed as inflammatory rheumatologic disease (rheumatoid arthritis (RA), ankylosing spondylitis (AS), undifferentiated connective tissue diseases (UCTDs)) and 6 patients were diagnosed as Diffuse Idiopathic Skeletal Hyperostosis (DISH). Their symptoms subsided after the medical treatment for inflammatory joint disease.

Conclusion

While degenerative joint disease was observed frequently in our patient group similar to the literature, inflammatory rheumatologic disease was also discovered in three patients. Distinguishing these two joint disease is important, because response to medical treatment is dramatically good in inflammatory disease than the degenerative disease. A multidisciplinary approach involving endocrinology and rheumatology is imperative for appropriate management of these patients.

**Acromegaly and pregnancy: case reports**

A Abreu[1] & A Rueda[2]
[1]Centro Médico Imbanaco, Cali, Colombia; [2]Universidad Libre, Cali, Colombia.

Acromegaly is a rare clinical disorder characterized by progressive somatic disfigurement and a wide range of systemic complications which include gonadotrophic dysfunction, menstrual abnormalities and infertility. Thus, pregnancy in patients with acromegaly is a rare and challenging medical situation. Furthermore, the evidence about the use of somatostatin analogs (SSAs) during pregnancy in patients with acromegaly and its outcomes is still limited. Here we describe the clinical characteristics and outcomes of two patients with acromegaly who were treated with SSA during pregnancy, which add to the previous reports of similar cases. Case 1: 19 y.o. female, G1P0 with a GH- and prolactin-producing pituitary tumour (macroadenoma) previously treated with transesphenoidal surgery for tumor resection and cabergolide 0.5 mg 4x/w, octreotide LAR 30 mg IM every 28d. She continues on octreotide LAR 30 mg IM every 28d since week 9 of pregnancy achieving normal term pregnancy (38w3d gestation, 3200 g, 51 cm newborn) and 76, 34 and 30% reduction in GH and IGF1 levels and tumour size reduction, respectively. Case 2: 25 y.o. female, G1P0 with a GH- and prolactin-producing pituitary tumour (macroadenoma) previously treated with transesphenoidal surgery for tumor resection and bromocriptine 2.5 mg QD PO. She is started on lanreotide ATG 60 mg Q3 every 28 days since week 11 of pregnancy achieving normal term pregnancy (39w2d, 3120 g, 49 cm newborn) and a 66, 64 and 14.2% reduction in GH and IGF1 levels and tumour size reduction, respectively. These cases suggest that SSAs during pregnancy in patients with acromegaly reduce GH and IGF1 levels and tumor size with no effect on fetal growth or development.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1488

**Pegvisomant and cabergoline combination therapy in acromegaly**

I Bernabeu[1], C Alvarez-Escola[2], A Paniagua[3], T Lucas[4], I Pavon[5], J Cabezas Agricola[1], F Casanueva[1] & M Marazuela[6]
[1]Hospital Clinico Universitario Santiago de Compostela, La Coruña, Spain; [2]Hospital Universitario La Paz, Madrid, Spain; [3]Hospital Infanta Cristina, Parla, Madrid, Spain; [4]Hospital Universitario Puerta de Hierro- Majadahonda, Madrid, Spain; [5]Hospital Universitario de Getafe, Getafe, Madrid, Spain; [6]Hospital Universitario La Princesa, Madrid, Spain.

Objective
Combination with cabergoline may offer additional benefits to acromegalic patients on pegvisomant monotherapy. We evaluated the safety and efficacy profile of this combination and investigated the determinants of response.
Design
An observational, retrospective, cross-sectional, registry-based study.
Patients and methods
Fourteen acromegalic patients (9 females), who were partially resistant to somatostatin analogs and on pegvisomant monotherapy. Cabergoline was added because of the presence of persistent increased IGF1. The mean follow up time was $18.3 \pm 10.4$ months. The efficacy and safety profile was assessed. The influence of clinical, biochemical, and histological characteristics on treatment efficacy was studied.
Results
IGF1 levels returned to normal in 4 patients (28%) at the end of the study. In addition, some decline in IGF1 levels was observed in a further 5 patients. The % IGF1 decreased from $158 \pm 64\%$ to $124 \pm 44\%$ ($P=0.001$). The average change in IGF1 was $-18 \pm 27\%$ (range $-67$ to 24%). Lower baseline IGF1 ($P=0.007$), female gender ($P=0.013$), lower body weight ($P=0.031$), higher prolactin (PRL) levels ($P=0.007$), and positive tumour PRL immunostaining ($P=0.029$) were associated with a better response to combination therapy. There were no significant severe adverse events. Significant tumour shrinkage was observed in 1 patient.
Conclusions
Combination therapy with pegvisomant and cabergoline could provide better control of IGF1 in patients with acromegaly. Baseline IGF1 levels, female gender, body weight, PRL levels, and PRL immunostaining affect the response to this combination therapy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Influence of the family environment during the early years in life in the vulnerability to the development of pituitary adenomas**

A Afonso & D Carvalho
Centro Hospitalar São João, Faculdade de Medicina da Universidade do Porto, Porto, Portugal.

Introduction
Prolactinomas are the most common pituitary adenomas. Several authors hypothesized that there is an association between the development of pituitary adenomas and psychologically significant experiences, especially traumatic ones. This is particularly well-established for Cushing's disease. When it comes to prolactinomas, it was suggested that prolactin acts as an alternative to cortisol in the response to stress, especially in patients who present with passive coping strategies. We looked at the influence of traumatic experiences before the age of ten on the susceptibility to the subsequent development of prolactinomas.
Methods
We compared a group of 33 patients with the diagnosis of prolactinoma to the same number of patients of the same age and gender with non-functioning pituitary adenomas and Cushing's disease. We studied the difference between the patients with prolactinomas and the two other subtypes of adenomas in relation to the absence of a father before the age of ten, and to the presence of an alcoholic or violent father during the same period.
Results
We observed a higher frequency of traumatic childhood experiences, especially the presence of an alcoholic father, in patients with prolactinomas (33,3%) when compared to the other adenomas (9,8%, $P<0.05$). Contrary to what we expected, patients with Cushing's disease reported not living with their father during childhood the most. This result is similar to that found in previous studies, where there was also an association between traumatic events and the development of these neoplasms.
Conclusion
Traumatic experiences during childhood seem to increase the susceptibility to the development of prolactinomas, especially in patients who lived with an alcoholic father. On the contrary, the absence of a father seems to favor the development of Cushing's disease. Experiencing traumatic situations during childhood may interfere with epigenetic processes which silence tumor suppressor genes and promote the development of pituitary adenomas.

## P1490

**Hyperprolactinemia in polycystic ovary syndrome- diagnostic and therapeutic approach**

D Amzar, M Balas, I Golu, M Vlad & I Zosin
University of Medicine and Pharmacy 'V.Babes', Timisoara, Romania.

Background
Prolactin (PRL) hypersecretion is the most common endocrine abnormality due to hypothalamic-pytuitary disorders. Hyperprolactinemia occurs in 20–30% of cases with polycystic ovary syndrome (POS). It is considered that hyperprolactinemia is not involved in POS etiopathogeny, but other factors are implied.
The aim of the study: was to retrospectively evaluate the diagnostic tools (Rotterdam criteria) and therapeuthic approach applied in 78 women with POS, evaluated in our clinic in the last 5 years. Out of the twenty six POS patients with hyperprolactinemia, half presented associated hyperprolactinemic conditions. A percentage of 15.3% presented an associated mycroprolactinoma (46.1% of the hyperprolactinemic cases). Plasma levels of PRL were significantly higher in the patients with mycroprolactinomas as compared to hyperprolactinemic women without a tumor ($P<0.001$). Other causes of hyperprolactinemia were represented by: combined contraceptive therapy (five cases), psychotropic medication (two patients), chronic methoclopramid treatment (one case), and severe hypothyroidism (three cases). The treatment of tumoral cases consisted of dopaminergic agonists (cabergoline, bromocriptine), in usual doses. The response was favorable, similar to the patients with microprolactinomas, but without POS. Mild hyperprolactinemic cases were regularly followed-up, noticing that the PRL values didn't increase significantly over time.
Conclusions
Due to the increased incidence of PRL secreting pituitary tumors in patients with POS, often hyperprolactinemia imposes also imagistic diagnosis (pituitary MRI). In hyperprolactinemic patients, factors which could further increase the PRL secretion should be avoided.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1491

**Hypothalamo-pituitary dysfunction in patients with chronic subdural hematoma**

M Kosak[1], V Masopust[2], D Netuka[2], Z Lacinova[1], M Krsek[1], J Marek[1], L Pecen[3] & V Hana[1]
[1]First Faculty of Medicine, Charles University in Prague and General University Hospital in Prague, Prague, Czech Republic; [2]First Faculty of Medicine, Charles University in Prague and Central Military Hospital Prague, Prague, Czech Republic; [3]Academy of Sciences of Czech Republic, Prague, Czech Republic.

Introduction
Hypothalamo-pituitary dysfunction has been reported in patients after traumatic brain injury or subarachnoid hemorrhage with relatively high frequency according to published studies. Assessment of hypothalamo– pituitary functions in patients with chronic subdural hematomas has not been published yet, although dysfunction of hypothalamo- pituitary unit could be expected (head trauma, compression and oedema of the brain, shifting of the midline structures).

Aims
Evaluation of the pituitary functions in patients with chronic subdural hematoma immediately after surgical treatment and during one year follow-up.
Patients and methods
We have examined 59 patients (49 males, mean age 68.3 years, 36–88 years). Patients in the first days after evacuation of the hematoma and then 3 and 12 months after the operation were tested. Basal levels of pituitary hormones and hormones of dependent peripheral glands, plasma cortisol during 250 mcg ACTH test, GH after GHRH + arginine stimulation and TSH after TRH stimulation were assessed.
Results
Central hypogonadism was diagnosed in 13 patients (37%, $n=35$) in an acute phase, but in most of the cases had a transient character. GH deficiency was diagnosed according to the GHRH + arginine test in 25 patients (51%, $n=49$) in acute phase and according to the control tests 12 months after the operation was present in 18 patients
(37.5%, $n=32$). We did not find any serious case of hypocortisolism, hypothyroidism, nor diabetes insipidus centralis. Partial hypocortisolism was found in two cases, but has resolved according to the control tests. No relation between extension of SDH or clinical severity and development of hypopituitarism was observed.
Conclusions
There was GH deficiency or hypogonadism present in some patients in our cohort. No serious hypocortisolism, hypothyroidism, diabetes insipidus nor SIADH was observed. The possibility of hypothalamo-pituitary dysfunction should be considered in patients with subdural hematoma especially in those with history of trauma.

**Mood Disorders and Quality of Life in Patients with Acromegaly after Pituitary Adenomas**

L Lasaite[1], R Knispelis[2], J Lasiene[1,2] & I Purtokaite-Labutiniene[1,2]
[1]Institute of Endocrinology, Kaunas, Lithuania; [2]Department of Endocrinology, Kaunas, Lithuania.

Objective
To evaluate frequencies of mood disorders in males and females with acromegaly and to compare their quality of life with that of control males and females of the same age.
Patients and methods
males (age 48.8 ± 10.3 yers) and 16 females (age 52.9 ± 13.7 years) with acromegaly after pituitary adenomas; 13 control males (age 46.3 ± 18.6 years) and 43 control females (age 54.8 ± 9.8 years).
Mood disorders diagnosed by Mini-International Neuropsychiatric Interview (MINI), quality of life evaluated by WHO Bref Quality of Life Questionnair.
Results
Current depression was diagnosed in 2 (18.2%) males and 1 (6.7%) female with acromegaly, depression episodes in the past - in 0 males and 1 (6.7%) females with acromegaly, social phobia - in 0 males and 2 (13.3%) females with acromegaly, general anxiety disorder - in 4 (36.4%) males and 3 (20.0%) females with acromegaly.
Comparing quality of life
Domins of physical health (13.9 ± 2.5 vs 16.1 ± 2.8) and social relations (14.5 ± 2.0 vs 16.3 ± 1.6) were significantly worse in acromegalic than in control males; environmental domain (15.2 ± 1.2 vs 12.8 ± 2.8) was significantly better in acromegalic than in control females.
In conclusion, Mood disorders were diagnosed in males and females with acromegaly after pituitary adenomas; quality of life (in domains of physical health and social relations) was found worse in acromegalic than in control males.
Declaration of interest

**Although dentists are frequently visited by acromegaly patients they do not diagnose the disease**

S Siegel[1,2], C Streetz-van-der-Werf[1], J Schott[1], K Nolte[2], W Karges[1] & I Kreitschmann-Andermahr[1,2]
[1]RWTH Aachen University, Aachen, Germany; [2]Erlangen University, Erlangen, Germany.

Objective
The aim of this study conducted in a German University Hospital was to systematically assess health care utilisation and delivery in patients with acromegaly and to thus identify possible starting points for the improvement of patient care.
Design/Methods
By means of a standardized anamnestic interview, 41 patients with biochemically proven acromegaly were questioned on the course of their disease. To investigate patient care the interview included questions on the time lapse of symptom onset, first seeking medical advice and time of diagnosis of acromegaly as well as questions on the medical speciality of the diagnosing doctor and other diagnoses made before. Patients were also asked to recall which symptoms they had noted first and to account which symptoms were still persisting.
Results
Time lapse between first symptoms and diagnosis was on average 3.8 years. 1.76 years elapsed while patients waited to see the doctor, a lapse of 2.05 years was due to delay in the diagnostic process. Among the most frequently mentioned symptoms experienced by the patients were teeth and jaw problems. 36.6% of the patients reported to have visited the dentist more than usual at any time during the disease. 9.8% even remembered this to be one of the first symptoms they experienced, 22% reported these symptoms to still persist. Nevertheless, none of the patients was diagnosed with acromegaly by a dentist. Most diagnoses were made by internists, neurologists, orthopedists or the family doctor.
Conclusion
Diagnostic delay is still considerable in patients with acromegaly. In part, this might be due to the fact, that although many patients with acromegaly visit dentists, the disease seems to be widely unknown to these. One starting point for the improvement of patient care might, therefore, be a better information on acromegaly for dentists.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1494

**The long term recurrence rates of cushing's disease in turkish patients after transsphenodal surgery: a single-center experience**

Yuksel Altuntas[1], Sayid Shafi Zuhur[1], Aysegu Ilhan[2], Selvinaz Velet[1] & Feyza Yener Ozturk[1]
[1]Sisli Etfal Training and Research Hospital, Istanbul, Turkey; [2]Sisli Etfal Training and Research Hospital, Sisli street, Istanbul, Turkey.

Introduction
The treatment of choice in Cushing's disease (CD) is transsphenoidal adenomectomy. However, the long term recurrence rate of the CD after transsphenoidal surgery in Turkish patients has not been determined so far.
Purpose
We aimed to determine the long term recurrence rates of CD in Turkish patients after transsphenoidal surgery.
Methods
The computer records of the 23 patients, operated for CD in our center during the interval 1999–2010, were retrospectively analysed.
Results
Nineteen (82%) of the patients were female and 4 (18%) were male [ranging in age between 20–62 years old, (41,7 ± 11,2 years)]. Among the 23 patients, 14 (87%) had microadenoma, 2 (13%) had macroadenoma and 7 had normal pituitary MRI findings. Bilateral inferior petrosal sinus sampling (BIPSS) were performed in 9 (39%) patients. Four of the patients were operated for at least 2 times and 16 patients were operated on once. Two patients denied surgery. Two patients underwent gammaknife therapy (one as primary therapy). All of the patients were followed-up for 38,5 ± 31,9 months (between 3–96 months) at 3–6 month intervals by basal cortisol, ACTH, urinary free cortisol levels and 1 mg dexamethasone supression test. Persistent cure was achieved in 11 patients (48%) at first surgery. Two (8,6%) patients had persistent disease after first surgery. Recurrence was determined in 8 (34,7%) patients after first surgery.

Recurrence was determined after 9 months from surgery in one patient, between 12–24 months in 2, between 24–60 months in 3 and at 95th month in 2 patients, respectively.
Conclusion
All patients who undergo transsphenoidal surgery for CD should be followed properly for a long time, because recurrence could occur after a very long time period in patients who thought to be cured at first surgery.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1495

**Xanthoma disseminatum with cutaneous and pituitary stalk involvement**

D Slattery[1], T Hussain[1], M O'Cathail[1], J Fitzgibbon[1], B Plant[1], M Murphy[2] & D O'Halloran[1]
[1]University Hospital, Cork, Ireland; [2]South Infirmary Hospital, Cork, Ireland.

Introduction
Xanthoma disseminatum (XD) is a rare, non - familial disease characterised by lipid deposition in skin and internal organs due to histiocytic cell proliferation, classified as a non-Langerhans cell histiocytosis. The disease is characterised by symmetrically distributed, coalescing cutaneous papules, initially red–brown then yellow involving the face, trunk, flexural and intertriginous areas. Involvement of mucous membranes has been reported. The upper and lower respiratory tract may also be affected, along with the gastrointestinal tract and bone. In addition, involvement of the pituitary gland, with diabetes insipidus (DI) is reported in 30–50% of cases. Central nervous system (CNS) involvement outside the pituitary/hypothalamus carries a poor prognosis.
Case
A 36 year old Caucasian female presented with a 5 month history of a symmetrically distributed, red–brown papular rash affecting the eyelids, axilla and groin regions. The appearance of the rash was shortly followed by symptoms of polydipsia and polyuria. A water deprivation test with a vasopressin challenge was diagnostic of cranial DI. The patient responded well to vasopressin therapy. Cerebral MRI imaging demonstrated pituitary stalk thickening with no other cerebral involvement. Anterior pituitary function and prolactin levels were normal. Isotope bone scan was unremarkable. High resolution CT thorax did not demonstrate any granulomatous lesions. Histological examination of a skin biopsy showed a mixed spindled and epitheloid fibrohistiocytic lesion with scattered Tuoton - like giant cells compatible with a diagnosis of non - Langerhans cell histiocytosis. The lesions of Juvenile Xanthogranuloma (JX) histologically are indistinguishable from XD. Iron staining showed faint background positivity which has been described in XD.
Discussion
XD is a rare cause of cranial DI. Our case illustrates the challenge which may arise diagnosing XD and differentiating it from JX. In addition, it demonstrates the importance of correlating clinical features with histological findings in diagnosing the disease.

## P1496

**Acromegaly and charles bonnet syndrome**

F Belhimer, L Bekkaye & F Chentli
Bab El Oued Hospital, Algiers, Algeria.

Introduction
Charles Bonnet syndrome is almost unknown by the endocrinologists. It is composed by visual hallucinations that do not react with the patient contrary to psychiatric hallucinations. The abnormal visions (generally hidden by patients) appear in subjects with an impaired vision of one of both eyes as in the following case:
Case report
A man aged 27, was referred for acromegaly secondary to a huge invasive somatolactotrope pituitary adenomas difficult to manage by surgery. He was very conscious, but almost blind because of bilateral optic atrophy. As the surgery failed, he was given somatostatin analogs plus a dopamine agonist (bromocriptine). One month later when his doctor was looking for bromocriptine intoxication (especially hallucinations) he complained about the fact that just after pituitary surgery he became totally blind and was seeing abnormal things. The medication was reduced then totally stopped, but after that the landscapes and cars visions remained. Psychological evaluation was absolutely normal and Brain MRI did not show anything apart from a consistent decrease of the huge adenoma.
Conclusion
Charles Bonnet syndrome, which is probably due to a reaction of the visual cortex to the rapid loss of the vision, should be known in endocrinology as it is a differential diagnosis with hallucinations due to dopamine agonist intoxication.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1497

**Planning for the future: preparing the endocrine specialist nurse of tomorrow**

M Carson[1,2]
[1]The University of Edinburgh, Edinbrugh, UK; [2]The Royal Infirmary, Edinburgh, UK.

We have come a long way in the UK over the past ten years towards our goal of meeting the educational needs of nurses specialising in adult endocrinology. Endocrine nurses are now able to access annual training updates and attend specific nurse-led sessions at scientific meetings thanks to the ongoing work undertaken by the Society for Endocrinology's nurse committee.
It is therefore time to turn our attention to how we can encourage nurses to want to specialise in endocrinology and to start to prepare them for such a role before rather than after they find themselves working in this field. One way to do this is to ignite their interest in endocrinology while they are still students. With this aim in mind the first undergraduate course in adult endocrine nursing in the UK was developed and introduced as part of the Bachelor of Nursing (Hons) programme at Edinburgh University for the 2011/12 academic session. The course, which runs over ten weeks, is available as an Honours option to students in their third and fourth years and is delivered as a series of lectures and tutorials. The content covers specific endocrine conditions and alongside these critically explores issues such as compliance with prescribed treatment, quality of life, patient support and patient self-management, the role of the specialist nurse and nurse-led clinics. It is taught primarily by an endocrine nurse/lecturer with some specific input from visiting speakers. In addition to the formal taught aspects students are encouraged to attend endocrine out-patient clinics, observe pituitary surgery and attend local patient support group meetings as well as national patient conferences.
Fifteen students have now successfully completed the course. Course evaluation has been extremely positive. Of the seven final year students, two are now proactively seeking endocrine nursing positions to apply for on graduation.
In class.

**Changes in body composition in patients with acromegaly**

S Fujio, M Habu, S Yunoue, H Hirano, H Arimura & K Arita
Graduate School of Medical and Dental Sciences, Kagoshima University, Kagoshima, Japan.

Introduction
With the advancement of surgical techniques and equipments, many patients with acromegaly have achieved complete remission after surgery. Normalization of growth hormone (GH) brings about improvement of vital prognosis, but recovery

from high GH hematologic disease induces various abnormalities. We focused on the body weight and body composition of the patients with acromegaly and examined the post-surgical changes.
Materials and Methods
19 patients with new-onset acromegaly who had surgery at our facility and achieved post-surgical complete remission were enrolled (Male: 6, Female: 13, average age: 52.4, range: 29–74). Body weight and body composition as well as lipid metabolism and glucose tolerance were examined at pre/post-operation and 3 months after operation.
Results
Pre-surgical mean BMI was 25.2 but decreased to 23.4 one week after surgery, then increased to 25.1 three months after surgery. Pre-surgical body fat percentage was 23.9% and remained at 23.3% one week after surgery, then increased to 27.0% at 3 months after surgery. Body fat amount decreased from pre-surgical 14.9 kg to 14.0 kg one week after surgery but increased to 17.2 kg at 3 months after surgery. On the other hand, body water content decreased from pre-surgical 33.7 kg to 32.2 kg one week after surgery, and further decreased to 31.7 kg at 3 months after surgery. Neutral fat decreased from pre-surgical 108.1 mg/day to 84.7 mg/day one week after surgery, and further decreased to 73.6 mg/day at 3 months after surgery. Glucose tolerance also has improved in many cases.
Discussion
Patients with acromegaly are observed with post-surgical transient weight loss, which is considered due to body water loss. Body weight then begins to increase due to body fat accumulation. Lipid metabolism and glucose tolerance improve in a short term. Finally, the effect of obesity on mind and body also needs examination in a long process.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1499

**Complications of pure endoscopic transsphenoidal surgery for pituitary adenoma**

G Zielinski, J Podgórski, A Koziarski & G Kaminski
Military Institute of Medicine, Warsaw, Poland.

Object
The aim of the study was to evaluate the safety and efficacy of the pure endoscopic removal of the pituitary adenomas with special references to the complications.
Material and methods
The authors analyzed retrospectively a database of 52 consecutive patients (16 males and 36 females) with pituitary adenomas who underwent endoscopic transsphenoidal surgery. Preoperative examination was based on radiological visualization of the tumor and endocrinological evaluation. The extend of the resection was gauged on postoperative contrast-enhanced 1.5 T MR imaging. Endocrinological remission was defined as normalization of the pituitary function (acromegaly: basal serum GH level $<1$ ng/ml and a nadir GH level $<0.4$ ng/ml after oral glucose load, Cushing's disease: early morning cortisol level $<2$ ug/dl, PRL-oma: serum PRL level $<20$ ng/ml).
Results
There were 15 patients with NFPA, 24 patients with GH-secreting pituitary adenoma, seven patients with ACTH-secreting pituitary adenoma and five patients with PRL-secreting pituitary adenoma. The majority of patients had macroadenomas. Remission rate was 69%. A retrospective analysis of complications was conducted. There were no fatal complications and permanent morbidity was 7.7% (one permanent diabetes insipidus and three pituitary insufficiency). Other surgical complications included one syndrome of inappropriate secretion of antidiuretic hormone, one epistaxix and one sinusitis. There were no medical compications.
Conclusions
Endoscopic transsphenoidal removal of pituitary adenoma is safe and effective method. It leads to a high rate of tumor resection and endocrionological remission. A number of surgical complications is low and comparable to those found in patients undergoing microsurgical transsphenoidal operation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1500

**A case of nephrotic syndrome hidden by cushing's disease**

A Paoletta[1], D Billeci[1] & F Fallo[2]
[1]Azienda ULSS 15 Alta Padovana, Cittadella, Italy; [2]University of, Padua, Italy.

We report a case of Cushing's disease associated to nephrotic syndrome. A 21-year old female was admitted to Cittadella-Hospital due to recent occurrence of weight gain, acne, hirsutism, amenorrhea and mild hypertension. Physical examination revealed truncal obesity, moon face, buffalo hump and a bilateral ankle edema. Suspected hypercortisolism was confirmed by elevated 24 h urinary cortisol (385 μg/24 h, normal range 32–250 μg/24 h) and failure to suppress plasma cortisol after 1 mg DST (42 μg/dl.). Plasma ACTH was high on two consecutive days (69.5–62.3 pg/ml, normal range 10–46 pg/ml) supporting the diagnosis of ACTH-dependent Cushing's syndrome. Brain MRI revealed in fact a tumor mass of 5 mm in the pituitary gland, and transsphenoidal pituitary adenomectomy was programmed. During pre-surgery hospitalization, biochemical tests revealed hypoalbuminemia (2 g/dl), hypercholesterolemia (345 mg/dl) and severe albuminuria (21.7 g/24 h) in the presence of normal creatinine levels (1.08 mg/dl), all consistent with a nephrotic syndrome. After surgery, ACTH and cortisol levels rapidly normalized and clinical features of Cushing's disease improved. Low serum albumin (2.1 g/dl) and proteinuria (6.89 g/24 h) persisted. Renal biopsy was then performed and microscopic examination showed a marked mesangial expansion, indicating a rather advanced stage of glomerulonephritis. Combined therapy with albumin, furosemide and exogenous glucocorticoids was of benefit on proteinuria but induced recurrence of Cushing's phenotype. Pituitary gland at MRI control was normal. The present case represents a rare association between endogenous hypercortisolism due to an ACTH-secreting pituitary adenoma and a nephrotic syndrome. We suggest that the renal damage was hidden by Cushing's disease and that normalization of cortisol levels due to pituitary adenomectomy triggered the full appearance of kidney disease.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1501

**Preliminary report of hypoglycemic response in obese metabolic syndrome males treated with metformin after weight loss intervention**

M Radman[1] & S Tešanović[2]
[1]University Hospital Center Split, Split, Croatia; [2]Hospital Dubrovnik, Dubrovnik, Croatia.

We conducted this study to determine the degree of obesity influence on the hypoglycemic response of growth hormone and cortisol after weight loss of 5%. A total of 45 non-diabetic, male subjects followed in the outpatient endocrinological department were divided into three groups comprising 15 subjects in each group, based upon body mass index (BMI) to healthy, overweight and obese group. Metformin was administered in the dose of 500 mg daily to the overweight and obese participants. Cortisol was measured at 0, 60 and 120 min. Growth hormone (GH) was measured at $-15$, 0, 30, 60, 90 and 120 min. Values of cortisol and GH were compared upon changes in hypothalamo–pituitary–adrenal (HPA) response to insulin induced hypoglycemia initially and after weight loss of 5% for overweight and obese participants.
The BMI of healthy group ranged 20.0–24.5 kg/m$^2$ ($Z=3.83$; $P\leq0.001$); overweight group ranged 25.9–29.7 kg/m$^2$; and obese group ranged 30.9–34.6 kg/m$^2$.
There were no significant differences of cortisol values among groups at 0 ($\chi^2=2.0$; $P=0.365$); 60 ($\chi^2=0.754$; $P=0.686$) and at 120 min ($\chi^2=0.466$; $P=0.792$).
The comparison among groups were significant for differences of GH values at $-15$ ($\chi^2=25$; $P\leq0.001$); 0 ($\chi^2=16.2$; $P\leq0.001$); 30 ($\chi^2=16.2$; $P\leq0.001$); 60 ($\chi^2=32.8$; $P\leq0.001$); 90 ($\chi^2=30.2$; $P\leq0.001$); and at 120 min ($\chi^2=27.3$; $P\leq0.001$). Healthy and obese subjects significantly differed in growth hormone response at $-15$ ($Z=4.67$; $P\leq0.001$); 0 ($Z=3.83$; $P\leq0.001$); 60 ($Z=2.78$; $P\leq0.005$); 90 ($Z=4.67$; $P\leq0.001$) and at 120 min ($Z=4.23$; $P\leq0.001$.
Changes on the various levels of HPA axis, when it is activated by a stress as it is in the case in insulin-induced hypoglycemia correspond to the degree of obesity. Weight loss of 5% was not enough for restoration of a normal stimulated growth hormone release and did not influence on the level of cortisol.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding

## P1502

**A difficult case of hyponatraemia in a neurosurgical patient**
F Wernig, A Kaura, K Wynne, R Nair & K Meeran
Imperial College Healthcare NHS Trust, London, UK.

A 40-year-old female presented with a 6 week history of right-sided headaches and nausea. She was found to have an Arnold-Chiari malformation and an unusual C3 syrinx on MRI brain scanning. She underwent a foramen magnum decompression and C1 laminectomy. Three weeks later, she was admitted with headaches, nausea and vomiting, and blurring of her vision on left lateral gaze. Whilst in the emergency unit, the patient had a tonic-clonic seizure.
Following the seizure, she was noted to have a left 6th nerve palsy. She was hyponatraemic (119 mmol/l) with a blood osmolality of 253 mOsm/kg, urine osmolality of 640 mOsm/kg (specific gravity 1.030) and urinary sodium concentration of 97 mmol/l. Brain imaging demonstrated a large pseudomeningocele which had not been present on previous scans.
Administration of intravenous saline following the seizure further exacerbated her hyponatraemia (114 mmol/l). She was reviewed by the endocrinologists and a diagnosis of syndrome of inappropriate ADH secretion (SIADH) was made; strict fluid restriction maintained her serum sodium level at 119 mmol/l. Her urine osmolality remained inappropriately high (531 mOsmol/kg). Five days into her admission placement of a ventriculo-peritoneal shunt resulted in volume reduction of the pseudomeningocele. Following sugery, she began to pass large amounts of urine and her urine specific gravity fell to 1.005 within 12 h. Her sodium level gradually improved back towards the reference range (139 mmol/l) over the following four days. Both her headache and 6th nerve palsy resolved.
Hyponatraemia is the most common electrolyte disorder in neurosurgical patients. Here we describe a difficult case of hyponatraemia due to SIADH. Risks and benefits of administering hypertonic saline or Tolvaptan had to be weighed against the possibility of further hyponatraemic seizures. Early diagnosis, strict fluid restriction and concerted management by a multidisciplinary team were crucial for a beneficial outcome.

Pseudo-meningocele at the site of the Foramen Magnum decompression prior to supratentorial VP shunt placement.

## P1503

**Invasive and giant pituitary adenomas in the elderly**
S Azzoug, S Hamrras & F Chentli
Bab El Oued Hospital, Algiers, Algeria.

Clinical presentation of pituitary adenomas is influenced by age of patients and stage of the tumour at diagnosis. In this study we intended to analyse the features of pituitary adenomas in old patients.
Subjects and methods
It is a retro- and prospective study concerning 37 patients (19F/18M) aged 60 years and over harbouring a pituitary adenoma, these patients were divided into two groups:

Group 1 (G1): Patients with invasive and/or giant tumours which means tumours $\geq$40 mm or tumours invading the cavernous sinuses
Group 2 (G2): Patients with tumours $<$40 mm without cavernous sinuses involvement

Clinical presentation, hormonal, radiological and ophthalmological finding were recorded.
Results
Thirty-eight percent ($N=14$) of the tumours were giants and/or invasive, the adenoma size was $40.53 \pm 11.38$ mm in G1 (with involvement of cavernous sinuses in 6 cases) and $22.7 \pm 7.96$ mm in G2, patients of G1 were older than those of G2: $70.71 \pm 6.70$ years vs $66.17 \pm 5.41$ years. Neuro-ophthalmological manifestations were appealing in 77% in G1 and 61% in G2; the tumour was incidentally discovered in 21% in G2 and in 7% in G1. No secreting adenomas were the more prevalent in the two groups (57% in G1 and 65% in G2), GH secreting adenomas were recorded only in G2. Pituitary deficiency wasn't different between the two groups (61% in G1 vs 60% in G2). Severe visual loss was more prevalent in G1 than G2: 71% vs 33%.
Conclusion
Pituitary adenomas in the elderly are predominantly no secreting, frequently diagnosed lately at an advanced stage of visual loss and pituitary deficiency.

## P1504

**Hyperprolactinemia: prolactinoma or pregnancy?**
S Belo[1,2], A Magalhães[1,2] & D Carvalho[1,2]
[1]Centro Hospitalar S. João, Porto, Portugal; [2]Universidade do Porto, Porto, Portugal.

Introduction
High prolactin levels may have several etiologies including the presence of a prolactin producing pituitary adenoma or the treatment with drugs of different classes. Certain physiological states, from which pregnancy stands out, are also characterized by elevated levels of prolactin.
Case
Woman, 28 years old, with no relevant medical history or chronic medication apart from oral contraceptives, begins with amenorrhea in May 2010, without galactorrhoea, headache or changes in visual acuity. She presented no history of menstrual irregularities. 'Home' pregnancy test was performed with a negative result. The patient was evaluated by a Gynecologist in June. An endovaginal ultrasound was performed with no evidence of pregnancy. Therapy with medroxyprogesterone, for 10 days, was attempted without success. Gynecological ultrasound was repeated, again without evidence of pregnancy. The patient was advised to consult an Endocrinologist (first visit in October, on the private sector). Analytical study was conducted with prolactin pool 219.9/182.8/156.8 ng/ml, FSH $<$0.05 mIU/ml and LH 0.42 mIU/ml. Pituitary MRI was performed later revealing an increased pituitary gland with homogeneous contrast enhancement, suggestive of pituitary hyperplasia. Treatment with bromocriptine was initiated (November) initially 1.25 mg/day with titration up to 5 mg/day. The patient was subsequently oriented to Neurosurgery appointments, from which she was sent to the Endocrinology department of the same institution. At that time, imaging and analytical study was found to be compatible with pregnancy ($\sim$33 weeks) confirmed with physical examination (fetal movement) and ultrasound. The analytical findings were normal 5 months after delivery.

Discussion
The onset of amenorrhea in women of childbearing age implies the exclusion of pregnancy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### DHEAS: a new marker in Cushing's disease? Preliminary results of 32 patients

T Burkhardt[1], J Aberle[2], M Mengel[3] & F Jörg[1]
[1]Hamburg, Germany; [2]Endocrinology, Hamburg, Germany; [3]Endocrinology, Wuppertal, Germany.

Introduction/objective
The objective was to determine if peri-operative levels of DHEAS correlate with levels of ACTH and cortisol and therefore are useful as a new marker for the definition of cure in patients suffering from Cushing's disease. DHEAS is an ACTH-dependent precursor of androgens and estrogens secreted from the adrenals. Numerous clinical trials have shown that DHEAS in humans and other mammals is a multi-functional steroid implicated in a broad range of biological effects, including obesity, diabetes, bone metabolism, neuroprotection and anti-tumorigenesis; it has not yet undergone research in the context of Cushing's disease.
Methods
Forty-three patients suffering from Cushing's disease were treated at our department from September 2009 to February 2011 and were perioperatively monitored for ACTH, cortisol and dehydroepiandrosterol-sulfate (DHEAS).
Preoperative and early postoperative ACTH, cortisol and DHEAS levels were correlated with each other to determine the usefulness of DHEAS as a parameter in patients suffering from Cushing's disease.
Results
Forty-three patients were included. All were treated for Cushing's disease via a transsphenoidal approach. Pre-operative blood samples were taken on the day before the operation and revealed high normal to elevated levels of ACTH (mean: 104 ng/l), cortisol (mean: 283 μg/l) and DHEAS (mean: 2.59mg/l) according to the pathology of Cushing's disease. Postoperative blood checks showed decreased levels of ACTH down to 15.5% (mean: 14.93 ng/l) of its preoperative figure. Cortisol levels were reduced down to 12.5% (mean: 35.39 μg/l) of its preoperative level and DHEA(S) levels decreased down to 19.61% (mean: 0.51 mg/l).
Two patients had decreased levels of all three hormons postoperatively (DHEAS 53.7% and 9%, Cortisol 11.2% and 5.3% and ACTH down to 28.4% and 11.8%), 1 showed elevated levels of DHEAS, ACTH and Cortisol on re-evaluation 5 months after the initial operation and had to undergo a second surgical treatment. The second patient underwent first surgical treatment in 2009 and is currently being re-evaluated as recurrent disease seems highly possible.
Statistical analysis showed a highly significant correlation between changes of ACTH and DHEAS levels and a significant correlation between changes of cortisol and DHEAS levels.

### Clinical experience with acromegalic patients who have macroadenomas and long term follow-up results

G Oruk, M Bahceci, A Oygen, A Olmezoglu & H Bezircioglu
Ataturk Training and Research Hospital, Izmir, Turkey.

The increased morbidity and mortality of acromegaly makes early diagnosis and therapy critical. Long term follow-up and investigating comorbidities of this disease is also important. We present here retrospective results of 70 patients. There were 41 female, 29 male patient included in the study. Follow-up period was longer than 5 years. Fifty-nine of the patients were macroadenoma, 4 of them were empty sella, 7 of them were microadenoma. Seven patients refused surgical treatment and they were followed only with medical treatment. Sixty-three patients were treated with surgical and medical treatment. Transsphenoidal surgery was the treatment of choice. For the patients whose macroadenomas were not controlled by surgery alone (22 patients), radiation therapy was applied after surgical and medical treatment for the residual tumor (7 gamma-knife, 10 conventional, 5 cyber-knife). One patient was operated sucessfully when she was 75 years old and there was no complication. In 1 patient acromegaly was a clinical component of multiple endocrine neoplasia type 1, 2 patients had fibrous dysplasia. Renal transplantation was applied to one patient because of diabetic nephropathy. One patient had a successful pregnancy period after she was diagnosed as acromegaly and she has a healthy child. Octreotid treatment was stopped during pregnancy. Malignancy was diagnosed in 5 patients (1 pancreas adenocarcinoma, 2 thyroid follicular carcinoma, 1 lung adenocarcinoma, 1 colon adenocarcinoma and thyroid papillary carcinoma coexistent in the same patient). Colonic polyps were discovered in 7 patients. As a result it can be concluded that acromegalic patiens have to be followed lifelong. Usually remission is not achieved easily. The patients should also be investigated for other comorbidities.

### Glucose metabolism and lipid disturbances in acromegalic patients before and during treatment with long-acting somatostatin analogues

A Kazmierczyk-Puchalska, E Andrysiak-Mamos, E Sowinska-Przepiera & A Syrenicz
Pomeranian Medical University, Szczecin, Poland.

Introduction
Acromegaly causes hyperlipidemia and glucose metabolism disturbances what finally results in increased mortality. Correctin of those lipid and glucose disturbances during treatment with long-acting somatostatin analogues was examined in this study.
Material and methods
Eleven patients (9 women and 2 men) with active acromegaly and macroadenoma diagnosed at our Department in the years 2008–2011 underwent monitoring of lipids and glucose levels before and during one-year treatment.
Results
The therapy with long-acting somatostatin analogues leaded to statistically significant reduction of GH and IGF1 level ($P=0.00585$; $P=0.0094$ respectively). Normoglycaemia occured in 45.45% of patients, diabetes mellitus was found in 9.09% impaired fasting glucose in 27.27% and impaired glucose tolerance in 18.18% before treatment. There was not statistically significant reduction of glucose level during therapy. The mean fasting glucose concentration and the level in 120 min of glucose test tolerance before treatment were $99.1 \pm 20.67$ and $107.37 \pm 44.84$ respectively and after therapy the levels were $94.43 \pm 18.62$ and $87.31 \pm 22.41$ respectively. There was observed impaired glucose tolerance in 9.09% of patients and normoglycaemia existed in 54.56% after treatment. According to the problems with lipid metabolism the lipid profile shows higher levels of total cholesterol in 72.72% of the patients, triglycerides in 27.27% and LDL-cholesterol in 90.09% with no statistically significant reduction of these parameters ($P=0.33$, $P=0.25$, $P=0.624$ respectively). Before and after therapy there were found no correlations between patient's age, GH level and fasting plasma glucose, total cholesterol, triglycerides. There were only correlations between the age and HDL-cholesterol level ($P=0.022$) and LDL-cholesterol and GH level before the treatment ($P=0.0045$).
Conclusions
The treatment with somatostatin analogues does not lead to improvement of total cholesterol, LDL-cholesterol, triglycerides and does not help to regulate glucose level in acromegalic patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1508

**The therapy with cabergoline evaluation of men with macroprolactinoma**

E. Andrysiak-Mamos, A. Kazmierczyk-Puchalska, E. Sowinska-Przepiera, L. Sagan, I. Kojder & A. Syrenicz
Pomeranian Medical University, Szczecin, Poland.

Introduction
Pituitary gland adenomas producing prolactin are one of the most common hormonally active tumours. A pharmacological treatment with the usage of dopamine receptors agonists is a therapy of choice in case of prolactinoma.
The aim of the study was evaluation of the therapy with cabergoline of men with macroprolactinoma basing on the clinical, hormonal and radiological examinations.
Material and methods
Ten men aged 18 to 65 (mean 41.9 ± 15.01) with the presence of the pathological mass in the pituitary gland sized 16.7 to 40.5 mm (mean 29.8 ± 9.38 mm) and elevated PRL level from 673 to 4700 ng/ml (mean 1608.2 ± 1771.6 ng/ml) were included into the study. The PRL and the remaining trophic hormones levels were evaluated after 1, 3, 6 and 12 months and the tumour size evaluation was performed in MRI examination after 12 months of the therapy with cabergoline.
Results
The therapy with cabergoline leaded in all patients to headaches remission, visual acuity correction and significant improvement within libido and erection. In 90% of patients the PRL normalization was achieved, just after first months of the therapy. The mean PRL concentrations were before and after 1, 3, 6 and 12 months of the therapy respectively 1608.2 ± 1771.6 and 263.4 ± 223.4, 136.1 ± 244.7, 91.31 ± 105.5 and 27.5 ± 57.7 ng/ml. The significant tumour size reduction was observed from 29.8 ± 9.4 mm, mean about 6 mm, that states 25.1% (from 4 to 48.5%). No significant correlation between the mean tumour size and PRL level was observed before and during the treatment. The decreased testosterone level before the therapy was proved and it's gradual increase during the treatment was observed.
Conclusions
The cabergoline administration in patients with macroprolactinoma is effective in reaching the PRL level normalization as well as in the tumour size reduction. The tumor size is not a prediction factor for the effectiveness of therapy with cabergoline.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1509

**Efficacy of testerone 2% gel replacement therapy on erectile function, muscle strenght and general wellbeing in men affected by normo-hypogonadotropic hypogonadism**

F. Lo Calzo, M. Galdiero, P. Vitale, F. Cariati, A. Cozzolino, L. Grasso, A. Colao & R. Pivonello
University "Federico II", Naples, Italy.

Background
Hypogonadism is a clinical entity characterized by low serum testosterone (T) levels associated with several clinical signs and symptoms which can negatively affect the quality of life. T replacement therapy (TRT), restoring serum T concentrations, improves signs and symptoms related to hypogonadism. Many T formulations are presently available. The aim of the study was to assess effects of 2% gel TRT on serum T concentrations, erectile function, muscle strength and general wellbeing in men affected by normo-hypogonadotropic hypogonadism.
Materials and methods
Twenty-five patients (mean age 33 ± 5 years) affected by mild to moderate normo-hypogonadotropic hypogonadism with different etiology (20 functional, 3 post-pituitary surgery, 1 autoimmune, 1 post-traumatic) were enrolled into the study. T 2% gel was administered at a dose ranging between 20 and 90 mg/day. Serum total T, DHT, International Index of Erectile Function-5 (IIEF-5) and the Aging Male Symptom Scale (items 1 and 10) questionnaires were evaluated before and after 3–6 months of TRT. IIEF-5 evaluates erectile function, whereas item 1 and 10 of AMSS evaluate respectively general wellbeing and muscle strenght.
Results
Normal serum testosterone levels were restored in all patients after 3–6 months of treatment. TRT determined a significant increase in serum total T ($P<0.001$) and DHT ($P=0.008$) levels. T normalization resulted in an improvement of sexual function ($P<0.001$), muscle strength ($P=0.004$) and general wellbeing ($P=0.002$). A direct correlation was found between the increase of total testosterone and the improvement of IIEF-5 ($P=0.002$), muscle strenght ($P=0.012$) and general wellbeing ($P=0.039$). No significant correlation was discovered neither between dose of T administered and improvement in IIEF-5 score ($P=0.15$) nor between dose of T administered and improvement of muscle strenght ($P=0.093$).
Conclusions
Transdermal 2% gel TRT is able to restore physiological total T levels in men affected by normo-hypogonadotropic hypogonadism improving signs and symptoms related to hypogonadism. Therefore, it can be considered an effective alternative TRT.

**Follow up of pituitary incidentaloma: a study in 140 patients**

C. Poiana[1,2], M. Carsote[2], R. Trifanescu[1,2], R. Danciulescu-Miulescu[1], M. Musat[1,2], D. Hortopan[1] & A. Dumitrascu[1]
[1]I.Parhon, Bucharest, Romania; [2]UMPh Davila, Bucharest, Romania.

Introduction
Pituitary incidentaloma is a relatively frequent imagistic finding. Since no therapy is necessary, the follow up protocol is the most important in patients' approach.
Aim
We present a study in patients diagnosed with pituitary incidentaloma, admitted in I.Parhon, Bucharest, between 1999 and 2011.
Patients and method
This is a retrospective study in 140 patients, diagnosed with pituitary incidentaloma based on CT or MRI. We included asymptomatic patients to whom an incidental imagistic scan found the pituitary tumor of less than 1 cm. The informed consent was obtained.
Results
One hundred and forty patients (p) were included. The female/male ratio was 130/10. The av. age was 40.84 ± 13.3 years, with ranges between 14 and 72 years. The av. values of pituitary hormones were normal according to patients' age: prolactine 14.18 ± 12.18 ng/ml, FSH 43.97 ± 55.08 mUI/ml, LH 16.93 ± 19.01 mUI/ml, TSH 2.52 μUI/ml, ACTH 35.52 ± 19.15 pg/ml. The secretor profile was found in one patient with prolactinoma that was ruled out. 3 p had bilateral incidentalomas. The av. transverse diameter was 0.57 ± 0.2 mm, and vertical diameter 0.39 ± 0.15 mm. 69 p had at least one evaluation in av. 35.33 ± 27.39 months (ranges from 6 to 108 months). For these patients, the initial av. transverse, respective vertical diameters were: 0.538 ± 0.17 mm, 0.374 ± 0.09 mm. The av. final values were: 0.545 ± 0.174, respective 0.368 ± 0.09 mm. The student ttest between initial and follow up evaluations was no statistically significant. In 25p increased the transverse diameter with av. 0.159 ± 0.119 mm, and in 32p the diameter decreased with 0.158 ± 0.132 mm. In 19 p the vertical diameter increased with 0.122 ± 0.182 mm, and in 37 p decreased with 0.115 ± 0.128 mm. In one case, the microadenoma increased to 110 mm.
Conclusions
Based on our study, once the non-secretor profile is established, the diagnosis of incidentaloma is sustained,and a follow up CT is not necessary sooner than 3 years.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1511

**Macroprolactin levels in healthy blood donors**

D. Horvath[1], Z. Locsei[1], C. Catomio[1], R. Jager[1], F. Hadarits[1], G. Kovacs[2] & E. Toldy[1,2]
[1]Markusovszky Teaching Hospital of County Vas, Szombathely, Hungary; [2]University of Pecs, Pecs, Hungary.

The incidence of macroprolactinemia decreased notably because of wide use of prolactin (PRL) assays measuring macroprolactin at a lower rate. However, in case of high PRL levels, measurement of monomeric PRL (mPRL) levels after polyethylene glycol (PEG) treatment is still required. Our aim was to determine – by the use of a second generation PRL assay – how total PRL (tPRL) levels in native sera of healthy blood donors change after PEG treatment. In women, the use of oral contraceptives (OC) was taken into consideration as well.
Methods
PRL levels were determined in 131 healthy blood donors (50 men and 81 women; age 33.5±10.5 years). Forty-one women were taking OC. tPRL was measured before and after PEG treatment with a fully automated method (ECLIA, Cobas e411, Roche). PRL recovery (PRL-r%) was determined as the quotient of mPRL/tPRL.
Results
There were increased tPRL levels in 16 native sera (11%). PRL levels after PEG treatment decreased into the reference range only in two of these cases. The other 14 women had mild true hyperprolactinemia (558±238 mU/l), 12 of them took OC. tPRL levels were significantly ($P<0.05$) higher in women than in men (312±224 vs 235±140 mU/l, respectively), but there were no significant differences in mPRL levels (255±173 vs 223±126 mU/l). PRL-r% was higher ($P<0.001$) in men than in the two groups of women. There was a significant, albeit week positive ($r=0.24$; $P<0.01$) correlation between age and PRLr %. There was no significant difference in the PRL levels between women taking or not taking OC.
Conclusions
According to our results the incidence of macroprolactinemia among healthy blood donors is only 1.5%. In women taking OC only true hyperprolactinemia was present. The weak, but significant positive correlation between age and PRLr% proves the increased antibody production during ageing.

## P1512

**Sleep apnoea syndrome in acromegaly**

H. Khemiri[1], Z. Turki[1], M. Yazidi[1], I. Kammoun[1], M. Turki[2], L. Ben Salem[1] & C. Ben Slama[1]
[1]National Nutrition Institute, Tunis, Tunisia; [2]Sleep Center, El Manar 2, Tunis, Tunisia.

Sleep apnoea syndrome (SAS) is common in acromegaly and both diseases are independently associated with hypertension and insulin resistance contributing to increased morbidity and mortality.
The aim of this study was to assess the prevalence and risk factors of SAS in acromegaly, to study clinical and polysomnographic particularities of SAS in acromegaly and to analyze the effects of acromegaly treatment on SAS.
It's a retrospective study on fifteen patients (nine women and six men). The mean age was 53.6 years (32–71). All patients had newly diagnosed acromegaly. All patients had biochemical assessment (IGF1, GH, fasting blood glucose). The overnight respiratory polygraphy was performed only before acromegaly treatment in three patients, in ten before and after treatment, and in two it was just performed after treatment. Echocardiographic parameters were measured before acromegaly treatment in twelve patients.
Among the thirteen patients tested before acromegaly treatment, ten had SAS (76.9%). In a multivariate analysis only age was associated with SAS. The values of GH and nadir of GH were associated to the severe cases of SAS. Diabetes, high blood pressure, goiter and left ventricular hypertrophy were more prevalent in patients with SAS, especially in severe cases. Among the patients from whom acromegaly was cured 40% recovered of SAS.
The prevalence of SAS in acromegaly is high especially in older patients. SAS can persist after recovery of acromegaly in several patients. Respiratory polygraphy or polysomnography should be included as routine procedure in the work up of acromegaly. Appropriate intensive treatment should be implemented to minimize the clinical impact of SAS in acromegaly.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1513

**Therapeutic trends, long-term outcome and efficacy of different treatment modalities in acromegaly: a single center registry covering a 40 year period**

M. Tzanela, O. Karapanou, A. Assimakopoulou, L. Papastathopoulou, M. Christophoraki & S. Tsagarakis
Evangelismos Hospital, Athens, Greece.

The aim of the study was to examine the therapeutic trends and the long-term outcome of available therapeutic modalities for acromegaly in a single center over a 40 year period.
We retrospectively studied 300 acromegalic patients (131 men, 169 women, 153 macroadenomas and 147 microadenomas) from 1970 until 2010; 154 patients were diagnosed before 1990 (group A) and 146 after 1990 (group B). Outcome was evaluated by IGF1 and GH (random plus post OGTT) measurements.
The outcome of each treatment modality in the two groups of the cohort is shown in Table 1.
Surgery (TSS) and somatostatin analoges (SSA) were used more often in group B (TSS: in 62% of patients vs 40% in group A, $P=0.0001$, SSA: 52 vs 6.4% respectively, $P=0.0001$), while pituitary irradiation was used less often in group B (30 vs 56.4% $P=0.0001$). Overall the outcome at latest follow-up following all treatment interventions in groups A and B respectively was as follows: 40.6 vs 66.3% achieved GH<2.5 ng/ml, $P=0.0001$; 20 vs 42.8% achieved GH<1.0 ng/ml, ($P=0.0001$); 15.2 vs 34.9% achieved GH nadir post OGTT <0.4 ng/ml ($P=0.004$); and 50.4 vs 68.1% achieved normal IGF1 ($P=0.04$).
Conclusions
These results indicate that in our cohort the evolution of treatment modalities in favor of TSS and medical treatment resulted in a better overall outcome of acromegaly in patients treated during the last 20 years. However, the disease still remains uncontrolled in a substantial proportion of patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Prevalence of the metabolic syndrome in patients with adult growth hormone deficiency before GH treatment**

M. Romero-Muñoz[1], C. Tenorio-Jiménez[1], M. Varsavsky[1], J. Luna-Del-Castillo[2], M. Muñoz-Torres[1] & E. Torres-Vela[1]
[1]San Cecilio Universitary Hospital, Granada, Spain; [2]Faculty of Medicine. University of Granada, Granada, Spain.

Introduction
A increased prevalence of metabolic syndrome (MetS) has recently been described in patients with adult growth hormone deficiency (GHD). This fact could influence the increased risk of cardiovascular morbidity and mortality observed in these patients. Our objective was to investigate the characteristics and prevalence of MetS in adult GHD.
Design and methods
Forty-nine adult patients (30 women, 19 men; 14 childhood-onset), mean age of 36.2±13.8 years, with severe GHD (mean duration 9.1±9.4 years) were evaluate

before GH replacement. Complete information on all MetS components were collected. MetS was defined according to the National Cholesterol Education Program's Adult Treatment Panel III (NCEP) and the International Diabetes Foundation (IDF). The prevalence of MetS was calculated, and associations were assessed between baseline variables and MetS.
Results
MetS was present in 14.9% (NCEP) and 31.8% (IDF) of our patients, lower than data from KIMS analysis (43.1%) and similar from the normal population (20–30%). The prevalences of MetS components (NCEP) were: waist circumference 26.5%, HDL 45%, triglycerides 47.8%, hyperglycaemia 4.3% and hypertension (14%). No childhood-onset patient fulfilled the definition of MetS, while 23.3% of adult-onset patients were diagnosed. The prevalence was higher in women (25 vs 5.8%, non-statistically significant). Mean age and GHD duration before GH replacement were similar among MetS and no-MetS patients; MetS patients had higher glycaemia ($P=0.005$), triglycerides ($P<0.001$), waist circumference ($P<0.001$), lower HDL-cholesterol BMI ($P=0.001$), and were shorter ($P=0.034$) than no-MetS patients.
Conclusion
The prevalence of MetS in our GHD patients were lower than KIMS study. That could be influenced by a lower age in our patients (13 years younger). However, we should diagnose and treat MetS components as they could contribute to the increased risk of cardiovascular morbidity and mortality found in GHD patients.

**Familial central diabetes insipidus with extremely high water intake**

E. Pigarova, L. Rozhinskaya, L. Dzeranova, T. Zenkova & A. Tiulpakov
Endocrinology Research Centre, Moscow, Russian Federation.

Water intake in central diabetes insipidus (CDI) usually falls in range of 3–20 l a day. Intake of more than 20 l is regarded as physiologically unnecessarily even in the absence of antidiuretic hormone. We describe a family with 8 members suffering from autosomal recessive form of CDI due to mutation C105Y (codon numeration is given for preprovasopressin) in AVP gene. In all family members disease had presented in neonatal period or early childhood. It is remarkable that without desmopressin the water intake/output ranges from 30 to 34 l a day and is up to 3–4 l on 0.8 mg of oral desmopressin.

## P1516

**Visceral adiposity index is associated with insulin sensitivity and adipocytokine levels in newly diagnosed acromegalic patients**

A. Ciresi, M. Amato, V. Guarnotta, A. Galluzzo & C. Giordano
Dipartimento Biomedico di Medicina Interna e Specialistica (Di.Bi.Mi.S), University of Palermo, Palermo, Italy.

Background
The Visceral Adiposity Index (VAI) has been suggested as a new gender-specific marker of visceral adipose dysfunction, strongly associated with insulin sensitivity in patients with cardio-metabolic risk.
Aim
To test VAI in active acromegaly for the assessment of disease-associated metabolic risk evaluating its association with hormonal data, adipocytokine levels, insulin sensitivity and secretion parameters in a cohort of 27 subjects (15 M, 12 F, mean age 54.9 years).
Methods
Glucose, HbA1c, nadir and AUC of GH during OGTT, AUC of C-peptide (CP) during a mixed-meal tolerance test (MMTT), M value during an euglycemic hyperinsulinemic clamp, leptin, adiponectin, TNF-α, IL-6 were evaluated in newly diagnosed patients grouped into those with normal (Group A, No 15; 55.5%) and high VAI (Group B, No 12; 44.5%).
Results
VAI value was positively correlated with age of patients ($P=0.048$), basal, nadir and AUC of GH ($P=0.001$, 0.007 and 0.002, respectively), IGF1 ($P=0.001$), TNF-α ($P=0.010$) and negatively with adiponectin ($P<0.001$). Group B showed 1) significantly higher levels of basal GH ($P=0.018$), AUCGH ($P=0.047$), IGF1 ($P=0.047$) and AUCCP ($P=0.018$); 2) significantly lower *M* value ($P<0.001$) and adiponectin levels ($P<0.001$); 3) higher prevalence of systolic blood pressure ($P=0.006$) and impaired glucose tolerance ($P=0.001$).
Conclusions
In active acromegaly, VAI appears to be independently associated with hormonal parameters, insulin sensitivity and secretion indexes, adiponectin and TNF-α levels. Therefore, VAI could be used as a new easy tool in daily clinical practice for the assessment of metabolic risk associated with active acromegaly.

**Isolated diabetes insipidus happened during premenopause solution ten years after**

J. Ory
General Hospital, Vesoul, France.

Pathologies of pituitary gland are often revealed by diabetes insipidus. Etiologies are, in first, tumors, inflammatory and granulomatosis diseases after, but stay idiopathic in 24% of French study, 52% of Italian study and 33% of Tunisian study.
Case report
Mrs A., 53 years old, consults in 1998 because polyuria–polydipsia, without diabetes mellitus. She is hospitalized during 2 days and hydric restriction test shows the organic reality. The others neuro-endocrine explorations stay unproductive, without confirmation of appearance of menopause. The brain and hypophysis examination by CT scan is found normal. The MRI shows pituitary stalk "thick", but lightly…And, haematologic perturbation, or inflammatory syndrome, or osteo-arthritis pain, or cardiovascular or nephrologic perturbation don't exist, and treatment by MinirinR has permitted to get back stabilized health status. The next MRI controls, executed at 6 and 24 months later, are perfectly stable, and so is clinical status. During 2008, Mrs A., consults because undulant fever and asthenia. Physical examination permits to discover bilateral tibia pain, erythematous lesions on the neck and thorax. Cutaneous biopsy, myelogram and bone biopsy permit to obtain diagnosis of Erdheim Chester syndrome, it's to say non Langerhans histiocytosis which aims are cardiovascular system, central and peripherical nervous system and the bone.
The initial having few symptoms situation can explain the time for diagnosis establishment. Nevertheless, in the beginning of the story, it was not justified to propose chemotherapy and supervision stayed justified.

**Metaplastic Rathke's cyst leading to hypopituitarism**

S. Muniyappa[1], S. Sinha[1] & J. Newell-price[2]
[1]Sheffield Teaching Hospitals, Sheffield, UK; [2]Sheffield University, Sheffield, UK.

A 22 years old woman, with secondary infertility, was found to have secondary hypothyroidism and referred to endocrinology. On review her symptoms consisted of headache for 6 months, amenorrhoea, weight gain and progressive loss of vision in the left eye for 6–9 months, which had been investigated by opticians and opthalmologists. Other history includes Von Willebrand disease type2. Clinical examination confirmed total loss of vision of the left eye and complete temporal defect in the right.

Investigation

Biochemistry confirmed secondary hypothyroidism with adrenal insuffieciency –serum $FT_4$ 5.1 pmol/l (12–22), TSH 0.72 mIU/l (0.27–4.2). A short synacthen test confirmed adrenal insufficiency with a plasma ACTH level of 8.6 ng/l, basal serum cortisol of 142 nmol/l rising to only 344 nmol/l at 30 min after 250 μg ACTH 1–24. Serum prolactin was normal, but serum oestrodiol, LH and FSH were low, consistent with secondary gonadal failure. Gadolinium-enhanced MRI confirmed a pituitary macroadenoma measuring 27 mm × 27 mm × 17 mm and extending to the suprasellar cistern and compressing the optic chiasm and left optic track with possible recent apoplexy. No sinus abnormality was seen.

Management

Appropriate replacement therapy was commenced. After discussion endoscopic transsphenoidal surgery was performed. Unexpectedly during surgery pus was encountered on first incision of the pituitary mass, resulting in decompression of the optic chiasm. Culture was negative. Histopathology revealed benign squamous epithelial metaplastic cystic lesion with acute on chronic inflammation, consistent with a Rathke's cleft cyst. Post-operatively she required desmopressin and full anterior pituitary replacement therapy. Remarkably her vision improved immediately after surgery and three months had returned to normal. Repeat MRI scan showed no evidence of recurrence of the cystic pituitary mass after 3 months of surgery.

Discussion

Complete recovery of vision after such an extended period of compression due to pituitary mass is unusual and fortunate in this case. Extensive squamous metaplasia in the Rathke's cleft cyst is unusual and it appears that this had undergone degenerative change with the formation of sterile pus, but the cause of this unusual presentation is unclear.

**Pituitary macroadenomas: benefit from early GH substitution after surgery**

N. Sauer, V. Dannheim, J. Flitsch & J. Aberle
III. Medizinische Klinik, Sektion Endokrinologie und Stoffwechsel, Hamburg, Germany.

Introduction

of non-functioning pituitary macroadenomas are associated with hyposecretion of the pituitary gland. In addition surgical therapy can lead to a partial or complete hypopituitarism. Data suggest that substitution of growth hormone can improve quality of life and reduce associated symptoms. However in many cases substitution is not started within the first 6–12 months after surgery. Therefore we intended to investigate if patients benefit from an early growth hormone treatment after surgery compared to control.

Patients and methods

Data was collected prospectively from 21 adult patients who were diagnosed with insufficiency of growth hormone axis using insulin hypoglycaemia test. Patients were divided into treatment and control group and followed 52 weeks after pituitary surgery. On each consultation laboratory testing was performed and body composition obtained. Also quality of life was assessed by a standardised questionnaire concerning health and life satisfaction.

Results

Whereas the control group showed a significant decrease of IGF1-levels after surgery the IGF1-levels of the treatment group stayed within the normal range.

Bioelectrical impedance analysis showed a significant increase of impedance as well as lean body mass in the treatment group compared to control ($P<0.05$). There was a significant difference in health status in the treatment compared to control.

Triglycerides, cholesterol and LDL-cholesterol increased to a greater extent in the control than in the treatment group without reaching statistical significance. Mean increase in HDL-level was 2.1 mg/dl in the control compared to a decrease of 0.2 mg/dl in the treatment group. Lpa-levels were reduced by 4.1 mg/dl in the treatment and by 2.7 mg/dl in the control group. Finally we saw a trend towards better improvement in pituitary function if GH was substituted.

Conclusion

Early supplementation of GH leads to a significant improvement in quality of life and body composition after pituitary surgery. It is possible that pituitary function recovers better with early GH substitution.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Pituitary insufficiency in the acute phase of traumatic brain injury or subarachnoid hemorrhage, prevalence and predictive factors: a prospective, population based study**

P. Sigurjónsson[1,2], Jónasdóttir[1,2], I. Ólafsson[1], S. Kárason[1,2], G. Sigthórsson[1] & H. Sigurjónsdóttir[1,2]
[1]Landspitali University Hospital, Reykjavik, Iceland; [2]University of Iceland, Reykjavik, Iceland.

Background

Traumatic brain injury (TBI) and subarachnoid hemorrhage (SAH) can cause long-term morbidity and death. Studies indicate that this may partially be due to transient or chronic hypopituitarism (HP). Guidelines recommend screening for HP in moderate and severe TBI patients (TBIp), Glasgow coma score (GCS) 9–12 and <9 respectively. The aim of this study was to evaluate markers of severity and physiologic changes as predictive factors for HP following TBI and SAH.

Subjects and methods

During 12 months, patients admitted to the National University Hospital were included, 21 TBIp, (6 moderate, 15 severe, 17 males, 4 females, mean age $34 \pm 13$ years) and 19 patients with SAH (SAHp) (12 males, 7 females, mean age $54 \pm 14$ years). Baseline hormone levels were measured on admission and on day 6 when a synacthen test was also performed. Variables recorded were GCS, Hunt and Hess grade (SAHp), Injury severity score (TBIp), APACHEII, length of ICU stay and occurrence of systolic blood pressure (SBP) <90 mmHg and SpO2 <90% anytime during the first 24 h. Correlation was tested in SPSS using Spearmans rho (rho).

Results

On day 6, 9 of 21 TBIp, and 5 of 19 SAHp, had HP of one or more axis. Lost to follow up on day 6 were 4 TBIp and 3 SAHp. A significant correlation was found between length of ICU stay and any HP (rho 0.473, $P<0.01$) and occurrence of SBP below 90 mmHg during hours 2–24 (rho 0.337, $P<0.05$). Correlation between HP and other variables was non-significant.

Conclusion

The prevalence of HP in the acute phase following TBI and SAH was 42.9% and 26.3% respectively. The length of ICU stay and episodes of SBP below 90 mmHg during hours 2–24 may indicate HP. Further studies are needed on predictive factors making screening for HP following TBI and SAH effective.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1521

**Difference of response to TRH (thyrotropin releasing hormone) stimulation according to octreotide response and the size of GH-producing pituitary adenomas**

S. Oh, S. Chin & S. Kim
Kyung Hee University School of Medicine, Seoul, Republic of Korea.

Objective

TRH induces GH secretion presumably by expression of TRH receptor dedifferentiated in pitutiary tumors, but it is not clear how the TRH elegantly stimulates GH secretion in tumoral states.

Design
The aim of this study was to investigate how GH-producing pituitary adenomas respond to TRH with respect to GH secretion and how it differs according to octreotide responses and their sizes of tumor.
Method
GH levels of 45 patients with newly diagnosed acromegaly were measured using a TRH stimulation test (TST), insulin tolerance test (ITT), and an octreotide suppression test (OST) sequentially. These values were compared according to the size of tumors and the response pattern to the OST.
Results
Thirty-six of 45 tumors were macroadenomas, and 23/36 macroadenomas appeared to be non-responders during the OST. Stimulated GH levels during the TST were not significantly different according to the size of tumor ($P=0.212$), even though baseline and recovered GH after stimulation had significant difference during the TST ($P<0.024$). Also, microadenomas and macroadenomas with non-responders had significantly different GH during the TST, but not the ITT ($P=0.073$).
Conclusion
According to the TST, dedifferentiation of tumor was firstly influenced by tumor size and then, OST responsiveness. Regardless of the tumor size, the effect of hypoglycemia to stimulate GH secretion was equivalent, though the result of the OST played a significant role to determine the responsiveness to hypoglycemia in macroadenomas.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1522

**Ovarian hyperstimulation syndrome due to a functioning gonadotroph adenoma**

C. Mohandas, O. Mustafa, J. Prague, B. Whitelaw, N. Thomas, A. King & S B. Aylwin
King's College Hospital, London, UK.

Background
Gonadotroph adenomas usually present as non-functioning pituitary adenomas.We describe a patient with a functioning gonadotroph adenoma presenting with ovarian hyperstimulation syndrome: an exceptionally rare presentation of pituitary disease.
Case history
A 26-year-old female presented with a 10-year history of worsening lower abdominal pain, bloating, dysmenorrhea and irregular periods in 2006. She was found by ultrasound to have multiple ovarian cysts that were surgically drained. Her symptoms recurred with re-growth of 19 ovarian cysts that prompted removal in March 2008. Abdominal pain further recurred in June 2008 and the repeat USS showed enlarged 11 ovarian cysts. As part of evaluation for subfertility an elevated prolactin was identified (PRL: 1338 mU/l $n<530$) leading to a pituitary MRI that revealed a right-sided ($11\times8\times7$ mm) pituitary adenoma.
Investigations
After endocrine evaluation, baseline hormone profile revealed extremely high oestradiol levels (20 000 pmol/l). Clinical and biochemical features were considered consistent with ovarian hyperstimilation syndrome (OHSS) in the absence of exogenous gonadotrophins and therefore presumed secondary to a gonadotroph secreting adenoma.The patient underwent endoscopic transphenoidal surgery in December 2008 with subsequent intact anterior pituitary endocrine axes, although requiring DDAVP. Oestradiol fell rapidly from 20 000 pmol/l down to a normal level, her menstrual cycle returned and was followed by two successful pregnancies. The pelvic cysts resolved and pelvic anatomy returned to normal on ultrasound. Serial MRI Pituitary scans have shown no evidence of residual tumour.
Conclusion
Gonadotrophin-secreting pituitary tumours should be considered in patients with multiple recurrent ovarian cysts and extreme elevations of Oestradiol. Although positive immunohistochemistry for gonadotrophins is common amongst pituitary tumours, functioning gonadotrophinomas are very unusual with only a handful reported in the literature and with variable outcomes. In our patient, the recognition occurred after propitious diagnosis by MRI.

Biochemical results

| Test | **30.09.08** (pre-op) | **18.02.09** (post-op) | **28.10.11** |
|---|---|---|---|
| Oestradiol (pmol/l) | 20 000 | 371 | 219 |
| FSH(U/l) | 8.8 | 2.1 | 7.4 |
| LH(U/l) | 2.5 | <0.8 | 4.9 |
| Prolactin (mU/l) | 1560 | 281 | 249 |

## P1523

**GH deficiency after treatment of medulloblastoma and thyroid cancer: is this the case for GH therapy?**

Z. Valkusz, S. Magony, K. Sepp, E. Csajbok, J. Julesz & L. Pavics
University of Szeged, Szeged, Hungary.

The hypothalamic–pituitary unit is a particularly radiosensitive region in the central nervous system. As a consequence, hypopituitarism commonly develops after radiation treatments for sellar and parasellar neoplasms, extrasellar brain tumours. Increasing tumour-related survival rates provide an expanding population at risk of developing hypopituitarism. The severity of hypopituitarism is related to the radiation doses given while whole body irradiation regimens to a dose of 18 Gy result merely in isolated GH deficiency. Somatotrophs are reported to be more radiosensitive in children as compared with adults: 59% of childhood cancer survivors show a blunted response on GH stimulatory tests. GH has consistently shown to be the most radiosensitive pituitary axis, with series reporting a prevalence of GHD between 50 and 100% after radiotherapy. Radiation-induced GHD is also progressive with time, developing more frequently in the first 10 years after radiation delivery. GHD severity and speed of onset closely correlate with lower final height, decreased lean body mass (LBM) and higher fat mass in children. There are several data indicating the significance of radiotherapy as a risk factor for hypothyroidism.
Children with malignancy treated with chemotherapy and radiation to the head, neck and mediastinum are at risk of developing hypothyroidism and thus should be monitored with regular thyroid function test surveillance up to around 10 years post-diagnosis. A 20 years old female patient's case is presented: after successful treatment of medulloblastoma at the age of 6, she was operated and treated with radioiodine for papillary type of thyroid cancer in her 15 years of age. As a consequence of her previous diseases and treatments last year we detect a severe GH deficiency. We show how is she currently managed.

## P1524

**Thyrotropinoma. A rare case report of hyperthyroidism**

H. Tamez-Pèrez[1], D. Quintanilla-Flores[1], M. Hernàndez-Coria[2], J. Cisneros-Franco[1], A. Tamez-Peña[1] & S. Proskauer-Peña[1]
[1]Facultad de Medicina y Hospital Universitario "Dr Josè Eleuterio Gonzàlez", Universidad Autònoma de Nuevo Leòn, Monterrey, Mexico; [2]Universidad Juàrez del Estado de Durango, Durango, Mexico.

Case presentation
A 84 year-old male without family history of thyroid disease was referred to our clinic by his cardiologist, diagnosed as having primary hypothyroidism, characterized by persistent elevated TSH without response to L-thyroxine over the course of a year. Co-morbidities included arterial hypertension, auricular fibrillation (AF) and glucose intolerance, treated with propafenone, clopidogrel, enalapril, and digoxine. On physical examination, he presented AF with tachycardia, mild distal tremor, and no goiter.
Thyroid function tests (TFT) reported TSH: 6.87 mU/ml (normal 0.4–4.5), $T_4$: 2.31 ng/dl (normal 0.8–2.0). Thyroid auto-antibodies were negative. It was decided to lower L-thyroxine dose. Six months later, the patient remained symptomatic despite treatment discontinuation. TFT were repeated, showing high TSH and $T_4$ levels. More specific tests and a MRI were ordered (Fig. 1).
TSH response to the TRH test was flat. The TSH alpha subunit (α-SU) and the α-SU/TSH molar ratio were elevated. The MRI showed a pituitary macroadenoma ($1.2\times1.1\times1.6$ cm) with extension to the supraselar cistern, left

deviation of the pituitary stalk, without involvement of the optic chiasm. A thyrotropinoma(TSH-oma) was diagnosed.
First-line therapy is surgical. If this is contraindicated or declined, pituitary radiotherapy, dopamine agonists, somatostatin analogs, or thyroid ablative treatment should be considered. Because of old age and co-morbidities, our patient was treated with ablative thyroid treatment with radioactive iodine. Six months later, TFT showed normal $T_4$ and high TSH levels, requiring no further therapeutic modifications.
Conclusion
TSH-omas are rare tumors -0.5% of all pituitary tumors-, classically causing central hyperthyroidism. High levels of α-SU or an α-SU/TSH molar ratio $>1$ are indicative of TSH-oma in more than 90% of the cases. MRI is the preferred tool to the diagnosis. Ablative thyroid therapy is a good option for some cases.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1525

**The dermatologic evaluation of acromegaly patients**
T. Saler
Haseki Training and Research Hospital, Istanbul, Turkey.

Aim
To evaluate dermatologic findings in diabetic and nondiabetic acromegalic patients and compare with nonacromegalic diabetic patients. Also to investigate any possible correlation between skin lesions and colonic and thyroid neoplasms.
Materials and methods
Data from dermatologic examination of 32 acromegalic and diabetic non-acromegalic patients were compared. Colonoscopic, ultrasonographic and biochemical findings of acromegalic patients were evaluated for any correlation.
Results
Twenty nondiabetic and 12 diabetic acromegalic patients had similar number of skin tags compared to each other and to 21 nonacromegalic diabetic patients. Only IGF1 levels were correlated with the presence and number of skin tags and colonic polyps. Insulin levels were correlated with the presence of colonic polyps and thyroid nodules but not correlated with skin tags. The presence of skin tags was significantly correlated with colonic polyps but not correlated with thyroid nodules.
Conclusion
In our study group, IGF1 and not insulin levels affected the formation of skin tags. Skin tags could be a marker of colonic polyps, but are not related to thyroid nodules.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1526

**Growth hormone effects on lipid profile in patients with acromegaly**
M. Mykytuyk, O. Khyzhnyak, T. Sulima & Y. Karachentsev
Institute for Endocrine Pathology Problems, Kharkiv, Ukraine.

Introduction
Active acromegaly is associated with increased mortality, which has been attributed largely to cardiovascular disease.
Aims
To evaluate the effects of chronic excess of GH and IGF1 on lipid metabolism in patients with active acromegaly.
Subjects and methods
Ninety-seven patients (37 men and 60 women; aged 18–76 years) with macroadenoma of hypophysis (67 – somatotropinoma, 30 – somatomammotropinoma) were under investigation. Blood samples for GH, IGF1, total cholesterol (TC), triglycerides (T), HDL-C, Apo A-I and Apo B were taken in fasting state. LDL-C and VLDL-C were calculated using the Friedwald formula. Disease activity was evaluated by means of OGTT according to the Consensus Conference criteria. Data are given as $M \pm SE$ and multiple regression model equations.
Results
In 40.4% of patients with somatotropinoma (GH – $22.8 \pm 3.5$ ng/ml; IGF1 – $620.81 \pm 301.30$ ng/ml) and somatomamotropinoma (GH – $26.3 \pm 5.3$ ng/ml; IGF1 – $651.69 \pm 295.64$ ng/ml) different types of dyslipidemias (WHO of classification) were found out: IIa type in 18.9%; III type – in 15.8%, and IV type – in 5.3% of patients. Moderately elevated level of TC, T, LDL-C, and VLDL-C was appropriate to both groups of patients with macroadenoma. It was found out nonlinear regression between HDL-C, ApoA-I, ApoB and IGF1 approximated by equations: $\text{HDL-C} \approx 1/(0.7+30.5/\text{IGF1})$ ($R2=52.8\%$, $P=0.002$); Apo A-I $\approx 1/(0.6+16.3/\text{IGF1})$($R2=22.1\%$, $P=0.01$); $\text{ApoB}=2.07-0.17*\ln(\text{IGF1})$($R2=21.2\%$, $P=0.01$).
Conclusion
The GH hypersecretion is associated with altered lipid profile. IGF1 mainly predetermines the level of HDL-C, Apo-I and ApoB lipoproteins. Patients with acromegalia are at increased cardiovascular risk through the atherogenic dyslipidemias that may accompany the chronic excess of GH.

## P1527

**Pituitary lesions: Pituitary adenomas and what else?**
I. Vourliotaki, A. Boumpaki, S. Alexaki & K. Stamataki
Venizeleio General Hospital, Heraklio, Crete, Greece.

Introduction
Pituitary lesions are quite often in the general population and can be symptomatic or not. Most are attributed to pituitary adenomas. Differential diagnosis also includes other causes, such as granulomatous diseases (sarcoidosis, histiocyttosis). Neurosarcoidosis is rare. Sarcoidosis pituitary infiltration is even more rare and usually reported in multifocal forms of the disease.
Case report
We describe a 34-year old female with headache and oligomenorrhea.
MRI showed a pituitary lesion 1.5 cm and normal pituitary stalk.
Pituitary hormone profile was normal, except for mild hyperprolactinaemia, with no diabetes insipidus.
The lesion was considered to be a non functional pituitary adenoma and the patient underwent trans-sphenoidal excision of the lesion.
Histologic examination showed a granulomatous inflamatous mass, negative for tuberculosis. Three months later no mass was found in pituitary MRI.
The patient was referred to a rheumatologist, but was lost to follow up for personnal reasons.
One year later, the patient had an MRI showing a new pituitary lesion 1.3 cm with mild hyperprolactinaemia. She was investigated for sarcoidosis but no systematic

disease was found. Considering diagnosis of sarcoidosis, prednizolone was prescribed. Being on prednizolone for three months reduced size lesion to 0.9 cm. Six months later it disappeared. This confirmed diagnosis of sarcoidosis.
She received prednisolone for 18 months in total. Afterwards, she was lost to follow up again for 6 years, off corticosteroids, and recently came back with recurrence of the lesion.
She is again administered prednisolone.
Investigation for systematic disease is still negative.
Conclusion
To our knowledge, there is no other reported case of neurosarcoidosis with unique infiltration of the pituitary that persists for 6 years with no other systemic disease.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1528

**Progressive combined pituitary hormone deficiency produced by Prop1 gene mutation**

C. Ghervan[1], M. Stroe[1] & J. Young[2]
[1]University of Medicine and Pharmacy "Iuliu Hatieganu", Cluj-Napoca, Romania; [2]University Paris Sud-11, Paris, France.

Introduction
The appearance and normal development of the anterior pituitary gland requires several signalling molecules and specific transcription factors, such as PROP1, POUF1, HESX1/RPX, LHX3, LHX4, PITX2, T-PIT, SOX2 and SOX 3. Gene mutations of these pituitary transcription factors may lead to different degrees of combined pituitary hormone deficiency (CPHD) associated or not with morphological changes of the hypothalamic–pituitary region.
Material and methods
We present the first Romanian case of progressive CPHD in two brothers from a consanguineous family. Clinical, hormonal and MRI follow-up were performed during 20 years.
Results
Growth hormone deficiency was certified at the age of 5, respectively 3 years, followed by gonadotropin deficiency diagnosed at the age of 21, respectively 19 years, and by central hypothyroidism diagnosed at the age of 23, respectively 21 years. Substitutive treatment with recombinant human GH (rhGH) was commenced, followed by testosterone and later thyroxin, in adequate doses. Adrenal function was normal during the follow-up. Magnetic resonance imaging (MRI) revealed anterior pituitary hypoplasia in both siblings, with a partially empty sella in the younger brother. Surprisingly, we found a thick midline septum in the sphenoid sinus in both siblings, which was not described in previous reports. The progressive CPHD suggested a PROP1 deficiency, which was confirmed by genetic analysis. The 301-302delAG homozygous mutation in the PROP1 gene was identified, resulting in a complete loss of promoter binding and transcriptional activation of the mutant protein.
Conclusion
Mutations in PROP1 gene are a very rare cause of pituitary insufficiency causing progressive CPHD. The progressive decline in the anterior pituitary axis requires continuous monitoring of the patients, in order to adjust the doses of their complex substitutive hormonal therapy, to insure the adherence to treatment and to identify the occurrence of new hormonal deficits.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1529

**Neurohypohysis tumors: about two cases**

F. Belhimer, S. Belahcene, S. Souachi, R. Baba Ahmed & F. Chentli
Bab El Oued Hospital, Algiers, Algeria.

Introduction
Neurohypophysis tumors also called pituicytomas are very rare low grade gliomas of the brain that developed in the posterior part of the pituitary gland. Our aim is to report two cases whose diagnosis was made by MRI in the first case and by histology in the second case.
Cases reports
Observation No. 1: a woman aged 33 consulted for polyuria and polydypsia due to central diabetes insipidus without pituitary insufficiency. The MRI discovered a 7 mm well limited tumor in the posterior part of the pituitary gland. According to different investigations a primary lesion was more likely than breast, thyroid, pulmonary or genital metastasis.
Observation 2: a man aged 55, consulted for headaches and decrease in visual acuity. Brain MRI showed an invasive pituitary tumor measuring $55 \times 32$ mm. Hormonal exploration argued for global pituitary insufficiency without any impairment of post hypophysis function, although the tumor was posterior. Histological exam argued for a pituicytoma.
Conclusion
Neurohyophysis tumors are very rare as less than 40 cases have been reported. They may be very small with diabetes insipidus as the only manifestation or be large or even huge with ophtalmological troubles and pituitary insufficiency without diabetes insipidus in spite of the posterior location as in our second observation. Surgery seems to be the best treatment for large tumors, but for small tumors wait and see attitude may also be another solution as these tumors grow slowly and are usually more vascularized than the anterior ones which makes the surgery more difficult and sometimes too risky.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Hypersomatotropism and glucose metabolism disorders**

F. Belhimer, S. Namani, A. Lyazidi & F. Chentli
Bab El Oued Hospital, Algiers, Algeria.

Introduction
Glucose metabolism disorder (GMD) is a classic complication of acromegaly, but its frequency varies from study to study.
Aim
We aimed to analyze GMD frequency in our population, and predictive factors such as: family history of diabetes mellitus (DM), age, gender, and growth hormone (GH) rates.
Subjects and methods
It is a prospective study where 75 hypersomatotropic subjects were analyzed. They all had fasting and postprandial blood glucose evaluation. When the last ones were normal glucose tolerance test was done and analyzed according to the WHO recommendations.
Results
In our group GMD were observed in 41 patients (22M/19F) = 55%. Diabetes mellitus was found in 27 subjects (65%), and impaired glucose tolerance (IGT) in 14 (35%). The diagnosis of DM was made before the hypersomatotropism's one in 37%, the delay was 5 years. Mean age at diagnosis for diabetic patients was $40 \pm 11$years, and $38 \pm 13$ years for non diabetic subjects. Glucose metabolism disorders were more frequent in women: 54% vs 46% for men, but the difference was not statistically significant. Mean plasma GH was = 75.25 ng/ml in DM subjects vs 46.1 ng/ml for non diabetic patients ($P < 0.05$). For family history of diabetes mellitus there was no difference between both groups.
Conclusion
In this study 55% hypersomatotopic subjects suffer from GMD. DM is more frequent than IGT (65% vs 35). On the statistical side, there is a positive correlation between GMD and GH concentrations, but not with gender, age and family history of DM.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Hyperprolactinemia: etiology, diagnosis and therapeutic aspects**

C. Crista, A. Vlazan, M. Scheau & A. Racolta
University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania.

The complex etiology of hyperprolactinemia was represented, in our study group (426 cases hospitalized during the period 2000 – 2010; F/M ratio = 372/54; age (years) = 40.29 ± 15.57), by the following entities: prolactin-secreting pituitary tumors (11.50%), growth hormone and prolactin-secreting pituitary tumors (1.64%), pituitary stalk compression (7.98%), primary myxedema (41.08%), polycystic ovary syndrome – PCOS (24.65%), iatrogenesis (8.69%) and chronic renal insufficiency (4.46%). The cases with prolactin-secreting pituitary adenomas (49 patients, F/M = 42/7, age = 32.53 ± 11.03) were divided in two groups (by clinical, functional and imaging criteria): macroprolactinomas (18 cases; F/M = 11/7; age = 32.39 ± 14.25); microprolactinomas (31 cases; F/M = 31/0; age = 32.61 ± 8.92).
The plasma prolactin levels were significantly higher ($P < 0.001$) in patients with macroprolactinomas comparing with microprolactinomas cases. It was also identified significant higher values of the plasma prolactin levels in prolactinomas in comparison with: iatrogenesis ($P < 0.001$), pituitary stalk compression ($P < 0.001$), primary myxedema ($P < 0.001$), PCOS ($P < 0.001$) and chronic renal insufficiency ($P < 0.05$). The patients with microprolactinomas showed a significant higher prolactin level versus the cases with PCOS.
All the cases with prolactinomas presented signs of hypogonadism and 8 patients with macroprolactinomas (F/M = 3/5) presented tumor mass effect. Excepting one case who imposed neurosurgical therapy, all the patients with prolactinomas were treated with dopamine agonist drugs with very good response regarding the lowering of prolactin level and tumor shrinkage (only one case didn't show a normal prolactin level despite the long term of medical therapy associated with tumor disappearance). Four women with macroprolactinomas became pregnant after one year of treatment with bromocriptine and all of them reached the parturition without any event (continuing during the pregnancy the therapy with bromocriptine).
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1532

**Clinical, biological and radiological confrontation in Cushing disease**

E. Haouat, T. Riahi, L. Ben Salem, H. Kandara, Z. Turki & C. Ben Slama
National Institute of Nutrition, Tunis, Tunisia.

Introduction
Cushing disease (CD) is a condition due to an ACTH-secreting pituitary adenoma that is usually a microadenoma. Seldom, the lesion may be atypical by his size or his radiological aspect.
The aim of this study is to analyze the clinical and biological data of CD with atypical radiological aspect (macroadenoma or other), to compare them to those of CD with a typical radiological aspect (microadenoma) and to determine the clinical or biological factors predictive of radiological aspect.
Methods
Retrospective study of 22 patients with CD comparing clinical and biological profiles of a group of patients with CD and a pituitary microadenoma on MRI or a normal pituitary MRI = (microadenoma) group, to a group of patients with atypical MRI aspect: macroadenoma or infiltrative lesion = (macroadenoma) group.
Results
Pituitary MRI showed a microadenoma in 59% of cases and a macroadenoma or an atypical aspect in 41% of cases. Clinical profile and non specific biological anomalies were comparable in the 2 groups. Basal cortisol and cortisol after low dose dexamethasone suppressing test were also comparable in the two groups. Free urinary cortisol of 24 h and cortisol after high dose dexamethasone test were higher in the (macroadenoma) group but with no significant difference. On the other hand, mean ACTH was significantly higher in the (macroadenoma) group (154 pg/ml vs 93 pg/ml; $P = 0.04$).
Conclusion
No clinical or biological factors can be predictive of tumoral size in CD. A particular attention should always be accorded to ACTH rate that may suggest a certain tumoral size.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1533

**Characteristics of giant and huge male prolactinomas**

F. Chentli, D. Belkhamsa, N. Ould Driss & S. Azzoug
Bab El Oued Hospital, Algiers, Algeria.

Introduction
Prolactinomas are more invasive in males. Giant (≥4 cm) and huge (≥6 cm) ones are relatively rare in literature, but in our population they are nearly common.
Aim
We have taken our 20 last cases to analyze their radiological aspects, and their endocrine, neurological and ophthalmological complications.
Methods
All of them had clinical exam, hormonal, ophthalmological, and radiological exploration based on cerebral MRI. Mixed adenomas were excluded. Positive diagnosis was based on clinical presentation, high prolactin concentration, positive response to dopamine agonists ± immunohistochemy study.
Results
Mean age = 42.45 years, mean tumor height = 50.12 (40–70) mm and mean volume = 48.6 $mm^3$ (15.5–184). Mean prolactin = 3199 ± 5437 ng/ml. Solid and kystic aspect, with or without calcifications, is observed in more than 50%. Cavernous sinuses are invaded in all except one. Other invasions are (parietal or frontal lobe: 9, posterior invasion = 9, anterior invasion = 9 (with orbital infiltration in 1case), ethmoidal invasion = 3. For endocrine complications we observed gonadic deficit in 78.9% cases, corticotrop and thyreotro insufficiencies were seen in respectively 35%, and 15.7%. Only 7 subjects had two or more pituitary deficits. Neurological and ophthalmological complications are as follows: the total loss of one or both eyes: 13, hydrocephaly: 2 cases, epilepsy: 2, conscious troubles or memory loss: 2, ptosis: 3, diplopia with or without strabismus: 2.
Conclusion
In this study concerning giant and huge male prolactinomas the total loss of one or both eyes is the most frequent abnormality (13/20). Severe neurological troubles are relatively frequent as they were observed in nearly one from 3 patients. But, multi pituitary deficits (7 cases) and active hydrocephaly (2 cases) are relatively rare, which argues for a low progression.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**A case of acromegaly in the presence of coincidental liver cirrhosis**

S. Topsakal, F. Akin, E. Yerlikaya & T. Korkmaz
Pamukkale University, Denizli, Turkey.

Acromegaly is a rare and serious syndrome and commonly associated with pituitary neoplasm. Classic cause of acromegaly in adults is the tumors of the somatotrophs that secrete growth hormone. Cirrhosis is the end stage of chronic liver disease and commonly cause of death. It is characterized by diffuse hepatic fibrosis resulting in altered construction of the lobular parenchyma with widespread connective tissue septae, circumscribed regenerative nodules of hepatocytes and anastomoses between vascular channels linking portal and central vessels. A 62-year old, male patient came to the hospital complaining of severe abdominal swelling. Laboratory and imaging findings were compatible with the presence hepatitis B virus related cirrhosis together with acromegaly. In this case, he had high GH level but lower IGF1 level because of hepatic failure which can impair IGF1 production by the liver. Definitive diagnosis was made by pituitary MR and 1 cm in diameter tumor was detected. This paper showed that cirrhosis can result in a low IGF1 level in patients with acromegaly. There is no previous report available of the in the presence of coincidental combination of acromegaly and cirrhosis in a patient.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### Adiponectin and cardiac structure in acromegaly

S. Gurbulak, F. Akin, E. Yerlikaya, S. Topsakal, H. Tanriverdi, B. Akdag & B. Kaptanoglu
Pamukkale University, Denizli, Turkey.

Adiponectin, is an adipocyte derived hormone possess insulin-sensitizing, antiatherogenic, and antiinflammatory properties. The aim of this study to evaluate adiponectin levels at acromegalic patients according to healthy subjects in relation with ecocardiographic findings. We included 30 subjects (15 male, 15 female) were diagnosed as acromegaly and 30 healthy (10 male, 20 female) subjects. Mean ages of both group were similar. Serum glucose, insulin, GH, IGF1 (insulin like growth factor 1), adiponectin levels were obtained and insulin resistance were calculated by HOMA-IR. Echocardiography of subjects were performed. Adiponectin levels were significantly higher at acromegalic group than control group. At acromegalic group, there was no statistically meaningful relation between serum adiponectin and GH, IGF1 levels. IVST (thickness of interventricular septum in diastole), PWT (thickness of left ventricular posterior wall in diastole), LVMI (left ventricular mass index), E/A ratio, DT (deceleration time of E-wave), ET(ejection time), IVRT (Isovolumetric relaxation time), VPR (velocity of mitral flow propagation), LVESV (left ventricle end systolic volume) values were increased results were statistically meaningful. At acromegaly group adiponectin levels were positively related with LVMI. Adiponectin levels may be indicator of the cardiac involvement acromegaly.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

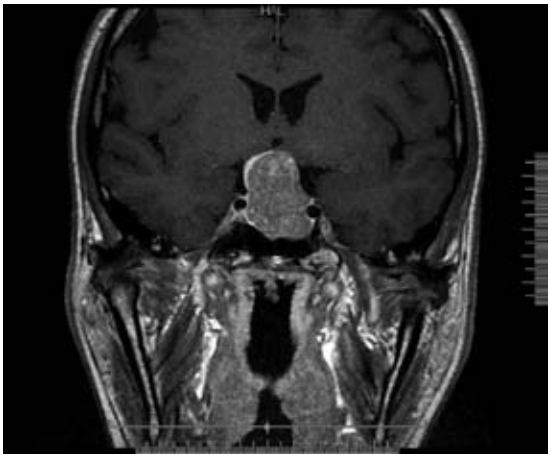
### A case of acromegaly diagnosed with diabetic ketoacidosis as a primary manifestation

S. Usui, M. Sue, A. Yoshihara, R. Oka, M. Ishikawa, N. Hiroi, K. Kuboki & G. Yoshino
Faculty of Medicine, Toho University, Oota-Ku, Japan.

Although diabetic ketoacidosis (DKA) is recognized one of complications of acromegaly, it is very rare as only five cases are reported as a primary manifestation.
A 43-year-old Japanese woman, who had never pointed out impaired glucose tolerance, had emergency admitted by DKA. Her plasma glucose was 440 mg/dl, HbA1c 15.7%, urinary keton body (3+), BGA pH7.257, then she was cured by rehydration of saline and continues intravenous insulin injection. She was unlikely of type1 nor type2 diabetes because her endogenous insulin secretion was kept, as fasting serum c-peptide was 1.49 ng/ml, urinary c-peptide 85.5 μg/day, GAD antibody negative, and she was not obesity (BMI 20.4 kg/m$^2$). Because she had acromegalic features, existence of acromegaly was suggested. Her GH and IGF1 levels showed high (155 ng/ml and 476 ng/ml) under hyperglycemia. There were double floor and ballooning in sella turcica Xp, a cauliflower-like change of the distal phalanx in finger Xp. And there are expansion of sella turcica and mass lesion on pituitary MRI (Default 1).
From the above, we had a diagnosis of the acromegaly due to GH-producing pituitary tumor, and DKA had developed from secondary diabetes by it. She finally needed 30 units of insulin a day for diabetes and got good plasma glucose control, and then was transferred for the purpose of receiving pituitary operations.
We experienced a case of acromegaly diagnosed with DKA as a primary manifestation. It is thought that diabetes is complicated with acromegaly as a result of insulin resistance increased by overproducing of the GH, and DKA occurs because of absolute or relative lack of insulin and counter hormones participates in it.



Therefore, like this case, it is necessary to be careful about possibility to be complicated with DKA about acromegaly.

### The role of long acting somatostatin analogues on glucose homeostasis in acromegaly

F. Yener Öztürk, E. Cil Sen, S. Velet, S. Shafi Zuhur, Karaman & Y. Altuntas
Sisli Etfal Training and Research Hospital, Istanbul, Turkey.

Introduction

Impaired glucose tolerance and diabetes mellitus are frequently seen complications of acromegaly. Insulin resistance due to chronic growth hormone (GH) excess and inhibition of insulin and glucagon secretion by long-acting somatostatin analogues (SA) used in the treatment are the main reasons of the impaired glucose tolerance.

Objective

To determine the effect of long-acting SA treatment on glucose homeostasis regarding the insulin resistance and pancreatic β-cell function.

Method

Totally 30 patients (17 male, 13 female; mean age:44.63 ± 11.85 years) were enrolled in the study. Serum IGF1 concentrations and glucose, insulin, GH levels at 0, 30, 60 and 120 min during OGTT were measured. Patients were categorized into 3 groups according to their disease activity. Patients cured after operation, patients with active disease after operation but in remission after SA therapy and patients with active disease after operation and SA therapy were defined as cure, remission and active group, respectively. For the interpretation of glucose homeostasis, formulas for insulin resistance (HOMA-IR, QUICKI) and β-cell function (HOMA-β, Insulinogenic index) were used.

Results

There was no statistically significant difference between groups for HOMA-IR and QUICKI ($P=0.78$; $P=0.781$) and also between disease activity and insulin resistance. For the insulinogenic index, which was the marker of early phase of insulin secretion, there was a borderline difference in significance between groups ($P=0.076$). HOMA-β of cure group was higher than the other two groups independent of disease activity. In the cure group, serum insulin levels and peak insulin secretion was higher, time to reach the peak level was shorter than the other groups ($P=0.420$; $P=0.176$).

Conclusion

Treatment with long acting SA in acromegaly inhibits insulin secretion from pancreatic β-cells, so causes deterioration in glucose homeostasis. Due to the increase in cardiovascular morbidity and mortality, patients on SA therapy should be routinely followed-up for glucose intolerance.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

Results of the insulin resistance and pancreatic β-cell function tests of the groups

| | Active | Remission | Cure | P |
|---|---|---|---|---|
| HOMA-IR | 2.21 ± 1.59 | 1.77 ± 1.34 | 2.12 ± 1.63 | 0.781 |
| QUICKI | 0.35 ± 0.03 | 0.37 ± 0.04 | 0.36 ± 0.04 | 0.781 |

### Clinical features of inferior and lateral invasive expansion of GH-producing adenoma

T. Asano, H. Yamada, A. Aoki, M. Sasaki, A. Ikoma & S. Ishikawa
Jichi Medical University Saitama Medical Center, Saitama, Japan.

The present study was undertaken to determine morphological and biochemical characteristics of GH-producing tumor. We collected consecutively 15 patients with acromegaly, and they were 6 males and 9 females with the ages of 58.5 ± 9.9 years. As for tumor size, 7 patients had macroadenoma, 5 had microadenoma and three had empty sella with some atypical expansions. Only 3 patients had intrasellar tumor and 2 patients had empty sella in MRI finding. Other 10 patients had atypical tumor growth and expansion. Invasive inferior expansion into sphenoid sinus with macroadenoma was found in 3 patients. Inferior and lateral expanded extrasellar tumor with empty sella was found in 2 patients. Unilateral or bilateral expansion along with microadenoma and macroadenoma was obtained in 3 patients. Other 2 patients had latero-inferior expansion, and both superior and inferior expansion of macroadenoma.

Endocrinological studies showed that serum GH and insulin growth factor (IGF1) levels were 33.3 ± 32.5 ng/ml and 699.3 ± 299.3 ng/ml in 7 patients with macroadenoma, 8.7 ± 7.4 ng/ml and 586.5 ± 35.2 ng/ml in 5 patients with microadenoma, 7.5 ± 2.9 ng/ml and 433.2 ± 91.0 ng/ml in 3 patients with empty sella and inferior expanded tumor. The increases in hormonal levels seemed to be dependent on tumor volumes, and did not relate with the direction of extrasellar expansion. Serum prolactin was mildly elevated to 17.49 to 90 ng/ml in 7 patients, that means simultaneous secretion of prolactin with GH in acromegaly. Hyperprolactinemia were not associated with compression of pituitary stalk and inhibition of prolactin-inhibiting factor. The present findings indicate that GH-producing tumors easily grow to macroadenoma, and the tumor growth may mainly develop to the inferior and/or lateral expansion by destroying bony tissues of sella turcica. The tumor expansion could be different from that of other functioning and non-functioning pituitary tumors in which tumors grow superiorly.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

### Predictive value of acute octreotide supression test in newly diagnosed acromegaly

I. Balcere[1,2], I. Strele[3], J. Klovins[4] & V. Pirags[1,2]
[1]Pauls Stradins Clinical University Hospital, Riga, Latvia; [2]University of Latvia, Riga, Latvia; [3]Riga Stradins University, Riga, Latvia; [4]Latvian Biomedical Research and Study Center, Riga, Latvia.

Background

It has been reported that primary treatment with somatostatin analogues (SSA) is effective in up to 60% of acromegaly patients, but predictive value of the acute octreotide suppression test (OST) for selection of patients with good response to depot SSA in long term treatment remains controversial.

Patients and methods

Twelve medical therapy naive patients (mean age 44 years, female 75%) with active acromegaly were included in prospective study. After administration of 100 μg octreotide the baseline and hourly GH measurements were taken for following 6 hours. GH response to the OST was defined as the percent reduction of GH from the baseline. Subsequently 6 patients received the long-acting SSA lanreotide (Somatuline Autogel), 120 mg every 28 days and 6 patients received long-acting SSA octreotide (Sandostatin LAR) 20–40 mg every 28 days for 3–24 month treatment period. GH and IGF1 were measured at baseline and during the treatment period.

Results

Fifty-eight percent of patients (7 out of 12) showed good response (>50% GH decrease) during the OST. 42% of them (3/7) reached target GH<2 ng/ml during the subsequent SSA therapy and only one patient (14%) achieved normalization of IGF1. 25% of patients (3 out of 12) showed moderate 30–50% GH decrease during the OST and only one reached normal IGF1 after administration of long-acting SSA. Despite that 17% of patients (2 out of 12) had only small <30% GH decrease during the OST, they reached the treatment target (GH<2 ng/ml) during the subsequent depot SSA therapy.

Conclusion

Acute OST has poor predictive value for effectiveness of subsequent long-acting SSA therapy and should not replace at least 3 month trial with depot SSA.

**An unusual plurihormonal pituitary adenoma**

M. Batisse Lignier[1,2], S. Maqdasy[1,2], B. Mestre[1], B. Roche[1], J. Chazal[1] & I. Tauveron[1,2]
[1]Hospital, Clermont Ferrand, France; [2]UMR6247/U931, Clermont Ferrand, France.

Introduction
Plurihormonality of pituitary adenoma can be defined as the ability to express more than one hormone. 1–30% of pituitary adenoma are plurihormonal. We describe a case of plurihormonal adenoma with GH and ACTH secretion and triple immunostaining for GH, ACTH and prolactin.
Case report
A 40 years old patient presented with sudden weight gain central obesity, hypertension, menstrual disorders, acne, hirsutism suggesting hypercortisolism. Laboratory evaluation confirmed Cushing's disease (serum cortisol 0 h 234 nmol/l, cortisol after low-dose dexamethasone suppression test 613 nmol/l, ACTH 8 h 56 pg/ml). Furthermore, laboratory data showed elevated IGF1 levels (440 ng/ml, reference range 101–267 ng/ml) with elevated GH after HGPO (3.3 mUI/l). Prolactin, TSH, FSH and LH serum level were in normal range. The sellar MRI demonstrated microadenoma. Transphenoidal removal of the tumor was performed. Immunohistochemistry analyses showed staining for ACTH (40%), GH (80%) and prolactin (50%). Ki67 was less than 0.5%. Laboratory data realized after surgery were normal.
Conclusion
The majority of plurihormonal adenomas produce GH, PRL and TRH because lactotroph, somatotroph and thyreotroph cells have the same progenitor. Association of ACTH and GH secretion with positive immunostaining for GH, PRL and ACTH has not been described previously. These unusual plurihormonal adenomas exhibit aggressive behavior and poor prognosis. Plurihormonality of pituitary adenomas linked with ACTH co-expression seems to predict a higher risk of tumor recurrence. Furthermore, higher morbidity due to mixed ACTH and GH secretion needs a strict follow up.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Results of pegvisomant therapy in patients with acromegaly**

E. Kan, A. Atmaca, G. Ecemis, H. Atmaca & R. Colak
Ondokuz Mayis University School of Medicine, Samsun, Turkey.

Introduction
Acromegaly is chronic debilitating disease related with excess GH and insülin-like growth factor 1 (IGF1) secretion. Pegvisomant is a GH receptor antagonist that competes with endogenous GH for its receptor and is often used as a medical therapy in patients with inadequate response to somatostatin analogs.
Methods
Forty-six patients are followed with the diagnosis of acromegaly in our clinic. We present the results of six acromegalic patients (five female and one male patient) treated with pegvisomant.
Results
The mean age was 49.8 years and the mean disease duration was 12.5 years. All of them were treated with surgery. Five patients received external radiotherapy and/or gamma knife surgery. All of the patients received octreotide LAR 30 mg/month therapy. Despite these therapies, IGF1 levels were higher than the upper limit of sex and age matched levels. We evaluate the patients for relapse or residual lesions before pegvisomant treatment and found macroadenoma in two patient, micraoadenoma in one patient and no lesion in three patients. Mean IGF1 level was 558 ng/ml before pegvisomant therapy. After 40 mg loading dose, we started pegvisomant 10 mg/day. Mean therapy duration was 11.6 months. During follow-up, IGF1 levels decreased in four patients, however, remained high in two patients. Therefore, the dose is increased to 15 mg/day in these two patients. IGF1 levels decreased in one of them, but was still high in the other. In one patient with macroadenoma, pegvisomant was stopped at the second month due to lipodistrophy. No adverse effects were seen in other patients. Treatment is completed to one year only in two patients and we found no increase in adenoma sizes in these patients.
Conclusion
Four of six patients responded to pegvisomant treatment. Pegvisomant seems to be effective in patients in whom remission cannot be acheived with other modes of therapy.

**Panhypopituitarism and central diabetes insipidus: a case report**

Y. Hu
Buddhist Tzu Chi General Hospital, New Taipei City, Taiwan.

Patient in the case, an 18-year-old male, complained of constant tiredness, frequent malaise, day time sleepiness, epigastric pain, poor appetite and consumption of great quantity of water. These conditions had persisted for 3–4 years. He had gone to many different physicians, with different tests taken, but without diagnose. Upon physical examination, the pale skin, scanty of pubic hair, and no presence of beard and axillary hair raised the possibility of Panhypopituitarism. This suspicion was reinforced by the result of blood examination which showed normocytic anemia, hypokalemia (*K*: 3.27 mg/dl), secondary adrenal insufficiency, secondary hypothyroidism and secondary hypogonadism. With further examination, the Pituitary stimulation test showed poor response. Water deprivation test indicated severe central diabetes insipidus. Bone density was relatively low (*Z*-score: $-2.3$). The result of pituitary MRI showed a soft tissue lesion in the pituitary stalk with heterogeneous enhancement.

## P1542.1

**Evaluation of the efficacy and safety of pasireotide LAR in patients with mild-to-moderate cushing's disease: a randomized, double-blind, multicenter, phase III study design**

M. Ligueros-Saylan[1], Y. Zhang[1], J. Newell-Price[2], S. Petersenn[3] & S. Lymperopoulos[1]
[1]Novartis Pharmaceuticals, East Hanover, New Jersey, USA; [2]University of Sheffield, Sheffield, UK; [3]ENDOC Center for Endocrine Tumors, Hamburg, Germany.

Background
Cushing's disease is associated with high morbidity and mortality, and there are currently no approved medical therapies. Twice-daily pasireotide sc showed efficacy in patients with mostly moderate-to-severe (UFC $\geq 2\times$ ULN) Cushing's disease in a large, randomized, double-blind, 12-month trial. A monthly long-acting release (LAR) formulation of pasireotide has been developed to provide a smoother pharmacokinetic profile, potentially a better efficacy/safety ratio, and to enhance convenience. The current study is designed to evaluate the efficacy and safety of pasireotide LAR in patients with Cushing's disease.
Patients
Adult patients with persistent/recurrent or *de novo* (if not surgical candidates) Cushing's disease, with baseline mean UFC $\geq 1.5$ and $\leq 5\times$ ULN (mild-to-moderate Cushing's disease). Diagnosis of Cushing's disease will be made by: i) the mean of three 24 h urinary free cortisol (mUFC) samples; ii) morning plasma ACTH within or above the normal range; and iii) confirmation of pituitary adenoma by MRI, IPSS or histopathology. Patients will be pasireotide naïve.
Design
Global, multicenter, randomized, double-blind, Phase III trial. Target enrollment is ~148 patients; recruitment is under way. Patients will be stratified based on baseline mUFC values and randomized to receive pasireotide LAR 10 or 30 mg im every 28 days for 12 months. If mUFC $> 1.5\times$ ULN and patients tolerate pasireotide LAR at month 4, dose uptitration will be performed at month 4 to either 30 or 40 mg respectively. Dose uptitration to 30 or 40 mg will also be performed at months 7, 9 and 12 in patients with mUFC $>$ ULN and no tolerability issues. Patients achieving mUFC $\leq$ ULN or significant clinical benefit at month 12 may enter a 12-month extension.
Endpoints
Primary efficacy endpoint is the proportion of patients with UFC $\leq$ ULN at month seven, regardless of dose titration. Secondary endpoints include: proportion of

patients with mUFC ≤ ULN at month 7 in patients who did not uptitrate at month 4; changes in UFC, plasma ACTH, and serum cortisol; changes in quality of life, and signs and symptoms of Cushing's disease; tolerability and safety.
Conclusions
This phase III study will provide the basis for the evaluation of long-acting pasireotide as a medical therapy for patients with mild-to-moderate Cushing's disease.
Declaration of interest
The authors declare that there is a conflict of interest.

### P1543

**Anti-inflammatory effect of a high dose of corticosteroids is associated with some paradoxical pro-inflammatory effects**

P. Dandona, H. Ghanim, S. Abuaysheh, S. Dhindsa, K. Green & K. Frachetti
State University of NY at Buffalo, Buffalo, NY, USA.

We have previously demonstrated that a low dose of hydrocortisone (100 mg) given intravenously suppresses intranuclear NFκB and AP-1 binding and the expression of pro-inflammatory genes like MMPs. We have now investigated the effect of a high dose of hydrocortisone (300 mg = 60 mg prednisolone) on NFκB binding and the expression of TLRs, the mediators of TLR signal transduction, MyD88 and TRIF and HMG-B1. Ten normal subjects were injected intravenously with 300 mg of hydrocortisone or saline in 2 separate visits one week apart in a randomized crossover study. Blood samples were obtained at 0,2,4,8 and 24 h after the injection. Mononuclear cells (MNC) were prepared by standard techniques and were tested for NFκB binding and the expression of TLRs, MyD88, TRIF, chemokines and chemokine receptors and HMG-B1. Plasma concentrations of glucose, FFAs, NO metabolites, chemokines and HMG-B1 were also measured. Following the injection of this dose, there was a significant increase in glucose concentration from 92 ± 4 to 116 ± 6 mg/dl, a marked increase in FFA concentrations from 0.38 ± 0.1 to 0.804 ± 0.15 mM. While NFκB binding and the mRNA expression of MyD88, TRIF, chemokines and chemokine receptors was suppressed significantly in MNC, the mRNA expression of TLR 2, 5 and 9 and HMG-B1 was increased (by 103 ± 24%, 107 ± 19%, 56 ± 13% above the baseline, respectively) in the MNC as was the concentration of HMGB1 (by 37 ± 12%) and MMP-9 (125 ± 22%) in plasma. Thus, while this high dose of HC exerts a powerful anti-inflammatory effect as shown above, it also exerts certain paradoxical pro-inflammatory effects. Since both glucose and FFAs have been shown to be pro-inflammatory, it is possible that they contribute to these effects. These paradoxical pro-inflammatory effects may account for the inability of these drugs to show benefit in clinical trials of septicemia and other severe pro-inflammatory states.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### P1544

**Acute and chronic effects of low dose prednisolone on carbohydrate metabolism in subjects with inflammatory rheumatologic disease**

C. Petersons[1,2], B. Mangelsdorf[2], A. Jenkins[3], J. Greenfield[3], C. Thompson[1] & M. Burt[1,2]
[1]Flinders University, Adelaide, SA, Australia; [2]Repatriation General Hospital, Adelaide, SA, Australia; [3]Garvan Institute of Medical Research, Sydney, NSW, Australia.

High dose glucocorticoids reduce hepatic and peripheral insulin sensitivity and insulin secretion. However, the metabolic consequences of typical therapeutic glucocorticoid doses (e.g. prednisolone < 10 mg/day) are poorly characterised. The aim was to determine the acute effect of low dose prednisolone on carbohydrate metabolism and then assess whether subjects taking chronic prednisolone had increased adiposity that amplified carbohydrate metabolism perturbations.
Nine controls (4 female, age 58 ± 11 years, BMI 27.5 ± 5.8 kg/m$^2$) with inflammatory rheumatologic disease who were not taking oral glucocorticoids were studied before and after prednisolone 6 mg/day for 7 days. Baseline data were compared with 12 matched subjects (6 female, age 61 ± 8 years, BMI 27.4 ± 3.3 kg/m$^2$) taking long-term prednisolone (6.3 ± 2.2 mg/day). Peripheral insulin sensitivity was assessed by hyperinsulinaemic–euglycaemic clamp (80 mU/m$^2$ per min for 120 min) and insulin secretion by 60 min intravenous glucose tolerance test (IVGTT, 25mg/kg glucose). Total and visceral adiposity were quantified by DXA and abdominal CT. Quantification of hepatic glucose output (using 6,6-$^2H_2$ glucose) and insulin concentrations are underway (data to follow).
Glucose infusion rate during hyperinsulinaemic–euglycaemic clamp fell from 79.6 ± 5.9 to 68.9 ± 5.2 μmol/min per kg FFM ($P = 0.02$) after 7 days of prednisolone. Glucose AUC during IVGTT acutely increased after prednisolone (504 ± 14 to 579 ± 19 mmol/L*min, $P = 0.01$). There were no significant differences in total (27.8 ± 2.8 vs 26.5 ± 3.8 kg, $P = 0.78$) or visceral (97 ± 11 vs 108 ± 27 cm$^2$, $P = 1.00$) fat mass between chronic prednisolone users and controls. Glucose infusion rate during hyperinsulinaemic–euglycaemic clamp (68.7 ± 6.6 vs 68.9 ± 5.2 μmol/min per kg FFM, $P = 0.78$) and glucose AUC during IVGTT (564 ± 18 vs 579 ± 19 mmol/l*min, $P = 0.67$) were not significantly different in subjects taking chronic prednisolone and following acute prednisolone administration.
In conclusion, low dose prednisolone acutely reduces peripheral insulin sensitivity and may reduce insulin secretion. Perturbations of carbohydrate metabolism during chronic prednisolone therapy match those found acutely. These findings provide insight into targeting treatment of glucocorticoid-induced diabetes at the underlying metabolic abnormality.

**The influence of aromatizable and non-aromatizable steroids on anthropometric parameters**

H. Pospíšilová, M. Dušková, M. Hill, M. Meloun, B. Bendlová, M. Vanková & L. Stárka
Institute of Endocrinology, Prague 1, Czech Republic.

Objective
It is known sex steroids affect fat distribution with men and women. With men there is a tendency to deposit fat abdominally. Men are more likely to have more visceral fat than premenopausal women, with whom the preferential fat distribution is gluteofemoral and the percentage of body fat overall higher. Androgens may affect fat tissue with men either directly by androgen receptor stimulation, or indirectly by oestrogen receptor stimulation after aromatization. Interesting relationships between the parameters of metabolic syndrome and non-aromatizable metabolites of testosterone have been discussed in literature.
Aim of the study
The analysis of the relation between anthropometric parameters, lipid spectrum, glycemia, insulin resistance and the level of testosterone and dihydrotestosterone.
Methods
We examined a set of 195 men and determined their testosterone, dihydrotestosterone, SHGB, lipid spectrum, glucose metabolism parameters and the oral glucose tolerance test; also measured were their anthropometric parameters (weight, height, waist, hips, waist to hip ratio, 14 skin folds) and body composition was calculated.
Results
Comparing the hormone levels and anthropometric parameters, we found a negative correlation between weight, skin folds, waist, hips, waist to hip ratio, BMI, total cholesterol, LDL cholesterol and insulin resistance on one side and the level of both testosterone (T) and dihydrotestosterone (DHT5α) and SHBG on the other side. We found a positive correlation between HDL cholesterol and muscle mass on one side and the T, DHT levels and SHBG on the other side.
Conclusions
We found a negative relation between anthropometric parameters and both testosterone and dihydrotestosterone. We did not find any difference between aromatizable and non-aromatizable steroids with healthy, normosthenic men.

**Effect of smoking cessation on hormonal balance**

H. Hruskovicova, M. Duskova, K. Simunkova, H. Pospisilova, M. Hill, K. Vondra & L. Starka
Institute of Endocrinology, Prague, Czech Republic.

Introduction
Cigarette smoking is one of the most serious substance abuse problems. It is generally accepted that nicotine and other chemicals in tobacco smoke alter endocrine functions in men and adverse reproductive outcomes, including deterioration of sperm. Studies on the effects of smoking and smoking cessation on male sex hormones are inconsistent. We studied changes of hormonal levels in men during smoking cessation and we looked for a possible predictive marker of success in smoking cessation.
Methods
We examined 76 men before initiating of smoking cessation and after 6 weeks and after a year of abstinence. Basic anthropometric data and testosterone, cortisol, dehydroepiandosterone, dehydroepiandosterone sulphate, LH, FSH and SHBG were measured using imunoanalysis. Kruskal-Wallis robust ANOVA model was used for evaluation of the data. The local Ethics Committee approved the study and all patients signed an informed consent form.
Results
Successful men in smoking cessation did not differ from unsuccessful ones in the levels of steroid hormones observed. There was a trend in levels of testosterone, men who failed to quit smoking even for a short time had lower levels of testosterone. After smoking cessation there were a statistically significant increase in BMI and decrease in levels of SHBG. Decrease in levels of testosterone and DHEA was statistically insignificant. There were no changes in levels of cortisol. Changes of SHBG and testosterone levels did not correlate with BMI.
Conclusion
One year of smoking cessation is associated with increase in BMI and decrease in SHBG, which are possible effects of smoking cessation. Long term study could clarify these founding. Because insult of smoking is long-term and one year is short period to reparation.

**Conversion of 7α-hydroxyDHEA into 7-ketoDHEA: Role of type 2 11β-hydroxysteroid dehydrogenase**

C. Ngo-Duy[2], F. Labrie[1,2] & V. Luu-The[1,2]
[1]Laval University, Quebec, QC, Canada; [2]Endogenix Inc, Quebec, QC, Canada.

It has been suggested that DHEA metabolites, especially 7-hydroxy and/or 7-keto derivatives could possess anti-inflammatory activity and enhance immune, cognitive and metabolic functions in rodents. It is thus important to elucidate the exact pathway (s) leading to the formation of these metabolites. While the role of cytochrome P450 CYP7B1 in the transformation of DHEA into 7α-OHDHEA is well recognized, the role of type 1 11β-hydroxysteroid dehydrogenase (11β-HSD1) in the transformation of 7α-OHDHEA into 7-ketoDHEA, as suggested by many authors, remains questionable. While 11β-HSD1 prefers NADPH as cofactor and is thus, essentially, a reductive enzyme, the transformation of 7β-OHDHEA into 7-ketoDHEA is an oxidative reaction. Since 11β-HSD2 prefers NAD+ as cofactor, and is the oxidative counterpart of 11β-HSD1, we hypothesized that 11β-HSD2 could rather be the enzyme responsible for the transformation of 7α-OHDHEA into 7-ketoDHEA.
To verify this hypothesis, we cloned the coding region of human CYP7B1, 11β-HSD1 and 11β-HSD2 genes into pCMV expression vectors and transfected them into transformed human embryonic kidney HEK-293 cells. Using transfected cells in culture, without addition of cofactor(s), thus better reproducing physiological conditions, and using [C14]DHEA as substrate, we have clearly observed that CYP7B1 catalyzes the conversion of DHEA into 7α-OHDHEA, while, upon the addition of 11β-HSD2, 7α-OHDHEA is oxidized readily into 7-ketoDHEA, a reaction which does not occur in the presence of 11β-HSD1. The present data indicate that 11β-HSD2, rather than 11β-HSD1, is the enzyme responsible for the conversion 7α-OHDHEA into 7-ketoDHEA (DHEA –CYP7B1–» 7α-OHDHEA —11β-HSD2 –» 7-ketoDHEA) in the biosynthetic pathway of 7-ketoDHEA formation.

## P1548

**Steroid derivatives as pure antagonists of the androgen receptor**

S. Gauthier, C. Martel & F. Labrie
EndoCeutics Inc., Quebec City, QC, Canada.

Introduction
While the androgens of testicular origin (representing about 50% of total androgens in men over 50 years) can be completely eliminated by surgical or medical castration with GnRH (gonadotropin-releasing hormone) agonists or antagonists, the antiandrogens currently available as blockers of androgen binding to the androgen receptor (AR), namely bicalutamide (BICA), flutamide (FLU) and nilutamide have too weak affinity to completely neutralize the 50% of androgens made locally from dehydroepiandrosterone (DHEA) in the prostate cancer tissue by the mechanisms of intracrinology.
Description of methods/design
Series of steroid derivatives having pure and potent antagonistic activity on the human and rodent AR were synthetized. Assays of AR binding and activity in carcinoma mouse Shionogi and human LNCaP cells as well as *in vivo* bioavailability measurements and in vivo prostate weight assays in the rat were used.
Results
The chosen lead steroidal compound, namely EM-5854, has a 3.7-fold higher affinity than BICA for the human AR while EM-5855, an important metabolite of EM-5854, has a 94-fold higher affinity compared to BICA. EM-5854 and EM-5855 are 14 times more potent than BICA in inhibiting androgen (R1881)-stimulated prostatic specific antigen (PSA) secretion in human prostatic carcinoma LNCaP cells *in vitro*. MDV3100 has a potency comparable to bicalutamide in these assays. Depending upon the oral formulation, EM-5854 is 5- to 10-times more potent than BICA to inhibit dihydrotestosterone (DHT)-stimulated ventral prostatic weight *in vivo* in the rat. These data indicating the high potency of EM-5854 and EM-5855 are supported by respective 40-fold and 105-fold higher potencies of these two compounds compared to BICA to inhibit cell proliferation in the androgen-sensitive Shionogi carcinoma cell model.
Conclusion
The present data suggest the possibility of a much higher potency of EM-5854 or EM 5855 compared to BICA (Casodex) for the treatment of prostate cancer in men.
Declaration of interest
I fully declare a conflict of interest. Details below:

## P1549

**The cellular fate of CYP19A1 (aromatase) protein**

E. Pignatti, S. Ferioli, C. Carani, V. Rochira, F. Potì & M. Simoni
University of Modena and Reggio Emilia, Modena, Italy.

Introduction
Aromatase cytochrome P450 is uniquely responsible for estrogen synthesis in vertebrates. The protein is expressed in the gonads and other extraglandular tissues. Deregulated expression of aromatase has pathological relevance and targeting the CYP19A1 product could be an effective strategy for treatment of affected tissues. Nevertheless, very little is known concerning the role of protein oligomerisation, glycosylation and degradation. Here we studied the aromatase cellular fate and the effects of different mutations in an *in vitro* setting.
Design
The coding region of CYP19A1 gene was cloned and mutations previously identified by us in patients (R365Q, E210K, M127R, R375H) were introduced by site-directed mutagenesis. Then HEK 293 cells, not expressing aromatase, were

selected for *in vitro* transient expression. Aromatase cellular localization and protein expression were analyzed. Glycosylation and degradation were investigated with specific inhibitors, and aromatase activity was evaluated by estradiol assay.
Results
No differences in wild type and mutated aromatase protein cellular localization were found. The time course of protein expression by Western blotting showed the highest degradation rate for the E210K mutation followed by R365Q then M127R and R375H mutation. The same trend was observed for aromatase activity. Proteasome inhibition by MG132 resulted in the appearance of a non-glycosylated form, confirmed by tunicamycin treatment. Only the E210K mutation showed a degree of instability due to proteasome-mediated degradation. Other pathways were investigated but neither autophagy nor lysosomal inhibitors affected degradation, except for chloroquine (specific for lysosomes).
Conclusions
The reduced functional activity of the protein caused by different mutations appears to be due both to partially or completely inactivating effects, and to the increased instability of the mutated forms. Glycosylation confers stability to the protein, confirmed by MG132 and tunicamycin studies. Different degradation pathways could be involved depending on the degree of stability of the protein.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Detection of BclI and A3669G polymorphisms in glucocorticoid receptor gene in patients with rheumatoid arthritis

J. Antic[1], M. Petakov[1,2], N. Roganovic[3], D. Macut[1,2], S. Ognjanovic[1], M. Djurovic[1,2], M. Lakocevic, N. Dragicevic[1] & S. Damjanovic[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia; [2]Medical Faculty, University of Belgrade, Belgrade, Serbia; [3]Institute for Rheumatology, Belgrade, Serbia.

Introduction
Rheumatoid arthritis (RA) is a chronic inflammatory disease which is characterized with dysregulation of the immune system. Recent studies suggest that dysregulation of the HPA axis may as well play a contributory role in the pathogenesis of RA. Glucocorticoid hormones (GC) accomplish their effects through binding to glucocorticoid receptor (GR). Presence of GR gene polymorphisms can modulate GC effects. The A3669G polymorphism in human GR gene has been connected to decreased and BclI polymorphism to increased sensitivity to GC.
Study population/methods
The aim of this study was to detect frequency of BclI and A3669G polymorphisms and find possible association between these polymorphisms in 40 patients with RA (34 women, mean age $50.85 \pm 9.31$; 6 men, mean age $49.33 \pm 15.72$) and 160 healthy volunteers (92 women, mean age $46.29 \pm 9.28$; 68 men, mean age $45.47 \pm 7.28$) with presence of RA.
Healthy volunteers were recruited from the National Institute for Blood Transfusion. All subjects underwent medical, hormonal, genetic and biochemical testing. DNA was obtained from peripheral blood leucocytes. The BclI and A3669G polymorphisms were detected by using PCR, RFLP and DNA sequencing.
Results
The BclI polymorphism was detected in 26 (65%) patients and 47 (28.13%) healthy subjects, $P < 0.001$. A3669G polymorphism was found in 15 (37.5%) patients and 14 (8.75%) healty volunteers, $P < 0.001$.
Conclusion
The presented results show an increased frequency of BclI and A3669G polymorphisms carriers between RA patients, comparing to healthy volunteers. This may point to a contributory role of GC sensitivity in the predisposition to develop RA.

## P1551

### Aromatase activity after a short-course of Letrozole administration in adult men at sea level and in men at high altitude (with or without excessive erythrocytosis)

G. Gonzales, V. Tapia, M. Gasco & C. Gonzales-Castañeda
Universidad Peruana Cayetano Heredia, Lima, Peru.

Men living at high altitudes in Peru compared to sea level counterparts have erythrocytosis (Hemoglobin: 16–21 g/dl) or excessive erythrocytosis (Hemoglobin > 21 g/dl). High testosterone (T) levels in men at high altitude (HA) were associated with excessive erythrocytosis. High androgen levels could be due to a low aromatase activity or to an elevated rate of conversion from precursors to testosterone. The aim of this study was to evaluate aromatase activity and rate of conversion from precursors to testosterone before and after administration of the aromatase enzyme inhibitor letrozole (5 mg/day) for a 5-day period to men at HA and at sea level (SL). The response to short term aromatase inhibition was assessed in 30 adult men living at sea level, 31 native men at HA with erythrocytosis (Hb 16–21 g/dl) and 35 men at HA with excessive erythrocytosis (Hb > 21 g/dl). Serum hormone levels, estradiol/testosterone, testosterone/androstenedione, and testosterone/dehydroepiandrosterone sulfate (DHEAS) ratios were measured. Men with erythrocytosis had lower basal serum T/androstenedione ratios than men with excessive erythrocytosis at HA and men at sea level. Men at HA with excessive erythrocytosis had higher T/DHEAS ratios than men with erythrocytosis and than those at sea level before and after letrozole administration. After letrozole administration, both groups of men at high altitude (with erythrocytosis or with excessive erythrocytosis) showed lower aromatase activities than those at sea level. In conclusion, higher serum testosterone levels in men with excessive erythrocytosis were associated with an increased rate of conversion from DHEAS to testosterone rather than to a lower aromatase activity.

### Myostatin and Follistatin expression in orchidectomized rats submitted to exercise

D. Marine, P. Bueno, R. Silva, H. Selistre-Araújo, K. Nonaka & A. Leal
Federal University of São Carlos, São carlos, Brazil.

Myostatin (MSTN) is a negative regulator of skeletal muscle growth, while androgens are strong positive regulators of muscle growth and strength. Follistatin (FS) is a binding protein which inhibits MSTN action. Evidences suggest that MSTN and testosterone actions in muscle may be associated. However, the mechanisms of androgens actions are not fully elucidated. The objective of this study was to evaluate the influence of exercise training in the expression of MSTN and FS in orchidectomized rats submitted to exercise. Adult male Wistar rats were housed under controlled conditions (20–220 C, 12 h light-dark cycle) and were allowed free access to standard rodent chow. After 3 days of acclimation, rats were orchidectomized (O) or sham-operated (S). One group of animals was maintained intact (I). After 1 week, animals were randomly assigned to a training group (O-Train, S-Train and I-Train) or a sedentary group (O-Sed, S-Sed and I-Sed). O-Train, S-Train and I-Train were submitted to resistance training for 8 weeks. In the training protocol, animals climbed a 1.1-m vertical ladder with weights attached to their tails. The sessions were performed three times a week, with 4–9 climbs and 8–12 dynamic movements per climb. After this period, rats were decapitated and white gastrocnemius muscle were dissected, immediately frozen in liquid nitrogen and stored at −700 C for subsequent analysis. MSTN and FS mRNA was quantified by real time RT-PCR. The animals were maintained according to the local University Committee guidelines for the care and use of laboratory animals. $P < 0.05$ was considered statistically significant. MSTN mRNA expression was significantly higher in gastrocnemius muscle of O-Sed group than in I-Sed group. FS mRNA expression did not vary among the groups. The results indicate that MSTN expression increases in skeletal muscle of orchidectomized rats and is not influenced by resistance training.

**The role of long-acting parenteral testosterone undecanoate compound (Nebid 1000 mg) in the induction of secondary sexual characteristics (SSC) in males with hypogonadotropic hypogonadism (HH)**

V. Giagulli[1], V. Triggiani[2], G. Corona[3,4], E. Tafaro[2], B. Licchelli[2] & E. Guastamacchia[2]
[1]O.U. Metabolic Diseases and Endocrinology, Conversano, Italy; [2]O.U. of Endocrinology, Bari, Italy; [3]Sexual Medicine and Andrology Unit, Florence, Italy; [4]Maggiore-Bellaria Hospital, Bologna, Italy.

Testosterone (T) can induce SSC in young HH men. So far the T ester formulations have been used for inducing puberty in these patients. Moreover, it seems that the polymorphism CAG length of androgen receptor (AR-CAG) might co-regulate the effectiveness of testosterone therapy (Tth).
This study aims to evaluate the effectiveness of Nebid (1000 mg) for SSC induction in HH men and, secondly, whether these changes might be modulated by the AR-CAG.
Nine HH male (aged > 17), in particular, 6/9 suffered from idiopathic HH while 3/9 were affected by b-thalassemia were enrolled in our study. All patients underwent a determination of serum SHBG, total T, free T (FT) and the AR-CAG. For treatment, HH men received an oral testosterone undecanoate (Andriol, 120 mg/day) for 3 months, followed by Nebid every 14 weeks for 1 year, then every 12 weeks for a second year. Serum T and FT were assayed 3 months after the start of Andriol and also in the 10th week following the start of the second round of Nebid. Levels were also determined 12, 18, and 24 months after the start of Nebid.
Circulating T and FT increased in all HH men which allowed them to develop SSC progressively. Moreover, a slight delay in puberty development was observed in those patients with > 24 AR-CAG compared with those with < 24 AR-CAG, suggesting that AR-CAG might co-regulate the effectiveness of Tth. Nebid was able to induce the puberty in our HH patients, although additional studies are needed to elucidate the possible role of AR-CAG for SSC development in HH men.

**IL-6, Cortisol and early morning stiffness in patients with rheumatoid arthritis: endocrine changes associated with clinical improvement in a chronic autoimmune disease**

D. Jessop
University of Bristol, Bristol, UK.

Joint stiffness in rheumatoid arthritis (RA) is worse in the morning and has been associated with increased secretion of the pro-inflammatory cytokine IL-6 and in decreased secretion of cortisol, suggesting that clinical symptoms may be related to hormonal and immune circadian variations. We measured 24 h plasma profiles of IL-6 and cortisol in RA patients to determine any changes in IL-6 and cortisol following a two week course of prednisone administered orally in a specially designed timed-release tablet (TRT).
Nine patients with active RA were clinically assessed and had 24 h blood sampling before and after a 2 wk course of TRT prednisone (5 mg per day). Patients took the TRT orally at 2200 h and the prednisone was released at 0200 h. Changes in circadian variation in cortisol and IL-6 and clinical measures were compared using random coefficient regression modeling and Wilcoxon matched-pairs signed-rank test.
Significant alterations in circadian profiles and concentrations of IL-6 and cortisol were observed following TRT prednisone. The peak value of IL-6 fell from 42.5 to 21.3 pg/ml, and occurred earlier (0134 h compared to 0827 h) ($P < 0.005$). Following TRT prednisone, the peak value of cortisol increased from 14.1 μg/dl to 19.3 μg/dl and the trough fell from 2.9 μg/dl to 2.1 μg/dl ($P < 0.001$). There was a close correlation between reduction of IL-6 and improvement in morning joint stiffness following TRT. We propose that these changes in IL-6 and cortisol, prior to the onset of morning joint stiffness, are functionally important in mediating the improvement in joint stiffness following prednisone in RA patients.

**Fetal liver may reinstate activity of GABAergic steroids inactivated by placental oxidoreductases**

R. Kanceva[1], M. Hill[1], A. Parizek[2], L. Kancheva[1] & L. Starka[1]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]First Faculcy of Medicine, Prague, Czech Republic.

Recently we have completed steroid metabolomic study including unconjugated ($n = 39$) and conjugated steroids ($n = 30$) in maternal and fetal body fluids using GC-MS method with two separate multicomponent analyses (for unconjugated steroids and steroid polar conjugates). Our previous data indicate that primarily oxidative isoforms of pluripotent 17β-hydroxysteroid dehydrogenases and aldoketoreductases in placental tissue close to the fetal compartment convert 3α-,17β- and 20α-hydroxy-groups in progestogens, estrogens and GABAergic steroids to the corresponding ketones. Therefore, GABAergic steroids are mostly inactivated when entering the fetus, which may negatively influence neuroprotective potential of these substances in the fetal brain. In this study we investigated the role of fetal liver in the reinstatement of the steroid GABAergic activity. The trial was approved by the Ethics Committee of the Institute of Endocrinology of Endocrinology, Prague, Czech Republic. In the study participated twelve women giving uncomplicated birth after the 38th week of gestation and 38 women with preterm labors (28th–37th week) who were selected to provide maximum conformity of the steroid metabolome with the actual GA. The umbilical arteriovenous differences evaluated by Wilcoxon's robust paired test as well as by multivariate statistics indicated that the activity of GABAergic steroids inactivated by placental oxidoreductases may be reinstated by liver enzymes, most probably from the aldoketoreductase family.
Grants IGA NT/11513 and NT/12211 and the advanced education of own staff in clinical and molecular endocrinology (CZ.2.17/1.1.00/32386) supported the study.

**Unconjugated steroids and steroid sulfates in maternal blood show comparable predictivity for assessment of gestational age from the 28th to 41st week of pregnancy**

L. Kancheva[1], M. Hill[1], R. Kanceva[1], A. Parizek[2] & L. Starka[1]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]First Medical Faculty, Prague, Czech Republic.

Recently we demonstrated a close correlation between the gestational age (GA) and steroid metabolome in maternal and fetal body fluids using multivariate models including both unconjugated ($n = 39$) and conjugated steroids ($n = 30$) that were measured by GC-MS method including two separate multicomponent analyses (for unconjugated steroids and steroid polar conjugates). We focused on the comparison of the predictive value of the levels of unconjugated steroids

alone, conjugated steroids alone and conjugated and unconjugated steroids together in maternal blood (as obtaining a maternal blood is the least invasive procedure). The trial was approved by the Ethics Commitee of the Institute of Endocrinology, Pague, Cech Republic. In the study participated 12 women (giving an uncomplicated birth after the 38th week of gestation) and 38 women with preterm labors (28th–37th week). The predictive value of the free steroids alone (75.2% of variability in GA is explained by the unconjugated steroids) was slightly better than that for the steroid polar conjugates alone (74.3% of the variability). The results for unconjugated and conjugated steroids together showed 81.0% of the variability. These data demonstrate that analysis of both unconjugated and conjugated steroids can be replaced by less laborious analysis of the unconjugated steroids only. Free steroids (showing significant predictive value) shared the variability with the GA as follows: 16α-hydroxy-DHEA =72.9%, 16α-hydroxy-estrone =69.3%, 5-androstene-3β,7α,3β-triol =40.7%, 16α-hydroxy-progesterone =37.1%, DHEA =36.7%, 16α-hydroxy-pregnenolone =35.1%, estriol =33.3%, estrone =30.5%, 7β-hydroxy-pregnenolone =29.6%, 7α-hydroxy-DHEA =25.6%, 5-androstene-3β,7β,3β-triol =23.7%, estradiol =21.9%, epipregnanolone =21%, 17-hydroxy-progesterone =20.9%, pregnanolone =20.2%, androstenediol =13.6%, 20α-dihydroprogesterone =7.2%, 20α-dihydropregnenolone =6.4%.

Grants IGA NT/11513 and NT/12211 and advanced education of own staff in clinical and molecular endocrinology (CZ.2.17/1.1.00/32386) supported the study.

### Anabolic hormones in acute exacerbation of chronic obstructive pulmonary disease: relation of hypogonadism with indexes of severity and phlogosis

A. Di Marco Berardino, A. Mancini, R. Inchingolo, S. Raimondo, C. Di Segni, A. Pontecorvi, S. Valente & G. Corbo
Catholic University of the Sacred Heart, Rome, Italy.

Nowadays Chronic Obstructive Pulmonary Disease (COPD) is not considered a lung specific disease: nutritional alteration, weight loss due to increased energetic expenditure, loss of muscle mass are systemic effects, correlated with the risk of hospitalization due to exacerbation (AECOPD). AECOPD, characterised by augmented indexes like C reactive protein, interleukin-6, procalcitonin and serum amyloid A (SAA), negatively influenced natural history of the illness and were found to be related to muscle dysfunction. Hypogonadism could play a pivotal role.

Our study was aimed to evaluate possible relationships among prognostic indexes of AECOPD (represented by Acute Physiology and Chronic Health Evaluation, APACHE II Score), phlogosis (SSA), evaluated by immuno-electro-chemiluminescence, and hormonal axes involved in metabolic balance, insulin like growth factor (IGF-1), testosterone (T) and its metabolites, assayed by RIA. 24 patients, aged 75±13 years, 17 males, were studied. Data were not normally distributed, thus nonparametric statistics was applied.

Descriptive analysis showed reduced values of testosterone (T) (1.85 ±2.28 ng/ml), free-T (0.028±0.030 ng/ml), calculated by Vermeulen's formula, dihydro-T (0.18±0.19 ng/ml) and IGF-1 (91.84±74.19 ng/ml). Frequency distributions of Apache II score and SSA were calculated and, using tertile as cut off point, three categories were defined (SSA: ≤8 mg/ml, 9–160 mg/ml, ≥160 mg/ml; APACHE II: ≤10, 11–12; ≥12). Using this classification, an inverse correlation between SAA and T ($P$: 0.01), f-T ($P$ :0.01), DHT ($P$ :0.001) and IGF1 ($P$ :0.05) was found. Data showed the same inverse correlation between APACHE II tertiles on one hand and T ($P$ :0.01) and f-T ($P$ :0.02) on the other hand. No relationship was found between hormones and arterial blood gas analysis parameters.

Even if we cannot establish a causal relationship between hypogonadism and severity of the disease, our data suggest systemic effects of AECOPD and a possible mechanism explaining wasting syndrome in our patients

### Long-term evaluation of cross-sex hormone treatment in transsexual persons

K. Wierckx, S. Weyers, E Van Caenegem, G. Roef, G. Heylens & G. T'Sjoen
University hospital Ghent, Ghent, Belgium.

Objective

To describe the effects and side effects of cross-sex hormone therapy in both transsexual men and women.

Design

Single center cross-sectional study in one hundred transsexual persons post SRS and on average 10 years on cross-sex hormone therapy.

Methods

Hormone levels were measured by immunoassays. Physical health was assessed by physical examination and questionnaires on general health and specific side effects, areal bone parameters and body composition by Dual energy X ray absorptiometry (DXA).

Results

Transsexual men did not experience important side effects as cardiovascular events, hormone related cancers or osteoporosis. In contrast, a quarter of the transsexual women had osteoporosis at the lumbar spine and radius. Moreover, 6% of transsexual women experienced a thromboembolic event and another 8% experienced other cardiovascular problems after on average 11.3 hormone treatment years. None of the transsexual women experienced a hormone-related cancer during the treatment. Many transsexual men and women had several cardiovascular risk factors which could have affected future cardiovascular health.

Conclusion

Cross-sex hormone treatment appears to be safe in transsexual men. Transsexual women experience more tromboembolic and other cardiovascular events possibly related to life style factors, older age and estrogen treatment.

### Physiological relevance of peripherally produced gabaergic and glycinergic steroids in human late pregnancy and around parturition

M. Hill[1] & A. Parizek[2]
[1]Institute of Endocrinology, Prague, Czech Republic; [2]First Medical Faculty, Prague, Czech Republic.

Although neuroactive steroids are well characterized, their physiological relevance in human pregnancy remains indecisive. Hence, we attempted to derive this information from the combination of our metabolomic data, pharmacological data found in the literature and knowledge contained in gene expression databases. These results indicate that GABAergic steroids influence maternal CNS but have limited effect in the fetal brain and maternal and fetal periphery, partly because of the low expression of steroid-sensitive GABAA-R subunits and partly due to lower GABAergic steroid levels in the circulation compared to the brain. Placental overexpression of steroid low-sensitive GABAA-R ε subunits may be ascribed to compensation effect providing a space for modulatory effects of non-steroidal GABAergic modulators in the tissue with excessive amounts of GABAergic steroids. A specific role of GABAergic steroids may be expected for the GABAA-R π subunit, which is preferentially expressed in the uterus and which decreases at the onset of labor. Metabolomic, tissue expression and pharmacological data also indicate that the mechanism suggested by some authors(who demonstrated inhibition of HPA axis by GABAergic steroids in the rat pregnancy), may be also effective in human. Rapid withdrawal from the excessive concentrations of GABAergic steroids postpartum indicate that the increased expression of steroid-less sensitive GABAA-R subunits is linked to the mechanism participating in the pathophysiology of postpartal depressions. In contrast to specific expression of steroid-sensitive GABAA-R subunits, the uniform expression of steroid-sensitive glycinergic subunits points to the neuro-inhibitory effect of pregnenolone in the CNS but neuro-excitatory effect of its sulfate in the pregnancy-related peripheral tissues like uterus, cervix and placenta.

The trial was approved by the Ethic Committee. Grants IGA NT/11513 and NT/12211 and advanced education of own staff in clinical and molecular endocrinology (CZ.2.17/1.1.00/32386) supported the study.

### Influence of endogenous hormones and testosterone in the prostate cancer

A. Jimenez-Pacheco[1,2], M. Arrabal-Polo[1], M. Lopez-Torne[2], Y. Suleiman-Martos[1], A. Zuluaga-Gomez[1], F. Escobar-Jimenez[1] & M. Arrabal-Martin[1]
[1]San Cecilio University Hospital, Granada, Spain; [2]Santa Ana Hospital, Granada, Spain.

Introduction
Androgen stimulation of prostate cancer (PCa) cells has been the basis for extensive studies evaluating the role of androgen in PCa but the diagnostic measurement of androgen as well as androgen values that potentially influence prognosis are unclear in patients with PCa. The aim of this studies is to analyze the hormone behavior in the prostate cancer (PCa), as well as the relationship between PSA-testosterone and testosterone-aggressiveness tumor and compare these results with those obtained in patients with benign prostatic hypertrophy (BPH).
Methods/design
We performed an observational study of cases and controls, between January and October 2011. We selected 30 cases diagnosed with PC and 15 controls diagnosed with BPH. The concentrations of total testosterone, SHBG-testosterone, FSH, LH, Prolactin, Progesterone and Estradiol were measured in both groups. For statistical analysis we calculated the Pearson correlation test and Student t-test between variables in both groups, using the statistical package 17.0 SPPS.
Results
In the cases group it was found a negative correlation between PSA and testosterone levels ($P=0.03$), positive PSA with estradiol and progesterone ($P<0.01$), and positive relationship between LH and FSH ($P<0.01$). We did not found significant differences in hormone levels.
Conclusions
No significant differences were found between groups or between patients with PCa based on their aggressiveness, as well as significant correlations between the values within each group.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Hypothyroidism is associated with increased intestinally derived lipoprotein particles and postprandial endothelial dysfunction

A. McGowan, W. Widdowson, G. Boran & J. Gibney
The Adelaide and Meath Hospital Incorporating the National Children's Hospital, Dublin 24, Ireland.

Atheroma is accelerated in overt hypothyroidism (OH) and possibly in subclinical-hypothyroidism (SCH), and is not completely explained by increased LDL-cholesterol. There is little data available regarding post-prandial metabolic changes in OH or SCH.
Subjects with OH ($n=21$), SCH ($n=28$) and age, sex and BMI matched controls ($n=50$) were studied fasting and for up to 8-h following a mixed-meal. Investigations included apolipoprotein(apo)B48, a marker of intestinally-derived lipoproteins, and flow-mediated-dilatation (FMD) of the brachial artery, a measure of endothelial dysfunction.
Under fasting conditions, lipid variables and FMD did not differ between groups. Data from SCH subjects were similar to normal subjects and are not shown. Triglyceride concentrations increased similarly in all groups postprandially, while apoB48 levels increased more markedly and significantly in overtly hypothyroid subjects compared to fasting conditions. FMD decreased significantly postprandially in the OH group only. At the 4-h time-point, apoB48 and FMD differed significantly between OH and normal subjects.
Intestinally-derived lipoprotein particles are increased and endothelial function impaired post-prandially in overt but not sub-clinically hypothyroid patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### IgSF1 gene defects in children with central congenital hypothyroidism and macroorchidism

A. Escudero[1], D. Gorbenko[2], R. Barrio[3], E. Vallespín[1], J. Nevado[1], L. De Graaff[2], P. Lapunzina[1], A. Hokken-Koelega[2] & J. Moreno[1]
[1]Institute for Medical and Molecular Genetics (INGEMM). La Paz University Hospital, Madrid, Spain; [2]Sophia Children's Hospital. Erasmus University Medical Center, Rotterdam, Netherlands; [3]Ramón y Cajal University Hospital, Madrid, Spain.

Central Congenital Hypothyroidism (CCH) is caused by an innate TSH deficiency. Known molecular bases of human CCH only involve mutations in TSHB and TRHR genes. Activins-Inhibins are a complex system of endo- and autocrine factors with opposing effects and important roles in pituitary and reproductive organs, but so far unreported actions on the thyroid axis. IgSF1 has been proposed as a membrane receptor for Inhibin-B.
Aim
To investigate the molecular cause of CCH-macroorchidism using genome-wide genetic techniques.
Patients and methods
Three patients from two pedigrees with X-linked CCH-macroorchidism were studied with complete hormonal profiles and clinical follow-up till completion of puberty. Comparative Genomic Hybridization (CGH)-arrays and Next Generation Sequencing were performed on patients DNA.
Results
CCH was diagnosed by T4-based neonatal screening or clinical hypothyroidism (sTSH:1.4-3.9 mU/L; FT4:7.2-8 pmol/L) and readily treated. Poor TSH response at TRH tests indicated pituitary hypothyroidism. Excessive testicular growth was detected from 3-6 years of age (3-5 ml Prader). GnRH test showed stimulation of FSH and LH, but discrepantly low testosterone levels. Normal puberty started at 12.5 years with initial testicular volume of 8 ml (N: 2), reaching 35-40 ml at the end of puberty (N: 20-25). Inhibin-B (425-500 ng/L; N:200-400) and Antimullerian hormone (19-48 μg/L;N:5-9) were markedly elevated, suggesting increased Sertoli cell mass. In Patient1, CGH-array showed a 200 Kb deletion of the entire IGSF1 gene. In Patients 2 + 3, massive sequencing of Chr.X revealed a missense mutation (p.C942R) in IgSF1 cosegregating with the phenotype in a large pedigree. Cys942 is structurally essential for the IX Immunoglobulin(Ig)-like extracellular loop of IgSF1.
Conclusions
IgSF1 is a novel candidate gene for central hypothyroidism. We propose IgSF1 defects may disturb pituitary and testicular functions through disruption of the counterbalancing effect of Inhibin-B over the Activin A-derived signaling pathways in thyrotropes, gonadotropes and/or Sertoli target cells.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector

## P1564

**Hypothalamic mTOR pathway mediates thyroid hormone-induced hyperphagia in hyperthyroidism**

N Martinez Sanchez[1,2], L. Varela[1,2], L. Martins[1,2], P Martinez de Morentin[1,2], R. Gallego[1], M. Vazquez[1,2], J. Roa[2,3,4], M. Gandara[1], E. Schoenmakers[5], R. Nogueiras[1,2], K. Chatterjee[5], M. Tena Sempere[2,3,4], C. Dieguez[1,2] & M. Lopez[1,2]
[1]School of Medicine, University of Santiago de Compostela-Instituto de Investigación Sanitaria, Santiago de Compostela, Spain; [2]ISCIII (Instituto Carlos III), Madrid, Spain; [3]University of Córdoba, Córdoba, Spain; [4]Instituto Maimónides de Investigaciones Biomédicas (IMIBIC), Córdoba, Spain; [5]University of Cambridge, Cambridge, UK.

Hyperthyroid rats and humans exhibit increased energy expenditure and marked hyperphagia. Recent evidence has pointed that alterations of thermogenesis linked to hyperthyroidism are associated to dysregulation of hypothalamic AMPK and fatty acid metabolism; however, the central mechanisms mediating hyperthyroidism-induced hyperphagia remain largely unclear.
Objective
The aim of our study was to assess if alterations in feeding in hyperthyroidism are associated with impairment of hypothalamic mammalian target of rapamycin (mTOR) signalling.
Methods
We used adult male Sprague–Dawley rats. Hyperthyroidism was induced by chronic subcutaneous administration of L-thyroxine. Intracerebroventricular treatments and stereotaxic microinjection of $T_3$ and adenoviral expression vectors. Analysis by blood biochemistry, *in situ* hybridization, Real-time quantitative PCR, Immunohistochemistry and western blotting.
Results
Here, we demonstrate that hyperthyroid rats exhibit marked upregulation of the hypothalamic mammalian target of rapamycin (mTOR) signalling pathway associated with increased mRNA levels of agouti-related protein (AgRP) and neuropeptide Y (NPY), and decreased mRNA levels of proopiomelanocortin (POMC) in the arcuate nucleus of the hypothalamus (ARC), an area where mTOR colocalizes with thyroid hormone receptor alpha (TRα). Central administration of thyroid hormone ($T_3$) or genetic activation of thyroid hormone signalling in the ARC recapitulated hyperthyroidism-effects on feeding and mTOR pathway. In turn, central inhibition of mTOR signalling with rapamycin in hyperthyroid rats reversed hyperphagia and normalized the expression of ARC-derived neuropeptides, resulting in substantial body weight loss.
Conclusion
Overall, these data indicate that in the hyperthyroid state, increased feeding is associated with thyroid hormone-induced upregulation of mTOR signalling. Furthermore our finding that different neuronal modulations influence food intake and energy expenditure in hyperthyroidism pave the way for a more rationale design of specific and selective therapeutic compounds aimed at reversing the metabolic consequence of this disease.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Potassium iodide, but not potassium iodate, as a potential protective agent against oxidative damage to membrane lipids in porcine thyroid**

M. Milczarek[1], J. Stepniak[1], A. Lewinski[1,2] & M. Karbownik-Lewinska[1,2]
[1]Medical University of Lodz, Lodz, Poland; [2]Polish Mother's Memorial Hospital – Research Institute, Lodz, Poland.

Introduction
Fenton reaction ($Fe^{2+} + H_2O_2 \rightarrow Fe^{3+} + {}^{\prime}OH + OH^-$) is of special significance in the thyroid gland, as both its substrates, i.e. $H_2O_2$ and $Fe^{2+}$, are required for thyroid hormone synthesis. Also iodine, an essential element supplied by the diet, is indispensable for thyroid hormone synthesis. It is well known that iodine affects red-ox balance. One of the most frequently examined oxidative processes is lipid peroxidation (LPO), which results from oxidative damage to membrane lipids.
The aim of the study was to evaluate effects of iodine, used as potassium iodide (KI) or potassium iodate ($KIO_3$), on LPO in porcine thyroid homogenates under basal conditions and in the presence of Fenton reaction substrates.
Methods
Porcine thyroid homogenates were incubated in the presence of KI (0.00005–500 mM) or $KIO_3$ (0.00005–200 mM), without or with addition of $FeSO_4$ (30 μM) + $H_2O_2$ (0.5 mM). Concentration of malondialdehyde + 4-hydroxyalkenals (MDA + 4-HDA) was measured spectrophotometrically, as an index of LPO.
Results
Potassium iodide, used in the lowest concentrations ($\leq$0.05 mM), did not affect LPO; KI in concentrations of 0.1–1.0 mM, resulting in thyroid level of inorganic iodine close to that observed under normal iodine supply, clearly decreased the basal LPO; in the highest concentrations of 10–500 mM, KI increased LPO. At the same time, KI used in the middle range of concentrations (10–50 mM) reduced Fenton reaction-induced LPO. In opposite, $KIO_3$ revealed, depending on the concentration, either no protective effect at all or even strong prooxidative action.
Conclusion
Potassium iodide, used in doses generally recommended in iodide prophylaxis, may prevent oxidative damage to membrane lipids in porcine thyroid. Toxic effects of iodide overload may result from its prooxidative action. Potassium iodate does not possess any direct beneficial effects on red-ox balance in the thyroid, which constitutes an additional argument against its utility in iodine prophylaxis.

**Response to high dose glucocorticoid therapy in patients with dysthyroid optic neuropathy (DON)**

D. Covelli, G. Vannucchi, N. Currò, I. Campi, C. Guastella, L. Pignataro, P Beck Peccoz & M. Salvi
Fondazione Cà Granda Policlinico IRCCS, Milan, Italy.

Dysthyroid optic neuropathy (DON) is a sight threatening complication occurring in 3–5% patients with Graves' orbitopathy. The medical treatment consists in the infusion of high dose of methylprednisolone (MP), while surgical orbital decompression is mandatory in patients non responding to the medical treatment. We aimed at studying the response to high dose steroids in DON and parameters for predicting therapy effectiveness. Twenty-three patients with DON were studied by complete ophthalmological evaluation. Visual acuity, Hardy Rand Ritter (HRR) for colour vision defects, visual field and fundoscopy were carried out in all patients at baseline and 1, 2 and 4 weeks after therapy. Twelve patients were treated with 500 mg while 11 with 1000 mg MP for 3 consecutive days over 2 weeks. Fourteen non responders patients were eventually decompressed. A complete DON recovery was observed in 5 and 11 patients who received 500 mg and 1000 mg MP, respectively. No response to treatment was observed in all 5 patients (21%) who at baseline showed optic disk swelling, 3 of whom treated with the lower and 2 with the higher steroid dose. At one month of follow-up a significant increase of the visual acuity ($P < 0.004$), an improvement of the colour perception ($P<0.001$) and of the visual field (defect $P< 0.03$ and pattern standard deviation $P<0.01$) were observed in responders. Non responders showed a significant decrease of pattern standard deviation ($P<0.004$), but only initial improvement with subsequent worsening was observed in all other parameters studied. Our data show that high dose MP may be effective in restoring visual function in about 40% of patients with DON. The efficacy of treatment was not dependent on MP dose but on the severity of baseline optic nerve function impairment. Severe colour vision impairment and visual field defects are parameters predictive of medical treatment failure.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Effect of environmental nitrates on the thyroid and salivary glands in the population affected by the chernobyl fall-out**

V. Drozd[1,2], T. Leonova[1,2], N. Akulevich[1,2], T. Mityukova[1,2], M. Lushchyk[1,2], T. Platonova[1,2], I. Shimanskaya[1,2], J. Biko[2,3] & C. Reiners[2,3]
[1]Belarusian Medical Academy for Postgraduate Education, Minsk, Belarus; [2]The International Fund "Help for patients with radiation-induced thyroid cancer 'Arnica'", Minsk, Belarus; [3]University of Wuerzburg, Wuerzburg, Germany.

Introduction
An increase in thyroid diseases after the Chernobyl, mostly due to radioactive iodine, has been scientifically recognized. It is also known the effect of nitrate on iodine metabolism: being a competitive inhibitor of sodium-iodine symporter nitrate prevents iodide uptake by the thyroid and compromises thyroid hormone synthesis.
The aim of the study was to investigate the incidence of thyroid and salivary glands' abnormalities by ultrasound (US) screening according to drinking water nitrate concentration.
Methods
Thyroid and salivary glands US with the volume estimation was performed in 264 Belarusian subjects living in the areas of Brest region polluted by radionuclides after the Chernobyl accident. The participants average age was $21.0 \pm 4.5$ yr. The urine iodine concentrations and nitrate drinking water levels were measured.
Results
Median urinary iodine varied from 160 to 175 μg/l indicating no iodine deficiency. According to nitrate concentration (Median) in drinking water, the examined subjects were divided in three groups: 1 – Stolin-city (20 mg/l), 2 – Olmany village (334 mg/l), 3 – Olshany village (880 mg/l). Thyroid hyperplasia was detected in 3,8% of 157 subjects in the group 1; in 11,4% – in the group 2 (out of 79 persons) and in 17.9% – in the group 3 (out of 28 persons) ($P<0.05$). The salivary gland ultrasonic abnormalities were found more frequently in people in Olshany village (abnormal echogenicity with hyperechoic threads in 53.6% of cases vs 17.7% in the group 2 and 22.3% in the group 1, ($P<0.01$).
Conclusion
The villages Olmany and Olshany of Brest region may be considered the areas with high nitrate drinking water levels, according to WHO criteria. Unfavorable ecological conditions such as high drinking water nitrate levels may contribute to the thyroid and salivary glands abnormalities' development and potentiate relative iodine deficiency even in the areas with normal iodine supply.

**Quantitative comparison of deiodinase I and II mRNA expression in ovine tissues**

H. Dehghani & M. Foroughi abari
Biotechnology, Mashhad, Islamic Republic of Iran.

Iodothyronine deiodinases are important enzymes for metabolism of thyroid hormones. These enzymes which are expressed in a variety of tissues are able to catalyze removal of iodine from thyroid hormones. Iodothyronine deiodinases I and II (DIO1 and DIO2) remove iodine from T4 to convert it to a more biologically active T3. The relative contribution of different tissue deiodinases to the establishment of a euthyroid state (proper production and concentration of T3) is not known. The objective of this study was to quantitate the amounts of transcription of DIO1 and DIO2 deiodinases in different ovine tissues. Using real-time reverse transcription polymerase chain reaction (RT-qPCR) and a comparative cycle threshold analysis, we found that DIO1 deiodinase is transcribed in skeletal muscle, kidney, and heart, more than thyroid, in diaphragm in quantities very similar to thyroid, and in liver, spleen, lung, and mammary gland lower than thyroid. We also found that the level of DIO2 transcription in all other tissues was lower than that in thyroid. Skeletal muscle, heart, and diaphragm transcribed between 84% to 87%; liver, kidney and lung transcribed between 62% to 72%; and spleen and mammary gland transcribed around 40% of DIO2 amount which is transcribed by thyroid. The biological significance of the relative expression of DIO1 and DIO2 enzymes in different ovine tissues awaits further studies. However in clinical settings, measurement of DIO1 and DIO2 expression in a given tissue may provide important clues on the intensity of selenium deficiency and its effects on the metabolism of thyroid hormones.

**Correlation between thyroid volume and body mass index 2 and 6 years later**

D. Chen[1,2], K. Tonks[1,2], J. Greenfield[1,2], C. El-Nouty[3], S. Hercberg[3,4] & S. Czernichow[5,6]
[1]St Vincent's Hospital, Sydney, NSW, Australia; [2]Garvan Institute of Medical Research, Sydney, NSW, Australia; [3]Universite Paris, Paris, France; [4]Hôpital Avicenne, Bobigny, France; [5]Hôpital Ambroise Paré, Boulogne-Billancourt, France; [6]University Versailles St-Quentin, Boulogne-Billancourt, France.

Background
Thyroid volume correlates positively with body mass index (BMI). This correlation holds true for both iodine-sufficient and mild/moderate iodine-deficient areas. We examined the association between thyroid volume and BMI and change in BMI over 4 years in middle-age adults recruited from the general population.
Methods
A total of 2495 subjects, for whom thyroid volume, $FT_4$ and TSH were available (women aged 35–60 years and men aged 45–60 years), were derived from the Supplementation en Vitamines et Mineraux Antioxydants (SU.VI. MAX) cohort study conducted in France since baseline (1994). Weight and height were measured 2 and 6 years after inclusion. Linear univariate and multiple regression analyses were performed to evaluate correlations between thyroid volume and BMI at 2 and 6 years and BMI change from year 2 to 6.
Results
Baseline thyroid volume was positively correlated with BMI at 2 years (men: $\beta=0.09$, $P<0.01$; women: $\beta=0.09$, $P<0.01$) and 6 years after inclusion (men: $\beta=0.10$, $P<0.01$; women: $\beta=0.09$, $P<0.01$). The correlation between thyroid volume and BMI at 2 and 6 years remained significant after adjusting for free $T_4$, TSH, gender, age, smoking, alcohol consumption and TSH-thyroid volume interaction factor ($\beta=0.11$, $P<0.01$). Baseline thyroid volume was not correlated with BMI change from year 2 to 6 in linear regression analysis.
Conclusion
In French adults, thyroid volume predicted BMI at 2 and 6 years. This association may be explained by the observation that leptin stimulates biosynthesis of TRH *in vitro*.

## P1570

**The relation between severity of obstructive sleep apnea and diagnosis of Hashimoto's thyroiditis**

N. Colak Bozkurt, B. Karbek, E. Cakal, E Cakir Özkaya, M. Ozbek & T. Delibasi
Ankara Diskapi Yildirim Beyazit Training and Resesarch Hospital, Ankara, Turkey.

Background
We investigated the frequency for diagnosis of Hashimoto's thyroiditis (HT) in obstructive sleep apnea (OSA) patients, based on rising interest in potential links of OSA's pathogenesis with impaired auto-immune mechanisms.

Design and methods
Polysomnography was performed to 245 euthyroid eligible subjects consecutively. Study population divided according to apnea-hypopnea index (AHI) as control ($n=59$, AHI$<5$), mild OSA ($n=59$, $5\leq$AHI$<15$), moderate OSA ($n=61$, $15\leq$AHI$<30$) and severe OSA ($n=66$, AHI$\geq30$) groups. All subjects undergone thyroid ultrasound; serum anti-thyroglobulin (anti-TG) and anti-thyroid peroxidase (Anti-TPO) levels were measured for diagnosis of HT.
Results
Diagnosis of HT was significantly lower in control subjects (32%) compared to severe OSA patients (51%) ($P=0.02$). Among OSA patients the HT frequency was %42 and %46 for mild and moderate groups respectively ($P=0.05$). HT was detected in 62% of females, 29% of males and 43% of overall study population ($P<0.001$). While 73.3% of severe female OSA patients were found to have HT, the ratio was %18.7 in male control subjects ($P<0.001$). OSA patients had the highest antibody levels compared to controls; as 1000 U/ml versus 400 U/ml for Anti-TG, and 4490 IU/ml versus 650 IU/ml for Anti-TPO respectively ($P<0.001$). There was no significant correlation between thyroid volume and severity of OSA but isthmus thickness was significantly correlated to AHI ($P<0.01$, $r=0.22$).
Conclusions
OSA patients were found to have higher HT prevalence parallel to severity, especially among women. These results may lead to further investigations on potential casual relation between OSA and auto-immune thyroid diseases, besides may lead to development of screening schemas for OSA patients for early diagnosis of HT before development of hypothyroidism, which are clinically overlapping.

**An audit and patient satisfaction survey of the telephone endocrine clinic at University Hospital Lewisham, London**

O. Mustafa, J. Gan, K. Evans, C. Mohandas & J. Miell
University Hospital Lewisham, London, UK.

Introduction
The telephone endocrine clinic (TEC) was established as an adjunct to the face-to-face endocrine clinic to follow and monitor the progress in a selected group of patients after they were seen in main endocrine clinics. This model of care has been tried successfully in other specialities but not as widespread in endocrinology. We audited the effectiveness of TEC and patient satisfaction. Methods: A retrospective analysis of records of all patients contacted in TEC in 2010 ($n=209$, 79% female). Six patients were excluded due to incomplete data. Mean age was 46.26years (range 20–85). Patient satisfaction was assessed through a postal questionnaire. Results: The 203 patients identified had a total of 735 telephone encounters (March 2005-July 2011). The mean telephone encounters were $3.62\pm2.22$ per patient (range 1–11). There were 203 failed telephone encounters ($1\pm1.09$ per patient, range 0–5). Conditions managed include: Graves' disease including during pregnancy (43%), other thyrotoxicosis (14%), primary hypothyroidism including during pregnancy (10%), post-radioiodine hypothyroidism (6%), prolactinoma (11%), post-thyroid/parathyroid surgery (4%), hypocalcaemia/hypercalcaemia/hypovitaminosis D (2%), testosterone replacement (2%). Fifty-five percent ($n=111$) of patients were discharged to GP at the end of follow-up and 10% ($n=21$) were referred back to the main endocrine clinics because of patients' choice or changes to their clinical status that could not be dealt within the TEC. Two patients (1%) were lost to follow-up. Eighty percent of patients surveyed were satisfied most or all of the time and 75% said that the TEC was convenient for them. Eighteen percent would have preferred a face-to-face consultation instead. Conclusions: This model of telephone consultation service is effective and convenient for patients. Our data shows that this model is a useful adjunct to the main endocrine clinic in selected cases, which would free up clinic slots to for new patients, decrease waiting time and manage more complicated cases.

## P1572

**Gestational hyperthyroidism in women from mild to moderate iodine deficiency (ID) areas**

S. Presti, M. Moleti, B. Di Bella, G. Sturniolo, F. Di Mauro, F. Trimarchi & F. Vermiglio
University of Messina, Messina, Italy.

Graves' disease (GD) and gestational transient thyrotoxicosis (GTT) are the main causes of hyperthyroidism in pregnancy, their prevalence ranging between 0.1–0.4% and 0.3–11%, respectively.
Aim of the study
To evaluate both prevalence and outcome of gestational hyperthyroidism in mild to moderate ID areas.
Subjects and methods
482 consecutive pregnant women who had never undergone thyroid function evaluation before and enrolled within 13 wks of gestation. Serum FT3, FT4, TSH levels were measured every 6 wks up to pregnancy term, while anti-TPO antibodies at enrollment only. Anti-TSH receptor antibodies (TRAb) were tested when TSH was below the lower limit of the trimester-specific reference range (1st 0.03 mU/L; 2nd and 3rd 0.3 mU/L).
Results
Thirty-two/482 (6.6%) pregnant women had serum TSH values $<0.03$ mU/L at first sampling. Of these, 17/32 (53.1%) were overtly hyperthyroid, and 15/32 (46.9%) had subclinical hyperthyroidism. TRAb assay revealed the autoimmune origin of hyperthyroidism in 6/32 (18.7%) women. Of the remaining 26/32 (81.2%) TRAb-negative women, 12/26 (46.1%) were diagnosed with GTT and 14/26 (53.8%) showed isolated hypothyrotropinemia. Of the 6 GD women, 1/6 spontaneously recovered from hyperthyroidism at early 2nd trimester, whereas 2/6 were given anti-thyroid drugs, and 3/6 showed FT4 levels that were consistently at the upper normal limit for general population. TRAb titer decreased of 33–82% over gestation in 4/6, and became undetectable in the remaining 2/6 GD women. Of the 12 GTT women, 1/12 miscarried at early gestation. In the remaining 11/12, spontaneous remission of hyperthyroidism occurred, mostly within the 20th week.
Conclusion
The high prevalence of autoimmune hyperthyroidism (6/482, 1.2%), occasionally found in pregnancy, represents a further reason for recommending systematic and early thyroid function testing in pregnant women.

## P1573

**The association between thyroid volume, L-thyroxine therapy and hepatocyte growth factor levels in euthyroid and hypothyroid goitrous and non-goitrous Hashimoto's thyroiditis**

M. Kilic, S. Akin, M. Topcuoglu, Y. Yesilkaya, K. Aydin, N. Cinar, J. Karakaya & A. Gurlek
Hacettepe University, Ankara, Turkey.

Background and aim
Hashimoto's Thyroiditis pathogenesis remains unclear in spite of many factors currently suggested. Aim of the study was to explore the relationship between hepatocyte growth factor (HGF) and Hashimoto's Thyroiditis (HT), goiter formation, and to see if HGF levels are adjusted by TSH suppression.
Materials and methods
Sixty-one premenopausal women who admitted our department between November 2010-September 2011 were enrolled in the study. Three groups were determined according to their thyroid function tests (TFTs). (Euthyroid Hashimoto's, control and subclinical Hashimoto's groups; *n*: 26, 23, 12 respectively). Basal TFTs and lipit profiles, Anti-TPO, Anti-Tg, thyroid USG and HGF were performed. Subclinical hypothyroid group received levothyroxine sodium replacement therapy and was re-assessed for the same laboratory and radiologic features after a median 3,5 months of follow-up.
Results
The main age of patients were $26.39\pm5.7$. Statistical analysis showed no relationship between HGF and other parameters. In the subclinical hypothyroidism group pre- and post-treatment HGF change was statistically insignificant (*P*:0.496). Basal HGF did not differ between groups (*P*: 0.504).
Conclusion
In contrast with the existing literature, HGF level was not found different between patients diagnosed with Hashimoto's Thyroiditis and control group, also no

difference was shown whether nodular goiter is present or not. L-$T_4$ replacement therapy did not alter HGF levels.

**Adaptation of the hypothalamo-pituitary-thyroid axis to pubertal development and exposure to acute and chronic physical stresses**

A. Younus[1], A. Naseem[1], S. Aslam[2], M. Irfan[1], F. Tahir[3], M. Qayyum[1], R. Mansoor[4], S. Murtaza[3] & S. Rizvi[1,5]
[1]PMAS Arid Agriculture University, Rawalpindi, Pakistan; [2]Government College university, Lahore, Pakistan; [3]National Institute of Health, Islamabad, Pakistan; [4]Rawalpindi Medical College, Rawalpindi, Pakistan; [5]Pakistan Science Foundation, Islamabad, Pakistan.

The hypothalamo-pituitary-thyroid axis undergoes adaptive changes in response to increased energy expenditure at puberty, a process called thyroidarche. Furthermore, the secretion of thyroid hormones (THs) is influenced by various kinds of acute and chronic stresses. Amongst others, persistent and severe physical stress may affect the secretion of THs. The present study investigates changes in the secretion of thyrotropin releasing hormone (TSH), trioiodothyronine (T3) and tetraiodothyronine (T4) during puberty and the effect of acute and chronic physical stresses on the secretion of TSH, T3 and T4. Blood samples were obtained from non-working school/college going and working boys between the age of 10 and 20 years ($n=594$), plasma concentrations of TSH, T3, T4 and cortisol were determined using specific ELISA. Data were analyzed using Student's *t*-test, ANOVA and Pearson correlation. The secretion of TSH peaked at 14th year and was maintained until 18th year in non-working boys. In working boys, TSH peaked at 11 years and was maintained by 18th year. The concentrations of T3 increased progressively until 17 years. In working boys, T3 peaked at 10, 16 and 20 years. T4 concentrations increased significantly at 11, 15 and 17 years. In working boys, T4 peaked at 10, 13 and 18 years. In non-working boys, the concentrations of TSH and T3 were lower at early puberty and higher at mid and late puberty, whereas concentrations of T4 were higher at early and mid puberty. In both groups, a positive correlation was seen between plasma TSH and T3 concentrations and linear growth velocity during early and mid puberty. The concentrations of cortisol were significantly higher in working boys of all age groups. In conclusion, the present study demonstrates that the secretion of TSH and T3 increases at puberty and that acute stress increases TSH and T3 concentrations whereas chronic stress reduces them.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1575

**Thyroid nodules treated with percutaneous radiofrequency thermal ablation: a comparative study**

V. Ramundo[1], F. Fonderico[1], A. Assanti[2], F. Marciello[1], M. Del Prete[1], V. Marotta[1], G. Lombardi[1], C. Misso[1], L. Marzano[1], A. Colao[1], S. Spiezia[2] & A. Faggiano[1,3]
[1]"Federico II" University of Naples, Naples, Italy; [2]"Incurabili" Hospital ASL Napoli 1 centro, Naples, Italy; [3]National Cancer Institute, "Fondazione G. Pascale", Naples, Italy.

Introduction
Percutaneous radiofrequency thermal ablation (RTA) is a new promising therapeutic approach to manage compressive thyroid nodules (TNs).
Aim
To investigate effectiveness and safety of RTA in the treatment of compressive TNs in patients not receiving surgery or radioiodine.
Study design
Forty patients (31–86 years) with compressive TNs were enrolled. Twenty-two patients had non-toxic TNs and 18 had toxic TNs and were treated with methimazole. Patients were randomized in two groups: group A (20 patients: 12 non-toxic, 8 toxic TNs) were treated with RTA; group B (20 patients: 10 non-toxic, 10 toxic TNs) did not receive any treatment. There was no significantly different characteristics between groups. RTA was performed by using a RITA© Starburst needle under ultrasonographic guidance. All patients were clinically, biochemically and morphologically evaluated 1, 3 and 6 months after baseline.
Results
At baseline, TN volume was $13.3\pm8.0$ ml in group A and $11.3\pm6.9$ ml in group B ($P=$NS). After treatment, TN volume significantly decreased in group A ($P<0.0001$), both in patients with non-toxic TNs and in those with toxic TNs, while remained stable in all patients of group B ($P=$NS). At 3 and 6 month evaluation, TN volume was significantly lower in group A than in group B ($P<0.0001$). At the end of the follow-up, pressure symptoms were improved in all patients of group A while persisted unchanged in group B. In the subgroup of patients with toxic TNs, hyperthyroidism completely recovered in 40% and improved in 40% of group A, while it persisted unchanged in all patients of group B. RTA was safe and well tolerated in all patients.
Conclusions
RTA significantly decreases toxic and non-toxic TN volume, resulting in parallel improvement of pressure symptoms and hyperthyroidism. RTA represents a valid therapeutic approach in patients with TNs not receiving conventional treatments.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1576

**Predictors of long-term remission in patients with Graves' disease-a single centre experience**

P. Anagnostis, F. Adamidou, S. Polyzos, S. Katergari, E. Karathanasi, C. Zouli, A. Panagiotou & M. Kita
Hippokration Hospital of Thessaloniki, Thessaloniki, Greece.

Introduction
Antithyroid drugs (ATD) remain the first-line therapy in patients with Graves' disease (GD), despite high relapse rate. The purpose of the present study was to identify predictors of long term remission of GD in patients who received ATD as primary treatment.
Description of methods/design
We restrospectively identified patients with Graves' disease initially treated with ATD between 1984 and 2011 and extracted relevant data from the electronic records database. Patients with follow-up data of $>6$ months after ATD discontinuation were included.
Results
Two-hundred and eleven patients (mean age $47.2\pm13.8$ years, 44 males) were studied. One-hundred and thirty-five (64%) were treated with ATD only, 82 of which (61%) maintained remission during a follow-up of $56.6\pm57.5$ months. Mean duration of first ATD therapy was $38.6\pm26.3$ months.
Females ($P=0.049$), non-smokers ($P=0.017$), patients without orbitopathy ($P=0.033$) and those who developed hypothyroidism during therapy ($P=0.018$) experienced longer remission.
Duration of remission was positively associated with ATD therapy duration (rs$=0.151$, $P=0.03$), maximum TSH levels during ATD therapy ($rs=0.241$, $P=0.001$), TSH levels at the end of treatment ($rs=0.280$, $P<0.0001$) and at 3 months after ATD discontinuation ($rs=0.341$, $P=0.003$). There was a negative association with FT4 ($rs=-0.426$, $P<0.0001$) and FT3 levels at 6 months after ATD discontinuation ($rs=-0.467$, $P=0.038$). Age, block-and-replace therapy, type or dose of ATD were not associated with longer remission.
Conclusions
Female gender, non-smoking status, absence of orbitopathy and occurence of hypothyroidism during therapy were favorable predictors of remission in patients with GD treated with ATD. Longer duration of therapy, higher TSH levels during, at the end and at 3 months after ATD discontinuation, lower FT4 and FT3 levels at 6 months after ATD discontinuation were associated with longer remission.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector

## P1577

**The effect of L-thyroxine substitution on lipid profile, glucose homeostasis and coagulation in patients with subclinical hypothyroidism**

Z. Efstathiadou, P. Anagnostis, F. Dogramatzi, A. Slavakis, D. Selalmatzidou, S. Katergari, D. Kleta & M. Kita
Hippokration Hospital of Thessaloniki, Thessaloniki, Greece.

Introduction
Subclinical hypothyroidism (SH) is associated with increased risk for atherosclerosis, mainly attributable to dyslipidemia, diastolic hypertension, altered coagulability and increased levels of inflammation markers. However, conflicting data exist regarding the effect of L-thyroxine substitution on these parameters.
The purpose of the present study was to quantify the effect of L-thyroxine therapy on lipid profile, coagulation markers, high-sensitivity C-reactive protein (hsCRP) and glucose homeostasis in patients with SH.
Description of methods/design
It was a comparative, prospective study conducted in the department of Endocrinology at a tertiary medical centre of northern Greece from November 2009 to November 2011. Patients with diabetes mellitus, cancer, renal, liver failure or receiving drugs affecting lipid metabolism or coagulation, were excluded.
The following parameters were measured before and 6 months after restoration of euthyroidism with increasing doses of L-thyroxine: anthropometric data, total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), triglycerides (TG), apolipoprotein B (apoB) and A1 (apoA1), lipoprotein (a) [Lp(a)], fasting plasma glucose and insulin, homeostasis model assessment-insulin resistance (HOMA-IR), hsCRP, antithrombin III (AT-III), protein C (PC), protein S (PS), fibrinogen and homocysteine.
Results
Thirty-two patients (30 women) aged $52.1 \pm 13.9$ years with SH completed the study. Mean TSH levels at baseline were $6.79 \pm 2.58$ mIU/ml. L-thyroxine and achievement of euthyroidism significantly reduced systolic blood pressure (BP) in patients with SH (from $135.2 \pm 18.5$ to $129.7 \pm 15.8$ mmHg, $P = 0.03$) and diastolic BP only in those with baseline TSH levels $>7$ mIU/ml (from $79.5 \pm 9.8$ to $72.1 \pm 7.3$ mmHg, $P = 0.03$).
No significant changes in body weight, waist or hip circumference, TC, LDL-C, HDL-C, TG, apoB, apoA1, Lp(a), glucose, insulin, HOMA-IR, hsCRP, AT-III, PC, PS, fibrinogen or homocysteine levels after restoration of euthyroidism.
Conclusions
Except for reduction in systolic and diastolic BP, thyroid substitution therapy does not affect lipidemic profile, systematic inflammation, glucose homeostasis or coagulation in patients with SH.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1578

**A novel familial variation of the thyroid hormone receptor beta gene (I276N) associated with resistance to thyroid hormone**

S. Moia, A. Monzani, F. Prodam, A. Petri, G. Genoni, R. Ricotti, V. Agarla & G. Bona
University of Piemonte Orientale, Novara, Italy.

Introduction
Resistance to thyroid hormone (RTH) is a dominantly inherited syndrome, first identified in 1967 by Refetoff, characterized by reduced organ responsiveness to thyroid hormone. The most typical pattern being an elevated serum free T4 (fT4) concentration in association with non-suppressed TSH, usually accompanied by high serum levels of free T3 (fT3), with a considerable inter-individual variation and heterogeneous phenotype. The most frequent defect which causes RTH involves the thyroid hormone receptor beta gene (THRB) located on chromosome 3.
Methods
Genomic DNA was isolated from peripheral blood. Molecular analysis of THRB gene was performed. Exons 7 through 10 and their flanking intronic regions were amplified by PCR and the products were analyzed by direct sequencing.
Results
Molecular analysis of THRB gene identified a novel missense variation in exon 8 in the heterozygous state (I276N). The patient was a 3-year-old girl referred to our Pediatric Endocrinology Unit for statural and ponderal growth retardation. She presented elevated thyroid hormone levels with unsuppressed TSH, in presence of an unusual positivity to anti-thyroperoxidase antibodies for age. The child's mother, a 42-year-old women, reported from 25-years of age a history of tachycardia, high stool frequency and goiter, elevated fT3 and fT4 with normal TSH, increased levels of anti-thyroperoxidase and anti-thyroglobulin antibodies and a thyroid ultrasound and cytological pattern suggestive for lymphocytic thyroiditis. The same THRB variation was identified also in the mother in the heterozygous state.
Conclusion
We described the case of a child and her mother affected by RTH presenting with different clinical phenotype even if they carried an identical novel THRB missense variation. In both of them RTH was associated with the presence of anti-thyroid antibodies. RTH should be suspected every time elevated thyroid hormones and unsuppressed TSH are found, independently of the clinical phenotype, even in association with an autoimmune thyroiditis.

## P1579

**Short-term combined treatment with L-thyroxine plus L-triiodothyronine in drops (LT4 plus LT3) in patients with persistent hypothyroidism and malabsorption during replacement therapy with L-T4.**

S. Ippolito, D. Arpaia, C. Peirce, G. Lombardi & B. Biondi
University of Naples Federico II, Naples, Italy.

The objective of our study was to evaluate the potential benefit of short-term combined treatment with LT4plusLT3 in patients with persistent hypothyroidism and malabsorption. We report ten cases of patients with hypothyroidism secondary to total thyroidectomy, in which high doses of L-T4 (2,7-3.5 mcg/kg/die) were not adequate to normalize thyroid function. TSH was persistently high (from 10 to 100 mU/L) with low serum levels of thyroid hormones.
All of the patients presented severe symptoms of hypothyroidism and did not have history of recent intake of drugs interfering with gastric function or history of previous gastric surgery, other disorders or alcohol abuse.
Anti-endomysium and anti-tissue transglutaminase tests, lactose hydrogen and 13C-Urea breath test, parasitic search in the stool were performed in all of the patients. Gastric endoscopy was necessary in few patients. An Helicobacter pylori infection was found in 4 of the patients. One patient presented a gastroesophageal reflux associated with congestive gastropathy, whereas lactose intolerance was found to be responsible for the malabsorption in 2 patients. In 3 of the patients the cause of malabsorption was not identified.
Combined therapy with L-T4 and L-T3 (45 drops of LT4 and 30 drops of LT3 mean dose) was started in all of the patients to improve the severity of hypothyroidism. This combined treatment was able to normalize serum TSH, improving the symptoms of hypothyroidism in all of the cases in about two weeks. TSH values progressively normalized, and L-T3 administration was withdrawal. Specific treatment for the causes responsible for malabsorption was contemporary performed and we were able to shift treatment to L-T4 in tablets.
Our results support the potential benefit of combined treatment with LT4plusLT3 in patients with persistent hypothyroidism due to malabsorption.

**The role of surgery in the treatment of amiodarone-induced thyrotoxicosis (AIT)**

L. Tomisti, G. Materazzi, A. Marchello, M. Moretti, L. De Napoli, S. Brogioni, P. Miccoli, F. Bogazzi & E. Martino
University of Pisa, Pisa, Italy.

Introduction
AIT develops in 15–20% of patients receiving amiodarone. Patients with persistent thyrotoxicosis or those with instable cardiac function, may be candidate

for thyroidectomy; however, thyrotoxicosis and underlying cardiovascular disease may increased surgical risk.
Matherials and methods
We retrospectively selected 23 AIT patients treated with a total thyroidectomy, from January 2000 to December 2010 [19 men, 4 women; mean (+SD), age 61.4±9.4 years, range, 46–79 years]. Nineteen patients have been operated, during hyperthyroidism, after a short course of iopanoic acid (1 g/die for 15.2 ±7.7 days).
Results
No death occurred during surgery; in addition no excessive bleeding or intraoperative arrhythmic event occurred. One subject presented atrial fibrillation 24 hours after surgery, requiring a short course of sotalol, with reinstitution of sinus rhythm. One patient experienced hypoparathyroidism and one experienced laryngeal nerve injuries. No deceased after a 12-month follow-up. Impaired cardiac conditions, with ejection fraction (EF) < 35% (mean 27±6.7%), was observed in 8 patients before surgery. In these patients a significant EF improvement (mean 37.2±8.38%, $P=0.05$) was observed 60 days after surgery and reinstitution of euthyroidism
Conclusions
Total thyroidectomy is a valid option for treating AIT patients that require a rapid restoration of euthyroidism, which is associated with improvement of cardiac function.

## P1581

### Carbimazole induced ANCA associated renal vasculitis

D. Singh, A. Jayashekara & F. Kaplan
Lister Hospital, Stevenage, UK.

A 22-year old female diagnosed with thyrotoxicosis with raised free thryroxine (16.8 pmol/l) and suppressed thyroid-stimulating-hormone (TSH < 0.03 mIU/l). She was started on Carbimazole 20 mg during end of August 2011. A fortnight later she presented with nausea, vomiting, fever and rigors. Her renal functions were deranged with a creatinine of 704 μmol/l, which worsened over the next 48 h. She subsequently needed renal replacement therapy with haemodialysis. She was cytpolasmic anti-neutrophil cytpolasmic antibody (c-ANCA) positive with raised proteinase-3 (PR3) titers (28AU/ml) (see Table). She was negative for anti-thyroid stimulating hormone (TSH) receptor antibodies, anti-glomerular basement membrane (GBM) antibody and for anti-nuclear antibodies with normal complement levels.
It was proposed, perhaps this could be drug-(carbimazole)-induced renal vasculitis with positive c-ANCA; for which carbimazole was stopped and a renal biopsy revealed concentric necrotizing-glomerulonephritis consistent with c-ANCA-positive-vasculitis. She was further treated with high dose prednisolone and cyclophosphamide following which her renal functions improved and she was weaned-off haemodialysis; subsequently her thyroid function tests also normalized without any further anti-thyroid therapy.
Conclusion
Our case report re-iterates that anti-neutrophil-cytoplasmic-antibody-(ANCA)-associated-vasculitis is a potentially life-threatening adverse effect of anti-thyroid drugs like carbimazole. Altered immune environment associated with auto-immune thyroid disease is not sufficient to develop ANCA but treatment with thionamides (which accumulate in neutrophils) is important in promoting ANCA

## P1582

### Thyroid dysfunction following cranial and craniospinal radiation in young adults

E. Bobrova[1], V. Fadeev[1], P. Mariya[1], Y. Sych[1] & N. Mazerkina[2]
[1]I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; [2]Burdenko Neurosurgery Institute, Moscow, Russian Federation.

Purpose
Radiation-induced anterior pituitary hormone deficiencie is the most common long-term complications of successful cancer treatment. The aim of our study was to analyze thyroid status in young adults after radiotherapy in childhood and their relationship with dose of radiotherapy.
Materials and methods
Thyroid function (TSH, free T4, free T3) and thyroid ultrasound were evaluated in 29 young adults with a history of radiotherapy for brain tumors (BT) and acute lymphoblastic leukemia (ALL) in childhood:
Group 1(lower irradiation dose cranial irradiation 18 Gy): 2 men and 10 women (median age 22.5 yrs (range 16–30)), 5.9±3.4 years after treatment for ALL. All patients received chemotherapy BFM-90.
Group 2(higher irradiation dose, craniospinal irradiation 55 Gy): 7 men and 10 women (median age 21.1 yrs (range 15–26), 4.4±2.1 years after treatment for brain tumors (BT). All patient received chemotherapy M-2000.
Results
One patient from group 1 had one thyroid nodule (FNA – follicular neoplasm, postoperative hystology of follicular adenoma). No patient had signs of hypothyroidism (mean TSH was 1.28 mME/ml (0.5–1.88), fT4 – 12.82 pmol/l (11.1–15.4), and fT3 – 10.03 pmol/l (7.1–15.0)).
Three patients (20%) from group 2 presented signs and symptoms of central hypothyroidism (fT4 5.2 (4.1–6.3)). They received substitution with L-thyroxine. Thyroid nodules were found in 2 patients (both colloid goiter after FNA). Mean TSH value (exept for three cases of central hypo) was 2.53 mME/ml (1.32–4.53), mean fT4 – 10.17 pmol/l (5.9–19.8), and mean fT3 – 6.22 pmol/l (4.1–13.0). The study is in progress.
Conclusions
These data indicate that treatment of cancer in childhood is associated with development of thyroid abnormality later during the life, and there is a possible link between exposure to higher total radiation dose and incidence of hypothyroidism.
Declaration of interest
I fully declare a conflict of interest. Details below:

## P1583

**Multi nodular goitre: when is it time for the surgeon?**

L. Dam[1], K. In 't Hof[2] & E Nieveen. van Dijkum[1]
[1]Academic Medical Center, Amsterdam, The Netherlands; [2]Flevoziekenhuis, Almere, The Netherlands.

Introduction
Multi Nodular Goitre(MNG) has a slow, progressive growth. An apparently asymptomatic MNG can already have caused retrosternal upper airway obstruction. Yet MNG can also cause compressive manifestations without retrosternal extension. Timing of surgery can be critical for patients with a large goitre. The evidence is poor to guide management of large MNG with absolute indications for surgery. The aim of this uni-centre study is to analyze patients with large MNG and their surgery results.
Methods
We retrospectively searched the surgical database of the Academic Medical Centre for patients who underwent a Thyroid operation, between September 2009 and September 2011, because of large MNG. We analyzed patient characteristics, surgical aspects, and complications post-operative.
Results
120 patients (age $\geq$ 16 years) underwent thyroid operation during Sept. 2009 to Sept. 2011.
Forty-five (38%) had MNG with a preoperative contents of $\geq$80cc or post-operative specimen weight of $\geq$80 gram. Patients were 80% female and 20% men, mean age 52 years (range 16–81 years). Duration of the MNG was between 4 months to 30 years. All patients had complaints of their MNG, 24 (53%) experienced dyspnoea. Sixteen (36%) of the patients had retrosternal MNG. Twenty-one (47%) patients had tracheal deviation and obstruction. Seven patients underwent awake fiberoptic intubation. In one case tracheostomy was necessary. Complications occurred in 13(29%) of the MNG group, compared to 10(15%) in the smaller thyroid group. Mortality was 4% (2/45). One patient had an anaplastic carcinoma (MNG 150 cc) and one patient (MNG 200 cc) had an inhospital cardiac arrest 15 days postoperatively. In the smaller thyroid group 1 patient, with an Amiodarone-induced Thyrotoxicosis, died after an inhospital cardiac arrest.
Conclusion
Resection of large goiters is associated with a higher complication rate. Therefore we conclude that earlier referral to a thyroid surgeon might influence the operative results.

**Amiodarone- induced thyroid dysfunction in an iodine- deficient region**

S Ismailov, N Abdusalamova & N Kayumova
Tashkent Pediatric Medical Institute, Tashkent, 100140, Bogishamol street 223, Uzbekistan.

Objective
To determine the incidence of thyroid dysfunction in a cohort of patients started on amiodarone therapy at a cardiac clinic in Tashkent, Uzbekistan, which is believed to be an iodine- deficient area.
Methods
Pharmacy records were used to obtain the names of patients who received amiodarone between 2006 and 2009.
Results
The original sample size was 96; 3 patients were excluded to incomplete data and data analysis was completed for 93 patients (21 women and 72 men).
The mean age was $59 \pm 15$ years (range, 22–89). The indication for amiodarone therapy were supraventricular tachycardia ($N=64$, 68.8%), ventricular tachycardia ($N=22$, 23.6%), and prophylaxis against tachycardia ($N=7$, 7.5%). The median duration of amiodarone treatment was 679 days (range, 3–6425 days) in the entire cohort. The median duration of amiodarone therapy in euthyroid patients was 547 days. The median duration of amiodarone therapy until thyroid disorder developed was 943 days. This was a significantly longer time period compared with euthyroid patients ($P=0.05$).
Discussion
There were 24 (25.8%) new thyroid dysfunction cases; 18 patients (19.3%) hadthyrotoxicosis, 1 (0.6%) had subclinical hyperthyroidism, 4 (4.3%) had hypothyroidism, and 1 (1.1%) had minor changes in thyroid function.
Conclusions
We found a high incidence of new-onset thyroid dysfunction, similar to the highest rates reported by other investigators. Any additional etiological factors responsible for this in Uzbekistan need to be investigated.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1585

**Hashimoto thyroiditis and carbohydrate metabolism disorders in patients hospitalized in Department of Endocrinology and Diabetology of Ludwik Rydygier Collegium Medicum in Bydgoszcz between 2001 and 2010**

M. Gierach & R. Junik
University Hospital, Bydgoszcz, Poland.

Chronic lymphocytic thyroiditis, also known as Hashimoto thyroiditis, is the most frequent type of thyroiditis. An average 2% of the population suffer from the disease. The incidence of the disease is estimated as 0.3–1.5/1000 people a year. The main cause of the disease includes autoimmune disorders, that result in increased risk of diabetes type 1. Furthermore, during the course of Hashimoto thyroiditis, hypothyroidism may originate carbohydrate metabolism disorders, which lead to the increase of insulin resistance.
We examined 54 patients (45 females and 9 males at the age of 17–87) with the diagnosis of Hashimoto thyroiditis based on clinical picture and examination (autoantibodies anti-TPO and anti-Tg). The patients have been hospitalized in the Department of Endocrinology and Diabetology Nicolaus Copernicus University in Torun, Collegium Medicum in Bydgoszcz between 2001 and 2010.
In the tested group with Hashimoto thyroiditis, diabetes was confirmed in 27.8% of the patients; impaired fasting glycaemia (IFG) or impaired glucose tolerance (IGT) occurred in 16.6%, whereas normoglycaemia was confirmed in 55.6% of the patients.
It has been proved there is a connection between the incidence of either hypothyroidism or hyperthyroidism and carbohydrate metabolism disorders. The abnormalities of glycaemia levels are directly proportional to the hormone disorders of the thyroid gland.
Carbohydrate metabolism disorders in the form of type 1 diabetes connected with an autoimmune process, as well as type 2 diabetes connected with the increase of the insulin resistance, occur in average of half of the patients with Hashimoto thyroiditis.

**Endocrine bioengineering: reconstruction of a bioartificial thyroid lobe using its natural, three-dimensional (3D) stromal / vascular matrix as a scaffold**

V. Strusi[1,8], N. Zini[2], D. Dallatana[1], S. Mastrogiacomo[1], A. Parrilli[3], R. Giardino[3], G. Lippi[4], G. Spaletta[5], E. Bassoli[6], A. Gatto[6], M. Iafisco[1,7], M. Sandri[7], A. Tampieri[7] & R. Toni[1,8]
[1]University of Parma School of Medicine, Parma, Italy; [2]CNR-IOR, Bologna, Italy; [3]IOR, Bologna, Italy; [4]Maggiore Hospital, Parma, Italy; [5]University of Bologna, Bologna, Italy; [6]University of Modena and Reggio Emilia, Modena, Italy; [7]CNR, Faenza, Italy; [8]Tufts Medical Center – Tufts University School of Medicine, Boston, MA, USA.

To test the feasibility of reconstructing *ex situ* an entire bioartificial thyroid gland suitable for transplantation we have bioengineered a rat thyroid lobe using its decellularized stromal / vascular matrix, eventually 3D recellularized with thyroid stem / precursor cells. Sprague-Dawley male rats (220–240 g) were used as thyroid donors, and lobe matrixes obtained by freezing / detergent / enzyme processing. Test matrixes were made electrondense and analyzed by microtomography (microTC). Primary thyroid cells and ABCG2-positive, thyroid stem/precursor elements were expanded and isolated either in primary monolayer or 3D matrigel cultures for 72 h, using low-glucose DMEM and high vs low serum media. Following trypsinization, 250–450.000 cells were harvested to coat the empty follicular and vascular cavities of the inner matrix surface, and grown up to 21 days in static conditions. The colonized matrixes were either fixed in aldheydes for processing by light (LM), transmission (TEM) and scanning electron (SEM) microscopy or denaturated to get total proteins, and run for ABCG2 westen blotting. Culture supernatants were collected every 48 h, and free thyroid hormone levels assessed with chemiluminescent immunoassays. Complete decellularization and maintenance of the 3D native architecture of the thyroid SVS were achieved. Thyroid-derived cell, including differentiated thyrocytes, elements showing epithelial-mesenchymal transitions, and stem/precursor cells were found both to heterotopically migrate inside matrix septa and to orthotopically aggregate, link and give rise to intracytoplasmic cavities, up to recellularize the decellularized follicular spaces. Thyroid hormone secretion occurred for at least 7 days. These results show that the natural 3D matrix of the rat thyroid acts as a scaffold to bioengineer *ex situ* a functional thyroid lobe with progenitor-like elements (Fig.), suggesting that a biocompatible construct can be realized for eventual transplantation replacement. **Thyroid hormone stimulates hepatic fatty acid metabolism via lipophagy**

R. Sinha & P. Yen
Duke-NUS Graduate Medical School, Singapore, Singapore.

Autophagy is a catabolic process that promotes hepatic cell survival during starvation and metabolic stress. Currently, little is known about the endocrine regulation of autophagy. Recent studies by Singh et al. (Nature 458, 1131–1135 (2009)) showed a critical link between autophagy and beta oxidation in hepatocytes. Accordingly, we examined whether hormones known to promote beta oxidation of fatty acids also stimulated autophagy in hepatic cells. Surprisingly, we found that T3 stimulated autophagy in human hepatic cells *in vitro* and in mouse liver in vivo. In particular, T3 increased LC3 II and decreased p62 protein expression levels in HepG2TRalpha cells and hepatocytes. Moreover, studies using chloroquine treatment to block autophagsome/lysosome fusion and microscopic localization of RFP-GFP flurorescent tagged LC3 both demonstrated that T3 increased overall autophagic flux. Bodipy-staining and electron microscopy studies of hepatic cells showed that T3-induced autophagy remarkably involved formation of lipophagosomes that ingest lipids from fat droplets and fuse with lysosomes before fatty acid delivery to mitochondria. This T3-mediated lipophagy was also associated with increased beta-oxidation as T3 increased Cpt-1$\alpha$ expression. In this connection, knockdown studies using ATG5 siRNA demonstrated that T3-dependent beta oxidation of fatty acids was dependent upon autophagy. Our findings show that T3 plays a critical role in the regulation of fatty acid metabolism by co-ordinately inducing lipophagy and beta-oxidation. They also suggest that T3 or its analogs may be useful for the treatment of NAFLD, a common condition with high morbidity caused by excess fat accumulation in the livers of patients with obesity and diabetes.

**Linking thyroid and central nervous system functions of cathepsin K: Implications for non-classical thyroid regulation**

S. Dauth[1], M. Rehders[1], R. Sîrbulescu[1], E. Wirth[2], D. Braun[2], B. Batbajar[1], U. Schweizer[2], M. Bröcker-Preuss[3], D. Führer[3], P. Saftig[4], S. Jordans[1] & K. Brix[1]
[1]Jacobs University, Bremen, Germany; [2]Charité Universitätsmedizin, Berlin, Germany; [3]Universitätsklinikum Essen, Essen, Germany; [4]CAU Kiel, Kiel, Germany.

Cathepsin K is a cysteine protease known for its importance in bone remodelling. Inhibitors of cathepsin K are in clinical trials for osteoporosis treatment, but side effects included altered levels of related cathepsins in peripheral organs and in the central nervous system (CNS). Importantly, cathepsin K has been identified not only in osteoclasts but also in most epithelia and, recently, in brain parenchyma. Lately, we have also shown that cathepsin K deficiency in mice induces structural and functional alterations in the CNS which are associated with learning and memory deficits. In addition, we demonstrated that cathepsin K contributes to thyroid hormone (TH) liberation from the thyroid gland, because cathepsin K- and L-double deficient mice are considered hypothyroid due to reduced serum T4 levels and enlarged thyroids. These findings led us to hypothesize that brain and thyroid functions of cathepsin K are linked. Ctsk-/- mice exhibit enlarged thyroids but no alterations in serum or brain T4, T3 or TSH levels nor in brain deiodinase 2 activity were observed. Cerebellum development is TH dependent and altered upon hypothyroidism. However, we show here that neither the overall structure nor single cells, like Purkinje cells or Bergmann glia in the cerebellum, are altered in Ctsk-/- mice. Thus, Ctsk-/- mice do not suffer from classical hypothyroidism. Interestingly, trace amine associated receptors (TAAR) as well as TH transporters appeared deregulated in the CNS of Ctsk-/- animals compared to WT mice. Since all markers of classical TH action were comparable in WT and Ctsk-/- mice, but markers of non-classical TH action like the TH transporters and TAARs differed significantly, we believe to have identified an animal model suited to study non-classical TH actions on the CNS as a target organ.

**SECISBP2 syndrome: Mouse models for an atypical form of resistance to thyroid hormone**

S. Seeher[1], E. Wirth[1], Y. Mahdi[1], A. Miniard[2], D. Driscoll[2], B. Carlson[3], D. Hatfield[3] & U. Schweizer[1]
[1]Charité, Berlin, Germany; [2]Cleveland Clinic, Cleveland, OH, USA; [3]National Institutes of Health, Bethesda, MD, USA.

An atypical form of resistance to thyroid hormone (RTH) leads to retarded growth and bone age in humans. Aberrant thyroid hormone levels (high T4, low T3, elevated rT3 and high/ normal TSH) indicate a defect in deiodinase-dependent thyroid hormone metabolism. Findings of reduced concentrations of plasma selenoproteins (SePP, GPx3) suggested a generalized defect of selenoprotein biosynthesis and led to the identification of mutations in the SECISBP2 gene. SECISBP2 is thought to play an essential role for selenoprotein biosynthesis. Mutations in the SECISBP2 gene lead to reduced expression of selenoproteins and cause a syndrome with relatively mild to more severe phenotypes. Our group set out to create mouse models to test whether Secisbp2 is essential for selenoprotein biosynthesis and to study the changes in the thyroid axis of mutant mice.

First results showed the essentiality of Secisbp2: A homozygous null mutation leads to early embryonic death. In contrast, Secisbp2 heterozygotes have no obvious phenotype. They are fertile and their thyroid function tests are normal. Biochemical examination revealed only minimal changes in selenoprotein expression. Hepatocyte-specific Secisbp2 knock-out mice appear normal too, but show a dramatic reduction of hepatic selenoprotein expression.

Neuron-specific Secisbp2 knock-out mice have a more severe phenotype. They are smaller and weight less than their wildtype littermates. Their neurological phenotype involves a movement disorder and histological stainings demonstrated a specific loss of parvalbumin positive interneurons. It will be interesting to analyze Secisbp2-mutant mice carrying point mutations found in human patients.

**Polymorphism of the PPAR-γ2 gene and Graves' orbitopathy: the Ala variant confers decreased risk of eye symptoms**

J. Daroszewski[1], E. Pawlak-Adamska[2], M. Bolanowski[1] & I. Frydecka[1,2]
[1]Medical University, Wroclaw, Poland; [2]Polish Academy of Sciences, Wroclaw, Poland.

Introduction
Peroxisome proliferatior-activated receptor-γ2 (PPAR-γ2) plays a crucial role in adipogenesis and has been shown to be involved in the control of immunoregulation and inflammation. Orbital fibroblast differentiation to adipocytes is a PPAR-γ dependent process essential for pathogenic tissue remodeling in Graves' orbitopathy (GO). Genetic variation in PPAR-γ2 gene may modulate expression and/or function of molecule encoded by this gene.
Purpose
The occurrence and associations of the PPAR-γ2 Pro12Ala mutation with clinical manifestation of GO were studied.
Material and methods
The Pro12Ala polymorphism was determined in total 742 Lower Silesia Caucasians including 276 Graves' disease (GD) patients (212 GO patients and 64 subjects without eye changes) and 466 healthy controls using PCR-RFLP technique (with the use of restriction enzyme HpaII).
Results
The distribution of The Pro12Ala polymorphism did not differ between GD patients and healthy subjects. Within the GD group the Ala allele and a presence of Ala variant (Pro12Ala or Ala12Ala genotype) decreased the risk of GO (OR = 0.33, $P$ = 1.2e–5, 95%CI:0.19–0.55 and OR = 0.32, $P$ = 0.00013, 95%CI:0.17–0.58, respectively). Moreover, Ala12Ala genotype was observed only in patients without GO (5.2%, $P$ = 0.007, after Yate's correction). However the distribution of genotypes and alleles in studied marker was similar in patients shared-out according to severity as well as activity status of GO. The female carriers of Ala12 allele statistically seldom develop GO ($P$ = 0.0005, OR = 0.31, 95%CI:0.16–0.61). Additionally, the presence of Ala12 allele increased the risk of active GO in men ($P$ = 0.04 after Yate's correction, OR = 6.47, 95% CI: 1.25–33.52).
Conclusions
For the first time we pointed that the presence of Ala variant (Ala12Ala and/or Pro12Ala genotype) in unique exon B in PPAR-γ2 gene strongly reduces the risk of GO and the Al12Ala genotype was seen only in patients without GO so may be considered as a protective factor.

**Thyroid hormone T3 induces ovarian activity in rat follicles and granulosa cells**

C. Verga Falzacappa, G. Santaguida, A. Furno, M. Centanni & S. Misiti
Sapienza Università, Roma, Italy.

Background
The menstrual pattern is influenced by thyroid hormones directly through impact on the ovaries and indirectly through impact on SHBG, PRL, and GnRH secretion and coagulation factors. Treating thyroid dysfunction can reverse menstrual abnormalities and thus improve fertility.
Aim
Elucidating the molecular mechanisms underlying the link between thyroid and ovarian function is important for determining the relationship between thyroid status, fertility and menstrual disorders. Our previous work has demonstrated how granulosa cells population can be considered a thyroid hormone target, being its survival induced by T3 under specific circumstances via cell cycle and metabolism regulation.
Materials and methods
To characterize thyroid hormone action in the ovary, the direct effect of triiodothyronine T3 was analyzed *in vitro* using a culture system of rat follicles and granulosa cells obtained directly from female rats, and their growth and function in response to T3 treatment (10–7M) have been evaluated.
Results
Our results showed that both cell growth and follicle dimensions were significantly incremented (up to 40%) by 2–7 days of hormone treatment, as shown by cell growth analyses and follicle dimensions measures. The same cells and follicles were moreover capable of a 50% incremented production of 17 B estradiol, in response to testosterone supply, when treated with 48 h T3 10–7 M. Even the basal production of estradiol was augmented by the hormone presence, as measured by chemiluminescence.

To investigate the mechanisms underlying the observed effects, the major steroidogenic genes were analyzed by RT-PCR, namely FSHR, cyp 19a1, cyp 17, p450 scc, 3BHSD and StAR. All the genes analyzed, and in particular the aromatase and 17B-HSD, which are directly responsible for estradiol production, were significantly upregulated by the 48 h T3 treatment.
Conclusion
In conclusion our data show unambiguously the T3 ability to promote ovarian function in rats, providing interesting results about the T3 ability of directly target steroidogenesis.

## P1592

**Recurrence of Amiodarone induced thyrotoxicosis after reinstitution of this drug**

S. Maqdasy[1,2], M. Batisse-Lignier[1,2], J. Lusson[3], D. Lamaison[3], B. Citron[3], B. Roche[1], F. Desbiez[1], P. Thieblot[1] & I. Tauveron[1,2]
[1]CHU Clermont-Ferrand, Clermont Université, Clermont-Ferrand, France; [2]UMR GReD, CNRS 6247, Clermont Université, Clermont-Ferrand, France; [3]CHU Clermont-Ferrand, Clermont-Ferrand, France.

Introduction
Amiodarone-induced thyrotoxicosis (AIT) contributes to increased morbidity and mortality in patients invariably having underlying heart disease. In clinical

practice, amiodarone therapy often needs to be restarted. When amiodarone is reintroduced, what happens then?
Objective
The aim of study is to evaluate the progression of thyroid function after reinstitution of amiodarone in patients with a previous history of AIT. Secondarily, to determine the efficacity of thionamides to prevent the recurrence of AIT.
Methods
Retrospectively, between 2000 and 2011, patients with a previous history of AIT, in whom amiodarone needed to be reintroduced, were included. Type and severity of 1st AIT, and thyroid function evolution after reinstitution of amiodarone where investigated.
Results
patients were included in our study. Mean age when AIT diagnosed was $62.2 \pm 16$ years old with male sex predominance. 65.8% of patients had type I AIT. Duration of treatment with amiodarone before developing AIT was shorter in these patients in comparison to patients with type II AIT ($20.5 \pm 20.1$ vs $40.2 \pm 20.0$ months: $P=0.006$). Before reinstitution of amiodarone, 6 patients had radical treatment. In 22 patients, amiodarone was reintroduced without a prophylactic therapy, while a thionamide was introduced in parallel with amiodarone reinstitution in 24 patients. After a mean follow up of $34.9 \pm 39.1$ months, AIT recurred in 14 (29.8%) patients, 12 (25.5%) patients developed hypothyroidism and 20 (48.6%) patients had normal thyroid function. Hyperthyroidism recurred in 62% of patients with amiodarone reinstitution without a preventive treatment, in parallel, only 16% of patients with a prophylactic thionamide suffered from recurrent AIT. Prophylactic thionamide may prevent recurrence of hyperthyroidism ($P=0.06$).
Conclusion
During median follow up of 3 years after reintroduction of amiodarone, the risk of recurrence of hyperthyroidism tends to be high (29.8%) but not compulsory. A prophylactic treatment with a thionamide could prevent or decrease recurrence of hyperthyroidism.

## P1593

**Subclinical and overt hyperthyroidism in a long-term iodine sufficient area of Sweden (Gothenburg) 2003–2005**

H. Filipsson Nyström, S. Jansson & G. Berg
Sahlgrens' Academy at University of Gothenburg, Sahlgrenska University Hospital, Gothenburg, Sweden.

Introduction
The incidence of hyperthyroidism is influenced by iodine nutrition. Sweden is a long-term iodine sufficient (IS) area with an iodination fortification program since 1936.
Methods
In 2003–2005, all referred cases of subclinical (SH) and overt hyperthyroidism (OH) were registered from a targeted population of 631239 individuals in Gothenburg. Information on age, gender, etiology, smoking, thyroid associated ophtalmopathy (TAO), thyroid hormone levels, TSH receptor antibodies (TRab), thyreoperoxidase antibodies (TPOab) and planned treatment was collected at diagnosis. Incidences were calculated. Comparisons between SH and OH for Graves' disease (GD), toxic multinodular goiter (TMNG) and solitary toxic adenoma (STA) were made and for GD also smokers vs non-smokers, $TRab^+$ vs $TRab^-$, $TAO^+$ vs $TAO^-$, and correlations between thyroid hormone levels, age and autoantibodies.
Results
The total incidence of hyperthyroidism was 27.6/100000/year (OH 23.8/100000/year, SH 3.8/100000/year; GD 21.4/100000/year, TMNG 4.3/100000/year and STA 1.8/100000/year). SH was more common among TMNG and STA (40.2% and 45.7%)than in GD (15.1%). SH-GD patients were older, more often smokers and had lower TRab levels than patients with OH-GD. FT4 and T3 levels in GD were higher than in TMNG and STA. FT4, T3 and TRab decreased with age in GD patients (Spearman $-0.23$, $-0.35$, $-0.26$), $P<0.0001$. $TRab^-$ patients had lower T3 than $TRab^+$ patients ($3.7 \pm 1.7$ vs $5.7 \pm 2.8$), $P<0.001$ but similar FT4 levels. TRab was positively correlated to FT4 (Spearman 0.39), $P<0.0001$. TAO occured in 20% of GD patients. $TAO^+$ patients was younger than $TAO^-$ patients. Concentration of FT4 and T3 were similar but TRab was higher in $TAO^+$ patients. Smokers did not have more TAO.
Conclusion
The total incidence of hyperthyroidism was relatively low. The dominating cause was GD with an age-related decrease of thyroid hormones and TRab. The spectra of hyperthyroidism in this long-term IS area probably reflects the future for many countries with shorter history of IS.

## P1594

**Enhanced expression of the B cell activation factor (BAFF) and baff-receptor (BAFF-R) in the thyroid and in the orbital adipose tissue from patients with graves' disease (GD) and associated orbitopathy (GO)**

I. Campi[1], G. Vannucchi[1], D. Covelli[1], S. Rossi[2], P. Doi[2], N. Currò[1], L. Pignataro[1], C. Guastella[1], P. Beck-Peccoz[1] & M. Salvi[1]
[1]University of Milan, Fondazione IRCCS Cà Granda, Milan, Italy; [2]University of Milan, S. Paolo Hospital, Milan, Italy.

BAFF, a member of the TNF family, promotes autoantibody production by increasing B cell survival and proliferation. We have previously shown that serum BAFF concentrations are increased in GD patients. In the present work, we studied the expression of BAFF and BAFF-R, by immunohistochemistry (IHC) on paraffin embedded sections of: 1. orbital adipose tissue from 22 patients (5 men, 17 women) with GO (3 of them with active GO) associated with GD or Hashimoto thyroiditis in 19 and 2 patients, respectively. One subject was affected with euthyroid GO (EGO); 2. extra-ocular-muscles (EOM) biopsies of 10 patients (2 men, 8 women) with GO (2 of them with active GO) associated with GD; 3. thyroid of 27 patients (20 women, 7 men) with GD and GO. Samples were stained using a panel of antibodies directed against the following antigens: BAFF, BAFF-R, CD3, CD4, CD8, CD20, CD34, CD79, CD1a, CD68, CD163. Thyroid histology showed nodular hyperplasia (NH) in 8 of 27 patients, diffuse hyperplasia (DH) in 19 of 27. Reactivity for BAFF and BAFF-R was found on thyrocytes and on the lymphocytes infiltrating the thyroid. BAFF expression on thyrocytes was higher in DH than NH; conversely, lymphocytes surrounding the areas of NH exhibited a stronger staining for BAFF-R, compared to DH. In 15 of 22 samples, B and T-cells infiltrating orbital adipose tissues expressed BAFF. Interestingly, BAFF staining was stronger on B compared to T lymphocytes. BAFF-R staining was detected in 5 of 22 samples from orbital adipose tissue, but only on B lymphocytes. Orbital fibrocytes expressed BAFF and BAFF-R only rarely (3 of 22 samples). Tissue samples from EOM biopsies were negative either for BAFF or BAFF-R reactivity. In this study we report, for the first time, the increased expression of BAFF and BAFF-R in orbital and thyroid tissue samples from patients with GO and GD. This finding, together with the recent observation of increased serum BAFF levels in GD, suggests an involvement of BAFF and its receptors in the pathophysiology of GD and GO.

**Utility of thiazide diuretics in the management of post- thyroidectomy hypocalcemia: a pilot study**

R. Panchangam
Mamata Medical College and Superspeciality Hospital, Khammam, India.

Introduction
The incidence of post thyroidectomy hypocalcemia varies from 10–50%. Treatment is either prophylactic or therapeutic calcium and vitamin D supplementation. We evaluated the utility of thiazide diuretics in the management of hypocalcemia prospectively.
Material and methods
This study was conducted in Endocrine Surgery department of a teritiary care teaching hospital. We included 104 patients of total thyroidectomy in the study. 44 cases had normocalcemia (Group A), 29 cases developed biochemical hypocalcemia (Group B) and 31 patients suffered from clinical hypocalcemia (Group C). All the three groups were subdivided in to non- intervention and

intervention groups. 25 mg of thiazide was given orally in intervention subgroup. Results were analysed with SPSS 12.0. ($P$ value $< 0.05$ was taken as significant)
Results
In group A, 4 patients in intervention and 2 in non-intervention subgroups developed biochemical hypocalcemia and 2 in intervention and 3 in non-intervention subgroups developed clinical hypocalcemia respectively. $P$ value was non-significant at 0.116. In group B, 1/15 patients in intervention subgroup and 6/14 patients in non-intervention subgroup progressed to clinical hypocalcemia. This result was 0.03 (statistically significant). In group C, mean duration of calcium infusion was 19 hours (12–36) in intervention subgroup and 27.5 hours (24–72) in non-intervention group. Result was not statistically significant ($P$ value $=0.09$)
Conclusion
These preliminary results could justify the additive role of thiazide diuretic in the secondary prophylaxis of post-thyroidectomy hypocalcemia

**Maternal Graves' disease induces more perinatal complications and higher risk of thyroid dysfunction at early childhood**

X. Cao, L. Wnag, C. Yang, X. Mo, Y. Li & H. Xiao
First Affliated Hospital, Sun Yat-sen University, Guangzhou, China.

Objectives
The most common cause of maternal hyperthyroidism during pregnancy is Graves' disease (GD). The aim of this study was to investigate the perinatal complications and the risk of thyroid dysfunction at early childhood of mothers with GD during pregnancy.
Method
Pregnant women with GD ($n=93$) and aged-matched randomly selected healthy pregnant women ($n=140$) were recruited retrospectively. The prenatal and newborn data were collected and analyzed. Toddlers with GD mothers ($n=30$) and non-GD healthy mothers ($n=36$) were also recruited for thyroid function and growth assessments.
Results
Newborns of mothers with GD had significantly higher complications than of non-GD mothers (34.41% vs. 7.86%, $P < 0.05$). Maternal hyperthyrodism was an independent risk factor of stillbirth, infants with a low birth weight and congenital malformation with odds ratios of 9.33, 9.33 and 7.29 respectively. Antithyroid drugs (ATDs) reduced fetal distress and stillbirth of GD mothers from 9.52% and 23.81% to 6.94% ($P < 0.05$) and 4.17% ($P < 0.001$), respectively. Toddlers' serum levels of FT3, FT4, anti-thyroglobulin antibody, and anti-thyroid peroxidase antibody were significantly higher than those of non-GD mothers (all $P < 0.05$).
Conclusion
Pregnancy with GD increased the risk of stillbirth, infants with a low birth weight and congenital malformation. Euthyroidism by ATD treatment reduced GD-induced perinatal complications effectively. Maternal GD may also induce a higher risk of autoimmue thyroid dysfunction at early childhood.

## P1597

**No Correlations between TSH receptor antibody levels assayed with Elecsys TRAb and the activity or severity of Graves' ophthalmopathy**

J. Noh, K. Iwaku, M. Suzuki, K. Sekiya, M. Matsumoto, H. Ohye, Y. Kunii, A. Yoshihara, N. Watanabe, K. Mukasa, Y. Kosuga, K. Ito & K. Ito
Ito Hospital, Shibuya-ku, Japan.

Objective
This study was designed to determine whether TRAb levels are correlated with the activity and severity of Graves' ophthalmopathy (GO).
Subjects and Methods
The subjects were 179 untreated Graves' disease patients. TRAb was assayed with Elecsys TRAb at the initial visit, and an ophthalmic assessment was performed within 3 months. The activity of the ophthalmopathy was assessed by clinical activity scores (CASs) and MRI T2 relaxation times. Exophthalmos was measured with Hertel's exophthalmometer, and the measurements in both eyes were summed (exophthalmos score). Eyelid swelling was evaluated by inspection, scored from 0 to 3 in each eye, and scores were summed (eyelid swelling score). Swelling of each extraocular muscle was evaluated, scored from 0 to 4 by MRI, and the scores were summed (extraocular muscle score).
Results
According to the activity of the ophthalmopathy the numbers of active, inactive, and recovery phase patients were 18, 152, and 1, respectively. CASs ranged from 0 to 3 points, and the numbers of patients with each CAS were 57, 76, 37, and 9, respectively. The median (range) TRAb level of the active phase patients and inactive phase patients was 6.55 IU/L (0.6–40.0) and 13.6 IU/L (0.3–40.0), respectively ($P=0.0298$). The TRAb levels of the patients whose CASs were 0 to 3 were 8.9 IU/L (0.3–40), 13.4 (0.3–40), 18.7 (1–40), and 16 (1.8–40), respectively, and there was no significant difference among them (Wilcoxon test, $P=0.087$).
TRAb levels did not correlate with exophthalmos scores ($r=0.1133$, $P<0.131$), eyelid swelling scores ($r=0.1454$, $P=0.0521$), or extraocular muscles scores ($r=-0.0653$ $P<0.3879$).
Conclusion
The TRAb levels were not correlated with either GO activity or severity.

## P1598

**The influence of recombinant human thyroid stimulating hormone (rhTSH) on the efficacy of radioiodine therapy in patients with toxic nodular goitre with low RAIU**

S. Abdelrazek, F. Rogowski, P. Szumowski, M. Daniluk, M. Winska & M. Szorc
Medical University of Bialystok, Bialystok, Poland.

The aim of our study was to evaluate the influence of rhTSH on the efficacy of radioiodine therapy (RIT) in patients with toxic nodular goitre(TNG) with low RAIU. Materials and methods: The study was performed on 30 patients with TNG (22 female and 8 male aged 45–78years) referred for 131I therapy. All patients had low RAIU (16–18%) 24 hours after a diagnostic dose of I-131 (4 MBq). All the patients received a single intramuscular dose of 0.05 mg rhTSH (thyrogen). 24 h later diagnostic dose of 131I was administered and thyroid scan with RAIU after 24 and 48 h was estimated. Therapeutic dose of 131I was given on the third day of rhTSH administration. Serum levels of TSH, fT4 and fT3 were determined, 24 h, 72 h after rhTSH administration and on the 3rd day after RIT. The therapeutic activity of 131I calculated by Marinelli's formula and ranged between 280 and 600 MBq. The absorbed dose ranged between 160 and 300 Gy. Follow up control was done every 6 weeks. Thyroid ultrasound, and thyroid scan were done again after12 months of RIT
Results
A significant increase (2–8 fold) in 24hr RAIU was observed after rhTSH administration. The distribution of radioiodine was more homogeneous 48 hours after rhTSH injection. After 12 months 93% of patient were in euthyroidism and 7% (2 patients) develop hypothyroidism. After six months the mean reduction in goitre volume was 20% and 45–50% after twelve months. The medium therapeutic activity of 131I was 280 Mob. Conclusions: Pre-treatment with rhTSH reduce the therapeutic dose of 131I by 50–58% without compromising the result of thyroid volume reduction. rhTSH makes RIT of TNG more effective in the patients with low RAIU.

## P1599

**Peripheral blood lymphocyte apoptosis and its relationship with thyroid function tests in adolescents with hyperthyroidism due to Graves' disease**

M. Klatka, E. Grywalska, A. Surdacka, I. Ben-Skowronek & J. Rolinski
Medical University, Lublin, Poland.

The aim of the present research was to assess changes in the degree of peripheral blood (PB) lymphocyte apoptosis during methimazole treatment in the group of teenage children.
Material and methods
The percentage of PB apoptotic lymphocytes, assessed by the decrease in mitochondrial transmembrane potential (CMXRos staining), was measured in 30 adolescents at the time of diagnosis, as well as after receiving the normalization of the thyroid hormones levels.
Results
The percentage of apoptotic lymphocytes in previously untreated patients with GD ($5.16 \pm 2.81\%$) was significantly lower ($P = 0.000001$) than the percentage of the apoptotic cells in the same group of patients after receiving methimazole-induced euthyreosis ($10.72 \pm 4.66\%$). There was a correlation between the increase of the mean percentages of apoptotic lymphocytes and the reduction of the FT4 levels ($R = 0.63$, $P < 0.0001$), as well as the reduction of TT3 levels ($R = 0.95$, $P < 0.0001$). The more signs and symptoms accompanied the diagnosis of the GD, the higher increment of the degree of lymphocyte apoptosis was observed during the MMI-treatment ($R = 0.74$, $P < 0.0000001$). The methimazole dosage correlated ($R = 0.85$, $P < 0.0001$) with the percentages of apoptotic cells.
Conclusions
Apoptosis induction of human PB lymphocytes seems to be one of the indicators of proper hyperthyroidism treatment.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Individual plasma ghrelin changes evaluated in the same patients in hyperthyroidism, hypothyroidism and euthyroidism**

M. Ruchala, E. Gurgul, A. Stangierski, J. Kosowicz & H. Zamyslowska
Poznan University of Medical Sciences, Poznan, Poland.

Ghrelin is a peptide discovered in 1999 as the first natural growth hormone secretagogue. It also proved to be an essential regulator of metabolism increasing appetite, body weight and stimulating peristalsis. Thyroid plays an important role in the maintenance of energy balance. Thus, correlation between ghrelin and thyroid function is worth consideration. Previous studies suggested, that ghrelin production is increased in hypothyroidism and decreased in hyperthyroism. However, since ghrelin production depends on many factors, including individual features, studies conducted on different groups of patients may not be accurate. We evaluated plasma ghrelin concentrations in the same patients in hyperthyroid, hypothyroid and euthyroid phase, assuming, that such assessment would be the most relevant analysis of plasma ghrelin changes in thyroid disorders.
The study group was selected from the patients with hyperthyroidism treated with radioiodine and followed-up after therapy. Ghrelin level was firstly assessed in hyperthyroid phase. In 12 patients, who developed hypothyroidism after radioiodine, the second measurement was performed. The third analysis was made in euthyroid phase after L-thyroxine replacement therapy. Blood samples were collected from antecubital vein at fast. Plasma ghrelin was measured with a commercial radioimmunoassay.
The study revealed, that in 11 patients ghrelin concentration was the lowest in hyperthyroidism, the highest in hypothyroid phase and reached medium value in euthyroidism. Mean ghrelin levels in all 12 patients were also decreased in hyperthyroidism (TSH $0.006 \pm 0.002$ uIU/ml; ghrelin $144.47 \pm 84.15$ pg/ml) and increased in hypothyroidism (TSH $62 \pm 29.63$ uIU/ml; ghrelin $320.95 \pm 190.16$ pg/ml) in comparison to euthyroid phase (TSH $1.53 \pm 0.81$ uIU/ml; ghrelin $216.16 \pm 111.61$ pg/ml).
Plasma ghrelin changes may indicate its compensatory role in thyroid dysfunction. Low ghrelin level decreases metabolic rate in hyperthyroid patients and high ghrelin concentration leads to appropriate use of energy in hypothyroidism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This work was supported, however funding details unavailable.

## P1601

**The effect of radioiodine therapy in 950 patients with subclinical hyperthyroidism**

S. Abdelrazek, F. Rogowski, M. Szelachowska, M. Mojsak, A. Kraszynska, M. Kornas & M. Gorska
Medical University of Bialystok, Bialystok, Poland.

The aim of our study was to assess the influence of radioiodine (131I) therapy on the achievement of euthyroidism, prevention of adverse effects on the cardiovascular and prevent evolvement to overt hyperthyroidism. Material and methods: We treated 950 patients, aged 30–70 years; 87% of them were female and 13% male; 320 patients with multinodular goitre (MNG), and 630 patients with autonomous nodule (ATN). Some of the patients were treated with antithyroid drugs for 1 to 3 months before I131 therapy (90 patients). Malignant changes were excluded in all nodules by fine needle aspiration biopsy. All the patients had serum TSH levels $< 0.1$ mU/l and effective T-half was more than 3 days at the time of treatment. The activity dose was calculated by the use of Marinelli's formula and ranged between 200 and 600 MBq. The absorbed dose (Gy) ranged between 180 and 300, and was proportional to thyroid volume. Follow up control was done every 6 weeks. Results: Euthyroidism achieved in 99% of patient with ATN and 94% of MNG; 1% of patients with ATN and 6% of patients with MNG develop hypothyroidism. In all of the patients, the symptoms and signs of subclinical hyperthyroidism disappeared (palpitation, tachycardia, atrial fibrillation, exercise tolerance improved, the blood pressure normalised and the quality of life improved). One percent of the patients received 2nd dose of radioiodine. Conclusions: Our result is good and is in the range of the existing literature. The achievement of euthyroidism and the remission of the symptoms and signs of subclinical hyperthyroidism, were due to good diagnosis, well preparation of the patients; accurate measurement of administered activity, effective half-life, and well-organised follow up. We recommend early treatment of subclinical hyperthyroidism, and long period of follow up visits in our department to evaluate the long term effect of radioiodine therapy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Genetic susceptibility to Graves' ophthalmopathy: the role of polymorphisms in anti-inflammatory cytokine genes**

O. Khalilzadeh & M. Anvari
Endocrinology and Metabolism Research Center (EMRC), Tehran, Islamic Republic of Iran.

Background
Various polymorphisms occur in cytokine genes involved in inflammatory processes in Graves' ophthalmopathy (GO). Anti-inflammatory cytokines such as transforming growth factor-β (TGF-β), interleukin-10 (IL-10) and interleukin-4 (IL-4) are among those believed to be involved in the disease process. In this study, we investigated the association between 8 polymorphisms within the mentioned cytokines and GO.
Methods
The following polymorphisms were studied in 50 patients with GO, 57 Graves' patients without GO and 140 healthy individuals using polymerase chain reaction with sequence-specific primers: TGF-β (+869C/T, +915G/C), IL-10 (−1082A/G, −819C/T, −592C/A) and IL-4 (−1098T/G, −590T/C, −33C/T). A corrected $p$ value less than 0.05 was considered statistically significant.
Results
The TGF-β+915C allele (Odds Ratio (OR) = 2.20) and CC genotype (OR = 7.50) as well as +869C allele (OR = 2.21) showed significant correlations with GO. Regarding IL-4 polymorphisms, the −1098G allele (OR = 2.09) and GG genotype (OR = 7.49), and the −33T allele (OR = 2.05) and TT genotype (OR = 4.00) were significantly associated with GO. The IL-10 −819TT genotype (OR = 5.00) was significantly correlated with GO.
Conclusion
This is the first study to show that polymorphisms in anti-inflammatory cytokine genes are associated with susceptibility to GO.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1603

### The T and B cell subsets in thyroids of children with Graves' disease and Hashimoto's thyroiditis

I. Ben-Skowronek, L. Szewczyk, R. Piekarski, M. Klatka & E. Korobowicz
Medical University, Lublin, Poland.

Background
Autoimmune thyroid disorders (AITD) similar in pathomorphology picture results in hyper- or hypothyreosis. The differences between Graves' disease (GD) and Hashimoto thyroiditis (HT) suggested that changes in the subsets of T-cells may have an influence on the course of this reaction.
Methods
The study involved 90 children: 30 with GD, 30 with HT and the control group – 30 children. After thyroidectomy, standard histological examinations and immunohistochemical reactions in paraffin specimens with monoclonal antibodies against T-cell markers CD3, CD4, CD8 as well as against B-cells - CD79 alpha were performed. Ultrathin sections were examined in the Transmission Electron Microscope.
Results
The autoimmune reaction in GD consists in increased number of CD4+ cells (3.17±4.27%) and plasma cells (22.89±8.61%) producing TRAb and stimulating thyrocytes to activity. The number of CD4+ cells was increased in comparison to healthy children (0.19±0.05%) and to HT (0.93±9.90%). The autoimmune reaction in HT is consist in antibody dependent cytotoxicity in circumstances of a low number of CD4+ cells and an increased number of CD8+cells (20.54±0.68%) in the thyroid tissue in comparison to GD (6.86 ±3.46%) and control group (0.65±0.30%). Plasma cells (31.65±9.11%) in this situation produced the antibodies involved in cytotoxic reactions against thyrocytes.
Conclusion
The Graves'disease was characterised due to increased number of CD4+T cells and increased number CD8+T cells. Hashimoto's thyroiditis characterised by low number CD4+T cells and increased CD8+Tcells. CD8+T cells have the cytotoxic properties only in Hashimoto's thyroiditis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

|---|---|---|---|---|
| Graves'disease | 17.79 | 3.17 | 6.96 | 22.89 |
| Hashimoto's thyroiditis | 30.38 | 0.93 | 20.54 | 31.65 |
| Control group | 1.04 | 0.19 | 0.65 | 4.11 |

## P1604

### The thyroid gland is another victim of the insulin resistance syndrome university

E. Zakaria, N. Ghanem & R. Abd al salam
Cairo University, Cairo, Egypt.

Insulin is a thyroid growth factor that stimulates proliferation of thyroid cells in culture. It has been observed that insulin receptors are over expressed in most thyroid tumors as an early step in thyroid carcinogenesis.
Eighty women (mean age 36.85±4.71 years) were evaluated by a thyroid ultrasound (US), fasting plasma insulin and HOMA IR. Subjects were divided into four groups as follows: G1 (*n*: 24),subjects with IR and obesity; G2 (*n*: 20), subjects with obesity without IR; G3 (*n*: 16), subjects with IR and normal weight; and G4 (*n*: 20) control group (without IR and obesity).
The thyroid volume (TV), measured by US, was in G1, 17.15±1.6 ml; G2, 7.4 ±1.4 ml; G3, 16.53±1.9 ml; and G4, 6.07±0.95 ml. There was no significant difference in TV between G1 and G3, but differences between G1 and G2, and between G3 and G4 were significant at $P<0.05$. The percentage of nodular thyroid glands observed by US in each group was as follows: G1, 58%; G2, 15%; G3, 50%; G4, 5%. Again, the differences between G1 and G2 and between G3 and G4 were statistically significant ($P<0.005$ and $P<0.001$, respectively, for each comparison). Our study also showed that the greater waist circumference;(as one parameter of insulin resistance syndrome by IDF), the greater thyroid volume and the higher incidence of thyroid nodules.
Conclusions
High circulating levels of insulin cause increased thyroid proliferation resulting in a large thyroid volume and the formation of nodules. Thus, the thyroid gland appears to be another victim of the insulin resistance syndrome.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1605

### Four families with nonautoimmune hyperthyroidism harboring the same thyrotropin receptor germline mutation (Asn406Ser) in Kumamoto Prefecture, Japan

A. Hishinuma[2], J. Tajiri[1], N. Nakatake[1] & S. Fukata[1]
[1]Tajiri Clinic, Kumamoto, Japan; [2]Dokkyo Medical University, Tochigi, Japan.

Nonautoimmune hyperthyroidism (NAH) due to activating mutation of the TSH receptor (TSHR) gene is extremely rare. We report 4 unrelated families with NAH experienced for the last two years in Kumamoto Prefecture, Kyushu, Japan. TSHR gene mutation site of these four families are all the same: p.Asn406Ser (heterozygous). Thyroid functions observed in these families were subclinical hyperthyroidism or overt hyperthyroidism except for one case with euthyroidism. Thyroid autoantibodies (TRAb, TPOAb, TgAb) were all negative.
[Family 1] We have already reported about this family (Clin Endocrinol (Oxf).2011).
[Family 2] 29-year-old male showing hyperthyroidism with large goiter(estimated weight:84.2g).
[Family 3] 59-year-old male showing subclinical hyperthyroidism with with nodules in the thyroid gland which was diagnosed as papillary carcinoma.
[Family 4] 40-year-old female showing subclinical hyperthyroidism with nodule in the thyroid gland which was diagnosed as papillary carcinoma. Her son had overt hyperthyroidism.
[Conclusion] This mutation(p.Asn406Ser) has not been found outside the southern Kumamoto Prefecture. Many pedigrees of NAH may have accumulated in this area.

## P1606

**Antigen mimicry between aeroallergens and thyroid antigens can modify the levels of thyroid hormones and antibodies in thyroid autoimmunity**

I. Molnar[1], E. Kelemen[2] & E. Somogyine-Vari[1]
[1]EndoMed, Debrecen, Hungary; [2]EJK, Debrecen, Hungary.

The allergic sensitization represents an environmental factor for thyroid autoimmunity and highlights a common pathway between autoimmunity and allergy. Elevated IgE levels are connected to hyperthyroid Graves' disease. The allergic sensitization in thyroid autoimmunity seems mainly to be an associated immune reaction.
Allergic sensitization to 20 aeroallergens and the levels of thyroid hormones and antibodies were studied in 121 patients with Graves' disease, 104 patients with Hashimoto's thyroiditis and 65 healthy subjects. AllergyScreen test with quantitative evaluation was applied for the detection of allergic-specific IgE levels. The levels of TSH, $FT_4$, $FT_3$ and anti-thyroid peroxidase (TPO), anti-thyroglobulin (Htg) and TSH receptor antibodies were measured.
The house-dust mite II (D2) allergic sensitization was more frequent in thyroid autoimmunity than in controls (odds ratio (OR): 2.97, $P<0.002$ in Graves' disease; OR: 3.41, $P<0.01$ in Hashimoto's thyroiditis). The allergic sensitizations to alder (T2, OR: 2.85, $P<0.03$), birch ($T_3$, OR: 3.27, $P<0.03$), ragweed (W1, OR: 2.7, $P<0.01$) and grass-mixture (Gx, OR: 2.58, $P<0.04$) were higher in Graves' patients than in those with Hashimoto's thyroiditis. The mugwort (W6) allergic sensitization was associated with increased levels of TSH receptor antibodies ($11.7\pm13.5$ U/l vs $7.9\pm17.3$ U/l, OR: 6.47, $P<0.03$). The birch ($T_3$) and the ragweed (W1) allergic specific IgE levels were associated with increased anti-TPO (OR: 3.88, $P<0.04$) and increased $FT_4$ (OR: 2.73, $P<0.04$) in Graves' disease or lower TSH levels (OR: 8.27, $P<0.004$) in Hashimoto's thyroiditis, respectively. The modifying effect of allergic sensitization did not depend on the presence of allergic symptoms.
The results in matching of amino acid sequences demonstrated a high percentage of identities (42–50%) between W1, W6, $T_3$ aeroallergens and thyroid antigens (TSH receptor, TSH, TPO, Htg).
In conclusion, the role of antigen mimicry between ragweed, mugwort, birch allergens and thyroid antigens may be responsible for the alteration in the levels of thyroid hormones and antibodies.

## P1607

**Diagnostic accuracy of elastography in thyroid nodule ultrasound evaluation. A prospective multicenter trial**

P. Trimboli[2], I. Misischi[1], S. Morgante[3], F. Graziano[1], M. Deiana[3], D. Wolosinska[3], C. Pascucci[3], A. Bonifacino[3], C. Bellotti[3], S. Valabrega[3], G. Bizzarri[1] & A. Liverani[1]
[1]Regina Apostolorum Hospital, Albano Laziale, Italy; [2]Ospedale Israelitico, Rome, Italy; [3]S. Andrea Hospital, "Sapienza" University, Rome, Italy.

Background
Real-time elastography (RTE) was reported to improve the diagnostic accuracy of B-mode ultrasound (US) examination of thyroid nodules but the results on selected series of patients are still controversial.
Aim of the study
To blindly evaluate on a consecutive series of solid thyroid nodules, devoid of confounding factors, the diagnostic accuracy of RTE and to compare it with the traditional B-mode features.
Materials and methods
From September 2010 until June 2011, 323 consecutive solid thyroid nodules underwent fine-needle aspiration biopsy (FNA) at three thyroid referral centers in Rome. B-mode US and RTE examinations (Mylab 70, Esaote, Genoa, Italy) were performed before FNA and images were stored and blindly reviewed by six experienced endocrinologists. A RTE score (from I, soft, to IV, hard) was assigned on the basis of color pattern, according to a previous classification. Twenty-six nodules (8.0%) with non-diagnostic FNA were excluded and 297 cases were enrolled in the study. Patients with indeterminate, suspicious and malignant cytology were operated upon. Nodules with benign cytology had a clinical and US control after six months.
Results
Ninety-five nodules (32%) were malignant and 202 (68%) benign. The PPV for malignancy provided by the presence of at least one conventional US risk factor (marked hypoechogenicity, microcalcifications, spiculated margins and intranodular vascularization) was 98%, and the NPV due to the absence of any US risk factor was 34%, with a 71% diagnostic accuracy. The PPV for malignancy of class III and IV RTE scores, as a whole, was 60% and the NPV was 85%, with a 75% diagnostic accuracy. When evaluated separately, marked hypoechogenicity, microcalcifications, spiculated margins and intranodular vascularization showed a 90%, 75%, 61%, and 65% diagnostic accuracy, respectively.
Conclusions
In unselected solid thyroid nodules, and in absence of confounding sonographic factors, RTE showed a diagnostic accuracy similar to the single traditional US risk factors. The PPV for malignancy provided by the presence of at least one US suspicious finding, however, was superior to that of combined class III and IV RTE scores.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1608

**FOXA1 and FOXA2 oppositely regulate human type 1 Iodothyronine deiodinase gene in liver**

N. Kanamoto[1], T. Tagami[2], Y. Ueda[1], M. Miura[1], A. Yasoda[1], H. Arai[1] & K. Nakao[1]
[1]Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]National Hospital Organization Kyoto Medical Center, Kyoto, Japan.

Type 1 iodothyronine deiodinase (D1), a selenoenzyme that catalyzes the bioactivation of thyroid hormone, is expressed mainly in the liver. Its expression and activity are modulated by several factors, but the precise mechanism of its transcriptional regulation remains unclear. In the present study, we have analyzed the promoter of human D1 (hDIO1) gene to identify factors that prevalently increase D1 activity in the human liver. Deletion and mutation analyses demonstrated that a forkhead box (FOX)A binding site and an E-box site within the region between $-187$ and $-132$ bp are important for hDIO1 gene promoter activity in the liver. EMSA demonstrated that FOXA1 and FOXA2 specifically bind to the FOXA binding site and that upstream stimulatory factor (USF) specifically binds to the E-box element. Overexpression of FOXA2 decreased hDIO1 gene promoter activity, and short interfering RNA-mediated knockdown of FOXA2 increased the expression of hDIO1 gene mRNA. In contrast, overexpression of USF1/2 increased hDIO1 gene promoter activity. Short interfering RNA-mediated knockdown of FOXA1 decreased the expression of hDIO1 gene mRNA, but knockdown of both FOXA1 and FOXA2 restored it. The response of the hDIO1 gene promoter to USF was greatly attenuated in the absence of FOXA1. Taken together, these results indicate that a balance of FOXA1 and FOXA2 expression modulates hDIO1 gene expression in the liver.

## P1609

**Dyrk1A (dual-specificity thyrosine (Y)-phosphorylation regulated kinase 1A) overexpression is linked to congenital hypothyroidism in Down syndrome**

D. Kariyawasam[1], M. Martin-Pena[1], L. Rachdi[1], A. Carré[5], M. Houlier[1], C. Dupuy[5], N. Janel[4], J. Delabar[4] & M. Polak[1,2,3]
[1]Institut National de la Santé et de la Recherche Médicale (INSERM), Paris, France; [2]APHP – Hôpital Necker Enfants Malades, Paris, France; [3]Paris, France; [4]Centre National de la Recherche Scientifique, Paris, France; [5]Centre National de la Recherche Scientifique, Villejuif, France.

Introduction
Trisomy 21 or Down Syndrome (DS) patients have a predisposition for Congenital Hypothyroidism which can aggravate their mental status.
Hypothesis
The presence of three copy of Dyrk1a gene, localized in chromosome 21 in Humans, is responsible for a thyroidal dysgenesis.
Our aim is to understand the molecular mechanisms underlying this condition.

Methods
The transgenic Dyrk1a (TgDyrk1a) mouse, our DS murine model, contains three copies of the Dyrk1a gene and was obtained through electroporation of a Bacterial Artificial Chromosome containing the entire gene with its own regulatory sequences. We studied their thyroidal phenotype in young adults (8–13 weeks old) by histology, immunohistochemistry and blood $T_4$ hormonal dosages, reflecting the thyroidal function. We compared the thyroidal molecular phenotype of the TgDyrk1a and wild type mice: RNA levels of molecules involved in the thyroidogenesis were studied by qRT-PCR at different embryonic stages.
Results
The average surface of thyroidal follicles in young adult TgDyrk1a mice is smaller (TgDyrk1a: 2164 $\mu m^2$ versus wild type: 1420 $\mu m^2$; $P=0.005$; $n=6$). They presented also a lower plasmatic $T_4$ (TgDyrk1a: 2.4 ng/ml versus wild type: 3.7 ng/ml; $P=0.019$; $n=14$). The overexpression of Dyrk1a in the thyroids leads to an elevation of RNA level expression of Nkx2-1, Foxe1, Thyroperoxidase and Thyroglobulin, involved in thyroidogenesis, at E13.5 and E17.5.
Conclusion
Our first results show an abnormal thyroid function and histology in young adult TgDyrk1a mice and an overexpression of thyroidal developmental molecules. To further understand the molecular mechanism linking Dyrk1a overexpression to altered thyroid folliculogenesis and function we are studying some candidates as direct targets of Dyrk1a using thyroidal cell lines.

## P1610

**Impaired absorption of thyroxine in occult celiac disease**

C. Virili[1], M. Santaguida[1], M. Cellini[1], I. Gatto[1], P. Gargiulo[2] & M. Centanni[1]
[1]"Sapienza" University of Rome, Latina, Italy; [2]"Sapienza" University of Rome, Roma, Italy.

Some case report suggested that increased need for thyroxine may occur in overt celiac disease (CD). However, overt CD (with typical gastrointestinal symptoms) only represents 10 to 20% of cases of CD, being the majority represented by the atypical CD and other occult forms, in which extra intestinal symptoms prevail. Few data on the need for oral $T_4$ in patients with occult CD are available. In this study we analyzed the replacement $T_4$ dose in 68 hypothyroid patients with isolated Hashimoto's thyroiditis (HT) and in 35 patients bearing both HT and atypical occult CD. We have evaluated the ability of the same dose of $T_4$ to reach target TSH in 21/35 patients before and after gluten free diet (GFD). In the remaining 14/35 CD patients, noncompliant with GFD, we have analyzed replacement $T_4$ dose and compared with the one observed in the 68 patients with hypothyroid HT without CD. In patients with isolated HT, the desired serum TSH (median = 1.02 mU/l) was reached in all patients after $5 \pm 2$ months of treatment at a median $T_4$ dose of 1.31 μg/kg per day. After similar period and dose of $T_4$, higher levels of TSH (median = 4.20 mU/l) have been observed in patients with HT and CD. In 21 CD patients, target TSH (median TSH = 1.25 mU/l) has been attained after $11 \pm 3$ months of GFD without increasing $T_4$ dose (1.32 μg/kg per day). In the remaining 14 patients, noncompliant with GFD, target TSH has been achieved but at higher $T_4$ dose (median = 1.96 μg/kg per day; +49%; $P=0.0002$) than in hypothyroid patients without CD. Our data shows that absorption of thyroxine is impaired even in occult celiac disease and this effect is reversed by GFD or overcome by increasing $T_4$ dose. Malabsorption of $T_4$ may be a tool to unveil the presence of occult forms of celiac disease in $T_4$ treated patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1611

**Frequency of PDE8B gene polymorphisms in patients affected by sporadic and familiar nonautoimmune subclinical hypothyroidism**

P. Agretti, E. Ferrarini, G. De Marco, A. Dimida, A. Molinaro, F. Niccolai, A. Pinchera, P. Vitti & M. Tonacchera
University of Pisa, Pisa, Italy.

Background
Nonautoimmune subclinical hypothyroidism is characterized by elevated serum levels of TSH in the presence of normal thyroid hormone levels and absence of anti-thyroid antibodies. As a result of a genomic-wide study, a strong association between three polymorphic variants in exon 1 of human phosphodiesterase 8B (PDE8B) gene (rs4704397, rs6885099 e rs2046045) and serum levels of TSH has been recently reported. The aim of the present study was to evaluate the frequency of PDE8B gene polymorphisms in a group of patients affected by sporadic or familial nonautoimmune subclinical hypothyroidism.
Methods
The study group comprised 113 patients affected by sporadic (101) or familial (12) nonautoimmune subclinical hypothyroidism with elevated serum TSH levels (medium serum TSH $8.997 \pm 12.48$ μU/ml) and normal free circulating $T_3$ ($FT_3$) and $T_4$ ($FT_4$) levels. Genomic DNA was obtained from whole blood of patients using standard procedures to genotype patients for specific single nucleotide polymorphism (SNP) of PDE8B gene by TaqMan SNP genotyping assay and to sequence the entire coding region of the TSH receptor (TSHr) gene.
Results
The ancestral allele associated with increased TSH level was present in 82/113 patients (73%) for rs4704397, in 79/113 patients (70%) for rs6885099 and in 84/113 patients (74%) for rs2046045. However, similar values of serum TSH were detected in patients with minor or major allele for each polymorphism. Genetic analysis revealed the presence of TSHr gene mutations at the heterozygous state (D36H, P52T polymorphic variants; P68S, R109Q and P162A mild inactivating mutations) in 17/113 patients.
Conclusion
A prevalence of the minor allele of PDE8B gene SNPs associated with elevated serum levels of TSH was demonstrated in patients affected by sporadic or familial nonautoimmune subclinical hypothyroidism, however significant differences in circulating TSH in patients with minor or major alleles for each polymorphism were not identified demonstrating the lack of association between the polymorphisms and circulating TSH levels in these patients.

## P1612

**MicroRNA expression profile helps to distinguish benign and malignant thyroid nodules starting from cells of fine needle aspiration**

P. Agretti[1], E. Ferrarini[1], T. Rago[1], A. Candelieri[2], G. De Marco[1], A. Dimida[1], F. Niccolai[1], A. Molinaro[1], G. Di Coscio[1], A. Pinchera[1], P. Vitti[1] & M. Tonacchera[1]
[1]University of Pisa, Pisa, Italy; [2]University of Calabria, Cosenza, Italy.

Objective
MicroRNAs (miRNAs) are small endogenous non-coding RNAs that pair with target messengers regulating gene expression. They are involved in biological processes including development, organogenesis, tissue differentiation, cell cycle and metabolism. Changes in miRNA levels occur in human cancers, including thyroid cancer. Fine needle aspiration (FNA) with cytologic evaluation is the most reliable tool for malignancy prediction in thyroid nodules, but cytologic

diagnosis remains indeterminate for 20% of nodules. In this study we evaluated the expression of miR-146b, miR-155, miR-187, miR-197, miR-221, miR-222 and miR-224 to distinguish benign and malignant thyroid nodules.
Methods
The study included 88 samples obtained by FNA of thyroid nodules from 86 patients (45 benign, 43 malignant). miRNA expression was evaluated by quantitative RT-PCR and statistical analysis of data was performed.
Results
All miRNAs increased in malignant nodules with respect to benign ones, but only the expression of miR-146b, miR-155, miR-187, miR-221, miR-222 and miR-224 significantly raised. Using data mining techniques we obtained a criterion able to classify a nodule as benign or malignant on the basis of miRNAs expression values. The decision model based on the expression of miR-146b, miR-155 and miR-221 was valid for 86/88 nodules (97.73%). To evaluate how much general is the criterion in correctly classifying a nodule not present in our study group, we adopted cross-validation techniques, obtaining a reliability of 78.41% (Sensitivity = 79.07% and Specificity = 77.77%).
Conclusions
The expression profiles of three miRNAs allowed to distinguish benign from malignant thyroid lesions starting from FNA, and may improve the accuracy of cytological analysis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1613

**Effect of combination therapy with potassium iodide and 15 mg of methimazole for Graves' hyperthyroidism**

Y. Mashio[1], N. Senshu[1], M. Beniko[1], H. Ikawa[1] & A. Ikota[2]
[1]Sapporo Kosei Hospital, Sapporo, Japan; [2]Kin-ikyo Sapporo Hospital, Sapporo, Japan.

Introduction
Iodide administration is generally recommended in combination with anti-thyroid drugs when a rapid return to normal thyroid hormone levels is required, such as in the treatment of patients with 'thyroid storm'. However, there are few reports concerning the combination therapy for many patients with Graves' hyperthyroidism. In this paper, we studied the effects of potassium iodide (KI) combined with 15 mg of methimazole (MMI) to the initial treatment for hyperthyroidism, and to the changes in TRAb titers and goiter sizes during 2 years treatment.
Patients and methods
One hundred and thirty-two Japanese patients, who had moderate or severe thyrotoxicosis, were divided into two groups. The patients in group A (50 cases) were treated with 50 mg of KI and 15mg of MMI once daily, and those in group B (82 cases) were treated with 15 mg of MMI alone. There were no differences in the initial data between the two groups. The mean duration of KI administration was $11.4 \pm 6.9$ weeks in group A. In both groups, the MMI doses were gradually reduced to a maintenance level after the patients became euthyroid.
Results
1 After 4 and 8 weeks of treatment, normal $FT_4$ was observed in 42% and 80% of patients in group A, and in 30% and 65% of patients in group B, respectively. The mean time required to become euthyroid was $5.9 \pm 3.5$ weeks in group A, and $7.3 \pm 3.7$ weeks in group B. The difference was statistically significant ($P = 0.008$) . 2. The mean TRAb level before therapy was $55.0 \pm 21.7$% in group A and 52.6 $\pm 22.8$% in group B. Those in both groups significantly decreased after 6 months of treatment. The percentage of TRAb-positive patients decreased from 100% before therapy to 56% after 1 year and to 43% after 2 years of treatment in group A, from 96% to 60% and to 45% in group B, respectively. The mean goiter size before therapy, shown by cm in diameter, was $5.5 \pm 1.1$ cm in group A, and 5.3 $\pm 1.1$ cm in group B. After 2 years of treatment, the mean goiter size was $5.1 \pm 0.8$ cm in group A, and $5.2 \pm 1.2$ cm in group B, respectively. There were no differences in TRAb levels or goiter sizes between the two groups during therapy.
Conclusions
These results demonstrate the combination therapy is adequate for the treatment of patients with Graves' hyperthyroidism, especially who have moderate or severe thyrotoxicosis, without increasing doses of MMI and risks of adverse reactions.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1614

**Estrogens block the apoptotic action of tgfb in human thyrocytes**

M. García-Rendueles, S. Bravo, J. Rodrigues, A. García-Rendueles, F. Barreiro, J. Cameselle-Teijeiro & C. Alvarez
CIMUS-IDIS-CHUS-USC, Santiago de Compostela, Spain.

Introduction
Multinodular Goiter (MNG) is a thyroid neoplastic disease thirteen times more common in women than in men. While a local effect of estrogens at cellular levels could affect there can be other causes to explain the gender difference in incidence such as diet, environmental factors, genetic causes or alterations in metabolic pathways.
Cellular effects of estrogens in human thyrocytes although previously studied are not completely clarified. Some reports suggest that they increase cell proliferation while others do not.
TGFb is a cytokine that has an important role in the normal function of the thyrocyte. It has two independent actions: an antiproliferative and a pro-apoptotic action. Previous results in our group, show that in the absence of other growth factors TGFb reveals its pro-apoptotic action and such action is related to a decrease in the levels of p27Kip1.
Aims
To study the effect of estrogens in the apoptotic action of TGFb in human normal thyrocytes in comparison with MNG thyrocytes.
Materials and methods
We used primary cultures of normal human thyrocytes (NT) and MNG from our bank of human thyrocytes in culture (BANTTIC). Our follicular cells in culture maintain the thyroid phenotype (TaqMan) and express alpha and beta estrogen receptors (immunohistochemistry). They were treated with TGFb or vehicle in the presence of a range of physiological concentrations of b-estradiol or vehicle following a time-course.
Apoptosis was measured by Hoescht. p27Kip1 levels were quantified by Western blot.
Results
In NT and MNG, the presence of physiological doses of estradiol (0.01 to 1 nM) blocked the pro-apoptotic effect of TGFb. In parallel, estradiol blocked the effect of TGFb on the repression of p27Kip1 levels.
Conclusions
Our results suggest an antiapoptotic action of estrogen against TGFb. This action may be mediated through p27Kip1.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1615

**TRAb level and ophthalmopathy index as predictive factors of poor response and of severity of Graves ophthalmopathy in patients treated with anti-thyroid drugs and radioiodine**

A. Baldys-Waligorska[1], S. Andrzej[2], F. Golkowski[1] &
A. Hubalewska-Dydejczyk[1]
[1]Medical College, Jagiellonian University, Krakow, Poland; [2]Cracow University of Economics, Krakow, Poland.

Introduction
In a prospective study we determined factors affecting GO activity and poor response to glucocorticoid therapy in patients treated with radioiodine (131-I group) or with anti-thyroid drugs (ATD group).
Material and methods
The ATD and 131-I groups consisted of 168 patients (mean age $52.2 \pm 11.2$ years) and of 46 patients (mean age $52.1 \pm 13.3$ years), respectively. SoluMedrol pulses (8.0 g) were applied, followed by orbital irradiation (20 Gy). Levels of TSH, $FT_4$, and TRAb, CAS and IO were evaluated in all patients prior to treatment, and 1, 6, and 12 months after.
Results
Age, sex, GO duration, IO, CAS and $FT_4$ levels were similar in patients of both groups. In the 131-I group TRAb levels were significantly higher over the course of observation ($P < 0.05$). As evaluated using logistic regression, pre-treatment TRAb concentration was related to severe GO ($IO \geq 5$) only in the 131-I group ($RR = 1.047$, 95% $CL = 1.003–1.092$, $P \leq 0.05$). Poor responders were 69/167 of ATD and 13/46 of 131-I patients who required further oral glucocorticoids following SoluMedrol pulses. Only pretreatment TSH and IO were predictive of poor response ($P < 0.05$), with $IO \geq 6$ threshold, as based on discriminant analysis (sensitivity 0.47, specificity 0.71). In the ATD group, IO was found to be correlated with TRAb concentration at 0, 1, and 6 months ($P < 0.05$; e.g. for TRAb-0 vs IO-0, $r = 0.326$). In the 131-I group, correlation was stated between TRAb concentration and IO over the time of observation ($P < 0.05$, e.g. TRAb-12 vs IO-12, $r = 0.436$).

Conclusions
Pretreatment TRAb is predictive of risk of severe GO only in 131-I patients. Pretreatment TSH and IO are risk factors of being a poor responder to glucocorticoid therapy in ADT and 131-I patients. Correlation between TRAb and IO was found in both groups.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1616

**A possible common link between Graves' disease and allergic immune response**

H. Kim[1], S. Kim[1], J. Chae[1], D. Kim[2], S. Baek[3], K. Won[4] & Y. Sung[5]
[1]Eulji University School of Medicine, Eulji General Hospital, Seoul, Republic of Korea; [2]Hanyang University College of Medicine, Seoul, Republic of Korea; [3]Korea University College of Medicine, Seoul, Republic of Korea; [4]Yeungnam University College of Medicine, Seoul, Republic of Korea; [5]Ewha Womans University College of Medicine, Seoul, Republic of Korea.

Background
The elevation of serum immunoglobulin E (IgE) has been recently reported to be associated with Graves' disease (GD). Interleukin 13 (IL-13) is a major cytokine involved in IgE synthesis and therefore may be a potential candidate gene influencing the clinical course of the GD. The aim of this study are to evaluate whether the atopic parameter such as total IgE is related to TSH receptor antibody (TRAb, thyrotropin-binding inhibitory immunoglobulin: TBII) and whether IL-13 gene polymorphisms are associated with the course of GD.
Methods
In 405 patients with GD, we investigated the history of common allergic diseases by questionnaire and measured total IgE and TRAb. We also examined IL-13 gene single-nucleotide polymorphisms in the 5' promoter region at position −1112 (C to T change, C-1112T) and in exon 4 at position −2044 (G to A change, G2044A).
Results
Log-transformed TRAb was higher in patients who had clinical symptoms of asthma ($2.30 \pm 1.44$ vs $1.79 \pm 1.36$, $P = 0.011$) and treatment history of it within a year ($3.37 \pm 2.15$ vs $1.84 \pm 1.36$, $P = 0.014$). Log-transformed TRAb was related positively with log-tranformed total IgE ($r = 0.136$, $P < 0.01$). Subdividing GD patients according to the clinical symptoms of asthma, −1112T/T + C/T genotypes had significantly increased in patients with asthma symptoms (42 vs 26%; $\chi^2 = 5.788$; $P = 0.016$). Subdividing them according to the treatment history of asthma within a year, −2044A/A + G/A genotypes had significantly increased in patients with treatment history (100 vs 51%; $\chi^2 = 4.687$; $P = 0.030$).
Discussion
TRAb was significantly related with total IgE, known as an atopic marker. TRAb and IL-13 gene polymorphisms were both significantly increased in patients with clinical symptoms or treatment history of asthma. Our results suggest that there might be a possible common link between autoimmune thyroid disease and allergic immune response.

**Subclinical hyperthyroidism (SH) in the elderly: symptoms, depression and quality of life (QoL) and relationship with TSH concentration in a prospective cohort of 110 patients**

B. Goichot[1], S. Vinzio[1], J. Kuhn[2], N. Meyer[1], J. Wémeau[4], P. Caron[3], F. Luca[1] & J. Orgiazzi[5]
[1]Hôpitaux Universitaires, Strasbourg, France; [2]CHU Rouen, Rouen, France; [3]CHU Toulouse, Toulouse, France; [4]CHU Lille, Lille, France; [5]CHU Lyon Sud, Lyon, France.

SH is defined by a decrease of TSH with normal thyroid hormone (TH) concentrations. The clinical picture is not clear, whether these patients may have symptoms or alterations of QoL. It is well known that in overt hyperthyroidism, symptoms may be absent in old patients. In SH, one study in young patients has reported an increased symptom score and a slight decrease of QoL but these results have not been confirmed in middle-aged subjects. We report the initial data of the Pirathes study, an ongoing randomized study comparing radioiodine treatment vs monitoring in SH. We particularly analyzed the results regarding the 'grade' of SCH as some authors have proposed to distinguish patients with TSH below 0.1 and patients with $0.1 \leq TSH < 0.4$ mU/l.
Inclusion criteria were: age $> 50$, durably $TSH < 0.4$ mU/l, normal TH, signs of thyroid autonomy on a thyroid scan and sinusal heart rhythm. After randomization, patients are seen every 4 months. At each visit, they fill 3 questionaries: one on thyroid related symptoms, one on anxiety and depression (HADS) and one on health-related QoL (SF36). We report here the data at inclusion of the first 110 patients included.
Patients (M27, F83) had a mean age of $64.6 \pm 8.8$, and a TSH $0.09 \pm 0.09$ mU/l. 72.6% had a $TSH < 0.1$, 26.4% between 0.1 and 0.4 mU/l. 28.8% could considered as symptomatic, mainly with symptoms of hyperthyroidism but 11% of the whole population had rather symptoms of hypothyroidism. HADS anxiety score was $8.6 \pm 3.6$ and HADS depression score $4.5 \pm 3.7$. SF36 was comparable to that of the general population (PCS $47.0 \pm 8.1$, MCS $45.5 \pm 11.9$). There were no differences between 'grade 1' and 'grade 2' patients for BMI, heart rate or blood pressure. Patients with $TSH < 0.1$ had a tendancy to be more anxious and more depressive ($-0.7$ and $-1.0$ respectively) and to have a decrease of QoL but the differences were significant only for PF and RP components of the SF36. Symptoms were also more pronounced in these patients. HADS, QoL and symptoms scores were highly correlated.
Our study shows that elderly patients with SH have few symptoms and no clear alteration of QoL. However, patients with $TSH < 0.1$ have a tendancy to be more anxious and depressed and to have slight alterations in Qol and this could bring a clinical basis to the recent concept of 'grading' SH.

**Thyroid function of Japanese elderly**

S. Kato[1], T. Kuwahara[1,2], T. Tagami[3] & S. Nishi[1]
[1]Osaka Saiseikai Ibaraki Hospital, Ibaraki, Japan; [2]Lifeport Ibaraki, Ibaraki, Japan; [3]National Hospital Organization Kyoto Medical Center, Kyoto, Japan.

Serum TSH is the most sensitive index of thyroid function in the absence of hypothalamic–pituitary disease.
However, TSH reference limits are controversial, particularly the upper limit. District and age subpopulations have unique TSH distribution. We investigated characterization of thyroid hormones in Japanese elderly. 859 participants (mean age 74.3 years) over 60 years without known thyroid disease were surveyed.
Percentages of people whose TSH were over 5.0 mU/l were respectively 9.2, 18.7, and 30.1% in male and 11.2, 15.4, and 16.4% in women among 60s, 70s, and over 80 years. A progressive increase in prevalence of TSH above 5.0 mIU/l with age existed.
Of 744 participants who were assayed concentrations of free $T_4$, 703 subjects were within limits of free $T_4$. Additionally, TSH, free $T_4$, and free $T_3$ of 610 subjects were assayed at the same time. A progressive decrease was observed in the concentration of free $T_3$ with age in both sex, and TSH mildly increased with age.
In elder people, especially over 80 year male, these tendencies were clearer. Conversion from $T_4$ to $T_3$ might be decreased in Japanese elderly.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1619

**Assessment of cognitive function in hypothyroidism using P300 evoked potentials**

R. Sahay[1], R. Reddy[2] & S. Pallagolu[1]
[1]Osmania General Hosptial, Hyderabad, India; [2]Osmania Medical College, Hyderabad, India.

The P300 wave is an event related potential which is used to assess cognitive function, it is recorded as positive deflection in voltage at latency of roughly 300 ms. P300 latency suggests that shorter latency times are related to cognitive performance. This study was undertaken to evaluate objectively effect of hypothyroidism on latencies of ERPs and response to thyroxine replacement.
Biochemically proven new onset cases with hypothyroidism were enrolled into study. After detailed history and physical examination and routine biochemical investigations P300 cognitive potentials were recorded using a Nicolet Viking Select neuro-diagnostic system version 10.0. Study was done in electrophysiology lab in Osmania Medical College.
Results
Patient characteristics (i.e age, sex, BMI) of both cases and controls were comparable. Cases consisted of 2 groups overt hypothyroid cases −24, mean TSH values in them was 94.1.subclinical −21 cases in whom mean TSH value was 12.3.
Mean P300 latencies of all cases at Cz was 342.42±29.5, and at Pz was 345.4 ±30. Mean P300 latencies of controls at Cz was 296.4±34 and at Pz was 297.9±33.Difference between cases and controls was highly significant p value $<0.001$. Mean P300 values in overt cases was 362.6±32.9 at Cz, and at Pz it was 362.5±33.9. Mean P300 values in subclinical cases was 319.3 +/30.9at Cz, and at Pz it was 316.4±27.9. P300 values in overt cases was highly significant compared to controls. Whereas p300 values in subclinical cases vs controls was just significant.
There was statistically significant difference in p300 values (at Cz and Pz) before and after treatment in overt ($P$ value $<0.001$)as well as subclinical cases ($P$ value $<0.009$).
P300 latency prolongation in both clinical and subclinical hypothyroid cases shows that cognitive function is affected adversely even in subclinical hypothyroid cases. Most psychometric tests assessing cognitive function can identify gross defects in cognition,hence these will not be able to detect subtle changes in subclinical hypothyroidism. Such subtle defects may not be of importance in elderly individuals but willaffect performance of younger individuals in day to day life.
This test of auditory evoked potentials p300 may be useful to identify patients with subclinical hypothyroidism who will benefit with treatment as against those who can be followed up.

## P1620

**Successful treatment of hyperthyroidism is associated with significant risks of overweight/obesity independent of the treatment modality employed**

B. Torlinska, R. Holder, J. Franklyn & K. Boelaert
University of Birmingham, Birmingham, UK.

Introduction
Obesity is a growing health concern in developed countries. Patients undergoing treatment for hyperthyroidism frequently express concerns regarding excessive weight gain, especially when offered treatment with I-131.
Methods
We investigated 1047 patients with overt hyperthyroidism attending a specialist thyroid clinic to determine the extent of weight changes and to identify risk factors for weight gain following treatment. Weight differences were calculated by comparing weight at presentation and at discharge from clinic.
Results
(69.4%) patients gained ≥5% of their presenting body mass (mean gain 9.9 ±0.2 kg; mean BMI increase 3.6±0.08 kg/m$^2$) during 22.03±0.42 months. 44.2% of patients with normal BMI at presentation became overweight or obese and 44.6% of overweight patients developed obesity at the end of treatment. Weight gain was most intense during the initial 6 months of treatment but continued relentlessly during 36 months when body weight had increased >10% ($P<0.001$). At discharge, the proportions of obese men and women were significantly higher when compared with age and gender specific population of the West Midlands ($P<0.001$). Similar proportions of subjects gaining weight were observed in those treated with thionamides and subjects receiving one or multiple doses of I-131 (weight gain in 66.8%,70.5%,72.3% respectively, $P$=NS) . The reporting of weight loss prior to presentation (n=702, AOR: 3.0, $P<0.001$) , higher presenting serum $fT_4$ concentrations (AOR: 1.01 per 1 pmol/l, $P<0.001$), longer treatment duration (AOR: 1.02 per month, $P=0.001$), and male gender (n=226, AOR: 1.44, $P=0.05$) were independently associated with increased probabilities of weight gain. Patients' age, smoking status, ethnic origin, weight status at presentation, the treatment modality and the development of hypothyroidism were not associated with increased likelihoods of weight gain.
Conclusion
Cure of hyperthyroidism is associated with marked weight gain and significantly increased risks of becoming overweight or obese, independent of the treatment modality employed. Subjects with more severe hyperthyroidism, those reporting prior weight loss, patients requiring longer treatment and men are particularly at risk of gaining weight.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1621

**Oral anticoagulant therapy: is it the same in hyperthyroid patients?**

C. Barbu[1,2], C. Giba[2], D. Ionita[2], S. Florea[2] & S. Fica[1,2]
[1]Carol Davila University, Bucharest, Romania; [2]Elias Hospital, Bucharest, Romania.

Aim of this study was to evaluate the effectiveness and safety of oral anticoagulant therapy in patients with atrial fibrillation and hyperthyroidism compared to those presenting the same cardiac disorder, but with normal thyroid function.
Material and methods
The study included 61 patients admitted to the Endocrinology Department in Elias Hospital between January 2011–October 2011 with mean age of 64 years: 25 patients had primary hyperthyroidism and atrial fibrillation, 36 patients had atrial fibrillation with normal thyroid function, used as a control group. The patients were followed during the hospitalization (mean period 10 days) regarding the thyroid function tests (TSH, Free $T_4$) the international normalized ratio (INR) and the dose of oral anticoagulant taken (acenocumarol).
Results
All patients (20 women and 5 men) in the hyperthyroid group had a supressed TSH (below 0.01 UI/l) and a near upper limit values of free $T_4$. They were recently diagnosed with either Graves's disease (18 pts) or toxic multinodular goiter (7 pts) and received antithyroid therapy at admitance in the hospital. The acenocumarol dose at the admitance was an average of 0.36±0.19 mg daily with an average INR of 1.8±1.1.
In the control group (23 women and 13 men refeered for thyroid disfunction but proved to have normal TSH and free $T_4$ and no history of thyroid disfunction), the average dose of accumarol was 0.71±0.2 daily at the admitance with an average INR of 2.16±0.6.
We found a significantly lower dose of acecumarol needed in the hyperthyroid patients (0.3 comparing to 0.7 mg) comparing to controls with no significant differences in the INR values between groups. Taking into account the dynamic of the INR values during the follow up, we found a significantly higher variations of the INR values in the hyperthyroid group (from 1.8 to 2.7 average). In this group we have noticed 5 cases of minor adverse effects comparing to none in the control group during the follow up period.
Conclusion
Achieving and maintaining target levels of efficiency and safety of oral anticoagulant treatment throughout the hyperthyroidism might be more difficult due to important fluctuations of INR values during the antithyroid treatment.
Therefore hyperthyroid patients require more frequent monitoring of INR because imbalances especially in the sense of overdose are unpredictable and can have serious consequences.

**Thyroid hormone abnormalities in haemodialyzed patients: low triiodothyronine as well as high reverse triiodothyronine are associated with increased mortality**

J. Horacek[1], S. Dusilova Sulkova[1,2], M. Kubisova[1], R. Safranek[1], E. Malirova[1], M. Kalousova[3], I. Svilias[1], J. Maly[1], L. Sobotka[1] & P. Zak[1]
[1]Faculty of Medicine and University Hospital Hradec Kralove, Charles University in Prague, Hradec Kralove, Czech Republic; [2]Institute of Clinical and Experimental Medicine, Prague, Czech Republic; [3]1st Faculty of Medicine and University Hospital Prague, Charles University in Prague, Prague, Czech Republic.

Objective
Numerous abnormalities of thyroid hormones in end-stage renal disease (ESRD) have been described. Our aim was to analyze the impact of these abnormalities on survival.
Design
In 167 haemodialyzed ESRD patients, TSH and thyroid hormone levels (including reverse $T_3$, i.e. $T_4$, $fT_4$, $T_3$, $fT_3$, $rT_3$) were determined. The patients were then prospectively followed up for up to 5 years and the possible impact of any observed abnormalities on their mortality was studied.
Results
Only 16.8% patients had all six tests within the reference range. The pattern of nonthyroidal illness syndrome was found in 56.3%. Low $T_3$ was particularly common (44.3%), and clearly associated with increased 6- and 12-month mortality and decreased overall survival (log-rank test, $P=0.007$). Independent of $T_3$ levels (Spearman correlation, NS), increased $rT_3$ was more frequently observed (9.9%) than expected from the literature, and was also related to increased mortality and decreased survival (log-rank test, $P=0.021$).
Conclusions
Increased $rT_3$ may be more common in ESRD patients than previously expected, and together with decreased $T_3$ it may serve as an indicator of poor prognosis in subsequent months.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Perioperative clinical outcomes after robot-assited thyroid surgery by transaxillary approach**

D. Axente & N. Constantea
Cluj-Napoca County Hospital, Cluj-Napoca, Romania.

Background
Many endoscopic minimaly invasive procedures have been developed and are used now in thyroid and parathyroid surgery. However, the endoscopic approach is more technically demanding and due its limitations, endoscopic thyroidectomy remains limited in application and practiced in a relatively small number of centers. Recently robotic technology has been also applied to thyroid surgery. The aim of this study is to present our experience and to demonstrate the technical feasibility, intraoperative safety and efficacy of robotic thyroidectomy.
Methods
The technique that we are practicing use the unilateral transaxillary approach without gas insufflation. We used the da Vinci SI Surgical Robotic System for all interventions and we performed 35 total unilateral lobectomy and 7 total thyroidectomy. Patients were diagnosed with unilateral thyroid nodules and 7 of them, whit bilateral thyroid nodules. For each patient we analyzed the clinical characteristics, tumor size, pathologic type, operative time, amount of drainage, duration of hospital stay, postoperative complications, postoperative neck and anterior chest pain, and cosmetic satisfaction.
Results
All operations were performed successfully without any need for conventional open conversion. The mean overall operation time was 155 min respectively 80 min console time. The mean tumor size was 3.5 cm. There was one temporal brachial plexus neuropraxia and 4 wound seroma. There were 2 malignant thyroid lesions at the final histopathological results. In this situation we perform total thyroidectomy by open cervicotomy during the same hospitalisation.
Conclusions
Robotic technology overcame some technical limitations associated with conventional endoscopy. Robotic thyroidectomy by gasless transaxillary method is feasible, safe, and provided good outcomes.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1624

**Hyperthyroidism in patients with acute atrial fibrillation attended at an emergency room**

C. Moreno, H. Esperto, N. Silva, I. Fonseca, L. Ruas, A. Vieira, M. Alves, G. Sofia, J. Saraiva, J. Nascimento Costa & M. Carvalheiro
University Hospitals of Coimbra, Coimbra, Portugal.

Introduction
Atrial fibrillation (AF) is the most common cardiac complication of hyperthyroidism, with significant mortality and morbidity resulting from embolic events. In patients who attend at an emergency room (ER) with acute AF, the thyroid hormones aren't usually evaluated given the low prevalence of hyperthyroidism in the general population.
Aims
To assess the prevalence of thyroid dysfunction in adult patients who presented at an ER with acute AF.
Methods
Prospective study of consecutive patients with acute AF that attended our hospital's ER; excluded those with hypothalamic or pituitary disease, pregnancy, corticosteroid or dopamine therapy, hemodynamic instability. Selected as controls patients in sinus rhythm who presented at the ER on the same period of time. All patients answered a brief questionnaire (age, medications in use, medical history, saline restriction), underwent clinical examination, electrocardiogram and blood samples for thyroid function tests. Those with an altered serum TSH level were subsequently reevaluated for confirmation of thyroid dysfunction.
Results
Total of 105 individuals, 61 patients (acute AF) and 44 controls (sinus rhythm). Cases had a higher prevalence of thyroid dysfunction (37.7% vs 9.1%, $P=0.001$), total hyperthyroidism (24.6% vs 2.3%, $P=0.002$), overt (14.8% vs 0%, $P=0.008$) and subclinical hyperthyroidism (9.8% vs 2.3%, $P=$n.s.). There was a negative correlation between serum TSH levels and heart frequency of the arrhythmia ($\rho=-0.36$, $P=0.004$) and also between serum TSH levels and the number of anti-arrhythmic drugs necessary for treatment ($\rho=-0.313$, $P=0.014$). The odds-ratio of an acute AF patient having hyperthyroidism was 14.02.
Conclusions
The high prevalence of hyperthyroidism in patients with acute AF attended at our ER suggests that routine thyroid testing is required. Serum TSH level negatively correlates with heart frequency, emphasizing the importance of thyroid function in conversion to sinus rhythm.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1625

**Alterations in adiponectin concentration in hyper- and hypothyroid patients; possible underlying mechanisms and role of metformin treatment in experimental animals**

N. Ramadan, H. Shawky, N. Ghanem & M. Gamal
Faculty of Medicine, Cairo University, Cairo, Egypt.

Recent reports on the interplay between adiponectin, thyroid hormones and metformin have given conflicting results. Our study aimed to investigate adiponectin concentration in thyroid disorders and to assess the possibility of involvement of adiponectin in the regulation of thyroid hormone production, also to clarify the role of pituitary-thyroid axis in the modulation of adiponectin production and to assess the interplay between metformin treatment, thyroid function and adiponectin. The study was designed on 2 modules; In the human 30 study females were included in 3 groups; control, hyperthyroid and hypothyroid. Body mass index (BMI), serum adiponectin, thyroid profile, total cholesterol

(TC), high density lipoprotein(HDL) and HOMA-IR were measured. In the animal study, female albino rats divided into control, experimentally-induced hyperthyroid, experimentally-induced hypothyroid, hyperthyroid + metformin, hypothyroid + metformin groups. gC1q gene expression (in thyroid tissue), adiponectin, TSHr, PPARγ in adipose tissue were measured. Results: increased serum adiponectin, decreased BMI, unchanged HOMA-IR or lipid profile in hyperthyroid patients. Decreased serum adiponectin and HDL, increased TC and HOMA-IR in hypothyroid patients. increased adiponectin expression in hyperthyroidism rats and its decrease in hypothyroidism without observed weight changes with unchanged TSHr expression in different thyroid states. In hypothyroidism decreased PPARγ expression which was improved by metformin, which also improved thyroid function and adiponcectin expression. Decreased gC1q expression in thyroid disorders and its increase by metformin. Conclusion: increased adiponectin concentration and expression in hyperthyroidism and their decrease in hypothyroidism. These observed changes in adiponectin could contribute to changes in HOMA-IR and lipid profile detected hyper and hypothyroidism. Adipose tissue TSH receptors are not involved in the modulation of adiponectin production. In case of hypothyroidism, there is a link between decreased adiponectin secretion and expression, decreased PPARγ receptors and dyslipidemia. Metformin improved thyroid function in hypothyroidism and has an antiapoptotic effect in both thyroid disorders.

## P1626

### A liquid formulation of L-thyroxine (L-T4) solves problems of incomplete normalization/suppression of serum TSH caused by proton pump inhibitors (PPI) on conventional tablet formulations of L-T4

G. Saraceno[1], R. Vita[1], F. Trimarchi[1] & S. Benvenga[1,2,3]
[1]Policlinico Universitario, Messina, Italy; [2]Università di Messina, Messina, Italy; [3]A.O.U. Policlinico G. Martino, Messina, Italy.

Background

PPI are known to diminish the intestinal absorption of L-T4, which is commonly ingested as tablets of L-T4 sodium salt. However, a liquid formulation is available (Tirosint, oral solution, IBSA Farmaceutici Italia s.r.l., Italy), in which the hormone is solubilized in 28.8% ethyl alcohol. One ml of this formulation (=28 drops) contains 100 mcg L-T4 sodium salt in 243 mg ethanol. Because this formulation contains L-T4 (which is a lipophilic hormone) already solubilized in an organic solvent, as opposed to L-T4 contained in a powder within a tablet, there could be the advantage of virtually skipping the dissolution in the stomach, and subsequent quick, direct arrival of L-T4 in the upper intestine segments (duodenum, jejunum) where most of it is absorbed.

Patients & methods

Upon consent, 1 woman under replacement therapy [100–125 mcg/day] and 9 patients (7 women and 2 men) under TSH suppressive therapy [82–135 mcg/day], all 10 with PPI-induced malabsorption of LT4, were switched to Tirosint oral solution while maintaining the daily dose of L-T4 and continuing ingesting the PPI as before. The PPI were: lansoprazole, omeprazole or pantoprazole. Post-switch serum TSH was re-assayed after a minimum of 2 months.

Results

In the hypothyroid woman, TSH fell to 2.0–2.7 mU/L down from 5.0–7.3. In the other 9 patients, TSH fell to $<0.01$ to 1.97 mU/L (median: 0.10; mean $\pm$SD: $0.68 \pm 0.91$), down from 0.28–2.95 (median: 0.81; mean $\pm$SD $1.02 \pm 0.74$; $P=0.0004$ by ANOVA after log10-transformation), and with 65% of the post-switch TSH levels at 0.10 mU/L or below compared to 0% (zero%) of the pre-switch levels ($P<0.0001$ by Fisher's exact test).

Conclusion

The liquid formulation of L-T4 is an extremely effective means to circumvent the problem of incomplete absorption of the L-T4 caused by the PPI-induced increase of the gastric pH.

### Serum chemokine CXCL10 is increased in chronic autoimmune thyroiditis associated with autoimmune gastritis

M. Santaguida[1], S. Ferrari[2], S Del Duca[1], P. Fallahi[2], M. Centanni[1] & A. Antonelli[2]
[1]"Sapienza" University of Rome, Latina, Italy; [2]University of Pisa, School of Medicine, PISA, Italy.

Autoimmune thyroiditis (AT) may occur as a single disease or associated with further endocrine and non endocrine autoimmune diseases (NEAD). Chronic autoimmune gastritis (CAG) is the more frequently associated NEAD. A prevalent Th1-representative pattern of cytokines and chemokines has been described in isolated autoimmune thyroiditis. However, the behaviour of chemokines when AT is associated with CAG is not known. Aim of the study has been to measure serum levels of CXCL10 in patients with chronic autoimmune thyroiditis in association with CAG. Serum CXCL10 was assayed in 95 consecutive AT patients, in 95 gender and age-matched healthy volunteers (Controls, C) and in 45 patients with autoimmune thyroiditis plus CAG. All patients studied were free from: a) active infectious diseases in the last three months; b) treatment with drugs known to interfere with immune system, namely cytokines, interferon, corticosteroids, NSAIDs, amiodarone, lithium; c) pregnancy and lactation over the previous 6 months; d) the presence of acute or chronic systemic diseases. High CXCL10 levels (defined as a value higher than mean+2SD of controls; i.e. $>103$ pg/ml) were observed in 3% of controls, in12% of patients with isolated AT and in 45% of patients with AT+CAG, ($P<0.0001$). Hence, the mean serum levels of CXCL10 were significantly higher in patients with AT, isolated or associated with CAG, than in control subjects ($C=49 \pm 27$ pg/ml, $AT=74 \pm 29$ pg/ml, $AT+CAG=126 \pm 121$ pg/ml; $P=0.003$). Moreover, AT+CAG patients also showed significantly higher CXCL10 levels than those with isolated AT (Bonferroni-Dunn: $P=0.0004$). In conclusion, in patients with AT and autoimmune gastritis, circulating CXCL10 concentrations are significantly higher than in patients with isolated autoimmune thyroiditis.

## P1628

### Association between preoperative value of TSH and pathological findings in nodular thyroid disease

M. Paja, E. EtxeberrÍa, N. Iglesias, T. Gutiérrez, A. Ugalde, A. Oleaga, V. Arosa & R. Elorza
Hospital de Basurto, Bilbao, Spain.

Higher serum TSH has been recently postulated as a predictor of thyroid malignancy in nodular thyroid disease. In addition, some reports have demonstrated its association with more advanced stages of differentiated thyroid cancer (DTC).

Material and methods

We collected retrospectively preoperative serum TSH from patients who underwent total thyroidectomy in the period 2005–2011 in a single tertiary center. We recorded demographic data, nodule number, tumour size and final anatomic pathology. Patients with Graves disease or primary hypothyroidism under treatment previous to surgery were excluded, and so were cases with medullar or anaplastic thyroid cancer.

Results

524 patients including 187 with malignancy; 453 females, 154 with malignancy (34%), as 33 of the 71 males (46.5%). Patients with cancer were younger ($51.6 \pm 14.7$ yr) than those with benign nodules ($55.7 \pm 14.3$ yr, $P<0.001$). It was uninodular disease in 17.2% of benign disease and 34.2% of diagnosed as malignancy ($P<0.0001$). Preoperative mean TSH levels were higher in patients with malignancy vs. benign pathology ($2.53 \pm 2.5$ vs. $1.50 \pm 1,8$; $P<0,0001$). Out of the 187 cases of DCT, 48 were incidental microcarcinomas (INCM), with mean TSH of $2.10 \pm 1.82$, still different from bening cases ($P=0.004$). Excluding these, the mean TSH was $2.68 \pm 2.69$ in the remaining DTC ($P<0.001$ vs INCM). There was difference in mean TSH between follicular adenomas (FA) (n:65; $2.51 \pm 3$) and hyperplastic goitres (n:264; $1.21 \pm 1.2$); but no between FA and CPT ($P=0.25$). Median TSH in DTC shows a tendency to be higher with bigger tumour size (1.78 vs 2.14; $\leq 2$ vs $>2$ cm; $P=0.099$).

Conclusions
Our series, as others published, depicts benign lesions having lower TSH level, with difference between pathologic subtypes, while DTC, and similarly to FA, being associated with higher level. The correlation among histotype, tumour size and TSH level suggests a role of TSH in the carcinogenesis of DTC and pathogenesis of FA.

## P1629

**Clinical presentation (symptoms and complications) of hyperthyroidism in a cohort of 1,144 patients: results of the Thyrdel study**

B. Goichot[1], S. Bouée[4], N. Ndaye[1], P. Caron[2] & F. Landron[3]
[1]Hôpitaux Universitaires, Strasbourg, France; [2]CHU, Toulouse, France; [3]Lyon, France; [4]Bourg la Reine, France.

Symptoms and physical signs are variable and non specific in hyperthyroidism (HT). We report the results of a large study conducted among 263 French endocrinologists. Each investigator was asked to include all consecutive patients seen for HT during the study period. For each patient, symptoms, physical signs, biological data and treatment were recorded. The endocrinologists included 1,144 patients with HT: 802 Grave's disease (GD), 121 multinodular goitres (MNG), 112 iatrogenic HT (mainly amiodarone), 69 toxic adenoma and 40 thyroiditis. 18.3% had subclinical HT (GD 11.0%, MNG 49.5%, iatrogenic HT 7.9%, toxic adenoma 61.4%, thyroiditis: 35.3%).
Mean age was 48.7 years (ranging from 42.7 for thyroiditis to 63.6 for MNG), 76.3% were females (78 to 83.5% for every etiology except for iatrogenic: 27.2%) Most patients (81.9%) were diagnosed because they had clinical signs of HT except those with iatrogenic HT (mainly diagnosed by specific screening): 72.1% had palpitations, 74.5% had fatigue, 28.4% had digestive symptoms, 51.8% had thermophobia/sweating/polydipsia, 65.5% tachycardia, 16.7% had arrythmia (more frequently among iatrogenic HT: 55.4% and MNG: 24.2%), 66.5% weight loss (on average $-6.3$ kg), 32.2% had a clinical goiter. Symptoms were more frequent among GD, toxic adenoma and thyroiditis. Palpitations, thermophobia/sweating/polydipsia and weight loss (but not the other signs) were more frequent among patients whose TSH was below 0.1 mU/L compared to patients with $0.1 < \text{TSH} < 0.4$ mU/L ($P < 0.05$). Patients older than 65 years had less thermophobia/sweating/polydipsia symptoms, slower heart rate but more cardiac arythmia compared with younger subjects. More than 2/3 of patients with subclinical HT had at least one symptom of HT, they had a significantly higher heart rate but no symptom appeared discriminant with overt HT.
This large cohort study will improve our knowledge on epidemiological and clinical presentation of HT.

**Beta (CCL2) and alpha (CXCL10) chemokines modulation by cytokines and by peroxisome proliferator-activated receptor-alpha agonists in Graves' ophthalmopathy**

A. Antonelli, S. Ferrari, S. Sellari-Franeschini, A. Corrado, C. Mancusi, M. Ferrini, E. Ferrannini & P. Fallahi
University of Pisa, Pisa, Italy.

Introduction
No study has evaluated the effect of cytokines on the prototype beta chemokine (C-C motif) ligand (CCL)2 in Graves' ophthalmopathy (GO), nor of peroxisome proliferator-activated receptor (PPAR)alpha activation on this chemokine secretion in fibroblasts or preadipocytes in GO.
Design and methods
We have tested the interferon (IFN)gamma and tumor necrosis factor (TNF)alpha effect on CCL2, and for comparison on the prototype alpha chemokine (C-X-C motif) ligand (CXCL)10, and the possible modulatory role of PPARalpha activation on these chemokines secretion in normal and GO fibroblasts or preadipocytes in primary cell cultures.
Results
The present study shows that IFNgamma alone, or in combination with TNFalpha was able to stimulate the secretion of CCL2 in primary orbital fibroblasts or preadipocytes from patients with GO, at levels similar to those observed in controls. IFNgamma and TNFalpha stimulated also CXCL10 chemokine secretion as expected. The presence of PPARalpha and -gamma in primary fibroblasts or preadipocytes from patients with GO has been confirmed. PPARalpha activators were able to inhibit the secretion of CXCL10 and CCL2, while PPARgamma activators were confirmed to be able to inhibit CXCL10, but had no effect on CCL2. PPARalpha activators were stronger inhibitors of chemokines secretion than PPARgamma agonists.
In conclusion, CCL2, and CXCL10, are modulated by IFNgamma and TNFalpha in GO. PPARalpha activators are able to inhibit the secretion of the main prototype alpha (CXCL10) and beta (CCL2) chemokines in GO fibroblasts or preadipocytes, suggesting that PPARalpha may be involved in the modulation of the immune response in GO.

**Thyroid function in large elderly population – results of multicenter study performed in Poland**

E. Bar-Andziak[1], A. Milewicz[2], D. Jedrzejuk[2], A. Arkowska[2], U. Mieszczanowicz[2], B. Krzyzanowska -Swiniarska[3] & J. Sierdzinski[1]
[1]Medical University of Warsaw, Warszawa, Poland; [2]Medical Academy of Wroclaw, Wroclaw, Poland; [3]Pomeranian Medical University, Szczecin, Poland.

Multidimensional studies of medical aspects of ageing were performed in 6 provinces of Poland, the protocol included cross sectional analysis of thyroid function parameters.
The sample was randomly chosen and included 4,051 respondents (49.2% females).
Group consisted of 3,502 elderly subjects aged 65–90+y, divided into approximately equal six age subgroups; and 549 younger cohort, aged 55–59 y.
Thyroid function was assessed by TSH measurement (IRMA, reference range 0.2–4.5 mIU/ml.). Clinical data were not included.
Mean TSH concentration in the population was $2.55 \pm 6.7$ mIU/ml; median 1.6. Gender related differences were found. TSH was higher in women than in men ($2.9 \pm 8.6$ vs $2.2 \pm 4.6$; $P < 000018$); median respectively:1.7 and 1.55. In 25% of the cohort TSH exceeded 2.5 mIU/ml. TSH did not differ between age subgroups.
About 11% of the population had abnormal TSH suggesting thyroid dysfunction.
Among elderly subjects 7.9% were assessed as hypothyroid (10% women and 5.6% men) and 2.9% as hyperthyroid (3.5% women and 2.4% men).
In the youngest group 7.65% were hypothyroid and 1.8% hyperthyroid.
Upon the simultaneous fT4 measurements, thyroid dysfunctions were classified as subclinical in 98% hypothyroid and in about 70%. of hyperthyroid subjects. Most of cases of advanced thyroid dysfunction were found among the oldest subjects.
Conclusions
This large population study revealed thyroid dysfunction in over 10% elderly subjects. There is some possibility of misinterpretation of TSH resulting from the influence of extrathyroidal factors; yet wide reference range of TSH used in this study decreased this risk.
This study reminds the need of careful attendance to the dysfunctions in elderly patients, especially that symptomatology of thyroid disease in this age groups can be misleading.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1632

**Late manifestation of subclinical hyperthyroidism after goitrogenesis in an index patient with a N 670 S TSH receptor germline mutation causing familial non-autoimmune autosomal dominant hyperthyroidism (FNAH)**

S. Paschke[1], M. Oezerden[2], J. Schaarschmidt[1], H. Jaeschke[1], S. Huth[1], M. Eszlinger[1], J. Meller[2] & R. Paschke[1]
[1]Leipzig University, Leipzig, Germany; [2]Goettingen University, Goettingen, Germany.

In the 27 families with FNAH the onset of hyperthyroidism varies from 18 months to 60 years. Also the manifestation of goiters is variable in these families.
A 74 year old women first presented at the age of 69 years in 9/2006 with tachyarrythmia and hypertension. After the initial treatment of her hypertension and oral anticoagulation for her intermittant atrialfibrilation 3/2007 a thyroid workup revealed a suppressed TSH of 0.029 (normal < 0.4 mU/l) and normal fT3 and fT4. TPO, TSH-receptor and thyreoglobulin antibodies were negative. Thyroid ultrasound reveiled a thyroid volume of 102 ml with several nodules with diameters of up to 2.6 cm right and up to 1.8 cm left. Szintigraphy showed a homogeneous Tc uptake of 1.95%. She was treated with 1 GBq I 131 in 6/2007 which normalised her thyroid function untill 12/2007 (TSH 3.05 mU/L). Her brother and sister do not suffer from thyroid diseases. Her 45 year old daughter and her 16, 12 and 11 year old grandsons do not have symptoms of hyperthyroidism and display normal TSH, fT3 und fT4.
Because of the diffuse Tc uptake and the negative TPO, TSH-receptor and thyreoglobulin antibodies her TSH receptor gene was analysed in DNA extracted from EDTA blood.in spite of her negative family history for hyperthyroidism. Sequencing revealed a N 670 S TSH receptor germline mutation. This TSH receptor germline mutation's constitutive activity could previously only be demonstrated in HEK but not in COS cells (Mueller et al. 2009).
This case illustrates the necessity to analyse patients with hyperthyroidism accompanied by diffuse Tc uptake and negative TPO, TSH-receptor and thyreoglobulin antibodies (so called antibody negative Graves' disease) for TSH receptor germline mutations. Moreover, it illustrates that TSH receptor germline mutations may first lead to long standing nodular goitrogenesis before the late manifestation of subclinical hyperthyroidism.

## P1633

**The alterations of the endothelial function, haemostatic and inflammatory parameters in subclinical and overt hyperthyroidism**

A. Poplawska-Kita, K. Siewko, A. Modzelewska, J. Mysliwiec, J. Dzieciol, M. Górska & M. Szelachowska
Medical University of Bialystok, Bialystok, Poland.

Subclinical hyperthyroidism (SH) is characterised by supressed serum TSH concentration accompanied by fT3 and fT4 levels maintained within their reference ranges. The vascular endothelium as a specific target of thyroid hormones is strongly affected in hyperthyroidism. We aimed to compare the alterations of the endothelial function, haemostatic and inflammatory parameters in patients with SH in comparison with overt hyperthyroidism (OH) due to Graves' disease and toxic nodular goiter. In the present study, we determined serum levels of soluble forms of ICAM-1, VCAM-1, vWF, IL-6, IL-12, IL-18 and CRP to elucidate a possible role of those parameters as markers of endothelium dysfunction (ED). 117 patients were included into the study: 56 patient with OH, 61 with SH and 39 euthyrotic controls (CG). In our study fibrinogen, vWF, PAI-1 and VCAM-1 levels increased significantly in study groups compared with the CG. We also found an increase in serum CRP, IL-6, IL-12 and IL-18 levels in OH and SH groups. In SH group we observed the highest levels of serum CRP and IL-6. Similar values for sICAM-1, E-selectin were demonstrated in study and CG. These results may reflect a relative hypercoagulability state both in subjects with SH and OH. In summary, our results suggest that hyperthyroidism is accompanied by the endothelial damage, which depends both on the cause of thyrotoxicosis and on degree of hyperthyroidism. Elevated concentrations of the markers of the endothelial damage may serve as a confirmation that persons with hyperthyroidism are extremely predisposed to the occurrence of the cardiovascular diseases.

## P1634

**Prediction of remission rate in the patients with Graves' disease after treatment with a minimum maintenance dose of Methimazole**

M. Beniko, H. Ikawa, T. Mori, H. Kudo, A. Matsumoto, M. Sekiguchi & Y. Mashio
Sapporo-Kosei Hospital, Sapporo, Japan.

Introduction
According to the guideline for medical treatment of Graves' disease by the Japan Thyroid Association in 2011, discontinuation of antithyroid drug is recommended when normal thyroid functions have been maintained for a certain period ($\geq$6 months) after treatment with a minimum maintenance dose (mentioned below). We prospectively studied the remission rates in the patients with Graves' disease.
Methods
The subjects were 108 patients with Graves' disease, who were newly diagnosed from 2003 to 2008 (mean age, 46.2$\pm$13.2 years old, 22 men and 86 women). They were treated with methimazole (MMI) at the initial dose of 15 mg/day. MMI doses were gradually decreased to minimum maintenance dose (5 mg every other day).In this study, the duration of minimum maintenance dose was defined as 12 months. We finally discontinued MMI when their serum FT4 and TSH had been kept within normal range for 12 months. After discontinuation of MMI, they were followed every 4–6 months to confirm continuous remission.
Results
Eighty-six patients could reach minimum maintenance dose. The percentage of patients who reached minimum maintenance dose was 46% at 1 year, 68% at 2 years and 78% at 3 years. In 63 patients, in whom MMI was stopped after therapy for 23$\pm$8 months, remission rates were 86% at 1 year, 74% at 2 years and 67% at 3 years after MMI discontinuation. The levels of TRAb (TRAb-CT) and the ratio of TRAb positive patients at the time of drug cessation were 13% and 46% in remission group after 2 years. In relapse group within 2 years, those were 15% and 46%, respectively. There were no differences between the two groups.
Conclusion
The present study indicates that a minimum maintenance dose of MMI to keep euthyroid state for 12 months is a useful and practical procedure for treatment of Graves' disease.In this protocol, TRAb might give little additional informations for prediction of remission.

## P1635

**Predictors of relapse of Graves' disease after thionamide drugs treatment in clinical practice**

V. Peña, A. Vicente, E. Maqueda, J. Sastre, F Del Val, A. Marco, I. Luque & J. López
Hospital Virgen de la Salud, Toledo, Spain.

Background
One of the main drawbacks of primary treatment of Graves' disease (GD) with thionamide drugs (TD) is the high relapse rate estimated to be 50–60%. Fear about side effects, specially agranulocitosis and hepatic complications, is other drawback of this treatment option.
Objective
To evaluate the clinical and/or biochemical characteristics that might predict relapse in patients with GD treated with TD.
Design and patients
Clinical records of 264 hyperthyroid patients due to GD referred to our hospital outpatient clinic between 1998 and 2008 were reviewed. They were treated with a course of TD at least 6 months. TD were stopped when they had undetectable thyroid-stimulating antibodies (TSAbs) and/or were euthyroid. At the end of the treatment, patients were followed-up for at least 1 year.
Results
214 patients were females. Mean age at diagnosis was 40.38$\pm$13.68 years (14-80). Mean treatment duration was 19.9$\pm$6.2 months (6–51). Only seven patients were treated with propylthiouracil. Mean time of follow-up after stopping TD was 30.5 months. Relapsing Graves' hyperthyroidism was observed in 154 (58.3%) patients. In univariate analysis, relapse was associated with younger age ($P<0.05$), higher level at diagnosis of free thyroxine (T4) ($P<0.05$) and free triiodothyronine (T3) ($P<0.001$) and higher TSAbs levels at the end of the TD course ($P<0.0001$). By multivariate analysis only initial free T4 and free T3 levels and TSAbs level at withdrawal were indepently associated with relapse. The percentage of relapsing patients at 12, 24 and 60 months after discontinuation of TD was 60.1%, 82.5% and

94.4%. Only 36 patients (13.6%) have maintained euthyroidism after 60 months of TD withdrawal. No major adverse reaction was observed. Minor adverse effects occurred in 11 patients (4.2%).
Conclusions
Hyperthyroidism relapse in patients with GD treated with TD in our study group was associated with analytical features of severe hyperthyroidism at diagnosis and higher TSAbs levels before stopping TD. Moreover, a low percentage of patients were in remission after 60 months of TD discontinuation. This may help early consideration of alternative therapy for those patients who have aggressive disease at diagnosis and/or who are TSAb-positive before TD withdrawal. In our study, TD showed to be safe, with a low rate of minor adverse effects.

## P1636

**The significance of TSH receptor blocking antibody levels in gestational stage**

Maiko Nishizawa[1], Toshiyuki Horiuchi[1], Fumiko Iwashima[1], Sayaka Suzuki[1], Masanori Murakami[1], Yoshiko Ohtaka[1] & Hiroshi Fukazawa[2]
[1]Tokyo Metropolitan HMTC Toshima Hospital, Tokyo, Japan; [2]KKR Suifu Hospital, Mito, Japan.

Background & objectives
There are multiple forms of functional TSHR autoantibodies which stimulate or inhibit the thyroid. The TSH-Receptor blocking antibody (TSBAb) exists in the serum of Graves' disease, which is functionally different from TSH receptor stimulating antibody (TSAb). TSBAb that blocks the action of TSH is also associated with idiopathic myxedema and some Hashimoto's disease. We measured TSBAb levels and evaluated the pathogenetic significance of TSBAb in gestational women.
Subjects & methods
Thirty two Japanese pregnant women were enrolled to measure TSBAb, TSAb, thyroglobulin antibody (TgAb) and anti-thyroid peroxidase antibody (TPOAb), TSH, free T4 and Free T3. Thyroid function was evaluated with TSH levels (standard values; 0.55 to 4.18 μU/l). The biological activity of TSBAb were assayed with porcine thyroid cell suspensions using cAMP measurement by RIA.
Results
Demographic data were $30.2 \pm 6.2$ years olds for age, $12.6 \pm 5.3$ weeks for the gestational stage, thirteen women on hyperthyroidism, four women on hypothyroidism and fifteen women on euthyroidism. TSBAb levels in pregnant women were not correlated with the gestational periods. In thirteen hyperthyroid and fifteen euthyroid state TSBAb were within normal range, whereas three of four hypothyroid women demonstrated high levels of TRBAb (more than 45.6%). Two hypothyroism subjects with high titer of TRBAb, TgAb and TPOAb.
Speculation & conclusions
In the gestational stages thyroid function varies from hypo- to hyper-function of thyroid, our results suggested that TSBAb might play an important role in hypothyroidism of the pregnant women with or without Hashimoto's disease.

## P1637

**Evidence of humoral response to extracellular matrix proteins in Grave's diseace and thyroid associated ophtalmopathy**

M. Romano[1], B. Capuani[1], R. Bei[1], C. Nucci[1], D. Pastore[1], A. Andreadi[1], G. Sconocchia[2], M. Caputo[1], A. Modesti[1], D. Lauro[1], A. Bellia[1] & A. Bertoli[1]
[1]University of Rome "Tor Vergata", Rome, Italy; [2]National Council Research (CNR), Rome, Italy.

Thyroid Associated Ophtalmopathy (TAO) is considered one of the most difficult pathologies to treat and a big threat for Graves Disease (GD) patients. This has enhanced the interest in finding a marker that can predict the onset and the prognosis of TAO. It has been demonstrated that GD is a chronic inflamed tissue that there is a remodelling of the ECM structure which elaborate inflammatory signals itself and also promotes the recruitment of cells from the bloodstream; these events can lead to ECM self-epitopes exposition and induce autoimmune phenomena.
Aim of this study, is to determine whether the occurrence of anti-ECM autoantibodies is associated with GD and TAO.
We studied 50 outpatients affected from GD (24 affected by TAO) and 40 healthy donors: sera were assayed for the presence of autoantibodies to CI, CIII, CIV, CV, LM and FN. When compared with HD control sera, GD sera resulted significantly positive to all individual anti-ECM antibodies of the IgG and IgM isotype with exception of the anti-LM IgM antibodies. Remarkably, anti-CIII autoantibodies were significantly associated with GD TAO+ patients ($P = 0.045$).
Our results demonstrated that among the anti-ECM autoantibodies in GD patients those reacting with CIII were able to discriminate $TAO^+$ from $TAO^-$ GD patient cohort.
In conclusion our results suggest an involvement of anti-ECM antibodies also in GD and a possible specific role of anti-CIII IgG in TAO GD patients.
Declaration of interest

## P1638

**Thyroid dysfunction in rheumatoid arthritis**

F. Mohammadi, S. Zayeni, A. Jafarnejhad, M Hedayati Omami & N. Amini
Guilan University of Medical Sciences, Rasht, Islamic Republic of Iran.

Introduction
Rheumatoid arthritis, the most common inflammatory arthritis, is commonly seen with thyroid hormone autoantibodies and thyroid dysfunction.In this survey we evaluate the thyroid function and the prevalence of thyroid autoantibody, autoimmune thyroiditis and other forms of thyroid dysfunction to determine whether these patients should be screened for thyroid disease.
Material and methods
Our study included 224 rheumatoid arthritis patients (195 female, 29 male), all fulfilling the revised ACR criteria for the diagnosis of RA who consecutively admitted to Rheumatology clinic of university based, internal medicine centre of Razi hospital in Rasht, the capital city of Guilan province in north of Iran. Mean age was $49.05 \pm 13.53$. For each patient, demographic data were recorded. Each patient was evaluated for the personal and family history of thyroid disease. All patients underwent tests for Free T4, Free T3, TSH, Anti Thyroid Peroxidase (Anti TPO), and Anti Thyroglobulin (Anti Tg).
Result
(19.6%) patients had positive family history for thyroid disease. Laboratory evidence for thyroid dysfunction in the form of hypothyroidism was obtained in 42 (18.8%) patients who all were women. Hypothyroidism was more common in Patient with a positive family history of thyroid disease which was statistically significant. We could not detect such a relation regarding to sex and age. In this study no case of hyperthyroidism was detected. Autoimmunity was detected in 39 (17.4%) patients. All cases were women which was statistically significant ($P < 0.008$).Physical examination and thyroid sonography revealed simple goitre, multinodular goitre, simple nodule in 3(1.3%), 3(1.3%) and 2(0.8%) cases respectively.
In 19 (43.2%) patients with thyroid disease, the family history for thyroid disease was positive. When contrasting patients with positive family history of thyroid diseases with patients without such a family history, the results were statistically significant only in the case of hypothyroidism ($P < 0.02$). A statistically significant relationship between sex and thyroid abnormalities was found only in the case of autoimmunity ($P < 0.008$).
Conclusion
Thyroid dysfunctions are common in rheumatoid arthritis. It seems wise to evaluate these patients for the investigated abnormality especially the autoimmunity.

## P1639

**The usable markers of atherosclerosis measured by Doppler Ultrasound of lower limb artery in treatment- naïve hypothyroid females**

Z. Gluvic[1], J. Tica[1], Z. Rasic-Milutinovic[1], M. Vujovic[1], V. Popovic-Radinovic[1], M. Lackovic[1] & E. Isenovic[2]
[1]Zemun Clinical Hospital, Zemun, Serbia; [2]Institute Vinca, Belgrade, Serbia.

Background
It has been shown that hypothyroidism is associated with atherosclerosis. The presence of atherosclerosis process could be registered by use of some Doppler Ultrasound parameters (DUP) – intima-media complex thickness (IMCT) and systolic velocity (SV). In this study we present initial DUP on the lower limb artery in treatment-naïve hypothyroid females and the influence of thyroid hormone levels and some metabolic components.
Methods and design
In this study 45 female patients were involved and divided into three groups regarding the thyroid hormone levels at the time of presentation: subclinical hypothyroid group, clinical hypothyroid group, and control euthyroid group. At the initial visit, some of metabolic components were measured: BMI, systolic and diastolic blood pressure, blood glucose and lipid levels. All patients were referred for DUP measurement on the proximal segment of right superficial femoral artery (RSFA). Data were statistically analyzed by using SPSS for Windows.
Results
An average IMCT and SV at presentation were $0.86 \pm 0.21$ mm and $0.53 \pm 0.13$ m/sec, respectively. The values obtained for SV were not differ between groups, while IMCT values were find to be different ($F = 8.212$, $P < 0.01$), with no contribution of difference between subclinical and clinical hypothyroid group. The patients average age ($48 \pm 11$ years) influenced significantly on IMCT ($r = 0.494$, $P < 0.01$). The overall initial average levels for TSH and fT4 were 7.21 mIU/L and $12.7 \pm 3.2$ pmol/L and both hormones significantly influenced on IMCT ($\rho$TSH = 0.584; $\rho$fT4 = −0.41; $P < 0.05$), but not on SV. The levels of triglycerides, glucose, cholesterol and its fractions ware not found to influence on IMCT.
Conclusion
This study clearly indicates that abnormal IMCT is a better marker of atherosclerosis in treatment of naïve hypothyroid patients than SV. Since TSH and fT4 levels may influence IMCT, both hormone levels should be used as the valid markers of serious atherosclerosis presence, in contrary to measured metabolic components.

## P1640

**Maternal-neonatal relationship of iodine metabolism in perinatal period: Changes in urinary iodine excretion in Japanese mothers and newborn infants**

Y. Fuse[1], H. Ogawa[2], M. Fujita[2], N. Arata[3], S. Harada[1], T. Ohashi[4], Y. Shishiba[5] & M. Irie[5]
[1]National Research Institute for Child Health and Development, Tokyo, Japan; [2]Ogawa Clinic, Yokohama, Japan; [3]National Medical Center for Children and Mothers, Tokyo, Japan; [4]Institute of Microchemical Technology, Kawasaki, Japan; [5]Foundation for Growth Science, Tokyo, Japan.

In the perinatal period iodine deficiency results in growth and mental impairment in fetus and newborns. However, there are limited data on iodine metabolism in mother and infants during this critical period.
Objective
To assess the changes in urinary iodine concentration (UIC) in mothers and neonates.
Methods
From July 2010 to October 2011, 155 pregnant women($31.1 \pm 2.1$ years) without thyroid disease and their term infants ($38.7 \pm 4.7$ weeks) were consecutively studied. The spot urine and blood samples were collected in the third trimester of pregnancy and one day before birth, the 2nd and 30th postpartum day. Neonatal urine was collected using a small self-adhesive sterile bag in the first, 5th and 30th postnatal day. The subjects with thyroid antibodies or serum TSH and FT4 values out of the reference interval were excluded.
Results

i) In neonates ($n = 95$), median UIC was 121.0 μg/L in the first voided urine, then increased to 223.0 μg/L in the 5th day and reached to 271.0 μg/L in the 30th day.
ii) Maternal median UIC was 166.5 μg/L in the third trimester and not significantly different from that in one day before birth (158.5 μg/L). At the 2nd postpartum day urinary iodine excretion abruptly increased to 256.0 μg/L, then decreased to 115.0 μg/L at the 30th postpartum day($n = 150$).
iii) The maternal UIC in one day before birth was well correlated with that of their neonates at birth (Spearman $r = 0.214$, $n = 126$).
iv) At one month the median UIC of the formula-fed infants was 108.0 μg/L and significantly lower than that of breast-fed infants (246.0 μg/L).

Conclusion
In Japan, an iodine-sufficient area, newborn infants have sufficient iodine store at birth and excrete as much iodine as adults' level after 5th postnatal day. Major iodine source is breast milk and the iodine store might be not depleted at least one month after birth.

**Is Japan an iodine excess country? Current iodine status assessed by urinary iodine and food frequency questionnaire**

Y. Fuse[1,2], T. Tanaka[2], H. Ogawa[3], M. Fujita[3], Y. Fuse[4], S. Yamaguchi[5], M. Yamaguchi[5], N. Arata[6], S. Harada[1], T. Ohashi[7], Y. Shishiba[8] & M. Irie[8]
[1]National Research Institute for Child Health and Development, Tokyo, Japan; [2]Savai Clinic, Yokohama, Japan; [3]Ogawa Clinic, Yokohama, Japan; [4]Nakamachidai Clinic, Yokohama, Japan; [5]Yamaguchi Hospital, Funabashi City, Japan; [6]National Medical Center for Children and Mothers, Tokyo, Japan; [7]Institute of Microchemical Technology, Kawasaki, Japan; [8]Foundation for Growth Science, Tokyo, Japan.

Japan has been regarded as a nongoitorous country due to the regular intake of iodine-rich food. However, nationwide information on current status of iodine intake is not available because there is no survey system for iodine nutrition in Japan.
Objective
The objectives of this study is to characterize current iodine status in Japan.
Methods
Since 2002 we have conducted studies on iodine nutrition in the Metropolitan area including Tokyo, Chiba and Kanagawa prefectures. Spot urine samples were collected in healthy subjects without known thyroid diseases and urinary iodine concentration (UIC) was measured by the ammonium persulfate digestion on microplate method based on the Sandell Kolthoff reaction. Serum TSH, free thyroxin and thyroid autoantibodies were measured if blood samples are available. Dietary iodine intake (DII) was assessed by using an iodine-specific food frequency questionnaire developed and verified by us.Iodine content was calculated on the basis of data from the standard tables of food composition in Japan 2010.
Results
Median UICs according to age groups are summarized in the table. Median daily DII in healthy adults was 471.0 μg /day (IQR:256.7, 859.8) and there was no significant difference in DII value between male (453.1 μg /day) and female (503.5 μg /day). The questionnaire data correlated well with urinary iodine excretion (Spearman $r = 0.32$).
Conclusion
According to WHO/ICCIDD criteria for iodine deficiency disease median UICs of 100–199 μg/L at population level indicate adequate iodine intake and optimal

nutrition and the median UIC over 300 μg/L in local schoolchildren is regarded as excessive. Our results indicate that current iodine status in Japanese is sufficient, not excessive, although the data is local.

### Determinants of children's iodine nutrition and epidemiological features of children's goiter and nodule in iodine-excessive areas

S. Lv[1], D. Xu[1], Y. Wang[2], Y. Du[1], L. Jia[1], Z. Chong[1], J. Ma[1] & J. Zhao[1]
[1]Hebei Provincial Center for Disease Control and Prevention, Shijiazhuang, China; [2]Hengshui Municipal Center for Disease Control and Prevention, Hengshui, China.

Introduction

Excessive iodine intake can cause iodine overnutrition, goiter and other thyroid disease. This study is to probe the determinants of children's iodine nutrition and their goitrous and nodular prevalence in areas with excessive iodine in drinking water in Hebei province of China. Methods Three townships were selected by simple random sampling among the 8 townships with median water iodine being 200–300 μg/l in Hengshui prefecture of Hebei province. No less than 200 children aged 8–10 years old were randomly selected in each of the 3 townships to measure their thyroid volume by ultrasound, and to detect the urinary iodine of half of them. Drinking water samples were also collected by systematic sampling in the villages where these children lived to measure the iodine content. Results The median urinary iodine of 326 children aged 8–10 years in these 3 townships ranged from 478.4 to 571.3 μg/l, and the portions of urinary samples with iodine content over 300 μg/l varied from 77.9% to 86.6%. Children's median urinary iodine had a linear correlation with median water iodine in 12 villages of these 3 townships($R=0.83$, $F=22.0$, $P=0.001$), and the linear regression equation was as followed: urinary iodine $=318.1+0.829$*water iodine. A total of 452 children aged 8–10 years was measured by ultrasound in these 3 townships, identifying 37 cases of goiter with goiter rate being 8.2%. There was no significant difference in goiter rates across gender and age groups. In 2 out of the 3 townships, 15 cases of nodules were detected with average detection rate being 5.6%. The detection rates across gender and age groups were not significantly different. Conclusions Children's urinary iodine in these areas was excessive which mainly derived from iodine excess in drinking water. Goiter prevailed in these areas, and a high detection rate of thyroid nodules was also identified.

### Control of 217 hypothyroid women during pregnancy

C. Familiar, T. Anton, A. Marco, M. Tapia, M. Villa, A. Ramos & I. Moraga Mostoles Hospital, Mostoles, Spain.

Introduction

The new guidelines for the management of hypothyroidism (HP) during pregnancy recommend a tighter treatment with levothyroxine (Lt4) to reach TSH values similar to those of pregnant women without thyroid dysfunction (TSH $<2.5$ mU/l in the 1st trimester-T- and TSH $<3$mu/l in the 2nd and 3rd T).

Objectives

To assess the degree of control of HP in women followed during pregnancy according to the current criteria and the possible association between control of TSH in each T and: miscarriage%, preterm deliveries% and few gestational complications frecuencies (pregnancy induced hypertension-HTA-, gestational diabetes-GD-) and birth weight.

Patients and methods

Study of 217 pregnant women with primary HP followed in our hospital for Lt4 adjustment.We describe miscarriage %, preterm deliveries%;few gestacional complications% and birth weight.

Results

23.2% of women did not take a minimum 150 μg daily iodine supplements in their first assessment. % of women with TSH $<4.3$ mU/l (normal superior reference range -NSR-in non-pregnant population) changed from 78.7% before pregnancy to 64.8% in the 1st T, 84.8% in the 2nd T and 95.1% in 3rdT ($P<0.05$) . % of pregnant women with TSH $<$ NSR for pregnant population was significantly lower: 31.3%, 63.9% and 86.8% in the 1st, 2nd and 3rd T respectively. This % was higher in those patients submitted earlier (1st T:76%) than late (in 3rd T: 91%, $P<0.05$). There were no significant differences in preterm deliveries %, HTA, GD comparing women with TSH values within the control goals to those with TSH above goals in any trimesters. We found a non significant trend toward greater % of preterm deliveries with high TSH values in 2 nd T. Mothers% whose newborns weighed $<2300$ g was higher in those with 3erT TSH$>4.3$ mU/l vs TSH $\leq 4.3$ (20 vs 2.7%, $P=0.04$) and with TSH 3erT$>3$ vs $<3$ mUi /l (11.5 vs. 2.3%, $P=0.05$).

Conclusion

Early assesment of pregnant women is necessary to achieve goals of control (possibly in the preconceptional period). The high level of controlled patients% in 3erT could explain the lack of significant differences in the% of complications.

## P1644

### Vitamin D deficiency is not associated with thyroid autoimmunity

G. Effraimidis[1], K. Badenhoop[2], J. Tijssen[1] & W. Wiersinga[1]
[1]Academical Medical Centre, University of Amsterdam, Amsterdam, The Netherlands; [2]University Hospital Frankfurt, Frankfurt am Main, Germany.

Context

Vitamin D deficiency has been identified as a risk factor for a number of autoimmune diseases including type 1 diabetes and multiple sclerosis.

Objective

We hypothesized that low levels of vitamin D are related to the early stages of autoimmune thyroid disease.

Design

Two case-control studies were performed. Study A: cases were subjects from the Amsterdam AITD cohort (euthyroid women who had 1st or 2nd degree relatives with overt AITD) who at baseline had normal TSH and no thyroid antibodies; controls were healthy women examined at the same time period. Study B: cases and controls were subjects from the Amsterdam AITD cohort who at baseline had normal TSH and no thyroid antibodies and during follow up developed TPOAb (cases) or remained without thyroid antibodies (controls). Controls in both studies were matched for age, BMI, smoking status, estrogen use, month of blood sampling and in study B for the duration of follow up.

Results

Study A: The 78 cases had a higher serum 25(OH)D concentration than the 78 controls ($21.0\pm7.9$ ng/ml vs. $18.0\pm6.4$ ng/ml, $P=0.01$). The prevalence of 25(OH)D deficiency ($<20$ ng/ml) was lower in cases than in controls (48.7% vs. 64.1% respectively, $P=0.05$); the same was true for the prevalent rates of 25(OH) D deficiency and insufficiency ($<30$ ng/ml) (83.3% vs. 94.9%, $P=0.02$).

Study B: The 25(OH)D levels in ng/ml were $22.6\pm10.3$ vs. $23.4\pm9.1$ at baseline and $21.6\pm9.2$ vs. $21.2\pm9.3$ at follow-up (67 cases vs. 67 controls, NS). The frequency of 25(OH)D deficiency ($<20$ ng/ml) at baseline was comparable in cases and in controls (49.2% vs. 34.3% respectively, $p=0.05$); the same was true for the prevalent rates of 25(OH)D deficiency and insufficiency ($<30$ ng/ml) (79.1% vs. 86.5%, $P=0.25$). Similar figures were obtained at the time of seroconversion.

Conclusions
Early stages of thyroid autoimmunity (in study A genetic susceptibility and in study B development of TPOAb) were not related with low vitamin D levels.

### Iodine prophylaxis in pregnant women: effects on offspring and the mother's thyroid hormones

P. Santiago[1], I. Velasco[2], J. Muela[3], B. Sanchez[1], J. Martínez[1], C. Sánchez[1], A. Rodriguez[3], F. Soriguer[2] & Maria Berrio[2]
[1]SAS/Ch Jaen, Jaen, Spain; [2]SAS/ Hospital de Riotinto, Huelva, Spain; [3]Universidad de Jaen, Jaen, Spain; [4]SAS/Hospital Carlos Haya, Malaga, Spain.

Background and aims
Use of potassium iodide (PI) supplements during gestation in mild to moderate iodine deficiency areas remains a controversial issue.
Objective
Comparing the pharmacological effect of iodized salt versus iodide potassium supplements on the maternal thyroid function and neurodevelopment (Bayley Scales) of the progeny.
Methods
One hundred and thirty one pregnant women were included from the first trimester (below 10 weeks of amenorrhea) with random allocation in three groups: A) Iodized salt B) 200 mcg of iodide potassium (PI) per day and C) 300 mcg of PI per day.
Main outcome measures
Thyroid function parameters (TSH, FT4, FT3 and urinary iodine excretion) and Bayley-III Scales of Infant Development in children.
Results
The thyroid function tests in three trimesters of gestation and postpartum have not shown significant differences between the three treatment groups, except in urinary iodine excretion (higher in group treated with 300 mcg PI/day). In direct scores of psychometrical scales, we found higher scores within the sons whose mothers were supplied with lodizet salt at 300 mcg PI/day. We found a positive relation between motherbreed urinary iodine, mental scales and Bayley tests in every age group; However, there is not any relation between urinary iodine and psychomotor scale.
Conclusions
Actually It is necessary to maintain an accurate iodic nutrition on these women in fertile age, that is why the usage of pharmacological supplements of 200–300 mcg of PI is well recommended in iodine deficient areas.The use of pharmacological supplements of PI is safe and doesn't alter the maternal thyroid function, even improves the urinary iodine excretion. But if you use iodized salt regularly, you may not have need for iodine supplementation in the future.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Low prevalence of postpartum hyperthyroidism in women after radioiodine treatment for Graves' disease before the pregnancy

A. Yoshihara, J. Noh, K. Mukasa, H. Ohye, N. Watanabe, K. Sekiya, Y. Kunii, M. Suzuki, M. Matsumoto, Y. Kosuga, K. Iwaku, K. Ito & K. Ito
Ito Hospital, Shibuya-ku, Japan.

Context
Postpartum hyperthyroidism (PH) is one of the postpartum thyroid disorders that occurs during the first year postpartum and PH is caused by destructive thyroiditis and recurrent Graves' disease. PH is an exacerbation of an underlying autoimmune thyroiditis that is aggravated by the immunological rebound that follows the partial immunosuppression that occurs during pregnancy. The prevalence of PH among women with Graves' disease (GD) who had been treated with radioiodine (RI) before their pregnancy has never been investigated.
Objective
Our objective was to determine the prevalence of PH among women who had been diagnosed with GD and undergone RI therapy before their pregnancy.
Subjects and methods
We reviewed the cases of women with GD who became pregnant between January 1, 1999 and December 31, 2010, and selected the 188 women who had undergone RI therapy before the pregnancy as the subjects of this study. Of the 188 women, 110 were on replacement therapy with levothyroxine (25–175 μg/day, mean 87.5 μg/day) (Group 1) and 78 were euthyroid without medication (Group 2). The control subjects were 107 women who became pregnant during 2009 who had been treated with antithyroid drugs and were in remission throughout the pregnancy. All subjects were followed up for at least one year after delivery. We monitored the TSH receptor antibody (TBII) level of all of the women during pregnancy and the postpartum period.
Result
Transient hyperthyroidism was observed in one of the 110 women in Group 1 (0.9%) and in three of the 78 women in Group 2 (3.8%). No cases of permanent hyperthyroidism were observed in either Group 1 or Group 2. PH was observed in 59 of the 107 women (55%) in the control group. In 41 of the 57 women it was transient hyperthyroidism, and in the other 18 it was recurrent Graves' disease and required medication. After delivery the TBII level increased in 15 cases in Group 1, in 19 cases in Group 2, and in 34 cases in the control group.
Conclusion
The results of this study provided evidence that RI treatment before pregnancy is effective in preventing PH.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1647

### The outcome of radioiodine therapy after five years in patient with non-toxic nodular goitre

S. Abdelrazek, F. Rogowski, P. Szumowski, M. Mojsak, A. Zonenberg & K. Siewko
Medical University of Bialystok, Bialystok, Poland.

The aim of our study was to evaluate the short term efficacy of radioiodine therapy (RIT) to reduce thyroid volume with minimal risk of hypothyroidism in patients with non-toxic nodular goitre. Material and Methods: We treated 120 patients, aged 20–76 years; (88%) of the studied groups were female and (12%) male. Initial 24 h RAIU was ranged between 22–44% and effective half-life was more than 3 days. Thyroid volume ranged between 42–170 ml. Malignant changes were excluded in all nodules by fine needle aspiration biopsy. The activity dose was calculated by the use of Marinelli's formula and ranged between 200–800 MBq. The absorbed dose ranged between 150 and 260 Gy. Thyroid ultrasonography, and thyroid scan was done before, after 12 month and yearly for four year of RIT. Follow up control was done every 6 weeks in the first year, then every 6 months. Results: After 12 months of radioiodine therapy a mean thyroid volume reduction of 46% was achieved. Euthyroidism persist in 91% of patients, and hypothyroidism develop in 9% of patients. After 3 years of RIT 10% of patient develop hypothyroidism. After 5 years a mean thyroid volume reduction of 49% was achieved and 11% of patients develop hypothyroidism. All patients were highly satisfied; the compressive symptoms relieved. Conclusions: Radioiodine is non-invasive, safe and cost effective method of therapy for reduction of non-toxic goitre and should not be restricted to elderly patients, or to patients with high surgical risk, but should be used as first choice in every patient with non toxic nodular goitre with thyroid volume $> 40$ ml. Surgery should be reserved as first choice if malignancy is suspected. The reduction of thyroid volume with low percent of hypothyroidism, were due to well accurate measurement of administered activity, relatively high effective half-life, and well-organised follow up.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector

## P1648

**Langerhans cell histiocytosis of the thyroid and pituitary gland**

C. Feeney, M. Reddy, J. Todd, N. Tolley & S. Robinson
Imperial College, London, UK.

Langerhans cell histiocytosis is a disease caused by clonal proliferation of a group of antigen-presenting cells known as Langerhans cells. Its manifestations range from isolated lesions to multisystem disease usually involving bone, skin and the pituitary stalk. Thyroid involvement is rare.

A 44-year old woman presented to the joint thyroid clinic with a short history of neck swelling, confirmed to be a smooth goitre on clinical examination. Initial blood tests results were: TSH 0.24 mu/l (0.30–4.20), T4 8.2 pmol/l (9–19), TPO antibody negative.

A neck ultrasound demonstrated a diffuse thyroid abnormality with generalised hypoechoic echotexture, widespread microcalcification and level 6 lymphadenopathy. No focal lesions were identified. FNA of the thyroid was suggestive but not diagnostic of medullary carcinoma. Carcinoembryonic antigen was 6.5 ug/l (1–5), but calcitonin was undetectable.

Total thyroidectomy was recommended by the MDT. However, dissection of the left lobe was technically challenging and a left hemi-thyroidectomy only was performed as the Recurrent Laryngeal Nerve failed to stimulate post lobectomy. As the pathology was unknown at the time it was decided not to embark upon surgery on the right side.

Histologically, histiocytes were seen on a background of numerous eosinophils and a lymphoid infiltrate. Immunohistochemistry revealed positivity for CD1a and S-100. These features were in keeping with a definitive diagnosis of LCH.

Following surgery she developed multiple skin lesions suggestive of multifocal involvement and more recently she has been found to have pituitary dysfunction (Table 1).

LCH initially presenting in the thyroid as seen in our case is extremely rare. The management of this multisystem disease remains a challenge.

**Celiac disease in patients with autoimunne thyroiditis – pilot study**

M. Krcma, K. Balihar & E. Dvorakova
University Hospital Plzen, Plzen, Czech Republic.

Introduction

Benefit of general screening for concomitant autoimunne diseases in patients with chronic autoimunne thyroiditis (AIT) is serious problem from medical, even from economic point of view. Some authors advice for screening, some advert to mass occurence of AIT and warn about huge expenses. Situation vary from one country (region) to another.

Aim

To assess incidence of celiac disease in patients with chronic autoimunne thyroiditis and find any risk factors.

Methods

200 consecutive patients with autoimunne thyroiditis was selected for the study. Including criteria was positive sonographic findings of AIT and/or positive antibody/ies (anti-thyreoperoxidase, anti-thyreoglobulin). In all patients was measured level of anti-transglutaminase antibodies and IgA, as well as current level of anti-thyreoperoxidase antibodies. Enterobiopsy was performed in patients with positive anti-transglutaminase and sample was assessed according to Marsh's clasification.

Results

Valid data was gained from 186 pacients, 134 women and 52 men. 9 patient has positive anti-transglutaminase antibody and 8 patients (4.3%) has significant histologic changes for celiac disease. There was no difference in gender, weight (BMI), presence of other autoimunne disease (primarily diabetes mellitus type 1), dose of levothyroxine, little, but not significant difference in age −(33.0 [25.0–38.5] years in celiac group vs. 24.5 [27.3–41.8] in healthy group; $P=0{,}09$) and significant difference in anti-thyreoperoxidase levels (396 [210–967] IU/ml in celiac group vs. 152 [35–443] IU/ml in healthy group; $P=0.05$). No difference was observed in anti-thyreoglobulin antibodies.

Conclusion

Small number of patients made comprehensive statistical arrangement difficult, but this preliminary results indicate usefullnes of celiac disease screening in asymptomatic patients with AIT, especially with elevated anti-thyreoperoxidase antibodies.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector

## P1650

**Is thyroid volume (TV) in children related to the urinary iodine concentration (UIC) in urine spot sample?**

M. Trofimiuk-Müldner[1], M. Buziak-Bereza[1], G. Sokolowski[1], A. Zygmunt[2], Z. Adamczewski[2], Z. Szybinski[3], A. Lewinski[2] & A. Hubalewska-Dydejczyk[1]
[1]Jagiellonian University, Medical College, Krakow, Poland; [2]Medical University of Lodz, Polish Mother's Memorial Hospital – Research Institute, Lodz, Poland; [3]Krakow, Poland.

Goiter prevalence (GP) and median UIC in population studies are both considered markers of iodine nutrition. Controversy exists which of them is more reliable.

Aim

To assess correlation between UIC and thyroid volume in Polish schoolchildren.

Material and methods

9402 Polish schoolchildren (51.3% girls, 48.7% boys) aged 6–12 years were examined in 1999–2011 ('Thyromobil' action). 40.9% of children were born at least one year after implementation of obligatory iodine prophylaxis (IOIP). TV was assessed ultrasonographically, GP was evaluated according to both 1997 and 2004 WHO reference values. To avoid age influence TV(ml)/BSA(m2) ratio (TVBR) was calculated. UIC in urine spot samples was measured by Sandel-Kolthoff's method.

Results

Median UIC was 96.18 mcg/l. Median TVBR was 3.97 ml/m2. GP for age (GPA) was 5.5% and 55.7%, for BSA 4.9% and 56.5% according to 1997 and 2004 reference, respectively. GPA was 5.7% and 5.2% according to 1997 reference, and 56,8% and 54.5% according to 2004 reference, for UIC $<$ and $\geq$100 mcg/l, respectively. GPA was 6.5% and 4% according to 1997 reference, and 56.6% and 58.7% according to 2004 reference, for children born before and after IOIP, respectively. Median TVBR was 4.1 and 3.8 ml/m2 ($P<0.0001$) for children born before and after IOIP, respectively. Median UIC was 91 and 104.3 mcg/l ($P<0.001$), for children born before and after IOIP, respectively. Median UIC was 96.5 and 91.9 mcg/ml ($P=0.43$), and 97.8 and 95.0 mcg/l ($P=0.025$) for children without and with goiter according to 1997 and 2004 age reference, respectively. TVBR was 4.05 and 3.97 ml/m2 ($P<0.0001$) for UIC $<$ and $\geq$100 mcg/l, respectively. Negative, statistically significant correlation between TVBR and UIC was observed ($r=-0.033$, $P<0.005$).

Conclusions

Statistically significant correlation between UIC and TV was confirmed. However, neither 1997 nor 2004 WHO reference values seem to reliably estimate influence of iodine prophylaxis on TV.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1651

**Evaluation of health related quality of life and general symptoms in Hashimoto's thyroiditis: are factors other than thyroid function effective? Analysis of preliminary results**

C. Anil, A. Kut, C. Demir, U. Mousa, Y. Bozkus & N. Bascil Tutuncu
Faculty of Medicine, Baskent University, Ankara, Turkey.

Introduction
Factors affecting health related quality of life (HRQOL) in Hashimoto's thyroiditis (HT) are controversial and research on the topic is limited. This study aimed to evaluate the factors that may affect HRQOL and admitting symptoms in a group of patients with HT.
Methods
For the evaluation of HRQOL, SF-36, Beck anxiety scale and Beck depression scale were performed on subsequent 57 cases with HT admitting to outpatient clinic of Endocrinology department of Baskent University Hospital. Also, according to the admitting symptoms of the patients, they were asked to score between 0 and 10 expressing severity for each of the nine most frequent symptoms. Thyroid function tests, thyroid autoantibodies were studied, and thyroid sonography was performed to each patient.
Results
The most frequent symptoms mentioned were dysphagia, dyspnea, feeling of swelling in the neck, difficulty in collared clothing, snoring, night sweating, headache, lightheadedness, and pain in the neck. According to SF-36 form assessment, there was a correlation between thyroid volume and mental health ($P<0.05$; $r=-0.31$) and physical role limitation ($P<0.05$; $r=+0.30$) subscales. As for general symptom evaluation, headache and light-headedness were more severe in patients who were not on L-$T_4$ than those on L-$T_4$ ($P<0.05$ and $P<0.01$ respectively). Corelation analysis revealed a positive relation between the symptom of difficult breathing and thyroid volume ($P<0.01$; $r=+0.39$).
Conclusion
Determining almost no relation between HRQOL scales and thyroid hormone levels, but detecting some relations between some scales and thyroid volume may be meaningful in HT cases, i.e. possible contributions of morphological factors. The final results of our ongoing study may reveal us more on the topic.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1652

**Proptosis reduction in patients with Graves' orbitopaty (go) at 12 weeks after intravenous steroid therapy is associated to disease inactivation**

G. Vannucchi[1], I. Campi[1], D. Covelli[1], N. Currò[1], V. Cirello[1], D. Dazzi[2], P. Beck-Peccoz[1] & M. Salvi[1]
[1]Fondazione Cà Granda, IRCCS, Milan, Italy; [2]Ospedale di Fidenza, Fidenza, Italy.

We have retrospectively studied the clinical outcome of 58 patients (14 men and 44 women) with autoimmune thyroid disease and active GO, treated with high dose intravenous methylprednisolone (MP; cumulative dose 7.5 g). Ophthalmological assessment was performed at baseline and at 6, 12 and 24–30 weeks after the first MP infusion. In 43/58 patients we have also studied NR3C1gene polymorphism, which has been associated to different sensitivity to steroids. The therapeutic outcome has been assessed as: i) reduction of clinical activity score (CAS) $\geq 2$ point or ii) of proptosis $\geq 2$ mm or iii) improvement of diplopia according to the Gorman score, in relation to age, gender, duration of thyroid or orbital disease, smoking habits, serum parameters (TRAb, TSH, $FT_3$, $F_4$ concentrations) and genetic data (NR3C1gene polymorphisms). A significant clinical improvement was observed in 67% of patients at 6 weeks and in 80% at 12 weeks; this rate decreased to 70% at 24 weeks as a consequence of relapse of GO in 8 patients (13%). At 12, but not at 6 and 24 weeks, the reduction of the CAS, observed in 80% of patients, was more evident in non-smoking patients (62.5%) than in smokers (37.5%; $\chi^2$; $P<0.045$). A decrease of proptosis $\geq 2$ mm was also significantly associated with the reduction of CAS $\geq 2$ in 34.3% of the patients, who at 12 weeks had a significant response to treatment ($\chi^2$; $P<0.003$). No significant changes in the Gorman score were observed after treatment. No association was found between the therapeutic response to MP and clinical, serological and genetic parameters. Our data show that: i) the therapeutic response of MP is observed in as many as 70% of patients; ii) treatment may be more responsive in non-smoking patients and iii) proptosis reduction is the ophthalmological parameter better associated to inactivation of GO after MP.

**Evaluation of the effect of radioactive iodine treatment on urea breath test**

A. Arduc[1], U. Ozuguz[2], Y. Tutuncu[1], B. Aycicek Dogan[1], M. Tuna[1], I. Peksoy[1], F. Gokay[1], D. Berker[1] & S. Guler[1]
[1]Ministry of Health, Ankara Numune Research and Training Hospital, Ankara, Turkey; [2]Gulhane Military Medical Academy, School of Medicine, Ankara, Turkey.

Introduction
*Helicobacter pylori* (HP) infection is the most significant cause of gastritis and related morbidities. Radioactive iodine treatment (RAIT) is an important option in the treatment of hyperthyroidism. In addition to thyroid gland, RAI accumulates in stomach in significant amounts. In our study, we planned to investigate whether RAIT has an effect on carbon-14-urea breath test (UBT) in patients with hyperthyroidism.
Materials-method
The study included 71 patients that were planned to give RAIT due to hyperthyroidism. Patients that used antibiotics in the last month and proton pump inhibitor in the last week, pregnant women, individuals with stomach operation history were excluded from the study. The entire patients were implemented UBT an hour before RAIT for the detection of HP infection. Patients whose test came out positive were repeated UBT one month following the treatment.
Results
Of the 71 patients, 62 had positive UBT before RAIT. Of the 62 patients, 52 were female and 10 were male, and the mean age was $53.9 \pm 12$. Following an average 15 mci (10–20) RAI dose, UBT became negative in 10 out of 62 patients (17.3%). The rate of negativity was found to be 17.3% in females and 10% in males; and significant difference did not occur ($P=1$). When the patients were divided into groups as 20 mci (group 1), 15 mci (group 2), and 10 mci (group 3) based on RAI doses, UBT negativity rates were 7 (25%), 2 (10.5%), and 1 (6.7%), respectively, and the difference was not statistically significant ($P=0.206$).
Conclusion
RAIT in low doses does not have an effect on UBT. However, UBT negativity rate increases parallel to the treatment dose. Further studies that investigate the relation between HP radiosensitivity and RAI dose are needed.
Keywords: *Helicobacter pylori*, radioactive iodine treatment, carbon-14-urea breathe test.

**Review of a thyrotoxicosis shared-care scheme: treatment choice and outcomes**

T. Howlett, V. Kieffer, C. Robinson, I. Peat, M. Kong, H. Gleeson & M. Levy
Leicester Royal Infirmary, Leicester, UK.

Since 1994, after initial outpatient review (OPD) for thyrotoxicosis, we have minimised OPD attendance and provided shared-care advice to primary care physicians on thyroid function tests (TFT) and anti-thyroid drug (ATD) and levothyroxine ($T_4$) dose titration using our electronic patient record (EPR). Using EPR data we analysed treatment (Rx) choice, effectiveness and outcomes, classifying patients as autoimmune (+ve TPO or other Graves' features), nodular, mixed or other (no recorded features of either).
Results
2696 patients (13–94 years; 77%♀), 55 079 TFTs (median 18, max 97/patient), 13 840 patient-years observation (median 4.1 y, max 17.4 y), median 2.9 y from last OPD. Rx choice was patient-driven after appropriate information was given: overall 90% had ATD (84% carbimazole; 11% PTU; median first course

1.50 y; mean # courses 1.6, median 1), 21% radioiodine (RAI) and 7% thyroidectomy. Rx and outcomes are summarised in table. RAI was used more often in nodular disease, and fewer patients became hypothyroid, but many cases of every aetiology chose to continue ATD as an alternative. 'Long-term' ATD (stated strategy or actual use >1000d) was used in 20% and ongoing in 12%; longest ongoing Rx was 24.8 y duration.

$T_4$ ($tT_4$ or $fT_4$)/TSH/Both were normal in 92/59/55% of 55,079 TFTs reported. Control was best in patients on no Rx (94/66/63%) compared to patients on $T_4$ alone (95/58/55%) or ATD (90/54/50%). Control on long-term ATD (92/65/60%) was better than shorter-term courses (89/51/47%) but best control was observed in the minority of TFTs on a block and replace regime (95/63/61%). Control was not better in TFTs taken after RAI: 91/51/48% overall; 86/49/43% on no Rx; 95/56/53% when on $T_4$ Rx.

Conclusions

Thyrotoxicosis can be effectively monitored by a specialist clinic using EPR whilst minimising the need for patient attendance in hospital. Good control of $T_4$ was observed but achieving a normal TSH is more challenging. Long term use of ATD is a valid patient treatment choice which achieves TFT control better than RAI in our hands.

### Left-shifted set point of calcium/PTH-relation in patients with Grave's thyrotoxicosis

M. Annerbo, P. Stålberg, H. Hultin & P. Hellman
Department of Surgical Sciences, Uppsala, Sweden.

Patients with Grave's disease (GD) are more prone to develop low serum calcium values than patients operated on because of goitre after total thyroidectomy. Moreover, some patients with GD achieve hypercalcemia probably due to active bone disease. We have used citrate-calcium clamping (CiCa) in order to investigate the calcium homeostasis in detail in patients with Grave's disease.

Material and method

Our series of patients undergoing total thyroidectomy for GD ($n=$xx) and gioter ($n=$yy) were scrutinized for postoperative hypocalcemia and need for calcium and/or vitamin D substitution. CiCa-clamp (Schwarz P, Sörensen HA 1992, 1993) were used in 11 patients and 24 controls to quantify the secretion of PTH in relation to ionized plasma calcium level. The wet point equal to the plasma ionized calcium concentration at which 50% of the maximal secretion of PTH is inhibited, as well as other CiCa-related parameters were calculated.

Results

The rate for having hypocalcemia was 48% in our patients overall, but patients with GD have lower calcium levels, 16% had < 2.00 mmol/l compared to 4.5% in the goiter group; need more calciumsubstitution during the hospital stay (6.5 vs 5.1%) and at discharge (33.2 vs 12.9%).

The GD group have a significant more left sided set point than the normal group, 1.14 vs 1.20 mmol/l $P<0.001$ (Mann–Withney $U$ test) as well as an increased response in release of PTH to hypocalcemic stimulus.

Conclusion

Patients with GD have a left-shifted calcium/PTH set point compared to normal controls. We also noted a faster and higher level of PTH response to hypocalcemic stimuli in GD, presumably related to known derangements in these patients, such as high bone turnover. The CiCa response mimicks that of obese patients in which vitamin D insufficiency has been proposed as an underlying cause.

### Correlation between thyroid hormone values and carotid intima media thickness in patients with subclinical hypothyroidism

V. Velkoska Nakova[1], B. Krstevska[2], E. Srbinovska[2] & M. Bosevski[2]
[1]University Goce Delcev, Stip, The Former Yugoslav Republic of Macedonia; [2]University Kiril and Methodius, Skopje, The Former Yugoslav Republic of Macedonia.

Purpose

The aim of the study was to investigate the influence of TSH and free thyroxin ($fT_4$) hormones on carotid intima media thickness (cIMT).

Material and methods

Sixty nine consecutive patients who attended to the Department of University Clinic of Endocrinology, Diabetes and Metabolic disorders with newly diagnosed subclinical hypothyroidism (ScH) were evaluated for mean and maximal cIMT. ScH were defined as elevated TSH with normal $fT_4$ serum values.

Results

Mean TSH, $fT_4$, cIMT, and max cIMT were: 7.9±3.6 mU/l, 14.5±2.8 pmol/l, 0.61±0.1 mm, and 0.65±0.1 mm, respectively. Statistically significant positive correlation were evaluated between TSH value and mean and max cIMT ($r=0.28$, and $r=0.29$, respectively, $P<0.05$). While $fT_4$ statistically significant negative correlated with mean and max cIMT ($r=-0.35$, and $r=-0.33$, respectively, $P<0.01$).

Conclusion

Thyroid hormone values are correlated with carotid intima media thickness in patients with subclinical hypothyroidism.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1657

### miRNA expression of the thyroid after goiter formation and involution using different iodine regimens

J. Mao[1,2], W. Chong[1,2], Z. Shan[1,2] & W. Teng[1,2]
[1]The First Hospital of China Medical University, Sheyang, China; [2]China Medical University, Shenyang, China.

Background

Thyroid damage is known to occur during experimental iodine-induced goiter. MicroRNAs (miRNAs) are a class of small non-coding RNAs regulating gene expression. Dysregulation of specific miRNAs can interfere with tissue homeostasis. The purpose of this study was to investigate the dynamic expression profiles of miRNAs during adequate or mild-excess iodine supplementation in the iodine-deficient thyroid.

Methods

Hyperplastic goiter was induced in rats by feeding a low-iodine (LI) diet for 12 weeks. Subsequently, involution of hyperplasia was obtained by administering an adequate/1- (Group 1) or 2-fold (Group 2) physiological dose of iodine for 4 weeks with a control group receiving adequate iodine intake. MiRNAs expression was analyzed in all the groups using miRNA microarray technique.

Results

In the LI group, during hyperplastic goiter formation, there were 20 miRNAs decreased and 8 increased compared to the control group. Among them, miR-708 was downregulated up to 93% and miR-144* was upregulated 8.7-fold.

After involution of the glands of Group 1 and 2, 7 common miRNAs still remained dysregulated similar to the hyperplastic phase, but 8 common miRNAs recovered to levels as found in the control group. Notably, Group 1 had more recovered miRNAs than Group 2.

Compared to the control group, some new dysregulated miRNAs emerged in Group 1 and 2 after involution. Of these, there were 6 identical miRNAs in group 1 and 2, but the amount of new misexpressing miRNAs in Group 2 was obviously larger than in Group 1. In Group 2, miR-878 was even 6-fold higher than in Group 1.

Conclusions
Our results indicate that misexpression of miRNAs is involved in iodine-induced goiter formation by a low-iodine regimen and that supplementation with adequate iodine could be more helpful to restore homeostasis than mild-excess iodine. However, further functional studies of some specific miRNAs are needed.

**Autoimmune thyroid disease and cardiovascular risk factors**

C. Neves, C. Esteves, M. Pereira, C. Dias, C. Palmares, O. Sokhatska, D. Carvalho, L. Delgado & J. Medina
Faculty of Medicine, São João Hospital, University of Porto, Porto, Portugal.

Aims
To examine whether Graves' disease (GD) and Hashimoto thyroiditis (HT) are associated with insulin resistance (IR) and other cardiovascular risk factors. Patients and methods: We analyzed 479 patients with autoimmune thyroid disease, 354 (74%) with HT and 126 (26%) with GD, 94% woman, with a mean age of $46 \pm 16$ years. The patients in both groups were properly treated in order to normalize TSH, $FT_3$ and $FT_4$ levels. We recorded thyroid function tests, BMI, IR markers comprising the homeostasis model assessment for insulin resistance, the quantitative insulin sensitivity check index, the hepatic insulin sensitivity index, the whole-body insulin sensitivity index, and the insulinogenic index. A 75-g OGTT was performed and measurements of plasma glucose, insulin, and C-peptide were obtained at 0 min ($'$), 30$'$, 60$'$, 90$'$ and 120$'$. We also recorded the levels of total cholesterol (TC), HDL, LDL-cholesterol, triglycerides (TG), apolipoprotein B (ApoB), ApoA1, lipoprotein (a), homocysteine, C-reactive protein, folic acid and vitamin B12 levels. Statistical analysis was performed with the Mann–Whitney $U$ test and Spearman's correlations tests. Results are expressed as mean $\pm$ S.D. A two-tailed $P \leq 0.05$ was considered significant.
Results
We found that patients with HT had significantly higher levels of BMI ($26.5 \pm 5.3$ vs $24.8 \pm 4.7$ kg/m$^2$, $P=0.03$); C-peptide at 30 min ($7.3 \pm 2.8$ vs $6.6 \pm 2.5$ ng/ml; $P=0.03$); C-peptide at 60 min ($10.5 \pm 4.2$ vs $9.3 \pm 3.3$ ng/ml; $P<0.01$). In patients with HT we also found significantly higher levels of LDL-cholesterol ($124 \pm 31$ vs $116 \pm 33$ mg/dl; $P<0.01$), TG ($116 \pm 70$ vs $104 \pm 75$ mg/dl; $P=0.034$), ApoB ($97 \pm 23$ vs $86 \pm 24$ mg/dl; $P<0.001$), B12 vitamin ($467 \pm 308$ vs $372 \pm 174$ pg/ml; $P=0.02$), anti-thyroglobulin antibody ($141.7 \pm 179.0$ vs $121.2 \pm 160.3$ UI/ml, $P=0.01$). We found a negative correlation between TSH and TRAb levels ($r=-0.180$; $P<0.001$). In the whole group TSH positively correlated with TC ($r=0.097$; $P=0.04$) and ApoB ($r=0.117$; $P=0.02$). Conclusions: After treatment to normalize thyroid function, HT patients have a higher cardiovascular risk than GD patients, associated with overweight, subclinical inflammation and atherogenic lipid profile.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1659

**The syndromes of thyroid autoimmunity among patients with antiphospholipid syndrome**

S. Jelic[1,2], L. Stojanovic[1], D. Marisavljevic[1,2] & D. Popovic-Kuzmanovic[1]
[1]Bezanijska kosa Clinical Hospital Center, Belgrade, Serbia; [2]University of Belgrade, Belgrade, Serbia.

Background
Literature data regarding the prevalence of the syndromes of thyroid autoimmunity (AIT) in antiphospholipid syndrome (APS) are rather limited. However, quite frequently it is hypothesized on common pathophysiologic mechanisms underlining these disorders.
Objectives
The aim of this investigation was to evaluate the frequency of disorders of thyroid function and occurrence of anti-thyroid antibodies (ATAs) among patients with antiphospholipid syndrome (APS) included in the Serbian National APS Registry.
Methods
Started in January 2006, Serbian National APS Registry currently records information about 267 patients (206 females) in its database. These patients had a mean age of $44.89 + 12.95$ years and mean disease duration of $4.41 + 4.07$ years. Authors are planning to analyze serum levels of TSH, free thyroxine ($fT_4$), anti-thyroglobulin antibody (TgAb), anti-thyroid peroxidase antibody (TPOAb) and thyroid receptor antibody (TRAb) in all of these patients. Now, we are presenting initial results obtained from 68 patients (comprising 25.46% of all patients included in Serbian National APS Registry) who undergone endocrinology screening during last year.
Results
Thyroid involvement was observed in 30.9% (21 patients, 20 females) of studied patients with APS. All of these patients were positive for at least one of the anti-thyroid antibodies, TgAb or TPOAb. On the contrary, no one of them was found positive for TRAb. We found no case of active hyperthyroidism in this sample, but according to previous medical data six of them had a history of treatment for hyperthyroidism. Hypothyroidism requiring substitution treatment was found in 14.8% (ten patients) of patients with APS. All of these patients were positive for at least one of the anti-thyroid antibodies.
Conclusion
Coexistence of the syndromes of thyroid autoimmunity and antiphospholipid syndrome in significant percent of patients is obvious. However, mutual genetic and/or pathophysiologic mechanisms connecting antiphospholipid syndrome and autoimmune thyroid diseases have yet to be proven.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1660

**Anti neutrophil cytoplasmic antibody levels in graves patients using propylthiourasil**

H. Baser[1], F. Balkan[1], A. Dirikoc[1], F. Saglam[1], R. Ersoy[2] & B. Cakir[2]
[1]Ankara Ataturk Training and Research Hospital, Ankara, Turkey; [2]Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey.

Aim
Antineutrophil cytoplasmic antibody (ANCA) positivity is usually determined in medium and large vessel vasculitis. This antibody has two different forms. Cytoplasmic ANCA (PR3-ANCA) occurs against proteinase-3, while perinuclear ANCA (MPO-ANCA) occurs against myeloperoxidase and bactericidal-permeability increasing proteins. The presence of ANCA is mostly seen in systemic vasculitis and also in drug induced vasculitis. There is no sufficient data about prevalence of positivity ANCA and development of antithyroid antibodies after treatment. In this study our aim was to investigate MPO-ANCA and PR3-ANCA levels in Graves's patients using propylthiourasil (PTU).
Material and method
Graves patients (9 men, 41 women) using PTU and 37 healthy control group were included in the study. ANCA levels of patients and control groups were evaluated.
Results
Mean level of PR3-ANCA in Graves group was significantly higher than control group ($P=0.025$). No significant difference was found between levels of MPO-ANCA ($P>0.05$). Positive correlation was observed between Anti-TPO, Anti-Tg with PR3-ANCA in patient group (respectively, $P=0.001$, $r=0.47$; $P=0.03$, $r=0.310$). Longer duration of treatment in the patient group showed increased levels of PR3-ANCA ($P=0.024$, $r=0.314$). PR3-ANCA levels in Anti-Tg positive patients were higher than those with negative ($P=0.018$). MPO-ANCA and PR3-ANCA were positive in two Graves patients while only MPO-ANCA positive in two patients.
Conclusion
PTU may cause ANCA positivity but vasculitis not develop in all cases. In our study; higher ANCA levels were found in Graves's patients receiving long term PTU treatment.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1661

**A rare case of interferon-α-induced hyperthyroidism in a patient with chronic hepatitis C with granulocytopaenia and transaminasemia treated successfully with radioiodine**

A. Czarnywojtek, J. Waligorska-Stachura, E. Szczepanek-Parulska, M. Zgorzalewicz-Stachowiak, I. Bereszynska, P. Kurdybacha, A. Stangierski, J. Harasymczuk, E. Florek, R. Wasko & M. Ruchala
University of Medical Sciences, Poznan, Poland.

Background
Conventional management of Interferon-α-Induced Hyperthyroidism (IIH) with radioactive iodine (RAI) may be used when treatment with β blockers or antithyroid drugs (ATD), proves ineffective or is contraindicated.
Case presentation
We present a 38-year-old woman who has been treated with combined pegylated interferon alpha (INF-α) and Ribavirin for chronic hepatitis C. Destructive thyrotoxicosis appeared after four months of continuous IFN-α therapy and a β blocker was prescribed. Initially, the patient presented normal TSH 2.4 μIU/ml, however during therapy with INF-α, TSH diminished to 0.05 and thyroid hormones were elevated: $fT_4$ 23.1 pmol/l, $fT_3$ 7.2 pmol/L. Ultrasound examination showed completely irregular and greatly decreased echogenicity of the thyroid gland. The radioiodine uptake (RAIU) was deeply decreased to 2 and 3% at 5 h and 24 h, respectively. The thyroid scintiscan showed lack of isotope accumulation. Hypothyroidism developed and L-thyroxine was prescribed. The following year, hyperthyroidism reoccurred with TSH 0.08 μIU/ml, $fT_4$ 26.4 pmol/l, $fT_3$ 8.2 pmol/l, positive TSHR-Abs 6.2 (normal $<2$ IU/l) and mild Graves' Ophthalmopathy (GO). RAIU values were 23% at 5 h and 46% at 24 h. Thyroid scintiscan showed diffuse goiter. At this point β blocker was introduced and ATD was started. After three months of therapy an increased level of aminotransferases and granulocytopaenia were observed. Hence, the patient received RAI and glucocorticosteroid, while INF-α therapy was continued. After approximately 4 months, hypothyroidism reappeared with insignificantly raised TSH level. One year later the patient was euthyroid and required no further treatment.
Conclusions
Our report suggests that: i) radioiodine therapy might be an effective and safe method of treatment in cases of IIH with mild GO. ii) IFN-α therapy need not be discontinued in patients with IIH.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1662

**Elastography in the differential diagnosis of thyroid nodules**

E. Çakal[1], M. Sahin[1,2], I. Öztürk Ünsal[1], A. Güngünes[1], E. Tutal Akkaymak[1], E. Çakir Özkaya[1], N. Çolak Bozkurt[1], M. Özbek[1] & T. Delibasi[1]
[1]Ankara Diskapi Training and Research Hospital, Ankara, Turkey; [2]Ankara University School of Medicine, Ankara, Turkey.

Objective
Despite the publication of a recent meta-analysis of elastography in thyroid nodules, further work is necessary on this issue in different populations. In this study we aimed to evaluate the clinical value of elastography in nodular goiter in mild iodine defficient region without excluding according to nodule charecteristics.
Materials and methods
This prospective study was conducted between April 2010 and December 2011 in Yildirim Beyazit Diskapi Research Hospital Endocrinology outpatient clinic. Five hundred and twenty eight nodular goiter patients underwent included whom thyroid fine-needle aspiration biopsy (FNAB) were included in our study.
Results
There were 471 females and 57 males and their age ranged from 45 to 78 years. Total 586 nodules were evaluated in these patients. Elastography score and index were measured with real time ultrasound elastography (Hitachi EUB 7000 HV machine with using 13 MHz linear transducer). The area under the curve (AUC) for the elasto score (AUC) was 0.90 ($P<0.0001$) and AUC for the strain index was 0.945 ($P<0.0001$). We suggest that strain index reflects malignancy better than the elasto score. We conclude that 3.5 (68% sensitivity and 99% specifity) is cut-off point for elasto score. For strain index we conclude that 3.9 (73% sensitivity and 99% specifity) is cut-off point.
Conclusion
Strain ratio and strain index measurements of thyroid nodules in our population is efficient and increase the diagnostic performance of the sonography.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1663

**Assessment of left atrial mechanical function in thyroid dysfunction**

T. Karabag, S. Dogan, T. Bayraktaroglu, M. Sayin, I. Akpinar & M. Aydin
Zonguldak Karaelmas University, Zonguldak, Turkey.

Introduction
The objective of this study was to investigate left atrial mechanical function (LAMF) and to associate these measurements with diastolic function in subclinical (SHT) and overt hypothyroidism (OHT).
Methods
Twenty-six newly diagnosed patients with SHT (20F, 6M, mean age 42.2 $\pm$12.5 years), 21 patients with OHT (17F, mean age 40.2$\pm$8.5 years) and 28 healthy volunteers (control group, 21F, 42.4$\pm$11.2 years) were enrolled in this study. Standart M-mode measurements, mitral Doppler flow analysis, tissue Doppler parameters at lateral, septal and right ventricular annulus. Diastolic functions with both conventional and tissue Doppler method were measured. Left atrial maximal volume, minimal volume and volume at atrial systole measured using the disc method. Parameters reflecting left atrial mechanical function were measured.
Results
Active emtptying volume (AEV) and active emptying fraction (AEF) were found to be significantly increased in the OHT and SHT group compared to controls. Passive emptying volume and passive emptying fraction were lower in the OHT and SHT group compared to controls but did not reach statistically significance. Conduit volume was significantly lower in the OHT and SHT group compared to controls. The E/A ratio were significantly lower in the SHT and OHT groups compared to the controls. The lateral and septal E/Em were significantly higher, septal Em/Am was significantly lower in the OHT and SHT group compared to the controls. A correlation analysis revealed that the E/A ratio was negatively correlated with LAAEV and LAAEF ($r=-0.28$; $P=0.02$, $r=-0.29$; $P=0.012$ respectively). The E/Em ratio measured at the septal annulus was positively correlated with AEV and AEF ($r=0.24$; $P=0.04$, $r=34$; $P=0.003$ respectively). There was a negative correlation between the septal Em/Am ratio and AEF ($r=-0.26$; $P=0.03$).
Conclusion
LAMF are impaired in patients with thyroid dysfunction. We consider that impairment of LAMF is primarily caused by seconder to impairment of left ventricular diastolic functions.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1664

**Prevalence, risk and clinical features of subclinical hyperthyroidism in patients with type 2 diabetes**

J. Díez & P. Iglesias
Hospital Ramón y Cajal, Madrid, Spain.

Introduction
Both subclinical hyperthyroidism and type 2 diabetes (T2D) have been associated with an increase in cardiovascular disease risk and mortality. We aimed to assess the prevalence of newly diagnosed subclinical hyperthyroidism in a cohort of patients with T2D, and also to analyse the relationships between diabetes-related characteristics and the presence of subclinical hyperthyroidism.

Methods
Nine hundred and thirty-three diabetic patients without previous history of thyroid disease (45.4% females; mean age, 66.3 year; median duration of diabetes, 10 years; mean HbA1c, 7.8 ± 1.6%) were evaluated. A sample of 911 non-diabetic subjects without known thyroid dysfunction was studied as control group. Serum concentrations of thyrotropin were measured in all subjects. When thyrotropin values were lower than 0.40 mU/l serum concentrations of free thyroxine and triiodothyronine were also quantified.
Results
Subclinical hyperthyroidism was found in 22 female (4.3%) and 15 male (3.5%) diabetic patients. No case of overt hyperthyroidism was found. In comparison with control subjects, the relative risk (OR and 95% confidence interval) for subclinical hyperthyroidism was 1.67 (0.98–2.85). This OR was significant in women (3.69 (1.56–8.71), $P=0.001$), but not in men (0.78 (0.38–1.61)). In comparison with patients without hyperthyroidism, patients with subclinical hyperthyroidism were older, had longer duration of diabetes, had a higher percentage of goiter, a higher percentage of subjects treated with diet, and a lower percentage of subjects treated with oral antidiabetics. Furthermore, fasting glucose levels were lower in patients with subclinical hyperthyroidism. Logistic regression analysis showed that age and the presence of goiter were significantly related to subclinical hyperthyroidism in patients with T2D.
Conclusion
The risk for subclinical hyperthyroidism is increased in women with T2D. Advanced age and the presence of goiter are significantly and independently related with the presence of subclinical hyperthyroidism in diabetic population.

**Softgel capsules of levothyroxine in the treatment of patients with gastric disorders: preliminary results**

M. Santaguida[1], C. Virili[1], S. Del Duca[1,2], L. Gargano[2] & M. Centanni[1,2]
[1]'Sapienza' University of Rome, Latina, Italy; [2]AUSL Latina, Latina, Italy.

Increased need for thyroxine has been described in several gastrointestinal disorders (*H. pylori* infection, gastric atrophy, celiac disease), even in their occult or symptomless forms. A transitory or stable impairment of gastric acidity, by increasing pH value, seems to interfere with thyroxine availability, highlighting a novel role for the stomach in the following intestinal $T_4$ absorption. Distinctive dissolution profiles of different $T_4$ preparations (tablets and/or softgel capsules) have been described and softgel $T_4$ capsules performed better than tablets in alkaline pH. In patients with gastric disorders, where larger doses of thyroxine tablets are required, softgel capsules of $T_4$ may help to reach the therapeutic target and this represented the aim of our study. To this end, we have enrolled patients in therapeutic thyroid homeostasis, presenting with impaired gastric acid secretion and longlasting $T_4$ treatment (>5 years) with the same brand of tablets. All these patients had been advised and agreed to take oral thyroxine under fasting conditions, waiting at least 1 h before eating. Patients bearing additional conditions interfering with thyroxine treatment (e.g. drugs, intestinal disorders, pregnancy, etc.) were excluded from the study. A total of 30 patients (28F/2M; median age = 51 years; median $T_4$ dose = 2.05 μg/kg per day) met these criteria and switched from the usual tablets treatment to the softgel $T_4$ capsules at a significantly lower dose of thyroxine (median $T_4$ dose = 1.77 μg/kg per day; $P=0.0082$). Thyroid function and TSH were measured after 3, 6, 12 and 18 months from the treatment switch. Most of patients (18/30; 60%) showed a TSH increase after 3 months of treatment, with no change in $FT_4$ levels. However, after 6 months, TSH returned to the baseline values in about 2/3 of patients despite the reduced dose of $T_4$. Thyroid hormones were not changed during the study ($P$ = NS). These preliminar findings strongly suggest that treatment with softgel $T_4$ capsules may reach the therapetic goal at a lower dose than a $T_4$ tablet preparation in patients with impaired gastric acid secretion.

## P1666

**Serum thyrotropin, leptin concentrations, thyroid autoimmunity and smoking status, in an euthyroid, iodine-sufficient, Mediterranean population with different body mass index**

A. Lucas[1,2], M. Granada[1], I. Olaizola[1], C. Castell[3], M. Julian[1], S. Pellitero[1] & M. Puig-Domingo[1,2]
[1]Germans Trias i Pujol, Hospital, Badalona, Spain; [2]Autonomous University of Barcelona, Badalona, Spain; [3]Generalitat of Catalonia, Barcelona, Spain.

Introduction
A positive correlation between serum thyrotropin concentrations (TSH) and body mass index (BMI) has been demonstrated. Some studies not shown this, in euthyroid subjects, or observed only if thyroid autoimmunity (TA) is present or in non-smokers (NS). Leptin (Lp) could be the major link between BMI and TSH.
Design
To analyze the relationship between TSH, free thyroxine ($FT_4$), Lp, TA (peroxidase and/or thyroglobulin antibodies) and smoking status in a representative sample of euthyroid, iodine–sufficient, non-hospitalized population of Catalonia, with different BMI. Data collected included if each person smoked or had smoked. Glycemia and insulinemia were also determined and HOMA index, calculated.
Results
Eight hundred ninghty four adults (390 men) of 44.87 ± 15.03 years and BMI 26.19 ± 4.61 kg/m$^2$ (17.01–52.70) with normal TSH (0.33–3.96 mIU/l) and $FT_4$ (0.87–1.90 ng/dl), and median urine iodine concentration 150.0 μg/l were studied. Lp correlated directly with BMI ($P=0.00$). There was no correlation between TSH and BMI. In men, TSH correlated directly with Lp ($P=0.00$) and in women, directly with Lp ($P=0.00$) and HOMA ($P=0.03$) and inversely, with $FT_4$ ($P=0.02$). Only in smoker men, TSH correlated directly with Lp ($P=0.01$) and HOMA ($P=0.02$). In smoker women, TSH correlated directly with Lp ($P=0.00$) and in NS women, inversely with $FT_4$ ($P=0.04$). The multivariate analysis showed that in men, the significant predictors of TSH variations are Lp, directly ($P=0.02$) and age, inversely ($P=0.01$). In women, the predictors are Lp and the presence of TA, directly ($P=0.04$; 0.00) and $FT_4$, inversely ($P=0.01$).
Conclusions
Leptin is a predictor factor of TSH concentration variations, in euthyroid subjects. Other predictor factors are different in men and women. The smoking status can influence the relationship between TSH and some predictor factors. These data should be taken into account before drawing conclusions about the parameters that influence TSH concentrations in euthyroid people with different BMI.

**Resistance to thyroid hormone: clinical, biochemical and genetic features of Mediterranean population**

A. Amor[1], J. Oriola[1], C. Quirós[1], R. Alfayate[7], V. Borrás[3], A. Escribano[4], C. González[6], A. Gutiérrez[4], M. Mauri[7], P. Pérez[5], A. Picó[7], I. Vourliotaki[2] & I. Halperin[1]
[1]Hospital Clínic, Barcelona, Spain; [2]Venizelio General Hospital, Heraklio, Greece; [3]Hospital General de Granollers, Granollers, Spain; [4]Hospital Virgen de la Arrixaca, Murcia, Spain; [5]Hospital Marina Baixa, Villajoyosa, Spain; [6]Hospital Sant Pau, Barcelona, Spain; [7]Hospital General Universitario, Alicante, Spain.

Introduction
Resistance to thyroid hormones (RTH) is a genetic disorder caused in 85% of cases by mutations in thyroid hormone receptor beta gene (TRβ). The current information about it in Spanish population is scarce, limited to case reports or short series of patients. Thus, we aimed to describe the clinical, biochemical and genetic features of Mediterranean patients with RTH referred to our institution (one of the referral centres in Spain) for genetic testing during the last 15 years.
Material and methods
One hundred and sixty-six blood samples of Mediterranean patients (164 Spanish and 2 Greek patients) were received for RTH genetic testing between January

1997 and December 2011. Genetic testing was performed by PCR amplification followed by sequencing of exons 7, 8, 9 and 10. Clinical and biochemical features were obtained from available information sent by referring hospitals.
Results
In all, mutations were identified in 49 patients (28 probands and 21 relatives). 64.6% were women, and mean age at diagnosis among probands was $33.2 \pm 20.5$ years. The following clinical features were recorded: goitre in 50%, hyperkinetic behaviour in 32%, and tachycardia in 29%. Up to 19% of the probands had suffered some type of ablative therapy (radioiodine or thyroidectomy) before diagnosis. As for biochemical features, mean TSH was $10.2 \pm 21.5$ mUI/l (NV 0.4–4 mUI/l), and mean $fT_4$ was $2.75 \pm 0.9$ ng/dl (NV 0.8–2 ng/dl). We found seven new mutations not previously described: p.Ile276del, p.Arg320Ser, p.Phe451Leu, p.Pro452Arg, p.Leu456fsx9, p.Glu457Gly and p.Phe459Leu. The most frequent mutation in our population was p.Arg243Gln, present in three families. Surprisingly, none of our patients harboured the mutation p.Arg338Trp, which is the most common in the published series.
Conclusions
Clinical and biochemical features of our sample of Mediterranean population with RTH are similar to those previously described in the medical literature. However, genetic findings differ, with the identification of seven new mutations in TRβ gene.

## P1668

**Diagnosis and therapeutic practices of hyperthyroidism in france. results of a survey on 263 endocrinologists and 1214 patients (the thyrdel study)**

B. Goichot[1], P. Caron[2], S. Bouée[3], F. Luca[1] & F. Landron[4]
[1]Hôpitaux Universitaires, Strasbourg, France; [2]CHU, Toulouse, France; [3], Bourg la Reine, France; [4]Lyon, France.

There are considerable variations in diagnosis and therapeutical practices in hyperthyroidism (HT) between countries. Few of these differences rely on a scientific basis. we present the results of a study conducted among a representative sample of 263 French endocrinologists. All consecutive patients seen for HT during the study period were included. Symptoms, biological data and treatment were recorded. 1214 patients with hyperthyroidism were included, 1144 had an identified etiology: 802 Graves' disease (GD), 121 multinodular goitres (MNG), 112 iatrogenic hyperthyroidism (mainly amiodarone), 69 toxic adenoma and 40 thyroiditis. Antithyroid antibodies were measured in about half of the population (antiTPO 48.2%, antiR-TSH 56.3%). Ultrasonography was performed in 93.8% whereas scintigraphy was done in only 40.3% of the patients. Therapeutic management depended on the etiology. For the first episode of GD, antithyroid drugs (ATD) alone were the first line treatment in 90.9% of the patients, combined to surgery in 6.1% and with radioiodine in 2.9%. Surgery was preferred to radiodiodine in MNG (51.7 vs 22%) and toxic adenoma (57.3 vs 23.5%).
Euthyroidism was achieved after 3 months in 64.4% of GD, whereas 17.1% were still hyperthyroid and 18.4% were hypothyroid. Block and replace antithyroid regimen was used in 54.6% of the patients. After 3 months, 74.2% patients were euthyroid in the group block and replace vs 64.2% patients in the group with ATD alone ($P = 0.009$). For MNG, toxic adenoma and thyroiditis, around 75% of patients were euthyroid after 3 months, whereas it was the case for only 59.4% of patients with iatrogenic HT.
These results show large discrepancies between practices among a representative sample of French endocrinologists compared with recent American guidelines. Further studies are needed to determine the optimal management of HT.

**The impact of TSH on diffusion of thyroglobulin through follicular lumina: possible relation to hormone formation**

Z. Milicevic[1], V. Bajic[2], J. Kasapovic[1] & J. Ciric[3,4]
[1]Laboratory of Molecular Biology and Endocrinology, 'Vinca' Institute of Nuclear Sciences, University of Belgrade, Belgrade, Serbia; [2]Institute of Biomedical Research, 'Galenika' a.d., Belgrade, Serbia; [3]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia; [4]School of Medicine University of Belgrade, Belgrade, Serbia.

Although the physico-chemical properties of colloid are not usually considered among the factors regulating thyroid function, it is conceivable that decreasing the viscosity of the intrafollicular colloid may facilitate diffusion of thyroglobulin (Tg) molecules within the lumina. The resulting increase in the number of contacts between Tg molecules and peroxidase at the apical membrane may promote the coupling reaction. Rats on a hormonal diet were given 0.5 μg $T_4$/ml of drinking water or 20 μg $T_4$ s.c. for 2 days up to 4 weeks to suppress endogenous TSH. 0.5 IU TSH was then injected together with 125 J. Animals were killed at intervals from 30 min up to 8 h. One thyroid lobe was used for autoradiography, the other for analyses of labeled iodoaminoacids by paperchromatography. Eight experiments with slightly varying design were performed. Within 4 h the total 125J uptake is not increased by TSH ($0.22 \pm 0.03\%$ (S.E.M.) vs $0.31 \pm 0.09\%$ in controls). However, in rats treated with $T_4$ s.c. for 2 days the percentage of 125J–$T_4$ rises from $3.6 \pm 0.2$ to $9.7 \pm 0.07\%$ within 1 h after TSH. While in controls 80% of all follicles with a diameter $> 30$ μm show the classical ring reaction, TSH decreases the relative fraction of ring labeled follicles to 30%. After long term preparation by $T_4$ given in the drinking water, the 125J–$T_4$ rises from $2.5 \pm 0.09$ to $7.0 \pm 1.0\%$ within 4 h after TSH. Whereas in controls, ring labeling was still present in 40% of the follicles, virtually all follicular lumina were homogeneously labeled in TSH treated animals.
Since $T_4$ formation is simultaneously accelerated, the enhanced contact between intraluminal Tg molecules and the membrane bound peroxidase may be the mechanism by which TSH promote early $T_4$ synthesis before iodine uptake is increased.

**Iodine supply and prevalence of thyroid autoimmunity and autoimmune thyroiditis in children and adolescents between 1 and 16 years old in our city**

E. Garcia-García[1], M. Vázquez-López[2], E. García-Fuentes[3], F. Rodríguez-Sanchez[2], J. Muñoz-Vico[2], A. Bonillo[2] & F. Soriguer[3]
[1]Virgen del Rocío Hospital, Sevilla, Spain; [2]Torrecárdenas Hospital, Almería, Spain; [3]Carlos Haya Hospital, Málaga, Spain.

Introduction
Thyroid autoimmunity is related to iodine supply. Iodine nutrition has improved in our country, but the prevalence of autoimmune thyroiditis in our children is unknown.
Objectives
To determine the status of iodine nutrition in children and adolescents in our city. To calculate local prevalence of thyroid autoimmunity and autoimmune thyroiditis in pediatric ages.
Design
Cross-sectional epidemiological study.
Subjects and methods
By a multistage probability sampling 1387 children and adolescents aged between 1 and 16 were selected. Physical examination was carried out including neck palpation. Parents were asked about eating habits, social and demographic aspects. Urinary iodine, free thyroxine, TSH and antiperoxidise and antityroglobulin antibodies were measured. Thyroid autoimmunity was diagnosed when any antibody was positive and autoimmune thyroiditis when autoimmunity was associated with impaired thyroid function or goitre. To study the relation between thyroid autoimmunity and urinary iodine with independent variables we used binary and multiple logistic regression and multiple lineal regression.

Results
Median urinary iodine was 199.5 μg/l. The prevalence of thyroid autoimmunity and autoimmune thyroiditis were 3.7% (2.4–5.0) and 1.4% (0.4–2.4). Thyroid autoimmunity is associated with female sex (OR 2.78; $P<0.001$) and age (OR 1.30; $P<0.001$). Iodine status is associated with milk and dairy products ($P<0.001$) and vegetable intake ($P=0.021$), but not with use of iodated salt at home ($P=0.1$).
Conclusions
The iodine supply in children and adolescents in our city is optimal. Milk and dairy products are the most important iodine source. Thyroid autoimmunity and autoimmune thyroiditis are prevalent in pediatric ages in our city mainly in females and older subjects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Table 1**

| | Thyroid autoimmunity<br>Prevalence (% and confidence interval at 95%) | Autoimmune thyroiditis<br>Prevalence (% and confidence interval at 95%) |
|---|---|---|
| Total group | 3.7 (2.4–5.0) | 1.4 (0.4–2.4) |
| Males | 2.3 (1.1–3.5) | 0.8 (0.0–2.8) |
| Females | 5.0 (3.4–6.6) | 1.9 (0.9–2.9) |
| Prepubertal | 2.4 (1.2–3.6) | 0.5 (0.0–1.8) |
| Pubertal | 6.8 (4.2–9.4) | 3.0 (1.4–4.6) |
| 12–16 years old | 6.2 (4.9–7.5) | 3.2 (0.0–6.5) |
| 6–12 years old | 4.6 (2.6–6.6) | 1.2 (0.0–2.4) |
| 1–6 years old | 0.6 (0.0–2.6) | 0.0 (0.0–0.9) |

### Prevalence of thyroid diseases in a population of non-endocrine tumors in north-east Italy

S. Lio & I. Roiter
Ospedale Civile-ASL N.9, Oderzo-TV, Italy.

Few data on prevalence of thyroid diseases in neoplastic groups of patients has been reported. A slight increased prevalence of hypothyroidism and autoimmune thyroiditis in patients with breast cancer and cutaneous melanoma are been described.
Aim
Of the study was to evaluate the prevalence of thyroid diseases in a group of non-endocrine neoplasm consecutively evaluated by the oncologist and endocrinologist in a iodine-sufficient area of north-east Italy. Three hundred twenty two patients (Group A)(128 women and 194 men, aged 38–88 years, median 65 years) were observed at the Department of Medicine (Endocrine Unit and Day-Hospital Unit) between 2007 and 2010 and compared with a group of three hundred consecutively hospitalized patient for non-oncological diseases of similar age and sex (Group B). 64 pts of group A were affected by pulmonary, 56 by breast, 84 by colon, 35 by gastrointestinal-biliary-pancreatic and 32 by urogenital cancer; 13 pts were affected by other neoplasms. Thyroid diseases were present in 9.9% of patients (32 pts) of group A (female 13.2% and male 7.7% of total group; 2.1% hypothyroidism, 2.4% autoimmune thyroid disease, 0.6% nodular toxic goiter and 6.0% multinodular nontoxic goiter) compared with 14.3% (43 pts) of group B (female 13.0%, male 5.4%; $P<0.01$; 4.1% hypothyroidism, 5.0% autoimmune thyroid disease, 1.0% nodular toxic goiter and 4.2% multinodular nontoxic goiter) . The prevalence of thyroid disease was 9.3% in pulmonary, 12.5% in breast, 7.1% in colon, 11.4% in gastrointestinal–biliary–pancreatic and 17.1% in urogenital cancers, 0% in other neoplasms.
In conclusion, these data shows that in this group of patients the prevalence of thyroid diseases is lower to that of a general non-oncologic hospital population and this may be due to the fact that patients were predominantly male. The higher prevalence of thyroid disease is observed in the urogenital and mammary cancer.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1672

### Serum concentrations of thrombospondin-1 and adiponectin in patients with hyperthyroidism before and after normalisation of thyroid function

K. Dabrowska[1], K. Lewandowski[1], E. Skowronska-Jozwiak[1], A. Brona[2], A. Milewicz[2] & A. Lewinski[1]
University of Lodz and Polish Mother's Memorial Hospital Research Institute, Lodz, Poland; [2]Medical University of Wroclaw, Wroclaw, Poland.

Background
Hyperthyroidism is a common endocrine disorder that is linked to increased cardiovascular morbidity and mortality. Thrombospondin, the matricellular protein, is an important player in the process of cardiac remodelling with complex effects on cardiovascular disease (e.g. prothrombotic and antiangiogenic effects vs potential protective effects in heart failure). Adiponectin is an adipose tissue-derived hormone that shows beneficial effects on atherogenesis, endothelial function, vascular remodelling and insulin resistance. Effects of treatment of thyrotoxicosis on serum adiponectin and thrombospondin concentrations have been poorly investigated, so far.
The aim of this study was to evaluate the circulating levels of adiponectin and thrombospondin-1 in patients with hyperthyroidism before and after normalisation of thyroid function.
Methods
We studied 15 patients (four males), (age $51.8\pm15.3$ (mean $\pm$ S.D.) years) with hyperthyroidism due to Graves' disease, toxic adenoma or toxic multinodular goitre, treated with thiamazole. Thyroid function was normalised after 6–10 weeks. Patients were evaluated at time of diagnosis and again after normalisation of thyroid function with appropriate therapy. Serum concentration of free $T_3$, free $T_4$, TSH, adiponectin and thrombospondin-1 were measured in all subjects before and after treatment with thiamazole.
Results
There was a significant decrease in free $T_3$ and free $T_4$ concentrations (from $8.74\pm4.79$ to $3.54\pm2.40$ pg/ml, and from $4.48\pm2.21$ to $1.02\pm1.07$ ng/ml, $P<0.001$), for free $T_3$ and free $T_4$ respectively. There were, however, no significant differences in adiponectin ($30807.3\pm12996.2$ *vs* $32755.3\pm16638.8$ ng/ml, $P=$NS) and thrombospondin-1 levels ($37400.7\pm11097.7$ vs $40850.7\pm9426.4$ ng/ml, $P=$NS) between patients evaluated at time of diagnosis and again after normalisation of thyroid function.
Conclusions
Our results suggest that reductions of cardiovascular risk due to immediate effects of treatment of thyrotoxicosis are unlikely to be directly related to changes in serum adiponectin and thrombospondin-1.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1673

### Changes in serum homocysteine, lipid, vitamin B12, folate levels and glomerular filtration rate before and after treatment in overt hypothyroidism

F. Kutluturk, S. Yuce, T. Tasliyurt, B. Yelken & P. Aytan
Faculty of Medicine, Gaziosmanpasa University, Tokat, Turkey.

Overt hypothyroidism is associated with an increased risk for cardiovascular disease. We aimed in this study, to assess the changes in renal function, serum lipids, vitamin B12, folate and homocysteine levels before and after treatment in hypothyroid patients.
Fifty-four (male/female;7/47) hypothyroid patients enrolled to study. We measured homocysteine(tHcy), total cholesterol(TC), triglyceride(TG), HDL-cholesterol (HDL-C), creatinine, folic acid, and vitamin B12 levels in both hypothyroid and euthyroid state. Table 1 summarizes the clinical and laboratory data of patients before and after L-$T_4$ replacement. Homocystein levels in hypothyroidism ($9.67\pm5.24$ mmol/l) were significantly higher than in euthyroid state ($8.16\pm3.38$ mmol/l, $P=0.038$). Serum creatinine was higher and GFR was lower before treatment. Following L-$T_4$ replacement, renal functions significantly improved. After achieving the euthyroid state, folate levels significantly increased although vitamin B12 remained unchanged. Serum lipids were significantly high before treatment. After L-$T_4$ replacement, lipid levels statistically significant decreased. We demonstrated a negative correlation between GFR and lipids and a positive correlation with tHcy and lipids in hypothyroid state. All of these correlations became not significant after L-$T_4$ replacement.
In conclusion, our study confirmed previous reports on the effects of thyroid status to cardiovascular risk factors namely hyperlipidemia and hyperhomocysteinemia.

Furthermore, we concluded that, there was a strong correlation between serum lipids and both of GFR and tHcy in only hypothyroid status.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Table 1** Clinical and laboratory characteristics of the patients in hypothyroid and euthyroid state.

| | Hypothyroid state($n=54$) | Euthyroid state($n=54$) | *P* value |
|---|---|---|---|
| TSH (μIU/l) | 37.05±34.15 | 2.32±1.55 | <0.001 |
| $fT_4$ (ng/dl) | 0.64±0.33 | 1.31±0.29 | <0.001 |
| Creatinine (mg/dl) | 0.78±0.23 | 0.68±0.13 | <0.001 |
| Homocysteine (μmol/l) | 9.67±5.24 | 8.16±3.38 | 0.038 |
| GFR (ml/min) | 98.42±24.32 | 111.48±20.79 | <0.001 |
| Total cholesterol (mg/dl) | 227.75±56.56 | 196.92±36.34 | <0.001 |
| LDL-C (mg/dl) | 140.97±45.32 | 115.37±33.01 | <0.001 |
| HDL-C (mg/dl) | 52.94±16.35 | 48.83±15.72 | 0.001 |
| Folate (ng/ml) | 7.61±2.76 | 8.53±3.19 | 0.017 |

## P1674

### Decreased echogenicity and increased vascularization of fetal thyroid on 2D-ultrasonography caused by mother's Graves' disease

M. Gietka-Czernel[1], M. Debska[1], P. Kretowicz[1], H. Jastrzebska[1] & G. Wasniewska[2]

[1]Medical Center of Postgraduate Education, Warsaw, Poland; [2]Bielanski Hospital, Warsaw, Poland.

Fetal ultrasonography is recommended in pregnant women with elevated TSH receptor antibodies (TRAK) or treated with antithyroid drugs in attempt to recognize fetal thyroid dysfunction. We report two cases of pregnant women with Graves' disease in whom fetal thyroid ultrasonography was especially useful in diagnosing child involvement.

A 33-year-old woman at 30-week pregnancy with 3-months history of hyperthyroidism treated with propylothiouracil (PTU) 150 mg daily. Patient TSH was 0.033 μIU/ml (normal, 0.4–4.0 μIU/ml), $fT_4$ 9.24 pmol/l (normal, 11.5–22.7 pmol/l), $fT_3$ 6.1 pmol/l (normal, 2.8–6.5 pmol/l), TRAK 17.28 IU/ml (positive results >1.8 IU/ml). Fetal ultrasonography identified enlarged hypoechoic thyroid gland with increased peripheral vascularization. Fetal hormones concentrations obtained through cordocentesis were indicative for subclinical hypothyroidism: TSH 18.5 μIU/ml (normal, 2.4–12.8 μIU/ml), $fT_4$ 11.0 pmol/l (normal, 9.7–16.7 pmol/l), $fT_3$ 1.17 pmol/l (normal, 1.1–3.7 pmol/l).

The second patient, 30-year-old woman at 35-week pregnancy with 5 months history of hyperthyroidism and inadequate PTU treatment. Her TSH was <0.001 μIU/ml, $fT_4$ 27.8 pmol/l, $fT_3$ 18.1 pmol/l, TRAK 35.5 IU/ml. Fetal ultrasonography revealed hypoechoic goiter with increased central vascularization. The diagnosis of the mother and fetal hyperthyroidism was established.

Our results show that fetal thyroid gland when affected by transplacental passage of of maternal TRAK can demonstrate the same characteristic ultrasound pattern of Graves' disease as in adults: enlargement, hypoechogenicity and hypervascularization. In accordance to previous observation the mode of blood flow within fetal thyroid enables discrimination between fetal hyperthyroidism and hypothyroidism caused by ADT overdosing. The 2D- ultrasound images of fetal goiter with increased blood flow are demonstrated.

Decreased echogenicity, increased thyroid size and increased peripheral vascularization of the fetal thyroid (A); decreased echogenicity, increased thyroid size and increased central vascularization of the fetal thyroid (B).

### Measurement of TSH, $FT_4$ and $FT_3$ with immunoassays based on LOCI technology

T. Lepoutre[1], C. Daumerie & D. Gruson

Universitaires Saint Luc, Brussels, Belgium.

Background

Measurements of TSH, free tetraiodothyronin ($FT_4$) and triiodothyronin ($FT_3$) are essential to achieve assessment of thyroid function. Luminescent Oxygen Channelling Immunoassays (LOCI) have recently been developed for the measurement of biomarkers of thyroid function. Such homogeneous immunoassays allow a faster delivery of the results. The aim of our study were therefore to determine the reference values for LOCI TSH, $FT_4$ and $FT_3$ assays and to compare LOCI assays with our routine assays.

Method

Serum samples from 129 healthy individuals (mean age: 54 years, 45 females and 84 males) were evaluated with the LOCI TSH, $FT_4$ and $FT_3$ assays on the Dimension Vista (Siemens). In addition, patients' samples from our laboratory routine flow ($n=177$) were used for method comparison with the DxI assays (Beckman Coulter), a 'conventional' heterogenous immunoassay.

Results

The reference intervals obtained from the healthy volunteers group were for LOCI assays: .27–2.89 μU/ml for TSH, 0.80–1.30 ng/dl for $FT_4$ and 2.61–4.06 pg/ml for $FT_3$. The LOCI assays were significantly correlated with our routine assays ($r=0.987$, $P<0.0001$ for TSH; $r=0.924$, $P<0.0001$ for $FT_4$ and $r=0.514$, $P<0.0001$ for $FT_3$). For the method comparison, the Passing and Bablok regression analysis showed intercepts of −0.015; 0.098 and 0.297 for TSH, $FT_4$ and $FT_3$ respectively. The slopes were 1.107 for TSH, 1.333 for $FT_4$ and 1.075 for $FT_3$. No significant deviation from linearity for these three parameters was observed. Bland and Altman plots revealed mean differences of −1.8 for TSH, 0.36 for $FT_4$ and 0.47 for $FT_3$.

Conclusion

Our study has provided reference values for the LOCI TSH, $FT_4$ and $FT_3$ assays. Furthermore, we have demonstrated a good agreement between LOCI assays and 'conventional' immunoassays.

### Thyroid function tests in acute kidney injury

P. Iglesias[1], T. Olea[2], C. Vega-Cabrera[2], M. Heras[3], M. Bajo[2], G. del Peso[2], M. Arias[2], R. Selgas[2] & J. Díez[1]

[1]Hospital Ramón y Cajal, Madrid, Spain; [2]Hospital La Paz, Madrid, Spain; [3]Hospital General, Segovia, Spain.

Methods

A prospective study in 35 patients hospitalized for AKI for two consecutive years was carried out. TFT (serum thyrotropin, TSH; free thyroxine, $FT_4$; and total triiodothyronine, $T_3$ concentrations) were measured in each patient on three occasions: at admission, at hospital discharge and at their first outpatient visit.

Results

Total prevalence of alterations in TFT was 82.9% ($n=29$). Of those, euthyroid sick syndrome (ESS) with low $T_3$ only was the most common ($n=13$, 37.1%) derangement. In the whole group of patients TSH (0.93 (0.35–2.27) μU/ml) and $FT_4$ (1.2±0.3 ng/dl) were normal, whereas $T_3$ was low (0.7±0.1 ng/ml). TSH, $FT_4$ and $T_3$ were similar in different types of AKI. In the simple regression analysis we only found a negative correlation between TSH and serum urea concentrations ($\rho=-0.382$; $P=0.024$). At hospital discharge (median hospital stay 6 days (2–10)), TFT showed significant changes only in $T_3$ concentrations (0.8±0.3 ng/ml, $P=0.013$). At this point, the percentage of patients with normal TFT increased from 17.1% at baseline to 40% at discharge and then to 66.7% at their first outpatient visit. We found no association between the presence and type of alterations in TFT and clinical (sex, age, personal history of diabetes and/or hypertension, number and type of drugs used, signs and symptoms, and degree, type and etiology) and

prognostic (hospital stay, recovery of renal function, need of renal replacement therapy, residual chronic renal failure and mortality) factors associated to AKI.
Conclusion
Over 80% of AKI patients exhibit alterations in TFT. The commonest derangement is ESS (~70%), mainly low $T_3$ syndrome, which is present in about one third of the patients with altered TFT. ESS recovers spontaneously as renal function improves. The presence of TFT alterations seems not to be associated with clinical and prognostic implications in AKI patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Spectrum and prevalence of thyroid diseases detected by ultrasonographic examination in west black sea region of Turkey, the MELEN study

Y. Aydin, F. Besir, M. Erkan, H. Demirin, Yazgan, A. Gungor, E. Önder, L. Aydin & S. Dikici
Düzce University Faculty of Medicine, Duzce, Turkey.

Objective
Aim of the study was to investigate the spectrum and prevelance of goiter and thyroidal diseases by ultrasonography in moderately iodine deficient area.
The MELEN study is a prospectively designed survey on the prevalence of cardio metabolic risk factors and thyroid diseases in Turkish adults. A total of 2298 subjects with a mean age of 50 (age range 18–92) were interviewed. Thyroid ultrasonography was performed and interpreted by the same experienced physician, using the same equipment with a 5–12-MHz linear-array transducer. Goiter prevalence was defined according to Gutekunst's criteria. After an overnight fast, blood samples were collected from all the study subjects for the determination of serum free thyroxine, TSH were measured.
Results
The rate of goiter showed a significant female predominance (35% in women and 23% in men, $P<0.001$). According to ultrasonographic examination, the most common thyroid disease was multinodular goiter (MNG; 42%), followed by nodular goiter (NG; 14.6%). Taking into account that subjects had been operated possibly due to NG/MNG, the crude prevalence of nodular disease in the region reached up to 65%. The rate of normal thyroid gland was only 27.4%. According to TSH values, thyrotoxicosis (TSH $<0.35$ μIU/ml) rate was 12.9% and subclinical and overt hypothyroidism (TSH $>$ 4.5 μIU/ml) rate was 7.1%.
Conclusion
In an iodine-deficient community, a progressive increase with age in goiter prevalence, thyroid nodularity, and functional autonomy was observed. Thyrotoxicosis and nodular thyroidal diseases are more important and predominant thyroid diseases.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1678

### Optimal timing of thyroxine dose adjustment for treating patients with primary hypothyroidism: what is the estimated time required to reach stable TSH levels?

S. Kohler[1], O. Senn[2], L. Saleh[1], J. Wass[2] & C. Schmid[1]
[1]University of Zurich, Zurich, Switzerland; [2]University of Oxford, Oxford, UK.

Aim
Serum TSH is the target value by which adequate thyroid hormone supply can easily be monitored in patients with primary hypothyroidism. It is controversial when TSH should be measured before thyroxine dose adjustments are made, 4–8 weeks are recommended. To define the time when dose adjustments of thyroxine are feasible more clearly, we looked at the time required to reach stable TSH levels.
Methods
We prospectively studied a case series of patients with newly diagnosed hypothyroidism (TSH $>10$ mU/l and $fT_4<12.3$ pmol/l). Treatment was initiated with standardised doses of thyroxine, 0.05 mg/day if there was a history of cardiac disease and 0.1 mg/day in all other cases. Blood pressure, pulse, weight, TSH, $fT_4$, $fT_3$, cystatin C and creatinine were recorded once weekly on the same day for a total of 8 weeks. Thyroxine dose was kept constant until the change in TSH between one week and the next was $<2$ mU/l, and it was increased by 0.025 mg every 8 weeks until TSH normalised.
Results
Twelve (six male) patients, 44.6 + 11.6 (mean + S.D.) years old with a median TSH at baseline of 57.6 mU/l (range 11.2–151.8 mU/l) and a median cystatin C at baseline of 0.77 mg/l (range 0.47–1.3 mg/l) gave informed consent. The patients were observed for a minimum of 8 weeks and a maximum of 24 weeks (eight patients for 8 weeks, one patient for 16 weeks and two patients for 24 weeks), resulting in 19 observation periods. Nine patients were euthyroid by the end of the study, the remaining three patients could not participate for a further 8 weeks due to work responsibilities. After adjusting for the number of observation periods for each patient, the mean time to achieving stable TSH (defined as a change in TSH of $<2$ mU/l per week) was 3.45 weeks (95% CI, 2.44–4.46 weeks).
Conclusion
TSH does not seem to change significantly after a mean of 3.5 weeks after an alteration of thyroxine dose. Dose adaptations can be made after 4 weeks of treatment without having to wait 6–8 weeks.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1679

### The concept of ultrasonographic thyroid pattern: re-evaluation after 10 years

D. Peretianu[1], C. Poiana[2], M. Carsote[2], D. Staicu[1] & A. Clodeanu[1]
[1]SCM Povernei, Bucharest-Bucuresti, Romania; [2]Institute of Endocrinology, Bucharest-Bucuresti, Romania.

Aim
To re-analyze the concept of echographic thyroid patterns (ETP) and clinical diagnostic in thyroidology, proposed 10 years ago.
Material/method
i) Between 1996 and 2012, $>25\,000$ thyroid ultrasound, linear probes, 7.5 MHz. ii) Description – eight ETP: pattern 0 – lack of thyroid, 1 – hypoechogenous pseudonodular; 2 – hypoecogen homogenous; 3 – micronodular hypoechogenous; 4 – macro ($>$ 10 mm; ±micro) nodular; 5 – neomogenous hypo/hyperechogenous pseudonodular; 6 – micronodular anechogenous; 7 – hyperecogenous diffuse (normal). iii) Patients: 1092 HT, 5 'sero-negative' thyroiditis (T S-N), 61 thyroiditis with hyper-ATG-emia (T-ATG), 70 idiopathic mixedema (IM); 67 Graves-Basedow disease (GBD) without HT; 995 control. D. Fiability analysis = specificity 2011/specificity 2003.
Results
i) Number echographies/pattern/disease in table.
ii) Sensitivity, specificity, predictive positive value and accuracy for P1: 62,64; 89,73; 88,79; 74,73.
iii) Test X2 (7 degree of freedom): $\gg 24.36$ $<P\ll 0.001$. iv) Reliability 96%.
Conclusions
i) From sensitivity, specificity and predictive positive value analysis, the classification proposed in 2003 (*Rom. J. Endocrinol. Metab.*, 2003, **2**(3) 40. OC.22) is extremely exact and correct (reliability: 96%). ii) VPP ~90 asks the diagnostic to be corroborated with antibody levels. Description 'hypoechogenous-pseudonodular' does not mean implicitly HT (could be T-ATG, too). iii) VPN 80% (pattern 4), means that, when there is a nodule over 10 mm, then HT is improbable. iv) When there are pattern 6 or 7, normality is almost sure. v) Pattern 5 suggest thyroiditis/ Graves-Basedow disease and thyroid hyperfunction.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Table 1** Number of echographies per pattern per disease.

| | HT | T S-N | T-ATG | IM | GBD | Control |
|---|---|---|---|---|---|---|
| Pattern 0 | 9 | 0 | 0 | 5 | 4 | 9 |
| Pattern 1 | 1038 | 1 | 41 | 12 | 4 | 74 |
| Pattern 2 | 175 | 0 | 3 | 34 | 12 | 86 |
| Pattern 3 | 70 | 0 | 3 | 3 | 4 | 127 |
| Pattern 4 | 113 | 4 | 13 | 9 | 9 | 439 |
| Pattern 5 | 181 | 0 | 8 | 0 | 31 | 63 |
| Pattern 6 | 6 | 0 | 0 | 0 | 0 | 43 |
| Pattern 7 | 65 | 0 | 3 | 9 | 11 | 217 |

### The role of color-flow Doppler ultrasonography for differential diagnosis between gestational transient thyrotoxicosis and Graves' disease

Sayid Shafi Zuhur[1], Alper Ozel[2], Mehmet Sait Bugdaci[3], Esra Cil[1] & Yuksel Altuntas[1]
[1]Sisli Etfal Training and Research Hospital, Endocrinology and Metabolism Department, Istanbul, Turkey; [2]Sisli Etfal Training and Research Hospital, Radiology Department, Istanbul, Turkey; [3]Sisli Etfal Training and Research Hospital, First Internal Medicine Department, Istanbul, Turkey.

Introduction
The differential diagnosis between Graves' disease (GD) and gestational transient thyrotoxicosis (GTT) is difficult in the absence of history and clinical features of GD. In this study, we aimed to determine the role of peak systolic (PSV) and end-diastolic velocities (EDV) of the right and left inferior thyroid arteries (ITA) as measured by color-flow Doppler ultrasonography (CFDUSG) for discriminating GTT from treatment naive GD.
Methods
ITA-PSV and EDV of 41 patients with GTT, 31 age matched pregnant patients with GD, 24 age and sex-matched non-pregnant patients with GD and 25 age and sex-matched healthy euthyroid subjects were assessed by CFDUSG. Patients were diagnosed based on the history, clinical findings and TSH-receptor antibody (TRAb) levels.
Results
The mean ITA-PSV and EDV in patients with GTT were significantly lower compared to pregnant patients with GD and higher compared to healthy euthyroid subjects. However, the mean ITA-PSV and EDV in pregnant patients with GD were significantly lower compared to non-pregnant patients with GD (Table 1). ITA-PSV and EDV were positively correlated with TRAb levels ($r=0.515$ for right ITA-PSV, $r=0.463$ for left ITA-PSV, $r=0.615$ for right ITA-EDV and $r=0.526$ for left ITA-EDV respectively). However, in spite of the significant difference between mean ITA-blood flow velocities, an overlap was found between ITA blood-flow velocities in a considerable number of patients with GTT and pregnant patients with GD.
Conclusion
Due to the overlap occuring between a substantial number of patients, the measurement of ITA-blood flow velocities by CFDUSG is not a useful diagnostic tool for differential diagnosis between GTT and GD during pregnancy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Table 1** ITA-blood flow velocities of the study participants.

| | GTT ($n=41$) | Pregnants with GD ($n=31$) | Non-pregnants with GD ($n=24$) | Healthy euthyroid ($n=25$) | $P$ (ANOVA) |
|---|---|---|---|---|---|
| Right ITA-PSV* | 24.3±7.3 | 37.58±10.89 | 57.03±25.7 | 17.08±4.83 | <0.001 |
| Right ITA-EDV* | 10.39±3.7 | 15.9±6.2 | 24.03±11.87 | 7.78±3.07 | <0.001 |
| Left ITA-PSV* | 24.75±6.15 | 35.19±11.19 | 59.4±22.77 | 17.37±4.81 | <0.001 |

## P1681

### The prevalence of hypercreatininemia in patients with primary hypothyroidism

R. Danciulescu, D. Margina, C. Poiana & M. Musat
University of Medicine and Pharmacy Carol Davila, Bucharest, Romania.

Background and aims
Clinical studies demonstrated that hypothyroidism can be a cause of hypercreatininemia. The aims of the present study were to investigate the prevalence of hypercreatininemia in patients with primary hypothyroidism.
Materials and methods
We retrospectively studied serum creatinine levels in 54 patients with primary iatrogenic hypothyroidism (iatrogenic hypothyroidism result seccondary to radioactive iodine therapy and surgery). Results were compared with measurements in 44 subjects with euthyroid state.
Results
The subjects of study group: 31 women (57.40%) and 23 men (42.59%) were between 44 and 71 years mean age S.D. 62.42±6.34 years. In the hypothyroid state, mean TSH levels, free thyroxine (free $T_4$) and creatinine levels were 16.1 ±2.7 mU/l, respectively 0.3±0.1 ng/dl, 1.1±0.1 mg/dl. Fuve patients (9.25%) had creatinine levels greater than the reference intervals There was significant correlation of TSH levels with creatinine levels ($r=0.661$, $P<0.001$). The prevalence of hypercreatininemia in patients with primary iatrogenic hypothyroidism was 9.25% (five patients – three women and two men). In control group no subjects had a creatinine levels greater than the reference intervals.
Conclusion
We conclude that hypercreatininemia is common, in patients with primary iatrogenic hypothyroidism. The mechanism by which hypothyroidism induces hypercreatininemia is incompletely understood but creatinine levels should be evaluated in any patient with hypothyroidism.
Key words: primary hypothyroidism, creatinine levels, TSH.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1682

### Prevalence of thyroid diseases in patients with colon cancer and benign colon polyps

A. Dirikoc[1], A. Oguz[1], E. Akin[1], S. Tuna[1], D. Ozdemir[1], C. Aydin[1], O. Ersoy[2], R. Ersoy[2] & B. Cakir[2]
[1]Ataturk Training and Research Hospital, Ankara, Turkey; [2]Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey.

Aim
In this study, we aimed to evaluate thyroid functions, thyroid antibody positivity, thyroid ultrasonography (US) findings and prevalence of thyroid cancer in patients with colon cancer and benign colon polyps. Also, we aimed to compare prevalence of thyroid diseases in two groups.
Materials and methods
Fifty-seven patients with colon cancer and 50 patients with colon polyps were included in the study. All patients were evaluated with thyroid US and thyroid fine needle aspiration biopsy (FNAB) was performed in indicated nodules.
Results
There were 57 (53.27%) patients with colon cancer and 50 (46.23%) patients with colon polyps. There was no difference in terms of age and sex distribution between groups ($P=0.622$ and $P=0.529$ respectively). Ultrasonographically, nodular and multinodular goiter was observed in 30 (52.63%) patients with colon cancer and 29 (56%) patients with polyp. FNAB was performed in 23 patients in cancer groups and 14 patients in polyp group. Cytology was reported as malignant in one patient with cancer and in one patient with polyp. In these two patients and in another colon cancer patient with suspicious FNAB result, thyroid cancer was confirmed histopathologically. Presence of thyroid disease defined as thyroid dysfunction or positive antithyroid antibody or presence of nodule or thyroiditis in US was found in 44 (77.19%) patients with cancer and 44 (88.0%) patients with polyp ($P=0.228$).
Conclusion
This study showed that thyroid dysfunctions, thyroid US findings and prevalence of thyroid cancer are similar in patients with colon cancer and colon polyps. Since thyroid pathologies are observed in more than tow or three of patients in both groups, we think laboratory examinations for thyroid functions and thyroid antibodies and thyroid US should be a part of investigation in patients with colon cancer and colon polyps.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1683

**'Racing heart': a case of unrecognized hyperthyroidism presenting as monomorphic ventricular tachycardia**

A. Lim & M. Sedurante
University of the Philippines-Philippine General Hospital, Manila, Philippines.

Ventricular tachycardia may occur in the setting of primary hyperthyroidism despite the absence of typical hyperthyroid symptoms. The case is a 40-year old female coming in for epigastric pain and vomiting who was incidentally found to have monomorphic ventricular tachycardia. Despite this she was in no respiratory distress, and exhibited no symptoms of heart failure. Other than agitation, physical examination showed no signs of hyperthyroidism. Initial management included numerous electric cardio-versions and Amiodarone, which was immediately discontinued after thyroid function tests revealed a low TSH ($<0.005$ mIU/l) and elevated free $T_4$ (35 pmol/l) consistent with primary hyperthyroidism. A neck ultrasound revealed normal sized glands and no increased vascularity. Transthoracic echocardiogram showed normal-sized left ventricle with multi-segmental wall motion abnormalities and depressed overall systolic function (EF = 49% by Teicholz's). After a few months of treatment with Methimazole 20 mg/day and Propranolol 40 mg/day, free thyroxine levels normalized with no recurrence of ventricular tachycardia. Thyroid scan done 6 months after Amiodarone intake and 1 month off anti-thyroid medications showed normal-sized glands and normal 2/24 h uptake values, and a repeat TTE showed normal geometry and improved ejection fraction at 78%. Patient remains functional on her daily activities and remains asymptomatic.

Conclusion

Ventricular tachycardia as an initial presentation of autoimmune hyperthyroidism is rare, the most common arrhythmia being atrial fibrillation. However treatment with anti thyroid medications, β-blockers and close monitoring can result to improved clinical outcomes.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1684

**A rare case of periodic hypokalaemic paralysis secondary to Graves' thyrotoxicosis**

F. Wernig, C. Wincup & K. Wynne
Charing Cross Hospital, London, UK.

A 42-year-old gentleman of Ghanaian origin presented with a 1 month history of worsening severe proximal myopathy. On presentation his symptoms had progressed to the extent that he was unable to mobilise from his bed. Prior to this illness he had been fit and well. Examination revealed severe proximal myopathy and a uniformly enlarged, smooth thyroid gland. There was no clinical evidence of hyperthyroidism.

Blood tests on admission showed a serum potassium level of 2.1 mmol/l, TSH $<0.05$ mU/l, $FT_3$ 20.3 pmol/l, $FT_4$ 35.0 pmol/l. TSH receptor antibodies were strongly positive at 24.5 μ/ml. A diagnosis of thyrotoxic periodic paralysis (TPP) was made. Within 3 h of commencing intravenous potassium replacement the proximal myopathy resolved entirely.

Following an overnight stay in hospital he was discharged on a combination of Carbimazole 40 mg once daily and Propanolol 40 mg tds. His serum potassium level at discharge was 4.4 nmol/l and remained normal at 6 weeks follow up without additional potassium supplementation. Following normalisation of his thyroid hormone levels he had no further episodes of paralysis.

TPP is a rare, but potentially life-threatening complication of hyperthyroidism due to a sudden intracellular shift of potassium. The electrolyte shift is most probably due to an increased activity of the sodium–potassium adenosine triphosphatase pump (Na/K-ATPase) either directly by the thyroid hormones or indirectly via adrenergic stimulation[1]. It appears likely that TPP patients have a genetic predisposition to activation of the Na/K-ATPase genes[2]. TTP is predominantly seen in patients of Asian descent[3,4]. Here we present a rare example of an Afro-Caribbean man developing hypokalaemic periodic paralysis in the context of Graves' thyrotoxicosis.

## P1685

**Ultrasonographic aspects in *post-partum* thyroiditis**

M. Stanciu, F. Popa & I. Totoian
Lucian Blaga University of Sibiu, Sibiu, Romania.

Introduction

*Post-partum* thyroiditis (PPT) is an autoimmune disorder of the thyroid gland, which occurs in the first year after parturition. *Post-partum* thyroiditis occurs in 50% of TPO AB + ve women and is characterised by transient hyperthyroidism followed by transient hypothyroidism during the first 6 months, *post-partum*. A third of the latter group develop permanent hypothyroidism. The aim of this study was to evaluate sonographic characteristics in a group of PPT patients in Sibiu county in 2 years (2009–2011).

Material and method

The study group consisted of 39 PPT patients and 40 normal *post-partum* women as the control group. Physical examination of thyroid, value of TSH, $FT_4$, TPO and ultrasonography were carried out monthly in PPT patients until remission for up to 6 months *post-partum*.

Results

Visible goiter was detected in 19.1% of patients and 6.1% of the control group ($P<0.001$). Hypoechogenecity in thyroid sonography was present in 91.9% of patients and 6% of the control group ($P<0.001$). At 6 months after delivery, only four patients had abnormal thyroid function tests, while three patients with TSH $>10$ mU/l still showed hypoechogenicity in thyroid sonography. In conclusion, sonography may be recommended as an adjuvant to laboratory tests in evaluation of PPT patients.

Conclusion

Prolonged follow-up of the subsequent thyroid function and ultasonographyc characteristics may be needed in women who experience PPTD and/or show a high titre of antithyroid antibody.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1686

**Primary and secondary autoimmune thyroiditis in rheumatoid patients**

V. Odin, V. Tyrenko, E. Tzygan, M. Blohin & N. Avtandilashvily
Military Medical Academy, St Petersburg, Russian Federation.

Aim

Studying of features autoimmune thyroiditis associated with rheumatoid arthritis (AIT/RA).

Methods and materials

Twenty-nine women with AIT/RA were examined. Study design included: special protocol of anamnesis, sonography of thyroid gland, evaluation of thyroglobulin antibodies (Tg-Ab), thyreoperoxidase antibodies (TPO-Ab), the

thyroid hormones ($T_3$, $T_4$) and TSH in serum. Two groups of patients have been allocated: I group ($n=21$) – persons at whom RA debuted after debut AIT (primary AIT/RA), II group ($n=8$) – persons at whom debuted the first RA with the subsequent debut AIT (secondary AIT/RA).
Result
The persons with primary AIT/RA were majority – 72%. The age of a debut primary AIT/RA was at $44.3 \pm 1.2$ years, while secondary AIT/RA debut – $55.4 \pm 1.6$ years ($P<0.05$). Thus in II group of 88% of patients had debut of AIT in the postmenopausal period (mean age of a menopause $51.2 \pm 1.2$ years), while the majority of patients of I group – 86% in the menstrual period. Thyroid volume exceeded normal values at 38% of patients of I group and at 25% of patients in II group. Hypothyroidism has been revealed at 90% of patients of I group and at 75% of patients of II group, in most cases was in subclinical grade. Cases of thyrotoxicosis were absent. Tg-Ab level in I group was considerable above, than in II ($507.5 \pm 48$ vs $272.5 \pm 57$ IU/ml accord., $P<0.05$), TPO-Ab level also was above in I group ($P<0.05$).
Conclusions
Primary AIT/RA was observed much more often, than secondary AIT/RA and had debut on a late menstrual phase of ontogeny, while secondary AIT/RA had debut at on early postmenopausal period. Primary AIT/RA had antibodies level in higher concentration in comparison with secondary AIT/RA especially Tg-Ab level and had more often impairments of thyroid function mainly observed as a subclinical hypothyroidism.

**The effect of radio-iodine treatment on *Helicobacter pylori* eradication**

A. Usluogullari[1], S. Caner[1], E. Ozdemir[1], E. Onal[1], O. Ersoy[2], R. Ersoy[2] & B. Cakir[2]
[1]Ankara Ataturk Training and Research Hospital, Ankara, Turkey; [2]Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey.

Aim
Radioactive treatment after surgery forms the basis of treatment of differentiated thyroid cancers (DTC) and also used as permanent theraphy of hyperthyroidism. Iodide is being transported into the thyrocytes by the NIS system that located on the thyrocytes' cell membran. NIS system also has been shown at the gastric mucosa. In this study we proposed to analyse the effect of low and high dose radio-iodine treatment on *Helicobacter pylori* eradication.
Material and methods
Total 87 patients included for study. The patients investigated detailed about medications and gastrointestinal symptoms. Patients have neither dyspeptic symptoms nor any usage of $H_2$ receptor bloker, proton pump inhibitor, antiasit or any form of antibiotics. Urea breath test before and 2 months after radio-iodine treatment have been made for detection of *Helicobacter pylori* eradication.
Results
The radio-iodine treatment has been planned to give as permanent threapy to 76 patient (87.4%) with hyperthyroidism and 11 patient (12.6%) with differantial thyroid cancer. The average dose of given radio-active iodine to patients for ablation purposes is $115 \pm 3.3$ and $22.7 \pm 1.4$ mCi. Before RAI treatment, in the group of DTC the urine breath test result of the 44 patients had positive HP and 32 of them had negative HP, and for hyperthyroid patients four of them had positive HP and seven of them had negative HP. All patients having initial positive test results had also positive control test results at the 2nd month of the RAI treatment (100%). Both patient group having initial negative test results, had also negative control test results (100%).
Conclusion
There are some literature studies shows that RAI treatment is effective on HP eradication. Our results indicate that low and high dosage of RAI treatment does not have any effect on HP eradication in early period.
Declaration of interest

**Hashimoto's (chronic) thyroiditis in perimenopausal women**

M. Katai, N. Kondo, J. Yokota, N. Kazuka, K. Todoroki, M. Kawamata, K. Yamaguchi & K. Otsuka
Medical Center East, Tokyo Women's Medical University, Tokyo, Japan.

Background
One in 10–30 women in general population has Hashimoto's (chronic) thyroiditis. Development of thyroid dysfunction depends on age. The ratio of woman around 50 with TSH elevation is 10% in general population. Menopause occurs at this age for most women. Many symptoms of hypothyroid state are similar to symptoms of menopause except hot flashes and night sweats. We analyzed the relationship of Hashimoto's disease and menopausal symptoms.
Methods
Subjects are 271 women, new patients range 17–79 years of age (mean: 48.7 years old) at our clinic between January and May, 2010. We performed questionnaires about their menstruation and menopausal symptoms, also measurement of serum F-$T_3$, F-$T_4$, TSH, antithyroglobulin antibodies and anti-thyroid peroxidase (anti-TPO) antibodies at the first visit. Subjects are assorted to four groups depending on menstrual condition. That is pre group (regular menstruation) is 35.7%, peri group (irregular menstruation before menopause) is 24.0%, post group (1–5 years after menopause) is 9.0%, post–post group (over 5 years after menopause) is 31.3%.
Results
Of the total, 28.8% of all subjects has antithyroid antibodies (antithyroglobrin antibodies 21.1%, anti-TPO antibodies 12.7%). The breakdown by groups is pre 20.6%, peri 23.1%, post 45.8%, post–post 37.6%. Hypothyroid state (TSH $>4$ μIU/ml) was observed 11.8% of all. The breakdown by groups is pre 9.9%, peri 22.6%, post 4.2%, post–post 7.1%. Seventy six per cent of all has menopausal symptoms.
Conclusions
Menopausal symptoms in Hashimoto's disease women are characterized by that coldness and fatigability are significantly higher, on the other hand hot flashes, night sweats and irritability are significantly lower than women without Hashimoto's disease. In this study, the frequency of hypothyroid in premeopausal women is higher than postmenopausal women among women with antithyroid antibodies. It is presumably that overt hypothyroid patients tend to visit clinics earlier than menopause.

## P1689

**Hyperglycaemia in hyperthyroidism predictive factors**

S. Azzoug[1], D. Remini[2], S. Fellah[2], E. Koceir[2] & F. Chentli[1]
[1]Bab El Oued Hospital, Algiers, Algeria; [2]Bab Ezzouar University, Algiers, Algeria.

Glucose abnormalities are frequent in hyperthyroidism; the aim of our study is to determine the predisposing factors of glucose disturbances in hyperthyroidism.
Subjects and methods
It is a retro and prospective study including 263 hyperthyroid subjects, patients having fasting glycaemia $<1$ g/l and/or glycaemia after OGTT $<1.40$ g/l (G1) were compared to patients having fasting glycaemia $\geq 1$ g/l and/or glycaemia after OGTT $\geq 1.40$ g/l (G2).
Results
Seventy-five patients (G2) had glucose abnormalities. Patients of G2 were older than those of G1, underlying hypertension and familial diabetes were more prevalent in G2. There was no difference between the two groups for the other factors studied (Table 1).
Discussion and conclusion
Ageing, underlying hypertension and familial diabetes are risk factors for glucose abnormalities in hyperthyroid subjects whereas the severity of hyperthyroidism is not which suggest that hyperthyroidism may worsen glucose metabolism in patients at risk of type 2 diabetes.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Table 1** Predictive factors of hyperglycaemia during hyperthyroïdism.

| | G1 | G2 | P |
|---|---|---|---|
| Number (%) | 188 (71.48%) | 75 (28.52%) | |
| Family Diabetes (%) | 31.38% | 48% | <0.05 |
| Hypertension (%) | 6.91% | 25.33% | <0.05 |
| Age (years) | 40.07±1.22 | 49.27±1.96 | <0.01 |
| BMI (kg/m$^2$) | 22.94±0.33 | 24.05±0.67 | NS |
| FT4 (pmol/l) | 43.55±2.43 | 32.62±3.51 | NS |

## P1690

### An unusual case of hyperthyroidism

A. Boumpaki, I. Vourliotaki, I. Bonapart, S. Alexaki & K. Stamataki
Venizeleio General Hospital, Heraklio, Crete, Greece.

Introduction
During embryogenesis the descent of the thyroid may not proceed normally and may stop at various sites from the base of the tongue to any site of the thyroglossal duct.
Ectopic thyroid tissue, defined as thyroid tissue not located at its normal site (anterolaterally to the second and fourth tracheal cartilages) is rare. Most often, ectopic tissue is located in the base of the tongue.
Case report
We report a 75-year old female referred to our Department for subclinical hyperthyroidism, diagnosed during investigation of atrial fibrillation and weight loss.
She had negative antithyroid autoantibodies, elevated ESR and normal full blood count.
On Tc-99 thyroid scan there was no uptake. Ultrasound showed an enlarged gland with two nodules 1.6 and 1.2 cm on the right and left lobe respectively. Subacute thyroiditis was diagnosed and no special treatment was administered.
Four months later she came back in a worse clinical condition and clinical hyperthyroidism. Considering the possible diagnosis of an ectopic thyroid gland, a whole body scan with Tc99 was performed. It showed hyperfunctioning thyroid tissue in the base of the tongue, with simultaneous suppression of the eutopic thyroid.
She was prescribed antithyroid drugs.
Macroscopic physical examination of the oral cavity was negative, as well as the MRI of the area.
Conclusion
To our knowledge, it is the first case of hyperfunctioning lingual thyroid with simultaneous existence of the eutopic thyroid gland.
Additionally, in reported cases so far ectopic thyroid tissue is usually diagnosed in childhood or adolescence and is usually accompanied by hypo- and not hyperthyroidism.
In most cases, lingual thyroid is visible as a mass in the base of the tongue, in contrast to our case, where it was invisible.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Do thyroid hormone levels in critical illness predict outcome? Experience from a medical ICU in north east India

U. Saikia[1], S. Gadve[1] & S. Choudhury[2]
[1]Gauhati Medical College, Guwahati, India; [2]N L Medicare and Research Centre, Guwahati, India.

Alterations in thyroid hormone levels are commonly observed in critical illness with thyroxine replacement remaining a controversial issue. We undertook a prospective observational cohort study in medical intensive care unit of Gauhati Medical College to evaluate whether thyroid hormone levels at admission could be used to predict mortality and compared it to the well established APACHE II scoring system for ICU patients. Serum $T_3$, $T_4$ and TSH were estimated at admission in 100 consecutive adults without prior history of thyroid disease admitted to the medical ICU. An APACHE II score was calculated for each patient on the day of admission. The patients were followed up and were divided subsequently into survivors and non-survivors. The TSH, $T_4$, $T_3$ and APACHE II scores were compared in both groups. Non-survivor group had 46 patients while survivor group had 54 patients. TSH and $T_3$ levels in the non-survivor group ($0.505 \pm 0.515$ mIU/l and $0.684 \pm 0.10$ nmol/l respectively) were significantly lower than that in the survivor group ($1.149 \pm 1.08$ mIU/l and 0.934 $\pm 0.223$ nmol/l) respectively. Total $T_4$ in non-survivor group (65.32 $\pm 40.84$ nmol/l) was also lower than that in the survivor group (75.56 $+34.0$ nmol/l) but this difference was not statistically significant ($P=0.18$). There was a statistically significant inverse correlation between APACHE II score and total $T_3$ and TSH. ROC curve analysis was done for comparing the prognostic value of different parameters. AUC for APACHE II, $T_3$, TSH and $T_4$ were 0.96, 0.85, 0.74 and 0.59 respectively.
TSH and total $T_3$ at admission has prognostic value in patients admitted to the medical intensive care units. Low TSH and $T_3$ correlates with APACHE II score in predicting poorer outcome.

### Vitamin E and selenium have a protective role in apoptosis induced by $H_2O_2$ in human thyrocytes

S. Yan, S. Shi, Y. Wang, X. Yu & L. Wang
Hospital of Qingdao University Medical College, Qingdao, China.

Objective
To investigate the influence of vitamin E (VE) and selenium (Se) on apoptosis of human thyrocyte induced by $H_2O_2$.
Methods
The human thyroid epithelium cells (TEC) from normal para-adenoma tissues of patients with thyroid adenoma resection were cultured. In prevention groups, vitamin E (50 μmol/l), selenium (10–7 mol/l) or serum-free medium was respectively added into thyrocytes of monolayer culture before $H_2O_2$ (200–800 μmol/l) with different concentrations added, while in treatment groups $H_2O_2$ (200–800 μmol/l) was added firstly. The survial rates of thyrocyte were detected by MTT stain, and the apoptosis rates by flow cytometry.
Results
When the thyroid epithelium cells exposed to $H_2O_2$ (200–800 μmol/l) only for 24 h, the cell survial rates declined and cell apoptosis rates increased ($P<0.01$) in both prevention and treatment groups, with a relation of dose-effect response. Adding VE (50 μmol/l) and Se (10–7 mol/l) into cell culture for prevention and treatment, the cell survial rates increased and the thyrocyte apoptosis reduced compared to the corresponding simple $H_2O_2$ intervention groups. Above differences were particularly significant ($P<0.05$) when thyrocytes exposed to 400 and 800 μmol/l $H_2O_2$. The decrease of cell apoptosis rates in group with selenium pre-intervention was more significant than that in group with VE pre-intervention ($P=0.018$) when cells exposed to 400 μmol/l $H_2O_2$. While the decline in group with VE was more obvious than that in group with selenium ($P<0.05$) when cells exposed to 200 and 400 μmol/l $H_2O_2$ in treatment groups.
Conclusion
VE and selenium could have protective effect on apoptosis of human thyrocytes induced by $H_2O_2$ in human thyrocytes.

**Exophtalmoses due to a bilateral lacrymal gland MALT lymphoma in first occurrence of Graves'disease**

C. Solmon[1], O. Gisserot[2] & D. Hammoutène[1]
[1]Hyères General Hospital, Hyères, France; [2]Army Instruction Hospital Sainte Anne, Toulon, France.

Introduction
Bilateral exophtalmoses is common at Graves' disease diagnosis, but context and clinical abnormalities lead sometimes to consider other diagnosis.
Case report
A 52-year-old man had a previous history of pulmonary MALT lymphoma in complete remission and Hashimoto's thyroiditis, which were diagnosed simultaneously 6 years before. He presented recently with hyperthyroidism (TSH $<0.001$ mUI/l; $T_4=25$ pmol/l) after 2 months of L-thyroxine discontinuation, associated with mild goiter, bilateral exophtalmoses and periorbital edema. TSH receptor antibodies (13 UI/l) were positives, which confirmed Graves' disease. Thiamazole were started (5 mg/J) with low dose because of renal failure but led to hypothyroidism in the following 2 weeks. Exophtalmoses worsened with major edema and palpable masses of the orbits despite correction of hypothyroidism. A MRI showed bilateral severe infiltration of both lacrimal glands, without abnormalities of ocular muscles. Biopsy revealed bilateral mucosa-associated lymphoid tissue (MALT) lymphoma (CD 20+). Tumor staging showed no other location. Chemotherapy using weekly Rituximab and chlorambucil with progressive dose during 6 weeks led to an important improvement of the lymphoma. Maintenance treatment is on going.
Conclusion
In this case, the two occurrences of MALT lymphoma were coincident with thyroid auto immunity diseases, which emphasizes the possible relation between these two conditions. To our knowledge, it is the first reported case of bilateral lacrymal gland lymphoma diagnosed silmutaneously with Graves' disease. The presence of palpable lacrymal glands could suggest this differential diagnosis of Graves' ophtalmopathy.

## P1694

**A correlation study of thyroid nodule cytopathology and histopathology**

P. Roldán, C. López-Tinoco, I. Mateo, L. Larrán, B. Ojeda, I. Gavilán, E. Vallejo, D. Martínez-Parra & M. Aguilar-Diosdado
Hospital Puerta del Mar, Cádiz, Spain.

Background
Fine-needle aspiration (FNA) biopsies are the cornerstone of preoperative evaluation of thyroid nodules, but FNA diagnostic performance has varied across different studies. We conducted a study to evaluate the effectiveness of ultrasound guided FNA in the thyroid nodule and to review the correlation between cytopathology and histopathology.
Methods
Prospective FNAs were collected from 511 patients who underwent a ultrasound guided FNA between 2008 and 2011. One hundred sixty-two patients underwent thyroidectomy. Cytology and surgical pathology results were matched in this group and sensitivity, specifity, positive predictive value and negative predictive value were calculated.
Results
The mean age was $54.7\pm13.4$ years old (440 women and 71 men). The average size of nodules was $2.2\pm1.2$ cm ($2.75\pm1.45$ in patients undergoing thyroidectomy). Multinodular goiter presented with dominant nodule 406 patients (79.5%) and 105 single nodule (20.5%). The FNA was inconclusive in 7.8% of cases. Benign cytology had 80.4% of patients, 9% indeterminate cytology and 1.8% malignant cytology. One hundred sixty two patients underwent thyroidectomy (58.8%, total thyroidectomy). From this population histopathology malignancy rates for prospective clinic FNAs were 10.7% for cytology indeterminate cases and 88.8% for cytology malignant cases. The FNAs had a sensitivity of 89%, specificity of 99%, positive predictive value of 89% and negative predictive value 99%.
Conclusions
Ultrasound-guided FNA provides important information for the diagnosis and the preoperative evaluation of thyroid nodules. The low rate of false-positive and false-negative results suggests that it might be enough for surgical planning for thyroid nodule.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1695

**Prevalence of thyroid dysfunction in a subgroup of male patients with HIV**

R. Sanchez-Ortiga, R. Cerezo-Vidal, M. Sanchez-Pacheco Tardon, M. Mijares, G. Negueruela-Avella, J. Portilla-Sogorb, A. Pico-Alfonso & O. Moreno-Perez
Hospital General Universitario Alicante, Alicante, Spain.

Introduction
Thyroid dysfunction has been described as a common clinical entity in HIV infected patients, commonly with negative autoimmune tests. The aim of this work was to determine the prevalence of thyroid abnormalities in a cohort of HIV-infected males in a stable clinical state, the effect of exposure to ART on thyroid function and to identify the risk factors.
Materials and methods
This is a cross-sectional, observational study of 90 HIV infected males ($42\pm8.2$ años). Exclusion criteria: HCV co-infection, AIDS-defining active disease, drug abuse or therapeutic non-compliance. Statistical analysis: descriptive, Pearson/ρ Spearman correlation of quantitative variables; Student-$t$ or Mann–Whitney $U$ test for differences of TSH–$FT_4$ on qualitative variables; $\chi^2$ test between thyroid alterations and qualitative data; statistical significance $P<0.05$.
Results
Prevalence of thyroid abnormalities was 6.7% (95% CI 3.1–13.8): 1/90 subclinical hyperthyroidism, 2/90 subclinical hypothyroidism, 2/90 low $FT_4$, 2/90 antiTPO positive. $FT_4$ concentration was associated with CD4 nadir ($r$: 0.221, $P=0.037$), whereas TSH levels were correlated with viral charge (RNA cop./ml; $r$: $-0.26$, $P=0.01$). antiTPO antibodies were correlated both with CD4 concentration ($r=-0.28$, $P=0.008$), and viral charge ($r$ 0.29, $P=0.005$). We did not find any association between HIV treatment and thyroid dysfunction.
Conclusion
Male patients with HIV infection in stable clinical state have similar prevalence of thyroid dysfunction than general population, with lower prevalence of autoimmunity. The mechanism and clinical consequences of low $FT_4$ are not yet known and have to be studied.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1696

**Thyroid concentrations and leptin levels in patients with anorexia nervosa**

M. Nikolic Djurovic, D. Jankovic, M. Petakov, J. Antic & S. Damjanovic
Institute of Endocrinology, Belgrade, Serbia.

Anorexia nervosa (AN) is known as a state of gonadotrophin and leptin deficiency. Leptin, the product of OB gene, secreted by adipocytes, is proved to play an important role in regulating apetite and energy expenditure. Thyroid hormones are Important regulators of total energy expenditure are thyroid hormones and also are able to increase oxygen consumption by tissues. The aim of the study was to evaluate a possible interaction of thyroid hormones ($T_3$, $T_4$, TSH) with leptin in a patients with AN. We evaluated 19 patients with AN, female age $21\pm1.3$ years who have gained weight (BMI $14.8\pm0.6$–$19.1\pm0.5$ kg/m$^2$). At the moment of diagnosis, serum leptin levels were $2.1\pm0.3$ μg/l while after behavioural therapy and hypercaloric diet for 3–12 months serum leptin levels

rose to 6.5±1.5 μg/l not different from 11 healthy female subjects (age 29±5.2 years, BMI 21.1±0.3 kg/m$^2$) whose serum leptin levels were 9.3±0.7 μg/l ($P>0.05$). Thyroid function was assessed by measuring serum fasting triiodo thyronine ($T_3$), thyroxine ($T_4$) and TSH. None of the subjects was taking any medications. Leptin values correlated well with BMI and the mean serum leptin contrecations in AN subjects was 2.39±0.15 ng/ml as compared to 9.3 ±1.1 ng/ml in control subjects ($P<0.01$). No significant differences in thyroid hormone levels ($T_3$ 1.2±0.3 vs 1.8±0.4 nmol/l, $P>0.05$, $T_4$ 88.3±10.1 vs 110.2±28.3 nmol/l $P>0.05$, TSH 1.5±0.4 vs 1.9±0.9 mUI/l, $P>0.05$) were recorded. Thyroid hormone axis remains normal in secondary leptin deficiency.
Keywords: leptin, anorexia nervosa, thyroid hormones.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1697

### Congenital hypothyroidism as a rare cause of precocious puberty

P. Hoxha[1], E. Puca[2], B. Dyrmishi[3], Z. Ylli[4], A. Ylli[4] & E. Puca[4]
[1]UHC 'Mother Teresa', Tirana, Albania; [2]American Hospital II, Tirana, Albania; [3]Neo Style Clinic, Tirana, Albania; [4]UHC 'Mother Teresa', Tirana, Albania.

Severe hypothyroidism is a rare cause of precocious puberty, because long-standing primary hypothyroidism traditionally leads to both pubertal and growth delay. We report a case of a 4.7 year old girl presented with abdominal/pelvic pain and vaginal bleeding since 1 week. The child was diagnosed as a case with a right ovarian mass and was planned for surgery. She was born at term pregnancy without complication. Physical examination revealed typical features of hypothyroidism. Growth velocity was decreased and contrasted with exaggerated weight gain. She weight 21 kg (weight 90th percentile), height was 92 cm (height <3rd percentile), stature development was 2 year and 9 months, bone age corresponding to 1 year. Breast development was at stage II (S2), no axillary (A0) and no pubic hair (PO). The serum thyroid-stimulating hormone level was enlarged >75 mIU/l (range 0.3–5.0), total thyroxine ($TT_4$) and total triiodothyronine($TT_3$) were undetectable, follicle stimulating (FSH) was 5.1 UI/l (3–8), and luteinizing (LH) 0.2 UI/l (range 1–7), prolactin was elevated, at 29.6 ng/ml (2.7–8.7). Thyroid ultrasound showed absence of thyroid gland in normal location. Scintigraphy with Technetium 99 showed light isotope uptake in the sublingual region and absence of isotope uptake in the normal thyroid position. These results were consistent with the diagnosis of primary hypothyroidism as a result of thyroid agenise. She was treated with L-thyroxin 25 μg/day for the first two weeks than to 50 μg once daily fasting in the morning. Vaginal bleeding was stopped after few days that we start treatment and was not seen again. Breast development, size of uterus and ovaries returned to the prepubertal stage after 6 months of the L-thyroxin therapy.
In conclusion children with precocious puberty having solitary masses on ovary, decreased growth velocity and bone age delay should be assessed for hypothyroidism in order to avoid unnecessary surgery on the ovaries.

## P1698

### Evaluation of subclinical thyroiditis among Egyptian type 1 diabetic patients by Hesham El-Hefnawy, Atef Bassyouni*, Mohamed Abdel-Kareem**, Nibal Abdel-Rahman***, Mary Aziz****And Ibrahim Emara****

M. El Hefnawy
National Institute for Diabetes and Endocrinology, Cairo, Egypt.

Autoimmune thyroiditis (AIT) is a group of inflammatory thyroid disorders with either hyperthyroid, euthyroid or hypothyroid state. The aim of this study is to detect the subclinical thyroiditis among the Egyptians type 1 diabetic patients and to study the relation of the thyroid antibodies to different metabolic control indices of diabetes. The study group consisted of 50 type 1 diabetic patients aged from 8 to 18 years. They were selected from the out-patient daily clinics of National Diabetes Institute (NIDE). The control group consisted of 20 healthy subjects comparable for age, sex and socioeconomic classes of study group. Both groups were having no signs or symptoms of thyroid dysfunction. They were subjected to the following: quantitative determination of free $T_3$ and free $T_4$ in serum, quantitative determination of TSH in serum, estimation of thyroid auto-antibodies using ELISA for the semiquantitative detection of thyroglobulin antibodies (TG-AB), and thyroid peroxidase antibodies (TPO-AB) or microsomal autoantibodies. The results of this study revealed that 1.5% of the type 1 diabetic patients were with strong positive of both thyroid auto-antibodies and the same percentage were for diabetic patients with strongly positive T-antibodies, while 22% were positive for M-antibodies. The number of diabetic patients, with weak positive TG-antibodies, were nine patients (18%) and 14 patients (28%) for TPO-Abs. While the weak positive results for both antibodies were six patients (12%). It could be concluded that thyroid antibodies should be done periodically for every type 1 diabetic patient. Patients with positive antibodies should be monitored for TSH elevation at yearly intervals.

### Significant immune associations in chronic thyroiditis

C. Poiana[1], M. Carsote[1], A. Clodeanu[2], D. Staicu[2] & D. Peretianu[2]
[1]Institute of Endocrinology, Bucharest-Bucuresti, Romania; [2]SCM Povernei, Bucharest-Bucuresti, Romania.

Objectives
To investigate how the immune associations (IA) may have significance for diagnosis or therapy in thyroiditis.
Material and method
Patients: A. 'Classical' Hashimoto thyroiditis (hyper-ATPO-emia, HT) =1092, B. thyroiditis with isolated hyper-ATG-emia, with normal ATPO (T-ATG) =61, C. thyroiditis 'sero-negative' (normal ATPO and ATG, pathology diagnosis) =5, D. idiopathic myxedema (hypothyroidism, no A, B,C) =70; E. control =998. 2. Statistical analysis: $\chi^2$ test.
Results
1 Total IA: TH =189 (17.31%, $P\ll0.001$); T-ATG =15 (24.59%, $P=0.002$); 'sero-negative' =1 (14.29%); idiopathic mixedema =10 (14.29%); control: 99 (9.46%). 2. Main IA: A. Graves-Basedow disease: TH: 141 (12.91%), T-TAG: 3 (4.92%); B. Vitiligo: TH =35, $P=0.0001$; T-ATG =2; Control =9. C. Dermatitis: TH =16, $P=0.004$. D. Immune ovaritis with precocious menopause: TH =12, $P=0.024$. E. Biermer anemia: only in HT =11; $P=0.001$. F. Drug allergy: TH: 17, $P=0.01$. G. Rheumatoid arthritis: TH =8, but in controls =18; (NS); Mixedema: 2 (NS). 3. Multiple associations: cerebral vasculitis with Sneddon sd, pulmonary fibrosis, cryoglobulinemia, virus C hepatitis (IFN) and sicca sd; Sarcoidosis with drug allergy, scleroderma, adenomegaly and arthritis; IDDM plus widespread vitiligo and hyperthyroidism; bronchial asthma with postpartum trombophilia and antiphospholipidic sd; selective alopecia areata (no eyebrows), ferriprive anemia and miopia; Sharp disease, zona zoster, dispepsia, alopecia areata and trombocytosis.
Conclusions
i) HT and T-ATG has immune associations with increased frequency. ii) The most significant and prevalent association are: Graves-Basedow, vitiligo, Biermer anaemia, drug allergy, early menopause with immune ovaritis. iii) HT, T-ATG and idiopathic mixedema are not significantly associated with other immune conditions: rheumatoid arthritis, IDDM, B/C hepatitis. iv) Multiple immune associations are common. v) Breast cancer are not associated with chronic thyroiditis. vi) Amiodarone administration did not induce TH, T-ATG, significantly.

### On cohorts (over 1000 patients), there are relationships between antithyroperoxydase antibody levels and thyroid function in chronic thyroiditis

M. Carsote[1], C. Poiana[1], D. Staicu[2], A. Clodeanu[2] & D. Peretianu[2]
[1]Institute of Endocrinology, Bucharest-Bucuresti, Romania; [2]SCM Povernei, Bucharest-Bucuresti, Romania.

Aim and objectives
To investigate the rapport between the level of thyroid function, through blood level of TSH, both at onset, and in evolution and the level of antithyroperoxydase antibodies (ATPO) and antithyroglobuline antibodies (ATG) in Hashimoto thyroiditis and related diseases.
Material and method
Diagnosis: a. ATPO $>34$ μ/ml = Hashimoto thyroiditis (HT); b. ATPO= normal with high ATG = thyroiditis with only hyper-ATG (T-ATG); c. hypothyroidism without high ATPO/ATG = idiopathic mixedema (IM). 2. Thyroid function: TSH (and $FT_4$) 3. Statistical analysis: linear correlation test.
Results
I. ATPO/ATG at onset: 1. ATPO: A. Number: HT-1092, T-ATG-61, IM-70. B. Average: TH-651,25; SD: 1055 (!); T-ATG-9,1; IM-10. 2. ATG in T-ATG: 539,81; SD: 940 (!).
II. Evolutional types for ATPO/ATG: 1. All ATPO in HT: no.1812, av: 662 μi/ml. 2. ATPO evolution in HT: undulatorious: 142 (41.4%), decreasing: 132 (38,5%), increasing: 69 (20.1%). 3. All ATG in T-ATG: no. 83, av: 494. 4. ATG in T-ATG: undulatorious: 2 (11.76%), decreasing: 9 (52.94%), increasing: 6 (35.29%).
III. TSH. 1. onset HT: av: 9.05 mU/l; S.D. 20.7. 2. onset T-ATG: 4.02 mU/l, S.D. $=4.33$. 3. All HT: av. 7.43.
IV. Linear correlation ATPO-TSH: 1. in HT: a. HT at onset: $r=0.17$, $P<0.001$, slope: 8.31. b. all TH values: $r=0.11$, $P<0.001$; 2. in T-ATG: a. at onset: $r=-0.19$, $P\gg0.1$ (NS), slope: $-35$; b. all T-ATG values: $r=-0.17$, NS; c. MI at onset/and all values, $r=-0.12$, $P\gg0.1$.
V. Linear correlation ATPO-FT4: 1. HT at onset: $r$: $-0.11$, $P<0.001$, slope: $-9.32$. 2. T-ATG at onset: $r=0.001$, NS.
Conclusion
1 A certain correlation is: between thyroid function and only ATPO (not ATG) and only in cohorts (400–1000 probes). 2. ATPO evolve unpredictably: high levels of ATPO occur in hypothyroidism, euthyroidism and hyperthyroidism, too.

## P1701

### How evolves thyroid function in Hashimoto thyroiditis and related disorders

C. Poiana[2], M. Carsote[2], D. Staicu[1], A. Clodeanu[1] & D. Peretianu[1]
[1]SCM Povernei, Bucharest-Bucuresti, Romania; [2]Institute of Endocrinology, Bucharest-Bucuresti, Romania.

Aim
Analyzing the evolution of thyroid function in thyroiditis and related disease during 1–15 years.
Materials and methods
A) Diagnostic: Hashimoto thyroiditis (HT): i) antithyroperoxydase antibodies (ATPO) cut-off 34. ii) If ATPO=normal (N), was considered thyroiditis with only antithyroglobuline antibodies (T-ATG); iii) idiopathic mixedema (IM): hypothyroidism, no ATPO, no ATG, no TRAB.
B) Patients: i) HT: 1092; T-ATG: 61; IM: 70. Women/men: HT: 1041/51; T-ATG: 58/3; IM: 59/11 (more men: $P<0.001$).
C) Statistic analysis: test $\chi^2$.
Results
A) At the diagnostic moment. i) HT: euthyroid (EUT): 490 ($\sim$45%), hypothyroid (HOT): 443 ($\sim$40.5%), hyperthyroid (HIT): 159 ($\sim$14.6%) – from these: 141 ($\sim$89%) associated with Graves-Basedow disease (GBD)-(TRAB+; more than in T-ATG).
ii) T-ATG: EUT: 36 (59%, more than in HT), HOT: 19 (31%), HIT: 6 (9.8%) – from these: 3 (50%) associated with GBD-(TRAB+).
iii) IM: (by definition): HOT: 70 (100%).
iv) Significant difference between TH-T-ATG: $P=0.09$ (NS).
B) Follow-up: i) HT: a. 28 (5.71%) with EUT became HOT after 0.2(!)-8 years (av $=2.77$, S.D. $=2.11$). ii) 3 (0.61%) with EUT become HIT (all GBD). iii) 100% HOT remained HOT. iv) 15 (9.43) with HIT become EUT after 1.5–2 years and maintain at least 5 years. v) 4 (2.52%) with HIT become spontaneously HOT (two with GBD).
ii) T-ATG: only two HIT become EUT (33.3%). EUT&HOT remain the same.
iii) IM: all remained HOT, with one exception (man under amiodarone who return spontaneously to EUT after withdrawal amiodarone).
Conclusions
i) Thyroiditis with only hyperATG could be considered different from HT. ii) HT, T-ATG and IM presented differently as hormonal function. iii) H-TAG more than HT (but both) presented more as EUT than HOT. iv) Only 5% EUT-HT become HOT, during first 8 years. v) No EUT-HT after 8 years modified function. vi) Patients with HOT at diagnostic time, either HT, T-ATG or IM, remain HOT.

### Influence of thyroxin replacement therapy on cardiovascular system in patients with primary hypothyroidism and arterial hypertension

Y. Orlov, D. Kileynikov[1], V. Mazur[1,2], D. Platonov[1,2] & E. Mazur[1]
[1]Tver State Medical Academy, Tver, Russian Federation; [2]Tver Regional Clinical Hospital, Tver, Russian Federation.

Introduction
We investigated short-term influence of thyroxin replacement therapy on blood pressure (BP) and cardiovascular status in patients with first identified primary hypothyroidism (PH) and earlier diagnosed arterial hypertension (AH).
Methods
52 patients with PH and AH were observed twice: prior to replacement therapy and after reaching euthyroid status. All patients underwent daily BP monitoring, echocardiography, and high frequency ultrasound dopplerography of nail ridge arterioles with detection of maximal systolic and end-diastolic velocity and calculation of Purselo index (PI). Results are presented as delta with 95% confidence intervals.
Results
Decrease in systolic (daytime by 8.9 (5.5–12.3), nighttime by 5.0 (2.5–7.5) mmHg) and diastolic BP (daytime by 9.4 (6.4–12.4) and nighttime by 4.5 (2.3–6.7) mmHg), interventricular septum thickness by 0.08 (0.03–0.13) cm, posterior wall thickness by 0.08 (0.04–0.12) cm, left ventricle diastolic diameter by 0.14 (0.05–0.23) cm, left ventricular mass by 24.5 (13.9–35.1) g, maximal systolic velocity by 2.5 (0.8–4.2) cm/s, and PI by 0.13 (0.06–0.20) CU were observed in patients with PH after reaching euthyroid state.
Conclusion
Compensation of thyroid state in patients with PH and AH leads to decrease in BP and improvement of ultrasound left ventricular and peripheral homodynamic parameters.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Table 1** Dynamics of cardiovascular parameters in patients with PH and AH after achievement of euthyroid status.

| Parameters | Hypothyroid status | Euthyroid status |
|---|---|---|
| Systolic BP (daytime; mmHg) | 133.4 (130.3–136.5) | 124.5 (119.8–129.2)* |
| Systolic BP (nighttime; mmHg) | 118.4 (115.4–121.4) | 113.4 (110.5–116.3)* |
| Diastolic BP (daytime; mmHg) | 85.7 (80.0–91.4) | 76.3 (71.3–80.3)* |
| Diastolic BP (nighttime; mmHg) | 74.5 (70.3–78.7) | 70.0 (66.6–73.4)* |
| PWT (cm) | 1.20 (1.13–1.27) | 1.12 (1.05–1.18)* |
| IVST (cm) | 1.12 (1.06–1.17) | 1.04 (.99–1.09)* |
| LV DD (cm) | 4.78 (4.69–4.88) | 4.64 (4.56–4.72)* |
| LVM (g) | 197.2 (181.6–212.8) | 172.7 (159.8–185.6)* |
| *Vs* (cm/s) | 13.1 (11.2–15.0) | 10.6 (8.9–12.3)* |
| *Vd* (cm/s) | 3.9 (3.0–4.8) | 4.3 (3.6–5.0) |
| PI (CU) | 0.72 (0.67–0.77) | 0.59 (0.55–0.63)* |

PWT, posterior wall thickness; IVST, interventricular septum thickness; LV DD, left ventricular diastolic diameter; *Vs*, maximal systolic velocity; *Vd*, end-diastolic velocity; PI, Purselo index. *$P$ value for $\Delta<0.05$.

**Psychosis in hyperthyroidism: a case report**

P. Nacpil
University of the Philippines–Philippine General Hospital, Manila, Philippines.

Background
The most common psychiatric syndromes in thyrotoxicosis are anxiety and mood disturbances. Psychosis, however, is a rare complication. Here is a report of such a case.
Case report
A twenty-six year old female presented with a 13 year history of palpitations, easy fatigability and anterior neck mass. Patient denies any comorbid conditions. No family history of psychiatric illness. On March 2011, she was admitted due to logorrhea, auditory hallucinations, delusion of persecution and frequent attention calling from family members, and suicidal ideations. Clinically she was thyrotoxic with a diffuse goiter. $FT_4$ 39.6 pmol/l (11–24) and TSH $<$ 0.005 μIU/l (0.3–2.8). There was no evidence of infection. Diagnosis of thyrotoxic psychosis was made, and was started on Propylthiouracil 150 mg q8 and Propranolol 40 mg BID.
After her marked improvement, she was discharged on Propylthiouracil, Propranolol, Olanzapine and Clonazepam. All her psychiatric symptoms gradually resolved and weaned off from Olanzapine and Clonazepam. During her regular follow up, there was note of occasional episodes of agitation. Six months later, after euthyroidism was achieved, patient underwent radioactive ablation, with complete resolution of her psychiatric symptoms.
Conclusion
Thyrotoxicosis may be a precipitant of acute psychosis. This can be promptly controlled with the use of anti-thyroid drugs. Concomitant psychotropic drugs maybe indicated if the symptoms are severe. In cases of treatment failure, a more radical approach such as radioactive iodine ablation and thyroidectomy maybe considered.

**TSH receptor antibody measurement in the diagnosis and management of Graves disease**

D. Ylli, Z. Ylli, G. Husi, V. Hoxha & A. Ylli
CHU Mother Teresa, Tirana, Albania.

Introduction
Graves' hyperthyroidism is an autoimmune disease sustained by autoantibodies binding to and activating the TSH receptor located on the thyroid follicular cell. The objective of study was to determine the presence of anti-receptor TSH antibodies for the diagnosis of Grave's diseases and the following up after surgery, iodine and treatment with antithyroid drug.
Results
In years 2006–2010 in our clinic in 265 patients for thyroid disorders 77.3% (205) were diagnosed with Grave's diseases (154 female, 51 males with a ratio 3.01:1. Mean age was 44 years old ± 16.2 s.d.); 6% with multinodular toxic goiter; 4.3% with thyroiditis and 12.4% were euthyroid. All the patients were examined for the presence of anti-TSH receptor ab by RIA (Cisbio) and the cut off for positivity was $>$1.0 U/ml. The anti-rec-TSH ab antibodies were positive in 90.7% of patients with Graves' disease before treatment with an average level 8.89 U/l ± 13.71 s.d. with a range 1.1–105, the antimicrosomal antibodies (M ab) were present in 76.5% and thyroglobulin antibodies (Tg ab) in 33%. In those without Graves' disease, anti-rec-TSH ab were positive in 1.6%. In our study we found that anti-rec-TSH ab values before anti thyroid treatment had no any significance in predicting the remission of Graves' disease after 1 and 2 years of anti thyroid drug therapy. In patients with positivity lowered down or became zero during the treatment the remission was very good, while the patient which remained with high level of anti-rec TSH ab the remission is not achieved and they remained hyperthyroid. No differences in patients treated with antithyroid drug and those treated with surgical intervention (total thyroidectomy): the positivity for anti-Rec TSH ab go down gradually in 50–60% of the cases they do remission with lower or disappeared antibodies. In the patients treated with radioiodine those with high titer of anti-rec TSH ab remain still positive after 1 or 2 years.
Conclusion
We conclude according our study that it is important to determine the anti receptor TSH antibodies for the diagnosis of Grave's diseases and to predict the efficacy of the treatment.
Declaration of interest

**Life-threatening amiodarone induced thyrotoxicosis: optimizing the treatment and choosing radical therapy according to clinical course: own experience**

M. Kostecka-Matyja, A. Fedorowicz, M. Motyka, D. Pach & A. Hubalewska-Dydejczyk
Medical College, Jagiellonian University, Krakow, Poland.

Amiodarone is a widely used antiarhrythmic agent. Although life-threatening side effects of amiodarone therapy are well known, it's not always possible to replace it with dronedarone. Some clinical trials showed that treatment with dronedarone led to significantly more unfavourable end-points (e.g. in congestive heart failure). Therapy of amiodarone induced thyrotoxicosis still raises many questions concerning optimal treatment choice to achieve euthyreosis as soon as possible. In our experience each case should be considered individually according to clinical course, comorbidities, etc.
Fourty patients (15 females, 25 males, mean age: 61 years) with severe amiodarone induced thyrotoxicosis were hospitalized in our Department between 2001 and 2011. 60% of them had life-threatening cardiological diseases. Mean $FT_3$ and $FT_4$ concentrations were respectively 13.3 pmol/l (*n*: 3.1–6.8) and 62.3 pmol/l – in nine patients $FT_4$ levels were $>$100 pmol/l (*n* 11–22).
Median time of hospitalization was 4 weeks (2–13 weeks), mean time of reaching euthyreosis – 14 weeks. Most common treatment was combined antithyroids and steroids iv. About a half of the patients were finally treated with I-131, after regaining iodine uptake. There were three deaths. One of the patients died because of severe heart arrhythmias. Another one, unresponsive to pharmacological treatment, was disqualified from thyroidectomy because he developed acute respiratory distress syndrome, underwent plasmaphereses, finally died of respiratory failure. The third one died due to massive gastric bleeding caused by hemorrhagic gastritis – complication of steroid treatment. However, in one of the patients, unresponsive to standard therapy, a thyroidectomy was successfully performed.
Conslusions
– Each patient with amiodarone induced thyrotoxicosis requires an individual approach.
– It's substantial to determine the moment of radical treatment.
– Upon reaching euthyreosis it's advisable to treat the patient with I-131 if further treatment with amiodarone is recommended.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

**Thyroid hemiagenesis and bilateral parathyroid adenoma**

M. Oruci[1], I. Markovic[1,2], M. Buta[1], I. Djurisic[1], M. Jevric[1], G. Pupic[1] & R. Dzodic[1,2]
[1]Institute of Oncology and Radiology of Serbia, Belgrade, Serbia; [2]School of Medicine, University of Belgrade, Belgrade, Serbia.

We present a 66 year old patient with right thyroid hemiagenesis and double parathyroid adenoma one on the side of hemiagenesis and the other on the side of present left lobe. The patient came to our Clinic because of pain in the neck and was diagnosed a primary hyperparathyroidism with elevated parathyroid hormon as well as Hashimoto thyroiditis with high level of Tg and TPO antibodies. Ultrasound and technetium sestamibi scintigraphy determined the absence of the right lobe but not adenoma of parathyroid glands. The patient underwent exploration of the neck which confirmed right thyroid hemiagenesis. Left loboistmectomy was performed with excision of left inferior parathyroid adenoma. Five months after the operation, parathormon level was still increased with calcium values at the upper limit. Sestamibi scintigraphy was performed again which showed increased accumulation of MIBI in the projection of the right

lower parathyroid gland. We performed reexploration of the neck and excision of the right upper parathyroid adenoma wich was located behind cricoid laryngeal cartilage. After surgery we observed a normalization calcium and parathormon value. Thyroid hemiagenesis is a rare anomaly, more common in female (ratio 3:1) and with predominace of left lobe involvment (ratio 4:1). The first to describe this anomaly was Handfield Jones in 1852. From available literature we have not found the case that described double parathyroid adenoma which one on the side of thyroid hemiagenesis.

Hemiagenesis, double parathyroid adenoma.

**Laminin and poly-laminin, a polymeric form of laminin assembled at acidic pH, differentially modulate PCCL3 thyroid cell behavior**

C. Palmero, M. Barroso, E. Souza, C. Merlmestein, C. Takiya, D. Carvalho, L. Miranda-Alves & L. Nasciutti
Federal University of Rio de Janeiro, Rio de Janeiro, Brazil.

The extracellular matrix protein laminin forms polymers both *in vivo* and *in vitro*. Acidification of pH leads to the formation of an artificial polymer with biomimetical properties, named poly-laminin (polyLM). Follicular cells in the thyroid are in close contact with laminin, but their response to this important extracellular signal is still poorly understood. Thyroid PCCL3 epithelial cells cultivated either on glass, regular laminin (LM) or laminin previously polymerized in acidic pH (polyLM) showed distinct cell morphologies and proliferative rates, as well as differences in the organization of their actin cytoskeleton. While on polyLM cells displayed a typical epithelial morphology and presented actin fibers radially organized, on LM they spread irregularly on the substrate, lost cell contacts and produced thick actin fibers, which expanded to the whole cytoplasm. From a functional standpoint, both substrates of laminin induced a slight decrease in the expression of the sodium iodine symporter (NIS), but a significant decrease in iodine uptake was detected when cells are cultivated on laminin in comparison with cells cultivated on glass. In this study we demonstrated that PCCL3 cells can discriminate between LM and polyLM and that they respond to the latter by better preserving their phenotype as in the thyroid tissue.

**Steroid-responsive encephalopathy associated with Graves' disease**

R. Dobrescu[1], D. Morosanu[2], S. Jercalau[2], C. Tiu[2] & C. Badiu[1,2]
[1]National Institute of Endocrinology, Bucharest, Romania; [2]University of Medicine and Pharmacy, Bucharest, Romania.

A 29-year-old female diagnosed 1.5 years ago with Graves' disease, presented with severe thyrotoxicosis and a large, diffuse goiter after an attempt to taper the anti-thyroid medication. She had also noticed 4 days before presentation right arm mild paresis. The neurological exam confirmed the sensitive and motor deficit. Blood assays confirmed severe thyrotoxicosis (TSH $<0.03$ mUI/l, $fT_4=$ 25.6 pmol/l, $T_3>500$ ng/dl), high levels of anti-thyroid antibodies (TPOAb $>$ 3000 UI/ml; TRAb = 52.8 U/l), without major biochemical abnormalities. She has sinus tachicardia at 130 b.p.m., with features of hyperkinetic heart on ecocardiography but no signs of heart failure. She received increased doses of anti-thyroid medication and β-blocker (Metimazole 20 mg tds and Metoprolol 50 mg tds). Few hours after admission she presented an episode of acute dizziness and lost consciousness for 4–5 min with no seizures. She recovered spontaneously but remained confused, with fluctuating consciousness, severe nausea and headache. The brain CT was normal, excluding a stroke, and the CSF analysis excluded infection. There were nonspecific changes on the EEG, while the brain MRI showed high signal abnormalities in the subcortical white matter of the parieto-occipital areas. In the setting of the high levels of anti-thyroid antibodies, the neurological picture was interpreted as Hashimoto's encephalopathy, and the patient was started on high dose intravenous corticosteroids (500 mg Metilprednisolone daily) with progressive neurological improvement over the following days.

A rare cause of confusion and altered mental status, Hashimoto's encephalopathy is an immune-mediated neurological disorder that occurs in the setting of high levels of anti-thyroid antibodies and responds promptly to corticosteroid therapy. Rarely it can be seen in the setting of hyperthyroidism, which can exert its own neurological effects (tremor, confusion, myopathy), further complicating a rather nonspecific neurological picture. Hashimoto's encephalopathy must always be considered in a female patient with occult neurological manifestations.

Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1709

**Evaluation of the cytopathologic findings of the thyroid nodules which include macrocalcification**

D. Arpaci[1], D. Ozdemir[1], N. Cuhaci[1], A. Dirikoc[1], A. Kilicyazgan[1], G. Guler[2], R. Ersoy[2] & B. Cakir[2]
[1]Ankara Ataturk Training and Research Hospital, Ankara, Turkey; [2]Faculty of Medicine, Yildirim Beyazit University, Ankara, Turkey.

Aim
In our study, we aimed to evaluate the cytologic findings of the thyroid nodules, in which macrocalcification is determined with ultrasonography.
Method
We evaluated retrospectively 907 nodules of 269 patients, who have nodular or multinodular goiter and have macrocalcification at least in one nodule. The same patients' nodules that don't have macrocalcification are taken into the control group. Patient's thyroid function tests, ultrasonographic features and cytologic results of the nodules were evaluated. Cytologic findings are classified as benign, non-diagnostic, suspected and malign.
Results
79.9% of the patients were female, 20.1% were male. Macrocalcification was positive in 420 nodules (Group 1A: peripheral macrocalcification ($n=53$), Group 1B: macrocalcification was intranodular ($n=367$). In Group 2 ($n=487$) no macrocalcification was found. Mean nodule size in group 1A, 1B, 2 was respectively $12.94\pm6.26$, $25.50\pm14.27$ and $15.72\pm7.53$ mm ($P<0.001$). Compared the ultrasonographic features of Groups 1 and 2, peripheral irregularity and presence of halo were similar. In group1 microcalcification was positive in the 61.4% of nodules, whereas it was 17.5% in Group 2 ($P<0.001$). Solid nodule ratio was 11.7% in Group 1 and 49.9% in Group 2 ($P<0.001$).
Conclusion
Malign cytology was similar in the nodules, which have macrocalcification or not. In the nodules with peripheral calcification, high ratio of suspected cytology can demonstrate that macrocalcification is associated with malignacy, contrast to the usual opinion. Therefore, we think that, presence of macrocalcification does not always regard as benign nodule.

## P1710

**Autoimmune and allergic diseases associated with autoimmune thyroid diseases**

I. Dagdelen, K. Agbaht, I. Soykan & S. Gullu
Ankara University, Ankara, Turkey.

Background
Sometimes, although the serum thyroid hormone levels are in desired ranges, the patient still has complaints. On the other hand, the dose of levothyroxine replacement may be variable in patients with hypothyroidism. These factors directly influencing the clinical practice may be, to some extent, associated with other immunological/allergic diseases that accompany autoimmune thyroid diseases (ATDs).

Aim
To document the other autoimmune/allergic disorders in patients at follow-up for ATDs in a tertiary care university hospital.
Methods
During the study period, consecutive 274 patients diagnosed with and/or at follow-up for Hashimoto's thyroiditis (HT) and 53 with Graves' disease (GD) were included in the study. All the patients were examined and when clinically suspected for other autoimmune/allergic disease, further investigations were applied.
Results
65 (23.8%) patients with HT and 7(13.2%) patients with GD had at least one additional clinical autoimmune/allergic disorder. The distribution of these disorders were as: 28 (10.2%) gastrointestinal (chronic atrophic gastritis, celiac disease, autoimmune pancreatitis, ulcerative colitis, primary biliary cirrhosis), 19 (6.6%) allergic (asthma, chronic urticaria, rhinosinusitis), 12 (4.4%) rheumatological (rheumatoid arthritis, systemic lupus erythematosus, Still disease, Sjögren syndrome, Behçet's disease, ankilosying spondylitis), 10 (3.7%) skin (vitiligo, psoriasis, idiopathic pruritus, total alopecia), 4 (1.5%) endocrinological (hypoparathyroidism, type-1 diabetes mellitus, hypophysitis), 1 (0.4%) hematological (idiopathic thrombocytopenic purpura), 1 (0.4%) renal (crescenteric glomerulonephritis) involvements in HT. In GD, these distributions were similar: 2 (3.8%) gastrointestinal, 2 (3.8%) allergic, 2 (3.8%) skin, 1 (1.9%) rheumatological, 1 (1.9%) hematological. Additionally, 50 (18.2%) patients with HT and 1 (1.9%) with GD found to have vitamin B12 deficient-anemia ($P=0.001$). 28 (10.2%) of HT and 1 (1.9%) of GD patients had dimorphic (both vitamin B12 and iron deficiencies) anemia.
Conclusion
Patients with ATDs are prone to additional autoimmune/allergic diseases. The mostly involved organ system is the gastrointestinal tract in both ATDs. Probably this involvement takes play in exaggaration of some symptoms by leading to anemia caused by both vitamin B12 and iron deficiencies, especially in patients with HT.
Declaration of interest

### L-Thyroxine therapy and depression in subclinical hypothyroidism

M. Unal[1], D. Yazgan Aksoy[1], N. Cinar[2], B. Okan Yildiz[2], M. Bayraktar[2] & A. Usman[2]
[1]Etlik Ihtisas Research and Training Hospital, Ankara, Turkey; [2]Faculty of Medicine, Hacettepe University, Ankara, Turkey.

Background and aim
Subclinical hypothyrodism (SH) appears to be associated with mood and changes. The aims of this study were: i) to determine whether depression is more common in SH, and ii) to investigate the effects of L-thyroxine ($LT_4$) therapy on depressive symptoms.
Methods
31 patients with SH and 36 age amd BMI matched healthy controls were included. Beck and Hamilton scales were used to evaluate depression in all participants at baseline and in patients after they have reached euthyroid status by $LT_4$ therapy.
Results
TSH was higher and $FT_4$ was lower in patients with SH ($P<0.0001$ and $P=0.001$ respectively). Scores of depression scales were similar between the patients with SH and controls. $LT_4$ treatment resulted in an increase in $FT_4$ and decrease in TSH, Beck or Hamilton scores did not change significantly after treatment.
Conclusions
Our results suggest that depressive symptoms are more common in patients with SH and that achievement of euthyroid status by $LT_4$ does not have an effect on depression.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### 'Too slow for the heart to go': a case of hypothyroidism-induced cardiomyopathy presenting as acute cardiogenic shock

A. Lim & M. Cruz
University of the Philippines–Philippine General Hospital, Manila, Philippines.

Cardiomyopathy can occur due to hypothyroidism or hypocalcemia but often resolves with judicious treatment with levothyroxine and correcting calcium levels to acceptable levels. We discuss a case of a 37-year-old woman presenting with acute cardiogenic shock and a history of total thyroidectomy 6 years prior for papillary thyroid carcinoma stage 1 (T2N1aM0). Patient was non-compliant to levothyroxine treatment and developed easy fatigability and exertional dyspnea 5 months before consult. Patient had no previous co-morbidities, and no family history of heart diseases. Workup was consistent with primary hypothyroidism with an elevated TSH and low free thyroid hormones. Serum calcium was also low and was attributed to post-surgical hypoparathyroidism. Neck ultrasound confirmed absent thyroid glands. Chest radiograph show massive cardiomegaly, which on trans-thoracic echocardiogram (TTE) showed minimal pericardial effusion, global hypokinesia, an ejection fraction of 20%, and a dilated left ventricle. After initial stabilization with inotropes, patient was started on low dose of levothyroxine at 25 μg/day and digoxin. Hypocalcemia was corrected to lower limit of normal with calcitriol 0.5 μg/day and calcium carbonate 2 g/day. She was discharged after a few weeks with gradual up-titration of levothyroxine at 12.5 μg/day depending on clinical tolerability. Euthyroidism was achieved at levothyroxine 125 μg/day and 8 months post-discharge, previous functional capacity was achieved at 4–10 METs with an improved ejection fraction of 62% on repeat TTE.
Keywords: hypothyroidism, hypocalcemia, cardiomyopathy, cardiogenic shock.

### Graves' disease and gene polymorphism of TNF-α, IL2, IL6, IL12, and IFN-γ

M. Anvari, O. Khalilzadeh & A. Esteghamati
Endocrinology and Metabolism Research Center (EMRC), Tehran, Islamic Republic of Iran.

The role of genetic factors in the pathogenesis of Graves' disease (GD) is not clear. The purpose of this study was to investigate the association between single nucleotide polymorphisms in pro-inflammatory cytokine genes and GD in Iranian patients. A case–control hospitalbased study was carried out on 107 GD patients and 140 healthy controls. Cytokine typing was performed by PCR with sequence-specific primers (PCR-SSP) assay. The allele and genotype frequencies of the following cytokine genes were determined: TNF-α (−308A/G, −238A/G), IL2 (−330T/G, ?166G/T), IL6 (−174C/G, A/G nt565), IL12 (−1188A/C), and IFN-γ (UTR 5644A/T). The following alleles and genotypes were significantly overrepresented in patients: TNF-α −308A allele ($P$ 0.01) and AA genotype ($P$ 0.05), IL2 −330G allele ($P$ 0.01) and GG genotype ($P$ 0.01), IL 6 −174C allele ($P$ 0.01) and CC genotype ($P$ 0.01), IL12 −1188C allele ($P$ 0.01) and CC genotype ($P$ 0.01), IFN-γ UTR5644T allele ($P$ 0.01) and TT genotype ($P$ 0.01). In conclusion, this is the first study to show a significant association between GD and IL2 −330G, IL12 −1188C, and IFN-γ UTR 5644T alleles.
Our results support the hypothesis that polymorphism in pro-inflammatory.

### Evaluation of $CD4^+CD161^+CD196^+$ and $CD4^+IL17^+$ Th17 cells in the peripheral blood of young patients with Graves' disease and Hashimoto's thyroiditis

A. Bossowski, M. Moniuszko, M. Dabrowska, M. Jeznach, B. Sawicka, H. Borysewicz-Sanczyk, M. Rusak & A. Bossowska
Medical University in Bialystok, Bialystok, Poland.

Up till now, altered balance of Th1 and Th2 immune cells has been postulated to play an important role in the pathogenesis of autoimmune thyroid diseases (AITD). However, recent studies on thyroid diseases suggest a new role for Th17 (T helper 17) cells that have been classified as a new lineage, distinct from Th1, Th2 and Treg cells. Despite wide interest, role of Th17 cells in the pathogenesis of inflammatory and autoimmune diseases is still debated. Th17 cells are involved in immune responses against extracellular pathogens and have the ability to secrete cytokines: IL17, IL17F, IL22 and IL21. Th17 cells can be characetrized by several surface markers, i.e. CCR6 (CD196), IL23R, IL12Rβ2 and CD161.
The aim of the study was to estimate the frequencies of circulating $CD4^+CD161^+CD196^+$ and $CD4^+IL17^+$ Th17 cells in patients with Graves' disease (GD), Hashimoto's thyroiditis (HT) and in healthy controls.
Polychromatic flow cytometry and several fluorochrome-conjugated monoclonal antibodies were applied to delineate Th17 cells with either $CD4^+CD161^+CD196^+$ or $CD4^+IL17^+$ phenotype.
In untreated patients with AITD we observed a tendency to increased frequencies of $CD4^+CD161^+$ $CD196^+$ and $CD4^+IL17^+$ Th17 lymphocytes in comparison to the healthy controls. In cases with HT, positive correlation between percentage of $CD4^+CD161^+CD196^+$T cells and serum level of anti-TPO antibodies was detected.
We conclude that the increase percentage of Th17 cells in children with Graves' disease and Hashimoto's thyroiditis can suggest their role in initiation and development of immune processes in AITD.

### Study thyroid function in patients with acromegaly

T. Shestakova, A. Dreval, I. Ilovaiskaja & E. Zaharevich
M. F. Vladimirskii Moscow Regional Research and Clinical Institute, Moscow, Russian Federation.

Goal
Study thyroid function in patients with acromegaly. Materials and method: 88 patients with acromegaly, age 54.6 ± 13.2 years, mediana diagnosis acromegaly 4 years, IGF1 528 (265; 701.3 ng/ml, HG 10.4 (3.7; 30.1) μE/ml, only 12 patients had a remission of disease. All patients were taken TSH, $fT_4$, TPO antibodies, revealed anamnesis of thyroid diseases.
Results
19 from 88 patients (21.6%) had hypothyreosis and 2 (2.3%) had subclinical thyrotoxicosis, that higher average prevalence these disease (2 and 1% correspondently). The causes of hypothyreosis were different: eight paitents (9.1%) had central hypothyreosis mainly due surgical ttreatment of acromegaly (seven from eight patients); 12 patients (13.6%) had hypothyreosis due thyroidectomy (six patients) or autoimmune thyroidit (six patients). Thyroidectomy was performed for thyroid cancer in five from six patients. There is interesting combination of different thyroid dysfunction at two patients. One patient 53 years old had acromegaly for 1year. She had hypothyreosis due thyroidectomia 5 years ago and took 75 μg L-thyroxine. But then central hypothyreosis was added after surgical treatment of acromegaly: TSH 0.53 μE/ml, $fT_4$ 8.5 pmol/l on the same dose of L-thyroxine. Doctor has to consider this combination dysfunction because TSH is not informative at patients with central hypothyreosis. The cause of subclinical thyrotoxicosis was toxic polynodular goiter. One patient had combination subclinical thyrotoxicosis with central hypothyreosis. At first, central hypothyreosis was appeared after surgical treatment of acromegaly and the patient took L-thyroxine for 6 years. Then $fT_4$ was increased up to 24 pmol/l, L-thyroxine was stopped but $fT_4$ remained high ($fT_4$ 22 pmol/l, TSH 0.01 μE/ml). Scintigraphy revealed 'hot' nodule. In this case there are two causes of suppressed TSH: central hypothyreosis and subclinical thyreotoxicosis.
Conclusion
The patients with acromegaly have high prevalence of hypothyreosis (21.6%) and subclinical thyrotoxicosis (2.3%). Thyroid dysfunction develops as a result of impact of IGF1 and GH to thyroid and TSH falls after surgical treatment of acromegaly. This simultaneously impact to thyroid function leads to combination of some thyroid diseases and makes the treatment of patients difficult.

## P1716

### Subclinical hypothyroidism and thyroid autoimmunity during the 1st quarter of pregnancy in oran area

M. Amani[1], F. Chentli[2], S. Amani[3], N. Midoun[1], N. Benfeghoul[4], A. Rih[4], L. Zemour[1] & N. Boumansour[1]
[1]EHU 1st November 1954, Oran, Algeria; [2]CHU Bab-el-Oued, Algiers, Algeria; [3]CHU Benzerdjeb, Oran, Algeria; [4]Djilali Liabes University, Sidi-Bel-Abbès, Algeria.

Introduction
Subclinical hypothyroidism and euthyroid thyroiditis have in common the clinically asymptomatic character. These two diseases can occur during pregnancy with no clinical impact.
Our objectives are:
– Prevalence of subclinical hypothyroidism during the 1st trimester of pregnancy.
– Frequency of autoimmunity in euthyroid pregnant women in 1st quarter.
– Analysis of the association of thyroid autoimmunity with the parity.
Description of methods
Prospective study, made in Oran area, on 270 pregnant women in 1st quarter. Women who smoke (active smoking confessed) and those followed for thyroid disease or taking medications that interfere with the thyroid gland were excluded.
– Study protocol: clinical examination, TSH, free thyroxine ($fT_4$), free triiodothyronine ($fT_3$), thyroid antibodies (anti-peroxidase, anti-thyroglobulin and anti-TSH receptor) and cervical ultrasonography.
– Statistics tests: collection of data on EPI INFO 5.1, bivariate analysis (the $\chi^2$ test, the Pearson $\chi^2$ test, the Yates corrected $\chi^2$ test, the Wilcoxon $\chi^2$ test (log rank sum) or Mann–Whitney, the variance analysis method (ANOVA), the $r$ correlation test, significance level $P<0.05$, multivariate analysis (SPSS: 10 version and MedCalc).
Results
– 23/270 pregnant women (8.5%) had subclinical hypothyroidism (TSH > 2.5 mUI/l, $fT_4$ and $fT_3$ normal) with 7/23 (30.4%) wich had thyroiditis.
– 215/270 pregnant women (79.6%) were euthyroid with 24/215 (11.2%) wich had thyroiditis.
– No association was found between anti-TPO positivity and numbers of pares both in patients with subclinical hypothyroidism than those in euthyroid ($P=0.72$ and 0.45 respectively).
Conclusions
The prevalence of thyroid autoimmunity in the 1st trimester of pregnancy is significant. Only a determination of anti-TPO is able to unmask these euthyroid thyroiditis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Evaluation of hearing and balance functions in patients with Hashimoto's thyroiditis

A. Arduc[1], S. Isik[2], S. Allusoglu[1], A. Iriz[1], F. Gokay[1], B. Aycicek Dogan[1], Y. Tutuncu[1], C. Gocer[1], D. Berker[1] & S. Guler[1]
[1]Ministry of Health, Ankara Numune Research and Training Hospital, Ankara, Turkey; [2]School of Medicine, Gulhane Military Medical Academy, Ankara, Turkey.

Introduction
It is commonly known that hearing and balance functions are affected in thyroid function disorders. In literature, there are very few studies demonstrating that hearing may be affected due to autoimmunity in euthyroid Hashimoto's

thyroiditis (HT) independent from thyroid functions. In addition, hearing disorders have also been reported in other autoimmune diseases. For this reason, we investigated the functions of the peripheral and central sections of auditory system in patients with euthyroid HT.
Materials and methods
The study included 21 patients with euthyroid HT without any hearing complaints and 21 healthy individuals. Patients with histories of systemic disease, central nervous system pathology, ototoxic drug-substance use, acoustic trauma were excluded. Otoscopic examinations of the patients were normal. Both groups were implemented tympanometry, audiometry, distortion product otoacoustic emission (DPOAE), Brain stem evoked auditory potentials (ABR), vestibular evoked myogenic potentials (VEMP) tests.
Results
Demographic data of patient and control groups were similar ($P>0.05$). A difference was not established between the groups in terms of TSH, free $T_4$, and free $T_3$ values ($P=0.46$, $P=0.39$, $P=0.62$). Thyroid antithyroglobulin and antithyroperoxidase levels were high in the patient group ($P<0.05$). When compared the right and left ear audiometry average results of the groups, hearing threshold was found to be significantly higher at 250 dB in the patient group ($P=0.015$). A significant difference was not found between the two groups in other audiological and vestibular tests. A correlation was not established between thyroid antibody titer and hearing threshold at 250 dB ($P>0.05$).
Conclusion
The fact that low frequency hearing threshold we established in our euthyroid HT patients was higher may be correlated with autoimmune cochlear damage reported in literature. However, since this disorder was not possible to be demonstrated in other tests, we believe that further studies are of necessity.

## P1718

**Stessful life events and Graves' disease**

I. Kostoglou-Athanassiou[1,2], A. Gkountouvas[2] & P. Kaldrymides[2]
[1]Red Cross Hospital, Athens, Greece; [2]Metaxa Hospital, Pireaus, Greece.

Stress appears to activate the immunoneuroendocrine network and seems to be related to the development of autoimmune diseases. Graves' disease is a multisystem disorder characterized by hyperthyroidism, eye disease and pretibial myxedema. Stress appears also to be related to the development of Graves' disease.
The aim was to describe cases of Graves' disease which developed immediately after a stressful life event.
Patients, ten female, aged 35–56 years old, presented with severe hyperthyroidism after a stressful life event. Within this cohort, three female patients had lost their father, immediately before the development of hyperthyroidism, two female patients had lost their mother immediately before the development of hyperthyroidism, three female patients had lost their husband immediately before the development of hyperthyroidism, one female patient had lost a child and one female patient had lost her husband 1 year earlier and one of her three children immediately before the development of hyperthyroidism.
Hyperthyroidism developed in these female patients in eight of them within a month after the loss of the beloved person and in two within 2 weeks after the loss of the beloved person. Hyperthyroidism was severe and was accompanied by involvement of the eyes only in two of the described cases. TSH receptor antibodies were detected in seven of the described cases. In all cases hyperthyroidism responded to the administration of antithyroid drugs.
In conclusion, stressful life events, in particular the loss of a beloved person, may be an initiating factor for the development of Graves' disease. In these cases hyperthyroidism seems to be severe and to develop shortly after the loss of the beloved person. Thus, it appears that a strong emotional insult may be accompanied by activation of the immunoneuroendocrine axis and the development of a multisystem autoimmune disease, such as Graves' disease.

## P1719

**Thyrotoxic storm: clinical challenges**

Q. Altaf, A. Syed, J. Shakher, A. Karamat & A. Kamal
Heartlands Hospital, Birmingham, UK.

Thyrotoxic storm is one of the rare but serious, and sometimes life threatening endocrine emergencies, the mortality rate ranges from 20 to 30%.
We report the case of a 44-year-old female who had an emergency hospital admission with diarrhoea, vomiting and palpitations in September, 2011. She was diagnosed with Graves thyrotoxicosis in 2004 and was commenced on carbimazole. She was non compliant with the treatment and did not attend her hospital appointments regularly. Her past medical history included anxiety, suspected anorexia nervosa in the teenage years and iron deficiency anaemia. Examination revealed bilateral basal crackles and peripheral oedema. Bloods confirmed thyrotoxicosis. The diagnosis of thyrotoxic storm with high output heart failure was made and she was treated with β blockers, propylthiouracil, IV steroids and Lugol's Iodine. Few hours following the admission, she suffered asystolic cardiac arrest and was resuscitated successfully. During the ITU stay, her liver functions deteriorated significantly. It was thought to be either due to propylthiouracil or ischaemic hepatitis secondary to cardiac arrest. Propylthiouracil was swapped with carbimazole and liver functions improved slowly but steadily. On discharge, her thyroid and liver functions had stabilized on Carbimazole and she was referred to ENT team for the consideration of thyroidectomy.
This case poses clinical challenges at multiple steps. Continual non compliance was assumed to be the precipitating factor for the thyrotoxic decompensation. She was lost to follow up due to multiple non attendances and the impact the possible psychiatric history had on her condition was not evaluated further. Propythiouracil use in the acute illness could have contributed to the liver failure. Propylthiouracil is still being used in severe thyrotoxicosis due to its inhibitory effect on $T_4$ conversion to $T_3$. The 2009 FDA warning regarding propylthiouracil and hepatic failure should prompt revision of thyrotoxic storm management guidelines.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1720

**A case of toxic multinoduler goiter coexists in TSH-producing pituitary tumor**

Y. Kunii, J. Noh, K. Mukasa, M. Matsumoto, M. Suzuki, K. Iwaku, H. Ohe, N. Watanabe, K. Sekiya, A. Yoshihara & K. Ito
ITO Hospital, Tokyo, Japan.

Introduction
The frequency of toxic multinoduler goiter (TMNG) is different among the countries depending on an intake of iodine, but it is said to be ~1% of adenomatous goiter in Japan. In addition, the frequency of TSH-secreting pituitary adenoma (TSHoma) is rare with 0.5–1.0% of pituitary gland tumor. There is no report that TMNG coexists in TSHoma so far.
Case
A 58 years old female was complained swelling of thyroid and palpitation. We found several nodules which were low echogenic masses of up to 28 mm on both thyroid lobes by cervical sonography. Her blood tests showed hyperthyroidism ($fT_3$ 6.3 pg/ml, $fT_4$ 2.3 ng/dl, TSH 3.20 μIU/ml, TgAb 10 IU/ml, TPOAb 5.1 IU/ml, HTg 167.6 ng/dl, TRAb (ECLIA) 0.3 IU/l). From above data which is syndrome of inappropriate secretion on TSH, we underwent her pituitary gland MRI, then we found the 8 mm mass. A TRH stimulation test: TSH (μIU/ml) was 4.258 (0 min), 5.496 (30 min), 5.303 (60 min). We diagnosed TSHoma and introduced her to a brain surgeon. She underwent a trans-sphenoidal neurosurgery by an endoscope. Though TSH was fallen back to 0.044 μIU/ml, $fT_3$ and $fT_4$ values were continued high even after 3 months of surgery. Therefore she was referred back to us for a close investigation of thyrotoxicosis. As the purpose of thyrotoxicosis differentiation diagnosis, she administered $^{123}I$ for thyroid scintigraphy. There were the hot uptake regions of both lobes and we diagnosed TMNG. After she took 500 MBq of $^{131}I$, her thyroid function returned to normal in a few months.
We also examined the thyroid hormone before treatment of 8 TSHoma cases that we experienced in our hospital. There was no difference of thyroid function between TSHoma alone and this patient.

Conclusion
TSHoma has many invasive cases and there are a lot of recurrence cases after surgery. Because it is difficult to deny complication of TMNG and TSHoma just from thyroid function, we think there might be more patients like this case.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1721

**Pattern of thyroid dysfunction in metabolic syndrome**

P. Gyawali, R. Shrestha & P. Bhattarai
Dhulikhrl Hospital, Kathmandu University Hospital, Dhulikhel, Nepal, India.

Introduction
Thyroid dysfunction is a common endocrine disorder affecting 300 million people around the world and over half are expected to be unaware of the condition. The number of people suffering from metabolic syndrome is also on the rise and it is estimated that a quarter of the world's adults have metabolic syndrome. Thyroid dysfunction and metabolic syndrome (Met S) are both associated with atherosclerotic cardiovascular disease, hyperlipidemia and low grade inflammation. It is possible that coexistence of these disease entities may substantially increase cardiovascular risk and facts can aid in early treatment that might reduce the risk. Moreover, little is known about the relationship between metabolic syndrome and thyroid function. Thus, the current study was intended to determine the pattern of thyroid dysfunction in metabolic syndrome subjects.
Methods
A total of 128 previously diagnosed subjects with Met S (defined by NCEP-ATP III panel and IDF guidelines) were recruited during a routine health checkup at Dhulikhel Hospital-Kathmandu University Hospital in Dhulikhel, Nepal. The serum TSH, free $T_3$ and free $T_4$ levels were measured to categorize thyroid dysfunction. Statistical analysis was performed using SPSS version 11.5. The results were expressed as percentage to determine the pattern of thyroid dysfunction in Met S.
Results
The overall prevalence of the thyroid dysfunction was 31.25% (40). Of the 128 subjects, 28.90% (37) had subclinical hypothyroidism, 1.55% (2) had overt hyperthyroidism, 0.80% (1) had subclinical hyperthyroidism and 68.75% (88) were euthyroid. Overt hypothyroidism was not present in any of the subject.
Conclusion
Thyroid dysfunction is associated with metabolic syndrome in particular subclinical hypothyroidism and the coexistence of the two will substantially increase cardiovascular risk. Thus, it necessitate the need for evaluating the thyroid status in patients with metabolic syndrome which can help in early treatment that might reduce the risk.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1722

**Alteration of clinical characteristics of subacute thyroiditis in last two decades in our hospital**

K. Hamamatsu, R. Matsumoto, K. Takeshima, G. Yamada, H. Murabe & T. Yokota
Kurashiki Central Hospital, Kurashiki, Japan.

Objective
Subacute thyroiditis (SAT) is a transient inflammatory disease of the thyroid. As we hypothesized that clinical characteristics of SAT were changing recent years, we evaluated data of our patients.
Patients and methods
We retrospectively reviewed the medical records of 192 patients (45 men and 147 women) with SAT who visited our hospital from 1990 to 2009. We analyzed these records dividing into two groups by decade, i.e. the first 10 years (1990–1999) and the following 10 years (2000–2009).
Results
In each decade, female patients were 50/65 (76.9%) vs 97/127 (76.4%), more than 50-year-old patients were 29/65 (44.6%) vs 71/127 (55.1%), CRP higher than 5 mg/dl was observed in 25/60 (41.6%) vs 49/127 (38.6%), and F-$T_4$ higher than 3 ng/dl was observed in 38/65 (58.5%) vs 69/127 (54.3%). Ratio of older patients tended to increase in the second decade ($P=0.13$). We noticed that seasonal distribution of SAT onset changed in two decades. In the first decade, SAT onsets were often seen in spring. On the other hand, in the second decade, the peak in spring became less remarkable and onsets between late summer and autumn were increased. Onsets between August and October in each decade were 16/65 (24.6%) vs 50/127 (39.4%), and significant difference was observed ($P=0.04$).
Conclusion
We observed that seasonal distribution of SAT onset changed. SAT was generally considered to be developed by viral infection, so this alteration may be due to the transition of viral environment.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1723

**Disseminated tuberculosis involving the thyroid: an unlikely scenario**

A. Lim
Philippine General Hospital, Manila, Philippines.

Tuberculosis involving the thyroid gland is known to be rare with 76 cases being reported as of 2006, and may vary in their presentation*. We present a case of a previously well 67-year-old male who consulted for decreased sensorium, jaundice and hypotension, all attributed to sepsis. Patient exhibited no hyper-or hypothyroid symptoms and physical examination did not reveal clues to an underlying thyroid disease. Cultures of the blood, urine and sputum were inconclusive and despite empiric antibiotics and inotropic support, patient succumbed to multi-organ failure. Post-mortem examination revealed disseminated tuberculosis involving the thyroid as well as the liver, lungs, spleen, kidneys, pancreas, adrenals and various lymph nodes in the thoracic and abdominal regions.
Discussion
Disseminated tuberculosis by itself is rare even in countries endemic to tuberculosis. Its non-specific symptoms lead to a low detection rate, and despite tuberculous involvement of the thyroid glands, this may be clinically inapparent and may not require treatment. Thyroid function tests may be warranted however in the setting of extensive thyroid involvement.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1724

**Prevalence of goiter and thyroid nodular disease in patients with class III obesity**

P. Sousa, L. Guimarães, H. Freitas, J. Carneiro, C. Mayan, M. Pinheiro, S. Liechocki, M. Vaisman & P. Teixeira
Hospital Universitário Clementino Fraga Filho, Rio de Janeiro, Brazil.

Aim
To evaluate the prevalence of goiter and nodular disease in patients with class III obesity, and also correlate the findings with serum insulin, leptin and HOMA-IR.
Methods
A cross-sectional study with thyroid ultrasound and serum glucose, insulin, leptin and TSH was performed with obese patients and a control group without known thyroid diseases, matched for age and sex, but with BMI of $<25\ kg/m^2$.
Results
Twenty-one patients and 40 controls, $36.7 \pm 8.8$, $35.9 \pm 9.1$ years old, respectively, were included. Median BMI was $50\ kg/m^2$ (patients) and $23\ kg/m^2$ (controls). Median TSH and thyroid volume were 2.2 mUI/ml and $7.9\ cm^3$ (patients) and 1.8 mUI/ml and $7.4\ cm^3$ (controls); $P=0.200$ and $P=0.369$. Medians of serum leptin were 4194 and 762 ng/ml ($P<0.001$).

Medians of HOMA-IR were 5.6 and 1.1 ($P<0.001$). Thyroid volume was correlated with BMI (rs=0.356, $P=0.04$) and HOMA-IR (rs=0.291; $P=0.016$) in the whole group. This last association was stronger in the obese group (rs=0.571, $P=0.01$), but also also present among the controls (rs=0.251, $P=0.05$). This correlation was independent from confounding parameters (TSH, BMI, leptin), as detected in the partial correlation, controlled for BMI (rs=0.349; $P=0.04$). The correlation between BMI and volume was related to the serum levels of leptin and HOMA-IR. Leptin only correlated with volume in obese patients. Normal ultrasound was found in 47.6% of patients and in 75% of controls, $P=0.30$. Nodules were found in 35 and 20%, respectively; $P=0.171$. The nodules were on average higher in patients, but not significantly.
Conclusion
The prevalence of thyroid nodular disease was not significantly

**Serum nesfatin-1 levels in overt and subclinical hyperthyroidism**

A. Güngünes[1], Z. Ginis[1], T. Demirci[1], E. Cakir[1], B. Karbek[1], M. Sayki Arslan[1], I. Ozturk Unsal[1], E. Tutal Akkaya[1], B. Ucan[1], E. Cakal[1], S. Gultuna Ozguclu[2], M. Ozbek[1], M. Sahin[2], O. Topaloglu[1] & T. Delibasi[1]
[1]Diskapi Yildirim Beyazit Training and Research Hospital, Ankara, Turkey; [2]School of Medicine, Ankara University, Ankara, Turkey.

Objective
Nesfatin-1, was recently discovered in the brain which is derived from nucleobindin2 (NUCB2). Central and peripheral administration of nesfatin-1, inhibits food intake, dose-dependently. Hyperthyroid patients have increased appetite and food intake with a craving for carbohydrate-rich food, at the beginning of disease, but the physiological mechanisms underlying this behavior is not known exactly. In this study, we investigated whether nesfatin-1 is involved in the regulation of appetite and body weight in hyperthyroidism, or not.
Methods
A total of 70 patients with subclinical and overt hyperthyroidism compared with 35 control patients. Serum nesfatin-1 level was measured from all samples by commercial ELISA kit.
Results
Serum free $T_3$ and free $T_4$ levels in the overt hyperthyroidism group was significantly higher and serum TSH level in the overt hyperthyroidism group was significantly lower than subclinical hyperthyroid and control group respectively ($P<0.001$). In addition, the TSH levels in the subclinical hyperthyroid group was significantly lower than control group ($P<0.001$). Serum nesfatin-1 levels were similar between three groups ($P=0.293$). After adjusting for age and body mass index, nesfatin-1 levels in control group was not different from subclinical and overt hyperthyroid group respectively ($P=0.567$ and $P=0.519$). However, there was a significant correlation between nesfatin-1 and platelet, free $T_3$ vs TSH receptor antibody levels ($P<0.05$).
Conclusion
These data showed that serum nesfatin-1 levels do not significant change in overt and subclinical hyperthyroidism.

## P1726

**Spontaneous splenic rupture following plasmapheresis in a patient with refractory amiodarone-induced thyrotoxicosis**

R. Streuli, D. Pfisterer, S. Fischli, L. Burget, J. Metzger, M. Kauper & C. Henzen
Luzerner Kantonsspital, Luzern, Switzerland.

Introduction
Amiodarone-induced thyrotoxicosis (AIT) is a well-known complication of amiodarone therapy. Type 1 AIT is caused by excessive iodine-induced thyroid hormone synthesis in abnormal thyroid glands and treated with thionamides; type 2 AIT is a drug induced destructive thyroiditis that responds to glucocorticoids. Mixed forms of AIT need a combined treatment of thionamides and glucocorticoids. In refractory cases of AIT plasmapheresis before total thyroidectomy is an efficacious treatment.
Case report
A 56-year-old woman was admitted to the emergency department with thyrotoxic symptoms of poorly controlled AIT that was diagnosed 3 months ago. Medical history revealed a coronary and valvular heart disease. Laboratory findings were TSH 0.04 mU/l (normal range 0.27–4.20), fT4 52.3 pmol/l (12–22), and fT3 5.6 pmol/l (3.1–6.8). Ultrasound of the thyroid gland showed two nodules and hypovascularisation of the parenchyma, therefore mixed AIT was diagnosed. Lithium and potassium perchlorate were added to the treatment with high dose prednisolone and carbimazole, and amiodarone was discontinued. However, within a week's time thyrotoxicosis aggravated to fT4 over 100 pmol/l and fT3 to 7.0 pmol/l. Because of the severe thyrotoxicosis refractory to medical therapy, we decided for plasmapheresis and total thyroidectomy. After the second plasmapheresis sudden pain in the left upper abdomen and hypotension occurred. A CT scan of the abdomen disclosed a splenic rupture and splenectomy was performed after another plasmapheresis, followed by total thyroidectomy.
Conclusions
Spontaneous splenic rupture is an extremely rare complication in plasmapheresis. To date and to our knowledge this is the first case of spontaneous splenic rupture occurring during plasmapheresis in a patient with AIT. In addition to anticoagulation during plasmapheresis hyperdynamic state caused by thyrotoxicosis may have contributed to splenic rupture.

## P1727

**Does serum inflammatory and cytokine profile influence graves disease severity at diagnosis?**

S. Martin[1,2], A. Sirbu[1,2] & S. Fica[1,2]
[1]Elias Hospital, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Autoimmune thyroid disease affects 1% of the population and comprises several disorders, including Graves' disease(GD). Local and serum cytokines are increased in patients with Graves disease, play a central role in co-ordinating immune reactions and have immunolgical and functional effects on thyroid cells.
Aim
To investigate serum inflammatory and cytokines profile in untreated patients with Graves' disease at diagnosis, when the immune response is presumably more specific.
Materials and Methods
We evaluated 118 patients (81.4% women), mean age 47.46 years, 91(77.1%) with GD compared to a control group of 27 with other ethyologyc forms of hyperthyroidism: toxic multinodular goiter, amiodaron induced hyperthyroidism, toxic nodule and subacute thyroiditis.
Results
GD patients were younger, with higher HR, FT 4 and TT3 than the control group. C-reactive protein, TNFα, ESR and fibrinogen levels showed no significant difference when compared to control group. GD patients with personal history of autoimmune diseases had higher TNFα ($P=0.007$) and those with personal history of thyroid diseases had higher CRP ($P=0.003$) and TNFα($P=0.01$) than those without. In the GD group smokers and those with oftalmopathy did not have a modified inflammatory profile. In the GD group: CRP, TNFα, ESR and fibrinogen did not correlate with FT4 or TT3 at diagnosis; CRP positively correlated with age ($P=0.025$); TNFα positively correlated with systolic BP($P=0.031$); ESR positively correlated with age, BMI, trigliyerides and fibrinogen positively correlated with triglycerides.
Conclusion
These results indicate that there may be only a limited role for measurement of CRP, TNFα, ESR and fibrinogen levels in the diagnosis of GD, yet inflammation significantly correlates with other important features.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1728

**TSH according to age and sex. The future of normality**

M. Menacho Roman[1], G. Perez Lopez[1], J. del Rey Sanchez[1], A. Becerra Fernandez[1], R. Villar[2] & E. Ripoll Sevillano[1]
Hospital Universitario de Fuenlabrada, Madrid, Spain.

Introduction
Reference ranges for classifying a patient as hyper-, normo- and hypothyroidism vary from one laboratory to another, because the techniques used, regional factors (race, iodine..), but there is also the variables of age and sex of the patient are not taken. Article Thyroid Volume 21, Number 1, 2011, 5–11 Boucai et al, published equations to adjust the normal range in terms of these variables. Evaluate these equations and see if there are significant changes to normal.
Materials and Methods
We studied 520 outpatients that have requested TSH from the health center.
Our reference range for TSH is between 0.35 and 4.94 mUI/mL, so adapting the equations described in the article the following equations are obtained to study:
TSH(2.5) = 0.35 + 0.00073*Age − 0.031*Sex
TSH(97.5) = 4.94 + 0.05*Age − 0.223*Sex
Considering age in years and sex 0 for men and 1 for females
Results
With our classification reference range of thyroid function: are 12 hyperthyroid patients (2.3%), normothyroid are 472 (90.8%) and hypothyroid are 36 (6.9%). Applying the equations to study the following results: 13 (2.5%), 498 (95.7%) and 9 (1.8%) respectively.
hyperthyroid patients have antibodies and the patient requested the equation presented discrepant antibody negative. Of the 36 hypothyroid patients, only 14 had requested antibodies, with 28% negative.
patients with negative antibodies with the equation would be reclassified as normothyroid. But of the 10 patients with positive antibodies, 5 would remain hypothyroid and the other 5 would then normothyroid.
Conclusions
These equations to determine new TSH reference ranges are attractive because they allow us to dispense with the verification of results, enlargement of new assays, such as T4, T3 or antibodies. As we have only tested on a working day studies are higher, increasing the size of the sample, obtained by decades of age groups homogenous and making sure that all the patients studied made antibodies present.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Evaluation of the psychoemotional status of patients after surgical treatment of Graves' disease by catamnesis data**

O. Nechaeva, A. Dreval, T. Mamedova, T. Shestakova, I. Chikh & I. Komerdous
Moscow Regional Research Clinical Institute of M.F.Vladimirsky, Moscow, Russian Federation.

Materials and methods
The study included 58 patients (50 female, 8 males) aged from 38 to 60 years, have received surgical treatment for GD with the period of follow-up after treatment for 2 to 10 years. The patients were divided into 2 groups depending on the initial level of TSH. In the first group (33 persons) included patients with low-normal level of TSH (0.4–2.5 mU/ml), the in second group (25 persons) with upper-normal level of TSH (2.6–4.0 mU/ml). An estimation of the psychoemotional status was conducted by means of a scale of depression of Beck and Spielberg-Khanins test.
Results
The groups were comparable for gender, duration after treatment, dose of L-T4. In the first group the median age of patients was 43 years (35;50), the amount of points depression was 10 (2;19), which corresponds to easy depression, the median amount of points situational anxiety 39 (23;50), personal alarm 40 (23;59), which corresponds to a moderate level of anxiety.
In the second group the median age was 56 years (49;64), the amount of points depression was 16 (2;29), which corresponds to mild depression, the median amount of points situational anxiety 44 (25;60), personal alarm 44 (31;67), which corresponds to a moderate level of anxiety.
In the evaluation of mean values of the psychoemotional status in the first and second group, statistically significant differences were observed on all scales ($P < 0.05$).
Conclusions
there are significant differences of the psychoemotional status (presence of anxiety and depression) among patients with upper- and low-normal TSH. It is established that patients with upper-normal TSH had the worst performance, in the course of our study revealed a statistically significant difference between all scales, but most likely due to age.

**Quality of life of patients after surgical treatment of Graves' disease by catamnesis data**

A. Dreval, O. Nechaeva, T. Mamedova, T. Shestakova, I. Chikh & I. Komerdous
Moscow Regional Research Clinical Institute of M.F.Vladimirsky, Moscow, Russian Federation.

Materials and methods
The study included 58 patients (50 female, 8 males) aged from 38 to 60 years, have received surgical treatment for GD with the period of follow-up after treatment for 2 to 10 years. The patients were divided into 2 groups depending on the initial level of TSH. In the first group (33 persons) included patients with low-normal level of TSH (0.4–2.5 mU/ml), the in second group (25 persons) with upper-normal level of TSH (2.6–4.0 mU/ml). Quality of life was assessed with the help of the using the questionnaire Short-Form SF-36.
Results
In the first group the median age of patients was 43 years (35;50),median follow-up after treatment 7 years (5;10), the average level of TSH 1.8 mU/ml (1.55;2.3), a median dose of L-T4 100 mcg (100;125), the median quality of life of 8 scales questionnaire SF -36 ranged from 54 points (vitality) up to 85 (pain).
In the second group the median age was 56 years (49;64), the median follow-up after treatment of 8 years (7;10), the average level of TSH 3.8 mU/ml (3.2;4), a median dose of L-T4 75 mcg (75;100), the median quality of life of 8 scales ranged from 40 points (vitality) to 58 (physical functioning).
In the evaluation of mean values of the quality of life in the first and second group, statistically significant differences were observed on all scales ($P < 0.05$).
Conclusions
The average quality of life of patients were on average and high level, however, there are significant differences in quality of life among patients with upper- and low-normal TSH. It is established that patients with upper-normal TSH had the worst performance, in the course of our study revealed a statistically significant difference between all scales.

**Thyroid dysfunctions in patients with chronic hepatitis c virus infection with and without interferon therapy**

A. Hammad[1], F. Hamad[2], O. Fawzy[2], Z. Hassan[2], D. Abaza[2], S. Elshazly[2] & I. Eltayeb[2]
ALazhar University for Girls, Cairo, Egypt.

Objective
to assess the frequency and pattern of thyroid dysfunctions (TD) in Egyptian patients with chronic hepatitis C virus infection (HCV) with and without interferon alpha (IFN) therapy.
Methods
thyroid function as well as thyroid peroxidase antibodies (TPO Ab) were assessed in 40 untreated Chronic HCV patients (HCV group), 30 HCV patients under IFN alpha therapy, for more than three months (IFN group) and 50 healthy age and sex matched controls.

Results
TD, either overt or subclinical, was detected in 12.5% of HCV group, 33.4% of IFN group and 2% of controls. Among HCV group, 5% had overt hypothyroidism, 7.5% subclinical hypothyroidism and no one had hyperthyroidism. While overt hypothyroidism was detected in 10% of IFN group, subclinical hypothyroidism observed in 16.7% and hyperthyroidism reported in 6.7%. Among controls, 2% had subclinical hypothyroidism whereas no one had overt hypothyroidism or hyperthyroidism. TD was more often detected in females (47.8%) compared to males (5.1%). Higher levels of TPOAb were observed among IFN group compared to HCV group and controls ($P<0.01$ & $P<0.01$, respectively). The study showed significant association between thyroid dysfunctions and TPO Ab positivity ($P=0.027$).
Conclusion
TD among Egyptian HCV patients, especially those treated with IFN was more frequent than usually reported. It is likely that HCV and IFN act in synergism to trigger TD in patients. Women appear to be more vulnerable to TD than men. The predominant TD is hypothyroidism. In view of high frequency of TD, routine screening and surveillance of HCV patients, especially after receiving IFN, is recommended.

## P1732

### Elevated levels of thyroid hormones without TSH suppression in two patients

I. Vourliotaki[1], A. Boumpaki[1], S. Alexaki[1], J. Oriola[2] & K. Stamataki[1]
Hospital Clinic, Barcelona, Spain.

Introduction
Resistance to thyroid Hormones (RTH) is a syndrome characterized by reduced tissue responsiveness to thyroid hormones (TH).
This results to constantly elevated levels of TSH despite high levels of free T3 (FT3) and free T4 (FT4).
RTH is due to mutations of the gene encoding the b-isoform of the receptor of TH (THR-b gene), inherited in the autosomal dominant manner.
Clinical expression of RTH varies reflecting different levels of tissue resistance to TH, different mutations and genetic heterogeneity of factors affecting TH action.
Most patients are asymptomatic. Few present with hypo- or hyperthyroidism.
Coexistence of both hypo- and hyperthyroidism symptoms in the same patients is not rare. Goiter is quite common.
Case report
We describe two patients with RTH; a 36-year old female (1st patient) and a 58-year old male (2nd patient).
Both patients had undergone total thyroidectomy for multinodular goiter.
After thyroidectomy, increasing doses of levothyroxine were not enough to lower TSH down to normal, whereas FT3 and FT4 levels were elevated.
Negative pituitary MRI and normal TSH response to TRH stimulation excluded thyrotropinoma (TSH-secreting adenoma) in both patients.
Genetic analysis revealed RTH.
In the first patient analysis of the exon 10 (chromosome 3) showed a C insertion in codon 448, that lengthens the polypeptide chain by two aminoacids.
In the second patient there was a heterozygous replacement of C to T in codon 383 resulting to a change from arginine to cytosine.
In both cases further increase in levothyroxine dose reduced TSH levels to slightly above normal.
Conclusion
Elevated FT3 and FT4 levels without suppression of TSH should raise suspicion of RTH.
Pituitary MRI and TRH stimulation test are necessary to exclude thyrotropinoma.
RTH is confirmed by genetic analysis.
In many patients RTH is 'unmasked' after thyroidectomy, because post-thyroidectomy hypothyroidism is difficult to treat

## P1733

### Hyper - and hypothyroidism without symptoms - how much can a patient tolerate ?

J. Zmire, K. Peroš, K. Kljajić Babić, K. Martinac, B. Čolak & L. Sokolić
KB Merkur, Zagreb, Croatia.

Disturbances of thyroid hormones produce clinical symptoms but hormonal level at which this happens vary from patient to patient. In order to determine how much hormonal change patients can tolerate before developing symptoms we retrospectively collected data of 86 hyperthyroid and 48 hypothyroid patients, 120 females and 14 males aged 28–85 and 23–74 yrs respectively. We included only patients who at some time during treatment had abnormal values of TSH and/or thyroid hormones and/or antibodies but had no disease symptoms at all. We found that patients tolerate TSH values from low $<0.005$ to high 60 and even 105 mIU/L without any complaints. On 94 occasions TSH was below and on 72 above normal levels, majority of elevated values up to 30 mIU/L above upper normal limit. Free thyroxine ranged from $<2.0$ to 75.6 pmol/L(n.v 9.8–16.8) with majority (52) of elevated values up to 20 pmol/L above normal; few patients had higher values (1 up to 30, 5 up to 40, 2 up to 50 and 1 up to 80 pmol/L above upper normal limit) and at that time without any symptoms. Asymptomatic patients had free triiodothyronine from 1.4 to 36.8 pmol/L (n.v.4.6–7.8), majority of elevated values (49) up to 15 pmol/L above upper limit.
46 euthyroid patients with positive thyroid antibodies had no symptoms, 3 patients had symptoms but also other problems. We conclude that many patients have no symptoms at all with hormones slightly, moderately or even extremely elevated or decreased. Our patients do not feel positive thyroid antibodies. The cause for this phenomenon probably involves thyroid hormone receptors and/or sympathoadrenergic system.

### The influence of chronic stimulation of thyrotropin on nodular thyroid goiter

S. Medenica, B. Trbojevic, J. Ciric, B. Beleslin & M. Stojkovic
Clinic of endocrinology, diabetes and metabolic disorders, Clinical Centre of Serbia, Belgrade, Serbia.

Introduction
Nodular goiter is clinically recognizable restricted structure changes of the thyroid gland. FNA is the first line diagnostic test for an enlarged thyroid gland. TSH is known as a thyroid growth factor, but the pathogenic role of this hormone in thyroid oncogenesis is unclear.
Objective
The aim of this study is to analyze the relationship between elevated serum TSH concentrations and thyroid malignancies in patients with nodular thyroid goiter.
Material and Methods
We retrospectively reviewed the 637 reports of thyroid FNA cytology of samples obtained by puncture of patients with nodular thyroid goiter, at Department of thyroid gland, Department of Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia in the period from October 2007. by January 2010. year. We analyzed the relationship between findings of cytopathological diagnostic categories and serum concentrations of TSH. The data were statistically tested using Kruskal Wallis test of differences using the computer program SPSS 12.0 software package.
Results
Of total 637 patients 3.45% (22/637) had a malignant, and 4.87% patients (31/637) cytopathological indeterminate findings. 91.52% (583/637) patients were with benign findings, and only one puncture failed. The average value of TSH in a group of patients with a diagnosis of malignancy was 9.83 $\pm$17.48 mmol/l with a median 3.31 mmol/l. In all three diagnostic categories (benign, malignant and unspecified) most patients are with the normal concentrations of serum TSH, but there is a relatively large proportion of 27.3% (6/22) of patients with malignant cytopathological findings in the group of patients with elevated TSH concentration. Statistically significant differences between diagnostic categories by group TSH values($P=0.017$).
Conclusion
It is concluded that the risk of developing thyroid malignancy increases in patients with elevated serum TSH concentrations. TSH should be used as an additional diagnostic tool in identifying high-risk patients who require further investigation and / or surgical treatment.

**Ischemic stroke without cardiac arrhythmia in a middle age female with thyrotoxicosis**

C. Palermo[1], O. Torres[1], J. Martinez[1], E. Gonzalez[1], M. Miranda[1], J. Figueroa[2], J. Gonzalez[2], F. Silva[2] & F. Kolodjiev[2]
[1]San Juan City Hospital, San Juan, Puerto Rico; [2]School of Medicine UPR, San Juan, Puerto Rico.

51 y/o female with past medical history of migraine headache, brought to UR because of hypoactivity, generalized weakness, confusion, lack of balance and dysarthria since one day of evolution. No medications. No Habits. Past history: negative for hypertension, cardiac disease or dyslipidemia. Physical examination: normal vital signs and weight. Alert, awake, and oriented only in person. Palpable nontender left thyroid lobe. Bilateral hyperreflexia.
Labs: CBC, CMP, toxicology, urinalysis, ANA screen, RPR, and Anti-TPO: negative. Sed rate: 40 mmh TSH: 0.159 mIU/mL. TSI: negative. Anti-Thyroglobulin Antibody: positive. Anticardiolipin: negative.
CT scan of head: bilateral basal ganglia infarcts.
24 hours RAIU: 0.4%. Thyroid scan: thyroiditis.
Thyroid Ultrasound: small bilateral nodules. LP: negative. EEG: diffuse cortical dysfunction as seen in encephalophathy states. ACEI, statin and asa were started. Echocardiogram and carotid Doppler: negative. She was discharged after moderate clinical improvement.
Brain SPECT: negative.
MRI/MRA: Vasculitis cannot be excluded.
Hyperthyroidism is associated with atrial fibrillation and cardioembolic stroke. In thyrotoxic patients without cardiac arrhythmia, only 7 cases of acute cerebrovascular ischemic disease have been identified. Hyperthyroidism may be associated with cerebrovascular thrombosis (CVT), Moya-moya disease, antiphospholipid syndrome (APS), giant cell arteritis (GCA). The mechanism contributing to the association between hyperthyroidism and stroke are not fully understood. Possible explanations are: inflammatory factors and metabolic changes, leading to increases in carotid artery intima-medial thickening.
CVT is a very uncommon disease associated with several causes and risk factors, such as inherited thrombophilia, oral contraceptives, pregnancy, and puerperium. APS is a combination of arterial or venous thrombosis, recurrent fetal loss, and lupus anticoagulant or anticardiolipin antibodies. GCA is a chronic vasculitis among individuals $>50$ years of age. Moyamoya is a rare cerebrovascular disorder characterized by bilateral stenosis of the internal carotid which has been ruled-out in view of the MRI findings.

## P1736

**Middle age female with long standing multinodular goiter, cardiac arrhythmia and thyroid dysfunction: the endocrinology and cardiology connection**

C. Palermo[1], O. Torres[1], J. Martinez[1], E. Gonzalez[1], M. Miranda, J. Figueroa[2], J. Gonzalez[2] & F. Silva[2]
[1]San Juan City Hospital, San Juan, Puerto Rico; [2]School of Medicine UPR, San Juan, Puerto Rico.

67 y/o old female, with long history of hyperthyroidism, without treatment and hypertension. Two months prior to admission, she received amiodarone 200 mg daily due to cardiac arrhythmia. One week prior to admission, she developed symptoms of Congestive Heart Failure and weight loss. Family history: hyperthyroidism in two sisters. Physical examination: acutely ill, thin female, in moderate respiratory distress. Alert, oriented x 3.BP: 155/119 mmHg HR: 150.Prominent findings: multinodular goiter. Bilateral crackles up to 2/3 lung fields. Irregular rhythm. Bilateral pitting edema. EKG: A-Fib with fast ventricular response. Echocardiogram: Left/Right atrial enlargement. Diuretics, nitrates, morphine, valsartan, anticoagulants and an Amiodarone drip were started. Laboratory tests: Thyroid panel compatible with hyperthyroidism. Positive Anti - TPO. 24 hours urine iodine: 6428.1 ug/L. TSI: negative.
Thyroid sonogram: hypervascular multinodular goiter. Normal 24 hours thyroid uptake. Thyroid scan: multinodular goiter with functional and non functional nodules. After Endocrinology evaluation, Amiodarone drip was discontinued. Patient improved and was discharged on methimazole 30 mg daily, carvedilol, digoxin and warfarin. At OPD, methimazole was switch to PTU due to body rash. FNAB: negative for malignancy. Three months after discharge patient remained clinically and biochemically hyperthyroid.
Amiodarone is an iodinated compound with 37% iodine by weight. Thyroid dysfunction has been reported to affect 2–24% of amiodarone users. Amiodarone-induced thyrotoxicosis (AIT) is 3%. Excess iodine-induced thyroid hormones synthesis is known as type I AIT, usually occurs in patient with underlying thyroid pathology; whereas destruction of thyroid follicles resulting in a thyroiditis is known as type II AIT. Distinguishing one type from the other may be troublesome and is important because it has a major influence on subsequent management. AIT is associated with a 2.7 fold increased risk of major adverse cardiovascular events. AIT is a condition that is difficult to manage, because of the long half-life of amiodarone.

**Body Mass Index and goiter in school children. Are there any relationship?**

N. Khalili & M. Hashemipour
Isfahan University of Medical Science, Isfahan, Islamic Republic of Iran.

Introduction
Iodine deficiency is a common problem of public health that usually causes thyroid enlargement called goiter. It is estimated that 750 million people worldwide are at risk of Iodine Deficiency Disorders (IDD). IDD can be presented with a wide variety of clinical manifestations, which induce congenital anomalies, cretinism, deaf mutism, psychomotor defects and severe goiter.
About 17 years after the initiation of salt iodization in Iran, this study considered the prevalence of goiter and possible association between BMI and it in school children in Isfahan, Iran.
Methods and materials
In this cross sectional study, 2293 school children aged 6–13 were enrolled by multi-stage random sampling. The exclusion criteria were: a history of exposure to radioactive iodine, thyroid surgery or significant underlying disease such as cardiopulmonary, liver or renal problems based on available medical records and interviews with parents and teachers. Then goiter grading was done by inspection and palpation of it according to recommended criteria of WHO/UNICEF/IC-CIDD.[Grade 0: No palpable or visible goiter; Grade1: thyroid is palpable but not visible when the neck is in the normal position; Grade 2: A swelling in the neck that is clearly visible when the neck is in a normal position and is consistent with an enlarged thyroid when the neck is palpated.]. Weight and standing height were measured. Height was recorded to the nearest 0.1 cm and weight was recorded to the nearest 100 g. Body Mass Index (BMI) was calculated using the following formula: BMI = weight (Kg)/height (m) 2.
Results
The mean age $\pm$ SD was $9.39 \pm 1.18$ years for girls and $9.47 \pm 1.12$ years for boys and female to male ratio was 1.6. Overall had goiter (33.1%) that 39.5% of them were boy and 60.5% were girl. Goiter prevalence among girls was 32.4% while 33.7% of boys were goitrous ($P=0.518$).
The mean $\pm$ SD of BMI in the goiterous and non-goiterous children were $15.59 \pm 2.31$ and $16.98 \pm 3.35$ respectively($P=0.00$).
Conclusion
Our study showed goiter is still prevalent between Iranian children and BMI was significantly less in goiterous than in nongoiterous children. Therefore there is an association between BMI and goiter. More researches should be done to distinguish this possible connection.

**The concept 'one thyroid specific immune mechanism - a specific thyroid disease'. Pleading for adoption of a new nomenclature for immune thyroid diseases**

D. Peretianu[1], M. Carsote[2], C. Poiana[2], D. Staicu[1] & A. Clodeanu[1]
Institute of Endocrinology, Bucharest-Bucuresti, Romania.

Aim, Objectives
Conceptualizing new data related to type and level of autoantibodies in thyroiditis Hashimoto, Graves-Basedow disease and releated conditions.
Material
###1. Adoption the integrative concepts of immune network (Nobel Prize, 1984) for immune thyroid diseases. 2. Searching on "www.ncbi.nlm.nih.gov/pubmed" for papers with keywords: thyroid autoantibody, thyroiditis (~2500 papers). 4. New (auto)-antibodies (and antigens/epitopes) found in immune thyroid diseases.
Method
###1. Thyroid diseases pathogenesis is mostly immune. 2. Patients have autoantibodies and the disease is called autoimmune. 3. If there is a pathogenetic antibody, then there must be a pathogenic antigen. 4. Asserting a/one specific immune pathogenic mechanism, there cannot be overlapped disease because there could not be overlapped/more pathogenic mechanisms. 5. Understanding pathogenetic steps means: only one immune mechanism could act. 6. Other antibodies presence (along with the specific one) in patient should be related to upstream and downstream regulation mechanisms of the immune network. 7. Immune thyroid disease name should be linked on a sole mechanism.
Results
1. Medical literature specify 4 clinical situations: Hashimoto thyroiditis, idiopathic mixedema, Graves-Basedow disease, Riedel thyroiditis. 2. Criteria for defining these entities did not allowed overlapping especially for specific auto-antibodies. 3. Thus a disease should be linked to a single immune mechanism and a single auto-antibody. 4. If there are many antibodies in a clinical situation, then there is more than one diseases. 5. Association of many thyroid immune disease in a patient is not a rare situation.
Conclusions
###1. Hashimoto thyroiditis is only ATPO related. 2. Graves-Basedow disease is only TRAB related. 3. Riedel thyroiditis is only IgG4 non-ATPO/ATG/TRAB related. 4. Thyroiditis with only ATG should be name specifically. 5. Idiopathic mixedema is that immune destruction with no yet specific antibody/antigen identify complex. 6. Pathogenesis linked on new immune complexes pendrine/anti-pendrine, NIS/anti-NIS could lead to define new clinical entities.

**The metabolic syndrome in thyroid disorders**

A. Ogbera
Lagos State University Teaching Hospital, Ikeja, Lagos, Nigeria.

Introduction
The objective of this report is to determine the presence of the metabolic syndrome and its components in people with thyroid disorders.
Methods
112 subjects with a history of thyroid disorders were consecutively enrolled for the study. Clinical data was obtained by interviewing the patients and referring to their Case folders and their prescriptions. The subjects were categorized into three; thyrotoxic, euthyroid, hypothyroid based on clinical parameters and or thyroid function tests. The study subjects were weighed and their anthropometric indices were documented. The laboratory parameters that were analysed for included total cholesterol, high density and low density cholesterol and triglyceride. Statistical analysis included usage of Student's t test, One way Anova test and chi square.
Results
The study subjects were aged between 14–76 years with a mean age of 44.5 (14) years and a female:male ratio of 97:15. The mean age and anthropometric indices were comparable in subjects with thyrotoxicosis, hypothyroidism and euthyroidism. The overall prevalence of the metabolic syndrome was 28% and the frequency of occurrence of the metabolic syndrome in subjects with thyrotoxicosis, hypothyroidism and euthyroidism were 24%, 40% and 42% respectively. The commonest occurring metabolic syndrome defining criterion was dysglycaemia and hypertension and elevated triglyceride were the least documented of the criteria.
Conclusion
The metabolic syndrome occur in one in every four persons with thyroid disorders and as such, routine screening for this cardiovascular risk factor may be of benefit in this group of people.

## P1740

**The influence of cure of subclinical hyperthyroidism on the level of serum triglycerides and cholesterol fractions**

G. Kaminski, G. Zielinski & J. Podgorski
Military Institute of Medicine, Warsaw, Poland.

Introduce
Subclinical hyperthyroidism (SH) affects 0.2 - 11.8% of world human population and is associated with important cardiovascular risk factors. It remains controversial whether or not to treat patients with low serum TSH levels. Between unwanted potential outcomes of treatment of SH there is an elevation of the level of serum triglycerides and cholesterol which may be responsible for higher risk of cardiac death.
Aim
To estimate an influence of cure of SH on the level of serum triglycerides and cholesterol fractions: total (Tchol), low density (LDL) and high density (HDL).
Method
44 patients (37 women, 7 men) aged mean 45, with 13 month history of only autonomous endogenous SH (mean TSH = 0.16 mIU/l) were examined twice: before and mean 6 months after TSH normalization (obtained mean TSH = 1.32 mIU/l) with radioiodine treatment (mean 12.1 mCi). The average time between examinations was one year.
Results
The cure of SH caused statistically insignificant increase of serum triglycerides from 95.2 to 102.6 mg/dl ($P = 0.273$) and Tchol from 204.6 to 211.1 mg/dl ($P = 0.11$) but significant increase of LDL from 114.3 to 121.9 mg/dl ($P = 0.018$) and HDL from 64.02 to 66.25 mg/dl ($P = 0.041$).
Conclusions
1 Cure of autonomous subclinical hyperthyroidism insignificantly increases levels of serum triglycerides and total cholesterol. 2. Potential deleterious effect of statistically significant increase of serum LDL could be abolished by significant increase of serum HDL. 3. Further investigations are needed.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1741

**Increase of Serum Adiponectin And Stable Concentrations of Matrix Metalloproteinases Confirm Safety of Radioiodine Treatment of Thyrotoxicosis**

A. Lewinski[1], A. Brona[2], K. Lewandowski[1], M. Bienkiewicz[1] & A. Milewicz[2]
The Medical University of Wroclaw, Wroclaw, Poland.

Background
Matrix metalloproteinases (MMPs), together with their tissue inhibitors (TIMPs), remodel extracellular matrix under physiological and pathological conditions and are implicated in pathogenesis of cardiovascular diseases, cancer and in chronic inflammation. We have endeavoured to assess whether concentrations of MMPs, TIMPs, proinflammtory thrombospondin and anti-inflammatory adiponectin are altered by administration of radioiodine during treatment of thyrotoxicosis.
Material & Methods
We measured serum concentrations of MMP-2, MMP-9, TIMP-1, TIMP-2, thrombospondin and adiponectin as well as lipids, TSH, fT4, and fT3 before radioiodine administration (RIA), visit 1 (V1), seven days post RIA, visit 2 (V2), and two-three months post RIA, visit 3 (V3) in 20 subjects (2 males), treated for thyrotoxicosis (age (mean ± SD) 52.3 ± 12.4 years).
Results
RIA did not cause any acute change in serum MMP-2, MMP-9, TIMP-1 and TIMP-2, thrombospondin or adiponectin (V1 versus V2). Subsequently, however,

there was a significant increase in serum adiponectin (from 15201 ±8860 ng/mL(V1) to 19373±8657 ng/mL (at V3), $P<0.05$), and TIMP-2 at visit 3 (from 129±45 ng/mL (V1) to 149±38 ng/mL (V3), $P<0.01$). There was no significant change MMP-2, MMP-9, TIMP-1 and thrombospondin between V1 and V3. There was a decrease in fT4 and fT3 from 24.4±15.4 pmol/L (V1) to 14.7±10.6 pmol/L (V3), and from 10.0±5.65 (V1) to 6.1±4.8 pmol/L (V2), $P<0.01$, for fT4 and fT3, respectively. This was accompanied by an increase in total and LDL cholesterol between V1 and V3 ($P<0.01$), however, without significant change in HDL cholesterol ($P=0.23$).

Conclusions

Radioiodine treatment of thyrotoxicosis appears vey safe, as administration of radioiodine does not alter serum MMP-2, MMP-9, TIMP-1 or thrombospondin concentrations either acutely or after about three months of observation. An increase in serum adiponectin might reflect favourable effects of radioiodine administration on cardiovascular risk factors, while an increase in TIMP-2 (principal MMP-2 inhibitor) might lead to a decrease in free MMP-2 concentrations.

**Hyperthyroidism and Pregnancy**

M. Amani[1], F. Chentli[2], S. Amani[3], N. Midoun[1], N. Benfeghoul[4], A. Rih[4], L. Zemour[1] & N. Boumansour[1]
[1]EHU 1st November 1954, Oran, Algeria; [2]CHU Bab-el-oued, Algiers, Algeria; [3]CHU Benzerdjeb, Oran, Algeria; [4]Djilali Liabes university, Sidi-bel-abbès, Algeria.

Introduction

Hyperthyroidism affects 2 to 3% of pregnant women. The prevalence of clinical hyperthyroidism during pregnancy is variously appreciated. Hyperthyroidism prior to pregnancy is probably more common than in connection with the gestationnal state as gestational hyperthyroidism usually blocks fertility. Our objectives are the prevalence and the causes of hyperthyroidism in pregnant women in the 1st quarter.

Description of methods

Prospective study, made in Oran area, on 270 pregnant women in 1st quarter. Women who smoke (active smoking confessed) and those followed for thyroid disease or taking medications that interfere with the thyroid gland were excluded.
-Study protocol: clinical examination, thyroid stimulating hormone, free thyroxine, free triiodothyronine, thyroid antibodies (anti-TPO, anti-thyroglobulin and TSI) and cervical ultrasonography.
- Statistics tests: collection of data on EPI INFO 5.1, bivariate analysis (the chi-squared test, the Pearson chi-squared test, the Yates corrected chi-squared test, the Wilcoxon chi-squared test (Log rank sum) or Mann-Whitney, the variance analysis method (ANOVA), the r correlation test, significance level $P<0.05$, multivariate analysis (SPSS: 10 version and MedCalc).

Results

−2/270 Pregnant women in 1st quarter (0.7%) had hyperthyroidism.
-The etiology of thyrotoxicosis was related to gestational transient hyperthyroidism.
- No case of Graves' disease was found.

Conclusion

Hyperthyroidism is a rare disorder during pregnancy but the consequences are serious for both mother and offspring.

**Histopathological results of patients that were undergone thyroid-ectomy due to results of repeated non-diagnostic cytology**

D. Arpaci[1], N. Cuhaci[1], F. Saglam[1], G. Kiyak[1], S. Yalcin[2], S. Akbaba[1], G. Guler[2], R. Ersoy[2] & B. Cakir[2]
[1]Ankara Ataturk Training and Research Hospital, Ankara, Turkey; [2]Yildirim Beyazit University, Faculty of Medicine, Ankara, Turkey.

Objective

In our clinic we aimed to assess ultrasonographic and histopathologic data of thyroid nodules of patients with nodular thyroid disease reported their repeated cytologic results as non-diagnostic.

Methods

Seventy-five patients with nodular thyroid disease whom their TFNAB results were reported 2–3 times non-diagnostically (due to large nodule, ultrasonographically suspicious nodule, high elastosonographic score or strain index, family history of thyroid cancer) have enrolled in this study and their data were assessed. Demographic and ultrasonographic features of these patients and of who their cytologic results were reported malignant features of tumor were also assessed.

Results

40(53.3%) of patients had euthyroid multinodulary goiter (MNG), 8(10.7%) euthyroid nodulary goiter(NG), 17(22.7%) toxic MNG, 6(8%) toxic diffuse MNG, 1(1.3%) toxic diffuse NG, 1(1.3%) relapsed operated MNG and 2(2.7%) relapsed operated NG.. 45 of patients (60%) were euthyroid, 25(33.3%) hyperthyroid and 5(6.7%) hypothyroid. In 41 patients(54.7%) nodul(es) was/were localized at right lobe, in 34(45.3%) at left lobe. Ultrasonographically, microcalcification was found in 30 nodules(40.0%) whereas macrocalcification was found in 20 nodules. 45 nodules(60%) had irregular borders, 28 nodules (37.3%) had hypoechoic halo. Peripheral vascularity was found in 17(22.7%) nodules, peripheral macrocalcification was found in 1 nodul(1.3%). After surgery 57 nodules(76%) were reported benign, 18(24%) malignant. Of malignant nodules 17 nodules (94.4%) had papillary carcinoma whereas 1 nodul had follicular carcinoma. Mean tumour diameter was 0.77±0.63 (range 0.1–2.2) cm. In one patient(5.6%) vascular invasion, in 5 (27.8%) capsular invasion, in 1(5.6%) extracapsular extension and in 6 (33.3%) multicentricity was found.

Conclusion

In our study we found the rate malignancy 24% as high for thyroid nodules which were performed FNA biopsy and reported repeated non-diagnostic cytology results. Therefore, we conclude that when treatment is planned for the patients that have non-diagnostic cytology possibility of high rate of malignancy as we found in this study may be considered.

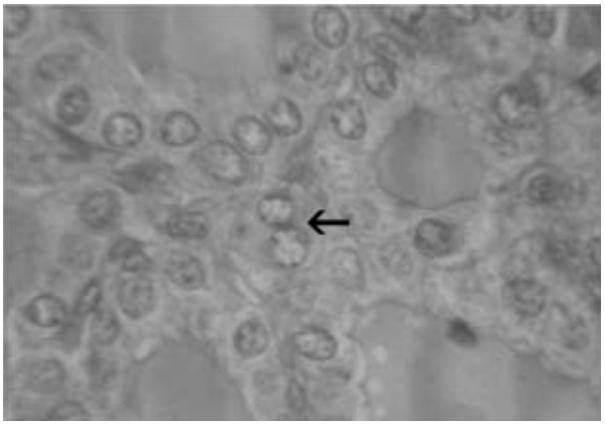
**Chlorpyrifos induced alterations in serum electrolytes (calcium, phosphate and magnesium) and endocrine glands (calcitonin cells and parathyroid gland) of Wistar rat**

S. Tripathi & A. Srivastav
DDU Gorakhpur University, Gorakhpur, India.

Wistar rats (male) were divided into three groups – group A (GA) served as control, group B (GB) were daily administered orally chlorpyrifos at a dose of 5 mg/kg b wt. and animals in group C (GC) received daily an oral administration of chlorpyrifos at a dose of 10 mg/kg b wt. Rats were sacrificed on 1st, 2nd, 4th, 6th, and 8th week after initiation of the experiment. Changes in serum electrolytes (calcium, phosphate and magnesium) and endocrine glands (calcitonin cells and parathyroid glands) were determined. In chlorpyrifos exposed rats hypocalcemia, hypophosphatemia and hypomagnesemia were recorded. At later intervals an increased levels of serum calcium and phosphate were observed. The parathyroid



glands and calcitonin cells exhibited increased activity which is evident by increased nuclear volume of these cells. This is the first report describing effects of toxicant on serum magnesium level of mammals.

### Utility of sonographic features and citology obtained by ultrasound-guided fine needle aspiration in preoperative management of thyroid nodules

L. Pacheco, F. Rius, M. Hernandez, P. Buetas, X. Matias-Guiu, D. Mauricio & F. Maravall
Hospital Universitario Arnau de Vilanova, Lleida, Spain.

Introduction
Nodular thyroid disease is common in the general population, but only 5% of thyroid nodules are carcinomas. The diagnostic challenge is to identify those nodules that are malignant neoplasias. Some sonographic features of nodules have been correlated with the risk of malignancy, but at present, thyroid cytology obtained by ultrasound-guided FNA is probably the best tool in the preoperative management of nodular disease.
Design
We designed a prospective study that included all patients referred to our department for thyroid nodular disease, with at least one ultrasound-guided FNA. Our aims were to determine the combination of ultrasound variables that have the capacity to discriminate malignancy, and correlate the sonographic and cytologic features with histopathologic analysis after surgical excision.
Results
We present preliminary analysis after the first year of study. A total of 552 nodules were aspirated in 275 patients with ultrasound-guided FNA. The samples were representative in 82.7%. In 45.80% (243) the dominant nodule was located in the left thyroid lobe, 76% of nodules were $\geq$ 1 cm, 74% were solid, 91.32% had regular margins and 76% well defined, 45.47% had no perinodular halo, 67.7% had no calcifications, 47.5% were isoecogenic and 75.10% had only perinodular vascularization. Cytology suggestive of malignancy was significantly correlated with hypoecoechogenicity, and a larger nodular size. 29 patients were referred for surgery, 10 underwent surgery, (of which 6 were thyroid carcinomas), 21 are awaiting thyroid scintigraphy for surgical decision, and the remaining patients are on follow-up.
Conclusions
The hypoechogenicity and increased nodule size were significantly correlated with cytology suggestive of malignancy; therefore, this may be useful in making surgical decisions. These are preliminary results and we need to complete the study

### Thyroid disorders and lipid abnormalities: An association between primary hypothyroidism and lipid profile pattern

D. Acharya[1], 1R. Dhital[2] & R. Mahato[2]
[1]Dhulikhel Hospital, Kathmandu University Hospital, Kavre, Nepal; [2]Nobel College, Kathmandu, Nepal.

Introduction
The correlation between lipid profile changes & overt hypothyroidism is well established. Overt hypothyroidism is associated with increased risk for cardiovascular disease (CVD) as indicated by hypertension, elevated lipids levels, hypercholesterolemia, and particularly increased low-density lipoprotein cholesterol (LDL-C) levels. However, lipid profile alterations in primary and subclinical hypothyroidism are controversial. There are hardly any studies from this region that intensify the association of lipids with thyroid hormones. Hence this study aims to determine the pattern of lipid profile abnormalities in patients with primary and subclinical hypothyroidism.
Methods
Forty patients (6 of primary hypothyroidism and 34 of subclinical hypothyroidism), diagnosed in the Department of Clinical Biochemistry (ELISA, Lab Life ELISA 2007, RFCL, India) were subjected for lipid profile testing (Erba Chem 5 Plus, Germany) from August to October 2010 at Dhulikhel Hospital-Kathmandu University Hospital, Nepal. The results of this prospective study were statistically analyzed by SPSS 14.0.
Results
Majority of the patients were female (90%) of the age 11 to 66 years (38.625 $\pm$13.93). Of all 40 patients enrolled, 35% (14) had mean serum cholesterol $>$200 mg/dl, 30% (12) had LDL-C $>$150 mg/dl, 17.5% (7) had triacylglycerol (TAG) $>$150 mg% and 42.5% (17) had HDL cholesterol (HDL-C) $<$40 mg/dl. The evidences for primary and subclinical hypothyroidism showed a strong correlation between elevated TSH and total cholesterol, HDL-C, TAG ($r=0.388$, $P<0.05$). However, there is a weak correlation between TSH and LDL-C ($r=0.201$, $P<0.214$).
Conclusion
Total cholesterol, TAG and HDL-C showed statistically significant higher values. This association of two separate states of disorders might be helpful in the treatment and management of hypothyroidism.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Clinical experience in a high-resolution thyroid nodule clinic

N. Sebastián-Ochoa, A. Sebastián-Ochoa, D. Fernández-García, J. Fernández-García, I. Mancha Doblas & F. Tinahones Madueño
Virgen de la Victoria Hospital, Málaga, Spain.

Background and objectives
The finding of a thyroid nodule is a very common occurrence in clinical practice. Management of thyroid nodules requires a multidisciplinary approach that may be eased by a high-resolution thyroid nodule clinic. We report our clinical experience and outcomes in a high-resolution thyroid nodule clinic.
Patients and methods
All patients referred to Virgen de la Victoria Hospital (Málaga) from 2005 to 2007 were evaluated following thyroid nodule guidelines. Statistical analysis was performed using SPSS software.
Results
In the study period, 658 patients (mean age 48.6 years, 89.8% females) were seen at the thyroid nodule clinic. Thyroid nodules were discovered in 85.5% of patients. Mean nodule diameter was 1.96 cm. Of these nodules, 74.2% were solid, 55.8% hypoechogenic, and 4.7% showed microcalcifications. Fine needle aspiration (FNA) was performed in 475 patients (76.5% of all cytological samples were benign, 19.1% had suspected malignancy, 2.1% were malignant, and 2.3% inadequate). Referral for surgery was required in 23.3% of patients (mainly because of nodule size or suspected malignancy). Malignancy was confirmed in 24.9% of nodules. Sensitivity and specificity of cytology (considering biopsy as gold standard) were 81.8% and 94.7% respectively.
Conclusions
Implementation of a high-resolution thyroid nodule clinic decreases delay in diagnosis and optimizes available resources, thus providing for satisfactory clinical outcomes

**Hypothyroxinemia and pregnancy**

M. Amani[1], F. Chentli[2], S. Amani[3], N. Midoun[1], N. Benfeghoul[4], A. Rih[4], L. Zemour[1] & N. Boumansour[1]
Djilali Liabes university, Sidi-bel-abbès, Algeria.

Introduction
The maternal hypothyroxinemia would be an adaptive process of the thyroid gland to iodine deficiency, regardless of the TSH. Our objectives are the prevalence and pathophysiological approach of hypothyroxinemia in pregnant women in the 1st quarter.
Description of methods
Labor-looking statements, made in Oran area, on 270 pregnant women in 1st quarter. Women who smoke (active smoking confessed) and those followed for thyroid disease or taking medications that interfere with the thyroid gland were excluded.
Study protocol: clinical examination, TSH, FT4, FT3, anti-TPO, anti-thyroglobulin, TSI and urinary iodine. Statistics tests: collection of data on EPI INFO 5.1, bivariate analysis (the chi-squared test, the Pearson chi-squared test, the Yates corrected chi-squared test, the Wilcoxon chi-squared test (Log rank sum) or Mann-Whitney, the variance analysis method (ANOVA), the r correlation test, significance level $P<0.05$, multivariate analysis (SPSS: 10 version and MedCalc).
Results
-22/270 pregnant women in 1st quarter (8.1%) had a hypothyroxinemia which 21/22 had benefited from a determination of iodide.
−06/21 cases (28.6%) had an inadequate iodine intake (urinary iodine $<150$ µg/l).
-09/21 cases (42.9%) had correct urinary iodine (between 150 and 250 µg/l).
−06/21 cases (28.6%) had a more than adequate iodine intake (urinary iodine $\geq 250$ µg/l).
Conclusion
Although the pathophysiological mechanisms of hypothyroxinemia during pregnancy are not yet well understood, the knowledge of the disease is nevertheless appropriate given its harmful consequences.

**A case of subacute thyroiditis in a patient on Adalimumab for treatment of refractory palmo-plantar pustular psoriasis**

A. Chiriac[4], C. Miron[1], L. Foia[2], A. Chiriac[2], C. Solovan[3] & C. Ancuta[2]
Nicolina Medical Center, Iasi, Romania.

We describe a case of subacute thyroiditis in a psoriatic patient treated with Adalimumab, with a very good clinical evolution with nonsteroidal anti-inflamatory medication.
Tumor necrosis factor alpha (TNF-α) is a pleiotropic cytokine produced by a variety of cells, comprehending T lymphocytes. TNF-α mediates its effects through two receptors, known as p55 (TNF-R1), and p75 (TNF-R2). TNF-α plays a primary role in both the induction and the maintenance of inflammation in autoimmune reactions: as soon as the inflammation begins, TNF-α acts to activate T-cells and macrophages, up-regulating the expression of endothelial adhesion molecules, and pro-inflammatory cytokines.
Adalimumab is a TNF-alfa human monoclonal antibody blocking agent used in severe psoriasis, with an increased risk of infections. Adalimumab tightly binds to human TNF-α, which is a naturally occurring cytokine involved in the acute phase of inflammatory immune responses.
As the use of biologic drugs becomes more widespread over years,clinicians from a variety of disciplines are increasingly likely to encounter cutaneous side effects of this treatment.Liason between dermatologists and, in this case, endocrinologists, will help to determine the prevalence of these reactions and to provide insights into the very complex mecanisms of both diseases.

## P1750

**Indoleamine 2,3-dioxygenase 1 (IDO1) and thyroid carcinoma: Ret/PTC appears as a strong genetic determinant for IDO1 expression**

E. Menicali[1], S. Moretti[1], P. Voce[1], R. Melillo[2], M. Sponziello[3], S. Filetti[3], N. Avenia[1], M. Santoro[2] & E. Puxeddu[1]
University of Rome 'Sapienza', Rome, Italy.

Indoleamine 2,3-dioxygenase 1 (IDO1) is a single chain oxidoreductase that catalyzes tryptophan degradation to kynurenine. In cancer, it appears to exert an immunosuppressive function as part of an acquired mechanism of immune escape. In view of this notion, IDO1 has started to be considered a novel target in cancer therapy. Objective of this study was to evaluate IDO1 expression in papillary thyroid carcinoma (PTC) and to correlate its expression with genetic determinants of thyroid carcinogenesis. IDO1 expression was evaluated by QPCR in 105 PTCs and by immunohistochemistry in a subgroup of 55. IDO1 expression was also analyzed in 5 human thyroid carcinoma-derived cell lines and in PCCL3 cells characterized either by the doxycycline-inducible or stable expression of BRAFV600E and ret/PTC3. IDO1 expression resulted significantly higher in PTC than in normal thyroid. In basal growing conditions, IDO1 was overexpressed in FTC133 and B-cpap cells, but after stimulation with γ-interferon, all analyzed cell lines (including also TPC-1, 8505c and C643) showed up-regulation of the enzyme. Correlation of IDO1 expression with genetic background in PTC demonstrated a close to statistical significant association between higher IDO1 mRNA expression and BRAFWT status, which was lost at immunohistochemistry. However, while BRAFV600E-expressing PCCL3 cells did not show IDO1 overexpression, ret/PTC3-expressing ones demonstrated an increase of the enzyme. Ret/PTC3-induced activation of STAT1-IRF1 pathway appeared as the signaling cascade involved in IDO1 overexpression in the studied cell line. This study shows for the first time that papillary thyroid carcinoma overexpresses the immunomodulating protein IDO1 and that this event is correlated either to genetic determinants as ret/PTC or to the responsiveness of genetic programs to stimuli coming from the tumor microenvironment. Because the metabolite of IDO1 enzymatic reaction, kynurenine, has been shown to promote tumor cell growth and motility and to inhibit immune cell proliferation and function, these data put forward the possible importance of testing novel targeted therapies against IDO1 for the treatment of papillary thyroid carcinoma.

**Androgen receptor expression in human thyroid cancer tissues: a potential mechanism underlying the gender bias in the incidence of thyroid cancers**

J Stanley[1,2], S Esakky[2], N Ramalingam[2], A Kannan[2], C Maharajan[2], M Aruldhas[2] & S Banu[1]
[1]College of Veterinary Medicine and Biomedical Sciences, Texas A&M University, College Station, Texas, USA; [2]University of Madras, Chennai, India.

Gender bias in the incidence of thyroid cancer is well known, however, the underlying mechanism is largely unknown. The current study determines variations in the molecular characteristics of thyroid cancers between men and women. Normal and cancerous thyroid tissues were collected from a total of 125 men and women who underwent surgical removal of the thyroid gland. Elevated

levels of testosterone in serum and thyroid cancer tissues were observed in women while it decreased in men compared to respective control groups; whereas, ligand binding activity was increased in men and decreased in women. Androgen receptor (AR) mRNA expression increased in a majority of men while it decreased in a majority of women except women with follicular thyroid carcinoma (FTC). In thyroid cancers of women, Pearson's correlation analysis showed a positive correlation of AR mRNA with AR protein, CBP and Sp1, whereas AR mRNA showed a negative correlation with p53. In case of men, AR mRNA showed a positive correlation with AR and cyclin D1 protein in papillary thyroid carcinoma (PTC); and CBP and Sp1 in follicular thyroid adenoma (FTA), whereas AR mRNA showed a positive correlation with p53. Our study identified for the first time that AR is posttranscriptionally regulated by miR-124a. Further, our *in vitro* studies with a PTC cell line (NPA-87-1) showed miR-124a as the potent inhibitor of AR that inhibited NPA cell proliferation even in the presence of testosterone. Thus, the current study suggests that: i) the varying pattern of testosterone level and AR status in thyroid tissues of men and women may predispose to the gender-specific incidence of thyroid tumors ii) miR-124a plays a significant role in determining the AR gene expression pattern and thus, androgen mediated thyroid tumor growth.

### cAMP analogs as potential therapeutic agents for poorly differentiated thyroid cancer

E Grassi[1], A Dicitore[2], M Borghi[2,1], T de Filippis[2], G Vitale[1,2] & L Persani[1,2]

[1]Università degli Studi di Milano, Milan, Italy; [2]Istituto Auxologico Italiano, IRCCS, Milan, Italy.

Thyroid cancer is the most common endocrine malignancy characterized by a good prognosis. However, the subgroup of poorly differentiated thyroid carcinomas (PDTCs) includes neoplasia highly aggressive and scarcely responsive to currently available therapies.

Site-selective cAMP analogs are able to inhibit the growth of poorly differentiated solid tumors and may represent valuable candidates for the therapy of PDTCs.

We evaluated the effects of a PKA I-selective cAMP analogs association and another analog (8-Cl-cAMP) on a panel of 6 cell lines from papillary, follicular, poorly differentiated and anaplastic thyroid cancer. The targets of our pharmacological study were modifications of cell-cycle, apoptosis and principal signaling pathways involved in cell proliferation.

8-Cl-cAMP had a significant anti-proliferative effect on all the cell lines tested, with EC50 values between 1.0 and 16.8 μM; PKA I-selective analogs showed a preferential cytostatic action on PDTCs (8505c, HTC-C3 and SW579 cell lines) with an EC50 between 37.2 and 44.5 μM.

In particular, 8-Cl-cAMP was able:

1) to influence cell cycle progression as evidenced by a reduction in the G0/G1 fraction and an accumulation in S phase;

2) to induce apoptosis, as determined by FACS and Annexin V/propidium iodide-staining.

Otherwise, PKA I-selective analogs caused a slight increase in the G0/G1 cell fraction without apoptosis induction. Furthermore, the analysis of intracellular pathways showed that both treatments were able to reduce Akt activation, one of the principal regulator of cell proliferation. Moreover PKA I-selective analogs significantly reduced ERK1/2 activation in SW579 cell line.

In conclusion, 8-Cl-cAMP may represent a powerful broad-spectrum, pro-apoptotic anticancer drug, while PKA I-selective analogs seem to preferentially inhibit undifferentiated cancer cell growth. These studies prompt further *in vivo* experimentation to test the efficacy and safety of these agents.

### The cross-talk between estrogen receptor and peroxisome proliferator-activated receptor gamma in thyroid cancer cells

R Chu, C van Hasselt & G Chen

The Chinese University of Hong Kong, Hong Kong, Hong Kong.

Both of peroxisome proliferator-activated receptor gamma (PPARγ) and estrogen receptor (ER) contribute to the development of thyroid cancer. Previously, the activation of ERα was found to promote the proliferation of thyroid cancer cells, whereas activation of either ERβ or PPARγ resulted in apoptosis of thyroid cancer cells. Furthermore, a transactivation between ER and PPARγ was reported in estrogen-responsive malignancy, such as breast cancer. However, the relationship between ER and PPARγ in thyroid cancer remains unknown. In this study, we used thyroid papillary carcinoma cells (K1) and anaplastic carcinoma cells (FRO) to examine the interaction between ER and PPARγ. We found that PPARγ protein expression and activity was reduced by over-expression of either ERα or ERβ. PPARγ agonist rosiglitazone (RTZ) could overcome the effects of ERα or ERβ over-expression on PPARγ. The application of RTZ also reduced the expression of ERα and ERβ proteins. Furthermore, knockdown of PPARγ increased ERα and ERβ expression, as well as ER activity. The results of MTT and wound healing assays showed that increment of ERα and ERβ had opposite effects on cell proliferation and migration. While the enhancement of PPARγ by RTZ lessened the proliferative effect of ERα but raised the inhibitory impact of ERβ, especially in K1 cells. Finally, the interaction between ER and PPARγ altered levels of cytoplasmic fractions of apoptosis-inducing factor (AIF), cytochrome *c* (cyto *c*), caspase 3 and mitochondrial Bax, indicating involvement of the non-genomic apoptosis pathway. Collectively, these findings provide evidence of cross-talk between ER and PPARγ and a cooperatively inhibitory function of ERβ and PPARγ in thyroid cell proliferation and migration. These findings support the cross-talk between ER and PPARγ contributes to thyroid carcinogenesis and they may provide some clues for the development of novel therapeutic strategy against thyroid cancer.

### Thyroid autoimmunity and risk of malignancy in thyroid nodules submitted to fine-needle aspiration cytology

G Grani, A Calvanese, G Carbotta, M D'Alessandri, A Nesca, M Bianchini, M Del Sordo & A Fumarola

Sapienza University of Rome, Rome, Italy.

Background

It is a controversial issue whether the risk of cancer for a thyroid nodule is different in patients with Hashimoto's thyroiditis (HT) and in patients without

thyroid autoimmunity. Some studies have reported an increased risk of malignancy in thyroid nodules associated with HT while only limited data based on fine-needle aspiration cytology (FNAC) are available.
Methods
Between May 2005 and April 2011, 3279 ultrasonography-guided FNACs were performed on 2255 patients. In all patients serum $FT_4$, $FT_3$, TSH, CT, anti-thyroglobulin (TgAb) and anti-thyroperoxidase (TPOAb) antibody were determined.
Results
Patients with suspicious nodules had lower age ($44.00 \pm 16.24$ vs $55.56 \pm 13.33$ years; $P < 0.001$) and smaller maximum lesion diameter ($13.23 \pm 7.2$ vs $15.69 \pm 7.93$ mm; $P = 0.004$). Patients with TgAb positivity had suspicious nodules more frequently than patients without TgAb (8.5 vs 5.1%; $P = 0.03$), independently from TSH levels. No significant difference was recorded between benign and suspicious nodules in gender ratio, in the rate of positive TPOAb or in the rate of both autoantibody positivity. Risk factors for thyroid cancer suspicious cytology were: younger age (OR 0.94; $P < 0.001$), smaller maximum diameter (OR 0.95; $P = 0.004$), single lesion (OR 1.99; $P = 0.007$), microcalcifications (OR 3.80; $P < 0.001$), and TgAb positivity (OR 1.73; $P = 0.04$). Mixed content of the lesion resulted as a protective factor (OR 0.30; $P < 0.001$). All these factors being included into a multivariate logistic regression analysis model, only age, mixed content and microcalcification confirmed significance. By computing FNAC report classes separately, no significant difference results between TPOAb positive or negative groups and between TgAb positive or negative groups.
Conclusions
Thyroid nodules in patients with HT are not more frequently cancerous than those in patients without thyroiditis. Positive TgAb is – however - an independent predictor for suspicious cytology in thyroid nodules, independently from TSH levels.

### The TRHR gene is associated to hypothalamo-pituitary sensitivity to levothyroxine in thyroidectomized patients

G Brigante[1], G Spaggiari[1], K Cioni[1], V Gnarini[1], E Pignatti[1], L Casarini[1], M Marino[1], F Tüttelmann[2], C Carani[1] & M Simoni[1]
[1]Modena, Italy; [2]Institute of Human Genetics, University of Münster, Münster, Germany.

Background
Patients thyroidectomized for thyroid cancer need variable doses of levothyroxine ($LT_4$) to obtain TSH suppression. A predetermined thyroid function set-point for each individual has been hypothesized, suggesting a genetic influence in the regulation of pituitary-thyroid axis. We hypothesized of the TRHR gene could be associated with a different hypothalamo-pituitary sensitivity to the negative feedback of the thyroid hormones.
Methods
We performed a case–control association study, enrolling 107 thyroidectomized patients, in follow-up for differentiated thyroid cancer, and 99 volunteer controls. Patients were evaluated first when TSH levels were suppressed ($< 0.1$ mIU/l), by the lowest effective $LT_4$ dose, and then when TSH was subsuppressed ($0.1 < \text{TSH} < 0.5$ mIU/l). We selected two SNPs of TRHR gene, rs3134105 and rs3110040, identified as informative markers, using the online database 'HapMap'. We performed a frequency analysis of the mapped SNPs, followed by a linkage analysis using the HaploView software. Genotyping was performed using the High Resolution Melting technology.
Results
The selected SNPs were in linkage disequilibrium. A significant difference between the three possible genotypes for rs3134105 was found for $fT_4$/TSH ratio ($P = 0.03$). Moreover, despite similar serum concentrations of fT3 and fT4 obtained by similar levothyroxine doses, carriers of at least one A allele of rs3134105 had significantly lower serum TSH levels ($P = 0.04$) as well as higher fT3/TSH ($P = 0.05$) and fT4/TSH ratios ($P = 0.02$).
Conclusions
We demonstrated an association between TSH and discrete alleles of the TRHR gene identified by the markers SNPs rs3134105 and rs3110040 in totally thyroidectomized patients with diagnosis of thyroid cancer under subsuppressive $LT_4$ therapy. The TRHR gene is a determinant of hypothalamo-pituitary sensitivity to levothyroxine in such patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1756

### Role of cAMP analogs in the therapy of medullary thyroid cancer

A Dicitore[1], E Grassi[2], M Borghi[1,2], T de Filippis[1], L Hofland[3], L Persani[1,2] & G Vitale[1,2]
[1]Istituto Auxologico Italiano, Cusano Milanino, Italy; [2]Università degli Studi di Milano, Milano, Italy; [3]Erasmus MC, Rotterdam, The Netherlands.

Medullary thyroid carcinoma (MTC) is a neuroendocrine tumor highly resistant to chemo-and radiotherapy. Since several reports showed that cAMP has an antiproliferative effect on different types of solid tumors both *in vitro* and *in vivo*, we evaluated the potential anti-neoplastic activity of cAMP analogues (8-Cl-cAMP and the equimolar combination of 8-PIP-cAMP and 8-HA-cAMP) in two MTC cell lines (TT and MZ-CRC-1 that harbor C634W and M918T RET mutations, respectively).
Both 8-Cl-cAMP and 8-PIP-cAMP/8-HA-cAMP significantly inhibited MTC cells in a dose-dependent manner, evaluated by MTT proliferation assay, after 6 days of treatment. Interestingly, the antiproliferative effects for both compounds were more prominent in TT (8-Cl-cAMP: IC50 = 4.4 μM, maximal inhibition = −75%; 8-PIP-cAMP/8-HA-cAMP: IC50 = 9.7 μM, maximal inhibition = −70%) than in MZ-CRC-1 cells (8-Cl-cAMP: IC50 = 8.8 μM, maximal inhibition = −47%; 8-PIP-cAMP/8-HA-cAMP: IC50 = 12.8 μM, maximal inhibition = −63%).
After 6 days of incubation, 8-Cl-cAMP (25 μM in TT and 50 μM in MZCRC-1) significantly decreased the population of TT and MZCRC-1 cells in S phase, as suggestive for a delay in G0/G1-S phase transit, while there was no significant effect on the cell cycle during incubation with 8-PIP-cAMP/8-HA-cAMP in both cell lines. In addition, 8-Cl-cAMP induced a potent stimulation of apoptosis in TT and MZCRC-1 cells, as determined by Annexin V/propidium iodide staining and flow-cytometric analysis. While, a moderate increase of apoptotic MTC cells was observed during incubation with 8-PIP-cAMP/8-HA-cAMP.
These studies uncover a novel potential role for cAMP analogs in the treatment of MTC, thus prompting further *in vivo* experimentation on the efficacy and safety of these drugs.

### Optimal prophylactic and definitive therapy for bicalutamide induced gynaecomastia: results of meta-analysis

M Tunio & M Asiri
King Fahad Medical City, Riyadh, Saudi Arabia.

Objective
Bicalutamide is approved as an adjuvant to primary treatments (radical prostatectomy or radiotherapy) or as monotherapy in men with locally advanced, nonmetastatic prostate cancer (PCa); however, this treatment induces gynaecomastia in most of patients, which results in treatment withdrawal. Optimal therapy for these breast events is not known so far. We conducted a meta-analysis to assess the efficacy of different treatment options for bicalutamide induced gynaecomastia.
Patients and methods
The Medline, CANCERLIT, Cochrane library database and Google search engine were searched to identify prospective and retrospective controlled studies published in English from January 2000 to December 2010 comparing prophylactic or curative treatment options with control group (no treatment) for PCa patients who developed bicalutamide induced gynaecomastia. Further, radiotherapy induced cardiotoxicity was evaluated.

Results
Nine controlled trials with a total patient population of 1573 were identified. Pooled results from prophylactic trials showed a significant reduction of gynaecomastia in PCa patients treated with prophylactic tamoxifen 20 mg daily dose (odds ratio 0.06 95% CI 0.05–0.09 ($P$ 0.09)) and pooled results from treatment trials showed significant response in gynaecomastia with definitive radiotherapy (odds ratio 0.06 95% CI 0.01–0.24 ($P<0.0001$)). Aromatase inhibitors and weekly tamoxifen were not found effective as prophylactic and curative options. For the radiotherapy, skin to heart distance (SHD) was found important risk factor cardiotoxicity ($P$ 0.006). The resultant funnel plot of meta-analysis showed significant heterogeneity (Egger test $P<0.00001$) due to low sample size.
Conclusion
Our meta-analysis suggests use of prophylactic tamoxifen 20mg daily as first line preventive measure for bicalutamide induced gynaecomastia and radiotherapy as first line treatment option shall be considered for patients who are not candidates for tamoxifen. The aromatase inhibitors and weekly tamoxifen are not recommended.
Keywords
Meta-analysis, bicalutamide induced gynaecomastia, prostate cancer.

### BRAFV600E mutation is an indipendent predictive prognostic factor for persistent/recurrent disease in low risk differentiated thyroid cancer patients: a 5 year follow up study

D Viola, L Torregrossa, R Giannini, C Ugolini, A Biagini, C Romei, E Molinaro, L Agate, F Basolo, A Pinchera, P Vitti & R Elisei
University of Pisa, Pisa, Italy.

BRAFV600E mutation is the most frequent genetic alteration (29–83%) of papillary thyroid carcinoma (PTC). Many authors have demonstrated that the presence of the mutation is associated with a more advanced tumor stage at diagnosis and a worse outcome but anyone assessed if BRAFV600E mutation could be useful prognostic marker in low risk PTC patients (T1-T2N0M0, 7th TNM classification).
Aim of this study was to evaluate if the presence of BRAFV600E mutation in the primary tumor could be a predictor of persistent/recurrent disease in this subgroup of patients.
We retrospectively analyzed the clinicopathological features of 431 consecutive PTC patients treated with total/near total thyroidectomy and iodine-131 (when appropriate) and we selected 319 low risk PTC patients.
Genomic DNA was purified from paraffin-embedded tumoral tissue. A PCR SSCP analysis of exon 15 of BRAF was performed and direct genomic sequencing of SSCP positive cases was made.
The mutation was present in 106/319 patients (33.2%) and was significantly associated to the absence or invasion of tumoral capsule ($P<0.0001$), aggressive histological variant ($P=0.0001$) and multifocality ($P=0.02$). After 5 years of follow up, 24 (8.5%) patients had persistent disease and 295 (85.3%) were free of disease. BRAFV600E mutation was present in 89 patients (89/295 = 30.2%) free of disease and in 17 (17/24 = 70.8%) patients with persistent disease. At univariate analysis persistent disease was associated only with the presence of BRAFV600E mutation in the primary tumoral tissue ($P<0.0001$).
In conclusion, our results show the correlation of BRAFV600E mutation with aggressive features also in low risk PTC patients and indicate that the presence of BRAFV600E mutation is a bad prognostic factor for persistent/recurrent disease also in low risk PTC patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1759

### Is elevated preoperative TSH level predictive for differentiated thyroid cancer

M Tuna, F Gokay, A Arduc, B Dogan, U Ozuguz, S Isik, D Berker & S Guler
Ankara Numune Training and Research Hospital, Ankara, Turkey.

Introduction
Although numerous noninvasive markers are being used in order to determine preoperative thyroid cancer risk in patients with multi-nodular goiter, none of them are optimal. The objective of this study was to compare retrospectively the TSH level between two groups of subjects who underwent total thyroidectomy for a nodule and whose final histology was benign or malignant.
Methods
Our study included 208 patients that underwent thyroidectomy due to nodular goiter in our hospital between 2008 and 2010. While differentiated thyroid cancer (DTC) was established in 151 patients, pathology of 57 patients was detected to be benign. Patients were evaluated in terms of age, gender, and preoperative TSH levels.
Results
There was no significant difference between the two groups in terms of age, sex, family history of thyroid disease. Preoperative TSH level was established as 1.63 in the group with DTC and as 1.61 in the control group ($P$:0.923). A correlation was not established between the tumor size and TSH ($P$:0.79).
Conclusion
There are studies in literature that established positive correlation between elevated preoperative TSH and DTC. In our study, a correlation was not found between preoperative TSH level and DTC with tumor diameter. The reason for this may be the fact that patients with subclinical hypothyroidism and subclinical hyperthyroidism were included in the study.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1760

### Remarkable enhance in CYP24A1 expression in human thyroid cancer tissue

B Balla, J Kósa, B Tóbiás, C Halászlaki, I Takács, H Horváth, G Speer, J Horányi, Z Nagy, B Járay, E Székely & P Lakatos
Semmelweis University, Budapest, Hungary.

Background
It is well established that 1,25-dihydroxyvitamin D3 (1,25-D3) inhibits cell growth and induces apoptosis in numerous tumors. Increased expression of 1,25-D3 inactivating enzyme, (24-hydroxylase - CYP24A1), has been observed in numerous thyroid cancer cell lines after calcitriol treatment *in vitro*. We examined the expression of CYP24A1 as well as the activating 1-α-hydroxylase (CYP27B1) gene in human thyroid cancer tissue.
Methods
The gene expression analyses of thyroid carcinoma samples were carried out by Taqman probe-based quantitative real-time RT-PCR. Total RNA was isolated from each sample with Roche High Pure Total RNA Isolation kit.
Results
CYP24A1 mRNA expression was markedly increased in all but one papillary cancers compared to that of normal thyroid tissue, reaching sometimes 300-fold elevation. No significant alteration was seen in CYP27B1 gene activity between neoplastic and normal tissues.
Conclusions
If the observed increase in CYP24A1 expression proves to be true on a larger samples size of human thyroid cancers, the use of higher doses of vitamin D3 and/or the development of CYP24A1 inhibitors or 24-hydroxylase-resistant vitamin D analogues could open a new approach to the effective treatment of thyroid cancers.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1761

### Differential proteomics in human normal or papillary thyroid carcinoma cell cultures

J Rodrigues[1], M Garcia-Rendueles[1], A Garcia-Rendueles[1], S Perez[1], F Barreiro[2], J Cameselle -Teijeiro[2], C Alvarez[1] & S Bravo[1]
[1]IDIS-CIMUS, School of Medicine, University of Santiago de Compostela, 15707 Santiago de Compostela, Spain; [2]IDIS-Hospital Clinico Universitario, University of Santiago de Compostela, 15707 Santiago de Compostela, Spain.

Up to now there are few studies about differential proteomics in thyroid. Our group has developed a method for standard human primary thyroid culture maintaining the phenotype through passages. Thus, we believe of great interest the search for biomarkers in these cultures by 2D-PAGE coupled to MALDI-TOF/TOF-MS.

Aims

i) To standardize the conditions for sample extraction and controls. ii) To compare and identify the differential proteomic pattern between normal or benign thyroid (Pendred's Sd. Hyperplasia) pathologies against thyroid papillary carcinomas, combining (2D) gel electrophoresis, image analysis (PDQuest) and mass spectrometry (MALDI-TOF/TOF-MS).

Results

Soluble proteins of the human thyroid culture samples (NT, T-PS, T-PC), were suspended in a lysis buffer containing 7 M Urea, 2 M Thiourea, 4% CHAPS and 40 mM DTT. 50 µg proteins were rehydrated in 7 M Urea, 2 M Thiourea, 5% CHAPS, 1.2% DeStreak, 0.5% of ampholytes 3–10, loaded in 11 cm pH gradient strips (IPG 3–10 l, Amersham) and focused for 6000 V. Second-dimension separation was performed in 15% SDS-PAGE. Spots were visualized by silver staining. Three replicate gels per sample were scanned with a GS800.

Spot detection, pattern evaluation and normalization were performed using the PDQuest software (vs 8.0.1, Bio-Rad).

The individual protein spot quantity was normalized to the total quantity of all valid spots and is expressed as parts per million (PPM).

Individual protein quantities were evaluated by the Student's *t*-test within the PDQuest analysis in order to compare the two groups and identify sets of proteins that showed a statistically significant difference with a confidence level of 0.05.

Twenty two spots were statistically different in tumoral cultures (T-PC) vs normal thyrocytes (NT) and benign pathologies (T-PS). Of them, 12 were specifically increased and eight decreased in T-PC.

MALDI-TOF/TOF-MS identified some of the last spots. One of the most interesting is a low molecular weight variant protein-spot 8002.

We are performing several functional studies in order to validate this protein.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### Lymphocytic chronic thyroiditis and papillary thyroid carcinoma: relation with prognostic factors

R Martins[1,2], J Couto[1], A Santos[1], A Polónia[1], C Lobo[1], L Antunes[1], I Lucena[1] & I Torres[1]
[1]Portuguese Institute of Oncology, Oporto, Portugal; [2]School of Medicine, Oporto University, Oporto, Portugal.

Introduction

Recent studies have shown that chronic lymphocytic thyroiditis is associated with increased risk of developing papillary thyroid carcinoma (PTC). Although still controversial, these carcinomas appear to have a better prognosis. This study aims to evaluate the presence of thyroiditis in thyroids with PTC and the association with histological variables of prognostic value, Tg and evidence of metastasis in $^{131}$I scan.

Methods

Descriptive study of all PTC submitted to thyroid surgery during 24 months ($n=192$). Information on demographics, histology, Tg at the time of ablative therapy with $^{131}$I ($^{131}$IAT) and fixation in the post-therapy scan ($n=116$) was obtained. The association between variables was assessed using chi-square tests, multivariate analysis was done using binary logistic regression.

Results

The mean age at diagnosis was $46.9 \pm 15.7$ years, 82.3% were female patients. Most (77.1%) underwent total thyroidectomy, the average size of the largest tumor focus was $1.4 \pm 1.2$ cm. The prevalence of thyroiditis was 42.1%. Thyroiditis was significantly more frequent in females ($P=0.042$), classic variant of the PTC ($P=0.002$), presence of capsule invasion ($P=0.022$) and in patients with undetectable Tg ($P<0.001$). There were no significant associations between thyroiditis and tumor size, encapsulation, presence of necrosis, multifocality, perineural or vascular invasion, extra-thyroid extension, involvement of surgical margins, lymph node metastasis and evidence of distant metastases in $^{131}$I scan. Multivariate analysis in the total group of patients showed that only female gender and classic variant of PTC were associated with higher prevalence of thyroiditis, while in the group of patients that underwent $^{131}$IAT (in which the variable Tg was included), only absence of detectable Tg and classic variant maintained statistical significance.

Conclusions

Thyroiditis was associated with female gender, classic variant of PTC and absence of detectable Tg, which seems to be in favor of a better PTC prognosis when associated with thyroiditis.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1763

### Ultrasound-guided fine-needle aspiration biopsy (US-FNAB) of thyroid nodules: effects of the operator's experience on adequacy of sampling: the MoCyThy (Modena's Cytology of the Thyroid) DATABASE

S Vezzani[1], A Ansaloni[1], L Zirilli[1], K Cioni[1], C Diazzi[1], M Simoni[1,2], B Madeo[1] & V Rochira[1]
[1]Azienda Unità Sanitaria Locale of Modena, Modena, Italy; [2]University of Modena and Reggio Emilia, Italy, Modena, Italy.

Introduction

Thyroid FNAB is the gold standard to discriminate malignant from benign thyroid nodules. However, inadequate cytology ranges from 1 to 20% (up to 33.6%) in different settings and could depend on several factors, including the operator's skills.

Aim

To evaluate the effect of operator's experience on US-FNAB diagnostic adequacy we reviewed 7029 US-FNABs performed from January 2006 to March 2009.

Materials and Methods

US-FNABs were performed by 15 different operators; of them four had more than 5 years of experience, and 11 < 2 years of experience. All clinical data of the patients were collected and analyzed using the MoCyThy DATABASE, which is the part of the institutional database ENDOBASE (based on the MyQ16L open source technology) devoted to store data of all institutional US-FNABs.

Results

Five hundred twenty one (7.41%) of 7029 US-FNABs resulted inadequate. The inadequate sample rate was higher in the group of less experienced (<2 years) than in the group of more experienced (>5 years) physicians (9.05 and 6.98% respectively; $P=0.009$ at $\chi^2$ test). Furthermore, US-FNABS in the hands of less experienced operators resulted in a higher number of slides in comparison with the more experienced operators ($11 \pm 0.081$ vs $8 \pm 0.048$; $P<0.001$ at Kruskal–Wallis test). The number of slides, however, was not significantly related to sample inadequacy ($P=0.059$ at Kruskal–Wallis).

Conclusions

The experience of the operators is determinant for a better outcome in terms of lower inadequate sample rates and a lower number of slides needed to obtain a diagnostic outcome. In clinical practice, these results point out the impact of the operator's experience on US-FNAB procedure, suggesting that US-FNABS is cost-effective and less time-consuming in skilled hands.

Declaration of interest

**Value of repeated US-guided fine-needle aspirations (US-FNAB) in the follow-up of thyroid nodules: the MoCyThy (Modena's Cytology of the Thyroid) DATABASE**

A. Ansaloni, S. Belli, S. Vezzani, A. Granata, L. Zirilli, K. Cioni, C. Carani, B. Madeo & V. Rochira
University of Modena & Reggio Emilia, Azienda Unità Sanitaria Locale of Modena, Modena, Italy.

Introduction
There is no consensus about the usefulness of repeating the US-FNAB during the follow-up of nodules when a benign (Thy2) or indeterminate (Thy3) report is obtained at first US-FNAB.
Aim of the study
To investigate the clinical value of repeating US-FNAB after a previous adequate Thy2 or Thy3 US-FNAB.
Methods
We reviewed the US-FNABs performed from 2006 to 2009. All clinical data of the patients were collected and analyzed using the MoCyThy DATABASE, which is the part of the institutional database ENDOBASE (based on the MyQ1L open source technology) devoted to store data of all institutional US-FNABs. Among 7983 records, we searched out 288 patients (327 nodules) undergoing at least two consecutive adequate US-FNABs for a total of 686 US-FNABs. We compared the first US-FNAB (Thy2 or Thy3) at baseline with the results of the following US-FNABs (2nd or 3rd US-FNAB).
Results
Of the 327 baseline US-FNABs, 58% were Thy2 and 42% Thy3. Of the 189 Thy2 at baseline, 157 (83%) were confirmed as Thy2 at follow-up, while 32 (17%) did not confirm the first diagnosis: 29 (15%) of them were Thy3 and 3 (2%) Thy4. No modifications of volume or US-features were recorded in these Thy4 from baseline. Of the Thy3 at baseline, 55 (40%) were confirmed as Thy3 at the follow-up, 84 (60%) did not confirm the first diagnosis: of them 6 (4%) were Thy4/5 and 78 (56%) Thy2.
Conclusions
The outcome of a subsequent US-FNAB is often discordant compared with the first cytological diagnosis. A first cytological diagnosis of Thy2 does not completely exclude a malignant (Thy4) or an indeterminate (Thy3) lesion. A second US-FNAB after 6–12 months may be useful, in clinical practice, to definitively confirm benign lesions or to reduce the rate of malignant tumor or of follicular lesions unrecognized by the first US-FNAB.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**The Association between thyroid carcinoma and Hashimoto's thyroiditis: is really Hashimoto's thyroiditis increase the risk of thyroid cancer?**

S. Cakir, O. Celik & O. Acbay
Cerrahpasa Medical School, University of Istanbul, Istanbul, Turkey.

Aim
The aim of the study was to determine the association between Hashimoto's thyroiditis (HT) and differentiated thyroid carcinoma (DTC).
Patients and methods
Seven hundred seventy two patients with thyroid nodular goiter who underwent fine-needle aspiration cytology (FNAC), followed up at Endocrinology and Metabolism out-patient clinic of Cerrahpasa Medical School, University of Istanbul between January 2000 and December 2010 were included retrospectively in this study. All patients were evaluated for the presence of HT diagnosis by measuring thyroid autoantibodies. If a patient had at least one positive thyroid autoantibody, then the patient was defined as HT with thyroid nodules. Demographic features, ultrasonography (US) findings and cytology results of the patients were evaluated.
Results
Three hundred ninety three patients (39 male and 354 female, mean age 46.11 $\pm$12.53) with thyroid nodules associated with HT (HT group), 379 patients (53 male and 326 female, mean age 47.5 $\pm$12.6) with thyroid nodules without HT (control group) were determined. The prevalance of DTC in the patients with HT was 6.6%. In contrast, it was 12.9% in the control group ($P=0.03$). US findings were similar in both groups. When the whole population is considered in terms of autoimmunity, positive anti-TPO rate was found significantly higher in benign nodules ($P=0.008$).
Conclusion
The malignancy rate in the patients without HT was twice more than the patients with HT. Many of the US features of benign thyroid nodules are similar in patients with and patients without HT.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1766

**Clinicopathological characteristics of patients with thyroid papillary microcarcinoma; preliminary results**

S. Akin[1], S. Akin[2], D. Yazgan Aksoy[3] & M. Bayraktar[1]
[1]Faculty of Medicine, Hacettepe University, Ankara, Turkey; [2]Ulus Public Hospital, Ankara, Turkey; [3]Etlik Ihtisas Research and Training Hospital, Ankara, Turkey.

Background and aim
The clinical significance of papillary thyroid microcarcinoma (PTMC) is debatable. The purpose of this study is to analyse the clinicopathological characteristics of patients with PTMC and document the risk factors for poor prognosis.
Materials and methods
Eighty-eight patients (18 males, 70 females) were included in the study. Clinical and laboratory parameters were recorded.
Results
The mean age of the patients were 47.6 $\pm$ 11.4. The most common presenting symptom was swelling in the neck but half of them (45 patients) were incidentally diagnosed. 4 patients had a family history of thyroid cancer. 78 (88.6%) patients were operated for suspicion of malignancy after fine needle aspiration biopsy. One had Graves' disease, one had hyperparathyroidism and rest of them were operated for large nodule size $\geq$ 3 cm. 48 patients had tumor size $<$5 mm, 40 had 6–10 mm tumors. Lymph node invasion was present in seven patients and three patients had capsule invasion. Only tumor size was an independent risk factor for lymph node metastasis at diagnosis.
Conclusion
Increased tumor size increases the risk for poor prognosis. Tumor size should be considered in the follow-up for these patients.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1767

**Differentiated carcinoma in dysembriogenetic thyroid lesions**

G. Sturniolo, M. Violi, S. Presti, M. Moleti, B. Di Bella, F. Di Mauro, F. Trimarchi & F. Vermiglio
University of Messina, Messina, Italy.

The prevalence of differentiated thyroid carcinoma (DTC) in lingual thyroid (LT) and thyroglossal duct cysts (TDC) is around 1%. Nowadays, almost 200 cases of DTC were reported in TDC and $<$60 cases in LT. Here we report four cases of neoplasia in LT (1/4) and TDC (3/4) in a consecutive series of 950 DTC patients (0.4%).
Case 1
D.F. 63 year-old woman with thyroid follicular carcinoma in ectopic gland located at her tongue's basis. March 2009: the lesion, infiltrating surrounding tissues, presented insular-like areas (T3N1Mx). July 2009 and 2010: two radiometabolic treatment (cumulative dose of 224 mCi of $^{131}$I) with no evidence of local/distant metastases and undetectable serum thyroglobulin (Tg), following the last radioiodine administration.

Case 2
B.B. 37 year-old woman with TDC. October 2001: exeresis of a thyroid papillary carcinoma (PC) in TDC infiltrating soft local tissues (T3NxMx). December 2001: Total thyroidectomy (tTx) with histologic finding of benign adenomatous goiter. 2002–2008: five radiometabolic treatment (cumulative dose of 500 mCi of $^{13}$1I) due to iodine uptaking lung metastases. September 2009: persistence of elevated Tg levels (56.1 ng/ml) following recombinant human TSH stimulation. Proposal of further radiometabolic treatments refused.
Case 3
B.S. 42 year-old man. November 2001: PC of thyroglossal duct infiltrating the surrounding fibro-adipose tissue with lymphatic and intravascular diffusion. March 2002: tTx with evidence of two foci of PC (T3bN0Mx). July 2002: 100 mCi of $^{13}$1I, Tg undetectable and WBS negative.
Case 4
D.B. 21 year-old woman with a PC follicular variant in TDC. July 2010: tTx with histologic evidence of benign macrofollicular goiter.
Conclusions
The higher prevalence of DTC (also in form of aggressive variants) in dysembrogenetic than in eutopic thyroid tissue (0.4 vs 0.004%) argues in favor of a close monitoring of all the dysembriogenetic thyroid lesions.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1768

**Nursing assistance increases the efficiency of ultrasound-guided fine-needle aspiration biopsy (US-FNAB) in the management of thyroid nodules: the MoCyThy (Modena's Cytology of the Thyroid) DATABASE**

S. Belli, C. Carani, A. Ansaloni, K. Cioni, L. Zirilli, M. Velasco, M. Simoni, B. Madeo & V. Rochira
University of Modena & Reggio Emilia, Azienda AUSL of Modena-NOCSAE of Baggiovara, Modena, Italy.

Introduction
US-FNAB is the most cost/effective and accurate diagnostic procedure for the evaluation of thyroid nodules. In the clinic, the nursing assistance is not always available for the US-FNAB procedure in all endocrinological centers and its value remains to be established.
Aim of the Study
To demonstrate the role of nursing assistance in US-FNAB procedures in improving the efficiency of this procedure.
Methods
All clinical data of the patients were collected and analyzed using the MoCyThy DATABASE, which is the part of the institutional database ENDOBASE (based on the MyQ5L open source technology) devoted to store data of all institutional US-FNABs. Of the 7377 US-FNAB performed at the Unit of Endocrinology of Modena from 2006 to 2009, we compared 4831 US-FNAB performed with nursing assistance with 2546 US-FNAB performed by the same medical team, but without nursing assistance.
Results
The number of US-FNAB performed for every work session ($7.57 \pm 3.94$ vs $6.59 \pm 3.03$), the number of slides assessed for every work session ($77.55 \pm 42.93$ vs $41.61 \pm 31.81$), the number of slides prepared for each FNA ($10.23 \pm 3.2$ vs $6.31 \pm 2.89$) were all significantly higher in the sessions with nursing assistance than in those without nursing assistance ($P < 0.001$ at Mann–Whitney Rank Sum Test).
Conclusions
The support of nursing assistance has a relevant impact on the efficiency of the US-FNAB procedure in terms of the number of US-FNAB performed in each session and of number of slides prepared for each session and for each US-FNAB. In clinical practice, nursing assistance may improve the outcome of US-FNAB procedures and is cost-effective.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1769

**Multiplicity as a prognostic factor of papillary thyroid carcinoma**

J. Kim, J. Won, K. Ko & B. Rhee
Sanggye Paik Hospital, Inje University College of Medicine, Seoul, Republic of Korea.

Backgrounds
Mutiplicity of papillary thyroid carcinoma (PTC) are not an unusual finding, although the origin of these foci is unclear. Either intraglandular metastases from a single dominant tumor or unrelated neoplastic clones were definitively proven as the means by which multicentric PTC form. In addition, there is insufficient clinical information concerning multicentric PTC presentation, prognosis, and long-term follow-up studies after treatment. Multiplicity of PTC has not been considered as an independent prognostic factor from a variety of tumor staging systems.
Aims
To evaluate whether that the presence of mulciplicity would be associated with tumor recurrence in PTC patients.
Methods
A total 249 PTC patients at a single institution who underwent total thyroidectomy and node dissection were retrospectively reviewed; the mean follow-up period was 2.8 years. Postoperative radioactive iodide ablation for thyroid remnant was performed after surgery for most patients.
Results
Of all the PTC cases reviewed, 85 cases (34%) were categorized as multicentric PTC. Compared with patients with unifocal PTC, multicentric PTC patients demonstrated higher cervical lymph node metastasis and tumor recurrence. Multiplicity was also significantly associated with tumor recurrence; 6 vs 1% with and without multiplicity, respectively ($P = 0.022$ by log-rank test). However, this association was lost on multivariate analysis adjusting for conventional clinicopathological predictors of recurrence.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1770

**Frequency and predictive factors of malignancy in residual thyroid tissue after partial thyroidectomy for differentiated thyroid cancer**

F. Gokay, D. Berker, U. Ozuguz, S. Isik, M. Muslim Tuna, Y. Yalcin, A. Arduc & S. Guler
Ankara Numune Training And Research Hospital, Ankara, Turkey.

Background
The main objective of this study is to establish the rate of malignancy in residual thyroid tissue in patients with DTC, and whether the serum thyroglobulin (Tg) level before complementary thyroidectomy and histopathologic characteristics of the tumor would be able to foresee malignancy in residual tissue.
Methods
Our study included 58 patients with DTC that underwent complementary thyroidectomy that results were analyzed retrospectively. Patients were then divided into two groups as patients that were established to have tumor in residual tissue (group 1) and not to have tumor in residual tissue (group 2) based on the pathology findings of residual tissue following complementary thyroidectomy. Both groups were compared in terms of serum Tg levels before complementary thyroidectomy and histopathologic characteristics of tumor.
Results
Fifty three patients were found to have papillary thyroid cancer and five had follicular thyroid cancer. Median tumor diameter was 0.8 cm (0.1–5.5 cm), 16 patients (27.6%) was found to have multifocality, 4 patients (6.9%) had perithyroidal invasion, 16 patients (27.6%) had capsular invasion, and 7 patients (12.1%) was established to have vascular invasion. Following the complementary thyroidectomy, 13 patients (22.4%) out of 58 patients with DTC were found to have malignancy in residual tissue. A statistically significant difference was not observed between the two groups in terms of gender, age, serum Tg level before complementary thyroidectomy, type of tumor pathology, tumor size, bilaterality multifocality, arterial invasion, capsular invasion, and extrathyroidal invasion presence ($P > 0.05$).
Conclusions
Factors that enable foreseeing malignancy in residual thyroid tissue are not completely known. In our study, we established that serum Tg level before complementary thyroidectomy and histopathologic characteristics of tumor does

not have a predictive value in foreseeing malignancy in residual thyroid tissue; however, other studies containing more patients are of necessity to clarify the issue.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1771

### Ultrasound (US) features of thyroid nodules with cytology suspicious for malignancy

E. Taliani, A. Ansaloni, C. Diazzi, A. Granata, C. Carani, V. Rochira & B. Madeo
University of Modena & Reggio Emilia, Azienda Unità Sanitaria Locale, Modena, Italy.

Introduction
Several studies in literature have shown that some features of thyroid nodules at US are associated with malignancy. However, previous studies were focused mainly on subjects affected by multinodular goiter (about 70%) rather than subjects with thyroid cancer (about 30%). Furthermore, the main limitation of previous studies was the lack of thyroidectomy in all subjects.
Aim of the study
To evaluate the diagnostic value of US features in a selected sample of patients with thyroid nodules cytologically suspected for malignancy (THY4–THY5) by comparing US features of each nodule with the results of histological analysis after thyroidectomy.
Methods
In this prospective study, we enrolled 54 patients with cytological result suspicious of malignancy. All subjects underwent thyroid ultrasound before thyroidectomy. We evaluated the following US features: size, content, shape, margins, echogenicity, calcification, halo sign, vascular pattern, for all the nodules (those citologically suspected and those not suspected). All enrolled patients underwent total thyroidectomy, therefore all benign and malignant nodules previously assessed at US received histological verification.
Results
In all the 54 patients a diagnosis of differentiated thyroid cancer was confirmed. Each of the following features: microcalcifications, macrocalcifications, irregular margins and hypoechogenicity at US correlate with malignancy at histology by using chi-square ($P<0.001$).These features have high specificity but low sensitivity (microcalcifications 93.9–40.4%, macrocalcifications 98–22.8%, hypoechogenicity 96–21% respectively). Irregular margins is the feature with the best pair of sensitivity (65%) and specificity (65%).
Conclusions
These results confirm and reinforce previous studies that showed a correlation among microcalcification, irregular margins, hypoechogenicity and malignancy in a highly selected sample of patients undergoing thyroidectomy. Furthermore, in contrast with literature, we found a strong correlation also between macrocalcification and malignancy. US is a valid tool to select which nodules require FNA evaluation according to sonographic features closely related to malignancy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1772

### Incidence of ultrasound thyroid scan anomalies in healthy volunteers in modena, italy

V. Gnarini[1], G. Brigante[1], E. Della Valle[1], E. Taliani[1], C. Carani[1] & M. Simoni[1,2]
[1]University of Modena & Reggio Emilia, Azienda AUSL-NOCSAE of Baggiovara, Modena, Italy; [2]University of Modena & Reggio Emilia, Modena, Italy.

Introduction
We assessed the incidence of ultrasound (US) thyroid scan anomalies in adult volunteers in the district of Modena
Methods
From December 2010 to October 2011 we performed US thyroid scan (Siemens Acuson Antares, 10 Mega Hertz-Linear scanner- B mode) in a cohort of 201 volunteers, recruited by local advertisement, women ($n=135$) and men ($n=66$), mean age $46\pm10.7$. All participants were unaware of any thyroid disease and at their first thyroid US scan. Fine needle aspiration cytology (FNA) was performed in 13 subjects.
Results
US thyroid scan anomalies were found in 101 subjects (50.3%): 93 nodular goiters (95%) and 13 subjects with ultrasound features of thyroiditis (12.8%), 11 of them confirmed by positive anti Tg and/or anti TPO antibodies. Positive family history was present in 30% of subjects affected by thyroid US anomalies. In all subjects with nodules serum calcitonin was normal. 13 subjects (6.5%) with nodular goiter underwent FNA with the following citology: 10 patients THY 2 (77%), 1 patient THY 3 (7.7%), 2 patients had THY 4 (15%) followed by histological confirmation of thyroid papillary carcinoma after total thyroidectomy (both women aged 48)
Conclusions
The incidence of thyroid anomalies, mainly nodular goiter, is very high in subjects unaware of any thyroid disease in the district of Modena, Italy. Thyroid cancer was found in 1% of all subjects, 2% of those affected by nodular goiter. Among subjects who underwent FNA the prevalence of cancer was 15%. Compared to other well-established screening programs like breast and colorectal cancer providing a yearly detection rate of about 0.45% and 0.27% respectively, the incidence of thyroid cancer seems to be much higher: thyroid US mass screening could allow the detection of asymptomatic cancer at a very early stage with a high cost-benefit ratio.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1773

### Surgical treatment of locally advanced thyroid carcinoma with larynx infiltration: case report

I. Djurisic[1], A. Mikic[2], M. Buta[1], M. Oruci[1] & R. Dzodic[1]
[1]Institute for oncology and radiology of Serbia, Belgrade, Serbia; [2]Institute of ORL KCS, Belgrade, Serbia.

Introduction
Infiltration of larynx by thyroid cancer represents fourth stage of the disease and is threatening disease. Lethal outcome of advanced thyroid cancer, which invades trachea and larynx, is usually associated with airway obstruction.
Patient and method
We are presenting 58 year old woman operated due to the advanced papillary carcinoma Patient underwent total thyroidectomy, central neck dissection, modified radical dissection of the right side, selective dissection on the left side, auto-transplantation of left parathyroid gland, partial vertical laryngectomy and reconstruction of defects with epiglottis and surgical tracheotomy. After surgical treatment she received a dose of 5.5 GBq J 131st. Postoperative stenosis of the larynx was treated twice with laser surgery.
Results
Traheostomy has been closed and the phonatory and respiratory functions were preserved after treatment. One year of follow up has passed with no signs of relapse.
Conclusion
Decision of resectability of the tumor with reconstruction of the defect in the larynx is the most commonly intraoperative decision. Radical surgery is a logical and rational therapeutic approach for thyroid cancer in the fourth stage.
The goal of radical surgery in locally advanced thyroid cancer is to prevent lethal outcome but can also be curative form of therapy with good quality of life.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1774

**Role of intensity modulated radiation therapy in patients with non-anaplastic thyroid carcinoma: king fahad medical city experience**

M. Tunio & M. Asiri
King Fahad medical City Riyadh, Riyadh, Saudi Arabia.

Background
To evaluate outcomes and toxicities in patients with non-anaplastic thyroid cancer treated with intensity modulated radiation therapy (IMRT).
Materials and methods
This was a single institution retrospective review of 18 patients with non-anaplastic thyroid cancer treated with IMRT at King Fahad Medical City between April 2005 and December 2010. The median age was 69 years. Among the 18 patients, fifteen had papillary carcinoma, two had T3 and 12 had T4 disease, twelve had N1 disease, and one had distant metastases. Radioactive iodine was given to all patients, while the median radiotherapy (RT) dose was 60 Gy (range; 60–66Gy).
Results
Median follow-up was 30 months (range: 6-to-64 months). The Kaplan-Meier estimates of 3-year local control, locoregional control, and overall survival rates 90, 90, and 80% respectively. Nine patients (50%) had grade 2 skin toxicity, nine had grade two mucositis (pharyngitis, esophagitis), 1(11.1%) had grade G4 mucositis, 2 (22.2%) had grade 2 laryngitis, and 1(11.1%) had grade 3 laryngitis. Few grade 1 late toxicities were observed. Multivariate analysis showed poor prognostic factors for local and overall survival were; age above 45, postoperative gross residual disease, distant metastasis (DM) and no radioactive iodine (RAI) treatment. In patients with no DM and no postoperative LR disease, adjuvant RAI ablation reduced both LR failure (relative risk (RR) 0.29) and DM (RR 0.2).
Conclusion
IMRT is effective in the postoperative setting for high risk patients of thyroid cancer to reduce locoregional recurrences with acceptable morbidity. Long-term follow-up is still needed to assess the incidence of late toxicities.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1775

**Urine neopterin levels in differentiated thyroid cancer**

S. Soytac Inancli[1], S. Caner[2], F. Balkan[2], A. Tam[2], G. Guler[2], R. Ersoy[2] & B. Cakir[2]
[1]Near East University, Faculty of Medicine, Lefkosa, Cyprus; [2]Ankara Ataturk Education and Research Hospital, Ankara, Turkey.

Aim
Neopterin is a mareker of inflammation secreted from monocytes and macrophages. It is found to be increased in malignant diseases. The aim this study was to evaluate the urine neopterin levels in thyroid cancer.
Materials and methods
Sixty nine patients with thyroid cancer, 76 patients with benign thyroid pathology and 33 healthy subjects were evaluated. First morning urine samples were collected from the patients and the normal subjects for neopterin and creatinin measurment and stored at −20 °C until analyzed.
Results
Neopterin levels were 149.3 (15.2–1602.2) μmol/mol creatinin in the malignant group, 32.0 (5.2–275.6) μmol/mol creatinin in the benign group and 9.2 (2.7–78.7) μmol/mol creatinin in normal subjects. Urinary neopterin levels were significantly higher in patients with throid cancer than patients with benign thyroid pathologies and normal subjects. There was 22 (%31.9) patients with chronic thyroiditis and 47 (%68.1) patients without chronic thyoiditis in the malignant. Urinary levels of neopterin didn't differ in both groups (168.6 (21.3–716.8) μmol/mol creatinin and 135.3 (15.2–1602.2) μmol/mol creatinin respectively, $P=0.381$). Patients who had capsul invasion, vascular invasion and lymph node invasion had a higher urine neopterin level although not statistically significant.
Conclusion
Urinary neopterin levels are high in thyroid cancer and this result is not affected from the presence of chronic thyroiditis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Hyperthyroidism and thyroid cancer-a prospective study**

D. Askitis, E. Eufraimidou, M. Karanikas, A. Mitrakas, A. Polychronidis, G. Tripsianis & N. Lyrantzopoulos
University General Hospital of Alexandroupolis-Democritus University of Thrace-School of Medicine, Alexandroupolis, Greece.

Introduction
The effect of hyperthyroidism on the development of differentiated thyroid cancer (DTC) has been controversial in the international bibliography. The aim of our study was to find the possibility of thyroid cancer appearance in patients with hyperthyroidism who underwent total thyroidectomy in comparison with patients without thyroid hyperfunction.
Material-Methodology
Between 2005–2010 228 patients (182 females/46 males) underwent total thyroidectomy for a variety of functional and non-functional thyroid disorders and the specimens were analysed in the Pathology Department of our Hospital.
Results
34 patients with single non-functional thyroid nodule (14.9%),152 with non-toxic multinodular goiter (66.7%),26 with toxic multinodular goiter (11.4%), 6 with toxic adenoma (2.6%) και 10 with Graves disease (4.4%) were operated.In the two first groups we found respectively 11 people (32.4% of the patients with single nodule) and 21 (13.8% of the people with non-toxic multinodular goiter) with differentiated thyroid cancer. Conclusively 17.2% of the people with non-functional thyroid disorders were diagnosed with DTC. On the contrary from the 42 patients of the other three groups with hyperthyroidism only one young male with papillary carcinoma and Graves disease was detected (10% of the patients with Graves or 2.4% of the total hyperthyroid patients) ($P=0.014$, odds ratio 8.5).
Conclusion
The presence of hyperthyroidism in the material of our clinic possibly reduces significantly the potential of differentiated thyroid cancer appearance in comparison with the cases of single non-functional nodule and non-toxic multinodular goiter.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1777

**Coexistence of chronic lymphocytic thyroiditis and well differentiated thyroid cancer-a prospective study**

D. Askitis, E. Eufraimidou, M. Karanikas, A. Mitrakas, A. Polychronidis, G. Tripsianis & N. Lyrantzopoulos
University General Hospital of Alexandroupolis-Democritus University of Thrace-School of Medicine, Alexandroupolis, Greece.

Introduction
The coexistence of Hashimoto thyroiditis with welll differentiated thyroid carcinoma (DTC) has been discussed as far as the follow-up and prognosis of patients with chronic autoimmune thyroiditis (CAT) are concerned. The aim of our study was to find the coincident appearance of the two disorders in histologic specimens from patients who underwent total thyreoidectomy.
Material-Methodology
Between 2005–2010 228 patients (182 women/46 men) were operated with total thyroidectomy in our clinic. The surgical specimens were studied in the Pathology Department of our hospital.
Results
In 228 surgical specimens thyroid cancer was found in 33 (14.5%), from them 31 were DTC (13.6%),while elements of chronic lymphocytic thyroiditis were found in 56 (24.6%).Coexistence of Hashimoto and DTC was detected in 6 patients (19.3% of the DTC diagnosed patients, females/males 5/1). In the population of patients with autoimmune thyroiditis the cancer prevalence was 10.7%. There was no statistically significant difference as far as the age is concerned ($P=0.677$).

Conclusion
Further analytical clinical studies are required in order to establish a possible association between Hashimoto thyroiditis and DTC.Our results show that a careful examination and follow-up of the patients and mainly the women with the frequent diagnosis of the autoimmune thyroiditis is essential.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1778

**Thyroid papillary carcinoma, 30 years of experience**
B. Costa Leite, S. Neves, A. Moreira da Costa & A. Canha
Hospital Santo António -CHP, Porto, Portugal.

Papillary carcinoma is the most common histological type of thyroid cancer. The optimal treatment remains controversial, particularly with regard to the papillary microcarcinoma ($\leq$ 10 mm).
The aim of this study is the characterization of patients with this condition undergoing surgery in our hospital over a period of 30 years, evaluating treatment outcomes.
Between January 1, 1980 and December 31, 2010, a total of 564 patients underwent surgical treatment for thyroid disease, with histological confirmation of papillary carcinoma.
Of these, 461 patients were female (81.7%) and 103 males (18.3%), aged between 12 and 86 years.
The presence of papillary thyroid microcarcinoma was found in 209 patients (37%).
The morbidity and survival in our series were similar on the published literature.

**Thyroid cancer in multinodular toxic goiter: A report of two cases in the philippines**
Q. Ngalob & I. Tan
University of the Philippines-Philippine General Hospital, Manila, Philippines.

Synopsis
Thyroid cancer with concomitant thyrotoxicosis is variably reported to be rare. Malignancy occurs as postoperative incidental finding of a small malignant focus in Graves' disease, as part of a toxic multinodular or a toxic adenoma. We report two cases of large toxic multinodular goiters with metastasis diagnosed preoperatively as follicular neoplasm and confirmed postoperatively as differentiated thyroid cancer. Review of literature, pathophysiology and treatment strategies will be discussed.
Case 1
A 49 year old female presented with twelve year history of enlarging goiter and mass in the sternal notch which developed over one year. Examination revealed a large multinodular goiter measuring 12$\times$12 cm with 7$\times$7 cm mass in the sternal notch. Investigations revealed follicular neoplasm on fine needle aspiration biopsy and T3 toxicosis. A 1.6$\times$1.8 cm functioning nodule in the superolateral right lobe was demonstrated on thyroid scintigraphy. She underwent total thyroidectomy and excision of the manubrial mass. Histopathology showed follicular variant of papillary cancer with metastasis to the manubrium.
Case 2
A 71 year old female presented with recurrent thyroid nodules of 21 year duration. She had three thyroid surgeries in the past which revealed follicular cancer. She was lost to follow-up after each surgery and received no subsequent treatment. She again consulted for recurrence of the thyroid masses but no symptoms of hypo/hyperthyroidism, obstruction or voice changes. Examination revealed a large multinodular goiter measuring 10$\times$6 cm which yielded follicular neoplasm on fine needle aspiration biopsy. TSH was suppressed at 0.008 mIU/l (NV: 0.3–3.8). Free T4 was elevated at 36.2 pmol/l (NV: 11–24). Thyroid scintigraphy showed functioning thyroid tissues with a conglomerate size of 8$\times$5.6 cm. Chest imaging revealed lung metastasis. She is presently being treated with Methimazole 40 mg daily in preparation for thyroidectomy.

**CLM94, a novel cyclic amide with anti-VEGFR-2 and antiangiogenic properties, is active against primary anaplastic thyroid cancer *in vitro* and *in vivo***
A. Antonelli, G. Bocci, C. La Motta, S. Ferrari, P. Fallahi, I. Ruffilli, A. Di Domenicantonio, F. Da Settimo & P. Miccoli
University of Pisa, Pisa, Italy.

Introduction
The antitumor activity of a novel cyclic amide, CLM94, with anti-VEGFR-2 and antiangiogenic activity, in primary anaplastic thyroid cancer (ATC) cells *in vitro* and *in vivo*, has been studied.
Design and Methods
CLM94 was tested: i) in two human cell lines (HMVEC-d, dermal microvascular endothelial cells; 8305C, undifferentiated thyroid cancer) at 0.001–100 mcM; ii) in ATC cells at the concentrations of 10, 30, 50 mcM; iii) in a ATC-cell line (AF) in CD nu/nu mice.
Results
CLM94 significantly inhibited VEGFR-2 and EGFR phosphorylation in HMVEC-d, and proliferation in HMVEC-d and 8305C cell. A significant reduction of proliferation with CLM94 in ATC cells ($P<0.01$, ANOVA) and a slight but significant reduction of proliferation with CLM94 30 and 50 mcM in normal thyroid follicular cells ($P<0.01$, ANOVA) were shown. CLM94 increased the percentage of apoptotic ATC cells dose-dependently ($P<0.001$, ANOVA) and inhibited migration ($P<0.01$) and invasion ($P<0.001$). AF-cell line was injected sc in CD nu/nu mice and tumor masses became detectable 25 days after. CLM94 (40 mg/kg/die) inhibited significantly tumor growth (starting 10 days after the beginning of treatment). CLM94 significantly decreased the VEGF-A gene expression in the AF cell line and the VEGF-A protein and microvessel density in AF tumour tissues.
Conclusions
The antitumor and antiangiogenic activity of a new 'cyclic amide' compound CLM94 is very promising in anaplastic thyroid cancer, opening the way to a future clinical evaluation.

**PI3K/HIF and ATM signalling in radio-resistance of thyroid-carcinoma: new therapeutic implications?**
N. Burrows[1], J. Williams[1], B. Telfer[1], K. Williams[1] & G. Brabant[2,3]
[1]University of Manchester, Manchester, UK; [2]University of Luebeck, Luebeck, Germany; [3]The Christie, University of Manchester, Manchester, UK.

Background
Anaplastic thyroid-carcinomas (ATC) and a subset of papillary (PTC) and follicular (FTC) thyroid carcinomas behave aggressively showing metastatic spread and radio-resistance. Both the PI3K and HIF pathways are associated with aggressiveness and metastasis in thyroid carcinoma.

Aims
To assess if the PI3K/HIF pathways contribute to radio-resistance and assess the effect of PI3K/HIF inhibition on radio-sensitivity of thyroid-carcinoma cells (8505c, FTC133, WRO, BcPAP) *in vitro* and *in vivo*.
Methods
PI3K was inhibited pharmacologically (via PI-103/GDC-0941) and genetically (via PTEN rescue in PTEN-null FTC133 cells). HIF-1 activity was inhibited using a dominant-negative variant of HIF-1α (dnHIF). Cells were irradiated with 0, 2, 4 and 6 Gy with/without PI-103/GDC-0941 under normoxia/hypoxia (1% oxygen) /anoxia. *In vitro* DNA double-stranded breaks (DSBs) were assessed by gamma-H2AX expression, HIF-1α activity by use of luciferase reporter assays and migration by use of the scratch-wound migration method. Activity of PI3K, ATM and DNA-PK (proteins critically involved in the DNA damage response) were analysed by assessing pAKT/pATM/pDNA-PK expression. *In vivo*, mice bearing FTC-xenografts were exposed to 5×2 Gy with/without GDC-0941 (orally), tumour pAKT, pATM and pDNA-PK expression and volumes were assessed. Spontaneous-lung metastasis was quantified by clonogenic assay.
Results
GDC-0941, dnHIF and PTEN rescue increased and prolonged radiation-induced DNA-DSBs under normoxia/anoxia in carcinoma cells and had no effect on immortalised 'normal' thyroid cells. Mechanistically this was via inhibition of pATM, with the degree of inhibition being dependent on oxygen environment and cell-type. Radiation-induced HIF-1alpha activity/expression in normoxic/anoxia FTC133 s. GDC-0941 reduced HIF-1alpha activity and clonogenicity in irradiated FTC133 and 8505c cells. Radiation increased FTC migration, which has important therapeutic implications. PI-103/GDC-041 and PTEN rescue inhibited migration in irradiated cells. GDC-0941 increased growth delay of irradiated tumours and reduced radiation-induced pAKT and pDNA-PK in FTC-xenografted mice.
Conclusions
These data link PI3K inhibitors combined with radiotherapy may improve therapeutic response.

### Functional and molecular characterization of cancer stem cells in anaplastic thyroid carcinoma

V. Carina, G. Zito, G. Pizzolanti, P. Richiusa, L. Tomasello, M. Pitrone, C. Baiamonte, V. Guarnotta & C. Giordano
Faculty of Medicine, University, Palermo, Italy.

Anaplastic Thyroid Carcinoma (ATC) is the most aggressive thyroid gland malignancy characterized by undifferentiated morphology. It has been suggested that cancer stem cells (CSCs) might play a central role in ATC. Previously on the basis of CD133 positivity, our group suggested that CD133+ cancer stem cells (CSCs) might play a central role in ATC. Here we analyzed a panel of different stem cell markers in order to identify a peculiar CSC pattern in ATC.
Aim
i) to characterize CSCs from ex *vivo* ATC specimens; ii) to evaluate in a well characterized ATC cell line (SW1736) the percentage of CSCs and the influence of transcription factor SOX2 on Oct-4 and Nanog expression and drug resistance.
Methods
Ex *vivo*: Eight formalin-fixed, paraffin-embedded ATC specimens were analyzed by RT and qRT-PCR, immunohistochemistry and immunofluorescence for pluripotent CSC markers (CD133, SSEA4, Thy1, ABCG2, c-kit, SOX2, Oct-4, Nanog, Lin28, Klf4 and c-Myc). *In vitro*: CSC marker expression was evaluated in SW1736 cells by qRT-PCR, flow cytometry and immunofluorescence; the SOX2 effect on Oct-4 Nanog and ABCG2 expression and chemosensitivity were evaluated after SOX2 silencing by siRNA method.
Results
Stem cell markers expression in ATCs and SW1736 cell line proved to be as follows in the table.
SOX2 plays a pivotal role in this model: SOX2 silencing down-regulated Oct-4 (67.6%±2.0 $P<0.05$) and Nanog (85.5%±5.4 $P<0.01$) expression. SOX2 silencing sensitized SW1736 cells causing a significant mortality increase of 1.8 fold with 10 μM cisplatin and 1.4 ($P<0.01$) fold with 1.5 μM doxorubicin in comparison to control cells. Conclusions: The analysis of multiple pluripotent stem cell markers is useful to identify CSCs in ATC. In particular, SOX2 exerts a fundamental role in regulating Oct-4 and Nanog expression. Our data suggest that SOX2 switch-off may be essential for overcoming CSC chemotherapy resistance in ATC.

### Regulation of hPTTG expression and phosphorylation: autocrine interactions with growth factors in thyroid cells

G. Lewy[1], G. Ryan[1], M. Read[1], J. Fong[1], R. Seed[1], N. Sharma[1], V. Smith[1], P. Kwan[1], S. Stewart[1], A. Warfield[2], S. Melmed[3], M. Eggo[1], J. Franklyn[1], C. McCabe[1] & K. Boelaert[1]
[1]University of Birmingham, Birmingham, UK; [2]Queen Elizabeth Hospital NHS Foundation Trust, Birmingham, UK; [3]University of California, Los Angeles, California, USA.

Introduction
The human Pituitary Tumor Transforming Gene (hPTTG) is a phosphorylated proto-oncogene induced in multiple tumour types. hPTTG phosphorylation is mediated by cyclin-dependent kinase 2 (CDC2) and expression is regulated by specificity protein 1 (SP1). In thyroid cancer, hPTTG induces genetic instability and propagates growth through induction of growth factors (GFs).
Methods
The interplay between hPTTG phosphorylation, SP1 regulation and GF induction was evaluated in thyroid cells *in vitro* and in mouse models of PTTG over- and underexpression *in vivo*.
Results
EGF(5nM), TGF-α(5 nM) and IGF1(10 ng/l) induced hPTTG protein in K1(twofold, 3.6-fold and 2.3-fold, $P=<0.01$) and TPC-1 papillary thyroid carcinoma cells(twofold, 4-fold and 2.6-fold, $P=<0.01$) and in human primary thyrocytes(threefold, 2.4-fold and 2-fold, $P=<0.01$). These effects were associated with activation of mitogen activated protein kinase (MAPK) and phosphoinositide three-kinase (PI3K), but not with increased cellular proliferation rates. GF treatment of TPC-1 cells following siRNA knockdown of CDC2 or SP1 confirmed that GFs induce hPTTG independently of these hPTTG regulators. CDC2 depletion in TPC-1 cells resulted in enhanced expression and phosphorylation of hPTTG and reduced cellular proliferation. Transient transfection with hPTTG induced EGF (1.7-fold, $n=4$, $P=0.004$), IGF1 (1.6-fold, $n=5$, $P=0.002$) and TGF-α mRNA (1.6-fold, $n=3$, $P=0.024$) expression. Treatment of human primary thyrocytes with conditioned media from hPTTG transfected cells resulted in autocrine upregulation of hPTTG protein, which was ameliorated by GF depletion or GF receptor inhibitors. *In vivo* evaluation of our transgenic mouse model with thyroid-targeted hPTTG overexpression confirmed increased mEGF (2.7-fold, $n=3$, $P=0.012$) and mIGF1 (2.0-fold, $n=3$, $P=0.02$) mRNA, compared with WT mice. Further, mEGF mRNA expression was downregulated in the thyroids of $PTTG^{-/-}$ knockout mice (0.4-fold, $n=4$, $P=0.001$), consistent with reduced EGF mRNA expression in TPC-1 cells transfected with hPTTG siRNA (0.68-fold, $n=4$, $P<0.05$, compared to scrambled controls).
Conclusion
Together, our results indicate that hPTTG is involved in autocrine signalling mechanisms with GFs in the thyroid, independently of CDC2 and SP1, and that aberrant control of these pathways may enhance transformed cell growth.

**Mass spectrometry allows accurate measurement of serum thyroglobulin (Tg) in the presence of anti-thyroglobulin auto-antibodies (TgAB)**

R. Taylor, B. Netzel, J. Theobald, D. Barnidge, B. McIver, A. Algeciras-Schimnich, R. Singh & S. Grebe
Mayo Clinic, Rochester, Minnesota, USA.

Background
Serum thyroglobulin (Tg) measurements are one of the main pillars of thyroid cancer follow-up, because of the high organ and disease specificity of Tg in athyrotic patients. However, 20–25% of patients have detectable serum anti-Tg auto-antibodies (TgAB), which might cause false low Tg measurements in immunometric assays (IMA). This can lead to significant challenges in patient management. Measurement of Tg by liquid chromatography-tandem mass spectrometry (LC–MS/MS) after tryptic digestion can in theory overcome this problem, as TgAB and Tg are both digested equally, and Tg-specific tryptic fragments can be detected selectively. Proof of concept for such a LC–MS/MS Tg assay was shown for TgAB-negative patients in 2008 (Clin Chem 54:1796–1804). We extended these observations to TgAB-positive patients.
Methods
Samples were depleted of albumin and other low/mid molecular weight proteins, trypsin digested, and purified by solid phase extraction after addition of synthetic non-radioactive isotopic peptide internal standard (IS). The extracts were analyzed by LC–MS/MS for a highly ionizable proteotypic Tg fragment and its corresponding IS. Purified Tg, matched to the international Tg reference preparation, was used for calibration.
Results
The assay's limit of detection was 2 ng/mL. Inter-assay imprecision (CV) was 4–12% (Tg range: 3.8–150 ng/ml). Method agreement with the Beckman Coulter Tg IMA in 119 TgAB-negative patients with detectable Tg showed a slope of 0.75, intercept: +3.8, R-squared: 0.87. By contrast, in 20 TgAB-positive patients with detectable Tg, the slope was 1.77, consistent with under-recovery of Tg in the IMA. Consistent with these observations, a comparison of Tg recovery between LC–MS/MS and IMA, following addition of high TgAB concentrations to Tg samples, showed under-recovery in the IMA.
Conclusion
Tryptic digest-based LC–MS/MS assays can measure Tg accurately in the presence of TgAB that lead to false low IMA measurements.

## P1785

**Dual specificity phosphatase 5 (DUSP5), a specific negative feedback regulator of ERK signaling, is controlled by serum response factor (SRF) and Elk-1 transcription factors**

C. Buffet[1], C. Garcia[1], M. Catelli[1], K. Hecale-Perlemoine[1], X. Bertagna[1,2], J. Bertherat[1,2] & L. Groussin[1,2]
[1]Institut National de la Santé et de la Recherche Médicale U567, Centre National de la Recherche Scientifique UMR8104, Institut Cochin, Université Paris Descartes, Paris, France; [2]Assistance Publique-Hôpitaux de Paris, Hôpital Cochin, Paris, France.

Mitogen-activated protein kinase (MAPK) pathway abnormalities, specifically rearrangements (RET/PTC) or activating mutations (RAS or BRAF), are highly prevalent in papillary thyroid carcinomas (PTCs). Constitutive activation of this signaling cascade causes sustained phosphorylation of extracellular signal-regulated kinase (ERK). DUSP5, which is positively regulated by ERK signaling, acts as a negative regulator of its activity. We have previously shown that DUSP5 is overexpressed in PTCs. We sought to characterize the regulation of DUSP5 expression.
We demonstrated, using pharmacological inhibitors in NIH3T3 (murine) and PC12 (rat) cell lines, that DUSP5 is an early response gene regulated by the MAPK pathway, mostly at the transcriptional level. We next focused on DUSP5 transcriptional regulation. Analysis of DUSP5 promoter region allowed us to identify two contiguous CArG Boxes, binding SRF, and several Ets responsive elements (EBS), binding Elk-1, which is positively regulated by ERK signaling. We studied in NIH3T3 the implication of these responsive elements by transient transfection of luciferase reporter genes corresponding to wild type or mutated responsive elements DUSP5 promoter (i.e. mutation of CArG Box and/or EBS). These experiments demonstrated a role for SRF and Elk-1 in the transcriptional regulation of DUSP5, confirmed by EMSA and CHIP assay. Our data indicate that the CArG Boxes play a key regulatory role in DUSP5 expression.
DUSP5 expression tracks in tandem with MAPK pathway activation. DUSP5 is regulated mainly at the transcriptional level by the transcription factors Elk1, a known target of ERK signaling and SRF. These factors can form a ternary complex (Elk1-SRF-DNA) on the DUSP5 promoter, thereby providing a link to the ERK signaling pathway. These data highlight an important feedback loop that allows a tight regulation of pERK levels.

Bonichon[10], E. Morelon[1], S. Leboulleux[11], C. Bournaud[1], A. Kelly[12], P. Niccoli[13], M. Schlumberger[11] & F. Borson-Chazot[1]
[1]University hospital Lyon, Lyon, France; [2]University hospital Toulouse, Toulouse, France; [3]University hospital Saint Louis, Paris, France; [4]University hospital Nancy, Nancy, France; [5]University hospital Montpellier, Montpellier, France; [6]University hospital Nantes, Nantes, France; [7]University hospital Lille, Lille, France; [8]University hospital Paris La Pitié, Paris, France; [9]University hospital Angers, Angers, France; [10]Institut Bergonie, Bordeaux, France; [11]Institut Gustave Roussy, Villejuif, France; [12]Centre Jean perrin, Clermont-Ferrand, France; [13]CHU La Timone, Marseille, France.

Context
An increased mortality by cancer is reported in grafted patients.
Objective
This multicentric study aimed to investigate whether the prognosis of thyroid cancer was modified by transplantation
Results
Sixty nine patients (35 M/34 F; median age 41 years) with a history of both thyroid cancer and transplantation were recruited via specialized networks (TUTHYREF and DIVAT). Evolution and outcome were retrospectively analyzed after a median follow-up of 13 years. Ninety one per cent were papillary and 9% of the follicular type.
Thyroid cancer had been diagnosed before transplantation in 33/69 patients from whom 36.4% had a high risk cancer. At the time of the graft, 31 were in remission, four of them after a recurrence. Two patients recurred after transplantation and a remission was obtained after a complementary treatment. In a young female patient who presented before transplantation lung metastases, a 2 years complete remission was observed after bilateral lung transplantation for cystic fibrosis.
In 36 patients thyroid cancer was diagnosed after transplantation from whom 47% were at high risk of recurrence. After a median follow-up of 14 years, 31 patients were in remission, four had persistent disease, one deceased from progression of thyroid cancer. In nine cases, a second transplantation was performed 6.5 years after thyroid cancer diagnosis. During follow-up, a remission after two local recurrences occurred in one patient, persistent disease remained stable in one and there was no recurrence in the seven other patients.
As a whole, 90% of patients were in remission at the time of the study. Seven per cent of patients experienced a recurrence and all of them were N1.
Conclusion
The prognosis of thyroid cancer does not seem to be hampered by transplantation. This suggests that thyroid cancer should not be considered as a contra indication to transplantation, even in patients with persistent disease.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1787

**Simultaneous occurrence of BRAF mutation and RET/PTC rearrangement is frequent in papillary thyroid carcinoma**

A. Guerra[1], V. Marotta[2], V. Di Stasi[1], A. Volpe[1], A. Murino[1], M. Di Stasi[1] & M. Vitale[1]
[1]University of Salerno, Baronissi, Italy; [2]University of Naples Federico II, Naples, Italy.

Context
Initial studies reported that RET rearrangements, RAS mutations and BRAF mutation are mutually exclusive genetic events in papillary thyroid carcinoma (PTC). Subsequently, simultaneous occurrence of BRAF mutation and RET/PTC or H4-PTEN has been described in few PTC cases, indicating that these genetic alterations might coexist in PTC in the same cell or in different cells, at least sporadically. In light of the recent finding that frequently BRAF mutation is present only in a subset of cells in PTC, we analyzed more extensively the possibility that BRAFT1799A and RET/PTC can coexist in the same tumor.
Study design
Total RNA extracted from 75 FNABs classified as PTC at histology, were analyzed by Southern blot on RT-PCR for the presence of RET/PTC-1 and RET/PTC-3 rearrangements. Genomic DNA extracted from the same samples was analyzed by pyrosequencing for the presence of the BRAFT1799A mutation.
Results
RET rearrangements were present in 28 over 75 PTC (37.3%, 9 RET/PTC-1 and 19 RET/PTC-3). In one sample, both RET rearrangements coexisted. BRAFT1799A was present in 42 (56%) in the range 44.7–5.1% of total BRAF mutated alleles. In 14 samples, both a RET rearrangement and BRAF mutation were present (14.7%). In these tumors, BRAF mutation was always as a subclonal or oligoclonal occurrence in the range 37.5–6%.
Conclusions
These data demonstrate that RET rearrangements and BRAF mutation are not mutually exclusive but rather are frequently co-expressed in the same PTC. The data, do not exclude the hypothesis of a coexistence of the two oncogenes in different cells within the tumor.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1788

**Immunohistochemical expression of βIII-tubulin and cell-cell adhesion proteins in papillary thyroid carcinoma: a preliminary report**

C. Colato[1], F. Monzani[2], P. Brazzarola[1], G. Martignoni[1], M. Chilosi[1] & M. Ferdeghini[1]
[1]University of Verona, Verona, Italy; [2]University of Pisa, Pisa, Italy.

Introduction
Tubulin is a multifunctional cytoskeletal protein involved in key cellular processes, including cell movement, intracellular transport and mitosis. An increased expression of βIII-tubulin (TUBB3) has been observed in several cancer types and associated with aggressive and drug refractory disease.
Expression of claudins (CLDNs), the main component of tight junctions, is frequently altered in human cancers, including papillary thyroid carcinoma (PTC). E-cadherin (E-CD) plays a critical role in the maintenance of epithelial phenotype. Loss of E-CD expression is considered as the hallmark of epithelial-to-mesenchymal-transition.
Aim
To analyze the presence of TUBB3 protein in PTC samples in relation to expression of molecules with cell-cell adhesive role (E-CD, CLDN1 and CLDN7).
Methods
The study included 70 PTCs, 17 lymph node metastases, seven follicular adenomas and five nodular hyperplasias.
Results
No positivity was observed in follicular epithelium, nodular goiter and follicular adenoma. In PTC samples, the reactivity was heterogeneous and demonstrated strong cytoplasmic staining in widely infiltrating PTCs associated with fibrous stroma, particularly at invasive front of tumour, or in moderately differentiated PTCs with loss of cellular polarity/cohesiveness. In these areas, CLDN1/7 expression were decreased or less intense in comparison with the center of neoplasia. Decreased E-CD staining was also observed at invasive front of tumour. Conversely, PTCs with expanding margins or well-developed follicles were constantly negative.
The majority of lymph node metastases showed strong TUBB3 immunoreactivity.
Conclusions
We report for the first time TUBB3 expression in thyroid tissue.
In analogy with carcinomas of other sites, TUBB3 expression appears to be increased in PTCs with 'aggressive' histological features, thus suggesting that changes in tubulin isotype composition could modulate the invasive and metastatic potential of cancer cells.
The decreased CLDNs and E-CD expression in combination with the TUBB3 positivity, at invasive front of tumour, could be a possible morphological indicator of epithelial-to-mesenchymal-transition in PTC.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding
This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector.

## P1789

**The occurrence of mutations in the CHEK2 gene in patients with papillary thyroid carcinoma and its impact on the course of the disease and the coexistence of other neoplasms**

A. Kowalska[1], D. Gasior-Perczak[1], I. Palyga[1], M. Sioĺek[1], B. Kozak-Klonowska[1], A. Kowalik[1], J. Lubinski[2], C. Cybulski[2], R. Mezyk[1] & S. Gozdz[1]
[1]Holycross Cancer Centre, Kielce, Poland; [2]Pomeranian Medical University, Szczecin, Poland.

Introduction
CHEK2 is a gene encoding a protein involved in the mechanism of repairing damaged DNA. Mutations in the CHEK2 gene are associated with an increased risk of various neoplasms. The most common mutations in the Polish population are: I157T, less frequently IVS2+1G> A and 1100delC.
Materials
The study consisted of 277 patients with papillary thyroid carcinoma: 252 female, 25 male, aged 15 to 76 years.
Method
Patients underwent testing of the CHEK2 gene using PCR-HRM and sequencing of DNA isolated from peripheral blood. Age, severity of disease at diagnosis and the incidence of other neoplasms were assessed.
Results
Mutations in the CHEK2 gene were confirmed in a total of 47 patients, of which 38 had I157T mutation, and 9 had IVS2+1 G> A mutation.
The average age of the patients at the moment of making the diagnosis was 48 years old, both in the groups with or without the mutation.
Stage of disease progression in carriers of CHEK2 mutations at time of diagnosis ($n=47$): I-72%, II-11%, III-11%, IVA-6%.
Stage of disease progression in patients without mutations at time of diagnosis ($n=230$): I-77.4%, II-6.5%, III-12.6%, IVA-3%, IVC-0.5%. The reported differences were not statistically significant ($P=0.5727$).
Occurrence of other neoplasms were found in 28% (13/47) of patients with the mutation compared to 5.2% (12/230) of patients without mutations in the CHEK2 gene. The reported difference was statistically significant ($P<0.0001$).
Conclusions
i) Mutation of the CHEK2 gene are present in 17% of patients with papillary thyroid carcinoma.
ii) The occurrence of mutations in the CHEK2 gene are associated with a higher risk for other neoplasms, most often breast cancer especially in the case of I157T mutation (21%).
iii) There was no observed influence of mutations in the CHEK2 gene on the degree of advancement of neoplasm at the time of diagnosis.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Risk of malignancy in thyroid incidentalomas detected by $^{18}$F-fluorodeoxyglucose positron emission tomography. A systematic review**

K. Soelberg, S. Bonnema, T. Brix & L. Hegedüs
Odense University Hospital, Odense, Denmark.

Background
The expanding use of $^{18}$F-fluoro-deoxy-glucose positron emission tomography ($^{18}$F-FDG PET) has led to the identification of increasing numbers of patients with an incidentaloma in the thyroid gland. The aim of this study was to review the proportion of incidental thyroid cancers found by $^{18}$F-FDG PET or PET/CT imaging.
Methods
Studies evaluating thyroid carcinomas discovered incidentally in patients or healthy volunteers by $^{18}$F-FDG PET were systematically searched in the PubMed database from 2000 up to 2011. The main exclusion criteria were known thyroid disease, lack of assigned diagnoses, investigation of diffuse uptake only, or investigation of patients with head and neck cancer, or cancer in the upper part of the thorax.
Results
Twenty-two studies met our criteria comprising a total of 125754 subjects. 1994 (1.6%) had an unexpected focal hypermetabolic activity, while 999 of 48 644 individuals (2.1%) had an unexpected diffuse hypermetabolic activity in the thyroid gland. A diagnosis was assigned in 1051 (271 had surgical confirmation) of the 1994 patients with a focal uptake (366, corresponding to 34.8%, were malignant), and in 168 of 999 patients with diffuse uptake (7, corresponding to 4.4%, were malignant). In the eight studies reporting individual maximum standard uptake values ($SUV_{max}$), the mean $SUV_{max}$ value was 4.8 (SD 3.1) and 6.9 (SD 4.7) in benign and malignant lesions, respectively, ($P < 0.001$).
Conclusions
Incidentally found thyroid nodules, using $^{18}$F-FDG PET, are at high risk of harboring malignancy if uptake is focal. SUV-values are significantly higher in malignant than in benign nodules. The pronounced inhomogeneity and other shortcomings of the studies are discussed.

## P1791

**Desmoplastic stromal reaction and extrathyroidal invasion predict lymph node involvement in sporadic macro medullary thyroid cancer**

A. Berdelou, S. Aubert, F. Pattou, P. Pigny, V. Gnemmi, B. Carnaille, M. D'Herbomez, J. Wémeau & C. Do Cao
University hospital, Lille, France.

Background
Locoregional nodal metastases are the first step of tumor spread in MTC and have been shown to be a prognostic factor for survival. Neither palpation nor neck ultrasound can estimate nodal staging accurately.
Aim
To identify predictive factors for LNI in MTC through a retrospective study on 142 consecutive patients operated in Lille University Hospital between 1995 and 2010.
Methods
Analyses were carried on 54 patients (median age = 52 (41–61), M/F ratio = 0.54; mean tumor size = 25 mm (15–35), median calcitonin (CT) value = 1177 pg/ml (304–3470)) after exclusion of familial MTC ($n = 38$) and microMTC ($n = 27$). Total thyroidectomy plus LN dissection was performed in 98%. Pathologic slides were reviewed. Pre and postoperative CT (pre/postCT) were all available.
Results
Twenty-six (48%) patients with a sporadic macroCMT had LNI, 6 (23%) of whom had a curative resection confirmed by undetectable postCT. All LN free cases had accordingly undetectable postCT. Thirty three percent of MTC with preCT > 2000 pg/ml were unexpectedly LN free with undetectable postCT. Under univariate analysis, age and tumor size did not influence LN status. Male patients ($P = 0.027$) and higher preCT level ($P = 0.001$) were more likely associated with LNI. Positive correlation was observed between LNI and DSR ($P = 0.001$), no peritumoral capsule ($P = 0.001$), peritumoral invasion ($P = 0.00004$), vascular invasion ($P = 0.0004$) and ETI ($P = 0.003$). Multivariate analysis showed both DSR (OR = 131.67; $P < 0.0001$) and ETI (OR = 255.03; $P = 0.01$) to be independent factors for LNI. The rate of RET somatic mutation found in 45% of 29 analyzed tumors was not significantly higher in MTC with LNI.
Conclusion
At surgery, 52% of sporadic macro CMT was LN free. Though higher preCT may be indicative of LNI no threshold can be set. Since no preoperative factor can ascertain nodal status, a systematic LN dissection is still requiered. ETI and DSR are strong predictors of LNI: their impact should be addressed on further survival studies.

## P1792

**Circulating BRAFV600E in the diagnosis and follow up of differentiated thyroid cancer**

C. Pupilli, P. Pinzani, F. Salvianti, B. Fibbi, M. Rossi, L. Petrone, M. De Feo & G. Forti
Careggi Hospital and University of Florence, Florence, Italy.

Introduction
Although overall accuracy of fine needle aspiration (FNA) in identifying thyroid cancer is considered excellent, 20–30% of aspirates do not allow definitive diagnosis of malignancy. Proto-oncogene somatic mutations such as BRAFV600E in FNA strongly suggest the presence of malignancy. However, only few studies reported the use of circulating BRAFV600E-mutated alleles in plasma as an useful marker for non invasive diagnosis and follow up of this disease.
Methods
We propose an allele specific Taqman-based real-time PCR assay to measure plasma-circulating BRAFV600E concentration in patients affected by thyroid nodules ($n = 100$) and healthy subjects ($n = 33$) used as control group.
Results
Plasma-circulating BRAFV600E concentration (ng/ml) was significantly higher in the cytological categories of follicular lesions (Thy 3; $n = 47$, mean ± S.E.M: 2.2 ± 0.9, $P = 0.04$) and suspicious plus diagnostic for malignancy (Thy 4 + Thy 5; $n = 29$ mean ± S.E.M: 1.7 ± 0.5, $P = 0.01$) than in control group (mean ± S.E.M: 0.3 ± 0.1). Plasma-circulating BRAFV600E levels in patients with negative for malignancy cytology (Thy 2 group; $n = 27$ mean ± S.E.M: 0.8 ± 0.4, $P = 0.6$) were not significantly different compared to control subjects.
In 18 subjects affected by differentiated thyroid carcinoma the level of circulating BRAFV600E decreased significantly after surgery (from 3.1 ± 0.8 to 0.8 ± 0.3 ng/ml, $P = 0.02$).
ROC curve analysis indicated that BRAFV600E absolute concentration has the maximal diagnostic relevance with 76% sensitivity and 82% specificity.
At present all the patients with Thy 3 cytology are submitted to surgery. In this group, the comparison of the BRAFV600E status with the histological examination demonstrated a negative predictive value of 73%.

Conclusions
The present results suggest that circulating BRAFV600E might be used in the diagnosis of differentiated thyroid cancer. It may be also helpful in the follow-up of these type of cancer, especially in the cases in which thyroglobulin (Tg) is not informative, i.e when antiTg antibodies are present, preoperatively Tg is undetectable and patients were not subjected to radioablation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1793

**Screening for thyroid diseases in people from former Soviet Union emigrated in USA after Chernobyl accident**

I. Branovan & V. Drozd
Project Chernobyl, New York, New York, USA.

Research objective
After the Chernobyl nuclear reactor accident, there was a dramatically increase in thyroid cancer incidence in children and adolescents in Belarus, Ukraine and the Russian Federation. The increasing incidence of thyroid cancer in last 10 years not only in former Soviet Union but also in the United States, is real medical problem. 'Project Chernobyl' has been established in New-York for early diagnostics of radio induced thyroid cancer among people that were irradiated during Chernobyl accident and later emigrated in USA.
The study was aimed at the investigation of prevalence of thyroid diseases by screening in people who have emigrated in USA after Chernobyl accident.
Patients and Methods
A two cohorts of people (total 6870 subjects are living now in New-York area) why have emigrated from former Soviet Union underwent ultrasonography screening of thyroid and examination of thyroid function on the basis of TSH, FT4, Ab-TPO, Ab-Tg levels in serum. First cohort consisted of 2550 subjects (mean age $59 \pm 7$), exposed to fallout from Chernobyl. Second cohort consisted of 4320 subjects (mean age $53 \pm 2$) that have not been exposed to the radiation.
Results
Prevalence of nodular goiter was more higher in irradiated subjects, comparing to the not-irradiated-cohort (43.0 vs 17.5%). Thyroid cancer (8.6 vs 4.0%) and different type of thyroid dysfunction (19.0 vs 6.0%) are two times more common among of the subjects, exposed to the radiation. The patients from the cohort of the radiation exposed people have required more aggressive type of treatment. The frequency of the total thyroidectomy was more higher (95 vs 73%) in the cohort of the patients, exposed to radiation in the result of the Chernobyl accident.
Conclusions
Significantly higher frequency of serious thyroid disorders among the people exposed to radiation during Chernobyl accident and emigrated in USA was diagnosed by screening investigation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1794

**About the reproducibility of a Thyroglobulin assay**

A. Georges, J. Brossaud & J. Corcuff
University Hospital, Bordeaux, France.

Thyroglobulin (Tg) is a tumoral marker of differentiated thyroid cancer (DTC). Iterative Tg assays are then mandatory for their follow-up. The maximum imprecision of any Tg measurement should be $<5\%$. However, it is unlikely that current Tg assays can maintain such tight precision over the 6–12 months time period used for monitoring patients with DTC. This precision can be overcome by measuring archived frozen samples from the patient in the same run as the current specimen. This aims to minimise inter-assay variability and to avoid inappropriate therapeutic action.
We retrospectively investigated the systematic re-assay of archived serum samples from the last 10 year: 2992 out of a total of 16689 sera. From the re-assayed sera, we analysed only those $<2.5$ ng/ml ($n=2063$). The same kit was always used: thyroglobulin IRMA, CIS bio international. Intra-assay CV were 6.4 and 3.5% at 11.6 and 37.1 ng/ml, respectively. Inter-assay CV was 4.6 (1.1–10.2)% and 4.5 (0.8–8.6)% for the last 2 year for the two controls of the kit (about 11 and 36 ng/ml).
One thousand seven hundred seventy four results were $\leq 1$ ng/ml. The median (2.5th-97.5th percentile) coefficient of variation between the two assays was 0.0 (0.0–2.2)%. When reassayed, 1748 results were $\leq 1$ ng/ml. The 26 'discordant' results ranged from 1.01 to 1.52 ng/ml. When the recommended threshold (1.5 ng/ml) for analytical variability was considered there was 1 'discordant' result (1.52 ng/ml).
Two hundred eighty nine results were $>1$ and $<2.5$ ng/ml The coefficient of variation between the two assays was 8.7 (0.4–36.7)%. When reassayed, 64 results were "discordant": 23 were $\leq 1$ ng/ml and 41 were $\geq 2.5$ ng/ml (range (2.5–4.1) ng/ml). When analytical variability was considered, this amounted to 3 'discordant' results (4.02, 4.07, 4.1 ng/ml).
Although some physicians do not draw clinical conclusion from Tg values $<1$–2 ng/ml, the assay precision is excellent throughout this measuring range questioning the opportunity of systematic retesting prior archived samples at each individual run.
Declaration of interest

## P1795

**Ret somatic mutations are not an early event in the tumoral transformation of sporadic medullary thyroid cancer**

C. Romei, B. Cosci, C. Ugolini, V. Bottici, E. Molinaro, L. Agate, A. Tacito, F. Basolo, P. Miccoli, A. Pinchera & R. Elisei
University of Pisa, Pisa, Italy.

The reported prevalence of RET somatic mutations in sporadic MTC is about 40–50% and the most frequent somatic mutation is Met918Thr in exon 16. MTC harboring a somatic RET mutation have been demonstrated to have a more advanced stage at diagnosis and a worse outcome. Although RET mutations are believed to be driving events in the MTC tumorigenesis only the finding of somatic mutations in microMTC can confirm this hypothesis.
Aim of the present work was to search for RET somatic mutations in sporadic microMTC ($<1$ cm) and to compare their prevalence between microMTC and MTC of bigger size.
We selected a group of 148 MTC cases in which RET exon 16 point mutation was analyzed by direct sequencing. Tumors were classified according to the size of the nodule as follows: group A, $<1$ cm; group B, $>1$ and $<2$ cm; group C, $>2$ and $<3$ cm; group D, $>3$ cm.
The overall prevalence of RET mutation was 18.24% (27/148). RET mutations were differently distributed in the four groups. In particular it was 4.6% (2/43) in group A, 12.5% (8/64) in group B, 40% (8/20) in group C and 42.8% (9/21) in group D, thus showing an increasing rate according to the increase of the tumor size. Furthermore, when comparing the prevalence of mutations in the four groups we found a lower prevalence in microMTC ($P<0.0001$).
In conclusion these data indicate that: i) the overall prevalence of RET somatic mutations is lower than expected; ii) the prevalence of RET somatic mutations is very low (4.5%) in microMTC suggesting that they are not an early event in MTC tumorigenesis. As an alternative to this hypothesis we have to suppose that microMTC could be caused by other oncogene(s) with a lower transforming activity.

## P1796

**A proposal of a new clinical, ultrasonographic and cytological scoring system for thyroid nodules: the 'cut' score**

F. Ianni, C. Rota, P. Campanella, A. De Rosa, F. Gallo, V. Di Donna, P. Locantore, V. Luotto, M. Nestola, S. Corsello & A. Pontecorvi
Università Cattolica del Sacro Cuore, Rome, Italy.

Aim
To develop a cost-effective instrument to evaluate the preoperative malignancy risk of thyroid nodules (TNs).
Patients&Methods
A meta-analysis of the clinical (C) and ultrasonographic (U) features associated with an increased risk of malignancy was conducted searching in the PubMed database. For each of them we computed the odds ratio and we consequently assigned a score. The resulted C + U score along with the 5-tiered score of fine-needle aspiration (FNA) result (T = 1–5) designed the CUT score of the TN.
Moreover we enrolled 673 consecutive patients (514W/159M) with 689 TNs, we submitted them to clinical evaluation, ultrasonography and US-guided FNA. Hence we applied the CUT score and we correlated it with the histopathological diagnosis of the 79 TNs that underwent surgery.
Results
Features associated with a higher risk of malignancy resulted: male sex, family history of thyroid cancer, single nodule, size $>4$ cm, taller-than-wide shape, solid structure, hypoechogenicity, irregular margins, absent halo, microcalcifications and intranodular vascularization. A score was assigned to each of them.
Out of the 35 TNs with histopathological diagnosis of benign nodule, the average C + U score was 3.7 for the 3 TIR1 TNs, 2.5 for the 16 TIR2 TNs, 3.7 for the 11 TIR3 TNs and 4.1 for the 5 TIR4 TNs. Nevertheless out of the 44 TNs with histopathological diagnosis of malignancy, the average C + U score was 5.7 for the 8 TIR3 TNs, 7.6 for the 10 TIR4 TNs and 7.7 for the 26 TIR5 TNs. Sensitivity and specificity of the C + U score were respectively 96 and 56% with a cut-off of 3.5 and 67 and 94% with a cut-off of 6.5.
Conclusion
The CUT score can be a useful and cost-effective instrument in the preoperative management of TNs, especially for those with indeterminate or repetitively non-diagnostic FNA.

## P1797

**Papillary thyroid carcinoma with high percentage of BRAFV600E alleles have a higher recurrence rate**

A. Guerra[1], L. Fugazzola[2], V. Marotta[3], M. Cirillo[1], V. Di Stasi[1], A. Volpe[1], A. Murino[1], M. Di Stasi[1] & M. Vitale
[1]University of Salerno, Baronissi, Salerno, Italy; [2]University of Milan, Milan, Italy; [3]University of Naples Federico II, Naples, Italy.

Context
Although unexplained conflicting results are present in the literature, most of studies report the association of BRAFV600E in papillary thyroid carcinoma (PTC) with a more advanced disease and with a worst prognosis. We recently demonstrated that in most of the cases PTC consists of a mixture of tumour cells with wild-type and mutant BRAF. Hence, we examined the association of percentage of BRAFV600E alleles with clinicopathologic parameters at diagnosis and disease outcome in a large series of PTC.
Study design
Tumour genotyping for BRAFV600E was performed by Big Dye Terminator and pyrosequencing in 168 patients with PTC. The association between clinico-pathologic characteristics including disease recurrence at follow-up (median = 5.1 years) and the percentage of BRAF mutant alleles was determined.
Results
The prevalence of BRAFV600E was higher by pyrosequencing then by Big Dye Terminator (53.6 vs 36.9%). In the PTC positive for BRAFV600E, the percentage of mutant alleles ranged 5.1–44.7% of total BRAF alleles, with a median of 20.6%. The presence or the percentage of BRAFV600E alleles did not correlate significantly with gender, multicentricity, lymph node metastasis, and tumour stage. The percentage of BRAFV600E alleles directly correlated with age at diagnosis and tumour volume ($R^2 = 0.223$, $P = 0.039$ and $R^2 = 0.166$, $P < 0.001$ respectively). The percentage of BRAFV600E alleles ($P = 0.014$), tumour volume ($P = 0.012$) and lymph node metastasis ($P = 0.008$) predicted the disease outcome. The odds ratio of recurrence in PTC with BRAFV600E alleles $\geq 30\%$ was a 5.31-fold higher ($P = 0.002$) in comparison with PTC with BRAFV600E alleles $< 30\%$.
Conclusions
High percentage of BRAFV600E alleles defines a PTC molecular subtype with a poorer disease outcome. Analysis of BRAF mutation by pyrosequencing is useful to refine the risk stratification of patients with PTC.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1798

**Sentinel lymph node biopsy in differentiated thyroid carcinoma and decision for selective modified radical neck dissection**

R. Dzodic[1,2], I. Markovic[1,2], I. Djurisic[2], M. Buta[2], G. Pupic[2] & Z. Milovanovic[2]
[1]University of Belgrade School of Medicine, Belgrade, Serbia; [2]Institute of Oncology and Radiology of Serbia, Belgrade, Serbia.

Background
The accuracy of sentinel lymph node biopsy (SLNb) in decisions for surgical management of lymph nodes in differentiated thyroid ccarcinoma (DTC) was demonstarted in a few previous studies.
Aim
To determine whether SLN biopsy of first draining node/s in jugulo-carotid chain is accurate technique to select patients with true positive LN for selective modified radical neck dissection (MRND).
Patients and methods
We have performed SLN biopsy in 172 patients with DTC. Before mobilization of the thyroid gland, 0.2 ml of 1% solution of methylen blue dye was injected peritumorally. After 10 min the dissection was continued around omohyoid muscle, towards the internal jugular vein and carotid artery until blue stained LN were found and sent for frozen-section examination. An extended dissection of level III/IV was done consecutively. All LN were examined by frozen section and conventional (HE) histopathology examination. If positive, MRND was performed after total thyroidectomy and routine dissection of central neck compartment.
Results
Identification rate of SLN was 93.5%. Specificity and sensitivity of the method were 100 and 80% respectively. Negative and positive predictive values were 94.7 and 100%. Overall accuracy of the method was 95.6%. Conclusions: According to previous data, status of lower jugulo-carotid LN significantly predicts the status in upper two thirds. Our results imply that SLNb in the jugulo-carotid chain using methylene blue dye mapping, is feasible and accurate method for estimating LN status in the lateral neck compartment. The method may support a decision to perform selective MRND in patients with DTC.

## P1799

**Therapeutic outcome and prognosis in young patients with papillary and follicular thyroid cancer**

J. Lin, C. Huang, T. Chao, C. Hseuh, K. Lin & S. Lin
Chang Gung Memorial Hospital, Chang Gung University, Taoyuan Hsien, Taiwan.

The aims of this study are to assess the clinical characteristics of papillary and follicular thyroid cancer in young patients. We performed a retrospective analysis of 116 patient aged 20 years who underwent thyroidectomy and a mean follow-up of $11.1 \pm 0.6$ years. There were 28 (24.1%) patients were classified into the residual cancer or relapse groups. Two of the 28 patients died of thyroid cancer. Thirteen patients who showed relapsed underwent 131I whole body scan; six of the 13 patients were diagnosed with distant metastases. Among the young patients, the 5- and 10-year progression-free survival rates were 79.1 and 73.4%, respectively. In conclusion, the progression-free survival in young patients with papillary and follicular thyroid cancer was lower than the patients of age 20–45 years; otherwise, cancer survival higher than age group over or equal 45 year-old.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

### High prevalence of BRAFV600E mutation in the papillary thyroid carcinomas in Korea by peptide nucleic acid clamp real-time PCR

S. Kim, S. Kim, M. Paik, D. Jeong, Y. Jeong, J. Lee, Y. Whangbo, H. Cho, M. Oh, S. Yang & C. Kim
Soonchunhyang University, College of Medicine, Cheonan, Republic of Korea.

Introduction
Activating somatic mutation of the BRAF gene (V600E) has been identified as the most common genetic event in papillary thyroid carcinoma (PTC) with a variable frequency (32–87%) in various races by different methods.
In this study, we report the genetic analysis of BRAF mutation in a Korean cohort of 211 PTC by peptide nucleic acid clamp real-time PCR.
Methods
PNA clamp real-time PCR was applied for BRAF analysis in 211 PTC tissues. Statistical analyses for clinicopathological findings were obtained by means of Fisher's exact test or Student *t*-test.
Results
The BRAF gene was mutated in 90% of Korean TPC. The BRAF mutation occurred at a significantly higher frequency in male patients than in female patients ($P=0.002$). Age, tumor size and tumor stages were not correlated with BRAF mutation, while lymph node metastasis ($P=0.004$) and tumor multi focality ($P=0.03$) were correlated with BRAF mutation. Extra thyroidal invasion had tendency to correlate with BRAF mutation ($P=0.058$). BRAF mutation was highly occurred in all variants of PTC.
Conclusions
The present study on the BRAF mutation in Korean PTC by PNA clamp real-time PCR shows highest prevalence ever reported, and we can confirmed that this mutation is the key role in tumorigenesis of PTC. The PNA clamp real-time PCR method for the BRAF mutation detection is very sensitive test. So it can be applicable in clinical setting as with minute amount of cells by FNA.

### Role of realtime elastography in diagnostic of thyroid cancer

D. Stoian, M. Cornianu & F. Lazar
University of Medicine and Pharmacy "V. Babes", Timisoara, Romania.

Background
The most important aspect in the diagnostic approach of thyroid nodule is identifying the malignancy. Elastography is a newly technique that measures the elasticity of tissue, after applying a external force, standardized control. US elastography is currently used in differentiation of malignant from benign lesions.
Material, Method
This prospective study included 69 patients, mean age 50.08±12.43 years, 67 females and 2 men, with thyroid nodules on conventional US, with a volume higher than 0.20 ml: a total of 107 nodules. Conventional, Doppler ultrasound and real time sonoelastography was performed with a HITACHI EUB 7500 HV machine with 6–13 MHz variable frequency linear probe, with Doppler and elastography software, with recording of frames of all lesions prospectively on color elastography color map 1 (red-yellow-green-blue color map); Hitachi Medical System, Tokyo, Japan. All patients underwent surgery after complete evaluation. Extemporaneous and postsurgical histopathological exam was performed in all cases. Tissue stiffness was scored from one (greatest elasticity) to 5 (no strain), according to the UENO scale.
Results
###27 nodules had score 1 on US elastography and 37 nodules had score 2. All nodules were benign on histopathological exam. Score 3 was found in 33 cases, 32 benign and one papillary carcinoma. Score 4 as found in 10 cases, all carcinomas. ES score of 4 is highly predictive for malignancy (sensitivity of 90.9%, specificity of 98.96%, positive predictive value of 100%, negative predictive value if 98.60%). The diagnostic quality of elastography was independent of the nodule volume.
Conclusion
US elastography has a good potential in diagnosing thyroid malignancy, independent of nodule volume, allowing the study of small nodules, less than 0.5 ml.
Predictive value of us elastography in patients with histopathological diagnostic

**Coexistence of multiple lipomatosis and differentiated thyroid cancer: more than a coincidence?**

B. Lecumberri, P. Parra, M. LLaro, J. Cárdenas, C. Álvarez-Escolá & L. Pallardo
La Paz University Hospital, Madrid, Spain.

Subcutaneous lipomas (SL) are the most common benign mesenchymal tumors with an estimated prevalence of 1%. They usually appear single, between 50–60 years of age, without gender differences. However, multiple lipomatosis (ML) occurs in 5–10% of patients, more frequently in men and almost 30% of them have family history of ML. Cytogenetic abnormalities are found in 50–80% of cases (at 12q15) and the presence of an underlying mitochondrial dysfunction has been suggested. Up to this date, there are no reports of SL/ML prevalence in patients with differentiated thyroid cancer (DTC). We have reviewed 240 patients with DTC, identified those with SL/ML and compared their features with those of the whole group. Among 194 women and 46 men (19%) with DTC, being 5% Hürthle cell carcinomas (HCC), we found 15 patients, 9 women and 6 men (40%), with ML mainly in arms, back and legs. Twelve of them (80%) referred appearance of ML in several members of their families at an early age. In the ML group there were 5 HCC (33%) (4 mixed with areas of multicentric papillary thyroid microcarcinoma), 1 multicentric mixed papillary-follicular carcinoma and 9 papillary (1 diffuse sclerosing variant, 2 microcarcinomas and 4 multicentric). Four men had suffered nonthyroid cancer (NTC): 1 seminoma, 2 melanomas and 1 colon cancer. Eleven patients had first-degree relatives with NTC mostly lung, breast and liver. Only 2 cases remained free of DTC. In our series the prevalence of ML is significantly higher than that of the general population with an increased frequency of familiar forms. When compared to the whole DTC group, ML is significantly associated with a higher rate of men, HCC, mixed forms, multicentricity and less probability of remaining free of disease (all $P<0.001$). Based on our findings ML could be considered a new bad prognostic marker in DTC.

**Thyroid follicular lesion of undetermined significance - the risk of malignancy in postendemic area**

D. Slowinska-Klencka, S. Sporny, E. Wozniak, B. Popowicz & M. Klencki
Medical University of Lodz, Lodz, Poland.

The introduction of the new classification of the thyroid FNAB results which stratifies the risk of malignancy of thyroid follicular lesions is of special interest in endemic and postendemic areas. In such regions patients with non-neoplastic nodular goitre predominate and nodules diagnosed previously as 'follicular neoplasm' showed to be thyroid cancer less frequently than in iodine-rich areas. The aim of the study was to evaluate the frequency of "follicular lesion of undetermined significance" (FLUS) diagnosis and to assess the risk of malignancy in this category in postendemic areas.

In 2010 our Department adopted six-category diagnostic approach in reporting thyroid FNAB results that was based on National Cancer Institute (NCI) recommendations. In this system aspirates from follicular lesions are classified into 2 categories: FLUS and SFN (suspicious for a follicular neoplasm). The study included 5480 patients in whom 8877 nodules were biopsied between May 2010 and November 2011.

There were 218 nodules diagnosed as FLUS (2.5%) in 203 patients, including 4 cases of the oxyphilic type. In 92 cases the follow-up was determined: 51 patients underwent control FNAB and 48 patients were treated surgically (7 patients were operated after control FNAB). The results of control FNAB showed: papillary cancers in 2 cases, lesion suspicious for papillary cancer - 1, SFN - 1, FLUS - 19 and benign lesions - 24. In 4 patients control FNAB was non-diagnostic. Histopathological examination showed papillary cancer in 4 patients (in 1 patient it was microcancer in the contralateral lobe), follicular adenoma in 4 patients, chronic thyroiditis in 3 patients and hyperplastic nodule in 37 patients. In total the thyroid cancer was found in 4.3% (4/92) of verified patients with FLUS.

In postendemic areas the incidence of thyroid cancer in the nodules diagnosed as FLUS is lower than 5–15% reported by the NCI. It suggests that such lesions should be followed up clinically without prompt surgical intervention.

## P1804

**TSH levels do not associate with the risk of papillary thyroid microcarcinoma in Korean patients**

S Kim
Chosun university hospital, Gwangju, Republic of Korea.

Background
Thyroid cancer has been increasing worldwide and became one of the most popular cancer. Recent reports have shown that an elevated thyrotropin(thyroid stimulating hormone, TSH) level is associated with risk of thyroid cancer. Nevertheless, the association between TSH level and thyroid cancer risk is not yet known in patients diagnosed with papillary thyroid microcarcinoma (PTMC).
Methods
We collected cases of 212 patients who underwent thyroid surgery and were diagnosed with PTMC between 2009 and 2011. We also investigated data from control group patients who were diagnosed with benign nodules $\leq$ 1 cm in size by US-guided fine needle aspiration. Patients who have multinodular disease, were not euthyroid or took thyroid medication were excluded.
Results
The mean age of all patients was $52.5 \pm 16.0$ years and 70.8% were women. The mean age of those with PTMC was significantly lower than that of the control group. The mean TSH level was $1.47 \pm 0.93$ mIU/L, and the mean free T4 level was $15.96 \pm 2.32$ pmol/L. There was no difference in TSH level between the PTMC and control groups ($1.49 \pm 0.93$ mIU/L vs. $1.46 \pm 0.76$ mIU/L, $P=0.93$). After adjusting for age, TSH level was not correlated with tumor size ($r=0.02$, $P=0.77$) in the PTMC group.
Conclusion
TSH levels did not differ between PTMC patients and control group. Therefore, further studies are needed to use serum TSH as a tumor marker for thyroid nodule in euthyroid patients.

**Differentiated thyroid cancer and hemodialysis: Long-term outcomes and safety after radioiodine use.**

E. Navarro Gonzalez, A. Martinez Ortega, R. Guerrero Vazquez, M. Martinez Brocca & J. Cuenca Cuenca
Virgen del Rocio Universitary Hospital, Seville, Spain.

Introduction
The use of radioiodine is a common treatment for differentiated thyroid cancer. However, special care should be exercised in treating patients who are on hemodialysis, due to the renal elimination of the radionuclide, which implies several technical difficulties and safety concerns. We have previously described the procedure and the short-term outcome and safety in three patients (Jimenez et al, Thyroid 2001; 11(11):1031–1034). Our results showed that the radioactive iodine therapy was a safe procedure in these patients. Nevertheless, that report was limited to the short-term outcome.
Objective
To determine the long-term safety and outcome in patients on hemodialysis treated with radioiodine
Methods
We conducted a retrospective descriptive study, searching our clinical record database from 2000 to 2010. Inclusion criteria: Differentiated thyroid cancer and radioiodine treatment on hemodialysis. Exclusion criteria: anaplasic thyroid cancer, medullary thyroid cancer, multiple endocrine neoplasia, peritoneal dialysis. Final sample $n=9$.

Results
All time periods are expressed as median values. Baseline characteristics: $n=5$ males, age 48 years; $n=8$ papillary thyroid cancer, $n=1$ follicular thyroid cancer; $n=5$ nodal invasion; $n=1$ metastatic disease. After 7.5 years since radioiodine treatment on hemodialysis, $n=7$ patients were deemed free of thyroid disease, while only one persisted with non-localized disease. 3.25 years after radioiodine treatment, $n=4$ patients underwent renal transplantation without complications related to the radioisotope use. The other four patients were not eligible for transplantation due to causes not related to their thyroid disease or the I131 treatment, and no changes in the evolution of their renal disease were recorded. One patient died from cardiac arrest, free of thyroid disease.
Conclusions
The radioiodine treatment in patients on hemodialysis with differentiated thyroid cancer is a safe and effective procedure at medium-long term, and allows renal transplantation without developing a higher risk of complications compared to patients which are not on hemodialysis.
Declaration of interest

## P1806

**Utility of repeated recombinant human TSH (rhTSH)-stimulated tiroglobulin (Tg) test in patients with differentiated thyroid carcinoma (DTC) without evidence of disease at their initial rh-TSH-stimulation test**

A. Oleaga, F. Goñi, M. Paja, A. Izuzquiza, C. Moreno, V. Arosa, N. Iglesias & J. Espiga
Basurto Hospital, Bilbao, Spain.

Current guidelines recommend measurement of rhTSH-stimulated Tg, with neck ultrasound 6–12 months after the initial therapy for DTC (Total thyroidectomy plus 100 mCiI131 ablation of the thyroid bed). Uncertainty persists regarding whether the subsequent follow up should be based on measurement of basal serum Tg or whether rhTSH-stimulated Tg should be performed and at what frequency. The aim of our study was to evaluate the utility of repeated rhTSH-stimulated Tg. This was a retrospective study of 40 patients; 30 female; mean age was 45.5 years (25–74); Histology: 32 Papillary, (3 follicular variant and 1 tall cell variant); 7 Follicular. Initial disease stage I $n=28$; II, $n=3$; III, $n=7$; IV, $n=2$. Mean tumor size was 2.61 cm. Pre-I131 ablation Tg levels were 7.4 ng/mL (0–29.2)(functional sensitivity 0.9 ng/mL). All of them had an undetectable rhTSH-stimulated Tg with undetectable Tg antibodies at initial evaluation. The number of repeated tests performed varied from 1 to 3 during a follow-up period of 48–132 months. (1 in $n=40$; 2 in $n=34$; 3 in $n=12$).
Tg was undetectable in all patients in the first test. In three patients Tg become detectable in the second or third: 1 patient false positive, 1 patient showed supraclavicular nodal disease (basal Tg was also detectable) and other developed lung metastases. Both patients were older than 65 years old and had at the time of diagnosis a stage III disease with extrathyroidal extension of the tumor and unfavorable histology (columnar cell).
In our patients with DTC, the first rhTSH-stimulated Tg is an excellent predictor of remission independent of clinical stage at presentation. In our experience repeated rhTSH stimulating testing was of limited value although a second negative test performed 5 years after initial treatment might assure clinical remission. Most of the patients can be followed up with basal Tg and neck ultrasound.

## P1807

**Epidemiology of refractory thyroid cancer**

D. Ancelle, A. Dalac, J. Pochart, S. Fieffé & C. Schvartz
Institut Jean Godinot, Reims, France.

Introduction
Thyroid carcinomas (TC) are rare; the incidence in the French Marne-Ardennnes thyroid registry is 10/100.000 in 2010. The 10 year survival rate is greater than 90%. Nevertheless some TC are refractory to conventional therapy.
Aim of the study
To describe frequency and clinical features of refractory TC (RTC).
Patients and methods
Retrospectiv study from the database of the registry. 1427 patients with TC were diagnosed between 01/01/1983 and 31/12/2005. We used AJCC, 6th edition. RTC included metastatic differentiated TC (DTC) refractory to radioiodine therapy, metastatic or locally advanced medullary TC (MTC), anaplastic TC (ATC).
Results
RTC represented 99/1427 (7%).
34 DTC: 2.5% of all DTC; 23 women, 11 men, mean age at diagnosis 63.5 years, mean tumor size 52.5 mm. 28/34 (82.3%) were stage pT3 or pT4 and 18/34 (52.9%) M1 at diagnosis. Classification has RTC occured after 40.8 months, mean survival was 7.8 years. 23.5% were papillary (2/18 papillary NOS, 1/18 follicular variant, 4/18 diffuse sclerosing, 1/18 columnar cell carcinoma); 53%, were follicular (1/18 minimally invasive; 5/18 widely invasive; 12/18 oxyphilic cell type) and 23.5% insular (8/34)
19 MTC: 22.6% of all MTC; 9 women, 10 men, mean age at diagnosis 59.3 years. 11/19 sporadic and 1 familial case, no genetic results for 7/19, mean tumor size 30 mm. 17/19 were stage IV. Mean survival was 4 years when they were M1 at diagnosis, 11 years for M0.
46 ATC: 33 women, 13 men, mean age at diagnosis 72.6 years, mean tumor size was 73.7 mm, 16/46 M1 at diagnosis. Mean survival was 7 month.
Conclusion
In this retrospectiv study 7% (99/1427) of all patients with TC are refractory: 34% DTC, 19% MTC and 47% ATC. 74% were diagnosed refractory at diagnosis and 26% during the follow-up. We need prospectiv epidemiological studies to confirm these preliminary results.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1808

**Glucagonlike Peptide-1 Receptor Imaging as diagnostic tool in patients with Medullary Thyroid Carcinoma (MTC) - preliminary report.**

A. Sowa-Staszczak[1], D. Pach[1], A. Jabrocka-Hybel[1], M. Tomaszuk[1], E. Przybylik-Mazurek[1], R. Mikolajczak[2], B. Janota[2] & A. Hubalewska-Dydejczyk[1]
Institute of Atomic Energy, Radioisotope Center POLATOM, Otwock-Swierk, Poland.

Introduction and aim
MTC accounts for 5–10% of all thyroid cancers. Because of elevation postoperative calcitonin, short doubling time of calcitonin and no disease in available imaging techniques in some MTC patients, searching for new targets for radioisotope diagnostics is necessary.
Among other overexpression of GLP-1 receptors have been shown on parafollicular thyroid C-cells.
The aim of this study was to present the first experiences with the use of 99mTc-labeled GLP-1 analogue in MTC imaging.
Material and method
99mTc-GLP-1 receptor scintigraphy with [Lys40(Ahx-HYNIC-99mTc/EDDA) NH2]-exendin-4 was performed in 3 patients: man 70y, dissemination of MTC (2008), qualified to PRRT, local recurrence of MTC (2011); man 74y, metastatic lesions of MTC in liver and lymph nodes (2009), qualified to PRRT, since then stabilization of disease; man 22y, with genetically confirmed MEN2a syndrome, suspicion of local recurrence after abnormal pentagastric test (2009), USG revealed hypogenic leasion with following negative biopsy result. The lyophilized kit prepared by IAE POLATOM was used for preparing the tracer. WB scans were performed at 6 time points and SPECT at 3 points. The hybrid device SPECT/CT was used for performing examinations.
Results
In the first patient, 99mTc-GLP-1 scintigraphy confirmed the recurrence of the disease. In the second patient, a pathological tracer accumulation in the liver was found. For both patients the similar images to GLP-1 scintigraphy were obtained in SRS scintigraphy. In the third patient, the GLP-1 scintigraphy showed the tracer uptake in the same place as 99mTc and 131I scans. Due to lack of other lesion localizations, the patient was qualified to surgery. In all patients no side effects after the tracer injection were observed.
Conclusion
[Lys40(Ahx-HYNIC-99mTc/EDDA)NH2]-exendin-4 seems to be an promising new tracer for clinical practice in case of MTC patients, to assess recurrence and advancement of the disease especially when standard imaging techniques failed.

## P1809

**ARG982CYS is a new variant of the RET proto-oncogene: is it a polymorphism or a transforming mutation?**

B. Cosci, A. Tacito, C. Romei, A. Vivaldi, E. Molinaro, L. Agate, A. Pinchera & R. Elisei
University of Pisa, Pisa, Italy.

In this study we describe a new allelic variant of RET, identified in a family with Medullary Thyroid Cancer (MTC) and negative for the classical RET mutations, that causes an Arg982Cys substitution in exon 18.
The "in silico" analysis has shown that this variant has a reduced compatibility [score 15] with the normal biological activity of the native protein and could therefore be a transforming mutation.
The aim of this work was to verify whether this new variant was correlated to MTC development.
The study was conducted on 6 family members, 2 affected with MTC and 4 healthy subjects, and on 172 patients with sporadic MTC. We also studied 176 healthy controls. The new RET variant was analized by direct sequencing of PCR amplified DNA.
Our data showed the presence of the Arg982Cys variant in 3 subjects of the family, including 2 healthy subjects and 1 patient with MTC. In the group of sporadic MTC tumors the Arg982Cys variant was observed in 12/172 (6.9%) cases. The allelic frequency of Arg982Cys was 3.5% (12/344). Among the 176 control subjects, 10 (5.7%) had the Arg982Cys variant and the allelic frequency was 2.8% (10/352). Comparing the allelic frequency of the Arg982Cys variant in the two groups [MTC vs. healthy subjects] no statistically significant difference was observed.
In conclusion, this study describes a new variant of RET that does not seem to be predisposing to the development of MTC but may instead be considered a true polymorphism, never described up to now. The "in silico" analysis identifies an altered biological activity of the mutant protein that could still play a pathogenic role in other diseases. It should be noted that this variant has been described in some cases associated with Undine's syndrome, which was not observed in our subjects.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1810

**Utility of the perciutaneous ethanol injection (PEI) in the treatment of metastatic adenopathies of thyroid carcinoma**

J. Santamaria, T. Ruiz de azua, R. Batanero, E. Elias, I. Martin & D. Peteiro
Hospital Cruces, Barakaldo, Spain.

Introduction
Surgery is the usual therapeutic approach for treatment of recurrent lymph node metastases due to thyroid carcinoma. However, there is no evidence of improvement in the final prognosis and is not an option without risk, especially in patients such as those who already underwent several surgeries or suffered from comorbidities.
PEI is a useful alternative for treatment of selected thyroid diseases. Here, we present our experience in patients with recurrent lymph node metastases.
Patients and methods
Patients: 24 recurrent metastatic lymphadenophaties in 8 patients, previously diagnosed of thyroid carcinoma with high risk of surgical complications. Histology: 4 medullary and 4 differentiated thyroid carcinomas.
Methods: Ethanol (0.4–1 mL) was infused inside adenopathies under ultrasonographic control. Maximum diameter and vascularisation pattern of each adenopathy, serum thyroglobulin (TG) and calcitonin (CT) were measured previously and 3 months after the injection. Time of follow-up was 3 to 31 months. Persistence of vascularisation as well as positivity of biochemical markers were criteria for repeat PEI. We defined as success criteria: adenopathy disappearence or decreased in size with absence of vascularisation and decreament of CT or TG levels.
Results
Sixteen out of 24 adenopathies disappeared or decreased in size with absence of vascularisation (two embolizations were needed in four cases).
In the rest: Six out of 8 decreased in size and are waiting for a new PEI; the other two adenopathies were in the same patient, who developed distant metastases and died before receiving any other treatment.
TG values decreased in all patients (from 82 to 100% compared with its initial value), whereas serum CT showed no change in 2 patients and decreased in the other two.
Conclusion
PEI could be considered as a useful therapeutic tool for treatment of metastatic lymphadenophaties in selected cases.

## P1811

**Genotype - phenotype correlations and timing of prophylactic thyroidectomy in patients with familial medullary thyroid carcinoma**

J. Podoba, M. Podobová, M. Grigerová, E. Weismanová & K. Závodná
St.Elizabeth Cancer Institute, Bratislava, Slovakia.

Background
Recommendations on the timing of prophylactic thyroidectomy (PTTE) in patients with familial medullary carcinoma (FMTC) are based on classification of RET mutations into four risk levels according to genotype - phenotype correlations. In clinical practice it is/was not always possible to fulfill the recommended timing of PTTE.
Objectives
To study the clinical course of FMTC patients with various RET mutations who were operated with a time delay against recommended timing.
Patients and methods
Retrospective analysis of clinical course in 42 RET mutation carriers from 12 FMTC and MEN 2A families.
Results
###25 high risk mutation carriers (codone 634) undergone an operation at the age 13–48 years. In all but one aged 13 years MTC was histologically confirmed. 30% of them continued to suffer from persistent disease after delayed operation and 70% achieved remission. One patient operated after 40 years of age died from the progression of MTC after 6 years.
###12 patients with low risk mutations (codone 618 and 620) had surgery aged between 16–60 years. In all but one aged 52 years MTC was verified. In the whole group of patients remission was achieved only in 58%.
In 3 least high risk mutation carriers (codones 791) aged 36, 40 and 42 years respectively TTE was indicated after possitive calcium stimulation test. It was completelly prophylactic, only C-cell hyperplasia was revealed.
Conclusions
Our data confirm the necessity to fulfill the guidelines on the timing of PTTE at the age of 5 years for high risk mutation (codone 634) carriers, while in least high risk mutation carriers surgery may be postponed untill an abnormal stimulation test result is observed (delay even to young adulthood). Our results in a small group of "low" risk mutation carriers (codones 618 and 620) suggest the need to be much more radical. In the case of negative results of thyroid USG and calcitonin stimulation test PTTE can be postponed no later than to the age of 10 years.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.
Funding

## P1812

**Morphology and metastatic potential of papillary thyroid carcinoma**

A. Abrosimov, S. Kozhushnaya & E. Lushnikov
Medical Radiological Research Center, Obninsk, Russian Federation.

Papillary thyroid carcinoma (PTC) is a malignant tumor of follicular cell origin that is characterized by a broad diversity of morphological features. There are 15 different histological types of PTC in the recent edition of WHO classification. Morphology of PTC is important to estimate a metastatic potential of tumor and to make an accurate prognosis of clinical behaviour.
Objective of the work is to study a relationship between frequency of regional metastasis and morphological variant of PTC, size of primary tumor and breadth of invasiveness.
Materials and methods. Histological sections, paraffin blocks and pathology reports of 325 PTCs in 322 patients (60 males and 262 females aged from 10 to 76 years) were studied. Histological typing was made in accordance with WHO classification (2004). Conventional type of PTC was subclassified into variants with and without focal tall cell component.
Results. Conventional type of PTC (86 tumors) is diagnosed in 85 patients, follicular variant - in 11, solid - in 26, encapsulated - in 7, oxyphilic type - in 4, Warthin-like - in 9, tall and columnar cell variant - in 7 cases. Conventional type of microPTC (122 tumors) is revealed in 120 patients, microcarcinoma with follicular architecture - in 25, with solid architecture - in 28 cases. Regional metastases are revealed with high frequency in PTCs of oxyphilic type (100%), tall and columnar cell (71%) and solid variants (62%); with moderate rate in PTCs of conventional (49%), follicular (45%), Warthin-like variants (44%) and microPTC of conventional type (32%); with low frequency in microPTC of solid-follicular type (11%). PTCs with regional metastasis have biger size of primary tumor and higher frequency of vascular invasion than PTCs without metastasis. MicroPTCs of conventional type with focal tall cell component are characterized by higher frequency of regional metastasis (50%) in comparison with microPTCs in patients of the same age, gender and tumor invasiveness without focal tall cell component (24%).
Conclusions. Frequency of regional metastasis is varied in different histotypes of PTC and is dependent on the size of primary tumor and vascular invasiveness. Papillary microcarcinomas of conventional type with focal tall cell component have higher metastatic potential in comparison with microcarcinomas without tall cell component in patients of the same age, gender, tumor size and invasiveness.

## P1813

**Surgical Management of Primary Thyroid Carcinoma Arising in Thyroglossal Duct Cyst**

R. Dzodic[1], I. Markovic[1], B. Stanojevic[3], V. Saenko[2], M. Buta[1], I. Djurisic[1], M. Oruci[1], Z. Milovanovic[1] & S. Yamashita[2]
Institute for Nuclear Science "Vinca, Belgrade, Serbia.

Background
Thyroid carcinoma in a thyroglossal duct cyst is very rare and surgical management is based on the individual experience.
Patients and methods
Twelve cases of primary TDC thyroid carcinoma operated in one Institution during last 25 years. Sistrunk's procedure was done in all cases followed by dissection of submental and prehyoid lymph nodes and bilateral biopsy of level 3. In the same act 11 of 12 patients underwent total thyroidectomy. In cases of synchronous thyroid gland carcinomas central neck dissection and frozen-section examination of level IV LN was done. In cases of LN involvement modified radical neck dissections (MRND) were performed.
Results
Definitive pathology revealed 11 papillary and one follicular TC in TDC. Synchronous thyroid gland carcinoma was found in 3 cases (27%). LN metastases were found in six patients (50%) MRND was done in 5 cases and central neck dissection in four cases. Radioiodine therapy was applied in five patients. All our patients are alive.
Conclusion
TDC carcinoma is essentially a thyroid carcinoma and must be treated as a primary thyroid cancer. Our results imply that TC in TDC were associated with synchronous thyroid gland carcinomas in one-third and LN metastases in half of cases Active searching for cervical metastases is highly recommended considering the high incidence of LNM in papillary thyroid carcinoma. In a lack of surgical consensus, this algorithm can be safely applied to obtain optimal radical surgery in those patients.

**Differentiation of thyroid nodules using Acoustic Radiation Force Impulse Imaging**

M. Friedrich-Rust[1], N. Dauth[1], C. Berner[1], G. Meyer[1], K. Holzer[1], F. Gruenwald[1], L. Voelkl[1], E. Herrmann[2], H. Schroeter[2], S. Zeuzem[1] & J. Bojunga[1]
Praxis-Klinik für Diagnostik (PKD) am Städel, Frankfurt, Germany.

Objective
Acoustic Radiation Force Impulse (ARFI)-Imaging is a novel ultrasound-based elastography method enabling quantitative measurement of tissue stiffness. The aim of the present study was to evaluate ARFI for the differentiation of thyroid nodules and to compare it with the well known qualitative Realtime-Elastography (RTE)
Materials and Methods
ARFI-imaging involves the mechanical excitation of tissue using short-duration acoustic pulses to generate localized displacements in tissue. The displacements result in shear-wave propagation which is tracked using ultrasonic, correlation-based methods and recorded in m/s. Inclusion criteria were: nodules $\geqq 5$ mm, non-functioning or hypo-functioning on radionuclide scanning, and cytological/histological assessment. All patients received conventional ultrasound, real-time elastography and ARFI-imaging.
Results
###129 nodules in 113 patients were available for analysis. One-hundred-fourteen nodules were benign on cytology/histology, and 15 nodules were malignant (8xpapillary carcinoma, 4xfollicular carcinoma, 3xmedullary carcinoma). The median velocity of ARFI-imaging in the healthy nodule-free thyroid gland, as well as in benign and malignant thyroid nodules was 1.74m/s (range:0.89–3.33m/s), 1.91m/s (range:0.72–3.73m/s), and 3.63m/s (range:0.80–6.83m/s), respectively. The velocity in malignant nodules was significant higher than in benign nodules ($P=0.001$). The negative predictive value of ARFI for the diagnosis of malignant thyroid nodules was 94% using a cut-off of 3.0m/s. This was comparable to RTE with a NPV of 95%.
Conclusions
ARFI can be performed in the thyroid tissue with reliable results. This novel quantitative elastography-method can be performed with negative predictive value in the diagnostic work-up of thyroid nodules.

## P1815

**Calcitonin levels in washout of cytology needle on thyroid nodule without suspicion of medullary thyroid carcinoma**

T. Martin, C. Garcia, N. Gonzalez, P. Sanchez, A. Barco, V. Martin & A. Sendon
University Hospital Virgen Macarena, Seville, Spain.

Introduction
We study the calcitonin levels measurement in the washout of FNAB needles after sampling each thyroid nodule (FNAB-CT) as an approach to calcitonin normal value in them and distinguish of MTC and to correlate with serum CT (sCT) and cytology FNAB.
Material & Methods
109 consecutive subjects (mean age $53.7 \pm 13.4$, range 18–85 yr, 79.8% females, 27.5% smokers, 18.3% autoimmune thyroid disease) initially no suspicious for MTC who underwent FNAB for thyroid nodule served as study poblation (mean size $20.1 \pm 9.3$ mm.) FNAB was performed in thyroid nodule and the same needle

and syringe used for FNAB was washed with 1 mL of % 0.9 sodium chloride solution and sent to the laboratory for calcitonin evaluation (FNAB-CT). Both serum and washout calcitonin were measured by chemiluminescence assay (IMMULITE 2000)
Results
In patients with a thyroid nodule under evaluation, sCT were $3.07 \pm 3.22$ ng/l (range 2–19.4 ng/l) and and FNAB-CT values $3.98 \pm 10.36$ ng/l (range 2–97 ng/l) , respectively. In 2 patients, FNAB-CT values were 10x higher than the highest values found, but cytology results were compatible with a benign thyroid lesion and papillary carcinoma; both were submitted to surgery found MTC (serum CT/FNAB-CT: 382/32.250 ng/ml, respectively) and microMTC/C-Cell hyperplasia (serum CT/FNAB-CT: 4.5/1.150 ng/ml, respectively) In the other cases FNAB-CT values not show significative correlation with any study parameters (age, sex, autoimmune thyroiditis, tobacco, BMI) except weakly with sCT ($r$: 0.17, $P < 0.04$).
Conclusion
Assaying calcitonin (CT) in the wash-out fluid from fine-needle aspiration biopsies (FNAB.CT) can be an additional and precocious approach to diagnosis of MTC
Values are expressed as mean $\pm$ DE and range. sCT (serum calcitonin) nCT (calcitonin in thyroid nodule FNAB-washout)

### Thyroid paraganglioma. Report of 3 cases and description of an immunohistochemical profile useful in the differential diagnosis with medullary thyroid carcinoma, based on complementary DNA array results

E. Castelblanco[1,2,3], P. Gallel[1,2,3], S. Ros[1,2,3], S. Gatius[1,2,3], J. Valls[1,2,3], A. De-Cubas[4], A. Maliszewska[4], M. Yebra-Pimentel[5], J. Menarguez[6], C. Gamallo[7], G. Opocher[8,9], M. Robledo[4,10] & X. Matias-Guiu[1,2,3]
Centro de Investigación Biomédica en red de enfermedades raras, Madrid, Spain.

Thyroid paraganglioma (TP) is a rare disorder that sometimes poses problems in differential diagnosis with medullary thyroid carcinoma (MTC). So far, differential diagnosis is solved with the help of some markers that are frequently expressed in MTC (TTF1, calcitonin, and CEA). However, some of these markers are not absolutely specific of MTC and may be expressed in other tumors. Here we report 3 new cases of TP and describe our strategy to design a diagnostic immunohistochemical battery.
First, we performed a comparative analysis of the expression profile of head and neck paragangliomas and MTC, obtained after complementary DNA array analysis of series of fresh-frozen samples of paragangliomas and MTC, respectively. Seven biomarkers showing differential expression were selected (NDUFA4L2; COXIV2; VMAT2; CGRP/calcitonin; CEA; and TTF1) for immunohistochemical analysis. Two tissue microarrays were constructed from 2 different series of paraffin-embedded samples of paragangliomas and MTC.
We provide a classifying rule for differential diagnosis that combines negativity or low staining for CGRP (histologic score, $<10$) or calcitonin (histologic score, $<50$) together with positivity of any of NDUFA4L2; COXIV2; or VMAT2 to predict paragangliomas, showing a prediction error of 0%. Finally, the immunohistochemical battery was checked in paraffin-embedded blocks from 4 examples of TP (1 previously reported case and 3 new cases), showing also a prediction error of 0% (Default 1).
Our results suggest that the comparative expression profile, obtained by complementary DNA arrays, seems to be a good tool to design immunohistochemical batteries used in differential diagnosis.

**Table 1** Summary of the main immunohistochemical results

| Antibody | TMA MTC Hscore, Mean Range | TMA PGL Hscore Mean Range | Case 1 Hscore | Case 2 Hscore | Case 3 Hscore | Case 4 Hscore |
|---|---|---|---|---|---|---|
| Anti-NDUFA4L2 | 149 (100 –206) | 215 (112 –285) | 250 | 195 | 210 | 240 |
| Anti-COXIV2 | 126 (15 – 165) | 154 (101 260) | 220 | 210 | 250 | 210 |
| Anti-VMAT2 | 83 (20 – 100) | 98 (0 – 130) | 170 | 140 | 170 | 170 |
| Anti-CGRP | 242 (70 – 296) | 0.97 (0 – 7.5) | 0 | 0 | 0 | 0 |
| Anti-calcitonin | 253 (168 – 295) | 1.7 (0 – 40) | 0 | 0 | 0 | 0 |
| Anti-TTF1 | 72 (0 – 205) | 0 (0 – 0) | 0 | 115 | 0 | 0 |
| Anti-CEA | 150 (0 – 295) | 0 (0 – 0) | 0 | 0 | 0 | 0 |

### Clinical trial of thyroid RFA for papillary microcarcinomas

N. Fukunari, M. Nakano & K. Arai
Showa University, School of Medicine, Yokohama, Japan.

The management of papillary thyroid microcarcinomas (PTMC) has been controversial and only observation without surgery has been advocated for the low-risk PTMC. Radio-frequency ablation(RFA)has been applied to thyroid nodule, which shows safe and useful results for benign thyroid nodules. In our institution, not only benign nodules, but thyroid malignancies have been attempted to be therapeutic objectives by RFA. The aim of this study is to evaluate the efficacy of RFA for primary PTMC.
Objectives
Eighty-nine cases were treated by RFA from 2007 in our institution, which consisted of 55 hyperplastic nodules, 9 AFTNs, 5 local recurrences of papillary carcinomas, 11 metastatic LNs and 9 primary PMTCs. All of 9 patients with PTMC were initial cases without the history of previous thyroid surgery or irradiation, and refused the surgery because of cosmetic and private reasons.
Methods
RFA has carried out under general or local anesthesia and under careful US imaging guidance. The equipment of 17–18G needle electrodes were applied to thyroid RFA: STARmed RF electrode (STARmed, Korea) As an intra-operative assessment for the estimation of extent of ablated area, gray-scale US, color-Doppler imaging, Elastography and contrast enhanced US were applied to judge the satisfactory ablation.
Results
All cases showed no side effect or thermal damage, and discharged after one night observation. The efficacy of RFA has been verified with both imaging diagnosis and repeated FNA. Post therapeutic FNA revealed no cancer cells remained in 8 of 9 PTMC cases.
Conclusions
The efficacy of RFA has shown satisfactory results and a possibility to be one of alternative treatments for PMTC. Long-time follow-up and careful attention for thermal damage to surrounding tissues are required.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Intraoperative calcitonin stimulation testing in an individualized surgical strategy of medullary thyroid cancer - primum non nocere**

K. Obtulovicova[1], A. Kalis[1], K. Dancova[2], M. Pura[2], P. Vanuga[2], A. Vanuga[2] & M. Sicak[1]
The National Institute of Endocrinology & Diabetology, Lubochna, Slovakia.

Context and Objectives
The prognosis of medullary thyroid carcinoma (MTC), derived from parafollicular C-cells, depends on the completeness of the first surgical treatment. The C-cells produce calcitonin, a peptid hormone that is used as biochemical and immunohistochemical tumor marker. The aim of study was to evaluate an individualized approach to patients with C-cell disease, i.e. MTC and C-cell hyperplasia (CCH), using the intraoperative calcitonin testing-assisted surgical strategy as a predictor of the final outcome after surgery.
Design
An unicentral cross-sectional study.
Patients and Methods
Since June 2009 to September 2011, sixteen patients with MTC/CCH were surgically treated primarily ($n=11$) or were reoperated for persistence of the disease ($n=5$). Depending on the result of an intraoperative calcitonin stimulation testing (iCST), patients underwent total thyroidectomy with or without lymph node dissection. All patients were tested repeatedly in postoperative period (range 2 to 27 months).
Results
The results of iCST correlated with postoperative findings - if intraoperative testing was negative, it stayed negative in postoperative follow-up period. If serum calcitonin showed increase in iCST, it persisted positive postoperatively.
Discussion
Surgical treatment is the only modality that possibly can lead to complete cure of the patient. An importance of initial operation, including total thyroidectomy and lymph node dissection of adjusting metastases including micrometastases is indubitable. The aim of the surgery is to be equally radical, avoiding an over-resection and considering complications.
Conclusions
The results encourage to use the individual approach to patients with MTC/CCH, e.g. to be less radical surgically in cases of negative iCST, and to be more radical in those patients with persistent increase of serum calcitonin. The absence of poststimulation calcitonin elevation in iCST seems to be a good prognosis indicator, but longer follow-up is needed.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Detection of novel genetic changes in the ras genes in papillary thyroid carcinoma**

V. Sykorova[1], E. Vaclavikova[1], S. Dvorakova[1], T. Halkova[1], A. Ryska[2], J. Laco[2], D. Kodetova[3], R. Kodet[3], J. Duskova[4], J. Astl[5], J. Betka[5], J. Hoch[6], J. Cap[2], P. Vlcek[6], J. Lukas[7] & B. Bendlova[1]
Na Homolce Hospital, Prague, Czech Republic.

Introduction
Activating point mutations in the RAS genes (H-RAS, K-RAS, N-RAS) are reported in thyroid tumors. The aim of this study was to determine the frequency of RAS mutations in 98 patients with thyroid tumors.
Methods
DNA was extracted from 72 fresh frozen thyroid samples and 26 paraffin-embedded formalin-fixed samples. The cohort contained 83 PTCs (56 FVPTCs, 14 mixed follicular-classical types, 11 classical variants and two other rare variants), one FTA, 7 FTCs, 4 poorly differentiated carcinomas (PDC) and 3 anaplastic carcinomas (ATC). The presence of RAS mutations in exon 1 and exon 2 of the H-RAS, K-RAS, N-RAS genes was determined by direct sequencing and detected missence RAS alterations were evaluated in silico analysis using PolyPhen-2, Align-GVGD and SIFT software.
Results
Mutations in six PTC patients was found in codon 61 of the activating domain of K-RAS (2 patients) and N-RAS genes (4 patients). The polymorphism 81T-C in H-RAS gene was found in 41% PTC, in one FTA, 3 FTC, 3 PDC and one ATC. We detected other 7 silent, 6 missence and one nonsense genetic changes. The alterations were found only in follicular variant of PTC. The association with phenotype was not apparent.
Conclusion
RAS mutations in our cohort of thyroid cancer were screened. In addition to mutations in codon 61 (GTPase domain) in six patients, we revealed other genetic changes. However, their influence on the development of PTC needs to be confirmed.

## P1820

**Elastosonographical characteristics, cytological results and histopathological features of nodules in patients with hurthle cells**

D. Tuzun[1], R. Ersoy[2], A. Kilicyazgan[1], A. Oguz[1], G. Kiyak[1], G. Guler[2] & B. Cakir[2]
Yildirim Beyazit University, Faculty of Medicine, Ankara, Turkey.

Objective
In this study, we aimed to evaluate ultrasonographical and elastosonographical characteristics, cytological results and histopathological features of nodules in patients with Hurthle cells in cytological examination and operated for various reasons.
Method:57 patients and 57 nodules detected to have Hurthle cells in thyroid fine needle aspiration biopsy (FNAB) were included in the study.
Results
Among 57 nodules with Hurthle cells in cytological examination, 49 (86%) were classified as Bethesda 1 and 8 (14%) were classified as Bethesda 3. Histopathologically, 45 (78.9%) nodules were benign and 12 (21.1%) were malignant. When nodules were grouped according to Bethesda results, nodule volume, ultrasonographic features in gray-scale and vascularization pattern were similar in two groups. There was no signicant difference in terms of elastosonographic scoring and mean strain index (SI) between groups. Elastosonography scores determined in transverse axis were found to be more predictive for malignancy compared to scores determined in longitudinal axis ($P=0.023$ and $P=0.867$, respectively). However, mean SI values in longitudinal axis were significantly higher than mean SI values in transverse axis ($P<0.05$). Hurthle cells were significantly higher in Bethesda 3 nodules compared to Bethesda 1 nodules ($P<0.01$). Cytological features were compared in histopathologically benign and malignant nodules. Nuclear groove, transgressing blood vessel (TBV) and absence of colloid were observed with a higher frequency in malignant nodules compared to benign nodules ($P<0.05$).
Conclusion
Nuclear groove, TBV and absence of colloid in cytomorphological evaluation seem to be the features that support malignancy in nodules including Hurthle cells cytologically. Higher SI values obtained during elastosonographical examination in malignant nodules compared to benign nodules suggest that SI might be used as a parameter to predict malignancy. Since malignancy rate in our patient group was 21.1%, we think total or near total thyroidectomy should be preferred in nodules with Hurthle cells in cytological examination.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector

## P1821

**Usefulness of selective sentinel lymph node biopsy in determining the surgical approach of papillary thyroid cancer**

C. Zafon, G. Obiols, O. Gonzalez, J. Fort, M. Ruiz-Marcellan, I. Roca & J. Mesa
Hospital Universitari Vall d'Hebron, Barcelona, Spain.

Introduction
Routine central lymph node dissection (CLND) in papillary thyroid carcinoma (PTC) is controversial. Selective biopsy of the sentinel lymph node (SLN) could

improve the surgical approach, as negative cases would benefit from avoiding a more aggressive technique and in positive samples a more accurate staging would be obtained.
Aim
To analyze the usefulness of SLN biopsy in the surgical treatment of PTC.
Patients and Methods
21 women and 4 men with diagnosed or suspected PTC were selected for the study. The day before surgery lymphoscintigraphy with intratumoral injection (99mTc-nanocolloid, 4 mCi, ultrasound-guided punction) was performed to obtain planar and SPECT-CT images 2–4 hours after injection. Localized SLN was biopsed with gammaprobe localization. They all underwent a total thyroidectomy and a CLND. Lateral LND was performed in the cases diagnosed as preoperative stage N1b and when a SLN was found in the lateral compartment.
Results
One case showed no drainage in lymphoscintigraphy. Nine cases (36%) had a negative biopsy for both SLN and CLND. Fourteen cases (56%) had a lateral drainage and in 4 of them (28.5%) a metastatic SLN involvement was detected. One negative SLN was reported to have micrometastases in the final biopsy.
The sensitivity of SLN biopsy was 95%.
Conclusions
SLN biopsy could be useful in staging and in surgical approach of PTC. CLND could be avoided when no SLN involvement was found and a lateral LND would be indicated in lateral SLN affected cases.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1822

**Prevalence of differentiated thyroid cancer is relevant in patiens with familial adenomatous polyposis: a case-control prospective study**

C. Diazzi[1], P. Benatti[2], L. Zirilli[1], V. Gnarini[1], B. Madeo[1], S. Romano[3], G. Rossi[2], C. Carani[1], M. Ponz de Leon[2], L. Roncucci[2] & V. Rochira[1]
Unit of Diabetology, Modena, Italy.

Introduction
Familial adenomatous polyposis (FAP) is a dominantly inherited disease characterized by colorectal adenomas, extracolonic gastrointestinal manifestations and extraintestinal diseases. Among them, differentiated thyroid cancer (DTC) is considered very frequent with an approximately risk 160 times higher than in general population, and with a prevalence of the cribriform-morular variant. As this esteem comes from scattered data, we evaluated in a prospective controlled study the prevalence of DTC in patients with FAP.
Methods
We enrolled 54 outpatients with FAP and 196 healthy subjects involved in a program of screening of thyroid diseases. All subjects underwent hormonal assay for thyroid function, ultrasonography (US) of the thyroid, fine-needle aspiration biopsy (FNAB) of all detectable nodules. Subjects with cytology suspicious for malignancy were addressed to thyroidectomy for histological verification.
Results
From the 54 FAP patients 19 (35.1%) had thyroid nodules: 2 (3.7%; mean age 34.05 ± SD 13.77 yrs) had a confirmed diagnosis of papillary thyroid carcinoma. From the 196 subjects of the control group 97 (49.4%) had thyroid nodules and 2 had a diagnosis of DTC (1%; mean age 48.17 ± SD 0.12 yrs).
Conclusion
Thyroid nodules is a common disease in patients with FAP (35.1%), as it is in the general population and in the control group of this study (49.4%). The prevalence of DTC was higher in FAP than in the control group and speak in favor of screening patients with FAP for thyroid cancer. The mean age at the time of the diagnosis of thyroid cancer in patients with FAP was lower than in the general population. These data confirm a possible correlation between FAP and DTC, suggesting the importance of a careful follow-up of thyroid lesions in these patients, even at young age.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1823

**The role of serum levels of selenium, superoxide dismutase, catalase and thiobarbituric acid reactive substances in the association between Hashimoto's thyroiditis and papillary thyroid cancer**

F. Kilicli, H. Dokmetas, Y. Tutar & F. Acibucu
Cumhuriyet University, Sivas, Turkey.

Introduction
Hashimoto's thyroiditis can be accompanied by thyroid cancer. It is reported that there is an association between selenium deficiency and thyroid cancer. In addition, it is known that chronic inflammation is another causal factor in the etiology of cancer.
In this study, we aimed to determine whether selenium or oxidative stress is a modifying factor for the association between Hashimoto's thyroiditis and cancer.
Methods
As indicators of lipid peroxidation and oxidative stress that occur during the course of these diseases, we determined the serum levels of thiobarbituric acid reactive substances (TBARS) as well as those of selenium and the activities of catalase and superoxide dismutase (SOD). We divided the subjects into 3 groups as follows: 20 subjects with papillary cancer plus Hashimoto's thyroiditis (1st group), 20 subjects with Hashimoto's thyroiditis alone (2nd group), and the subjects with papillary cancer without Hashimoto's thyroiditis (3rd group).
Results
Levels of selenium, SOD, catalase and TBARS were measured in serum. Selenium levels were 73.0 ± 3.83 μg/l in the 1st group, 65.0 ± 3.22 μg/l in the 2nd group and 68.1 ± 4.62 μg/l in the 3rd group. SOD levels were 0.27 ± 0.01 U/ml in the 1st group, 0.25 ± 0.02 U/ml in the 2nd group and 0.29 ± 0.01 U/ml in the 3rd group. Catalase levels were 47.34 ± 6.64 nmol/min/ml in the 1st group, 43.34 ± 5.13 nmol/min/ml in the 2nd group and 30.78 ± 4.73 nmol/min/ml in the 3rd group. TBARS levels were 8.2 ± 3.0 nmol/ml in the 1st group, 7.5 ± 0.86 nmol/ml in the 2nd group and 5.55 ± 1.01 nmol/ml in the 3rd group.
Conclusions
Antioxidants such as selenium, SOD, catalase and oxidative stress due to chronic inflammation were not found to be associated with the progression to papillary thyroid cancer in patients with Hashimoto's thyroiditis.
Serum selenium, SOD, catalase, TBARS levels of the patient groups.

**Iodine-131 lung uptake in bronchiectasis: a potential pitfall in the follow up of differentiated thyroid carcinoma (DTC)**

V. Triggiani[1], V. Giagulli[2], E. Tafaro[1] & E. Guastamacchia[1]
O.U. Metabolic Diseases and Endocrinology, P.O. Monopoli-Conversano, Bari, Italy.

DTC carries a good prognosis when adequately treated by means of total thyroidectomy, iodine-131 (I-131) treatment and TSH-suppressive therapy, and carefully followed up (i.e. serum thyroglobulin, I-131 total). In some cases, however, false-positive scans can occur. A 42-yr-old woman with recurrent chest infections and bronchiectasis was submitted to total thyroidectomy because of a13 mm nodule in the right lobe that showed a papillary thyroid carcinoma at FNAB histological examination. The patient was then submitted to I-131 treatment with 3700 MBq after L-thyroxine withdrawal. The post therapeutic dose total body scan showed a residual iodine uptake in the thyroid bed attributable to thyroid remnant, compatible with the thyroglobulin serum level (tg = 6.49 ng/ml), and a low bilateral uptake in the lung fields. A I-131 total body scan (185 MBq) following recombinant (rh)-TSH administration four months after the therapeutic dose of radioiodine showed a marked and diffuse uptake in the lungs with tg levels below the detection levels. A CT of the chest confirmed the bronchiectasis appearance of the bronchial tree. No further therapeutic dose of

radioiodine was administered and the patient was followed up with periodic serum tg level determination during TSH suppressive treatment and neck echographic evaluation. Two years later, another I-131 scan (rh-TSH) showed the same picture of diffuse uptake of radioiodine in the lungs, with undetectable stimulated serum tg, while CT of the chest confirmed the presence of bronchiectasies with no other lesions referable to metastatic involvement of the lungs. This case claim attention about the possible false-positive results of I-131 scan in DTC follow up in patients affected by infective and inflammatory diseases of the lungs, emphasizing the importance of interpreting the I-131 uptake on the bases of clinical context, imaging and laboratory findings (serum tg). Recognition of false-positive cases permit to avoid further radioiodine therapeutic doses administrations that are not indicated and potentially associated by side-effects (sialadenitis, gastritis, other malignancies, and pulmonary disease with lung fibrosis). and that can cause an emotional trauma for the patient, often leading to legal controversies.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

**Prognostic markers in Papillary Thyroid Cancer by immunohistochemistry**

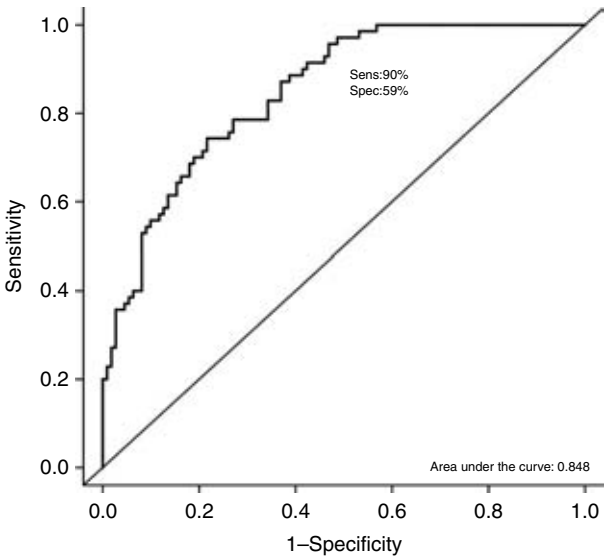
E. Castelblanco[1,2,3], P. Gallel[1,2,3], M. Martinez[3], L. Barrera[1], I. Capel[4], P. Moreno[5], G. Giménez[6], M. Puig-Domingo[7], R. Bella[4], M. Porta[8], I. Halperín[8], S. López[1,3], R. Orellana[4], J. Cameselle[9], X. Matias-Guiu[1,2,3], D. Mauricio[1,2,3], M. Robledo[10] & J. Maravall[1,2,3]

Centro Nacional de Investigaciones Oncológicas, Madrid, Spain.

Papillary thyroid cancer (PTC) is the most common endocrine malignancy. Its management has not changed significantly in recent decades, and most patients receive the same treatment. Moreover, there are not alternative treatments for low response or aggressive neoplasias. The availability of reliable prognostic markers that would allow the PTC to be identified based on their aggressiveness at the time of diagnosis would derive in an individualized treatment. In a previous study, our group identified a transcript profile by DNA microarray that allows a prognostic classification with an accuracy level of 95% over its evolution. The current study aimed to establish an immunohistochemical profile to help determine the prognosis of evolution of the PTC

Materials and methods

We have performed Tissue Microarrays immunohistochemistry in a large series of 184 cases of PTC, clinically well characterized, with 17 antibodies (Ab) against proteins encoded by some of the genes identified in our previous study. For statistical analysis, we used the intra-individual mean obtained from four experimental replicates to measure Ab expression. We used the Mann-Whitney U to compare the values of the histoscore group as defined by the prognosis, and adjusted logistic regression model to identify those that contribute significantly to explain tumor poor prognosis



Results

Preliminary analysis of the samples showed differences between groups defined according to forecasts for 12 Ab. The multivariate logistic regression model to explain and distinguish poor from good prognosis showed that five Ab achieved an area under the curve of 0.85 [0.79, 0.90] and an optimal cut-off levels of sensitivity of 90% and specificity of 59%

Conclusions

The preliminary results provide promising results for differentiating good and poor prognosis of PTC. The combination of Ab identified may contribute to the prognostic stratification of PTC (with potential clinical applications)

**Cytological thyroid: comparison (intra and interobserver) of results issued by pathologists with different skills of experience**

N. Carvalho, O. Zocratto, A. Rodrigues & T. Nascimento

Universidade Federal de Ouro Preto, Ouro Preto, Brazil.

The wide variability of analysis obtained from the fine needle aspiration cytology (FNAC) of thyroid nodules is attributed to experience differences in their interpretation. It is known that reproducibility is a critical parameter for the clinical usefulness of a diagnostic test. However, interobserver and intraobserver reproducibility of cytological examinations of the thyroid has been very little investigated. We studied 74 patients who underwent FNAC and a thyroidectomy. The examinations were reviewed by two pathologists, one experienced and one novice. Interpretations of the smears occurred on two separate occasions, with a time interval of six months between the first and second. The results revealed consistent intraobserver reproducibility after a lapse of six months, both for the experienced pathologist (K = 0.82 [0.71 to 0.94], Kw = 0.79, $P = 0.988$) and for the novice (K = 0.78 [0.64 to 0.91], Kw = 0.71, $P = 0.291$). There was no difference for the experienced and novice pathologist, respectively, in terms of rate for insufficient material, follicular neoplasm (FN), false-positive, false-negative and proportion of malignant tumors identified. The analysis of interobserver reproducibility showed a significant difference in both the first analysis (K = 0.55 [0.38 to 0.72], Kw = 0.50, $P = 0.011$) and the second (K = 0.54 [0.37 to 0.71], Kw = 0.44, $P = 0.021$). There was also a difference in the number of unsatisfactory results in both the first ($P = 0.001$) and second ($P = 0.021$) examination and FN in the second analysis ($P = 0.015$). However, there was no difference in the first and the second analysis, respectively, in terms of proportion of malignant tumors identified, false-positive and false-negative. The intraobserver reproducibility in the interpretation of FNAC is consistent and independent of experience to the examination, however, interobserver reliability is influenced. Examiner experience significantly influences the proportion of unsatisfactory results and cases compatible with FN. Surgical thyroidectomy should take into account the high rate of false-negative results, which occurs even when performed by an experienced pathologist, as well as the high rate of unsatisfactory results, mainly due to the high rate of malignancy observed in these samples.

**Follicular Neoplasms: Clinical, Sonographic and Cytological Determinants and its Histological Correlation**

J. Couto, R. Martins, A. Santos, P. Monteiro & I. Torres

Portuguese Institute of Oncology of Porto, Porto, Portugal.

Introduction

Fine-needle biopsy(FNB) is an essential diagnostic tool in the evaluation of thyroid nodules, however, follicular neoplasm(FN) does not exclude malignancy. Some sonographic and cytological features have been described as being associated with increased risk of malignancy. The authors aimed to identify

demographic, sonographic and cytologic features associated with malignancy in patients with a cytological diagnosis of FN.
Methods
Descriptive study of all patients(pts) with a cytological result compatible with FN, who underwent thyroid surgery at our institution in 2010. Gender, age, nodule size, TSH, sonographic and cytological features were recorded. Statistical analysis was performed with SPSS, v.17.0, using chi-square and Mann-Whitney tests.
Results
78 pts, 58 F(74%), 20 M(26%), mean age 48.5±14.7 years(22–79). FN: 69 patients (88.5%), Hurthle cell neoplasm: 9 patients(11.5%). Average nodule diameter: 25.2 mm(8–81). Single nodule: 48 pts(61.5%), multinodular goiter: 30 pts(38.5%). Histology: 12 pts with malignant lesions(15.4%) - papillary carcinoma:9 pts, follicular carcinoma: 2 pts, medullary carcinoma: 1 pt; 64 pts with benign lesions(82.1%) - follicular adenoma(including Hurthle cell): 47 pts(60.2%), nodular hyperplasia: 17 pts(21.8%), well-differentiated tumor of uncertain malignant potential (WDTUMP): 2 pts(2.6%). Incidental histological findings: papillary microcarcinoma(MP): 12 pts(15.4%), WDTUMP: 1 pt(2.6%). The average age of patients with malignant lesions was lower than the group with a benign histology(37.7±12.5 vs. 50.0±14.3), $P=0.007$. No statistically significant differences were found between malignancy and sonographic characteristics(eg size, echogenicity, texture, peripheral halo, borders, micro-calcifications), cytological features and TSH.
Discussion
The retrospective nature of the study, the size and heterogeneity of the sample and the limited description of sonographic and cytological features were important limitations. The significantly lower age of pts with malignant disease may indicate the need for a more aggressive approach. Future studies will be necessary towards the confirmation of these results.
Declaration of interest

## P1828

**Ultrasoundelastography: a useful tool to differentiate benign and malignant thyroid nodules?**

V. Congedo[1], A. Franchi[1], G. Fiore[1], G. Raggiunti[1], M. Di Nicola[2], E. Ballone[2] & B. Raggiunti[1]
G.d'Annunzio University, Chieti, Italy.

Introduction
Ultrasoundelastography (USE) evaluates the tissue elasticity according to the local tissue displacement after a small compression applied by an ultrasound transducer. This technique is based on the concept that a hard lesion is associated to a higher risk of malignancy. The USE has been recently applied for characterization of thyroid nodules. The aim of our preliminary study was to assess the validity of USE for screening benign and malignant thyroid nodules.
Methods
This preliminary study includes 57 thyroid nodules in 39 patients (32 females and 7 males, mean age: 52±11 years old) who were referred to the Endocrinological Unit at Atri hospital consecutively from March to December 2011. All nodules were examined using ultrasonography, USE and fine needle aspiration cytology. Nodules with cystic pattern or Thy 1 cytology were excluded. USE results were classified on the basis of the degree and the distribution of elasticity in 5 patterns: 1, 2, 3a, 3b and 4. All nodules were defined as benign or malignant on the basis of histological results.
Results and conclusions
The histological results revealed 50 benign nodules and 7 malignant lesions. The chi squared test showed that the association between the USE pattern and the histological definition tends to be statistically significant. In fact, USE pattern 4 was associated to a malignant lesion in 67% of the cases. In addition, the association with malignancy was found in 2% of the cases for the pattern 2, in 14% for pattern 3a and 8% for pattern 3b. However, a validation of these results might be obtained only by increasing our sample size.

## P1829

**Differentiated Thyroid Cancer in Diabetic Patients**

S. Akin, S. Akin, J. Karakaya & N. Gulcelik
Hacettepe Medical School, Ankara, Turkey.

Objective
Patients with differentiated thyroid carcinoma have an increased prevalence of insulin resistance and, diabetes increases the risk of thyroid cancer. In this study we aimed to evaluate tumor features in diabetic and non-diabetic differentiated thyroid cancer patients.
Methods
One hundred patients with differentiated thyroid cancer were enrolled in the study. Twenty one of the 100 patients were diagnosed as diabetic and 79 non-diabetic. All participants underwent a physical examination, detailed history and anthropometric measurements including BMI, waist to hip ratio and blood pressure. The characteristics of the thyroid cancer-histology, tumor size, tumor invasion, nodal and distant metastasis, radioiodine treatment and thyroglobulin levels were measured.
Results
Weight and waist-to-hip ratio were higher in diabetic patients compared to non-diabetic patients. Thyroglobulin levels were lower in diabetic subjects ($P<0.05$). We observed no significant difference between diabetic and non-diabetic patients in respect for age, gender, TSH levels, tumor invasion, nodal metastasis and persistant disease. The differences in risk by groups for the papillary and folicular types were not significant ($P=0.888$).
Conclusion
Although diabetes has been associated with increased risk of thyroid cancer, presence of diabetes was found not to be associated with more aggressive tumor features.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1830

**Diagnostic value of thyroglobulin and antithyroglobulin antibody in the early follow-up of well differentiated thyroid carcinoma**

A. Kowalczyk[1] & P. Kowalczyk[2]
Medical University of Warsaw, Warsaw, Poland.

Objectives
Thyroglobulin (Tg) play an important role in managements of well-differentiated thyroid carcinoma (DTC). Undetectable TSH-stimulated serum Tg level in the absence of antithyroglobulin antibody (AbTg) indicates complete remission. Circulating AbTg may interfere with Tg assay and may cause false negative results. Moreover, undetectable Tg is observed in a part of patients after total thyroidectomy(TT), even if serum AbTg concentration is low.
The aim of our study was to evaluate a clinical significance of Tg and AbTg levels measured before and 6-12 month after thyroid ablation.
Materials and methods.
329 patients after TT because of DTC were treated with radioiodine(RIT). Diagnostic procedures - including whole-body scan (WBS) and measurements of Tg and AbTg levels were performed before and 6–12 month after 131I administration. Finally, we analyzed the subgroup of 104 patients, who had: 1) no evidence of distant metastases, 2) undetectable Tg (<1ng/ml) and/or elevated level of AbTg (>60U/ml) before RIT 3) complete data for study variables.
Results.
Among the 329 patients, 143 (43.5%) had elevated (↑) Tg and normal (n) AbTg level, 32 (9.7%) - Tg(↑) and AbTg(↑), 109 (33.1%) - Tg(n) and AbTg(n), 45 (13.7%) - Tg(n) and AbTg(↑)
Our group of 104 patients included
16 patients - Tg(↑) and AbTg(↑)
66 patients - Tg(n) and AbTg(n)
22 patients - Tg(n) and AbTg(↑)
6–12 months after 131I therapy, all these patients had undetectable Tg level. Among 38 patients with AbTg(↑) previously, 21 (55.3%) had AbTg (n)- subgroup A, 9 (23.7%) - AbTg decreased, but were still elevated- subgroup B, 5 (13.2%) - AbTg on the same level - subgroup C and 3 (7.9%) - AbTg increased - subgroup D. Diagnostic WBC was positive (persistent thyroid bed uptake) in 11/38 patients: 6 in A, 3 in B, 1 in C and 1 in subgroup D.
In the rest of 66 patients /(Tg(↑) and AbTg(↑) WBS was positive in 6.

Conclusions
In more than 50% of patients with DTC serum Tg concentration could not be used as an indicator of the effectiveness of thyroid ablation - because of coexistence of AbTg or/and undetectable level of Tg before treatment. WBS provides more important information and should be routinely used in early follow-up of patients after thyroid ablation.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1831

**Prostate and bladder metastasis of Medullary Thyroid Carcinoma**

S. Maqdasy[1,2], M. Batisse-Lignier[1,2], N. Costes-Chalret[1], J. Boiteux[1], B. Roche[1], P. Chollet[3], I. Tauveron[1,2] & P. Thieblot[1]
Centre Jean Perrin, Clermont Université, Clermont-Ferrand, France.

Introduction
Medullary thyroid carcinoma MTC represents 5% of all thyroid cancers. It is familial in 30% of the cases. The most frequent metastatic localizations are lymph nodes, liver, lung and bone. We describe prostatic and vesical localizations of a MTC in a patient with multiple endocrine neoplasia (MEN 2B).
Case report
A 44 years old patient with MEN 2B operated in 1989 for MTC, bilateral pheochromocytoma and had a cutanuous neurofibroma. He presented with persistent dysuria and abdominopelvic pain with testicular irradiation. Computed tomography detected a heterogeneously enlarged prostate and another mass at left uretero-vesical junction. Histopathological study after a radical operation in 2009 confirms the existence of a neuroendocrine tumor (NET) with positive immunostaining to chromogranin A, synaptophysine and calcitonine. Re-analysis of the two lesions with the previous thyroid slides confirms the identity of a MTC with its metastatic lesions. Serum calcitonin declined postoperatively from 233 to 65 pg/ml.
Discussion and conclusion
Few metastatic localizations of NET in the prostate are described. Calcitonin positive prostatic tumor is reported in the literature. It might be an indicative of either a MTC or a NET, as calcitonin immunostaining is possible in a normal endocrine tissue of the prostate. Bladder localizations are never documented. Absence of a primary NET, bladder localization devoid of prostatic tissue and improvement of elevated calcitonin levels in our patient make us to consider these localizations as metastatic lesions of MTC rather than a NET of prostate.
Elevated neuroendocrine markers with unexplained chronic urinary tract symptoms and/or a prostatic tumor in young patients in the context of a NET should evoke a NE localization. Neuroendocrine immunohisochemical staining should be done to line out the management of these rare tumors, as the prognosis of a MTC, primary prostatic adenocarcinoma or a NET is not identical.

## P1832

**Role of FGR2 in thyroid tumor progression and their involement in the correlation between thyroid cancer and melanoma**

P. Grilli, C. D'Ercole, S. Federici, A. Giannella, S. Ceccarelli & C. Marchese
Sapienza Università di Roma, Roma, Italy.

Thyroid cancer is the most common endocrine malignancy. It is known that cancer progression involve dysregulation of growth factors (FGFs) and their receptors (FGFRs) have been identified. In thyroid tumors. In particular, FGFR1 and FGFR3 are expressed in most well differenziated tumors, FGFR4 is predominantly expressed in aggressive tumor types and cells lines, while FGFR2 is the only receptor consistently detected in normal human thyroid tissue and its expression is downmodulated in thyroid cancers and carcinoma cells lines.
The study is conduced on a series of 7963 patient undergoing t.t. in the Department of Surgical Science, Policlinico Umberto I, Sapienza University of Rome, from 1996 to 2011of these patients 1391 had a diagnosis of thyroid cancer.The aim of the study is the evaluation of a possible correlation between FGFR2 expression and progression/prognosis of thyroid cancer, analyzing FGFR2 downregulation in normal thyrocytes, in term of proliferation, differentiation, apoptosis and expression of tumoral markers.
Recent studies have identified an association between cutaneous malignant and thyroid carcinoma. Molecular studies show that TSHR is expressed by cutaneous melanocytic lesions, with higher expression in malignant and premalignant lesions, and that cultured melanoma cells, but not melanocytes, are induced to proliferate by TSH; this suggests that hypothyroidism may promote the development and progression of melanoma.
We will set up a retrospective analysis of FGFR2 expression in patients with thyroid carcinoma that have successively developed a melanoma or vice versa, in order to identify differences in FGFR2 expression in "double positive" patients versus patients affected by only thyroid cancer or melanoma.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1833

**Clinical and Pathological Features of Pediatric Thyroid Carcinoma**

A. Brehar, A. Bulgar, C. Procopiuc, C. Dumitrescu, D. Paun, I. Gherlan, D. Ioachim, M. Ghemigian, B. Stanescu, M. Ionescu, D. Brasoveanu, A. Goldstein, M. Belgun & C. Dumitrache
"C. I. Parhon" National Institute of Endocrinology, Bucharest, Romania.

Introduction
Thyroid cancer in childhood and adolescence represents 1.5–3% of all carcinomas in this group of age. Our purpose is to define clinical and pathological features, therapeutical complications and follow-up characteristics and survival of a group of children and adolescents with thyroid carcinomas.
Design
We report a retrospective study of 26 children and adolescents with thyroid carcinoma who were investigated in our institution from January 2007 till July 2011. The study followed: historical data, clinical examination, hormonal profile, imaging, histological examination, side effects of therapeutic interventions, the locoregional/distant recurrence.
Results
There were 23 girls and 3 boys in our group. The average age at diagnosis was 14.9 years (15.1 years for girls and 13.33 years for boys). At the time of diagnosis 8 patients presented with unique nodule, 13 patients with nodule with laterocevical lymphadenopathy and 5 patients had multinodular goiter. The treatment applied was total thyroidectomy followed by radioiodine therapy. There was one case of persistent hipoparathyroidism and no other significant post-operative/radioiodine therapy were observed and no patients died from disease. Histological examination revealed papillary differentiated thyroid carcinoma: diffuse sclerosing papillary thyroid carcinoma and follicular variant were the subtypes observed. 30% of patients presented a tumor size between 3 cm and 4 cm. The involvement of thyroid capsule and surrounding tissue was observed in 40% of cases and multicentricity was described in 20% of cases. Postoperative surveillance was done by clinical examination, imaging and repeated dosing of thyroglobulin and antitireoglobuline antibodies. 4 patients exhibited local recurrence.
Conclusions
Compare with adult DTC, the pediatric DTC has an aggressive behavior at presentation, a higher risk of recurrences and a risk of induction of a secondary solid tumor after iodine therapy in later life, which require an improved protocol of treatment and follow-up.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

This research did not receive any specific grant from any funding agency in the public, commercial or not-for-profit sector

## P1834

**Malignancy rate of thyroid nodules which defined as follicular lesion of undetermined significance in thyroid cytopathology**

N. Cuhaci[1], R. Ucler[1], D. Arpaci[1], S. Akbaba[1], S. Yalcin[2], G. Kiyak[1], G. Guler[2], R. Ersoy[2] & B. Cakir[2]
Yildirim Beyazit University, Faculty of Medicine, Ankara, Turkey.

Objective
In the Bethesda classification (BC), which is used in cytopathologic evaluation of thyroid nodules, follicular lesion of undetermined significance (FLUS) does not involve sufficient cellular atypia for follicular neoplasia or malignancy, while it doesn't comprise the cytologic benign criteria. Therefore, there is no consensus for those nodules to follow-up and therapeutic approaches. In this study, we aimed to determine the ultrasonographic features and histopathologic results of the thyroid nodules which are defined FLUS in BC.
Methods
We evaluated 64 nodules of 62 patients, who have nodular or multinodular goiter and had diagnosed FLUS at least in one nodule with fine-needle aspiration (FNA). Operation indication was decided upon to the nodule size, suspected ultrasonographic feature (border irregularity, solid, hypoechoic nodule, presence of microcalcification), high elastosonographic score and strain index and family history of thyroid cancer.
Results
###87.5% of patients were female, 12.5% were male. Mean age was $46.5 \pm 12.6$ years. 51.6% of nodules were located in the right lobe, 45.3% in the left and 3.1% in the isthmus. According to the echogenite and component 43.8% of nodules were hypoechoic, and 57.8% were solid. Microcalcification, peripheral vascularization and border irregularity positivity was respectively 25.5%, 17.2% and 59.4% of nodules. After operation, 68.7% of nodules were benign ($n=44$), 31.3% ($n=20$) were malign. 85% of malign nodules were papiller thyroid carcinoma, 15% were follicular carcinoma.
Conclusion
In our study, we found malignancy rate 31.3% in FLUS compared to the 5–20% reported by different studies. Therefore, we think that, in the diagnostic and therapeutic approach of the FLUS nodules that challenge the clinician, this high ratio of malignancy must be kept in mind.

## P1835

**Appearance of secondary primary malignancies in patients with differentiated tumours of the thyroid gland**

K. Sepp, Z. Valkusz, M. Nagy, C. Csajbók, S. Magony, J. Julesz & T. Wittmann
First Department of Internal Medicine, Szeged, Hungary.

Introduction
thyroid carcinoma is an uncommon malignancy, but it's incidence appears to be increasing slowly (female 2–3.8/100.000 - male 1.2–2.6/100.000). This is the most common malignant endocrine tumour, represents about 1% of all malignancies. The majority of these patients females, mostly between the age of 30–60. The main differentiated histological types are papillary and follicular. The options of the treatment are surgical removal (mainly total), radioiodine therapy (ablation/repeated) and very rarely external beam radiotherapy, chemotherapy. The follow up of the patients are very important (postoperative levothyroxin therapy - TSH suppression and substitution, laboratory - thyroglobulin and thyroglobulin antibodies, ultrasonography).
Method and material
###341 patients are followed up with differentiated tumor of the thyroid gland at our Endocrinology Clinic continously. As they are regularly controlled, a lot of data are available to screen the patients.
Results
###8% of the patients had a secondary tumour (secondary primary malignancies), 25 female - 2 male case. The types of the tumours: breast, endometrium, cervix, skin, central nervous system, gastrointestinal tract. 60% of the patients the tumour of the thyroid gland was the first (50% breast cancer was the second tumour, averagely 16 years later than the thyroid), 22% of the patients the thyroid carcinoma was the second tumour (50% breast cancer was the first, followed averagely 7 years later by the thyroid), 18% of the patients unknown the order.
Conclusion
our data confirms that patients with thyroid gland tumours show a higher incidence of secondary malignancies. It emphasizes the role and importance of a follow up screening of the patients for a second malignancy. Furthermore we plan to investigate the oncogenetic background of these tumours.
Declaration of interest

## P1836

**Histological features of thyroid cancer in childhood and adolescence**

A Chrisoulidou, T. Vasileiadis, P. Iliadou, P. Mitsakis, L. Mathiopoulou, S. Mandanas, M. Boudina, K. Tziomalos, K. Michalakis & K. Pazaitou-Panayiotou
Theagenio Hospital, Thessaloniki, Greece.

Introduction Thyroid cancer (TC) is rare in childhood. The aim of the present study was to describe the tumoral characteristics of children and adolescents with TC and to investigate the frequency of microcarcinomas in that population.
Methods We studied the medical records of 101 children and adolescents ($\leq$ 21 years-old) who were diagnosed with TC between January 1977 and December 2011 in Theagenio Cancer Hospital. The following characteristics were recorded for each patient: year of diagnosis, patient's age and gender, histological type, tumor size, number of tumor foci, presence of: lymph node metastases, thyroid capsule invasion, vascular invasion and infiltration of the thyroid parenchyma or surrounding soft tissues. Microcarcinomas were defined as unifocal intrathyroidal papillary cancers $\leq$10 mm in diameter without lymph node involvement.
Results Tumor size was larger in patients with follicular, medullary and poorly differentiated thyroid cancer ($33.5 \pm 10.7$, $35.7 \pm 22.3$ and $32.7 \pm 21.9$ mm, respectively; $P<0.05$). Vascular invasion was more frequent in patients with follicular and poorly differentiated thyroid cancer (66.7% in both types; $P<0.005$). Patients older than 18 years showed infiltration of the thyroid parenchyma and the surrounding soft tissues less frequently than younger patients (42.4 vs. 64.3%, $P<0.05$ and 15.3 vs. 35.7% respectively, $P<0.05$). Other characteristics did not differ between patients older and younger than 18 years. There was no difference in any of the characteristics at diagnosis between males and females, or between the age groups $\leq$ 14, 15–18 and $>$ 18 years-old. Among the 89 patients with papillary TC and their variants, tumors $\leq$ 10 mm were present in 30 (33.7%) and microcarcinomas were present in 12 patients (13.5%).
Conclusions TC in children has more invasive characteristics than adolescents. 20.2% of patients had small ($\leq$ 10 mm) but invasive tumors. True microcarcinomas (13.5%) represent a minority of thyroid tumors.

## P1837

**A novel tandem germline RET mutations on the same allele in a patient with MEN 2B**

K. Nakao, T. Usui, M. Ikeda, Y. Mori, S. Kawashima, K. Nanba, T. Tamanaha, T. Tagami, M. Naruse, T. Yamamoto & A. Shimatsu
National Hospital Organization Kyoto Medical Center, Kyoto, Japan.

Multiple endocrine neoplasia type2 (MEN 2) (OMIM 171400) is an autosomal dominant inherited cancer syndrome caused by activating mutations in the RET proto-oncogene. MEN 2 is classified into three subtypes: MEN 2A, MEN 2B and familial medullary thyroid carcinoma(FMTC). MEN 2B accounts for 5–10% of MEN2 cases. More than 95% of MEN 2B patients carry M918T mutation of RET, and 2–3% harbor A883F mutation. There has been three reports of cases with MEN 2B phenotype caused by double RET missense mutations of codons 805], 806and 904 in cis with V804M mutation. The V804M/Y806C mutations were the first case reported in a patient with MEN 2B like phenotype, functional tests of which suggest that the transforming activity of this double mutation was similar to that of the M918T defect.

Clinical case
A 32-year-old female presented with neck mass. She had had bumpy lips and multiple nodules on her lips, tongue, buccal mucosa and conjunctiva since childhood, but besides that she had been in good health. There was no family history of endocrine diseases. Fine-needle aspiration biopsy showed the characters of medullary cell carcinoma of the thyroid with lymphmetastasis. Histopathological examination of the buccal mucosa nodule showed multiple dermal nodules which was diagnosed as schwanoma. The serum calcitonin level was 6080pg/ml, and caricinoembryonic antigen levels was 435.2ng/ml. A total thyroidectomy was performed with central and right radical neck lymph node dissection.
Mutation analysis of the RET gene
The proband's genomic DNA was extracted from the blood samples and was screened for mutations in exons 10, 11, and 13–16 of the RET gene by the PCR-direct sequencing analysis. We detected two heterozygous missense mutations V804M and Q781R. Subcloning analysis of the gene revealed that the both mutations were present on the same allele. The genotype of her parents were examined under their informed consent. Q781R mutation was found in her father, and no mutation was found in her mother.
Discussion
We have identified a novel combination of RET missense mutation, V804M and Q781R. Subclone analysis had demonstrated that the de novo V804M mutation is on the paternal allele. Although several double mutation cases have been reported to cause MEN2B, the combination of the present case has not been reported.

**Comparative examination of somatic oncogene mutation normal and pathologic thyroid tissues of Hungarian patients**

B Tobiás, B. Balla, J. Kósa, J. Horányi, I. Takács, E. Bölöny, C. Halászlaki, Z. Nagy, G. Speer, B. Járay, E. Székely, R. Istók & P. Lakatos
Semmelweis University, Budapest, Hungary.

It is established that somatic oncogene mutation (BRAF, NRAS, HRAS, KRAS) and gene translocations (RET/PTC, PAX8/PPAR-gamma) are associated with the development of thyroid cancer. Somatic single nucleotide polymorphisms were analyzed by LigthCycler melting method, while translocations were identified by real-time polymerase chain reaction technique. In 22 intraoperative thyroid tissue samples (11 pathologic and 11 normal). In tumorous sample 3 BRAF, 2 NRAS and one HRAS mutations were found, as well as one RET/PTC1 translocation. These results confirm international data. These oncogene mutations and translocations are linked to thyroid cancer. Cytological examination completed with genetic data may support the diagnosis of thyroid malignancies. In addition, genetic alterations may indicate malignant transformation and may become prognostic factors in future.

**Thyroid Metastasis of Clear Cell Renal Carcinoma**

B. Olivares, S. Piana, F. Grau, & R. Valcavi
Arcispedale Santa Maria Nuova, Reggio Emilia, Italy.

The clear cell renal carcinoma (CCRC) is the best known primary site of metastatic thyroid. The thyroid metastases can be the first sign of a kidney tumor, or appear long after the nephrectomy, in which case can may mistakenly diagnose a thyroid cancer early.
Goal
Examine ways of presentation, diagnosis and treatment of patients with thyroid metastases from clear cell renal carcinoma (TMCCRC).
Method
From January 1, 1985 to July 31, 2011 the diagnosis of TMCCRC was given to 9 patients at the Thyroid Center of Reggio Emilia. For the present study were enrolled eight because in one patient the clinical data were incompletes. In each patient we describe clinical manifestation, ultrasound description and anatomo-pathological aspects.
Results
Eight patients were enrolled: two women (25%) and six men (75%). The first diagnostic approach to TMCCRC was sporadic in three patients (37.5%), in two patients (25%) was by find increase in volume of the anterior region of the neck, in a patient (12.5%) for research of thyroid metastasis after nephrectomy for CCRC and in another two patient (25%) was the cytological reassessment after nephrectomy for a CCRC: both patients were previously cytological class T2. The TMCCRC were found in the right lobe in five patients (62.5%) and in the left lobe in three patients (28.57%).
Conclusions
The mode of presentation, the type of response, the clinical course and sonographic features of TMCCRC are heterogeneous. There is the possibility of confusing the TMCCRC with follicular neoplasm essentially in the absence of recognized previous CCRC. RECOMMENDATIONS. The finding of a nodule (s) of thyroid gland in patients with a history of CCRC must lead to the cytological analysis regardless of the ultrasound description. At the time of diagnosis of CCRC should evaluate the morphology of the thyroid.

**Diagnostic power of conventional and doppler ultrasound in identifying malignancy in thyroid nodules**

D. Stoian, M. Cornianu & F. Lazar
University of Medicine and Pharmacy "V. Babes", Timisoara, Romania.

Background
Conventional ultrasound remains the most used imaging evaluation in case of a thyroid nodule.
Material, method
This prospective study included 69 patients (107 nodules). Conventional and Doppler ultrasound was performed with a HITACHI EUB 7500 HV machine with 6–13 MHz variable frequency linear probe, with Doppler software. All patients underwent surgery after complete evaluation.Postsurgical histopathological exam was performed. We analyses at each nodule the following parameters: echogenity, halo sign, margins, shape, homogeneity; presence of calcification, color flow Doppler pattern.
Results
We diagnosed 11 cancer nodules: 1 (0.93%) huge nodule with follicular cancer, 10 cases with papillary carcinoma (9.45%).
The most predictive parameters, appreciate by the AUC under ROC curve in descendant order were: inhomogeneity (0.7985), dominant intranodular vessel (0.789), absent halo sign (0.7581), intranodular vascularization (0.7206), nodule taller than wide (0.712).
All the diagnostic parameters are presented in Table 1.
Conclusion
In cases of thyroid nodules, inomogeneity, presence of intranpdular doppler signal, absence of halo and intranpdular calcifications are the most predictive ultrasound parameters in diagnosis of suspect thyroid nodules.
Diagnostic value of different ultrasound parameters in identifying malignancy

**Table 1** Diagnostic value of different ultrasound parameters in identifying malignancy

| parameter | aspect | BN ($n=96$ ) | CA ($n=11$) | sensitivity (%) | specificity (%) |
|---|---|---|---|---|---|
| shape | oval | 69 | 5 | 45.45 | 26.04 |
| | tall | 25 | 6 | 54.54 | 87.5 |
| margins | well defined | 78 | 8 | 72.73 | 20.83 |
| | irregular | 18 | 3 | 27.27 | 81.25 |

**Malignancy rate of thyroid nodules which defined as atypia of undetermined significance in the thyroid cytopathology**

N. Cuhaci[1], D. Arpaci[1], S. Akbaba[1], G. Kiyak[1], S. Yalcin[2], G. Guler[2], R. Ersoy[2] & B. Cakir[2]
Yildirim Beyazit University, Faculty of Medicine, Ankara, Turkey.

Aim
In this study, our aim is to evaluate the ultrasonographic features and histopathologic results of the thyroid nodules which are defined as AUS and contribute to the therapeutic approach of these nodules.
Methods
We evaluated 95 nodules of 92 patients, who have nodular or multinodular goiter and had diagnosed AUS at least in one nodule with fine-needle aspiration (FNA). Patients' thyroid function tests, ultrasonographic features of the nodules and histopathologic results were evaluated.
Results
###81.1% of patients were female, 18.9% were male. Mean age was 47.5 ± 12.1 years. In the ultrasonographic features presence of microcalcification, border irregularity, peripheral vascularization and absence of hypoechoic halo was respectively 28.4%, 47.4%, 20% and 60%. 43.2% nodules were hypoechoic and 47.4% were solid. According to the histopathology, 63.2% of nodules (n = 60) were benign, 36.8% (n = 35) were malign. In malign nodules papiller carcinoma, well-differentiated thyroid neoplasm, follicular carcinoma and Hurthle cell carcinoma were found respectively 88.6%, 5.7%, 2.9%, and 2.9%. In malign nodules mean tumor size was 1.2 ± 1.1 cm. No lymph node metastasis was found.
Conclusion
In AUS, malignancy rate is reported 25% of operated patients, but it is thought 5–10% of the total. In our study we found this ratio 36.8%. Our high ratio may be due to few and heterogeneous literature data outcomes. So, this high malignancy ratio in AUS nodules, have to be considered in the decision of operation.

**Rradioiodine-thyroid cancer link: re-evaluation of Chernobyl consequences**

S. Jargin
Peoples' Friendship University of Russia, Moscow, Russian Federation.

Chernobyl accident was followed by numerous publications overestimating its medical consequences, where spontaneous diseases have been without sufficient reasons classified as radiogenic. Among medical consequences of the accident, cause-effect relationship between ingestion of radioiodine and thyroid cancer in patients exposed at a young age is regarded to be proven. Significant incidence increase of pediatric thyroid cancer started 4 years after the accident, coinciding with the onset of large-scale screening programs. High percentage of advanced thyroid cancers among the cases found shortly after the accident can be explained by the screening effect with detection of neglected tumors and by the fact that patients from non-contaminated areas were registered as Chernobyl victims. Older neglected tumors, larger in size and less differentiated, prevailed early after the accident, being gradually replaced by smaller cancers detected by means of improving diagnostic methods. Accordingly, features of supposedly radiogenic post-Chernobyl cancers can be related to the disease duration and a later stage of tumor progression. Iodine deficiency in some of the contaminated areas contributed to a higher yield of thyroid nodules, found by the screening and offering an opportunity of overdiagnosis. In conclusion, mass screening in the areas, where pediatric thyroid cancer had been rarely diagnosed before, in conditions of outdated equipment of histopathological laboratories, shortage of modern literature, and high tumor expectancy after the accident, should predictably have resulted in the incidence overestimation.

**Hyperfunctioning thyroid nodule and thyroid cancer**

A. OliveiraFilho[3,2], I. Bezerra[3], M. PorDeus[2] & A. Nunes[1]
Prefeitura Sao Domingos, Sao Domingos, Brazil.

Thyroid nodules are common and majority is benign. Even so, clinicians and patient always concern about the risk for malignancy. In the past it was believed that hyperthyroidism excluded the possibility of a thyroid carcinoma. We describe here two patients presenting "hot" thyroid nodules with final diagnosis of papillary thyroid carcinoma. Informed consent was obtained. Case 1: A 39-years-old female, presenting with irritability, disquiet, and neck swelling. A nodule was palpable in left lobe. Cervical ultrasonographic studies showed a nonhomogeneous nodule in an enlarged left lobe. Serum examinations demonstrated hyperthyroidism. 99m Tc and 131I scintigraphy showed hot area corresponding to the nodule in the left lower lobe. A total thyroidectomy was performed and post operative histological examination revealed a papillary carcinoma within the nodule of the lower left lobe. Macroscopically the white nodule measured 1.4 cm and surrounding thyroid tissue had no evidence of infiltration. No metastatic foci were recognized in adjacent tissues. Case 2: A 46-years-old female developed symptoms of neck swelling and palpitations. A large painless hard nodule was palpable in the right lobe of thyroid. Ultrasonography revealed a large right lobe with solid nodule without lymphadenopaties. Thyroid function tests showed TSH undetectable of $<0.01$ μIU/mL, free thyroxine was 1.99 ng/dL (normal 0.7–1.8), and her triiodothyronine was 5.6 pg/mL (normal 2–4.4). A 99mTc scan demonstrated a "hot" area corresponding to the nodule with a suppressed uptake in the remaining thyroid tissue. RAIU value was 46% (normal = 15–35%). Right loboisthmectomy was performed and the histological examination revealed a papillary carcinoma with no signs of angioinvasivity. The surrounding thyroid tissue showed no signs of infiltration or spreading. A completion thyroidectomy revealed metastasis in 5/6 limph nodes. Thyroid carcinoma rarely occurs concomitantly with dominant hyperfunctional nodules. Papillary thyroid cancer within a "hot" nodule is reported to be much less than 1%. These cases illustrated that malignancy cannot be always excluded even in autonomously functioning thyroid nodules consequently all thyroid nodules require careful diagnosis and appropriate management.

**Benefits and complications of total thyroidectomy as a surgical treatment for Graves'disease and for thyroid cancer**

H. Iwasaki[1], S. Shirayama[1], N. Gotoh[2,1], S. Hatori[2] & K. Nomura[1]
Atami Hospital, UHW, Atami, Japan.

Introductions
Some surgeons are easy to avoid total thyroidectomy as a surgical treatment for Graves'disease and even for thyroid cancer, because of possible complications (i.e. laryngeal nerve injury, hypoparathyroidism, etc). We studied the benefits and complications of total thyroidectomy in 206 patients with Graves' disease or with thyroid cancer who were treated in our institution.
Methods
Surgical outcomes were analysed in the following two groups. 101 patients with Graves' disease (group A) and 105 patients with thyroid cancer (group B) underwent total thyroidectomy in the past three years. We evaluated post-operative hypocalcemia, laryngeal nerve injury, and pathological findings in the both group and transition of TSH receptor antibody for group A.

Results
Post-operative hypocalcemias were recognized in 45 patients (44.6%) in group A and 38 patients (36.2%) in group B. Post-operative hypocalcemia appeared early in the patients with hungry bone. All of them except one recovered after taking some alfacacidol and calcium lactate for a couple of weeks. One patient in group B turned out permanent hypoparathyroidism. No laryngeal nerve injury was recognized. TSH receptor antibody was successfully decreased in almost all patients of group A. Incidentalomas (papillary carcinomas) were recognized in 5 patients (5.0%) of group A. Contra-lateral metastases were recognized in 7 patients (6.7%) of group B.
Conclusions
5 patients with Incidentaloma and 7 patients with contra-lateral metastases were received benefit from the total thyroidectomy. Although 83 patients (40.3%) were suffered from post-operative hypocalcemia, 82 patients (98.8%) recovered within a short term. All patients successfully underwent the surgery and most of them felt happy being free from their diseases. Ultimately, to avoid relapse or recurrence of their diseases, total thyroidectomy is acceptable surgery even though they have to take thyroid hormone for the rest of their life.

## P1845

**Bilateral adrenal metastases due to follicular thyroid carcinoma: case report and litterature review.**

L. Ahmed Ali[1], B. Latreche[2], C. Aimeur[2], R. Baba Ahmed[2], B. Mansouri[2] & F. Chentli[1]
Department of pathology, Algiers, Algeria.

Introduction
Apart from pulmonary and bone localizations, distant metastases from well differentiated thyroid carcinomas are very rare. Among them the adrenal ones are exceptional, and have generally a poor prognosis. The proof of the thyroid origin is not easy except if there is a histological confirmation by a CT guided biopsy of the adrenal tumor as in this observation
Observation
A woman aged 56 was referred to our unit for pulmonary metastases of a well differentiated thyroid carcinoma whose diagnosis was made by transthoracic puncture of one of the pulmonary nodules that reacted with anti thyroglobulin antibodies. In fact she was operated on twice (in 2005 and 2009) for thyroid disease diagnosed as an oncocytic metaplasia, and then she was lost in sight. During her hospitalization numerous bone and pulmonary metastases were found. Echosonography and CT scan showed two larges adrenals. A CT scan guided biopsy of the left adrenal confirmed the thyroid origin.
Conclusion
Adrenal metastases due to follicular thyroid cancer are exceptional. They may be uni or bilateral. Their prognosis is poor as they are diagnosed at the late stage of the disease as in our observation. A CT scan guided biopsy (when possible) is very helpful for the histological proof.

**Primary Thyroid Lymphoma Diagnosed During Pregnancy: Report of a Case**

E. Demir Onal, B. Polat, H. Korkmaz, B. Yalcin, F. Koybasioglu, R. Ersoy & B. Cakir
Yildirim Beyazit University Medical School Ataturk Teaching and Research Hospital, Bilkent, Ankara, Turkey.

Introduction
The incidence of non-Hodgkin lymphoma (NHL) during pregnancy is quite low. There have been a few anecdotal reports of NHL that arises from the thyroid gland.
Case Report
A 28-year-old female patient presented with a neck swelling, pain and respiratory distress while she was in the 17th week of her first pregnancy. Subtotal thyroidectomy was performed and combined histological and immunohistochemical analyses led to the diagnosis of diffuse large B cell lymphoma with a high proliferation index (Ki-67: 80%) and positive CD20, CD10 and BCL6. Chemotherapy (cyclophosphamide, doxorubicin, vincristine and prednisone (CHOP), 6 cycles every 4 weeks) was planned and the patient underwent the first 4 cycles without vincristine. Twenty weeks after the initiation of chemotherapy she had cesarean delivery of a healthy, full-term male infant. Four additional courses of chemotherapy were administered, after which the patient was reevaluated. She had no complaints and a total body CT did not show relapse of the disease.
Conclusions
Because of the rarity of NHL and the variety of subtypes of NHL during pregnancy it is not possible to make accurate assessment of outcomes. Our case is a one of the few examples that thyroid lymphoma associated with pregnancy can be successfully managed with a combination of surgery and chemotherapy.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1847

**The efficacy of 50mCi versus 100mCi radioactive iodine for thyroid remnant ablation after total thyroidectomy among patients with low stage differentiated thyroid cancer**

E. Consencino & R. Rosales
St. Luke's Medical Center, Quezon City, Philippines.

The recommended amount of administered radioiodine activity needed to successfully ablate thyroid remnants after total thyroidectomy is controversial. We compared the efficacy of 50mCi and 100mCi radioactive iodine for thyroid remnant ablation among patients with low stage and low to intermediate risk differentiated thyroid cancer who underwent total thyroidectomy through a retrospective cohort study in a tertiary multi-specialty referral center located in Quezon City, Philippines. A total of 74 patients who underwent total thyroidecomy for low stage differentiated thyroid cancer were included, with main exposure as the activity of radioactive iodine used for remnant ablation and main outcome measures were efficacy of remnant ablation, need for repeat RAI, adverse events and duration of stay at isolation. There were 16 patients (66.7%) in the 50mCi group and 38 patients (76%) in the 100mCi group who had successful remnant ablation (P value 0.526). Risk ratio for failure of remnant ablation among those who received 50mCi RAI is 1.389 (95% CI 0.656–2.942). There was no statistically significant difference in the need for repeat RAI between the two groups (RR 2.083, 95% CI 0.312–13.909, P value 0.440). The most common acute adverse events after administration of RAI reported were nausea (22% for the 100mCi group versus 4.2% for the 50mCi group) and neck pain (16% for the 100mCi group versus 4.2% for the 50mCi group). Adverse events were more likely to occur among those who received 100mCi versus 50mCi (36% versus 21%) although this did not achieve statistical significance (RR for total adverse events in the 50mCi cohort 0.579, 95% CI 0.244–1.372, P value 0.187). Nausea was more likely to occur among those who received 100mCi (RR 5.29, 95% CI 0.723–38.46). Duration of hospital stay was shorter among those who received 50mCi (median 2 days) versus those who received 100mCi (median 2.5 days), P value 0.090. Our results show that administration of 50mCi RAI may be as effective as 100mCi for ablation of residual thyroid tissue among patients treated with total thyroidectomy for low stage and low to intermediate risk of recurrence for differentiated thyroid carcinoma. Administration of 50mCi RAI is associated with fewer short term adverse events and a shorter stay in an isolation unit.
Declaration of interest
The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research project.

## P1848

**Radioiodine ablation can be avoided in intrathyroidal papillary thyroid cancers ≤2 cm (pT1N0M0)**

M. Perrino, C. Colombo, S. De Leo, L. Vicentini, P. Beck-Peccoz & L. Fugazzola
Fondazione IRCCS Ca' Granda, Milan, Italy.

The need for thyroid residue ablation in papillary thyroid cancer (PTC), classified with the TNM staging (AJCC, 2002) as pT1, with a maximum diameter comprised between 1 and 2 cm (pT1/1-2) and/or multifocal, is still debated. Aim of this study was to compare the outcome of pT1N0M0 patients submitted or not to postsurgical radioiodine ablation. Consecutive patients followed-up at this Institution from 1996 to 2010 were enrolled. All pT1/1-2N0M0 cases were radioiodine ablated before June 2002 and not ablated after that date. Patients with local or distant metastases at post-therapeutic whole body scan were excluded. The patients enrolled were 257 (214 F, mean age 47.3 yrs), the median follow-up was 88 months and the persistence/recurrence was evaluated according to the most recent European guidelines. Patients were submitted to total thyroidectomy, associated in 63 cases to central neck dissection. Tumors were classified as pT1/<1 (n=169, Group A) and pT1/1-2 (n=88, Group B). Multifocality was found in 35.5% of Group A and in 38.6% of Group B patients. Central neck dissection was performed in 18.3% (Group A) and 36.3% (Group B) of cases. Radioiodine ablation was performed in 26% of Group A (mean 131 dose: 74 mCi) and in 49% of Group B patients (mean 131 dose: 75 mCi). At the end of follow-up, persistent patients were 2/169 in Group A (both ablated) and 3/88 in Group B (all ablated). At a logistic regression analysis either age, gender, nodule diameter, central neck dissection, multifocality, or radioiodine ablation have been found not to influence the outcome. To our knowledge these are the first data showing that, in the pT1N0M0 category of PTCs, the outcome is not associated neither with the tumor size, nor with the therapeutic intervention, suggesting that radioiodine ablation can be avoided also in pT1/1-2 cases.

**Hürthle cell thyroid carcinoma metastatic to the choroid detected by radioiodine scintigraphy: a case report**

N. Besic & Z. Luznik
Institute of Oncology, Ljubljana, Slovenia.

In July 2010, a 69-year-old woman presented because of a CT proven 5th lumbar vertebral metastasis of thyroid carcinoma and in August she underwent a total thyroidectomy and central node dissection. Histopathology revealed a moderately differentiated Hürthle cell carcinoma which was according to TNM classification pT3N1M1 tumor. Thereafter, a right hemylaminectomy of L5 and metastasectomy was performed in order to decompress the L5 and S1 spinal nerves. The histopathology confirmed the diagnosis of metastatic Hürthle cell carcinoma. In October 2010, the patient had a radioiodine ablation of thyroid remnant using rhTSH, followed by an external beam irradiation of the lumbar spine with concomitant chemotherapy. Post-therapeutic whole body scintigraphy revealed lesions in bone and lungs and also an increased accumulation of radioiodine in the projection of the left orbit, which could be caused by a physiological accumulation of iodine in tear gland or a metastasis. In February 2011, the patient noticed an impaired vision in her left eye. During the next month a half of her left visual field was progressively appearing blurred. Echography of the left eye revealed a solid irregular choroidal lesion of approximately 6.5 mm thickness with some round hypoechogenic regions, causing exudative retinal detachment above the papilla. The echographic image was typical of an ocular metastasis. A MRI scan of the head confirmed a mass in the choroid of the left eye. Since radioiodine accumulated in this lesion, it was diagnosed as a thyroid carcinoma metastasis to the eye. Palliative external irradiation of the left orbit was performed, followed by administration of a therapeutic dose of radioiodine after rhTSH aplication. Only a trace of radioiodine accumulated in the projection of an eye metastasis. The control eye echography in July 2011 showed a partial regression of the metastatic choroidal tumor.

Magnetic resonance imaging coronal (A) and axial (B) scan showing left intraocular metastasis of Hürthle cell thyroid carcinoma.

**Features of incidental thyroid carcinoma in Gohierri county.**

J. Marti, A. Zurutuza, B. Lasa, J. Rodriguez Chinesta & M. Manrique
Osakidetza, Zumarraga, Spain.

Introduction

In the last years, has produced an increment in diagnosis of thyroid cancer. Incidental thyroid carcinoma is defined as a tumour diagnosed after surgery for benign lesions.

Aim. The objective of this study was to assess the clinical presentation, tumour characteristics and follow-up.

Patients and methods

We analysed clinicopathologic data of incidentally thyroid carcinoma from 351 thyroid surgeries carry out in our hospital between 01-01-2005 and 31-06-2010, for uni or multinodular goiter.Surgical criteria was nodule size.

Results

Of 351 surgeries in 28 cases incidental thyroid cancer was detected of these 18 were papillary micro carcinomas (PMC), all females of 55.11±11.34 year-old (range 37–79)with a size of 5.44±2.66 mm (range 1–9 mm);10 papillary(2 follicular variant), all women of 9.55±13.8 year-old with a size of 28.4± 13.1 mm. FNA previous surgery, was carried out all patients and were negatives for malignity in all cases.Total thyroidectomy was carried out by multinodular goiter to all patients. Association with Hashimoto thyroiditis was detected in 7 patients, benign follicular lesions in 5, multicentric tumor 3 cases.Lymph-node metastasis were not disclosed in histological study.Patients with papillary tumours and multicentric PMC were treated with radioiodine.

Mean of follow up 2.35±1.56 years. No metastasis or relapses or death have been detected during follow-up.

Conclusion

Incidental thyroid carcinoma are more common in women and PMC is the main diagnosis after total thyroidectomy. Lymph-node metastasis were not found in our study. Treatment with radioiodine was performed in papillary and multifocal PMC. The prognosis in our study has been good.

**The evaluation of fine needle aspiration biopsy results in thyroid nodules below and above one centimeter diameter**

S. Yazgan, F. Besir, O. Yazgan, R. Buyukkaya, H. Erdem, E. Onder, A. Buyukkaya, B. Erdogmus & Y. Aydin
Duzce University Medicine School, Duzce, Turkey.

Objective

We aimed to investigate the ultrasound (US) features and malignancy rates of thyroid nodules, below and above 1 centimeter diameter, according to fine needle aspiration biopsy (FNAB) results.

Materials and Methods
Total 157 nodular goiter patients, 60 patients' nodules were below 1 cm and 97 patients' nodules were above 1 cm, analyzed retrospectively. The nodules with pure cystic, peripheral calcification and inadequate cytological result were excluded. As a malignancy criterion at US, including hypo echoic pattern, solid structure, micro calcification features of nodule and not having peripheral halo feature of nodule were used. In statistical analyze, $P<0.05$ was accepted as significant.
Results
The malignancy or suspicions cytology rate was found 5% in nodules with below 1 cm, 17.5% in nodules with above 1 cm (total malignancy or suspicions cytology rate: 12.7%) and statistically it was not observed significant difference ($P=0.548$) . The statistical significant differences was not observed between thyroid nodules below and above one centimeter in terms of the US features of nodules for malignancy or suspicions cytology results.
Conclusion
In this study, we found that the US features of the nodules were not significant for determine to perform FNAB or not. Also, the thyroid nodules between below and above 1 cm of FNAB results were not statistically significant difference. Therefore, in our opinions, FNAB should be performed all thyroid nodules regardless of size and US features for early diagnosis of thyroid malignancy.

**Sonographic characteristics of thyroid nodules and the corresponding cytological results from the fine-needle aspiration biopsies**
M. Boyanov
Alexandrovska Hospital, Medical University Sofia, Sofia, Bulgaria.

Introduction
A major objective of the ultrasound of thyroid nodules is the stratification of the risk for possible malignancy and the selection of nodules for fine-needle aspiration biopsy (FNAB) and cytological examination.
Objective
The objective of this study was to assess the sonographic criteria used in the selection of thyroid nodules for FNAB and to compare them to the cytological reports.
Methods/Design
This was a retrospective study. 155 cases of FNAB of thyroid nodules for the last 3 years were suitable for analysis (147 women and 8 men). The thyroid sonography was performed on a Fukuda-Denshi 5500 device (Fukuda Corp., Japan) with a linear-array transducer 7.5 MHz. The ultrasound-guided FNABs were performed by the "free hand" technique; smears were fixed and processed according to Pappenheim.
Results
The following ultrasound features suspicious for possible malignancy were reviewed: hypoechogeneity to the surrounding parenchyma (which was the case in 51.6% of the biopsied nodules), spiculated margins (5.2%), blurred margins (48.4%), absence of halo (34.8%), presence of microcalcifications (5.8%), a taller than wide shape (7.7%), and a significant cervical lymphadenopathy (0.6%). 7.1% of all nodules had no suspicious features, 32.2% had only one, 45.8% - two, and 14.8% had three feautures. The cytology reports showed no risk of malignancy in the absence of suspicious features, a 10% risk - if one feature was present, a 16.9% - if two were present, and a 21.7% risk - if three ultrasound features were present.
Conclusion
The studied thyroid nodules had not been optimally selected by ultrasound prior to the FNAB.

**Surgery of Papillary Thyroid Carcinoma in Children and Adolescents**
R. Dzodic[1,2], I. Markovic[1,2], I. Djurisic[2], M. Buta[2], M. Oruci[2], M. Jevric[2], G. Pupic[2] & Z. Milovanovic[2]
Institute of Oncology and Radiology of Serbia, Belgrade, Serbia.

Background
Papillary thyroid carcinoma in children and adolescents is rare but it shows extremely aggressive behavior. Gross lymph node metastases and distant metastases are common on first clinical presentation.
Patients and methods
Forty five children and adolescents were operated due to PTC. Mean age was 16.6 years (range 7–21). At the time of diagnosis 13% had lung metastases. Total thyroidectomy or completion of thyroidectomy was performed in all cases followed with central neck dissection and frozen section examination of lower jugulo-carotid compartments
Results
Median tumor size was 1.9 cm. PTC was found in 44 and FTC in one patient. Multifocal tumors were found in 37% and capsular invasion in 29% and vascular invasion in 24% of cases. LNM in either central or lateral neck compartments were found in 76% of patients. Capsular and vascular invasion were significantly more frequent in children less than 16 years of age. Median follow-up was 127 months. Overall survival rate was 100%.
Conclusion
PTC in children is characterized with high incidence of loco-regional aggressiveness, multifocality, lymph node metastases and distant metastases at the time of diagnosis. Extensive surgical approach should be performed in both primary and recurrent disease in young patients with PTC.

**Diffuse Large B Cell Lymphoma of Thyroid Gland Presenting With Acute Tracheal Compression**
O. Incecayir, I. Anaforoglu, G. Kocak, S. Karyagar & E. Algun
Trabzon Numune Education and Research Hospital, Trabzon, Turkey.

Introduction
Non-Hodgkin lymphoma (NHL) involving the thyroid gland constitutues 2–3% of all NHL cases, 2–8% of all thyroid malignancies. The majority of lymphomas arising in the thyroid gland are MALT lymphomas and diffuse large B cell lymphomas commonly occuring in the setting of thyroiditis. Most cases are seen in adult or elderly females. The thyroid enlargement is often rapid and can lead to symptoms of tracheal or laryngeal compression. Herein, we present a case of diffuse large B cell lymphoma of the thyroid gland presenting with acute tracheal compression.
Case report
A 60 year-old woman had received a diagnosis of pneumonia with symptoms of cough, expectoration and dispnea. She had begun antibiotherapy. During treatment, a rapid progression of dispnea had occured. A huge, retrosternal goitre compressing trachea had been detected by computerized tomography. She had gave a history of a rapid increase in the size of swelling on her neck over 3-month period associated with difficulty in swallowing. She had been entubated and gone under urgent thyroidectomy and tracheostomy. After operation, she was extubated, followed by tracheostomy. Pathologic specimen established the diagnosis of diffuse large B cell lymphoma of the thyroid gland (Default 1). Bone marrow aspiration was negative for metastasis. Positron Emission Tomography performed for staging revealed involvement of locoregional lymph nodes; cervical, supraclavicular, and mediastinal lymph nodes (Figure 2).
She was given R-CHOP (Rituximab, Cyclophosphamide, Adriamycin, Vincristin, Prednisolon). A remarkable regression for the size of the lesions was observed after the first cure of therapy. Tracheostomy has been decanualeted and is being waited for healing.
Conclusion
Thyroid lymphoma is a rare disease. Fine needle aspiration and ultrasonography may be usefull for acutely swelling glands. Medical treatment and radiotherapy are first line treatments. Patients may present with acute compression symptoms as in our case. Surgery may be needed to overcome compression symptoms.

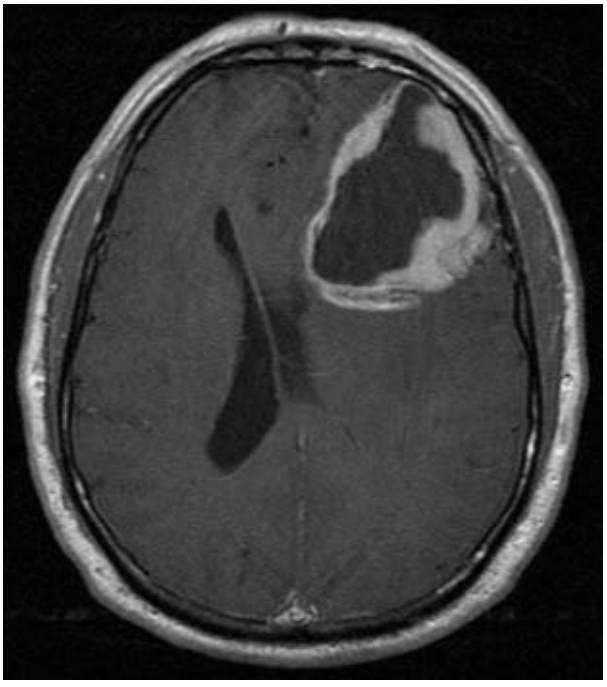
**Papillary thyroid carcinoma with a sollitary central nervous system metastasis**

C. Francés Artigas, J. Nicolau Ramis, R. Rivera Irigoin, M. García Bonafé, I. Rodríguez Rodríguez, A. Gil Palmer, J. Olivares Alcolea, L. Gómez Gómez & L. Masmiquel Comas
Hospital Son Llàtzer, Palma de Mallorca, Spain.

Introduction
Papilar thyroid carcinoma (PTC) is the most common thyroid neoplasia. It usually has a good prognose, being lymph node spread common. Distant metastasis are present in 9–10% of cases, worsening prognose. Cerebral metastasis are extremely rare, representing 1% of all metastasic PTC.



Case report
A 68-year-old man was sent to the Endocrinology Unit for follow-up of a PTC that had been operated (total thyroidectomy) 2 months before. After 100 mCi of I-131, total body scan(TBS) showed a pathological cervical lymph node. Due to this, a functional cervical lymph node dissection was performed. However, after stimulation with recombinant TSH, thyroglobuline was 59 ng/ml, so 100 mCi of I-131 were given again. The TBS showed a pathological uptake in the proximal third of the left femur, confirmed with a MRI, where a sollitary 15 mm bone lytic lesion was shown. No other images suggested metastasis, so excission of the bone lesion and hip replacement were done. The anatomic pathology report informed of a PTC metastasis with healthy tissue border. Thyroglobuline levels continued being high, so a PET with TSH-RH was done, reported as normal. However, due to high levels of thyroglobuline (138 ng/ml), additional150 mCi of I-131 were given. In the TBS done afterwards, no pathological uptakes were observed. The cervical ultrasound and CT-scan were normal. Six months later, the patient consulted urgently due to apathy and loss of language fluency that had started one month before. A CT-scan showed a 6.5 cm frontal left mass conditioning subfalcial and uncal herniation and hydrocephalus. The patient was operated, and excission of the mass took place. PTC hystology was confirmed.
Conclusions
Even if PTC usually has good prognose, practicians should bear in mind that distant metastasis are possible, and that an exhausting study including CNS should take place if the metastasic phocus is not localized in the most common territories.

**Papillary carcinoma in a hyperfunctioning thyroid nodule**

K. Peros[1], J. Zmire[1], T. Bozek[1], M. Stakor[2] & K. Babic[1]
Clinical Hospital Merkur, Zagreb, Croatia.

Introduction
Thyroid hyperfunctioning nodule usually represents benign tumor. Less than 1% of all cases have been reported as malignant lesion, especially in the presence of hyperthyroidism.
Case report
An asymptomatic 46-year-old man with a history of diabetes mellitus type 2 came for regular diabetic check. Two palpable thyroid nodules were detected during a routine physical examination. Thyroid function tests showed hyperthyroidism: TSH $<0.005$ mIU/L (0.63–4.19), FT4 31.1 pmol/L (11.5–22.7), FT3 9.7 pmol/L (3.5–6.5). Antithyroglobulin and antiperoxidase antibodies were present in elevated titre. Thyroid scintigraphy (Tc-99m pertechnetate) revealed mildly decreased glandular activity, a hyperfunctioning nodule in the left lobe and a nonfunctioning nodule in the right lobe. Thyroid ultrasound showed hypoechoic nodule (volume 3.3 ml) containing microcalcifications in the left lobe and hypoechoic nodule (volume 1.5 ml) in the right lobe. US-guided fine-needle aspiration cytology (FNAC) of a nonfunctioning nodule showed clusters of thyrocytes, phagocytes, and diffuse colloid. FNAC of the hyperfunctioning nodule was also done due to suspicious ultrasound nodule features, enlarged ipsilateral lymph nodes highly suggestive for malignancy and it revealed features of papillary carcinoma. Treatment with thiamazole was started and patient was subjected to operation as soon as he became euthyroid. A total thyroidectomy and level III, IV and V selective neck dissection were performed. Histology confirmed follicular variant of papillary carcinoma with intraglandular tumor dissemination and regional lymph nodes metastases. Postoperative whole body scintigraphy with 131I showed large inhomogeneous RI activity in the projection of the anterior cervical region. The patient received 100 mCi of the 131I for thyroid remnant ablation and levothyroxine treatment was started.
Conclusions
Papillary thyroid carcinoma rarely exists in an autonomously hyperfunctioning nodule. Clinicians should be aware that hyperfunctioning nodule, even if hyperthyroidism is present, does not exclude the presence of a well differentiated thyroid carcinoma. Although this pathology is rare, it is important to be correctly diagnosed and appropriately treated.

**Concomitant hyperthyroidism and thyroid carcinoma**

M. Diaconescu & S. Diaconescu
"Gr T Popa" University of Medicine and Pharmacy, Iasi, Romania.

Background
Recent reports have mentioned rising incidence of thyroid cancer (TC) detected before and after thyroidec-tomy (Tx) for hyperthyroidism but "hyperfunctioning" TC is however a rare entity.
Patients & Methods
Among a personal series of 464 patients which underwent Tx including 147 (33.6%) cases of thyroto-xicosis and 72 (13.6%) cases of TC, we founded 10 patients with hyperthyroidism and nodular or microscopic TC but only one case of TC with features of thyroid overactivity. History, clinical records, biohormonal picture, imaging studies, pathology findings and surgery notes with follow-up results were analysed.
Results & Discussions
The study enrolles 10 females and one male, age ranged from 16 to 62 years. Concurrent TC was present in 3 cases of Graves' disease, 5 cases of toxic multinodular goiter and 3 cases of toxic adenoma. None of these patients had recieved previous head or cervical irradiation. One woman underwent elsewere a subtotal Tx 18 years ago. In all but one cases the diagnosis was established by permanent section of the surgical specimen. There were 4 nodules with indeterminate results at frozen section but this procedure furnised a valuable indication in only one case with a follicular sample. Six papillary lesions was microcarcinomas. In the whole group we have 10 papillary and only one follicular cancer. Surgery was the mainstay therapy in all these lesions, the suspicion or presence of cancer imposing the extent of exeresis. Six near-total Tx, 4 hemiTx and one completion Tx were done. Appropriate additional mesures included radioiodine and hormonal therapy in 9 observations. Postoperative results were good with no morbidity and mortality. The long-term study showed 8 cases alive and disease-free in an average follow-up of 60 months.
Conclusion
Hyperthyroidism do not exclude the presence of TC, the latest being crucial for the choice of the surgical strategy and prognosis. The rising number of Tx in cases of hyperthyroidism will probably detect more observations with associated thyroid (micro)carcinoma.
